connecting them with other categories systematically, validating these relationships, and filling in categories that require refinement and development [49]. Also, the descriptive data obtained from the questionnaires were analyzed in in-depth analysis to determine the main themes of the problem, using the ATLAS program: The Qualitative Data Analysis & Research Software and the Microsoft Excel program for classifying [51]. In addition, the value stream analysis was employed to determine the effectiveness of SCRM modeling as a tool for interaction in the academic community through social media. The sampling was done through qualitative and quantitative methods. The method used for qualitative was using the exploratory method, then quantitatively using the method used was proportional random sampling from John Creswell. Data collection was also through a Google form interview questionnaire, and the technique of the questionnaire was carried out openly and closed. Data processing using ATLAS program assistance: analysis and research software then also using Microsoft office excel applications and value stream analysis [51].

V. RESULTS

A. Research Subject Demographic Data

The total research subjects were $N = 2421$ members of the academic community in universities and consisted of students ($N = 2141/88.43\%$), lecturers ($92/3.8\%$), education staff ($23/0.95\%$), and alumni ($165/6.82\%$). Furthermore, the male subjects were $N = 1449/60\%$, while the females were $N = 972/40\%$.

B. Ownership of Social Media Accounts in the Academic Community of the Universities

In this research, a survey was conducted regarding the ownership of social media accounts in the university community. Based on the results, the most popular platform is WhatsApp ($N = 2416$), followed by Facebook ($N = 1374$), Instagram ($N = 765$), Twitter ($N = 457$), YouTube ($N = 319$), Pinterest ($N = 250$), LinkedIn ($N = 134$), MySpace ($N = 64$), and Flickr ($N = 24$).

C. Social Media Visited by the Academic Community to obtain University Information

There were nine types of social media used to obtain university information, with the highest to the lowest order being Instagram ($N = 1783$), Facebook ($N = 946$), YouTube ($N = 869$), WhatsApp ($N = 509$), Twitter ($N = 159$), LinkedIn ($N = 156$), Pinterest ($N = 126$), MySpace ($N = 58$), and Flickr ($N = 17$). On further analysis, the three highest social media platforms used were Instagram ($N = 1783$), Facebook ($N = 946$), YouTube ($N = 869$), while the three lowest were LinkedIn ($N = 156$), Pinterest ($N = 126$), MySpace ($N = 58$), and Flickr ($N = 17$).

D. Social Media Utilization as a Tool for Interaction of the Academic Community

According to the analysis results of the social media utilization as a means of interaction for the academic community in universities, the total number of subjects was 2421. From this number, 1367 answered that they actively interacted on social media, 744 responded that it was

somewhat ineffective, 200 were inactive, and 110 stated they had not implemented social media in interactions. A graphic representation of the data distribution of the interaction of university communities is presented in Fig. 3.

E. Information Sought by the Academic Community through Social Media

According to the survey results, the most searched information on social media is lecture information ($N = 1368$). This is followed by information on requirements to become a student ($N = 1285$), tuition fees ($N = 1268$), research program accreditation ($N = 1174$), university accreditation ($N = 1114$), student activities ($N = 964$), facilities ($N = 846$), location of the university ($N = 715$), staffing ($N = 417$), alumni ($N = 360$), and cooperation links ($N = 292$).

The three most sought information by students were lecture information ($N = 1221$), requirements to become a student ($N = 1203$), and tuition fees ($N = 1159$), while lecturers majorly searched for information on student activities ($N = 50$), facilities ($N = 49$), and lectures ($N = 47$). Conversely, education staff looked for information on employment ($N = 10$), lectures and facilities ($N = 18$), alongside accreditation of research programs and the university ($N = 16$), while alumni often searched for information on lectures ($N = 91$), research program accreditation ($N = 83$), and university accreditation ($N = 80$).

F. University Marketing through Social Media

The survey regarding the assessment of university marketing by the academic community ($N = 2421$) discovered: 1) active implementation ($N = 1817$), 2) less active ($N = 522$), 3) inactive ($N = 53$), and 4) respondents who have not implemented social media ($N = 29$). A graphic illustration of the assessment of the university marketing strategy is presented in Fig. 4.

Fig. 3. Interaction between University Academics.

Fig. 4. Assessment of University Marketing.

G. Social Media as a Communication Tool in Universities

To find out whether the hypothesis proposed in this study is proven. The author conducts an analysis using the Value Stream Analysis technique to see how the relationship between social media as a communication tool in universities is. From the results of a survey conducted by four types of respondents in universities, namely students, lecturers, education staff, and alumni, stated that the interaction between the academic community in universities in terms of using social media, the results are as follows, in Fig. 5.

From the survey results, it can be seen that from N = 2421 that most of the interactions between the academic community in universities have used social media, only the implementation is still not the same in every university. Several social media platforms were recommended to help the higher education academic community, namely Instagram (N = 1929), followed by Facebook (N = 1149), WhatsApp (N = 1127), YouTube (N = 1040), Twitter (N = 329), LinkedIn (N = 161), Pinterest (N = 155), MySpace (N = 91), and Flickr (N = 43). Some platforms were also recommended for searching the information, namely Instagram (N = 1783), Facebook (N = 946), YouTube (N = 869), and WhatsApp (N = 509).

Hence, the four highest social media platforms recommended as communication tools in academic communities were Instagram (N = 1929), Facebook (N = 1149), WhatsApp (N = 1127), and YouTube (N = 1040). The reasons for this proposal were based on the findings that social media promoted: 1) ease of access (n = 1525), 2) complete information (1236), 3) updated information (1181), and 4) attractive appearance (704). Fig. 6 shows an infographic representation of social media recommended by the academic community in higher education.

An analysis to determine the modeling of Social Customer Relationship Management (SCRM) as a communication tool in universities through social media was conducted based on the

research findings and prepared via the value stream analysis technique. The results of this study are Social Customer Relationship Management (SCRM) as a communication tool for the academic community, and targeted promotions for universities. It can be seen that social media is often encountered to become a communication tool used by the academic community. One of them is that each university has a different perception of social media-based platforms.

That facilitates communication between academic community members through social media platforms that aim to enable information provision and acquisition. Based on research findings, social media platforms that allow the development of SCRM as a communication tool between members of the academic community are Instagram, Facebook, WhatsApp, and YouTube. These four platforms can enable connections and relationships alongside providing and conveying information, leading to their recommendation by academic communities as university communication tools. An overview of the connectedness of SCRM as a communication tool through social media in the value stream analysis is presented in Fig. 7.

Fig. 5. Social Media as a Communication Tool in Universities.

Fig. 6. Recommended Social Media to Help the Academic Community Find University Information.

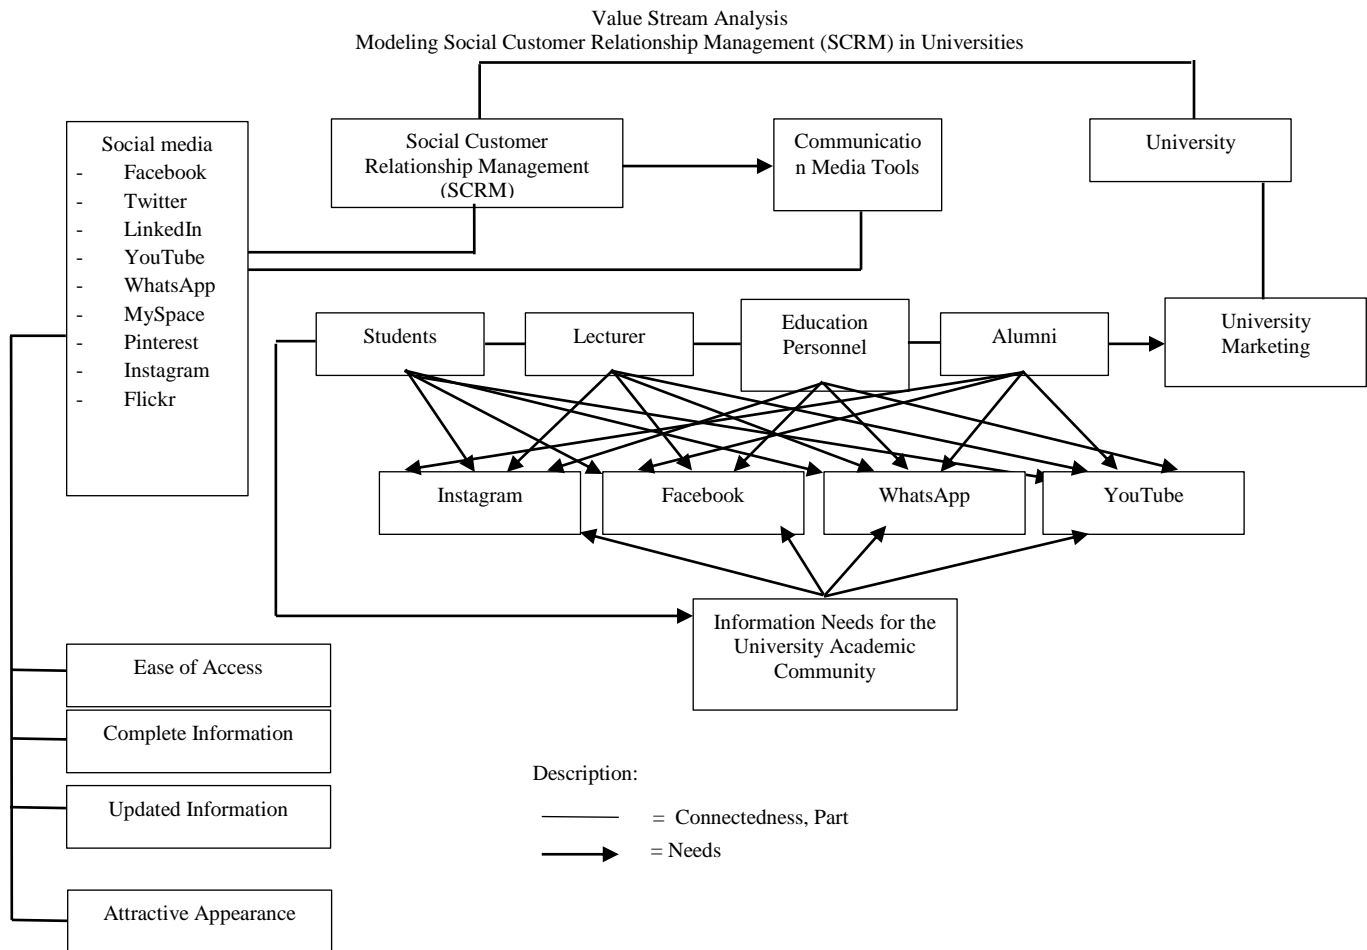

Fig. 7. Modeling Social Customer Relationship Management (SCRM) in Universities.

VI. DISCUSSION

The use of social media has grown and transformed into a communication tool [52], [53], including in modern times in academic communities. Based on survey data, the academic community members mostly used WhatsApp (N = 2416), Facebook (N = 1374), and Instagram (N = 765), while the rest chose other platforms. These three applications are the most used social media platforms in the world.

Meanwhile, the new form of CRM, known as SCRM [28], has become a necessity in universities as a means of communication and interaction between academic community members. Sigala [54] stated that SCRM could provide users with benefits and satisfaction [55]. Interaction between internet users is the core of the social web [56], and through social media, universities can join communities outside their official boundaries to obtain information [54]. It corresponds with Diffley and McCole [57], who stated that social CRM could represent routine activities, including in social networks, to build long-term relationships that involve customers, and create shared value in the development and empowerment [54] of university innovation.

Social media is a means of interaction and communication, as evidenced by its use in the academic community's search for university information in this research. The three most popular

social media platforms used as tools to obtain information were Instagram (N = 1783), Facebook (N = 946), and YouTube (N = 869), which are also some of the most common applications [46]. According to the result presented in Section 3, this study proves the hypothesis that the social media is a potential communication media between the academic communities in higher education.

Furthermore, 1367 (56%) respondents in this research admitted that they employed social media during interactions, while 1054 (54%) gave responses of less active, inactive, and unimplemented interactions. These findings necessitate the creation of a system that regulates social CRM through social media as a means of communication and interaction between members of the academic community in universities.

Social media is defined as a technology used for interaction through the web [58], [59]. Hence, academic communities need to properly engage customers on related platforms [60], [61]. Social media is one of the most effective tools for all kinds of information and has many advantages that allow its users to connect easily over the internet. It can also help students and the academic community in teaching and learning, global collaboration, and provide relevant opportunities in one click [62]. The search and distribution of information through social media by the academic community is presented in Table I.

TABLE I. INFORMATION WANTED BY THE ACADEMIC COMMUNITY

No	Academic Community	Information Sought on Social Media
1	Students	Information on lectures, requirements to become a student, and tuition fees
2	Lecturers	Information on student activities, facilities, and lectures
3	Education Personnel	Information on staffing, lectures, and facilities, alongside research program and university accreditation
4	Alumni	Information on lectures as well as research program and university accreditation

This study also proved that social media is an essential communication tool for the university academic community is very important, as evidenced by the recommendations to use related platforms, namely Instagram (N = 1929), Facebook (N = 1149), WhatsApp (N = 1127), and YouTube (N = 1040), to obtain information universities.

The current generation is probably the loneliest, and this can be tackled by image-based platforms such as Instagram [63]. This application was launched in 2010 through the App Store and reached 2 million users in precisely two months. It has also gained wide global popularity, where one of the recent trends consists of posting side-by-side photos comprising one ideal and realistic depiction [64]. It is highly remarkable compared to the development of other social media platforms, such as Twitter and Foursquare, which took one to two years to reach the same number of users [65]. In addition, Instagram has changed the scope of education because students can share experiences and exchange ideas and solutions with other students, lecturers, and individuals [66].

Meanwhile, Facebook is a platform that has rapidly developed and is the second-largest global social network and the largest in Turkey [67]. It has facilitated the most substantial impact on the intention to use social media [68], [69] and fulfills people's needs to show affection and vent feelings [70]. Facebook is used for making friends, surveillance, videos, photos, music, sharing ideas, games, organizations, politics, commerce, and communication in education [71]. The use of social applications in education helps expand the learning experience and enhance interactions inside and outside the classroom, such as WhatsApp, which fundamental functions as a tool for communication between members of the academic community [72].

WhatsApp is an application used to send messages [71] and complement face-to-face communication [73]. The WhatsApp messenger application is widely used among students and the academic community for sending messages, photos, videos, and audio [74]. According to Cheung et al. [75], WhatsApp is a mobile service that allows the academic community to interact socially, enables learning and solving difficulties, and considers an alternative platform for distributing assignments, ideas, and information. Hence, this platform has become essential to building feelings of unity with people [76].

Furthermore, as the most famous of these sites, YouTube exceeds two billion views per day, with new videos uploaded on an average every minute. Not only as a video content

channel but YouTube is also a new educational tool that attracts public attention [77] and is best understood as a means of disseminating information [78]. This application offers four ways to sort search results: relevance, upload date, number of views, and ratings [79]. It also has stringent quality requirements, such as detecting the packets belonging to the application in the packet stream and determining the appropriate quality parameters [80].

In addition, the assessment of marketing at universities by the academic community in this research showed that 1817 (75%) from the total of 2421 admitted that college marketing had actively implemented social media, proving its importance as an interaction system. Advancing the mission and programs of the academic community is very important to assess the effective use of social media from a public perspective. As stated previously, the public tends to accept and use information conveyed through social media, which is believed to be more credible than other platforms [40]. The use of social media is the key to developing interactions that should involve openness, transparency, usability, and interactive features [81], [82].

Social media should become a communication interaction system in universities. Social media is also referred to as social sensing in universities' academic communities for four reasons: ease of access, updated information, complete information, and attractive appearance. Meanwhile, the benefits are information sharing, and publicity, alongside offering and receiving support and advice [83], [84]. Hence, people in universities can interact freely without fear of adequate fluency in spoken English through social media [85], [86],[87].

VII. CONCLUSION

This study concludes that Social Customer Relationship Management (SCRM) can be a means of communication between the academic community in higher education. This is evident from the graphics contained in this study showing that social media is used as a communication tool. SCRM modeling is a bit difficult for readers to understand and understand from research. From the results, it was found that social media is a critical communication tool for the university's academic community, which is very important, as evidenced by the recommendation to use related platforms, namely, Instagram (N = 1929), Facebook (N = 1149), WhatsApp (N = 1127), and YouTube (N = 1040), for university information. Furthermore, 1367 (56%) respondents in this study admitted to using social media when interacting, while 1054 (54%) gave responses in inactive, inactive, and not implemented interactions. These findings require creating a system that regulates social CRM through social media as a means of communication and interaction between members of the academic community in universities, as seen in Fig. 5.

This research concluded that Social Customer Relationship Management (SCRM) could be a communication tool between academic community members in universities. It can be conducted by utilizing effective social media platforms, such as Instagram, Facebook, WhatsApp, and YouTube, integrated and connected as an information search center. Consequently, social media has become an SCRM tool due to: 1) ease of access, 2) complete information, 3) updated information, and

4) attractive appearance. A structured interview guide was used separately from the research questions in this study because this study used two methods at once. Thus, structured interview guides were used in a qualitative setting, while mixed questions were used in a quantitative setting. This study proves the hypothesis that social media is a potential communication medium between academic communities in higher education.

The author also recommends further research with a purely quantitative approach, such as (experiments, correlations, and surveys) so that the relationship between Social Customer Relationship Management (SCRM) can be seen significantly as a communication tool in the academic community in higher education.

VIII. RECOMMENDATION

Recommendations in this study are by looking at some of the weaknesses of this study. So that it becomes suggestions and input for future research. Such as: 1) Revealing more about technical barriers in the use of social media as an academic communication tool; 2) Using more diverse research methods, such as pure quantitative and other mixed-method approaches; 3) Conducting further research with survey analysis with a quantitative approach.

ACKNOWLEDGMENT

We would like to thank the management of Universitas Sriwijaya, Department of Engineering, Faculty of Engineering Universitas Sriwijaya. Faculty of Computer Science and Multimedia and Game Programming Laboratory, Universitas Sriwijaya, Indonesia, for supporting this research.

Abstract—Due to the nonlinearity of the luminance function produced by many medical recording devices, the quality of medical images deteriorates, which creates problems in the visual research work of physicians. X-rays can be taken as an example. This article examines methods of improving the contrast of graphic images methods of improving the quality of X-ray images. The research was carried out in several stages. Attempts were made to increase the contrast of several dozen X-ray images to select the best image brightness using brightness conversion methods in the MATLAB system. Contrast enhancement was observed during the experiments, resulting in the selection of a brightness range corresponding to the visual contrast enhancement. The selection of variables γ for the selected brightness range of the image was performed. The possibilities of the image histogram equalization method were considered. To obtain the best result before performing gamma correction the method of X-ray image histogram equalization is suggested. An enhancement version of this algorithm is presented because of the comparison. Application of the adaptive histogram equalization algorithm with contrast limitation provides a visual effect of improving the contrast of X-ray images. The NIQE and BRISQUE evaluation functions, which do not use reference images, are used to objectively quantify the conversion results.

Keywords—Digital X-ray image; image quality assessment; image enhancement; contrast enhancement; luminance transformation; adaptive image histogram equalization

I. INTRODUCTION

This One of the most powerful tools of modern informatics is medical imaging. Medical imaging is used to accurately and timely diagnose health problems, allowing patients to be treated more effectively. Nowadays, digital medical images are composed of many millions of pixels, which allows them to be considered big data. In some cases, there is a need to enhance the quality of medical images. However, in digital radiography, this may require increasing the radiation dose to the patient. Therefore, the goal of medical imaging is not to obtain a perfect image, but to obtain an image that is sufficient in terms of diagnosis concerning a particular medical problem and that causes minimal harm to the patient.

The essence of methods to enhance the quality of X-ray images is as follows: apply some mathematical methods to low contrast images and enhancement the quality of the digital medical image for a more accurate diagnosis of health problems.

II. LITERATURE REVIEW

In reviewing the experience of other researchers in this field, methods considered in the foreign literature have been studied. The paper [1] deals with contrast enhancement based on internal image decomposition, using Bregman split algorithm and CLAHE (Contrast limited adaptive histogram equalization). The authors show an enhancement meant in the images by evaluating the illumination and reflection levels using an internal image decomposition. A good contrast enhancement is obtained, but the proposed method is only for contrast enhancement and cannot be used for techniques like surface texture change, object insertion, etc.

In [2] Cheolkon Jung discusses the optimized perceptual tone mapping for contrast enhancement of images. The proposed method focuses on human visual attention by constructing a luminance histogram and performs contrast enhancement. The advantage of the method is that it enhances the performance without excessive contrast enhancement. Contrast enhancement by this method requires more time compared to HE (Histogram equalization), CLAHE methods.

S.S. Haung [3] has proposed an effective method to change the histograms and enhance the contrast of digital images. This paper presents an automatic transformation method that enhances the brightness of darkened images using gamma correction and brightness pixel probability distribution. It has been used to enhance the video data. The method proposed in the paper uses the differences between the frames to reduce the computational complexity. Experimental results have shown that the proposed method produces enhanced images of comparable or higher quality than those obtained using other methods.

M. Shakeri [4] proposed an algorithm for contrast enhancement based on local histogram equalization. The peculiarity of the algorithm is to determine the number of subhistograms and to separate the histogram based on saturation. The algorithm worked in three stages. Initially, the estimation of the number of clusters for image brightness levels is done using histogram alignment. In the next step, the image luminance levels are clustered and finally, the contrast enhancement for each cluster is included separately. The algorithm is compared with other methods based on quality and quantity measurements. The application of the method produces natural-looking images and enhanced contrast. The disadvantages of the algorithm are the loss of detail at high levels of image brightness and the presence of noise in the output image.

In work [5] the authors have proposed a new method for improving medical images. First, the original medical image is decomposed into an NSCT (contour transform without subsampling) region with a low-frequency subband and several high-frequency sub-bands. A linear transformation is then used for the luminance coefficients of the low-frequency sub-band. An adaptive thresholding method is used for noise reduction of the coefficients of the high-frequency sub-bands. All sub-bands were then reconstructed into spatial regions using the inverse NSCT transform. Next, unsharp masking was applied to increase the clarity of the details of the reconstructed image. Experimental results show that the proposed method outperforms other methods in terms of such characteristics as image entropy and PSNR (peak signal to noise ratio).

In [6] paper, the social network optimized approach for image fusion for contrast enhancement and brightness preservation is discussed. The social network optimization algorithm creates two quality images, one with better contrast, and increased entropy, and the second image with an increased peak signal-to-noise ratio. The two images are combined to produce an effective image later. Comparisons were made using HE, and linear contrast stretching. The results show that the proposed method provides a better peak signal-to-noise ratio, preserves brightness, and increases the contrast of any given image, resulting in a high-quality visual effect.

However, the number of edge pixels of this technique is large, while the fit value is smaller.

In [7], Se EunKim proposes an entropy-based method for contrast enhancement in the wavelet domain. Initially, he uses local entropy scaling in the wavelet domain to obtain the desired contrast. Mathematical methods were used, and then a color enhancement method was developed in the HSI (from hue, saturation, lightness (intensity)) color space. The algorithm worked in two steps: modifying the low frequencies in the wavelet domain and scaling the HSI color space by increasing the intensity component so that images in low light get detailed color information without any further processing. The peculiarity of the algorithm is that it is used in the HSI color space and provides an increase in the contrast of the image.

Huang Lidong [8] proposed a combination of adaptive histogram equalization with limited contrast and discrete

wavelet transform to enhance the image. The algorithm works in three stages. First, the original image is allocated to low- and high-frequency components using a wavelet transform. The low-frequency coefficients are enhanced using the CLAHE method, while the high-frequency coefficients remain unchanged. When the wavelet transform is reversed, the image is mounted successfully. The proposed method is applicable for improving the local details of the image, preserving the details well, and suppressing noise. But the high-frequency component, which contains most of the noise in the original image, remains unchanged.

The authors of [9] propose a high-speed quantile-based histogram equalization (HSQHE) to preserve brightness and enhance contrast in the image. Contrast enhancement by this method is suitable for high-contrast digital images. Recursive segmentation of the histogram is not performed, so minimal time is required for segmentation. Entropy metrics are used to estimate PSNR of contrast enhancement. AMBE (Absolute Mean Brightness Error) is used to estimate brightness preservation. HSQHE preserves image brightness more accurately in a shorter time interval, but a high PSNR value is achieved only for certain images.

In [10], the authors propose a histogram modification scheme with entropy maximization. The method of histogram modification by entropy maximization divides the global histogram alignment into two stages: the pixel populations emergence (PPM) stage, which corresponds to the entropy maximization rule, and the gray-levels distribution (GLD) stage. The method gives good enhancement results and avoids reinforced noise and distortions in the image, but there is a problem with excessive contrast stretching.

The proposed methods confirm the necessity of non-linear image brightness transformation methods for contrast enhancement, but it requires detailed study for more informative images after processing.

III. IMAGE ENHANCEMENT TECHNIQUES

Image enhancement techniques involve performing such transformations on the original image that lead to a result that is more suitable for a particular application [11]. Visual assessment of image quality is an extremely subjective process, and automatic calculation of the quantitative value of such an assessment is a very difficult task. To choose one or another method to enhance the contrast of a medical image, an evaluation of the result is necessary. Objective quality assessment algorithms are divided into benchmark and non-benchmark. The different reference criteria use a comparative quality assessment when the reference image is usually known to look like, and its characteristics are known [13]. When dealing with low-contrast medical images, there are no benchmarks for comparison. Therefore, it is necessary to select those evaluation options that do not require a reference image.

Image enhancement approaches fall into two categories: spatial domain processing methods and frequency domain processing methods. The term spatial domain refers to the image plane as such, and this category combines approaches based on the direct transformation of image pixel values.

Frequency methods involve changing the images after the Fourier transform.

Let us consider some methods related to spatial processing methods. Spatial methods are described by the equation [12]:

$$g(x, y) = T[f(x, y)], \quad (1)$$

where $f(x, y)$ is a function describing the original image, $g(x, y)$ is the transformed image, and T is an operator over f defined in some neighborhood of a pixel with coordinates (x, y) . The neighborhood of a pixel is understood as a square or rectangular area that is a subset of the image and is centered relative to the given pixel. The simplest version of the T operator occurs when the neighborhood consists of a single pixel, in which case the value of g is a function of $f(x, y)$ and T is called a point type conversion.

Histogram transformations are divided into the following groups: linear logarithmic and power transformations. Histogram alignment of a digital image is a transformation of the original image in which the histogram of the transformed image has a more horizontal shape than the histogram of the original image.

To enhance image quality, it is necessary to increase such parameters as brightness range, contrast, sharpness, and sharpness. In combination, these parameters can be enhanced by aligning the histogram of the image. Histogram equalization algorithms are widely used to enhance the processed digital grayscale image. In general, such algorithms are simple to implement, have relatively low computational cost, and yet show high efficiency. The essence of such algorithms is to adjust the levels of the halftone image according to the probability distribution function of a given image (2) and, as a result, the dynamic range of brightness distribution increases. This leads to enhancement meant of visual effects, such as: brightness contrast, sharpness, and clarity.

$$P(i) = \frac{n_i}{n}, i = 0..255;$$
$$H(j) = 255 \sum_{i=0}^j P(i) \quad (2)$$

where $P(i)$ is the probability of the appearance of a pixel with brightness i , the normalized function of the histogram of the original image, j are the pixel coordinates of the processed image, $H(j)$ is the transformed image [12]. Histogram equalization algorithms are divided into the following two types: local (adaptive) histogram equalization and global histogram equalization. In the global method, one chart is built, and the histogram of the entire image is equalized. In the local method, many histograms are constructed, where each histogram corresponds to only a part of the processed image. With this method, the local contrast of the image is enhanced, which makes it possible to obtain better processing results in general.

An enhancement version of the above algorithm is the Contrast limited adaptive histogram equalization (CLAHE) algorithm. The main feature of this algorithm is the limitation of the histogram range based on the analysis of the pixel

brightness values in the processed block (3), thus the resulting image looks more natural and less noisy [14].

$$da = \frac{nc}{n} \quad (3)$$

where da is the increment factor of the value of the histogram function, nc is the number of pixels that exceed the threshold value. It is worth noting that the classic CLAHE algorithm uses bilinear interpolation to eliminate boundaries between processed blocks. The *imadjust* function is the basic tool in the MATLAB package for converting the brightness of grayscale images. All input parameters of the *imadjust* function are real numbers in the range from 0 to 1, i.e., the range of brightness values must be normalized. The syntax of the function is defined as follows:

$J = \text{imadjust}(I)$.

$J = \text{imadjust}(I, [\text{low_in}, \text{high_in}], [\text{low_out}, \text{high_out}])$.

$J = \text{imadjust}(I, [\text{low_in}, \text{high_in}], [\text{low_out}, \text{high_out}], \gamma)$ (4)

The *imadjust* function converts the intensity values of the grayscale image I to new values and writes them as a matrix J . By default, *imadjust* discards 1% of all lower and upper brightness values in the I image, then applies a linear contrast stretch.

The function $J = \text{imadjust}(I, [\text{low_in}, \text{high_in}], [\text{low_out}, \text{high_out}])$ converts the original brightness values I into new values J from the range $[\text{low_in}, \text{high_in}]$ to the range $[\text{low_out}, \text{high_out}]$. The latter can be equal to $[0, 1]$.

The function $J = \text{imadjust}(I, [\text{low_in}, \text{high_in}], [\text{low_out}, \text{high_out}], \gamma)$ additionally performs gamma correction of the converted brightness values. By default, the parameter $\gamma = 1$, which corresponds to an identical mapping [9].

Histogram equalization in MATLAB is implemented by the *histeq* function, which has the syntax:

$J = \text{histeq}(I, n)$ (5)

Where I is the input image, n is the number of intensity levels set for the output image J . If n is equal to the total number of possible levels of the input image, then *histeq* simply implements the transform function. If this number is less than the total number of possible levels of the input image, then *histeq* will redistribute the levels, so that they approximate the flat diagram. A true implementation of this method uses the maximum possible number of levels for n , which is 256. The CLAHE algorithm is implemented by the function *adapthisteq*, which has the following syntax:

$J = \text{adapthisteq}(I, \text{Name}, \text{Value})$ (6)

The Name input parameters can be:

- Number of rectangular context areas (tiles) into which *adapthisteq* divides the image, specified as a 2-element vector of positive integers;
- Contrast enhancement limit, specified as a real scalar in the range $[0, 1]$;
- Number of histogram intervals used to build a contrast-enhancing transformation (256 by default);

- Desired histogram shape;
- Distribution parameter.

CLAHE works with small areas of the image, called tiles, rather than with the whole image. The contrast of each tile is increased so that the histogram of the output area roughly corresponds to the histogram specified by the "Distribution" value. Neighboring tiles are then combined using bilinear interpolation to eliminate artificially created borders. Contrast, especially in homogeneous areas, can be limited to avoid amplifying any noise that may be present in the image.

IV. INITIAL DATA AND DESCRIPTION OF EXPERIMENTAL STUDIES

We use X-ray images from the Kaggle database [15] to experiment with the application of image brightness conversion methods. The experiment aims to increase image contrast to obtain more information about a pulmonologist's lung image representation. The essence of methods to improve the quality of medical images is to apply mathematical methods to low contrast images and improve the quality of digital medical images to improve diagnostic accuracy.

Many experiments were conducted to apply the imadjust function to several X-ray images to select the most appropriate input parameters. The values for (4) were chosen in increments of 0.1 in the range from 0 to 1 (Table 1.).

The non-referential NIQE and BRISQUE evaluation functions were used to determine how much contrast was enhanced. The NIQE (Naturalness Image Quality Evaluator) and BRISQUE (Blind/Referenceless Image Spatial Quality Evaluator) functions are used in cases where no image reference is available. The NIQE (A) function compares the quality of image A relative to an abstract model image constructed from images of natural scenes. The BRISQUE (A) function compares the quality of image A with respect to another model image constructed from many images of natural scenes with certain distortions. The smaller the values of these functions, the higher the quality of the images.

TABLE I. SELECTION OF PARAMETER VALUES OF THE IMADJUST FUNCTION

Image title	Selected imadjust options	Original Score		Post-conversion assessment	
		Niqe	Brisque	Niqe	Brisque
1.png	[0.4,1] [0,1]	4.0372	16.1975	3.4770	32.7370
2.png	[0.5,1] [0,1]	4.2881	18.7059	3.8257	32.7584
3.png	[0.2,1] [0,1]	4.1413	10.4101	3.9845	32.8306
4.png	[0.3,1] [0,1]	4.2956	13.0724	3.8182	32.3951
5.png	[0.2,1] [0,1]	4.3203	25.7744	3.8746	33.5517
Normal	[0.1,1] [0,1]	3.1248	18.1867	2.7623	25.4380
Pneumonia1	[0.3,1] [0,1]	3.0242	36.0416	2.6395	36.6267
Pneumonia2	[0, 1][0, 1]	2.7003	34.2984	2.7003	34.2984
Pneumonia3	[0.2,1] [0,1]	3.0398	13.8546	2.9204	33.3662
Pneumonia4	[0.2,1] [0,1]	3.0501	45.8458	2.9693	42.2854

During the experiments we have tried many brightness ranges of source images, for which the attempts to increase the contrast of the X-ray images gave a positive result both visually and quantitatively. Table 1 shows examples of imadjust function parameters in determining the most appropriate value of parameter γ . If $\gamma < 1$, the resulting image will be lighter than the original one. However, in most cases there was no positive result in improving the image. If $\gamma > 1$, the curve of transformation of brightness values will be concave, and the resulting image will be darker than the original one. Here, for each selected value [low_in, high_in], [low_out, high_out], the parameter γ was selected from the range [1, 44.5] in increments of 0.5. From all [low_in, high_in] [low_out, high_out] the ones with the best γ values were selected, then they were compared in the table. For example, for image 1.png the results are shown in Table 2.

Thus, according to the data in Table 2, you can determine the best value of the input parameters of the imadjust function. When you select these parameters, you can visually display the result of the transformation and compare it with the original image (Fig. 1).

Figure 1. shows the original image(a) and the result of applying the imadjust function with the selected parameters(b). Here the NIQE score for the original image is 4.0372 and for the transformed image the score is 3.3252. We can note the higher contrast of the transformed image and the NIQE score shows a lower value than that of the original image.

Table 3 shows the best score values for the 10 test images.

When selecting the value of parameter γ , in most cases of performing the function, the result of transformation did not give improvement and visual perception and in the quantitative assessment of the result. For example, Figure 2 shows the results of the transformation of the original image 4.png.

TABLE II. RESULTS OF APPLYING THE PARAMETER Γ

Imadjust input parameters	Estimates for $\gamma = 1$		Best gamma value	Estimation	
	Niqe	Brisque		Niqe	Brisque
[0.2 1] [0 1]	3,8665	13,0019	$\gamma=4$	3,3524	16,0788
[0.3 1] [0 1]	3,7775	14,7344	$\gamma=2,5$	3,3252	26,8559
[0.4 1] [0 1]	3,4770	32,7370	$\gamma=2,5$	3,3790	25,9206
[0.5 1] [0 1]	3,6238	31,6125	$\gamma=2,5$	3,5020	28,2055

Fig. 1. Comparison of Imadjust ('1.png',[0.3, 1],[0, 1],2.5) (b) with the Original Image (a).

TABLE III. CHOICE OF Γ PARAMETER VALUE

Image title	brightness options	Estimates for $\gamma=1$		The best value of the parameter γ	Niqa evaluation	Brisque Evaluation
		Niqa	Brisque

Fig. 2. Original Image (a) and its Transformed Versions with Estimates (b)(c)(d)(e)(f).

Applying histogram equalization (5) of the original image before testing the imadjust function with the choice of the parameter γ , gives the result of enhancement image contrast (Table 4).

In the following experiment, histogram equalization techniques are applied to several images, comparing their results with the quality of the original image. For example, for the above image 4.png (a), the application of histogram equalization (b) and adaptive histogram equalization with contrast restriction (c) are shown in Figure 3.

Figure 4 shows the results of similar actions for another image person9_bacteria_39.jpeg. It can be seen in the figures that the application of the adaptive histogram equalization method with contrast restriction (c) compared to the HE images result (b) visually gives a better result, but the NIQA and BRISQUE estimates do not always match.

TABLE IV. IMAGE ESTIMATES AFTER HISTOGRAM EQUALIZATION

Brightness conversion	Estimates	
	Niqa	Brisque
source image(4.png)	4.2956	13.0724
imadjust(original,[0.2 1],[0 1])	4.0636	24.7639
imadjust(source,[0.2 1],[0 1],2)	4.4314	35.4912
Alignment of the histogram of the original image	4.2516	22.1638
imadjust(original aligned,[0.2 1],[0 1])	4.1986	36.9663
imadjust(source aligned,[0.2 1],[0 1],2)	3.8848	25.4878

Fig. 3. Comparison of the Results of Applying Histogram Equalization Methods to the Image with Non-reference Estimates for Image 4.png.

Fig. 4. Comparison of the Results of Applying Image Histogram Equalization Methods with Non-reference Estimates for the Person9_bacteria_39.jpeg (a) Image.

Table 5 shows the scores of 15 test images after applying the histogram equalization methods. In most cases, the results of applying the CLAHE method show a visual improvement in image contrast and a reduction in non-reference scores at the same time. In some cases, the estimates of the results of applying contrast-limited adaptive equalization do not decrease in value compared to the estimates of the original image.

As a result of analyzing the data in Table 5, it was decided that to improve the results of image contrast enhancement, it would be appropriate to replace the histogram equalization method with adaptive histogram equalization with contrast restriction. In the following experiment, function (6) was used to improve the contrast of image I in grayscale by transforming the values using adaptive histogram equalization with contrast restriction.

The application of this method was focused on the Distribution and SlipLimit parameters. The Distribution parameter takes the values 'uniform', 'rayleigh', 'exponential', which set the desired shape of the histogram. This parameter defines the distribution that adapthisteq uses as the basis for

creating the contrast conversion function. The selected distribution should depend on the type of input image. For example, underwater images seem more natural when using the 'rayleigh' distribution.

TABLE V. IMAGE SCORES AFTER APPLYING HISTOGRAM EQUALIZATION METHODS

Image title	Original image		Histogram equalization result		CLAHE result	
	Niqe	Brisque	Niqe	Brisque	Niqe	Brisque
1.png	4.03 72	16.19 75	3.80 41	18.59 71	3.27 15	10.64 72

person9_bacteria_39.jpeg	2.95 46	27.23 87	2.45 39	22.34 56	3.26 33	16.19 69
person17_bacteria_56.jpeg	2.69 56	38.59 77	2.69 56	38.59 77	2.69 56	38.59 77

The ClipLimit parameter is a contrast ratio that prevents oversaturation of the image, especially in homogeneous areas. These areas are characterized by a high peak on the histogram of a particular image fragment because many pixels fall within the same range of gray levels. Without clip limitation, the Adaptive Histogram Smoothing method can produce results that are, in some cases, worse than the original image. Its default value is 0.01.

The following steps were performed for several test X-ray images:

- To determine the optimal value of the 'clipLimit' parameter, we chose its values from the interval [0, 1] in steps of 0.01.

- Calculation of objective estimates for all transformed images.
- Plotting objective estimates for all versions of images.
- Determination of the minimal estimates NIQE and BRISQUE;
- Choosing the optimal visual representation of the image with the minimum objective estimates.

Construction of objective scores plots (Fig. 5) for several X-ray images showed that the values of cliplimit parameter can be limited from [0, 1] to [0, 0.2], as the following values were not informative. The minimal measures of the NIQE and BRISQUE estimates allow us to select images with improved contrast. This choice is related to the claim that the smaller the value of the non-reference score, the visually improved the image is. This assertion has been proven in previous studies, where a minimum NIQE score was more likely to coincide with an improved visual perception of the image.

Figure 6 shows a visual comparison of the original image (a) with the transformed one (b), where the clahe method is applied with the selected parameters and with the minimal NIQE score. Here the value of the distribution parameter is equal to 'rayleigh' and those obtained images are selected, at which the non-reference estimates had minimal values. For example, for the image 1.png the minimal estimate NIQE=2.9012 was received at cliplimit=0.12, and the BRISQUE=15.314 corresponds to it. For the image with minimal BRISQUE score equal to 9.1993 at value of cliplimit=0.01 the NIQE=3.2265 was defined. Here it can be noted that the decrease of the BRISQUE score in many cases does not correspond to the decrease of the NIQE score at which visual improvements were observed.

A visual comparison of the original image (a) with the CLAHE-transformed image (b) with minimal BRISQUE estimation is shown in Figure 7. Here the parameter distribution at value 'rayleigh' takes minimum BRISQUE value equal to 9.1993, which corresponds to NIQE=3.2365 at value of parameter cliplimit=0.01.

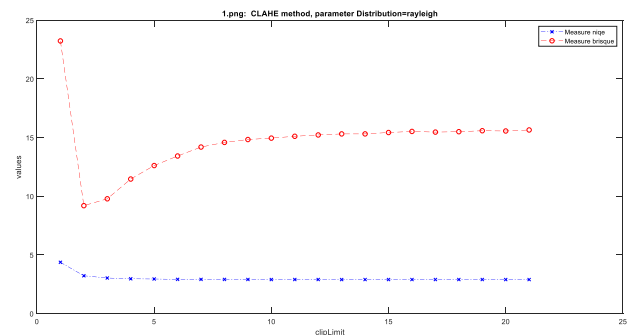

Fig. 5. Plots of Objective Estimates for the Transformed Images of the Original '1.png' with Distribution='Rayleigh'; and 'ClipLimit'=[0,0.2] with Step 0.01 (BRISQUE Estimates Marked in Red, Niqe Estimates Marked in Blue).

Fig. 6. Comparison of the Result of the Transformation of the Original Image (a) by the CLAHE Method (Distribution='Rayleigh', ClipLimit=0.12) (b) with the Minimum NIQE Estimate.

Fig. 9. Visual Comparison of the Original Image (a) with the Transformed CLAHE Method (Distribution='Exponential', ClipLimit=0.15)(b) and with the Minimum NIQE Estimate.

Fig. 7. Visual Comparison of the Original Image (a) with the Transformed CLAHE Method (Distribution='Rayleigh', ClipLimit=0.01) (b) and with the Minimum BRISQUE Estimate.

Fig. 10. Visual Comparison of the Original Image (a) with the CLAHE Transformed Image (Distribution='Exponential', ClipLimit=0.02) (b) with Minimum BRISQUE Estimation.

The plots of the objective estimates for the transformed images of the original '1.png' by the adaptive histogram equalization method with contrast constraint are shown in Figure 8. Here the distribution parameter takes the value 'exponential'; and the parameter 'clipLimit' receives values from the interval [0,02] with a step of 0.01.

A visual comparison of the original image (a) with the CLAHE-transformed image (b) with the minimum BRISQUE score is shown in Figure 9. Here the parameter distribution with 'exponential' value takes a minimum NIQE value of 2.8036, which corresponds to BRISQUE=12.6992 with the value of the parameter clipLimit=0.15.

A visual comparison of the original image (a) with the CLAHE-transformed image (b) with minimal BRISQUE estimation is shown in Figure 10. Here the parameter distribution at value 'exponential' takes minimum BRISQUE value equal to 6.9796, to which corresponds NIQE=3.0005 at value of parameter clipLimit=0.02.

The results of similar actions performed on the rest of the test images are shown in Table 6. Here are the non-reference estimates of the original image and the CLAHE transformation results with the selected values of the distribution parameter. For each value of this parameter, the minimum estimates of NIQE and BRISQUE, and their corresponding values of the clipLimit parameter and estimates have been determined.

Table 6 shows the values of the obtained non-referential estimates of the original image and the transformed images using the CLAHE method. Changing the values of the distribution and clipLimit parameters, when performing the adaptive equalization method with contrast restriction, gives positive results. An analysis of the values in Table 6 gives a preference for the value of the 'distribution='exponential' parameter for certain values of the clipLimit parameter. This is evidenced by the NIQE and BRISQUE non-reference scores, which decrease in value as the contrast of medical images improves. As demonstrated by the laboratory studies performed, in many cases the NIQE score was more consistent with image improvement.

As a result of the performed laboratory studies, a combination of the gamma correction method and the adaptive histogram equalization method, in which contrast enhancement is limited to avoid causing or enhancing noise in the image, is considered appropriate.

Fig. 8. Plots of Objective Estimates for the Transformed Images of the Original '1.png' with Values of Distribution='Exponential'; and 'ClipLimit'=[0,02] in Steps of 0.01 (BRISQUE Estimates Marked in Red, NIQE Estimates Marked in Blue).

TABLE VI. COMPARISON OF NON-REFERENCE ESTIMATES OF THE ORIGINAL IMAGE AND THE CLAHE-TRANSFORMED IMAGES WHEN CHANGING THE VALUES OF THE DISTRIBUTION AND CLIPLIMIT PARAMETERS

Image	Niqa (original)	Brisque (original)	distribution	min Niqa	for min Niqa, cliplimit	for min Niqa, Brisque	min Brisque	for min Brisque, cliplimit	for min Brisque, Niqa
1	4.0372	16.1975	'rayleigh'	2.9012	0.1200	15.314	9.1993	0.0100	3.2265

			'exponential'	2.7980	0	21.5236	18.7296	0.0100	3.1852

V. CONCLUSION

During the experiment, X-ray images were used, some of which visually improved without difficulty during luminance conversion, some of which took a darker shade after conversion, and the image quality remained poor. When working with such images, it was difficult to improve the contrast using gamma correction. To achieve better contrast, an image histogram alignment was performed before applying gamma correction. This resulted in better results. Based on the final Table 3, we can conclude that the best results were achieved with the input parameters [0.2 1] [0 1] with $\gamma = 2$. As a result of research of test image transformation variants, to improve the contrast of X-ray images it is recommended first to apply the histogram equalization procedure and then imadjust transformation with the parameters ([low_in 1] [0. 1], 2), where $0.2 \leq \text{low_in} \leq 0.4$. To improve the obtained results, it was decided to replace the histogram equalization with adaptive histogram equalization with contrast limitation. Because of applying this method, it was determined that the 'exponential' value is given preference when the distribution parameter is given a value values of the cliplimit parameter. It was also determined during the research that in most cases the quantitative measure of NIQA is more consistent with image improvement than the BRISQUE score when evaluating image quality.

Efficient Segment-based Image Ciphering using Discretized Chaotic Standard Map with ECB, OFB and CBC

Mohammed A. AlZain

Department of Information Technology, College of Computers and Information Technology
Taif University, P.O. Box 11099, Taif 21944, Saudi Arabia

Abstract—This paper presents a block-based ciphering scheme that employs the 2D discretized chaotic Standard map (CSM) in three different operation modes. The employed operation modes include the electronic codebook (ECB), the output feedback (OFB) and the cipher block chaining (CBC) modes. In the presented 2D discretized CSM with the OFB and CBC, the initiation vector (IV) is employed as the primary secret key. The presented 2D discretized CSM with the CBC has two merits. The first merit is the ability of the presented 2D discretized CSM with the ECB, OFB and CBC to encipher images of any dimensions in a comparatively short time. The second merit is the high level of security of the presented 2D discretized CSM with the OFB and CBC through the integration of both diffusion and confusion operations. Different security key metrics like histogram deviation, irregular, and coefficient of correlation, are examined to assess the functionality of the presented 2D discretized CSM with the OFB and CBC. The resistance to noise, uniformity of histogram, and encryption speed are also investigated. The suggested 2D discretized CSM with the OFB and CBC is compared with the 2D discretized CSM in ECB. The achieved outcomes demonstrate that the proposed 2D discretized CSM with the OFB and CBC has a high security than in ECB from cryptographic viewpoint. Also, achieved outcomes demonstrate that the proposed 2D discretized CSM has better noise immunity in OFB compared with ECB and OFB.

Keywords—Cryptography; 2D discretized CSM; ECB; OFB; CBC

I. INTRODUCTION

The cryptography field is especially important in the modern era, where information security is paramount. Security is an important issue for image communications and storage, and ciphering is considered as one of the most important ways to realize and ensure security. Ciphering has a lot of applications such as online communications, multimedia communications, medical image protection, telemedicine, military communications, pay TV, and video conferencing. Chaotic ciphering has an important role in current cryptography. The attraction of utilizing chaotic ciphering for implementing the current cryptosystems is due to several reasons which satisfy the traditional Shannon requirements of both diffusion and confusion [1-3]. These reasons may include its random-like behavior and parameters setting sensitivity and preconceived conditions [4]. Chaotic-based schemes have demonstrated some positive features in many of the affected

areas in terms of speed, integration complexity, security, power, and computational overhead. Now, some ciphers for securing images have been presented [5-8]. Other cryptosystems based on discrete chaotic systems have been suggested, but still they have some concerns about their security [9-15].

Actually, there exists two basic ways to approach digital images chaotic ciphering. In the first approach, a chaos-based stream cipher model is employed for generating pseudo-random access keys to hide the source plaintext [16]. This model is known as stream cipher. In the other scheme, the source text or secret key can be employed as initialization conditions or control parameters, and the chaotic system is iterated for several rounds to deliver the final encrypted data [17-18]. This model is known as block cipher. Now, the chaotic 2D maps have been developed into 3D to design symmetric cryptosystems, which are intended to increase security. The 3D chaotic Baker mapping introduced by Mao et al. and 3D chaotic Cat mapping introduced by Chen et al. [19-20] represent some examples of 3D chaotic maps.

In the article, a block-based ciphering scheme that employs the 2D discretized CSM with the ECB, OFB and CBC is presented. In the presented 2D discretized CSM with the OFB and CBC, the image is split into blocks, and the encryption is applied for each one of these blocks using the 2D discretized CSM with the ECB, CBC and OFB. The initiation vector (IV) is employed as the primary secret key. The 2D discretized CSM with the CBC provides two advantages. The first is the ability of the presented 2D discretized CSM with the ECB, OFB and CBC to encipher images of any dimensions in a comparatively short time. The second one is the high level of security of the presented 2D discretized CSM with the ECB, OFB and CBC through the integration of both diffusion and confusion operations. Several security key performance metrics like histogram deviation, irregular, and coefficient of correlation, are examined to assess the functionality of the presented 2D discretized CSM with the ECB, OFB and CBC. The resistance to noise, uniformity of histogram, and encryption speed are also investigated. The suggested 2D discretized CSM with the ECB, OFB and CBC is compared with the 2D discretized CSM and the RC5. The achieved outcomes demonstrate that the proposed 2D discretized CSM with the ECB, OFB and CBC has a high security from cryptographic viewpoint.

The remainder of this paper is structured as follows. Section II provides an overview of the traditional 2D CSM, 2D discretized CSM in addition to the utilized ECB, OFB and CBC operation modes. Section III presents the introduced image cryptosystem using 2D discretized CSM with the ECB, OFB and CBC. Section IV gives the design issues of the proposed image cryptosystem using 2D discretized CSM with the ECB, OFB and CBC cryptosystem. Section V provides encryption quality metrics used to evaluate the performance of the proposed image cryptosystem using 2D discretized CSM with the ECB, OFB and CBC. Section VI provides the results of the presented image cryptosystem using 2D discretized CSM with the ECB, OFB and CBC. Finally, the paper conclusions are listed in Section VII.

II. PRELIMINARY TOOLS

This part provides a compact overview for three conventional cryptosystems, the 2D CSM, 2D discretized CSM, and RC5 ciphers in addition to the utilized ECB, OFB and CBC operation modes. All of 2D CSM, 2D with the ECB, OFB and CBC are symmetric block ciphers. In both crypto ciphers, the utilized key is the same for both of encryption and decryption.

A. The 2D Chaotic Standard Map (2D CSM) and 2D Discretized CSM Cipher

With chaos-based image ciphering, the positions of pixels are arbitrarily changed. Different chaotic-based maps may be employed with chaos-based image ciphering like 2D Cat, 2D Henon, 2D Baker, line, and General maps. The Standard mapping, Cat mapping, Henon mapping, and Baker mapping employ processes of geometric modifications. The line mapping employs stretching of the whole pixels form a straight line, and employs folding according to certain rules. Then, the plainimage pixels are chaotically distributed in the resulted cipherimage and nearby pixels are no longer important. On contrary, a typical 2D CSM was developed by Boris Chirikov in 1969. The 2D CSM with continuous confusion is described as follows [21]:

$$\begin{bmatrix} u(i+1) \\ v(i+1) \end{bmatrix} = \begin{bmatrix} (u(i) + v(i)) \bmod 2\pi \\ (v(i) + k \sin u(i+1)) \bmod 2\pi \end{bmatrix} \quad (1)$$

If Eq. 1 is discretized, it will be mapped from $[0, 2\pi]$, to $M \times M$ through putting $u = uM/2\pi$, $v = vM/2\pi$, and $k = kM/2\pi$ to transform the 2D CSM to the 2D discretized CSM as follows [21]:

$$\begin{bmatrix} u(i+1) \\ v(i+1) \end{bmatrix} = \begin{bmatrix} (u(i) + v(i)) \bmod M \\ \left(v(i) + K \sin \frac{u(i+1)M}{2\pi} \right) \bmod M \end{bmatrix} \quad (2)$$

where k denotes a non-negative integer.

If the 2D discretized CSM is employed for image ciphering, $u(i)$ and $v(i)$ represent the pixel coordinates of the plainimage. $u(i+1)$ and $v(i+1)$ represent the pixel coordinates of the cipherimage.

The 2D discretized CSM is intended to achieve continuous map properties; it must be very close to the base map as the number of pixels is usually endless [21]. The resulted cipher of the 2D discretized CSM is a permutation cipher, which cannot modify the cipherimage histogram from its corresponding plainimage. Since this cipher is simple and fast, it does provide a high level of security, and its processing time grows as image dimensions increases.

B. The ECB Mode

The ECB mode starts through segmenting the input data into segments of equal sizes as illustrated in Fig. 1(a). Then every segment is separately encrypted using the same encryption key. The ECB operation mode can be mathematically represented using the following equation:

$$\text{Cipher}_j = \text{ENC}_k(\text{Plain}_j), \quad j=1,2,3,\dots,n \quad (3)$$

The ECB deciphering process can be represented as:

$$\text{Plain}_j = \text{DEC}_k(\text{Cipher}_j), \quad j=1,2,3,\dots,n \quad (4)$$

C. The OFB Mode

The OFB mode starts through ciphering the IV as illustrated in Fig. 1(b). Then, the resulted output bits are XORed with their corresponding plaintext block to result in the ciphertext block. In addition, the resulted ciphertext block bits are utilized an input IV to the next stage. The procedure is repeated till reaching the final block. The OFB operation mode can be mathematically represented using the following equation:

$$\text{Cipher}_j = \text{Plain}_j \oplus I_j, \quad j=1,2,3,\dots,n \quad (5)$$

The OFB deciphering process can be represented as:

$$\text{Plain}_j = \text{Cipher}_j \oplus I_j, \quad j=1,2,3,\dots,n \quad (6)$$

where $I_j = \text{ENC}_k(I_{j-1})$, $j=1, 2, 3 \dots n$, and $I_0 = \text{IV}$.

As CBC mode, ciphering phase should be strong enough to provide efficient immunity to any attack attempts to break it.

D. The CBC Operation Mode

The CBC operation mode is a segment encryption mechanism as illustrated in Fig. 1(c). The CBC operation mode has been employed for use with the 2D discretized CSM in the introduced cipher. In the introduced 2D discretized CSM cipher with CBC, the CBC mode utilizes IV of equivalent size to the segmented block size. First, each one of IV pixels is XORed with its corresponding block pixel in the 1st block. After that, the outgoing pixels are ciphered. The first block pixels are employed as IV to encipher the second block. The process is repeated with the same sequence until reaching the final block. The CBC operation mode can be mathematically represented using the following equation:

$$\text{Cipher}_j = \text{ENC}_k(\text{Cipher}_{j-1} \oplus \text{Plain}_j), \quad j=1, 2, 3, \dots, n \quad (7)$$

where $\text{Cipher}_0 = \text{IV}$, Cipher_j denotes the ciphered block, \oplus represents the XOR operation, and ENC_k denotes the 2D CSM encryption.

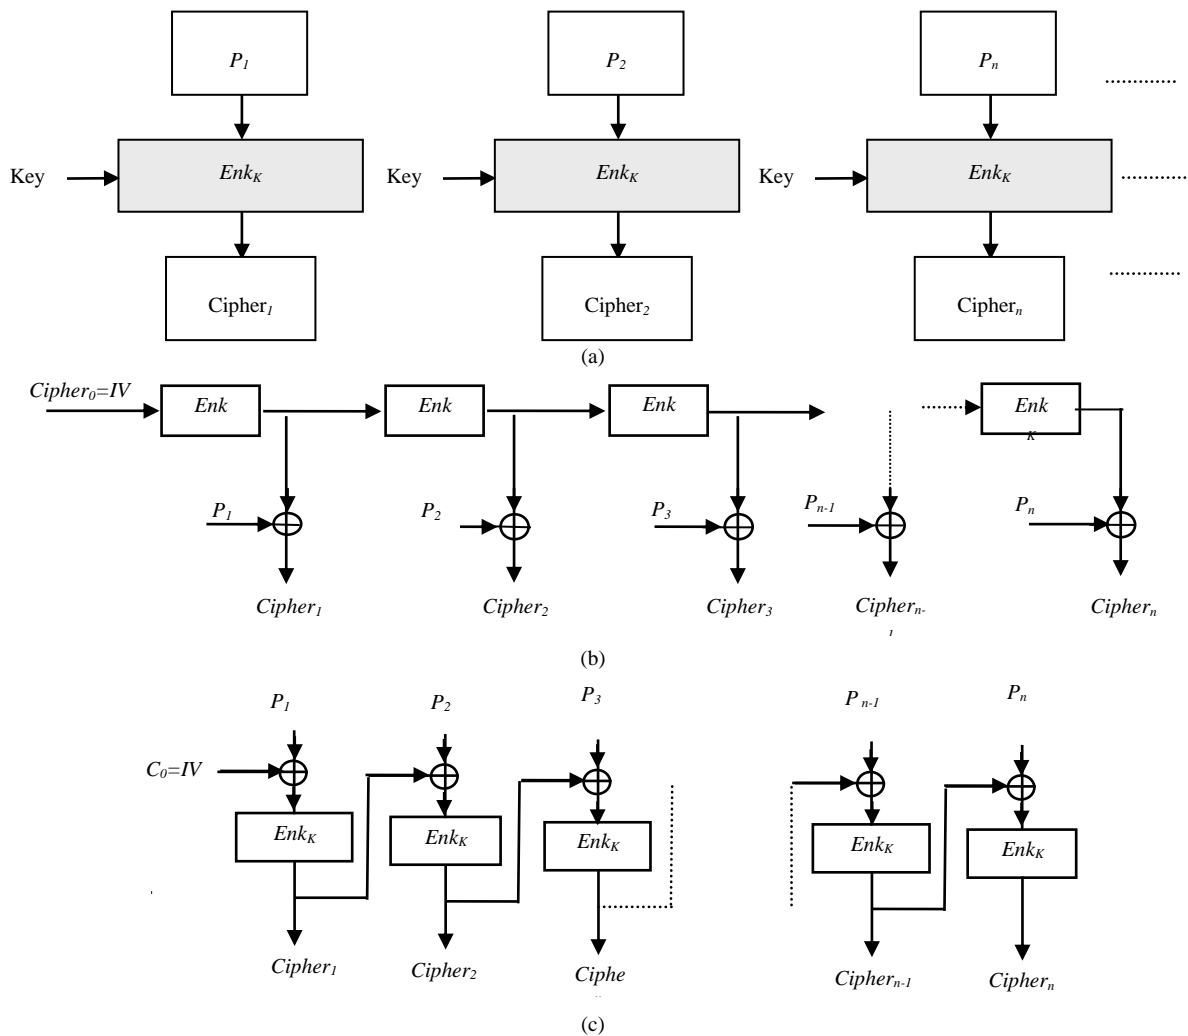

Fig. 1. The Employed ECB, OFB and CBC with Introduced 2D Discretized CSM Cipher as Depicted in (a), (b) and (c).

The CBC operation mode employs an integration method that employs dependence on each cipherimage block for all the previous cipherimage blocks. As a consequence, all eligibility for all previous cipherimage blocks is contained in the previous cipherimage blocks [22]. The CBC basic drawback disadvantage lies in the fact that an attack on just single cipherimage segment affects two plainimage segments when employing decryption [23]. The CBC deciphering process can be represented as:

$$\text{Plain}_j = \text{DEC}_k (\text{Cipher}_j) \oplus \text{Cipher}_{j-1}, \quad j=1, 2, 3, \dots, n \quad (8)$$

where DEC_k denotes the deciphering procedure.

III. PROPOSED 2D DISCRETIZED CSM-BASED IMAGE CIPHER WITH OFB AND CBC OPERATION MODES

This part is to provide an overview of the introduced 2D discretized CSM cipher with the ECB, OFB and CBC. The proposed 2D discretized CSM cipher with the ECB, OFB and CBC is designed with the potential of enhancing the security the cipherimage and providing a reasonable encryption/decryption speeds. For realizing these objectives, 2D discretized CSM encryption is employed with the ECB, OFB and CBC [24-29]. Three schemes of the 2D discretized

CSM with ECB, OFB and CBC are examined to determine which operation mode that will increase the efficiency of the proposed 2D discretized CSM cipher.

The operation of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC may be summed up as shown below in the next three steps. The steps of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC is depicted can be listed as:

- 1) The plainimage to be encrypted is scanned line by line.
- 2) The scanned image is segmented into blocks of; each block of has $n \times n$ pixels.
- 3) The segmented image blocks are ciphered using the proposed 2D discretized CSM cipher with the ECB, OFB and CBC modes of operation as depicted in Fig. 1.

IV. DESIGN POINTS OF THE 2D DISCRETIZED CSM CIPHER WITH THE OFB AND CBC

As mentioned previously, the proposed 2D discretized CSM cipher may be employed in ECB, OFB and CBC operating modes. It basically employs a 2D discretized CSM with the ECB, OFB and CBC as the main cipher scheme. It is

well known that scrambling employed in the 2D discretized CSM resembles like random behaviour [30]. The proposed 2D discretized CSM cipher with the OFB and CBC employs IV as a primary key. The IV should be random to be resistant against various types of brute force attacks. The utilized XOR among the IV fragments and data block fragments modifies pixel values, making the proposed 2D discretized CSM cipher with the ECB, OFB and CBC like a standard 3-D map. The proposed 2D discretized CSM cipher with the ECB, OFB and CBC also employs a secondary key, which is utilized in the 2D discretized CSM to shuffle pixels.

Finally, the proposed 2D discretized CSM cipher with the ECB, OFB and CBC image cryptosystem depends on segmenting the images to be cipher into various segments. The segment size in bits considered of a significant factor for affecting the performance of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC. The segment size impact on cipher quality is examined in details in the experimental results part. Since the Section IV provides an equivalent bits size as plaintext segment size, increasing the segment size will result in increasing the security. In addition, the proposed 2D discretized CSM cipher with the ECB, OFB and CBC has the ability for encrypting digital images of any size after splitting them into smaller segments.

V. CIPHER QUALITY KEY INDICATORS

The cipher quality testing is very important for image cipher. Visual encryption quality is not sufficient for this test. So, there is a need for mathematical cipher quality key indicator metrics. Here, four cipher quality indicators will be considered to assess and compare the effectiveness of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC. These quality key indicator metrics include correlation coefficient, irregular deviation, and deviations of histogram. In addition, two other quality key indicator metrics are also considered to assess cipher quality; histogram uniformity, and computational time [31-40].

A. The Correlation Coefficient

The correlation coefficient may be considered as a significant estimation for assessing the ciphering quality of any image cipher. As the correlation coefficient becomes near zero, the performance of the image cipher becomes good [31-32]. The correlation coefficient can be estimated as follows [31-32]:

$$CC = \frac{\text{cov}(x,y)}{\sqrt{D(x)}\sqrt{D(y)}} \quad (9)$$

where x and y denotes the pixels intensity levels at the same location in both the plainimage and ciphered image. The definitions for the covariance, standard deviation and mean are given below as follows:

$$\text{cov}(x,y) = \frac{1}{L} \sum_{i=1}^L (x(i) - E(x))(y(i) - E(y)) \quad (10)$$

$$D(x) = \frac{1}{L} \sum_{i=1}^L (x(i) - E(x))^2 \quad (11)$$

$$D(y) = \frac{1}{L} \sum_{i=1}^L (y(i) - E(y))^2 \quad (12)$$

where, L denotes the pixels number. As the correlation becomes near zero, the better the image cipher quality.

B. Histogram Distribution

The cipherimage histogram distribution can be utilized as an indicator for assessing the quality of the proposed 2D CSM cipher with the ECB, OFB and CBC. As the cipherimage has a uniform histogram distribution, the proposed 2D CSM cipher with the ECB, OFB and CBC has a good ciphering quality.

C. The Irregular Deviation

The irregular may be employed for assessing the ciphering quality in terms of how much it can reduce the deviation to be near the histogram of an ideally ciphered image [33-35]. The process of estimating the irregular deviation starts by calculating the absolute deviation among the plainimage and the enciphered image. After that it calculates the histogram of the resulted absolute deviation. Then, calculate the mean histogram of the resulted absolute deviation. Finally, calculate the histogram deviation absolute mean value.

The irregular deviation can be computed as given below:

$$D_I = \frac{\left| \sum_{i=0}^{255} H(i) - M_H \right|}{MxN} \quad (13)$$

As the irregular deviation becomes low, the performance of the image cipher becomes good.

D. The Deviation of Histogram

The deviation of histogram can be employed for assessing the ciphering quality in terms of how much it can magnify the difference among the plainimage and the enciphered image [36-38]. The process of estimating the deviation of histogram starts by calculating the histogram of the plainimage and the enciphered image. After that, calculate the absolute deviation among histogram of the plainimage and the enciphered image. Finally, compute the curve area beyond the absolute deviation divided by the total image area as follows [36-38]:

$$D_H = \frac{\left(\frac{d_0 + d_{255}}{2} + \sum_{i=1}^{254} d_i \right)}{MxN} \quad (14)$$

where d_i denotes is the absolute difference curve magnitude at intensity level i , M and N denote the image dimensions. As the deviation of histogram becomes high, the performance of the image cipher becomes good [25].

E. The Impact of Noise

Noise immunity demonstrates the cipher capability to withstand and against the noise. To examine and measure the impact of noise on the proposed 2D discretized CSM cipher with the ECB, OFB and CBC, noises of various SNRs are added to cipherimages, and after that the deciphering procedure is applied. If the resulted deciphered image is very close to its corresponding plainimage, it could mean that the proposed 2D

discretized CSM cipher with the ECB, OFB and CBC has a capability to resist the noise [39-42]. This proximity can be ensured numerically or visually using the correlation coefficients and the PSNR of the deciphered image, which can be denoted as follows [39-42]:

$$PSNR = 10 \times \log_{10} \left(\frac{M \times N \times 255^2}{\sum_{m=1}^M \sum_{n=1}^N (f(m,n) - f_d(m,n))^2} \right) \quad (15)$$

where $f(m,n)$ denotes the plainimage and $f_d(m,n)$ denotes its corresponding deciphered image.

VI. EXPERIMENTAL TESTS AND DISCUSSION

In experimental tests, test experiments were employed to investigate and examine the proposed 2D discretized CSM cipher with the ECB, OFB and CBC. With respect to the proposed 2D discretized CSM cipher with the ECB, OFB and CBC, the IV is employed as a portion of the enciphered Pirate image, and has an equivalent size with respect to the chosen segment size. Various segments of different sizes were examined in testing the proposed 2D discretized CSM cipher with the ECB, OFB and CBC as shown below:

- 1) $S_1 = IV = 4 \times 4$ with IV as a portion of the enciphered Pirate image.
- 2) $S_2 = IV = 8 \times 8$ with IV as a portion of the enciphered Pirate image.
- 3) $S_3 = IV = 16 \times 16$ with IV as a portion of the enciphered Pirate image.
- 4) $S_4 = IV = 32 \times 32$ with IV as a portion of the enciphered Pirate image.
- 5) $S_5 = IV = 64 \times 64$ with IV as a portion of the enciphered Pirate image.
- 6) $S_6 = IV = 128 \times 128$ with IV as a portion of the enciphered Pirate image.
- 7) $S_7 = IV = 256 \times 256$ with IV as a portion of the enciphered Pirate image.

The enciphered Pirate images using the proposed 2D discretized CSM cipher with the ECB, OFB and CBC and various segment sizes are depicted in Fig. 2. It is clearly noted from Fig. 2 that the proposed 2D discretized CSM cipher with the OFB and CBC has a better performance than the proposed 2D discretized CSM cipher with ECB especially with small segment sizes. Also, with increasing the segment size, the proposed 2D discretized CSM cipher with the OFB and CBC has a good performance in hiding all the details of the enciphered images.

The histograms distribution of Pirate plainimage and its enciphered image using the 2D discretized CSM image cipher with the ECB, OFB and CBC are depicted in Fig. 3. It is clearly noted from Fig. 3 that the 2D discretized CSM image cipher with ECB does not provide histogram uniformity and it has the same histogram of the original Pirate plainimage. This is due to the fact that the 2D discretized CSM image cipher with ECB performs just permutation which does not change the histograms of the encrypted images which may be considered

as a basic weakness. Finally, it is clear from Fig. 3 that the 2D discretized CSM image cipher with the OFB and CBC can provide histogram uniformity.

Fig. 2. Enciphered Pirate Images using the Proposed 2D Discretized CSM Cipher with the OFB and CBC with Various Segment Sizes.

Tables I, II, and III illustrates the numerical estimations of the evaluated key performance metrics like correlation coefficient (CC), irregular deviation (ID) and maximum deviation (MD) for the proposed 2D discretized CSM cipher with the ECB, OFB and CBC and various segment sizes.

The CC outcomes results listed in Table I demonstrated that the proposed 2D discretized CSM cipher with the OFB and CBC has lower CC values than in the proposed 2D discretized CSM cipher with the ECB. Also, with increasing the segment size, the CC values of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC becomes near the zero value.

The ID outcomes results listed in Table II demonstrated that the proposed 2D discretized CSM cipher with the OFB and CBC has lower ID values than in the proposed 2D discretized

CSM cipher with the ECB. Also, with increasing the segment size, the ID values of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC decrease.

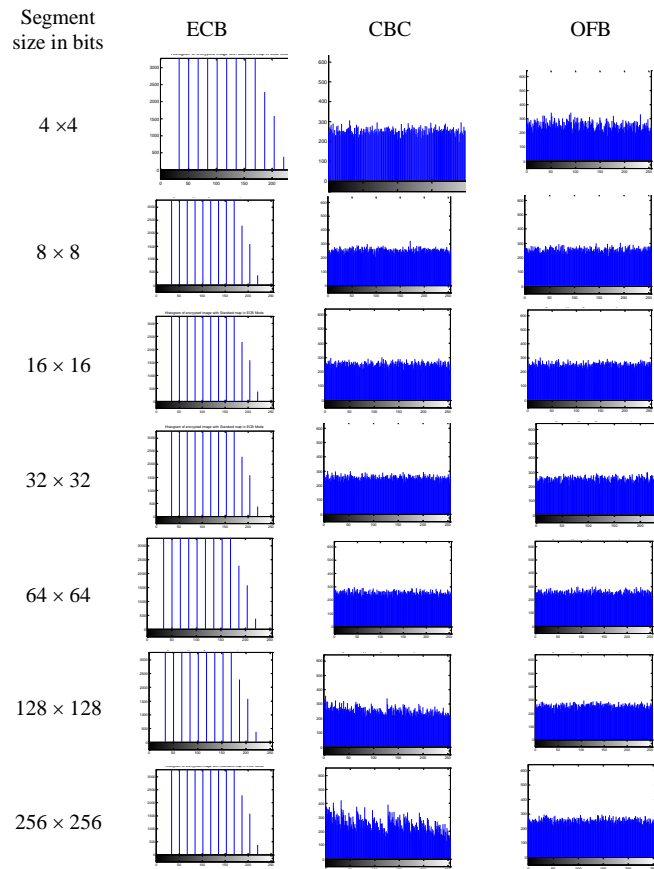

Fig. 3. Histogram of Enciphered Pirate Images using the Proposed 2D Discretized CSM Cipher with the OFB and CBC with Various Segment Sizes.

The MD outcomes results are listed in Table III and the outcomes results demonstrated that the 2D discretized CSM image cipher with ECB provides zero MD values. This is due to the fact that the 2D discretized CSM image cipher with ECB performs just permutation which does not change the histograms of the encrypted images.

Also, the proposed 2D discretized CSM cipher with the OFB and CBC has better MD values than in the proposed 2D discretized CSM cipher with the ECB.

4 × 4	0	1.8963	1.8920
8 × 8	0	1.8978	1.9002
16 × 16	0	1.8988	1.8988
32 × 32	0	1.8980	1.8986
64 × 64	0	1.8934	1.8970
32 × 128	0	1.9020	1.8977
256 × 256	0	1.8992	1.8969

To examine the impact of the noise for the proposed 2D discretized CSM cipher with the ECB, OFB and CBC, the additive white Gaussian noise (AWGN) of SNR equals to 5 dB is summed to the enciphered Pirate image, and the deciphering procedure is applied. The deciphering outcome results of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC and various segment sizes are depicted in Fig. 4. It is clearly noted from Fig. 4 that the proposed 2D discretized CSM cipher with the OFB has a better performance than the proposed 2D discretized CSM cipher with the ECB and CBC with small segment sizes. Also, the proposed 2D discretized CSM cipher with the OFB is more resistant to noise than the proposed 2D discretized CSM cipher with the ECB and CBC.

In addition, the OFB and CBC operation modes provide approximately equivalent performance in the existence of noise. Finally, the segment size has no impact on noise resistance of the proposed 2D discretized CSM cipher with the ECB, OFB and CBC.

Table IV and Table V illustrate the numerical estimations of the evaluated key performance metrics like PSNR and CC for the proposed 2D discretized CSM cipher with the ECB, OFB and CBC and various segment sizes. These PSNR and CC numerical key performance indicator values are estimated in the AWGN existence of SNR equals 5 dB. The PSNR and CC results listed in Table IV and Table V demonstrated that the proposed 2D discretized CSM cipher with the OFB has a better PSNR and CC than the proposed 2D discretized CSM cipher with the ECB and CBC.

64 × 64	21.1369	20.4960	29.5665
32 × 128	21.2714	20.8906	28.9257
256 × 256	21.3248	21.3151	29.4045

TABLE V. NUMERICAL CC VALUES OF THE 2D DISCRETIZED CSM IMAGE CIPHER, AND THE PROPOSED 2D DISCRETIZED CSM CIPHER WITH THE OFB AND CBC AND VARIOUS SEGMENT SIZES

Segment size in bits	ECB	CBC	OFB
4 × 4	0.9043	0.8862	0.9842
8 × 8	0.9057	0.8894	0.9834
16 × 16	0.9066	0.8892	0.9831
32 × 32	0.9002	0.8868	0.9836
64 × 64	0.9005	0.8856	0.9848
32 × 128	0.9036	0.8953	0.9824
256 × 256	0.9044	0.9042	0.9842

Also, the proposed 2D discretized CSM cipher with the OFB is more resistant to noise than the proposed 2D discretized CSM cipher with the ECB and CBC. Finally, it can be confirmed and ensured that the proposed 2D discretized CSM cipher with the OFB can provide a better trade-off among the security level and noise immunity.

VII. CONCLUSION

This paper introduces a 2D discretized CSM cipher with the ECB, OFB and CBC that depends on dividing the plainimage to be enciphered into segments and enciphering each segment with the 2D discretized CSM cipher with the ECB, OFB and CBC. The proposed 2D discretized CSM cipher with the OFB provides a better trade-off among the high noise resistivity and high security level. The tests demonstrated that the 2D discretized CSM cipher with the OFB and CBC also achieve a uniform histogram distribution that cannot be achieved using the proposed 2D discretized CSM cipher with the ECB. The 2D discretized CSM is compared in different modes of operation. The outcomes demonstrated that the proposed 2D discretized CSM with the OFB and CBC has a high security. Finally, the proposed 2D discretized CSM cipher with the OFB has good noise immunity than the proposed 2D discretized CSM cipher with the ECB and CBC.

Abstract—Text-based social media platforms have developed into important components for communication between customers and businesses. Users can easily state their thoughts and evaluations about products or services on social media. Machine learning algorithms have been hailed as one of the most efficient approaches for sentiment analysis in recent years. However, as the number of online reviews increases, the dimensionality of text data increases significantly. Due to the dimensionality issue, the performance of machine learning methods has been degraded. However, traditional feature selection methods select attributes based on their popularity, which typically does not improve classification performance. This work presents a population-based metaheuristic for feature selection algorithms named Flower Pollination Algorithms (FPA) because of their propensity to accept less optimum solutions and avoid getting caught in local optimum solutions. The study analyses tweets from Kaggle first with the usual Term Frequency-Inverse Document Frequency statistical weighting filter and then with the FPA. Four baseline classifiers are used to train the features: Naive Bayes (NB), Decision Tree (DT), Support Vector Machine (SVM), and k-Nearest Neighbor (kNN). The results demonstrate that the FPA outperforms alternative feature subset selection algorithms. For the FPA, an average improvement in accuracy of 2.7% is seen. The SVM achieves a better accuracy of 98.99%.

Keywords—Sentiment analysis; metaheuristic algorithm; flower pollination algorithm; machine learning; feature selection

I. INTRODUCTION

The introduction of the second generation of the web has resulted in the development of more interactive websites where users will play a significant role by contributing their thoughts, suggestions, and comments via the website's services. Large-scale communication, which is not limited to comments on news, services, or even goods or products, can also be used to facilitate conversation amongst website users within social networks. Social networks allow users to contact one another, engage, and collaborate to become content creators on a single platform known as social media. Through social media, they can provide views, comments, and experiences on an issue [1]–[6].

There are many web users, and there is also a large amount of information sharing in the form of reviews, which makes analyzing the reviews manually tricky and time-consuming. Sentiment Analysis (SA) has been introduced as a practical approach to determining the sentiments included in web materials to tackle this issue [7]–[10].

SA is a type of text classification problem that involves subjective statements. Another name for sentiment analysis is Opinion Mining (OP), where an opinion or comment is processed to determine the consumer's perception of a matter or issue. SA is one of the areas of data mining and text mining that falls under the category of web content mining techniques [8], [11]–[13]. It is defined as the computer study of public perceptions, beliefs, and moods around a specific topic [14]. It is a subset of natural language processing jobs that assesses a large amount of viewer content on social media, blog posts, e-commerce portals, and other user-editable online forums.

One of the primary challenges associated with sentiment analysis is the preprocessing phase of the text, in which they must handle user feedback on social media, webpages, and blog posts that contain irrelevant and noisy content. [15] studied the effects of text preprocessing in sentiment analysis. They found inconsistent text classification results, which is likely due to inefficient text preprocessing methods. Most researchers use only a fraction of the text preprocessing techniques [6], [16], [17]. In addition to improvements in the feature selection phase, the text preprocessing phase also plays a significant role in improving text or sentiment classification performance [2], [18]. According to [18], the habit will increase the results of text classification accuracy.

The magnitude of the feature dimension for text parsing is an additional key difficulty in sentiment analysis. Bag-of-Words is commonly used to represent document text in machine learning algorithms for sentiment categorization [19], [20]. Words in a text document contain feature vectors with large dimensions. As a result, the feature selection process focuses on selecting the optimal subset of features from a large-dimensional feature size. This is accomplished by removing cluttered and irrelevant features without altering the original data [14], [21].

According to [19], it is vital to select an optimal subset of features that represents the actual feature subsets to reduce feature size and increase classification accuracy. An optimization algorithm was utilized as the strategy for selecting features [14]. Previous research [22]–[25] has demonstrated that an optimization algorithm strategy for feature selection can handle feature selection and feature reduction issues in large amounts of data containing noise, redundant, and inaccurate information.

Flower Pollination Algorithm (FPA) is one of the algorithms inspired by nature. This algorithm has advantages in

terms of performance when it is applied in improving performance in various optimization issue problems as well as having few parameters [22], [26], [27]. According to [22], the FPA is a flexible and easily adaptable optimization method. However, research on the use of FPA in feature selection problems in sentiment analysis has not yet been conducted. So, this is necessary to study and further improve the performance of FPA for feature selection problems. Therefore, the development of feature selection methods that use FPA is expected to be able to select a more discriminatory feature set and improve the sentiment classification results.

On the other hand, the sentiment classification process is another issue in sentiment analysis technology due to the involvement of the textual data [5]. Furthermore, simple text classification and sentiment classification in text mining are two different things. Text classification in text mining identifies topics found in a data set. The classification of sentiment, on the other hand, is classified in terms of the type of sentiment in the text. When there are strategies to minimize the dimensions in large-sized data sets, sentiment classification performance can be enhanced [10], [28], [29]. This method generally serves to detect and eliminate irrelevant and overlapping data so that the sentiment classification results are meaningful.

The remaining sections of this work are structured as follows: The second section examines previous works on feature selection and the necessary component of FPA. Next, Section 3 provides an overview of the technique applied in this study, while Section 4 details the FPA algorithm proposed for feature selection in sentiment analysis. The findings of the experiments are discussed in Section 5, and the study is concluded in Section 6.

II. RELATED WORK

Different approaches for selecting features have been proposed and developed, and they are explored by researchers. Metaheuristic techniques improve solution performance over and over again [30]. These metaheuristic techniques are based on observations of natural phenomena such as ant colony optimization, bat algorithms, and flower pollination optimization. This metaheuristic is then used in the bandage feature selection method. This method has been gaining more attention recently [31] as it attempts to produce better solutions by applying knowledge gained from natural solutions. The wrapper approach in feature selection evaluates the quality of the selected features based on their classification performance. The wrapping method has two main steps: (1) finding a subset of features and (2) evaluating the selected features. Both of these steps will be repeated until the stop criteria are met. It starts with the production of a subset, and then the classification will evaluate the subset produced.

Previous studies proposed feature selection methods based on particle clustering optimization and the nearest k-neighbor classification [24]. In addition, based on an analysis from [32] also proposed a hybrid approach of feature selection based on genetic algorithms for the classification of Arabic texts using a wrapper model. In the first step, six feature evaluation methods are used simultaneously to select a subset of features. Then an

enhanced genetic algorithm is used to optimize the selected subset.

The technique of selecting the optimal subset of features using firefly's algorithm for sentiment analysis problems has also proven the ability of this metaheuristic algorithm [16]. While in a study conducted by [17] where researchers improved the whale optimization algorithm for feature selection of two types of sentiment analysis data, namely in Arabic and English. Moreover, the hybridization between the ant colony optimization algorithm and k-Nearest Neighbors has successfully improved the sentiment classification results as it has been applied to the feature selection process [6]. These studies report that their method is more effective compared to the use of filter methods.

The FPA is an algorithm inspired by nature that imitates the basic pollination activity of flowers. In [33], four rules are idealized. Rule 1 of global pollination incorporates biotics and cross-pollination, with the pollinating agent transporting pollen according to the Lévy flight. Rule 2 requires abiotic and self-pollination for local pollination. Next, for Rule 3, the flower constant can be interpreted as the reproduction probability proportional to the degree of resemblance between two flowers. Rule 4 is the exchange probability p [0, 1], which can be regulated by external factors such as wind between local and global pollination. Local pollination accounted for a sizeable proportion of the total pollination activity.

FPA was successfully adapted for several domains of optimization problems [22]. For the field of electrical and power generation, [34] has introduced a Modified FPA (MFPA) that employs dynamic switching probabilities, the application of Real Coded Genetic Algorithm (RCGA) mutations for global and local searches, and differentiation between searches temporary localization and optimal solutions. The MFPA was subsequently assessed for ten power system benchmarks, and the experimental results revealed lesser fuel costs than the FPA. Another study by [35] presented MFPA to assess the fuel funding and time required to get to the globally optimal solution. The Institute of Electrical and Electronics Engineers 30 (IEEE 30) bus test system demonstrated that MFPA outperformed FPA and metaheuristic algorithms.

Next, research involving FPA was conducted on the signal and image processing domains. The Binary Flower Pollination Algorithm (BFPA) has been implemented to solve the challenge of lowering the number of sensors necessary to identify individuals' electroencephalogram signals [36]. BFPA is used to choose the ideal selection of channels that provide maximum accuracy. Based on the Optimum-Path Forest classifier, the findings of the BFPA experiment indicate an identification rate of up to 87 percent. In addition, [37] has done a thorough evaluation of BFPA's performance in solving the Antenna Positioning Problem (APP) area. BFPA was evaluated with real, artificial, and random data of various dimensions and compared with Population-Based Increment Learning (PBIL) and Differential Evolution (DE) algorithms, two efficient APP domain methods. In the sphere of APP, FPA obtains more competitive technical advances than PBIL and DE.

FPA is also not left behind to be applied to the clustering and classification domain. The performance of the modified FPA is tested through a clustering problem. This algorithm was evaluated with several different optimization algorithms, including bat, firefly, and conventional FPA on 10 cluster data sets. From the 10 data sets, 8 were generated from pattern recognition, and 2 were generated artificially. The clustering result is calculated in terms of the value of the objective function and the time taken by the CPU on each run. The distribution length graph illustrates the convergence behavior of the algorithm. The results show that the modified FPA exceeds the comparable algorithm to achieve the best fitness value and reduce CPU processing time [38].

Aside from that, the BFPA was applied to feature selection problems and tested on six data sets, where it outperformed Particle Swarm Optimization (PSO), Harmony Search (HS), and Firefly Algorithm (FA) [39]. BCFA is a hybrid algorithm that combines the Clonal Selection Algorithm (CSA) with FPA to tackle feature selection issues. It was introduced in [40]. Using the Optimum-Path Forest classifier as an objective function with the proposed hybrid algorithm (BCFA) has led to superior performance compared to existing metaheuristics. A new methodology for multi-objective feature selection is based on FPA and rough set theory to identify the optimal classification feature set [41]. This model selects features using the filter and wrapper method. The filter approach is a data-driven methodology, whereas the wrapper method is a classification-based technique. Comparing this method against FPA, PSO, and genetic algorithms, the performance of the suggested method was validated using eight UCI data sets, which revealed that this method is extremely competitive. The addition of FPA to the Ada-Boost algorithm enhances the classification accuracy of text documents during the initial phase of feature selection. In contrast, it is utilized to categorise text materials. Three standard data sets were used to evaluate the performance of the proposed algorithm: CADE 12, WEBKB, and Reuters-21578. The experimental findings demonstrated that the suggested algorithm outperformed Ada-Boost and other algorithms [42].

This paper proposes a metaheuristic approach called the flower pollination algorithm for text feature selection based on the Twitter dataset to increase the accuracy of sentiment classification.

III. METHODOLOGY

In general, the SA methodology is intended to yield the optimal subset of features and the most accurate sentiment classification. As illustrated in Fig. 1, the approach for this study consists of four phases: text preprocessing, feature selection, sentiment classification, testing, assessment, and analysis. The tasks associated with these phases are described in the sections that follow.

A. Phase 1: Text Preprocessing

As tweets are composed by regular people who are not language specialists, the Twitter dataset underwent a cleansing procedure. As a result, misspellings, grammatical errors such as faulty punctuation and capitalization, slang words that do not exist in dictionaries, and abbreviations or acronyms for

common terminology are likely to be present in the datasets. The dataset is therefore subjected to two forms of text preprocessing: linguistic processing and natural language processing. This study's linguistic processing comprises five text processing approaches, including lowercase conversion, removal of '#', '@', and other symbols, and removal of punctuation. The document then undergoes spelling correction, an NLP approach. The preprocessing techniques used in this work are shown in Table I.

B. Phase 2: FPA for Feature Selection

Wind or pollinating agents, such as insects, butterflies, bees, birds, and bats, carry pollen from one flower to another during pollination. Flowering plants have evolved to generate nectar or honey in order to entice pollinators and ensure pollination [43]. In addition, a number of pollination agents and plant species, such as squirrels and ornithophilous flowering plants that are pollinated by birds, constitute a number of floral evolution constants [44]. Based on the main characteristics of pollination, a flower pollination algorithm has been developed by [33] developed an algorithm for flower pollination.

There are two fundamental types of flower pollination: biotic and abiotic processes. Biotic pollination, also known as cross-pollination, is the most common type of pollination and is carried out by pollinating agents like insects, birds, and others. This method of pollination is utilized by over 90 percent of blooming plants. When the pollinating agent travels and even flies at varying speeds, the movement of the pollen is quite remote; such pollination can also be considered global pollination when Lévy Flight rules [33], [45], [46] are used. If pollen is encoded as a solution vector, this operation corresponds to a global search. Abiotic pollination, also known as self-pollination, does not require an external pollinator. Approximately 10 percent of flowering plants utilize this kind of pollination, according to estimates. Since self-pollination and localised pollination are more likely to occur in this way, wind dispersal is an option [43], [44]. Typically, the distance traversed by a local movement is shorter, therefore the search might be deemed local. The aforesaid characteristics were utilised to plan the creation of the flower pollination algorithm (FPA) [33], an optimization algorithm.

The development of the FPA is based on the pseudo-code shown in Fig. 2. In general, the development of the FPA consists of three main parts - parameter declaration, initiation, and searching.

```

1  Parameter Declaration
2  Initialize population size randomly
3  Initialize stopping criteria (iteration number)
4  Set the switch probability
5  Set the best solution
6
7  Initiation phase
8  Check if stopping criteria meet
9  {
10
11  Searching Phase
12  Global pollination
13  Choose the best solution
14  Random solution < switch probability
15  Global pollination occurs
16  New solution produced
17  If new solution better
18      Subs the current solution with the new
19  Else
20      New solution rejected
21  Local pollination
22  Choose two random solution
23  Local pollination occurs
24  New solution produced
25  If new solution better
26      Subs the current solution with the new
27  Else
28      New solution rejected
29  Repeat step # 6
30 }
31 Select the optimal solution

```

Fig. 2. Pseudocode for FPA.

1) *Parameter declaration phase:* There are two types of parameters that must be set during the general parameter declaration phase: population size and the number of iterations. The population parameter choice for this experiment is based on a study by [47], which determined that the optimal population size for optimal results is 25. The number of generations is determined based on a study conducted by [33], i.e., the most appropriate number of generations is 100. This number of generations will be the termination criterion for the algorithm.

2) *Initiation phase:* In this initial phase, a subset of solutions will be randomly generated and stored in the form of a one-dimensional array, as in the example shown in Fig. 3. The illustration depicts a solution subset with ten feature attributes labeled F1 through F10. A cell with a value of 1

indicates the attribute of the selected feature, while a cell with a value of 0 indicates the attribute of the unselected feature. Next, all subsets of these generated initial solutions will be evaluated based on the performance of the sentiment classification accuracy assessment and sorted based on the classification accuracy score values obtained. A subset of this initial solution will be used to generate the following generation subset.

3) *Searching phase:* For the searching phase, the algorithm is divided into two parts, namely, global pollination and local pollination. Before proceeding to the search phrase, the termination criteria will be reviewed first. If the termination criteria are not met, the search phase will continue. Conversely, suppose the termination criteria have been met. In that case, the subset of features with the best sentiment classification score will be returned and used as a feature list for sentiment classification.

Global pollination begins when a solution is randomly generated. If its value is smaller than the exchange probability, the Levy flight rule will generate a new solution. Existing solutions will be selected along with these new solutions to get better scores. The crossover method in the global pollination method is illustrated in Fig. 4. The global pollination session will result in two new solutions, and both will go through a sentiment classification performance appraisal process. Only new solutions that are capable of producing higher scores than the existing solution score list is accepted into the population, and their position within the population is decided by the scores produced. On the other hand, this new solution will not be accepted if it gets a score that is less than the score of the existing population.

1	0	1	0	1	1	1	1	0	0

Fig. 3. Solution Subset Array.

Fig. 4. Global Pollination Process.

On the other hand, for local pollination sessions, it occurs when a solution is randomly generated and if its value is greater than the exchange probability. Therefore, two randomly generated solutions were selected to undergo local pollination. As depicted in Fig. 5, the process of learning between the two candidates in the FPA algorithm occurs via the crossover approach. The outcomes of the local pollination will generate two new solutions, which are then evaluated based on their performance in sentiment classification. If based on the obtained sentiment evaluation score, this new solution is deemed superior to the previous solution, it will be accepted and its population position will be changed. Alternatively, this solution will not be approved if it has a low score among the current solutions.

Fig. 5. Local Pollination Process.

These global and local pollination processes will continue until the termination criteria are reached. If the criteria for stopping are not reached, this procedure will be repeated. As illustrated in Fig. 6, the result of this algorithm is a subset of quality and modest characteristics that will be employed in the sentiment classification step.

Fig. 6. New Feature Subset that Selected.

C. Phase 3: Sentiment Classification

Classification is one of the key processes in machine learning that refers to determining input data assigned to one of predetermined categories or classes [48]. Classifiers will learn with a learning algorithm or classification algorithm, also known as a classification initiator, a supervised machine learning algorithm. Machine learning algorithms use a set of examples to learn to classify the class label of something that has not been seen or has not been learned. The classifier that has been learned will take the feature value or attribute of an object as input and the class label that has been defined as the output. A set of class labels is defined as part of a problem by the user.

Therefore, the third phase involves four machine learning classifier algorithms to carry out the sentiment classification process by matching a subset of the features generated with the feature information found in the text. The algorithms used are SVM, NB, DT, and kNN.

D. Phase 4: Testing, Evaluation and Analysis

1) *Dataset*: For this study, a benchmark Twitter data set in which has been used by the previous researcher [49] can be obtained from the Kaggle repository. This data set consists of 7086 positive and negative Twitter comments written in English.

2) *Baseline model*: The performance of the FPA feature selection technique was evaluated through a comparison with two baseline algorithms, namely, TF-IDF and Binary Cuckoo Search, by [49]. The evaluation is based on the sentiment classification accuracy from the tweets by using a subset of features selected from phase 3. A subset of these features is obtained upon the text preprocessing process, reduction of feature dimension size, and subsequently feature selection process. This study will not cover the time required for the text preprocessing phase, feature selection, and even classification. Thus, measurements of the time rate will not be performed.

3) *Evaluation*: The accuracy measure was used to evaluate the efficacy of the FPA feature selection technique in getting the optimal subset of features. The evaluation is based on the accuracy of the sentiment classification process outcomes. The classification algorithm generates a confusion matrix, which is used to guide the evaluation process. The confusion matrix displays information about the actual number of classes as well as the number of predictions made by the classification algorithm. True positive (TP) is a condition in which a positive case is successfully classified as positive. True negative (TN) are conditions in which a negative case is successfully classified as negative. A false positive (FP) is a negative case but is misclassified as a positive. False-negative (FN) are positive cases but misclassified as negative ones, as shown in Table II.

The accuracy of the proposed feature selection algorithm was used to evaluate its effectiveness. Accuracy is a simple performance metric derived as the ratio of successfully predicted values to total values. The equation is shown in Equation 1.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

TABLE II. THE CONFUSION MATRIX

		Actual Class	
		Yes	No
Classification Result	Yes	TP	FN
	No	FP	TN

IV. FLOWER POLLINATION FOR FEATURE SELECTION

For this experiment, the evaluation performance was evaluated based on accuracy. These values are compared with the results obtained from baseline algorithms, as presented in Table III.

Table III shows that the FPA feature selection algorithm achieves the highest accuracy value compared to the TF-IDF and Binary Cuckoo Search (BCS). Fig. 7 displays the overall accuracy values for the APB algorithm and TF-IDF and BCS based on the classification algorithm used. Based on Table III, it is found that the accuracy values for TF-IDF for NB, SVM, DT, and k-NN are 87.71%, 89.21%, 89.90%, and 88.42%, respectively. While for Binary Cuckoo Search, the resulting accuracy values are 96.26%, 96.54%, 96.26%, and 95.56% for the NB, SVM, DT, and k-NN, respectively. Based on Fig. 7, the FPA feature selection algorithm has produced the highest accuracy compared to the other two feature selection algorithms. This is where the accuracy values obtained for the NB, SVM, DT, and k-NN are 98.79%, 98.99%, 98.76%, and 98.91%, respectively.

This experiment went through 100 iterations. As shown in Fig. 8, at the 45th iteration, the algorithm is approaching the optimum value at a rapid pace of convergence. This indicates that the algorithm can discover a solution quickly. The increment on accuracy rate then slows until the 75th iteration. This is because this algorithm has consolidated nearly every high feature set. Achieving a subset of features capable of obtaining higher accuracy values got progressively challenging because the current feature set already had a relatively high quality of accuracy values—the accuracy rate value peaks as it reaches the 75th iteration. As a result, until the 100th iteration, this accuracy value remains constant.

TABLE III. ACCURACY PERFORMANCE FOR FPA, TF-IDF AND BCS USING NAÏVE BAYES, SUPPORT VECTOR MACHINE, DECISION TREE AND K-NEAREST NEIGHBOR

Classifiers	FPA	BCS	TF-IDF
Naïve Bayes	98.79	96.26	87.71
Support Vector Machine	98.99	96.54	89.12
Decision Tree	98.76	96.26	89.90

Fig. 7. Comparison of Accuracy for FPA, TF-IDF, and BCS.

Fig. 8. Classification.

The proposed algorithm for feature selection was able to attain greater accuracy than the two baseline techniques. This result demonstrates that FPA is more effective at extracting features than the baseline techniques.

V. CONCLUSION

This study compares and contrasts the NLP method, spelling correction in text preprocessing techniques, with other conventional text preprocessing techniques. In addition, the use of FPA algorithms for feature selection strategies to enhance the performance of sentiment classification has been proposed. Based on the accuracy results, our approach achieved promising results, confirming that implementing NLP (spelling correction) approach on text preprocessing technique and FPA algorithm on feature selection technique improved sentiment classification performance by 2.68 % compared to the baseline model.

In the future, we would like to employ the proposed technique for solving sentiment analysis tasks on a larger data set containing product review evaluations.

Abstract—A unified view of web application design and development is crucial for dealing with complexity. However, the literature proposes many denominations, depending on the development methodology, frameworks or tools. This multitude of Create, Read, Update and Delete (CRUD) approaches does not allow a holistic view of the web application. Besides, in a web application, the search for good practice in design, features and essential functions is still a relevant issue. A subset of essential CRUD operations is to provide code automation for web application rapid prototyping. Re-CRUD articulates the records management features into CRUD operation. This study aims to provide insight into the effectiveness and efficiency of Re-CRUD in web application development and to compare it with other web application frameworks' CRUD output. The qualitative feature analysis is used based on the evaluation guideline proposed in DESMET and reviewed by experts for validation. A document management system is developed and used as a case study for Re-CRUD evaluation. The feature analysis comprises Re-CRUD and four other web application frameworks CRUD, namely, CakePHP, Laravel, Symfony and FuelPHP. According to the review, Re-CRUD satisfies its expectations by providing more useful features and delivering higher code automation in the web application development process. Compared to the other existing CRUD generator, Re-CRUD has integrated records management features that are useful in providing support in managing born-digital data and also contributes to effectiveness and efficiency in web application development.

Keywords—Re-CRUD; web application; DESMET feature analysis; electronic records features

I. INTRODUCTION

Web technologies have significantly influenced web application (WA) development and information system. The innovation of web technologies has allowed software developers and engineers to develop responsive cross-platform web applications rapidly. These technologies include creating read update delete (CRUD) generator, web application framework (WAF) and libraries that promotes reusable codes, rapid development and feasible features. WA can be considered a software component that stores and manages information just like a traditional information system but uses explicitly the web paradigm and associated technologies [1], [2]. It is a software system whose primary purpose is to publish and maintain data using hypertext-based principles [3], [4]. WA offers ease of access, maintenance, and cross-platform compatibility compared to the traditional desktop application installed on a local computer [5]. WA can be characterized as one that uses Web architecture and other technologies

(database, browser) to construct an information system that serves organizational needs [6].

The technique of WA development has rapidly changed over these past few years with the born of WAF, which promotes better development experiences and resources management [7], [8]. The WA development has become easier with the adoption of the frameworks, and lots of web-based innovation has been produced by non-technical people due to the framework innovation [9]–[13]. The WAF has bridged the possibility of WA development by a non-programmer and unlocks many potential new software possibilities and ideas [9], [14]. Most of the WAF embraces the MVC architecture that supports rapid and parallel development through CRUD operation, asynchronous technique, and straightforward business logic implementation, making the WA development more practical [9]–[12].

CRUD is the four fundamental components that manage the web application (WA) resources [12], [13], [15]–[18]. The create component allows the user or the WA itself (or both) to add a new data item to the database. Read component is used to retrieve the items recorded in the database and render them into a web page. The update component enables the user or the WA to edit an existing item and have those changes written back to the database. The last component, delete, enable the user or the WA to remove an item record from the database [19].

The CRUD paradigm is widely used among WA developers since it allows them to construct basic WA routine code and define how items in WA are related to one another [20]–[22]. CRUD is a provision of assistance in code generation and basic functionalities to support the developer in accomplishing the task [23]. CRUD enables the developer to create a quick-start application to work as the foundation of the WA solution [7], [24]. CRUD is an excellent technique to start an MVC-based WA project as it provides automation in design patterns [25]. Further, CRUD is a handy time-saver. It generates the skeleton codes for the WA and enables the developer to get faster output and demonstrate the WA prototype (input, process and output) to the WA project stakeholder [26].

The implementation of CRUD in WA development provides a substantial productivity boost for developers [12], [13], [15]–[17]. Using CRUD, the developer does not have to worry about many of the subtle details of wiring up the controller for the MVC application [12], [13], [27]. Although it boosts the development process, the traditional CRUD

generator only generates the fundamental functions that still present problems: their inadequacy to deal with the form features, authentication, search, file management, and others. [12], [13], [28]–[30]. A standalone CRUD could not satisfy the development of decent and complex WA since it lacks standard modern WA features to support the functions such as authentication, authorization, files management, search, internationalization, form features, report, logging and others [12], [13], [29]. Further enhancement and manual code modification are required to improvise the half-baked generated CRUD, especially in the integration of the time-consuming features and comprise repetitive coding for each of the CRUD output [12].

There is also an argument that the CRUD operation is not yet a complete solution for web application development. Many redundant tasks include repetitive code modification for feature integration after generating the CRUD [12]. Coding the same routine code for WA features repeatedly takes a long time and increases development costs [31]. However, it has a huge potential to go beyond the limit where it can automate more components for WA development [32]. The primary purpose of this study is to provide insight into Re-CRUD effectiveness and efficiency in web application development using the qualitative feature analysis case study based on the proposed guide in DESMET [33]. The contributions of this work are as follows:

- This work implements the records management features into CRUD operation for web application development.
- This study analyzes the effectiveness and efficiency of Re-CRUD in providing more features for web application development.
- This work compares the features and output of Re-CRUD and other aristocratic CRUD generators in web application frameworks.

The article is organized as follows. Section 2 describes the main related studies that have been conducted in the field of web application development challenges and Re-CRUD. Section 3 presents the methodology, including the DESMET feature analysis procedure and the instrumentation. Section 4 describes and analyzes the results. Section 5 presents a brief discussion. Finally, Section 6 presents the conclusions.

II. LITERATURE REVIEW

A. Issues and Challenges in Web Application Development

Web application (WA) development is a complex and challenging task since it requires consideration of numerous factors and requirements, some of which may contradict [34]–[42]. Many researchers have widely discussed the scalability issues, and developing a WA that scales well is a challenge [34], [43], [44]. As the WA is becoming mission-critical, there is a greater demand for it to improve reliability, effectiveness, performance, integration and security [34], [45]–[48]. To comply with the diverse expectations and requirements of many different users with varying skills and knowledge is very challenging. Most of the end-users are visual-oriented, which focuses on WA having more multimedia elements instead of

focusing on the functions of WA. They expect to manage and find the information they need faster using WA [6], [34].

Most WA is designed with a WAF with multi plugins and third-party scripting to enhance the features and a database as the storage medium [24], [26], [49]. Integrating plugins requires extensive knowledge of the amalgamation of the plugin and the WA due to the different programming languages and processes [50]–[52]. The integration is crucial as it will affect the WA's performance and stability, including the WA's functionality [34]. The developer must ensure the plugin's compatibility with the WAF and standard web browser technology [49], [53], [54]. Incompatible plugin integration may lead to vulnerabilities and security issues for WA due to deprecated methods or coding, leading to data corruption and unstable WA processing [55]–[58].

Due to the overwhelming number of WAFs published can be a daunting task to determine the most appropriate WAF [59]. The most important is that it can increase the programming productivity through code and files generation automation using CRUD operation, security advantages, and open-source that will impact the cost, support and documentation [60]. The WAF selection is vital as the speed and quality of work depend on it [60], [61].

The usability features issues in WA are design layout, design consistency, accessibility, information content, navigation, personalization, performance, reliability, filtering, analysis and design standards [62]–[66]. User response reveals that the search functionality, consistent navigation throughout the system, authentication, authorization, responsiveness and data visualization and reporting aid most WA usability [34], [67], [68]. Search features have been vital components in WA as the rapid trends in born-digital data and information lead to information overload and exposure [69]. The proper search function enables the user to filter the relevant information based on the search query [69]–[71]. The search function is a complex component where the developer needs to understand the filtering algorithm to ensure that the search results respond to the requested queries [11], [72]. The common issue in the search function is unable to satisfy the user query request due to the incomplete filtering algorithm [34], [62].

Localization is adapting WA (regularly written in English) for use in other countries, considering their culture, standard, regulations, principles and technology conditions [34], [73], [74]. Localization is more than just a language translation, and WA needs to be precisely designed to accomplish this multifaceted condition [73], [75], [76]. The scalability, reliability, availability, maintainability, upgradability, usability, speed and security are the terms used to describe how well the WA meets current and future needs. These ilties describe WA architectural qualities [34], [46], [77]–[79].

The design and development of WA for mobile compatible and device-independent operations are very complex and challenging. It must address various additional aspects compared to the traditional information system or desktop application and needs to satisfy many different stakeholders besides the diverse range of users. Poorly designed and develop WA has a high probability of low performance or failure [80].

B. Re-CRUD

Re-CRUD was generally derived from the absence of electronic records management important features in the WAF CRUD. The conventional WAF CRUD operation is limited to only producing fundamental functions for WA, which requires further modification to include the other useful WA features to ensure the content can be managed systematically. Re-CRUD integrates the CakePHP framework CRUD operation with electronic records management important features that can produce additional useful functions and code automation. The following electronic records management important features are included in Re-CRUD [81]:

- Inventory: a descriptive listing of each record series or system, together with an indication of the location, access, and other pertinent data [82]–[84].
- Retention schedule: list how long each record series must be kept (the retention period), when the retention period starts (the cut-off), and the proper way to dispose of the record once retention is met (the disposition method) [84]–[87].
- Appraisal: the process of determining the archival value and ultimate disposition of records. Appraisal decisions are informed by several factors, including the historical, legal, operational, and financial value of the records [88]–[90].
- Disposition: the process of destruction of records or the transfer of records to another entity (most commonly an archival repository) for permanent preservation [91], [92].
- Role-based access control (RBAC): provides a role-based access control mechanism to offer protection from unauthorized access. Authenticated users with different roles have different authorization or access to the records [93]–[95].
- Search and retrieval: Enables the user to locate and retrieve records based on specific metadata, words or phrases. It is vital in any WA as it enables fast data retrieval via the search parameter [96], [97].
- Audit trail: provides log tracking for any changes to the electronic records to ensure validity and integrity [98], [99].
- Digital Archiving: transfer and store the valuable records into a repository that makes it non-active but still accessible through the system. It also helps to reduce the cluttered old and non-active records from the system [100], [101].
- Sharing: it provides the ability to transfer the record (internal to external or external to internal) in a single data or bulk data. There are several suggested formats such as CSV, XML and JSON [102], [103].
- Reporting: It summarises the current status of records such as total, active, inactive and the required appraisal attention and others [104], [105].

- Others: focused on the front-end framework for UI, data visualizer for reporting page, jQuery, DOMPDF and others supporting UI features. [82], [106].

Fig. 1 provides a simplified overview of Re-CRUD design based on the CRUD evolution using the console framework. It shows the evolution of the CRUD generation based on the traditional CRUD introduced in 1983 and is mainly used for the database abstraction process [17]. The technology continues to evolve into other application development segments, such as web application CRUD.

Fig. 1. Re-CRUD Console Framework.

III. METHODOLOGY

A. DESMET Feature Analysis

The DESMET method is designed to assist an evaluator in preparing and carrying out an unbiased and reliable assessment exercise within the framework of software engineering approaches and tools [33]. Feature Analysis is the term used by DESMET to describe a qualitative evaluation. Feature analysis focused on recognizing the requirements for a particular task and mapping it to the tool that was used to solve the task. Feature analysis is qualitative because it requires a subjective assessment of the relative importance of different features and how well they have been implemented. The qualitative case study is a feature-based evaluation performed by someone who has used the tool on an actual project. There are three main processes involved in carrying out a feature analysis, i) selection of feature; ii) feature scoring and ranking; iii) analysis and result interpretation, as explained in section V. For this research, the feature analysis is executed by the i) author and; ii) selected respondents, to compare and validate the feature analysis scoring from author bias. The following sub-section discusses the DESMET feature analysis procedure.

1) *Selection of features:* For features selection, the Re-CRUD features are grouped into four categories: CRUD operation, RBAC, electronic records management, and others, as shown in Table I. The sub-features are categorized based on the domain of the function.

2) *Feature scoring and ranking:* The Judgement Scale and Interpretation (JIS) is another definition that must be completed using DESMET. As described by Kitchenham [33], the JIS evaluation is according to the evaluator's perception.

As shown in Table II, if the feature is fully supported, the JIS is 1; if the feature is partly supported, JIS is 0.5; if the feature is not supported, JIS is 0 and -1 if the features make things worst [33]. The importance of a feature can be determined by deciding whether it is mandatory or merely desirable.

A method or tool that lacks a mandatory feature is unacceptable [33], [107], [108]. Non-mandatory features are considered desirable. This viewpoint on importance leads to two evaluation criteria: one that decides whether or not a feature is mandatory and the other that determines the degree to which a non-mandatory feature is desired. A ranking method is used to identify the electronic record important features are vital or only a desire for WA. Table III present the features set important weightage to identify the most imperative integrated features.

TABLE I. FEATURE SELECTION

Features		Sub-Features		Description
F1	CRUD operation	SF01	Code automation	The automation of code generation for persistent storage
F2	RBAC	SF01	RBAC	Provides a role-based access control mechanism to offer web content protection from unauthorized access.
F3	Electronic Record Mgt	SF01	Inventory	a descriptive listing of each record series, together with an indication of the location, access and other pertinent data
		SF02	Search	Ability to locate and retrieve data/record based on specific metadata, keyword or phrases.
		SF03	Audit Trail	provides log tracking for any changes to the electronic records to ensure that validity and integrity
		SF04	Transfer & Sharing	enable transfer or share the data (internal to external or external to internal) in a single or bulk data.
		SF05	Report	provides a summary related to the current status of records, active or inactive.
		SF06	Retention	list how long each record series must be kept
		SF07	Appraisal	the process of determining the archival value and ultimate disposition
		SF08	Archive	the records will be permanently stored, inactive but accessible for future references
		SF09	Disposition	the process of permanent destruction of records.
F4	Other web features	SF01	UI, visual design	the UI and other supporting components that supports the web application design and data presentation

TABLE II. JUDGMENT SCALE & INTERPRETATION (JI SCORE) [33]

Generic scale point	Definition of scale point	Score
Make things worse	Cause Confusion. The way the feature is implemented makes it difficult to use and/or encourages incorrect use.	-1
No support	Fails to recognize it. The feature is not supported nor referred to in the user manual.	0
Partly support	The feature is supported indirectly, for example, by using other tool features in non-standard combinations.	0.5
Full support	The feature appears explicitly in the feature list of the tools and user manual. All aspects of the feature are covered.	1

TABLE III. FEATURE SET IMPORTANT WEIGHTAGE [33]

Acronym	Level of importance	Weightage
M	Mandatory	4
HD	Highly desirable	3
D	Desirable	2
N	Nice to have	1

3) *The feature set and total score:* DESMET is an assessment technique that requires the assignment of scores to features and sub-features such as sub-feature importance levels, feature weights, and judgement scales. According to Marshall [108], the author first determined each score. At the initial stage, DESMET is required to determine the important level for each sub-feature. The identified features and sub-features set important weighting used in the feature analysis is shown in Table IV.

TABLE IV. FEATURES AND SUB-FEATURES SCORE USED IN THE ANALYSIS

ID	Feature Set	SF-ID	Subfeature: level of importance	Feature set Importance Weighting
F1	CRUD operation	F1-SF01	Mandatory	4
F2	RBAC	F2-SF01	Highly Desirable	3
F3	Electronic Record Management	F3-SF01	Desirable	2
		F3-SF02	Mandatory	4
		F3-SF03	Mandatory	4
		F3-SF04	Desirable	2
		F3-SF05	Highly Desirable	3
		F3-SF06	Highly Desirable	3
		F3-SF07	Mandatory	4
		F3-SF08	Mandatory	4
		F3-SF09	Mandatory	4
F4	Other web features	F4-SF01	Highly Desirable	3

The level of importance, together with the weightage for each of the sub-features, is identified. A feature will receive the highest possible score if all of the features in the set are completely present or supported. The level of importance for the features is determined by their implication and significance [108]. These weighted scores can be summed to obtain a percentage (%) score for each list of features. The following equation is used to compute the rating score for a feature set:

$$future\ set\ score\ \% = \frac{\sum\ of\ feature\ set\ score}{maximum\ score} \times 100 \quad (1)$$

In Table IV, the feature set is divided into four, F1 comprise one sub-features (F1-SF01), F2 comprises one sub-features (F2-SF01), F3 comprises nine sub-features (F3-SF01 to F3-SF09), and the F4 comprises one sub-feature (F4-SF01). The average (weighted) rate scores for each feature set are used to calculate a general percentage score for each model. A normalized score (percentage) is utilized because the feature set's sub-features vary.

For this calculation, the feature set weighting is used in Table V. The values here emphasize support for code automation via CRUD operation (F1) and for the electronic records management features (F3). Other weightings could be used, perhaps to emphasize usability, as tools to support the proposed solution to become more mature. The overall score for each CRUD generator can be determined using the following equation:

$$Overall\ score = \frac{\sum_{i=1}^4 (W_i TP_i)}{\sum_{i=1}^4 (W_i)} \quad (2)$$

W_i is the weighting for the i^{th} feature set and TP_i is the percentage (%) score for the i^{th} feature set.

TABLE V. FEATURE SET WEIGHTING

Feature Set	Weight
F1	0.4
F2	0.2
F3	0.3
F4	0.1

B. Instrumentation

The primary purpose of the evaluation is to provide insight into Re-CRUD effectiveness and efficiency. A qualitative feature analysis case study is used based on the evaluation of guidelines proposed in DESMET [33] and reviewed by experts for validation.

1) *Case study:* Electronic Document Management System (EDMS) is used as a case study to assess and validate Re-CRUD. EDMS is a software system used to manage (organize and store) different kinds of data, information, and records. For this research, the EDMS is focused on managing born-digital data where it should be able to:

- Capture and validate the data input.
- Protect content using authentication and authorization.

- Practice proper electronic records management for the content.
- Multi-device and platform friendly.

Fig. 2 shows the application module that is available in the EDMS. To ensure the content is protected, the user must register and authenticate before accessing the content. It also includes the authorization procedure. Most of the records management aspect is put into practiced in the document repository.

As discussed in the following sub-section, seven steps are involved in designing and administering the case study [52].

a) *Identify case study context:* The case study objective is to evaluate the effectiveness and efficiency of the proposed solution. Table VI [55]–[58] shows that effectiveness and efficiency are highlighted as usability features. In the context of WA development, Re-CRUD is used to generate codes and files to form a WA with integrated records management features, as highlighted in Table IV.

b) *Select the host projects:* The EDMS case study applies the potential electronic record important aspects and is used to evaluate its effectiveness and efficiency [109].

c) *Identify the method of comparison:* As a comparative method, a cross-platform comparison is performed. Four additional CRUD generators are used for the cross-platform comparison, one using Re-CRUD and the others using the existing CRUD generator. The characteristics of all other development methodologies and procedures will be the same.

d) *Minimize the effect of confounding factors:* A similar host project characteristic and data storage are adopted to minimize the confounding effects. The selected WAF CRUD also have the same programming language, shares the same web server environment and uses almost similar development architecture. The selected respondents also must have experience, knowledge and understanding of software development and the use of WAF together with the CRUD operation [110]. This ensures that they are familiar with the CRUD operation and can focus on the evaluation instead of learning how to perform the CRUD operation and reduce the learning curve. Besides, specific and detailed instruction on configuration, database schema, development method, and CLI command is provided for the case study development.

Fig. 2. EDMS Application Module used in Feature Analysis Case Study.

TABLE VI. SYSTEM USABILITY SCALE (SUS) QUESTIONNAIRE [115]

Usability aspect		Candidate item
Effectiveness (ES)	ES1	It allows me to accomplish my tasks. I think I would not need a system with more features for my tasks. I would not need to supplement Re-CRUD with an additional components. I found the system unnecessarily complex This system's capabilities would meet my requirements.
	ES2	
	ES3	
	ES4	
	ES5	
Efficiency (EC)	EC1	It saves me time when I use it. I found the various functions in this system were well integrated. I tend to reduce a lot of mistakes with this system. I don't make many errors with this system. I don't have to spend a lot of time correcting things with this system
	EC2	
	EC3	
	EC4	
	EC5	

e) *Plan the case study*: The following activities must be sequentially performed to complete the EDMS case study development. The listed activities require an understanding of software installation, configuration, MySQL database and PHP programming language.

- Gathering required files from the Github repository
- Host configuration
- Database migration and seeding
- Performed CRUD operation
- Output evaluation

f) *Executing the case study*: The author and respondents execute the development of the EDMS based on the given instruction and software development specifications. The respondents will fill in the online evaluation form at the end of the process.

g) *Analyze and report the results*: The score in the evaluation will be consolidated to identify the effectiveness and efficiency of the integrated electronic records management features in WA development.

2) *Expert validation*: Expert validation comprises opinion and judgement from the individual with knowledge and experience in the subject matter [111]–[113]. Expert validation is a methodology in which judgment is based on a particular set of requirements and/or experience obtained in a specific knowledge field, application area, product area, specific discipline, sector, and others [114]. The focus of this process is to validate the usability of the proposed solution. To execute the expert validation for this research, the experts must possess knowledge in software development, testing, maintenance and web-based technologies. The experts comprise representation from the industry, public sector and academician. The selected expert must respond to a set of questions as discussed in the following section.

3) *System usability scale questionnaire*: A set of questionnaires is provided to the respondents which are designed based on the System Usability Scale (SUS)

questionnaire [115]–[117]. The System Usability Scale (SUS) is an inexpensive yet effective and reliable tool for assessing the effectiveness and efficiency of a product [115]–[121].

The questionnaire is divided into two sections. First, the demographic comprises questions on the highest qualification, current working position, software development experiences, sector (mobile, web, IoT, desktop, cloud) and primary programming language. The second section will include the effectiveness and usability instrument and open-ended comments. The rating is based on 5 points Likert scale, which is anchored with one as strongly disagree and five as strongly agree [118], [122]–[124]. Table VI shows the usability aspect and the candidate item mentioned in the SUS questionnaire.

The SUS result is interpreted based on the grading scale, as shown in Fig. 3, to get a clearer picture of the effectiveness and efficiency of the proposed solution.

Fig. 3. The Adjective Ratings, Acceptability Scores and Grading Scales in Relation to the Average SUS Score [119].

The following equation is used to calculate the SUS score. The result will be interpreted based on Fig. 3.

$$sus\ score = \frac{(x \times 1) + (x \times 2) + (x \times 3) + (x \times 4) + (x \times 5)}{\text{total respondent} \times 5} \times 100 \quad (3)$$

IV. ANALYSIS AND RESULT

This section summarises the total scores for each CRUD generator for web application development. Table IV shows the feature weighting, and Table VII summarises the results of feature analysis for each of the WAF CRUD generators. This study aims to assess the effectiveness and efficiency of integrated records management aspects in CRUD operation from a web application development perspective. The feature analysis comprises five CRUD generators (embedded in WAF), i) Re-CRUD; ii) CakePHP; iii) Laravel; iv) Symfony and; v) FuelPHP. At the initial stage of DESMET evaluation, the importance level score has been given for each feature set as mentioned in Table IV and displayed in the sub-feature weightage score (C). The Judgment Scale and its Interpretation (JIS) is another definition that must be completed using DESMET. As described by Kitchenham [33], the JIS evaluation is according to the evaluator's perception.

Almost all sub-features in Re-CRUD have JIS = 1 since it is designed and developed based on the identified electronic records features important aspects, considering all intended features have been implemented. If the feature is fully supported, JIS is 1. If the feature is partly supported, JIS is 0.5. If the feature is not supported, JIS is 0 and -1 if the features make things worst [33]. Referring to Table VII, columns F, J, N, R and V show the JIS score for each sub-features of Re-CRUD, CakePHP, Laravel, Symfony and FuelPHP, respectively.

TABLE VII. FEATURE ANALYSIS RESULT

					Re-CRUD				CakePHP CRUD				Laravel CRUD				Symfony CRUD				FuelPHP CRUD

Total Score					36.5/40				12.5/40				11.5/40				12.5/40				8.5/40													
Feature Set Weighting Overall Score (%)					88.00				34.00				33.00				34.00				30.00													

SFWS - Sub-Feature Weightage Score (Mandatory - 4, Highly Desirable - 3, Desirable - 2, Nice to have - 1) [JIS*SFWS(C)]
 MFSS - Max-Feature Set Score [sum SFWS(C)]
 FIW - Feature Important Weightage (0.4, 0.3, 0.2, 0.1)
 JIS - Judgement Scale and Interpretation (Full supported - 1, Partly supported - 0.5, No support - 0, Make thing worst - -1)
 FSS - Feature Set Score (sum of each SFWS)
 FSS% - Feature Set Score Percentage (FSS/MFSS*100)
 Feature Set Weighting Overall Score - (F1 FSS%*F1 FIW)+(F2 FSS%*F2 FIW)+(F3 FSS%*F3 FIW)+(F4 FSS%*F4 FIW)

Based on the JIS score, the Sub-Features Weightage Score (SFWS) for each WAF CRUD is calculated (Re-CRUD (G); CakePHP (K); Laravel (O); Symfony (S) and; FuelPHP (W)).

The weight score is the multiplication of the JI with the respective Sub-Feature Weightage Score (SFWS) (C). For example, for F1-SF01, the SFWS for Re-CRUD is 4 (G), obtained by JIS(F)*SFWS(C). Next, from the SFWS, the

Feature Set Score (FSS) is calculated (Re-CRUD (H); CakePHP (L); Laravel (P); Symfony (T) and; FuelPHP (X)). This FSS is the sum of the SFWS grouped by the feature set. For example, in column H, the FSS for Re-CRUD feature set 3 (F3) is 28 is the sum of (2+4+2+2+3+3+4+4+4). In the sequence, the FSS percentage (Re-CRUD (I); CakePHP (M); Laravel (Q); Symfony (U) and; FuelPHP (Y)) is obtained by dividing the respective FSS with MFSS (D) for each feature set.

Finally, the overall score for each WAF CRUD is calculated with the sum of each FSS percentage, considering the feature set and sub-feature set important levels (Table VII). For instance, considering the FIW for F1 is 0.4, and the FSS% for F1 Re-CRUD is 100% (I), the % of the feature set weighting score is $100\% * 0.4 = 40\%$. For F2, the weighting score is 0.2; then, it is calculated using $50\% * 0.2 = 10\%$, and so on. In the end, all these values are summed, and the feature set weighting overall score is obtained. Each feature set score will be described in-depth in the following subsection.

Based on the feature set weighting overall score in Table VII, Re-CRUD leads the scores with a massive margin of difference, Re-CRUD: 88%; CakePHP: 34%; Laravel: 33%; Symfony: 34% and; FuelPHP: 30%. Technically, this is because Re-CRUD is specifically designed and developed based on the identified electronic records features mentioned earlier. Rather than integrating the electronic records features into the CRUD operation, Re-CRUD also has reconstructed the existing CRUD operation functions and features to make it more systematic and ensure that each of the features and functions still exists in the code automation generation. The score is within 30% to 34% for the other CRUD generators because the electronic records features are not present in the CRUD operation. Even though some of the features are present, the JIS score is 0.5 (partly supported), requiring modification or enhancement to the generated files and coding. Hence, even though Re-CRUD is new compared to the other listed aristocratic WAF CRUD elite, the integrated electronic records features make it more effective and efficient in WA development, especially in managing the born-digital content in the WA. The integrated important aspects have crucial roles in managing digital content by promoting appropriate electronic records management functions. It enables the semi-active record to be appraised, archived the inactive record, disposed of unused records, reporting, and other features contributing to WA usability.

A. Feature Set 1: CRUD

The CRUD is focused on code automation, where it generates the fundamental function of WA based on the WAF architecture. The CRUD operation is embedded into the respective WAF as a plugin to enable the developer to generate the WA prototype rapidly. During the case study, it was found that all of the listed CRUD generators can produce WA fundamental components as expected. Referring to Fig. 4, the Re-CRUD FSS is 100%, and the other CRUD generators score 50%. Based on the evaluation, all of the CRUD generators can produce a skeleton of WA with fundamental functions. The JIS score for Re-CRUD is 1 (fully supported) compared to the other's score is 0.5 (partly supported). The Re-CRUD operation provides a more comprehensive solution in generating the files

and codes for WA where the additional features from electronic records features are fully integrated and generated using the same command without any additional modification made by the developer. The other WAF CRUD operation is limited to producing the fundamental components only and requires further modification. This modification is considered a manual code modification where the developer must reconstruct some of the CRUD generated code to enhance and integrate with other features or other third-party plugins.

Fig. 4. Feature Set 1 - CRUD Operation (Code Automation) FSS.

From the developer's perspective, the electronic records feature integration is beneficial due to no code modification, reducing the repeating coding process, e.g., integrating search into different tables in WA and reducing the development timeframe. In accordance with the rapid application development methodology in CRUD operation and modern WA features requirements, the integrated electronic records features in Re-CRUD offer an effective solution for rapid development, fully-featured functions and code automation. The additional features generated in CRUD operation allow the developer to focus on the other vital features that the stakeholder requires.

Overall, based on the case study evaluation, all CRUD operations are working as expected and fully supported (code automation) to generate the fundamental component to form a WA. However, Re-CRUD can produce more functions to support the modern WA without having any additional extension or plugin. The MFSS for CRUD is 4 with FIW is 0.4, which considered that the CRUD operation is vital since it is the generator for code automation and crucial to providing a rapid WA development process.

B. Feature Set 2: Role-based Access Control (RBAC)

The RBAC is the authentication and authorization which enable the protection of WA data and content. The features are evaluated to determine whether the respective WAF CRUD can provide the functions without having manual code modification or a third-party plugin. The RBAC is categorized as highly desirable since it is considered one of the most important features that need to be available in WA. Fig. 5 shows the RBAC FSS where the Re-CRUD score is 50%, and the other WAF CRUD is 0%. The RBAC does not fully support the other WAF CRUD generator aptitude. Re-CRUD has embedded the RBAC into the CRUD operation where the process of the authentication data table is migrated and the seed

inside the same generator. However, the integrated RBAC in Re-CRUD is considered partly supported due to the RBAC environment is not entirely present where the authorization policy (who is allowed to access what) is not integrated with CRUD operation. The authorization policy is important to manage and process the user's permission to access a specific resource or function.

Fig. 5. Feature Set 2 – Role-based Access Control FSS.

The policy needs to be manually generated using the authorization policy. By default, the policy is available, but the CRUD operation did not update it. The developer is expected to have an option to generate the policy content during the CRUD process. This policy automation can be considered in the Re-CRUD future update.

C. Feature 3: Electronic Records Management

Feature set 3 (F3) comprises 9 sub-features, which is, inventory (F3-SF-01); search (F3-SF-02); audit trail (F3-SF-03); transfer and sharing (F3-SF-04); reporting (F3-SF-05); retention (F3-SF-06); appraisal (F3-SF-07); archive (F3-SF-08) and; disposition (F3-SF-09). Fig. 6 shows the highest FSS is by Re-CRUD with a score of 93.33% (Table VII).

Re-CRUD (F3) FSS is 26.5/30, showing that Re-CRUD supports most electronic record features. Based on the JIS, it shows that all of the Re-CRUD F3 sub-features scores are fully supported (JIS = 1) except for F3-SF-03 (audit trail). It is due to the audit trail requiring more in-depth functions to support the audit log process, which enables the edited records to be reverted to the original state and it is considered partly supported (JIS = 0.5). For the CakePHP and Symfony CRUD operation, they share the same FSS score, 30 %, which is 3.33% higher than Laravel's 26.67% score. Compared to the Laravel FSS, the difference between CakePHP and Symfony is the transfer and sharing features where this SFWS is tagged as desirable (2). Both of the WAF CRUD operations partly support (0.5) the feature. FuelPHP FSS for F3 is 16.67%, where most electronic records features are not present. The inventory JIS for FuelPHP CRUD is partly supported (0.5), and for disposition, the JIS is fully supported (1), which brings the SFWS to 5/40. Fig. 7 shows the complete analysis for features 3 (electronic records) components.

Fig. 6. Feature Set 3 – Electronic Records FSS.

Fig. 7. Feature 3 SFWS (Electronic Records).

TABLE VIII. RESPONDENTS DEMOGRAPHIC DATA

Respondent	Age	Gender	Highest Academic Qualification	Software Development Experience	Software Application Major Sector	Primary Programming Language
R1	36-40	Female	Degree	> 6 years	Web	Java
R2	26-30	Male	Degree	3 - 6 years	Web	PHP
R3	36-40	Female	Master	> 6 years	Web	PHP
R4	36-40	Male	Degree	> 6 years	Web	Python
R5	41-45	Male	Degree	> 6 years	Web	Java
R6	31-35	Male	Degree	> 6 years	Cloud	PHP
R7	36-40	Male	Degree	> 6 years	Cloud	Java
R8	31-35	Male	Master	3 - 6 years	Web	PHP

The audit trails should have a comprehensive function in managing the data history or content changes. The Re-CRUD audit trail aims to preserve the content by tracking the series of changes in the data or records. By tracking the changes, the authenticity of the data or content can be preserved and enable the system administrator to identify the authorized person that amended the content.

The inventory (F2-SF-01) shows that most of the CRUD generator is fully supported (JIS = 1). Most of the CRUD generator produces the index file where this index lists all data or records in the web application, which serve the same purpose of inventory but without the record series. The search (F3-SF-02) shows that Re-CRUD JIS = 1, CakePHP, Laravel and Symfony JIS = 0.5 and FuelPHP JIS = 0. The search feature should be generated in the CRUD operation as the search feature is vital in providing fast access and retrieval. With the integration, Re-CRUD can generate the search function embedded in the inventory and all necessary functions. This is very useful for the developer where they can save more time and reduce the process of coding the search routine code in every single table in the WA. Search is not integrated with the operation for the other web CRUD generator but can be integrated using a plugin. However, the integration required more time and testing the integration.

The sharing feature (F3-SF-04) shows that Re-CRUD has fully supported (JIS = 1), CakePHP and Symfony are partly supported (JIS = 0.5), where the Laravel and FuelPHP JIS = 0 due to not being supported by regular CRUD operation. The sharing feature enables the user to share the content using a link, email or QR code. Re-CRUD generates the sharing function and embeds it into the inventory and view layer. The link and QR code is dynamically generated for each of the content in the web application. However, the access is still subjected to the RBAC to ensure that the content is protected and secure. Without the integrated sharing feature, the developer needs to code the functions for each of the tables, and it requires more time for the development. The reporting feature (F3-SF-05) is considered one of the most crucial features in a web application where it provides a summary of data and records. This feature is useful for the system administrator to populate the data in the web application and retrieve the report, for example, the monthly statistic of the data entry, active and inactive records, archive records and others. Re-CRUD has fully supported this feature (JIS = 1), where the reporting functions are integrated into each generated table. The integration also utilized the data visualization feature from F4-SF-01, where the ChartJS is used to generate the chart to make the report more systematic and readable. However, the reporting features are not supported by the other CRUD generator.

For the retention (F3-SF-06), appraisal (F3-SF-07) and archived (F3-SF-08), it was found that only Re-CRUD is fully supported (JIS = 1), and the other generator is not supported. Retention enables systematic record management in the web application. It provides a duration for each of the records before deciding to be disposed of or archived permanently. The retention feature works together with the appraisal feature (F3-SF-07). The appraisal feature provides the function to evaluate the specific record that has past the retention due date before deciding to be disposed of or archived. Each of these functions is generated through the CRUD operation using Re-CRUD. The digital archival feature in Re-CRUD enables the system administrator to move the inactive record that still has significant value, e.g. fiscal, legal, historical and other vital records, to permanent storage. The records that have moved to the archive are permanently stored, and the edit feature is

disabled to protect the originality and authenticity of the records. This feature is critical to ensure that the web application is not burdened by the unnecessary records, which may lead to an information explosion due to unmanageable data and records in the web application.

The disposition feature (F3-SF-09) shows that all CRUD generators have the feature. The objective of this feature is to remove or dispose of the records from the web application database. Technically, this feature is considered a standard feature in the CRUD operation. Based on the objective, all CRUD operations are fully supported (JIS = 1) since they can delete the records from the web application database.

D. Feature Set 4: Other

Feature set 4 focused on the UI and other supporting features to support the WA design and data presentation. Fig. 8 shows the FSS for each of the WAF CRUD. The weightage score for F4-SF01 is highly desirable since it is important to render the responsive UI, generate charts for data reporting, generate PDF, and provide a WYSIWYG editor. Technically, Re-CRUD is fully supported (100%) with those features and successfully integrated into the CRUD output. For the other WAF CRUD generator, the FSS is 50% since some of the features are available. Although it is not fully similar to the specification, it is still natively able to provide equivalent functions; for example, the template can still render responsively. PDF can be printed using the default print method and others.

E. Expert Validation

To validate the result from Table VII, feature analysis has been carried out with industry professionals' participation to evaluate Re-CRUD. The result is compared with the author's feature analysis result. Expert validation comprises opinion and judgement from the individual with knowledge and experience in the subject matter [111]–[113]. Expert validation is a methodology in which judgment is based on a particular set of requirements and/or experience obtained in a specific knowledge field, application area, product area, specific discipline, sector, and others [114]. The focus of this process is to validate the usability of the proposed solution. To execute the expert validation for this research, the experts must possess knowledge in software development, testing, maintenance and web-based technologies. The experts comprise representation from the industry, public sector and academician. The selected expert must respond to a set of questions as discussed in the following section.

To get a concrete outcome for the case study, it is important to know that the selected respondent must have knowledge in the specific area of the testing and understand how the product can provide a decent solution for their problem [125], [126]. Previous studies have suggested that five respondents are sufficient for usability testing, revealing 80% of usability issues [127]. Another usability researcher stated that a group size of 10 respondents is sufficient where it reveals a minimum of 82% of the problem [128]. A group size of 7 respondents is optimal for studies; even where the study is quite complex will reveal 95% of the problem [129]. It is also suggested that the respondents have expertise in a specific selected field, and the

optimal sample size also should be influenced by the study's complexity and diversity of the respondents [126], [128].

Based on the optimal number of respondents as suggested by previous studies, the usability test for this study is performed by seven selected respondents. The selected respondent is a practitioner that is active and knowledgeable in WA development, where they must-have experience in WA development using WAF and CRUD operation. Considering their experiences and knowledge, the respondents are experts in WA development and familiar with the task domain, WAF, MVC architecture, CRUD and other related features and functions.

The expert validation is executed to compare and validate the feature analysis scoring from the author's bias. 10 Re-CRUD feature analysis case study invitation has been emailed to selected experts, and eight have completed the case study and evaluation. The same case study has been executed by eight selected experts using the same procedure and analyzed. Table VIII shows the respondent demographic data. The demographic information shows that six respondents are male and two female. Their age is in the range of 26 to 45 years old. Six respondents have a bachelor's degree, and the other two respondents have a master's degree. In terms of software development experience, six of the respondents have more than six years of experience, while the others have 3 to 6 years of software development experience, and their software development major sector is in web and cloud. Four of the respondents used PHP as their primary programming language, three respondents used Java, and the others used Python.

Table VII shows the Re-CRUD feature set overall weighting score is 88%, based on the author's evaluation. Fig. 9 compares the Re-CRUD feature set weighting score given by the author and another eight selected experts. A based-line score (88%) has been set and marked with a dashed line compared to the other experts' scores.

Fig. 10 shows the feature analysis responses from industry professionals. Based on the feature set weighting overall score, it was found that 7 (87.5%) of the responses from the experts' score were higher compared to the based-line score (88%) and only 1 (12.5%) scored 0.5 below the based line. Most of the response is above the baseline as the listed features can be generated during the CRUD operation and performed as expected.

Fig. 8. Feature Set 4 – UI & Others FSS.

Fig. 9. Comparison of Re-CRUD Feature Set Weighting Score between Author and Respondents.

FSW Overall Score (%)		90					98.5					86.5					100				

Fig. 10. Feature Analysis Responses.

As highlighted in Fig. 10, several features in the feature analysis score are partly supported. For the F2-SF-01 (RBAC), four respondents (R1, R3, R5 and R7) stated the score was partly supported and tallied with the author has given scores. It was found that the F2-SF-01 (RBAC) feature is considered incomplete because some of the sub-features are not present. As stated in B, the RBAC is partly supported because the authorization policy is not integrated and generated with the CRUD operation. The RBAC policy enables the developer to manage who can access/restrict specific resources. However, four respondents are satisfied with the RBAC, which is fully supported since the authentication is fully functional and the authorization policy is not a compulsory component. Technically, the authorization policy can vary depending on the WA requirement. The authorization can be achieved using the authentication group and session through a simple programming procedure.

One response (R3) stated that F3-SF03 (audit trail) is partly supported. This is due to the issues of the ability to restore the original content from the audit trail history. Re-CRUD is built to have audit trail features that can provide digital tracking of content changes and present a list of changes history. With the

more complex concept of audit trail, R3 expect to have a restoration procedure that can revert specific changes to the original state. This feature is currently not present in Re-CRUD since it was designed to capture and provide the history of the changes. Although the restoration ability can be integrated, it requires a more complex audit trail management. For example, the restoration also needs to be tracked where the RBAC policy must be appropriately configured to ensure that only authorized persons can access the features to revert the content to the original state.

For the F3-SF05 (Report), one (R3) of the respondents stated this feature is partly supported due to the absence of a dynamic report generator. Technically, Re-CRUD provides a report based on the current year and monthly data. However, the report is currently unable to generate customized request reports, for example reports based on a specific date range. Furthermore, three (R2, R6 and R7) respondents stated that F3-SF06 (Retention) is partly supported. Re-CRUD retention features are designed with a specific duration. Even though it has various options of retention duration (6 months, 1, 3, 5 and 7 years), these options may not match the developer requirement due to different policies by the WA stakeholder. The retention duration options are currently not flexible and require manual code modification, and may cause a repetitive task.

As mentioned earlier, most of the feature set weighting overall score is higher than the baseline score. However, one of the respondents (R3) score is 86.5% which is 1.5% lower than the baseline score since R3 is not satisfied with the F2-SF01 (RBAC), F3-SF03 (audit trail), F3-SF05 (retention) where for the F3-SF03 (audit trail) features, the SFWS is 4 (mandatory) which affect the scores. As explained in the previous paragraph, each integrated feature has a scope of functions and limitations. It may not generally be complete; however, it can still provide basic functions for each feature.

F. System Usability Evaluation Result

Eight experts have executed system usability evaluation after completing the case study for the feature analysis. This evaluation aims to capture feedback on Re-CRUD effectiveness and efficiency in web application development. Ten system usability scale (SUS) [115] questions have been asked, which focused on two aspects (effectiveness and efficiency). The index for every question was calculated from equation 3, and the results are presented in percentages. Table IX shows the collective score for effectiveness and efficiency together with the SUS score percentage.

Based on Table IX, in the effectiveness aspect (ES1, ES2, ES3, ES4, ES5), respondents strongly agree that Re-CRUD is effective in completing their task in web application development (ES1) and agreeing that it meets their requirements and is easy to use (ES4, ES5). The score for ES2 is 85%, where the developer required additional features to complete their task due to the other special requirement for a specific project. However, Re-CRUD is designed to be flexible to be applied in various types of web application projects. In the aspect of supplementing Re-CRUD with additional components (ES3), the score is 82.5%, where the respondents feel that they are still required to supplement Re-CRUD with

other components, but most of the required components are already exist in the Re-CRUD environment. The additional suggested component is automation in data/content backup, error logging, and testing from the respondent comments. Fig. 11 shows the score for Re-CRUD effectiveness. Overall, Re-CRUD effectively performs code automation for web application development.

TABLE IX. RE-CRUD EFFECTIVENESS AND EFFICIENCY SCORE

			Score					SUS Score (%)
			1	2	3	4	5	
Effectiveness (ES)	ES1	It allows me to accomplish my tasks.	0	0	0	0	8	100
	ES2	I think I would not need a system with more features for my tasks.	0	0	0	6	2	85
	ES3	I would not need to supplement Re-CRUD with an additional components.	0	0	1	5	2	82.5
	ES4	I found the system unnecessarily complex	0	0	0	1	7	97.5
	ES5	This system's capabilities would meet my requirements.	0	0	1	1	6	92.5
Efficiency (EC)	EC 1	It saves me time when I use it.	0	0	0	0	8	100
	EC 2	I found the various functions in this system were well integrated.	0	0	0	1	7	97.5
	EC 3	I tend to reduce a lot of mistakes with this system.	0	0	0	0	8	100
	EC 4	I don't make many errors with this system.	0	0	0	1	7	97.5
	EC 5	I don't have to spend a lot of time correcting things with this system	0	0	0	0	8	100

Fig. 11. Re-CRUD Effectiveness Score.

For the efficiency aspects (EC1, EC2, EC3, EC4, EC5), the respondents strongly agree with all questions in efficiency aspects. It can be seen from questions EC1 until EC5 that it has an indexed percentage above 95%. In terms of time consumption in completing respondent tasks (EC1, EC5), Re-CRUD can support rapid development, reducing the development time by providing more automation and reducing

the tendency to reduce mistakes in code writing due to human error. Re-CRUD also presented a high percentage of score in functions integration (EC2) and lower error from the default generated code automation (EC4). Fig. 12 shows the score for Re-CRUD efficiency, and it can be determined that Re-CRUD are efficient in reducing development time, systematic in features integration and reducing code error.

Fig. 12. Re-CRUD Efficiency Score.

V. DISCUSSION

Three types of evaluation have been conducted (case study, feature analysis and expert validation), and the results are used as the basis of these findings. The case study is used to execute EDMS development using Re-CRUD to demonstrate the code automation with the integrated important aspects. From the web application development perspective, Re-CRUD can establish the EDMS with the integrated features. The code automation from Re-CRUD can be executed appropriately in the web server environment and produces no error when performing a task. Therefore, based on the analysis of the evaluation results, Re-CRUD has reached the following conclusions without hesitation:

A. Integrated Web Application Important Features with Code Automation

The Re-CRUD output offers extra features and solutions for modern web applications. Technically the extra features can be considered must-have features since the most web application is designed to create, manage and maintain digital data or content. The records management features have been integrated into the Re-CRUD tested and compared with four other WAF CRUD generators. The feature analysis result shows that Re-CRUD has better CRUD operation output and offers more features than the other WAF CRUD generator.

B. Reduce Web Application Development Time and Code Error

With the integrated features, Re-CRUD enables the developer to speed up the development process; since all of the modern WA necessary routine features have been generated, the developer can focus on other important functions that the stakeholder requires. Using Re-CRUD also enables the developer to build the prototype and test the WA rapidly. Expert validation shows that EC1, EC3, and EC5 have the most excellent efficiency scores (100%), where Re-CRUD may

save developers time and minimize the time in code debugging due to code automation. With more code and features automation, the tendency of prone to coding error due to human mistakes also decreases.

C. Achieved Usability Attributes

Effectiveness and efficiency are the usability attributes identified for this research evaluation. An expert validation was commenced to assess the Re-CRUD with this attribute. Eight industry experts have been invited to participate in the validation process. The SUS questionnaire with 5 points Likert scale is used, and both of the usability attributes, effectiveness and efficiency result achieved the SUS acceptable score. Considering this result, there is no doubt that Re-CRUD is effectively and efficiently acceptable in handling WA development.

VI. CONCLUSION

The overall score indicates that Re-CRUD with the integrated electronic records management features is effective and efficient in developing a WA. Overall, Re-CRUD receives a perfect score for feature sets 1 and 4, while the other CRUD generators receive a 50% score for the same feature set. Re-CRUD provides integrated RBAC for feature set 2, although it is only deemed partially supported because the other CRUD generator does not provide integrated RBAC. The electronic records management capabilities emphasize Feature Set 3, and the majority of the features have been effectively integrated into Re-CRUD, with a score of 93.3%. Although other CRUD generators cover some electronic records management features, the function is only partially supported. More code modification and enhancement are required for the other CRUD outputs to incorporate key electronic records management features. Re-CRUD allows the WA developer to create a rapid WA prototype with a more practical solution to digital content management through the integration of records management tools. The integrated records management features in CRUD operation enable the developer to save more time in coding the routine code for the web application to provide the essential features such as search and reporting in the web application. It makes the development process faster with the code automation for all the routine codes. This research also has a limitation where Re-CRUD only includes eleven features with a specific task to be evaluated. Many other features can be included, but only the listed features are integrated and tested to maintain flexibility. Re-CRUD has been applied and tested on EDMS, small size of WA. A larger scale of WA may behave differently as the data table will be more prominent, and the data processing may be more complex. In future work, more features should be incorporated into Re-CRUD, i.e., progressive web apps (PWA) and improve the Re-CRUD practical ability in various web application development. At the same time, it can effectively provide mobile application ability to the generated CRUD.

ACKNOWLEDGMENT

The study was funded by the Encouragement Research Grant (Vote No. Q.K130000.3856.20J92) awarded by Universiti Teknologi Malaysia.

Abstract—Gujarati language is used for conversation by more than 55 million people worldwide and it is more than 1000 years old language. It is the chief language of the Indian state of Gujarat. There are many dialects of Gujarati like Standard Gujarati, Amdawadi Gujarati, Kathiawadi Gujarati, Kutchi Gujarati etc. The Gujarati language is very rich in morphology like other Indo-Aryan languages like Hindi. Many readability tests are available in the English language, but no readability complexity test is available for the Gujarati idiomatic text. The Complexity score is the sub concept of the readability test. In order to define complexity level of Gujarati text, complexity score of Gujarati text is calculated. We deployed a novel readability complexity score calculation method in which we considered the number of letters of each word, the number of diacritics of each word, Gujarati idiomatic text of n-gram where n=1 to 9, Gujarati idiomatic text of m-meaning idioms where m=1 to 7. The complexity score is calculated as the sum of word complexity score, diacritics complexity score, n-gram complexity score of Gujarati idioms and m-meaning complexity score of Gujarati idioms. We emphasized Gujarati idiomatic text for the calculation of complexity score as idioms make the text more complex to understand. This is an innovative and first of its kind work in the research community of Gujarati language. The results are hopeful enough to employ the suggested complexity score method for developing a readability test method for natural language processing tasks for the Gujarati language.

Keywords—Complexity; Gujarati; idiomatic text; natural language processing (NLP); readability

I. INTRODUCTION

Gujarati language is named after the people of Gurjar people who are said to have established in the middle of the 5th century CE. Gujarati language is used by more than 55 million people worldwide and it is more than 1000 years old language based on Indo-Aryan languages. Gujarati language stands in 26th position among the most spoken native language in the world. Gujaratis are spread all over the world. It is the chief language of the Indian state of Gujarat. It is also main language in the union territories of Daman and Diu, Dadra and Nagar Haveli. Outside of India, it is spoken all over the world in many countries like United States, Canada, UK, Southeast African countries etc. There are many dialects of Gujarati like Standard Gujarati, Amdawadi Gujarati, Kathiawadi Gujarati, Kutchi Gujarati etc. The spelling of Gujarati words is based on pronunciation [1][2].

A. Gujarati Script

Gujarati is written similar to the Devanagari script except it does not have the horizontal line above characters. The Gujarati alphabet has mainly 34 consonants, 13 vowels and 10 digits working as a building block of the Gujarati language. Sarth Gujarati dictionary consists more than 65000 words excluding technical or slang words [3]. Gujarat vowels and Gujarati consonants can be written as independent letters or by combining with diacritic marks. Diacritics play a very important role in building meaningful words and thus vocabulary of the Gujarati language. Fig. 1 shows the use of diacritics with the letter **દ**. Gujarati diacritics and conjuncts make Gujarati script more effective for written and communication purposes [4][5].

B. Gujarati idioms

An idiom is a group of words but whose meaning is established by the usage and not as the literal meaning of its separate words. Gujarati people are using Gujarati idioms for expressing thoughts, feelings and messages. Gujarati idioms are not understandable for non-Gujarati people as well as for children of a lower standard. Gujarati idioms can be understood by the surrounding context information [6]. Gujarati idioms can be classified on the base of N-grams and on the base of the number of m-meanings [8]. Gujarati idioms can also be classified as static idioms versus inflected idioms. Here we consider idioms as unfamiliar words. Example of Gujarati idiom is જાલ લેવું 'jala levum' i.e. to take a vow. It is bigram/2-gram and single-meaning idiom.

C. Text Complexity

English language consists of 26 alphabets with 21 consonants and 5 vowels for writing. Generally, three aspects are used to decide the complexity of the English text: quantitative measures, qualitative measures and concerns involving to the reader and task [7]. The Gujarati language is morphologically very rich compared to the English language. The Gujarati language consists of 18 diacritics [6]. Diacritics make many possible word formations by suffixing or prefixing any letter. Using diacritics various inflectional forms are possible for Gujarati verbs and Gujarati nouns [9]. Here only quantitative measures are considered for complexity as our text is just in written form. Factors such as sentence, word length and the frequency of unfamiliar words are used as quantitative measures of text complexity.

The rest of the paper is organized as follows: Section II corresponds to the literature review related to text complexity and Gujarati text; Section III represents the methodology including collection of idioms data and the method of calculating Gujarati text complexity; Section IV covers the results and analysis; finally, the limitations, conclusion and future work are represented in Section V.

II. RELATED LITERATURE REVIEW

A readability score is computer calculated score which roughly decides what level of knowledge needed by someone to be able to read a text easily. Various researches have been performed for the study of the readability and complexity of the various languages. Various work related to readability formula have been carried out.

Harvey [7] represented three-part model for measuring text complexity namely qualitative measures, quantitative measures and reader & task. Quantitative measures consider more lexile level text as more complex than less lexile text. A qualitative factor considers layout, text structure, language features, purpose and meaning etc descriptors. Reader & task is dependent on the professional judgment of teachers about the complex text. Author used a Rubric - a set of guidelines to decide the complexity of the English text.

Uccelli [10] considered parameters like word length, frequency of unfamiliar terms, sentence length and text cohesion for the quantitative dimension of the complexity of English language text. The author emphasized that multiple themes, multiple perspectives, content-specific knowledge, figurative or ambiguous language make English text very complex text.

Anet [11] defined text complexity as easy or hard text in terms of reading based on qualitative and quantitative text features. Important quantitative parameters for defining text complexity are structure, meaning or purpose, language and knowledge requirement for particular English text.

Barge [12] calculated the English text complexity Rubric using 10 dimensions; each dimension can receive a score between 0 and 10 to indicate the optimal benefit for students. 100 points is the best possible overall score for a text and interpreted collective text scores depend on the different points. The rubric provides a framework to assist educators.

Flesch and Kincaid [13] designed readability tests to indicate the difficulty of English passages to understand. They represented two tests namely Flesch Reading-Ease and Flesch-Kincaid Grade level. Same core measures of sentence length and word length are used by the authors for the two tests.

Tillman and Hagberg [14] used Swedish and English language to test the compatibility of readability algorithms.

They tested three algorithms namely Coleman-Liau index (CLI), Lasbarhetsindex (LIX) and Automated Readability Index (ARI) on Wikipedia articles. Authors concluded that CLI seem to perform less well on higher level text but works excellent on the Bible like easy to read text in Swedish and English languages, whereas LIX and ARI work on average as well as hard texts in both Swedish and English languages.

Venugopal et al. [15][16] analyzed the complex words in Hindi language sentences and experimented with whether classical readability parameters of the English language can be applied to the Hindi language or not for determining the complexity of the word. They demonstrated that the frequency parameter plays an important role in determining the complexity of a word in Hindi sentence. As per their study, the length of a word is not a significant factor; the number of syllables plays an important predictor of word complexity. Researchers used five tree-based ensemble models out of a total of eight classifiers to extract the important features.

Sinha et al. [17] presented that the English readability formulas are not helpful for Hindi and Bangla languages. They proposed two new readability models for Hindi text documents and Bangla text documents. They customized standard structural parameters like word length, sentence length, number of syllables/word, number of polysyllabic words, number of consonant-conjuncts and number of polysyllabic words per 30 sentences.

Mehta and Majumder [18] explored large-scale media text of three Indo-Aryan languages Gujarati, Bengali, and Hindi as a part of quantitative analysis. As per their statistical study of the corpus, Bengali piece of writing might be more difficult to read than Hindi or Gujarati; Gujarati corpus has more diversity in vocabulary and it contains double type-token ratio than that of Bengali; Hindi is less artificial compare to Gujarati but more compared to Bengali, etc.

Modh and Saini [19][20] collected 2-gram to 9-gram Gujarati idioms and classified them as single-meaning to seven-meaning idioms based on a number of meanings. Authors [6] detected Gujarati idioms from the entered text using diacritics and suffix-based rules. Researchers [8] also exploited IndoWordNet for deciding the meaning of idioms on the base of surrounding contextual information.

Based on this exhaustive literature assessment and evaluation, English language text is analyzed by many researchers in detail for deciding the readability score of the English text by applying different standard parameters. Indo-Aryan languages like Hindi, Bengali and Gujarati are analyzed by some researchers by comparing it with English parameters. Very less work is done specially for Gujarati language text. No researchers have calculated the readability complexity score of

the Gujarati idiomatic text and No other researchers have tried to identify Gujarati idioms from the Gujarati text.

The paper highlights on the study of the complexity of Gujarati text by considering parameters like the number of letters in the individual word and the number of diacritics of the individual word. This paper also considers the presence of idioms in the text and also considers the type of idioms in the text and decides the complexity level of the Gujarati text. The extent of this paper is to analyze letters, diacritics, words and idioms within Gujarati text. This deployment helps in the study of the complexity of Gujarati idiomatic text.

III. METHODOLOGY

For the calculation of the complexity score of Gujarati text, four parameters are considered (1) the number of letters of each word (2) the number of diacritics of each word (3) the number of Gujarati idioms. If Gujarati idioms are found in the text, then the idiom(s) are classified in two ways: N-gram classification and M-meaning classification. Different complexity points are allocated to different classifications of idioms. The complexity score is calculated as the summation of meaning complexity, gram complexity, word complexity and diacritics complexity.

Complexity Score=Meaning Complexity Score + Gram Complexity Score + Word Complexity Score + Diacritics Complexity Score

A. Collection of Data

By and large 3472 distinct Gujarati idioms are accumulated from different Gujarati language resources [21][22]. Idiom data collection is basically for the recognition of Gujarati idioms from the Gujarati text.

B. N-Gram Idiom Classification and Complexity Points

Idioms are classified on the basis of N-gram model. Idioms can be classified as 2-gram or bigram, trigram or 3-gram, 4-gram or four-gram, 5-gram, 6-gram, 7-gram, 8-gram, 9-gram.

Idiom up to 9-gram was found. 1-gram idioms are specific personage idioms that represent the historical or fictional special character identity in a play. Example of 7-gram Gujarati idiom is રાન રાન ને પાન પાન થઈ જવું 'rana rana ne pana pana thai javum' i.e. getting into a bad situation.

Table I shows the classification of idioms on the base of N-grams and their corresponding complexity point calculation method. Bigrams and trigrams are more in number, so both are getting relatively more complexity points compared to other N-gram idioms.

C. M-Meaning Idiom Classification and Complexity Points

Idioms are also classified on the base of their meanings. Gujarati Idiom has a single meaning or more than one meaning. For single meaning idioms, a dictionary based approach is used to understand the meaning of an idiom, but for multiple meaning idioms, surrounding contextual information is needed to understand the idiomatic text. So it is complex to understand multiple-meaning idioms. So M-meaning idioms, corresponding M-complexity points are assigned. Table II shows the classification of M-meaning idioms and corresponding complexity points for the calculation of the complexity score. Gujarati Idioms are found from single meaning to seven meaning idioms. More complexity points are assigned for 7-meaning idioms as it requires more effort to understand by studying the surrounding contextual text.

For example ઠેકાણું કરવું 'thek anum karavum' is a 7-meaning idiom as it has 7 different possible meanings depending upon the context like ઉપયોગમાં લેવું 'upayogamam levum' i.e. to use, કન્યાને સારે ઘેર પરજાવવી 'kanyane sare ghera paranavavi' i.e. marry the bride to the right person, કાસળ કાઢવું 'kasala kadhavum' i.e. to kill, ખલાસ કરવું 'khalasa karavum' i.e. use-up, છેવટની ક્રિયા કરવી 'chevatani kriya karavi' i.e. take the last action, મારીને દાટી દેવું 'marine dati devum' i.e. kill and bury, યોગ્ય સ્થાને ગોઠવી દેવું 'yogya sthane gothavi devum' i.e. arrange in the right place.

TABLE I. COMPLEXITY POINT CALCULATION FOR EACH N-GRAM IDIOM

Sr. No.	N-gram Idioms	Count	(Count/Total Idioms) *10	Complexity Point (Roundup to 2 decimal)
1	Unigrams	58	0.167050691	0.17
2	Bigrams	2102	6.054147465	6.06
3	Trigrams	992	2.857142857	2.86
4	4-Grams	244	0.702764977	0.71
5	5-Grams	63	0.181451613	0.19
6	6-Grams	9	0.025921659	0.03
7	7-grams	2	0.005760369	0.01
8	8-grams	1	0.002880184	0.01
9	9-grams	1	0.002880184	0.01
	Total Idioms	3472		

TABLE II. COMPLEXITY POINT TABLE FOR M-MEANING IDIOMS

Sr. No.	M-meaning idioms	Count	Number of meaning(s)	Complexity Point
1	single-meaning	1806	1	1
2	2-meanings	953	2	2
3	3-meanings	504	3	3
4	4-meanings	193	4	4
5	5-meanings	13	5	5
6	6-meanings	1	6	6
7	7-meanings	2	7	7
	Total Idioms	3472		

D. Diacritics Complexity Score

If there are no diacritics in the Gujarati word, then the particular word is considered simple and easy to read. For example, Gujarati word રમઝમ 'ramzam' i.e. ramzam has no diacritics. Another example of a Gujarati word, ચાદર 'chadar' i.e. sheet has 1 diacritics. If there are more diacritics in the particular word, then the particular word is difficult to read. If the count of diacritics of a particular word is 0 or 1, then that particular word is considered as simple, so 0 complexity point is assigned. If the count of diacritics of a particular word is 2, then 0.2 complexity point is assigned. If the count of diacritics of a particular word is 3 or 4, then 0.5 complexity point is assigned. If the count of diacritics of a particular word is 5 or 6, then 1 complexity point is assigned. If the count of diacritics of a particular word is greater than or equal to 7, then 2 complexity point is assigned. Table III shows the complexity point table on the base of number of diacritics of a particular word.

TABLE III. COMPLEXITY POINT TABLE ON THE BASE OF NUMBER OF DIACRITICS OF PARTICULAR WORD

Sr. No.	No. of diacritics of particular word	Complexity Point	Example
1	0	0	રમઝમ 'ramzam' i.e. ramzam
2	1	0	ચાદર 'chadar' i.e. sheet
3	2	0.2	વાદળી 'vadali' i.e. blue
4	3 to 4	0.5	ચાદરમાં 'chadarman' i.e. in the sheet
5	5 to 6	1	ચીડિયાપણું 'chidiyapanum' i.e. irritability
6	Greater than or equal to 7	2	પ્રતિદ્વંદ્વિત્વ 'pratidhvandhita' i.e. competition

TABLE IV. COMPLEXITY POINT TABLE ON THE BASE OF NUMBER OF LETTERS OF PARTICULAR WORD

Sr. No.	Number of letters of particular word	Complexity Point	Example
1	1 to 3	0	આકાશ 'aakash' i.e. sky
2	4 to 5	0.5	બતાવવી 'batavavi' i.e. showing
3	6 to 7	1	પ્રયોજનભૂત 'prayojanbhut' i.e. purposeful
4	Greater than or equal to 8	2	તત્વજ્ઞાનીઓનો 'tatvagnaniono' i.e. of philosophers

E. Word Complexity Score

If the count of letters of a particular word is 1, 2 or 3, then that word is considered as simple, so 0 complexity point is assigned. If the count of letters of a particular word is 4 or 5, then 0.5 complexity point is assigned. If the count of letters of a particular word is 6 or 7, then 1 complexity point is assigned. If the count of letters of a particular word is greater than or equal to 8, then a 2 complexity point is assigned. Table IV shows the complexity point table on the base of the number of letters of a particular word.

F. Database of Idioms

An Idiom database is required to store the collected Gujarati idioms. This idiom database is used to identify idioms from the input text to decide the complexity of the Gujarati idiomatic text. Idiom column stores the base form of the idiom in the idiom database. Fields like idiom, Gujarati meaning of idiom, English meaning of idiom and other related fields are created as a part of the Idiom database [6][23].

G. Proposed Model

Fig. 2 explains the steps for the proposed algorithm/model.

Step 1: Accept the Gujarati text from the user.
Step 2: Pre-processing step 2.1: Eliminate whitespaces from starting and ending side of the text 2.2: Eliminate all whitespaces in between the text
Step 3: Tokenize all the words of entered text.
Step 4: Eliminate Gujarati stop words from the entered text.
Step 5: Find out Gujarati idioms from the entered text using the idiom database
Step 6: Calculate the gram-complexity score for idioms as per Table I.
Step 7: Calculate the meaning-complexity score for idioms as per Table II.
Step 8: Count the number of letters of individual word
Step 9: Count the number of diacritics of individual word
Step 10: Calculate diacritics complexity score as per Table III.
Step 11: Calculate word complexity score as per Table IV.
Step 12: Calculate complexity score=Gram-complexity score + Meaning-complexity score + Diacritics complexity score + Word complexity score
Step 13: Display complexity level results of Input text.

Fig. 2. Algorithm for the Proposed Model.

The entered input is the Gujarati text which may or may not contain any unfamiliar words, including the Gujarati idioms. The output will be the analysis of Gujarati text with complexity score, which takes into consideration various factors, and the corresponding complexity level.

IV. RESULT AND ANALYSIS

Gujarati text containing zero or more idioms is given as an input and output shows the related complexity score and complexity level of the inputted Gujarati text. The algorithm ignores the stop words in calculating complexity scores. Output also shows the stop words found in the input text. It also displays total words, total stop words, total letters, and total diacritics used in the input Gujarati text. It calculates Gram complexity score, meaning complexity score, diacritics complexity score and word complexity score as per weight defined in Table I, Table II, Table III and Table IV. The proposed model implements Table V for showing the complexity type or complexity level as an output.

We now present a few examples for the execution of the proposed algorithm for calculating the novel complexity score for the different instances of the Gujarati text. In Example 1, Example 2 and Example 3, different Gujarati text is given as an input. In Example 1, the input text is taken from the standard 1 Gujarati textbook. The output confirms that the complexity type of the text is SIMPLE. This is expected for the text used for teaching the first graders in the age group of generally 5 to 6 years.

TABLE V. COMPLEXITY SCORE INTERPRETATION TABLE

Sr. No.	Complexity Score	Complexity Type	Notes
1	0.0-20.0	SIMPLE	Very easy words.
2	20.0-40.0	FAIRLY SIMPLE	Fairly Easy.
3	40.0-60.0	MEDIUM	Medium complexity
4	60.0-80.0	COMPLEX	Complex
5	80.0 or more	VERY COMPLEX	Extremely complex

Example1:

<p>INPUT TEXT=વરસાદ આવે રમઝમ વાદળી ચાલે ઝમઝમ, મોટા મોટા છાંટા પડતા આભથી એ નીચે સરતા. આકાશ આજે ધમધમ વીજ ચમકતી ચમચમ, ધરની લીલી ચાદર ઓઢે લીલી ચાદરમાં ધરની પોઢે. ઢમઢમ ઢોલ વગડાવો, વરસાદને સૌ વધાવો. ‘varasada ave ramajhama vadali cale jhamajhama, mota mota chanta padata abhathi e nice sarata. akasa gaje dhamadhama vija camakati camacama, dharati lili cadara odhe lili cadaramam dharati podhe. dhamadhama dhola vagadavo, varasadane sau vadhavo.’</p> <p>OUTPUT: STOP WORDS FOUND----> આવે, એ, નીચે, ‘ave, e, nice,’</p> <p>Total Words in input Text: 34 Total Idioms Found: 0 Meaning Complexity Score: 0 Gram Complexity Score: 0 Word Complexity Score: 6 Diacritics Complexity Score: 3.2 Total letters in input: 97 Total diacritics in input: 41 Total stop words in input: 3 Complexity Score = 9.2 Complexity Type = SIMPLE</p>
--

In Example 2, the input text contains the collection of 13 idioms. Output identifies these 13 idioms and from these 13 idioms, 8 idioms are with 1-meaning, 3 idioms are with 2 meanings, 1 idiom with 3 meanings and 1 idiom with 4 meanings. Output also identifies different N-gram wise idioms. Corresponding meaning complexity score and gram complexity score are calculated. Word complexity score and Diacritics complexity score is also calculated. Finally, the complexity score is calculated and the complexity type is decided on the base of the range of complexity score.

Example2:

<p>INPUT TEXT=એક કાને સાંભળી બીજે કાને કાઢી નાખવું ઢ સંસાર માંડવો આગ લાગવી અક્કલ ચરવા જવી આંખમાં પાણી આવવું આકાશ પાતાળ જેટલું અંતર આંખ બતાવવી અક્કડ ને અક્કડ રહેવું જમીન પર પગ ન મૂકવો નાક ઉપર માખી ન બેસવા દેવી એકે પથ્થર ઉથામ્યા વગરનો ન રહેવો રાત કહે તો રાત દહાડો કહે તો દહાડો ‘eka kane sambhali bije kane kadhi nakhavum dha sansara mandavo aga lagavi akkala carava javi ankhamam pani avavum akasa patala jetalum antara ankha batavavi akkada ne akkada rahevum jamina para paga na mukavo naka upara makhi na besava devi eke paththara uthamya vagarano na rahevo rata kahe to rata dahado kahe to dahado’</p> <p>OUTPUT: STOP WORDS FOUND----> એક, જેટલું, ને, રહેવું, પર, ન, ઉપર, ન, ન, તો, તો, ‘eka, jetalum, ne, rahevum, para, na, upara, na, na, to, to,’</p> <p>Total Words in input Text: 53 Total Idioms Found: 13</p> <p>8 Idioms With 1 Meaning(s) 3 Idioms With 2 Meaning(s) 1 Idioms With 3 Meaning(s) 1 Idioms With 4 Meaning(s) Meaning Complexity Score: 21</p> <p>1 Idioms With 8 Gram(s) 1 Idioms With 7 Gram(s) 2 Idioms With 6 Gram(s) 1 Idioms With 5 Gram(s) 2 Idioms With 4 Gram(s) 2 Idioms With 3 Gram(s) 3 Idioms With 2 Gram(s)</p>

1 Idioms With 1 Gram(s)
Gram Complexity Score: 26.5

Word Complexity Score: 3.5
Diacritics Complexity Score: 5.9

Total letters in input: 114
Total diacritics in input: 66
Total stop words in input: 11

Complexity Score = 56.9
Complexity Type = **MEDIUM**

In Example 3, the complexity score is calculated as 75.3, which is in the range of 60.0-80.0, so the output of the complexity type is COMPLEX.

Example3:

INPUT TEXT=અંતરવેદના અંધામૂંઘી અતિસૌરભ હાથ ઝાલ અનુસંધાન અવસન્નતા અવસન્નત્વ આશોકિત આદીનવ આમ્રવૃક્ષ ઇંદ્રશસ્ત્ર ઇંદ્રાયુધ ઇંમ્નિહાન ઉપદ્રવ ત્રિદશાંકુશ ત્રિદશાયુધ ધાતુરાજક નિરીક્ષણ પરિચારક પરેશાની પર્યેષણ પિકવલ્લભ પૂછપરછ પ્રતિકુળ પ્રિયાંબુ ભોગવિલાસ અંતર રાખ મજ્જાસ્સ મનોવ્યથા મુશ્કેલી મેઘજ્યોતિ મેઘભૂતિ રતિકલવ રતિકેવિ રતિસંહતિ રતિસુખ વજ્રાશનિ વસંતદૂત વસંતદ્રુ વસંતદ્રુમ વિટંબાણ વિરુદ્ધતા વિષયભોગ વિષયસુખ વ્યાકુલપાણું વ્યાકુળતા શતકોટી સહાયરૂપ સૌદામની સૌદામિની સ્ત્રીગમન સ્ત્રીસંસારી સ્ત્રીસુખ સ્ત્રીસેવન હેરાનગત

Total letters in input: 278
Total diacritics in input: 163
Total stop words in input: 0

Complexity Score = 75.3
Complexity Type = **COMPLEX**

V. CONCLUSION, LIMITATIONS AND FUTURE WORK

The proposed Gujarati text complexity prediction model was successfully implemented and it was based on the number of diacritics of the individual word, the number of letters of the individual word and on the number of idioms. Different complexity points are considered on the basis of N-gram idioms and M-meaning idioms. Gujarati idioms are considered as unfamiliar words to understand the Gujarati text. The complexity score of Gujarati text is calculated as the

summation of diacritics complexity points, word complexity points, N-gram idiom complexity points and M-meaning idiom complexity points.

The proposed model could not recognize idioms those are not stored in the idiom database for assigning complexity points. Future work is to assemble all Gujarati idioms to correct this drawback. In the future enhancement of the model, particular domain vocabulary can be used for defining complexity levels.

Based on the outcome achieved, it is advocated that the projected readability complexity score calculation method is worth implementing in the real world for the community of Gujarati language. To the best of our knowledge, it is the first and novel readability complexity score calculation method and complexity type prediction method for the Gujarati Idiomatic text. The proposed method considers the Gujarati idioms as unfamiliar words and assigns weightage accordingly by dynamically detecting them from the input text. The proposed method opens the path for other Gujarati language researchers in defining readability levels for Gujarati text as well as natural language processing tasks for the Gujarati language.

Abstract—The generation of daily massive amounts of heterogeneous data from a variety of sources presents a challenge in terms of storage and analysis capabilities and brings new problems into high-performance computing clusters. To better utilize this huge and heterogeneous data, the continuous development of advanced Big Data platforms and Big Data analytic techniques are required. One of the significant issues with in-memory Big Data processing platforms, such as Apache Spark, is the user’s responsibility to decide whether the intermediate data should be cached or not. In addition, the data may be kept in several storage systems and physically scattered over different racks, regions, and clouds. Data need to be close to the computation nodes and hence data locality issue is a challenge. In this paper, using a distinct memory management layer between the data processing layer and the data storage layer, which automatically caches data without the need for any interaction from the applications’ developers, is evaluated. K-means, PageRank and WordCount workloads from the HiBench benchmark beside a real case to predict the price of Real Estate that is implemented using Gradient Boosting Regression Tree model, are used to evaluate this framework. Experiments show that the memory management layer outperforms the Apache Spark in reducing the execution time.

Keywords—Apache Spark; Big Data; data analytics algorithms; memory management

I. INTRODUCTION

For both academic, business and engineering communities, Big Data analytics for storing, processing, and analysing large scale heterogeneous datasets has become a must-have tool. New Big Data analysis techniques [1], as well as the constant development of advanced Big Data platforms [2], are required to take full advantage of this massive and heterogeneous data. Fig. 1 shows the Big Data architecture. The architecture consists of four layers.

Data storage layer, which contains multiple storage systems such as distributed file systems Hadoop Distributed File System, GlusterFS, Ceph, etc, or remote access file systems such as Amazon S3, Swift, Google Cloud Storage, etc. and it can contain tools and techniques such as relational databases and NoSQL tools.

Resource management layer controls resource management, scheduling, and security. Examples of resource managers are YARN, Mesos, and Kubernetes K8s.

Data processing layer, which contains one of the Big Data platforms such as the open-source Hadoop Map Reduce [3], the Apache Spark platform [4], The Apache Flink, etc.

Application layer, the top layer, can contain any application type, such as batch, graph analytics, machine learning, streaming, etc.

The default Big Data architecture has many challenges [5][6], such as:

- In some Big Data platforms that support in-memory computing, such as Apache Spark and Apache Flink, developers can cache data that will most likely be reused. As a result, it is entirely up to the developer to decide which data to cache in memory. Determining which data should be cached is a difficult task when dealing with jobs that consist of operations with complex dependencies. When there isn’t enough memory, caching all data in memory will result in a significant performance loss. While disc caching saves RAM, it reduces the efficiency of in-memory computing;
- Data locality is another problem for data processing; data are physically scattered over different racks, regions, and clouds. Data must be near to where data computation occurs to be processed;
- The data needed by the application may be stored in different storage systems, the application developer must be aware of all Storage APIs, such as HDFS API, FUSE API, S3 API, REST API.

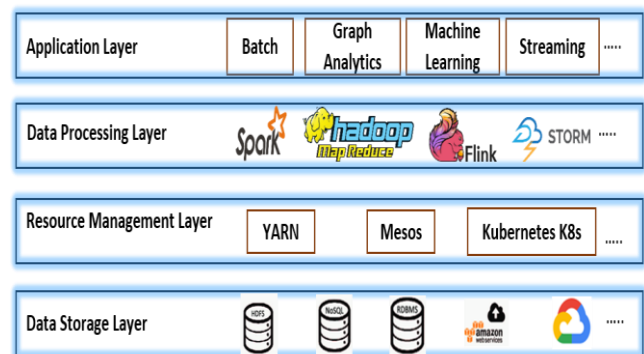

Fig. 1. The Big Data Architecture.

All the previous challenges necessitate the use of a distinct memory management layer between the data processing layer and the data storage layer.

In this paper, to evaluate the distinct memory management layer, the Apache Spark platform is used in the processing layer because Apache Spark boosts Hadoop's performance by up to 100x using in-memory cluster computing [7] and it is widely used in a variety of application domains, including bioinformatics [8], image processing [9], deep learning [10], finance [11], and astronomy [12], etc. The next section gives a background about Apache Spark and memory management layer. Three workloads from HiBench [13] are used for evaluation with randomly generated dataset, then a real case study to predict the price of real estate with real data set is developed to be used in the evaluation.

The rest of the paper is organized as follows. In Section 2 an overview about Apache Spark and memory management layer is given. In Section 3, a review of the related work is presented. In Section 4, the experimental setup and workloads are de-scribed. In Section 5, our experimental results are discussed. Finally, the conclusion of our findings is in Section 6.

II. BACKGROUND

In this section, an overview is given on Apache Spark which is used in data processing layer, Apache Spark Standalone cluster manager which is used in resource management layer, Hadoop Distributed File System which is used in data storage layer and the memory management layer.

A. Apache Spark

Apache Spark [14] is a computing engine and a suite of libraries for processing data in parallel on computer clusters. Apache Spark is one of the most used open-source engines for Big Data processing. Apache Spark is compatible with several popular programming languages (Python, R, Scala, and Java). It offers libraries for a wide range of operations, including data loading and SQL queries, as well as machine learning and streaming computation. The basic abstraction in Apache Spark is a Resilient Distributed Dataset (RDD). It acts as an immutable, partitioned collection of elements. These elements can be run in parallel.

The Apache Spark cluster can be managed by Apache Spark Standalone cluster manager or by other cluster managers as Mesos or YARN. The Apache Spark Standalone cluster manager is used to test Apache Spark performance in our experimental setting. As shown in Fig. 2, the Apache Spark master receives the application then a driver process is created and connected to the cluster manager through the SparkContext [4]. The cluster manager allocates the Apache Spark workers. Each worker contains an executor processes. The driver process is in charge of running the main () function, keeping track of the Apache Spark application's progress, responding to a user's program input, and analyzing, distributing, and scheduling work throughout the executors. The executors are in charge of completing the job that has been given to them and reporting the state of the computation back to the driver node.

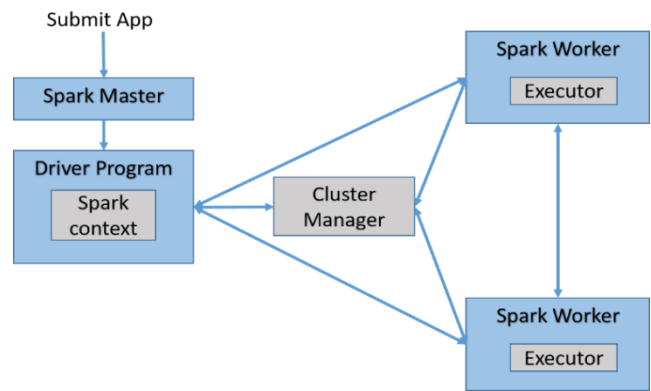

Fig. 2. Apache Spark Cluster Architecture.

Apache Spark was created to read and write data from and to Hadoop Distributed File System (HDFS) [15], allowing it to be used with Hadoop clusters. HDFS as a distributed file system allows users to access application data quickly. It allows enormous amounts of structured and unstructured data to be managed. HDFS is a file system that divides the processing of massive data sets across inexpensive hardware clusters.

HDFS has a primary NameNode, which keeps track of where the file is kept in the cluster and multiple of DataNodes on a commodity hardware cluster. Splitting huge files into little sections known as blocks is one of the major HDFS characteristics. These blocks hold a specific amount of data that can be read and written. The block size is set to 128 MB by default. Hadoop splits up blocks and distributes them across different nodes called DataNodes.

Another main characteristic in HDFS is replication which duplicates data blocks to provide fault tolerance and allows an application to select the number of replicas for a file. The replication factor can be specified when the file is created and can be changed later. If a node fails, you can still access the data on other nodes in the HDFS cluster that have a copy of the same data. By default, HDFS duplicates blocks three times.

B. Memory Management Layer

The challenges in the main Big Data architecture, as demonstrated in the introduction, necessitate the use of a distinct memory management layer between the data processing layer and the data storage layer. Fig. 3 shows the distinct memory management layer's location in the Big Data architecture.

This distinct memory management layer:

- Caches the most frequently used data automatically. A local storage space is set aside in each node of the processing cluster for hot and transient data. This storage could be of any type (memory, SSD or HDD). The size and type of storage are determined by the user. When an application attempts to read data that is only available in shared storage, the data are duplicated in local storage. When the local storage is full, one of the eviction policies [5] can be used to determine which data should be deleted.

- Handles the distributed storage system; because the data are duplicated in local storage, this can address the data locality issue in distributed storage systems.
- Serves as a global namespace, a global namespace is an important feature of a distributed file system that makes it easy to find and access data from multiple storage systems using a single control and administration layer. The global namespace can be considered as a global file directory that allows all data from several storage systems to seem as if they were stored in a single storage system. It automatically converts the standard client-side interface to any storage interface.

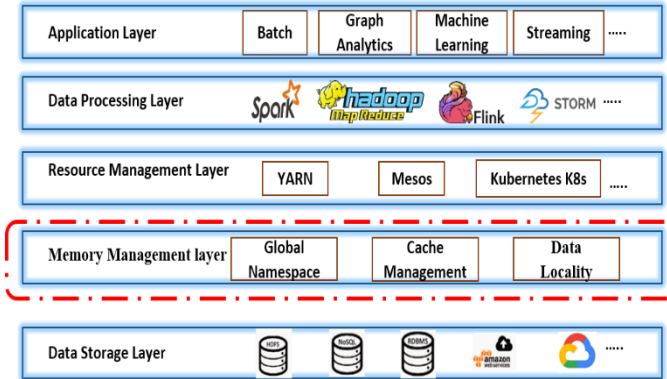

Fig. 3. The Big Data Architecture with a Distinct Memory Management Layer.

III. RELATED WORK

Many optimization strategies have been presented to improve memory management in Big Data frameworks. For Apache Spark, when the memory used to cache data reaches its capacity limit, data must be selected to be deleted to make way for new ones. Apache Spark’s cache replacement strategy uses Least Recently Used (LRU) criteria to determine which RDDs should be replaced, different cache replacement techniques were investigated [5] to improve Apache Spark performance. Apache Ignite [16], a high-performance, distributed in-memory computing platform for large-scale data sets has a cache management feature that keeps data in RAM as much as possible, having minimal interaction with the disk, but researchers in [17] observed that Apache Spark outperform Apache Ignite as Apache Ignite does not distribute well data among available nodes and it does not balance well the communication between the nodes. Other researchers are interested in investigating Apache Spark’s performance on various disk types. Doppio [18] proposed an I/O Aware performance study for Apache Spark, which measured the I/O impact of using hard disk drives (HDDs) and Solid-state drives (SSDs) with different combinations, and discovered the relationship between computation and I/O access by changing the CPU core number. As a result, the model could be used to locate the best configuration on the public cloud. Instead of reserving running memory for caching, RubiX [19], an open source project employs SSDs. It is utilized in the Azure HDInsight data caching service, which increases the performance of Apache Spark processes [20]. Delta Lake [21] by Databricks is another open source storage layer. Which also

leverages nodes’ local storage for caching, and the data is cached automatically anytime a file has to be retrieved from a remote site, resulting in much faster reading speeds. The user is not required to take any action throughout the caching process. Open Cache Acceleration Software [22], works with node memory to build a multilevel cache that optimizes system memory usage and automatically chooses the appropriate cache level for active data, allowing programmes to run quicker than they would on SSDs alone.

IV. EXPERIMENTAL SETUP

In this section, the used Big Data architecture is shown in Fig. 4, and fully described it in the following subsection then the used workloads and the implemented application are described.

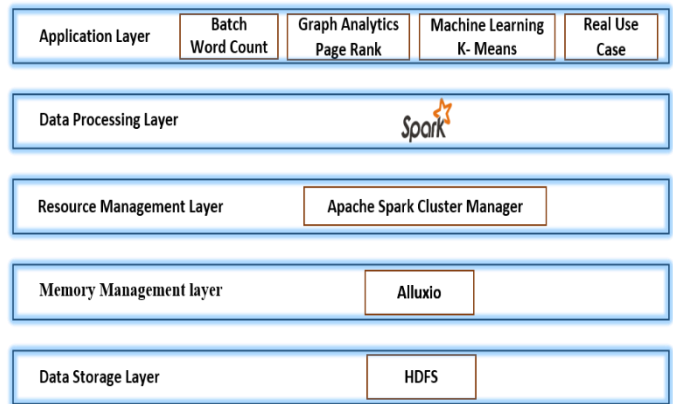

Fig. 4. Implemented Cluster’s Architecture.

A. Cluster’s Architecture

The experiments were deployed in a cluster at Electronics Research Institute. The Apache Spark cluster contains five servers, which is configured as one master and four slaves. There are 160 CPU cores and 640 GB of RAM in the cluster. The cluster services are shown in Fig. 5, and its specifications are listed in Table I. The data are stored on HDFS with data nodes on the same slaves.

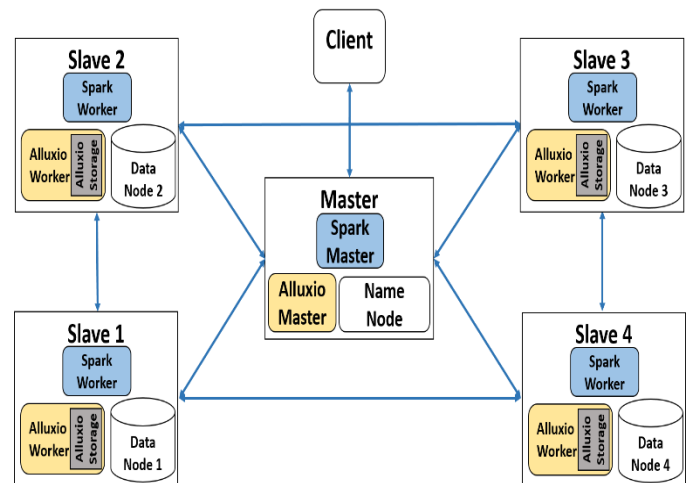

Fig. 5. Cluster’s Services.

TABLE I. CLUSTER'S SPECIFICATIONS

Servers Configuration	Processor: Intel(R) Xeon(R) CPU E5-2680 0 @ 2.70GHz Main memory:128MB Local storage:1 TB CPU cores: 32
Software	Operating system: Red Hat 4.8.3-9 JDK: 1.8 Hadoop:2.7.1 Spark: 2.4.6 Alluxio: 2.3.0
Workload	HiBench 7.1.1

In the experimental setup, Alluxio [23] a virtual distributed storage platform, is used in the memory management layer. The master and workers of Alluxio are running on the same Apache Spark cluster.

Alluxio enables users to integrate their data across multiple platforms. As shown in Fig. 6, Alluxio is made up of three different components: masters, workers, and clients. All user requests and file system metadata modifications are served by the Alluxio Master. The Alluxio Job Master is a lightweight scheduler for file system activities that are then executed on Alluxio Job Workers.

A specific amount of local Alluxio storage is determined for each Alluxio worker to store hot and transient data. Client requests to read or write data are fulfilled by Alluxio workers by reading or constructing new blocks within their local resources.

There are three scenarios for reading data:

- If the requested data are already in the worker local storage, then the client will read the file directly via the local file system (Local Cache Hit).
- If requested data are stored in another worker, the client will perform a remote read from that worker that does have the data. After the client finishes reading the data, it creates a copy locally for future reads (Remote Cache Hit).
- If the data are not available in any of the running workers, the client will read the data from the storage (Cache Miss).

Fig. 6. Alluxio Architecture.

Workers are only in charge of managing blocks; the master is the only one who keeps track of the file-to-block mapping. Because RAM has a finite capacity, blocks in a worker may be evicted if space is full. Eviction policies as least recently used and least frequently used can be used by workers to pick which data to keep in the Alluxio space.

In our experiments some parameters must be set in order to make the Apache Spark applications access Alluxio, the Alluxio client jar must be in the classpath of all Apache Spark drivers and executors so spark.driver.extraClassPath and spark.executor.extraClassPath parameters were added to spark/conf/spark-defaults.conf and was set to the path where the alluxio-2.3.0-client.jar is located. In order for HiBench to access Alluxio, hibench.hdfs.master parameter had been set to alluxio://{Alluxio_master_Hostname}:19998 in Hibench/conf/hadoop.conf, and the Hibench/sparkbench/assembly/target/sparkbench-assembly.jar had been copied to /spark/jars.

The following configuration had been added to hadoop/coresite.xml

```
<configuration>
  <property>
    <name>fs.alluxio.impl</name>
    <value>alluxio.hadoop.FileSystem</value>
  </property>
</configuration>
```

The experiments compared between Apache Spark framework with HDFS and Apache Spark framework with a distinct memory management layer and with different RAM size per worker.

B. Workloads

For a comprehensive evaluation, first three applications from HiBench, including K-Means as a machine learning algorithm for clustering workload, Page Rank as a graph analytics workload and WordCount as a batch processing workload were used with randomly generated dataset. Those workloads were chosen to compare Apache Spark cluster performance with and without memory management layer because of their distinct properties. Then a real use case was implemented to predict real estate sale price using Gradient-Boosted Trees as a machine learning algorithm for regression.

1) *K-Means*: K-Means [24] is a popular unsupervised machine learning clustering algorithm for data mining and knowledge discovery. The idea of the algorithm as shown in Fig. 7 that it divides a collection of samples into K groups or clusters, In Fig. 7, K is equal to 3. In the initialization, the algorithm defines K centroids randomly, and makes iterations of calculations to define new centroids in order to minimize the Euclidean distances between the points forming each cluster and its centroid. The iterations are repeated until the most optimum centroids are defined or the maximum number of iterations is reached. The input data in our experiment were 100,000,000 samples generated by GenKMeans dataset based on uniform distribution and Gaussian distribution. Based on

each sample's attributes, the algorithm assigns each sample to one of the k groups iteratively. The algorithm's input parameters used in the experiments were 5 clusters, 20 dimensions, and 5 iterations.

2) *PageRank*: PageRank [25] is an iterative graph analytics algorithm, as shown in Fig. 8, it ranks items based on the number and quality of their links. The PageRank's mathematics is completely general and may be used to any graph or network in any domain. As a result, PageRank and its variations are widely used in social and information network analysis, link prediction, and recommendation systems. It's even used in road network systems analysis [26]. The PageRank algorithm used in our experiments is implemented in apache Spark MLlib. The input data were generated from web data whose hyperlinks follow the Zipfian distribution. In the experiments, the input data parameters used were 5,000,000 pages and 3 iterations.

3) *WordCount*: The WordCount workload is a batch processing workload. It scans the input data once and counts how many times each word appears.

Random text writer generates the input data, the input data size used in the experiments was 30 GB.

4) *Real estate sale price prediction*: The prediction of real estate sale price in the presence of a large number of variables is a known problem, there are many models that were built with different methods to estimated house price by inputting house features [27] [28]. The data set used in this experiment has been downloaded from [29] and was collected from some popular portals for the sale of real estate in the period from 2018 to 2021. The dataset contains 5,477,005 records with 11 features. Fig. 9 presents the output of Python code to describe the dataset fields.

Where building type parameter could be { "1" for Panel, "2" for Monolithic, "3" for Brick, "4" for Blocky, "5" for Wooden and 0 for other type}. Object type indicates the apartment type and it could be { "1" for old buildings and "2" for new building}. Level indicates apartment floor. Levels indicates the number of stores in the building. Rooms indicates the number of living rooms and if the value is "-1" then it is for studio apartment. In our implementation, the data were read from HDFS once and once from Alluxio system. The code was written in Python. The dataset first passed through cleaning phase to remove any null values or negative values in the price column and take the log value of the price. Then the correlation matrix shown in Fig. 10 has been calculated to pick the most correlated features with the price.

Fig. 7. K-Means Algorithm.

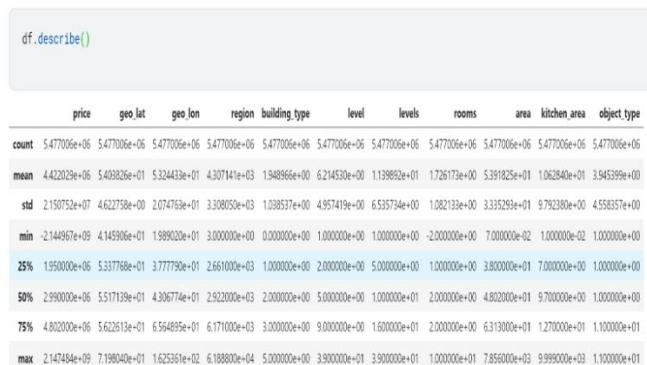

Fig. 9. Real Estate Data Set Parameters.

Fig. 8. Page Rank Algorithm.

Fig. 10. Correlation Matrix.

The data set was split randomly into training set and testing set with the ratio 70:30 respectively. Gradient-Boosted Trees (GBTs) learning algorithm [30] was used to predict the price. GBTs is one of the most powerful and frequently used algorithms by data scientists for building predictive models [31]. It acts as a machine learning technique for regression and classification problems. In our application, the algorithm was used as a regression technique using pyspark.ml.regression library. Given the input variables, regression analysis estimates the conditional expectation of the price variable. The results shown in the next section were for 5 iterations, 10 max depth. To evaluate the prediction model performance, the Root Mean Squared Error (RMSE) evaluation measure was used which considers the sample standard deviation difference between the predicted and real values. The lower the RMSE, the more accurate the model predictions will be. The average RMSE in all the runs was 0.13.

V. RESULT AND DISCUSSION

In this section, the results obtained after running the experiments are shown and evaluated. The execution time in minutes is used to calculate performance measures. In the experiment, the difference between utilizing the Apache Spark with HDFS and Apache Spark using a distinct memory management layer with Alluxio was evaluated.

The results illustrated how Apache Spark with Alluxio in the memory management layer improves the performance in all cases. Fig. 11 shows the execution time of running Real Estate application, K-means, PageRank, and WordCount algorithms on ERI cluster. The worker's RAM size varies between 4, 8, 16, 32 and 64 GB to study the effect of the memory management layer with respect to the RAM size.

It can be seen from the results that the memory management layer has better performance with smaller RAM size.

Fig. 11. The Execution Time of Running (a) Real Estate, (b) K-means; (c) PageRank and (d) WordCount on Apache Spark with HDFS and Apache Spark using Alluxio.

VI. CONCLUSION

In this paper, the impact of using a distinct memory management layer between the data processing layer and the data storage layer in Big Data Architecture was evaluated. This layer automatically caches the most frequently used data and handles the distributed storage system without the need for any interaction from the applications' developers.

First a HiBench benchmark was used with k-means, PageRank and WordCount algorithms with randomly generated workloads. Then a real case study with real dataset was implemented to predict real estate price using Gradient Boosting Regression tree. The results showed that when using distinct memory management layer, the execution time of the real estate application is up to three times faster than the normal case. So using memory management layer helps the applications' developers to get better performance up to three times faster with less effort. As a future work, other evaluations can be done with other tools, mentioned in section 3, other than Alluxio, such as Apache Ignite and RubiX.

Abstract—The purpose of this paper is to deploy a structural equation modeling approach through the Partial Small Square technique to validate the disruptions factors that affect livestock supply chain performance. The disruption prediction factors were obtained from the analysis of literature studies and data from the Department of Veterinary Services (DSV) and expert evaluation. Factors considered in the study model are Livestock Process, Finance, Breeders, Quality, Facilities, Technology, Demand, Supply, Information Communication, Sales, Transportation, Government Involvement, Disaster and Syariah Compliance. The results of the study found that the factors of Livestock Process, Finance, Breeders, Livestock Quality, Technology, Supply, Sales, Transportation, Government Involvement and Syariah Compliance were accepted as disruptions in the livestock supply chain. The findings of this study will assist farmers and livestock stakeholders to take necessary measures to minimise the disruption and further the government's goal of enlivening small and medium livestock enterprises in Malaysia.

Keywords—Supply chain management; disruption; livestock; structural equation modelling

I. INTRODUCTION

Livestock breeding is an agricultural activity that is one of the most important in the Malaysian agricultural industry [1]. According to United Nations [2], the importance of animal husbandry is seen as the “intensification of animal production as a way to ensure food supply”. The increasing demand for livestock meat supply in developing countries, including Malaysia, is driven by population growth, urbanization, industry, and increasing income. Households, the influx of foreign workers and an increase in the tourism industry [3]. Based on the Department of Statistics Malaysia (JPM), livestock in Malaysia contributed 14.9 percent to Gross Domestic Product (GDP) in 2018. This situation shows the livestock industry is one of the important sub-sectors in agricultural development in the country.

As reported by Institute of Supply Chain Management [4], a supply chain is defined as the smooth design of management, where the value-added process flows smoothly across organisational boundaries to fulfil the real needs of end customers. A supply chain, is an integration activity that occurs between one network and another to obtain raw materials,

transform raw materials into a semi-final product form, and finally become a final product, and then deliver the final product to customers through the distribution system [5].

Fig. 1 is the supply chain of the livestock industry as a whole. The livestock supply chain is generally the same for all livestock animals starting from the feed supplier to the end-user and through different livestock processes [6].

Breeding data is necessary to ensure that breeders have access to the most up-to-date information and can make informed decisions during the breeding process. Preliminary research indicated that farmers have no experience using information systems in livestock management, which is one of the types of disruption. The Department of Veterinary Services has built a system of information and technology exchange channels based on previous studies to ensure information is conveyed swiftly and accurately. Its purpose is to bridge the gap between officers and farmers in terms of communication. However, the study indicated that, with the exception of family support, social interactions, and internal drive, information and communication technology elements have no positive and substantial impact on farmer success [7]. The study also discovered that breeder information systems designed to aid livestock sector stakeholders were underutilized [8]. As a result, the Department of Veterinary Services (DSV) finds it difficult to get data on breeders and animals for data analysis, and the process of recording livestock reports cannot be implemented on time due to the difficulty in obtaining livestock data.

Fig. 1. Livestock Supply Chain.

*Corresponding Author.

The livestock industry in Malaysia is currently experiencing difficulties and disruptions in managing farms in a systematic manner to produce large-scale meat supplies, particularly to meet the demand of local consumers. Due to poor breeding rates, the cattle industry is experiencing a livestock population shortfall. Unsuitable breeds, high feed costs, and a lack of grazing land all contribute to the disruption. The role of private-sector involvement is also limited due to low-profit returns in the livestock sector, and this has resulted in the involvement of SME breeders still at a moderate level.

In addition, livestock practitioners in Malaysia often experience technical problems such as livestock selection, livestock breed selection, selection and provision of good livestock feed as well as farm management in accordance with the standards set by the government. The situation of livestock practitioners who still breed traditionally leads to unforeseen organizational management problems such as issues of destruction of livestock, management of labour or contract workers, credit loans and repayment methods that cannot be well followed by breeders. The issue of lack of DSV officers in some farming areas is seen to affect efforts to guide and channel accurate, up-to-date and direct information to farmers. Non-compliance of officials involved in financial management as well as lack of skills training also resulted in losses and tarnished the image of the government.

The demand for livestock meat supply in Malaysia is constantly increasing from year to year but the supply of stocks is always insufficient causing Malaysia to rely on import sources. The findings found that in 2017, a total of 167,439.17 metric tons of large ruminant meat were imported into the country [9]. The year 2020 saw the global Covid-19 pandemic had disrupted most of the country's economic activities due to movement control measures, including import sources of meat supply. To address this disruption, DSV is implementing efforts by providing guidance and educational activities to farmers as an incentive to increase meat production. However, the country still imports meat supplies from abroad. Table I refers to the time series statistics of the number of ruminants and pigs issued by the Veterinary Department from 2016 to 2020 in Malaysia.

TABLE I. NUMBER OF LIVESTOCK STATISTICS

Types of Livestock	2016	2017	2018	2019	2020*
Buffalo	59,740	54,632	48,195	47,652	47,266
Cow	654,602	620,521	589,113	581,567	585,597
Goat	350,370	318,032	289,361	256,159	264,922

Pig	1,370,763	1,412,737	1,448,122	1,468,788	1,463,000
Chicken	-	-	-	138,689,878	145,049,672
Duck	-	-	-	6,971,200	6,481,782

II. LITERATURE REVIEW

Every organization faces supply chain disruption at some point during the manufacturing process. The supply chain is a system consisting of organizations, human resources, technology, activities, information and resources involved in the activity of converting raw materials into finished products and delivered to consumers. Each supply chain activity has a different purpose. The supply chain in each organization is different and depends on the activities as well as the end product produced. Disruptions that occur in the supply chain complicate many parties including suppliers and end-users and expose various risks and disadvantages to all stakeholders in the supply chain [10].

In recent years, the supply chain process has become longer and more complex while the level and frequency of supply chain disruptions have shown an increase [11]. Disruption is defined as an event that disrupts the flow of material in the supply chain that causes the movement of goods to stop abruptly [12]. Disruption occurs due to several factors such as natural disasters, labour disputes, dependence on a single supplier, suppliers experiencing bankruptcy, violence, war and political instability. Transportation accidents, failure of public places and product failure and disruption of disasters after the occurrence of disasters such as haze, water crisis, forest fires and others. Particularly in Malaysia, natural disasters and extreme weather conditions are to some extent a threat to supply chain [13]. According to Pfohl, et al. [11], apart from natural disaster disruptions, other disruption factors identified are production machine failure, quality problems on final products, quality problems at the resource level, system failures, and problems from human resources, suppliers' delays, delays transportation and natural disasters themselves.

Each supply chain is exposed to its own dangers as a result of increased supply chain transit [14]. Each phase of the chain becomes more susceptible to different types of interference as the chain process becomes more efficient. Through the literature review, disruption caused by inefficiency in management, in turn, disrupts organisational activities as well as increases the cost of operating expenses and repairs [15]. A survey conducted on 559 companies representing 62 countries and 14 various the industry sector found that 85 per cent of the companies reported at least one supply chain disruption that occurred in the past 12 months [16]. While a recent study conducted in 2019 by the Business Continuity Institute reported despite the awareness of supply chain risk has increased, most companies remain at high risk of being exposed to disruptions. The study found that 74 per cent of respondents from a survey of 426 organisations had experienced at least one disruption in the supply chain of which 6 to 20 disruptions were reported each year, which is 50 per cent of companies, and experienced financial losses varying from 50 thousand to 500 million euros. While more than 23% of businesses reported losses of at least one million euros as a result of disruptions. Supply chain disruptions not only cause financial loss but potentially damage a company's brand or reputation as a result of third-party failures. According to the study, 27 per cent of businesses suffered a tarnished reputation, 58 per cent lost productivity, and 38 per cent lost

revenue. With a damaged reputation of 11.6 per cent, Asian countries are in fourth place [17].

There's no denying that the Covid-19 pandemic has shifted the country's economic landscape in unexpected ways. The livestock industry is no exception. The pandemic disruption that has hit the world presents a new form of challenge to farmers in Malaysia who are struggling to get the desired results. Farmers and livestock stakeholders face uncertain income and other disruptions in the supply chain and in turn expect assistance from the government for extensive assistance plans and long-term efforts to ensure the welfare of farmers is protected. The impact of the Covid 19 pandemic resulted in the distribution chain being affected due to the closure of operations, the absence of employees and declining cash reserves [18]. Physically disrupted supply chain disruptions have prompted entrepreneurs to take alternative measures by switching to online sales through social media including Facebook and WhatsApp, product delivery through private drivers and downsizing businesses to save operating costs [19].

Referring to the Table II are the sources of research findings past a discussion of the disruption factors identified in the supply chain.

TABLE II. FINDINGS OF POST DISRUPTION STUDIES IN THE SUPPLY CHAIN

Disruption Factors	References Study Findings
Production Facility Failure	[20] [21] [5] [21] [25] [26]
Quality Problems at The Resource Level	[21] [23] [24] [25] [20] [26] [27] [28]
Information Technology System Failure	[20] [21] [30] [29]

Communication Failure	[30] [29] [27] [22]
Political and Economic Instability	[21] [22] [24][77]
Regulatory and Legal Risks	[20] [25] [21] [23] [22][73]

The study also considered the SCOR Model and PESTLE analysis and the Behzad disruption framework to identify disruption factors according to the livestock industry.

1) *Model SCOR*: The SCOR model was developed in 1996 by Pittiglio Rabin Todd and McGrath and endorsed by

the Supply Chain Management Council as an industry-standard model in supply chain management [31]. Referring to Fig. 2, SCOR is process-oriented consisting of Plan (planning), Source (source), Make (manufacturing), Deliver (delivery) and Return (return) as in Fig. 2. This process encompasses the entire supply chain process from the point of view of suppliers, organizations and customers. The organizations involved are internal and external organizations.

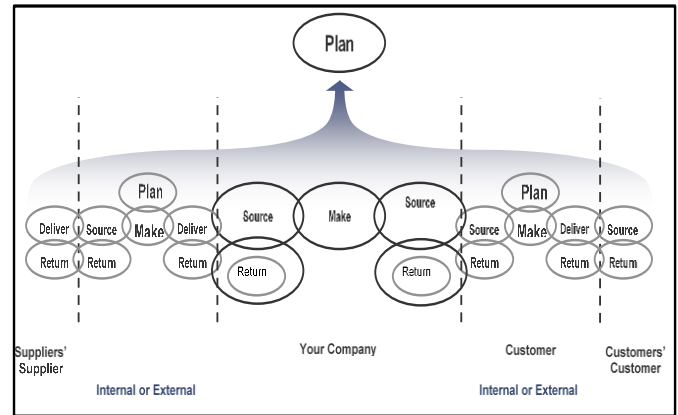

Fig. 2. SCOR Model.

2) *PESTLE Analysis*: There are six factors in the PESTLE framework. The factors are political, economic, social, technology, legal and environmental. PESTLE analysis is a method of analyzing the external environment to identify factors that contribute to the success or failure of an organization or industry. PESTLE analysis has a different structure from previous studies such as PEST and STEPE [32].

- **Political factors**: Politics plays an important role in business. In the livestock industry, politics plays a role in the effort to grow the industry through government involvement in assisting farmers by aiding further expand the livestock industry. For example, assistance from Majlis Amanah Rakyat to invest in industrial and commercial programs in the agriculture and food-based livestock sector is seriously and comprehensively needed to ensure that farmers rise up in the supply chain as well as increase the participation of Muslims in controlling the country's food supply meat industry.
- **Economic Factors**: Economic factors are measuring measures that are used to assess an organization's financial success. It is common that economic conditions often change over the life of an organization through comparisons of current levels of inflation, unemployment, economic growth and international trade. In the breeding process, financial difficulties are a huge and crucial issue. Farmers frequently complain about a lack of capital, which prevents them from increasing the number of farm animals. Only enough profit is made to be used as working capital.

- **Social Factors:** In a given situation or problem, social factors are used to assess the mentality of an individual or user. Demographic variables are also known as social factors. Indicators of social measurements are such as age distribution, population growth rate, employment level, income statistics, education level, religion, culture and social interaction. Apart from the aforementioned factors, the measurement of social factors also takes into account health and environmental concerns. At both the national and global levels, a variety of social and communication factors play a critical role. Among the several social sub-factors that can be considered to determine the measurement of social performance for an organization are social mobility, ethics and religion, lifestyle, level of education, historical issues, identity and beliefs, demographics and two-way cultural communication. The breeding process is influenced by the involvement of breeders who are 45 years old and older on average. The level of acceptance and openness in the breeding process makes the breeding field either a failure or a success and it results in a loss of cost and no return on capital that has been issued or vice versa. Similarly, the level of low or higher education among farmers affects the level of knowledge of the latest technology, and this can result in a lack of production of livestock products in the country or vice versa.
 - **Technology Factors:** When it comes to accurately assessing organisational performance, technology plays a big role. Technology advancements can improve internal efficiencies and prevent products or services from becoming obsolete. Every year the role of technology in the industry is increasing and technology in every chain is increasingly required to keep the process running effectively. Barn housing technology is one of the innovations that have been introduced into the livestock process [33]. Among other findings, livestock owners at present do not have to worry about the health of livestock because there is livestock automation technology based on the Internet of Things (IoT) that can monitor livestock remotely using drones and wireless network technology and able to collect data from sensors installed on livestock as well as water quality sensors in several water sources around livestock areas [34]. Among the technology sub-factors that can be considered to determine the measurement of technology performance for an organization are an information management system, quality and price, information change rate, minimize information retrieval problems, intellectual property, outsourcing, network coverage, patents and licenses, research and development, production efficiency and government legislative activities.
 - **Environmental Factors:** Environmental factors today are often seen as a threat to the environment. The livestock industry is no exception to environmental issues. Livestock activities, especially cattle breeding is carried out on the oil palm and rubber plantation lands that offer the potential to be cultivated in an integrated manner [9]. However, there are cases of livestock deaths recorded due to wild animal attacks, poisoning, negligence and deaths due to floods as well as accidents.
 - **Legal Factors:** The legal element is the final component of the PESTLE analysis. In this factor, the knowledge of laws and regulations needs to be known and learned importantly to prevent the occurrence of unnecessary legal costs. In carrying out livestock practices, there are guidelines that need to be followed through the Livestock Farm Practice Scheme to ensure good livestock practices to ensure the production of quality livestock and safe to eat. Good Livestock Practices (GAHP) MS 2027: 2006 includes livestock health management programs, biosecurity programs, sanitary and phytosanitary programs and farm waste and pollution management programs [9]. These farming practices cover all types of ruminant and non-ruminant livestock.
- Finally, PESTLE analysis is utilised to evaluate external factors that have an impact on an industry. The PESTLE analysis is an excellent starting point for developing the study framework [35]. Organizational owners need to identify the risks to be faced and use all of these factors and knowledge to make decisions to improve organisational performance. PESTLE can comprehensively understand the environmental picture of an organisation and can maximise opportunities as well as reduce the threat of disruption to the organisation [36].
- Political factors can determine how the direction of political parties affects business development and growth in animal husbandry. Economic factors are used to assess the impact of interest rates, taxes, stock markets, consumer confidence and other economic metrics. Breeders and livestock stakeholders need to be more competitive in line with current changes to withstand the challenges of lifting the livestock industry towards high-income economic transformation. Social factors affect lifestyle changes, advertising targets, ethics, demographics and culture. Technology factors are seen to help industry performance and ensure organizations use the latest technology in business. New high-tech approaches in the production of the livestock industry can help double the revenue from the livestock industry. Legal factors are expected to help regulate new laws and regulations that affect the operation of the industry and environmental factors can identify accidents and weaknesses that occur as well as solutions that can be considered, especially in the livestock industry.

3) *Behzad disruption framework*: Referring to Table III, the Behzad disruption framework is divided into three parts namely the organizational level, the network level consisting of demand, supply and transport and the environment level.

At the organizational level, there are several disorders identified like production machine failure, the occurrence of quality problems on the final product, the failure of information technology systems and the occurrence of problems from human resources due to the strike. While environmental disruptions are broken down into demand, supply, and transportation sub-factors. At the network level, disruptions at the demand level stem from the distribution network being stalled in the chain due to disruptions occurring in one of the chains and demand fluctuations in livestock supply. Disruption at the supply level is due to quality problems at the source level and the occurrence of some problems from the suppliers like delays and suppliers who suddenly experience losses (bankruptcy). Disruptions at the transportation level were identified as being caused by suppliers experiencing bankruptcy situations, transportation delays and strikes from employees. Meanwhile, disruption at the environmental level is caused by natural disasters, security risks like threats from terrorists, communication failures between several chains, political and economic instability and regulatory and legal risks. Findings from the study of [11] also found disruption factors also stem from natural disasters, security risks such as terrorist threats, the occurrence of communication failures between several chains, political and economic instability and regulatory and legal risks occurring at the chain network-level causing chain movements to pause.

TABLE III. BEHZAD FRAMEWORK

	Disruption Factors	
Organizational Level		Production machine failure
		Quality problems with the final product
		Information technology system failure
		Problems from human resources (strike)
Network Level	Demand	Network distribution disruption
		Demand fluctuates
	Supply	Quality problems at the resource level
		Supplier delays
		Supplier incurs losses (bankruptcy)
	Transportation	Bankruptcy of third-party logistics
		Transportation delays
		Strike
Environmental Level		Natural disaster
		Security risk (terrorist threat)
		Communication failure between several chains
		Political and economic instability
		Regulatory and legal risks

In total, this study presents 18 constructs of livestock disruption in the first circulation as in Table IV.

TABLE IV. LIST OF LIVESTOCK DISRUPTION CONSTRUCTS

No.		Factors	References
1	Organizational Level	Operating Process (Management)	[31][32] [37]

III. METHODOLOGY

This study adopts the study design proposed by Marakas [47]. The research methodology includes six main phases namely the problem analysis phase, the initial study phase, the model development phase, the instrument development phase, the model validation phase and lastly the model feasibility phase. The evaluation in each phase is using the Mini Delphi method for the rounds that are required as in the Model Development Phase. Conforming to the Reffi et al. [73] Mini Delphi is a technique that uses a discussion-based approach between moderators and involved experts. This study used a four-round Mini Delphi approach formally through face-to-face and email methods. In accord with Azizah et al. [74] panel responses were analyzed to identify the mean value for each construct.

The first phase of our research was to identify concerns and questions. Then the objective of the study was identified based on the issues and questions of the study, background and previous studies. This step of research results in a conceptual disruptor. The second phase includes a survey questionnaire as well as interviews with experts and stakeholders. Other factors

that lead to disruption other than those listed in the literature review are identified at this stage. Third phase: Assessment and selection of disruptive variables using a checklist tool. Data gathering based on the specified questionnaire in the fourth step. Model validation based on statistical analysis is the fifth phase. The Partial Small Square method was used to assess validation using the Structured Equation Modelling approach. The sixth phase entails creating a prototype of an information system based on the validated model.

IV. ANALYSIS

The data was analyzed using the Structured Equation Modelling (SEM) through Partial Least Squares Method. Structural Equation Modelling is a second-generation data multivariate analysis method used to test linear theory and causal augmentation models [48],[49],[50]. Analysis through Partial Least Squares Method approach was implemented through two levels of analysis. The first step involves examining the validity and reliability of the measurement model while the second step involves the evaluation and interpretation of the structural (theoretical) model [51]. The following is an explanation related to the analysis.

A. Convergence Validity

Convergent validity is defined as the degree to which some indicator can measure a given concept [50]. [52] proposed several criteria to measure the validity of convergence, which are factor loading, Cronbach Alpha (CA), Composite Reliability (CR) and Mean Variable Extraction (AVE). He also suggested that the load factor of the items should be greater than 0.7. The second criterion for convergent validity to convergence is composite reliability which refers to the degree to which a set of items consistently measures latent variables [52].

Through analysis, the Cronbach Alpha value and composite reliability were checked. The Cronbach Alpha value ranged from 0.8 to 0.873 while the composite reliability ranged from 0.873 to 0.902, which is significantly higher than the recommended level of 0.7 [53],[52]. Therefore, this result confirms that the validity of the convergent model has been tested. In addition, the average variance extracted (AVE) values were corrected to confirm the convergent validity of the external model. AVE is the mean-variance taken from several items related to the variance shared by the measurement error. In other words, AVE measures the variance shared by the metrics against the measurement error. If the AVE value is at least 0.5, then a latent variable can be inferred [52]. In this study, the AVE values ranged from 0.511 to 0.728, indicating that the study design constructs were validated [52].

B. Discriminant Validity

Discriminant validity has been used to measure the extent to which the constructs in the model differ from one another [50]. This validity is important because it ensures that the constructs in the model are unique and do not have high affinity for each other. In other words, items that measure the proposed construction should have high load, while items that do not measure the proposed construction will have low load. In the study, the validity of discrimination was measured using three criteria: Fornell Lacker, Cross Loading and HTMT.

1) *Fornell lacker*: The result of the square root of the AVE for the model's structures is placed on the diagonal of the correlation matrix. The model will be declared discriminant if the value of the square root AVE of each structure is greater than the elements in the column and row of each structure. The results of the study showed that the validity of the discriminant was confirmed because the squared value of AVE for each structure was greater than the mutual correlation of the columns and rows of the structure.

2) *Cross loading*: Cross-loading is the second approach to measuring the validity of discrimination. In this method items that are matched to the proposed constructs will have a high factor load while items matched to the proposed constructs will have a low load.

3) *Heteroit Monotrait (HTMT)*: Heterotope-monomer correlation ratio (HTMT) was used to assess the validity of the discrimination considered to be more accurate than other methods [54]. HTMT is recommended because it achieves higher specificity and sensitivity compared to cross criteria. An HTMT value close to 1 indicates invalid discrimination. Some authors recommend a cutoff of 0.85 [55], while others suggest a value of 0.90 [56]. If the value of HTMT is greater than this threshold, then selectivity is not valid. Result shows the HTMT clearly indicating that the HTMT value is less than 0.90 and further validates the validity of the discrimination.

C. Structural Model Assessment

Structural Model Evaluation will be carried out once the validation model has been validated. Generally, there are several approaches to measuring the structural model of multicollinearity, R-square, relevant and predictive coefficient routes.

1) *Multicollinearity*: Multicollinearity exists when two or more exogenous variables have a very high correlation [57]. It shows that some exogenous variables can be explained by other exogenous variables. Multicollinearity may result in inflationary problems of standard regression coefficients, which results in significant reduction in inflation [58]. Multicollinearity is said to occur when the correlation coefficient value is greater than 0.90 [52]. Additionally, collinearity issues can also be examined with reference to VIF values and tolerance. The author in [59] states that the VIF value should not exceed 5 to confirm that the structural model has no multicollinearity problem. The Fig. 3 shows the results of the alignment statistic (inner VIF) for each element. Each factor falls within the mean value from 1.102 to 2.812, which is within an acceptable range of less than 5.

2) *R-Square*: R-square is a measure of the predictive accuracy of a model and it is also considered as the combined effect of exogenous variables on endogenousness [60]. In other words, R-square provides the number of variants of endogenous variables that can be described by endogenous variables. In the PLS-SEM model, the R-square coefficient values of 0.67, 0.33 and 0.19 are classified according to three force levels, respectively, as medium and low [61]. According

to Henseler et al. [62], when structural models are explained by one or two modest exogenous variables, the R-square value is acceptable, and if the endogenous latent variables depend on some exogenous variable, the value of R-square is acceptable. The Fig. 4 shows the R-square value has significant level.

3) *F Square*: The F-square assesses the relative impact of each predictor construct on endogenous constructs [63]. Specifically, it measures the strength of an exogenous variable that impacts the endogenous variable in the R-square. According to the guidelines developed by [64], F-square values 0.02, 0.15 and 0.35 are considered as small, medium and strong [65]. The Fig. 5 shows the effect of the size of each exogenous variable on the endogenous variable.

Factor	Disruption
Transport	1.429
Supply	2.812
Disaster	1.889
Sales	1.701
Infrastructure	1.157
Government	1.991
Financial	1.902
Communication	1.932
Quality	1.559
Breeder	1.927
Demand	2.749
Livestock process	1.579
Syariah	1.102
Technology	2.179

Fig. 3. Multicollinearity.

Construct	R Square	R Square Adjusted
Disruption	0.795	0.785

Fig. 4. R-square Test Results.

Factor	Disruption
Transport	0.027
Supply	0.088
Disaster	0.001
Sales	0.017
Infrastructure	0.007
Government	0.069
Financial	0.045
Communication	0.035
Quality	0.038
Breeder	0.067
Demand	0.022
Livestock process	0.098
Syariah	0.03
Technology	0.228

Fig. 5. F-Square Test Results.

4) *Predictive relevance or blindfolding*: Q-Square analysis was performed to measure the relevance of exogenous constructs in predicting endogenous constructs [66],[67],[50]. When the Q-square value is higher than zero, this means that the model has a prediction relation, and if the value is zero and below, it indicates a lack of predicted prediction [68]. Based on result, the value of Q2 obtained by 0.415 is greater than the value of 0 which means that some exogenous variables can predict endogenous variables.

5) *Route coefficient*: Route coefficient is the standard version of the linear regression used to assess whether the proposed hypothesis is statistically significant or not significant. Each hypothesis proposed by the model is determined whether it is significant by means of path coefficient analysis. PLS-SEM uses a 5000-sample bootstrapping approach for hypothesis testing. A 95% confidence level with alpha 0.05 was used for hypothesis testing. The hypotheses show that a p value less than 0.05 is significant while a p value greater than 0.05 is not significant.

The Table V analysis results showed that 10 out of 14 hypotheses showed a significant value of p <0.05. Significant results mean that there is significant impact of exogenous constructs on endogenous constructs.

TABLE V. HYPOTHESIS RESULTS

Hypotheses	Relation	O. S.	S. M.	S. D.	Nilai t	p values
H ₁	Trasport -> Disruption	0.089	0.087	0.031	2.892	0.0040
H ₂	Supply -> Disruption	0.225	0.228	0.059	3.833	0.0000
H ₃	Disaster -> Disruption	0.021	0.024	0.039	0.538	0.5910
H ₄	Sales -> Disruption	0.077	0.075	0.038	2.01	0.0450
H ₅	Infrastructure -> Disruption	-0.04	0.039	0.025	1.607	0.1090
H ₆	Government-> Disruption	0.167	0.164	0.039	4.242	0.0000
H ₇	Financial -> Disruption	0.132	0.13	0.037	3.603	0.0000
H ₈	Communication -> Disruption	0.006	0.006	0.039	0.152	0.8790
H ₉	Quality -> Disruption	0.107	0.108	0.035	3.02	0.0030
H ₁₀	Breeder -> Disruption	0.122	0.12	0.036	3.418	0.0010
H ₁₁	Demand -> Disruption	0.006	0.008	0.046	0.126	0.9000
H ₁₂	Livestock process -> Disruption	0.147	0.148	0.035	4.201	0.0000
H ₁₃	Syariah -> Disruption	0.071	0.073	0.029	2.431	0.0150
H ₁₄	Technology -> Disruption	0.21	0.207	0.048	4.384	0.0000
<i>OS=Original Sample/SM=Sample Mean/SD=Standard Deviation</i>						

Thus, the ten constructs accepted in this study explain the disruptions in the livestock supply chain that occur and impact the livestock sector. The construct of this disruption needs to be emphasized so that the competitiveness and sustainability of the livestock sector can be enhanced from time to time.

V. CONCLUSION

Positive results are presented for H1, H2, H4, H6, H7, H9, H10, H12, H13 and H14 where the constructs of transport, supply, sales, government involvement, finance, quality, livestock, livestock processes, syariah and technology have a strong relationship positive to the disorder. The results obtained are in line with the disorder statement presented by Behzad [11] and Park et al. [69] which is found that disruptions factor consist of internal, external, supplier and end-user interference. The results of hypotheses H1, H2, H4, H6, H7, H9, H10, H12, H13 and H14 indicate disruptions occur and are accepted at the levels described by Park et al. [69]. This statement is also expressed by Gunasekaran et al. [38].

Meanwhile for H3, H5, H8 and H11 where the construct of disaster, facilities, communication and demand, the p value > 0.05. This indicates the construct did not have an impact as a disruption in the study. This result contradicts the Martha [12] statement that disruption can be caused by natural disasters, labour disputes, dependence on a sole supplier, suppliers experiencing bankruptcy situations, violence, war and political instability. Similarly, according to Fu et al. [70], communication in the supply chain is the latest advancement in information technology and scientific management that allows most industries to obtain and share information but communication is rejected as a distraction in this analysis. The demand construct was also rejected as a disruption in this study. The results of the demand hypothesis show that the supply-demand whether high or low has no role as a disruption although the study shows that the demand for livestock meat supply in Malaysia is constantly increasing from year to year and still unable meet the demand. This is because Malaysia has the option of relying on imported goods [9].

The future studies consider increasing the number of respondents, respondents with breeder status as well as expanding the sampling of the study to produce more accurate and comprehensive analytical results. In keeping with the next studies also need to consider external constructs like livestock management skills, livestock management experience, current planning and economics, social relationships, networking and marketing as well to be evaluated and given due attention in the livestock disruption model.

IoT Enabled Smart Parking System for Improvising the Prediction Availability of the Parking Space

Anchal, Pooja Mittal

MDU, Department of Computer Science, Rohtak, India

Abstract—Smart cities are a result of persistent technological advancements aimed at improving the quality of life for their residents. IoT-enabled smart parking is one of the foundations of smart transportation which seeks to be versatile, long-lasting, and integrated into a Smart City. One of the studies shows that the drivers who are searching for free parking space can cause congestion problems up to 30%. There is a possibility to reduce air pollution and fluidity noise traffic by combining Internet of Things (IoT) sensors positioned in different parking areas with a mobile application and help the drivers to search for free places in different areas of the city and also provide guidance toward the parking space. In this paper, we show and explain a unique Data Mining-based Ensemble technique for anticipating parking lot occupancy to reduce parking search time and improve car flow in congested locations, with a favorable overall impact on traffic in urban centers. In this paper multi scanning, IoT Enabled smart parking model is proposed along with ensemble classifier that improvises the predictive availability of the free parking space. The predictors' parameters were additionally optimized using a Bootstrap and bagging algorithm. The proposed method was tested an IoT dataset containing a number of sensor recordings. The tests conducted on the data set resulted in an average mean absolute error of 0.07% using the Bagging Regression method (BRM).

Keywords—IoT; Data mining; sensors; ensemble; decision tree; bagging technique; boosting technique

I. INTRODUCTION

Data Mining plays a significant role in the digitalization of the technologies fusion with the Internet of things, virtual reality, 5G connectivity, and many more. This technology's influence is not only restricted to information systems [1]. It also affect other sectors too such as design, transportation, healthcare, shipping, and business procedures. The integration and amalgamation of IoT, Data Mining, and pervasive interconnection can accumulate enormous data inside a city, distribute the data to the central database, and use it for processing. For example, to make city parking and operations more efficient, as well as to support the household waste and hospitality sectors [2]. It is important to recognize that a "Smart City" is not only a city that is interconnected with IoT technology or simply "uses" the data connection. Future Smart City is an interconnected system, a "brain," in which innovation, management, infrastructure, and residents all communicate with one another [3]. IoT and Data mining allows us to track the patterns in a city's everyday existence, then modify them according to the requirements to create them more effective and real. Tragedies, accidents for example, is discovered by direct reporting, permitting for quicker action

and actual traffic reporting to suggest alternate paths to escape congestion bottlenecks, simplifying movement and lowering consumption and CO2 emissions. In addition, to the persistent parking issue in large cities, Data Mining can assist both in terms of detecting and reporting to residents the available parking spots in the neighborhood, as well as in terms of emphasizing to governments where new ones are needed.

According to Juniper Research's "Smart Cities: Leading Platforms, Segment Analysis & Forecasts 2019–2023," innovative solutions for smart city traffic, which are used to alleviate traffic jams in towns, would produce \$4.4 billion in revenue in 2023, up from \$2 billion in 2019. Smart parking methods, which are a result of technological advancement, are causing a revolution in the parking industry. Nowadays, finding a parking space in a city is a time-consuming and difficult process that can quickly turn into a nightmare. Due to the Internet of Things and Data Mining, it become possible to examine, and discover parking utilizing technology instruments like sensors, cameras, linked, and integrated things. As a result, smart parking becomes an important component of smart cities. IoT enabled Smart parking is an approach that integrates technology and human to use fewer resources (time, energy, and area) for attaining quicker, and optimum parking of the vehicles during the time when the cars are not in use[4]. To put it another way, IoT-enabled smart parking systems determine which parking areas are engaged and which are vacant, as well as build a real-time parking map. Real-time maps are useful in different areas.

- Assist the drivers to search the vacant space rapidly by using the mobile application.
- Ability to make actual information accessible, which allows the agents to spot any problems.
- Assist individuals in deciding on another mode of transport if the parking area is unavailable.

To conclude, IoT enabled smart parking system is made up of sensors, collection of actual records and analytics, and a smart payment methods which permit users to search for parking space in the preferred location and make the payment in advance if required. Traffic is severely limiting mobility in cities around the world, resulting in enormous expenses not only for travelers but for society itself. According to the Texas Transportation Institute, the average U.S. passenger spent 34 hours in traffic in 2010, up from 14 hours in 1982, and is likely to spend more than 40 hours in 2020. In areas where people work and reside, traffic contributes to pollution and noise. IoT-enabled smart parking provides a solution to the problem.

As the above scenario is described, to designing a predictive analytics framework by using the predicting algorithm and IoT-enabled sensor-generated data is a big challenge. It can also be used in a variety of real-world situations, such as air pollution forecasts, novel healthcare services, weather forecasts, etc. [5, 6, 7]. We propose a predictive technique in the Smart Mobility realm, with an emphasis on parking space availability. To solve the cities' parking problem, we are providing a consistent immediate estimation of parking space availability. In this regard, the goal is to develop a reliable structure of day-to-day 1-hour and 4-hour range estimations based on data provided by IoT sensors. Data mining techniques are used to produce a 1/2-hours-horizon prediction of parking space availability, improving the prediction of the well-known methodologies.

A. Organization of the Article is as Follow

The paper is organized as follows. Literature survey is presented in Section 2. In Section 3 methodology is described that contains a block diagram of multi-scanning model for IoT Enabled smart parking system. In this section, an overview of different techniques are also described that will help in the prediction of parking space. In Section 4 the performance of these techniques is represented using the performance measure R2 and Mean absolute error (MAE). And finally, conclusion is presented in Section 5.

II. RELATED WORK

The section is related to the review of the literature and seeks to highlight the key terms, perceptions, and flows of thinking in the area of parking through the readings. The important concern is the Parking; the following section emphasizes the features relevant to the precise objectives of the study.

There are two subsystems in the parking management system. A vehicular detection method (VDM) and a vehicular control method (VCM) are both available. The VDM monitors the availability of free spaces for parking and delivers the data to the VCM module for distribution of the availability of the space to drivers [8]. An intelligent parking system is also proposed by another author Kumar et al.[9]. The authors compared different types of sensors used in smart parking systems and data generated by different sensors are sent to the central database in a predefined amount of time. Another author proposed a parking system with intelligence that is created on the visual processing, the technique decides the accessibility of the space using deep learning. The proposed model is equated using the methods that are exit in the PKLot and CNRPark_EXT[10,11,12]. Other authors implemented a prototype that uses, RFID, sensor, and IoT to identify vehicle particulars and also uses IR sensor to locate the vehicle's existence, allowing all details to be accessible via IoT devices[13]. Pawowicz et al. [14] used an RFID-based technique to better handle traffic control in an urban areas, although the issue of predicting continues with this technique.

The authors of Giufr et al. [15] suggested an Intelligent Parking Assistant. Their intelligent parking management system is based mostly on the utilization of sensor networks.

However, this research ignores the technique of machine learning and the benefits of the Internet of Things. Another author uses Haar-AdaBoosting and CNN algorithms, Xiang et al. [16] suggested a method for the identification of real-time parking utilization at gas stations. Another deep learning case study [17] developed an automatic valet parking that is based on robotic valets which uses hybridization in smart parking that helps to maximize the use of parking area that uses the well-known technique that is Deep Q-Learning, a reinforcement learning. The authors of Camero et al.[18] (2018) introduced a new technique for processing parking occupancy rate predictions that uses deep learning by combining recurrent neural networks. The paper [19] provided a framework for designing an efficient parking control system that uses an innovative video processing technology that will help to assign vehicles to the vacant open parking slot at the entry point. This method is used for real-time forecasting of events. Stolfi et al. [20] use a study using parking occupancy data to examine a variety of forecasting methodologies that includes time series, Fourier series, k-means grouping, and polynomial alteration. The developed model is still critical and does not include rising technologies such as IoT and can be improved. Bachani et al.[21,32] provided a thorough examination of one of the most important components to develop an intelligent parking system, which includes the selection of appropriate sensors and optimal placement for precise detection.

In this paper, we propose an IoT-enabled smart parking model that will help in predicting the available parking space that fuses two technologies that is data mining and IoT technology.

III. METHODOLOGY

In the literature, many works are presented as smart parking system but fails to meet the major challenges. The issues which are to be at the limelight are user privacy, selection of parking slots in quick time, presenting an efficient and real-time considerable system, etc. In the current work major of the issues presented are considered for a solution. The current work presents a predictive system, which uses data mining techniques for fast and easy retrieval. For complete prediction proves Ensemble technique is considered. The entire system is designed considering two different types of agents as detection agent and the smart parking agent, which reacts as per the learning and retrieval results.

A. System Model of IoT Enabled Smart Parking System

There is the number of models available but the shortcoming of the available models is that a large amount of data is generated by the sensors to handle that data there is no specific model available that will handle a large amount of data. That is the reason we proposed multi-scanning model because sensors generate a large amount of data every second and we need to accumulate only that data which is important for parking-related information. The main idea behind making the smart parking system is to utilize the available parking space efficiently.

“The block diagram of the multi-scanning proposed methodology is shown in Fig. 1”.

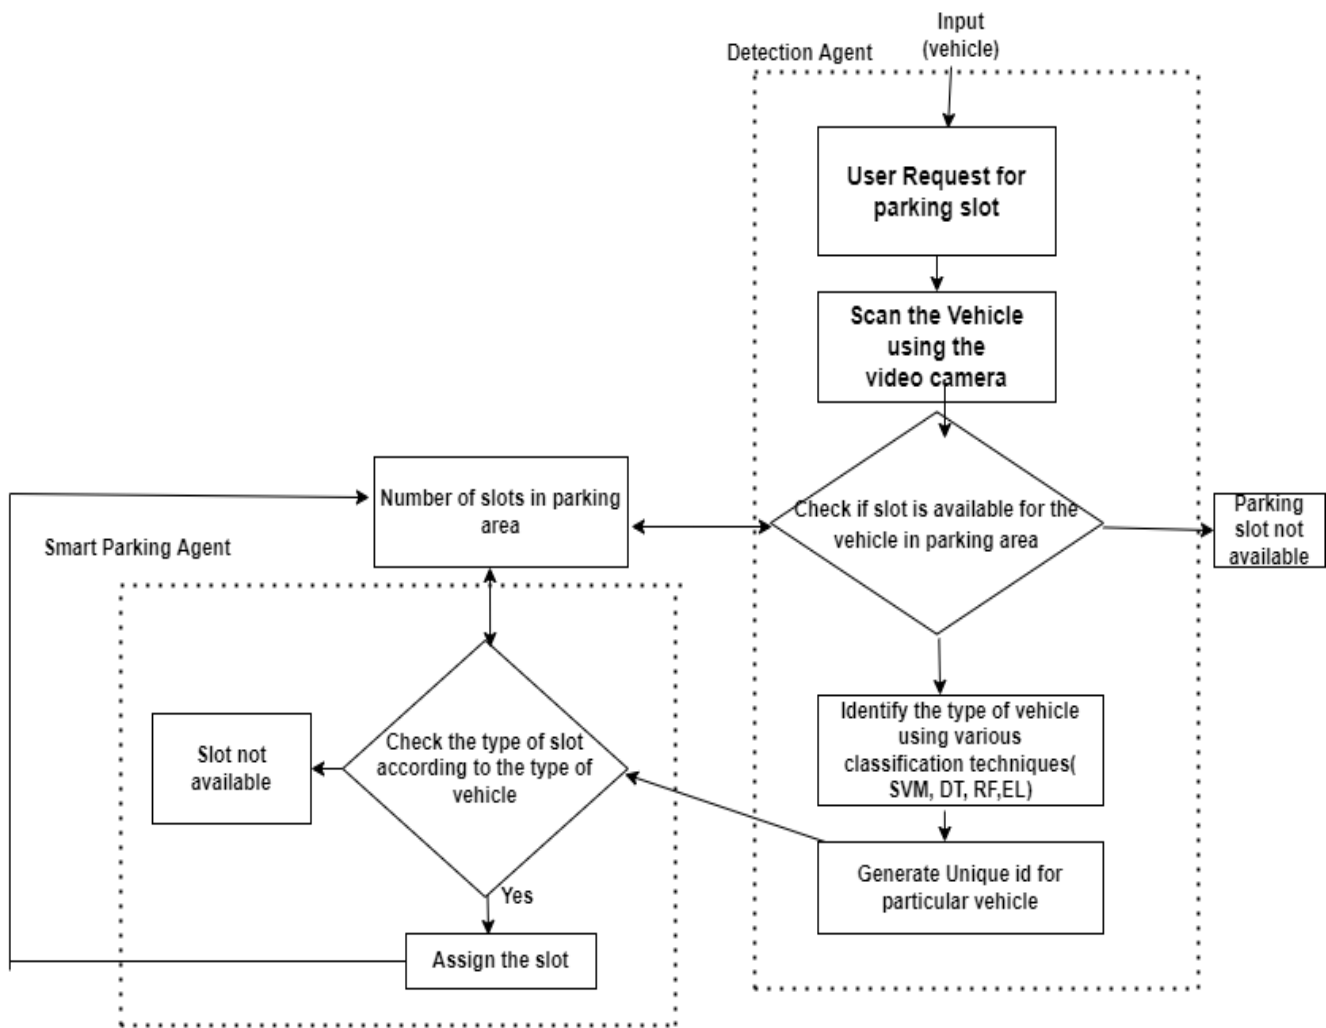

Fig. 1. Multi Scanning Model for IoT Enabled Smart.

The methodology is divided into two different parts:

- Detection agent.
- Smart parking agent.

The detection agent performs the identification of the type of vehicle. First, the user gives a request for an available parking slot. After getting the user's request, the system starts to detect the type of vehicle the sedan, coupe, SUV, bus, auto, etc., and assign a particular vehicle id to the specific vehicle. In the next part, the smart parking agent gives a particular location to the vehicle if the slot is available in the parking space. The slots of the parking areas are classified in advance by the smart parking agent according to the type of vehicle. Based on classified slots the smart parking agent will assign the available parking slot to the vehicle. The classifier that will help the smart parking agent is the ensemble technique.

The IoT-enabled smart parking model is a smart structure that uses a detection method to determine the parking space availability to assist the drivers with the accessibility of the parking space. A smart parking system needs the following elements:

- Sensors.
- Smart mobile application.
- Database.
- Gateway Hardware.

B. Ensemble Predictive Technique

This classifier combines several basic techniques such as decision tree or random forest. Every basic model provides an alternative approach to predicting the datasets and the final forecasting is the result of the combination of the basic models that will enhance the accuracy of the results. Because the uncertainty is significantly smaller than that provided by one of the individual base models that make up the overall model, the prediction technique of combining the predictions of a collection of individual base models often provides for more consistent and accurate output prediction. Therefore, the final ensemble-based model rectifies the individual errors generated by the fundamental models, resulting in a significant reduction in total error. The basic models should be required to meet two characteristics to be effective: they must be independent and weak models.

The original plan was to split the training data D into n basic data sets to train n models (m1;m2,..., mn). When n becomes high, however, this strategy is eventually outperformed because it promotes under-fitting. To deal with this kind of limitation various approaches are used that will re-sample the training data into n independent and greater data sub-samples to develop weak models. The number of techniques has been employed to accomplish it, the most well-known of which include bagging and boosting. As a result, the suitable algorithms for such kind of situations are volatile algorithms that include decision trees and neural networks that are modified during data set to produce a different model. A flow chart of a prediction system based on a set-based model is shown in Fig. 2.

The next sections covers our basic model which is decision trees and also contain two sampling strategies bagging and boosting and three-set models that contain the Random Forest regressor method (RFRM), Gradient boosting method (GBM), and Adaboost regressors(ARM) methods.

C. Decision Tree

The decision tree is used to depict the repeated division of the original entire space in the prediction tree technique. The terminal node or the leaves nodes represents a partition cell and is linked with a basic model that will apply only to that particular cell. For better understanding, think about a regress equation with two independent variables X1 and X2, and a continuous output variable Y. The concept is to divide the space into two sections and model the Y response (mean of Y) in every area separately. We again divide each section into two more sections and repeat the procedure till reaches a halt rule [22]. Each region's answer is frequently treated as a Cm constant.

$$\text{Minimize(SSE)} = \sum_{Ek=1}^{Em} \sum_{i=1}^n (yi - ck)^2 \tag{1}$$

$$\text{Minimize SSE} + \alpha|T| \tag{2}$$

The best Cm is simply the average of Yi in the Rm region because the optimization objective is to minimize the sum of squares [23]. Applied a cost complexity parameter (α) to identify the optimal region, which disciplines independent function in Equation (1) for leaf nodes of the tree T as given in Equation (2). The greedy algorithm is used to find the best division variable and split point. The optimal partition point for each splitting variable can be found by scanning all important parameters; it should be done fast. It is feasible to determine the finest pair of division parameters and division points by examining all of the input variables.

D. KNN for Regression

KNN uses non-parametric methods to resolve any regression problem, it is also known as lazy learner [24].If the incident values are categorical that it will assign the regression value by aggregating the nearest k neighbor values for quantitative occurrences or implementing the majority vote to the k neighbors. By aggregating the k neighbor outputs (constant weights) the values can be forecasted [25].

E. Ensemble Technique for Regression

The summary of the general idea is shown in Fig. 3 it shows that the model is based on three parts that is bootstrapping, intermediate model, and aggregation. Bootstrap split all the data D into n data D1 ,D2...Dn. Now we create an intermediate regressor Rj for each data set Dj and an aggregate of the successive regressors Ri will be the final regressor. The bootstrapping used in the Random Forest algorithm and the Boosting used by Gradient Boosting and Adaptive Boosting are two of the most powerful approaches derived from this fundamental principle.

Fig. 2. Ensemble Technique for Prediction of Real Time Parking Space.

Fig. 3. Basic Working Approach of Ensemble Technique.

F. Bootstrap Aggregation / Bagging Technique

1) *Bagging Regression Method (BRM)*: Bagging term is derived from "Bootstrap Aggregating." The algorithms are shown in the context of regression and they can be easily extended as a supervised classes. Random vector describes the learning data is denoted by the values that is (X, Y) , where X is in R^q and Y is in R . $D_n = (X_1; Y_1); (X_n; Y_n)$ is a sample that is independent and evenly distributed. The regression function (X, Y) and $m(x) = E[Y|X=x]$ are both defined by the same law. The mean square error of an estimated m and its bias-variance representation for $x \in R^p$ is as follows:

$$(\hat{m}(x) - m(x))^2 = (E\hat{m}(x) - m(x))^2 + V(\hat{m}(x)) \quad (3)$$

These comprise of integrating a number Z of models $m_1; m_2, \dots, m_z$ in such a way that:

$$\hat{m}(x) = \frac{1}{Z} \sum_{k=1}^Z (m_k(x)) \quad (4)$$

And

$$E(m(x)) = E(m_1(x)) \quad (5)$$

And

$$V(m(x)) = 1/Z V(m_1(x)) \quad (6)$$

As a result, the composite model's bias is the same as the m_k , but the variable reduces. By generating aggregated models on bootstrap samples, the bagging method attempts to reduce the correlation between them.

2) *Random Forest Regression Method (RFRM)*: It is a specific bagging approach that involves a collection of trees that is based on random factors. The classification and regression tree algorithm, whose concept is to iteratively split the space formed by the independent variable reciprocally, is most commonly used to create trees. For each phase of the partitioning, a section of the space is divided into two sub-parts based on a variable X_j [23].

G. Boosting Method

The basic idea behind this method is to create a group of models that are combined using a weighted average of predictions. In contrast to the previous bootstrap aggregation, the standard increase in subgroup formation is not random. The main impression behind boosting algorithms is to train forecasters in order, with everyone attempting to accurate the one before it [26,27]. Since every new subdivision is repeated on the former comprised features that could have been mislabeled by prior models, so the performance depends on the performance of preceding models. Most general boosting methods are AdaBoost and Gradient Boosting.

1) *AdaBoost Method (ABM)*: It is also known as the adaptive boosting method. It is centered on the assumption that a new forecaster pays a bit more recognition to the training sample under which the antecedent has adjusted to rectify the fault of its precedent. The outcome is the new predictor whose main focus is more on difficult cases. Let's take an example, Assume a predictor which is nothing more

than a decision tree for creating an AdaBoost classifier. Predictions on the set of patterns are made using a fundamental tree structure. After that, the weight assigned to the misclassified training instances is increased. The altered weights are then used to create a second classifier [28]. The second classifier predicts the outcome of the training game once more. After that, the weights are adjusted and the process will continue until all the predictors are in order, the set makes predictions in the same way as bagging do. The primary difference is that the weights of the generated predictors are dependent on their total accuracy calculated over the weighted training set [29].

2) *Gradient Boosting Method (GBM)*: Gradient Boosting is similar to AdaBoost in that it gradually adds predictors to a set, with each one attempting to rectify the faults of the one before it. Instead of modifying the class weights at each repetition as AdaBoost does, this method seeks to match the new classifier to the prior one's residual errors [29].

IV. IMPLEMENTATION RESULTS

The given section, analyzes and discusses the performance of the proposed methodology using a data mining classifier that is Ensemble technique. Section A, discuss about the dataset.

A. Dataset

Fig. 4 shows the real-time prediction of parking space using the ensemble technique. Sensors are installed in different parking areas in smart cities. These sensors are connected to the database that collects the IoT data with the help of sensors installed in different places. In this paper, data was collected using Birmingham in (U.K) dataset as a CSV file format. Parking sensors [30] collect over 6 months of data. The process of selecting relevant data involves removing inappropriate and duplicate information [30]. The Parking dataset consists following features.

- Code Number: It is described by an alphanumeric value that will identify the parked vehicle.
- Last Modification: It provides the time and date of the most recent updation for every parking block's availability data. Between 9:00 a.m. and 5:00 p.m., schedules are logged.
- Size: It contains the capability of each parking space.
- Occupancy: It includes every vehicle park's activities that are modified every 30 minutes.
- Status: It represents the status of the parking space i.e. free or available.

We created a particular feature called the accessibility rate (AR) from these characteristics, which is the ratio of the availability excluding the occupancy on the parking areas space at time t of the dated d . In our scenario, we use the following formula to calculate it:

$$AR_q(t) = \frac{Capacity_q - Occupancy_q(t)}{Capacity_q} \quad (7)$$

Fig. 4. Scattering of Availability of Parking Area as a Function of Time.

For reference, car park "BHMBCCMKT02" has a capacity of 455 parking spaces and an occupancy of 51 on 05/11/2020 at 06:49:32, thus we may infer our occupancy rate at this moment is 51/455, or 10.53 percent. The accessibility rate in the parking lot at the present time of day is 88.42%, indicating that the user can park here without causing traffic congestion. Fig. 4 illustrates the rate of parking availability as a function of time. Having the availability rates in real-time we are now applying data mining algorithms to forecast the future availability rates without knowing occupancy.

B. Performance Measure

We evaluated the performance of the model using two primary parameters to develop an ideal approach: the r-square (R2) and the mean absolute error (MAE). In various aspects, the two terms can be used to assess the gap between actual and predicted parking availability rates. The following formula is used [31].

$$R^2 = 1 - \frac{\sum_{j=1}^N (AR_{j,p} - AR_j)^2}{\sum_{j=1}^N (AR_{j,p} - AR_j)^2} \quad (8)$$

$$MAE = \frac{\sum_{j=1}^N |AR_{j,p} - AR_j|}{N} \quad (9)$$

Here N stands for a complete number of cases, AR_{j,p}, it is the predicted accessibility rate of the case j & AR_j is the actual available rate in the particular event. The use of a single metric may not always allow the models to be distinguished. The absolute error may reflect the effect of precision in the prediction of the waiting time, and R2 would also demonstrate to us the percentage of the exact waiting time that has been successfully predicted, whereas the MAE will show the error characterized by the deviation and mean between the predicted and the real by choosing the effects of high variations. The consistency of these two measures will lead to the best model.

C. Optimization of Hyper Parameters

Here we will compare the performance of different mining techniques discussed in the section for the prediction of available space in the parking lot. We separated our dataset as discussed in the section into two sets: a training set (80%) for building the models and a testing set (20%) for evaluating the model and comparing their performance. To begin, we searched for factors that would allow us to construct reliable and efficient models. It is important to determine the number of

iterations, the learning rate, and the optimal weak learner for the boosting procedure. The number of repetitions, the out-of-bag error, and the best weak learner is the most critical factors in bagging algorithms.

The tests that were conducted to choose these variables using a basic decision tree as a weak learner are shown in the figure.

The appropriate parameters for the boosting method are shown in Fig. 5. We can see from Fig. 5 that, how our model works on optimized parameters. The default value learning rate is 0.1, and the effective rate for Gradient Boosting is about 0.4. For AdaBoost, the same frequency might be used. The appropriate number of predictions for Gradient Boosting is at least 200, although it is not as necessary for Adaboost (about 30 predictor variables). Beginning with the estimation, a persistent optimum classifier based on bagging is created. The out-of-bag error is nearly zero. We can observe from the graph that the distribution of BRM followed by RFRM is more suitable for greater performance than GBM and ABM, which are both less efficient.

1) *Result analysis of total dataset of parking area:* In this, we evaluate the result on the total dataset of all the parking areas. To evaluate overall parking capacity, we used the attribute "Code Number" that is used for giving the identity numbers ranging from 0 to 25 for the 24 parking slots. The evaluations involved assessing and making comparisons of four different approaches. In the bagging algorithm, we use an optimization approach that is (BRM and RFRM) and boosting algorithm uses (GBM and ABM) approach. Table I shows the results, from which we created in Fig. 6 and Fig 7, which depict the comparison results. In comparison to the boosting method, the bagging methods (BRM and RFRM) produce the best results for all two metrics.

MAE produces 0.000771 & BRM produces 0.999951 here it is clear that BRM gave an optimal performance. In respect of R2, both BRM and RFRM achieved a near-perfect score of 0.999951. These results are somewhat better than RFRM, with an improvement of less than 0.00006 for these two metrics.

MAE and R2 received expert evaluations of 0.024523, and 0.982871 respectively, from GBM. These results were superior to ABM's 0.087872 and 0.834494 for these metrics, respectively. The findings of the two boosting methods evaluated (GBM and ABM) were substantially different from those of the very similar bagging methods, as demonstrated by the trend in Fig. 6 and 7. For the tests conducted, boosting approaches were slightly less effective than bagging approaches.

TABLE I. COMPARISON OF PERFORMANCE

		MAE	R ²
Bagging	BRM	0.000771	0.999951
	RFRM	0.000783	0.999949
Boosting	ABM	0.087872	0.834494
	GBM	0.024523	0.982871

Fig. 5. Optimized Parameters of Boosted Method.

Fig. 6. Comparison of Performance using Mean Absolute Error (MAE).

D. Result Analysis

To validate the algorithms, we performed two tests: the first on the total dataset of all parking areas, and another on every parking area data.

1) *Result analysis of every parking area:* We put our approaches to the test to see if we could estimate parking availability in each area separately. Comparison to earlier

work that simply employed one loss function. In Table II we compare the results using two loss functions that are Mean absolute error and r- square (MAE, and R2). We also compare the minimum, maximum and average performance (i.e. R2, MAE) values in the same table.

2) *Comparison of MAE of predicted value with each parking space with previous work:* MAE values of the various approaches, the RFRM technique finds the smallest mean value of 0.00055. For R2 we observe that BRM gave the optimal mean value i.e. 0.99980 compared to other approaches. As a result, we reached the conclusion that optimizing using the bagging method, particularly BRM, was the most effective way of estimating the available space in each parking space.

The fundamental goal of prediction is to forecast values that are close to accurate as feasible, we compared the results of our method to those achieved in earlier studies (Table III). In the previous work, only one measure is used i.e. MAE. The comparison table depicts that our best method (BRM) reduced mean absolute error by 7.6% on average when compared to RNN [18] and by more than 6.8 percent when compared to [20], which used and compared to time series(TS), Fourier series (F), k-means clustering (KM), shift and phase modifications (SP), polynomial(P), polynomial fitted by k-mean centroid (KP). Furthermore, the standard deviation is also low using BRM (0.00023) when compared to earlier work, which had a minimum of at least 0.026. Even improved, when compared to earlier algorithms, BRM proves to be faster.

Fig. 7. Comparison of Performance using r-square (R²).

V. CONCLUSION

Among the important features of smart cities that directly help residents on day to day, basis is urban transportation. One of the common problems in urban areas is congestion which is intensified by the search for free parking spaces by at least 35%. The capability to predict the available space for parking the vehicle in the urban cities is a big challenge and the smart solution will significantly lower traffic jams and also reduces metropolitan pollution. Some writers presented methodologies and models for the prediction of available space for parking the vehicle have several limitations. The proposed model helps the users to predict the parking space in advance using smart devices. As we know lots of data is generated every second it filters the data according to the need of the user and provides valuable information in less time using limited memory space. IoT enabled smart parking predictive model should allow us to take advantage of all of the interconnected devices in smart parking lots for the collection of data, evaluate it, and communicate the results with the users. Data mining technique that is Ensemble predictive analytic, enhanced the prediction of free space available in smart parking areas.

An Optimized Kernel MSVM Machine Learning-based Model for Churn Analysis

Pankaj Hooda, Pooja Mittal

Department of Computer Science and Applications, Maharishi Dayanand University, Rohtak, India

Abstract—Customer churn is considered as a significant issue in any industry due to various services, clients, and commodities. A massive amount of data is being created from e-commerce services and tools. Analytical data and machine learning-based approaches have been implemented and utilized for CA (churn analysis) to design a plan, i.e., required to comprehend the rationale for the CC (Customer Churn) and to generate a profitable and actual customer holding program. The analytics and machine learning approaches mainly focus on customer profiling, CC classification, and detection of features that affect churn. However, there are no specific techniques which can be used to determine how often a prospective customer is inclined to cover all the expenses whether they are churned or not. In this paper, an Optimized Kernel MSVM classification model is proposed to predict and classify churn. In the proposed work, MSVM algorithm has been used for classification. The kernel PCA and ALO optimizer method has been used for Feature extraction and selection. The proposed model Optimized Kernel MSVM has been implemented on Tele-communication sector customer churn database to demonstrate the proposed model's generalization ability. The Optimized Kernel MSVM model has achieved an accuracy of 91.05%, AUC 85% being maximum and reduced the RMSE score to 2.838. The implementation shows that both churn detection and classification may be examined at the same time while maintaining the highest overall accuracy and AUC.

Keywords—CA (Churn Analysis); CC (Customer Churn); OKMSVM (Optimized Kernel-MultiClass Support Vector Machine) Model; KPCA (Kernel Principle Component Analysis); A.L.O. (Ant Lion Optimization) method

I. INTRODUCTION

Identifying causes for client loss, evaluating customer retention, and recovering clients have become essential ideas for several businesses. Organizations do many studies and efforts to prevent losing clients in support of acquiring new clients. Due to the increasing green technologies, growing users, and valuation solutions. The unregulated and rapid development of this area has resulted in increased failure due to deception and technological challenges. As a result, creating new methodological approaches has become a necessity. This issue has become a pioneer in numerous studies in India's communications industry, experiencing massive consumer shortages. These are some of the uses of information retrieval: churn analysis, which is broadly employed across all sectors. Organizations need to develop initiatives to enhance customer satisfaction and formulate plans for improved customer retention by assessing which customers are likely to transfer providers. This research aims

to figure out how a telecommunication business loses consumers.

In the same way that causes are examined, determining which kinds of clients are abandoned is also studied [1]. There are different ways to define churn. The most important two ways are contractual churn and non-contractual churn. When a person does not extend their contract after the termination period has passed, this is known as contractual churn. Such churn starts when the customer loses interest in the products and comes to a point where reintegration is no longer feasible [2]. It's most commonly found in churn issues that occur whenever users terminate their savings accounts or move their wireless provider from one provider. Non-contractual churn is the second condition. Users can generally leave service without specific timelines in a non-contractual scenario. The customer operations team first establishes a churning state, after which a customer who meets that criterion is identified as a churned customer. The user's behavioral modification time is used to accomplish it. The individual is considered a churn client whenever the duration of idleness or changing behavior surpasses the limit.

The period is the interval established as the boundary of the inactive period throughout this operation [3]. There usually are two stages of churn prediction: (i) selection of features to evaluate the subsections of the characteristics that distinguish users would be preferable to locate the churned or not, and (ii) churn forecast. Customer churn is a helpful way to track how many clients are lost. Telecommunications firms frequently lose valued consumers and, as a result, revenue to competitors. The telecommunications business has seen significant transformations in recent decades, including the growth of different products, scientific innovations, and more competitiveness. Therefore, customer churn forecasting throughout the telecommunication sector has grown critical of players in the industry necessary to defend existing customer loyalty, maintain their competitive advantage, and enhance relationships with the customers [5]. Among the most complex difficulties in the telecommunication sector is supporting consumers with an elevated unemployment probability. Consumers usually choose churn choices due to the increased number of telecommunications companies and competitive pressures. As a result, telecommunications companies have realized the value of customer retention rather than obtaining new customers [16]. A variety of reasons influences customer churn. Prepaid clients, unlike post-paid subscribers, really aren't constrained by contractual arrangements; therefore, they frequently churn for the most little causes. As a result, predicting the customer churn rate is

challenging [27]. The additional aspect is client loyalty, which is influenced by the service providers' service and product performance. Customers may switch to a competitor with a more extensive range and higher transmission qualities due to broadband service and transmission reliability problems [17] [18]. Inadequate or unsatisfactory response to concerns and invoicing issues are other variables that increase clients' likelihood of emigrating to the opposition. Clients may transfer to the competitors based on shipping expenses, insufficient functionality, and obsolete equipment. Customers frequently evaluate suppliers and switch to whichever they believe offers a significantly better price. Even if it involves obtaining no potential clients, a telecommunications business can do OK, providing better care to established customers. The typical churn rate amongst telecommunication companies in the telecommunications business is around two per cent globally, resulting in a massive yearly loss of around \$1 trillion.

The research motivation to acquire the issue mentioned above, the corporation must accurately forecast the customers' behavior. There are two strategies for managing the churn rate: There are two types of reactions: (a) reactive and (b) proactive. In the reactive strategy, the corporation prepares for a reschedule from the user, following which it provides the appealing client decisions to maintain them. The likelihood of churning is predictable under the preventative approach, and clients present alternatives appropriately. It's a supervised learning [15] model in which churners and non-churners are differentiated. Machine learning, which comprises regression analysis, vector support network, RF, NB, LR, and others, has proven to be an extremely effective method for predicting data on the performance of formerly gathered information to address this challenge. Pre-processing and feature selection play an essential part in improving classification accuracy in machine learning techniques. Researchers have devised a slew of feature selection methods that can help minimize dimensionality, computational time, and overfitting. The supplied input sequence identifies the features relevant for predicting churn [4]. This research aims to group different consumers and identify the elements contributing to every category's turnover.

Furthermore, this study aims to design a churn prediction model using the OKMSVM model and apply it to predict churning consumers. This study will evaluate the information presented to establish that specific variables are associated with churning prediction. The number of variables gathered will be examined, and the system will be improved for the finished product. This study also seeks to determine churn prediction expense by determining the overall cost of clients who have churned to date and how much revenue can be avoided unless we can enhance our customer defection monitoring. Following the customer churn, a group will determine how maintenance strategies will be provided.

The organization of this work is as follows: The existing techniques of churn analysis are measured in section 2. In section 3, the existing issue and the problem is given. Sects 4 and 5 define the proposed work with a flow chart and result in an analysis with a detailed explanation. Sect 6 shows the conclusion and further work in the churn analysis.

II. RELATED WORK

In this section, existing methods for churn prediction are analyzed, and comparison tables are shown for better analysis. Jain et al. (2021) [6] proposed a multi-attribute strategic planning system combined with machine learning techniques. The name of the suggested strategy was the Worker's churn forecasting and retaining approach. A two-stage methodology was used for categorizing employees by creating an incredible achievement employment significance paradigm. The first proposal of the suggested methodology was to enhance the implementation of the entropy-based approach to allocating weighting factors to personnel achievements. Furthermore, for assessing the value of the personnel accomplishing and their class-based classification, an enhanced methodology (CatBoost) was implemented. The CatBoost method was then used to forecast employee churn by classification. Ultimately, based on the forecast findings and attribute rating, the authors had presented a retention strategy. Sarac, F., et al. (2021) [7] designed a two-level churn approach to evaluate whether a client would churn and determine how the consumer would pay for services. A classification technique called support vector machine was employed for such categorization component, and a recurring monthly cost was forecasted using machine learning-based support vector regression methodology. An autonomous feature selection technique, the multi-cluster attribute selection approach, was used to pick the most relevant features, including both evaluations. For uniformity, the same attribute selection strategy was employed in both evaluations to determine its effectiveness. The proposed scheme technique was then tested mostly on IBM. Telco Customer Churn set of data, which included over 7000 clients, to validate its relevance and generalization capabilities. Lalwani, et al., (2021) [8] proposed a machine learning-based approach. There are six steps to the proposed approach. Data pre-processing was the first step, and feature analysis was carried out during the second step. The third step used gravitation methodology to evaluate essential feature selection. The input was separated into two sections: training data and testing data, with an 80/20 proportion. On the training data, one of the most common estimation methods, such as LR (Logistic Regression, SVM (Support Vector Machine), Decision Tree (DT), etc., were implemented. The boosters, as well as ensemble approaches, were used for efficient predictive performance. Furthermore, K-fold cross-validation was performed over the training data for hyper parameter to minimize modeling fitting problems. Lastly, the confusion matrix and AUC curve were used to examine the test dataset outcomes. The Adaboost classification model was reported with 81.71 percent accuracy. Bayrak, A. T., et al., (2020) [9] proposed a churn estimation model with the help of an advanced learning technique. The designed model was based on LSTM (long short-term memory) technique. Clients' information was organized in a particular sequence in the customer information architecture. A long short-term memory design was produced using sequencing information to determine users' churn phases and therefore was compared with the existing categorization approaches. Including the assumptions, the suggested model achieved success and differentiated from the related research. Jain et al., (2020) [10] designed a framework for determining consumer attrition; the

proposed methodology was used two machine-learning methodologies: logistic boost and logistic regression. The testing was performed using the WEKA ML (machine learning) technology and an actual dataset from the Orange firm in the United States. Various assessment methods were used to display the results. Ullah, et al., (2019) [11] proposed study revealed churn characteristics, which were crucial in deciding churn's core origins. CRM might promote efficiency, offer suitable offers to talented churn clients associated with particular behavioral patterns, and drastically improve the corporation's advertising campaigns by identifying the main churn drivers from user information. The Receiving operating characteristic area, recall, Accuracy, Precision, and f-measure of the suggested churn estimation method were all examined. The findings demonstrate that by employing the R.F. method and k-means cluster formation, the suggested churn proposed method had obtained significant churn categorization and customer preferences. Alboukaey, et al., (2020) [19] suggested a regular churn forecasting-based model rather than quarterly churn forecasting, dependent on the user's regularly dynamic characteristics rather than his quarterly behavior. The authors expressed the everyday behavior of customers as multidimensional data and suggested four predictions based on the description to forecast the everyday turnover of the customers. A deep learning framework was suggested by Seymen, et al., (2020) [20] to determine if commercial consumers would churn in the later. The framework was validated against regression analysis and convolutional neural network approaches, both of which were usually applied in churn estimation analyses. Recall, A.U.C., and Precision evaluated the algorithms' outcomes with reliability classifiers. The analysis indicates that the trained model outperformed the other approaches in terms of prediction and classification. Hu, X., et al., (2020) [21] designed a machine learning-based

framework based on an integrated approach. The machine learning-based neural network and decision tree were used in the integrated approach. This work develops a composite churn prediction statistical model and tests its performance using statistical results. Ahmed, et al., (2019) [22] proposed a telecom churn prediction approach that integrates ensembles layering and uplifting-based techniques. Traditional performances and expense (cost) heuristics were used in the assessments, and expense heuristics received the most attention. The proposed methodology, operations had a high level of connection across performance metrics and business objectives, making the method suited for the majority of cost-sensitive operations. Yu, et al., (2018) [23] designed a methodology based on the machine learning technique and a particle categorization performance tuning back propagation (B.P.) networking for telephony customer churn estimation was proposed that periodically performs P.F.C. (Particle Fitness Computation) and PCO (Particle Classification Optimization). Abou el Kassem, et al., (2020) [24] and Khan, Y., Shafiq, et al., (2019) [25] developed estimation techniques for churn prediction with the help of machine learning approaches. Butgereit, et al., (2020) [26] used the machine learning technique to anticipate when consumers were poised to churn and while churning was examined. Such estimations were then applied to search through unstructured or semi-structured user input log files for explanations of why and how the user could be churning. In Table I, various existing methods for churn prediction are compared. The comparison is based on implementing methods, comparison techniques, and existing issues.

The existing methods of churn analysis with proposed parameters, comparison parameters are depicted in Table II. The conclusion of the current churn analysis with future enhancement is also described in Table II.

TABLE I. COMPARISON OF EXISTING METHODS OF CHURN PREDICTION

Author Name	Techniques	Proposed Method	Comparative Methods	Problems
Jain et al., (2021) [6]	Machine learning-based decision-making technique	Multiple attributes based decision-making Approach	LR (Logistic regression) DECISION TREE (DT) RANDOM FOREST (RF) CatBoost SVM (SUPPORT VECTOR MACHINE) XGBoost	More performance metrics are required for the reliability of the model
Sarac, F., et al., (2021) [7]	Two-level based hybrid support vector machine	Churn prediction based on machine learning methodology	SUPPORT VECTOR REGRESSION (SVR) SUPPORT VECTOR MACHINE (SVM)	More data will be collected for the reliability of the proposed model and need to reduce generalization issues
Lalwani et al., (2021) [8]	XGboost and Adaboost based classification model	Machine learning-based employee churn estimation approach	XGBoost LogGISTIC REGRESSION NAIVE BAYES CatBoost SVM (SUPPORT VECTOR MACHINE) RANDOM FOREST	Imbalanced datasets issues
Bayrak, A. T., et al., (2020) [9]	Long Short Term Memory-Based Model	Sequential statistics based LSTM (Long short term memory) technique	-	More Inaccurate predictions
Jain et al., (2020) [10]	Logit boost and Logistic regression-based model	Supervised learning based churn estimation technique for telecommunication	Fuzzy C-means technique Multilayer Perceptron Firefly based hybrid approach Support vector machine	Limited dataset for the reliability of the model
Ullah et al., (2019) [11]	Machine learning-based Random forest model	Random forest-based churn estimation in the telecommunication field	Multilayer perceptron (MLP) Random tree Logistic regression Naive Bayes	Insufficient results of churn prediction

TABLE II. EXISTING METHODS OF CHURN ANALYSIS: PARAMETERS, DATASET, CONCLUSION, FUTURE ENHANCEMENT

Author Name	Proposed Parameters	Datasets	Conclusion	Future Enhancement
Jain et al., (2021) [6]	Recall Accuracy Precision MCC (Matthew's correlation coefficient)	HRIS employee database	Using a multiple attribute judgment method, a unique incredible achievement personnel significance framework has been suggested to associates into several classifications based on the evaluation criterion	The proposed methodology will be implemented as a real-time approach
Sarac, F., et al., (2021) [7]	Root mean square error (RMSE) Accuracy	IBM telecommunication based dataset	The proposed methodology classifies the employees efficiently according to services charges	A deep learning-based approach will be implemented for more efficient outcomes
Lalwani et al., (2021) [8]	AUC Accuracy Recall F1-measure Precision	-	The gravitational search technique had provided effective results on feature selection and minimized the dataset dimensionality.	Based on deep learning and reinforcement learning proposed methodology will be improved in future
Bayrak, A. T., et al., (2020) [9]	Recall Precision F1-score	-	The proposed framework gives promising findings as well as efficient from other existing methods	The hybrid methodology will be implemented for more efficient results
Jain et al., (2020) [10]	MAE (MEAN ABSOLUTE ERROR) Kappa Statistic RMSE (Root Mean Square Error), Root relative square error Relative absolute error, Recall, Precision F-measure AUC	American Company Orange-based dataset	The proposed model employed two self-contained strategies that worked admirably; however, stand-alone procedures cannot incorporate all of the variables, improving the results.	A fuzzy theory-based framework will be implemented for effective outcomes
Ullah et al., (2019) [11]	Precision F-measure Accuracy Recall ROC	Telecommunication based dataset	For telecommunications company decision-makers, the proposed framework established client retention recommendations.	Lazy learning and eager learning approaches will be implemented in the future for efficient results

III. PROBLEM STATEMENT

Conventional customer churn estimation is based on corporate administrators' perspective that is being used inductive approach, so executives may anticipate turnover for existing clients relies on churned users' attributes.

Even so, expertise may be uncertain; specifically in the context of a problematic issue, no helpful instruction can also be provided solely based on expertise; because of a company's limited resources, finances should be decided to invest first in recapturing those clients with the most acceptable churn probability.

The traditional system of predicting that customers are willing to churn and which clients are much less inclined to turnover is ineffective.

As a consequence, if a company wants to make a logical forecast of churn prediction, it must employ numerical algorithms as well as "machines" to detect the connection among statistical features as well as customer churn, determine if clients are being churned, and will provide the churn probability [12].

In recent years, churn prediction has been a significant concern in the telecommunication sector. Telecom carriers must identify such clients before their churn to address this issue. As a result, creating a different classification that

accurately predicts churn is critical. This classification should determine clients who are likely to churn in the coming years, allowing the users to respond quickly with relevant deals and discounts.

Machine learning techniques for categorization, such as k-nearest neighbour, decision trees, logistical regression, neural networks, Nave Bayes, and others, are the most popular approaches for this objective. In addition, studies should concentrate on uncovering innovative capabilities that are the most successful in forecasting client attrition [13]. Various costs can cause customer churn, individual characteristics, information and service, facilitating conditions, economic indicators, promotional strategies, and competition' market participation. The best approach to recovering churned clients and lowering the churn rate is determining churn prediction's cause(s).

According to a brief overview of influential factors of churn prediction in recent times, academics' investigation on attempting to influence determinants of consumer churn in the telecommunications industry consists of three main components: 1st, usage factors like call period and usage portion, accompanied by quantitative client variables like personally identifiable information as well as maturity level, client revenue, and satisfaction of customers, as well as eventually, corporation relevant factors.

IV. RESEARCH METHODOLOGY

In this paper, a new model is proposed to analyze the churn. Fig. 1 shows various modules of the proposed model to perform churn analysis.

The initial input has different data elements collected from the dataset and considered labelled experiences for the machine learning model.

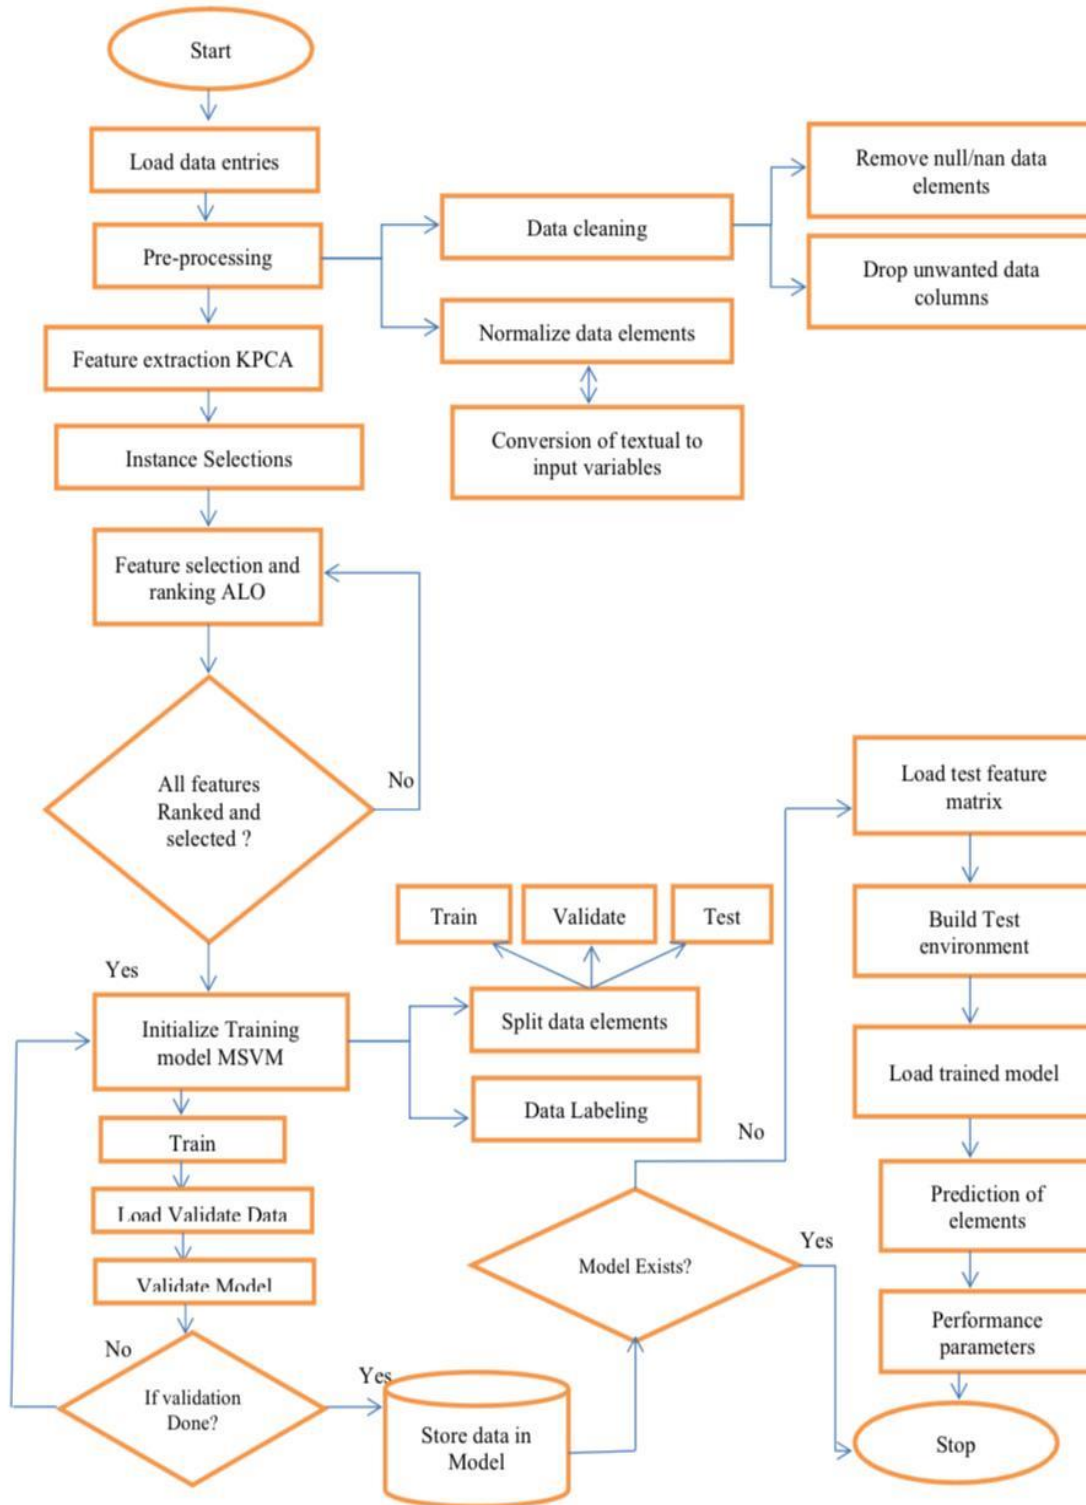

Fig. 1. Flowchart of Proposed Model OKMSVM.

These experiences are labelled data sources and help to create unique patterns for Churn analysis. The modules present in proposed model process the dataset and give the ability to model for further predictions.

The first phase of the proposed model is to pre-process the uploaded dataset. This process helps to clean the input data, remove all unwanted elements, remove or replace the String elements, remove non-processing data entries, etc.

The pre-processed data extracted the features and built unique feature patterns for training categories. The feature patterns combine numbers in the M*N matrix that form a unique combination against a particular case.

The feature extraction process is handled by the KPCA algorithm in the proposed architecture. KPCA algorithm is used to extract the features in a matrix. It reduces the dimensionality of data without much loss of data. It applied to the dataset that is linearly separable as compared to other methods.

KPCA utilizes a KF (kernel function) to project the database into a high dimensional feature space, linearly separable. Extracted features are used to process with the Ant Lion optimizer. ALO is an optimization module of the proposed architecture that helps reduce the feature set's error probability. The more miniature error probability training set provides more accuracy in the trained model. It is an iterative process to find the best cost solutions for input feature patterns.

Once all the cases are processed, the data element is processed with the initialization module of the prediction model. This module processes the optimized data elements and builds various subsets of the actual datasets. These subsets are used to train, validate and test the prediction model.

The training module in this phase is processed with the training subset and labels for those patterns. It introduces the MSVM model and stores it in the secondary storage device to load and perform test phases.

Testing the Churn analysis process predicts the possibilities on the given input dataset. The test set loads the test subset and the training module and then proceeds with the prediction method of MSVM. This method is a promising approach for predicting online datasets because MSVMs use a risk-minimization rule that contains the error.

After the prediction module, various performance parameters are used to calculate the performance of the proposed architecture. The computed performance metrics are used to build the comparison sets and validate the contribution of this enhancement.

V. SIMULATION RESULT ANALYSIS

This section describes the detailed dataset description, simulation tool, and performance metrics such as accuracy rate, AUC, etc.

A. Dataset Description

This proposed work has used "WA_Fn-UseC-Telco-Customer-Churn" dataset [14]. This proposed database defines

the raw information consisting 7043 rows ('users') and 21 columns (properties). Throughout the regression and categorization operations, characteristics 21 are employed as the target position. The churn columns are our target values.

B. Arithmetic Formula's

For the classification job with Optimized kernel MSVM, three parameters are utilized to measure the evaluation of the CCs (Churn Classification). They are AUC, Accuracy Rate (%), and RMSE rate. The area under the curve may be understood as an aggregate amount of classification evaluation to complete all expected categorization techniques. The accuracy rate may be expressed as;

$$Accuracy = 100 * \frac{\text{no.of correctly classified samples}}{\text{no.of all samples in the database}} \quad (1)$$

For the prediction and classification method with optimized kernel MSVM algorithm, RMSE (Root Mean Square Error Rate) is used to measure the calculation of the monthly charge. It may be expressed as;

$$RMSE = \sqrt{\frac{\sum_i^n (y1_i - y'1_i)^2}{n1}} \quad (2)$$

For the classification method with optimized kernel MSVM algorithm, the accuracy rate is the ratio of the correctly labeled churn values to the complete dataset. It may be defined as;

$$accuracy = \frac{tp+tn}{tp+fp+fn+tn} \quad (3)$$

Here, tn = True Negative, fp = False Positive, tp = True Positive, fn = False Negative, and n1 represents the number of all samples in the tele-comm dataset, $y1_i$ and $y'1_i$ are the intended and expected values, respectively. The database is divided into two modules to individually assess the approaches, such as testing and training modules. The training program is employed to the training purpose of the models, while the testing section is used to evaluate the models' efficiency. A 10-fold cross-validation methodology is acceptable including both CC (churn categorization) and forecasting activities to successfully perform the analysis. It indicates that the information is divided into subgroups with an equivalent amount of data in each. The residual set is also used to evaluate the strategy whereas alternative subgroups are used for training. This method is continued till all the subgroups have been analyzed separately and the training phase has been completed.

C. Implementation Results

This section describes the results of the churn analysis, and the research work has designed a script using the PYTHON language. This research work has worked on two different modules as the train and test module. The training module is created using the PYTHON language and is made. It will make the user interface for the man-to-machine interactions that the customer can easily click and see the output. The research will predict the test-set classes using an optimized kernel MSVM trained model and evaluate the accuracy rate, and AUC score shown in Fig. 2.

Fig. 2. AUC Score with the Proposed Model.

Generally, the classification and regression methods will perform better than the existing model. As the model utilized will be able to learn designs from the data, the proposed parameters are defined in Table III and shown in Fig. 2, 3 and 4 respectively. The table defines the performance metrics such as accuracy rate value of 91.05 per cent, rate value of 85.76 per cent, and RMSE Score value of 2.838. This proposed model will improve the performance metrics and reduce the error rates.

Initially, the proposed model will use train samples to construct a telecommunication sector customer churn analysis model with kernel PCA (principal component analysis) feature extraction. Table III defines the proposed parameters of various churn prediction methods. So, the proposed work will evaluate FE (feature extraction) using the KPCA model on all data to fetch the extract the feature values if train samples and test information, and now utilize the train samples which evaluate the optimized the dimensionality feature sets to reconstruct an OKMSVM (optimized kernel MSVM) model.

TABLE III. PROPOSED MODEL PERFORMANCE METRICS

Parameters	Optimized Kernel MSVM Classifier
Accuracy Rate (%)	91.05
AUC (%)	85.76
RSME score	2.838

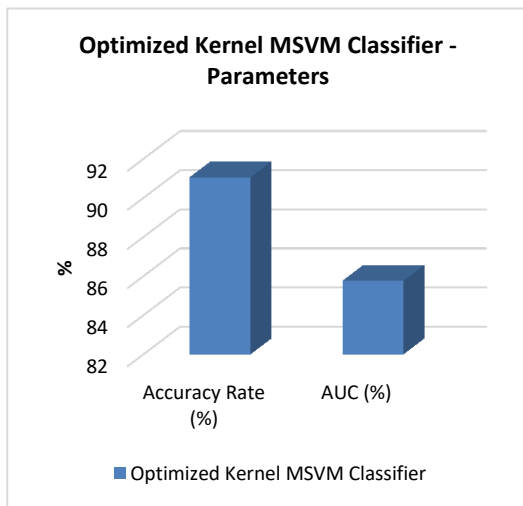

Fig. 3. Performance Metrics (Accuracy and AUC) with Optimized Kernel MSVM Classification Model.

Fig. 4. Performance Metrics (RMSE) with Optimized Kernel MSVM Classification Model.

VI. CONCLUSION AND FUTURE WORK

This paper proposed a hybrid classification model named OKMVM model. The proposed model is based on a system for CCA (customer churn analysis) of the telecommunication sector. To find high-rate mathematical information and implement it, a feature extraction process is handled by the KPCA algorithm in the proposed architecture. Extracted parts are used to process with the Ant Lion optimizer. ALO is an optimization module of the proposed architecture that helps reduce the feature set's error probability. The more miniature error probability training set provides more accuracy in the trained model. It is an iterative process to find the best cost solutions for input feature patterns. Once all the cases are processed, the data element is processed with the initialization module of the prediction model. This module processes the optimized data elements and builds various subsets of the actual datasets. These subsets are used to train, validate and test the prediction model. The training module in this phase is processed with the training subset and labels for those patterns. It introduces the MSVM model and stores it in the secondary storage device to load and perform test phases. The test set loads the test subset and the training module and then proceeds with the prediction method of MSVM. The classification outcomes are maximum accuracy rate, AUC, and optimized root means square rate compared with existing models. In future, the researchers can design novel ML-based and SC (soft computing) techniques that are more reliable for enhancing performance metrics. Furthermore, a forecasting framework will be developed to determine individuals likely to churn. Approaches like regression analysis, decision trees, and neural networks will create multiple algorithms to create forecasting models. Also, generalization ability can be specified using various FS (feature selection) and classification techniques and their uses over other databases.

Abstract—Student academic performance prediction is one of the important works in the teaching management, which can realize accurate management, scientific teaching and personalized learning by mining important features affecting the academic performance and accurately predicting academic. Due to the subjectivity of feature extraction and the randomness of hyperparameters, the accuracy of academic performance prediction needs to be improved. Therefore, in order to improve the accuracy of prediction, an academic prediction method based on Feature Engineering and ensemble learning is proposed, which makes full use of the advantages of random forest in feature extraction and the ability of XGBoost in prediction. Firstly, the feature importance is calculated and ranked by using the random forest method, and the optimal feature subset combined with the forward search strategy. Secondly, the optimal feature subset is input into the XGBoost model for prediction. The sparrow search algorithm is used to optimize the XGBoost hyperparameters to further improve the accuracy of academic prediction. Finally, the performance of the proposed method is verified through the experiments of the public data set. The experimental results show that the academic prediction method designed is better than the single learner prediction method and other integrated learning prediction methods. The accuracy result jumps to 82.4%. It has good prediction performance and can provide support for teachers to teach according to students' aptitude.

Keywords—Academic performance prediction; feature engineering; ensemble learning; random forest; XGBoost

I. INTRODUCTION

With the application and popularization of emerging technologies such as internet of things, big data and artificial intelligence, the intellectualization of education has been developing rapidly, which promoting the reform of education and triggering the change of educational paradigm[1]. At present, many colleges have carried out intelligent campus construction and collected a large number of data generated by educational activities [2]. By machine learning technology, how to mine the mode and value contained in the data has become one of the urgent problems to be solved. Academic performance prediction refers to the use of relevant theories such as pedagogy, computer science and statistics, which analyzing the data generated in the process of students' learning and predicting their future academic performance [3]. Through academic prediction, managers can effectively manage the school, carry out academic early warning for students with academic risk in advance, establish a dynamic early warning

mechanism, and accurately guide students out of difficulties. Teachers can realize scientific teaching; predict students' academic status and teaching effect in advance, so as to purposefully optimize teaching activities, formulating differentiated teaching plans, meeting the needs of students at different levels, and truly teaching students according to their aptitude. Students can realize learning personalization; find out in advance which behaviors are beneficial to learning and which behaviors affect learning effect in advance. In this way, it could consolidate beneficial behaviors and break bad habits. Therefore, whether from the perspective of efficient school management, scientific teaching of teachers or personalized learning of students, to investigate the characteristics of affecting students' performance and create a high-accuracy prediction model has become an important research direction under the background of educational intelligence.

Currently, the research on the prediction of students' academic performance has some problems such as: subjectivity of feature extraction and poor prediction accuracy. This paper proposes an academic prediction model based on feature engineering and ensemble learning. Firstly, the out of bag estimation method of random forest is used to calculate and rank the feature importance, and the forward sequence method is used to search the optimal feature subset, which could deal with the randomness of the selection of random forest feature subset. Then the sparrow search optimization algorithm is used to adjust the hyperparameters of XGBoost to obtain the optimal combination of hyperparameters. Finally, the optimal feature subset is input into the optimized XGBoost model for academic prediction. The two kinds of ensemble learning methods are combined orderly, making full use of the advantages of random forest in feature extraction and the ability of XGBoost in prediction, which could enhance the generalization and effectiveness of academic prediction methods.

II. RELATED WORK

With the extensive use of data acquisition equipment, the collection of student data has expanded from single-mode learning data to multi-mode data, which including learning behavior, life behavior and psychological behavior [4]. The data show exponential development in volume and high dimensionality in characteristics. The essence of prediction is to find the mapping relationship between features and targets. Because the original feature set contains associated features and redundant features, it is often necessary to extract features in order to achieve better prediction effect. Too little feature

extraction will lead to "under fitting", which will affect the prediction accuracy. Too much feature extraction will lead to "over fitting", which will not only increase the calculation difficulty, but also reduce the prediction accuracy. In order to extract the optimal feature subset, some researchers manually select the feature subset through domain knowledge or expert experience. For example, Hu and others divide the features into static features and dynamic features, which takes students' basic information features as static features and students' behavior features (early rising behavior, borrowing behavior, etc.) as dynamic features, and predict learning performance according to the selected features [5]. Fan divides the characteristics into three types: tendency characteristics, human-computer interaction characteristics and interpersonal interaction characteristics. It is pointed out that the prediction ability of propensity characteristics is strong in the early stage of learning. With the progress of learning, the prediction ability of human-computer interaction characteristics and interpersonal interaction characteristics have gradually enhanced [6]. Li constructed a student behavior analysis model including five dimensions: Students' basic information, classroom learning, extracurricular learning, campus life and entertainment [7]. Some researchers use filtering or packaging based feature engineering methods to automatically select feature subsets. For example, based on filtered correlation analysis and information gain method, Chen and others calculate the Pearson correlation coefficient between features and scores, sorting them in descending order according to the results, and select the first 9 features from the 16 features as the main influence features [8]. However, it does not make the optimal selection of features. Through correlation analysis, information gain ratio and chi square analysis, Febro has selected 14 features from 29 original features to form the optimal subset, and verified that the prediction result of the feature subset is better than that of the whole feature [9]. Cao extracted the characteristics of students' regularity and preciseness from the campus life data. It is found that students' regularity is positively correlated with their grades, and preciseness is significantly correlated with their grades [10]. Wen proposed a hybrid feature selection method based on packaging. This method first generates candidate feature sets through scoring and sorting, and then uses heuristic methods to generate the final results [11]. However, the computational complexity of this method is exponential and needs longer running time. The above research screened the features, but did not consider the redundancy between features, and did not check the dimension of the optimal features.

In terms of prediction methods, machine learning methods have gradually replaced probability and statistics methods and gradually become the main research methods, including linear regression, logical regression, decision tree, support vector machine, neural network, integration method and deep learning [12-14]. Wu compared four different performance prediction methods: decision tree, Bayesian network, neural network and support vector machine, and found that the performance prediction model of Bayesian network has high accuracy and recall [15]. Liu used support vector machine to predict students' grades [16]. Wang used correlation analysis and regression analysis to study the predictive effect of big five personality traits and individual intelligence on academic

achievement [17]. Considering the influence of the spatial and temporal characteristics of students' behavior data, Du proposed a serial hybrid deep learning algorithm of CNN and LSTM to predict learners' performance [18]. Cao proposed LSTM depth neural network method to predict learning achievement [19]. Ding uses the methods of random forest, SVM, KNN, decision tree and naive Bayes to predict students' academic performance. The results show that the prediction performance of random forest algorithm is the best [20]. Yao proposed a multi task learning achievement prediction framework based on learning ranking algorithm. [21]. The above studies mostly use the single classifier method for prediction. It is found that the integrated learner has better performance and higher accuracy than the single learner. Ensemble learning methods include two types: boosting and bagging. Boosting methods include AdaBoost, GDBT and XGBoost etc. Some researchers have applied ensemble learning to many fields and achieved good results. Hao used XGBoost model to predict whether learners can complete the course and obtain certificates [22]. Xu used XGBoost model to automatically identify students' classroom behavior [23]. Cao uses XGBoost to predict the online short rent market price. The experimental results show that XGBoost is better than the integrated learning method of LightGBM and AdaBoost [24]. When using ensemble learning methods, the above researchers often use default hyper parameters or set hyper parameters based on experience. Because there are many kinds of hyperparameters, these methods often cannot obtain the optimal hyperparameters combination, which will affect the prediction accuracy.

III. METHODOLOGY

A. The Framework of Academic Prediction

This paper designs the academic prediction framework, as shown in Fig. 1. Academic prediction mainly includes four processes. First, academic data preprocessing. It consists of three parts: clean up, convert and normalize the data. Second, feature extraction. The random forest model is used to rank the importance of data features, and the optimal feature subset is extracted according to the forward search strategy. Third, model training. Train XGBoost model based on sparrow search optimization algorithm. Fourth, performance evaluation. The performance of the model is evaluated according to the evaluation metrics.

B. Feature Engineering

Feature engineering is an important link in the process of machine learning prediction. It can effectively remove the associated features and redundant features, and use the appropriate search strategy to extract the optimal feature combination, which is helpful to reduce the complexity and improve the accuracy of the prediction method. Random forest (RF) is an integrated learning method based on decision tree. Its embedded feature importance evaluation mechanism has the function of analyzing the correlation between features. RF has the advantages of simplicity and good robustness in feature extraction. RF belongs to bagging method. Samples are randomly selected from the original data for basic learner training. The unselected data is called out of bag (OOB), which can be used as a test set. The error predicted according to OOB

is called generalization error. For a feature, the generalization error is calculated after its eigenvalues are randomly disrupted. If the difference between the two generalization errors is small, it means that the feature is not important, otherwise it means that the feature is important. When calculating the feature importance of random forest, the out of bag data is used to calculate the generalization error before and after the disturbance of feature data, and the difference between the two generalization errors is calculated. The calculation steps of RF characteristic importance are as follows:

1) $D = \{(X_1, Y_1), (X_2, Y_2), \dots, (X_n, Y_n)\}$ is the original data set $X_i \in R^T, Y_i \in R$, T represents the number of features and n represents the number of samples. m ($m < n$) samples are randomly selected from D in k times to generate k training sets, k OOB sets and k decision trees.

2) Calculate the generalization error e_t of OOB dataset corresponding to the t-th decision tree.

3) Keep other eigenvalues of OOB unchanged, randomly disrupt the order of eigenvalues of the i-th feature, and recalculate the generalization error e_t^i .

4) Repeat steps 2) - 3) to traverse the whole forest and calculate the importance of the i-th feature. As shown in formula (1):

$$\varepsilon^i = \frac{1}{k} \sum_{t=1}^k e_t - e_t^i \quad (1)$$

Through the above steps, the feature importance is calculated and sorted in descending order according to the importance. In order to extract the optimal feature subset, a forward search strategy is adopted. In the first round, the feature subset containing one feature is selected from the ordered feature set $F = \{f_1, f_2, \dots, f_t\}$. Obviously, the first feature f_1 is the selected feature subset of a single feature. In the i round, the first i features are formed into feature subsets, and their operation effects are compared with those of the first i-1 feature subsets. If the prediction accuracy is not as good as that of the first i-1 feature subset, the operation will be stopped, and the first i-1 feature subset is the best feature subset.

C. XGBoost Algorithm

XGBoost is an improved gradient boosting decision tree algorithm, which takes CART as the base learner and combines many base learners into high-performance integrated learners. For dataset $D = \{(\mathbf{x}_i, y_i)\} (i=1, 2, \dots, n)$, where \mathbf{x}_i represents the eigenvalue vector of sample i and y_i represents the label of sample i. Assuming that the XGBoost model contains T base learners, the predicted value of sample i is:

$$y_i = \sum_{t=1}^T f_t(\mathbf{x}_i), f_t \in F \quad (2)$$

F is all base learner spaces and $f(\mathbf{x})$ is the base learner function.

GBDT approximates the objective function by first-order Taylor expansion, while XGBoost approximates the objective function by second-order Taylor expansion to accelerate the convergence and improve the accuracy of the algorithm. In addition, in order to control the structural complexity of the model, XGBoost adds a regular term to the objective function to prevent the algorithm from over fitting and improve the generalization performance. The XGBoost objective function is:

$$obj(\theta) = \mathcal{L}(\theta) + \Omega(\theta) \quad (3)$$

$\mathcal{L}(\theta) = \sum_{i=1}^n (y_i - y_i)$ is the error function.

$\Omega(\theta) = \sum_{t=1}^T \Omega(f_t)$ is a regular item.

In the process of XGBoost training, the next base learner is trained according to the residuals of the previous trained model to minimize the objective function. After much iteration, an integrated model with high accuracy is generated. The objective function at iteration t is:

$$obj^t = \sum_{i=1}^n ((y_i - y_i^{t-1}) - f_t(\mathbf{x}_i)) + \Omega(f_t) + C \quad (4)$$

Fig. 1. Academic Prediction Framework.

f_t is a new basic learner function. C is constant. Carry out the second-order Taylor expansion of formula (4):

$$obj^t \approx \sum_{i=1}^n [L(y_i - y_i^{t-1}) + g_i f_t(\mathbf{x}_i) + \frac{1}{2} h_i f_t^2(\mathbf{x}_i)] + \Omega(f_t) + C \quad (5)$$

$g_i = \partial_{y_i} L(y_i, y^{t-1})$ is the first derivative.

$h_i = \partial_{y_i}^2 L(y_i, y^{t-1})$ is the second derivative. The complexity of XGBoost consists of the number of leaves and the structure of the tree, so the regularization term can be defined as:

$$\Omega(f_t) = \gamma T + \frac{1}{2} \lambda \sum_{j=1}^T w_{j(x)}^2 \quad (6)$$

γ and λ are constant. T is the number of leaf nodes. $w_{j(x)}$ is the real value of the leaf node to the sample. Therefore, formula (5) can be changed to:

$$obj^t \approx \sum_{i=1}^n [L(y_i - y_i^{t-1}) + g_i f_t(\mathbf{x}_i) + \frac{1}{2} h_i f_t^2(\mathbf{x}_i)] + \gamma T + \frac{1}{2} \lambda \sum_{j=1}^T w_{j(x)}^2 \quad (7)$$

The constant C does not affect the maximization of the objective function, so it can be omitted.

Define the sample set contained in the leaf node j :

$$I_j = \{i \mid \mathcal{Q}(\mathbf{x}_i) = j\} \quad (8)$$

According to formula (8), formula (7) is expressed as:

$$obj^t = \sum_{j=1}^T [(\sum_{i \in I_j} g_i) w_j + \frac{1}{2} (\sum_{i \in I_j} h_i + \lambda) w_j^2] + \gamma T \quad (9)$$

$$G_j = (\sum_{i \in I_j} g_i), H_j = (\sum_{i \in I_j} h_i)$$

$$obj^t = \sum_{j=1}^T [G_j w_j + \frac{1}{2} (H_j + \lambda) w_j^2] + \gamma T \quad (10)$$

The minimization of the objective function is transformed into the minimization of the quadratic function of w_j , and the optimal w_j^* is solved:

$$w_j^* = -\frac{G_j}{H_j + \lambda} \quad (11)$$

$$obj^t = \frac{1}{2} \sum_{j=1}^T \frac{G_j^2}{H_j + \lambda} + \gamma T \quad (12)$$

D. Sparrow Search Algorithm for Optimizing Hyperparameters

Although XGBoost improves GBDT, optimizes the convergence speed and improves the accuracy, the determination of XGBoost hyperparameters is still the key problem to improve its performance. The prediction effect is often not high when the hyperparameters are set according to experience. Therefore, it is necessary to set the hyperparameters through the optimization algorithm. Sparrow search algorithm (SSA) is a bionic intelligent optimization algorithm that simulates the foraging behavior and anti-predation behavior of sparrows [25]. Compared with other intelligent optimization algorithms, it has better global search ability, less iterations and high prediction accuracy. In the process of sparrow foraging, it is divided into discoverer, follower and police soldier. The discoverer updates his position according to the foraging rules and guides the population to forage. The follower obtains the food around the discoverer or competes for the food of other individuals and updates the position. When the sparrow group realizes the danger, it will carry out anti predation behavior and update the corresponding position. The discoverer update location rule is:

$$X_{i,j}^{t+1} = \begin{cases} X_{i,j}^t \exp(-\frac{i}{\alpha iter_{max}}), & R_2 < ST \\ X_{i,j}^t + Q, & R_2 \geq ST \end{cases} \quad (13)$$

$X_{i,j}^t$ represents the position of the i -th sparrow in the j -th dimension at the t -th iteration. $\alpha \in (0, 1]$ is a random number. $iter_{max}$ is the total number of iterations.

$R_2 \in [0, 1]$ is the warning value. $ST \in [0.5, 1]$ is the safety value. Q is a random number with normal distribution.

L is the matrix of $1 \times d$, whose values are all 1. $R_2 < ST$ indicates that the sparrow is in a safe state and can expand the foraging range. $R_2 \geq ST$ indicates that when a predator is found, all sparrows should fly away quickly.

The rule for followers to update the location is:

$$X_{i,j}^{t+1} = \begin{cases} Q \exp(-\frac{X_{worst}^t - X_{i,j}^t}{i^2}), & i > n/2 \\ X_p^{t+1} + |X_{i,j}^t - X_p^{t+1}| A^+ \cdot L, & i \leq n/2 \end{cases} \quad (14)$$

n represents the number of all sparrows. X_p and X_{worst} represent the position of the current discoverer and the worst position of all sparrows, respectively, L is the matrix of $1 \times d$, whose values are all 1. A^+ represents the pseudo inverse matrix. When $i > \frac{n}{2}$, it means that followers with low fitness value are difficult to capture food and need to fly to other places for feeding.

When aware of the danger, the sparrow updates the location rule as follows:

$$X_{i,j}^{t+1} = \begin{cases} X_{best}^t + \beta |X_{i,j}^t - X_{best}^t|, & f_i > f_g \\ X_{i,j}^t + k \left[\frac{X_{i,j}^t - X_{worst}^t}{(f_i - f_w) + \varepsilon} \right], & f_i = f_g \end{cases} \quad (15)$$

X_{best}^t is the best position among all sparrows at present. f_i , f_g and f_w represent the current sparrow fitness value, the worst fitness value among all sparrows and the best fitness value among all sparrows. β is the random value obeying (0,1) normal distribution. $k \in [-1, 1]$ is a random number. When $f_i = f_g$, it indicates that the sparrow is on the edge of danger and needs to be close to other sparrows.

IV. EXPERIMENTAL OF PREDICTION MODELS

The experimental environment of this paper is 64 bit Windows 7 operating system, the CPU is i5-3317u, the RAM is 4GB, the programming language is python, and the compilation environment is PyCharm.

A. Dominant Set and Data Preprocessing

This paper uses the score data set collected by the learning management system (LMS) of the University of Jordan. The data set contains 480 student records of 12 courses in 2 semesters, and each record includes a total of 16 features. These 16 characteristics are divided into four categories: demographic characteristics, knowledge background characteristics, parental behavior characteristics and learning behavior characteristics, as shown in Table I. It is divided according to 16 eigenvalue categories, including 5 binary features, 7 nominal features and 4 numerical features. The grades of each student's course are divided into three grades: L (0 to 69), M (70 to 89) and H (90 to 100). There are 127 students with L, 211 students with M and 142 students with H.

Data preprocessing is a very important step in machine learning. Standardized data processing can eliminate the impact of different data dimensions on prediction accuracy, and help to improve prediction performance while maintaining data distribution. It usually includes data cleaning (missing value processing), data conversion and data normalization. There is no missing value in the data set. Five binary feature data are transformed into {0,1}, and seven nominal features are mapped into quantitative feature values. Finally, all data are normalized by min-max method.

TABLE I. CLASSIFICATION OF DATA CHARACTERISTICS

Attribute type	Feature
Demographic Characteristics	Gender,Nationality, Place of birth,Parent responsible for student
Knowledge Background Characteristics	Educational Stages, Grade Levels, Section ID,Topic,Semester
Parental Behavior Characteristics	Parent Answering Survey,Parent School Satisfaction
Learning Behavior Characteristics	Raised hand, Visited resources, Viewing announcements,Discussion groups,Student Absence Days

B. Model Evaluation Metrics

The prediction results of this experiment are divided into three levels, which belong to multi classification problem. Accuracy and kappa coefficient are used as evaluation metrics. The value range of the two metrics is [0,1]. The larger the metric value, the better the prediction performance. The calculation formulas are:

$$Accuracy = \frac{d'}{Z} \quad (16)$$

$$Kappa = \frac{Accuracy - P_e}{1 - P_e} \quad (17)$$

$$P_e = \frac{d_1 \times d_1' + d_2 \times d_2' + d_3 \times d_3'}{Z \times Z} \quad (18)$$

Z is the total number of samples. d' is the number of samples with correct predictions. d_i' is the number of samples with correct prediction of type i . d_i is the total number of class i samples.

C. Feature Extraction

Based on the preprocessed data, the relative importance of features is calculated from equation (1) by using the random forest method. The results are shown in Fig. 2. Among the 16 features, the importance gap of each feature is obvious, and the five most important features belong to learning behavior features. It shows that students' learning behavior in class has a great impact on course performance. Too many or too few features will affect the prediction accuracy. In order to obtain the optimal feature subset, remove the unimportant features in turn according to the feature importance in Fig. 2, and calculate the Kappa index values of different feature subsets, as shown in Fig. 3. When the number of feature sets increases from 1 to 12, the Kappa index shows an increasing trend as a whole, reaches the maximum when the number of feature sets is 12, and shows a downward trend when the number of feature sets increases from 12 to 16. The main reason is that when the number of features is relatively small, the model training is insufficient, which affects the prediction accuracy. When the number of features is too large, the complexity of the model increases, resulting in over fitting training, which will also

reduce the prediction accuracy. Therefore, this paper selects the top 12 features of feature importance ranking for subsequent model prediction.

D. Comparison of Hyperparameters Optimization Methods

XGBoost parameters are divided into general parameters, lifter parameters and task parameters. General parameter setting is the overall function of the model, lifter parameter setting is the basic learner function, and task parameter setting is the optimization step. The parameters to be adjusted in this experiment and their adjustment range are shown in Table II.

In order to verify the efficiency of sparrow search algorithm in XGBoost hyperparametric optimization, comparative experiments are carried out by using manual experience method, grid search algorithm, random search algorithm and hyperparametric optimization method based on sparrow search algorithm. The experimental results are shown in Table III.

Fig. 2. Feature Importance.

Fig. 3. Kappa Value.

TABLE II. HYPERPARAMETERS AND RANGES

hyperparameters	ranges	content
n_estimator	(100,1500)	Number of decision trees
learning_rate	(0.01,0.15)	Learning rate
max_depth	(1,10)	Maximum depth of decision tree
min_child_weight	(1,10)	Minimum weight of leaf node

TABLE III. KAPPA VALUES OF DIFFERENT METHODS

	manual experience method	grid search algorithm	random search algorithm	sparrow search algorithm
Kappa values	0.7755	0.8083	0.7924	0.8242

It can be found from Table III that the Kappa index value of the hyperparametric optimization method based on sparrow search algorithm is the highest, followed by the grid search algorithm, and the worst is the manual experience method. The results of sparrow search algorithm are 4.87%, 1.59% and 3.18% higher than manual empirical method, grid search algorithm and random search algorithm respectively in Kappa index. It is verified that different combinations of super parameters have a great impact on prediction performance. Theoretically, when the number and value range of super parameters to be optimized are large, there will be many combinations of super parameters. The grid search algorithm needs to exhaust the whole parameter combination space, and the time complexity is very high; Random search algorithm makes random sampling in a given space, which has fast search speed, but it is easy to miss some better parameter combinations; The sparrow search algorithm gradually obtains the optimal solution after iteration and updating the position, which has the characteristics of fast convergence and high accuracy.

E. Comparison of Different Machine Learning Methods

In order to verify the prediction performance of the method designed in this paper, it is compared with the mainstream single machine learning method and integrated learning method. Single machine learning methods include support vector machine (SVM), decision tree (DT) and logistic regression (LR). Integrated learning methods include gradient boosting decision tree (GBDT), XGBoost (XGB) with default value and the algorithm in this paper (SSA - XGB).

In order to avoid the contingency caused by random data division, five experiments are used to calculate the accuracy respectively, and the data set is divided into training set and test set according to 8:2. The experimental results are shown in Fig. 4, and the average accuracy is shown in Table IV.

TABLE IV. AVERAGE ACCURACY OF DIFFERENT ALGORITHMS

	SVM	DT	LR	GBDT	XGB	SSA- XGB
Accuracy	0.776	0.694	0.775	0.793	0.795	0.824

The experimental results show that the SSA- XGB achieves the best effect in performance prediction, followed by XGBoost with default value, and the worst is decision tree method.

Compared with XGB and GDBT, the SSA- XGB is 2.9% and 3.1% higher. The three integrated learning methods are better than the three single learner methods. Theoretically, the ensemble classifier is composed of multiple base learners. The prediction error of one base learner can be corrected by other base learners. The prediction error of a single classifier cannot be corrected. XGBoost algorithm improves the shortcomings of GDBT, such as the second-order Taylor expansion of the

objective function and the addition of regularization term. Compared with the default XGBoost algorithm, SSA-XGB shows that the optimization of hyperparameters is helpful to improve the prediction performance.

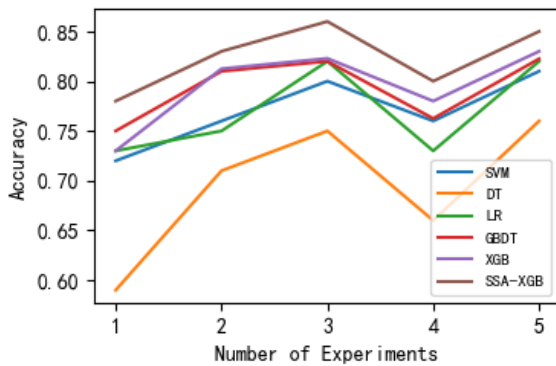

Fig. 4. Comparison of Accuracy of Different Algorithms.

V. CONCLUSION AND FUTURE WORK

The high dimension of academic data and the complex optimization of XGBoost hyperparameters are devoted to the paper research respectively. The important characteristics of academic data are extracted by random forest. The random forest algorithm using forward search strategy can effectively extract the feature subset and help to improve the prediction accuracy. The features which have a great impact on students' performance are mainly students' learning behavior characteristics, whose significance to 67 percent of all characteristics. Therefore, teachers should pay more attention to students' learning behavior status and help to improve students' academic performance. The adjustment of hyperparameters can improve the prediction performance of ensemble learning. Sparrow search optimization algorithm is more efficient than other methods of adjusting hyperparameters. Compared with other prediction methods, XGBoost prediction method has the perfect performance. The method designed in this paper enriches the methods of academic prediction in the field of educational data mining, and has a certain reference value for teachers to teach students according to their aptitude and students' personalized learning.

In future, the effects of different categories of guidance on students' academic performance can be studied respectively according to the characteristics of different categories. In addition, whether the combination of different features or the extraction of higher-order features is more conducive to academic prediction is also worth investing.

Muhammad Aliyu Suleiman³
Software Engineering, Nile University of Nigeria
Abuja, Nigeria

Abstract—Acoustic modeling is essential for enhancing the accuracy of voice recognition software. To build an automatic speech system and application for any language, building an acoustic model is essential. In this regard, this research is concerned with the development of the Hausa acoustic model for automatic speech recognition. The goal of this work is to design and develop an acoustic model for the Hausa language. This is done by creating a word-level phonemes dataset from the Hausa speech corpus database. Then implement a deep learning algorithm for acoustic modeling. The model was built using Convolutional Neural Network that achieved 83% accuracy. The developed model can be used as a foundation for the development and testing of the Hausa speech recognition system.

Keywords—Acoustic model; Hausa Phonemes; word level; CNN

I. INTRODUCTION

After several years of development and research, the accuracy of automatic speech recognition remains an important research issue. Many things influence the accuracy of a voice recognition application. Speaker and context variations are the most well-known. The use of acoustic modeling helps to improve accuracy. Any speech recognition system relies heavily on acoustic modeling.

The method of building statistic from voice waveform vectors is referred to as acoustic modeling for speech recognition. One of the most prevalent forms of acoustic model is the Hidden Markov Model [1, 2, 3]. Segmental models [4, 5, 6, 7, 8], super-segmental models such as hidden dynamic models [9], neural networks [10, 11], maximum entropy models [12], and hidden conditional random fields [13] are among the other auditory models.

Pronunciation modeling discusses fundamental units of speech sequences. These units include phonetics features. These phonetics features are utilized to present bigger speech units like phrases or words. To achieve noise robustness in speech recognition, acoustic modeling may also include the use of feedback [13].

The acoustic model describes the statistical features of sound occurrences in speech recognition. According to the acoustic model, the likelihood score $p(X|W)$ is calculated. Let's assume the acoustic model component representing an i th word W_i is Y_i , the $p(X|W) = p(X|Y_i)$ in an isolated-word speech recognition program with N -word vocabulary.

Hidden Markov Model (HMM), Support Vector Machine (SVM), Deep Neural Network (DNN), Artificial Neural Network (ANN), and Convolutional Neural Networks (CNNs) are some of the modeling techniques used [14].

The current work on acoustic model focused on international languages such English, French, Germany etc. Thus acoustic model developed for under-resource language are for Punjabi an India language, Amharic Ethiopian language and others [14].

The researcher implements a supervised Convolutional Neural Network. The Hausa acoustic model dataset was extracted from the Hausa Speech Corpus Database [15]. The researcher outlined the Hausa language alphabet and phonologies with examples.

The rest of the paper is organized as follows: Section II talked about Hausa phonology. Section III provides a review of acoustic modeling. Section IV presented the research methodology. Section VI described the implementation process. In Section V the result obtained was discussed and presented. Lastly, Section VII concludes this paper and mentions potential future work.

The major contribution of this paper is creating word-level phonemes, generating labels for the created phonemes, developing a Hausa acoustic model, testing and validating the developed model.

II. LITERATURE REVIEW

The Hausa language is a Chadic language spoken in West Africa. Hausa has two writing scripts. First, the Ajami writing script is written with the Arabic alphabet, and the Boko scriptwriting is written with the Latin alphabets.

This research is concerned with the Hausa Latin writing script. The Boko script has 36 Latin alphabet, which contain 31 consonants and 5 vowels. The language also has 23 phonetic sounds [16] as shown in Table I.

According to [17] Wurin/Gurbin furunci means a place of articulation. The consonant location in the vocal tract when a blockage occurs between active and passive articulators is known as the place of articulation. There are seven points of articulation for Hausa consonants which are:

Balebe meaning Bilabial: this is when the lower lip brushes up against or touches the upper lip.

Bahanke meaning Alveolar: when the tip of the tongue meets or touches the alveolar ridge.

Nade-harshe means Retroflex: when the tip of the tongue makes contact with the back of the alveolar ridge.

Dan Bayan Hanka meaning Post-alveolar: when the blade of the tongue comes close to or contacts the back of the alveolar ridge.

Bagande meaning Palatal

Bahande meaning Velar: is when the back of the tongue rubs on the velum or soft palate.

TABLE I. HAUSA ALPHABETS

A	B	B	C	D	D
E	F	Fy	G	Gw	Gy
H	I	J	K	K	Kw
Ky	Kw	Ky	L	M	N
O	R	S	Sh	T	Ts
U	W	Y	Y	Z	'
Consonants					
B	B	C	D	D	F
Fy	G	Gw	Gy	H	J
K	K	Kw	Ky	Kw	Ky
L	M	N	R	S	Sh
T	Ts				
Vowels					
A	E	I	O	U	

TABLE II. HAUSA PHONOLOGY

s/n	Phonology	Phonetic	Sample Word
1	Balebe=> Bilabial	/b/	“baka”
		/β/	“barawo”
		/m/	“malam”
		/φ/	“fata”
2	Bahanke => Alveolar	/d/	“dankali”
		/n/	“talata”
		/r/	“nama”
		/z/	“bara”
		/s/	“zakka”
		/l/	“lada”
		/ts/	“tsawa”
3	Nade-harshe => Retroflex	/ɽ/	“ruwa”
		/dʒ/	“ɗaki”
4	Dan Bayan Hanka =>Post-Alveolar	/ʃ/	“shara”
		/dʒ/	“jarida”
		/ʃ/	“canji”
5	Bagande =>Palatal	/j/	“yara”
6	Bahande =>Velar	/g/	“gado”
		/k/	“kaza”
		/k/	“kasa”
		/w/	“wasa”
7	Hamza => Glottal	/h/	“hannu”
		/ʔ/	“sa’a”

Hamza means Glottal: this refers to the closure or constriction of the glottis. Table II shows Hausa phonology, phonetic and sample word according to [17].

Acoustic Modeling (AM) is the first and crucial step in developing a speech recognition platform. The acoustic model generates a link between linguistic and acoustic units. Most of the computations performed in acoustic modeling are because statistical representation and feature extraction affect speech recognition development.

The extracted features are distributed based on a particular sound. This acoustic modeling is done to build a link between the structure of the linguistic model unit and the extracted features.

Different feature extraction methods, like voice production mechanism, and human perception were reported in [18, 19].

The selection of classification algorithms is also a crucial phase in the development of an acoustic model. Many studies on acoustic modeling using various classification algorithms have been published [20]. HMM, ANNs, DNNs, and Sequence to sequence acoustic modeling are some of the classification approaches used by researchers.

AM is associated with a variety of concepts. It necessitates knowledge of acoustic phonetics, microphone, and environment variability issues, gender variations, and dialectal variances. Furthermore, thorough training is required to determine the link between language units and auditory observation [21]. AM is also linked to pronunciation modeling, as well as speaker, environment, and context variability and modeling [22].

III. METHODOLOGY

A generalized acoustic modeling system includes raw data collection, preprocessing, feature extraction, and acoustic modeling. Fig. 1 illustrated the researchers’ acoustic modeling. The pipeline is divided into two components word-level phonology segmentation and word-level phonology labeling. The preprocessing block consists of word-level segmentation and word-level phonology labeling. Furthermore, feature extraction was implemented as the second block in the pipeline. The second block comprises phonemes and labels matched together for modeling purpose. The output of the feature extraction block was fed into the training block for acoustic modeling of the phonology utterances. Finally, a word-level Phonemes based acoustic model was implemented for this research. The word-level acoustic dataset was extracted from the Hausa Speech Corpus database [15].

Fig. 1. Hausa Acoustic Model Pipeline.

A. Data Distribution

Five thousand word-level phonemes were extracted from the Hausa Speech Corpus database [15]. Male and female speakers read these words. Table III shows the number of words per literature and the gender of the reader.

TABLE III. DISTRIBUTION OF WORD-LEVEL PHONE AND READER GENDER

S/N	Literature	Words	Gender
1	Gani Gareka	500	Female
2	Iliya dan Maikarfi	700	Female
3	Iki Magayi	700	Male
4	Wani Gari	500	Male
5	Komai Nisa Dare	500	Male
6	Koya Da kanka	700	Female
7	Magana Jarice	700	Male
8	Shehu Umar	700	Male
Total		5000	

The final audio dataset consists of Five thousand phonetically compact word-level phonemes. The phonetically compact words were divided into training, testing, and validation set. The dataset distribution is shown in Table IV.

TABLE IV. SPEECH DATASET

S/N	Division	Percentage	words
1	Training	70%	3500
2	Testing	20%	1000
3	Validation	10%	500

B. Model

Various categorization techniques have been created for audio modeling. HMM, and ANNs are, however, the most extensively utilized algorithms [16]. This work was implemented using deep learning acoustic modeling algorithm. The researchers developed the Hausa acoustic word-level models by implementing a Convolutional neural network (CNN).

IV. IMPLEMENTATION

A. Hardware and Software

The system was built on top of Google Collaborator (Colab) with the following hardware spec:

- CPU: Intel(R) Xeon(R) @ 2.30GHz.
- Disk: Size 79GB, Used-40GB, Available-39GB.
- Memory: Total:~13GB, Free:~10GB, Available:~12GB.

For the software requirement, all necessary modules and dependencies were installed and imported into Colab. Such as OS, Pathlib, MAplotlib, Numpy, Seaborn, Tensorflow, Keras, and Ipython display. The audio dataset is stored in eight different folders corresponding to each literature named: gani, iliya, jiki, wani, koya, and shehu. The audio clips were extracted and shuffle into a list. The dataset were divided into training, test, and validation set as 70:20:10 ratios, respectively.

B. Preprocessing

The dataset was processed at this phase by creating decoded tensors for the waveforms and labels. Each wav file contains time-series data that is sampled at a specific rate. The amplitude of the audio signal at any given time is represented by each sample. The researchers' WAV acoustic dataset files had amplitude values ranging from -32,768 to 32,767. A 16-bit system was employed. This dataset has a sample rate of 16 kHz.

The shape of the tensor returned by "ft.audio.decode_wav" is the [sample, channels]. The Hausa acoustic dataset contains mono recordings.

Three functions are defined: the first transform the dataset's WAV audio files into tensors. The second is the method that generates labels for each file based on its parent directories. Finally, there is the "get waveform and label" auxiliary function, which ties everything together.

The audio filename is the input and the output is a tuple with audio and label tensors, ready for supervised learning. The audio waveforms were plotted as shown in Fig. 2.

C. Waveforms to Spectrogram

The time domain is used to depict the waveforms in the collection. The waveforms are then converted to spectrograms. The converted spectrogram reveals the frequency variations over time which can be depicted as 2D images. Further, the Short-Time Fourier Transform (STFT) is used to convert from time-domain signals to time-frequency-domain signals. The spectrogram images are then fed into the neural network, which is used to train the model.

Fig. 2. Audio Waveforms.

Furthermore, a function for converting waveforms to spectrograms was created. The waveforms must be the same length for the spectrograms to have equal dimensions when converted. This can be accomplished by simple zero-padding audio snippets that are less than one second in length using (ft.zeros). In addition, a frame length and frame step options for tf.signal.stft are selected so that the resulting spectrogram "image" is almost square. The STFT generates a complex number of the array that represents magnitude and phase. In this situation, the researcher utilized the magnitude, which can be achieved by running ft.abs on the tf.signal.stft result.

Next, the data was explored by printing the shape of one sample tensorized waveform and the corresponding spectrogram. A function was defined to display a spectrogram. Lastly, sample audio was plotted displaying waveform over time and the corresponding spectrogram (frequencies over time) as shown in Fig. 3.

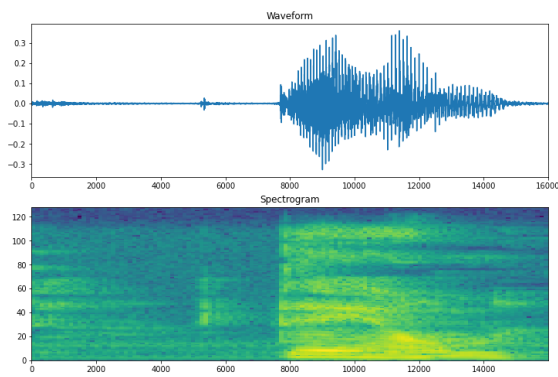

Fig. 3. Waveform and Spectrogram.

A function was then defined to transform the waveform dataset into spectrograms and their corresponding labels as integers. Map function was implemented across the dataset elements. Finally, the spectrograms for different samples of the dataset were examined as shown in Fig. 4.

Fig. 4. Samples of Spectrogram.

D. Training the Model

Preprocessing was done on the dataset. Batch training and validation sets were implemented for the model training. Dataset.cache and Dataset.prefetch operations were performed to reduce read latency while training the model.

Since the audio files have transformed into spectrogram images. For modeling a simple Convolution Neural Network was implemented. Keras preprocessing layers were also implemented such as resizing layers to down sample the input to enable the model to train faster. A normalization layer was implemented to normalize each pixel in the image based on its means and standard deviation. The Keras model was configured with Adam optimizer and the cross-entropy loss. The model was trained on 10 epochs for demonstration purposes. The model summary is shown in Fig. 5.

```

Input shape: (124, 129, 1)
Model: "sequential"

```

Layer (type)	Output Shape	Param #
resizing (Resizing)	(None, 32, 32, 1)	0
normalization (Normalization)	(None, 32, 32, 1)	3
conv2d (Conv2D)	(None, 30, 30, 32)	320
conv2d_1 (Conv2D)	(None, 28, 28, 64)	18496
max_pooling2d (MaxPooling2D)	(None, 14, 14, 64)	0
dropout (Dropout)	(None, 14, 14, 64)	0
flatten (Flatten)	(None, 12544)	0
dense (Dense)	(None, 128)	1605760
dropout_1 (Dropout)	(None, 128)	0
dense_1 (Dense)	(None, 8)	1032

```

Total params: 1,625,611
Trainable params: 1,625,608
Non-trainable params: 3

```

Fig. 5. Model Summary.

For better analysis, the data was run on several epochs. However, 50 epochs gave better accuracy. The output of the model is shown in Fig. 7.

```

Epoch 1/50
55/55 [=====] - 11s 195ms/step - loss: 0.2411 - accuracy: 0.8200 - val_loss: 0.5089 - val_accuracy: 0.8200
Epoch 2/50
55/55 [=====] - 11s 194ms/step - loss: 0.2169 - accuracy: 0.8231 - val_loss: 0.5097 - val_accuracy: 0.8200
Epoch 3/50
55/55 [=====] - 11s 195ms/step - loss: 0.2206 - accuracy: 0.8100 - val_loss: 0.5663 - val_accuracy: 0.8220
Epoch 4/50
55/55 [=====] - 11s 195ms/step - loss: 0.1959 - accuracy: 0.8337 - val_loss: 0.6023 - val_accuracy: 0.8300
Epoch 5/50
55/55 [=====] - 11s 190ms/step - loss: 0.1933 - accuracy: 0.8331 - val_loss: 0.6209 - val_accuracy: 0.8200
Epoch 5: early stopping

```

Fig. 6. Model Output.

V. RESULT

After running the model with 50 epochs, the summary and output of the model as shown in Fig. 5 and 6. Finally, the training and validation loss curves were plotted to see how the model progressed over time as shown in Fig. 7.

Fig. 7. Train-validation Loss Curves.

To evaluate the model’s performance, the model was run on the test set. The accuracy of the test was 83%.

To see how successfully the model classified each auditory word in the test set, a confusion matrix was plotted as displayed in Fig. 8.

Fig. 8. Confusion Matrix.

VI. CONCLUSION

This article started with an introduction to the acoustic model. Stated the previous and current techniques used for the development of an acoustic model for speech recognition and then introduces Hausa phonology, its examples, and alphabets. The researchers created word-level phonemes from the Hausa Speech Corpus database.

With the rise of deep learning algorithms for acoustic model development, the researchers implemented CNN base acoustic model development for the Hausa language. Hausa is a low-resourced and under-resource language. The goal is to create an acoustic model for the Hausa language.

The created model can be used for the development of Hausa speech recognition system. The outputs suggest that the

model recognizes Hausa phonetic with 83% accuracy. The researchers’ future work is to develop a language model for the Hausa language. The acoustic model and language model would be linked to developing an automatic speech recognition system for the Hausa language.

New Method for 4D Reconstruction of Medical Images

Lamyae MIARA, Said BENOMAR ELMDEGHRI, Mohammed Ouçamah CHERKAOUI MALKI

Department of Computer Science, University Sidi Mohammed Ben Abdellah
Faculty of Sciences Dhar El Mahraz, Fez, Morocco

Abstract—This paper proposes a new optimized method that is fast in rendering for 4D reconstruction from 2D medical images of human anatomy permitting their real-time refined visualization. This method uses the 3D reconstruction algorithm based on contour matching of medical image sequences and on the tessellation of recent GPU. In our framework, the construction of the low-resolution mesh that is based on contour extraction allows to create a 3D mesh without any ambiguity and exactly matches the real shape of the human anatomy. Such preliminary result is of great interest, since it permits to lead to other valuable realizations such as reducing the computation burden of basic meshes and displacement vectors. Moreover, one can achieve a very low storage memory, as well as one can ease the fast real-time 4D visualization with a high desired resolution. Hence, it is then straight forward that this study can contribute to easing the diagnosis and detection in real-time of human organs in motion damage and deterioration. Especially, 4D visualization technology that is still under development is highly important and needed for assessing some dangerously evaluative diseases, as in the case of lung diseases.

Keywords—2D medical image; 4D reconstruction; contour matching; recent GPU; 3D mesh

I. INTRODUCTION

From health and care perspectives, 4D visualization is the most effective method for assessing and preventing deadly diseases of human organs in motion. For instance, 4D visualization technology of lungs damaged can shed new light on the real possible dangers and eventual damage and complications on the patient health. As a real practical consequence, the use of computational methods in lung analysis may allow us to better understand and visualize what we cannot obtain from static 2D images, such as the respiratory behavior of muscles. To achieve this, the 4D reconstruction is an important and critical requirement.

More importantly, not to say that 4D reconstruction of the human organs in motion would be useful for visualization the correspondent mechanism, especially before surgery. For example, in patients suspected of having pulmonary diseases, the ability to visualize in 4D and observe the oxygen uptake capacity of the lungs would be useful for clinical diagnosis. So, a complete 4D reconstruction of the lungs may allow physicians to better understand the respiratory process (inspiration and expiration). Other disease states in which 4D modeling can potentially be useful for clinical decision making include pulmonary nodules, pneumothorax, and chronic diseases [1] characterized by irreversible decrease in bronchial caliber.

Unfortunately, the 4D reconstruction is a computationally intensive job, and therefore doctors use specific workstations [2].

In this paper, we propose a powerful and optimized algorithm to reconstruct a 4D image from segmented contours of 2D MRI images, to be able to do the 4D reconstruction in home computers.

Our proposed framework has the following advantages:

- Topological changes in 2D contours are automatically processed in both spatial and temporal dimensions.
- The result is a distortion-free mesh that corresponds to a good approximation that matches exactly the real human organs anatomy.
- The use of the tessellation of recent graphics cards makes the real-time display very fast.
- Memory usage is highly optimized by considering the large number of details in the 2D images.

The remainder of this paper is organized as follows. In section 2, an overview on the state of the art is presented and the limitations of some reported works are discussed. In section 3, our methodology is clearly exposed regarding to the previously reported studies. Section 4 presents some technical explanations and discussions on the proposed method and its obtained results. Finally, some necessary concluding remarks are provided in section 5.

II. RELATED WORK

Research studies on 4D reconstruction algorithms often focuses on both, improving the quality of 4D visualization from standard acquisition data and its fast execution. Among these algorithms is the Feldkamp-Davis-Kress (FDK) algorithm [3], which is a filtered back-projection algorithm widely used for 3D and 4D image reconstructions from cone-beam projections measured with a circular orbit of the x-ray source. There is also the Mc Kinnon-Bates (MKB) algorithm [4] in which a time-averaged 3D prior image is first reconstructed. It is then projected at the same angles as the original projection data, creating time-averaged re-projection that are next subtracted from the original (non-blurred) projections to create the well-known motion-coded differential projections. Such differential projections are reconstructed into PC differential images that are added to the well-sampled 3D image before creating a much higher quality 4D image.

Other distinguished algorithm is the ROOSTER algorithm [5] that iteratively computes volumes that minimize the sum of the least squares difference between simulated volume projections, real measured projections, and a spatiotemporal "total variation" term that favors distinct homogeneous regions with sharp edges. In addition, we also mention the Motion Compensated [6] FDK (MCFDK) algorithm [7] in which motion was estimated from 4DCT planning volumes by Deformable Image Registration (DIR) [8] between respiratory phase volumes using a B-spline method from the Elastix toolkit [9]. In addition, the 4DCT DIR produces Deformation Vector Fields (DVF) that are used as inputs to the MCFDK reconstruction. Note that the MCFDK algorithm can be interpreted as a variant of the FDK method where back-projection is performed along curved trajectories to account for motion. And lastly the Motion Compensated (MCMKB) algorithm which is an extension of [10], where 4DFDK reconstructions are used for DVF estimation. This study considers a much more under sampled acquisition than [10], which may explain why we were not able to produce convergent DVF estimates from the 4DFDK reconstructions.

Note that for the algorithms that use surface rendering, there is the classical method that uses interpolation between 3D images of to give a 4D result. These algorithms are effective alternatives for 4D reconstruction of medical images without the need for powerful machines, but they produce ghost artifacts that do not represent the exact anatomy of human organs and not achieve the determination of accurate motion trajectories. Another negative fact of using mentioned algorithms, is that it cannot lead to an instantaneous precise information on a particular organ and even to precise measurements on the organ to be reconstructed. In contrast, our proposed approach is based on the 4D surface rendering that allows a good visualization of the geometry and a precise topological shape associated to the three-dimensional structures of human organs and their spatial-temporal relationships. Moreover, such adapted procedure makes it possible for comparing the reconstructed data with the original data. For these reasons, it is stressed out that the surface rendering method eases the achievement of a fast real-time 4D visualization, thanks to the use of certain units of the graphic card originally conceived for 3D video games.

To recap, the main goal of this paper is mainly to propose a new algorithmic solution that is faster to compute based on accelerating rendering method and other efficient computational techniques. Moreover, the proposed methodology can achieve a high visual resolution by avoiding heavy drawbacks on memory storage and acquisition. Indeed, such improvement handles efficiently the limitations of the previously discussed algorithms that have been reported and recognized in the literature.

III. METHODOLOGY

This section describes the new method developed in this paper for an optimized and fast 4D visualization from standard 2D medical images. This method consists first of the 3D

reconstruction of a basic mesh from the 2D images of the C_m slices at time T_0 and the extraction of the lost data, in the form of displacement vectors, which will be stored in a displacement map. Thus, we perform the extraction of the displacement vectors of the 2D slices of each sequence from time T_1 to time T_{N-1} based on the mesh at time T_0 , i.e., without constructing the base mesh of times T_1 to T_{N-1} . In special cases, it is found that the number of contours at time T_i changes in time T_{i+1} , which makes it necessary to add additional parts in the base mesh. As a result, a high-resolution visualization can be achieved at the GPU map level by combining the different parts of the base mesh and the set of displacement maps.

The reminder of our contribution is as follows. In the first part given by section 3.1, we determine the input of our algorithm and explain the basic idea behind its conception. Next, the second and third and fourth parts considered in section 3.2 and 3.3 and 3.4 describe in more details the first steps of the proposed algorithm consisting of contours extraction and displacement maps. Some technical details are provided in section 3.5 to show how one can map the computed mesh at time T_i to the other at time T_{i+1} . Finally, it is shown how a high resolution 4D visualization can be handled in the last Section 3.6.

A. Overview

Our algorithm is based on a sequence of 2D medical images identified at successive time periods from time T_0 to time T_{N-1} . These images are subjected to a segmentation process to extract the target organ to be reconstructed and visualized in real-time. For this purpose, we apply the contour extraction algorithm on each slice C_k of each sequence S at each time T_i . In this way, we build the base mesh of the sequence at time T_0 and perform the extraction design of the corresponding displacement map, as well as for the other sequences (see Fig. 1). It is stressed out that, in the general, one may have a base mesh composed of other several bases mesh. The 4D reconstruction is then done with a single base mesh and $N+1$ displacement maps, which speeds up the rendering and optimizes memory usage.

In what follows, the illustration in Fig. 2 depicts the necessary steps to be executed to get the desired results for a fast and clear 4D visualization.

B. Extraction Des Contours

Based on the segmented slices, we need to extract the contours of the object to be reconstructed. For the detection of its contours, several methods can be possibly used. Such methods are grouped into several distinct classes. For instance, one can use those based on nonlinear filtering such as the median filter, or more recently the one in [11]. Other methods of interest are high-pass filtering, such as Prewitt, Sobel, and Canny detectors [12], or such that the multi-scale analysis developed with the wavelet theory [13] [14]; or the one based on the rare redundant dictionary approximation [15].

Fig. 1. Construction of Base Mesh and Displacement Map from a 2D Segmented Image Sequence.

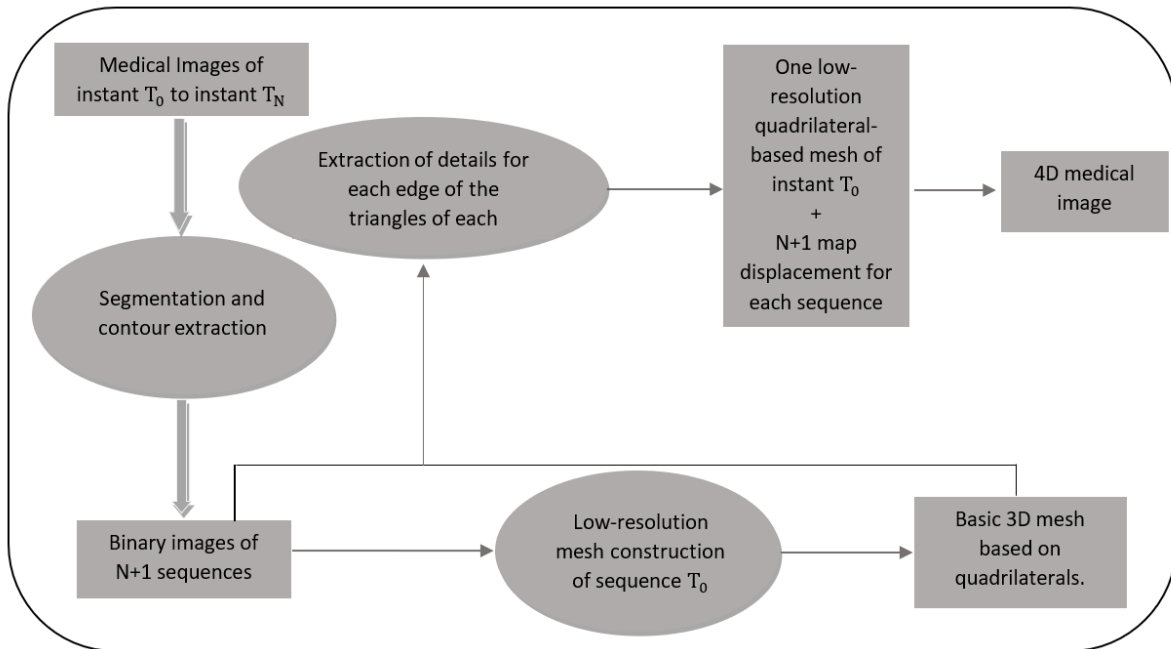

Fig. 2. Diagram Representing the Different Steps of our Algorithm

Note that the key role of the previously mentioned methods of contour traversal consists in defining the abrupt changes of pixel intensity. In fact, the real rising issue to overcome is that we should obtain a chained list of contour points, respecting a fixed order. So, the strategy we used is to extract a point from this contour, and then we must extract the other points in an ordered way following the path of these contours as it has been performed in [16].

To construct the displacement map, it is emphasized that the extraction of the contours shall be carried out for all the slices of all the sequences at the time periods T_i (see Fig. 3).

Fig. 3. Two Contours C_1 and C_2 of Two Successive Slices: the N Slice and the N+1 Slice at Time t.

C. Construction of the basic Mesh

The basic mesh is the first structure to be reconstructed without refined details. Note that in our design approach, the mesh construction consists in mapping the contours represented by triangles of each contour of each slice n with those of the slice $n+1$. As a matter of fact, drawing faces from the contours is not at all an easy task because this depends on the resolution of the following three hard problems [17]:

- Matching problem: How to connect the contours in slice n with a contour in slice $n+1$?
- Tiling problem: How to connect the points of contour C_n in slice n with the points of contour C_{n+1} in slice $n+1$?
- Connection problem: How to divide the contour C_i in slice n that corresponds to the contours C'_{n+1} and C''_{n+1} in slice $n+1$?

The illustration shown in Fig. 4 highlights the possibilities for solving the matching problem associated to the case when the number of contours in adjacent slices is not the same (the contours can be split or merged).

It is worth mentioning that for the determination of the relationship between the contours of two consecutive slices (see Fig. 5), we have used the correspondence factor method, see for instance [16].

D. Displacement Vectors

As it has been revealed in previous illustrations, the first constructed mesh is a basic mesh which does not reflect the true shape of the anatomy in question. It is then necessary to add to it the lost details in the construction of the base mesh during the real-time visualization. For this task, we shall then extract the displacement vectors using the available contour data and the edges of the quadrilaterals obtained after joining the triangles that represent the contours [18].

The strategy used to extract the displacement vectors is based on the discretization of the concerned contours (see Fig. 6). This approach has a great interest for two essential issues. On one hand, the generation of such discretized displacement vectors allows more precision for the construction of the real shape of the organ anatomy (see Fig. 7). On the second hand, through the discretization of the anatomy contour with a fixed point, this makes it easy to incorporate the suitable level of details in all polygons of the base mesh.

Fig. 4. Three Possible Solutions to the Topology Change Matching Problem.

Fig. 5. Base Mesh Construction for Two Contours of Two Consecutive Slices.

Fig. 6. Extraction of Contours with Displacement Vectors.

Fig. 7. Rendering with Hardware Tessellation to Generate the High-resolution Mesh.

Indeed, the key role of these constructed displacement vectors is that they can automatically generate the displacement map representing an image determined by its moving distances and directions from the points on the contour surface during the real-time display.

E. Reconstruction of the 4D Mesh

- Creation of sub-meshes and displacement vectors

Here, we are now able to characterize the 4D construction of the mesh. At the beginning of such construction, we start then from an already defined set of n sequences of slices from an initial time T_0 to a final time T_{n-1} . For each sequence we have m slices from C_0 to C_{m-1} . These slices are already segmented to extract only the object to be reconstructed (see Fig. 8).

This set of slices will be divided into $m-2$ sub-assemblies, each sub-assembly is represented by 2 consecutive slices of the n sequences. In particular, the first sub-assembly 0 will be represented by slice 0 and slice 1 of all the sequences.

Next, each subset must undergo some additional treatments as described in what follows:

For each sequence i we need to determine the different correspondences existing between the contours of 2 consecutive slices [16]. Contours that do not have a correspondent in the other slice will be neglected.

In Fig. 9, we have a correspondence between contour 1 and 2 of slice 1 and contour 1 and 2 of slice 2 respectively; contour 3 of slice 1 does not correspond to any contour in slice 2, so it will be deleted (see Fig. 10). Each correspondence gives us a base sub-mesh and displacement vectors that will be added to this mesh at time T_i .

The next step is to find for each sub-mesh its correspondent in the following defined sequences, for which we say that the correspondence of a sub-mesh of the sequence i to the sub-mesh of the sequence $i+1$ is satisfied if the contours of these two sub-meshes correspond to each other at each slice and with the same number (see Fig. 11).

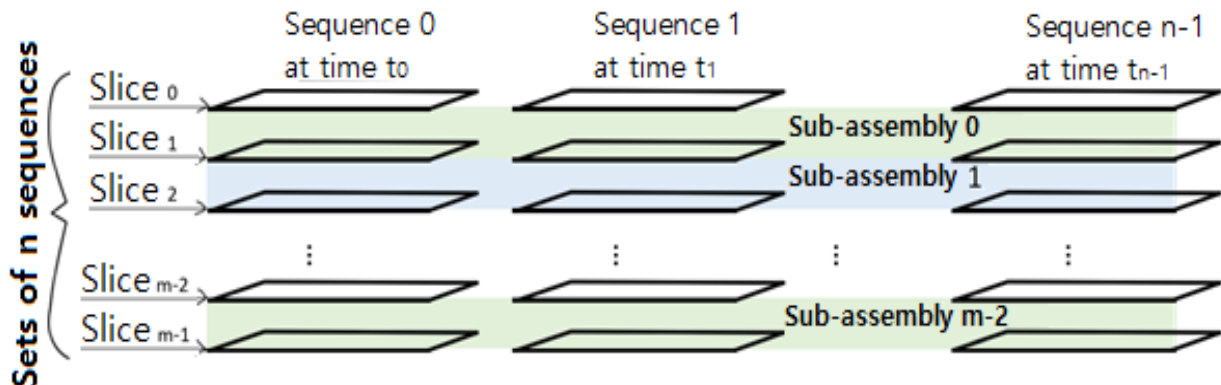

Fig. 8. The Input to this Algorithm is in the Form of a Sequence of 2D Slices for each Instant.

Fig. 9. Correspondence between the Contours of a Sequence.

Fig. 10. Representation of the Sub-meshes which Represent the Correspondences between the Contours of the same Sequence.

Fig. 11. The Sub-mesh of Sequence i Corresponds to the Sub-mesh of Sequence $i+1$.

If we fail to find the correspondence of a sub-mesh of a sequence i in the following sequence, the appearance of a new sub-mesh is obligatory, and it will be from the instant T_{i+1} (see Fig. 12).

Note that we can also have a new sub-mesh in a sequence i if we fail to find a correspondence between its contours and the contours of the sequence of the instant T_{i-1} (see Fig. 13).

Fig. 12. No Correspondence between These Two Sub-meshes (the Number of Contours in Sequence i is different from the Number of Contours in Sequence $i+1$).

Fig. 13. This Sub-mesh does not have a Correspondent in the following Sequence.

Finally, after applying this additional treatment to all the subassemblies, we obtained series of sub-meshes, each sub-mesh has the following information:

- Start sequence number (S_d).
- End sequence number (S_f).
- Displacement vectors for each edge in the different sequences from the first sequence to the final sequence.

Note that each sequence has its own displacement vectors that refine the corresponding base sub-mesh. Another fact shown the above table in Fig. 14, that sequences from 0 to i , sequences from $i+1$ to j , sequences from $j+1$ to k , as well as sequences from $k+1$ to $n-1$ do not share the same basic sub-mesh in a sub-assembly.

- Construction of the 4D mesh and interpolation

Following the previous development for the obtained results from N given sequences, we have by now all the necessary ingredients to form 3D meshes for all sequences in the form of a single compound base mesh and N displacement maps. Thus, the next treatment is the visualization of the dynamic 3D mesh using all the available data and the gathered

information. However, the success of this crucial procedure results from the number of given sequences and the required quality of the visualization in terms of display smoothness. In fact, if the number of sequences is not sufficient or the required quality is very high; an extra interpolation is then obligated to perform for additional renderings to maintain the desired display quality between each consecutive sequences. Especially, the interpolation will be applied to the displacement vectors. In the normal case, where there is a correspondence between the meshes of sequence i and those of sequence $i+1$, the position of these interpolated meshes between the two sequences is deduced by creating intermediate displacement maps based on the already computed displacement maps in sequence i and sequence $i+1$. In the opposite case of no existing correspondence between the meshes associated to consecutive sequences (see Fig. 15); then, the calculation of the intermediate mesh can be carried out after finding the suitable correspondence between the contours.

In this case, for example, where there is no correspondence between the mesh of sequence i and the mesh of sequence $i+1$, we must create a new sub-mesh at time i .

This sub-mesh will have the sequence i as the starting sequence. Thus, its elements must correspond to the elements of the sub-mesh of sequence $i+1$. To do so, we will use the correspondence factor between the contours of slice j of time i and the contours of slice j of time $i+1$ [16], to create a correspondence between the contours of the same slice, the correspondence direction, and the correspondence percentage.

According to the calculated correspondence factor of the contour C_1 with the contours C_2 and C_3 of the sequence $i+1$, we find that the green part of the contour C_1 corresponds to the contour C_3 (see Fig. 16), and the orange part corresponds to the contour C_2 . Thus, we can build the sub-mesh below which will be the sub-mesh used from the instant $i+1$:

	Seq. 0	Seq. 1	...	Seq. i	Seq. i+1	...	Seq. j	Seq. j+1	...	Seq. k	Seq. k+1	...	Seq. n-1
S.-M. ₁	Start			end									
S.-M. ₂					start		end						
S.-M. ₃								start		end			
S.-M. ₄											Start		End

These sequences use the same basic sub-mesh for a sub-assembly i

Fig. 14. This Table shows that each Sub-mesh has a Start and an end Number.

Fig. 15. No Correspondence between the Meshes of Two Consecutive Sequences.

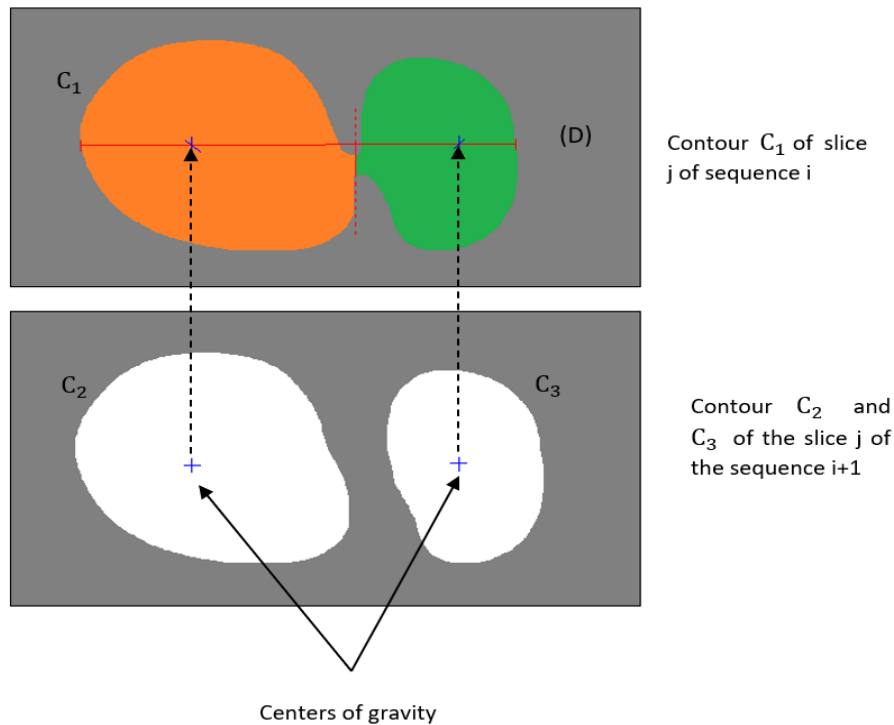

Fig. 16. Create a Correspondence between the Contour C_1 of the Cut j of the Sequence i and the Contours C_2 and C_3 of the Same Cut of the Sequence $i+1$.

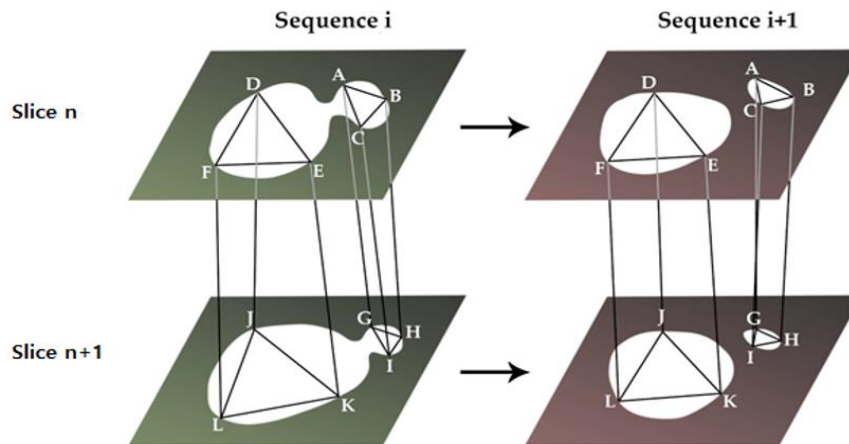

Fig. 17. Construction of the Sub-mesh which will be the Sub-mesh used from Time $i+1$.

After this operation, we can easily see that we have obtained a complete mesh associated to all the sequences (see Fig. 17). Based on such computed mesh, we can determine for each vertex at time T_i its corresponding in the next time T_{i+1} . As it can be deduced, this procedure allows the possibility to interpolate the meshes between any consecutive times.

IV. RESULTS AND DISCUSSION

The implementation of the proposed method of 4D mesh reconstruction from 2D medical images is based on the following steps:

- Detection and extraction of contours from a 2D medical image sequence.

- Construction of the basic 3D mesh of the T_0 sequence and of all the sequences that do not have some correspondence with the previous sequences.
- Extraction of displacement vectors for any sequence from the 2D images based on the corresponding 3D mesh.
- Interpolation of the 3D mesh between sequences based on the interpolation of the displacement vectors to have a smooth visualization.
- Construction of the high resolution 4D mesh from the obtained base mesh and the displacement vectors.

The first numerical result concerns the testing of our 4D reconstruction method in terms of the quality of the obtained 4D mesh. Effectively, the construction of the 4D mesh used by some classical methods is often based on the Marching Cubes algorithm combined with the interpolation method. It is worth mentioning that this approach causes ambiguity cases in some configurations [19]. In other negative situation, one may be confronted with complex areas causing an unexpected deformation during the mesh reconstruction [19]. In contrast, our new method leads to a low-resolution mesh based on contour extraction that makes it possible to create a 3D mesh without any ambiguity, matching exactly the actual shape of the anatomy. It is also noticed that the computed 4D mesh incorporate easily all the gathered anatomy information. Indeed, this shows that our method can overcome the staircase problem obtained with the classical method (see Fig. 18) (Marching Cubes with very small elementary cubes).

The second testified numerical result is related to the low storage level. For this purpose, we have compared the amount of information stored using the new adopted structure with the structure used in the conventional storage method (see Table I). As a result, by simplifying the calculations, we have applied both methods to a medical data volume of 512 x 512 x 38. This gives a size of the high-resolution mesh with the conventional method of about 2.48MB, which must be

multiplied by m (the number of given sequences). This represents a volume of about 50MB, while if we store the base mesh with the displacement vectors, we reach only 150KB. This is then a good storage reduction that is very important in practice.

The last important numerical result achieved by our algorithm is witnessed by the rendering speed. In the related numerical test, we have considered a set of 10 medical image sequences (T_0 to T_9), and in each sequence we have 38 slices. As a result, the table below shows the necessary rendering execution time for both methods (see Table II).

It is noticed that in the classical method we sent the high-resolution mesh of each time T_i directly to the GPU, while in our method we only sent to the GPU a set of basic sub-meshes with the displacement maps at each time T_n .

In another additional test, the same display is considered in both methods, by disabling in our method the interpolation between T_n time periods. The obtained comparison shows that the rendering time with the classical method is about 120 MS (8 frames per second) which is very slow about our method that achieved a rendering time equal to 19 MS only (52 frames per second). Roughly speaking, the obtained enhancement in speeding up the rendering is at least 6 times more.

Fig. 18. Our Method Allows to Overcome the Staircase Problem Obtained with the Classical Method.

TABLE I. COMPARISON BETWEEN THE AMOUNT OF INFORMATION STORED USING THE NEW STRUCTURE AND THE CONVENTIONAL STORAGE METHOD

	Basic mesh (bytes)	Number of sequences	Displacement vectors	Total (bytes):
The original method (MC)	2,480,892	20	0	=49,617,840
The new method	126,148 (T_0) 1,009 (T_5) 1,129 (T_{12}) 1,276 (T_{16})	The other sequences are based on these 4 basics meshes already sent	500*20 vectors *2 char (x,y) *1 octet	=149,562

TABLE II. COMPARISON BETWEEN THE RENDERING SPEED USING THE NEW METHOD AND THE CONVENTIONAL METHOD

	Data sent to the GPU	Size of the sent data	Average rendering time	Number of images displayed per second
The original method (MC)	High resolution meshes 10 of size 50 MB	50 Mo	120 ms	8,33
The new method	Basic sub-mesh set and 10 displacement cards	150 Ko	19 ms	52,63

V. CONCLUSION

In this paper, we have provided an enhanced algorithm that allows the reconstruction of a 4D mesh from a set of medical image sequences, using a base mesh and displacement vectors for each sequence. The use of displacement vectors to add extra details to the basic mesh has been shown to reduce the amount of information stored in the final 4D mesh. Another established fact is that the use of the tessellation unit of the graphics card allows speeding up the rendering time; since, the proposed method create the 4D mesh, based on the 3D reconstruction method that uses the GPU tessellation unit in the rendering. This modification aims to eliminate the cases of ambiguity, especially, in certain types of objects that cannot be treated easily with the reported conventional Marching Cubes method. This is also helpful for obtaining a low-resolution mesh that can be directly used in the rendering without going through a correction step.

Another particularity of the proposed method is that one can extract the contour of the anatomy to be reconstructed from the 2D images, and then build a basic mesh within a low computational time and with a reduced storage memory. By doing so, this basic mesh construction step is done for each sequence that does not have the same contours as the previous sequence, which leads to a very small number of basic meshes. Moreover, we generate displacement vectors for each sequence by discretizing the contours according to the desired level of details.

As a result, our framework has been proven to be efficiently suitable and adaptable for the following main technical issues:

- The construction of a low-resolution base mesh using the contour extraction and matching method overcomes the staircase problem as well as the ambiguity problems and generates a mesh that exactly matches the real anatomy.
- The computation of basic meshes and displacement vectors has a very low storage burden.
- The transmission of the information to the GPU allows accelerating the rendering time.

Given the important advantages of this 4D reconstruction method, it will be very useful to apply it to the vital organ that is the heart. Thus, we intend to do detailed research and analysis to treat all its particularities.

Abstract—With the widespread use of mobile phones and smartphone applications, protecting one’s privacy has become a major concern. Because active defensive strategies and temporal connections between situations relevant to users are not taken into account, present privacy preservation systems for cell phones are often ineffective. This work defines secrecy maintenance issues similar to optimizing tasks, thereby verifying their accuracy and optimization capabilities through a hypothetical study. Many optimal issues arise while preserving one’s privacy and these optimal issues are to be addressed as linear programming issues. By addressing linear programming issues, an effective context-aware privacy-preserving algorithm (CAPP) was created that uses an active defence strategy to determine how to release a user’s current context to enhance the quality of service (QoS) regarding context-aware applications while maintaining secrecy. CAPP outperforms other standard methodologies in lengthy simulations of actual data. Additionally, the minimax learning algorithm (MLA) optimizes the policy users and improves the satisfaction threshold of the context-aware applications. Moreover, a cloud-based approach is introduced in the work to protect the user’s privacy from third parties. The obtained performance measures are compared with existing approaches in terms of privacy policy breaches, context sensitivity, satisfaction threshold, adversary power, and convergence speed for online and offline attacks.

Keywords—Context-aware; privacy; active defence; privacy protection and mobile phones

I. INTRODUCTION

Mobile phones are used extensively, and apps are commonly produced for smartphones. “Context-aware applications specifically help users by providing contextually relevant tailored services [1], [2]. Context-aware applications may use sensors (e.g., GPS) to determine their owner’s location and state. These sensory data may be used to determine a user’s context or condition. For example, a user’s position may be relayed via GPS, their movement assessed by accelerometers, and their voice and scene captured by cameras and microphones. Context-aware applications may use the inferred context to provide context-aware tailored services [3]. Health Monitor can track daily activity and intelligently mutes the phone without the help of the user. Context-aware applications improve people’s lives and convenience yet also

compromise privacy. Some untrusted aware applications may be highly prone to leakage of user’s context privacy to the adversary. These adversaries may sell the user privacy for commercial purposes, resulting in a reduction of QoS of the context applications. In reality, most users would not object to allowing context-aware applications to access associated sensory data because of its convenience; thus, avoiding the danger of context-privacy exposure while delivering context-related services is becoming more important [4].

Constantly changing human situations and actions in everyday life make it difficult to maintain context-privacy for mobile phones [5]. As a matter of fact, a Markov chain may represent temporal relationships across human settings. By introducing temporal correlation among present contexts can estimate the past and future usage of context applications more efficiently. Because the naïve method ignores temporal connections between user contexts, it fails to secure critical user contexts. With MaskIt [6], sensitive and non-sensitive contexts may be silenced to reduce temporal connections between them. MaskIt’s ability to hide additional contexts reduces the QoS given by context aware smartphone applications. This approach uses passive defence, which inevitably reveals some information to opponents determining whether the hidden circumstances are sensitive or not is irrelevant to an opponent. Recent proposals include aggressive defence programmes. To reduce temporal correlations across contexts, the deception approach is introduced in each context called FakeMask. FakeMask releases scenarios that are not genuine but have significance (i.e. the user has a likelihood of being in that context at that moment) [7]. An increased number of actual contexts lead to greater service quality for consumers with such a deception strategy. As a result, it is not suitable for mobile devices [8]. In recent years, many researchers have been fascinated with cloud computing [9, 10] due to the efficient outcome for protecting privacy from the third party.

A. Motivation

With the rapid advances in technology, mobile phones play an important role in users’ daily lives. However, privacy leaks are one of the most common problems in smartphones. This research mainly focuses on preserving the privacy of

*Corresponding Author.

smartphone users in context-aware applications using cloud computing. The cloud computing platform can build a firewall between the user and the adversary. Few types of research into optimal policy users have been conducted, but raising the satisfaction threshold remains a challenging approach. However, these approaches do not protect the entire privacy of the user. Mainly location and environment privacy is leaked from the smartphones for commercial purpose. Preventing an adversary's attack requires an efficient approach to better protect user privacy. Although some types of research are taking place in this field, there is also high leakage of users' privacy. These major disadvantages motivate us to develop an efficient approach to protect user privacy from adversary attacks.

A lightweight privacy preservation approach is introduced to develop temporal correlation among every user context to protect one's privacy more effectively. Furthermore, the mobile phone context privacy problem is formulated as an optimization problem and then proves its validity. It is followed by a near-optimum problem (linear programming) to speed up the execution time. By addressing the linear programming issue, an efficient context-aware privacy preserving algorithm (CAPP) is constructed that can select how to release a user's current context to optimize the QoS of context-aware applications with privacy preservation. Extensive simulations are performed to analyze the method performance, and the simulation results show that the proposed algorithm is effective and efficient. This proposed work undergoes the following major contributions to show the better QoS of the developed model:

- This research work mainly focuses on developing a novel approach for preventing leakage of data in context-aware applications for smart phones using cloud computing.
- An effective context-aware privacy-preserving (CAPP) algorithm is introduced to address the linear programming issue.
- Minimax learning algorithm (MLA) is emphasized to optimize the policy users and improve the satisfaction threshold.
- To preserve the user's privacy, the cloud computing approach is evaluated. It mainly creates a firewall between the adversary and the user.
- The evaluation of the proposed work based on privacy policy breaches, context sensitivity, satisfaction threshold, adversary power, and convergence speed for both online and offline attacks are investigated and compared with traditional approaches.

The following sections are organized as follows: Section 2 presents the literature survey related to the developed model; Section 3 describes the proposed method; Section 4 provides results and discussion; Section 5 provides the conclusion of our proposed method.

II. LITERATURE REVIEW

A. Some of the Recently Published Papers are Surveyed below

Wang et al. [11] studied the context-aware implicit authentication of smart phone users based on multi-sensor behaviour. In this method, multi-sensor data like accelerometer, gyroscope, magnetometer, time stamp, pressure and touch size were initially encapsulated to determine one's behaviour. Here, gesture and touch features were drawn from sensed data using a statistical and distance calibration approach. The features are fused using the weighted sum fusion rule, and a one-class support vector machine (SVM) was used to classify the outcome. For experimentation, 1000 sensed data from 80 participants were considered. The overall equal error rate (EER) attained was about 0.0071% in the experimental scenario. However, this method was highly suffered due to leakage of the privacy to the third party.

Alawadhi et al. [12] performed the method toward privacy protection in context aware environment. In this method, the decision making process was introduced to monitor privacy behaviour and personal data usage. This method undergoes three stages: service classifier, privacy preference manager, and privacy controller. The privacy preference module places the privacy preference and analyses the user's data usage. The next module uses service providers under trusted, untrusted and under investigation. The privacy controller detects the usage of data based on service providers. The overall false positive rate (FPR) attained was about 1.5% in the experimental scenario. However, this method suffered due to high optimization problems.

Wan et al. [13] investigated privacy preserving blockchain enabled federated learning in 5G beyond networks. This method introduced machine learning (ML) technique to keep the data efficiently. To prevent raw data sharing, a federated learning-based privacy-preserving ML has been proposed. In addition, the Wasserstein Generative Adversarial Network (WGAN) with Differential Privacy (DP) was introduced to prevent unwanted malicious attacks by interpreting the context in FL. The WGAN approach has been proposed to construct the controllable random noise that meets the DP requirements. WGAN with DP helps to achieve the trade-off between privacy and data utility. In the experimental scenario, time delay, accuracy and efficiency were calculated. However, this method preserves data for a single user and cannot be used to preserve data for multiple users.

Ghosh et al. [14] developed the context-aware security scheme to preserve the data in an IoT-enabled society. In this method, an encryption policy attribute-based encryption scheme (CP-ABE) was introduced to efficiently preserve the user's context. In addition, a context-aware attribute learning scheme (CASE) has been proposed to learn the user's contextual information and reduce the size of the encryption data by learning the attributes. The CP-ABE technique manually enforces user data by leveraging edge intelligence in

context-aware applications. In the test scenario, the delay was reduced to 33% with a packet loss of 36%. However, this method suffered from the lack of preserving the users' environmental context information.

Sylla et al. [15] investigated secure and trustworthy context management for context aware security and privacy in the IoT (SETUCOM). In this method, device trust management (DTM) was introduced based on context aware and privacy as a service (CASPaS). The context information was secured using a Bayesian network and fuzzy logic, and it was considered the lightweight hybrid system. The elliptic curve integrated encryption scheme (ECIES) algorithm generated the security. Advanced encryption standard (AES) was evaluated for context information encryption. In the experimental scenario, the overall time taken to protect the information is about 1200ms. However, this method suffered due to insecurity of the user's privacy and it's highly occurs optimization problems.

Meng et al. [16] had defined the privacy-preserving and sparsity aware location based prediction method for collaborative recommender systems. In this method, a location-based collaborative recommendation algorithm was introduced to achieve the compromise between prediction accuracy and privacy protection. A random jamming approach has been proposed to preserve data users' QoS. In addition, the regional aggregation approach was demonstrated to preserve the location of users. Furthermore, a location-based tensor factorization approach was presented to establish a relationship between services and location to develop location-based predictions. In the test scenario, the overall accuracy achieved was about 92%. However, this method suffered from poor QoS quality and takes more time to preserve the user's location.

B. Problem Formulation

Recently, many advanced techniques have been introduced to prevent user privacy leakage in contextual applications. When used context-aware, third-party intrusion is considered unusual. This happens mainly due to the lack of QoS in the existing approaches. In general, both online and offline attacks occur in context-aware applications. However, these attacks are due to attackers for commercial purposes. The literature review mentioned above greatly affects the previous approaches due to major disadvantages; some of the common disadvantages are high leakage, privacy loss and slow process, etc. Some of the existing papers have large gaps and are manipulated in this section. In [11], the author studied the context-aware implicit authentication of smart phone users based on multi-sensor behaviour to the privacy of the user's context. However, this method was highly prone to leakage of users' privacy and lack of firewall. In [12], the author performed the method toward the privacy protection in context aware environment to preserve the environmental context of the user. However, this method suffered due to optimal issues that resulted in leakage of user privacy to the adversary. In [13] the author examined privacy preservation through blockchain-enabled federated learning in 5G beyond networks. In [14] the context-aware security scheme to preserve the data in an IoT-enabled society. However, this method was highly suffered due to user's location privacy

leakage. However, this method suffered due to programming complexity to preserve one's context privacy. In [15], the author proposed secure and trustworthy context management for context aware security and privacy in the IoT (SETUCOM) to improve the QoS of the context applications. However, this method suffered due to the high complexity process and the lack of preserving location privacy more effectively. In [16], privacy-preserving and sparsity aware location based prediction method for collaborative recommender systems has been proposed by the author. However, this method is only useful for getting the user's location.

Few researchers were undertaken to protect users' privacy based on cloud computing. The aforementioned related paper is efficient and shows a better outcome in terms of privacy preservation, but there also arises some leakage due to less improvement in the applied strategy. An effective novel approach needs to be introduced to preserve privacy to overcome this issue. This proposed method gives a clear solution for data protection with better accuracy.

III. PROPOSED METHOD

Context aware is the computation of the current situation and information about the environment, places, things that anticipate urgent needs, situate awareness, usable contents and experiences. In this work, a novel approach is developed to prevent an attack from an adversary concerning user's privacy. Initially, CAPP algorithm is introduced to enhance the quality of service (QoS) regarding context-aware applications. Then, the MLA algorithm is emphasized to equalize the optimal policy and improve the satisfaction threshold of the proposed work. The proposed work introduces cloud computing to encrypt users' privacy from a third party. Fig. 1 illustrates the framework of the proposed model.

Fig. 1. Framework of the Proposed Method.

Cloud computing is the collection of network servers coordinated with the aid of the internet. The cloud uses firewalls as privacy protection around assets to prevent intruding of third parties. To carry out this evaluation, real smartphones with traces of 94 users to find out the convergence speed of the algorithm. This paper mainly focuses on online and offline attacks due to continuous changing times and user variability.

A. Privacy Problems in Context Aware Privacy Preservation

The private contexts are said to be the context subsets in which leakage is considered the major drawback for the smartphone user. In order to prevent the leakage of privacy, the user must control the emitted information using middleware privacy preservation. Many existing approaches are introduced to overcome the leakage of the user's privacy. Privacy-preserving middleware is used to access the context-aware middleware for the users, but this middleware does not require any permission to access the user's data. Usually, the released data with granularity leaks the privacy of the user. Hence the accuracy of the context recognition is also reduced. The context-aware apps are mainly used for commercial purposes and are considered the adversary. The adversary is a third party intrusion, mainly focusing on reducing the user's utility by adding multiple attacks. The attacks mainly undergo two stages offline and online attacks.

The third party gets the user's personal information such as behavioral contexts, GPS location information, etc. These third parties sell the information for commercial purposes, and users are unaware that the attack leads to a privacy breach. In online attacks, the third party collects the sensed data from the user and understands the user's behavior based on the collected data. According to the behavior, the third party forces the user or makes the user indulge in blackmail or leads to violence.

1) *State transition for online attacks:* For the online attack, the adversary's strategy is unknown to the user, and the user blindly believes the adversary's strategy from the existing attacks. There are many reasons for the dependence on previous attacks. The third party collects the last context based on the previous approach. Then the present information is coordinated with the past information based on the proposed algorithm. Hence the user should encapsulate the adversary's attacks and which information has been attacked. The attacked time is denoted by n , which clearly shows the time the data gets leaked. The attack of the previous information is indicated as Wr^n , the value of Wr^n is 1 or 0. If the adversary successfully collects the information is denoted as D_{n-1} . The state transitions for the online attacks at the time n is given by, $R^n = \{Wr^n, D_{n-1}\}$.

2) *State transition for offline attacks:* In an offline attack, the adversary gets the user's personal data such as personal

behavior contexts, environmental context, GPS location etc. The adversaries sell one's personal information for money and lead to a privacy breach, and it is unknown to the user. The time n of the user's action is given by, $a^n_h = \{a^n_{h,1}, \dots, a^n_{h,E}\}$, the granularity of the sensor's data is denoted as $a^n_{h,E} \in [0,1], \forall E=1, \dots, E$. Here, E denotes the complete sensors for the purpose of recognition. The recognition of the context in terms of accuracy with the limit ranges from t ($0 \leq t \leq 1$) is given by,

$$t = \sum_{E=1}^E E_e a^n_{h,E} \quad (1)$$

Here, $\{E_e : \forall E\}$ denotes the weight of the context sensitivity based on context recognition accuracy.

The adversary's attacking capability needs to choose the correct subset of regretting the sensed data. A formula gives the time n with the adversary actions as,

$$a^n_b = \{a^n_{a,1}, a^n_{a,E}\} \quad (2)$$

Here, $a^n_{b,e}$ denotes the E th sensor of the retrieved data. The adversary actions with limited power adversary given mathematically as,

$$\sum_E a^n_{b,j} \leq L, 0 \leq a^n_{a,j} \leq 1, \forall E \quad (3)$$

Here, L denotes the adversary power limitations. Based on the limit $L \leq E$, the third party can capture the sensed data. Hence this adversary is said to be an unlimited power adversary.

The behavior of the adversary in online attacking the user can be determined in a probabilistic manner, and it is given by,

$$Pb[R^n | a^n_h, a^n_a] = Pb[Wr^{n+1} | Wr^n, a^n_h, a^n_a] Pb[D^{n+1} | D^n] = Pb[Wr^{n+1} | a^n_h, a^n_a] Pb[D^{n+1} | D^n] \quad (4)$$

The offline attack in case of adversary based on the probabilistic manner is given by,

$$Pb[R^{n+1} | a^n_h, a^n_a] = Pb[D^{n+1} | D^n] \quad (5)$$

B. Proposed Context Aware Privacy Preservation Algorithm

The optimization problem gets converted into a linear programming problem to improve the convergence speed. To overcome the linear programming problem, the CAPP algorithm is introduced. It generates the active policy users and increases the service quality for context aware applications with user privacy.

Fig. 2. Architecture of Privacy Aware.

Fig. 2 shows the architecture for privacy aware. The service provider gives a request to the PC about the priority. The PC does not request permission from the user directly and sends the requests through the PC module. The module provides the decision and notifies it to the OS that communicates with the SP consecutively. The user's privacy is stored in the privacy preference manager (PPM). It enables the user to set the privacy and sensitivity to context aware apps.

- Dividable.
- Not dividable.
- To be established.
- Cannot be established.

Dividable means the user feels comfortable for giving one's personal information. Not dividable denotes that the user feels insecure in sharing one's information. The data to be established depicts that when the user uses the application source for the first time; he sets the location permission to be dividable or cannot be dividable to the application. It cannot be established indicates that the user is unable to express to set the context priority that is sharable or not. The SC module describes the category of the service provider based on the context request and how it is divided among the SP. SP undergoes 3 stages: hopeful, hopeless, and examining. The hopeful SP is the one who asks only necessary information from the user. The hopeless SP is the one who asks for unnecessary that are not required for the adversary. The adversary is tested for hopeful or hopeless SP in the investigation category.

The PC module senses the user when the hopeless SP attacks the personal data. The deciding operation is done by three operation:

- Allow – allow access to context request.
- Deny – prevent access from context requests.
- Approximation- allow access to approximate the value based on the context request.

Algorithm For Context Aware Privacy Preservation

```

Step 1: Initialize service provider (SC)
Step 2: Allow request for PC to preference
Step 3: if, users data is sharable
  Allow PC to get service provider from SC
Step 4: else, users data not sharable
  Send decision to OS
  End
Step 5: if, SP is trusted
  Allow permission to access users data
  Send decision to OS.
  End
Step 6: else, SP is not trusted
  Access deny
  Send decision to OS
  End
Step 7: do, investigation and approximate range of SP
  Send decision to OS
  End
Step 8: else,
  Allow request for PC to preference
Step 9: if, SP is trusted
  Suggest to user to access the data
  Gets users decision from PC
  Send decision to OS
  End
Step 10: else,
  Suggest not to user to access the data
  Gets users decision from PC
  Send decision to OS
  End
Step 11: else,
  Suggest to user to set the approximate range
  Gets users decision from PC
  Send decision to OS
  End
  
```

The algorithm selects how to reveal a user's context while protecting their privacy. Even if an opponent knew the Markov model with associated probability matrices of emissions, they couldn't determine the original context from CAPP's output context sequence. Because privacy ensures a condition with which an adversary can never know the user when within the sensitive environment.

C. Mini Max Learning Algorithm

The minimax algorithm is a step by step process that aids the computer in working intelligently instead of not learning automatically. It mainly helps to improve the satisfaction threshold for the proposed approach.

The pair of the optimal policy is given by, $\phi^* = \{\phi^*_h, \phi^*_a\}$ for the game based context privacy is achieved by overcoming the convergence problem.

$$\tilde{U}^{n+1}(Wr) = (1 - \beta^{n+1})\tilde{U}^n(Wr) + \beta^{n+1}G_i[s_h(r, a^n_h, a^n_a) + \lambda\tilde{U}^n(Wr')] \quad (6)$$

Based on the eqn (1), using the learning approach, the $\tilde{U}^{\phi^*}_h(Wr)$ is obtained, and this can be obtained using upgraded rule based on the Q-learning approach.

$$\phi^* = \arg \max_{\phi_h} \min_{\phi_a} \{s_h(r, a^{\phi^*}) + \lambda \sum_{Wr'} (Tr[Wr' / a^{\phi^*}] \tilde{U}^{\phi^*}(Wr'))\} \quad (7)$$

The algorithm of minimax learning is shown below:

Mini-max learning algorithm

Input: the stochastic game for context aware privacy given by, Ψ

Output:

// (i) Start

1. $n \leftarrow 0, W_r^n = 0;$

2. $\tilde{U}^n(W_r=0) \leftarrow 1, \tilde{U}^n(W_r=1) \leftarrow -1;$

3. Start the pair for policy ϕ^n : distributed based on uniform

$$a^{n_h,j} = \frac{1}{P}, a^{n_a,j} = \frac{L}{P}, \forall j;$$

// (ii) Recursion

4. Iterate

5. Choose the action pair $\{a^{n_h}, a^{n_a}\}$ according to ϕ^* ;

6. Upgrade W_r^{n+1} after each user's taken into consideration as

$$\{a^{n_h}, a^{n_a}\}$$

7. Upgrade $\tilde{U}^{n+1}(W_r)$ convergence state notation as, based on equation (2).

8. Upgrade the optimized policy as ϕ^{n+1} based on the equation (1) with upgraded stated notations;

9. $n \leftarrow n + 1;$

10. Until equalize

The learning rate is indicated as, $\beta^n \in (0,1)$ for the convergence of learning algorithm, must degrade the high time operation. Set $\beta^n = \frac{1}{n} \tilde{U}^{n+1}(W_r)$ that is used as an approximate value and updated continuously until it equalizes.

Algorithm 1 evaluates the learning algorithm in an equivalent state, denoted as, $\tilde{U}_h^{\phi^*}(W_r)$. Initially, set the equalization state values as 1 and make the uniform distribution among the players of each policy. After that, the equivalent state values are continuously repeated based on equations (1) and (2). This repetition helps to occur optimal policy among the policy pair.

IV. RESULTS AND DISCUSSION

The context-aware privacy-preserving algorithm (dubbed CAPP) was developed and compared with currently present algorithms of privacies such as EfficientFake [8] and MaskSensitive, MaskIt (using the hybrid check) [7]. Basic method's MaskSensitive, which hides or suppresses all sensitive circumstances during the release of a non-sensitive one. The entire simulation was done using MATLAB. Initially, an effective context-aware privacy-preserving (CAPP) algorithm is introduced to address the linear programming issue. Then, minimax learning algorithm (MLA) is emphasized to optimize the policy users and to improve the satisfaction threshold. The performance measures such as privacy policy breaches, context sensitivity, satisfaction threshold, adversary power, and convergence speed for both online and offline attacks are investigated.

A. Analysis of Performance Metrics for the Proposed Model

To analyze the performance of the proposed method, a Markov chain is given to each user to train and assess protect the privacy context for every user. Because of the inadequacy

of previous beliefs and the probability of emission, privacy may not be ensured while gathering the user's trace. To ensure user privacy is maintained, the privacy value, which is set to 0.1, is used as the simulation parameter. It was to be noted as a higher privacy parameter, and then lower will be user privacies guarding levels with additional actual sensitive information being revealed. Selecting sensitive environments may be done in one of two ways. Unless, sensitive circumstances pertaining to every user is selected randomly, referred to as sensitive, unless otherwise noted. Alternatively, for each user, a random place is selected with the greatest probability of prior as the user's house, marking that sensitive, dubbed home as sensitive. Because the expected amount in released real context was utility about privacy-preserving technique, normalized utility is utilized as evaluation, defined as the proportion of release actual context. It's worth noting that context-aware applications give better service when their utility is greater. Identically, the amount of sensitivity contextual is splitted within the user's context sequence, which got discontinued by the user's context sequence length in evaluating privacy breaches. Three Methods: MaskIt [6], CAPP [16] and Efficient Fake [17], and everyone guarantee no violation of privacy, according to the definition. Mask because of the lack of assumption for the presence of temporary connections across the user's context, Sensitive is unlikely to be able to ensure the desired privacy.

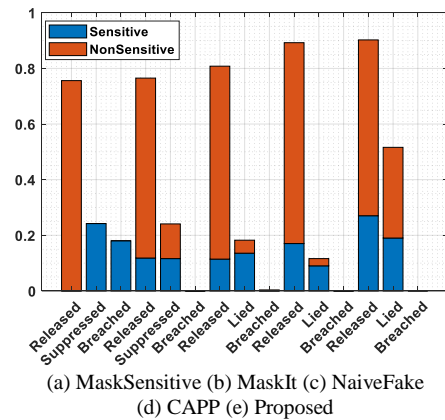

Fig. 3. Comparison for Privacy Policy Breaches (Home as Sensitive).

Fig. 4. Comparison for Privacy Policy Breaches (Sensitive as Random).

In the first example, comparisons are made for the privacy of CAPPs and MLA to violate the use of these alternative techniques. With certain conditions, three contexts were chosen by us randomly as sensitive about every user, whereas, in the other, each user's house is selected as sensitive. It's worth noting that a user's house has the greatest previous belief, indicating that the user must spend most of their time inside the house rather than elsewhere. In the preceding two instances, Fig. 3 and 4 shows released and repressed contexts in average proportions by different methods. All sensitive circumstances were surpassed by Mask Sensitive in entire instances, as can be seen in the images. Even though not every sensitive context was revealed within Mask Sensitive, opponents that understand the contexts of the Markov chain can predict around 40–60% sensitive contexts out of suppressed ones in both cases. The major reason is that the temporal connection across contexts gives an adversary enough information to conclude a greater post belief that can surpass correspondingly preexisting belief by privacy parameter. On the other hand, CAPP, EfficientFake, and MaskIt ensure that -privacy is maintained. Some sensitive and non-sensitive contexts are repressed and released in CAPP, EfficientFake, and MaskIt. CAPP also releases a higher percentage of genuine situations than MaskSensitive, MaskIt, or EfficientFake. MaskIt compromises less than 20% of Mask Sensitive's functionality to ensure anonymity, as seen in the numbers.

However, compared to Mask Sensitive, both EfficientFake and CAPP boost usefulness by about 20% while ensuring anonymity. The fundamental reason for this is that the new deception strategy makes it harder to antagonist in deriving posterior beliefs, allowing more genuine contexts to be released. Despite the fact that CAPP and EfficientFake were both formalized in linear programming problems, the proposed CAPP outperforms Efficient Fake techniques with both instances in terms of average utility. There are two primary reasons for this. The first difference is that in EfficientFake, the aim is to optimize emission probability solely. Still, with CAPP, the aim was to maximize the value of utility for a provided period of time. Secondly, Efficient Fake's space of resolution has shrunk significantly. The emission probability matrix' Shape in EfficientFake was reduced to a vectored representation, thereby significantly reducing the solution's precision in EfficientFake, resulting in lower utility than CAPP. On the other hand, CAPP does not shrink the solution space, allowing us to find a superior optimized solution.

The usefulness of the proposed CAPP is then compared to that of other techniques with various privacy settings ranging from 0.05 to 0.3. Separate sensitive settings are selected in the trials, just as in the previous ones: the sensitive environment for one person is their home, while the other is chosen at random. With the reduction in the privacy requirement, anticipate utility need to be rise. Fig. 5 and 6 shows that utility grows slowly as the number of people rise in both circumstances.

Moreover, the experimental analysis shows that, for similar privacy values, every solution executes in the best way within 2nd case. The context of random was designated

sensitive, compared with the first situation, when the home was designated as sensitive. Because locations of every having greatest belief of prior were picked sensitive context in the first scenario in Fig. 5, the number of sensitive contexts was greater than the 2nd situation in Fig. 6, in which sensitive context was selected at random. CAPP and Efficient Fake should release more fake contexts in the first case to give identical privacy levels. However, when related to other methods, the proposed CAPP outperforms them all due to its close approximation of the problem's optimum solution.

Fig. 5. Tradeoff for Privacy-utility (Home as Sensitive).

Fig. 6. Privacy-utility Tradeoff (Sensitive as Random).

Fig. 7. Comparison of Sensitive Context and Payoff Discount.

Fig. 7 represents the comparison of sensitive context and the sum of the discounted payoff for an online attack. When the sensitive context percentage increases, the myopic strategy [18] gets highly decreased. The users of high sensitive contexts result in more privacy leakage. But this strategy shows high leakage in the case of the privacy policy. In the fixed strategy [19], the same percentage of sensitive context results in the same sum of the discounted payoff. However, this strategy shows poor outcomes because of its insecure privacy. It is due to the constant quality of service, and it controls the payoff discount in case of a fixed strategy. In the case of the MDP approach [20], it is the same as the myopic strategy.

However, this approach works more efficiently in the case of privacy preservation than the myopic strategy. But, this method shows a lie outcome based on context aware privacy preservation. The proposed model shows better results in protecting the privacy of the user. By increasing the percentage of the sensitive context to 1, the sum of the payoff discount gets very much increased to 2.9 because of using an optimal algorithm with cloud computation.

Fig. 8 compares the satisfaction threshold and sum of the discounted payoff. The satisfaction threshold is compared with the existing application based on the sum of discounted payoff. From the graph, it is shown that if sum of the discounted payoff gets lower, the satisfaction threshold gets very much lower. If the satisfaction threshold gets increased, the quality of service gets lower. The existing approach results in low-quality service by comparing the proposed model with the myopic strategy. If the service quality decreases, it is harder to better accuracy in the outcome. Hence the satisfaction threshold must be lower to prevent the loss of leakage in privacy. In the case of the MDP approach, there attains a better quality of service. However, this method shows some drawbacks in hiding the information from the third party. The proposed model shows better privacy protection as the satisfaction threshold is only 0.15.

Fig. 9 represents the different context sensitivity based on optimal police based on online policy. Here, a, b illustrated in the graph denotes the released and leaked data. With the smaller context sensitivity of 0.25, the optimal policy achieves 1. When the context sensitivity becomes higher by about 0.87, the optimal policy attains a negligible value. In the case of smaller context sensitivity, the service quality variance improves, and vice versa, the loss of privacy dominates. Suppose both a and b go down, the context sensitivity increases. Due to this, the user chooses a more optimized strategy to protect their privacy efficiently. From the graph, it is clear that if the satisfaction threshold increases, the context sensitivity decreases. Suppose the user receives only low-quality service if the threshold becomes lower. Understanding the satisfaction threshold is considered an important parameter while developing context-aware privacy protection approaches.

Fig. 10 illustrates the different adversaries with optimal policies for the offline attack. Here, L denotes the adversary power of the privacy policy. Considering, at L=1, attains poor adversary power due to high leakage of privacy of the user. In

myopic strategy, the discounted payoff with different adversary power is higher than the proposed work. For efficient usage of context aware applications, the sum of discounted payoff should be too low. From the graph, it is shown that the sum of discounted payoff gets degraded, resulting in no leakage. In existing approaches, compared with the limited adversary power, the performance of the adversary power with unlimited power gets very worse. Mainly, the adversary with unlimited power occurs more leakage, and hence the user selects another strategy to protect their privacy.

Fig. 8. Comparison of Satisfaction Threshold and Payoff Discount.

Fig. 9. Different Context Sensitivity based on Optimal Policies.

Fig. 10. Different Adversaries with Optimal Policies.

Fig. 11. Comparison of Sensitive Context and Payoff Discounts.

Fig. 11 illustrates the comparison of sensitive context and payoff discounts. As per the graph, when the sensitive context percent increases, the discounted payoff's sum gets degraded. This denotes that sensitive users have to use the more encrypted forms to preserve user privacy. When the sensitive context percent increases in myopic strategy, the discounted payoff's sum gets degraded slowly. But this approach does not show better accuracy in preserving the user's privacy under offline attacks. In fixed strategy, the sum of discounted payoff gets diminished gradually with an increase in sensitive contexts. But this approach uses high complexity in protecting one's privacy from the third party. The MDP approach is also the same as the other existing approach because of the lack of new approaches to protect the privacy of the user. The proposal shows a better outcome because it performs effectively in preserving the privacy of the user.

Fig. 12 compares the satisfaction threshold and sum of the discounted payoffs. As per the graph, when the satisfaction threshold (accuracy) increases, the sum of the discounted payoff gets decreases slowly in the case of myopic strategy. This shows that this strategy is not suitable for preserving the privacy of the user due to low service quality. In the case of fixed strategy, the sum of discounted payoff decreases significantly with increased accuracy. This approach shows a lack of service quality due to the absence of a slow encryption process. Considering the MPD approach, the sum of the discounted payoff gets decreased with an increase in accuracy but is not efficient due to a lack of preserving privacy from the third party. When the sum of the discounted payoff gets decreased, the accuracy is very high. This shows that the proposed method with cloud computing helps the user protect their privacy effectively.

Fig. 13a, 13b, 13c shows the sum of discounted payoff at $L=1$, $L=2$ and with unlimited power. As per the graph, the discounted payoff gets reduced when the adversary's power gets increased. It is due to the increase of L , and the adversary can access more data. Hence it is influenced by the adversary to attack the user successfully. Considering the releasing data with less granularity shows the lower service quality or the user should depend on the same approach to protect user's privacy. This leads to more loss in privacy of the user and less

payoff. The existing approaches like myopic, fixed and MDP approach more leakage in the privacy of user due to low satisfaction threshold. The proposed method shows good encryption in protecting the user's privacy because of high satisfaction threshold.

Fig. 14 illustrates the cumulative distribution function (CDF) of various iterations in order to learn the optimal policy of the reality mining dataset. The operating speed of the proposed work is analyzed for 220 iterations. For the MPD process, the convergence speed is analyzed with 10^5 iterations. This shows that the proposed algorithm has a higher convergence speed than the MDP process. The proposal algorithm's equivalent state value helps reduce the high dimensionality for learning the process efficiently.

B. Discussion

This research mainly focuses on developing a novel approach for preventing data leakage in context aware applications for smart phones using cloud computing. An effective context aware privacy preserving (CAPP) algorithm is introduced to address the linear programming issue. Minimax learning algorithm (MLA) is emphasized to optimize the policy users and improve the satisfaction threshold. To preserve the privacy of the user, the cloud computing approach is evaluated. It mainly creates a firewall between the adversary and the user. The performance of the proposed work is compared with existing approaches like Naivefake, MaskIt, EfficientFake and CAPP models. But this method suffered due to multiple drawbacks. To protect the privacy of the user is not an easy task. Many issues like the third party intrude and cracking may occur due to the lack of advancements in sensor networks.

In the context-aware implicit authentication of smartphone users based on the multi-sensor behaviour, this method was suffered due to leakage of the privacy to the third party. EER attained was about 0.0071%. In the method towards the privacy protection in context aware environment; however, this method suffered due to high optimization problems in context aware scalable authentication (CASA). However, this method suffered due to high attacks from the adversary. FPR

attained was about 1.5%. An aware access control framework for software services (PO-SAAC) was introduced in the purpose-oriented situation. However, this method suffered due to high computational complexity and increased memory size. The memory size utilized about 1600 KB based on the response time in the secure and trustworthy context management for context aware security and privacy in the IoT (SETUCOM). However, this method suffered due to insecurity of the user's privacy and it's highly occurs optimization problems. The overall time taken to protect the information is about 1200ms. The evaluation of the proposed work based on privacy policy breaches, context sensitivity, satisfaction threshold, adversary power, and convergence speed for both online and offline attacks are investigated and compared with traditional approaches. Because of its outstanding performance avoids leakage and privacy loss in smartphones because of its outstanding performance.

V. CONCLUSION

The challenge of context-aware privacy preservation for cellphones is addressed in this study. The validity and optimality is verified by theoretical analysis by formalizing the problem of contextual privacy preservation as an optimization problem. To further speed up the computation, an effective, near-optimized strategy involving the linear programming problem was developed. A context-aware privacy preserving algorithm (CAPP) was presented due to the linear programming issue being solved. The experimental analysis proves that the suggested CAPP provides much more value than existing techniques while respecting the user's δ -privacy policy via thorough experimental evaluations on actual mobility traces. A cloud-based approach is introduced in this work to protect the privacy of the user from a third party. In addition to this, a minimax learning algorithm is emphasized for improving the accuracy of the context aware application and improving the optimal policy of the users. The performance measures obtained are compared with existing approaches in terms of privacy policy breaches, context-sensitivity, satisfaction threshold, adversary power, and convergence speed for online and offline attacks.

A. Future Scope

An exciting future project would be the development of an online context released judgment system that can generate faster and most effective judgments depending just on the user's current context while maintaining anonymity. Because this research focuses on preserving privacy for a single user, a future project will provide a privacy preservation technique that considers user interactions, given that people have group mobility.

ACKNOWLEDGMENT

I sincerely thank Thyagaraju G. S, R H Goudar, for their guidance and encouragement in carrying out this research work.

Abstract—New pedagogical tools have been introduced in educational contexts in recent years. They have been shown to impact learning compared to conventional education strategies positively. Before implementing new learning tools, a study of technological acceptance is needed for its application to succeed. For this reason, the objective of this research was to measure the intention and acceptance of the use of new digital learning tools, such as mobile applications, holograms, interactive platforms, and virtual or augmented reality, through the Technology Acceptance Model 3 (TAM3) in safety on-board training inductions in a mining company. This measurement was based on the analysis of a survey carried out in Google Forms based on the Likert scale; the results were processed using the partial least squares technique in structural equation models (PLS-SEM), processed through SmartPLS 3. As a result, we got positive correlations between the instrument's variables and acceptance by the participants studied. The findings indicate that it is essential to consider the participants' opinions a priori to implementing new digital education tools for managerial decision-making. It was considering highlighting the teaching about safety in mining companies since this allows contributing to engineering education and protecting the most precious resource of any company, the human being.

Keywords—Technology acceptance model 3; PLS-SEM; SmartPLS; mining company; safety; safety inductions; safety talk; learning; education; teaching; technology; learning tools

I. INTRODUCTION

Technology is developing exponentially; it has covered fundamental aspects of human beings such as learning, focusing on eight topics: institutional environment, presence, pedagogy, technological elements, design, behaviors, affective elements, and learning outcomes [1]. It is worth mentioning that new technologies are gradually replacing the traditional approach to teaching [2] with a more social learning approach [3] as the number of publications about how the use of technology can be successful so that teachers can teach effectively, taking advantage of the opportunities of technological advances, generating an innovative learning environment based on play. Awakening students' interest in its use will better understand information [4][5]. However, research on technology-enhanced learning has been written chiefly by authors working in the educational field,

representing approximately 70% of articles in all studies collected by a bibliometric analysis carried out in 2019; on the other hand, so only 9% were from articles written by authors who are working in engineering areas [6]. There is a lack of attention to applying digital learning tools in engineering, such as the training and inductions directed mainly through safety engineers in mining companies [7]. If the knowledge that they want to teach through training or induction is not transmitted adequately, the most valuable resource of companies, that is the human, would be more exposed to danger due to ignorance about the topics of safety, highlighting the great importance of education in the field of engineering.

The world's leading mining companies advise providing experiential learning in inductions and training through new interactive and immersive technologies such as podcasting, social media, interactive whiteboards, and virtual reality [8]. A study [9] examining the positive impact of the digital learning tool EPIC on 14,000 people found that the actor-based teaching application generates a more interactive and immersive pedagogical experience than a conventional classroom. It is also necessary to specify that a study [10] that used high fidelity simulation (HFS) identified that carrying out simulations more frequently and having the opportunity to "repeat" the experience would improve student learning. It is essential to mention that training, technical, and financial support requires the mining company's attention to implementing digital learning tools and achieving success in technology-supported education.

Technology acceptance model 3 (TAM3) was developed by Venkatesh [11]. It is essential to know the participants' opinions to analyze whether a new learning tool will be implemented and properly used, bringing considerable benefits [4] for students, teacher trainers, and the company where the pedagogical innovation would be applied. It has been researched with many different external variables in the literature [12]; it is an information systems theory that models how users come to accept and use technology.

The main objective of this work is to conduct a pilot test for practitioners and interns of mining companies in southern Peru to know their acceptance of digital learning tools using the TAM3.

II. RELATED WORK

Different works have been reviewed on the proposed theme that is shown below.

A. Digital Learning Tools

Xu, Zhang, and Hou, in their paper [13], indicate that the traditional teaching methods such as 2D presentations, conferences, and workshops have been innovated by technological learning tools such as simulations, immersive virtual reality, augmented and mixed reality, mobile devices, online training platforms, and game engine techniques, among others. The importance of learning tools lies in improving teaching quality to meet external challenges and demands in education [14].

1) *Benefits for students and teacher trainers:* The use of digital learning tools would allow the student to obtain more virtual practical experience, being able to make mistakes since it is considered a safe place, and thus improve their performance and dexterity when facing an actual situation [10], solving problems with confidence and without anxiety. This benefit would enhance the student's emotional attitude, making them feel motivated and satisfied with learning in a non-traditional way [15]. In the paper by Kurniawan, Suharjito, Diana, and Witjaksono [15], it is worth mentioning that using these tools allows the student to assimilate the information better when dealing with complex subjects to understand. It also creates opportunities for discussion within the classroom since digital learning tools allow students to play an active role, unlike conventional classes, where they play a passive role [16].

Digital teaching tools provide the teacher with better pedagogical technologies than traditional methods to explain and make their students understand, thanks to these tools' interactivity capacity, making the learning process more attractive, fun, and collaborative [17]. These results encourage teachers to continue using innovative learning tools with their students [3], increasing teacher effectiveness, increasing the quality of education, reducing the burden of teaching complicated subjects, and improving student performance.

B. Safety Culture and the Peruvian Regulation of Safety and Occupational Health in Mining

Mandhani, Nayak, and Parida [18] mention that safety is essential for all companies, especially mining companies, so the structure and culture of security are critical elements in safeguarding workers' lives.

The development of a safety culture in a mining company is essential to improve the rule-following behavior of employees to avoid the existence of incidents or accidents [19]. It is an indispensable medium for ensuring good performance in safety matters and significantly reducing accidents [20] [21]. According to Zhao, Zhao, Davidson, and Zuo [22], the economic loss due to occupational accidents represents approximately 8.5% of the project costs. For this reason, companies could be interested in providing safe working conditions to avoid expenses and safeguard human lives, where unique pedagogical campaigns such as training, inductions,

health promotion, risk assessment, and the environment can be offered [23]. In Peru, mining companies are governed under the D.S. N ° 023-2017-EM [24] in terms of occupational health and safety, article 72 specifies the minimum number of hours of necessary induction (eight (8) hours during four (4) days in mining activities of high risk and eight (8) hours for two (2) days in lower risk mining activities). There, an entry to the mining operation must carry out very apart from the necessary induction; the number of courses may vary according to the area to enter. In the required induction, topics such as occupational health and safety policies of the company, Internal Regulation of Safety and Occupational Health, Traffic Rules, High-risk jobs, emergency plans in the mining company, and definitions of danger and risk must be learned effectively. Risk controls, among others. So, trainers must be committed to the quality of learning that students will receive to ensure compliance with the law and safeguard lives.

C. Technological Acceptance Model (TAM3)

The TAM3 model was developed by Venkatesh [11] to determine the perceived usefulness and ease of use of the technology. The paper of Dönmez-Turan and Kir [25] indicates that the TAM3 was used to define the adoption of practitioners and interns working in mining companies in southern Peru to use new digital learning tools in safety inductions before entering the mine. As is shown in Table I, all the variables of the TAM3 used in the present investigation are defined. There is currently not enough research about implementing new digital learning tools in training and induction in mining companies. Since applying these tools in schools or universities is more studied, leaving aside the attention that industrial companies need in terms of education in security [26].

TABLE I. VARIABLES OF THE TAM3

Variable	Conceptualization
Image (IMG)	The level at which an individual feels that technological innovation will increase their social status [26].
Job Relevance (REL)	The degree to which a person believes that technological innovation can be applied to their work.
Output Quality (OUT)	The extent to which an individual believes that technological innovation can have a correct functionality in their work activities.
Result Demonstrability (RES)	The level at which a person thinks that technological innovation results can be observed and communicated.
Perceived Usefulness (PU)	The extent to which an individual perceives that technological innovation will improve their performance.
Computer Anxiety (CANX)	The degree to which an individual feels fear and insecurity when using technological innovations.
Computer Playfulness (CPLAY)	Level of enthusiasm that a person has when using technological innovation.
Computer Self-efficacy (CSE)	Measure which an individual feels capable of manipulating a technological innovation to carry out their activities.
Perceived Enjoyment (ENJ)	Level of enjoyment and satisfaction when using technological innovation.

Variable	Conceptualization
Objective Usability (OU)	The measure indicates how easy or difficult it will be to carry out a specific activity with technological innovation.
Perceptions of External Control (PEC)	The degree to which a person thinks there is adequate support to provide technical assistance for technological innovation.
Subjective Norm (SN)	Level of influence of one individual over another for the use of technological innovation.
Experience (EXP)	The extent to which an individual uses a technological innovation [11].
Voluntariness (VOL)	The degree to which a person would use a technological innovation without being forced [26].
Perceived Ease of Use (PEOU)	Measure how a person feels and how easy it will be to use technological innovation.
Behavioral Intention (BI)	Level of intention that an individual has to use technological innovation.
Use Behavior (USE)	Degree of permanence of a person in the face of technological innovation.

III. METHODOLOGY

A. Participants

This study was directed to 46 practitioners and interns from different mining companies in Southern Peru. They are between 20 and 30 years old; the majority are between 22 and 25 years old, representing 85% of the sample. The survey was shared using Google Forms [27]; so that it could have reached each participant by overcoming any territorial limitations. Next, Table II shows the distribution of survey participants; they were divided between people who work in surface mining (open pit) or underground mining (sinkhole).

TABLE II. DISTRIBUTION OF SURVEY PARTICIPANTS

Type of field	Number of participants	Percentage
Surface or open-pit mining	42	91%
Underground or sinkhole mining	4	9%
Total	46	100%

B. TAM3 Measuring Instrument

The Technological Acceptance Model (TAM3) proposed by Venkatesh was used. A network of variables was developed for adoption, information technologies use and empirically tested in the proposed integrated model, focusing on the application of TAM3 both a priori and after implementing the technology. It was shown that TAM3 provides necessary help in making managerial decisions to implement new information technologies [11]. The TAM primarily analyzes the technological acceptance of innovative methods and tools in education. It was shown to be an excellent instrument for understanding the participants' intentions [16]. We decided to use the TAM3 over other essential tools in the measurement of technological acceptance, such as the Unified Theory of

Acceptance and Use of Technology 2 (UTAUT2), since the latter includes variables such as age, gender, and price [28], whose parameters were considered not necessary for this research. A survey was conducted, taking into account the considerations of each TAM3 variable. They are defined in Table I. It was decided to use the Likert scale to establish a multiple-choice response range [29], having a range from 1 up to 7 points, where one meant "Strongly Disagree" and seven told, "Strongly Agree." Table III shows the questionnaire questions carried out on January 24, 2022.

TABLE III. QUESTIONNAIRE VARIABLES

Variable	Questionnaire
Image (IMG)	Receiving induction classes using learning technologies raises the status of the mining company where I work.
Job Relevance (REL)	I feel that using learning technologies in induction classes will positively impact the various tasks related to my work.
Output Quality (OUT)	Learning technologies could have excellent results in my understanding of different induction topics.
Result Demonstrability (RES)	It could explain why learning technologies can be beneficial in understanding the information received in induction classes.
Perceived Usefulness (PU)	I think it is possible that the use of new learning technologies in my induction classes would improve my job performance.
Computer Anxiety (CANX)	I feel safe and comfortable using new learning technologies.
Computer Playfulness (CPLAY)	I am excited about using new learning technologies in my induction classes.
Computer Self-efficacy (CSE)	I have the necessary skills to use new learning technologies without difficulty in induction classes.
Perceived Enjoyment (ENJ)	It would be more fun to use new learning technologies in my induction classes at the mining company.
Objective Usability (OU)	I think the new learning technologies would be easy and dynamic to use.
Perceptions of External Control (PEC)	Having the necessary opportunities, knowledge, and resources, it would be easy for me to use new learning technologies.
Subjective Norm (SN)	I think induction teachers think that new learning technologies could be helpful.
Experience (EXP)	I have experience in the use of a technological learning system.
Voluntariness (VOL)	I think that I would voluntarily access my induction classes with new learning technologies.
Perceived Ease of Use (PEOU)	I believe that new learning technologies will be easy to use.
Behavioral Intention (BI)	If I have the opportunity to take induction classes using new learning technologies, I would be happy to try it.
Use Behavior (USE)	I would use new learning technologies frequently in my induction classes.

C. Statistical Analysis with PLS-SEM

The obtained results in Google Forms were exported to an Excel file, delimited by commas. Finally, the Smart-PLS 3 software was used to obtain, through the partial least squares technique in structural equation models (PLS-SEM), statistical data such as minimum and maximum responses for each variable, standard deviations, the correlation coefficient between variables, coefficient route, hypothesis t-test, frequencies, percentages, arithmetic means, and discriminant validity [30].

IV. RESULTS

In Table IV, we observed that all the arithmetic means of the responses of each variable of the Technological Acceptance Model exceeded the neutral state given in the Likert scale (4 - "Neither disagree nor agree"). There is also highlighted that all the questions had the highest level on the Likert scale had a maximum score (7 - "Totally agree"), so we can affirm that the surveyed participants have the intention and acceptance of the use of new technology learning tools to be implemented in safety induction classes before entering the mining company. The variable with the highest average response was (BI), with a value of 6,326 on the Likert scale; this was followed by (USE) with a value of 6,196 on the same scale, reaffirming the technological acceptance by participants for the implementation of mining educational tools. Likewise, these last two were the variables with the lowest standard deviation, having a value of 0.957 and 0.947, respectively, which means the homogeneity of the surveyed responses. The variables with the lowest average response were Experience (EXP) and Subjective Norm (SN), with values of 5.500 and 5.674, respectively; in the same way, these two variables had the highest standard deviation with values of 1.514 and 1.445, respectively, demonstrating the high dispersion of responses from each intern and practitioner, having a minimum of 1 and a maximum of 7 on the Likert scale. It should be mentioned [11] that these are two of the most critical variables of the TAM3.

The bilateral correlation of the TAM3 variables is presented in Table V. It shows all the correlations have a strong and positive correlation, indicating coherence between variables. In Table VI, we appreciated to determine if the constructs have discriminant validity, a statistical test used to demonstrate the multicollinearity of the proposed model; this should be addressed if certain variables exceed the threshold for possible multicollinearity (0.7) [31]. We explained that the model has good reliability and construct validity.

In Fig. 1, the standardized trajectory coefficients between all the variables performed by Venkatesh [26] and the substantial variance (R²) in each of its four endogenous variables [32] can be appreciated. It is essential to mention that only four hypotheses were validated for the study according to the t-test where the value of 1.96 has to be exceeded [33], these being the relationships between IMG -> PU, REL -> PU, SN -> IMG, and BI -> USE, 2.422, 2.174, 4.139 and 5.488 respectively.

V. DISCUSSION

Our results show that interns' and practitioners' technological acceptance were successful since they are willing to adapt to new digital learning tools, such as in research where a group of students intends to use new pedagogical strategies [4]. They could find the implementation and functionalities interesting, supporting their knowledge, as happened in a study

that adopted an interactive web environment technology called MAgAdI at the University of the Basque Country [3]. It is intended to give the initiative to implement new digital learning tools in the mining industry, as recommended by a study where its findings foster crucial management decisions for the future implementation of information technologies [11]. It helps improve the academic performance effectively in the induction classes of the interns and practitioners before

entering the mine, as is the case of a study that provided facilities of its results to school providers to use new innovative pedagogical methods [34]. It is necessary to highlight that the topics offered in the induction classes of the participants are both theoretical and practical so that the new learning tools could contribute to the improvement of their performance, as argued in a study where the Perception of Mining Engineering students, concluding that the use of technology in education is necessary to improve student performance [4]. Learning tools allow the user to be transferred to a virtual environment where it is allowed to make mistakes and learn through experience safely, as indicated in an investigation with simulated immersive learning platforms where their findings indicated that students could avoid taking risks to demonstrate their capabilities in a safe environment [10]. A study conducted in 2019 mentioned that virtual laboratories might have the same or better learning outcomes than traditional laboratories [16], providing a unique learning experience [3], breaking the conventional scheme, and overlapping conventional learning [6], as we stated in the present study. In the present study, 46 pilot samples of different interns and practitioners of mining companies located in the macro-southern region of Peru were investigated to determine technological acceptance through TAM3, as was done in an article [35] where 44 respondents were studied, specifying that no there would be a problem in working with a small sample size since the results will be stable.

As we mentioned in the survey instructions, by new learning technologies, we mean: "virtual or augmented reality, holograms, interactive platforms, and mobile applications" according to the results had a positive impact on all TAM3 variables, as formulated by Venkatesh [35], especially in Use Behavior (USE) and Behavioral Intention (BI). The same situation occurred in a scientific production that shows that students' perception of virtual laboratories, simulators, interactive learning activities, and game-based learning positively influenced satisfaction, usefulness, and perceived ease of use [16]. An additional question was asked to the TAM3 to determine the preference of the studied participants towards a conventional class or a class with digital learning tools, where 89.13% of the total participants chose classes with innovative learning tools since these can keep employees focused positively and proactively as mentioned in a study conducted in Australia [23]. The participants in the presented studies rejected a conventional class, defined as a "lesson given by a teacher or trainer using 2D tools, such as slides, whiteboard, flipcharts, non-interactive videos"; it can generally cause stress and anxiety, reducing the value of learning [10] and being an obstacle to the adoption of a digital learning tool [25]. The present study used the partial least squares technique in structural equation models (PLS-SEM). Being very powerful and not having a minimum sample parameter gives us extra support for the validity of the results, as Said Al-Gahtani comments [32]. SmartPLS 3 software analyzed these data; it was used from the same firm by different studies associated with TAM evaluation [36] [37]. The results of the discriminant variance correlations mostly exceed the threshold of 0.7, confirming the construct's validity and the trajectory correlations of the present study. These were positive and strong, as evidenced by studies conducted between 2015 and

2021 [31][38]. The results also indicate that IMG significantly influences PU, as happens in a study carried out in Saudi Arabia, where it is specified that social influence processes were shown to affect perceived profit. On the other hand, the same study found that the instrumental cognitive function positively impacts Perceived Utility, as this article [32] did when validating the REL -> PU hypotheses.

It has been considered to use all external variables of Technology Acceptance Model 3 because they are considered more relevant concerning Unified Theory of Acceptance and Use of Technology 2 (UTAUT2), one of the essential acceptance models TAM3 [1]. The TAM3 was considered, unlike UTAUT2, because the external variables of the TAM3 facilitate the intention and maintain voluntariness [24], unlike UTAUT2, which predominates individual conditions such as gender, age, price value.

VI. CONCLUSION

Safety is necessary to provide qualified education to collaborators to increase their effectiveness by voluntary rules compliance, preserving the human resource that is the most crucial element of the companies, and saving accident expenses. It can be achieved using more effective pedagogical tools than traditional ones. However, it is essential to know if staff are willing to accept new learning technologies such as virtual or augmented reality, holograms, interactive platforms, and mobile applications. Before joining a mining company, interns and practitioners intend to use new technological learning tools in induction classes. We recommended expanding the sample of hired workers for future research work since they receive constant safety talks specified by the D.S. N ° 023-2017-EM, since integral management of the safety culture is being promoted, that goes from the highest rank to the lowest level; consequently, this would cause a change in attitude in the company members, making them take care of each other. We recommend mining and industrial companies implement new digital learning tools to train human resources and improve the development of their skills in occupational safety and health. There is limited research on technological acceptance to help management decision-making. It is necessary to imply that studies on the implementation of pedagogical technologies should not be centralized only in schools or universities, mining, and industrial companies where education can save lives, so we recommended developing scientific production in that theme and domain.

Abstract—Symbol recognition has generated research interest for image analytics of engineering diagrams. Techniques including structural, syntactic, statistical, Convolution Neural Network (CNN) were studied to identify gaps of research. Despite popularity, CNN requires huge learning dataset, which often involves costly procurement. To address this, combination between CycleGAN and CNN is proposed. CycleGAN generates more learning dataset synthetically, thus yielding opportunity to improve accuracy of symbol recognition. In the domain of for engineering symbols, standard CNN model is developed and used in experimental testing. Different ratios of training dataset were tested in multiple experiments using Piping and Instrument Diagram (P&IDs) drawings. Result of highest accuracy for symbol recognition is up to 92.85% against baseline and other method. The results determined that gradual reduction of training samples, the effectiveness of recognition accuracy performance after using proposed method was remained substantially stable.

Keywords—Symbol recognition; symbol spotting; engineering drawing; convolution neural network (CNN); CycleGAN; piping and instrument diagram (P&ID)

I. INTRODUCTION

Symbol recognition is a subset of ordinary pattern recognition which focusing on identifying, detecting, and recognizing components in technical drawings. Pattern recognition is a complicated process that requires to analyze data input, feature extraction, classification, and post processing. Therefore, various functions are needed for pattern recognizer. Recognizing familiar patterns automatically is an essential pattern. However, recognition does not work accurately when identifying and classifying unfamiliar objects. Insufficient data input is one of the factors.

An application of symbol recognition is for analysis of engineering drawing. Engineering drawings are frequently used in many fields such as Oil and Gas, manufacturing, construction, and engineering. In this study, Piping and Instrument Diagrams (P&ID) are selected. P&ID are schematic diagrams representing different components and flows in a manufacturing process design for a physical plant. These diagrams aid analysis of operability and safety of a process design.

More samples for engineering drawings may produce impactful benefits due to the application for plant safety. The technique is focusing on Oil and Gas field simultaneously can be generalized for other fields of engineering drawing too.

The motivation to study this technique is due to various factors:

- Current research & development trend focuses on smarter digital diagram for better image analytics. Application of the technology includes determining root cause and inferring risk of a safety deviation.
- Digitisation of schematic diagrams and image analytics are instrumental for Digital Twin (DT) in Cyber-Physical System (CPS) designs. DT provides richer information and more potentials than digital engineering drawing application. These include prospective planning, analysis of existing systems or process-parallel monitoring. In all cases, DT offers exceptional ability to create simulations in which various development and testing work can be carried out.

Identifying components inside a digital drawing is necessary in analysis. However, this is difficult because of the drawing's layout complexity. Wrong identification of any component can lead to a faulty analysis, thus posing risk to safety and operability.

There are three main types of pattern recognition mechanisms used to classify input data. Those types are statistical, structural (syntactic), neural. Statistical methods simply collect historical data and identify new patterns based on observations and analysis of that data. The structural technique is also known as the syntactic method since it is based on primitive sub-patterns. Machines do direct computing in the pattern recognition approaches covered so far. Mathematical and statistical techniques are used in direct calculations. Last but not least, neural approach applies biological concepts into technology for recognizing patterns. The result of this effort was the invention of artificial neural networks. A neural network is an information processing system. However, deep learning is becoming more popular as a result of its superior accuracy while training with huge volumes of data. A neural network-based deep learning method is used. Neural approach is less efficient at processing tasks than deep learning systems, which provide excellent efficiency and performance for tasks. Recently, Convolution Neural Network (CNN) is a class of deep neural networks with the most applications.

CNN has shortcomings for analysis of engineering drawings, in that the model used has not been sufficiently trained for engineering drawing domain. The challenge

concerns on huge quantity amount of data samples are required for training to obtain more accurate classification and recognition in training process. Some of the samples are difficult to collect for engineering drawings especially in P&ID diagrams [1]. The accuracy of recognition is important for analysis of engineering design issues such as operability and safety. Nonetheless, having to work hard to manually collect and correct a huge number of sample images for training remains a significant limitation[2]. Methods that rely on artificial training data are recommended. Therefore, a data augmentation technique is proposed called CycleGAN along with CNN to enhance the accuracy of symbol recognition.

The rest of this paper is organized as follows. Section II reviews the associated literatures with the research topic on pattern recognition approaches. Section III illustrates the proposed framework on enhancing the accuracy of recognition rate. Section IV presents the experimental results. Section V interprets the significant findings along with discussion. Section VI concludes the paper and mentions the future works in this study.

II. RELATED WORK

A. Symbol Recognition Trend

Symbol recognition and spotting is an innovative computer vision technology. This technology aims to replicate portions of the human visual system’s complexing, able to allow computers to recognize and interpret within images or videos. Engineering benefits mankind and technology symbolizes the future. Over the recent years, numerous challenges of computer vision were gradually emerged. Surprisingly, many

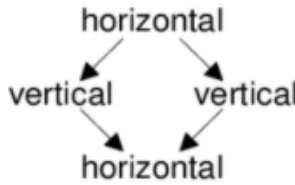

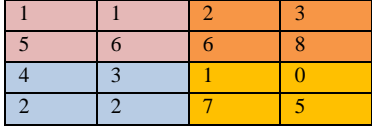

great efforts and solution have been cracked during the evolution timeline.

Table I summarizes the research trend for symbol spotting in the recent years. Symbol Spotting is an active topic in graphical symbol recognition and document analysis. In fact, some of the research papers are focusing on the sub-sections of the issues which are including symbol recognition, symbol detection, and primitive extraction. Those papers are altering from traditional symbol recognition towards the new conceptual of symbol recognition gradually. Symbol spotting has been enhanced in recent years persistently.

There is a demand to design an engineering drawings symbol recognition method compared to few approaches in Table I. Based on the review of history, the state-of-the-art approaches are keep replacing with better algorithms.

Statistical approach has been used precedent for pattern recognition since it is simple to manage. This approach mainly based on statistics and probabilities. Each pattern is obtained in terms of feature collection. The effectiveness of quality pattern depends on the set of feature extraction or measurement. It includes the pre-processing, and the segmentation is not required compared to local pattern representation. The decision boundary is established in the feature extraction via the analysis of probability distribution. Thus, different patterns allocate to the classes respectively. However, this approach has fault tolerant to image distortion since they tend to filter out small change in details.

TABLE I. EVOLUTION OF SYMBOL RECOGNITION TREND

Category approach	Pattern Recognition	Survey
Statistical: statistical features (geometric moments, R-signatures, etc.) + similarity measures	Number of segments: 4 Number of horizontal segments: 2 Number of vertical segments: 2 Number of diagonal segments: 0	Santosh et al. [3-5], 2015, 2016, 2018
Structural: graph-based matching + structural descriptors (visual primitives/ their spatial relations)

GNL method for both the small- and large-symbol networks		Kim et al.[11], 2021

In graphical documents, many objects can be graphically described, especially symbols [12]. Through structural recognition approach for symbols, the patterns can be represented as graphs. The characteristics of patterns are formed based on structure. Recognizing symbol is normally applied with structural recognition but this approach also can implement with other objectives such as learning, data structuring, indexing and others. It is also known as syntactic recognition occasionally since both are using the same formal language theory. Structural depends on the grammars to differentiate between data from several groups based on morphological interrelationships contained within the data. The sub patterns and the interactions between them that make up the data are represented by structural features, also known as primitives. However, recognize the primitives occur many troubles which primarily must focus on segmentation of noisy patterns and gram-mar inference from training data.

Syntactic recognition uses the structure of patterns and the syntax of language to construct a shape. The patterns are depended on the sentences in a language. The patterns are considered as sentences in a language, the primitives are viewed as the language's alphabet, and the sentences are formed using a grammar [12]. Thus, few numbers of primitives and grammatical rules are able to express complex patterns.

Structural and syntactic techniques are much closer to human comprehension. These techniques outperform the statistical in the case of complex symbols. However, the accuracy is obstructed the performance of the vectorization process, and matching based on graph representation which requires high computation cost.

Convolutional neural network (CNN) is a type of artificial neural network. This technique is the most popular to be applied in the recent year [8, 9, 13]. The employment of CNN is not restricted in image classification, recognition, and detection but also in Natural Language Processing (NLP). Therefore, the extensiveness of CNN application is broadly. The CNN achievements are also extravagance; produced many earth-shattering results in computer vision.

B. CNN Architecture in Image Processing

Most of the CNN architectures are based on supervised learning. A large amount of data is needed as a training sample to obtain more accurate classification and recognition in training process. Through enough training on data, CNN can overcome the limitations of the conventional methods such as inter-object interruption, morphological change, and noise problems [8]. However, some samples are difficult to collect. For example, the specific symbols in P&IDs drawings. It is extremely difficult to collect samples due to the limitations of the conditions.

CNN architecture model can be separated into two components which containing features extraction and classification. Feature extraction is performed by the convolution and pooling layers. Detect meaningful features in an image is a complicated task. The convolution layers have to learn such sophisticated features to illustrate the pattern shapes via pixels. Nan S. [14] experimented several feature extraction

algorithms at CNN model. FCN-CRF achieved highest average accuracy for image segmentation and average intersection-over-union compared with Support Vector Machine (SVM), K-means and FCN algorithms.

The few novelties [1, 6, 8] resulted the limited amount of training data for engineering drawing lower the accuracy of recognition. In additional, the lack of datasets occurs the class imbalance problem in classification.

C. Review Data Augmentation

Although more data samples can enhance the machine learning models, in fact collecting more data is not a best solution which channelling into a research topic. Data augmentation is a technique which providing more quantities of synthetic samples. This allows the algorithm to recognize and detect the specific components in an image precisely. Lan Goodfellow [15] proposed a framework called Generative Adversarial Network (GAN). The benefit of GAN can generate more synthetic samples to overcome the shortage and elevate the accuracy of object spotting. GAN is a type of machine learning model which consists of two neural networks compete with each other in order to provide more realistic image in the prediction.

GAN has been implemented in many applications previously for synthesizing more quality images and adding more training data in several studies. Shrivastava et al. [16] developed a GAN-based refiner network and enhanced the realism of simulated eye I mages by developing a GAN-based refiner network, resulting a 21% improvement in performance of an eye gaze estimation algorithm. In the field of medicine analyses, the shortage of image data is also commonly happened due to the lack of available images. Therefore, GAN play a role to synthesize realistic training data for liver lesion images [17], and brain MR images [18].

However, GAN training is highly unsteady because the discriminator and generator training needs to be delicately balanced. A common failure from mode collapse can be happened if the discriminator is too fierce or overwhelms the generator early during training, which results in convergence to a bad local optimum. Therefore, a new technique needs to be discovered instead of replacing GAN.

D. CycleGAN

CycleGAN is a subset of GAN technique which generating the automatic training of image-to-image translation models with unpaired examples. Some related works have been explored recently at the below.

Liu et. al. [19] applied stratified CycleGAN in medical images that generated graded variation in image quality. They resulted quality synthetic images using CycleGAN method. Zhang et. al. [20] presented a novel about road extraction method in generative adversarial network using Aerial images, require few samples and resulted better performance compared with several state-of-the-art techniques in term of detection accuracy. Park et. al. [21] implemented Dense-Net based framework in CycleGAN have eliminated data imbalance issue and deliver a better detection accuracy for wildfires images. Liu et.al. [22] equipped CycleGAN strategy to address ghosting problem. This work synthesizes video

context information and captures interframe stability better. Thus, CycleGAN is one of the impacts on the accuracy of recognition and spotting. The accuracy of the recognition can be influenced by producing more variance images.

III. METHODOLOGY

A. Symbols Dataset – Piping and Instrument Drawings (P&IDs)

Engineering drawings consists of several types of fields. Piping & Instrument Drawings is appointed to be our scope of study. The total number of collections from Piping & Instrument Drawings (P&IDs) is restricted into 7 sheets only due to limited public datasets available. However, this can highlight the problem then figure out a better solution.

In these experiments, only 7 types of symbols are extracted from the P&IDs. These types of symbols which including (a) Check valve, (b) Gate valve, (c) Gate_NC valve, (d) Globe valve, (e) Globe_NC valve, (f) Concentric reducer, (g) Weldcap. These symbols are shown in Fig. 1.

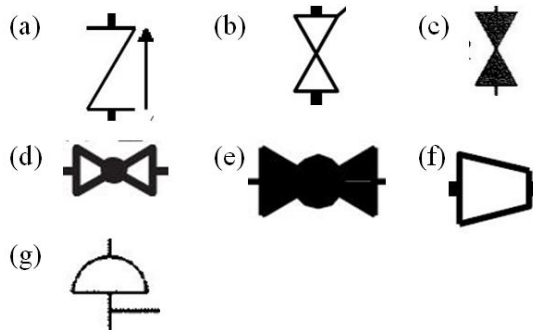

Fig. 1. Types of Symbols Extracted from P&IDs.

In additional, a total number collection of extracted symbols from P&IDs are 1,873. The following Fig. 2 summarized the number of symbols distributed for each class.

Each P&ID sheet displays different qualities of components. Qualities is one of the factors affects the accuracy for spotting. More data information with various qualities can provides the confidence to recognize the symbols precisely. Therefore, the limited symbols from P&IDs will conduct with advanced data augmentation technique to deliver more various qualities images.

Fig. 2. Class Distribution of Symbols in Whole Dataset.

B. Symbol Recognition – CNN Algorithm

Symbols require an algorithm tool for recognizing. Therefore, a basic Convolution Neural Network (CNN) algorithm to be implemented. The implementation of CNN able to predict several class probabilities and bounding boxes simultaneously.

The CNN architecture involves several convolutional layers, max pooling layers and fully connected layers. A tensor which representing the data structure is required to proceed through several convolutional layers. Then, it is converted to a vector and then transmitted through a dense layer. The overview of CNN architecture is displayed in Fig. 3.

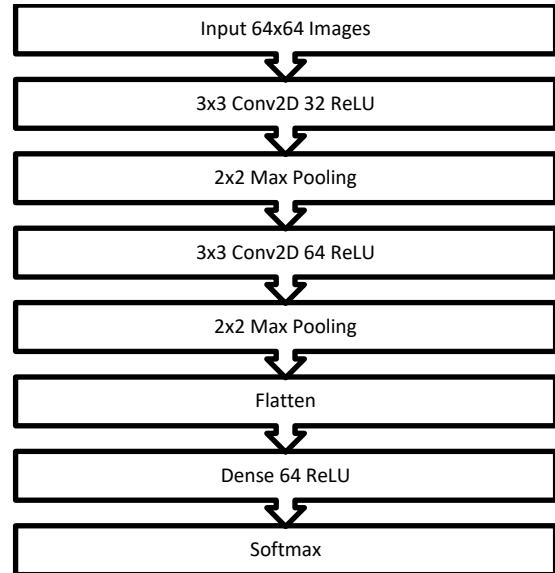

Fig. 3. Basic of CNN Architecture.

Input Images: All the extracted symbols from P&ID drawings and synthetics symbols are converted into 64x64 pixels.

$M \times M$ Conv2D N : In this basic CNN architecture, 2D convolution layer is used, this layer creates a convolution kernel or filter over the input data and perform an elementwise multiplication to produce a tensor of output pixel. Kernel is a convolution matrix or filter that used for features extraction in image processing including blurring, sharpening, embossing, edge detection, and others. $M \times M$ represents the size of filters, and N represents the numbers of filters that the convolution layer learns.

ReLU: Stands for Rectified Linear Unit. Commonly used as an activation function of the CNN layers and the fully connected layers because it is simple, fast, and empirically converge quickly and reliably when training a deep network.

$M \times M$ Max Pooling: Extract each patch from input featured maps. Generally, a filter of size 2x2 with a stride of 2 is implemented. The pooling is downsampling the feature map then spotlight the conspicuous feature in each patch.

Flatten: Also known as fully-connected layer for connecting the final classification model. Flatten the last output of feature map once the model has learnt the features. However, the flatten layer is used to convert the data into 1-dimensional array (1D) for the next layer's input.

Dense: A simple layer for neurons. Each neuron receives an input from the previous layer's neurons. This is used for classifying or predicting image based on the output from previous layers via shallow neural network.

Softmax: Commonly a final output layer in neural network. It is an activation function for generalization of the Sigmoid function but in multiple dimensions. It is used for performing multiclass classification and object recognition. Thus, it normalizes the output as probability distribution to each class.

C. Pre-processing

Prior to any work, the whole dataset containing different number of symbols for each class. All symbols were cropped into a size of 64 x 64 pixels.

According to previous related works, few novelties described the limitation of images. However, there is no findings specify an exact volume. Therefore, 3 methods were conducted in this study including Baseline CNN, CycleGAN + CNN, and Y.Zhang [9] algorithm as for comparison. Each method conducts several experiments with all the extracted symbols from P&IDs drawings. These symbols are classifying into three categories of datasets which including training dataset, validation dataset, and testing dataset. In these experiments, different ratios for training dataset are implemented while validation dataset and testing dataset remain unchanged. The highest ratio of training dataset is up to 4 and lowest ratio is 0.5. The scheme for classifying datasets and the description of each method is shown below:

In Fig. 4, the scheme illustrates the division for training dataset, validation dataset, and testing dataset. The ratio in whole dataset is 1:1:1. The training dataset is further using to implement on the synthetic models which described in Method 2 and Method 3 in the following paragraph. The synthetic images are generated via a model by applying the training dataset with different ratios.

Fig. 4. Dataset Division.

Method 1: Baseline CNN

In baseline CNN method, only extracted symbols of P&IDs to be implemented. The standard CNN algorithm is

used to determine the symbol recognition rate against Method 2 and 3. The numbers of extracted P&ID symbols are calculated as ratio. TABLE II shows the ratio of validation dataset and testing dataset were fixed into 1 while the ratio of training dataset was keep reducing to validate the diversity accuracy of symbol recognition.

TABLE II. BASELINE CNN DATASETS

Baseline (Datasets)		
Training	Validation	Testing
N/A	1	1
N/A	1	1
N/A	1	1
1 (100% training dataset)	1	1
0.75 (75% training dataset)	1	1
0.5 (50% training dataset)	1	1

Method 2: CycleGAN + CNN

Same as Method 1, all extracted P&ID symbols split into training dataset, validation dataset, and testing dataset. However, this method involved synthetic images generated via CycleGAN model to enlarge variation symbols. The synthetic images are added into training dataset for increasing and equalizing the ratio. Then, CNN is used to recognize and classifying the symbols.

In this TABLE III, different ratio numbers of training dataset were tested to discover the difference accuracy recognition of P&IDs symbols.

TABLE III. CYCLEGAN+CYCLEGAN DATASETS

CycleGAN (Datasets)		
Training	Validation	Testing
4 (100% training dataset + 300% synthetic samples)	1	1
3 (100% training dataset + 200% synthetic samples)	1	1
2 (100% training dataset + 100% synthetic samples)	1	1
N/A	1	1
0.75 (75% training dataset)	1	1
0.5 (50% training dataset)	1	1

Method 3: Y.Zhang[9] algorithm

In Method 3, Y.Zhang[9] algorithm was implemented as for the validation against other methods. Since the P&ID symbols used are different from the origin paper, the pattern of the symbols was customized to tally these extracted symbols of P&IDs while the parameters of algorithm remained unchanged in [9]. The feature of this algorithm is to augment synthetic images with various scales, rotations, and random noises. These experiments were applied the ratio of training dataset same as Method 2 in TABLE IV.

TABLE IV. Y.ZHANG [9] ALGORITHM DATASETS

Y.Zhang [9] algorithm (Datasets)		
Training	Validation	Testing
4 (100% training dataset + 300% synthetic samples)	1	1
3 (100% training dataset + 200% synthetic samples)	1	1
2 (100% training dataset + 100% synthetic samples)	1	1
N/A	1	1
0.75 (75% training dataset)	1	1
0.5 (50% training dataset)	1	1

D. Proposed Methodology

Data augmentation is necessary because the limited symbols unable to provide the confidence during recognizing. We proposed to employ CycleGAN [23] with Convolution Neural Network(CNN).

In Fig. 5, the overview of proposed framework is displayed. CycleGAN is an unsupervised deep learning method which conducting a bidirectional translation between the two source domains which are domain X and target domain Y. Generally, the images collection from the source domain and target domain are not requirement that they are associated in any manner. The characteristics of CycleGAN implements two generator networks and a discriminator network for appraisal. Generator (G) and Discriminator (D) networks compete with one another. D is a classifier which trying to distinguish the samples between the synthetic images that generated via generator (fake) and the actual distribution (real). On the other hand, role of G attempts to fool the discriminator by producing synthetic output image. The input of the generator is along with source domain image x from Domain X and its output is a synthetic image. In additional, the inputs of a discriminator D are the synthetic output and an unpaired random image from the target image y of domain Y.

Even though CycleGAN allows unpaired random image but we apply a set of symbol images from a random class for consistent comparison.

Each generator in CycleGAN model involves an encoder, a transformer, and a decoder. Role of the generator ensures the features of images are extracted and converted into transformer (latent space). Transformer uses an attention mechanism to transfer the sequence to decoder. Then, a new feature vector of image is converted and reconstructed as output image in decoder.

In cycleGAN, the discriminator model is implemented as a PatchGAN model [23] which aims at classifying images as real or synthetic. The discrimination starts undergoing an appraisal with identifying the image belongs to real or synthetic. For discrimination, we apply adversarial losses [23] into both mapping functions to match up between the output generated images and real images from domain Y . For the mapping function $G: X \rightarrow Y$ and the discriminator Domain Y, where Generator(G) seeks to generate images $G(x)$ which looking closely images of domain Y, while discriminator D_Y is applied to distinguish between generated images of $G(x)$ and real images y of domain Y. G aims to minimize this training objective but D that tries to maximize it. Therefore, adversarial loss function is used to inverse mapping the first generator resulting $\min_G \max_{D_Y} L_{GAN}(G, D_Y, X, Y)$. A same adversarial loss for the mapping function on second generator (F). According to Figure 5, $F: Y \rightarrow X$ and its discriminator D_X as well resulting $\min_F \max_{D_X} L_{GAN}(F, D_X, X, Y)$.

Adversarial training learns mappings between G and F to generate the outputs closely to target domains Y and X respectively. Nevertheless, adversarial loss alone is uncertain to map the learned function onto an individual input x_i to a desired output y_i . but stimulate the tolerance of the cycle consistency. The cycle consistent argued the learned mapping functions to be further narrowed the space of the possible mapping functions for each image x of domain X. Thus, the image proceeds with translation cycle function to return image.

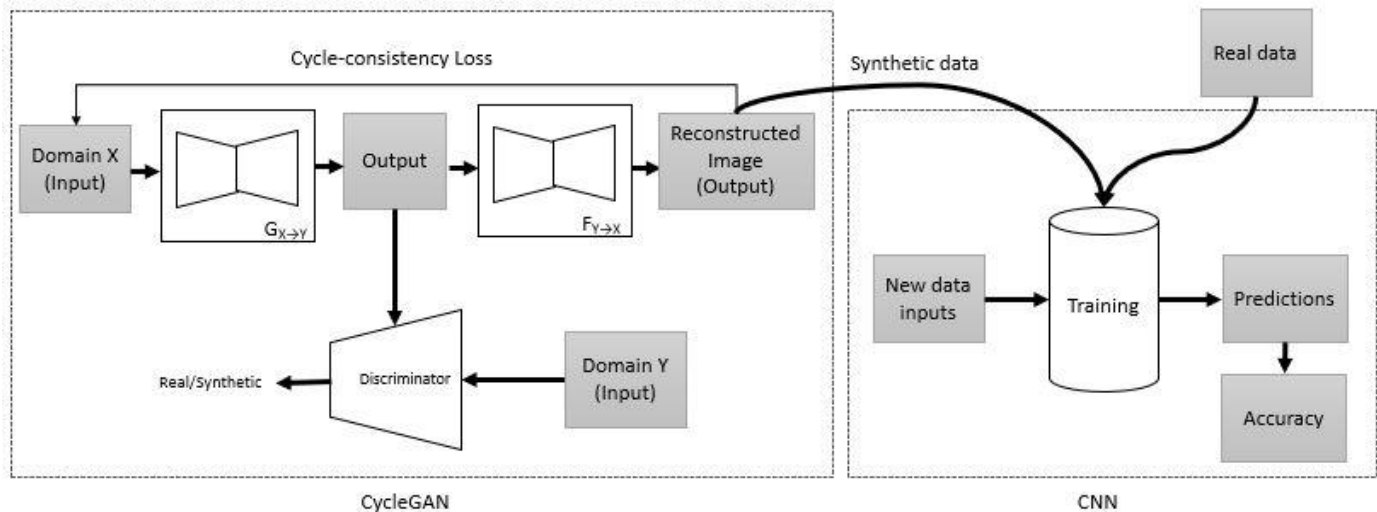

Fig. 5. Proposed Framework: CycleGAN (Generate Synthetic Samples) + CNN (Symbols Recognition).

x back to the original image intimately which resulting as $x \rightarrow G(x) \rightarrow F(G(x)) \approx x$. This referred to forward cycle consistency. Besides, every image y from domain Y , G and F should repeat with backward cycle consistency resulting $y \rightarrow F(y) \rightarrow G(F(y)) \approx y$. This function is impelled by a cycle consistency loss.

Algorithm 1: CycleGAN Pseudocode

```

1: procedure TRAINCYCLEGAN
2: Select samples  $\{x_i\}$  from domain  $X$ 
3: Select samples  $\{y_i\}$  from domain  $Y$ 
4: Compute generator  $G: X \rightarrow Y$ 
5: Compute the discriminator loss on Domain  $Y$ :

$$\mathcal{L}_{GAN}(G, D_Y, X, Y) = \mathbb{E}_{y \sim p_{data}(y)} [\log D_Y(y)]$$

$$+ \mathbb{E}_{x \sim p_{data}(x)} [\log(1 - D_Y(G(x)))] \quad (1)$$

6: Compute generator  $F: Y \rightarrow X$ 
7: Compute Cycle-consistency loss:

$$\mathcal{L}_{cyc}(G, F) = \mathbb{E}_{x \sim p_{data}(x)} [\|F(G(x)) - x\|_1]$$

$$+ \mathbb{E}_{y \sim p_{data}(y)} [\|G(F(y)) - y\|_1] \quad (2)$$

```

The generated synthetic samples via CycleGAN model to be transferred into second stage for CNN recognition predictions. In CNN stage, mixing synthetic samples and real training data to increase the numbers of dataset for training model. This adding more various patterns and finetune the training model to achieve more accurate performance.

E. CycleGAN + CNN Hyperparameters

The hyperparameter setups for CycleGAN [23] and CNN model were displayed in TABLE V and TABLE VI. These setups were standard in the Tensorflow implementation.

TABLE V. HYPERPARAMETERS FOR CYCLEGAN

Hyperparameters CycleGAN	
Learning rate	0.002
Epochs	50
Beta	0.5
Adversarial loss	L2 Distance
Cycle loss	10
Identity loss	5

TABLE VI. HYPERPARAMETERS FOR CNN

Hyperparameters CNN	
Learning rate	0.01
Batch size	32
Epochs	60

IV. EXPERIMENTS AND RESULTS

A. Evaluation Metrics

The evaluation metrics is implemented with the accuracy of recognition and confusion matrix.

According to the accuracy of recognition metric, Equation 3 is shown below:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

In this equation contains four important terminologies. TP represents the number of positives, TN represents the number of negatives, FP denotes the number of false positives, FN denotes the number of false negatives. The formula of Equation 3 is the total number of samples are divided by the sum of true positives and true negatives gives an overall assessment of the classifier performs across every classes.

Furthermore, another evaluation metric is confusion matrix, also called error matrix. It is a summarized table that is used to evaluate a classification model's performance. The number of positives and negatives predictions are totaled and broken down by class using count values. In confusion matrix table, predicted classifications are indicated by rows while true positives are indicated in every classes respectively by columns.

B. Experiments Results

The experiment results are displayed in TABLE VII. This table showed:

According to TABLE VIII, the results summarized the highest average accuracy is up to 92.85% which belonging to CycleGAN + CNN method. Compared to baseline CNN method with a ratio of 1:1:1, there are no synthesis images or symbol reduction in the dataset, the average accuracy is only 90.75%.

Furthermore, it is undeniable that the average accuracy is decreasing when reducing the number of training symbols in the Baseline CNN method. However, the CycleGAN+CNN method still has higher average accuracy at ratios of 0.5 and 0.75 as a training dataset compared to the Baseline and Y.Zhang [9] algorithm. In contrast, the CycleGAN model was able to generate a large number of synthetic images, but a ratio of 3 and a ratio of 4 average accuracy showed a significant drop in results as the training dataset size increased.

In Y.Zhang [9] method, the average accuracy in all ratios of training dataset are significantly lower compared to Baseline CNN and CycleGAN + CNN methods. These results showed that not all methods that can generate synthetic images improve accuracy due to several factors.

In Fig. 6, a clustered chart displayed the accuracy over the different ratio of training dataset based on the values from TABLE VIII. Various colors represent different methods. CycleGAN + CNN method achieved the peak accuracy values against another methods with all different ratios of training dataset.

TABLE VII. EXPERIMENTAL RESULTS - RECOGNITION ACCURACIES

Dataset Ratio			Baseline CNN (Without synthetic samples)					CycleGAN + CNN					Y.Zhang [9]

Fig. 6. Cluster Chart for Average Accuracies of Symbol Recognition.

The confusion matrix between Baseline method and CycleGAN method were shown in TABLE IX and TABLE X.

According to TABLE IX and TABLE X, each alphabet represents a type of symbol which is displayed in Section III. Both tables highlighted the difference of symbol recognition. As per comparison, (A) Check valve, (B) Gate valve, and (F) Concentric reducer showed the significant gaps. One of the reasons could be the variation issues. It requires more variation symbols to match with the P&ID symbols in testing dataset. In fact, CycleGAN model generate more variation synthetic images allow CNN architecture to recognize precisely especially these three types of symbols.

TABLE IX. CONFUSION MATRIX FOR THE BASELINE CNN MODEL

V. DISCUSSION

According to Section IV, several experiments were tested on different methods. Our proposed framework resulted the combination of CycleGAN and CNN performed effectiveness on accuracy of recognition. Highest average accuracy up to 92.85% was achieved. The result showed CycleGAN the potential when trained on the synthetic samples. It performed better than the algorithm used in Y.Zhang [9]. Using CycleGAN model, generated synthetic samples increased the dataset for training. This provides CNN model better classifying and recognizing with sufficient training. Nevertheless, the confusion matrix of our proposed framework displayed a greater total number of true positives which recognized the specific symbols accurately.

Another interesting aspect from the results, different ratios of training dataset were conducted during experiments testing. Significantly, the accuracy rate of recognition gradually lower down when applying ratio 0.5:0.75 as the training data samples. The work proved the superior of synthetic samples from proposed method. Added CycleGAN synthetic samples to increase back to 100% or ratio 1 of the training dataset. It performed great contribution to accuracy rate even achieved higher than the standard 100% of training dataset from baseline CNN method without adding any synthetic samples. In addition, the incremental ratio of synthetic samples is scaled up to 400%. The best accuracy rate was performed with ratio 2 while ratio 3:4 start declined the accuracy of recognition.

VI. CONCLUSION AND FUTURE WORKS

In this study, the accuracy enhancement for recognizing symbols of engineering drawings required a data augmentation technique. We proposed CycleGAN + CNN method for synthetic symbols to enlarge the quantities of symbols in Piping & Instrument Diagrams (P&IDs). Our work addresses the lack of labelled data in deep networks by utilizing CycleGAN to generate synthetic images to supplement training data. We achieved the highest average accuracy of this method as high as 92.85%, which is a significant enhancement over CNN recognition alone. However, excessiveness or insufficient images can reduce the accuracy of recognition rate due to some factors such as overfitting and underfitting.

Future work is schemed to apply spatial transformations in CycleGAN architecture. If there are too many changes, it is difficult for the generator to learn the basic style efficiently. Additionally, spotting all types of symbols in an engineering drawing. An advanced object detection algorithm will be studied especially design for symbols. This will allow to detect symbols precisely regardless the pixel of engineering drawings and the size of symbols.

Abstract—OLAP (Online Analytical Processing) is a tried-and-tested technology and a core concept in Business Intelligence. With data flowing from different and countless sources, exploring data in order to deliver actionable insights has become a daunting task with current OLAP tools despite the cycle of improvement that has gone through it. In the last decade, with the emergence of the big data phenomenon, NoSQL databases are seeing a spike in popularity and become more used in industry and academia as their value in handling a huge and varied amount of data become increasingly evident. Graph oriented database is one of the four chief types of NoSQL oriented databases that represent a promising technology candidate for big data analytics. In this paper we bring forward our contribution to graph-oriented analytical processing, which is twofold. First, we provide a novel approach for modeling a graph-oriented data warehouse. Second, we propose a data cube materialization through the precomputation of aggregated nodes. We present how typical OLAP queries can be performed against data warehouses stored in NoSQL graph-oriented database management systems. An implementation is conducted on a fictional data warehouse using Neo4j and the Cypher declarative language. The same dataset is stored in a relational data warehouse in order to compare storage space and query performance. Thus, the obtained results shows that graph OLAP implementation outperform clearly the relational alternative in term of query response time.

Keywords—Graph OLAP; data warehousing; graph databases; NoSQL; data cube; decision support system

I. INTRODUCTION

OLAP stands for (Online Analytical Processing) and describe a software technology dedicated to decision-making purpose. It is designed to locate meaningful intersections between multiple axes of analysis. The dimensional modelling is an integral part of OLAP systems and defines at the conceptual level the fact concept which holds measurements or metrics regarding a business process event, and the dimension concept which provides a context describing the fact. Data conversion from an OLTP (Online Transaction Processing) database of two-dimensional to the multi-dimensional model is done by an ETL (Extract, Transform, Load) tool. OLAP servers have historically been implemented mainly using four approaches: Relational-OLAP(ROLAP), Multidimensional-OLAP(MOLAP), Hybrid-OLAP(HOLAP) and Desktop-OLAP(DOLAP) [1], [2]. Each implementation has its strengths and its limitation and must be evaluated based on the business requirements.

With the IT revolution, and being aware of the potential of information, organizations around the globe has moved from the archaic age, which relies on industrial economy into a new era characterized by data driven economy. This race after technology in order to gain competitive advantages has contributed to the generation of large volumes of data. As a consequence, data analytics are becoming a huge challenge for traditional OLAP systems due its vertical scalability and its low computation ability. Indeed, earlier-generation of OLAP implementations are of poor storage and computational capacities, because they are built upon on old architectures and cannot match the requirement of big data analytics, especially data storage and data retrieval requirements. Another common problem is OLAP cube building over big data which could reach a critical complexity due to the increasing number of dimensions and the unstructured nature which characterize big data sets [3],[4].

To overcome the challenges of scale and complexity associated with today's data, OLAP researches moved in a new direction. Namely, the use of NoSQL databases in OLAP solutions which is considered as a promising alternative for traditional data storage tools [5]–[8], [9]. This revolutionary technology offers several interesting features that cannot be achieved with classical database management systems like cluster computing and the ability to process both semi-structured and unstructured data. In this paper, we are focused particularly in graph database, a class of NoSQL databases that uses a graph model composed of nodes and edges instead of relational model [10][11], and we claim that the graph data structure is suitable for data warehousing and online analysis.

Implementing an OLAP cube using a graph database is not a straightforward process. The multidimensional model used to instantiate the data cube must be converted to a logical model suitable to graph oriented database. Furthermore, typical OLAP queries must be translated to a specific language supported by this technology. The aim of this work is to illustrate the potentiality of graph databases to handle OLAP structures designed for reporting. In this context, we define a set of mapping rules in order to migrate dimensionally modelled data into the graph database. And we demonstrate how typical OLAP operations can be performed against a graph database. In Fig. 1, we position our proposal regarding the literature. The key contributions of this work can be summarized as follows:

- We propose an implementation of OLAP engines under graph database using two different logical models that are equivalent to ROLAP and MOLAP models. We define a set of rules used for the mapping from the multidimensional model to these models. An experiment is conducted to highlight the differences between the two meta-models using a case study.
- We propose an effective aggregation technique to build the lattice of cuboids from a data warehouse built upon a graph database management system.
- Then, we provide an extension of the declarative Cypher language to basic OLAP queries. We consider in this work Neo4j as a graph database engine.

The remainder of this paper is structured as follows. In the next section we present the background of our work, and we provide an overview of the state of the art related on Graph-OLAP. In Section III we present our modeling approach for graph OLAP. In Section IV we give an implementation of the proposed approach using the Cypher language. In Section V, we discuss experimental results. The last section concludes this work and suggests eventual research directions.

II. RELATED WORK

A. The Multidimensional Schema

The multidimensional schema is the starting point to design and implement data warehouse systems. It defines four major concepts: fact, measures, dimensions and hierarchies [12].

Formally, a Multidimensional Schema denoted S is a triplet $(F^S, D^S, Star^S)$ where:

- $F^S = \{F_1, \dots, F_n\}$ a finite set of facts.
- $D^S = \{D_1, \dots, D_m\}$ a finite set of dimensions.

$Star^S : F_i \rightarrow 2^{D_i}$ is an incidence function mapping each fact $F_i \in F^S$ to its associated dimensions $D_j \in D^S$.

A **fact** is the business process studied and is represented by a pair (N^{F_i}, M^{F_i}) where:

- N^{F_i} is the name of the fact.
- $M^{F_i} = \{m_1^{F_i}, \dots, m_n^{F_i}\}$ a finite set of measures.

A dimension $D_i \in D^S$ is defined by $(N^{D_i}, Att^{D_i}, H^{D_i})$ where:

- N^{D_i} is the name of the dimension.
- $Att^{D_i} = \{a_1^{D_i}, \dots, a_m^{D_i}\}$ a finite set of attributes.
- $H^{D_i} = \{l_1^{D_i}, \dots, l_k^{D_i}\}$ a set of hierarchy levels.

A hierarchy organizes measures at different level of aggregations. A hierarchy level $l_j^{D_i} \in H^{D_i}$ can be defined by $(N^{l_j^{D_i}}, Att^{l_j^{D_i}}, Weak^{l_j^{D_i}})$ where:

- $N^{l_j^{D_i}}$ is the name of the hierarchy level.
- $Att^{l_j^{D_i}} = \{a_1^{l_j^{D_i}}, \dots, a_m^{l_j^{D_i}}\}$ an ordered set of attributes.
- $Weak^{l_j^{D_i}} : a_j^{l_j^{D_i}} \rightarrow \{wa_1, \dots, wa_k\}$ is a function possibly associating parameters to a set of weak attributes.

B. The Graph Model

NoSQL graph-oriented database are based upon the concepts of graph model which organize data into collections of nodes and edges. Once data loaded, graph theory algorithms make it easy to handle semantic queries by calculating the shortest path between nodes. Graph database specify connections at insert time and avoid by then the problem of join index lookup performance as querying data becomes a matter of graph traversal. This makes graph engines optimum when the meta-model of data being stored has many overlapping relationships. This contrast with relational database which store the links between tables at the logical level and relies on relational algebra operations to manipulate the data stored in the database management systems in a relevant logical format.

Formally, a graph database denoted G is a set of properties $(N, E, \phi, L_N, L_E, P_N, P_E)$ comprising:

- N a set of nodes (also called vertices).
- $E \subseteq N \times N$ a set of edges (also called links).
- $\phi : E \rightarrow \{\{x, y\} \mid x, y \in N, x \neq y\}$ a function linking an edge to a pair of nodes.
- $L_N = \{l_1, \dots, l_n\}$ a set of node labels.

- $L_E = \{l_1, \dots, l_m\}$ a set of edge labels.
- $P_N = \{p_1^N, \dots, p_j^N\}$ a set of node properties.
- $P_E = \{p_1^E, \dots, p_k^E\}$ a set of edge properties.

A node $n_i \in N$ is a pair (l_i, a_{n_i}) , where $l_i \in L_N$ is the node label, and $a_{n_i} = [a_1, \dots, a_n]$ a set of attributes associated with the node. Identically an edge $e_j \in E$ is represented as $(l_j, a_{e_j}, \eta_x, \eta_y)$, where $l_j \in L_E$ the edge label, a_{e_j} a set of edge attributes, η_x the starting node and η_y the ending node.

C. Graph-Based OLAP

Over the last few years, big data analytics have known a meteoric adoption of NoSQL. Considerable attempts to model an OLAP cube with this technology have appeared. Several research works have been conducted to implement OLAP systems using columnar databases [5],[6],[7], others using the document-oriented database [8],[13],[14],[15],[16] and last but not least key-value stores [17],[18],[19].

Although graph databases are widely used in OLTP systems, especially when the need of modeling multiple connections is self-evident, it does not exist, to the best of our knowledge, any OLAP solution which uses a graph database at the physical level in the market. However, graph OLAP concept has been around for years. Indeed, some interesting works attempted to implement OLAP systems using graph technology. A decade ago, Chen et al.[20], [21] studied the possibility to perform multi-dimensional analysis on graph data, the authors developed a graph OLAP framework having two major subcases: Informational OLAP and Typological OLAP and proposed the basic definition of OLAP operations under this framework.

Many recent research works have been interested in implementing OLAP engines under property graph databases. In [22], the authors introduce a new data warehousing concept called Graph Cube which stands for an OLAP infrastructure that support analytical queries over a multidimensional network. In [23], the authors define the concept of GOLAP which is an extension of Online Analytic Processing(OLAP) under graph database, some features are listed such as semantics queries and structural analytics. In this work the authors address the challenges of speed and storage related to GOLAP and proposes possible solution to deal with them like graph data reduction and query result approximation when the execution time is too long, unfortunately the authors did not provide an implementation of the proposed framework and focus rather on the possible formalization. In [24], the authors propose a novel graph cube framework called Two-Step Multi-dimensional Heterogeneous(TSMH) which consists of an Entity Hyper Cube and Dimension Cube. In the Entity Hyper Cube n-meta path relation algorithm is used to guide the aggregation of the network and to extend drill-down/roll-up operations. In the Dimension Cube the efficiency of dimension operation is improved by using a hierarchical coding for entity type and dimensions.

Along the same vein, in [25] the author proposed an OLAP data structure that relies on typed nodes to store facts and dimensions, and introduced an extension of the Cypher language to basic OLAP queries. The authors didn't provide any experimental campaign to validate their proposal as they rather focused on the demonstration of its feasibility. In [26], [27], the authors proposed a formal multidimensional data model for graph analysis based on node and edge-labeled called graphoids, and presented a proof of concept implementation using a Neo4j graph database.

Regarding the instantiation of data warehouses using property graph database, in [28] the authors define a set of transformation rules for mapping between the multidimensional conceptual model and NoSQL graph model.

All the cited works present an interesting background for graph-based online analytical processing. The majority of them addressed the issue of the adaptation of graph structure to OLAP needs. Although they share some similarities with ours, the contribution of this work is quite different as we propose a novel approach for implementing both a data warehouse and OLAP engine based on efficient data cube materialization over graph database.

III. GRAPH OLAP MODEL

OLAP engines have been traditionally categorized whether they perform pre-computation of OLAP cuboids or not. Following this taxonomy, OLAP systems where all part of the cube is pre-computed and stored in memory or disk are called multidimensional OLAP systems (MOLAP) and systems where computation of OLAP cuboids is performed on-demand directly from the data warehouse are considered as Relational OLAP models (ROLAP).

In this section we define the logical graph model for data warehousing. We consider two approaches by analogy to the ROLAP and MOLAP models; each one differs in term of structure and content when the mapping from the conceptual model is performed. In the first approach, fact, dimensions and the link between them are materialized by nodes and edges following several mapping rules, while in the second approach we talk rather about an aggregate lattice modeled using the graph paradigm. In what follows, we will use a fictional electronics company as a running example. The star schema of our cube is depicted in Fig. 2:

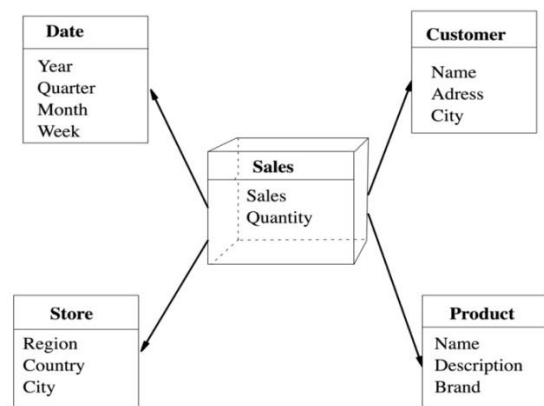

Fig. 2. The Star Schema.

A. First Approach

This approach corresponds to the lightly summarized data model. It defines a meta-model in which each component (fact and its associated dimensions) will be transformed to a node. The relation between nodes will be materialized by edges as detailed by the following mapping rules:

Rule.1. Each fact component $F_i \in F^S$ is converted to a node defined by (l_i, a_{n_i}) where:

- l_i is the name of the fact.
- Each measure $m_k^{F_i} \in M^{F_i}$ is converted to a node attribute $a_k \in a_{n_i}$.

Rule.2. Each dimension component $D_j \in D^S$ is translated to a node defined by (l_j, a_{n_j}) where:

- Each dimension attribute $a_k^{D_j} \in Att^{D_j}$ is mapped into a node attribute $a_k \in a_{n_j}$.
- Each hierarchy level $l_k^{D_j} \in H^{D_j}$ will be stored as a node alike dimension.
- Hierarchy levels are connected by edges to express how they are hierarchically linked.

Rule.3. The link between fact and its associated dimensions is represented by an edge (l_i, η_x, η_y) where:

- $l_j \in L_E$ is the name of the relation.
- η_x a node representing the fact.
- η_y a node representing an associated dimension

For the star schema represented in Fig. 2, the application of the aforementioned rules will give us the following meta-model, Fig. 3:

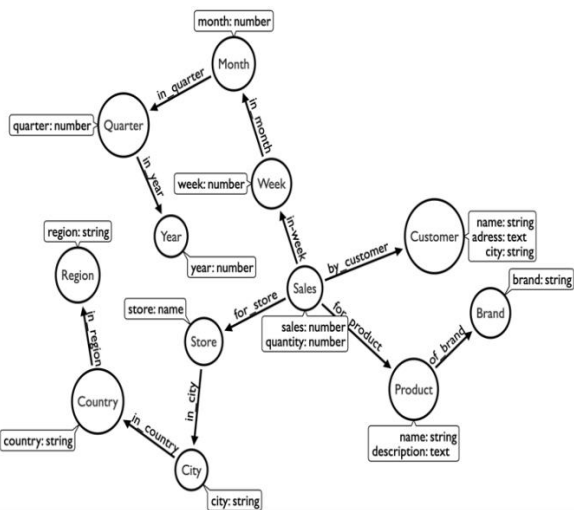

Fig. 3. The Graph-OLAP Schema According to the First Approach.

B. Second Approach

When we want to perform aggregation on a graph OLAP built according to the first approach, the query we should write is served on-demand and relies on fact nodes which are retrieved then aggregated using an aggregation function. This technique achieves the required result, but it is not optimized for a large data volume. Moreover, it is tending to the opposite of OLAP philosophy where data aggregation is pre-computed and stored.

The second approach corresponds to a highly summarized data model where measure aggregations are pre-calculated and directly available for the sake of query performance. The set of pre-computed aggregations is called an *aggregate lattice*. Concretely, fact measures are aggregated according to different combinations of dimensions and stored as a node with two labels.

- l_i identify the multidimensional concept $l_i = 'Aggregate'$.
- l_j a label which follows a particular pattern that identify uniquely which cuboid the aggregate is calculated for. This label is in the form of a bitmask starting with a letter that indicate the type of the aggregate (S for Sum, A for Average, etc.). The remaining part is an ordered sequence of n position (one of each hierarchy level), each position can have three possible values: (x) if the aggregate is calculated for all occurrences of the level, (1) if the aggregate is performed for each occurrence of the level and (0) if the aggregate is not calculated for the level.

If we refer to our running example and considering only high levels of granularity. Let's assume by convention that the order of position levels is:

Product.Brand-Product.Product-Store.Region-Store.Country-Date.Year-Date.Quarter.

An example of bitmask construction is depicted in Table I and Fig. 4 displays such a representation:

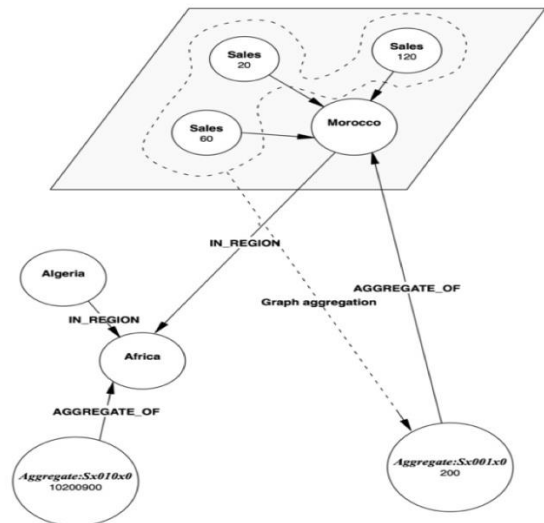

Fig. 4. Graph Aggregation According to the Second Approach.

TABLE I. CUBOID BITMASK CONSTRUCTION

Node label	Description	Scope
Aggregate:S10x0x0	Sum by Product.Brand	One level aggregate
Aggregate:Sx010x0	Sum by Store.Region	One level aggregate
Aggregate:Ax0x010	Avg by Date.Year	One level aggregate
Aggregate:S1010x0	Sum by Product.Brand and Store.Region	Two levels aggregate

IV. IMPLEMENTATION

A. Answering Typical Analytical Operation using Cypher

OLAP operations help users to view data from different perspectives providing a convenient environment for real-time data visualization and analysis. OLAP defines several basic operations; the most popular ones are roll-up, dicing and slicing. In this section we present how these operators can be expressed over a data cube designed according to the first approach.

Queries are written using the Cypher syntax, a declarative query language intended to be executed on a database engine built on the graph model. Cypher relies on the concept of pattern matching for querying and updating graphs [12]. A detailed description of the Cypher syntax is beyond the scope of this paper.

1) *Roll-up*: The roll-up operation (also called consolidation or aggregation operation) performs aggregation on a data cube in two ways, either by reducing the number of dimensions or by climbing up a concept hierarchy for a dimension. It is like zooming-out feature from the most detailed granularity level to the less detailed one.

In the query given in Listing.1, the rollup operation is performed by climbing up the concept hierarchy of *Product* dimension (*Product* → *Brand*), and of *Store* dimension (*Store* → *City*). The execution of the query results in the creation of a node containing the aggregated measures and two new relations linking the created node with its associated dimension hierarchies.

Listing. 1. Roll up-Aggregation of sales and quantities by product brand and store city.

1. MATCH (br:Brand)-[:]-(:prod:Product)-[:]-(:fact:Sales)
2. MATCH (ct:City)-[:]-(:st:Store)-[:]-(:fact:Sales)
3. WITH DISTINCT br, ct, SUM(fact.sales) AS SumSales, SUM(fact.quantity) AS SumQuantity
4. CREATE (br)-[:AGGREGATE_OF]-(:agg:Aggregate:S1010x0 {sales: SumSales, quantity: SumQuantity})-[:AGGREGATE_OF]->(:ct)
5. RETURN br,agg,ct;

2) *Dicing*: Dicing is the operation of selecting a subset over all the dimensions and picking only specific dimension parameter values. We can think of dicing as zoom feature using smaller scale.

In Listing.2 the dice operation is performed using a selection criterion over *Brand* and *Year* dimensions. The generated cube has two dimensions.

Listing. 2. Dice-Selecting the sum of sales for the brand Apple in 2018.

1. MATCH (br:Brand {brand: 'Apple'})<[*]-(:fact:Sales)
2. MATCH (year:Year {year: 2018})<[*]-(:fact:Sales)
3. RETURN SUM(fact.sales) AS Sales, SUM(fact.quantity) AS Quantity;

3) *Slicing*: Slicing is similar to dicing with a little difference. It emphasizes one specific dimension and provides a new sub-cube by filtering on a particular attribute. It can be considered as a specialized filter for specific dimension parameter value.

In Listing.3 Slice is carried out for the dimension *Region* using the criterion *Region*= 'Asia'.

Listing. 3. Slice- Selecting the sum of sales in region Asia

1. MATCH (reg:Region) <[*]-(:fact:Sales)
2. WHERE reg.name='Asia'
3. RETURN reg.region AS Region, SUM(meas.sales) AS Sales, SUM(meas.units) AS Units;

B. Aggregates Creation

We refer to the property graph in Fig. 3 and the set of aggregates in Table I, and then we show how we can perform pre-calculation of our sample cuboids.

1) *Aggregate by product brand*: Query results in cypher are evaluated by its core concept, namely, pattern matching. By using patterns, you describe the requested data shape, then the Cypher engine is responsible for restoring the data you are looking for. For example, to build the aggregate value *Aggregate:S10x0x0*, a join is implemented by means of matching *Sales* → *Brand* against the OLAP-graph. It is worth noting that the edge label linking the fact and the dimension nodes is not required as it is inferred from node types.

In SQL, this is equivalent to a join between the fact table *Sales* and the dimension table *Brand* followed by the aggregation function SUM and GROUP By clause over *Brand* attributes.

Listing. 4. Creation of the aggregate *Aggregate:S10x0x0*.

1. MATCH (brand:Brand)-[*2]-(:s:Sales)
2. WITH DISTINCT brand, SUM(s.sales) AS SumSales, SUM(s.quantity) AS SumQuantity
3. CREATE (a:Aggregate:S10x0x0 {sales: SumSales, quantity: SumQuantity})-[:AGGREGATE_OF]->(:brand);

Fig. 5 shows how the aggregate *Aggregate:S10x0x0* (By product brand) fits in the property graph (colored in grey). It is a one-level aggregate as it is calculated against one hierarchical level(colored in red).

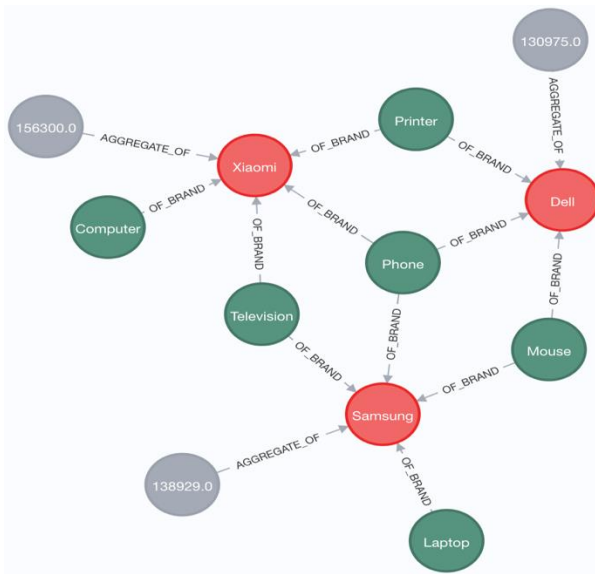

Fig. 5. Graph Visualization for Aggregates of Product Brands

2) *Aggregate by region*: In Listing. 5, the aggregate node *Aggregate:Sx010x0* (by region) is created:

Listing. 5. Creation of the aggregate *Aggregate:Sx010x0*

```

1. MATCH (r:Region)-[*4]-(s:Sales)
2. WITH DISTINCT r, SUM(s.sales) AS SumSales, SUM(s.quantity) AS
   SumQuantity
3. CREATE (a:Aggregate:Sx010x0 {sales: SumSales, quantity: SumQuantity})-
   [:AGGREGATE_OF]->(r);
    
```

3) *Aggregate by year*

Listing. 6. Creation of the aggregate *Aggregate:Sx010x0*

```

1. MATCH (y:Year)-[*3]-(s:Sales)
2. WITH DISTINCT y, AVG(s.sales) AS AvgSales, AVG(s.quantity) AS
   AvgQuantity
3. CREATE (a:Aggregate:Ax0x010 {sales: AvgSales, quantity: AvgQuantity})-
   [:AGGREGATE_OF]->(y);
    
```

4) *Aggregate by product brand and region*: In Listing.7, the two-levels aggregate node *Aggregate:S1010x0* (by product brand and region) is created:

Listing. 7. Creation of the aggregate *Aggregate:S1010x0*

```

1. MATCH (brand:Brand)-[*2]-(s:Sales)
2. MATCH (r:Region)-[*4]-(s:Sales)
3. WITH DISTINCT brand, r, SUM(s.sales) AS SumSales, SUM(s.quantity) AS
   SumQuantity
4. CREATE (brand)-[:AGGREGATE_OF]-(a:Aggregate:S1010x0 {sales:
   SumSales, quantity: SumQuantity})-[:AGGREGATE_OF]->(r);
    
```

Increasing the materialization of the aggregates can improve considerably query performance, but can also affect drastically storage space since aggregate nodes are stored on disk. The precalculation of all possible aggregate values is often not needed. Generally, OLAP engines chose the percentage of precomputed values based on business needs, the remaining aggregates are calculated in response to a query. We can imagine a scenario in which potentially requested aggregates are inferred from log files that contains previously executed queries.

V. RESULTS AND DISCUSSION

We conducted experiments to evaluate two aspects for the OLAP implementation under graph database: storage space and query performance. For this, the solution we propose is compared with a ROLAP implementation under Oracle relational database containing the same dataset. The experiment is carried out on a Unix machine (macOS) having a core-i7 CPU, 16GB of RAM and 1 TB of stockage memory and running Neo4j community edition v4.3.

A. Data Generation

The dataset used in the experiment is generated using a novel NoSQL star schema benchmark named KoalaBench [29], [30], [30]. This tool is developed with Java language and is derived from the reference benchmark TCP-H. For clarity and to fit the meta-model in our running example the Supplier is replaced with the Store dimension, LineItem is renamed with Sales, and for the equivalent graph model, only few dimension parameters are tracked. Datasets can be generated in different configurations (different file format including tab, csv, json, xml..., and multiple models). The size of the generated data by scale factor is detailed in Table II.

TABLE II. SIZE OF THE DATA GENERATED BY SCALE FACTOR (SOURCE¹)

		Lines	Disk Space in Byte (SF=1)	Avg. Disk space/line (Byte)
Tables	Sales (LineItem)	SF _x 6000000	862558617,6	143,76
	Product (Part)	SF _x 200000	28521267,2	142,6
	Customer	SF _x 150000	16043212,8	1069,54
	Store (Supplier)	SF _x 10000	1677721,6	167,77
	Nation	25	367	14,68
	Region	5	73,4	14,68
	Date	SF _x 2556	168522	65,93
Size on disk			0,85 GB	-

B. Experiment 1: Memory Consumption Per Scale Factor

In this experiment we use a global flat CSV file representing data in a flat meta-model. In the appendix (Listing.8), we attach the Cypher script for loading data from an CSV file into Neo4j database according to our modeling approach. A fragment of the generated graph is represented in Fig. 6. The number of nodes and edges for the corresponding graph is depicted in Table III.

	BY_CUSTOMER	6000000	30000000	60000000
	IN_STORE	6000000	30000000	60000000
	IN_NATION	10000	50000	100000
	IN_REGION	25	25	25
	IN_MONTH	6000000	30000000	60000000
	IN_QUARTER	79	395	790
	IN_YEAR	27	135	270
Size on disk	3,3 GB	16.6 GB	33.2 GB	

From the Table III, we can see that a snowflake schema on a graph database requires more storage space than in a relational one (more than 3 times for SF=1). This is easily

explained: property graph databases store relationships physically on disk using edges while the concept of foreign key is used instead by relational databases. Furthermore the metadata is stored individually for each record in graph database unlike relational model which define the structure of the data at a higher level(the table itself). Which means that property names are repeated for each item. Indeed, graph databases are very storage intensive. This is traded for higher query performance. Since nowadays hard disks are inexpensive, it would be worthwhile trade-off to buy more storage space than keeping users waiting.

C. Experiment 2: Query Performance

The purpose of this experiment is to measure empirically the performance of graph-OLAP to process analytical queries when scaling up in comparison with the ROLAP implementation under Oracle database. We have exposed the system to a scale factor equal to 10 wich generates 11,6 Go of random data in csv file format. Query configuration includes queries involving gradually an increasing number of dimensions as depicted in Table IV. Each query was executed three times and the average of the elapsed time is presented in Fig. 7.

Experiment results show that the relational implementation defeats the Graph alternative when the query involves one dimension, but when the query dimensionality increases the graph alternative show better performance ranging from 1,82 to 2,29 times faster. Indeed, in relational databases the deeper we go in joining tables the more queries show slower processing time because it requires scanning of all table involved in the query which has a considerable cost. Unlike relational databases which suffer the pain of joining tables, graph databases express relationship at the physical level. That means, the links between nodes exists physically on disk and are named and directed which, makes graph traversal easier.

TABLE IV. QUERY CONFIGURATION

Query	Dimensionality	Dimension attributes	Measure
Q1	1D	Date:year	Sum(sales)
Q2	2D	Product:name Store:region	Sum(sales)
Q3	3D	Product:name Store:region Date:month	Sum(sales)
Q4	4D	Product:name Store:region Date:quarter Customer:name	Sum(sales)

Fig. 7. Query Response Time by Dimensionality.

VI. CONCLUSION

The ability of graph technology to handle highly interconnected data makes it suitable for interactive analysis and more relevant for businesses today. In this paper, we addressed the topic of extending NoSQL graph-oriented databases to OLAP. We have proposed a modeling approach for implementing graph-based data warehouses using labeled nodes and edges. We have also shown how materialized aggregates can pre-computed across different levels to speed up query processing. At the physical level Neo4J engine is used as a graph-oriented database management system. Typical OLAP queries are rewritten using its declarative query language Cypher.

The Graph-OLAP implementation is compared to ROLAP one in terms of query performance and storage space, results show clearly that graph implementation of OLAP presents better performances than relational alternative in term of query response time when facing a huge data volume.

In the forthcoming extended work, we look forward to extending Cypher to support OLAP features by writing a user-defined aggregation function using the low-level API provided by Neo4J engine.

Without any doubt, using NoSQL technology to support OLAP features is a promising research direction. Therefore,

we claim that implementing OLAP engines under column-oriented and document-oriented databases using novel frameworks would be an interesting research issue that can be addressed.

Sentiment Analysis to Explore User Perception of Teleworking in Saudi Arabia

Malak Nazal Alotaibi, Zahyah H. Alharbi

Management Information Systems Department

College of Business Administration, King Saud University, Riyadh, Saudi Arabia

Abstract—Due to the emergence of the COVID-19 pandemic in 2019, many public and private organizations from different sectors in Saudi Arabia were forced to enforce teleworking as the main work arrangement. This paper seeks to understand the experience and attitude of the public toward remote work by analyzing Twitter data from March 2020 to July 2021 by using "Mazajak" the online Arabic analyzer. A corpus of 39,523 tweets with hashtags mentioning the teleworking program in Saudi Arabia was obtained. The results indicate that neutrality was the most prevalent sentiment with 58.21%, followed by positive sentiment with 30.67%. Thematic analysis was used to identify themes in the tweets with positive and negative sentiment. Flexibility, teamwork, teleworking preference, and learning were the major themes related to positive sentiment, while themes related to negative sentiment were private sector, companies, and fake.

Keywords—Mazajak; sentiment analysis; thematic analysis; telework; remote work

I. INTRODUCTION

Recently, the concept of teleworking or work from home (WFH) has been gaining in popularity due to the advancement in information technology and the emerging tools and applications for communication and task management. There are many definitions of teleworking, one of which views teleworking as a type of "work arrangement with high flexibility in which employees perform all or a substantial part of their work physically separated from the location of their employer, using IT for communication and operations" [1].

In 2020, a global public health crisis emerged due to the spread of the COVID-19 virus. The ensuing pandemic forced many national governments worldwide to adopt lockdown policies. Social distancing became mandatory, which compelled organizations to transition their employees away from regular work and toward telework, the aim being to protect employees and reduce the societal impact of the virus. These radical changes in the work environment have had both advantages and disadvantages. Ipsen et al. investigated the advantages and disadvantages of teleworking during the pandemic in Europe, classifying them into the following six categories: work-life balance, work efficiency, and work control (as the advantages), and home office constraints, work uncertainties, and inadequate tools (as the disadvantages) [2].

Before the COVID-19 pandemic in Saudi Arabia, firms from different sectors had limited experience with teleworking as a work arrangement. However, the situation after the pandemic in Saudi Arabia was – and continues to be – similar

to other countries around the world. In March 2020, teleworking was enforced on firms and organizations from different sectors as part of the precautionary measures to combat the COVID-19 pandemic. As a result, the pandemic gave rise to a forced experiment that led to significant changes in work methods across Saudi Arabia.

Several years before the pandemic, in 2016, the Saudi Ministry of Human Resources and Social Development launched a teleworking initiative [3], the aim of which was to fill the geographical gap between employers and job seekers based on the use of electronic work environment [4]. Despite the initiation of this teleworking program, teleworking was not popular prior to the pandemic. Understandably, its popularity has increased dramatically in Saudi Arabia in the wake of the ongoing pandemic.

In this research, we conducted a preliminary study in which 187 employees were targeted from different sectors. The sample consisted of 79.8% females and 20.2% males, 68.6% of whom were aged between 20 and 40 years. 30.3% of the sample was aged 41 to 60 years, and only 1% were older than 60. The majority of the participants (68.6%) held a bachelor's degree and 19.1% have a master's degree. The sectors represented in the sample were the educational sector (37.2%), public sector (32.4%), private sector (26.1%), and healthcare sector (4.3%). The results of this study show that 63.8% of the participants had never tried teleworking before the pandemic, which indicates that the teleworking concept is regarded as a relatively novel concept in the Saudi labor market.

This study's preliminary results suggest that the pandemic has prompted Saudi organizations to implement teleworking as a way of adapting to the global changes. These changes in the work dynamics around the world can be characterized as a double-edged sword in that they may affect both organizations and employees positively or negatively. This can cause different perspectives on the impact of teleworking.

Studying Public perspectives on the teleworking experience during the pandemic is an important factor for analyzing the overall experience and learning how to improve it. Furthermore, knowing the reasons behind the negative or the positive perspective of workforces is expected to aid businesses in utilizing teleworking to maximize its benefits. One way to analyze people's opinions toward a topic is through sentiment analysis. Sentiment is defined as the emotion behind a mention of a certain topic, brand, or service in the social universe. It is a way of gaining an understanding

of the feeling surrounding a topic, brand, or service [4]. A popular way to analyze sentiment toward a subject is by analyzing their social media posts, such as tweets, Facebook posts, and Instagram posts. Although there are several social media platforms for posting and sharing comments, Twitter was targeted in this paper. Twitter is an informal microblogging social media platform that allows users to share posts of up to 280 characters called “tweets” [5]. It provides an accessible and large amount of data, particularly given that there was an average of 206 million daily active users in 2021 [6]. Consequently, the large, timely, rich, and easily accessible data available on Twitter were the reasons for choosing this social media platform as the data source for this paper.

Despite the importance of analyzing the teleworking experience, the situation in Saudi Arabia has not been studied, to the best of the researcher's knowledge. This study aims to fill this gap by answering the following question: What is society's perspective and the public's opinion toward the teleworking experience in Saudi Arabia? In addition, this study seeks to achieve the following objectives:

- To investigate the teleworking experience in Saudi Arabia from the societal perspective.
- To explore the themes that correlate with positive and negative opinions using sentiment analysis, visualization, and thematic analysis.

The remainder of this paper is organized as follows. Section 2 presents related work in the form of a literature review. Section 3 introduces the methodology used in this paper to collect and analyze data. Section 4 discusses the results of the sentiment and thematic analysis. Section 5 discusses the results and presents recommendations. Lastly, Section 6 draws concluding remarks for this study.

II. LITERATURE REVIEW

Previous studies on the concept of telework or WFH were mostly performed before the COVID-19 outbreak. More recent studies on the concept cover the impact of COVID-19 on teleworking using different techniques, including sentiment analysis. In this section, a review of the literature is given focusing on the concepts of telework, sentiment analysis, and Arabic sentiment analysis.

A. Telework

In 1973, Nilles [7] coined the term “telework”. The author identified telework as a work arrangement that “includes all work-related substitutions of telecommunications and related information technologies for travel”. The evolution of teleworking has since progressed through three generations [8]. The first generation is the home office, where employees exclusively work from home. The second generation is the mobile office, where working hours were partially replaced with teleworking. The third generation is the virtual office, which refers to an informal work arrangement that has fewer regulations than the usual work arrangement. Currently, with the use of smartphones and advanced technologies, organizations are part of the third generation of teleworking. Employees who work from home (i.e., teleworkers) are classified into three main types, according to Vries et al [1].

The first type is home-based teleworkers, where employees perform their tasks at home. The second type is teleworking from remote offices, where employees perform their tasks in an office that is remote from the main office. The third type is mobile telework, which includes employees who need to travel or visit customers as part of their job. Briefly, teleworking is a spectrum of practices, not a homogeneous entity [9].

The negative and positive effects of telework have been the subject of many research projects. Teleworking can impact employees, management, and the organization as a whole. Telework can affect employees' effectiveness as well as their personal life. For example, Adamovic [10] conducted a study to investigate the effect of teleworking on job stress and telework effectiveness. The study's hypotheses were tested using a three-phase survey targeting 604 teleworkers from different countries and a variety of organizations in different sectors. The survey measured cultural values, beliefs toward telework, and job stress. The results showed that telework only reduces job stress when employees do not believe that teleworking leads to social isolation. Furthermore, the results indicated that employees with high power distance scores typically held negative beliefs about telework, whereas employees with high individualism scores tended to have strongly positive beliefs regarding the effectiveness of telework.

An equally significant aspect of teleworking is its impact on employees' quality of life, which was studied by Nedelcu in [11]. Nedelcu conducted a survey with 261 employed undergraduate and graduate students from Nicolae Titulescu University in Bucharest. The results showed that telework can positively impact the quality of employees' personal and professional life due to the following factors: reduction of work-related stress, increasing employee autonomy, reducing costs related to work, and increasing motivation and commitment. Conversely, the study indicated that 73% of dissatisfied employees agreed that their dissatisfaction with telework experience was because they were unable to separate their personal time from their professional time. Moreover, 86% of the respondents agreed that their dissatisfaction was related to the loss of social interactions and team spirit. Similarly, Golden in [12] stated that telework can affect employees' commitment, exhaustion, and turnover intention. The researcher used a sample of 393 teleworkers in a large firm in the USA. The results indicated that teleworking increases employees' commitment and lowers turnover intention.

While many previous studies have targeted employees from all levels, Silva et al. [13] focused on managers and their attitudes toward telework. The study used the technology acceptance model (TAM) as a theoretical framework and the collected data were analyzed using structural equation modeling (SEM). The results showed that the attitude of managers toward telework adoption was influenced by improvements in information security tools, employees' self-efficacy beliefs, and managerial practices.

Although many studies have investigated the effect of telework on different aspects of organizations and employees,

several recent studies have examined teleworking during the COVID-19 pandemic. For example, Belzunegui-Eraso et al. [14] and Ipsen et al. [2] both found that telework working conditions during the COVID-19 pandemic have mostly been positive. According to these researchers, the principal advantages of teleworking during the COVID-19 pandemic are work-life balance, work efficiency, and work control.

B. Sentiment Analysis

To the best of the researcher's knowledge, sentiment analysis has only been applied in two studies focusing on telework, both of which were undertaken during the time of the COVID-19 pandemic. The first study, Zhang et al. [15], aimed to understand the attitudes of the general public toward teleworking by analyzing tweets using natural language processing (NLP) techniques. The results uncovered themes among tweets including mental health, teamwork, leadership, and work-life balance. The other study was conducted by Goyal and Malhotra [16], and while it was similar to [15] regarding its objective and the use of tweets as the data source, the main difference is that [16] used the R programming language as the method for sentiment analysis. Both studies showed that public attitudes toward working from home have generally been positive.

C. Arabic Sentiment Analysis

Sentiment analysis for the Arabic language is different from English. One of the main reasons for this is that the Arabic language is more complex than English, richer in terms of its morphology, and has different dialects. In each dialect, the meaning of the words can be very different, which makes sentiment analysis for the Arabic language more challenging. The literature on Arabic sentiment analysis offers many ways to handle the challenging aspects of analyzing the Arabic language.

In [17], the researchers introduced an aspect-based sentiment analysis system for Arabic reviews of hotels. They implemented a deep recurrent neural network (RNN) along with a support vector machine (SVM) approach, and the results showed that the SVM approach outperformed the deep RNN approach. Moreover, in [18], Alayba, Palade, et al built a system for sentiment analysis based on the integration of convolutional neural networks (CNNs) and long short-term memory (LSTM) networks. The hybrid model was tested on two Arabic datasets and achieved high classification accuracy.

In a more recent study, Al-Alfy & Al-Azany in [19] had two goals: first, to compare the performance of machine learning algorithms in discovering the polarity of Arabic tweets using neural word embedding as the feature extractor; and second, to examine the effect of different oversampling techniques in handling the imbalanced nature of the data. The paper's findings were that the geometric mean (GM) attained its highest value when the stochastic gradient descent (SGD) classifier was used with oversampling. The GM improved in all cases when combined with oversampling except for the Gaussian naïve Bayes (GNB) and random forest (RF) classifiers.

A notable tool for Arabic sentiment analysis is Mazajak, which is the first online Arabic sentiment analyzer. In [20],

Abu Farah & M proposed this online system, which analyzes Arabic sentiment using a deep learning model. Mazajak achieved state-of-the-art results on many Arabic dialects. The system's results are based on the benchmark of three Arabic datasets: the SemEval 2017 task, ArSAS, and ASTD. Given that Mazajak has outperformed all other Arabic sentiment analysis systems, this paper utilizes the Mazajak system as a tool for sentiment analysis, as described in the next section.

III. METHODOLOGY

This section present the research methodology, which consisted of four phases: data collection and preparation, data analysis and performance evaluation.

A. Data Collection and Preparation

In this study, a dataset consisting of 39,523 tweets was retrieved from three hashtags (#_عمل_#_تعليق_العمل_في_#) السعودية. In addition to the hashtags, the tweets from the telework program account mention were retrieved for the period from January 2019 to July 2021. The details of the retrieved data are shown in Table I.

TABLE I. TWEET CLASSIFICATION

Sources	Number of Retrieved Tweets
@TeleworksKSA mention	8,235 tweets
#Telework	17,018 tweets
#Work_suspension_SaudiArabia	3,611 tweets
#Work-Susbension	10,659 tweets

Data preprocessing was conducted using RapidMiner, a Java-based open-source software that provides several operators for text processing. These operators include tokenization, stemming, and stopword filtering [21]. Furthermore, RapidMiner supports multiple languages, one of which is Arabic.

The first step was to integrate the four datasets shown in Table I into one large dataset. Following this, a data reduction phase was performed to reduce or eliminate noisy data (e.g., meaningless or irrelevant tweets). its involved scanning the data for specific words and deleting any tweets containing these words. For example:

Offers- designs- IELTS-CV-Marriage

الفاتورة - مسيار - ايلتس - سيرة ذاتية - تصميم - منتجات - عروض

After this step, the dataset was reduced to 22,587 tweets. To prepare the data, several data cleaning techniques were used such as normalization, transformation, tokenization, and stopword filtering. First, RapidMiner was used to clean the data in terms of links, http tags, and other symbols such as @, #, and [] using the Replac operator. The next process was data normalization, the goal of which is to reduce the complexity of a text and transform it into a simpler form. For example, the letters (ا , و , ي) were converted to (ا , و , ي). In turn, data transformation was applied. According to [22], in this preprocessing step, the data is converted so that the mining process result can be applied in a more efficient way. In the process of filtering stopwords, unimportant words such

as (أيضا, إلى, ثم) are removed from the data. RapidMiner supports this function for the Arabic language. The second process was tokenization, wherein each sentence is split into several words called tokens.

After tokenization, an operator for filtering tokens by length was used to filter any words with fewer than 4 characters or more than 25 characters. Stemming is considered an important step in the transformation process for English data to convert the words into their roots. This step was not used in this research since the dataset was in Arabic and stemming can negatively affect the classifier's overall performance and accuracy [23]. Instead of stemming, another technique was used to improve sentiment prediction: namely, replacing synonyms with a single word that have the same meaning. This improved the prediction because it made the dataset more unified and easier to process. An example is replacing the phrase "what is the solution", which is "وَشِ الحَلُّ / ما هو الحل" in Arabic with the word "problem", which is "مشكلة". Another example is replacing the Arabic phrase for "useless", which is "لا فائدة" with the word "عبث", which is the one-word Arabic synonym of the phrase.

B. Data Analysis

Sentiment analysis, also called opinion mining, is "a field of study that analyzes people's opinions, attitudes, emotions, and sentiments toward topics, events, products, or services, and their attributes" [24]. Sentiment analysis is a term used interchangeably with opinion extraction, sentiment mining, emotion analysis, and affect analysis. Sentiment analysis includes several steps and the final step is finding the polarity of the data [25]. A popular way to analyze people's sentiment toward a subject is by analyzing their social media posts. There are three main methods for analyzing sentiment in social media content: the machine learning approach, the lexicon approach, and the hybrid approach. The machine learning approach is divided into supervised learning and unsupervised learning, while the lexicon approach is divided into the dictionary-based approach and corpus-based approach. In supervised learning, classification models are used such as the naïve Bayes, Bayesian network, SVM, artificial neural network (ANN), and decision tree [26].

This study leveraged the existence of Mazajak, an online Arabic sentiment analyzer, due to its remarkable performance and state-of-the-art results [27]. Mazajak uses NLP and machine learning to classify tweets into three categories: positive, negative, or neutral. The model used in the system was built on a Convolutional Neural Network (CNN) that works as the feature extractor, after which the embeddings are fed into the max-pooling layer. In turn, the extracted features are fed into an Long Short Term Memory network (LSTM), taking into consideration the context and order of the words. The LSTM is followed by a softmax layer, which produces the output classes [20].

C. Performance Evaluation

To evaluate the performance of the online tool, we used three performance parameters: accuracy, precision, and recall.

Accuracy is calculated as the correct classifications divided by all classifications. In this study, it was calculated using Equation (1).

$$Accuracy = \frac{TP+TN+TNe}{TP+TN+TNe+FP+FN+FNe} \quad (1)$$

In the numerator of Equation (1), TP is the number of true positive predictions, TN is the number of true negative predictions, and TNe is the number of true neutral predictions. In addition, in the denominator, FP is the number of false positive predictions, FN is the number of false negative predictions, and FNe is the number of false neutral predictions.

The second measure is precision, which is also known as the positive predictive value. It measures the classifier's performance in predicting the true polarity of the test dataset [28]. Precision was calculated in this study as shown in Equation (2).

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

The third measure is recall, which measures the sensitivity of the classifier. This was calculated using Equation (3).

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

The results of the previous measures were high. In particular, the value of the accuracy was 88.04%, which indicates a high accuracy rate for the tool. Moreover, the precision and recall values were high at 0.97 and 0.88, respectively. Hence, the tool can be used to analyze the data.

IV. FINDINGS

A. Sentiment Analysis

The results of the sentiment analysis indicate that 58.4% of the tweets were classified as neutral. The percentage of positive tweets exceeded the negative tweets by more than the double, with 30.76% positive and 11.15% negative, as shown in Fig. 1.

Fig. 1. Data Polarity.

The frequencies of the words in the tweets were analyzed using a word cloud. Fig. 2 shows the results of the word cloud for the most frequently used words in the dataset.

Fig. 2. Word Cloud for the Dataset.

B. Thematic Analysis

To identify the factors that correlated with the polarity of the tweets, separate word clouds were created for the positive and negative tweets. However, it was necessary to exclude some words such as (كورونا, سلمان, وباء) which translates to (Corona, Salman, Epidemic). The rationale for excluding these words is that they negatively impacted the results. The results for both the word clouds are shown in Fig. 3 and Fig. 4.

Fig. 3. Positive Word Cloud.

Fig. 4. Negative Word Cloud.

The positive word cloud contained words such as “thank you”, “beautiful”, “team”, “home”, “better”, “technology”, “experience”, “communication”, “flexibility”, and “productivity”. On the other hand, the negative word cloud contained words such as “private”, “sector”, “problem”, “companies”, “sickness”, and “delusion”. From the previous figures, we can extract some themes that correlated with positive or negative opinions. The word “productivity” was one of the most frequently used words in positive tweets. Furthermore, its use was often accompanied by words such as “effectiveness” and “efficiency”. Examples of these tweets are:

“We left our offices but we increased our productivity and efficiency through trusting our employees.”

“Teleworking is a wonderful arrangement to avoid traffic and improve productivity, regardless of its challenges.”

“Teleworking can increase the team’s productivity if it is managed effectively and efficiently.”

“Teleworking taught us that productivity is about the quality rather than the quantity of work, and we have to consider reducing the number of working hours.”

Another theme was the comparison between the teleworking work arrangement and the regular work arrangement. One of the most frequently used words was “better”, which was often used to describe health, work, accomplishments, and standards during remote work. Examples of this theme are as follows:

“I noticed that transforming to teleworking maximizes the work output and allows everybody to communicate better in a shorter time; it is a better experience.”

“Having more breaks when teleworking contributes to better health.”

"As a teleworker, I think that work standards and accomplishments are better when teleworking – it's the right option for a better environment, and in the future, teleworking will be part of the digital transformation."

"Teleworking reduces costs and gives organizations an opportunity to hire better employees regardless of where they live."

The word "learning" was another common word used in the positive dataset. Teleworking was a new experience for many employees during the COVID 19 pandemic, which forced them to learn about new technologies and applications. Thus, "technology" was also a common word. Examples include the following:

"Teleworking has many advantages such as flexibility and productivity, and it is a great opportunity to learn new habits and skills."

"We are forced to go through this experience and we need patience and creativity to use it to learn."

"The teleworking experience is an enriching experience that has given us the opportunity to learn new technologies."

The word "team" was a popular word in the positive dataset. Tweets mentioning this word talked positively about the creativity of the team arising from telework, as well as trust and communication. The following are examples of this theme:

"A successful team during the period of telework is marked by trust, respect, and helping each other."

"Teleworking experience is fun and special, especially when you have the technology and tools to help and, most importantly, a creative and passionate team."

"A lesson we can learn from the teleworking experience is that building trust in your team is the greatest incentive for productivity."

"Your creative and professional team is the most important asset – communicate with them and encourage them to maintain their efficiency and productivity during working from home."

Lastly, working with flexible hours correlated with positive opinions about teleworking as it is considered one of the advantages of this work arrangement. Some of the tweets that mentioned flexibility are the following:

"Teleworking is flexible, which makes employees more productive and happier; it opens a new gateway to opportunities."

"The flexibility of teleworking gives us a better work-life balance."

"The idea of working from home is so much better and more flexible, which makes it easier."

"Having flexible working hours contributes to better health and life quality for employees."

On the other hand, two of the most common words in the negative dataset were "private" and "sector", which occurred

in 24.58% of the tweets in the negative dataset. Most of these tweets highlighted how the private sector continued to work as normal during the pandemic, whereas employees in the public sector were teleworking. In addition, the word "companies" (or "company") was mentioned frequently in negative tweets. Some examples are given as follows:

"The company that I work for misunderstands the concept of teleworking. Managers ask us to hold meetings and perform tasks all day – even at night – and on top of that, they've cut our salaries."

"Why are private-sector employees being forced to go into the office during the pandemic? We are humans too and we can get sick."

"Why doesn't the work suspension apply to private-sector employees? We can also get the virus and put our families in danger."

In addition, words such as "fake", "failed", and "problem" were common in the negative tweets, especially in tweets that mentioned the teleworking program. Specifically, the words "Fake", "Lie", and "Problem" were present in 14.09% of the negative dataset, and 12.52% explicitly mentioned the teleworking program.

In the tweets that mentioned the teleworking program, 39.41% were negative and only 13.67% were positive. The word "problem" was featured in 32.97% of the tweets that identified a problem with the website and described it as a failed system. The words "fake" and "lie" were present in 16.21% of the tweets, where people accused the program of being fake or offering fake job opportunities. Notably, this was the most common theme in tweets mentioning the name of the program. The following are some of the instances of this theme:

"Are you sure that the website is working? I applied for tons of jobs and I think it is all fake because the organizations ignored us and didn't even send an apology."

"This website is a lie – it's offering fake job opportunities."

"I applied for jobs aligned with my CV and nobody contacted me – I'm starting to think that it's all fake."

"The website is very slow and has many problems."

V. DISCUSSION AND RECOMMENDATIONS

From the results discussed previously, the first important topic we investigated was the overall experience of teleworking. The public orientation toward neutrality and positivity may be due to the national lockdown, which helped employees to focus more on job tasks and be less stressed about balancing work and social life. This led to many not viewing the situation as a negative experience.

Since the pandemic, the use of teleworking has increased and, as a result, work flexibility has become more common. This has elevated the importance for organizations to build a positive teleworking experience to achieve high productivity levels. Offering flexible hours for teleworkers can improve their productivity. In a study conducted in Japan, the

researchers found that suitable telework hours increased employee productivity, whereas long working hours decreased productivity [29]. For the teleworking program, the results showed that it is not a feasible program and it has not been well received by the public. We recommend a more transparent recruitment process and a user-friendly website to avoid problems with registering and applying for jobs [30].

VI. CONCLUSION AND FUTURE WORK

This paper performed sentiment analysis and thematic analysis focusing on the teleworking experience and teleworking program in Saudi Arabia. The purpose of this study was to gain insight into the experience of teleworking among the public in Saudi Arabia during the work suspension period, as well as to determine the public sentiment of the experience. Furthermore, this study sought to analyze public sentiment on the teleworking program. A dataset extracted from Twitter, consisting of tweets posted between March 2020 and July 2021, was used to analyze the public sentiment toward teleworking. Mazajak, an online Arabic sentiment analyzer, was used for data analysis. The results revealed that neutrality was the most prevalent sentiment in the tweets, followed by positive sentiment. Furthermore, the results detected themes of flexibility, teamwork, teleworking preference, and learning in association with the positive view of the practice. By contrast, the themes related to negative sentiment were the private sector, companies, and fake.

Future work should concentrate on comparing the public view of teleworking before and after the pandemic. In addition, it would be beneficial to study the emerged factors that affect the success of teleworking in Saudi Arabia to improve the experience and leverage its advantages. Finally, this research used data from public users on twitter with different economical and educational backgrounds. However, focusing on the impact of different demographics on the effectiveness and acceptance of teleworking deserve further research.

Framework for Development of 3D Temple Objects based on Photogrammetry Method

Herman Tolle*, Ratih Kartika Dewi, Komang Candra Brata, Benyamin Perdamean
Research Group of Media, Game and Mobile Technology, Computer Science Faculty
Brawijaya University, Malang, Indonesia

Abstract—Indonesia has a lot of cultural buildings that need to capture as digital objects for other purposes, especially for digital preservation. One of the methods of making 3D objects is using the photogrammetry method. The photogrammetry method makes 3D objects using many photos captured by the camera that will be integrated into the software and processed into 3D objects. In this research, the framework for modeling 3D objects of the cultural building is proposed based on the photogrammetry approach. This framework includes data capture, modeling and processing, and calibration. This framework was tested while making the 3D object of the Candi Badut temple and reported that the 3D model has significantly had similarities with the real object. The framework is useful for standard guidelines for making 3D modeling of historical relics efficiently.

Keywords—Photogrammetry; historical relic; 3D objects; digital preservation; virtual reality

I. INTRODUCTION

Indonesia has many cultures and ancient historical relics that need to be preserved. Digitization is one of the efforts that can be done to preserve historical buildings. One of the historical relics found in the Malang Regency is the Badut Temple. The Badut Temple is located in Karangbesuki, Dau District, Malang Regency, East Java Province, about 10 kilometers from Malang City. In Indonesia, the role of the temple is very important in the introduction of the cultural history of Indonesia [1]. Most of the temple has reliefs on its wall containing a series of important stories to capture and create lessons for the current generation.

By digitizing 3D objects, we can preserve the visual form of a historical object in more detail. The Building Information Modeling (BIM) method was often used in the construction sector to make the construction work process efficient. Along with the increase in conservation and preservation activities of historical buildings, the BIM method has also begun to be applied to historic buildings, so the term Historical BIM (HBIM) method has emerged [2].

Various studies and practical activities have proven the HBIM method's reliability in documenting and scanning all information on metadata-related historical building objects, such as historical data, conservation policies, and significance values [3], [4]. The accurate and representative 3D modeling supports efforts to develop a digital management system to preserve and preserve historic buildings. Realistic 3D building models benefit simulation purposes [5], [6]. A digital survey technique is needed to produce detailed 3D models that are

attractive and useful for various purposes in cultural heritage [7]. Image-based virtual 3D modeling technology currently uses three approaches: sketch-based modeling, for example, SketchUp; procedural grammar-based modeling; and photogrammetric-based modeling [8].

The formation of three-dimensional media required expertise and skills in mastering special software. One method of forming 3D objects is by using the photogrammetry method. So many photos captured by the camera will have digital information, then put together into software and processed into 3D objects [9]. Making 3D objects with a high level of difficulty and detailed object shapes in the old way can take a long time, while the photogrammetry method can save time [10]. This method has an accurate result, an effective for wide-area using aerial photos and saving time and money. Implementation of modeling 3D objects using photogrammetry varies in many areas like Agricultural Land Modeling [11], Aerial mapping [12], and infrastructure site monitoring [13].

To help recognize the shape of the temple, modeling is carried out through 3D software by applying a workflow or photogrammetry method steps. Thus, it is necessary to create a standard workflow for making 3D models through the photogrammetry method because of the complexity of the process and workflow. So, this research aims to design the workflow for making the 3D object based on the photogrammetry approach into a formal modeling framework.

This paper proposes a standard framework for developing 3D objects of historical relics based on photogrammetry methods. This framework can be used for making other 3D objects which are still a lot of historical objects in Indonesia. The framework, workflow, and the results of the case on the development of the Badut Temple 3D object from this study provide an important role as a model that can be applied to other cases efficiently and effectively. This research is also a part of making Indonesia's cultural heritage digital preservice database [14]. The framework is important as a standard guideline for creating many historical relics in Indonesia.

II. FRAMEWORK FOR HISTORICAL RELICS MODELLING

The method used for making a 3D model is the photogrammetry method. Based on the experience in developing 3D models using the photogrammetry method, we propose a workflow framework for making 3D models of historical relics, as shown in Fig. 1. This framework consists of four consecutive processes that must be carried out

*Corresponding Author.

carefully and thoroughly. These steps are coded as follows: A) Preparation; B) Photo Capturing; C) Photo Processing & Modelling; D) Finalization.

The framework starts with the preparation phase by determining which object will be processed into a 3D model, then visiting the site to see the situation while preparing all the equipment. The types of equipment to be prepared are a high resolution of digital camera and an Unmanned Aerial Vehicle (UAV) or drone. The site visit is important to make sure that the process for taking object photos is permitted since the object is a cultural heritage. While visiting the location, it needs to take some initial photos to determine the photo capture flow in the stage of photo planning. A document template of object data is used for structuring the plan, process, and the results as shown in Fig. 2.

The photo capturing process should start by creating the photo capture flow, as shown in Fig. 3. Photo capture flow consists of the plan for the spot for taking photos circularly of the object. It consists of 2 stages of the photo plan, the first is around the object (yellow circle), and the second is circularly from the top of the object (blue circle). Then photos are taken using a digital camera from each position, including the drone's top position. To ensure that all photos are clear and bright enough, it is better to take them in the morning when the sunlight is clear enough. Since the number of digital photos is huge, it should be documented carefully.

After all of the photos have been captured, it is ready to proceed using special software that implements photogrammetry. Several softwares like Autodesk Recap, Regard3D, COLMAP, Meshroom, and RealityCapture can be candidates for this process. Table I shows the comparison between this software. RealityCapture is the best software but the most expensive, while Meshroom is good enough with a better price [15]. Meshroom software is chosen because it has excellent fidelity and can work better in low-light situations. So, all processes of making 3D models from a series of photos can be implemented. Meshroom will work according to the stages of modeling work.

Fig. 2. Framework Document of 3D Temple Object Database.

There are four processes for creating 3D models. It starts with making the structure from motion, which is the stage for obtaining a point cloud. After the point cloud is obtained, create a depth map using the DepthMap function. The DepthMap stage connects the point clouds to form a field. After the DepthMap stage is complete, the work process continues to the Meshing stage. At this stage, the fields that have been obtained begin to be put together to form a 3D model. Then the last stage in Meshroom is the Texturing stage. At this stage, the 3D object forms a texture that matches the original object in terms of color, shape, and position.

The last process is finalization, consisting of refinement, evaluation, and distribution. The 3D model from the previous process should be refined using another 3D tool. At this stage, software like Blender™ can be used to remove all unnecessary objects in the 3D model. The final 3D model is then evaluated by calculating the real size of the real temple object compared to the size of the 3D models. Some refinement is needed to resize the 3D model if there is a different size between the real and the temple model. The last step is to distribute the 3D model into a common 3D object file format that can be exchanged between software.

III. PROCESS, RESULTS AND ANALYSIS

A. Object Selection and Preparation Process

The first thing to do in 3D modeling of historical relics is select the objects in the real world to be photographed into 3D objects. In this study, we chose the Badut Temple as the object to be studied. Initial site visiting has to be done to get some information and site photos to make the photo capture plan. The following is a view from the front side of the Badut Temple in Fig. 3. All process was planned in a document template as shown in Fig. 2.

Fig. 3. Front view of Badut Temple.

B. Photo Capture Flow Design

Before taking all the photographs of the temple, a photo capture flow has to be planned. The top view of the temple from Google Maps is used to draw the photo capture plan, as shown in Fig. 4. There are two stages to circularly taking photos; the first stage took 104 photographs with the distance of taking photographs (point A) to the object (point O) as far as 10 meters. The second stage took 104 photos with a photo-taking distance (point P) to the object (point O) as far as 3 meters. The angle between photographs is 3.5 degrees (A-O-B Angle and P-O-Q Angle).

Fig. 4. Badut Temple Photo Capture Flow.

C. The Results of Taking Photos of the Badut Temple

All photos were taken at the Badut Temple location using a high-quality digital camera and drone. As defined before, taking photographs of the Badut Temple was done in a circle, as shown in Fig. 4. The results of the Badut Temple photoshoot were obtained from as many as 208 photos and stored in a folder, as shown in Fig. 5. The number of photos varies depending on the size of the object.

Fig. 5. The Results of Taking Photos from the Badut Temple.

D. Photos Processing in Meshroom

After all of the photos are collected, we can proceed with the processing steps. *Meshroom* is used in this phase and consists of five processing steps: importing photos, structuring, creating a depth map, meshing, and texturing.

Fig. 6. Import Badut Temple Photos.

1) *Import stage of badut temple photos in meshroom:* Drag and drop photos saved in a folder into Panels Images on Meshroom. After the photograph enters the Panel Images, the work file is saved first. Then click start to start the operation. Display the Images panel in Meshroom as shown in Fig. 6.

2) *Stage structure from motion photo of badut temple in meshroom:* After the photos are put into the software, Meshroom will process them to generate the point cloud. The point cloud will be shown from the photo processing results. In Fig. 7, the point cloud obtained from this stage is 191,374 point clouds. This number already gives an idea of how the 3D model of the Badut Temple will be.

3) *Stage depthmap photo of badut temple in meshroom:* At this stage, the point cloud process obtained from the previous stage is more focused on unifying the point cloud so that it is close to the similarity to the object. The process at this DepthMap stage takes a long time and is prone to failure. Here's what the DepthMap stage looks as shown in Fig. 8.

4) *Meshing stage badut temple photo in meshroom:* At this stage, 3D objects from the Badut Temple have begun to be seen along with other objects caught by the camera. The shape of the Badut Temple 3D mesh is shown in Fig. 9.

5) *Texturing stage of badut temple photos in meshroom:* At this stage, the texturing process (shape and color) matches the texture of the real object of the Badut Temple. The 3D of the Badut Temple is shown in Fig. 10. This stage is the final stage of creating 3D objects in Meshroom software.

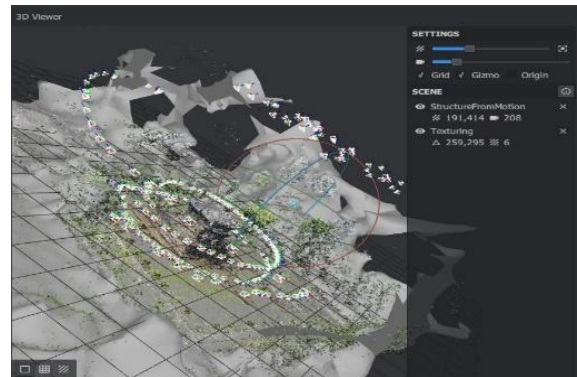

Fig. 9. Badut Temple Meshing Stage.

Fig. 10. Badut Temple Texturing Stage.

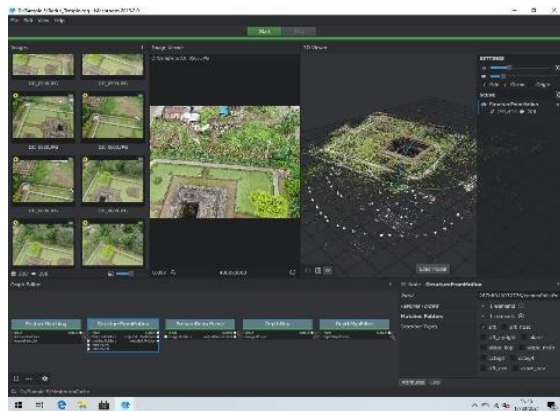

Fig. 7. The Stage Structure of the Badut Temple Movement.

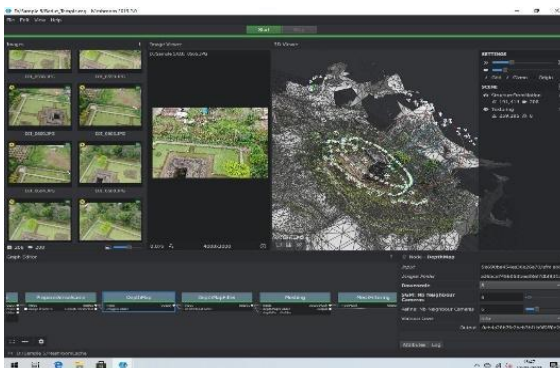

Fig. 8. Badut Temple DepthMap Stage.

After the Texturing stage is complete, the 3D object results in the Meshroom software are in the form of files that can be used for digital assets later. The following is a 3D file of the Badut Temple from the processing results in the Meshroom, as shown in Fig. 10.

In Fig. 11, there are several types of files from the processing results in Meshroom, which have different functions. The PNG file type results from the texture on the Badut Temple object, which contains a 2D image representation of the surface mapping of the Badut Temple 3D object. The MTL file type is a file that contains material information for the 3D Badut Temple object. A file of type 3D Object is a file that contains the final 3D object obtained. Files with this type of 3D Object will be used later for further work; in this case, the work is continued in Blender 3D.

E. 3D Object Model Refinement

The file of type 3D Object from the Meshroom results is then imported into the Blender 3D software, as shown in Fig. 12. When taking photos, the temple object is always focused in the middle, so the result of importing the 3D model of the Badut Temple will make the temple object located in the middle, among objects caught on camera but unused.

Fig. 12. Imported 3D Badut Temple Model.

At this stage, the removal or deletion of unused objects around the temple is carried out. The unused object is highlighted, and the deletion process is carried out. Then the final result of the 3D model in Blender 3D is obtained, as shown in Fig. 13.

Fig. 13. 3D Results of the Badut Temple Model.

F. 3D Object Evaluation

To calculate the level of accuracy of the 3D model, the model size has to be compared with the temple's original size. A measuring tape was made to get the measurement results in the field. Meanwhile, to measure the size of 3D objects in Blender 3D software, use the measure function. Both results were then compared to ensure that the 3D model has a proportional size to the model of a real object in a small size. This is also for calibration purposes.

1) *Field measurement results:* The results of measurements in the field are taken by measuring the parts of the temple. In this case, 15 samples were taken from each temple part using a measuring tape. For the sample of the front view of the temple, ten samples of the length dimensions D1 to D10 were taken, as shown in Fig. 14. For the left view sample of the temple, five samples of the length dimensions D11 to D15 were taken, as shown in Fig. 15. Then the measurement results are obtained as in Table II.

D13	6.1213
D14	1.5130
D15	1.2526

3) *RMSE calculation results:* After measuring the size of the real object and 3D model, the *Root Mean Square Error (RMSE)* formula is used to measure the differences between them using the equation (1).

$$RME = \sqrt{\frac{\sum (Y_i - \hat{Y})^2}{n}} \quad (1)$$

The first thing to do is to calculate the sum of the squares of the differences between the data obtained from 3D models and the data of the real object, as shown in Table IV. The summary obtained from Table IV is entered into the formula for calculating RMSE.

$$RMSE = \sqrt{\frac{0.080895 \text{ m}^2}{15}}$$

$$RMSE = 0.073437 \text{ m}$$

$$RMSE \approx 7.34 \text{ cm}$$

The accuracy of the 3D model of the Badut Temple obtained is 0.0734 meters, or equivalent to 7.34 cm. From the calculation results, the results obtained are smaller than 10 centimeters, so it can be said that the 3D Badut Temple model generated from the photogrammetry method is close to the shape of the Badut Temple in the field (original). Comparison of the Badut Temple photos and the processing of the Badut Temple in Meshroom and Blender 3D software as shown in Fig. 18 to 21.

4) *3D Object distribution:* The results obtained from Blender 3D are 3D objects in various files format, one of which is the Collada (.dae) file. The visualization of the Blender 3D results was obtained as shown in Fig. 22. The files obtained from Blender 3D can be used in other 3D processing software. The 3D model of the Badut Temple can be used as a digital asset for many purposes like digital preservation, video games, video animations, and others.

IV. CONCLUSION

This paper proposed a framework for digitizing historical relics using a photogrammetry approach. The process consists of 4 phases: Preparation, Photo capturing, Photo Processing & Modelling, and Finalization. All these processes can complete in just one week. Implementation of this framework in Badut Temple shows that the photogrammetry approach is efficient for creating a 3D model of historical relics.

In the photogrammetry approach, the series of circular views of the object photo is taken using a high-resolution

camera and UAV drone. Then all the photos are processed carefully using Meshroom software in four steps: structuring, depth map, meshing and texturing. Special software for processing 3D objects like Blender is then used for refinement and finalization. The result of the accuracy of the 3D model of the Badut Temple is below 10 centimeters. It means that the model has a precise size compared to the real object. So, this approach is also effective for creating 3D models precisely while maintaining the detail of the reliefs.

V. FUTURE WORK

The 3D model of the Badut Temple can be used as a digital asset for many purposes like digital preservation, video games, virtual reality, and others. This model will then use as part of the digitalization and creation of the digital database of historical relics in Indonesia. Our research group of Media, Game, and Mobile (MGM) Technology at the Computer Science Faculty of Brawijaya University is researching Indonesia's digital heritage of historical buildings, starting from many of the relics in East Java, Indonesia. We develop a web portal and digital database of the model of historical buildings in Indonesia, especially the temple, as shown in Fig. 23.

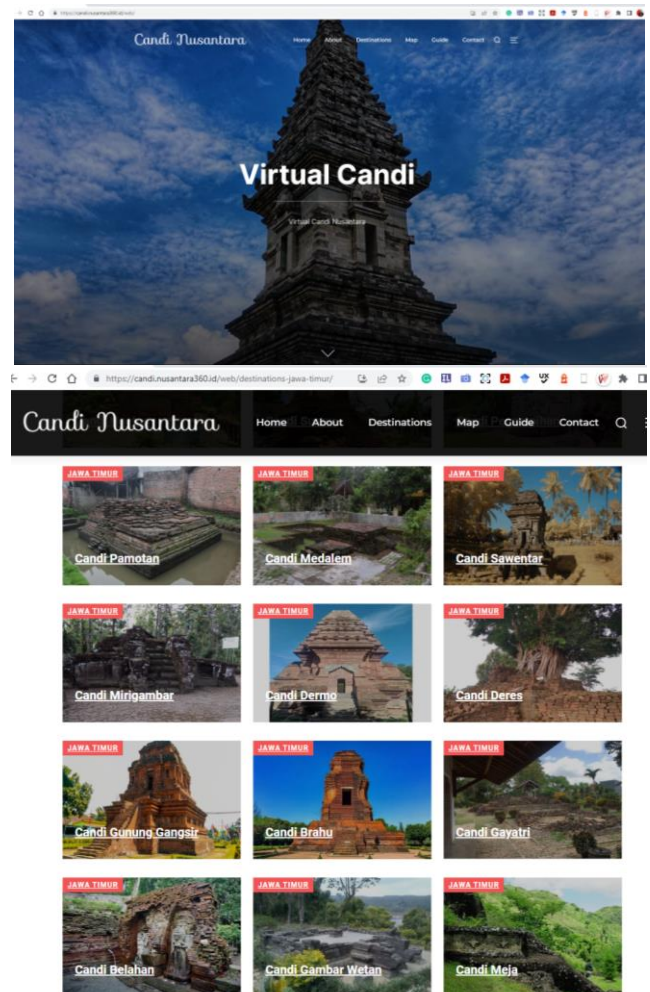

Fig. 23. Portal of Virtual Candi as Digital Database of Indonesian Historical Temple.

Since the temple wall has many reliefs that contain a visualization of a story, the 3D model created from this approach should be able to preserve it. Future work must be done to ensure that all the reliefs still exist. Digital restoration and refinement processes may proceed to make the reliefs exist like the original relics.

ACKNOWLEDGMENT

We thank all our participants for their contributions. This research work is funded by the Faculty of Computer Science at Brawijaya University and is part of making Indonesia's cultural heritage digital preserve database.

Dual-fast Greedy Heuristic Algorithm for Green ICT

Inas Abuqaddom

Dept. Computer Science

King Abdullah II School of Information Technology
The University of Jordan, Amman, Jordan

Abstract—The Internet power consumption represents 3.6% to 6.2% of the annual worldwide power consumption and is continually expanding. The awareness of this problem has increased, hence, a few strategies are being put into place to decrease the power consumption of the Information Communication Technology (ICT) sectors, in general. Backbone networks are the main part of the Internet power consumption because their line cards expend a lot of energy, also their links are commonly bundled and provide larger capacity than needed. Therefore, bundled links are partially shut down during times of low demand to reduce power consumption. Literature introduces a few heuristic algorithms that are run periodically to shut down bundled links partially. This paper proposes a Dual-Fast Greedy Heuristic algorithm (DGH), which significantly speeds up the power savings. DGH is examined on the topology and traffic of the Abilene backbone. The experimental results show that DGH provides competitive power savings with minimum execution time.

Keywords—Abilene backbone; backbone network; bundled link; capacity; Internet power consumption; power savings

I. INTRODUCTION

ICT (Information Communication Technology) handles the processes of communications such as telecommunications, broadcast media, intelligent building, network-based control, etc. [1, 2]. Green ICT is responsible for using computing resources efficiently and effectively with minimum impact on the environment, mainly by reducing their power consumption [2, 3]. Since the Internet is the pivot sector of ICT, network researches focus on reducing power consumption. The most popular power-saving technique is based on the power consumption of servers and wireless equipment [4]. However, reducing the power consumption of wired networks has been ignored, even though it is critical [5]. For example, powering the wired networks in the United States alone expenses an expected 0.5-2.4 billion dollars per year. Additionally, network architectures having better energy efficiency allow deploying networks in poor infrastructures [6].

The Internet has multiple backbone networks. Since a backbone network interconnects networks and provides paths for data exchange. Also, a backbone network is called a core network. Usually, the capacity of a backbone link is larger than the needs of backbone networks. The additional capacity is used to cover traffic shifts and to provide alternative paths for broken links [7]. For example, the average used capacity in backbone networks of big Internet service providers is no more than 30-40%, consequently, there are 70-60% extra capacities. Accordingly, using dynamic capacity instead of static capacity

for backbone networks will reduce the power consumption efficiently. The optimal technique to provide dynamic capacity is that the backbone links are partially shut down and powered as needed. Since the used capacity through off-peak hours is reduced to one-third or more of peak hours [5, 8].

A backbone link connects two routers and is structured as multiple physical cables that are dealt with as one logical bundled link [9]. Generally, a logical bundled link with all its physical cables is called bundled link, aggregate link, or composite link [9, 10]. Additionally, there is a line card at each end per physical cable to serve it. Nonetheless, bundled links are standardized by IEEE 802.1AX [10]. The capacity of a bundled link is the aggregate capacities of all its physical cables. Thus, to upgrade a bundled link i.e. increasing its capacity, you just add more physical cables to the existing cables. As a result, the capacity of a bundled link may exceed the capacity of the fastest physical cable. For example, given a bundled link of five OC-192 cables each with a 10 Gbps capacity, then the bundled link capacity is 50 Gbps.

The optimal power-saving approach shuts down and powers some physical cables of a bundled link as needed. In other words, this approach is an optimization problem that maximizes the power savings by shutting down the most possible physical cables of every bundled link, as it yet has enough capacity for future traffic. The physical cable selection is based on the current and expected traffic matrix, the network topology, and the bundled link capacity [11]. Thus, heuristic algorithms are used to find the optimal selection, which is an NP-complete problem [12]. Accordingly, these algorithms extremely vary in execution time, which increases the router overhead. However, the execution time of these algorithms is based on how they select physical cables of a bundled link to be shut down or powered [11].

This paper proposes the Dual-fast Greedy Heuristic (DGH) algorithm to reduce the power consumption of backbone networks with limited overhead on routers. DGH shuts down some physical cables and their corresponding line cards. Since line cards consume most of the router power consumption [8]. Moreover, DGH provides competitive power savings compared with other algorithms, in addition to its simplicity and high speed.

The rest of this paper is organized as follows; Section II describes the problem notations. Section III analyzes the literature review. Section IV portrays the proposed algorithm. Section V shows the experimental results. Finally, conclusions are shown in Section VI.

II. PROBLEM NOTATIONS

The backbone network topology is described as a directed graph $G(V, E)$ as V is a set of routers and E is a set of links. Usually, links are bundled and every bundled link $(u, v) \in E$, such that (u, v) connects two routers; $u, v \in V$ and has a capacity $c(u, v)$. Every bundled link consists of B physical cables. For example, a bundled link (u, v) consists of five 10 Gbps physical cables. Then $B=5$, which is the bundle size, and $c(u, v)=50$ Gbps, which is the bundled link capacity. The demand i.e. traffic between a couple of routers is described as a row (s_d, t_d, h_d) in the traffic matrix D , where s_d is the source router, t_d is the destination router, and h_d is the amount of demand between s_d and t_d combination. Furthermore, let $f_d(u, v)$ be the flow of the bundled link (u, v) and d is a demand amount through a bundled link (u, v) [13]. The aggregate flow of a bundled link (u, v) is denoted as $f(u, v)$ and shown in Equation (1). Usually, the flow $f(u, v)$ of a bundled link (u, v) does not exceed its capacity $c(u, v)$ [14].

$$f(u, v) = \sum_D f_d(u, v) \quad (1)$$

Furthermore, the extra capacity concept is the aggregate capacity of all unused physical cables of a bundled link. For example, Fig. 1 shows a partial backbone network, assuming there is a demand $d=4.5$ Gbps between a source router $s_{4.5}$ and a destination router $t_{4.5}$. Assume that every bundled link has a capacity of 10 Gbps, which are the aggregate capacities of ten 1 Gbps physical cables. As shown in Fig. 1, there are two paths between s and t , either $(s, 1, 2, 3, 4, t)$ or $(s, 4, t)$. Even though the demand is the same for both paths, its corresponding total flow varies. The total flow through the $(s, 1, 2, 3, 4, t)$ path is 22.5 Gbps, so the total extra capacities among all bundled links are 37.5 Gbps. However, the total flow through $(s, 4, t)$ path is 9 Gbps and the total extra capacities among all bundled links are 51 Gbps. Therefore, to minimize the total flow and maximize the total extra capacities, you have to select the shortest paths.

Accordingly, to maximize the total extra capacities of all bundled links, the traffic is routed through the possible shortest paths. Thus, the total flow through all bundled links is reduced. In other words, routing traffic through shortest paths minimizes the total flow of all bundled links and maximizes the total extra capacities of all bundled links, as shown in Equation (2).

$$\min \sum_{(u, v) \in E} f(u, v) \quad (2)$$

The network-management system runs an optimization algorithm periodically to reduce power consumption. The inputs of an optimization algorithm are a network topology $G(V, E)$, a bundle size B , and a traffic matrix D . Then, the optimization algorithm defines a network setup that utilizes the least physical cables from all bundled links, with the end goal of fulfilling all demands. The number of powered physical cables in a bundled link (u, v) is denoted as $n_{u, v}$. In other words, the outputs of an optimization algorithm are the selected powered physical cables per bundled link and the rerouting paths that some demands may use to increase the utilization of powered physical cables in the network [14].

Fig. 1. Backbone Network using Hierarchical Topology.

III. LITERATURE REVIEW

To control power consumption in local-area networks, Ethernet cards utilize off-peak periods to work in low power consumption modes. For example, Broadcom and Intel produce network cards containing programmable rest clocks, that can be controlled by algorithms to shut down a link for a while [15]. Nonetheless, some approaches shut down a router totally including all its bundled links and their corresponding line cards at that router [11]. However, these approaches are not compatible with wide area networks, because shutting down the whole bundled link must produce a packet loss [15].

In wide-area networks, literature shows approaches to control power consumption. One approach uses a sleep mode, such that the system puts network cards into the sleep mode. However, how does the system deal with traffic through sleeping network cards? There are two solutions; either using coordinated sleeping routers or uncoordinated sleeping routers. The coordinated sleeping router is a centralized solution, that reroutes traffic through sleeping network cards into alternative active network cards as could reasonably be expected. The drawback of this solution is that the router needs a dynamic protocol [6, 16, 17].

The uncoordinated sleeping router is an uncentralized solution. Every network card notifies its neighboring network cards before going to the sleep mode, which is allowable at low demand periods. Thus, an active network card wakes up the sleeping network card as needed by sending a wake-up packet. The drawback of this solution is the latency because of wake-up time and neighboring processing [6]. Furthermore, the authors of [15, 19] recommend an extreme suggestion as all network equipment should support a slow-speed mode to reduce power consumption.

Nevertheless, literature shows that the optimal power-saving approach shuts down and powers some physical cables of a bundled link according to the low demand time. This approach uses the extra capacities, which are determined by the traffic matrix of all bundled links. Generally, this approach maximizes the total extra capacities of all bundled links since the traffic is routed through the possible shortest paths. As mentioned in the Introduction Section, this approach uses heuristic algorithms to find a possible optimal selection among physical cables of a bundled link [6]. This section presents the most known heuristic algorithms, which utilize the unused capacity of powered physical cables. These algorithms are the Fast Greedy Heuristic algorithm (FGH), Exhaustive Greedy Heuristic algorithm (EGH), and Bi-level Greedy Heuristic algorithm (BGH) [19].

A. Fast Greedy Heuristic Algorithm

FGH is the fastest and simplest algorithm compared with EGH and BGH. Initially, FGH minimizes the total flow of all bundled links to maximize the total extra capacities of all bundled links, as shown in (2). Then FGH shuts down all extra capacities such that the remaining powered physical cables can serve all the network traffic. After that, FGH finds the physical cable with the largest unused capacity by using (3) [14].

$$f(u,v) \leq (n_{uv} \div B) c(u,v) \quad \forall (u,v) \in E$$

such that,

$$\max_{(u,v)} ((n_{uv} c(u,v) \div B) - f(u,v)) \quad (3)$$

Periodically, FGH attempts to shut down the physical cable having the largest unused capacity and reroutes its corresponding flow. According to the example in Section II, if you shut down one out of the remaining five physical cables, that carry out the demand $d=4.5$ Gbps, you have to reroute a demand $d=0.5$ Gbps into alternative paths. Then, FGH examines (2). If it is not satisfied anymore, FGH powers the shutting down physical cable and marks its bundled link (u, v) as “final”, so no more future attempts to shut down any of its physical cables. As long as (2) is satisfied, the shutting down physical cable is confirmed and (3) is calculated. FGH repeats until all bundled links are marked as “final” [14].

However, FGH has drawbacks; such as if FGH shuts down a physical cable that produces a suboptimal solution, it will never backtrack to revise the selection.

B. Exhaustive Greedy Heuristic Algorithm

EGH performs as FGH using different conditions to shut down a physical cable. EGH calculates a penalty value for every candidate-physical cable. Such that, EGH shuts down the physical cable having the smallest penalty. Nevertheless, the penalty for a physical cable is calculated based on the flow distribution before and after shutting down the physical cable. Thus, the penalty allows the algorithm to do a “look-ahead” decision on each physical cable before removing it. Usually, EGH finds an optimal selection consuming a larger execution time and increasing the router overhead because of penalty calculations [14].

C. Bi-level Greedy Heuristic Approach

BGH performs as EGH using the penalty condition, but in a different manner. BGH applies a penalty on a pair of physical cables and shuts down the pair having the smallest penalty. However, the penalty for a pair of physical cables is calculated based on the flow distribution before and after shutting down the physical cables. Therefore, BGH finds the optimal selection, consuming unreasonable execution time to make a removal decision [14]. Accordingly, the router overhead extremely increases because of the double penalty calculations per selection.

IV. PROPOSED ALGORITHM

As we mentioned previously, FGH is fast and simple. Literature shows that the three heuristic algorithms (FGH, EGH, and BGH) are close to each other in terms of power-saving amount, but they extremely vary in execution time.

Moreover, a network operator runs one of these algorithms very often to control the power consumption. Thus, it is essential to reduce the execution time, which is varied from a few minutes using FGH, a few hours using EGH, and countless times using BGH. Their execution times vary because of the (2) complexity, which is $O(|E|^2)$ for both FGH and EGH as is $O(|E|^3)$ for BGH. On the other hand, FGH and EGH are different in selecting a physical cable to be shut down. FGH selects a physical cable having the maximum unused capacity, as EGH selects a physical cable having the minimum penalty. However, penalty calculation is harder and consumes more time than unused capacity calculation. As a result, execution times of FGH and EGH are different, even though they have the same complexity of (2) [14].

Accordingly, this paper proposes a Dual-Fast Greedy Heuristic algorithm (DGH) to speed up the power-saving process consuming limited overhead on routers. Initially, DGH minimizes the total flow of all bundled links to maximize the total extra capacities of all bundled links. Then, DGH shuts down all extra capacities from all bundled links. After that, DGH randomly shuts down a physical cable from a bundled link (u,v) and reroutes the flow of the shutting-down physical cable into alternative shortest paths. As a test for optimality, DGH examines (2). If it is not satisfied, DGH powers the shutting down physical cable and marks its bundled link (u,v) as “final” to prevent future shut-down attempts on (u,v) . Otherwise, the shutting down physical cable is confirmed. Moreover, DGH repeats selecting a random physical cable from a random unmarked bundled link until all bundled links are marked as “final”.

DGH reduces the power-saving cost to the minimum because there is no calculation per selecting a physical cable. On the other hand, DGH could result in a suboptimal solution, since DGH randomly selects a physical cable. In other words, DGH is similar to other heuristic algorithms in the first part, which is shutting down all extra capacities from all bundled links. Then DGH randomly selects a physical cable to shut down without any extra calculations. Consequently, DGH provides power savings similar to FGH, EGH, and BGH, because of the first common part. Additionally, DGH consumes a lower execution time, because all further shutting down physical cables, after the first common part, are selected randomly.

V. EXPERIMENTAL RESULTS

The proposed algorithm DGH is examined using AMPL/CPLEX solver. CPLEX is an optimization package for linear, network, and integer programming. AMPL is an algebraic modeling language, which stands for A Modeling Language for Mathematical Programming. Generally, AMPL utilizes an optimization package such as CPLEX to solve optimization problems [20, 21]. As an experimental backbone network, the Abilene backbone network of 39 nodes is used. The experimental Abilene is examined using two topologies; Waxman and hierarchical topologies, as Table I presents their parameters, which are the number of bundled links as shown in “#Bundled links” column and the requested demands between any two nodes as shown in “Demands” column. The key difference between both topologies is connectivity. Such that

every existing bundled link between any two nodes is doubled to be in both directions for the hierarchical topology. However, some existing bundled links are doubled to be in both directions for the Waxman topology. Fig. 2 and 3 show examples of Waxman and hierarchical topologies, respectively. Results were collected on the Intel Core 2 processor running Ubuntu server 14.04.

TABLE I. PARAMETERS OF ABILENE TOPOLOGIES

Topology	#Bundled links	Demands
Hierarchical	148	2.450
Waxman	169	2.450

Fig. 2. Waxman Topology.

Fig. 3. Hierarchy Topology.

In the Waxman topology, the likelihood that two nodes are directly connected by a bundled link increases as the distance between them decreases. The hierarchical topology was created by GT-ITM [18]. Moreover, real demands were estimated by traditional entropy for urban traffic [22]. However, DGH is compared with FGH because it is the fastest algorithm.

Experimental results show that FGH and DGH provide similar power savings. Because both of them shut down all extra capacities from the beginning, also both of them fell into suboptimal solutions during the further steps. However, DGH outperforms FGH in terms of execution time. Fig. 4 shows the execution time of both FGH and DGH on Waxman topology. DGH outperforms FGH irregularly because of irregular topology. While Fig. 5 shows the execution time of both FGH and DGH on hierarchical topology. The curves of Fig. 5 reflect

the regular and little improvement of DGH due to the regular topology.

To translate the shown improvement into numbers, the improvement ratio is calculated using Equation (4):

$$IR = \text{avg}(T_{FGH}) - \text{avg}(T_{DGH}) \tag{4}$$

Where IR is the improvement ratio, as T_{FGH} and T_{DGH} are the execution time using FGH and DGH algorithms, respectively. Thus, DGH outperforms FGH in both topologies with improvement ratios of 18% and 36.17% on hierarchical and Waxman topologies, respectively.

Moreover, both Fig. 4 and 5 show that the bundled link size and the execution time are almost independent, because both DGH and FGH shut down all extra capacities in the first step.

Fig. 4. The Execution Time of FGH and DGH Algorithms Applied on Waxman Topology.

Fig. 5. The Execution Time of FGH and DGH Algorithms is Applied to Hierarchical Topologies.

VI. CONCLUSION

Green ICT is responsible for reducing the power consumption of computing resources to minimize their impact on the environment. The Internet represents up to 10% of the worldwide power consumption and is continually expanding. Furthermore, backbone networks are the main part of Internet power consumption. Since links of these networks are commonly bundled and provide larger capacity than needed.

A few approaches are proposed to reduce power consumption in the Internet backbone. One of them depends on shutting down individual cables of bundled links during times of low demand. However, optimal shutting down physical cables is an NP problem. Therefore, algorithms compete for increasing shutting-down cables in a reasonable time to provide more power savings. Accordingly, this paper proposes a dual-fast greedy heuristic algorithm (DGH), which shuts down all extra capacities from all bundled links. Then, DGH randomly shuts down a physical cable having an unused capacity. Also, DGH reroutes the flow of the shutting-down physical cable.

To assess DGH, the AMPL/CPLEX solver is utilized on the Abilene backbone. DGH is compared with the fastest algorithm, which is FGH. The experimental results show that DGH is faster than FGH and provides similar power savings as FGH. Nonetheless, the improvement ratios in terms of execution time are between 18% and 36.17% for Waxman and hierarchical topologies, respectively. The drawback of DGH is the suboptimal solution, which does not affect the power savings because DGH shuts down all extra capacities from the beginning. In a conclusion, DGH gets suboptimal selection to reduce the router overhead, which in turn reduces the power consumption. For future works, DGH could be examined using various backbone networks and various sets of parameters.

Abstract—Quadratic Assignment Problem is one of the most common combinatorial optimization problems that represents many real-life problems. Many techniques are applied to solve Quadratic Assignment Problem, these include exact, heuristic, and metaheuristic methods. A Genetic Algorithm is a powerful heuristic approach used to find optimal solutions or near-to-optimal for Quadratic Assignment problems. In this paper, we developed a Genetic Algorithm with a new crossover operator with new technology closer to that found in nature without a crossover point and a new suggested intelligent mutation operator, then we developed a Parallel Genetic Algorithm using the same crossover and mutation. The sequential Genetic Algorithm will be implemented in the Central Processing Unit (CPU), and the Parallel Genetic Algorithm will be implemented in the Graphical Processing Unit (GPU). This paper presents two comparisons, first calculates elapsed time for crossover, mutation, and selection in both CPU and GPU, then compares the results. This comparison clearly shows the enhancement degree of computation time in the parallel environment, which is around half the time executed in the sequential environment. The second comparison, iterates these operators into several generations, using twenty benchmark instances reported in Quadratic Assignment Problem Library with sizes from (12-70), population size equal to 600, the number of generations equal to 2000, and the maximum number of parallel threads will be 600. Proposed crossover and mutation give the optimal solutions with ten benchmarks with problem sizes from 12 to 32 in both Sequential Genetic Algorithm and Parallel Genetic Algorithm, the next ten benchmarks give solutions closed to the optimal solution with a small error rate.

Keywords—Component; Quadratic Assignment Problem (QAP); Genetic Algorithm (GA); Parallel Genetic Algorithm (PGA); Sequential Genetic Algorithm (SGA); Central Processing Unit (CPU); Compute Unified Device Architecture (CUDA); Quadratic Assignment Problem Library (QAPLIB); Best Known Solution (BKS); Average Percent Deviation (APD)

I. INTRODUCTION

The Quadratic Assignment Problem (QAP) is one of the most common combinatorial optimization problems that represents many real-life problems. The QAP involves the assignment of n facilities that have flows (weights) among them to n possible locations that also have distances among them to achieve the minimum sum of the distances multiplied by flows, this minimum sum will be reached by assigning high facilities to nearby locations and small facilities to far locations. The problem was first introduced as a mathematical

model for economic activities in 1957[1], then it was becoming a fundamental and important problem to represent several applications in different areas, such as computer backboard wiring, locating clinics with a hospital, locating machine and electronic components, assignment of buildings in a university campus, etc.

The quadratic assignment problem (QAP) consists of n facilities and n possible locations, exactly one facility for each location. For each pair of facilities, a flow matrix, $F = [f_{ij}]$ is defined, which consists of flow values that must be required to move from facility i to facility j . Also, for each pair of locations, a distance matrix, $D = [d_{kl}]$ is defined and it consists of distance values between location k to location l . The assignment of facility i is not independent of other assignments, so when assigning facility i to location k we must consider the assignment for all other facilities that have nonzero relationships with facility i . Let $a = \{a(1), a(2), \dots, a(n)\}$ be an assignment, where $a(i)$ represents the location of the facility i . The problem is to assign to each location exactly one facility to minimize the cost of the objective function as shown in Equation. 1.

$$Z_a = \sum_{i=1}^n \sum_{j=1}^n f_{ij} d_{a(i)a(j)} \quad (1)$$

Since the solution is derived from $n!$ possible assignments, it makes the problem impossible to solve in polynomial time with moderate problem size, even with modern computers.

The QAP solving methods can be categorized into three main classifications: exact methods, heuristic methods, and meta-heuristic methods. The exact methods give the exact optimal solution, but the drawback of such methods is the long computational time that makes the solution impossible. Therefore, the problem was restored to be solved using heuristics and meta-heuristic methods which overcome the problem of long computational time, but they also have their drawback. Heuristics and meta-heuristic methods do not guarantee to provide the exact optimal solution, but they instead provide a good solution, near to optimal solution, in reasonable computational time. Genetic algorithms, simulated annealing, tabu search, artificial neural network, etc., are some well-known heuristic methods, and genetic algorithm is considered as one of the best heuristic methods.

A Genetic Algorithm (GA) provides individual candidate solutions that do not hold any dependencies between them, so, it will be easy to implement such an algorithm in parallel to get a more considerable speedup.

This paper uses a parallelism concept which in turn becomes an effective way to simplify the difficult problems and reduce its computational time. Additionally, GA is a popular effective heuristic approach in both computation time and solution quality. So, they have motivated us to take the advantage of both GA and parallelism to solve that difficult problem.

This work exploits the recent improvement in the graphical processing unit (GPU) which is expanded to include parallel computation rather than just graphical purpose. So, we will propose a solution for QAP using a proposed genetic algorithm with enhancement in crossover and mutation. These enhancements are suggested new crossover operator with new technology which closer to that found in nature without crossover point and new intelligent mutation operator which in turn improve solution quality.

II. BACKGROUND AND RELATED WORK

Genetic algorithms were first invented on QAP by John Holland at the University of Michigan in 1975[2]. The first applied for GA in QAP was in 1994 by Fleurent and Ferland[3]. GA is considered as a type of stochastic and local search technique, which are based on three natural operators: selection, crossover, and mutation. Also, there are many recent efficient algorithms, we will present a brief study about them to explore the new techniques and take advantage of them.

Radomil Matousek et al [4] presented Metaheuristic Optimization Using HC12 Algorithm. It is categorized as a parallel algorithm implemented on GPU. It used HC12 which is a Genetic Algorithm using binary encoding which depends on the next population is a population from the current solution neighborhood. This algorithm gives the optimal solutions for 8 problems with sizes (12 -32) in a short run time of an average of 1.89 seconds.

Takeshi Okano et al [5] proposed variant k-opt local search (vKLS) which is categorized as a sequential algorithm in a CPU environment, vKLS used a variable depth approach that depends on exchanging multiple nodes at a time rather than just two nodes. They combine two strategies best-improvement move and the first-improvement move. vKLS tested on 48 QAPLIB instances with a range of 20 - 150 in a fixed period equal to 60 seconds.

Ensieh et al improved the performance of the (NIFLS) Fast Local Search algorithm in the sequential environment by adding Temperature characteristics from simulated annealing to conduct the search to explore the search space wider[6]. The algorithm gets 0.26 APD in average execution time 1207 seconds.

Erdener et al developed ILS (Iterated Local Search) algorithm using GPU parallelism[7]. They implement the multi-start technique, use the delta function instead of

calculating object function for each neighbor and design a mutation operator to escape the local optimum. The algorithm works 6.31 to 11.93 times faster than sequentially one.

Omar Abdelkaf et al. [8] suggested Parallel iterative Tabu Search (PITS) by parallelizing an existing TS algorithm called Ro-Ts using a grid of 5000 CPUs. PITS works with 350 iterations inside the process, 100 global iterations, and 40 processes. PITS gives an average standard deviation equal to 12.19 in average time equal to 13.01 minutes with problems with size 343.

Also Emrullah et al presented an algorithm called the Parallel Simulated Annealing method with multi-start technique (PMSA) using GPU parallelism[8]. PMSA starts the next SA algorithm with the best previous generated value rather than a random permutation, this technique is called the multi-start approach. It provides the optimal solution for 196 instances except for 14 instances in time less than 60 seconds.

Lopez et al presented GA-CPLS algorithm which is a type of CPU level parallelism[9]. CPLS operation depends on a group of nodes called explorers. GA-CPLS performed the Genetic algorithm as the main explorer to generate the population as a head node, other explorer nodes execute the Extremal Optimization Algorithm and robust Tabu search. GA-CPLS gives 0.054 APD on an average time of 82.7 minutes.

Seyda et al improved sequential Hybrid GA called IHGA[10]. Its idea takes from combining genetic algorithm, simulated annealing algorithm, and the greedy algorithm. It enhances the solution by 13.33, 7.94, 2.50, and 0.29 percent better than the greedy algorithm, DA, classical GA, and SA respectively.

Soukaina et al developed a Hybrid Chicken Swarm Optimization (HCSO)[11]. HCSO applies GPU level parallelism and integrates Chicken Swarm Optimization CSO with Greedy Randomized Adaptive Search Procedure GRASP. GRASP run with a 2-opt Local Search for constructing the initial population. HCSO finds the optimal solution for 85% of 30 QAP instances.

Mohamed et al enhanced Whales Optimization Algorithm by integrating it with Tabu Search (WAITS)[12]. WAITS was applied in a sequential environment, and it enhances the speed of convergence and local search inside the Whales Algorithm (WA). WAITS provides the optimal solutions for 86 instances out of 122 instances.

Previous studies explored many recent heuristics and metaheuristics algorithms in solving QAP either in parallel or in a sequential environment. Parallelism can be designed at the CPU level or GPU level. As we see from reviewed algorithms, parallel algorithms designed by GPU produced better results in computational time and algorithms like GA will provide a high-quality solution in a reasonable time. This will motivate us to design a new GA with a new crossover operator with new technology closer to that found in nature, it depends on arranging genes in a specific way without the need for a crossover point, and also suggested an intelligent mutation operator in the GPU environment.

The proposed method will be implemented and tested in a sequential environment and then in parallel to compare results and to show the degree of parallel improvement using benchmark instances available in QAPLIB[13].

This paper was organized into sections, each section treats a part of our works. The second section shows the methodology of our works, the next section illustrates the overall structure of the proposed algorithm, the fourth section analyzes and explores the results, and finally the conclusion.

III. METHODOLOGY

A. Population Initialization Method

Population sets will be initialized randomly concerning the problem size. Additionally, make sure this population does not have incomplete or invalid individuals and all nodes are existing and forming a complete solution. Also, be sure the individual does not have redundant nodes or invalid nodes.

B. Selection Method

The proposed GA applied the selection to two places in the algorithm. First, parents' selection is called the stochastic remainder selection method. It works by assigning a probability to every individual to be chosen as a parent. This method takes each individual's fitness then divides it by average fitness, the integer part of the division represents the number of appearances of the individual as a parent, and the remaining fractional part is used to stochastically fill the remaining parents to stochastic places.

The second application of selection was after crossover operation when deciding about if a current parent will stay for the next generation or be replaced by its best offspring. This type of survivor selection is called the steady-state approach.

C. Crossover Operator

In this paper, we propose a new crossover method that produces an individual who inherits from parent's characteristics as much as possible. This method will preserve the order of the inherited nodes from both parents without making a crossover point.

The following example will illustrate the proposed crossover method by using the facility matrix and distance matrix that is used in the "Hud12" benchmark. If we have two parents parent1 with cost = 1956 and parent2 with cost = 1936 each with size 12, as shown in Fig. 1 and Fig. 2, and offspring will be as shown in Fig. 3.

Parent1:

5	4	12	6	10	9	7	1	8	3	11	2
---	---	----	---	----	---	---	---	---	---	----	---

Fig. 1. Crossover _ parent1

Parent2:

12	6	9	2	4	11	10	1	5	8	7	3
----	---	---	---	---	----	----	---	---	---	---	---

Fig. 2. Crossover _ parent2.

Offspring:

5	4	12	6	10	9	2	11	1	8	7	3
---	---	----	---	----	---	---	----	---	---	---	---

Fig. 3. Crossover_offspring.

There are two indexes (index1= 0) which point to the first index in parent1, (index2=size-1=11) which point to the last index in parent2. Start filling offspring by these two indexes, at the same time, as shown in Fig. 4.

Step1: index1=0, index 2=11, offspring will be:

5											3
---	--	--	--	--	--	--	--	--	--	--	---

Fig. 4. Crossover First Step.

5 is the first node in parent1, 3 is the last node in parent2, increment index 1, decrement index2, index1=1, index2=10.

Step2: index1=1, index2=10, before inserting must check if the new node exists in new offspring if not just insert it, if exist go to the next node in the corresponding parent, offspring will be , as shown in Fig. 5.

5	4								7	3
---	---	--	--	--	--	--	--	--	---	---

Fig. 5. Crossover Second Step.

4 is the second node in parent1, 7 is the second node from the last in parent2, increment index 1, decrement index2, index1=2, index2=9.

Step3: index1=2, index 2= 9, before inserting must check if the new node exists in new offspring if not just insert it, if exist go to the next node in the corresponding parent, offspring will be as shown in Fig. 6:

5	4	12						8	7	3
---	---	----	--	--	--	--	--	---	---	---

Fig. 6. Crossover Third Step.

12 is the third node in parent1, 8 is the third node from the last in parent2, increment index1, decrement index2, index1=3, index2=8.

Step4: index1=3, index 2= 8, before inserting must check if a new node exists in new offspring if not just insert it, if exist go to the next node in the corresponding parent, offspring will be , as shown in Fig. 7.

5	4	12	6					1	8	7	3
---	---	----	---	--	--	--	--	---	---	---	---

Fig. 7. Crossover Fourth Step.

6 is the fourth node in parent1, 5 is the fourth node from the last in parent2 but 5 exists in offspring, so go to the fifth node from the last in parent2 which is 1 then check if doesn't exist in offspring insert 1, increment index1, decrement index2, index1=4, index2=7.

Step5: index1=4, index 2= 7, before inserting must check if the new node exists in new offspring if not just insert it, if exists go to the next node in the corresponding parent, offspring will be as shown in Fig. 8.

5	4	12	6	10			11	1	8	7	3
---	---	----	---	----	--	--	----	---	---	---	---

Fig. 8. Crossover Fifth Step.

Ten (10) is the fifth node in parent1, 10 is the sixth node from the last in parent2 but 10 exists in offspring, so go to the

seventh node from the last in parent2 which is 11 then check if does not exist in offspring insert 11, increment index 1, decrement index2, index1=5, index2=6.

Step 6: index1=5, index 2= 6, before inserting must check if the new node exists in new offspring if not just insert it, if exist go to the next node in the corresponding parent, offspring will appear as shown in Fig. 9.

5	4	12	6	10	9	2	11	1	8	7	3
---	---	----	---	----	---	---	----	---	---	---	---

Fig. 9. Crossover Sixth Step.

Nine (9) is the sixth node in parent1, 4 is the eighth node from the last in parent2 but 14 exists in offspring, so go to the ninth node from the last in parent2 which is 2 then check if doesn't exist in offspring insert 2. The cost for the generated offspring = 1868 which is better than the cost of parents.

Crossover must be simple as possible to achieve maximum utilization of GPU benefits. The generated offspring was produced by simple crossover but inherit many features from parents selected by a strong selection method.

D. Mutation Operators

The proposed GA uses a new mutation operator that works as scanning the individual to find the maximum product (flow * distance) located between facility(i) to the facility (i+1). Then swap facility (i+1) with random node from the individual.

This proposed mutation can be illustrated as shown in the following example: The following individual belongs to the "Had12" benchmark with cost = 1902, as shown in Fig. 10.

4	6	3	1	8	2	9	10	7	12	5	11

IV. STRUCTURE OF THE PROPOSED PARALLEL GENETIC ALGORITHM

The following algorithm shows the general structure of the proposed PGA, followed by a system diagram to represent the PGA structure, as shown in Fig. 12.

PGA exploited graphical processing unit (GPU) for non-graphical parallel computation, the proposed algorithm uses a large single population of individuals which is distributed among several threads in GPU. Each thread performs three GA operators Crossover, Mutation Survivor, and Selection because they are suitable to implement in the parallel environment as shown in Fig. 12. This means, does not need to force threads to communicate between each other or lock other threads, or wait for other threads until unlocking, this parallelism technique maintains data integrity and consistency also threads' waiting time is almost non-existent. The proposed algorithm was shown in Table I.

TABLE I. ALGORITHM I

V. RESULT AND DISCUSSION

This section will show an analysis, discussion, and illustration of the output and results of the proposed method in this paper, results are going to be analyzed in two ways. The

first analysis will present six tables that show elapsed time for GPU and CPU during the execution of proposed crossover, mutation, and selection. The second analysis presents a test of the proposed method in GPU and CPU after embedding it inside several iterations (generations).

The proposed method was tested in CPU of type intel® core™ i7-8565U CPU @ 1.80GHz (8 CPUs) and GPU of kind NVIDIA GeForce MX250 using both CUDA (Compute Unified Device Architecture) and C++ programming languages.

The following four figures show a comparison between CPU and GPU using common QAP benchmarks, while N means the size of population, CPU and GPU time is measured in milliseconds.

A. First Test Illustration

This test shows elapsed time for GPU and CPU during the execution of proposed crossover, mutation, and selection.

Fig. 13. CPU and GPU Time Illustration with Problem Sizes.

1) For the “lipa20a” benchmark: “lipa20a” benchmark with problem size equal to 20. We notice that when population size equal to 100, 200, 300, and 400 CPU show better results than GPU. Here the problem size is small, and we will only see the enhancement in GPU when the size of the problem and population increase. After increasing the population size to 600 we will observe the GPU enhancement and CPU time become approximately twice the time of GPU. Fig. 13 shows a graphical representation of this problem.

2) For the “lipa30a” benchmark: The enhancement on GPU begins at N=300, then the CPU time will take an increasing rate when population size increases. Compared to GPU time, GPU time does not take a significantly increasing rate while the population size increases, it just took a small increasing rate ≈ of 0.56 milliseconds, as shown in Figure IV.1. CPU continues increasing until it reaches more than 2x time of GPU time at N= 600. Fig. 13 Shows a graphical representation of this problem.

3) For the “lipa40a” benchmark: The improvement on GPU starts when N=300, then the CPU time will increase when population size increases until it reaches nearly 2x the time of GPU at N= 600. On the other hands, GPU time takes a small increasing rate ≈ of 0.58 while the population size increases. Fig. 13 shows a graphical representation of this problem.

4) For the “lipa50a” benchmark: shows the same result as “lipa40”. The CPU looks better than GPU when N=300, but after that, it becomes worse when N>300. CPU becomes around 2x time of GPU at N= 600. As we noted earlier GPU time is not affected much by population increase, as shown in Fig. 13.

5) For “lipa60a” and “lipa70a” benchmarks: CPU looks worse than GPU when population size > 200, it becomes around 2.3x time of GPU at problem size =60 and N= 600 and it becomes around 2.5x time of GPU at problem size = 70 and population size N= 600, as shown in Fig. 13.

6) Fig. 14: shows the worst CPU time state when population size = 600, it becomes around 2x GPU time and it increases at a significant rate when the problem size increases.

B. Second Test

Table II presents a test set using a group of common QAP benchmarks in size range (12 - 70) and population size N =600. After inserting the proposed tested method into the whole Genetic Algorithm program, we will show their elapsed CPU and GPU time after 2000 generations then show the best solution found in both CPU and GPU. Also, measure Average Percent Deviation to measure how much the solution is closed to best known solution (BKS), as shown in Equation. 2.

$$APD = \frac{\text{solution} - \text{BKS}}{\text{BKS}} \quad (2)$$

Fig. 14. CPU and GPU Time when Increased Problem Size and N=600.

TABLE II. SOLUTIONS AND ELAPSED TIME FOR CPU AND GPU

The proposed crossover and mutation give the optimal solution with the first ten benchmarks with problem sizes from 12 to 32 in both sequential Genetic Algorithm and Parallel Genetic Algorithm, next ten benchmarks give a solution close to the optimal solution with a small error rate, CPU and GPU time are measured in milliseconds.

VI. CONCLUSION

After this study, we found that the GPU time is not affected much by increasing either population size or problem size compared to CPU time. GPU time was increased by a small rate \approx of 0.61 when increasing population size and take a small rate \approx of 4.5 when the size of the problem increases. Also, the CPU time shows its worst when the population size = 600, it becomes around 2x GPU time, and it increases at a significant rate when the problem size increases.

This paper concentrates on applying proposed GA to QAP, which in turn, gives a successful result in finding optimal solutions or solutions near to optimal.

Also, this paper applies proposed GA in the parallel environment which shows a good result in execution time enhancement. As mentioned before, the proposed solution uses a large population size; therefore, a lot of synchronous threads will be needed. So, as future works, we can increase the number of threads by increasing the size of the screen card (NVIDIA). Furthermore, the proposed PGA can be generalized

to cover other optimization problems such as TSP (traveling salesman problem) or VRP (Vehicle routing problem).

As a future work we try to enhance some drawbacks that make algorithm slower such as sequential parent selection, it needs to convert to be work in parallel environment.

Abstract—Cars play an important role in many aspects of people's social life, and the effective handling of car quality complaints is of great significance to the proper running of cars and the reputation maintenance of car brands; effective classification of car quality complaint texts is the basis of the efficient handling of corresponding quality complaints, while relying on manual classification has disadvantages such as heavy workload, experience dependence, and error proneness; machine learning methods have been quite widely used in the automatic classification modeling for different types of natural language texts. It is of great practical significance to construct the automatic classification model of car quality complaints based on machine learning. Based on the characteristics of car quality complaint texts, this study vectorized the texts after word segmentation, performed feature selection and dimension reduction based on correlation analysis, and combined the progressive model training method and support vector machine to construct the classification model; in model reliability analysis, it was evaluated based on the effect of data amount on the modeling and the effect of text length on the prediction probability distribution. The results show that based on the method in this study, effective automatic classification model of car quality complaint texts could be constructed.

Keywords—Car; quality complaint; natural language text; classification modeling; machine learning

I. INTRODUCTION

The studies on text classification are quite extensive, but there are few related studies on complaint text, and the applicability of classification methods is closely related to text characteristics. The composition and structure of cars are relatively complex; during the long-term use of cars, quality problems might gradually appear, reasonable handling for the quality problems has important effect on the normal operation of cars and the maintenance of user experience, which is also an important decision-making influence factor for people choosing car brand and car product.

Machine learning has been quite extensively applied to natural language text classification in recent years [1-4]. Text classification based on machine learning mainly involves two core links: text vectorization and classification modeling. The methods used in text vectorization mainly include the methods based on word frequency [5-7], the methods based on distributed static word vectors [8-11], and the methods based on distributed dynamic word vectors [12-13]. The methods

used in the classification modeling mainly include classical machine learning methods [14], various neural networks [15-19], ensemble learning [20] and so on.

II. TECHNICAL ROUTE

The technical route of this study includes seven parts, including data sorting, data characteristic analysis, word segmentation, feature extraction, classification modeling, model reliability analysis, summary and prospect.

The part of data sorting includes the acquisition of basic data, and the construction of research dataset based on the text characteristics and research purposes. The part of data characteristic analysis conducts a comprehensive overview of the dataset mainly from the aspects of data distribution, text length characteristics, the distribution of car type, the distribution of purchase time, and the distribution of car brand.

The research object of this study is Chinese text and the study involves word segmentation. The word segmentation part in the technical routes include using Jieba for word segmentation, removal of stop words, word frequency distribution analysis, classification feature word analysis, etc. The removal of stop words aims mainly at removing function words which have little significance for classification, such as the connectives in complaint texts. Word frequency distribution analysis mainly analyze the discrimination and contribution potential of high-frequency words in the classification of car quality complaints, from the perspective of the word frequency distribution of global high-frequency words in different categories. Classification feature word analysis mainly analyzes the characteristics of high-frequency words in each category after removing stop words, and conducts preliminary data status analysis.

The feature extraction part mainly involves three links: text vectorization, feature correlation analysis, and feature selection. In the text vectorization process, the text data is converted to vector form based on bag-of-word method, which doesn't include stop words. In the feature correlation analysis link, the frequency correlation of word features is analyzed through correlation matrix constructing, and the feature selection is performed by removing highly correlated word features to reduce vector dimension so as to improve the efficiency of modeling and classification.

In the classification modeling part, the progressive strategy is used, the proportion of the features used in modeling is gradually increased in multiple stages; the modeling effects under different proportions of features are compared to obtain the optimal modeling feature quantity. The meaning of the progressive strategy is that too few features might don't contain enough necessary information for building an effective classification model, at the same time, too many features might confuse the core information and reduce the classification ability of the model, furthermore, too many modeling features would also result in negative effects on the efficiency of modeling and classification. The classification modeling uses the method of support vector machine, and the evaluation of modeling effect is analyzed from two aspects: the classification quality on the whole dataset and the quality on different categories of complaint texts.

The model reliability analysis part includes three aspects: the effects of data amount on the overall modeling indexes, the effects of data amount on the classification effect in each category, and the effects of text length on the probability distribution of the classification prediction. The amount of training data commonly has an important effect on the reliability of the model, too little data might don't be enough to train a reliable and stable model, and the model's predict ability to new data outside the research dataset might be insufficient or unstable, generally, based on more data, more stable model could be obtained; at the same time, after the amount of data reaches a certain threshold, the continued increase of the data amount commonly no longer has significant effect on the stability of the model. For different types of texts, the amount of data required for classification model training commonly varies. This study analyzes the effect of data amount on the classification modeling of car quality complaint texts by incrementally adding of data and comparing multiple rounds of model training; the evaluation and analysis are carried out from two aspects: the effect of data amount on the overall indexes of modeling, and the effect of data amount on the classification effect in each category. In addition, the text length might have effect on the text classification prediction effect, and the discrimination of the classification prediction probability distribution could reflect to some extent the reliability of the classification prediction, therefore, in this study, the effect of text length on the probability distribution of classification prediction is regarded as another aspect of the reliability evaluation.

At the end of the study, the results are summarized to obtain effective conclusions, and the deficiencies of the study are analyzed, so as to provide reference for subsequent related research and application.

The technical route of this study is shown in Fig. 1.

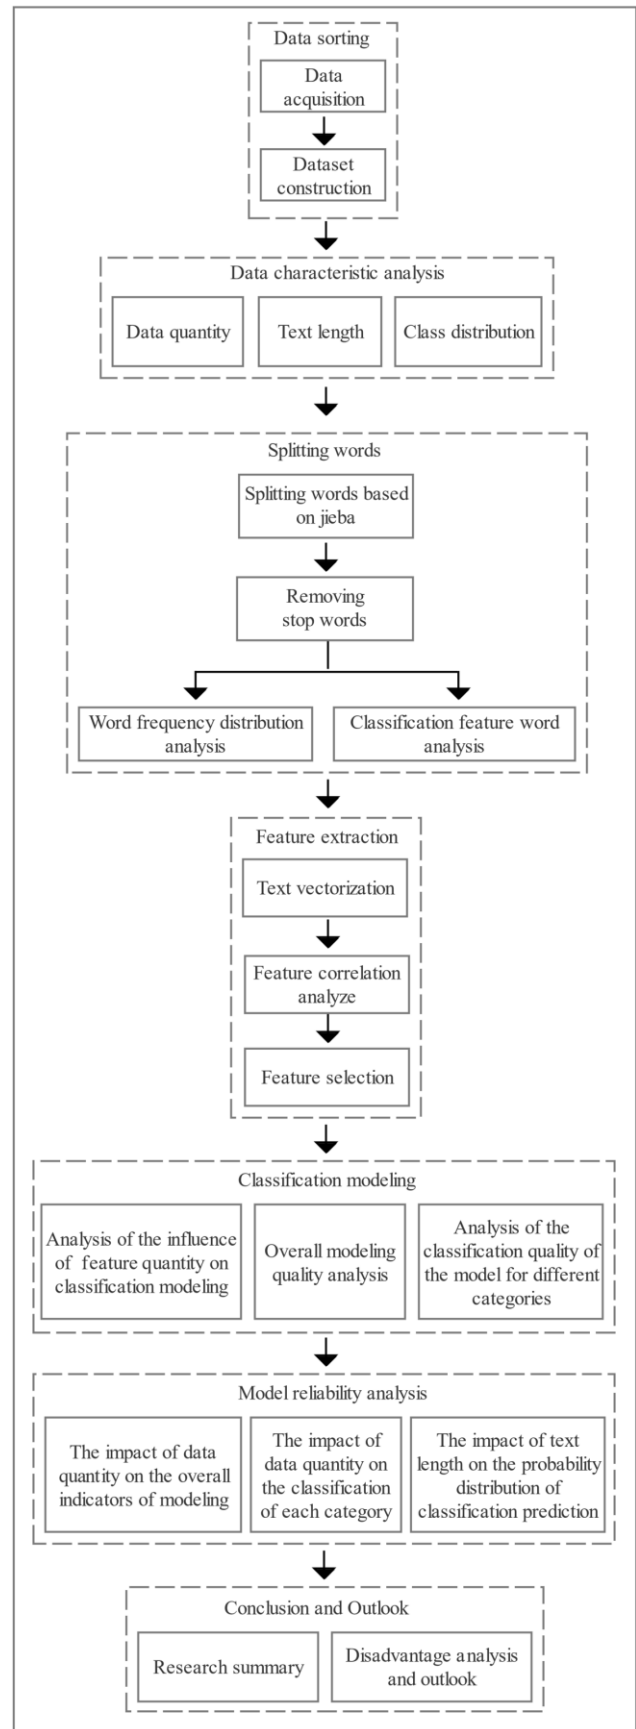

Fig. 1. Technical Route.

III. DATA

The research data of this study comes from the Beijing Car Quality Net Information Technology Limited Company. The dataset of this paper includes 8 categories of car quality complaint text data, including engine/electric motor, transmission, clutch, steering system, braking system, tires, front and rear axles and suspension system, car body accessories and electrical appliances. The data amount is 2400,

and for every category, the data amount is 300. The data amount and text length characteristics are shown in Table I.

The car quality complaint texts involve attribute labels such as car type, purchase time, car brand, etc., and the attribute differences might influence the classification model training and the texts classification prediction. The data distribution of the dataset used in this paper in terms of car type, purchase time, and car brand is shown in Fig. 2.

TABLE I. DATA DESCRIPTION

No.	Category	Data amount	Average length of text	Maximum length of text	Minimum length of text	Text length standard deviation
1	Engine / electric motor	300	18.0267	27	14	1.8194
2	Transmission	300	17.8567	25	14	1.8332
3	Clutch	300	17.9000	24	15	1.7436
4	Steering system	300	17.7767	23	15	1.7214

9	All	2400	17.8946	27	14	1.8071

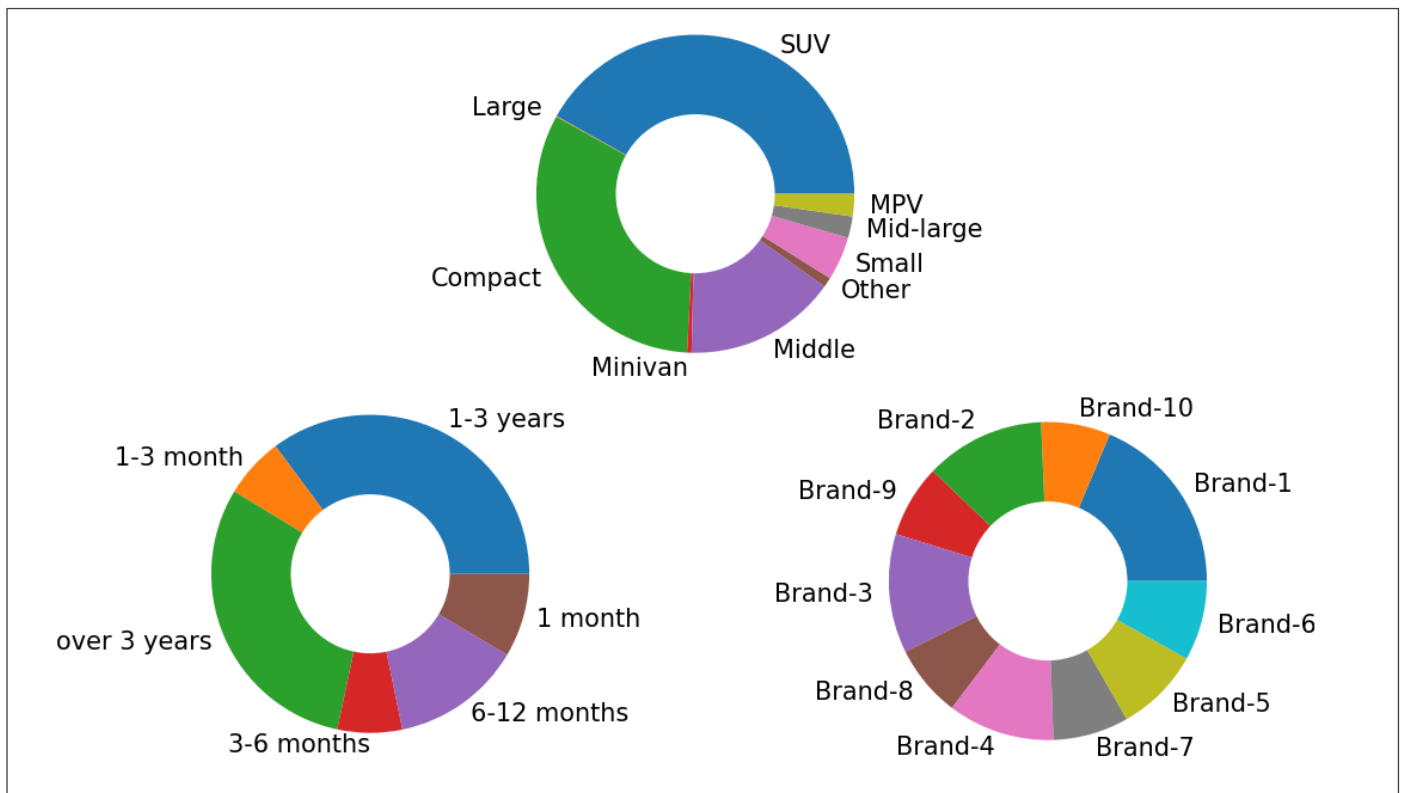

Fig. 2. Data Distribution Characteristics.

IV. SPLITTING WORDS

The research data of this study is Chinese text, and it is necessary to divide texts into words. This study uses the Jieba word segmentation tool which is widely used in the field of Chinese word segmentation to separate the words; the statistics and analysis for word segmentation results are carried out from the aspects of category, number of characters, number of separated words, number of unique words, repetition rate, etc. The word segmentation results are shown in Table II.

Fig. 3 depicts the word frequency distribution of the global high frequency words in different categories. The difference of

the frequency distribution in different categories of the global high frequency words is an important reference factor for the evaluation of the potential classification discrimination contribution ability of these words. If there are widely significant differences in the word frequency distribution of global high-frequency words in different categories, the method based on word frequency might have well applicability for corresponding text classification modeling scene.

After the word segmentation and the removal of stop words, the top 20 high-frequency feature words of each category are shown in Table III.

TABLE II. WORD SEGMENTATION RESULTS

No.	Category	Number of characters	Number of separated words	Number of unique words	Repetition rate

V. FEATURE EXTRACTION AND CLASSIFICATION MODELING

This study uses bag-of-word method which is based on word frequency for text vectorization; the correlation of features is analyzed based on correlation matrix; and feature selection is performed based on feature correlation to reduce the dimension of text vectors and improve the efficiency of classification model training and text classification. The correlation heatmap of the global high-frequency words after removing stop words is shown in Fig. 4. Due to space limitations, Fig. 4 only shows the relevance of the top 15 high-frequency words in the global word frequency.

This study uses a progressive feature selection strategy to incrementally set the feature usage ratio; the classification model is trained based on the SVM method, and the modeling results are evaluated and analyzed from the perspectives of overall accuracy, overall recall, overall F value, and F value of each category. The progressive feature selection strategy is beneficial to obtain a reasonable threshold of the model feature quantity, if too few features are used, the modeling effect might be adversely affected due to insufficient information, while if too many features are used, the model quality, model training efficiency, and classification prediction efficiency might be adversely affected due to the introduction of non-core information confusion. The training results of the classification model are shown in Table IV.

Fig. 4. Correlation Matrix Heatmap.

VI. MODEL RELIABILITY ANALYSIS

Model reliability analysis is of great significance to the evaluation of model quality. This study analyzes the reliability of the model from two aspects: the effect of data amount on the classification modeling and the effect of text length on the classification prediction. The training data amount commonly has direct effect on the reliability and stability of text classification model, too little data might lead to limited applicability of the trained model and unstable prediction ability for new data, after the amount of model training data reaches a certain value, the effect of incremental data on the model training effect is commonly no longer significant.

Based on incremental data setting, this study compared multiple rounds of text classification model training, and the result parameters are shown in Table V. Text length is an important factor in text classification model training and classification prediction, the difference of the probability distribution in the classification prediction for different lengths of texts is another effective measure of the reliability of the classification model. In this study, the first 8 texts and the last 8 texts in the global ranking of text length are selected to analyze the probability distribution in the classification prediction; the results are shown in Table VI.

VII. CONCLUSION AND OUTLOOK

This study focuses on the automatic classification of car quality complaint, the research content mainly includes data characteristic analysis, word segmentation, feature extraction, classification modeling, and model reliability analysis. The research results show that based on the method combining the text vectorization based on word frequency, the feature selection and dimensionality reduction based on correlation analysis, and the feature increase SVM model training, the effective classification model for car quality complaints texts could be obtained; in this study, the best modeling effect is obtained when using 938 features for model training, among the global indexes, the accuracy, recall, and f1-score reach 0.9375, 0.9375, and 0.9384 respectively, the highest f1-score of each category is 1.0000, and the lowest is 0.8657; in the model reliability evaluating based on incremental data amount, after the data using ratio reaches 75%, the training effect is almost stable, the classification prediction probability distribution analysis based on the global long texts and global short texts shows that the classification probability values obtained from the model shows a high degree of discrimination overall.

In general, based on the method of this study, effective modeling for the automatic classification of car quality complaint texts could be realized; at the same time, the research content of this study belongs to theoretical research which has not been applied to practice, it is expected that this study could provide effective reference for subsequent research and practical application.

Abstract—Numerous strategies for determining the most influential nodes in a connected network have been developed. The use of centrality indices in a network allows the identification of the most important nodes in the network. Specific indices, on the other hand, cannot search for a network's entire meaning because they are only interested in a single attribute. Researchers frequently overlook an index's characteristics in favour of focusing on its application. The purpose of this research is to integrate selected centrality indices classified by their various properties. A symbolic regression approach was used to find meaningful mathematical expressions for this combination of indices. When the efficacy of the combined indices is compared to other methods, the combined indices react similarly and outperform the previous method. Using this adaptive technique, network researchers can now identify the most influential network nodes.

Keywords—Centrality indices; combination; symbolic regressions; influential nodes

I. INTRODUCTION

For years, the prediction of the most influential nodes has been a source of contention [1]. The node with the most impact is ranked first, and the one with the least effect is ranked last [2]–[4]. Several research had been carried out to enlist the importance of nodes detection which is such as in finding importance suppliers [5], [6], detection of cancer or virus gene [7] or as well as to monitor the terrorist activities [8].

Over the years, over 403 indices have emerged from the four major indices: Degree Centrality (DC), Betweenness Centrality (BC), Eigenvector Centrality (EV), and Closeness Centrality (CC). Individual task and node importance priorities are claimed to impact the development of various indices. Various centrality measures have been employed to predict node outcomes, with the underlying assumption being that the more centrally situated the nodes are in the network, the greater their spreading potential [9], [10].

However, there were limitations to using indices as a single centrality metric because they could focus on one application area. DC for example, is a good indicator of a node's total connections [11]. Still, it does not necessarily imply a node's value in linking nodes or how central it is to the main group. CC on the other hand, determines how close a node is, but an independent network will not profit from its supremacy if two nodes are placed in distinct components [9]. In the case of BC,

the result will be zero if many nodes are not on the shortest possible path to the remainder of the network [12].

A single centrality metric proved to be insufficient for accurately predicting the network's most important nodes [13]. Combining centrality indices to determine the most influential nodes has been floated. According to [7], [14], there is no single centrality measure that can accurately identify key nodes, but the combination of at least two centrality measures is the most accurate. Combining multiple indices is considerably more accurate than using one index while assessing a node's influence capacity [11]. The influence of a node may be evaluated by its location and surroundings.

The researchers have recursively investigated this topic and determined that each indices have distinct features. This attribute, known as network topology, is reflected differently by different methods, and the evaluation results may include flaws or deficiencies. Borgatti [15] observed two forms of network topology: geodesic paths and walking paths. In the following research, Ashtiani [16] determined that centrality measures may be categorized into five classes based on the reasoning and formulas used. This characterization of centrality indices is also used by [17] while accessing the topological structure of student network.

The goal of this research is to investigate the effectiveness of centrality indices combination. Genetic programming-based symbolic regression (SR) is used here to find expressions to combine the selected indices. Two datasets examined to test the performance of a mix of indices based on their individual properties. Vignery's topology principles guided the selection of the centrality indices in this study. Combination outcomes are compared to results from a previous combination strategy to get a better sense of how effective the combinations are. At the end of this research, the possibility on applying symbolic regression to combine centrality indices will be clarified, and whether the categorization of indices according to their characteristics similarities has an impact on the combined indices.

II. MATERIALS AND METHODS

A. Data

Zachary and Les Misérables (Les-M) datasets, both weighted and unweighted, were used in this investigation. Thirty-four people from the karate club were included in the

Zachary dataset, which documented 78 connections between members who interacted outside the club. The novel Les-M features 77 nodes and 254 edges, including co-occurring characters. Both networks were depicted in the Fig. 1, with information on the most connected nodes.

B. Theoretical Topology of Centrality Indices

The definition of Vignery's eleven centrality indices is simplified and shown in Table I. Several of the indices had the same features and hierarchical clustering analysis is executed to observe whether the indices can be clustered into a single component to justify where the indices are converging. The dendrogram is built up by clustering observations and their similarity levels at each stage and assessing the similarity (or distance) levels of the produced clusters. As a first stage in the modeling technique, the value for each index is computed for each node. Following that, the indices was categorized based on their commonalities. The higher a cluster's similarity level, the more related the variables in that cluster are. These indices are divided into five theoretical groups, explained in Table I.

Fig. 1. Representation of both Networks.

TABLE I. VIGNERY'S CENTRALITY INDICES SELECTION

Type of centrality	Definition	Indices involved
Geodesic Distance and Path	A simple measure of the shortest path between two vertices. The length of a geodesic path is called geodesic distance or shortest distance.	Eccentricity (EC), Closeness (CC), Residual closeness (RC), Geodesic K-path (GK), Betweenness (BC), Bottleneck (BN)
Connectivity	Number of direct connections a node has, which means that every pair of vertices has a path linking them.	Eigenvector (EV), Hub & Authority (HUB & AUT), PageRank (PR)
Neighbor's prestige	Measures the number of shortest pathways a specific node has between any other two nodes and is based on the premise that a node with the shortest paths controls communication flows.	EV, HUB & AUT, PR
Nodes' adjacent	The neighbourhood of a node is the collection of all vertices near the vertex.	Cross-clique connectivity (CQ), Maximum Neighborhood Component (MNC)

C. Combinations of Indices

Network dynamics are examined as a function of the structure. The best estimate is made by combining a given number of indices based on the features of the component clusters. Genetic programming (GP) with symbolic regression (SR) is employed to generate mathematical expressions that may predict the simulation response values based on the topological indices used. SR is a technique that uses collected data to construct mathematical equations that may be used to test hypotheses [18]. With SR, the parameters and equation form are automatically searched, unlike typical regression methods that require a fixed-form model built from prior knowledge. GP is commonly utilized in SR because of the high computational complexity imposed by a vast search space that generates new solutions using the notion of biological evolution as a meta-heuristic [18], [19]. SR method's results will then be compared with those from other methods that use centrality indices as a comparison metric. Three algorithms are chosen for comparison which is provided by Eq. (1), (2) and (3).

- C(v) algorithm: Wang [20] developed a combination formula with the integration of DC, diffusion degree (DD) and BC as denoted in Eq. 1 with $a + b + c = 1$.

$$C(v) = aDC(v) + bDD(v) + cBC(v) \tag{1}$$

- BC and Katz (BKC) algorithm: Zhang [21] merged BC and Katz's centrality. Eq. 2 expresses the relationship between BC and KC.

$$BKC(v) = aBC + bKC \tag{2}$$

- Integrated Value of Influence (IVI): Consider topological dimensions [22], IVI consider six key network centrality measurements (normalizes connectivity (NC), ClusterRank (CR), BC, collective influence (CI), DC and local index (LH)) into account as given in Eq. 3.

$$IVI = ((NC' + CR')(BC' + CI'))(DC' + LH'_{index}) \tag{3}$$

III. RESULT AND DISCUSSION

A. Cluster Analysis

Clustering is used to group comparable data objects using a similarity measure. The similarity is a value that displays the strength of a relationship between two data items; it represents how similar data patterns are. The topological framework classifications from Vignery will be extended. We wanted to see how well the indices matched, so we applied a simple hierarchical clustering algorithm.

The results of clustering are depicted in Fig. 2a and 2b. We discovered that for both networks, all the indices could be clustered into four groups. Take note that the component clustering is quite close to Vinery's recommendations. The final partition specifies how the indices will be clustered. In those eleven indices, both networks were supposed to cluster similarly into four groups, except for Les-M, where PR will be in Cluster 2 rather than Cluster 3 (as in Zachary). EC has the

lowest similarity score and is not assigned to any category. EC was not assigned to any cluster because it has the lowest similarity score (10.56 and 7.00) compared to the other indices.

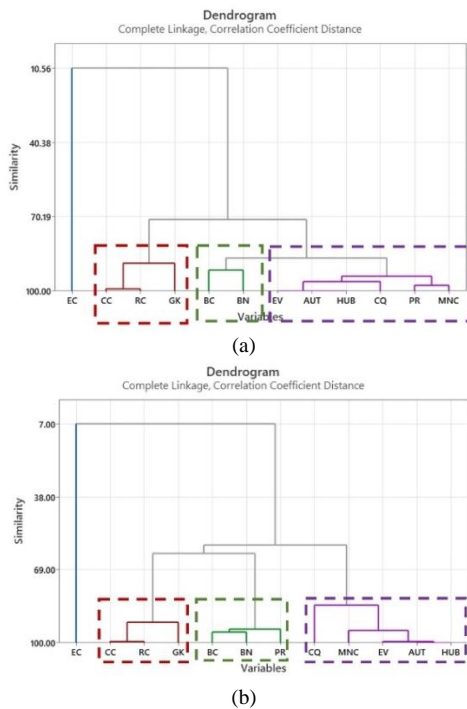

Fig. 2. (a). Hierarchical Clustering of Indices for Zachary. (b). Hierarchical Clustering of Indices for Les-M.

B. Combinations of Indices

Turingbot software was applied to execute the symbolic regression codes, which entails combining a set of base functions into simple formulas to produce a regression model. Fig. 3 depicts the steps we take to generate different mathematical formulations for each cluster. Because the output of SR will vary, we choose the phrase with the lowest value in terms of root mean square error (RMS error) and the highest R-squared (R-sq). Finally, we obtained four distinct expressions for each cluster specified, namely C1, C2, C3, and C. C is an expression that includes all the indices involved. As a result of efficient training and shifting, the analytic equations for both networks are shown in Table II are derived.

C. Pearson Correlation Analysis

The combined indices and component clusters employed in the earlier approach are compared. The correlation technique can be used to discover the similarity of combined centrality indices. The dataset also includes an average value (AVE) for the average result for each node from the Combined, IVI, BKC, and C(v). This AVE value will serve as the reference result to which the correlation converges.

Correlation for both networks show a significant and favorable relationship as shown in Tables IIIa and IIIb. In Zachary, there is a high correlation between AVE and IVI, BKC, and C(v). There is a high association between IVI and the clustered group and all other combined indices. The concept of combining indices while considering their spreaders and hubs can be extended for future use. With a correlation coefficient of 0.797, the relationship with C is likewise satisfactory. It is fascinating to notice that the C1 and C2 are more closely linked to AVE than is C, while C3 is obviously diverged from correlation toward others.

Results for Les-M also give results like Zachary's network when looking at each cluster component, with C1 and C2 being more correlated than C and C3. However, it is interesting to observe that IVI is quite diverging for this network. According to these findings, the SR modeling combination model has successfully identified influential nodes. In the following section, the node's ranking position is being observed.

D. Node's Ranking of Position

In this section, the placements of nodes were analyzed and arranged in descending order. When comparing procedures side by side in Tables IVa and IVb, the top ten ranking position of each approach is considered. Node AVE is a reference column that contains the average positioning value of nodes for each method, as expressed by the average positional value of nodes for each technique. Zachary and Les-M discovered that BKC and C(v) have a very similar node detection to AVE when comparing the two algorithms.

Nodes in IVI react similarly in Zachary, whereas they deviate significantly in Les-M. However, when compared to C for both networks, C1 and C2 show more comparable node detection for both networks when compared to C. To better understand the similarity result, we use the Jaccard similarity (JS) score and Kendall's tau-b to access the top ten nodes' ranking positions. Kendall's tau-b indices are used to measure the strength of a method's ranking position to understand the similarity result from the JS-score better.

Fig. 3. Illustrations on Indices Combination for each Group.

- Jaccard similarity score

Jaccard similarity (JS) score compares two sets of scores by counting the number of elements in each group. JS can be calculated numerically by dividing the intersection of sets by the union of sets [23]. The higher the value, the greater the correlation between the two data sets. The higher the Jaccard similarity indices, the closer two sets of data are to one. Definition of JS is formulated as in Eq. 4.

$$JS(A, B) = \frac{\text{number of observations in both sets}}{\text{number in either set}} = \frac{|A \cap B|}{|A \cup B|} \quad (4)$$

For Zachary, C has a higher similarity score than Les-M when looking at the Jaccard scores for the two networks. If we look at Zachary and compare C to the previous combined technique, we see that C has the same top ten ranking entities for IVI (0.6667), BKC (0.8182), and AVE (0.6667). C has a low degree of similarity (less than 0.5) to IVI, BKC, and AVE in Les-M. C1 and C2 are interestingly comparable to C with the IVI, BKC, and C(v), which follow similar patterns. The JS-score heatmap for both networks are shown in the Tables Va and Vb. The greater the degree of resemblance between methods, the darker is the color.

• Kendall's tau-b

When comparing the rankings of different methods, Kendall's tau-b is applied to determine the ordinal relationship between pairs of observations [24], [25]. Correlation strength and direction are measured using Kendall's tau-b correlation coefficient. According to the theory of rank correlations, the closer two sets of data are linked together, the more closely they are related. Within this range, positive and negative numbers can indicate concordance or discordance, which is characterized by increasing or decreasing values, respectively. The correlation value between two variables increases when the ranks of the observations are similar; the correlation value decreases when the positions of the observations are different. Kendall's tau-b is defined as in Eq. 5.

$$\tau_b(A, B) = \frac{m_c - m_d}{\sqrt{(m - T_0)(m - T_1)}} \quad (5)$$

The top ten ranking of nodes using Kendall's tau-b results for Zachary and Les-M are shown in Tables VIa and VIb. Comparing C with IVI, BKC, C(v), and AVE shows that C has a rather low and moderate positive tau value in the Zachary network, while it has a high-rank similarity for the Les-M network. C also has significance and a strong positive tau correlation with C1 (0.644). C1 also shows the importance and positive correlation with C2. Observe from AVE analysis shows that results were significant in Les-M compared to Zachary except for C3. Since there were differences in C2 and C3 for Zachary and Les-M, it might affect the way on the rank behavior.

IV. CONCLUSION

The selection of influential nodes is crucial for fostering knowledge and behavior adoption in a network because they can influence other nodes. It is possible to gain a better understanding of network structure and behavior by using prominent nodes. The importance of centrality in identifying influential network spreaders in this scenario cannot be overstated.

Our results show that combining centrality indices can identify the influential nodes in a network. To combine these indices, symbolic regression can identify appropriate mathematical expressions that will fit the network's features. When it comes to recognizing significant nodes, the newly constructed mathematical expression's function performs similarly or better than previous methods (IVI, BKC, and C(v)) that were validated using Pearson correlation, Jaccard similarity score, and Kendall's tau-b correlation of ranking.

It was discovered while clustering indices based on similar attributes that each cluster component may have the same impact as aggregating all indices. Clustering can reduce the total number of indices to be combined while achieving the same overall result. It was also discovered that index selection is critical. A few indices, including Katz centrality and Closeness centrality, could not be computed. Katz's centrality fails to detect connections between high-centrality nodes. To function, closeness centrality requires a well-connected network, and it fails when two nodes belong to different components. Large, complex datasets necessitate more computationally intensive methods. Clustering for the indices involved would be difficult, as it is here.

In future work, the selection of suitable indices to be combine is important. Analyzing their features as well as the computational time required to run each of the indices may be put into factor selection. It is also a good idea to run another run-up for a different network with a different number of weighted nodes if possible.

ACKNOWLEDGMENT

The author would like to extend a special thank you to the FRGS-RACER/2019/FTKMP-COSSID/F00412 grant, Centre of Research and Innovation Management (CRIM), Faculty of Mechanical and Manufacturing Technology, Universiti Teknikal Malaysia Melaka, Malaysia for funding this research. Appreciation also goes for Faculty of Communication and Information Technology and Ministry of Education Malaysia.

Improving Computational Thinking in Nursing Students through Learning Computer Programming

Leticia Laura-Ochoa, Norka Bedregal-Alpaca, Elizabeth Vidal
Universidad Nacional de San Agustín de Arequipa
Arequipa, Peru

Abstract—Computational thinking is a fundamental skill for problem-solving, it uses computational concepts and other types of thinking such as algorithmic. The experience of improving computational thinking in nursing students using block-based programming environments such as Code.org, Lightbot, and the Python textual programming language is described. The results obtained are analyzed by applying a pre-and post-test of computational thinking to the students. The methodological design is quasi-experimental since it did not work with a control group. The study group was made up of 30 students from the Professional School of Nursing of the National University of San Agustín de Arequipa. The results show that teaching programming allows the understanding of computational concepts and improves computational thinking. It is concluded that block-based programming environments and the Python language facilitate the development of algorithmic thinking and computational thinking.

Keywords—Computational thinking; computational thinking assessment; computational thinking test; programming; programming environments

I. INTRODUCTION

Computational Thinking (CT) is a fundamental skill that influences different disciplines and professions, not only those related to science and engineering [1][2]. It is considered a transversal competence that goes beyond the use of computers and coding [3] since it includes algorithmic and parallel thinking, which involve different types of thought processes, such as compositional reasoning, pattern matching, procedural thinking, and recursive thinking. [2], which are required by new generations of students in different areas of knowledge.

According to Román-González et al. [4], programming is the main demonstration of the ability of the CT through the use of the computer, because it allows the development of algorithmic thinking, problem-solving, logic, and debugging skills [5]. In this context, textual programming is considered the final educational goal at the end of the K-12 level in most countries [4], because students in adolescence value the higher cognitive load of textual languages. However, text-based programming can make learning difficult for beginning students, overwhelming their cognitive ability [6]. Furthermore, it is considered a difficult task due to the lack of complete development of computational thinking in students [7]. Therefore, it is necessary to select the appropriate didactic tools and strategies that facilitate the teaching of programming with an approach oriented to the development of computational thinking. For [8], block-based programming environments are a good way to introduce beginning students to programming.

In addition, in [9] they consider that these environments facilitate the understanding of programming concepts; but both block-based and text-based programming environments allow the development of skills related to computational thinking.

In addition, Tikva and Tambouris [10] have found that teachers face challenges in incorporating TC practices, so more capacity building frameworks and interventions that support teachers for successful integration of TC into their teaching practices are required. They believe that the relationship between tools and TC development should be explored as future work to provide information on which tools support which TC learning strategies.

Consequently, the aim of this work is to show the programming tools that were used in the experience and how they favor the acquisition of computational concepts and the development of computational thinking practices and skills, which can be of help and reference for teachers who need to incorporate computational thinking in their teaching work. This experience was carried out in an online learning environment with higher education students from the professional school of nursing, a career different from science and engineering, where the majority of students are usually women.

In this work, the experience of the use of programming environments based on blocks and text is described, to improve the development of computational thinking skills for beginning students in programming a Basic Computer course, which includes as a learning unit the Introduction to programming. An analysis of the pre- and post-test results of computational thinking applied to students is carried out to verify the improvement of computational thinking. In the experience, Code.org and Lightbot block programming environments were used prior to the Python textual programming language to facilitate the understanding of computational concepts and the acquisition of computational thinking practices.

II. RELATED WORK

In the work of Brackmann et. al. [11], a quasi-experiment was presented in two primary schools in Spain, to develop the computational thinking skills of students through disconnected activities, students' ages are between 10 and 12 years old. Their results show that the students of the experimental group, who participated in the disconnected activities, significantly increased their computational thinking skills, compared to those who did not participate in the disconnected activities, evidencing the effectiveness of the disconnected approach for the development of computational thinking skills. However,

they consider that this approach has limitations, and there may come a point where it loses its effectiveness and the use of computing devices is required to further develop these skills.

Vasquez and Luján [12] carried out an evaluation of aptitude level on the development of computational thinking in students of the basic level of secondary school. They identified the need to strengthen skills related to computational thinking such as analysis, algorithm design, and data abstraction, because their average scores did not exceed 50% of the total number of questions evaluated. Likewise, they found that the maturity of the students and the cognitive development according to the academic degree do not establish the level of development of computational thinking skills. Since their cultural environment must also be considered. The authors considered that the results of the computational thinking test can be used to design and develop a computational thinking course that allows strengthening skills that require it. Montes-León et al. [7] describe their experience of the application of computational thinking activities that positively influences the improvement of learning in a course of fundamentals of programming. They carried out an analysis of the results of a pre and post test of computational thinking applied to secondary students divided into control and experimental groups, to evaluate the improvement of computational thinking. The ages of the participating students were between 15 and 16 years old. They also analyzed the results of the evaluation applied in the course. The activities that were carried out in the experimental group were some exercises from the international Bebras contest, mathematical problems, exercises from a university entrance test and mental games.

Laura-Ochoa and Bedregal-Alpaca [13] found that the incorporation of computational thinking practices allowed students to improve their performance on the first Python programming course, where they used support tools such as PSeInt, CodingBat and the turtle graphic library for the development of skills related to computational thinking, conducted an analysis of the grades obtained by the students of the control and experimental group in the midterms and final average of the programming course, where the students of the experimental group showed an improvement in their learning results. As future work, they suggest the application of computational thinking measurement assessments by following a practice-oriented programming teaching approach to computational thinking.

III. METHODOLOGY

The methodological design used was quasi-experimental, since it did not work with a control group. In the study group, there were 30 students enrolled in the Basic Computer course (groups B and F) of the academic semester 2020-B of the Professional School of Nursing of the National University of San Agustín de Arequipa (Peru).

The Basic Computer Science course at the Professional School of Nursing of the National University of San Agustín de Arequipa - Peru, is given in the second academic semester. It is developed for 17 weeks. It has 4 practice hours a week, lasting 50 minutes each, equivalent to 2 credits.

The students of the experiment were 30 women (100%), who participated in the pre- and post-test of computational thinking, as well as in the development of the third learning unit: Introduction to Programming. This unit is developed during five weeks, with two weekly sessions of 2 hours each.

In the practice hours, the students experimented with the use of visual programming environments: Code.org, Lightbot and Python textual programming language. The method used in the class sessions was expository-participatory.

The computational thinking test developed by Román-González et al. [14] was used to measure the level of development of computational thinking in students. Its test is consistent with other computational thinking tests aimed at middle/high school students [15], it is mainly aimed at Spanish students between 12 and 14 years old (7th and 8th grade of primary school), but it can be used in lower and higher grades. It is aligned with some CT computational concepts defined by Brennan and Resnick [16] and partially aligned with some computational practices.

The students who participated in the experience completed the computational thinking test [14] in the first week of classes on the subject and at the end of the third learning unit: Introduction to programming, accessing an online test through a Google Apps form.

To measure the improvement of computational thinking, a comparison of the scores obtained by the students in the pre-test and post-test of computational thinking was made, to check if the activities carried out in the third learning unit: Introduction to Programming allowed the acquisition of computational concepts and development of skills related to computational thinking.

IV. DESCRIPTION OF THE EXPERIENCE

Block-based visual programming environments (Code.org, Lightbot) and Python programming language were selected for teaching the introduction to programming and development of skills related to computational thinking in the third learning unit of the Basic Computer course taught to students of the nursing professional career in the period 2020-B.

Table I shows the programming topics that were developed using the selected programming environments, where the students learned computational thinking concepts considered in the work of Luo, Antonenko and Davis [17], such as sequential instructions, conditionals, and loops.

Students began learning the block-based visual programming language using Code.org by completing exercises in the "hour of code" tutorials that enabled them to understand concepts of sequential statements, loops, and functions. An example of block programming on Code.org is shown in Fig. 1, where students understood the utility of iterative statements by replacing repetitive blocks of code (left) with loops (right) to draw the geometric figure of the square, in which the students acquired some computational thinking practices such as iteration and abstraction through the identification of repetitive patterns, which allowed them to acquire the ability to reduce unnecessary details and propose new solutions.

TABLE I. PROGRAMMING TOPICS

Tools	Sequential Instructions	Conditional Instructions	Repetitive Instructions	Functions
Code.org	X		X	X
Lightbot	X		X	X
Python	X	X	X	

Fig. 1. Replacing Repetitive Blocks of Code with Loops at Code.org.

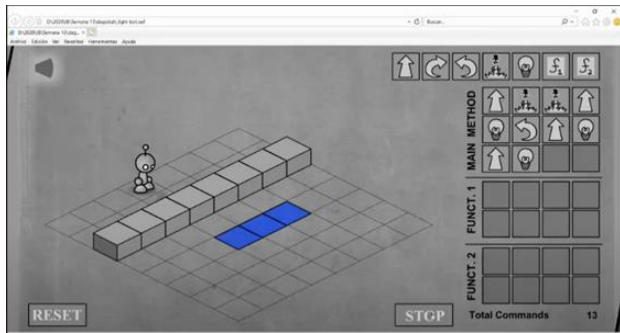

Fig. 2. Sequential Instructions with Repeating Patterns.

The Lightbot video game was used to reinforce algorithmic thinking skills in students by thinking in sequence of instructions for problem solving. Fig. 2 shows an example of the Lightbot third level solution using only sequential instructions (move, jump, turn left) in the MAIN METHOD for the robot to move and turn on all blue blocks, which is the objective of the video game, where repetitive patterns such as moving forward and turning on are identified.

In Fig. 3, a second solution for the third level of Lightbot is shown, where students, through generalization (identification of repetitive patterns go forward and turn on), abstraction (reduction of unnecessary details) and decomposition of the program using one of the functions (FUNCT. 1), acquire the ability to find better solutions to the problem and make use of code reuse.

In addition, the students practiced the Lightbot video game from Code.org, where they used recursion to create loops in the PROC1 procedure (Fig. 4).

After experience with the block-based programming environments, the students learned the syntax and semantics of the Python textual programming language using the Google Collaboratory environment for the creation and execution of code, with which they reinforced their understanding of computational concepts, such as sequential statements, conditionals, and loops. Fig. 5 shows some examples of codification of single and double selection structures; but there was also done double selection instructions (nested).

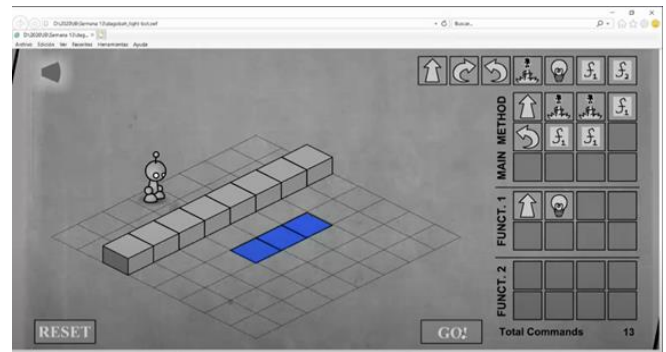

Fig. 3. Program Decomposition and Code Reuse with Functions.

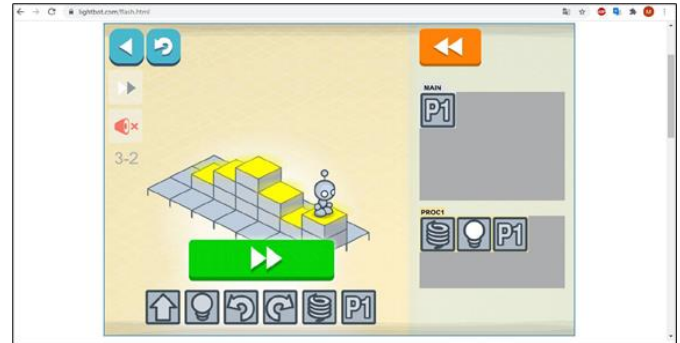

Fig. 4. Looping using Recursive Calls in Lightbot from Code.org.

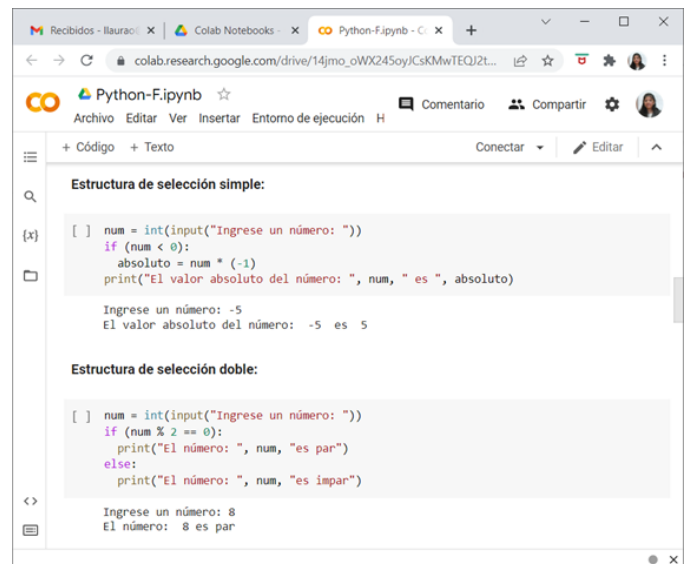

Fig. 5. Coding with Single and Double Select Structures using Python.

With the programming environments used in the experience, computational thinking skills are used, such as automation and debugging for the execution of programs and logical analysis for the verification of the results.

Therefore, students acquired computational thinking practices such as abstraction, decomposition, iteration, and debugging.

V. RESULT AND DISCUSSION

The computational thinking test [14] was applied at the beginning of the Basic Computer Science course before taking Unit 3 of Introduction to programming, serving as a pre-test for the evaluation of said unit.

Fig. 6 shows the percentage of correct answers per question in the pre-test. The regression line shows the progressive difficulty of the test. The average correct percentage of the 28 questions was 64.64%.

At the end of the third learning unit, the computational thinking test was applied again [14].

Fig. 7 shows the percentage of correct answers per question in the post-test. The regression line shows an improvement in terms of the progressive difficulty of the pre-test. The average correct percentage of the 28 questions was 80.6%.

Table II shows some descriptive statistical data related to the total scores obtained by the students in the pre and post-test. The total scores are evaluated from 0 to 28.

Fig. 8 and 9 show histograms with the distribution of said total scores, where the improvement in the total, mean, median and mode scores of the post-test are evidenced. In the post-test, the median and mode have the same value of 23.

Fig. 10 shows box plots for the scores obtained through computational thinking pre- and post-test. In the post-test, an atypical value is observed that corresponds to a student who obtained a total score of 15 points. The median, maximum value, minimum value, quartiles are higher in the post-test.

Table III shows the averages of the percentages of correct answers of the questions for the computational concepts that are addressed in the computational thinking test, obtained by the students in the pre and post-test.

TABLE II. DESCRIPTIVE STATISTICAL DATA OF THE TOTAL SCORES

	Pre-Test	Post-Test
Minimum	11	15
Maximum	26	27
Mean	18.1	22.567
Median	17.5	23.0
Mode	16	23
Standard deviation	3.791	2.885

Fig. 8. Histogram with the Distribution of Total Scores (Pre-test).

Fig. 9. Histogram with the Distribution of Total Scores (Post-test).

Fig. 10. Box Plots of the Scores Obtained in the Pre and Post Test.

Fig. 6. Success Percentage per Question in the Pre-test.

Fig. 7. Success Percentage per Question in the Post-test.

TABLE III. SUCCESS PERCENTAGES FOR COMPUTATIONAL CONCEPTS

	Pre-Test (%)	Post-Test (%)
Basic directions and sequences	91	94
Loops 'Repeat Times'	78	91
Loops 'Repeat Until'	63	83
Simple Conditional 'if'	59	73
Complex conditional 'if/else'	60	83
While conditional	36	53
Simple functions	66	88

Fig. 11. Success Percentage for Computational Concepts.

Fig. 11 shows that the percentages of success in the post test are higher for each of the computational concepts addressed in the test.

Therefore, it can be affirmed that the performance of the students has improved in the post-test, evidencing an improvement in computational thinking, after the development of the third learning unit, in which the introduction to programming was made using visual programming environments based on Code.org blocks, Lightbot and the Python textual programming language.

According to the experience described, the programming environments used allowed the acquisition of computational practices such as abstraction, decomposition, iteration and debugging, which correspond to the computational thinking practices defined by Brennan and Resnick [16] and adapted in the work of Luo, Antonenko and Davis [17]. In addition, students developed skills such as algorithmic thinking, generalization, automation, and debugging, which are part of the computational thinking skills identified in five featured articles in the work of [18]. It was achieved that students had a means to acquire methodological tools, deepen knowledge, and cultivate skills [19].

We agree with a previous work [20] that learning text-based programming is important for the development and professional performance of students, because in addition to reinforcing concepts and practices of computational thinking, they can expand their learning for the creation of applications, analysis or visualization of data.

In programming courses aimed at beginners, we consider it important to carry out activities related to computational thinking at the beginning of the course to improve their learning, where visual programming environments based on blocks can be used. Likewise, in [8] they consider block-based programming environments a good way to introduce beginning students to programming.

Likewise, we agree with Zapata-Cáceres et al. [21], in that computational thinking is not limited only to the activities of computer scientists; it is applied in daily life and in different areas of knowledge, so it is a necessary skill to adapt to the future.

VI. CONCLUSION

This article has presented the experience of developing computational thinking skills through a block and text-based

programming activities to improve students' computational thinking. We examined the total scores obtained by the students in the pre-test and post-test, there is evidence of an improvement in the scores in the post-test with the programming environments used in the learning unit of introductory programming, which indicates the effectiveness of programming for understanding computational concepts addressed in the test. We concluded that the visual programming environments based on blocks in combination with the textual programming language using Python allow the student to acquire computational concepts and computational thinking practices such as abstraction, decomposition, iteration, and debugging in introductory programming courses directed mainly to beginning students of non-computer related careers.

ACKNOWLEDGMENT

The authors' thanks are expressed to the National University of San Agustín de Arequipa for the support received in the realization of the proposal and the results are expected to benefit the institution.

Improving Social Engineering Awareness, Training and Education (SEATE) using a Behavioral Change Model

Azaabi Cletus, Benjamin Weyory, PhD, Alex Opoku, PhD
School of Sciences, University of Energy and Natural Resources, Sunyani, Ghana

Abstract—Social Engineering (SE) Awareness, Training, and Education (SEATE) is one of the recommended defenses against SE attacks among users of Information Systems. However, many of these SEATE programs fails to achieve the desired impact leading to exposures. This study sought to explore SEATE programs to identify gaps/challenges and propose relevant content, Delivery Methods, and a novel behavioral change Model to improve SEATE programs among users. An explorative Literature Search was conducted on the relevant SEATE Content, Delivery methods and the challenges of SEATE Programs. Consequently, the relevant and critical content and delivery methods were proposed. The challenges that impede the efficient and effective conduct of SEATE Programs were established. A behavioral change Model known as Social Engineering Awareness, Transition, Adaptation and Consolidation (ATAC) based on Stable-Quasi-Stationary Equilibrium theory was proposed. The model was validated using Expert Opinions. Five (5) expert in cybersecurity were recruited to appraise the model based on five metrics; fit for purpose, novelty, ease of use and structure. The results show that, challenges still exist in the conduct of SEATE programs. To improve SEATE programs requires relevant and innovative content, and delivery method (Hybrid Approach). Validation of the proposed behavioral change model showed an average score at 73.6% and performance metrics at 92%. As the menace of SE attacks rages on and exploiting the user, the need for SEATE programs remains imperative. A well-developed and relevant content, delivery methods and a clear understanding of the challenges is required to improve SEATE. Following the model developed, and the repeated use of it will lead to improving user resistance and or immunity to SE attacks and by extension improve security culture among users.

Keywords—Social engineering; user training; user awareness; user education; ATAC model

I. INTRODUCTION

Globally, cyber-attacks remains a major threat affecting individuals, small and medium enterprises, multi-national corporations, nation states and indeed all global stakeholders in the cyber space [1], [2], [3], [4], [5]. This is occasioned by the ushering in of the 4th Revolution (information superhighway), the growth and expansion of the internet, the Internet of Things (IOT), cloud computing and extensive penetration of smart phone telephony [6].

Even though these statistics are positive signals towards cyber inclusion, the problem of ensuring that, the data and information stored in computers and in Critical Information

Infrastructure(CII) are protected against unauthorized access, modification, vandalism and others poses a big challenge particularly attacks against the human wall (the weakest link) also known as social engineering (SE). [7] describe, SE as gaining access to systems, buildings, data by exploiting humans using psychology instead of using technical procedures to break in. [8] sees it as influencing a person to an action that may or may not be in his/her interest. Consequently, the increased use and adoption of these technological assets has expanded the cyber-attack surface in general and SE in particular, resulting in exposures to critical information asset and the concomitant effect of reputational loss, financial loss, legal issues [9].

Consequently, cyber criminals realizing that, the ‘wet ware’ is easier to compromise have resorted to employing SE attack methods to perpetuate cybercrimes by gaining access to confidential information [10]. Hence, the need for programs to protect users against such SE attacks.

Over the years, defenses against social Engineering attacks have been varied. The most common SE defenses has been user education [11] [12], user Awareness [9] [5], user Training [13]. Other recent defense programs included Gamification [14]), the use of Apps [15], Serious games [16], Virtual labs [17], conferences and tournaments [5]. The rest of the programs include the use of predictive and preventive tools [18] and Recognition tools [19].

As organization realizes the impact of user awareness as a means to complement the technology-based defenses, many have increased budgetary allocation, time and effort to ensure security among users using policies and other behaviour-based approaches such as awareness, training and education [20], [21].

Even though these programs are aimed at building the resistance of users and ensuring that they are well prepared to defend against various SE attacks, they fail to achieve their intended purpose due to how these programs are organized, the content and the pedagogy used; thus, leading to exposures of confidential information and its consequential impact.

This paper sought to explore SEATE programs establishing the challenges, exploring and proposing relevant Content, delivery methods, and a model to be used to conduct SEATE effectively and efficiently that will lead to permanent SE security culture, resistance to SE attacks and reflective

behavior of users when faced with an SE attack. To do this, the following research objectives were set:

- Explore and proposed relevant SE Content, Delivery methods and challenges of SEATE programs.
- To propose a behavioral change model to improve SEATE programs among users.

The contribution/value/novelty of this work;

There is a limited academic study on the use of behavioral change models in improving SEATE programs. Consequently, this study and its findings is a modest contribution to SEATE programs in particular and improvement of user resistance in general. Hence, this study is a modest contribution to knowledge in the field of SE in particular and Cybersecurity in general.

Specifically, the study contributed to knowledge in the following ways:

1) Critically analyzed literature and established relevant content, Delivery methods and challenges of SEATE. Through this approach, we proposed innovative and relevant SEATE Content and the key points that should be included and emphasized during SEATE Programs.

2) We also highlighted the industry delivery methods and their challenges and thus proposed a hybrid approach so as to complement the deficiencies in each of them.

3) Proposed a model to be followed to improve SEATE resulting in improvement of 92% in model performance metrics rating.

4) Contributed in design process, methodology that can be used by practitioners to improve upon their SEATE projects.

The rest of the paper is structured as follows:

In Section 2, Theoretical and Related Works; Section 3, Content, Delivery Methods and challenges of SEATE Programs; Section 4, Proposed Model and Validation, Section five 5, Results, section 6, Discussions of the Findings, Section 7, Conclusion and Future Works and at the end are the references of the study.

II. THEORETICAL FRAMEWORK AND RELATED WORK

A. Theoretical Framework

The concept of SE mainly refers to attacks aimed at tricking the user (Holder of a vital information Asset) to divulge such information against the wish of the user [8]. As an attack against the user, any defense or protective mechanism should aim at the user. This will ensure that, the user is aware of such attacks, modify their behavior about SE attacks and manage the needed change to prevent, and or mitigate the attack.

The study [22] is regarded as the father of change management (CM). He proposed the 3 –step model indicating that, a successful change passes through 3 steps; unfreezing, moving and refreezing [22]. He contended that to manage change process, the organization must unfreeze; change from

current state to a neutral position, to enable the unlearning of the old behavior, and to ensure that the new behavior can be adopted and adapted successfully. Once the change occurs, the organization refreezes into the new state. This is often referred to as Stable –Quasi- stationary- Equilibrium.

Extending and applying this theory, we indicated, that, SE as a cyber-phenomenon, requires that all stakeholders are offered the required SEATE with the aim of improving resistance to such attacks, creating permanent cyber/SE security culture and consciousness and permanent behavior change against SE attacks.

Reasoning on this principle, we proposed a model known as Awareness, Transition, Adaptation and Consolidation (ATAC) model to improve SEATE programs. A review of related works in social engineering awareness, trainings programs follows in the next section.

B. Related Work

Research into security Awareness program in general and social engineering in particular has gained pace in recent years especially in programs aimed at improving security against SE attacks [5], [9], [21],[6].

The author in [6], proposed an educational model for systematic adaptation to cyber security training programs. However, this model is for generic cyber security awareness and fails to address the issue of SE. Specifically, using the modus operandi in social engineering differs with other technology or traditional hacking methods.

A web-Based System (SAWIT tool kit) was proposed and translated into a prototype to improve security awareness. It was based on knowledge sharing among employees [21].

The author in [5] delivered a conference paper on challenges of implementing training and awareness programs targeting cybersecurity social engineering. They suggested budgetary constraints for trainings, lack of understanding of information security, bad organizational cyber security culture as some of the challenges facing SEATE. He recommended the use of security preparedness exercises and awareness programs as a means to improve security.

The author in [23] proposed a framework to evaluate the risk inherent in the Internet of Things (IOTs) based on the situational awareness. The focused on awareness in IOT devices and how promote situational awareness of security. Other studies considered SE awareness on the bases of the business environment such as technology, organization etc. as a way to improve SEATE. Social issues as a limitation against SEATE was also conducted [11].

Notwithstanding the number of studies conducted in social engineering awareness trainings, not much is done in clearly identifying the key critical challenges of a SEATE programs, the required and relevant content and delivery methods and a model that can improve user behavior change to ensure permanent cybersecurity culture in general and SE in particular. Thus this paper explored relevant SEATE programs, content, delivery methods and the challenges and proposed a novel behavioral change model for the improvement of SEATE programs. The next section explored

the Content, Delivery methodologies and challenges/setbacks of SEATE programs.

III. CONTENT, DELIVERY METHODS AND CHALLENGES OF SEATE PROGRAMS

A. Cybersecurity Social Engineering Content

Social Engineering attackers continue to plague the cyber world with new and novel attacks. Even though organization is spending huge sums of money to ensure security, their effort always most times fails due to user vulnerability to social engineering attacks. To ensure improved security, organizations' employees' knowledge need to be improved using awareness, training and education programs [20]. This should include exposure to security policies, processes and best standards that promote corporate cybersecurity in general and social engineering in particular. The content should contain awareness programs at the base for starters. These are programs aimed at exposing the user to SE attacks towards changing the behaviour of the user [2].

Training programs should follow this, which enables the user to make appropriate security choices in their daily personal and work life. Users are trained on specific actions to take in specific cases and should be selected and implemented based on the set objectives.

Finally, the SEATE program should graduate to education where individuals interested to take careers in cybersecurity are given specialized education in specific area by providing in-depth knowledge in the area of security. Thus, SEATE programs should follow a learning continuum, which begins with awareness creation, cumulatively building into training and eventually evolves into education as shown in Fig. 1 known as the cybersecurity learning continuum.

Fig. 1. Learning Continuum.

The author in [20] suggests that most information security awareness programs are generic in nature, too much information leading to information overload. This makes it difficult for users to decipher the relevant content to concentrate. Even with the relevant content, the delivery approach is also relevant to ensure that the right and relevant content is well delivery to the user.

B. SEATE Program Delivery Methods

There are many and varied methods used in the delivery of SEATE programs. [2] Suggested face-face method (lectures, storytelling and workshops), self-directed learning which can be static in nature (text and web based) or flexible/dynamic (videos and games) and finally, teachable options such as embedded delivery methods such as online learning. In the face-face, approach involves a physical environment with or without an expert who facilitates the process. The self-directed learning involves a virtual platform where the SEATE program is delivered such as web-based trainings, text-based and video based approaches. In the case of teachable delivery

method, embedded links and content is attacked for user to learn.

[24] contend that, security awareness delivery methods include the conventional methods such as posters, stickers, leaflets, newsletters; Instructor- led; formal presentations, training sessions and online delivery methods such as electronic articles or emails, web-based security awareness methods, alert messages and game-based methods.

It is worthy of note that even though many of these approaches are proposed towards achieving maximum benefit from such programs, many fail due to inherent challenges such as too much information, cost, boring, inexperience instructors, monotony leading to security breaches.

C. Challenges to Cybersecurity SEATE Programs

The use of SE security training awareness, education and other programs aimed at protecting users against SE attacks is well documented in literature [25],[9]. These programs aim at improving user resistance, and increased SE attack consciousness. [5]opine that, several factors militate against SE training and awareness; the Business Environment, Social issues including industry competition, the compliance or legal frameworks with the country, organizational issues, economic and personality issues or traits that serves as challenges to a successful SE education, training and awareness.

Other methods to SE education, training and awareness include the current methods such as games, Apps, Virtual labs, tournaments, conferences [5]. However, these have challenges such as coordination in the case of serious games, and personality issues about collaborative approaches. Others include real-life simulations and videos. These simulations are generic and fail to cater for the individuals in the organization.

The earlier methods to SEATE programs include manual reminders, the use of posters, awareness campaigns, online courses and physical access programs [20]. However, these methods are said to be boring, tedious and time consuming and lack practical exposure for employees.

From the forgoing, time constraints, Budgetary constraints, generalized nature of the training and awareness program without recourse to the individual users, characteristics such as educational level, organization level (operational, management and levels) pose a major challenge in the successful conduct of SEATE projects. Thus, to be able to effectively and efficiently carry out SEATE programs to achieve the intended objective, there is the need for relevant content, innovative delivery methods and organizational and behavioral change models [21]. The next section will consider the characteristics of relevant content, innovative delivery method and propose a social engineering security behavior change model for effective and efficient SEATE programs.

IV. METHODOLOGY

The study aimed at exploring the SEATE content, delivery methods and the challenges faced in achieving the intended objectives and to propose innovative content and delivery methods and a novel behavioral change model to improve SEATE programs.

TABLE I. PROPOSED RELEVANT SEATE CONTENT AREA AND DESCRIPTION

Comprehensive Knowledge of a Social Engineer.	Clear understanding of the goals, objectives and motives of a Social Engineer, types, characteristics and tricks
Comprehensive knowledge of vectors in use.	Understanding of both semantic, syntactic and AI based vectors, forms of vectors, categories, their deployment strategies and how to overcome them.
Comprehensive knowledge of users/ victims.	Understanding of user vulnerabilities, traits that makes users vulnerable, level of training and exposure to cybersecurity issues etc.
PsychoSocial factors used in social engineering attacks.	Clear understanding of the psychosocial factors used in carrying out an attack; strong effect, diffusion or responsibility, overloading authority, urgency etc.
Relevant standards and regulations.	ISO/IEC27001 &27002, PCI/DSS, FISMA, GRAMM-LEACH BLILEY ACT, HIPAA, Red Flag Rule, GDPR. These will provide users and third party contractors with policies, procedures, cardholders information, information assets risk management, responsibilities and compliance, employee management and training, system failures, create awareness to raise red flag as when a threat shows up, general data protection to monitor, compliance, awareness, training and audit to ensure data security.

To achieve this, literature was explored to establish the challenges of SEATE programs. Then a meta-data analysis of the industry-based SEATE Contents was explored and compared with our proposed innovative content as illustrated in Table I.

Secondly, we compared the traditional delivery methods, identified their gaps, and proposed an innovative Hybrid method for delivering SEATE programs. The proposed hybrid approach is shown in Fig. 2. The use of the hybrid was proposed because the weaknesses in the traditional methods will be complemented by combining them.

To improve overall SEATE programs objectives, we proposed a behavioral change model known as Awareness, Transition, Adaptation and Consolidation (ATAC) to improve SEATE programs. The figure below shows the model and brief description of it.

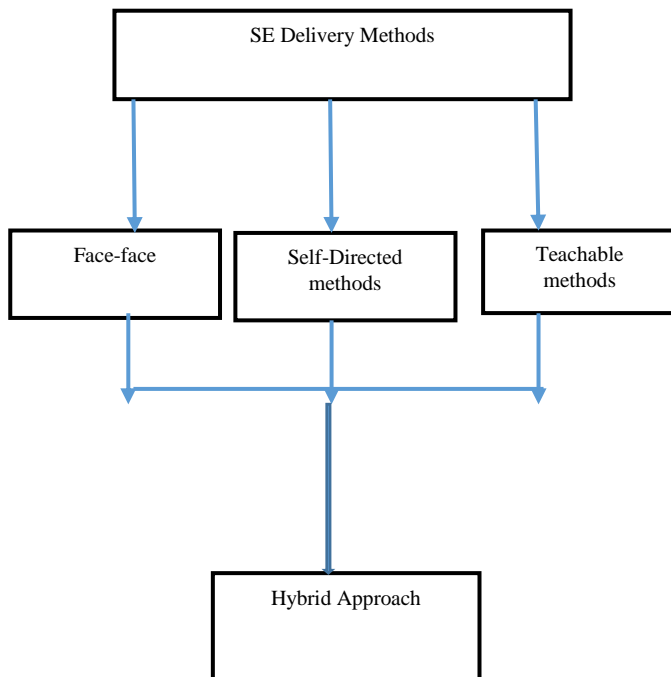

Fig. 2. Proposed Hybrid Delivery Approach.

A. Proposed Model and Description

We proposed a model known as “Awareness, Transition, Adaptation and Consolidation (ATAC) as a solution to improving SEATE and by extension S.E Attacks. The Model is as shown in Fig. 3.

The model is in four (4) phases; Awareness, Transition, Adaptation and Consolidation with an arrow depicting the needed force of change such as cybersecurity consciousness (internal or external). This is how the model works:

1) *Awareness phase:* Making users aware of their behavior deficiency to SE risks is needed. When users’ awareness of the implication of their current deficient state is made known and the associated Danger, they begin to think of how to change.

2) *Transition state:* Users are now aware of the dangers associated with their behavior; Hence, wanting to change from their current state to the proposed new state.

3) *Adaptation phase:* In this stage, the user has transitioned into the new or required state and are now prepared to live such a new life; being security conscious and taking calculated actions to ensure that his behaviour does not lead to exposure.

4) *The consolidation phases:* this phase ensure that, the use is now ready and living the desire organization security culture. Enforcing this new behaviour through monitoring, reminders, penetration testing will ensure that the user do not relapse to the old state.

Such a cycle of creating awareness among users and exposing them to the dangers leads them to want to change. This leads to transition where the user switches from the lack of knowledge to the new state. This desire enables the user to adapt to the new way of cybersecurity conscious life. Consistent use of this will lead to consolidation, where the desired behavior is enforced to become part of the user and the process continues back to the awareness when new requirement for change is necessitated. To ensure the potential usefulness and usability of the proposed model, it needs to be validated.

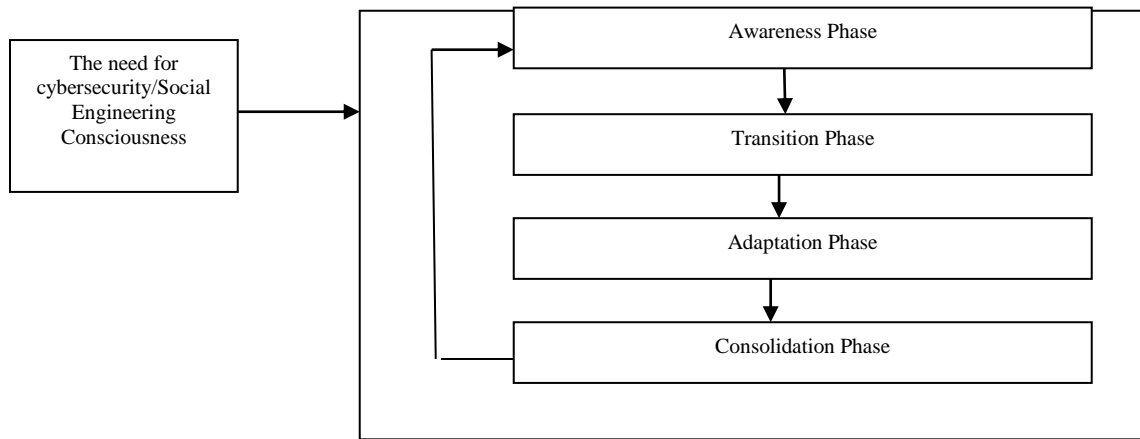

Fig. 3. Proposed ATAC Model.

TABLE II. COMPARISON OF HYBRID DELIVERY MODEL WITH EXISTING DELIVERY METHODS

Delivery Method	Lecture	Workshop	Story	Embeddded Links	Flexible	Videos Games	Static
Face-Face	✓	✓	✓	X	X	X	X
Self-Directed Teachable Moments	X	X	X	X	✓	✓	✓
Hybrid	X	X	X	✓	X	X	X

B. Model Validation

To validate the model, Expert Opinions were elicited to ascertain the usefulness and usability of the artefact. This was done using Observational Empirical Research whereby the

The researcher did not intervene in the assessment of the model by the Experts. The aim was to gain useful information about the expected usability and usefulness of the proposed artefact in a real-world context [26]. Experts were to rate the model in dimensions/metrics such as fit for purpose, novelty, ease of use, architectural structure. Each metric was to be rated on a scale of 1 to 5 based on the expert’s view of the model to that metric. The result is shown in Table I. Descriptive statistics were used to represent the data. We measured the central tendency using Arithmetic means as this describes the center of the data if divided equally among the subjects (Howard & Fletcher, 2016). The results of the study are presented in the next section.

The result of the proposed relevant SEATE Program Content, the proposed Hybrid delivery method and the Expert Opinion were analyzed and presented as shown in Table I, Fig. 3 and Table II, respectively.

V. RESULT

This study sought to explore SEATE programs and to propose relevant Content, Delivery Methods, Challenges and to propose innovative SEATE Content, Hybrid Delivery method, and a novel behavioral change Model to improve SEATE programs among users. The result of the study was presented according to these objectives using tables and graphs.

In research objective 1, the aim was to propose a relevant SEATE content for the improvement of SEATE programs to obtain the desired impact and results. This is demonstrated in Table I.

The next objective was to compare the existing SEATE delivery methods with our proposed hybrid approach. The result of the proposed SEATE Delivery methods and the proposed innovative approach is as shown in Table II.

To improve the conduct of SEATE programs, we proposed a behavioral change model and evaluated it. The model was validated using Expert opinion as a means to scaling to practice. Experts were to rate the model based on the dimensions given on a scale of 1 to 5 for all the dimensions. The result of the opinions is presented in table. The overall Expert score of the model by Experts is presented in Fig. 4 whiles that of performance metric measures is shown in Fig. 5.

Fig. 4. Overall Percentage Sore of the Model by Experts.

Fig. 5. Percentage Score of the Model on Metrics.

VI. DISCUSSION

The study sought to explore the content, delivery methods, challenges of SEATE programs and suggest Relevant SE content, innovative Delivery method and a model for improving SEATE programs.

The findings from the study demonstrated that, the content of SEATE programs is relevant to the success of the program. To have an effective SEATE Content, a critical analysis of the SE attack cycle is relevant. We argue that, having knowledge of the Social Engineer such as goals/motives(financial, espionage, competitive advantage, revenge), types of social engineers(hackers, penetration testers, disgruntled employees, government's foreign intelligence people, spies) and all relevant information about Social Engineers when included in the SEATE program improves the understanding and knowledge of the user [27]. Also of relevance to improving SEATE Programs content is knowledge of social engineering vectors (syntactic, semantic and AI Based attacks). These vectors include phishing, pharming, water holing, spyware, adware, rootkits, Trojans, etc. [7]. Thirdly, knowledge and comprehensive understanding of the User and the vulnerability to SE attacks is relevant as part of the content to be included in the SEATE programs. Moreover, an effective SEATE program should also include the psychosocial factors used in SE attacks. These among others include, elucidation, strong effect, urgency, reciprocation, diffusion of responsibility, authority [8],[9]. Finally, knowledge of the relevant industry standards and regulations needs to be explained to users. These include ISO/IEC27001 & 27002 to provide all employees, contractors and third parties the policies, procedures, for their job; PCI/DSS for employees to understand the cardholder information and to acknowledge it. Federal information security management Act for employees to understand the information assets, risks, responsibilities and compliance. Gramm-Leach Bliley Act for users to understand the risks to customer information, employee management and training, information systems knowledge, and managing systems failures. Health Insurance Portability and Accountability Act (HIPAA) implement security awareness and training programs for all employees. The use of the Red Flag Rule for user to be able to identify threats and raise Red Flags when there is need and General Data Protection Regulation (GDPR) to create awareness, training, monitor compliance, and audit to ensure Data security as depicted in Table I.

The delivery methods used in conducting SEATE programs has an impact on the outcomes of such programs. Such programs are many and varied. The author in [2] opined that, they are face-face, self-directed and teachable methods. According to [24], the delivery methods include conventional methods, Instructor-led and online methods. However, these methods have their individual downside when used alone. Consequently, we argue that, using all of them together will complement each other's deficiencies. Hence, the proposal for the use of the hybrid approach in delivering based on the peculiarity of the problem being addressed. The use of the hybrid approach will ensure that the weaknesses in each of the proposed traditional methods are complemented and compensated by the other method. This will lead to SEATE programs being effective and leads to improved security to social engineering attacks in particular and cybersecurity in general and SEATE programs in particular.

To propose a behavioural change artefact to improve SEATE programs, we propose a model known as Awareness, Transition, Adaptation and Consolidation (ATAC) following two theories (Conscious Competence Model and the stable Quasi-Random Equilibrium Model): [28],[22].

The CCM is a framework that describes the stages individuals have to pass through when learning a skills or behavior change to move from being unconscious/unskillful to becoming conscious/skillful. It is made up of four stages; Unconscious incompetence, where the individual as unaware, do not understand or know about a particular issue; in this case, SEATE programs and its impact. The second stage is Conscious Incompetence where the individual becomes aware of their skill/knowledge attitudinal deficit, hence, expresses the need to learn the skills or behavior change. At the third stage, called Conscious Competence, the individual have made progress and have acquired a reasonable level of the needed skill, but does things with little difficulty.

Finally, continuous use of the skill knowledge/ attitude over and over leads to Unconscious Competence where he/she performs the art/skill without thinking or with less effort.

The other theory is the stable quasi-stationary equilibrium, which describes change as a transition between two dynamic states in which each of the state itself is dynamic. It comprises unfreeze or unlock from present position to or behavior by creating an enabling environment through education training, motivation. The second is move from the present to the new state by implementing the new way of thinking or attitude. Thirdly; refreeze; by making the new system, the accepted way the system should work [22]. Consequently, following these principles/theories we argue that, the use of the ATAC model not only improve user SEATE knowledge/behavior, but will lead to permanent behavior/knowledge change and lead to permanent immunology among Users against Social Engineering Attacks. An Expert Opinion or Observational Empirical Research conducted showed very high rating for the metrics such as fit for purpose, novelty, ease of use and architecture/structure with 92% on average. This suggests that such a model has the potential to influence behavior change among users with overall average expert score of 73.6%.

VII. CONCLUSION AND FUTURE WORK

The study aimed at Improving Social Engineering Awareness, Training and Education (SEATE) by exploring SEATE Content, Delivery methods, challenges and proposing an innovative Content, a hybrid Delivery method and a behavioral change model as a Non-Technical defense Approach to S E attacks defense.

The findings shows that SEATE fails due to poor content and poor delivery methods coupled with other challenges such as generic nature of training, limited budget provision, poor security policies and compliance and user resistance to changes. The use of relevant an innovative content, hybrid delivery methods, and a behavioral change model improves the conduct of SEATE programs.

As the cyber warfare in general and Social Engineering in particular rages on, with daunting challenges, cyber criminals have found innovative ways of penetrating the parametric defenses and delivering malicious content to users with the aim of compromising their systems. When that happens, the user becomes the last line of defense; to click or not to, update or not to. These critical binary decisions require that users understand the relevant SE Content conducted through well-delivered and innovative delivery methods. Consequently, following the novel model improves the immunity or resistance of users to SE attacks and enables them to know how to react in such attack circumstances. Thus, adopting the novel behavioral change model (ATAC) showed a high potential at improving the conduct of SEATE programs that improved user immunity/Resistance to SE attacks. One limitation of the model is the fact that, it was qualitatively evaluated; future effort will empirically follow the model to conduct a quantitative longitudinal study to practically establish the dimensions of the artefact (model) and to automate same for conduct of SEATE programs.

Evaluating Learning Management System based on PACMAD Usability Model: Brighten Mobile Application

Masyura Ahmad Faudzi, Zaihisma Che Cob, Ridha Omar, Sharul Azim Sharudin

Department of Informatics, College of Computing and Informatics, Universiti Tenaga Nasional, Kajang, Malaysia

Abstract—During the pre-COVID-19 pandemic, mobile learning is just an optional or a supplementary module in learning process. However, when the pandemic hit the world in the middle of 2020, a large number of students were forced to move from traditional learning process to online learning. This has become a critical issue especially for new online learners. Usability of a mobile learning application is important in ensuring that learners are able to learn efficiently and effectively with ease. This study evaluates the usability of the Brighten mobile application; a Moodle-based Learning Management System (LMS) which is currently used by all Universiti Tenaga Nasional's students. The evaluation is based on People at the Center of Mobile Application Development (PACMAD). The results indicate that Brighten mobile application is acceptable in terms of usability's effectiveness, efficiency, learnability, memorability and error-tolerance. Learners' satisfaction level shows a "marginally acceptable" result based on the SUS Adjective Rating Scale and the result for cognitive load shows that the highest cognitive load was in terms of the performance factor.

Keywords—Mobile learning; usability; PACMAD; learning management system; Moodle

I. INTRODUCTION

Mobile learning is the process of learning that allows learners to obtain learning materials anytime and anywhere, using mobile devices, such as mobile phones and tablets. Before the COVID-19 pandemic hits the world in 2020, mobile learning has been used as complimentary learning resources for the traditional in-class teaching [1]. However, the pandemic forced most of the students across the world to rely more on online learning. This can be seen in the increased number of online learning users in Malaysia up from 9.5% to 20.8% in 2020 [2]. In 2021, mobile learning has been seen as an increasingly popular learning method as it is able to improve and make learning easier for students around the world [3].

One of the methods of applying mobile learning technique is through a Learning Management System (LMS). LMS is an application that is used for administering e-learning practices, i.e. planning, implementing and accessing the learning and development programs [4]. One of the most widely used LMS is the Modular Object-Oriented Developmental Learning Environment (Moodle), which is an open-source software that allow personalization of its learning environment [5]. Brighten mobile application is a customized Moodle for students of Universiti Tenaga Nasional (UNITEN) [6]. It is widely used

for online and blended learning in UNITEN. During the peak of COVID-19 pandemic, Brighten has become the main source of learning delivery process in UNITEN.

Usability of a system is when the system can be used by it intended users, in a specified context of use, to achieve goals effectively, efficiently and satisfyingly [7]. Usability testing of applications on mobile device needs to consider challenges such as small screen size [8][9][10], restricted input [11] and design issues [12][13]. People At the Center of Mobile Application Development (PACMAD) Usability Model is a usability model that is developed specifically for measuring mobile application performance based on the seven usability attributes by Harisson, Flood and Duce [14]. It takes into consideration ~~on~~ attributes, which are normally neglected by the other usability models when applied to mobile devices. PACMAD focuses on the effectiveness, efficiency, satisfaction, learnability, memorability, errors and cognitive load factors.

Despite LMS being widely used since 1960s, there are a lot of problems in terms of its usability. These usability problems include inconsistency in design, issues with navigational links and search functions, inappropriate contents and difficult to be use [15]. These issues are very crucial as they might interrupt the effective process of knowledge transfer [16].

The objective of this research is to evaluate the usability of Brighten mobile application using PACMAD usability model. In order to evaluate the usability of the Brighten mobile application, the research questions can be divided into three parts, which are:

RQ1: What is the effectiveness, efficiency, learnability, memorability and errors of the Brighten Mobile Application?

RQ2: What is the satisfaction level of the Brighten Mobile Application's user after using the application?

RQ3: What is the cognitive load of the Brighten Mobile Application's user while using the application?

The remainder of this paper is structured as follows: Section 2 discusses relevant works related to mobile learning and usability testing. This is then followed by Section 3, which explains the details of the methodology used in the experiment. Section 4 discusses the result of the experiment. Finally, in Section 5 provides the conclusions and suggestions for future work.

II. LITERATURE REVIEW

Mobile learning or sometimes known as m-learning is simply defined as a learning process, in terms of pedagogy and education [17], that takes place through mobile devices. Using the mobile technology, mobile learning can be accessed from any location at any time [18]. Ozdamli and Cavus mentioned that this learning method should be ubiquitous, portable, blended, private, interactive, collaborative and instant [19].

Mobile learning is performed through a mobile phone, a tablet, a Personal Digital Assistance (PDA), an iPod, a palmtop or any special ubiquitous handheld devices. Although laptops and notebooks are portable devices, they are not considered as a mobile learning device as they are much bigger and heavier [20].

Mobile learning is applied through mobile medium such as SMS/MMS, email, message boards, forums, blogs and video conferencing. El-Sofany and El-Haggar divided these teaching tools into three categories, which are social networks (such as Facebook, Twitter, Blogs and Youtube EDU), web-based platform (such as Rapid Cycle Evaluation Coach, TED-ed and Moodle) and Internet of Things (such as Smart classroom environment device, attendance system and real-time feedback on lecture quality) [21].

As mobile learning is the extension of e-learning, it inherits all the advantages of e-learning such as supporting distance learning and enhancing student-centered learning [22]. Visual learners gain benefits from mobile learning as compared to learning through textbooks. There are improvements in the communication process between teachers and learners through mobile learning environment. Learners can control their learning process and pace. This leads to efficient learning [23] and positively motivates them to learn [24].

LMS is a system that enables educators to administer, build, track, maintain, update and report information related to a learning program [25][26]. It supports online and offline discussions, formative and summative evaluations and practical-related contents [27]. It assists the learning process in an e-learning environment and can be divided into two (2) types; proprietary LMS and open source LMS [26]. Moodle, Open edX and Chamilo are among the most popular open source LMS [28].

Moodle was developed by Martin Dougiamas and Pete Taylor in 2002 and has established itself as a leading LMS in 2007. Moodle evolved since then and as of 2020, there are more than 190 million of Moodle users around the world [29]. Among the advantage of Moodle compared to the other system is that it can be used by users from different platforms (Windows, Mac, UNIX and Linux) without modification. It supports learning management activity through learning materials, videos, discussion and forums, chat and assessments [26].

Brighten is a customized Moodle that is currently being used in Universiti Tenaga Nasional, Malaysia. It was first implemented in June 2021 to replace the earlier Moodle system. The customization of Moodle into Brighten was done after an informal study conducted on the data usage and data

redundancy of the “older” Moodle LMS. The main interface of the Brighten application is shown in Fig. 1.

Based on International Organization for Standardization (ISO), the evaluation of a system’s effectiveness, efficiency and satisfaction determines the usability of a system [30]. ISO also mentioned that there are three (3) factors that need to be considered when evaluating the usability of a system; user, goal and context of use. Nielsen’s usability model consists of efficiency, satisfaction, learnability, memorability and errors [31].

Despite both of the usability models being widely used, it does not fulfill the context of use when it comes to mobile applications. Hence, PACMAD was introduced to overcome the limitation of the common usability models. PACMAD looks into the context of use for mobile application, such as mobile context, connectivity issues, small screen size, different display resolution, limited processing capability and power and different data entry method [14]. It combines the attributes from both ISO and Nielsen’s usability model and it is designed specifically for mobile application [32]. PACMAD has seven attributes. These attributes are efficiency, effectiveness, learnability, memorability, error, satisfaction and cognitive load. This usability model includes cognitive load as one of the measuring attributes as its main contribution [33]. These attributes are very important for applications that run on mobile devices as mobile devices have different task setting and size limitation compared to desktop PC [34].

Based on these studies, we can conclude that PACMAD is usability model that is created specifically for mobile application. It evaluates the cognitive load of a user. Cognitive load is among the most important factor, which needs to be focused upon when knowledge transfer process takes place. In the current situation where some of the learning process needed to be done online, it is very crucial to have a mobile learning application that can assist in teaching, and not a burden to learners. As such, based on the results of this usability testing, the Brighten mobile application can be further improved.

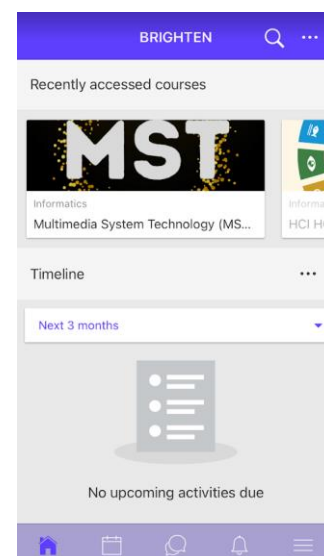

Fig. 1. Brighten Main Page.

III. METHODOLOGY

An experiment was designed which comprises of three (3) tasks and three (3) questionnaires based on the requirements of PACMAD usability model. The participants will evaluate the usability of the Brighten Mobile Application. The experiment was divided into three parts:

- Part 1: Questionnaires to gather participants' information such as age, gender, program of study, year of study, mobile OS, frequency of mobile phone usage per day and average time spends on mobile learning
- Part 2: Evaluate the effectiveness, efficiency, learnability, memorability and error of the tasks that need to be implemented by the participants on Brighten Mobile Application. During this phase, participants are required to perform 3 tasks; Task 1 - sending a private message to the teacher/friend/group, Task 2 - downloading a file (notes, support document, lab manual) and Task 3 - uploading a file (project/lab/assignment submission). For these tasks, participants are required to repeat the process 3 times for different receiver (Task 1) and file types (Task 2 and Task 3). Time will be taken to calculate the efficiency, effectiveness, learnability and memorability attributes. Errors will be calculated manually by the participants during the experiment.
- Part 3: Questionnaires to evaluate the participants' satisfaction level and cognitive load through System Usability Scale (SUS) questionnaire and NASA-TLX, respectively. Participants can add their personal comments about Brighten application and the issues that troubles them during the experiment. The flow of the experiment is as shown in Fig. 2.

The execution of the experiment was done online, through MS-Teams. This was done online, because at that period Malaysia was under the Movement Control Order (MCO) due to COVID-19 pandemic. MCO restricted the mobility of the participants as well as the researchers.

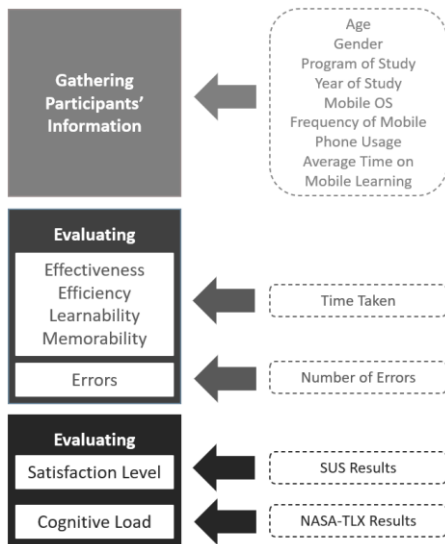

Fig. 2. The Experiment Flow.

IV. RESULT

A. Participants

77 participants were involved in the usability testing. However, 3 of the students pulls out in the middle of the experiment. As such their data are not counted in the result.

All participants are undergraduate students from six different bachelor degree programs (at UNITEN), taking Human Computer Interaction (HCI) subject. Age group, gender, program of study, year of study, mobile OS are the demographics characteristics that have been included in this study as shown in Table I. From 77 participants, more than half of the participants (54%) are between 21 to 23 years old, most of them are male (61%) and almost 80% of the participants are second year students. 61% of the participants are Android users.

Participants were asked on their daily frequency mobile phone usage. A large group of the participants spent between 6 to 12 hours using mobile phone daily as shown in Fig. 3.

Generally, the participants used their mobile phone for communication (WhatsApp, Telegram, Line and Signal), social media (Facebook, Instagram, Twitter and TikTok), mobile learning (Brighten and MS-Teams) and playing games as shown in Fig. 4.

The average students' spending time on mobile learning is shown in Fig. 5. Most participants spent between 1 to 3 hours on mobile phone utilizing mobile learning where they attended lectures, read and download notes, doing quizzes and assignments.

TABLE I. THE DEMOGRAPHICS CHARACTERISTICS OF THE STUDY

Information about the Participants		
Age Group	18-20 years old	30
	21-23 years old	42
	24-26 years old	3
	27 years old and above	2
Gender	Female	30
	Male	47
Program of Study	Bachelor in Computer Science (Hons) (Software Engineering)	25
	Bachelor in Computer Science (Hons) (Cyber Security)	27
	Bachelor in Computer Science (Hons) (System and Networking)	4
	Bachelor in Information Technology (Hons) (Information System)	7
	Bachelor in Information Technology (Hons) (Graphics & Multimedia)	4
	Bachelor in Information Technology (Hons) (Visual Media)	10
Year of study	1	11
	2	61
	3	5
Mobile OS	Android	47
	iOS	30

Fig. 3. The Average Time Required for Participants to Complete the Tasks, for each Round.

Fig. 4. Frequency of Mobile Phone usage per Day.

Fig. 5. Common Task on Mobile Phone.

B. Result

The results obtained are based on all the seven elements in PACMAD – effectiveness, efficiency, learnability, memorability, error-tolerance, satisfaction and cognitive load.

1) *Effectiveness*: The result of effectiveness depends on the ability of the participants to complete the tasks given. Table II shows that 98% of the participants managed to complete the tasks in Round 1, 100% in Round 2 and 99% in Round 3. Some of the participants failed in completing the tasks in Round 1 and Round 3 which is either due to network problem or system error that leads to failure in downloading the files.

2) *Efficiency*: Efficiency is calculated based on the speed and accuracy of the participant in completing the tasks measured using the task completion time, as indicated in

Table III. It shows the task per second calculation that demonstrate the number of tasks completed in a second. Overall, the efficiency of the system increases with the number of rounds.

3) *Learnability*: Learnability measures how easy a task is for the users to accomplish it when they first time encounter the interface. It also measures the number of repetitions that the users take to become efficient at that task. Learnability is measured by the time taken for the participants to finish a task and the number of rounds they need in learning on using the system. According to the Nielsen Norman Group, the same task needs to be repeated until the time taken for the participants to finish the task started to plateau. However, in this research, we have fixed the number of rounds to be 3, as mentioned in the Methodology Section.

Several of the participants were eliminated from the calculation as they were facing some technical problem when completing the task. Only 64 results from the participants are included in the calculation for Task 2 and Task 3. The average time required by the participants for each task in each round is shown in Fig. 6.

It can be seen that the time taken for each task is decreasing when it is being repeated for the second and third time.

TABLE II. TASK COMPLETION RESULTS

	Round 1	Round 2	Round 3
Completion Rate	98%	100%	99%

TABLE III. TASK EFFICIENCY

TASK	ROUND		
	1	2	3
1	0.0197 task/second	0.0494 task/second	0.0699 task/second
2	0.0184 task/second	0.0335 task/second	0.0420 task/second
3	0.0202 task/second	0.0515 task/second	0.0545 task/second
Overall relative efficiency	1.94%	4.48%	5.54%

Fig. 6. Average Time Spend on Mobile Learning per Day.

4) *Memorability*: Memorability is about how easy is for the users to reestablish their skills after a long time of no use. Comparing task completion task 1, 2 and 3 on Round 1, Round 2 and Round 3. Based on the task completion on Table II, Round 2 performed the best by 100% had completed the task. Whereas, in Round 1 less than Round 2 which are 98%. Therefore, the task had been increased in Round 3 which are 99% successful completing the task. Mostly student can perform and not give up completing the task. For Round 1, most student spend most time to understand the task given and some students do not understand the task given. But then, they can do the task smoothly for the next round. Issues that affect the performance of the participants are unresponsive application and unstable connection.

5) *Error-tolerance*: Error is measured by calculating the number of errors that are done by the participants in completing the task. Among the error listed are; wrongly entered an input, click the wrong page – need to go to sitemap/menu, click the wrong page – need to press back button, understanding error (doing the wrong task) and press submit button when some questions were left unanswered. Each of the error will be counted including the repetitive errors. If the error faced by the participants is not in the list, participants are required to write the error and how it affects their process in completing the task.

As can be seen in Fig. 7, the number of errors for each of the task can be seem to be decreasing as the number of rounds increasing. The global errors are obtained by dividing the number of errors for a particular round with the number of tasks. Table IV shows the global errors obtained in Round 1, Round 2 and Round 3.

6) *Satisfaction*: SUS questionnaire is used to measure user satisfaction of the apps and the results are shown in Fig. 8. The average score from all respondents is calculated and the results were converted to SUS adjective rating.

The average score from all participants is 61.13. Thus, the result falls in the 'OK' range based on the SUS Adjective Rating Scale.

The participants explained that they are still confused with the "downloading" system during the execution of the task. They are not sure whether they actually have downloaded the file or not. Besides that, the difference between Brighten App via mobile phones and desktop/laptop in terms of UI design also can lead to several confusion and complication. Overall, Brighten App is still acceptable to participant's perceptions of usability value but it needs a bit of improvement in terms of downloading files, IU design, etc.

7) *Cognitive load*: The level of cognitive load involves while using the application is measured to determine the

cognitive processing needs. NASA Task Load Index (TLX) is used to assess work load on five 7-point scales. Increments of high, medium and low instrument consists of five dimensions (one question associated with each dimension) was used to determine the cognitive load of students in performing the given tasks (refer Table V.). The specific dimensions determined the activity's contribution to the cognitive workload and measured using a Likert Scale that range from 1-Very Low and 7-Very High. The overall cognitive workload that the participant experiences is calculated by adding up all the scores and then the average is calculated by dividing the total score with the six different dimensions. The higher score indicated the higher the cognitive workload that the participant experienced.

The highest response is rating 5 with 34% for the performance dimension with the average rating of 5.5, indicating high cognitive load for this dimension. The next average rating of 3.9 for the temporal demand dimension followed by effort, mental, frustration and physical dimension (average scores 3.7, 3.6, 3.4 and 3.2 respectively).

8) *Comments from participants*: Most of the participants managed to complete the tasks without any critical issues. However, some of them has provided some comments and issues on Brighten application that they faced while implementing the tasks. The comments and issues are categorized into five categories. The comments are shown in Fig. 9.

Fig. 7. Total Number of Errors based on Tasks and Rounds.

TABLE IV. GLOBAL ERRORS FOR EACH ROUND

	Round 1	Round 2	Round 3
Total Number of Errors	173	44	29
Global Errors	57.67	14.67	9.67

Fig. 8. SUS Questionnaire Score.

TABLE V. THE NASA-TLX RESULT

Dimension	Questions	1	2	3	4	5	6	7
Mental Demand	How mentally demanding was the task?	7%	22%	16%	25%	21%	7%	3%
Physical Demand	How physically demanding was the task?	14%	23%	18%	21%	22%	3%	0
Temporal Demand	How hurried or rushed was the pace of the task?	4%	18%	21%	21%	19%	11%	7%
Performance	How successful were you in accomplishing what you were asked to do?	0	1%	4%	10%	34%	27%	23%
Effort	How hard did you have to work to accomplish your level of performance?	10%	23%	15%	11%	25%	10%	7%
Frustration Level	How insecure, discouraged, irritated, stressed, and annoyed were you?	21%	26%	5%	18%	8%	12%	10%

*The output from these questions will be measured using Likert Scale that range from 1-Very Low and 7-Very High

Fig. 9. Comments from Participants.

The most common problem-faced is regarding the difficulties in finding items or functions in the application. In the message sending task, the participants are having problem in finding the send message function or the receiver's name. The application requires the exact full name of the receiver in order to ensure that the message is send to the right person. As the application allows the message to be sent to any user in the university, there is a possibility that the message will be sent to the wrong person.

In the downloading file task, the participants are having problem in finding the location of the files that have been downloaded. The application neither allows the participants to choose the location for the file to be saved nor informing the participants on the location of the saved file.

Some of the participants are having issues in navigating the application. Among the issues that slow down page navigation are; pages kept on reloading and the location of the button is not at common location. Most of these participants find that the mobile version of the application is not as friendly as the web version.

Several participants find that the color template used in the application is too pale and it is difficult to distinguish the sections. This can be seen in Fig. 10.

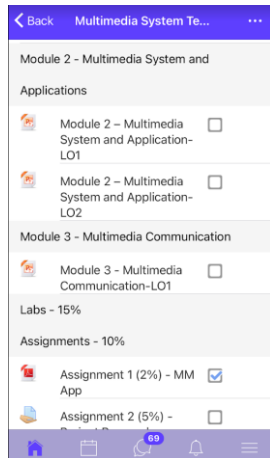

Fig. 10. Brighten Application Subject Page.

Slow response and no task feedback are issues faced by 15 of the participants, where they find that it takes sometimes for the application to respond despite good internet connection. In the task where the participants are required to answer quiz questions, they complained that there is no timer to indicate the time available for them. They find that this is very demotivating.

V. DISCUSSION

From the result, it can be seen that Brighten application passed all of the usability testing with minimum issues. The result of the effectiveness, efficiency, learnability, memorability and errors of the Brighten Mobile Application are acceptable where the learners have no major issues in implementing the tasks.

The average SUS score is 61.13, as mentioned in the previous section. This raw SUS score is below the average of common raw SUS threshold which is 68. This result is deemed as marginally acceptable.

In terms of cognitive load, the participants seemed to have a high cognitive load on performance dimension. This shows that the learners find it quite difficult to successfully accomplishing the given tasks.

In the comment section, some of the participants did mention that they find that the Brighten application on mobile device is difficult to be used compared to the web version. The participants are having problems in finding some of the menu buttons and users.

One of the main issues that interrupted the participants from completing the task is the network issue. Network issues

not only affecting the usability testing result but also the communication between the researcher and the participants.

In this experiment, the number of errors is counted by the participants themselves. To ensure a more reliable result is being obtained, it is suggested that for the experiment to be conducted in face-to-face mode where the researcher can assist the participants in counting the number of errors that they encountered. This can also ensure that the testing is not being interrupted by network issue.

VI. CONCLUSION

This study evaluates the usability of the Brighten application based on PACMAD usability model where it evaluates the application in terms of effectiveness, efficiency, learnability, memorability, error-tolerance, satisfaction and cognitive load. On the surface, the result of the effectiveness, efficiency, learnability, memorability, error, satisfaction of the Brighten mobile application are acceptable with minor issues.

Using SUS and NASA-TLX shows that there are problems in using the application. However, most of the issues are being detailed out in the comment from the participants sections. It was observed that the issues that prevent full satisfaction from the learners and burden the cognitive of the learners comes from the navigation and user interface design.

Future work can be carried out by developing a guideline/framework for mobile learning user interface design that will increase learners' satisfaction and improve their cognitive load.

ACKNOWLEDGEMENT

Voice Biometrics for Indonesian Language Users using Algorithm of Deep Learning CNN Residual and Hybrid of DWT-MFCC Extraction Features

Haris Isyanto, Ajib Setyo Arifin, Muhammad Suryanegara

Department of Electrical Engineering
Universitas Indonesia, Depok, Indonesia

Abstract—This research develops a Voice Biometrics model for the Indonesian language users by using deep learning algorithm of CNN Residual and Hybrid of DWT-MFCC Feature Extraction. The voice dataset of Indonesian speakers were created with a duration of 5, 10, 15, 20, and 25 minutes. The testing phase of speaker recognition and speech recognition were carried out by comparing the model of CNN Residual with CNN Standard. In the phase of speaker recognition, CNN Residual model has obtained the best results with the highest precision percentage of 99.91% and the highest accuracy of 99.47% at 25 minutes voice samples, compared to the CNN Standard obtaining precision of 96.83% and accuracy of 99.00%. In the phase of speech recognition, CNN Residual model has reached the best performance at 100% accuracy during 20 trials, while CNN Standard only gave 95% accuracy. CNN Residual Model provides a better performance for its accuracy and precision, but it is slightly slower than the CNN Standard, with a time difference of 0.03 – 1.28 seconds.

Keywords—Voice biometric; deep learning; CNN; DWT-MFCC; security

I. INTRODUCTION

The crime of fraud and identity theft has become a crucial threat in cybercrime. It can be associated with the excessive use of the Internet for miscellaneous activities, including online transactions, social networking, and the storage of personal information. To minimize these problems, a biometric identification method was developed, especially for high-level security entry and privacy of sensitive data access in banking transactions [1-3].

The biometric-based personal identification method is one of the alternatives developed especially for high-level security entry, such as government or military buildings, access to sensitive data or information, and theft prevention. Voice biometrics is a biometric technology that utilizes the biological characteristics of the human voice for the identification and authentication of unique patterns for each individual [4-6]. Voice biometrics includes the voice commands, allowing devices such as smartphones, computers, or laptops to receive what the user has spoken and translated into certain electronic commands. The communication of voice commands between the user voice and the device is also known as human-machine interaction [7-9]. The development of the implementation of voice biometrics technology is a solution to maintain the

privacy and security of individual identity data and to avoid frauds.

The voice biometric has been perceived providing a more secure and a more reliable identification and authentication process. In principle, the authentication mechanism can be conducted remotely using a common device such as smartphones and laptops, while the cost of implementing voice biometrics is lower than other biometric solutions because it does not require special devices, such as fingerprint readers or retina scanners. It also has higher security, easy to operate, and accurate identification method to identify a person [10-13].

Currently, voice object recognition research is being developed using the CNN deep learning model. Deep learning Convolutional Neural Network (CNN) technology is one of the neural network algorithms that can assist in solving problems with large amounts of data and data complexity in the object identification process [14-16]. However, most of the previous research provides a separate discussion between the performance of speaker recognition [17-19] and speech recognition [20-22]. Meanwhile, most of the paper discussions on voice biometrics still use machine learning methods, in which it has the disadvantage of not being able to process large amounts of data and not being able to handle the complexity of large data in the identification process of voice biometrics.

In this paper, a Deep Learning voice biometric model was developed using CNN Residual and Hybrid of DWT-MFCC Extraction Feature. The use of CNN Residual is done to simplify the training and validation process, as well as to improve classification accuracy [23, 24]. Meanwhile, the hybrid extraction feature, the Discrete Wavelet Transform (DWT) [25, 26], and Mel-Frequency Cepstral Coefficients (MFCC) extraction features are used to eliminate noise interference, recognize the shape of the voice pattern from a person's characteristics and select the required voices [27, 28].

The test was carried out on 2 security system processes that apply to voice biometrics [29, 30], namely the speaker recognition security system to detect "Whose voice is the person speaking?" [31, 32]. And a speech recognition security system to detect "What keywords are spoken?" [33, 34]. If both securities are successfully accessed, then the system will be "Accepted". But if these two securities fail to be accessed, then the system will be "Rejected". Furthermore, testing is also carried out by measuring the processing time required to carry out a voice biometrics process.

To test the model, this paper compares the performance of the proposed model with the CNN Standard. The comparison is essential to see how the performance of the CNN Residual model may significantly improve the performance of voice biometrics, especially on its accuracy, which lead to better security system.

The remainder of the paper presents Underlying Theories in Section II, elaborates the theory of voice biometric, its relevant studies, and the theory of DWT and MFCC. Section III presents the architecture of the deep learning model, Section IV presents the results and analysis, while Section V concludes this paper.

II. UNDERLYING STUDIES

A. Voice Biometrics

As shown in Fig. 1, the voice biometrics system consists of 2 (two) processes, namely the user enrollment and user verification/authentication [35-38]. The user enrollment is the process of identifying the user's voice identification for registration of the user's voice data into the database. The user enrollment process begins with a capturing process where the user's voice as input is captured by the microphone as a voice sensor. The user's voice input contains the speaker's voice and speech content. Preprocessing is the process of converting analog user input voice signals into digital ones. The process of creating this template is a user identification process that is carried out to register the identity of the user's voice which is a unique individual characteristic, which registers the speaker's voice (speaker recognition) and the speech recognition content which is stored in the database [36]. The workflow of the user enrollment and verification process can be shown in the first line of Fig. 1.

The second process, namely user verification or authentication, is the process of verifying the user's voice by matching the user identification between the incoming voice and the voice that has been registered in the database. In this process, there is a template match process that is intended to verify the voice data by matching the user identification between the incoming voice data and the voice sample data template that has been registered and stored in the previous

database. The output is Voice Biometrics Authentication with validation of the user's voice data (accepted/rejected).

As shown in Fig. 1, in the context of verification, basically the core of the voice biometrics security system works on 2 phases [29, 30], i.e. speaker recognition to detect "Whose voice is the person speaking?" [31, 32], and speech recognition to detect "What keywords are spoken?" [33, 34]. If the voice recognition on both phases are successful, then the system user will be verified, otherwise, it will be rejected. However, most of previous studies discussed the phase of speaker recognition and speech recognition separately.

B. Relevant Studies

The relevant studies of Speaker Recognition, Speech Recognition and their combination on build up the voice biometrics are shown in Table I.

In the previous research, several papers have discussed voice biometric by using machine learning methods, including machine learning k-Nearest Neighbors (k-NN) [35], SVM machine learning, and MFCC extraction features [36], GMM machine learning and MFCC extraction features [37]. However, it is rare for papers to discuss using deep learning algorithms.

The weakness of using deep learning methods ANN and DNN is less reliable than RNN and CNN [48, 49]. While RNN is a sequential data modeling unit, RNN includes less feature compatibility when compared to CNN. The weakness of this RNN has a gradient loss problem. To avoid the problem of disappearing gradients, the RNN is combined with the LSTM. However, this LSTM has the disadvantage that it requires more memory to train [46, 50-52]. CNN is considered more reliable than ANN and RNN. And the weakness of using machine learning methods GMM, GMM-UBM, GMM-HMM, and HMM is only able to process data in smaller amounts and is less able to process complex data [53, 54]. Therefore, the advantages of CNN are having reliable computing capabilities, having a high accuracy, having the ability to process large training data, having an ability to automatically detect important features without human supervision, and being able to classify data complexity in the voice identification process [17-22].

Fig. 1. Process Workflow of user Enrollment and user Verification [36].

TABLE I. RELEVANT STUDIES

Studies of	Research by	Methods	Explanation
Speaker Recognition	[55]	i-vector with machine learning GMM, PNCC, and RASTA PLP feature extraction	PNCC, RASTA PLP and MFCC are sensitive to noise and Machine Learning (ML) is only able to process smaller amounts of data and is less capable of processing complex data
	[56]	i-vector with machine learning GMM-UBM, and MFCC extraction features	
	[57]	i-vektor with deep learning DNN and MFCC extraction features	DNN is less reliable in computing capabilities
	[17-19]	deep Learning CNN	No extraction feature
	[39]	deep-learning CNN and MFCC extraction features	MFCC is sensitive to noise
Speech Recognition	[40]	i-vector with machine learning GMM	ML is only able to process smaller amounts of data and is less capable of processing complex data
	[41]	machine-learning GMM and HMM	
	[42];	machine-learning HMM, MFCC extraction feature	The explanation of ML and MFCC is the same as above
	[43];	machine-learning HMM and deep learning ANN	ANN and DNN are less reliable in computing capabilities
	[44]	deep-learning DNN	
	[45];	deep-learning RNN	RNN only has less feature compatibility compared to CNN
	[46];	deep-learning RNN and LSTM	
	[20-22], [47].	deep-learning CNN and LSTM	No extraction feature
Voice Biometrics	[35];	machine-learning k-Nearest Neighbors (k-NN)	MFCC is sensitive to noise and ML is only able to process smaller amounts of data and is less capable of processing complex data
	[36];	machine learning SVM and MFCC extraction features	
	[37].	machine-learning GMM and MFCC extraction features	
	The Model developed in this research	deep-learning CNN Residual and Hybrid of DWT-MFCC extraction features	Deep-Learning CNN Residual is able to solve problems of large amounts of data, to process complex data, to reduce the number of parameters and arithmetic operations in convolution operations and is able to simplify the training and validation process, thus may increase the classification

			accuracy. In addition, the Hybrid of DWT-MFCC extraction feature can remove noise, recognize the shape of a voice pattern from a person's characteristics, and select the required voices.
--	--	--	--

From the feature extraction point of view, studies in [55, 56] discussed the performance of speaker recognition, while studies in [40-43] discussed the performance of speech recognition with the i-vector extraction features, PNCC, RASTA PLP, and MFCC. They had performed an accuracy of about 76%. Research on speaker recognition [17-19, 39] and speech recognition [20-22, 44-47, 57] by using a deep learning model with i-vector extraction features and MFCC, have obtained an accuracy of around 71-90%.

C. Deep Learning CNN Standard

This CNN standard is a deep learning algorithm technology that has high performance and has been used for database training and testing. With the performance of the CNN standard algorithm, it is expected to improve higher performance compared to using the previous machine learning algorithm.

The architecture of CNN standard is shown in in Fig. 2. It consists of 1 input layer, 5 layers 3x3 Convolution 16 Filters, 1 layer 3x3 Convolution 32/2 Filters, 3 layers 3x3 Convolution 32 Filters, 1 layer 3x3 Convolution 64/2 Filters, 3 layers 3x3 Convolution 64 Filters, 1 layer 3x3 Convolution layer 128/2 Filter, 3 layer 3x3 Convolution 128 Filter, 1 layer Adaptive Average pool, 1 layer Flatten, 1 layer Fully connected and 1 layer output layer.

In CNN Standard, the input layer is a layer for processing data as a set of features. In each Convolution layer, there is a filter/kernel size (filter size) convolution matrix of 3x3 with some filters 16, 32, 64, and 128. This convolutional layer carries the main part of the network computing load, which does most of the heavy computational work. The convolution layer is needed to speed up the extraction of spatial features in the data so that the number of parameters that need to be used to extract features can be reduced, and in the end, will speed up runtime training. Each Convolution layer contains Batch Normalization and ReLu. The batch normalization layer is a normalization technique performed between the layers of the Neural Network, which standardizes the input to the layer for each mini-batch. This is done with mini-batches instead of full datasets. This serves to speed up the training process and uses a higher learning rate, making learning easier. Batch normalization is also able to solve the main problem called internal covariate shift.

ReLU (Rectified Linear Unit) is a node or unit that implements the network layer activation function. ReLU is useful for helping prevent the exponential growth in the computations required to operate neural networks. The adaptive average pooling layer is an easy average pooling operation layer, which gives the input and output dimensions,

to calculate the correct kernel size required to produce an output of the given dimensions from the given input. The flatten layer is a layer that involves taking the combined feature maps generated in the pooling step and converting the data into one-dimensional vectors, to be inserted into the next layer; by flattening the output of the convolution layer to create one long feature vector. And it is connected to the final classification model, which is called the fully-connected layer. Furthermore, a Fully Connected Layer is a layer where all inputs from one layer are connected to each activation unit of the next layer. The last few layers are full connected layers that compile the data extracted by the previous layer to form the final result. The fully connected layer is a full process of Batch Normalization and ReLU data input.

D. MFCC Method for Extraction

As shown in Fig. 1, feature extraction plays an important role to provide good accuracy. Mel Frequency Cepstral Coefficients (MFCC) is believed to be a method that has the highest level of accuracy with speech recognition rates and the fastest feature extraction time compared to other voice feature extraction methods [58]. It is so that the MFCC method is good in accuracy for feature extraction in speech recognition processing in voice biometrics. MFCC is one of the feature extraction methods and methods that are most often used in various fields of voice processing, because it is considered very good in presenting the characteristics of a signal, such as in speech recognition technology, both voice biometrics, speaker recognition, and speech recognition. MFCC is used to recognize the shape of the voice pattern from the extraction of a person's characteristics and choose only the voices that are needed from other voices that are not needed. The feature extraction process with MFCC is a process of taking from feature extraction using a discrete Fourier transform. The Fourier transform can only determine the frequency that appears in a signal, but cannot determine when that frequency appears. The sequence process for the MFCC block diagram can be shown in Fig. 3 [59].

The following is the sequencing process for the MFCC block diagram:

1) *Pre-emphasis*: Used for the filtering process which compensates for the high-frequency portion of the voice signal that is suppressed during the voice production mechanism. The pre-emphasis process is following Equation (1) [28, 59].

$$y(n) = s(n) - a \cdot s(n - 1) \tag{1}$$

where $y(n)$ = signal from the calculation result of pre-emphasis process, n = serial number of voice signal, $s(n)$ = voice signal before pre-emphasis process, a = constant of pre-emphasis filter, with a value of $0.9 \leq a \leq 1.0$ and s = voice signal.

2) *Framing and windowing*: In the framing process, analyze the speech signal of the voice in the form of frames. The signal is divided into several pieces, to facilitate the calculation and analysis of voice signals. Each frame is represented with an interval of 20-40 ms and the signal is continued every 10 ms, which overlaps the previous signal and the next signal [60]. Windowing is used to avoid discontinuity between signals. The most widely used type of window is the hamming window [28, 59, 61].

3) *Fast Fourier Transform (FFT)*: In the Fourier transform, the digital voice signal is transformed into a frequency signal. FFT is an algorithm that has a very fast calculation to perform Fourier transforms in the discrete domain. The results of the FFT process produce detection of frequency domain waves in discrete form [28, 59].

4) *Mel filterbank*: Filterbank is used to determine the energy size of a certain frequency band in a voice signal. Filterbanks are overlapping bandpass filters. Mel is a unit of measure based on the frequency perceived by the human ear. Based on the Mel scale, it is linear below the 1 kHz frequency and logarithmic above it. Mel scaling process according to Equation (2) as follows [27, 59, 60]:

$$mel = 2595 \log_{10} (1 + f / 700) \tag{2}$$

where Mel is the output of the Mel filterbank, and f is the input of the filterbank. While 2595 and 700 are fixed values that have been widely used in the MFCC method in many studies. Mel spaced filterbank as in Fig. 4, the filter bandwidth below 1 kHz is linear while above 10 kHz is logarithmic [59].

5) *Discrete Cosine Transform (DCT)*: DCT is used to calculate the MFCC of a single frame. DCT aims to produce a Mel spectrum to improve recognition quality. The DCT process is following Equation (3) [59].

$$C_m = \sum_{k=1}^K (log_{10} Y[k] \cos [m(k - \frac{1}{2}) \frac{\pi}{K}]); m = 1, 2, \dots \tag{3}$$

In this case, C_m = Coefficient, where $Y[k]$ = the output of the filterbank process on the index, m = the number of coefficients, and K is the expected number of coefficients.

Fig. 2. The Architecture of CNN Standard (CNN No Residual).

Fig. 3. MFCC Block Diagram [59].

Fig. 4. Example of Mel Spaced Filterbank [59].

6) *Delta coefficients*: Delta coefficients have been used mostly, in addition to the MFCC extraction method. The accuracy of the speech recognition system can be improved by adding the time derivative to obtain stable basic parameters. The equation for calculating the delta can be seen in Equation (4) [59].

$$dt = \frac{\sum_{n=1}^N n(c_{t+n} - c_{t-n})}{2 \sum_{n=1}^N n^2} \quad (4)$$

where dt is the delta coefficients of the t frame. In general, the value of N is 2. The data for the sum of the delta coefficients is the same as the MFCC, the number of coefficients is 13. The sum of the MFCC data plus the delta coefficient is equal to 26 features of the data dimensions [28, 59, 61].

E. DWT Method for Hybrid Extraction MFCC

This MFCC method has drawbacks, where the feature extraction method of voice signals is sensitive to noise [61]. From several previous studies, there is still a need to improve the performance of MFCC. To improve the performance of MFCC on the voice biometrics identification system, a method that can eliminate noise frequencies is needed. There is a need to develop a hybrid method which will help to provide better performance solutions. It is signified that the voice biometrics with a Hybrid DWT-MFCC extraction feature can be used to eliminate noise interference, recognize the shape of the voice pattern from a person's characteristics and choose only the voices that are needed from other voices that are not needed. With the Hybrid MFCC-DWT feature extraction method, it is hoped that reliable features can be formed and produce a high level of accuracy and are better than before [62, 63].

Based on previous research, Discrete Wavelet Transform (DWT) is a good method to eliminate noise (denoising) in signal processing so that the voice quality in voice biometrics is better. The wavelet signal processing is suitable for

nonstationary signals, whose spectral content changes over time. Each wavelet transforms measurement according to a fixed parameter will provide information about the time-temporal range of the signal and information about the frequency spectrum of the signal. The wavelet transform provides an approach to multi-analytical signal resolution and this technique has been used to identify voice signal features. The wavelet transform is an integral part of the raw signal $x(t)$ multiplied by the scale, type shift of the basic wavelet function $\psi(t)$.

Continuous wavelet transform (CWT) is calculated in Equation (5) as follows [26, 63, 64]:

$$CWT(a, b) = \int_R x(t) \frac{1}{\sqrt{a}} \psi^*\left(\frac{t-b}{a}\right) dt \quad (5)$$

where a is the scaling parameter and b is the time localization parameter. DWT is often more efficient than CWT to avoid counting on each CWT scale.

With parameter changes, DWT is defined in Equation (6) as follows [62]:

$$DWT(j, k) = 2^{-j/2} \int_R x(t) \frac{1}{\sqrt{a}} \psi^*(2^{-j} t - k) dt \quad (6)$$

After changing from CWT to DWT, the original continuous wavelet function becomes a discrete wavelet function and a scaling function. The discrete wavelet function and the scaling function as Low Pass Filter (LPF) and High Pass Filter (HPF). The DWT process works like Fig. 5 [63].

Fig. 5. Process of DWT Signal Filtering [63].

Thus, architecturally it can be described, Referring to Fig. 1, the hybrid extraction process is carried out on the processing results (signal in Fig. 1) which is then carried out with the extra feature DWT-MFCC process to help eliminate noise interference, recognize the shape of the voice pattern from someone and selects the required voices.

III. THE FRAMEWORK

A. The Architecture

Fig. 6 shows the architecture of the voice biometric model which is developed in this research. In principle, the user enrollment/training is processed by using the DWT-MFCC for the part of feature extraction and CNN Residual model for the part of training process. This training process is a capability learning process where the CNN model is trained to identify user voice datasets using large GPU and CPU computing devices. In this training process, the user identification process is carried out to register the user's voice identity which is stored in the database. After completing the training process, the CNN

model that has been trained will produce a Trained CNN Model. Such a trained CNN model will be subsequently used for the user verification process.

This user verification process is the process of classifying and authenticating voice datasets. This user verification process will directly apply the new voice data to the Trained CNN Model and use it to conclude the output. So, when a new user's voice data is entered into the Trained CNN Model, the system will verify the voice data by matching the user identification between the new voice data and the voice data that has been registered in the database. Next, the system will issue predictions based on the prediction accuracy of the data that has been trained on the Trained CNN Model. The Trained CNN Model classification is optimized to maximize prediction performance to achieve high accuracy. The output of the trained CNN model classification is user voice authentication, in the form of data validation (valid / not) or (accepted/rejected) of the user's voice data.

B. CNN Residual as Deep Learning used in this Research

In this research, the architecture of CNN Residual is shown in Fig. 7. The architecture of CNN Residual lies in the implementation of the Residual 8 Shortcut layer by stepping over every 2 layers, which consists of 1 input layer, 5 layers

3x3 Convolution 16 Filters, 1 layer 3x3 Convolution 32/ 2 Filters, 3 layers 3x3 Convolution 32 Filters, 1 layer 3x3 Convolution 64/2 Filters, 3 layers 3x3 Convolution 64 Filters, 1 layer 3x3 Convolution layer 128/2 Filters, 3 layers 3x3 Convolution 128 Filters, 1 layer Adaptive Average pool, 1 Flatten layer, 1 fully connected layer, and 1 output layer.

For CNN Residual, Residual Shortcut is a branching technique for CNN layers, where one branch is a shortcut over 1 or several other branch layers. Initially, the CNN Residual technique was intended to deal with the problem of saturation by increasing the number of layers. Difficult iteration problems and a large number of layers tend to cause a decrease in the quality of classification in terms of speed and accuracy. With the increasing amount of large data, it will affect the increasing capacity of the CNN model, on the number of parameters, filters, and layers. By using the residual technique, the iteration training can be shorter, and the accuracy value will increase, along with the increase in the number of parameters, filters, and layers. The following is the general equation of the shortcut residual identity function, which can be seen in Equations (7) and (8) [24].

$$y = F(x, \{W_i\}) + x \tag{7}$$

$$y = F(x, \{W_i\}) + W_s x \tag{8}$$

Fig. 6. Framework of Voice Biometrics Model for user Enrollment/Training and user Verification/Authentication Processes, based on DWT-MFCC and CNN Residual.

Fig. 7. The Architecture of CNN Residual.

y is a feature map after residual, $F(x, \{W_i\})$ is a filter (residual mapping) whose optimal value is determined, and x is a feature map input. W_i is the layer group that is skipped, and W_s is a linear projection in adjusting the dimensions for x and y when performing shortcuts such as downsampling or upsampling. Although there is almost no change in arithmetic operations and the number of parameters, the addition operation performed can be neglected for the computational load. The application of this residual technique will result in a shorter iteration process and affect the classification results for the better [65, 66]. To further improve the performance of the voice biometrics system, it is proposed to optimize CNN using a CNN residual model. The optimization of this CNN residual is needed to simplify the training and validation process, as well as increase the classification accuracy.

C. CNN Standard as a Comparison of Performance

The performance analysis of CNN Residual model is conducted by comparing with CNN Standard. The essential differences between them are about the Total Parameters and Parameter Size, in which the parameters on CNN Residual Model are greater than the CNN Standard Model. This will affect the working process of the CNN Residual Model which is longer than the CNN Standard Model. CNN Standard Model Parameters and CNN Residual can be seen in Table II.

TABLE II. PARAMETERS OF CNN STANDARD AND CNN RESIDUAL MODEL

No.	Parameter	CNN Standard Model	CNN Residual Model
1.	Total Parameters	707,386	718, 586
2.	Parameter Size (MB)	2.70	2.74

D. Data Set of Indonesian Language

In this research, the original voice dataset of Indonesian language speaker was created. It is essentially used on training the CNN Model algorithm. The creation of the voice dataset begins with the user's voice input via the microphone on the smartphone. The making of this voice dataset involved 10 users, starting from Voice Biometric0 to Voice Biometric9 (VB0 - VB9). Each VB user input contains the unique speaker and speech. Each VB user contributes the voice sample by speaking in Indonesian language for 50 minutes duration.

To make a uniform voice sample files in the dataset, it is necessary to set the following parameters: First, changing the stereo voice to mono voice; Second, changing the frequency of the voice sample rate to 16,000 Hz; Third, truncating the silence to eliminate the pause in the user's voice, so that the result is that every VB user is sampled for 25 minutes, without any pauses; Fourth, segmenting the voice samples for each VB user into 1500 files each; Fifth, changing the voice sample file in the form of a WAV file type format. Finally, with the number of 10 users, a voice dataset is obtained with a total number of voice samples being 15,000 files.

Furthermore, the voice dataset is processed with the DWT-MFCC extraction feature so that it can recognize the shape of the voice pattern from a person's characteristics, can choose only the voices that are needed, and can eliminate noise disturbances. After completing the feature extraction process,

the voice dataset is ready to be trained with the CNN model algorithm.

E. Testing

In this research, the system's performance was tested by conducting a performance assessment.

1) The first phase of Performance Testing, namely Speaker Recognition with the CNN Residual Model Algorithm using DWT-MFCC, (compared to CNN Standard).

2) The second phase of Performance Testing is the performance of Voice Biometric from Speech Recognition with the CNN Residual Model Algorithm using DWT-MFCC, (compared to CNN Standard).

3) Performance Testing of Training Process Time on Voice Biometric with Algorithm CNN Residual Model using DWT-MFCC, (compared to CNN Standard).

Each test was carried out for a sample duration of 5 minutes, 10 minutes, 15 minutes, 20 minutes, and 25 minutes.

IV. RESULT AND DISCUSSION

A. Performance Testing of Speaker Recognition ("Whose Voice is the Person Speaking?")

Performance testing of speaker recognition on the CNN Model is to test the performance of speaker recognition with the CNN Residual Model Algorithm using DWT-MFCC, (compared to CNN Standard). This performance measurement uses the confusion matrix which is a machine learning classification method. This confusion matrix provides information on the comparison of the classification results carried out by the CNN Training model system with the actual classification results. From the results of the CNN Trained Model, it will be used to measure performance with the Confusion Matrix [67, 68]. In this research, a classification system for identifying voice datasets was carried out, where the input data were grouped into 10 VB users to classify the VB voice datasets. In determining the best model, the confusion matrix method becomes important to consider in choosing the best model between deep learning CNN Residual models using DWT-MFCC (compared to CNN Standard).

This performance measurement uses a confusion matrix, which is divided into 4 (four) combinations representing the results of the classification process, namely True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN). From the values of TN, FP, FN, and TP, the accuracy and precision of speaker recognition performance with the CNN Standard Model and CNN Residual algorithms are obtained at 5, 10, 15, 20, and 25 minutes of voice sample duration. The analysis data on speaker recognition performance testing with the CNN Standard and CNN Residual Model algorithms can be seen in Table III and IV, and Fig. 8 and 9.

Based on the comparison of accuracy on speaker recognition performance with CNN Residual model using DWT-MFCC, the best results were obtained with the highest percentage accuracy value of 99.47% for the 25 minutes duration voice sample. Accordingly, the larger the number of voice sample durations or the larger the number of voice sample files executed, the higher the percentage of accuracy

performance in prediction. It can be shown in Table III and Fig. 8.

Based on the comparison data of precision on speaker recognition performance with CNN Residual model using DWT-MFCC, the best results were obtained with the highest percentage precision value of 99.91% for the 25 minutes duration voice sample. Based on data analysis, the larger the number of voice sample durations or the larger the number of voice sample files executed, the higher the percentage of precision performance in prediction. It can be shown in Table IV and Fig. 9.

By comparing the performance of Speaker Recognition between CNN Residual Models and CNN Standard, the main results are as follows:

1) The accuracy of CNN Residual is higher than CNN Standard, in which CNN Residual is about 96.10% - 99.47% while the later is 95.80% - 99.00%; as can be seen in Table III and Fig. 8.

2) The precision of CNN Residual is higher than CNN Standard, in which CNN Residual is about 80.05% - 99.91% while the later is 78.85% - 96.83%; as can be seen in Table IV and Fig. 9.

3) The CNN Residual's best results or the highest percentage value are 99.91% precision and 99.47% accuracy for 25 Minutes voice sample duration. The same condition is also applied to the CNN Standard of 96.83% precision and 99.00% accuracy.

It can be implied that the greater the number of voice sample files and the more voice sample training carried out, the higher the level of precision and accuracy in prediction performance will be. By looking at the comparison results, the highest percentage value shows the best value for the precision and accuracy of Speaker Recognition on CNN Residual. It can be concluded that the speaker recognition performance of the CNN Residual model is better than the CNN Standard.

B. Performance Testing of Speech Recognition (“What Keywords are Spoken?”)

Performance testing of speech recognition on the CNN Model Algorithm aims to test the accuracy of speech recognition performance with the CNN Residual Model Algorithm using DWT-MFCC (compared to CNN Standard) at 5, 10, 15, 20, and 25 minutes of voice sample duration. This is done by matching keyword speech or matching speech content.

TABLE III. COMPARISON OF ACCURACY ON SPEAKER RECOGNITION PERFORMANCE WITH CNN STANDARD AND CNN RESIDUAL USING DWT-MFCC

Duration of Voice Samples (Minutes)	Accuracy of Speaker Recognition Performance (%)	
	CNN Standard	CNN Residual
5 Minutes	95,80	96,10
10 Minutes	96,33	96,58
15 Minutes	96,76	97,05
20 Minutes	97,25	97,95
25 Minutes	99,00	99,47

TABLE IV. COMPARISON OF PRECISION ON SPEAKER RECOGNITION PERFORMANCE WITH CNN STANDARD AND CNN RESIDUAL USING DWT-MFCC

Duration of Voice Samples (Minutes)	The precision of Speaker Recognition Performance (%)	
	CNN Standard	CNN Residual
5 Minutes	78,85	80,05
10 Minutes	81,02	82,63
15 Minutes	84,52	86,12
20 Minutes	89,74	93,18
25 Minutes	96,83	99,91

Fig. 8. Comparison of Accuracy on Speaker Recognition Performance with CNN Standard and CNN Residual using DWT-MFCC.

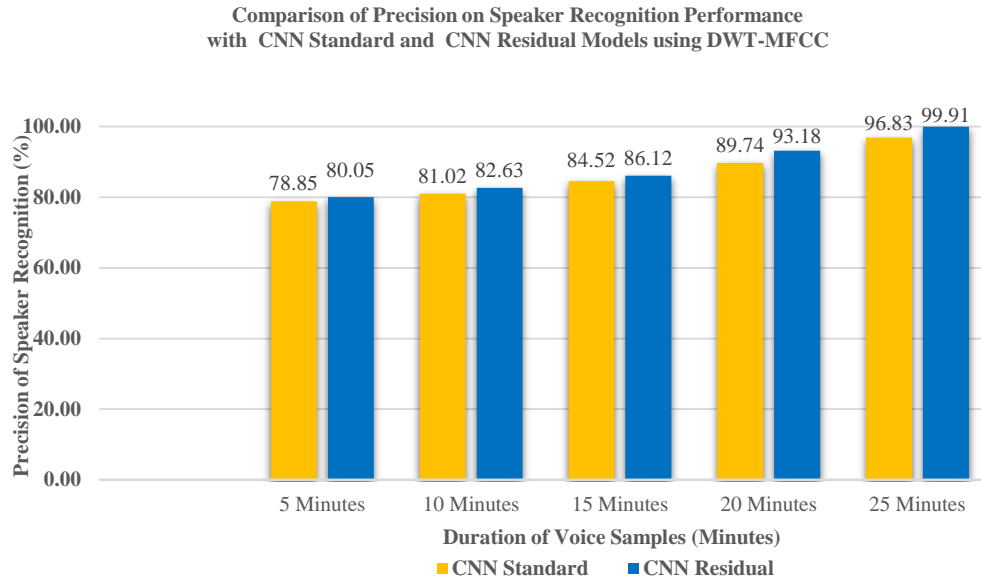

Fig. 9. Comparison of Precision on Speaker Recognition Performance with CNN Standard and CNN Residual using DWT-MFCC.

This test uses a speech content of keyword "Open Access", spoke by the Indonesian users. If the statement is match or correct (True), it will be accepted, while if the speech is wrong or unclear (False), then it is rejected.

Fig. 10 shows that speech recognition performance test has been carried out with the CNN Standard and CNN Residual. It was tested by 20 voice pronunciations, with a total of 10 VB users saying "Open Access". The results show that the percentage of Speech Recognition accuracy performance obtains the best results with the highest percentage value in the

100% CNN Residual, which is higher than the 95% CNN Standard.

The testing has signified that CNN Residual model is better than the CNN Standard. Optimizing the CNN Residual model can improve the validation performance of voice biometric training accuracy, speaker recognition accuracy, and speech recognition accuracy. This is because the CNN Residual model can simplify the training and validation process, as well as increase accuracy in voice biometric classification.

Fig. 10. Comparison of Accuracy of Speech Recognition Performance on Standard CNN Model Algorithm and CNN Residual using DWT-MFCC.

C. Analysis of Time Process for Training

The performance testing of training process time on voice biometrics with CNN Model Algorithm is to test the performance of training process time on the voice biometrics with Algorithm CNN Residual Model using DWT-MFCC, (compared to CNN Standard). This test is to determine how long the processing time is needed for 40 epochs in each running of voice biometrics training on CNN Standard and CNN Residual on voice sample durations of 5, 10, 15, 20 and 25 minutes.

From Fig. 11, the comparison of the performance testing of the voice biometrics training process shows that the CNN Standard training process time performance results are faster than the CNN Residual training process time. This happens because the total number of parameters and the parameter size

of the CNN Residual Model is more than the Standard CNN Model, so it requires a longer processing time, with a time difference of 0.03 – 1.28 seconds. It can be implied that the more training time and the more voice sample files are performed, it will result a higher level of accuracy in prediction. It is also indicated that the larger the file duration, the higher the processing time but with a not too big difference.

By analyzing the performance of training process on voice biometrics for a sample duration of 5, 10, 15, 20, and 25 minutes, it can be signified that the accuracy value are consistently above 95%. Accordingly, it can be concluded that by only using the sample of 5 minutes, the voice biometrics system can recognize and identify the speaker with a decent performance.

Fig. 11. Comparison of Performance Testing of Training Process Time on Voice Biometric with CNN Standard and CNN Residual Model using DWT-MFCC.

V. CONCLUSION

This paper has developed a Voice Biometric research model for Indonesian language speaker using the CNN Residual Deep Learning algorithm, which uses Hybrid Feature Extraction DWT-MFCC. Testing is done by comparing the model with the CNN Standard. In this study, a voice dataset was created with 10 users (VB0 – VB9). Each VB is a unique speakers who speak in Indonesian language, resulting a total number of 15,000 voice samples with a voice sample duration of 5, 10, 15, 20, and 25 minutes.

The testing was conducted in the phase of speaker recognition and speech recognition. For the speaker recognition phase, the CNN Residual model has obtained the best results with the highest percentage value of 99.91% precision and 99.47% accuracy at a voice sample duration of 25 minutes, compared to Standard CNN of 96.83% precision and 99.00% accuracy. For the speech recognition phase, CNN Residual has achieved the best results of accuracy which is

100% accurate in 20 trials, while Standard CNN only gave 95% accurate results.

From the results of performance testing of training process time for a sample duration of 5, 10, 15, 20, and 25 minutes, the accuracy value has been consistently above 95%. It can be implied that by only using 5 minutes voice data set, this developed system is able to recognize who is the speaker as well as to identify what keywords are spoken.

Optimizing the CNN Residual model can improve the validation performance of voice biometric training accuracy, speaker recognition and speech recognition accuracy as well as its precision. However, CNN Residual is slightly slower than the CNN Standard, with a time difference of 0.03 – 1.28 seconds.

It can be concluded that the performance of the CNN Residual model provides better results for its accuracy and precision. This research is expected to assist in developing a new model that is able to apply an accurate and efficient individual voice identification and authentication algorithm for

voice biometrics systems for security and privacy systems to access sensitive data in banking transactions.

Hybrid Deformable Convolutional with Recurrent Neural Network for Optimal Traffic Congestion Prediction: A Fuzzy Logic Congestion Index System

Sara Berrouk, Abdelaziz El Fazziki, Mohammed Sadgal
Computer Science Engineering Laboratory
Faculty of Sciences, Cadi Ayyad University, Marrakech, Morocco

Abstract—In the field of Intelligent Transportation Systems (ITS), traffic congestion is considered as an important problem. Traffic blockage usually affects the quality of time, travel time, economy of the country, and transportability of people. The information of traffic congestion is collected and analyzed in ITS, and the methods to prevent the traffic congestion are predicted. However, the tackling of huge data is still challenging. The rapid increase in vehicle usage and road construction has resulted in traffic congestion. Various studies are undergone in ITS to recognize the traffic management system by adopting few resources. Real time-based traffic services are implemented to prevent the traffic congestion in existing areas. These services provide high expense accuracy. This paper plans to develop a new technique to predict the traffic congestion using improved deep learning approaches. At first, the benchmark dataset is gathered and the pre-processing of data is performed with removing the bad data, organizing the raw data, and filling the null values. The optimized weighted features are selected from the pre-processed data by adopting a new meta-heuristic Hybrid Jaya Harris Hawk Optimization (HJHHO) algorithm. The prediction of congestion parameters such as speed reduction rate, very low speed rate, and volume to capacity ratio of vehicles are performed by the proposed Improved Deformable Convolutional Recurrent Network (IDCRN) prediction model. These predicted measures are subjected to fuzzy interference system for congestion index computation. From the experimental analysis, it has proved that the proposed method has reduced the error rate while comparing with other deep learning and machine learning approaches.

Keywords—Optimal traffic congestion prediction; deformable convolutional network; recurrent neural network; Hybrid Jaya Harris Hawk Optimization Algorithm; congestion index computation; fuzzy interference system

I. INTRODUCTION

Population growth and the rapid urbanization in economy have increased the traffic clogging drastically in most developing cities and large areas in all over the world. It also increases both the road rage statistics and commute time. Consequently, the cause of accidents is increasing due to high traffic congestion [1]. Nowadays, the study for traffic management is highly significant among the researchers. The traffic clogging can be prevented by developing the infrastructure of transportation, which is expensive or else by organizing possible traffic schemes, like analyzing the blocking pattern or prediction of traffic congestion in short

term that can be more effective for road networks in a short time [2].

The timely congestion prediction models focus on the traffic factors such as speed, volume, and traffic stream on group of roads, one way road and especially small rural roads due to the unavailability of data. The limitation on predicting the road networks causes trouble for both the traffic agencies and commuters [3]. The researchers use the data, which is gathered from sensors like CCTV cameras, road sensors etc. These road sensors are located everywhere in road and even in vehicle networks to operate in all routes. This type of data is inconvenient because the process of operating, installation and maintenance is difficult, and it is expensive as it requires permission to access the data for third parties [4]. The real time traffic information like the average speed and blocking level on the section of roadway are provided in the web services such as Seoul Transportation Operation, Google Traffic, Information Service (TOPIS), Baidu Map and Bing Map [5]. Therefore, these web services are freely accessible and offer traffic congestion-related information to the majority cities all over the world, but only few studies are available based on this web services. The data requires multiple inputs, which are in time series, the processing of numerous input traffic images is complex due to high cost [6].

In past years, the data-driven methods were followed by the researchers to develop the mathematical and statistical models to detect the relation of time series in traffic data, also known as parametric method [7]. Mainly, the existing works were related to the presumption of stationary and linearity to capture the prediction trends such as smoothing model, error component method, and historical average method [8]. The seasonal pattern and long-term trends are decomposed to detect the pattern using Autoregressive Integrated Moving Average (ARIMA) model. However, it is unable to focus on the mean value of time series and incapable to predict the intense. The researchers began to concentrate on machine learning parametric models due to the limitations in parametric model [9]. The nonparametric model depends on the training data to establish parameter numbers and structural model[10]. The machine learning approach called K-Nearest Neighbor (KNN) predicts the traffic stream by searching the closer neighbor matching to the present data from the traditional database. The Support Vector Machine (SVM) approach minimizes the structural risk and has advantages in high dimensional data and minute samples [11]. The Bayesian Network (BN) approach

detects the issues in partial data, which is related to the message transferring mechanism [12]. Similarly, the deep learning approaches are also applied in these fields like time series production, recognition and translation, etc. because of the ability in data mining [13]. However, deep learning approach is difficult to use and preprocessing the output and input series in high dimensional data is very slow. The other deep learning-based approach is Convolution Neural Networks (CNN) that is used to extract the significant data from the raw data [14] [15][16]. The hybrid network attains promising results than simple networks due to its capability in mining the attributes from the input traffic data [17]. Therefore, a hybrid networks method shows better results in predicting the traffic congestion. The traffic congestion prediction with hybrid network contains very few works due to the shortage of high-quality traffic congestion data.

The major contribution of the suggested traffic congestion prediction is given here:

- To design a new model to predict the traffic congestion by employing the traffic dataset with new hybrid algorithm for feature selection and hybrid architecture for prediction with congestion index computation by fuzzy interference system.
- To select the weighted features with HJHHO algorithm by optimizing the weight and selecting the features from the pre-processed data through minimizing the variance of features.
- To evaluate a proposed IDCNR prediction with Deformable Convolution Network (DCN) and Recurrent Neural Network (RNN) architecture by optimizing hidden neuron count of DCN, learning rate of DCN, epoch count of DCN and further, hidden neuron counts of RNN using HJHHO algorithm. The objective function of IDCNR is to minimize the MAE and RMSE.
- To compute congestion index computation by considering the inputs as the speed reduction rate, very low speed rate and volume to capacity rate by the well-performing fuzzy interference system.
- To determine the performance of the suggested model with other existing approaches by evaluating different measures to examine the outcomes of the proposed model.

The other sections of this paper are illustrated here. Section II represents the related works. Section III denotes the architectural view of optimal traffic congestion prediction with new hybrid heuristic algorithm with fuzzy logic system. Section IV denotes the enhanced traffic congestion prediction with new optimized weighted feature selection. Section V depicts the optimal traffic congestion prediction by hybrid deep learning with traffic congestion index computation by fuzzy model. Section VI denotes the result and discussion. Section VII indicates the conclusion.

II. LITERATURE SURVEY

A. Related Work

In 2018, Tseng et al. [18] have applied Apache storm in real time traffic congestion prediction scheme by analyzing various data such as rainfall volume, road density and traffic incidents. The new SVM-based Real-Time Highway Traffic Congestion Prediction (SRHTCP) method has gathered the traffic incident data reported in roadways from the Taiwan police broadcasting service and the weather reports were collected from Taiwan Central Weather Bureau. Here, the fuzzy set theory was used to estimate the traffic congestion in real time with regarding rainfall volume, road density, and road traffic incidents. The road speed for next timeline was predicted with SRHTCP method by analyzing the weather data and traffic flow data. The suggested SRHTCP scheme has achieved better accuracy prediction than other prediction models based on weighted exponential moving average approach.

In 2020, Ranjan et al. [19] have proposed three techniques to predict the traffic congestion like, an effective and low-cost data attainment scheme by captivating a snap of traffic clogging from the online open source web service TOPIS and a hybrid deep learning approach to predict the traffic congestion level by extracting the temporal and spatial information. The relationship of temporal and spatial for predicting the traffic congestion level was analyzed efficiently and effectively by the proposed model. This suggested model effectively has outperformed other Deep Neural Network (DNN) models.

In 2020, Shin et al. [20] have proposed a deep learning approach to predict the traffic congestion and in addition to correct the missing spatial and temporal values. The proposed model was pre-processed with outlier removal method using the Median Absolute Deviation (MAD) of traffic data. Therefore, the spatial and temporal values were corrected using spatial and temporal trends and pattern data. The proposed prediction model was combined with LSTM for learning the data in time series. The suggested model was compared over other existing model and has achieved better prediction results.

In 2019, Zhao et al. [21] have proposed an optimized GRU architecture to predict the speed of trucks on urban roads under non-periodic congested situations. The driving data of struck in Beijing Road was gathered. To get rid of the unwanted data, the pre-processing and screening of data were approached, and then, sequence of traffic speed was extracted. The learning rate was not adjusted by the Suitable Development Goals (SGD) weight optimization algorithm. The weight was optimized by Adadelta, Rmsprop and Adam in this proposed GRU model. The accuracy of the suggested model was verified based on four scenarios, such as accident, workday, rainy and weekend.

In 2020, Zaki et al. [22] have suggested a new Hidden Markov Model to determine the traffic stages in two dimensional (2D) spaces during the high peak hours. The proposed model has captured variance in traffic pattern data using the contrast and mean speed. The proposed model has enhanced the prediction error than other neuro fuzzy and HMM approaches. In 2019, Wena et al. [23] have suggested a Hybrid Temporal Association Rules Mining mode to predict the traffic clogging. The traffic states were predicted using DBSCAN algorithm, which has suitable rules in analyzing the traffic congestion in road ways. The temporal associated rules in traffic states were extracted using genetic algorithm based temporal association rules mining algorithm. The classification process was used to predict the traffic congestion level. The prediction and the stimulation tests were studied in different sizes of road ways. The stimulation results have determined that the suggested model has predicted the traffic congestion with high precision.

In 2016, Li et al. [24] have proposed an adaptive real time prediction model. This scheme has comprised a traffic pattern recognition algorithm related to an adaptive threshold calibration method, the adaptive K-means clustering and a 2D speed prediction method. The patterns from traffic data were obtained by the adaptive K-means clustering. The adaptive threshold calibration method was applied to recognize the traffic congestion and prediction. The obtained result has shown that the adaptive K-means clustering has recognized the traffic pattern better than Gaussian Mixture method. The proposed model has performed well in real time application of traffic congestion prediction and gained better accuracy.

In 2019, Song et al. [25] have applied the k-means clustering algorithm to classify the spatio-temporel distribution of congested roadways. Then, the spatiotemporal features were mined to extract the potential factors using geo-detector. The congested patterns were selected from six inter- regional and intra-regional roads on weekdays. The public properties like tourist spots, hospitals and green spots were often congested in off peak and peak hours. The result has suggested that the roads built-in high-density areas could reduce the repeated trips in center of the city. The land utilizing plan has involved with a detailed design of the environment to enhance various travel approaches in order to reduce the traffic congestion and increase the effectiveness of traffic. More advanced techniques were applied in land use plan and traffic congestion based on multi source real time data.

B. Problem Statement

Multi source data are collected and evaluated to predict and prevent the traffic congestion and traffic stream in transportation system. The training of all this data is still challenging. Various studies were undergone to handle this type of huge road data, which prevented the real time traffic congestion by using different techniques. Table I shows the features and challenges of traditional congestion prediction on traffic flow methods. SVM [18] returns better prediction accuracy and the car speed of the proceeding time period is predicted by the SRHTCP model. But, used open datasets are not verified using t-test technique. CNN and LSTM [19] train the image data using a large resolution on a smaller resource and better performance is achieved with respect to the computing time. Still, it does not enhance the performance of the model by including external factors such as weather information for every road. LSTM [20] solves the long term dependency problem and time-series features associated with the traffic data are learnt. Yet, it does not enhance the accuracy in the urban areas and low-speed regions. HMM [21] enhances the recovery vehicle count in a specific stretch of road at particular times and also supports the enhancement strategies and the traffic management on the longer term like ramp metering. But, the technique of contrast is not verified on extra datasets. GRU [22] offers an efficient information service for truck drivers and simultaneously meets the efficiency and accuracy of matching. Still, the applicability is not considered for the real traffic systems. GA [23] minimizes the correlation in the environments and also predicts the traffic congestion with a low error. Yet, it does not automatically choose the best parameter values. Adaptive K-means cluster [24] is insensitive for the actual congestion probability and also enhances the prediction performance in the case of real time. But it does not consider the external influencing factors like mega-event and weather for enhancing the traffic mode recognition. Mining technique [25] improves the accessibility for distinct travel modes and also identifies the potential urban form factors and the traffic congestion hotspots. Still, it does not consider the useful knowledge for the improved decision making using novel approaches. Thus, it is necessary to introduce novel deep learning methods for predicting the congestion in the traffic flow management system in order to reduce the error and enhance the accuracy of the overall system.

TABLE I. FEATURES AND CHALLENGES OF TRAFFIC CONGESTION PREDICTION MODELS

Author [citation]	Methodology	Features	Challenges
Tseng et al. [18]	SVM	The car speed of the proceeding time period is predicted by the SRHTCP model. It returns better prediction accuracy.	The used open datasets are not verified using t-test technique.
Ranjan et al. [19]	CNN and LSTM	Better performance is achieved with respect to the computing time. The image data is trained using a large resolution on a smaller resource.	The performance of the model is not enhanced by including external factors such as weather information for every road.
Shin et al. [20]	LSTM	The time-series features associated with the traffic data are learnt. The long term dependency problem is solved.	The accuracy is not enhanced in the urban areas and low-speed regions.
Zhao et al. [21]	HMM	It supports the enhancement strategies and the traffic management on the longer term like ramp metering. The recovery vehicle count is enhanced in a specific stretch of road at particular times.	The technique of contrast is not verified on extra datasets.
Zaki et al. [22]	GRU	It simultaneously meets the efficiency and accuracy of matching. An efficient information service is offered for truck drivers.	The applicability is not considered for the real traffic systems.
Wena et al. [23]	GA	The traffic congestion is predicted with a low error. The correlation in the environments is minimized.	The best parameter values are not automatically chosen.
Li et al. [24]	Adaptive K-means cluster	The prediction performance in the case of real time is enhanced. It is insensitive for the actual congestion probability.	The external influencing factors like mega-event and weather are not considered for enhancing the traffic mode recognition.
Song et al. [25]	Mining technique	It identifies the potential urban form factors and the traffic congestion hotspots. The accessibility is improved for distinct travel modes.	The useful knowledge for the improved decision making is not considered using novel approaches.

III. ARCHITECTURAL VIEW OF OPTIMAL TRAFFIC CONGESTION PREDICTION WITH NEW HYBRID HEURISTIC ALGORITHM WITH FUZZY LOGIC SYSTEM

A. Proposed Model and Description

Traffic congestion is one of the most important issues in all over the world. The current infrastructure is unable to cope with new traffic applications. The small spaces and other construction activities influence the traffic congestion. Due to the cause of traffic blockage, the fuel costs and the travel time of employers and distributing workers is affected. Traffic congestion is defined as the transportation vehicles surpass the capacity of roadway in peak time. The congestion indicators are mostly used to evaluate the traffic congestions in the urban road routes. Millions of peoples are affected by traffic congestion. This also causes noise and air pollution in whole surroundings. The impact of traffic blocking can be associated to fuel price raise, environment related matters, and transits cost. Various studies and researchers were undergone to overcome the traffic congestion. The timely prediction of traffic congestion in real time can prevent the unnecessary blockage. Deep learning and machine learning approaches were implemented to predict the traffic congestion. Machine learning-based model is most popular than other non-parametric models. It analyses the traffic patterns with low restrictions and gives better prediction results. Deep learning approaches are discussed to predict the real time traffic congestion. The traffic data are huge data, which are difficult to train. In this case, various techniques were executed to train the

huge data volume and to enhance the prediction accuracy. The architectural diagram for the proposed traffic congestion prediction is given in Fig. 1.

The proposed traffic congestion prediction model covers five main phases (a) data collection (b) Pre-processing (c) Feature selection (d) Prediction and (e) Congestion index computation. The benchmark dataset is gathered from Radar traffic counts, which is publicly available. These datasets are pre-processed by three methods such as removal of bad data, organizing the raw data and filling the null values. In this pre-processing phase, the raw data are cleaned by eliminating the unwanted data and filling the missing data. The pre-processed data is inputted to the optimized weighted feature selection phase, where the weighted feature selection is enhanced by hybrid HJHHO algorithm by optimizing the weight and features. The selected features are given to the classification phase. The features are predicted with DCN and RNN architecture by optimizing the hyperparameters like hidden neuron count, learning rate and epoch count using HJHHO algorithm. As the prediction uses hybridization of two deep leading models with architecture optimization, the proposed model is termed as IDCRN. The main purpose of the proposed prediction is to minimize the error rate and maximize the prediction performance. The predicted parameters such as speed reduction rate, low speed rate, and volume to capacity rate are attained from IDCRN. Finally, the predicted parameters are inputted to fuzzy interference system for congestion index computation such as high, low, moderate and very high.

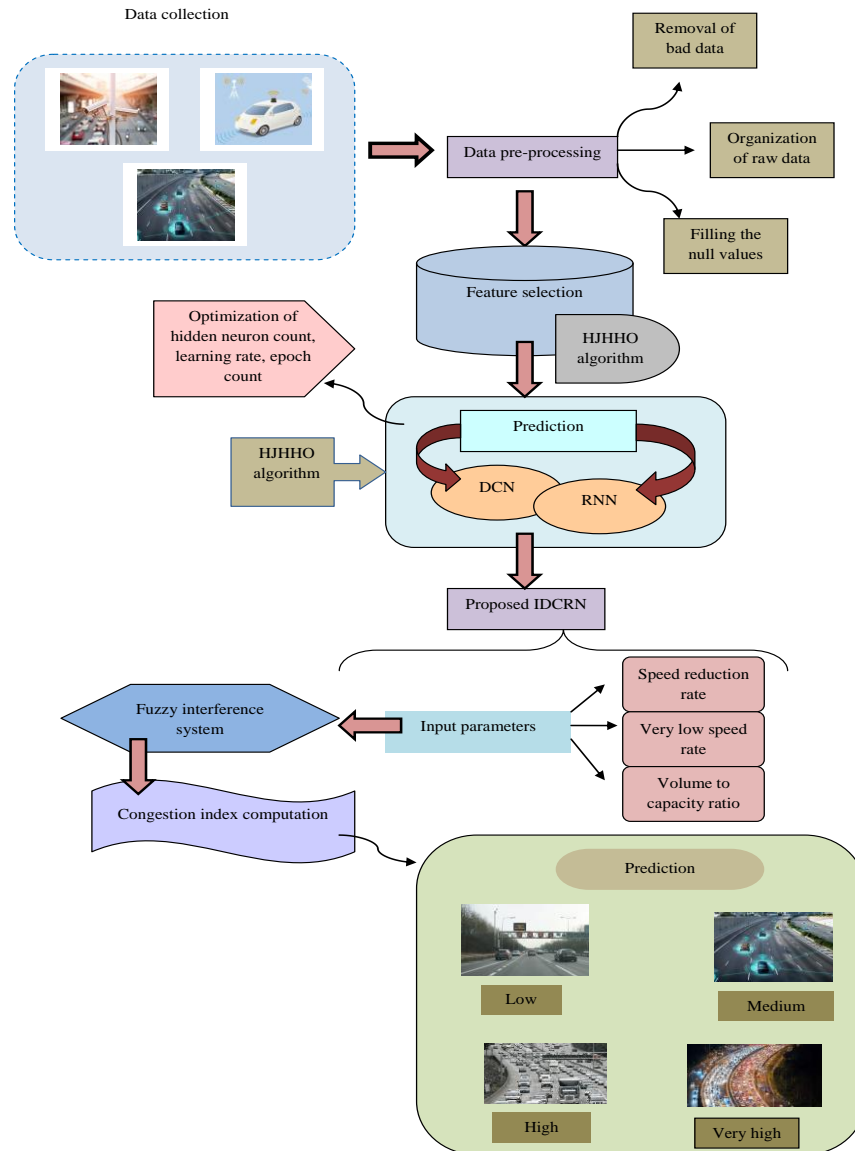

Fig. 1. Architectural Illustration of the Proposed Traffic Congestion Prediction Method with Congestion Index Computation.

B. Dataset Description

The benchmark dataset Radar Traffic counts are collected from “<https://data.austintexas.gov/Transportation-and-Mobility/Radar-Traffic-Counts/i626-g7ub>”- Access date: 24-12-2021. The traffic speed and count are gathered from various Wavetronix radar sensors, which is taken from the city of Austin. The dataset contains the hourly transportation of vehicles with 6.83 million of rows and 17 columns. The 70% of data is used for training and 30% of data is used for testing.

The collected input data is determined as T_f^{ip} , where $f = 1, 2, \dots, F$, here the term f is indicated as the total number of gathered dataset.

C. Data Pre-processing

The process of converting the collected raw data into suitable format is known as data pre-processing. The gathered

raw data are pre-processed to remove the unwanted data and to eliminate the noises before utilization. The pre-processing of raw data is essential for accurate precision analysis. In this proposed work, the pre-processing phase is performed with removal of bad data, organizing the raw data, and filling the null values.

Removing bad data: The input data T_f^{ip} is given to bad data removal process. Data cleaning or removal of bad data is a process to remove the unwanted data in the gathered dataset. The conversion of data from a structure or format to another is known as data transformation. It is essential to remove the bad data before utilization. In this process, the corrupted data, duplicate data, missing data are removed or fixed from the dataset. The presence of duplicate or unwanted data results in producing error in the prediction performance. The removal of bad data is denoted as T_f^{bad} .

Organizing the raw data: The data gathered are mostly unorganized or non-systematic, which are known as raw data. The deconstruction analyze method is used to manipulate or organize the data. The obtained raw data are in the form of recorded values and the systematic process of organizing them is referred as raw data organization. The organized data is denoted as T_f^{org} .

Filling the null values: The traffic data are usually affected in two different categories. First, the data are missed in certain time periods and locations. The entire data is necessary for the prediction and modelling of transportations. Second is the loss of statistical information. It causes violation of missing traffic patterns. The null values are filled with appropriate methods. When the missing values are to predict, the 0 or NA is used instead of the missing values. Filling the null values generates robust data models. Finally, the pre-processed data is denoted as T_f^{pre} and it is applied to feature selection phase.

IV. ENHANCED TRAFFIC CONGESTION PREDICTION WITH NEW OPTIMIZED WEIGHTED FEATURE SELECTION

A. Optimal Weighted Feature Selection

The pre-processed data T_f^{pre} are given to HJHHO algorithm for the feature selection. From the evaluated mining features, the optimized weighted features are obtained by multiplying with the optimized weight with the extracted features Fe_d^{sel} as given in Eq. (1).

$$Fe_{d^*}^{sel^*} = OP_d \times Fe_d^{sel} \quad (1)$$

In the above equation, the optimized weight is indicated as $OP_d, d = 1, 2, \dots, ND$, where ND indicates total number of features being considered and the term $Fe_{d^*}^{sel^*}$ is denoted as weighted optimal features. The weight is optimized with HJHHO algorithm in the range of $[0,1]$. The maximum iteration is fixed as 10. The main objective function of the weighted feature selection is to optimize the weight by minimizing the variance of the selected features. The number of optimal features selected from the extracted features is counted as 10.

$$objfn1 = \arg \max_{\{OP_d, Fe_d^{sel}\}} \left(\frac{1}{\text{var}} \right) \quad (2)$$

In Eq. (2), the term var refers to the variance, $objfn1$ is the objective function, the variance is defined as “a statistical measurement of the spread between numbers in a data set. More specifically, variance measures how far each number in the set is from the mean and thus from every other number in the set” as given in Eq. (3).

$$\text{Var} = \sigma^2 = \frac{\sum_{d=1}^r (y_d - \bar{y})^2}{r-1} \quad (3)$$

Here, the term y_d denotes the d^{th} data feature, \bar{y} represents the data features and r denotes the total number of data features. Consider, the optimal weighted features as $Fea_{d^*}^{sel^*} = Fe_1^{sel}, Fe_2^{sel}, Fe_3^{sel}, \dots, Fe_{ND}^{sel}$, where the total number of optimized weighted features are represented as ND^* .

The representation for optimal weighted feature selection is given in Fig. 2.

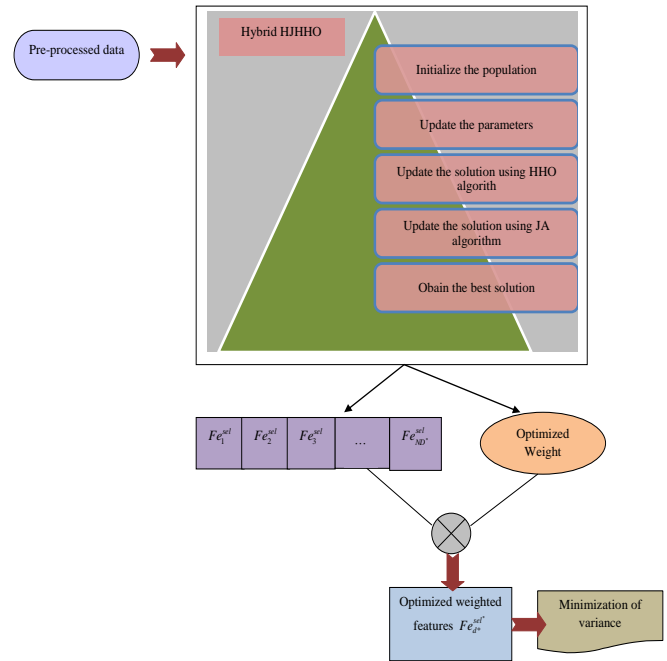

Fig. 2. Representation of Optimal Weighted Feature Selection.

B. Proposed HJHHO

The proposed HJHHO algorithm is used for selecting the optimized weighted feature selection from data by optimizing the selecting the features and weight and improving the hybrid based IDCRN prediction performance by optimizing the hidden neuron count of DCN, learning rate of DCN, epoch count of DCN and further, hidden neuron counts of RNN.

HHO [26] algorithm is flexible and used in various optimization problems to attain optimal solutions. It has high efficiency and predicted the failure probability using key factors. The exploration phase is maximized using compound agents. However, the HHO algorithm suffers from challenges like population diversity problem and local optima in high dimensional issues. To over these challenges in HHO, JA algorithm is used. JA [27] algorithm is easy and simple to implement and it contains few parameters in a single phase. It is applied to resolve various problems in optimization and finds optimal solutions within less computational time. The proposed hybrid HJHHO algorithm enhances the problems in optimization and more efficient than other optimization algorithms. If escaping energy $|B| \geq 1$, the position is updated using HHO through exploration phase, otherwise the position is updated using JA algorithm.

HHO algorithm is inspired by exploring and attacking behavior of Harris hawks. The HHO algorithm is gradient free population-based optimization technique, which can be proposed to all kinds of optimization problems. The exploration phase of HHO is utilized in HJHHO. Harris hawks can spot and track their prey with their powerful eyes. The prey is not visible often. The hawk waits in the desert spot for several hours to observe, monitor, and to detect the prey. The candidate solutions are denoted as Harris hawks and the best candidate solution is referred as the intentional prey. The hawk waits in a location for hours to detect the prey in terms of two strategies. The term r is denoted as the strategy of each perching, hawks perch depend on the position of their family members and the rabbit. If the condition $r < 0.5$, they perch on random trees is given in Eq. (4).

$$C(n+1) = \begin{cases} C_{rand}(n) - m_1 |C_{rand}(n) - 2m_2 C(n)| & r \geq 0.5 \\ (C_{rabbit}(n) - C_k(n)) - m_3 (FS + m_4 (WS - FS)) & r < 0.5 \end{cases} \quad (4)$$

In above equation, the term $C(n+1)$ is denoted as the position of hawks in next iteration n , $C_{rabbit}(n)$ denotes the position of rabbit, the term $C(n)$ is the current position of hawks, the random numbers are represented as m_1, m_2, m_3, m_4 , and r in $(0,1)$, the random numbers are upgraded in all iterations. The terms WS and FS are the lower and upper bounds of the variables, $C_{rand}(n)$ denotes the selected hawks from the present population, and C_k represents the average position of hawks from the present population.

At first, the solutions are generated depend up on its random location of hawks. Secondly, the location difference of the best candidate and the average position of the other hawks add a component depend on the ranges of variable. The scaling component m_3 increases the nature of rules once when m_4 get closer to the value 1 and similar distribution takes place. Based on this rule, a randomly scaled movement is added to FS . Then, a randomly scaled coefficient is considered to the component to offer more diversity trends and to explore various region of the attribute space. A simple rule is utilized to imitate the behavior of hawks. The average position of the hawks is represented in Eq. (5).

$$C_k(n) = \frac{1}{A} \sum_{o=1}^A C_o(n) \quad (5)$$

Here, the term $C_k(n)$ denotes the position of every hawk in iteration n and A refers to the total number of hawks. The average position is attained in various ways, but the simplest rule is utilized here. The HHO algorithm transfers the exploration phase to exploitation phase based on their escaping behavior. The escaping energy of the prey is denoted in Eq. (6).

$$B = 2B_h \left(1 - \frac{n}{N} \right) \quad (6)$$

Here, the term B denotes the escaping energy of the prey; the maximum iteration is represented as N and B_h is the initial stage of energy. The value B_h differs in interval $(-1, 1)$ at all iteration. If the B_h values decrease from 0 to -1, that means the rabbit is failing, and when the B_h value maximizes from 0 to 1, that means the rabbit is strengthening. When the escaping energy of the rabbit is $|B| \geq 1$, the hawks search the rabbit in various locations, hence the exploration phase takes place and when $|B| < 1$ JA algorithm is used in exploitation phase.

JA algorithm [27] is very simple and used to resolve all optimization problems. The main purpose of JA algorithm is when a best solution is attained once for a certain problem, the results are obtained by eliminating the worst solutions immediately. JA algorithm obtains the optimal solution by ignoring the worst solution. It resolves the constrained and unconstrained optimization problems. Let $e(z)$ is denoted as the minimized major function. There are h number of intended variables ($w = 1, 2, \dots, h$) in all iteration n , o represents the candidate solution. The best candidate attains the best value of $e(z)$ ($e(z)_{best}$) in all candidate solution and further, the worst solution attains the worst value of $e(z)$ ($e(z)_{worst}$) in whole candidate solution. If $Z_{k,d,v}$ is the given value of k^{th} candidate in iteration n , the modified value is denoted in Eq. (7).

$$Z'_{k,d,v} = Z_{k,d,v} + m1_{k,v} (Z_{k,best,v} - |Z_{k,d,v}|) - m2_{k,v} (Z_{k,worst,v} - |Z_{k,d,v}|) \quad (7)$$

In above equation, the term $Z_{k,best,v}$ represents best candidate of variable k and the term $Z_{k,worst,v}$ is denotes the worst candidate of variable k . The term $Z'_{k,d,v}$ is the upgraded value of the terms $m1_{k,v}$, $Z_{k,d,v}$, and $Z_{k,d,v}$ are the two number of k^{th} candidate, in iteration at range $[0,1]$. The term $m1_{k,v} (Z_{k,best,v} - |Z_{k,d,v}|)$ indicates the inclination of the solutions to neglect the worst solution and the term $m2_{k,v} (Z_{k,worst,v} - |Z_{k,d,v}|)$ denotes the tendency to avoid the worst solution. At the end of iteration, the attained functional values are given to the next iteration. The pseudo code for designed HJHHO algorithm is given in algorithm 1.

Algorithm 1: Designed HJHHO

```

initialize of population
calculate the fitness of hawks
update the position of the hawks using Eq. (4)
update the position of rabbit using Eq. (4)
Determine the parameters  $B$  escaping energy
If  $|B| \geq 1$ 
    Update the solution using HHO
    update the position using exploration phase using Eq. (5)
else
    Update the solution using JA
    update the position using Eq. (7)
end for
    
```

The flowchart of designed HJHHO algorithm is given in Fig. 3.

Fig. 3. The Flowchart for Designed HJHHO Algorithm.

V. OPTIMAL TRAFFIC CONGESTION PREDICTION BY HYBRID DEEP LEARNING WITH TRAFFIC CONGESTION INDEX COMPUTATION BY FUZZY MODEL

A. Proposed IDCRN

The proposed IDCRN is a hybridization of improved DCN and RNN, which is used to predict the traffic congestion parameters in the proposed mode. The main function of IDCRN is to predict the data by optimizing hidden neuron count of DCN, learning rate of DCN, epoch count of DCN and further, hidden neuron counts of RNN by HJHHO algorithm. The proposed IDCRN minimizes the MAE and RMSE measures, thus reducing the error rate.

DCN [28] architecture is used to extract the deep features and predict the data. The offset vector for each sampling is introduced with DCN. However, generalization ability of DCN can be reduced in some extent. In addition, the RNN are used in time series prediction as it retains information about previous input and it is capable to remember all information throughout time. However, the computation of RNN is slow and it is difficult to train. To overcome the drawbacks in CNN and RNN, the hybrid IDCRN model is introduced. The parameters related to the traffic congestion index are predicted using IDCRN.

DCN are used to extract the input feature maps, where the field of offset is calculated with convolution networks. The offset obtained from the additional convolution network is inputted to the original convolution network. The present location of the random sampling is realized by the kernels and the location is not inadequate for the standard grid. Each offset location is learned by the network rather than the convolutional kernels. The end-to-end spatial transformations are effectively and easily realized by DCN. To analyze the 2D convolutions, the regular grid N is used to model the input feature map y and the addition of sample values is weighed by a . The dilation and size of receptive fields are defined with the grid N . The convolution kernel 3×3 with dilation 1 and $N = \{(-1, -1), (-1, 0), \dots, (0, 1), (1, 1)\}$ is taken. In each location r_o , the output feature map x is given as represented in Eq. (8).

$$x(r_o) = \sum_{r_s} a r_s \cdot y(r_o + r_s) \quad (8)$$

Here, the term r_s computes the location in N . In DCN, the regular grid N is enhanced with the offsets $\{\Delta r_o | n1, \dots, N\}$, where $S = |N|$. The modified equation is given in Eq. (9).

$$x(r_o) = \sum_{r_s} a r_s \cdot y(r_o + r_s + \Delta r_s) \quad (9)$$

Here, the term $r_s + \Delta r_s$ represents the irregular location of offset, in which, Δr_s is naturally fractional. The bilinear interpolation is given in Eq. (10).

$$y(r) = \sum_t K(t, r) \cdot y(t) \quad (10)$$

Here, the term $r = r_o + r_s + \Delta r_s$ indicates the fractional location, t denotes all spatial location present in feature map y , the term $K(\cdot, \cdot)$ denotes the bilinear interpolation of kernel. The bilinear interpolation defines the linear interpolation in Y direction and X direction. The term K is divided into 2D dimensional kernel is referred in Eq. (11).

$$K(t, r) = k(t_y, r_y) \cdot k(t_x, r_x) \quad (11)$$

Hence, the weighted feature data are predicted using DCN architecture.

RNN [is another type of Artificial Neural Networks (ANN), which is applied in prediction of sequential traffic data by using previous traffic data. RNN generates the sequential information and each sequence of the element executes the similar task. The information is recorded in the memory of RNN. The input sequence of RNN is represented as C , which analyses the state t_{xx} at time xx . The different function v is applied with the previous state t_{xx-1} . The term t_{xx-1} does not contain the previous information. The RNN weight parameters are denoted as B , D and Y respectively. The RNN formula is given in Eq. (12) and Eq. (13).

$$t_{xx-1} = t_{xx-1} * Y + c_{xx} * B \quad (12)$$

$$o_{xx} = t_{xx} * D \quad (13)$$

The RNN model reduces the loss function and the errors in the predictions are compared with the actual values. The loss function is denoted as w , with regards the output state at given time xx . The correlation of gradient parameters is given here.

$$\frac{\partial w}{\partial_{xx-1}} = \frac{\partial w}{\partial_{xx}} Y \quad (14)$$

$$\frac{\partial w}{\partial B} = \sum_{xx=0}^E \frac{\partial w}{\partial_{xx}} c_{xx} \quad (15)$$

$$\frac{\partial w}{\partial Y} = \sum_{xx=0}^e \frac{\partial w}{\partial_{xx}} t_{xx-1} \quad (16)$$

Finally, the prediction data outcomes are attained from RNN. The optimized weighted features are inputted in DCN and RNN and the parameters such as speed reduction rate, volume to capacity rate and very low speed rate are predicted. The average from both the prediction models is utilized to perform the traffic congestion prediction.

B. Objective Function for IDCRN-based Parameter Prediction

The proposed IDCRN-based parameter prediction approach is used to predict the traffic congestion. The data is predicted using DCN and RNN. The parameters such as volume, time and speed of vehicles are inputted to IDCRN. The obtained output parameters such as volume to capacity rate, speed reduction rate and very low speed rate from IDCRN are subjected to fuzzy interference system to predict the congestion index computation in traffic flow. The main aim of the proposed prediction model is to optimize the hidden neuron count of DCN, learning rate of DCN, epoch count of DCN and further, hidden neuron count of RNN by minimizing the MAE and RMSE is given in Eq. (17).

$$objfn2 = \arg \max_{\{HN, LR, EN, HRN\}} (MAE + RMSE) \quad (17)$$

In above equation, the term HN denote the hidden neuron count of DCN that is ranging from $[5, 255]$, LR denotes the learning rate of DCN lies in the range of $[0.01, 0.99]$, EN represents the epoch count of DCN with the bounding limit of $[2, 20]$ and further, the hidden neuron count of RNN HRN ranging from $[5, 255]$. The term MAE indicates Mean Absolute Error and $RMSE$ denotes Root Mean Square Error. MAE is known as the “measure of errors between paired observations expressing the same phenomenon” as shown in Eq. (18).

$$MAE = \frac{\sum_{o=1}^r |xx_o - yy_o|}{r} \quad (18)$$

RMSE “is one of the most commonly used measures for evaluating the quality of predictions. It shows how far predictions fall from measured true values using Euclidean distance” as shown in Eq. (19).

$$RMSE = \frac{\sqrt{\sum_{o=1}^r \|yy_o - xx_o\|^2}}{r} \quad (19)$$

In above equations, term xx is represented as actual value and yy is denoted as forecasted value. The congestion measures like speed reduction rate, volume to capacity rate and very low speed rate are inputted to fuzzy interference for congestion index computation, each of these parameters indicates the traffic flow rates accurately. The fuzzy interference gives less error rate. The architectural diagram for IDCRN-based prediction parameters is given in Fig. 4.

C. Congestion Index Computation by Fuzzy Interference System

The training of different congestion measures has individual advantages and drawbacks. The congestion is an incident which is caused by various factors and the efforts are incorporated in different measures. The traffic congestion measurement is significant to detect the passenger perception. The boundary between each passenger differs due to the travel situations. These limitations are considered and fuzzy interference system is incorporated to detect the indistinct boundary in a set, and to find the solution uncertainty problems. The values of input parameters are calculated, categorized into various groups, determined different stages of traffic congestion and then finally established the congestion index computation.

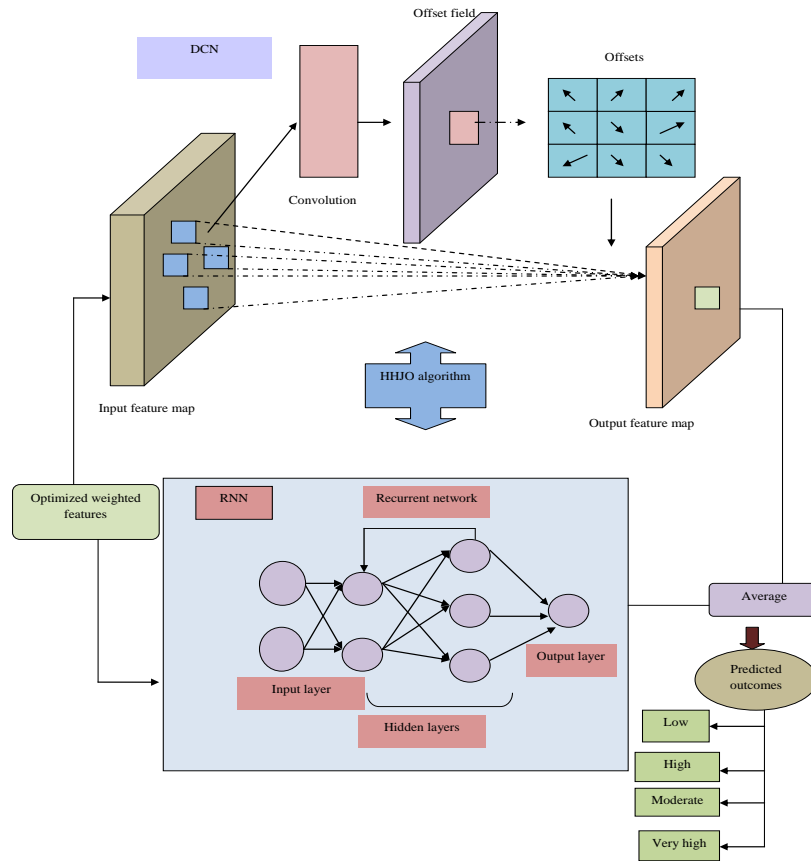

Fig. 4. Architectural diagram for IDCARN-based Parameter Prediction

Input parameters: The input parameters are observed from proposed IDCARN and then combined to form a single fuzzy measure. The three parameters such as speed reduction rate, volume to capacity ratio and very low speed rate are compared with traffic volume and traffic travel time to roadway capacity rate. These three parameters are calculated separately based on the gathered data and combined according to fuzzy interference system rule. The traffic condition is represented with these three input parameters, by varying the volume to capacity, average speed and the variation in speed.

Speed reduction rate: Speed reduction rate is used to minimize the speed of vehicles that causes traffic congestion. The congestion in various routes during peak and non-peak situation are compared with speed reduction rate as given in Eq. (20).

$$\text{Speed reduction rate} = \frac{(NPS - PS)}{NPS} \quad (20)$$

In above Eq. (20), the term NPS denotes the non-peak flow speed and PS denotes the peak flow speed. The speed obtained value ranges from [0, 1], where 1 is considered as the worst state when the peak flow speed is nearer to 0. The 0 is denoted as best state when the peak range is equal to or larger than non-peak flow speed.

Very low speed rate: It is defined as the amount of travelling time at very low speed when compared over the total travel period as given in Eq. (21).

$$\text{Very low speed rate} = \frac{TSD}{TT} \quad (21)$$

In Eq. (21), the term TSD is represented as times spend in delay and the term TT denotes total travel time. The obtained value ranges from [0, 1], where 0 denotes the best state with no delay and 1 denotes the worst state with delayed travel time. The delay is referred as the time travel speed, which must be lesser than 5km/hr.

Volume to capacity ratio: It calculates all traffic block during peak hour situations. The volume is computed by taking the vehicles unit per hour, when the capacity of the roadway is increased as given in Eq. (22).

$$\text{Volume to capacity ratio} = \frac{VP}{CR} \quad (22)$$

In Eq. (22), the term VP denotes the volume of vehicle in peak hour and CR represents the capacity of roadway. The obtained value ranges from [0, 3], where the value closer to 0 is the best condition, when the capacity to ratio is minimized and value 3 is the worst condition when the huge volume of

vehicles moving towards the roadway by comparing to its capacity.

Output parameters: The output process is termed as congestion index, which is grouped into four phases low, high, very high and moderate. The function condition is given in a scale range from 0 to 1, where 0 is denoted as good and 1 as bad. The congestion condition of the four phases is determined in terms of this scale value.

Rules: The task of compiling three inputs and evaluating the traffic congestion measures are executed with a fuzzy inference system. When the speed reduction rate is considered as S, the very low speed rate is denoted as R, the volume to capacity ratio is indicated as V, and the congestion is referred as the term C. Here, S, R, V and C denote the degree of congestion. In the following rule, IF part is known as antecedent and THEN part is known as consequent. The exemplary representation of the generated fuzzy rules is given below.

- IF the speed reduction rate is low, AND the volume to capacity ratio is low, AND the very low speed rate is low, THEN, the congestion is low.
- IF the speed reduction rate is high, the volume to capacity ratio is high, AND the very low speed rate is high, THEN, the congestion is very high.

In the same way, totally, 54 numbers of rules are considered, among them three intense conditions are appropriate for using the combination of three categories such as volume to capacity ratio, speed reduction rate and very low speed. Among these rules, 38 numbers of suitable rules are

evaluated in this process to get required output. In this way, the traffic congestion index is computed. The architectural illustration for congestion index computation with fuzzy inference system is given in Fig. 5.

D. Output of Congestion Index by Fuzzy Inference System

The output of congestion index by fuzzy inference system in terms of membership function is given in Fig. 6.

Fig. 6. Input and Output of Fuzzy Inference System for “(a) Speed Reduction Rate, (b) Very Low Speed Rate, (c) Volume to Capacity Ratio and (d) Final Congestion Index.

VI. RESULT AND DISCUSSION

A. Experimental Setup

The proposed model traffic congestion prediction was implemented in python and the experimental results were evaluated. The performance of the suggested model was compared over various existing models in terms of different measures. The suggested model was compared with different heuristic algorithms and prediction approaches. The maximum iteration was 10 and the number of populations was 10. The proposed is compared over various heuristic algorithms like GWO-IDCRN [29], WOA-IDCRN [30], HHO-IDCRN [26], JA-IDCRN [27] and prediction models like LSTM [31], CNN [32], RNN [33], and CNN-RNN [34].

B. Performance Metrics

The performance measures used for traffic congestion prediction are given here.

1) *L1-Norm* “is the sum of the magnitudes of the vectors in a space. It is the most natural way of measure distance between vectors that is the sum of absolute difference of the components of the vectors” as shown in Eq. (23).

$$L1 - Norm = \|yy\|_1 = \sum_{o=1}^{rs} |yy_o| \quad (23)$$

2) *L2-Norm* “is also known as the Euclidean norm. It is the shortest distance to go from one point to another” as shown in Eq. (24).

$$L2 - Norm = \|yy\|_2 = \sqrt{\sum_{o=1}^{rs} yy_o^2} \quad (24)$$

3) *L-infinity Norm* “is the vector space of essentially bounded measurable functions with the essential supreme norm and only the largest element has any effect” as shown in Eq. (25).

$$L - infinity\ norm = \|yy\|_\infty = \max_{1 \leq o \leq rs} |yy_o| \quad (25)$$

4) *MAE*: it is given in Eq. (18).

5) *Mean Absolute Scaled Error (MASE)* “is a measure of the accuracy of forecasts. It is the mean absolute error of the forecast values, divided by the mean absolute error of the in-sample one-step naive forecast” as shown in Eq. (26).

$$MASE = \frac{1}{RS} \sum_{o=1}^{rs} u_o \quad (26)$$

6) *Mean Effective Pressure (MEP)* “is a theoretical parameter used to measure the performance of an internal combustion engine” as shown in Eq. (27).

$$MEP = \frac{100\%}{rs} \sum_{o=1}^{rs} \frac{xx_o - yy_o}{xx_o} \quad (27)$$

7) *RMSE*: It is given in Eq. (19).

8) *Symmetric Mean Absolute Percentage Error (SMAPE)* “is used to measure the predictive accuracy of models” as shown in Eq. (28).

$$SMAPE = \frac{1}{rs} \sum_{o=1}^{rs} \frac{|xx_o - yy_o|}{(|xx_o| + |yy_o|) / 2} \quad (28)$$

C. Performance Analysis on Heuristic Algorithms

The performance analysis of the suggested model HJHHO-IDCRN algorithm is compared with other meta-heuristic algorithms by varying the learning percentage is given in Fig. 7. The MAE of proposed HJHHO-IDCRN algorithm is 1% higher than GWO-IDCRN, 3% higher than WOA, 1% higher than HHO-IDCRN and 4% higher than JA-IDCRN at learning percentage 60. The MEP measure had attained higher results over other heuristic algorithms, thus the proposed HJHHO-IDCRN algorithm is 3% superior to GWO-IDCRN, 2% superior to WOA-IDCRN, 4% superior to HHO-IDCRN and 2% superior to JA-IDCRN at learning percentage 40. The performance of the suggested algorithm has reduced the error rate and obtained high prediction accuracy than other existing algorithms.

D. Performance Measures on Prediction Models

The performance analysis of the proposed HJHHO-IDCRN algorithm is compared with other prediction models by varying learning percentage is given in Fig. 8. At learning percentage 55, the L-infinity form measures of proposed HJHHO-IDCRN algorithm is 12% higher than LSTM, 16% higher than CNN, 11% higher than RNN and 16% higher than CNN-RNN. The MAE measures of HJHHO-IDCRN algorithm are 2% is improved than LSTM, 1% improved than CNN, 3% improved than RNN and 5% improved than CNN-RNN at learning percentage 75. The MEP measures had obtained higher results over other heuristic algorithms, thus the proposed HJHHO-IDCRN algorithm is 8% superior to LSTM, 4% superior to CNN, 5% superior to RNN and 6% superior to CNN-RNN at learning percentage 85. The proposed algorithm has gained high prediction accuracy than other prediction models and reduced the error rate.

Fig. 8. Analysis of Traffic Congestion Prediction over other Prediction Models by Varying Learning Percentage in Terms of (a) L1Norm (b) L2-Norm (c) L-Infinity Norm (d) MAE (e) MASE (f) MEP (g) RMSE (h) SMAPE.

E. Overall Performance Analysis on Algorithms

The overall performance analysis of traffic congestion is evaluated with HJHHO-IDCRN is illustrated in Table II. The SMAPE measures of the proposed HJHHO-IDCRN algorithm is 5% higher than GWO-IDCRN, 3% higher than WOA-IDCRN, 1% higher than HHO-IDCRN and 6% higher than JA-IDCRN. The RMSE measures of proposed HJHHO-IDCRN algorithm is 15% superior to GWO-IDCRN, 11% superior to WOA-IDCRN, 14% superior to HHO-IDCRN and 9% superior to JA-IDCRN. The MAE measures of proposed HJHHO-IDCRN algorithm is 3% higher than GWO-IDCRN, 1% higher than WOA-IDCRN, 5% higher than HHO-IDCRN and 4% higher than JA-IDCRN. Therefore, the outcomes of the proposed HJHHO-IDCRN algorithm obtain better results than other heuristic algorithms while evaluating with all the measures.

F. Overall Performance Analysis on Prediction Models

The overall performance measures of the proposed HJHHO-IDCRN algorithm are compared with various prediction models and the prediction measures are given in Table III. The MASE measures of proposed HJHHO-IDCRN

algorithm is 2% better than LSTM, 4% better than CNN, 3% better than RNN and 6% better than CNN-RNN. The MEP measures of proposed HJHHO-IDCRN algorithm is 11% better than LSTM, 22% better than CNN, 16% better than RNN and 15% better than CNN-RNN. The MEP measures had gained higher results over other prediction models, thus the proposed HJHHO-IDCRN algorithm is 15% superior to LSTM, 22% superior to CNN, 15% superior to RNN and 16% superior to CNN-RNN. The suggested HJHHO-IDCRN algorithms give better prediction performance and reduce the error rate.

G. Results on Traffic Congestion Index

The obtained congestion parameter results are illustrated in Table IV. The three parameters capture the real condition of traffic congestion. The results have shown when a particular input parameter is high, then the other two parameters are on lower state. This state defines the moderate condition. When all the three parameters are on higher state, it results in high congestion result. In other hand, when all three parameters are in lower state, the congestion index results in very low values. The proposed model gives accurate results in traffic congestion prediction while comparing to other existing methods.

VII. CONCLUSION

In this suggested work, a hybrid-based deep learning approach with congestion index computation by fuzzy model was implemented to predict the traffic congestion. The traffic data was gathered from a publicly available database. The dataset was pre-processed with three phases to remove the unwanted data and to fill the missing data by removing bad data, organizing the raw data and filling the null values techniques. The weighted feature selection of data was performed with proposed HJHHO algorithm by optimizing the weight and minimizing the variance. The prediction phase was done with proposed IDCRN. The main purpose of prediction phase was to minimize the MAE and EMSE measures by optimizing the hidden neuron count of DCN, learning rate of DCN, epoch count of DCN and further, hidden neuron counts of RNN. The congestion parameters such as speed reduction, volume to capacity ratio and very low speed rate obtained from IDCRN were subjected to fuzzy interference system for congestion index computation. Finally, the proposed HJHHO-IDCRN algorithm has improved the performance of prediction. The performance analysis has shown the MAE measures of HJHHO-IDCRN algorithm was 5% higher than GWO-IDCRN, 3% higher than WOA-IDCRN, 1% higher than HHO-IDCRN and 6% higher than JA-IDCRN. Thus, the suggested HJHHO-IDCRN algorithm has attained better prediction in traffic congestion. In future works, the proposed model will be run over different datasets of different road networks and furthermore it will be deployed in route planning solutions.

Impact of the Pandemic on the Development and Regulation of Electronic Commerce in Russia

Svetlana Panasenko, Maisa Seifullaeva, Ibragim Ramazanov
Elena Mayorova, Alexander Nikishin, A.M. Vovk
Plekhanov Russian University of Economics
Moscow, Russia

Abstract—The article deals with topical issues of legal support for the development of electronic commerce in the Russian Federation. The analysis of the main categories of e-commerce has been carried out, the content of which is standardized in domestic regulatory legal acts, the following is among them: elements of the purchase and sale process, the concept of types of trading activities, electronic signature, digital assets, digital currency, smart contracts, digital transactions, etc.). The categories have been defined, the concept of which is absent in the normative legal acts of Russia: the concept of digital goods, e-commerce infrastructure, e-commerce services, delivery channels in online stores, the concept of a courier/courier service, the concept of smart applications, the definition of varieties of online stores, etc. The problem of research is defined: insufficiently effective legal support of economic activity in electronic commerce. An imperfect system of planning strategies for the development of trade organizations in the online environment has been revealed. The conclusions have been formed that the process of digitalization and the consequences of the pandemic have a significant impact on the dynamics of legal support for the development of electronic commerce, but its level is currently not high enough and requires improvement (by making additions to several regulatory legal acts, such as the Law on Trade, the Strategy for the Development of Electronic Commerce in Russia, etc.). The study used system, situational, complex methods, graphical, block grouping, methods of comparative analysis of normative legal acts, and synthesis of conclusions and proposals.

Keywords—Legal support; strategy; development; electronic commerce; Russian federation; digitalization; informatization; online stores; delivery channels; digital product

I. INTRODUCTION

An important place in the progressive and dynamic development of electronic commerce in Russia is occupied by the issues of optimizing the legislative and regulatory framework that regulates the development of this segment of the country's economy. It is very relevant to determine the level of legal support for the development of electronic commerce in the Russian Federation, identify problems and features of existing regulatory legal acts, and form proposals for their improvement, which will ensure faster progress of electronic commerce, which is the driver of the development of the Russian economy, especially in the era of its digitalization. These issues are particularly relevant given the experience of the pandemic and the way out of it, which created additional impulses for the development of electronic commerce and caused the need for further improvement of information and legal support for this process.

A review of sources on this topic showed that the issues of legal support for electronic commerce are being studied both in Russia and abroad. Foreign authors mainly devote their attention to the peculiarities of the legal regulation of electronic commerce, taking into account the experience of specific foreign countries. For example, Gulomrizoi [1] investigated the legal costs of implementing the law on electronic commerce in the Islamic Republic of Iran. Belyavskaya [2] analyzed the issues of regulation of e-commerce in Ukraine. Mukhopadhy [3] studied the issues of e-commerce and data localization from the perspective of developing countries. Some other foreign authors, such as Olifirova and Yagmur [4] analyzed more narrow issues of legal support for electronic commerce (including cost accounting and calculations in interactive commerce: their organizations and methods). Khasenova [5] studied regional aspects (legislative aspects of the strategic development of the economy of the regions of Kazakhstan).

Russian authors Kandybko, Denisov, Petrochenko [6] focused their attention on the history of the emergence and development of electronic commerce in Russia in the field of public procurement for defense, and, accordingly, investigated the issues of assessing the current state and problems of legal regulation of electronic procurement methods for defense, indicating the positive and negative aspects of the transition to electronic closed bidding procedures using the functionality of specialized electronic platforms and the formation of further ways to improve the legal support of procurement in electronic form (purposefully in the segment of public procurement for the defense of Russia). Other Russian authors, Makarevich and Rudneva [7] focused their research attention on the prospects of using blockchain technology for the development of electronic commerce and the features of its legal support. Most often, researchers studied the features of the legal regulation of electronic commerce for certain types of goods. For example, Shvedov [8] studied the problems of legal security of electronic jewelry trade in the Russian Federation. Domestic authors paid attention to certain aspects of electronic commerce in other works, for example, procurement activities in the study of Andreeva [9], the use of innovative mechanisms in electronic commerce, and the regulation of these issues [10], legal regulation of the use of intangible assets in electronic commerce [11], regional features of the development of electronic commerce and consideration these features in local regulatory legal acts [12], the peculiarities of rationing of the retail trade network [13].

It should be noted that there are works by various authors on the study of the legal support of electronic commerce in Russia as a whole [14, 15, 16, 17], but such works are not enough taking into account the latest and not fully researched the experience of the pandemic. Therefore, there is a need to conduct such studies, which would allow a more balanced approach to the issues of modern legal support of electronic commerce in Russia in the future in the process of gradual recovery from the pandemic.

The following research problem has been identified: insufficiently effective legal support for economic activity in electronic commerce, as well as an imperfect system for planning strategies for the development of trade organizations in the online environment. This problem has significantly worsened against the background of the manifestation of the crisis phenomena associated with the pandemic.

The research objective is to identify the features of legal support for the development of electronic commerce in Russia and identify areas for its improvement, taking into account the experience of the pandemic. Research objectives: the systematization of the experience of domestic and foreign authors on the issues of legal support for the development of electronic commerce, conducting a comparative analysis of the fundamental legislative acts regulating the legal support for the development of electronic commerce in Russia, forming conclusions and proposals for improving the legal support for the development of electronic commerce in Russia, taking into account the experience of the pandemic. The research object: electronic commerce. Research subject: legal support for the development of electronic commerce in Russia.

The article describes the results of the study: analysis of the legislative consolidation of key elements of e-commerce processes, analysis of strategic documents on the development of electronic commerce, analysis of the legal regulation of e-commerce categories related to remote biometric identification and signature, conclusion with conclusions and recommendations.

II. METHODS

The study used system, situational, complex methods, graphical, block grouping, methods of comparative analysis of normative legal acts, and synthesis of conclusions and proposals. The system method was used to analyze all elements of the system of legal support for electronic commerce in the Russian Federation, the situational approach was used to determine the current impact of the pandemic on the development of trading activities in the online environment, the graphical method was used to create an effective visualization of the results of the study, the block grouping method allowed us to identify groups of concepts of electronic commerce that are meaningfully enshrined in the current regulations in Russian legislation and groups of concepts, which are absent (while trade practice requires their further legislative consolidation), the method of comparative analysis allowed for a consistent analysis of various legislative and regulatory acts on electronic commerce (especially in terms of the rules for conducting trade transactions in an online environment).

III. RESULT AND DISCUSSION

The study of the main categories of the e-commerce process in the modern legislative and legal field of Russia in the context of the transition to the digital economy has shown that the digitalization process and the consequences of the pandemic have a significant impact on their dynamics.

A. Analysis of the Legislative Consolidation of Key Elements of E-Commerce Processes

It has been revealed that the key categories of elements of e-commerce processes, such as purchase and sale, informatization, and others, are legally fixed. The analysis showed that the Civil Code of the Russian Federation [18] describes various rights (ownership, use, disposal of property). In addition, the concept of payment for goods is noted, the sale of goods based on the remote method of selling goods, the buyer's rights in the event of the sale of goods of improper quality to him/her, the concept of providing information about the goods to the buyer is interpreted.

The Arbitration Procedure Code of the Russian Federation [19] interprets the right to appeal to the arbitration court to protect their rights. Economic disputes (which in practice are addressed by trade organizations, including in the field of commodity circulation) can also be resolved in a pre-trial order. The arbitration court allows considering the documents signed with an electronic signature.

Federal Law No. 381-FZ in Article 2 contains several concepts that are relevant to the structural elements of the competitive environment of the sphere of commodity circulation (Table I) [20].

In our opinion, the absence of terms in Article 2 directly related to various types of trade as part of the sphere of commodity circulation (including electronic commerce) is among the shortcomings of Federal Law No. 381-FZ [20]. This Federal Law does not contain the concepts of e-commerce, online store, marketplace, etc.

Federal Law No. 487-FZ and Articles 5 and 8 of Federal Law No. 381 contain the concept of the product code [20, 22]. The same Federal Law indicates the list of goods subject to labeling.

TABLE I. THE CONCEPTS SPECIFIED IN FEDERAL LAW NO. 381 AND GOST R 51303-2013

The concepts specified in Federal Law N 381 [20]	The concepts specified in GOST R 51303-2013 [21]
Trading activity, wholesale trade, retail trade, retail network, food products, goods marked with identification means, goods subject to mandatory marking by means of identification, identification tool, marking code, identification code, verification code	Wholesale and retail trade, consumer market, buyer, wholesale buyer, seller, trade organization, trading company with a specialized assortment, trading company with a combined assortment, trading company with a mixed assortment of goods, distribution center warehouse, general goods warehouse, specialized warehouse, universal warehouse

Article 2 in Federal Law No. 149-FZ presents the following basic concepts that are relevant to electronic commerce: a website on the Internet, a domain name, a network address, etc. [23].

Federal Law No. 63-FZ (the latest version) uses the following basic concepts that are important for electronic commerce: electronic signature, electronic signature means, participants in electronic interaction, etc. [24].

Federal Law No. 2300-1 includes a description of the following terms that are also used in electronic commerce: consumer, manufacturer, seller, lack of goods, owner of an information aggregator, etc. [25]. The presence of legislative consolidation of such fundamental concepts is of particular importance in the process of overcoming the pandemic (in the context of the growth of both effectively operating online stores that have an excellent reputation among consumers, the expansion of the activities of aggregators (marketplaces), and the growth of fictitious and unreliable online organizations selling goods of questionable quality).

Further, the study showed that GOST R 51303-2013 "Trade. Terms and definitions" contains a much more complete list of terms related to trade, but only a part of them can be indicated among those related to electronic commerce [21]. The concepts of trading activity, wholesale trade, retail trade, retail chains, food products are interpreted in GOST in the same way as in Federal Law No. 381-FZ. The following concepts are given separately in GOST (Table I).

The GOST indicates the difference in terms of distance selling, mail-order trading, and e-commerce. GOST also gives a clear definition of what an electronic trading procedure is. GOST also indicates the concept of online commerce. The advantages of GOST, in our opinion, should include an extremely wide list of basic trade concepts that are fully applied in electronic commerce (goods, price, assortment, types of assortment, types of prices, quality of goods, etc.). At the same time, a major drawback of the State Standard for Trade is the lack of concepts of various types of online stores (as retail objects). In addition, a significant disadvantage and drawback of these regulatory legal acts is the lack of concepts of digital goods, e-commerce infrastructure, the concept of information about the product presented on official Internet pages (this is especially important for describing and familiarizing with the product on the website of the online store, which excludes tactile and physical contact with the product, possible distortion of colors during electronic color rendering and other restrictions). There is no concept of electronic trading services, online purchases, delivery channels in online stores, the concept of a courier or courier service, electronic means of payment in GOST and Federal Law No. 381-FZ.

B. Analysis of Strategic Documents on the Development of Electronic Commerce

A study of strategic documents on e-commerce in Russia showed that certain shortcomings were eliminated in the draft Strategy for the development of e-commerce until 2025, developed in 2017, which proposed a description of such terms as digital economy, digital economy ecosystem, e-commerce

(B2C e-commerce sector), use of the Internet channel by retail, online store, cross-border e-commerce, online purchase, digital goods, mobile commerce, B2G e-commerce sector, B2B e-commerce sector, electronic trading platform (marketplace), e-commerce transaction, O2O business (from "online to offline"), machine-to-machine interaction (M2M), aggregator of goods (services) [26].

Some terms were excluded in the updated version of the draft Strategy for the development of Electronic Commerce (as part of the Strategy for the Development of Trade in the Russian Federation for 2019-2025, published in September 2019 [27]). It should be noted that in the latest version of the Strategy for the Development of Trade in the Russian Federation for 2019-2025, the terms for e-commerce are not given in the text of the Strategy for the Development of e-commerce, but in the form of an Appendix to the entire Strategy for the Development of Trade and currently includes the following terms: digital economy, electronic commerce, e-commerce, internet trading, online store, cross-border e-commerce, B2G e-commerce sector, wholesale e-commerce (B2B), electronic trading platform (marketplace) [27].

Let us present the terms that were excluded from the latest version of the draft Strategy for the Development of Electronic Commerce until 2025 (published in September 2019): an ecosystem of the digital economy, use of the online retail channel, online shopping, digital goods, mobile commerce, electronic transaction, O2O business (from "online to offline"), machine-to-machine interaction (M2M), aggregator of goods (services). In our opinion, the exclusion of certain terms from the new version of the draft Strategy for the Development of Electronic Commerce until 2025 (published in 2019) (digital product, Internet purchase, use of an Internet channel, electronic transaction) made the last list of terms on electronic commerce not sufficiently complete and meaningful [28].

In addition, it should be noted as a disadvantage that the latest version of the E-Commerce Development Strategy does not justifiably contain a description of such concepts as electronic money, electronic product information, electronic signature, e-commerce infrastructure, various types of online stores, information protection, electronic means of payment (for example, an electronic wallet), digital transactions [27].

Let us complement: the definitions of the Internet channel and Internet purchases are neither reflected in GOST R 51303-2013 "Trade. Terms and definitions" nor in the latest version of the Draft Strategy for the Development of Electronic Commerce in the Russian Federation until 2025. The urgent need to interpret these terms, taking into account the experience of the pandemic, is of high importance.

The definition of the B2C sector in the draft Strategy for the Development of Electronic Commerce until 2025, and in its updated version from 2019 is not quite correctly formulated in terms of informing the seller about the intention to buy a product or give feedback after the purchase (which in practice can occur both online and offline).

In our opinion, it is necessary to distinguish the terms Internet commerce (as a form of electronic commerce) and the B2C Sector (as a special type of sale and/or provision of

services to the end consumer individuals). Currently, these terms are being mixed in the modern version of the draft Strategy for the Development of Electronic Commerce until 2025.

The analysis also showed that the terms "Information, Information Technology and Information Protection" are described neither in GOST R 51303-2013 "Trade. Terms and definitions", nor in the latest version of the Draft Strategy for the Development of Electronic Commerce in the Russian Federation until 2025, nor in the Federal Law of December 28, 2009, No. 381-FZ. It is necessary to focus on Federal Law No. 149-FZ, which presents the following concepts: information, the confidentiality of information, a website on the Internet, a domain name, a network address, the owner of a website on the Internet, a hosting provider, a unified identification and authentication system, a search engine, etc. [23].

In addition, the analysis showed that the "information protection" term in Federal Law No. 149-FZ is not considered in the list of terms in Article 2, but is interpreted in Article 16: information protection is the adoption of legal, organizational, and technical measures.

Additional information in this regard is provided by the Decree of the President of the Russian Federation No. 646 and the Decree of the President of the Russian Federation No. 203 [29, 30]. The following basic concepts are used in the Information Security Doctrine of the Russian Federation: information security, means of ensuring it, etc.

The Decree of the President of the Russian Federation No. 203 includes the following definitions: information society, information space, processing of large amounts of data.

Thus, as the analysis of the terminology for the information block shows in terms of definitions that would refract and take into account the specifics of e-commerce in the digital economy in the face of recovering from the pandemic, this direction is insufficiently provided (although it is information that becomes the most important factor in the development of the entire economy in general, and its segments in particular). This is especially significant in the era of the development of information technologies, knowledge, and intelligence, in the process of overcoming the crisis associated with the pandemic. In our opinion, it is necessary to add a description of terms for the protection of information in electronic commerce (as a practice of preventing unauthorized access, use, disclosure, distortion, modification, research, recording, or destruction of information in electronic transactions for the sale and purchase) and information security in the legislative and legal field of Russia.

The analysis showed that the "E-commerce infrastructure" term is also not sufficiently developed. This term ("Infrastructure of electronic commerce") is legally described neither in GOST R 51303-2013 "Trade. Terms and definitions", nor in the latest version of the Draft Strategy for the Development of Electronic Commerce in the Russian Federation until 2025, nor in Federal Law No. 381-FZ.

In addition, the text of the draft Strategy for the Development of Electronic Commerce until 2025 mentions the technical and logistics infrastructure of electronic commerce in

the list of directions for the development of electronic commerce, but the interpretation of these concepts is not given in the list of terms [27].

In our opinion, to improve the legal support of electronic commerce in Russia, we should propose a structural-block approach to describing the elements of the electronic sales format infrastructure (which should be reflected in the relevant regulatory legal acts of the Russian Federation):

- 1) Technical and technological block (including software and platform software);
- 2) The communication unit (for electronic exchange and use of data, including in promotion);
- 3) Logistics unit (aspects of warehousing and delivery);
- 4) Electronic transaction block;
- 5) The HR support unit with the predominance of digital competencies of personnel.

The combination of these elements makes up the infrastructure of the electronic sales format in the field of circulation in the digital economy. These definitions are recommended for inclusion in the list of terms, as it is one of the key ones that allows presenting a complex of the most important structural components of electronic sales in electronic commerce in the digital economy in the long-term (strategic) perspective in the process of overcoming the pandemic.

C. Analysis of the Legal Regulation of E-Commerce

Categories Related to Remote Biometric Identification and Signature

The study showed that categories such as "Remote biometric identification and cloud signature", which have become urgently in demand in the pandemic and in the process of recovering from it, are relatively new terms, which in practice require high technologies of the latest generation.

The remote identification mechanism was developed by the Bank of Russia as part of the implementation of the main directions of the development of financial technologies [31]. The creation and development of a platform for remote identification make it possible to transfer financial services to a digital environment, increase the availability of financial services for consumers, including people with disabilities, the elderly, and the disabled, as well as increasing competition in the financial market.

Biometric data of a citizen should be stored in an impersonal form, and separately from personal data, which significantly increases the level of security. User data is transmitted via secure communication channels and placed in the almost impenetrable cloud infrastructure of the system operators.

It should be noted that concerning the terminology of cloud technologies, a significant contribution was made by the Decree of the President of the Russian Federation No. 203, which includes definitions of cloud computing, processing large amounts of data, etc. [30].

An analysis of another category of e-commerce – "cloud signature" – showed that this concept is also quite new and

rapidly developing in the conditions of recovering from the pandemic. A cloud signature is an analog of an electronic signature that has all its properties and functions, but with one significant difference – the cloud signature certificate is stored not on a token or a smart card, but the server of the certification center. Accordingly, the document signing process also takes place remotely, the user only needs to confirm the operation using a mobile application or entering a one-time password on any device connected to the Internet. Cloud signing does not require additional devices and software tools (tokens, password generators, electronic signature software, scratch cards).

A cloud signature has several advantages over an electronic signature:

1) The cloud electronic signature is not linked to a specific computer. The signature is placed on the server of the certification center in a certified secure cell ("cloud") provided to the client for use. It can be accessed from any device (for example, from an iOS or Android smartphone).

2) Cloud-based encryption technologies minimize the cost of buying tokens, as well as the cost of installing and updating special cryptographic software necessary for servicing an electronic signature certificate.

3) Increased reliability and protection due to the refusal to use the key carrier. The cloud signature cannot be lost or broken, and the security is fully provided by the certification center.

In other words, cloud signature is the optimal solution that allows securely signing documents, giving them legal significance, at any time and from any device.

With the help of a cloud signature system in the field of circulation in the digital economy, customers' intentions to submit applications for participation in procurement procedures, authentication, creation and execution of documents, the facts of receiving and/or familiarizing users with certain information can be confirmed.

A Certificate of compliance was issued by the FSB of Russia for performing actions with authentication and confirmation of cloud signature generation operations using mobile applications for IOS and Android.

The experience of using remote biometric identification and cloud signature is in its infancy on the territory of Russia, but in the future, the process of overcoming the pandemic has the potential to grow, including in electronic commerce in the digital economy, so these terms are also recommended for inclusion in the list of necessary terms and categories in the future.

In addition, the analysis of such categories of electronic commerce in the digital economy as: "Smart contracts, smart applications" showed that their emergence and use is associated with the development of "smart" technologies. Federal Law (draft) No. 419059-7 "On Digital Financial Assets" [32] was prepared to regulate this activity in Russia, which proposes the following basic concepts: smart contract, digital wallet, digital financial asset, cryptocurrency, etc.

There is no concept of smart applications in the draft Federal Law No. 419059-7 "On Digital Financial Assets", but there is an urgent need for its development, especially taking into account the experience of the pandemic. So far, there are separate ideas about the essence of this definition. It has not fully developed yet. We can offer the following as one of the interpretations: smart applications are software specially developed for a specific platform (iOS, Android, Windows Phone, etc.), which is intended for use on smartphones, tablets, and other devices and provides unique opportunities for expanding the functionality of mobile devices.

Federal Law No. 259-FZ was prepared based on Federal Bill No. 419059-7 [33]. Taking into account the rapid growth of the practice of using smart technologies, such categories as digital assets, digital currency, smart contracts will gradually enter the field of e-commerce in the digital economy, taking into account the experience of the pandemic.

It should also be noted that an analysis of another category, such as "Public networks", was performed, which showed that one should be guided by Federal Law No. 126-FZ [34]. According to the law, the Internet is a general-purpose network. In addition, the Decree of the President of the Russian Federation No. 203 gives the following definition to the varieties of this category: industrial Internet, new generation communication networks, the Internet of Things [30].

Thus, the analysis of the entire complex of categories relevant to online sales showed that these concepts and their content are not fully covered by the regulatory legal acts of Russia regulating the development of electronic commerce in the Russian Federation.

IV. CONCLUSION

We conclude that the considered categories of elements of the e-commerce process in the Russian Federation in the digital economy are highly significant and relevant, but the level of legal support for the development of e-commerce is not at a high level and requires several improvements.

On the one hand, the categories of e-commerce processes were identified, the content of which is normalized in regulatory legal acts (sales of goods, their payment, buyer's rights, the concept of electronic signature, digital assets, digital currency, smart contracts, digital transactions, etc.). At the same time, it was revealed that several categories related to electronic commerce are absent in the regulatory legal acts of Russia: there is no concept of digital goods, e-commerce infrastructure, e-commerce services, delivery channels in online stores, the concept of a courier/courier service, the concept of smart applications, the definition of varieties of online stores, etc.

As a result, the conclusions have been formed: even though the process of digitalization and the consequences of the pandemic have a significant impact on the dynamics of legal support for the development of electronic commerce, its level in Russia is not yet high enough and requires improvement. For example, it requires the revision of the GOST on trade (which should include such concepts of various types of online stores, digital goods, e-commerce infrastructure, the concept of product information presented on official Internet pages, the

concept of electronic trading services, online purchases, delivery channels in online stores, the concept of a courier or courier service, electronic means of payment. Strategic documents on the development of e-commerce also need to be finalized: it would be desirable to include a description of the following concepts in the e-Commerce Development Strategy: electronic money, electronic product information, electronic signature, e-commerce infrastructure, various types of online stores, information protection, electronic means of payment (for example, an electronic wallet), digital transactions. The Law on Trade in the Russian Federation also needs additions (which should include such terms as the concept of e-commerce, online store, marketplace, etc.).

Timely revision and improvement of the conceptual and categorical apparatus in the legal support of electronic commerce in Russia, its unification, consolidation of these concepts and their content in the Russian regulatory framework, their wider use in domestic post-pandemic practice will eliminate objective obstacles to faster development of electronic commerce in the Russian economy, especially taking into account the pandemic-related crisis recovery and the acceleration of digitalization processes.

Among the prospects of our research, it should be noted the need to continue scientific and analytical work in the direction of studying the changes being made to the legal support of electronic commerce in the conditions of exiting the pandemic at the present time, in the medium and long term (taking into account the prolonged cumulative impact of the pandemic on the development of electronic commerce). In the future, there is also the study of changing strategic documents on e-commerce at the national level, taking into account the process of digitalization, the study of various strategic alternatives for the development of e-commerce, its strategic trajectories. Promising, in our opinion, is not only the continuation of the study of the All-Russian level of development, but also regional (the level of individual large regional entities - subjects of the Russian Federation). This will make the study more comprehensive, in-depth and meaningful in the future.

ACKNOWLEDGMENT

The research was carried out within the framework of the state task of the Ministry of Science and Higher Education of the Russian Federation FSSW-2020-0009 "Development of a methodology for managing the competitiveness of enterprises in the field of commodity circulation in the digital economy".

Department of Public Health, Faculty of Science, Buriram Rajabhat University (BRU), Buriram Province, Thailand³

Abstract—This research aims in developing an application for the waste management via the QR code system: 1) to study the quality of the application and 2) to study the satisfaction of users of the application by using the system development life cycle (SDLC) principle. There were 388 people of sample groups in this research which consisted of community leaders, village health volunteers, youth and the general public of Ban Yang Sub-district, Mueang Buriram District, and Buriram Province. The research instruments were the application for a waste management via the QR code system, Application Quality Assessment Form, and the application satisfaction questionnaire. The statistics used in the data analysis were mean and standard deviation. The results of the research revealed that there were three main functions of the application for a waste management via the QR code system as follows: 1) The quality assessment of the application in all aspects at a high level (Mean = 4.41, S.D.=0.10). 2) Study of satisfaction of the application users in all aspects at a high level (Mean = 4.42, S.D. = 0.45). 3) The application of waste management application via the QR code system allowed group members in the community to reduce the process of managing household waste more conveniently and create a positive attitude in using waste to elevate through the work of the group members in the community.

Keywords—Application; QR-Code system; waste management; SDLC; community information

I. INTRODUCTION

Ban Yang Subdistrict Administrative Organization, Mueang Buriram District, Buriram Province has an area of approximately 30.24 square kilometers and a total population of 13,397 [1]. The community in Ban Yang is a model for waste management by sorting and has a management process within the group with the support of the Ban Yang Subdistrict Administrative Organization in which Panrak Pansuk Waste Bank was established. Household waste is classified as wet waste, general waste, recyclable waste and hazardous waste. This causes reduced waste in Ban Yang Sub-district and can be managed within the group using rules and agreements which has clearly divided the structure of the group, such as general administrative subdivision, sales management, and accounting and finance. Source operating profit rewards were shared among members within the group and used to manage other aspects of community welfare, such as funerals, scholarships, care for the poor, the elderly and the disabled, etc. From the strong operation of the group resulted in various awards, such as the Dhamma and Golden Land Village Award 1992, the Outstanding Development and Environmental Conservation

Village Award and the Outstanding Community Plan Village 2008 [2].

The development and expansion of the community since 1980 has resulted in the amount of waste, leftovers, scrap materials, as well as dense living; therefore, increasing population. This results in waste within the community of 1.52 tons per month, causing the cost of transportation in order to get rid of the waste approximately 277,120 Baht per year. This in turn causes environmental pollution problems and the problem of dengue fever due to the large number of Aedes mosquitoes in the community. In the past, the community had managed the waste by segregating it among households. However, it was always difficult to find a place to dispose of the waste. The municipality of Ban Yang Subdistrict, therefore had to dispose of it in the landfill of the municipality of Satuk Subdistrict, which is far away. This results in higher management costs. Furthermore, the behavior of community members remains unaware of the need to maintain a sanitary waste disposal system. The resolution of problems in the past had to depend mainly on government agencies, also the lack of integration of work, and the involvement of all agencies in concrete [3]. According to group leaders on waste management, neighboring communities still lack adequate waste management practices. As a result, the amount of waste in the community continues to increase.

The software development life cycle System Development Life Cycle (SDLC) means development of the system has been set to go in the same direction and set a procedure that is a guideline for analyzing the system by trying to have as few flaws as possible because the current system analysis work is more complicated than in the past. System analysts have to standardize in the development of such work system. Therefore, a system development cycle has been invented to meet the needs of system analysts. SDLC consists of 1) problem definition, 2) analysis, 3) design, 4) development, 5) testing, 6) implementation, and 7) maintenance. This provides an effective framework and method to develop software applications. This helps in effective planning before starting the actual development. SDLC allows developers to analyze the requirements, helps in reducing unnecessary costs during development. During the initial phases, developers can estimate the costs and predict mistakes which may cause expenses, enables developers to design and build high-quality software products. This is because they follow a systematic process that allows them to test the software before it is rolled

out, provides a basis when evaluating the effectiveness of the software. This further enhances the software product [4].

II. LITERATURE REVIEW

Developing the application for a waste management via the QR code system proposed the concept, related theories and research as follows:

1) *Application*: Application is a program that facilitates various aspects designed for Mobile phones, tablets, or any other mobile communication device that we know [5] – [8]. In each operating system, there will be many application developers to meet the needs of users. The author in [9] is available for both free and paid downloads including education, communication, or even entertainment, etc. Mobile applications are divided into three types which are Native Application, Hybrid Application and Web Application.

- Native Application is an application developed with a Library or SDK [10], an instrument for developing programs or applications of the operating system on a mobile phone, OS Mobile (Operating System Mobile), especially, for example, Android uses Android SDK, iOS uses Objective C and Windows Phone uses C#, etc. [11] – [17].
- Hybrid Application [18] – [19] is an application which has been developed for the purpose in order to run on every operating system by using the framework to be able to work on all operating systems [20] – [21].
- Web Application is an application [22] that is written as a browser for the use of various web pages, which are customized to display only the necessary parts in order to reduce the processing resources of the device of a smartphone or tablet. This enables the website load faster. In addition, users can use the internet and intranet in low speed as well [23] – [27].

2) *Theory of System Development Life Cycle: SDLC* [28]

- Planning: The purposes of this phase are to find out the scope of the problem and determine solutions, resources, costs, time, benefits and other items which should be considered here [29].
- System Analysis and Requirements: The second phase is where teams consider the functional requirements of the project of the solution [30].
- System Design: The third phase describes, in detail, the necessary specifications, features and operations that will satisfy the functional requirements of the proposed system which will be in place [31].
- Development [32]: Now the real work begins. The development phase marks the end of the initial section of the process. Additionally, this phase signifies the start of the production. The development stage is also characterized by instillation and change.
- Integration & Testing [33]: This phase involves systems integration and system testing (of programs

and procedures) normally carried out by a Quality Assurance (QA) professional to determine if the proposed design meets the initial set of business goals.

- Implementation: The sixth phase is when the majority of the code for the program is written, and when the project is put into production by moving the data and components from the old system and placing them in the new system via a direct cutover [34].
- Maintenance [35]: The last phase is when end users can fine-tune the system, if they wish to boost performance, add new capabilities to meet additional user requirements.

3) *Theory of QR-Code*: The QR code system was invented in 1994 by Masahiro Hara from the Japanese company Denso Wave. The initial design was influenced by the black and white pieces on a Go board [36]. Its purpose was to track vehicles during manufacturing; it was designed to allow high-speed component scanning.

ISO/IEC 18004: 2015 defines the requirements for the symbology known as QR Code [37]. It specifies the QR Code symbology characteristics, data character encoding methods, symbol formats, dimensional characteristics, error correction rules, reference decoding algorithm, production quality requirements, and user-selectable application parameters.

The amount of data that can be stored in the QR code symbol depends on the data type (mode, or input character set), version (1, ..., 40, indicating the overall dimensions of the symbol, i.e., $4 \times \text{version number} + 17$ dots on each side), and error correction level. The maximum storage capacities occur for version 40 and error correction level L (low), denoted by 40-L.

TABLE I. CHARACTER REFERS TO INDIVIDUAL VALUES OF THE INPUT MODE/DATA TYPE

Input mode	Max. characters	Bits/char.	Possible characters, default encoding
Numeric only	7,089	31/3	0, 1, 2, 3, 4, 5, 6, 7, 8, 9
Alphanumeric	4,296	51/2	0-9, A-Z (upper-case only), space, \$, %, *, +, -, ., /, :
Binary/byte	2,953	8	ISO 8859-1
Kanji/kana	1,817	13	Shift JIS X 0208

From Table I, there are four input modes: 1) Numeric only: The maximum character is 7,089, and the minimum character is three and one third. 2) Alphanumeric: The maximum character is 4,296, and the minimum character is five and one half. 3) Binary/byte: The maximum character is 2,953 and the minimum character is 8. 4) Kanji/kana: The maximum character is 1,817 and the minimum character is 13.

4) *Waste management*: Solid waste refers to [38], the garbage generated from various activities in the community, such as homes, commercial establishments, business centers, shops, entertainment spot, fresh-food markets and institutions. The type of waste consists of organic waste: food scraps, leaf scraps, and grass clippings, etc.; recycled waste: glass, plastic,

aluminum, rubber, etc.; general waste: remnant of cloth, wood scraps; and other materials, including hazardous waste from the community. Solid waste management principles are as follows:

- Solid waste collection [39] is the collection of solid waste arising from various sources by considering the solid waste containers or trash cans, which can be classified and stored efficiently, as well as designated collection points for solid waste to facilitate the collection, save time and money.
- Transportation of solid waste [40] is the process of bringing the garbage that people from each household put in the solid waste bin to be transported for further disposal by solid waste truck. That should take into account the suitability of the area and the amount of solid waste that collects each day by demarcation of the solid waste collection route to be effective, save resources, and cost.
- Solid waste disposal [41], large-scale waste disposal technology, including composting system by decomposing organic matter through the biological process of microorganisms, the decomposition transforms them into minerals that are relatively stable. Sanitary landfill system, the solid waste is brought to the landfill in the area that has been prepared according to academic principles in terms of economic, social, environmental, engineering, architecture and public consent. There are measures to prevent potential impacts such as contamination of wastewater. In addition, measures must be taken to prevent flooding, smell pollution and impact on the landscape. The incinerator system is a solid waste management method in the incinerator that has been properly designed and constructed because it may cause air pollution, such as small dust particles, various toxic gases like sulfur dioxide, etc. Therefore, it is necessary to have an air pollution control system and to prevent the air passing through the flue into the atmosphere exceeds the air quality standard from the furnace.

III. METHODOLOGY

Develop an application for a waste management via the QR Code system. The principles of the System Development Life Cycle (SDLC) were used as follows.

1) *Requirement definition stage*: Studying documents and related research, as well as studying the problems and situations in the community regarding the classification of waste in order to determine the value of the purchase in the group, including waste management of Ban Yang sub-district communities to analyze and define the application development model.

2) *System analysis stage*: Analyzing and studying application patterns of applications in waste management via the QR code system to be consistent with community waste management activities; designed a context diagram containing information about the administrator, community

administrators, and community group members by defining the related work processes, including junk data management, member information management, QR code data management, reward information management, information management, and report display.

3) *System design stage*: Planning and defining work procedures to be consistent with the timeline, budget, and scope of the application for a waste management via the QR Code system. Determining the responsibilities for the working team and coordinated with people in the community involved, as is shown in Fig. 1.

4) *System development stage*: Developing the application for a waste management via the QR Code system, divided into two parts: 1) The user section, consists of the login screen, QR code scanning by managing the validation and designing with JAVA language and XML language, as well as managing database storage with MySQL engine. 2) The administrator section, manages application usage data to perform QR code scanning and the information management on the website, display Press release information, activity pictures, and display the household coordinates of the group members.

5) *System testing stage*: Testing the system using the application for a waste management via the QR Code system to check the operation of the system before it was put into actual use along with improving the syntax of the application's instruction set to meet the needs of users.

6) *System installation stage*: Executing the installation of the system to use the application for a waste management via QR Code system by using it in parallel with the existing community waste bank model and creating relevant documents such as a QR code diagram of the waste classification and application manual.

7) *System maintenance stage*: Improving the error from the operation of the application for a waste management via QR Code system including tracking the results of use and listening to suggestions on problems that arose in order to improve the system further.

After finishing the developing of an application for a waste management via the QR Code system, application technology dissemination is presented as is shown in Fig. 2.

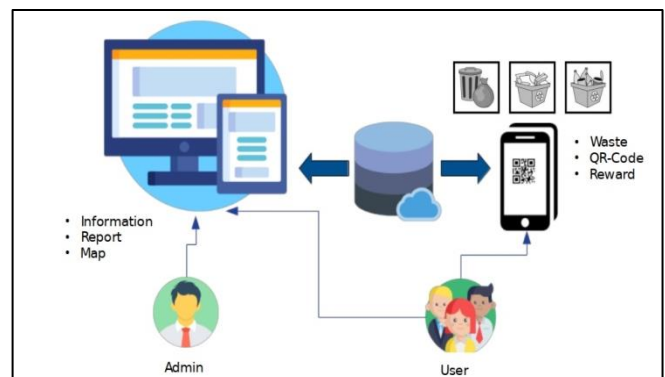

Fig. 1. Designing the Application for a Waste Management via the QR Code System.

Fig. 2. Presentation for Application Technology Dissemination.

IV. RESEARCH RESULT

A. Results of Analysis

Designing and developing of the application for a waste management via QR Code system use data from the study of problems in waste management in Ban Yang sub-district communities, Muang Buriram district, and Buriram province. These were analyzed and created a context diagram to show an overview of the system performance. The scope of the work studied in relation to the external environment of the system consists of the user menu. This can be checked by the member's points to be redeemed for rewards. Admin data management menu can manage member information, household coordinates, press release information, and QR code information, as is shown in Fig. 3.

B. Results of a Study

1) *Results of a study* on the quality of the application for a waste management via QR Code system by three experts and analyzed the data using mean and standard deviation according to the Likert method [42]. Details are shown in Table II.

From Table II, the results of the study on the quality of the application for a waste management via QR Code system by three experts revealed that the overall quality of the application was at a high level. The application design aspect was at the highest level. In terms of application usage and information security aspects were at a high level.

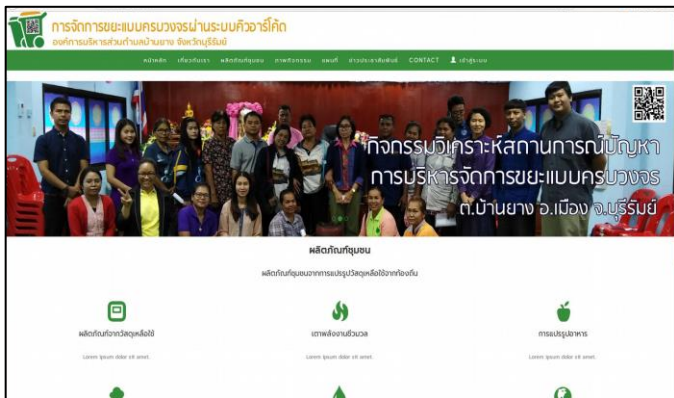

Fig. 3. Admin Data Management Menu.

TABLE II. THE RESULTS OF THE STUDY ON THE QUALITY OF THE APPLICATION FOR A WASTE MANAGEMENT VIA QR CODE SYSTEM

Appraisal item	\bar{x}	S.D.	Quality level
1. Application usage aspect	4.33	0.01	high
2. Application design aspect	4.46	0.30	the highest
3. Information security aspect	4.44	0.00	high
Total	4.41	0.10	high

Following Fig. 4 is a prototype of the application for a waste management via the QR-Code System.

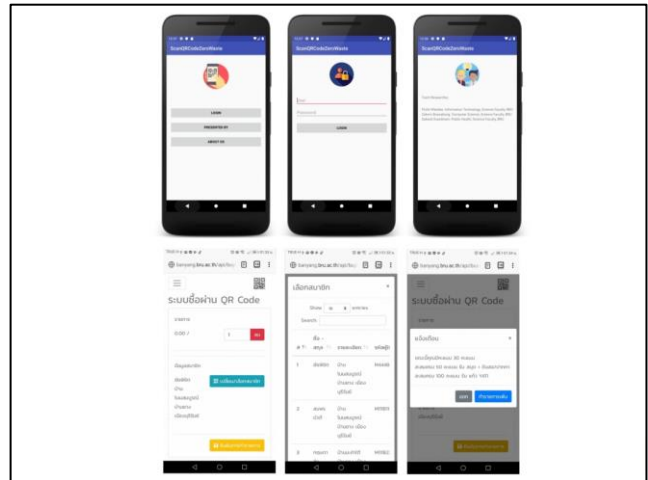

Fig. 4. Prototypes of the Application.

The system was installed and the developed application was tested with 388 people of sample groups, then the satisfaction study results were analyzed by basic statistical values compared to the criteria and summarized [43]. Details are shown in Table III.

TABLE III. THE RESULTS OF THE SATISFACTION ASSESSMENT OF THE APPLICATION USERS

Appraisal item	\bar{x}	S.D.	Satisfaction level
Application design aspect			
1. The font size was appropriate.	4.61	0.49	the highest
2. The topics used in the application were categorized appropriately.	4.27	0.62	high
3. Graphics used in the application were appropriate.	4.25	0.45	high
4. The use of color tones was appropriate and gorgeous.	4.23	0.42	high
5. The layout of the application components was uncomplicated to understand.	4.03	0.25	high
Performance in use aspect			
6. Users could scan the QR code easily and conveniently.	4.76	0.43	the highest
7. Users could manage information conveniently.	4.53	0.49	the highest
8. Users could speedily access information within the application.	4.91	0.45	the highest
9. The application performance overview was appropriate.	4.23	0.42	high
Total	4.42	0.45	high

The results of the satisfaction assessment of the users of the application for a waste management via QR Code system revealed that the overall was at a high level. When these were considered for each item, users were satisfied with the speed access to inform within the application at the highest level with the average 4.91 followed by users who could scan a QR code easily and conveniently with the average of 4.76. The font size was appropriate with the average of 4.61. The users could manage information conveniently with the average of 4.53. The topics used in the application were categorized appropriately with the average of 4.27. The graphics used in the application were appropriate and the application performance overview was appropriate with the average of 4.23. And the layout of the application components is uncomplicated to understand with the average of 4.03.

V. DISCUSSION AND CONCLUSION

From the research and development of the application for a waste management via the QR Code system, the related document was studied based on the System Development Life Cycle [44] through a process of participation in Ban Yang Sub-District Community, Mueang Buriram District, Buriram Province. The study analyzed the approach to waste management by applying application technology to store data and related information, divided into two parts: the application part was used in the QR scanning management to classify the types of waste in order to buy waste directly from the community group members by using the motivation to collect 100 points, and would receive a reward. That could check the history of buying waste of the group members, display a list of QR codes and report on the amount of waste by period [45]. This has been consistent with the research on QR CODE in Thailand and Application of QR Code Technology in the Hospitals in Thailand 4.0 by using QR code technology in service, thereby reducing errors streamlines the operations of various procedures, reducing redundant management, and making the service users get the most benefit.

The results of the quality assessment of the application by the experts were at a high level, which have been consistent with the research on Using QR-Code Technology for Public Relations of Community Enterprises Antique Hand-Woven Cloth Group, Padee Pha Tho, Tambon Bo Suak, Mueang district, Nan province. However, the users of the application for a waste management via QR Code system were satisfied with the system at a high level. The researchers in [46], in terms of application design and data accuracy [47] have been in line with the research on The Application of Two Dimension Barcode Technology for Providing Tourist Information Services at Tourism Destination Case Study: Doi Suthep Temple, Chiang Mai, which was designed and developed an application for information display that met the needs of users. That was easy access to information and convenient in service.

However, this should be further developed regarding the variety of applications in other uses, such as household location data in order to link the data to make it accessible to all. Local governments and community leaders should promote and support it as a learning area to be a role model in community waste management and to publicize knowledge and technology to nearby areas and people who are interested.

ACKNOWLEDGMENT

This research project was funded by the National Research Council of Thailand (NRCT). Thank you to the Research Progress Assessment Committee, Research and Development Institute, Buriram Rajabhat University. Thank you to the administrators of the Ban Yang Subdistrict Administrative Organization, Muang Buriram District, Buriram Province, officials, community leaders, seniors, youths, and people in the area for participating in research activities.

Abstract—Spatial analysis techniques are widely used as an effective approach for prone road traffic accident classification. This paper will present the results of empirical behavioral testing on the spatial analysis for prone road traffic accident classification using the Multicriteria Decision Making (MCDM) method. The performance of MCDM is compared on arterial and collector road types processed with multicriteria parameters. MCDM was chosen because it can be used as a decision making based on an alternative selection with many criteria. Empirical tests of the MCDM method used include Weighted Sum Model (WSM), Weighted Product (WP), Simple Additive Weighting (SAW), Weighted Product Model (WPM), Multi-Attribute Utility Theory (MAUT), Technique for Others Reference by Similarity to Ideal Solution (TOPSIS), and Analytical Hierarchy Process (AHP). The multicriteria parameter weight values are based on expert judgment and the Fuzzy-AHP method (EJ-AHP), which comprises volume-to-capacity ratio (VCR), international roughness index (IRI), vehicle type, horizontal alignment, vertical alignment, design speed, and shoulder. Then, the performance of the models was compared to determine the value of accuracy, precision, recall, and F1-score as decision-making on the prone road traffic accident classification using Multicriteria Evaluation Techniques (MCE). The empirical test results on arterial roads show that the SAW and TOPSIS methods have the same performance and are superior to other methods, with an accuracy value of 63%. However, the results on the collector road type show that the accuracy value of the AHP method outperforms other methods with an accuracy value of 70%.

Keywords—Spatial Analysis; GIS; prone road traffic accident; MCDM Model; WSM; WP; SAW; WPM; MAUT; TOPSIS; AHP

I. INTRODUCTION

The rate of road traffic accidents (RTA) that results in deaths increases every year. Data for 2004-20130 states that RTA is the leading cause of death, which is ranked 9th in the world; WHO estimates that in 2030 the RTA will increase to the 5th rank if there are no efforts to overcome this problem [1]. The number of deaths due to RTA annually reached 1.35 million worldwide in 2016 [2].

The case study for the spatial analysis for prone road traffic accident classification in the discussion of this paper is on the type of arterial and collector roads in the Province of East Java, Indonesia, which is one of the areas with a very high accident-prone. The Global Status Report on Road Safety 2018 states that in Indonesia, with a population number is 261,115,456 people in 2016, the number of deaths due to RTA reached 31,282 million people [2]. The accident factors include 69.70% due to the human factor, 21.21% due to road facilities, and 9.09% due to road infrastructure factor (Komite Nasional Keselamatan Transportasi, 2016). In 2010 the United Nations General Assembly declared a Decade of Action for Road Safety year 2011-2020 aimed at stabilizing the level of fatality of global casualties by increasing activities undertaken at national, regional, and global scales [1][3][4]. The spirit of the Road Safety Action Declaration 2011-2020 is in line with the mandate of Law Number 38 of 2004 [5], Number 34 of 2006 [6] concerning roads, and Law Number 22 the Year 2009 concerning road traffic and transportation [7] to prepare a National General Plan for Road Safety 2011-2035 in Indonesia [8] as outlined in and Regulation of the President of the Republic of Indonesia Number 2 of 2012 concerning the national transportation safety committee [9].

Spatial data modeling (GIS-spatial analysis) is a part of multicriteria decision-making (GIS-MCDM). Spatial analysis in geographic information systems (GIS) is the process of developing artificial intelligence (AI) formulations by combining geo-referenced data (spatial data) with multicriteria parameters as value assessment attribute data (decision-makers preferences and uncertainty) to obtain the appropriate information in georeferencing-based decision making. GIS is commonly regarded as a technology capable of integrating, storing, manipulating, analyzing, and displaying spatial data and attribute data for decision-making and decision-supporting operations [10]. The MCDM method provides a collection of procedures and AI algorithms for formulating decision-making problems, designing, evaluating, and prioritizing alternative decisions [11][12]. This empirical study aims to analyze the sensitivity of the methods tested through spatial data modeling with MCE. MCE evaluates the methods [13] by

testing the extent to which the values of accuracy, precision, recall, and F1 scores when multicriteria parameters systematically vary on various interests.

The characteristic of GIS-Spatial MCDM is to determine the weighting of the spatial datasets used for spatial data modeling. The literature study [14]–[18] summarizes several issues related to GIS-spatial relationship modeling for prone-roads classification traffic accidents (PRTA) using the MCDM method. First, GIS-Spatial relationship modeling using multicriteria decision-making methods (GIS-Spatial MCDM) is a spatial analysis process to perform spatial data modeling that involves multicriteria parameters from the expert judgment in spatial decision making. The spatial analysis involves multicriteria parameters in building software GIS for spatial decision-making based on combined theory, methods, and measurement tools from expert judgment [19][20]. An expert judgment is required to validate the spatial dataset parameters used [19].

Many researchers give parameter-weighted values only from the point of view of expert judgment. The expert judgments give a subjective and objective risk and bias in the evaluation process for weighting and parameter priority scale [21]. The weighted value given to the multicriteria parameter will impact the accuracy of the spatial data modeling results for PRTA classification [22][23]. Many researchers claim that the multicriteria parameters used are effective and capable of determining the PRTA classification [24]–[32].

Secondly, classification techniques are needed to produce accurate spatial data modeling without overlapping interests and to avoid overfitting problems, and the deep-neuro-fuzzy classification method is used for road weight measurement [33]. The analytical hierarchy process (AHP) method can improve the road safety audit technique used to identify and prioritize black spots in the absence of statistical data of accidents that were not recorded correctly. [34]. The AHP method is used to perfect the weighting value generated from literature studies and expert assessments [31][35] by determining the priority scale ranking of the parameters using the random forest (RF) [31] method, preference ranking organization method for enrichment of evaluations (PROMETHEE), and VlseKriterijuska Optimizacija I Komoromisno Resenje (VIKOR) method [35].

The literature study shows that the MCDM method such as SAW and AHP methods and Fuzzy AHP for determining the weight can help decisions process in Road Safety Analysis (RSA) such as road management prioritization and provide mitigating actions against the most vulnerable to accidents. In another literature study, the TOPSIS classification model is used to manage road safety to reduce the number of traffic accidents by knowing the position of a road safety study based on various quantitative and qualitative criteria [36]. Besides that, the simple ranking (SR) method and the empirical Bayes (EB) combine the type and severity of the accident to the data series in Australia, then proposed to evaluate alternative indicators with multiple criteria parameters for the identification of accident-prone road (blackspot). The SR and EB method is used to calculate the value of accidents by type

of case, societal cost of any accident, and the crash prediction models using data series [37].

GIS is region specific [38][39], where 96% [14] of research uses private spatial datasets with small dataset characteristics. The challenge for small datasets is at the data pre-processing stage to produce optimal performance on the AI method used. The GIS-Spatial MCDM approach is proposed in this study based on the characteristics of the MCDM model based on multi-criteria parameter weighting. The weighting that has been carried out by expert judgment will be combined with the AHP computational method (EJ-AHP) as a means of measuring the resulting weight value.

Based on the review of these literature studies, however, no research studies specifically for evaluating and comparing through an empirical study approach in the spatial analysis using the MCDM method (WSM, WP, SAW, WPM, MAUT, TOPSIS, and AHP methods) for prone road traffic accidents. The classification of multicriteria parameter weight values is based on expert judgment and the AHP method (EJ-AHP). Therefore, this study proposed a combination of expert judgment and Fuzzy-AHP (EJ-Fuzzy-AHP) to produce weighting values in spatial datasets and provide the appropriate parameter priority scale values. Fuzzy-AHP has a procedure following decisions that involve expert judgment, so it can be used to combine data knowledge in Fuzzy-AHP with expert judgment. Then, these weighting values were used in the MCDM method for GIS-based spatial modeling for PRTA classification based on multicriteria parameters, namely speed design, volume/capacity ratio (V/C Ratio) [40], the width of the road, the number of lanes, road shoulders, median strip, horizontal alignment, vertical alignment, road condition [40], and vehicle type.

The discussion structure in this paper includes section II: which discusses multicriteria parameters through the description of spatial datasets, section III: which discusses research methodology; section IV: which describes results and discussion; and section V: which discusses the conclusion and future works directions.

II. SPATIAL DATASETS

The spatial dataset parameters in this study were obtained from private data sources, so a decision-making model using GIS-Spatial MCDM is proposed. The GIS decision-making system is used for specific regions case studies in which 96% of researchers use private data types on specific regional case studies [14] with multicriteria parameters from the expert judgments. The MCDM method is applied to making decisions through management priority ranking related to existing or specific region-specific planning policies [41]. The MCDM method is one of the right approaches to deal with the problem of the PRTA classification because it uses several road and environmental criteria, both quantitative and qualitative; MCDM is related to the results of decision making for planning that involves stakeholders [42].

According to the Republic of Indonesia Law No.38 of 2004 article 8, the type of road based on its function is divided into 4 (four), namely arterial roads, collector roads, local roads, and environmental roads. The arterial road is a public

road with the number of access roads is limited efficiently, works to serve the main transport which connects provincial capitals with the characteristics of long-distance travel dan high average speeds [43]–[45]. The collector road is a public road that works to serve vehicle which connects between regency capitals with medium distance travel characteristics, medium average speed, and a limited number of entrances [43][44]. Local roads are public roads with an unlimited number of access roads that serve local transport, which link the sub-district cities with short-distance travel and low average speeds [43][44]. The environmental road is a public road that serves environmental transportation between villages with short-distance travel characteristics and low average speed [43][44].

In this study, the spatial analysis datasets include the types of primary arterial networks and primary collector networks since both types of roads are the main roads that supply sufficient datasets for this study. The case study involves the research objects in Indonesia with data retrieval from the National Road Development Center, Police Corps and Traffic Police of Indonesia, Traffic Corps National Police, and Transportation Department. Descriptions of the spatial datasets on the multicriteria parameters used are shown in Table I were to the range and score for Spatial Datasets from:

- The Directorate General of Highways Standard Specifications for Geometric Design of Urban Roads. Ministry of Public Works, Directorate General of Highways, Jakarta 1992.
- Indonesian Highway Capacity Manual (IHCM), 1997
- TRB Highway Capacity Manual. Transportation Research Board Special Report 209; Washington D.C. USA 1985. Revised 1994.
- SNRA Manual on Calculation of Capacity, Queues, and Delay in Traffic Facilities (in Swedish). Swedish National Road Administration Report TV 131, 1977.

Geospatial Datasets comprised spatial data needs for a base map (layer) and attribute data requirements for multicriteria parameters that were utilized for spatial analysis of PRTA classification. The data requirements used in this study used private data types from the National Road Implementation Center, East Java Bali, Indonesia. Spatial datasets include:

1) *The base map*: consists of attributes road number, suffix, road names, length of roads (km), and road function.

- a) *Arterial primary networks*
- b) *Collector primary networks*

2) *Multicriteria parameters*

a) *Volume-to-capacity ratio (VCR)*: to measure the overall service quality provided. If the VCD is high, it indicates a high risk of accidents.

b) *International Roughness Index (IRI)*. Condition of the pavement. If the IRI is heavily damaged, the likelihood of an accident increases significantly.

c) *Vehicle Type*: vehicle types 2/1 UD, 2/2 UD, 4/2 UD, 4/2 D, and 6/2 can pass through arterial or principal collector roads.

d) *Horizontal alignment (HA)*. Projection of the axis of the road for roads without a median or the projection of the inner edge of the pavement for roads with a median. If the horizontal alignment is sharp, the potential for accidents is high.

e) *Vertical alignment (VA)*: the intersection of the vertical plane with the road pavement surface through the road axis for 2-speed 2-way roads or through the inner edge of each pavement for roads with a median. If the vertical alignment is high, the potential for accidents is high.

f) *Design speed (Vr)*: The vehicle speed can be achieved safely when running without interruption. If the speed is high, then the accident potential is high.

g) *Shoulder*: The lane is located side by side with the traffic lane. If the shoulder there isn't, then the potential for an accident is high.

TABLE I. SPATIAL DATASETS PARAMETERS

Arterial Road			
Parameters	Range	Description	EJ Scoring
VCR (%)	$VCR \geq 0.85$ && $VCR < 1.00$	The condition reaches capacity with 2000 units of passenger cars (pcu/hour), 2 directions.	5
	$VCR \geq 0.70$ && $VCR < 0.85$	The conditions approach unsteady flow with traffic volume reaching 85% of the capacity, namely 1700 units of passenger cars (pcu/hour), 2 directions.	4
	$VCR \geq 0.45$ && $VCR < 0.70$	Traffic flow conditions are still stable, with traffic volume reaching 70% of capacity (pcu/hour), 2 directions	3
	$VCR \geq 0.20$ && $VCR < 0.45$	The start of a stable flow condition with traffic volume reaching 45% of the capacity is 900 units of passenger cars (pcu/hour), 2 directions.	2
	$VCR < 0.20$	The conditions free flow with traffic volume reaching 20% of the capacity, namely 400 units of passenger cars (pcu/hour), 2 directions.	1
IRI (m/km)	$IRI \geq 12$	Heavy Damage	4
	$IRI \geq 8$ && $IRI < 12$	Light Damage	3
	$IRI \geq 4$ && $IRI < 8$	Moderately	2
	$IRI < 4$	Good	1
HA(rad/km)	$HA \geq 3.50$	Poor	3
	$HA \geq 0.25$ && $HA < 3.50$	Fair	2
	$HA < 0.25$	Good	1
VA	$VA \geq 45$	Poor	3

Arterial Road			
Parameters	Range	Description	EJ Scoring
(m/km)	$VA \geq 5$ && $VA < 45$	Fair	2
	$VA < 5$	Good	1
V_r (km/jam)	$V_r \geq 100$	Traffic speed more than 100 kilometres per hour.	6
	$V_r \geq 80$ && $V_r < 100$	Traffic speed is more than 80 kilometers per hour.	5
	$V_r \geq 65$ && $V_r < 80$	Traffic speed more than 65 kilometres per hour.	4
	$V_r \geq 60$ && $V_r < 65$	The speed limit is reduced to 60 kilometers per hour.	3
	$V_r \geq 50$ && $V_r < 60$	The average pace of traffic is approximately 50 kilometers per hour.	2
	$V_r < 50$	Traffic moving at a speed of fewer than 50 kilometers per hour.	1
Road Type	2/2 UD	The traffic road is a two-lane two-way without a median (2/2 UD)	5
	4/2 UD	The traffic road is a four-lane two-way without a median (4/2 UD)	4
	4/2 D	The traffic road is four lanes two-way with a median (4/2 D).	3
	6/2 D	The traffic road has six two-way lanes with a median (6/2 D).	2
	2/1 UD	The traffic road has two lanes with no median (2/1 UD).	1
Shoulder	No	No, there is no roadside shoulder.	2
	Yes	Yes, the roadside shoulder is available.	1
Collector Road			
Parameters	Range	Description	EJ Scoring
VCR (%)	$VCR \geq 0.90$ && $VCR < 1.00$	The condition reaches capacity with 2000 units of passenger cars (pcu/hour), 2 directions.	5
	$VCR \geq 0.75$ && $VCR < 0.90$	The conditions approach unstable flow with traffic volume reaching 90% of the capacity, namely 1800 units of passenger cars (pcu/hour), 2 directions.	4
	$VCR \geq 0.50$ && $VCR < 0.75$	Traffic flow conditions are still stable, with traffic volume reaching 75% of capacity (pcu/hour), 2 directions	3
	$VCR \geq 0.30$ && $VCR < 0.50$	The start of a stable flow condition with traffic volume reaching 50% of the capacity is 1000 units of passenger cars (pcu/hour), 2 directions.	2
	$VCR < 0.30$	The conditions free flow with traffic volume reaching 30% of the capacity, namely 600 units of passenger cars (pcu/hour), 2 directions.	1
IRI (m/km)	$IRI \geq 12$	Heavy Damage	4
	$IRI \geq 8$ && $IRI < 12$	Light Damage	3
	$IRI \geq 4$ && $IRI < 8$	Moderately	2

Arterial Road			
Parameters	Range	Description	EJ Scoring
HA (rad/km)	$IRI < 4$	Good	1

Shoulder	Yes	Yes, the roadside shoulder is available.	1

III. RESEARCH METHODOLOGY

The proposed MCDM experiment procedure in Fig. 1 has major differences from the existing framework [46]–[48]. Fig. 1 describes the proposed MCDM experiment procedure, namely:

- The requirement gathering a primary data set as a base map to determine the category of roads to be studied. This research uses private data types. The base maps used include primary arterial and primary collector networks.
- Attribute data for the multicriteria parameters used is based on an assessment by expert judgment, including VCR, IRI, vehicle type, horizontal alignment, vertical alignment, design speed, and shoulder. The data requirements are described in Table II.
- Conduct a literature study related to the multicriteria parameters used in each road category based on expert judgment assessment with the results in Table II.

- Mathematical modeling for spatial data analysis through empirical study for PRTA classification based on the MCDM method using WSM, WP, SAW, WPM, MAUT, TOPSIS, and AHP methods. In this case, the data pre-processing process will be carried out for the classification analysis process, that is:
 - Determine the priority weight of the parameters using the AHP method.
 - Determine the multiclass classification range obtained from the final value of the results of mathematical modeling on the MCDM method using the Guttman Scale. This process is carried out because there is no standardized assessment from expert judgment regarding the value of the PRTA classification range based on the multicriteria parameters used.
- The results of the multiclass classification will be validated through the value of accuracy and F1 score, which the F1 score is derived from the precision and recall.

A. The Priority Weight of the Parameters

Spatial decision-making based on multicriteria parameters is almost always faced with the problem of determining the

level of importance or influence between parameters. Decision-makers will weigh each parameter based on the importance or influence between these variables, which is usually done by expert judgment. The AHP method can solve the complex multicriteria parameter problems into a hierarchical unit. The hierarchy represents a complex problem in a multilevel structure, where the first level is the goal, followed by the factors level, criteria, sub-criteria, and the last level of alternatives. With a hierarchy, complex problems can be described in groups which are then arranged into a hierarchical form so that problems will appear more structured and systematic.

How to overcome the biases from the weighting given by expert judgment overdue of various factors of interest, then the decision-maker can perform parameter weighting using the AI method. The AHP is a pairwise comparison method through an analytic hierarchy process. The parameter weights are determined by normalization through the eigenvectors associated with the maximum eigenvalues in the unit ratio matrix. The weighting between parameters in this study is accomplished by the AHP method approach based on flow depicted in Fig. 2.

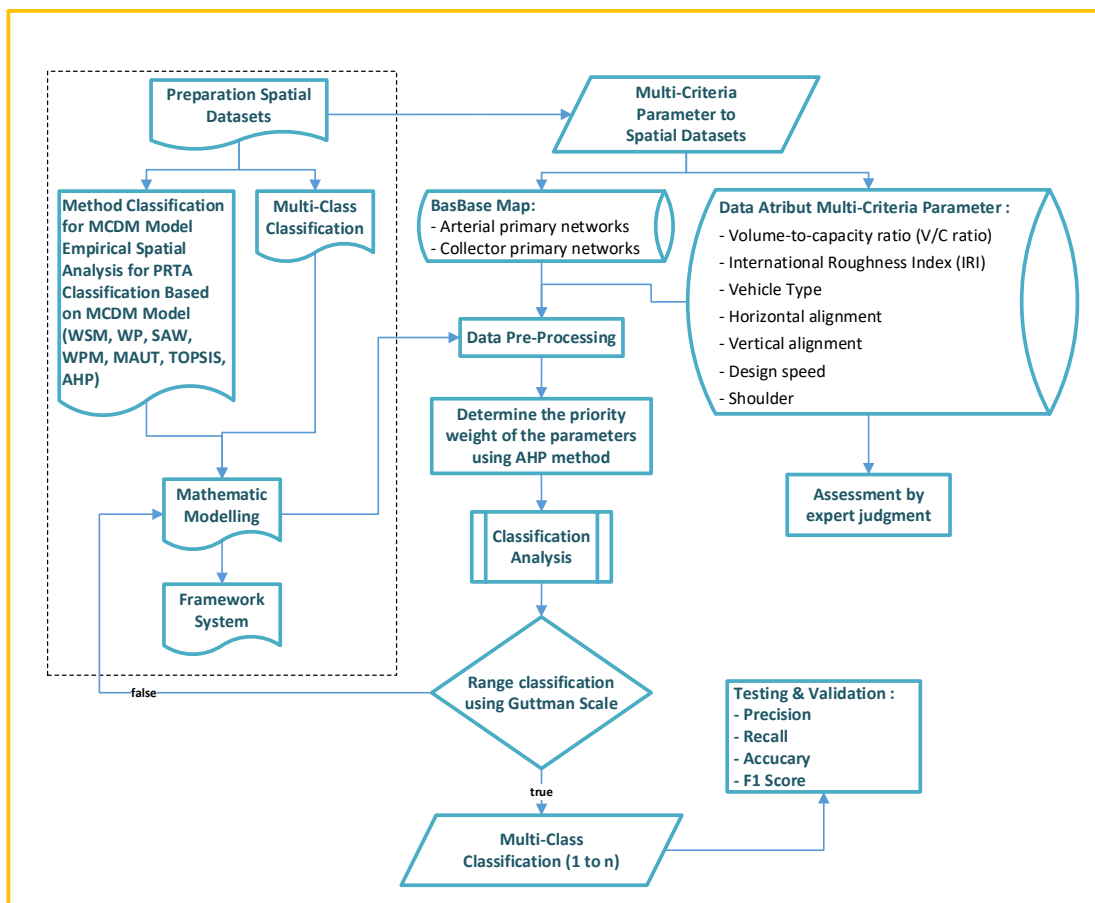

Fig. 1. Proposed MCDM Experiment Procedure.

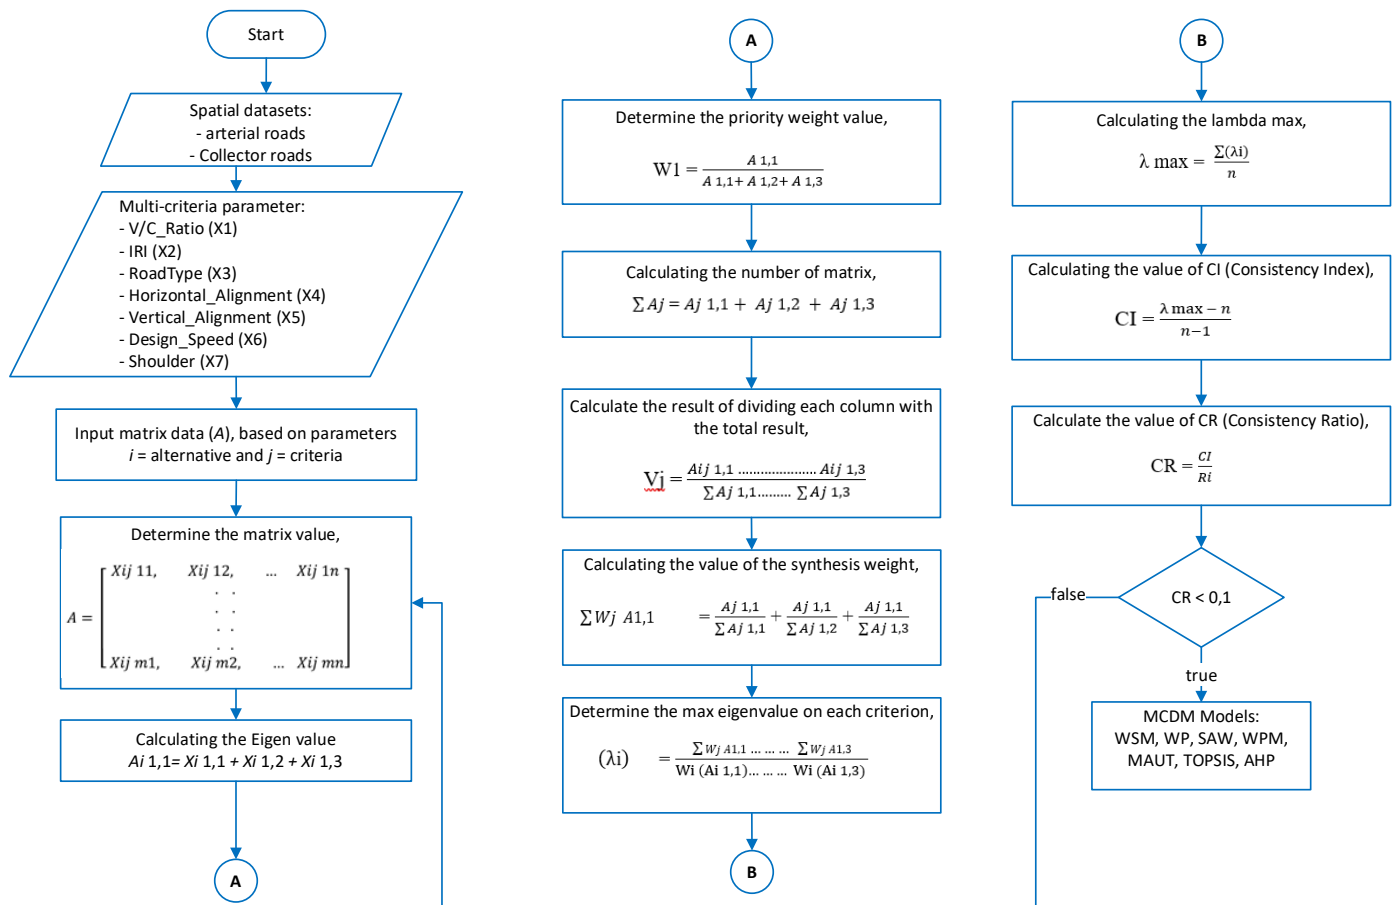

Fig. 2. The Priority Weight of the Parameters using the AHP Method.

Which consists of the following:

Step 1: Input the spatial datasets based on the base map used, namely the arterial and collector roads network.

Step 2: Input data multicriteria parameters, provide the labeling of the parameters used, namely VCR (X1), IRI (X2), Road Type (X3), HA (X4), VA (X5), Vr (X6), and Shoulders (X7).

Step 3: Input matrix data (A), based on parameters. Where i variable is an alternative, and j variable is criteria.

Step 4: Determine the multicriteria parameters matrix value (A) using pairwise comparison based on Eq. (1). A value is assigned to each criterion in accordance with the specifications of the hierarchical structure based on the number of multicriteria parameters present.

$$A = \begin{bmatrix} X_{ij 11}, X_{ij 12}, \dots X_{ij 1n} \\ \vdots \\ X_{ij m1}, X_{ij m2}, \dots X_{ij mn} \end{bmatrix} \quad (1)$$

The recommended values for creating a pairwise comparison matrix, where the values referring to Table III [49].

TABLE II. THE RECOMMENDED VALUES FOR CREATING A PAIRWISE COMPARISON MATRIX

Value	Description
1	Equally important (equal)
3	A little more important (slightly)
5	More importantly, with a strong type (strongly)
7	More importantly, with a very strong type (very strong)
9	More important to the extreme (extreme)

Step 5: Calculate the eigenvalues of each element in each pairwise comparison matrix. The eigenvalues are the weight of each element used to determine the priority of items in each hierarchical structure. Operate for adding values to each column in question to obtain the normalization of the matrix, based on Eq. (2).

$$A_{i 1,1} = X_{i 1,1} + X_{i 1,2} + X_{i 1,3} \dots X_{i 1,n} \quad (2)$$

Step 6: Calculate the priority weight value of the parameter (Wi) using Eq. (3), adding up each column's values in the pairwise comparison matrix, then dividing each value in the column by the total number of related columns obtain a normalized matrix. Where, $\sum A_{ij}$ is the number of matrices,

$$W_i = \frac{A_{i 1,1} \dots A_{i 1,5}}{\sum A_{ij}} \quad (3)$$

Step 7: Calculate the result of divide each column by the result of the total number (V_j) using Eq. (4), where $\sum A_j = A_{j,1,1} \dots \dots A_{j,1,5}$. Addition the values of each row and divide them with the number of elements to get the average value.

$$V_j = \frac{A_{ij,1,1} \dots \dots \dots A_{ij,1,5}}{\sum A_{j,1,1} \dots \dots \dots \sum A_{j,1,5}} \quad (4)$$

Calculate the value of the synthesis weight (W_j) to j using Eq. (5). Where $\sum W_j$ is the result of adding V_j to calculate the weight value of the synthesis.

$$\sum W_j = V_{j,1,1} \dots \dots \dots V_{j,1,5} \quad (5)$$

Step 8: Determine the max eigenvalue (λ_i) on each criterion using Eq. (6). Where, $\sum(\lambda_i)$ is $(\lambda_i) A_{1,1} \dots \dots (\lambda_i) A_{1,5}$.

$$(\lambda_i) = \frac{\sum W_j A_{1,1} \dots \dots \sum W_j A_{1,5}}{W_i (A_{i,1,1}) \dots \dots W_i (A_{i,1,5})} \quad (6)$$

Calculate the Lambda max (λ_{max}) using Eq. (7). Where, $\sum(\lambda_i)$ is the total value of the sum of the eigenmax max, and n variable is the number of criteria.

$$\lambda_{max} = \frac{\sum(\lambda_i)}{n} \quad (7)$$

Step 9: Check the consistency of the hierarchy by calculating the value of the consistency ratio using the consistency index (CI) using Eq. (8), where:

- If the CI value 10%, then the consistency ratio is correct
- If the CI value is > 10%, then the consistency ratio is wrong, so data assessment must be corrected and reviewed.

$$CI = \frac{\lambda_{max} - n}{n - 1} \quad (8)$$

The consistency ratio (CR) value can be calculated using Eq. (9). Where R_i is a random index value determined by the hierarchy structure, as described in Table III, where:

- If $CR < 0.1$, then the level of consistency shown is quite rational in the pair comparison matrix.
- If $CR > 0.1$, it indicates an inconsistent assessment of the pair comparison matrix.

$$CR = \frac{CI}{R_i} \quad (9)$$

B. Weighted Sum Model (WSM)

WSM is a simple method that is extensively used in decision-making on single-dimensional problems. Attribute normalization is done by altering the value of the numeric column in the data set to the same scale to obtain a balance on the overall attribute value. Spatial data modeling with the WSM method is an approach to determining the weight of the priority value of each parameter of the attribute parameter, then multiplying with the data of each attribute to take a high alternative value as a solution [50]–[53].

The following sequence of the steps spatial analysis process for the PRTA classification using the WSM method:

Step 1: Follow the steps in the flow in Fig. 2 to define the criteria used as a benchmark for solving the problem and determine the priority of parameter weights.

Step 2: Calculate the priority values for each layer dataset by using the matrix of Eq. (10) [51].

$$A_i^{WSM-score} = \sum_{j=1}^n W_j X_{ij}; \text{ for } i = 1,2,3, \dots m \quad (10)$$

Where, $A_i^{WSM-score}$ is potential WSM score, X_{ij} a variable is an alternative to the i data score based on the j relative weight criterion, and W_j a variable is the j relative weight criterion

Step 3: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11).

$$I = R / K \quad (11)$$

Where the I variable is the interval range, the R variable is the result of the calculation of the highest scores value of A_i minus the lowest score value of A_i , and the K variable is the number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of A_i minus the value of I variable as shown in the result of Eq. (12).

$$\begin{cases} \text{PRTA, if } A_i \geq \text{the scale range} \\ \text{Non_PRTA, if } A_i < \text{the scale range} \end{cases} \quad (12)$$

C. Weighted Product (WP)

The WP method is a decision support system that connects attribute ratings through multiplication operations to be raised to the power of the appropriate attribute weights. The normalization process to handle different units of measurement is done through multiplication operations on attribute ratings [54].

The following sequence of the steps spatial analysis process for the PRTA classification using WP method:

Step 1: Follow the steps in the flow in Fig. 2 to define the criteria used as a benchmark for solving the problem and determine the priority of parameter weights. Determine the initial and final input to change the name of the input into a rating value and determine the weight of each criterion. Improve the weights of each criterion by adding up the weights of each criterion, followed by dividing the result of the sum of the weights of the criteria by the starting weight of each criterion divided by the result of the sum of the weights of the criteria.

Step 2: Calculate the normalization value using Eq. (13) to get the alternative preference value of each criterion represented by the vector S_i . Where the S_i variable is the value of alternative preference, X_{ij} is the variable value of the alternatives on each attribute. The W_j variable is the value of the weight of the criteria, the n variable is the number of criteria, the i variable is an alternative value 1,2,..,m, and the j variable is the criterion value.

$$S_i = \prod_{j=1}^n X_{ij}^{W_j} \quad (13)$$

Step 3: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I variable is the interval range, the R variable is the result of the calculation of the highest scores value of S_i minus the lowest score value of S_i , and the K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of S_i minus the value of I variable as shown in the result of Eq. (14).

$$\begin{cases} \text{PRTA, if } S_i \geq \text{the scale range} \\ \text{Non_PRTA, if } S_i < \text{the scale range} \end{cases} \quad (14)$$

D. Simple Additive Weighting (SAW)

The SAW method is a multi-process method in spatial decisions making with multicriteria parameters. The SAW method performs a weighted summation of the performance ratings on each alternative attribute. The process of normalizing the decision matrix (X) to a scale that can be compared with all existing alternative ratings [55]. The advantage of the SAW method compared to the decision support system method that involves other multicriteria parameters lies in its ability to make a more precise assessment because it is based on the criteria value and the weight of the level of importance required.

The following sequence of the steps spatial analysis process for the PRTA classification using the SAW method:

Step 1: Follow the steps in the flow in Fig. 2 to define the criteria used as a benchmark for solving the problem and determine the priority of parameter weights.

Step 2: Perform normalization using Eq. 15 for each alternative value on each attribute by calculating the performance rating value.

$$r_{ij} = \begin{cases} \frac{x_{ij}}{\text{Max}_i x_{ij}}, & \text{if } j \text{ is benefit attribute} \\ \frac{\text{Min}_i x_{ij}}{x_{ij}}, & \text{if } j \text{ is cost attribute} \end{cases} \quad (15)$$

where r_{ij} variable is the normalized performance rating of alternative A_i on attributes C_j and j , $\text{Max } X_{ij}$ variable is the greatest value of each criterion i , and $\text{Min } X_{ij}$ variable is the smallest value of each criterion i , X_{ij} variable is the attribute values that each criterion has. If the largest value is the best, then it is included in the benefit attribute category. If the smallest value is the best, then it is included in the cost attribute category.

Step 3: Calculate the value of preference weight on each alternative (V_i) using Eq. (16). Where the V_i variable is the ranking for each alternative. the W_j variable is the ranking weight value of each criterion, and r_{ij} variable is the normalized performance rating value.

$$V_i = \sum_{j=1}^n w_j r_{ij} \quad (16)$$

Step 4: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I variable is the interval range, the R variable is the result of the calculation of the highest scores value of V_i minus the lowest

score value of V_i , and the K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of V_i minus the value of I variable as shown in the result of Eq. (17).

$$\begin{cases} \text{PRTA, if } V_i \geq \text{the scale range} \\ \text{Non_PRTA, if } V_i < \text{the scale range} \end{cases} \quad (17)$$

E. Weighted Product Model (WPM)

Spatial data modeling with the WPM method is a process to determine the weight of the priority value on each attribute parameter criterion, perform weighting by dividing the attribute weights by the weight of all attributes to get the total value equal to 1, determining the total vector value S to produce the vector V in produce the highest value that will be used as an alternative selection [51]–[53] The WPM method can be used for MCDM single or multi-dimensional categories [56].

The spatial data modeling process for the PRTA classification using the WPM method. The following sequence of the steps is as follows:

Step 1: Follow the steps in the flow in Fig. 2 to define the criteria that will be used as a benchmark for solving the problem and determine the priority of parameter weights.

Step 2: Calculate the normalized decision matrix value using Eq. (18) to get the alternative preference value of each criterion represented by the vector S_i . Where the S_i variable is the value of alternative preference, X_{ij} is the variable value of the alternatives on each attribute, and the W_j variable is the value of the weight of the criteria, the n variable is the number of criteria, the i variable is an alternative value 1,2,..,m, the j variable is the criterion value.

$$S_i = \prod_{j=1}^n x_{ij}^{w_j}, i = 1,2,3,\dots, m \quad (18)$$

The normalized decision matrix value is calculated in order to obtain the x_{ij} value by providing the i -th alternative performance rating value on the j -th sub-criteria in the normalized decision matrix value computation. Furthermore, the value of the performance rating is elevated to the relative weight value (w_j), where w_j will be positive for the benefit attribute and negative for the cost attribute, depending on the attribute being evaluated. The sum of the w_j values for each sub-criteria on the same criteria will be worth 1. The value of w_j is calculated using Eq. 4.19.

$$w_j = \frac{w_j}{\sum w_j} \quad (19)$$

Step 3: Calculate the relative preference value of each alternative V_i using Eq. 20. Where, V_i variable is the relative preference of each i -th alternative. x_{ij} variable is the criteria value for each alternative to the i -th and the criteria j -th. w_j variable is the weight of the criteria or sub-criteria and the n variable is the number of criteria.

$$V_i = \frac{\prod_{j=1}^n x_{ij}^{w_j}}{\prod_{j=1}^n x_j^{*w_j}}, i = 1,2,3, \dots, m \quad (20)$$

Step 4: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I variable is the interval range, the R variable is the result of the calculation of the highest scores value of V_i minus the lowest score value of V_i , and the K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of V_i minus the value of I variable as shown in the result of Eq. (21).

$$\begin{cases} \text{PRTA, if } V_i \geq \text{the scale range} \\ \text{Non_PRTA, if } V_i < \text{the scale range} \end{cases} \quad (21)$$

F. Multi-Attribute Utility Theory (MAUT)

Spatial data modeling with the MAUT method is to determine the value of $U(A_i)$ With the weight value on each sub-criteria parameter and the priority value of each attribute parameter's interest, calculate the number of criteria in each attribute [57][58]. the more value of sub-criterion of every single parameter, the obtained value will end up with a high value $U(A_i)$ [59].

The MAUT method will change from several parameters of importance to a numerical value with a scale of 1-5, where a scale of 1 is the worst choice, and a scale of 5 is the best choice. The results of the MAUT method will provide a ranking order of alternative evaluations that describe the choices of policymakers. The spatial data modeling process for the PRTA classification using the MAUT method. The following sequence of the steps is as follows:

Step 1: Follow the steps in the flow Fig. 2 to define the criteria used as a benchmark for solving the problem and determine the priority of parameter weights.

Step 2: Make the normalized matrix using Eq. (1). Where the $U(x)$ variable is the normalized alternative weight, the x is the alternative weight, the x_i^- is the minimum weight of the x -th criterion, and the x_i^+ is the maximum weight of the x -th criterion using Eq. (22).

$$U_{(x)} = \frac{x - x_i^-}{x_i^+ - x_i^-} \quad (22)$$

Step 3: Calculate the evaluation value of each alternative $V_{(x)}$ by multiplying utility $U_{(x)}$ by weight using Eq. (23).

$$V_{(x)} = \sum_{i=1}^n w_j * x_{ij} \quad (23)$$

Where the $V_{(x)}$ variable is the evaluation value of each alternative of the PRTA classification for the i -th data, the value of the division between the parameter weighting value and the number of sub-criteria on each parameter then multiplied by the weight of the attribute priority value at each parameter criteria. The w_k variable is the weight of the attribute sub-criterion on each parameter of the parameter until the k -th data and $u_k(x_{ik})$ is the parameter of the k -th data multiplied by the priority value of each parameter x_{ik} . The A_i variable is the weighting value of multicriteria parameters.

Step 4: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I

variable is the interval range, the R variable is the result of the calculation of the highest scores value of V_x minus the lowest score value of V_x , and the K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of V_x minus the value of the I variable as shown in the result of Eq. (24).

$$\begin{cases} \text{PRTA, if } V_x \geq \text{the scale range} \\ \text{Non_PRTA, if } V_x < \text{the scale range} \end{cases} \quad (24)$$

G. Technique for Others Reference by Similarity to Ideal Solution (TOPSIS)

The TOPSIS method is a decision-making method that involves multicriteria parameters used to overcome alternative problems due to uncertainty/inconsistency [60]–[62]. The TOPSIS method also determines the distance of the ideal solution to smaller and larger before making the determination of alternative value with the result of alternative calculation has the final value < 1 [50]–[53]. The concept of selecting the best alternative in the TOPSIS method is that the best-selected alternative consists of alternatives with the shortest distance from the positive ideal solution and the longest distance from the negative ideal solution.

The spatial data modeling process for the PRTA classification using the MAUT method used the following sequence of the steps is as follows:

Step 1: Follow the steps in the flow in Fig. 2 to define the criteria used as a benchmark for solving the problem and determine the priority of parameter weights.

Step 2: Calculate a normalized decision matrix using Eq. (25) [63]. Where the r_{yx} variable is the normalized value for each y -th alternative to the x -th criteria with $i=1,2,\dots,m$ and $j=1,2,\dots,n$.

$$r_{yx} = \frac{x_{yx}}{\sqrt{\sum_{i=1}^m x_{yx}^2}} \quad (25)$$

Step 3: Calculate a weighted normalized decision matrix using Eq. (26). Multiply the weight of the parameter criteria with the value of each attribute.

$$v_{yx} = W_{yx} * r_{yx} \quad (26)$$

Where v_{yx} variable is the weighted normalized value, the variable w_{yx} is the weight of each criterion, and the variable r_{yx} is the normalized value of each alternative against the j -th criterion with $i=1,2,\dots,m$ and $j=1,2,\dots,n$.

Step 4: Calculate the ideal solution based on the maximum value of A^+ using Eq. (27) [51] [64] and the negative ideal solution based on a minimum value of A^- using Eq. (28) [51] [64].

$$A_x^+ = \{v_{y1}^+, v_{y2}^+, v_{y3}^+\}$$

$$A^- = \{\max y_1, \max v_2, \max v_3, \dots, \max v_n\}$$

Where,

$$v_x^+ = \begin{cases} \max v_{yx}; & \text{if } yx \text{ is benefit attribute} \\ \min v_{yx}; & \text{if } yx \text{ is cost attribute} \end{cases} \quad (27)$$

$$A_x^- = \{v_{y1}^-, v_{y2}^-, v_{y3}^-\}$$

$$A^- = \{\min v_1, \min v_2, \min v_3, \dots, \min v_n\}$$

Where,

$$v_x^- = \begin{cases} \max v_{yx}; & \text{if } yx \text{ is benefit attribute} \\ \min v_{yx}; & \text{if } yx \text{ is cost attribute} \end{cases} \quad (28)$$

Step 5: Calculate the positive and negative ideal solution spacing, as referenced in Eq.s (29) and (30) [51] [64]. In this research, the ideal positive solution is based on the maximum value of D + of the Eq. (29) [51] [64] and the ideal negative solution distance based on a minimum value of D - of Eq. (30) [51] [64].

$$D_y^+ = \sqrt{\sum_{y=1}^n (v_{yx} - A_x^+)^2} \quad (29)$$

$$D_y^- = \sqrt{\sum_{y=1}^n (v_{yx} - A_x^-)^2} \quad (30)$$

Where the D_y^+ variable is used to calculate the maximum ideal solution distance as much as the y-th data. The D_y^- variable is used to calculate the minimum ideal solution distance as much as the y-th data.

Step 6: Calculate the preference value for each alternative to be generated by Eq. (31) [51] [64].

$$V = \frac{D_i^-}{D_i^- + D_i^+} \quad (31)$$

where D_i^- is the ideal minimal solution distance value of the i-th data dan D_i^+ is the maximum ideal solution distance value as much as a number of i data.

Step 7: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I variable is the interval range, the R variable is the result of the calculation of the highest scores value of V_i minus the lowest score value of V_i , and the K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of V_i minus the value of I variable as shown in Eq. (32) .

$$\begin{cases} \text{PRTA, if } V_i \geq \text{the scale range} \\ \text{Non_PRTA, if } V_i < \text{the scale range} \end{cases} \quad (32)$$

H. Analytical Hierarchy Process (AHP)

The Analytical Hierarchy Process (AHP) is a pairwise comparison method through an analytic hierarchy process, where the parameter weights are determined by normalization through the eigenvectors associated with the maximum eigenvalues in the unit ratio matrix. The weighting between parameters in this study is accomplished by the AHP method approach based on flow depicted in Fig. 2. Which consists of the following:

Step 1-9: Use the process in section III subsection A for the priority weight of the parameters using the AHP method.

Step 10: Determine the range of PRTA classification values using the Guttman scale based on Eq. (11). Where the I

variable is the interval range, the R variable is the result of the calculation of the highest scores value of CR variable minus the lowest score value of CR variable, and K variable is a number of alternatives. The alternative assessment criteria for the PRTA classification are obtained from the result of the calculation of the highest scores value of CR variable minus the value of I variable, as shown in the result of Eq. (33).

$$\begin{cases} \text{PRTA, if } CR \geq \text{the scale range} \\ \text{Non_PRTA, if } CR < \text{the scale range} \end{cases} \quad (33)$$

I. Multicriteria Evaluation techniques (MCE)

This research method evaluation uses the accuracy, and F1 score approaches. The F1 score is obtained from the values of precision and recall. A confusion matrix [65] is used in this evaluation technique, consisting of two positive classes and a negative class to compare actual data and classification data [66]. Multi-class classification [65] is used in the discussion of this paper: prone road traffic accident (PRTA), and non-prone road traffic accident (Non-PRTA). The precision and recall value is calculated with the average value in each class.

Accuracy in the measurement of a method is used to determine the accuracy value in clarifying the results of classification data with actual data with Eq. (34) [65]. Precision describes the amount of positive-valued data divided by total positive-valued data in Eq. (35) [65]. The recall describes the percentage of data in the positive category classified by the system with the calculation in Eq. (36) [65]. Results of precision and recall values are used to calculate F1-score, as in formula (37) [65]. The accuracy of the data generated in classification is known from the percentage after testing between the actual data in the form of an analog map of the classification of the watershed erosion zone and prediction data with MAUT, WPM, WSM, and TOPSIS methods. Performance value classification with categories 91% – 100% is very good classification, 81% – 90% is good classification, 71% – 80% is fair classification, 61% – 70% is poor classification, and values below 60% are false classification [67].

$$Accuracy_M = \frac{\sum_{i=1}^l \frac{TP_i + TN_i}{TP_i + FN_i + FP_i + TN_i}}{l} \quad (34)$$

$$Precision_M = \frac{\sum_{i=1}^l \frac{TP_i}{TP_i + FP_i}}{l} \quad (35)$$

$$Recall_M = \frac{\sum_{i=1}^l \frac{TP_i}{TP_i + FN_i}}{l} \quad (36)$$

$$F - score_M = \frac{(\beta^2 + 1) Precision_M Recall_M}{\beta^2 Precision_M + Recall_M} \quad (37)$$

Where TP_i is the amount of data + which when the classification is true by the method used for the i-th class. TN_i is the amount of data. When the classification is true by the method used for the i-th class. FP_i is the amount of + data that is classified as false by the method used for the i-th class. FN_i is the amount of data - which when the classification is false by the method used for the i-th class. l is the number of classification classes. Average accuracy is the average value of method accuracy in all classification class. $Precision_\mu$ is the precision value of each classification class. $Precision_M$

represents the average value of the precision in all classification classes. $Recall_{\mu}$ is the recall value of each classification class. $Recall_M$ represents the average value of recalls in all classification classes. $Fscore_{\mu}$ is a performance matrix to calculate the average of precision and recall values in each classification class. $F-score_M$ is a performance matrix to calculate the average of precision and recall values in all classification classes.

IV. RESULT AND DISCUSSION

Based on the private spatial datasets and quantitative attribute data explained in section III, the results of this study are discussed in the following subsections.

A. Parameter Priority Weight

In each of the methods used in the MCDM, the weight of each parameter priority value in this study uses the opinion of EJ (score) and mathematical calculations using AHP based on the score given by EJ (EJ-AHP). Tables IV and V are the results of mathematical calculations of the pairwise comparison matrix of the AHP method to produce the priority weight of the parameters based on the flow in Fig. 2 with the process in Section III for sub-section A.

TABLE III. PARAMETER PRIORITY VALUE WEIGHTING RESULTS

B. The Guttman Scale to Determine the Classification of Accident Prone Roads

The Guttman scale [68] is used to measure the generated classification values in this paper. This scale is used to draw conclusions from qualitative data [69]. It is also used to estimate the value of the classification resulting in an intervention value that is still ambiguous due to uncertainty [70]. It is possible to assess the uncertainty factor of a variable class defined using the Guttman scale [71] in Eq. (11) for a dataset that employs a weight in the analysis process and delivers a value.

The test data consisted of 180 primary arterial roads and 201 primary collector roads, where the data is categorized as a small-scale dataset. The value of the scale on the SAW, WP, SAW, WPM, MAUT, TOPSIS, and AHP methods using Eq. (12), (14), (17), (21), (24), (32), and (33) based on the process calculations in section III sub-sections B to H, respectively.

TABLE V. THE SCALE TO DETERMINE THE CLASSIFICATION OF ACCIDENT PRONE ROADS

MCDM Models	Arterial Road Scale	Collector Road Scale
WSM	$\begin{cases} PRTA, \text{if } A_i \geq 0,2729 \\ Non_PRTA, \text{if } A_i < 0,2729 \end{cases}$	$\begin{cases} PRTA, \text{if } A_i \geq 0,2886 \\ Non_PRTA, \text{if } A_i < 0,2886 \end{cases}$
WP	$\begin{cases} PRTA, \text{if } S_i \geq 0,2367 \\ Non_PRTA, \text{if } S_i < 0,2367 \end{cases}$	$\begin{cases} PRTA, \text{if } S_i \geq 0,2579 \\ Non_PRTA, \text{if } S_i < 0,2579 \end{cases}$
SAW	$\begin{cases} PRTA, \text{if } V_i \geq 0,5753 \\ Non_PRTA, \text{if } V_i < 0,5753 \end{cases}$	$\begin{cases} PRTA, \text{if } V_i \geq 0,6037 \\ Non_PRTA, \text{if } V_i < 0,6037 \end{cases}$
WPM	$\begin{cases} PRTA, \text{if } V_i \geq 0,0060 \\ Non_PRTA, \text{if } V_i < 0,0060 \end{cases}$	$\begin{cases} PRTA, \text{if } V_i \geq 0,0055 \\ Non_PRTA, \text{if } V_i < 0,0055 \end{cases}$
MAUT	$\begin{cases} PRTA, \text{if } V_x \geq 0,2886 \\ Non_PRTA, \text{if } V_x < 0,2886 \end{cases}$	$\begin{cases} PRTA, \text{if } V_x \geq 0,4723 \\ Non_PRTA, \text{if } V_x < 0,4723 \end{cases}$
TOPSIS	$\begin{cases} PRTA, \text{if } V_i \geq 0,4073 \\ Non_PRTA, \text{if } V_i < 0,4073 \end{cases}$	$\begin{cases} PRTA, \text{if } V_i \geq 0,4157 \\ Non_PRTA, \text{if } V_i < 0,4157 \end{cases}$
AHP	$\begin{cases} PRTA, \text{if } CR \geq 0,00229 \\ Non_PRTA, \text{if } CR < 0,00229 \end{cases}$	$\begin{cases} PRTA, \text{if } CR \geq 0,000080 \\ Non_PRTA, \text{if } CR < 0,000080 \end{cases}$

C. Model Performance Evaluation

The MCDM spatial analysis model was developed to assist the decision-making process by selecting alternatives in the multi-class classification [52][72]. The steps in the MCDM model are to determine the multicriteria parameter that will be an alternative to the multi-class classification, to describe the quantitative data requirements that will be processed to have an impact on the alternatives of the multi-class being processed, then to process the numerical values on the

qualitative data to determine the rating on each of the multicriteria parameters.

Table VI results from multicriteria evaluation techniques using a confusion matrix based on the process in section III sub-section I. The accuracy values in the experimental test of arterial road type data using the WSM and TOPSIS methods were 63% superior to other methods, followed by the MAUT, SAW, WP, and WPM methods, and the AHP method, namely 59%, 58%, 54%, 43%, respectively. However, the AHP method is superior in the collector road type experiment with an accuracy value of 70%, followed by the TOPSIS and WSM, SAW, MAUT, WP, and WPM methods, namely 58%, 57%, 53%, 41%, respectively.

Fig. 3 is a sampling test of the spatial analysis results of accident-prone road classification using the WSM method on the North Rim Probolinggo arterial road type, Indonesia. Calculate the weight value for each multicriteria parameter using Flow in Fig. 2 with the results in Tables IV and V. Perform the calculation process based on section III subsection B, then obtain the value of the variable A_i is 0.3593, referring to Table VI, the road is included in the PRTA classification.

TABLE VI. THE MCDM MODEL PERFORMANCE

MCDM Models	Accuracy	F1-Score
Arterial Roads		
WSM	63%	54%
WP	54%	55%
SAW	58%	52%
WPM	54%	55%
MAUT	59%	53%
TOPSIS	63%	54%
AHP	43%	53%
Collector Roads		
WSM	58%	49%
WP	41%	45%
SAW	57%	48%
WPM	41%	45%
MAUT	53%	47%
TOPSIS	58%	49%
AHP	70%	47%

Fig. 3. Results of Spatial Analysis of Accident Prone Roads using the WSM Method on Arterial Road Types.

V. CONCLUSION AND FUTURE WORKS

This paper presents an empirical study to determine the ability of the MCDM model based on multi-criteria parameters that combine the weight values given by expert judgment and mathematical computation using the AHP method (EJ-AHP). MCDM model is a method that depends on the value of weights and the priority scale of parameter values that depends on expert judgment. Weight analysis on the MCDM model by combining EJ-AHP can bridge the difference between subjective and objective risks that are biased in the evaluation process for weights and parameter priority scales between expert judgments. The labeling results in this research can be used as a labeling basis for further research on the category of the private dataset types with small dataset scales in determining the category of PRTA or Non-PRTA classification based on multi-criteria parameters.

The parameter weight values generated in the EJ-AHP computation process will be used as the basis for the empirical study for the spatial analysis of the PRTA classification based on the MCDM model using a comparison of the WSM, WP, SAW, WPM, MAUT, TOPSIS, and AHP methods to measure the performance of the method. The performance evaluation results of this method will be used as a reference for whether or not a method is feasible to be developed further. The accuracy value in the whole process of the MCDM model performance is below 71% (Table VI), where each method produces a different rating value, and this concludes that a new alternative method can be applied to produce a high accuracy value. Therefore, it is essential to further research using machine learning (ML) by applying several alternative scenarios through performance tests on ML single classifier, ML parameter tuning, and ML hybrid ensemble learning to improve the performance of the resulting classification values.

Abstract—Constantly increasing political events and socially related changes have led governments worldwide to adopt strategies to reduce their negative effects on the cohesion of societies, which requires developing assessment frameworks that include realistic, measurable, and useful indicators for analyzing the family disintegration causes, taking into consideration the circumstances surrounding the countries and the development trends that they adopt. Therefore, this study aims to identify and prioritize indicators of a decision-making support framework for evaluation, ranking, and structural comparison of the family disintegration causes resulting from the child marriage phenomenon in Yemen. To achieve this, the Fuzzy Delphi Method was applied. Firstly, a set of related literature and theories were analyzed to extract the expected framework's suitable initial indicators. Then, with the participation of twenty-four local experts, the extracted factors were revised, and the most suitable factors were selected. As a result, one social factor out of nine social-health factors was excluded due to its inappropriateness, and a framework of eight indicators was built. Also, with a rating average of 0.727, it was consistently agreed that the indicator "Increasing divorce rates in marital cases that do not take place according to the common desire of the spouses" is the most important indicator. Also, with high consistent evaluation averages (0.652–0.658), all three health indicators were ranked in the second and third places, while the other four social indicators were ranked in the last three positions (fourth–sixth). Finally, the real applications of the proposed framework were recommended.

Keywords—Family disintegration; child marriage; early marriage; Fuzzy Delphi Method; multi-criteria decision making; Yemen

I. INTRODUCTION

The family system is considered one of the oldest social systems throughout history, and it plays an essential role in the raising and upbringing of children and in determining their orientations, tendencies, and desires within the framework of customs and traditions that link the members of each system together. At the same time, individuals of the same society's family systems are linked by numerous cohesive linkages and relationships that contribute to the creation and growth of socially cohesive societies and generations capable of working, giving, and creating. And in return, the disintegration of family bonds in any society prompts the emergence and development of many types of manifestations that hinder human energies from fulfilling their intended roles and contribute to pushing members to embrace negative behaviors towards their society, which could negatively impact the process of society's development [1]. Therefore, the family is an important part of the social system, and its cohesion has a significant impact on society's progress.

On the other hand, the family is also affected by the society to which it belongs, and its structures, practices, and events fluctuate with changing economic, social, and political conditions and events in it. Such transformations in today's world have a particular impact on the central functions of the family and can sometimes amount to a breach of its social role, which in turn contributes to an increase in antisocial behavior among juveniles, and the intentional or unintentional violations of their civil rights [2]. The persistence of such manifestations in societies often has negative consequences

and creates new barriers to achieving sustainable development in countries [3], particularly those with high rates of instability, economic hardships, conflicts, and wars, such as Yemen.

Within this context, during the last ten years, the Republic of Yemen has witnessed a lot of political events that eventually led to the deterioration of the sustainable development situation in Yemen, economically, socially, and environmentally [4]. Issues such as poverty, interruption of employee salaries in most government sectors, high and doubling prices of basic goods and services, the displacement of some families from areas experiencing conflicts and wars to relatively safe areas, and the loss of some families for their dependents, with women and children bearing the responsibilities and the brunt of the suffering, are but a few of the manifestations that Yemeni society is experiencing as a result of those events.

As a result of this tragic state of poverty, as well as other factors such as misunderstandings of religion, customs, and traditions, and a lack of awareness, the rate of early marriage for young girls has risen dramatically as one of the negative adaptive methods for survival, with the percentage of girls between the ages of ten and nineteen years marrying accounting for one-eighth of all girls' marriages. In any case, the early marriage phenomenon—as a negative phenomenon imposed on Yemeni society—has become a threat to the local family stability state. In this regard, studies [5] confirmed that it could negatively impact the compatibility between spouses, which constitutes the main element of family stability, not to mention that it is one of the main contributing factors to the high rates of conflict, negative conflict, violence, divorce, psychological cases, and the early death of underage wives [6], [7], [8], [9], which constitute the main causes of family disintegration at the local and international levels [4], [10], [11].

Research problem: Over the past decade, Yemen has been subjected to many political events, economic and cultural changes, causing an increase in the spread of the early marriage phenomenon, which has led to the emergence of risks and threats to the family stability of Yemeni society. This makes the local government responsible for taking objective and effective decisions that contribute to limiting the negative effects of this phenomenon on the life, welfare, and stability of Yemeni society by studying and analyzing the causes of family disintegration related to this phenomenon, prioritizing their treatments according to society's developmental circumstances and its development priorities, and conducting structural comparisons of these causes in different regions, in a manner that ensures optimum utilization and equitable distribution of available and limited resources and budgets. This cannot be practically realized without developing appropriate, realistic, and measurable local indicators through the active participation of a group of local experts.

Accordingly, this study aims to identify and arrange indicators of a local decision-making support framework evaluation, ranking, and structural comparison of the causes of

family disintegration resulting from the phenomenon of early marriage in the Republic of Yemen and through the participation of a group of Yemeni experts.

The remainder of this work is arranged in the following manner. The second section gives a quick summary of relevant sociological theories, their perspectives on family disintegration, and the causes and variables most directly linked to family breakup as a result of early marriage. The concepts and principles of Delphi techniques to enable multi-criteria group decision-making, as well as the proposed Fuzzy Delphi model for solving the problem, were discussed in the third section. In Section 4, the proposed assessment model, and the findings are presented, followed by a discussion, limitations of study, its applications, and future work, and conclusion in the last three parts.

II. RELATED WORK AND LITERATURE REVIEW

This section reviews the literature on the study's topic, including a basic background on the concept of early marriage, the concept and manifestations of family disintegration, key social theories about family disintegration, the factors of family disintegration most associated with the phenomenon of early marriage, and the MCDM tools chosen to solve the problem.

A. The Concept and Causes of Early Marriage in Yemen

The phenomenon of early marriage is particularly prevalent in Yemeni society, especially in rural areas. The causes of this phenomenon have been many. In economic terms, early marriage is an important economic factor for rural families. Yemeni rural families tend to marry their male children at an early age in order to join their children's wives in assisting them by doing the animal and agricultural work they practice as their main source of income. Let them have children early, and also contribute in the future to the same tasks. From another economic perspective, some Yemeni families agree to marry girls at an early age because they are unable to support them for reasons such as poverty, low family income, the death of one or both parents, or other reasons reviewed in the introduction. From a social and cultural standpoint, customs and traditions also play a role in the spread of this negative phenomenon. Males and females are married early for various reasons, such as protecting them from falling into vice, being subjected to violence or harassment, or preventing the spread of extrajudicial sexual relations, which is not accepted by some local cultures. In any case, local studies such as [4], and [7] provide more details about this phenomenon and can be consulted for more information.

From a procedural standpoint, this study defines early marriage as a legitimate marital relationship that begins at a young age for both sexes, or for one of them, and qualifies each other for self-reliance in respect of their obligations to the other, as well as their qualification to have and raise legitimate children born as a result of this relationship, with the early age of that relationship being determined for children under nineteen years of age.

B. The Concept of Family Disintegration and its Manifestations

The literature has reviewed a variety of definitions of family disintegration, which is defined as a situation that occurs as a result of the death of one or both parents [12], divorce [13], the abandonment of the family's head, polygamy, or the absence of the family's head for an extended period of time. Others refer to it as "family dispersion," which can occur as a result of polygamy, the death of one or both parents, or divorce [14]. It also includes residences that have been demolished as a result of a divorce, separation, or the death of one or both parents [15]. Family disintegration is a term used to describe the tension, rupture, or loss of control that occurs within a family system. The collapse of familial bonds and ties between family members, whether by divorce, abandonment, separation, or the loss of one or both parents, whether by death, jail, or otherwise due to particular socio-economic conditions [14], has the same meaning. The disruption of family functions, the collapse of family roles and structure as a result of early marriage, the resulting tension and ongoing family conflicts, or the weakness of family relations are the procedural definitions of family disintegration in this study.

C. Social Theories and Family Disintegration

Based on current and previous studies, the theoretical trends serve as a point of reference for determining the nature of the direction in which the contemporary family has evolved as a result of the social changes that have occurred. Previous family disintegration studies used a variety of theories to investigate the causes and effects of family breakup. This section examines family disintegration studies in the literature and discusses the implications of a number of significant theories, including functional constructivism, conflict theory, and symbolic interaction theory.

1) *Functional constructive theory*: According to this idea, family stability is accomplished by completing the social functions of the family, which include proper socialization, meeting fundamental life requirements, providing economic security, and reducing individual conflict. The belief that society is a system made up of a series of social subsystems that must be balanced and complimentary is central to proponents of functional constructionism [16].

The belief that society is a collection of regulated social systems, as well as the balance and complementarity of their components, is central to proponents of functional constructivism. The most essential aspect of this theory is that it analyzes family responsibilities and functions and emphasizes the family's valuable functions [17]. This indicates that any component of the family system whose functional role is broken, obstructed, or disrupted may eventually lead to dysfunction and family collapse. Therefore, early marriage may be a cause of family break-up if either spouse breaks up, fails to perform his or her functional role, or evades responsibility. According to the study [18], if this requirement is met, it is likely to result in increased psychological pressure on the spouses, or at least one of them, as well as a role

conflict, which can lead to acceptable practices such as multiple employment, or unethical or illegal practices to adapt to the new situation requiring each other's role, or to meet the personal or family needs that have been lost as a result. According to the researchers, this could lead to various forms of family disintegration, such as diversion and relocation of family members, particularly if the new means of adjustment require the obligation of caring for the family to be separated from its members.

2) *Conflict theory*: Conflict theorists argue that conflict is a continuous phenomenon that only ends with the demise of society and that conflict and the process of social change are thus inextricably linked [19]. But, since disagreements are inevitable in married life, may they be a source of family disintegration? According to the study [20], positive family differences can be seen as a means of obtaining rights and as a good way of improving the marital relationship, whereas negative conflicts lead to mismatch and dilution of marital relations, weakening the level of compatibility and harmony between spouses and eventually developing into situations of family disintegration. From this perspective, early marriage can be viewed as a cause of family disintegration if it results in negative conflicts, especially because there are many differences and conflicts associated with early marriages, often due to the selfishness and self-love of one or both of the immature spouses, the dysfunctional role of one of the spouses vis-à-vis the other or the children, or the difference in marital life reality from one or both of the immature spouses' expectations about rigor. According to numerous studies, the persistence of such negative conflicts has a negative impact on marital harmony and harmony situations and may eventually lead to family disintegration.

3) *Symbolic interaction theory*: According to this theory, the family plays an important role in preparing individuals for their future roles. The family's role is to instill in children a set of symbols, values, and standards. As a result, children can evaluate their actions and shape their future roles [7]. These symbols and meanings differ from family to family, and the individual first attempts to absorb the role expected of him before attempting to adapt a course based on his experiences and knowledge. The individual's daily interactions in his life, the circumstances surrounding his upbringing, and the foundation of symbols he learns from his family are among the most important factors influencing the construction of his personality [21]. According to this viewpoint, early marriage can be regarded as one of the causes of family disintegration in two cases: (1) if one or both spouses are unable to build a sufficient knowledge base that allows each of them to cope with married life and develop a common language with each other; or (2) if one or both spouses are unable to succeed in instilling sound educational values in their children, develop their feelings of love and loyalty to society, and develop their skills and abilities to interact with the members of society in a manner that enhances their integration and cohesion.

D. The Social Factors of Family Disintegration Related to Early Marriage

According to those points of view and based on studies on early marriage and previously analyzed theories, marriage requires a degree of love, desire, a sense of security, and the ability to properly raise and raise children, which can only be achieved in the case of so-called [19] cognitive readiness, which many boys and girls who marry early do not achieve. As a result, ignorance of marital life and adjustment requirements endangers marital peace and harmony (F1) and leads to family breakdown [20]. Furthermore, selfishness, selfishness, and the inability of some child couples to meet the requirements and duties of marriage and upbringing have caused family conflicts [22], which have sometimes escalated to the use of physical or verbal violence (F2), which is considered unacceptable in Yemeni society and is a major cause of divorce [8]. Authors in [9] goes on to say that the proper child rearing necessitates adequate knowledge of the foundations of sound socialization, health and psychology, and basic rules of care, and that one minor spouse's lack of such knowledge causes a dysfunctional role for the other or for the children [11] (F3), which can lead to family disintegration and disruption. On the other hand, that study [11] also, emphasized that the family was responsible for meeting the emotional needs of their sons and daughters, such as kindness, compassion, love, and justice, as well as releasing them from fear, anxiety, and anything else that might jeopardize their social and psychological well-being. According to the study, underage wives were found to be ineffective in this capacity [22]. Failure of minor spouses to fulfill their functional role in satisfying children's demand for family attachment (F4) is counterproductive, according to [19], resulting in emotions of alienation rather than feelings of family and community in children.

Locally, the study [23] indicates the existence of an expulsion relationship between early marriage and divorce, in which some minor spouses are subject to their guardians' desire to marry and choose the other partner, which causes a situation of incompatibility between the spouses, sometimes leading to separation (F5). Also, there have been a few instances when young children have been paired with adult females for various social reasons. Regardless of the reasons or motives, the age gap between them plays a crucial role in the incompatibility and harmony between the couples. In some of these circumstances, however, repeated marriages while keeping the first wife is a socially acceptable approach. Multiple marriages with the abandonment of the first wife (F6), on the other hand, is a bad outcome.

E. Health Factors of Family Disintegration and their Relationship to Early Marriage

Pregnancy and childbirth, in terms of health, are a substantial risk to the lives of teenage mothers [11] and can result in death, which is considered a cause of family breakdown. Some early marriages result in "early pregnancy," which leads to an increase in the number of underage mothers dying during childbirth (F7), has a negative impact on the mother's health, and even causes a variety of disorders (F8). In this context, the survey found [23] that two-thirds of Yemeni

moms had their babies aborted during their first trimester in 2008. According to the same survey, underage wives accounted for 19% of all moms who died during childbirth.

Psychologically, one of the minor spouses' incapacity to fulfill his functional role toward the other or to meet the needs of the children, as well as the consequent negative confrontations, leads to the escalation of psychological problems (F9) [20], [24].

III. METHODOLOGY

A. The Fuzzy Delphi Method

At the beginning of the sixties of the last century, the Delphi method was developed by two world scientists, "Olaf Helmer and Norman Dalkey" [25]. It is considered not only one of the most widely used and reliable surveying and expert judgment collection methods [26], [27], but one of the most widespread methods for solving numerous group decision-making problems by selecting and/or ranking factors, criteria, questionnaire elements, or measuring index elements [28]. Among the most prominent features of this method are that responses collected during its implementation remain uncharted and unknown, rely on a conditional phased statistical processing operation, and on countable, limited, and repeated processes that are managed and controlled by a phased outcome-based feedback operation. Besides, its outputs constitute consistent, revised, and collective statistical scores. Moreover, it is also characterized by the ability to address qualitative nature-based problems by relying on multiple survey rounds, which helps researchers in formulating additional quantitative survey rounds and promoting consensus opinions and effective decisions. So, it has been widely used to obtain a sequential series of consistent and revised responses and answers through multiple-round expert-opinion-based surveys in a lot of multidisciplinary studies [26], [27], [28].

TABLE I. THE PRIMARY FAMILY DISINTEGRATION FACTORS MOST ASSOCIATED WITH THE EARLY MARRIAGE PHENOMENON

Type	Factor	Description
Social factors (SF)	F1	Weakness in marital harmony and compatibility.
	F2	Increasing the domestic violence rates
	F3	The imbalance of the spouses' roles towards each other and towards their children.
	F4	Parents' failure in the proper family upbringing of their children.
	F5	Increasing divorce rates in marital cases that do not take place according to the common desire of the spouses.
	F6	Increasing of abandonment cases as a result of the heterogeneity arising from the presence of large age differences between spouses.
Health Factors (HF)	F7	Increasing the death rate among underage mothers during childbirth.
	F8	Negatively impacts on the health status of mothers
	F9	Increasing the rates of psychological cases among underage wives

While the efficiency of this technique and the widespread use of it over time have been proven, the inappropriateness of its application for many group decision-making situations has also been proven [29], [30]. For instance, some of these scenarios are: (1) limited time and financial resources of researchers due to the multiplicity of rounds imposed by the phased outcomes of surveys, especially when the assessment processes are conducted in fuzzy environments by a large number of heterogeneous experts, which requires more survey rounds to reach an acceptable convergence level in experts' prediction values, causing an increase in effort and costs. (2) cases that necessitate the use of uncommon and time-sensitive experts. In such multi-round survey situations, a shortage in the number of experts in the advanced survey rounds or a loss of the phased assessment data of some of them could occur, which also negatively affects the quality of the results. Furthermore, (3) evaluation cases that occur in ambiguous environments where conducting the evaluation process quantitatively is practically impossible due to a clear and unified understanding of measuring level. Rather, experts are forced to express their opinions through qualitative measures, which often have different meanings, connotations, and interpretations. Because this strategy is unable to deal with such uncertainty, it may produce erroneous results, lowering the quality of final decisions.

In any case, the current study is characterized by the above three cases, which means that this technique in its traditional version is not suitable for use. In this regard, the fuzzy version of this method has been developed by [31], and its calculation procedures rely on fuzzy numbers and allow experts to express their opinions through them. It is also able to deal with the uncertainty problem on the one hand. On the other hand, it relies on a limited number of survey rounds, which contributes to reducing the costs, effort, and time of researchers and experts at the same time. It also enhances an expert's interest and desire for continuity, which contributes to raising the recovery rates of their questionnaires. It helps to enhance the completeness and consistency of opinions as it provides a mechanism to deal with non-consensus cases and obtain consensus in the opinions without subjecting the original opinions of experts to change, which also leads to more realistic and objective decisions.

B. FDM Implementation Procedures

Given that decision-making processes require a good study and analysis of decision requirements [32], [33], [34],[35] and the selection and application of the appropriate systematic tools to solve them [36], [37], [38],[39] and based on the recommendations of previous studies that have demonstrated the effectiveness of Fuzzy based techniques in general [40],[41] compared to traditional evaluation techniques [42],[43] and taking into account the efficiency of the Fuzzy version of the Delphi method, this study relied on this method to solve the study's problem and on the following implementation steps [30] [44] [45]:

Step 1: Determining the main areas of the factors to be evaluated according to the nature of the study.

Step 2: Reviewing pertinent theories and literature and suggesting significant factors for each main area.

Step 3: Developing the data collection tool, selecting the panel of experts, and gathering judgments of the decision group on each factor: Determine the assessment score of each factor's importance as presented by each of them through the application of a five-point Likert variable and convert the collected scores to their equivalent fuzzy numbers.

Step 4: Data Processing and Analysis:

Step 4-1: Calculating the average fuzzy rating scores of group decisions for each alternative factor.

As noted above, the evaluation process of the causes of family disintegration is usually accompanied by a case of ambiguity, which requires a conversion of the assessment data obtained using Likert's five-point evaluation scale into equivalent fuzzy numbers within a specific fuzzy logic set. In this regard, the literature provides many forms of those numbers, such as triangular and trapezoidal numbers. The fuzzy set in the subset of real numbers (X) is defined by a two-part combination, the first representing the "x" component, while the second reflects the degree to which that element belongs to the fuzzy set. A numerical membership function (MF) is used to determine whether an element belongs or does not belong to that fuzzy set, and its values are limited to the range [0,1]. The closer this value is to zero, the less the fact that the element belongs to the set, and the opposite is true, as the validity of that statement increases the closer the value of the function is to one.

Given that the personal opinions of experts about the appropriateness of a particular factor to be an indicator of a general domestic framework for measuring, ranking, and structured comparing of family disintegration causes associated with early marriage in the Republic of Yemen are relative and probabilistic and cannot be determined accurately and objectively, the use of MF functions constitutes an appropriate and acceptable solution to deal with this case of ambiguity. As shown in Table II, fuzzy numbers with relative values limited to the range [0,1] were used in this study to represent cases of ambiguity among respondents.

However, the analysis process requires calculating the average fuzzy rating scores of group decisions for each alternative factor. Assuming the assessment value of the appropriateness of No. "z" factor given by an expert No. "r" of a total number "n" experts is $\tilde{w}_{rz} = (a_{rz}, b_{rz}, c_{rz})$, $r = (1.2 \dots n)$, $z = (1.2 \dots m)$.

Then the average fuzzy number \tilde{w}_z of No. "z" factor is defined as [44], [45]:

$$\tilde{w}_z = (a_z, b_z, c_z) = \left(\frac{1}{n} \sum_{r=1}^n a_{rz}, \frac{1}{n} \sum_{r=1}^n b_{rz}, \frac{1}{n} \sum_{r=1}^n c_{rz} \right) \quad (1)$$

TABLE II. LIKERT AND FUZZY SCORING SCALES

Likert scale scoring	Linguistic variable	Fuzzy Scale scoring
1	Highly Not Agree	(0,0,0,0,2)
2	Not Agree	(0,0,0,2,0,4)
3	Moderately / Not sure	(0,2,0,4,0,6)
4	Agree	(0,4,0,6,0,8)
5	Highly Agree	(0,6,0,8,1,0)

Step 4-2: Defuzzification: convert the calculated average fuzzy rating score \widetilde{w}_z of each factor "z" to its equivalent crisp numbers.

In this study, the simple center of gravity approach was applied to defuzzify the aggregated fuzzy rating scores (D_z) of factors as follows.

$$D_z = \frac{(a_z \cdot b_z \cdot c_z)}{n} \quad (2)$$

Step 5: Examine the acceptability of the evaluation domain.

Step 5-1: For each factor "z", calculate the difference value (D_{rz}) between the average fuzzy number (\widetilde{w}_z), and each expert's fuzzy evaluation value (\widetilde{w}_{rz}) using equation 3.

$$D_{rz} = \sqrt{\frac{(a_z - a_{rz})^2 + (b_z - b_{rz})^2 + (c_z - c_{rz})^2}{3}} \quad (3)$$

Step 5-2: Determining the threshold value (Th_z) of each factor "z" by using equation 4.

$$Th_z = \frac{1}{n} \sum_{r=1}^n D_{rz} \quad (4)$$

Step 5-3: Testing the threshold value (Th_{domain}) of each evaluation domain by using equation 5.

$$Th_{domain} = \frac{1}{n} \sum_{z=1}^m Th_z \quad (5)$$

Based on the " Th_{domain} " value, the acceptability of the evaluation domain should be determined. In this study, an evaluation domain is accepted if $Th_{domain} \leq 0.02$.

Step 6: Testing the Expert Group Consensus:

Using equation 6, calculate the expert agreement on each evaluated factor.

$$EA_z = \frac{E_z}{n} \% \quad (6)$$

Where the " E_z " is the total number of experts, who's the distance between their fuzzy evaluation values (\widetilde{w}_{rz}) on a particular factor "z" and the average fuzzy number of all experts on that factor (\widetilde{w}_z) is ≤ 2 . Based on an expert's agreement value " EA_z ", the expert group consensus for each factor should be determined. In this study, an expert's agreement with a " $(EA_z) \geq 75\%$ " is used to screen out the expert group consensus for each factor. Factors with an expert consensus of less than 75% are ignored.

Step 6: Testing the final acceptability decision of each evaluation factor.

Once the evaluation domain is accepted and the list of factors with an acceptable expert consensus level is defined. The selected accepted factors should be analyzed based on the overall group evaluation crisp scores (D_z). These factors should be ranked, and the low-rated (low-ranked) factors should be discarding. In this study, the value of "0.4" was applied to describe the low-ranked factors.

C. Assessment Model of Study

Based on the previously described implantation stages of the Fuzzy Delphi Method, the assessment model for

developing the general framework's indicators to evaluate, analyze, and compare the family disintegration causes associated with the early marriage phenomenon in the Republic of Yemen was designed and applied. Fig. 1 describes it.

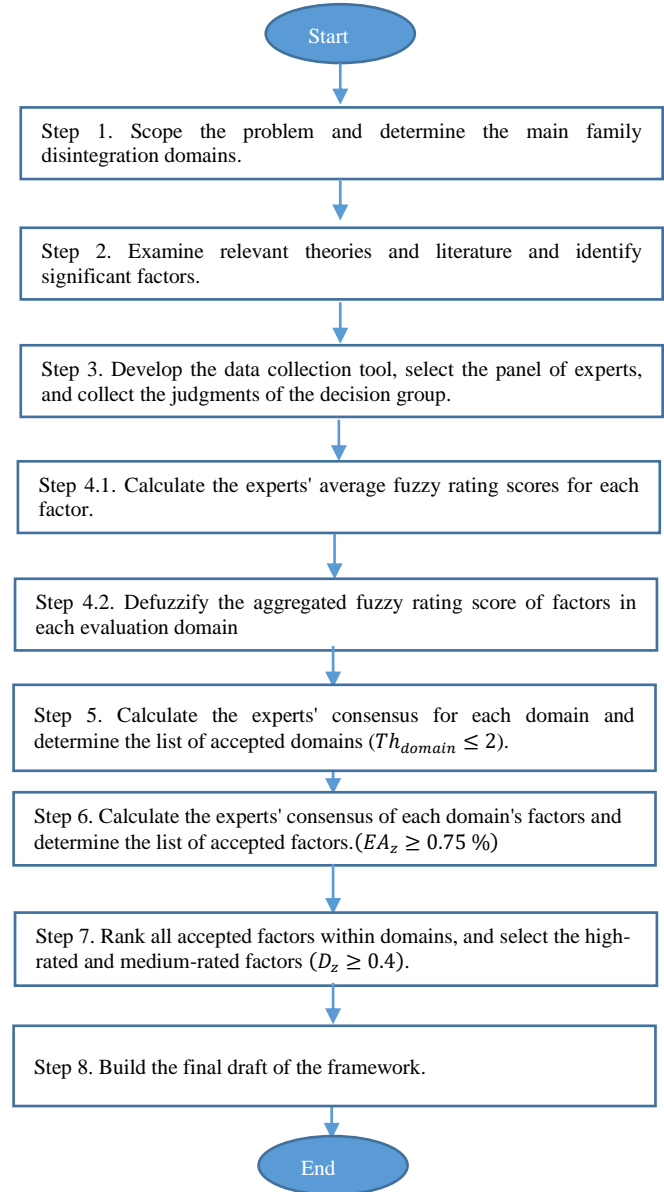

Fig. 1. The Assessment Model of Study.

IV. ASSESSMENT MODEL APPLICATION AND RESULTS

A. Scoping the Problem

The social and health domains of the family disintegration factors that are related to the phenomenon of family disintegration were chosen as the two main areas of factors to be identified and prioritized (refer to Section 1).

B. Reviewing Pertinent Theories and Literature and Suggest the Significant Factors

Nine major factors of family disintegration that are highly related to early marriage have been proposed, six of which are

social factors, and three others are health. These factors were proposed based on reviewing more than thirty relevant studies (refer to Section 2), accordingly, the primary family disintegration factors most associated with the early marriage phenomenon were crystallized, as shown in Table I.

C. Developing the Data Collection Tool, Selecting the Panel of Experts and Collecting Judgments of the Decision Group

This study followed the recommendations of previous studies on the application of FDM, whereby at least 10 experts must be selected in a purposeful manner that meets the requirements of homogeneity in order to participate in the evaluation [30], [44], [45]. To achieve the requirements of homogeneity, this study followed the recommendations of the study [30], and a total of twenty-four experts have been selected, all of whom are currently engaged in thematic work close to the topic of this study and have accumulated knowledge and experience for more than 10 years in a related domain. Depending on the specialization, they are equally split up into three directions: demography science, sociology, and health and psychological sciences. This study used an assessment tool (questionnaire) to collect data from experts. A number of 24 closed questionnaires were sent by e-mail to all experts, each questionnaire containing nine factors, and they were asked to indicate their level of agreement on the

appropriateness of these factors as indicators of a general domestic framework for measuring, ranking, and structured comparing of family disintegration associated with early marriage in the Republic of Yemen, using the five-point Likert scale (strongly disagree = (1), strongly agree = (5)). Subsequently, all questionnaires were also received by e-mail. After that, all ratings were converted to their equivalent fuzzy number scores using the conversion table proposed by [44] (see Table II). Table III illustrates the fuzzy ratings of all experts.

D. Data Processing and Analysis

For this purpose, a simulation program has been developed using the Excel 2013 application. Using that tool, the average fuzzy rating score of all experts (\widetilde{w}_{rz}) on each factor (z) was calculated (\widetilde{w}_z) and defuzzified (D_z) using equations (1) and (2), respectively.

These two rating score vectors are illustrated in Table IV. Subsequently, the experts' consensus of the two evaluation domains of study (Th_{domain}) was examined using equations (3), (4), and (5). Both domains were accepted ($Th_{domain} \leq 0.02$). After that, the experts' consensus on each evaluation factor was tested using equation (6). This step adopts factors with a threshold (EA_z) above or equal to 75%

TABLE III. EXPERTS' FUZZY RATING SCORES

TABLE IV. THE FUZZY AVERAGE EVALUATION SCORES (\bar{w}_z), AND THEIR EQUIVALENT DEFUZZIFIED (D_z) VALUES

Type	F	\bar{w}_z	D_z
SF	F1	(0.383,0.583,0.783)	0.58
	F2	(0.375,0.575,0.775)	0.57
	F3	(0.367,0.558,0.758)	0.56
	F4	(0.375,0.575,0.775)	0.57
	F5	(0.525,0.725,0.925)	0.72
	F6	(0.125,0.325,0.525)	0.32
HF	F7	(0.458,0.658,0.858)	0.58
	F8	(0.458,0.658,0.858)	0.57
	F9	(0.450,0.650,0.850)	0.56

As a result, all factors have been accepted at this stage. Then, factors were ranked in accordance with the defuzzified assessment values (D_z), and only the high-rated and medium-rated factors were selected.

The ranking step uses factors with a defuzzified value of 0.4 or above, and those factors with a defuzzified value of less than 0.4 are ignored. However, with an average group assessment rate of more than 0.4 and an average group evaluation consistency rate of more than 75%, eight out of all nine evaluated factors were agreed to be general local framework's indicators for measuring, ranking, and structured comparing of family disintegration associated with an early marriage phenomenon in the Republic of Yemen, while, with the an acceptable consistency rate ($EA_z=96\%$) and an average group assessment rate of ($D_z=0.325<=0.4$), the last social factor (the sixth factor) was agreed to be inappropriate for that.

Table V shows the obtained consistency ratios of the evaluation domains (Th_{domain}) and factors (EA_z), the defuzzified evaluation scores (D_z) and levels (EL) of each factor, the accepted and deleted factors (Status), and the ranking order of accepted factors (R).

TABLE V. EVALUATION RESULTS

Type	Th_{domain}	F	D_z	EL	EA_z	Status	R
SF	0.081	F1	0.58	Moderate	96%	ACCEPTED	4
		F2	0.57	Moderate	75%	ACCEPTED	5
		F3	0.56	Moderate	96%	ACCEPTED	6
		F4	0.57	Moderate	92%	ACCEPTED	5
		F5	0.72	high	96%	ACCEPTED	1
		F6	0.32	Low	96%	REJECTED	
HF	0.096	F7	0.66	high	92%	ACCEPTED	2
		F8	0.66	high	92%	ACCEPTED	2
		F9	0.65	high	100%	ACCEPTED	3

V. DISCUSSION OF RESULTS

As mentioned earlier, Yemen's political conditions and the associated social, health, and economic changes have caused

domestic instability in Yemen. However, putting in place the necessary measures, solutions, and treatments, and distributing resources and services that contribute to limiting their effects, requires carrying out many relevant studies and analyses. Some examples of these requirements are: evaluation processes for the causes of disintegration; classification, clustering, and ranking of causes in each sector according to the probability and impact of each of the causes; classification and clustering of geographical sectors according to the factor's influence level on them and according to their need for relevant solutions and treatments; and determining the percentage of what each sector needs compared to others. Weaknesses in one or several areas related to the factors of disintegration.

In any case, these processes, which we briefly refer to in this study as assessment, arrangement, classification, and regular comparison, can only bear fruit by building the correct assessment framework, which includes comprehensive and accurate measurement indicators. So, this study aimed to build a general local framework that can later be used as a main tool for the implementation of these processes in order to solve this problem.

However, this paper fulfilled the purpose of the study. And the general local framework's indicators for measuring, ranking, and structured comparing of family disintegration associated with the early marriage phenomenon in Yemen was built by getting the consensus of a group of local experts on the relevance of the theoretically predefined factors using the Fuzzy Delphi Method.

The findings disclosed in the current paper indicate the consistency of experts' opinions on all indicators. The consistency rates across those indicators are acceptable (greater than 75%). A small degree of discrepancy (not exceeding 3%) between the experts' consistency ratio averages on the health (95%) and social (92%) fields' indicators was observed. This confirms the accuracy and integrity of the theoretical procedures followed for theoretically extracting the initial indicators of study. It also confirms the accuracy of the methodological procedures used in selecting a homogeneous sample of experts [41], and the accuracy and objectivity of experts during the evaluation process.

However, the expert opinions' consistency on indicators does not mean that all of them are appropriate. For example, with an average evaluation rate of 0.33 and a very high consistency rate of 96%, experts unanimously agreed on the poor suitability of the sixth indicator, "Incrementing of abandonment cases as a result of heterogeneity arising from the presence of large age differences between spouses," which represents 11% of all initial indicators, to represent a measurement indicator of family disintegration resulting from the phenomenon of early marriage. And this can be explained by the fact that this indicator is more related to the phenomenon of polygamy than to the phenomenon of early marriage. According to [46], this case is related to wives who marry boys younger than them and with large age differences, where large age differences over time cause cases of polygamy, especially in light of the unequal relationship between them.

In addition, for various reasons, which may be economic or social, some of these cases may result in the husband preferring to live with the second wife and abandoning the first wife, which may sometimes lead to divorce [47]; So, the sixth social factor may be considered a cause of family disintegration, but it is not mainly related to early marriage but rather to the phenomenon of multiple marriage.

Regarding the accepted indicators, with the exception of the sixth social indicator, all preliminary social and health indicators were accepted.

With an evaluation average of 0.72, the fifth indicator, "Increasing divorce rates in marital cases that do not take place according to the common desire of the spouses," came in first place. And this may be due to the local prevalence rate of these marriage cases [18], on the one hand, and their negative social effects on the compatibility and homogeneity between spouses [48], and their causing dire social consequences that reduce the cohesion of local families [49], on the other hand.

On the health side, with an average group evaluation score of 0.66, the seventh and eighth indicators, "increase in the number of deaths of underage mothers during childbirth" and "impact on maternal health" came in second place, and with a very small difference (-0.008), the ninth indicator, "Increasing the rates of psychological cases among underage wives," came in third place, which indicates the importance of the health factors of early marriage and the extent to which they cause family disintegration. And this may be due to the negative health effects of child marriage [6] and the resulting dire social consequences that hinder the wife from playing her integrative role in society [23].

These findings also emphasize the magnitude of health problems associated with early marriage, such as mental illness, personality disorders, disorders in sexual relations, depression and anxiety, increasing rates of induced abortions, and increasing rates of childbirth [4]. According to the International Women's Health Coalition (IWHC), women married before the age of 15 are "five times more likely to die in childbirth than women in their 20s and face a higher risk of pregnancy-related injuries [4]. Also, these findings highlight the need to consider health factors during the relevant monitoring, evaluation, and planning processes.

Socially, the average evaluation degree of the accepted social indicators (0.603) was slightly and almost insignificantly lower than its equivalent for health indicators (0.656), which also highlights the importance of indicators of a social nature within the proposed framework. In addition, with relatively different evaluation averages swinging between 0.58 and 0.57, the first four social indicators were ranked in the fourth, fifth, sixth, and fifth positions, respectively. And this confirms that there are no significant differences in their importance among experts.

Based on the foregoing, with the exception of the sixth factor, the experts' assessments confirmed that all factors that were theoretically derived could be considered as appropriate indicators to measure the family disintegration associated with the child marriage phenomenon in Yemen, and that they could be practically used to measure the causes of disintegration in

different regions of Yemen. Also, previous local and global studies such as [40, 50,51] on the development of planning and resource allocation decision support systems have confirmed that evaluation frameworks are a key component of the evaluation, ranking, comparison, classification, and clustering models of the national planning and resource allocation decision support systems, which are used to determine the actual needs of the geographical sectors; arrange and classify sectors according to their needs; and arrange and classify the causes according to the level of their spread and impact and the percentage of needs needed for each sector in comparison with other sectors.

These studies also indicate that these systems effectively contribute to the optimal utilization of resources, the promotion of sustainability practices, and the requirements of justice and the equal allocation of resources to address them. Taking into account all these assumptions, the researchers in this study recommend that decision makers adopt the proposed framework as part of the national decision support system for family and social stability planning and resource allocation management.

VI. LIMITATIONS, APPLICATIONS AND FUTURE WORK

The study addressed the development of indicators within the general framework that could be applied in practice for other research purposes and examined only social and health indicators of family disintegration linked specifically to the phenomenon of early marriage in Yemen and ignored other types of indicators or factors, such as social and health indicators associated with polygamy or economic factors associated with family disintegration in general. Also, the indicators' ranking process has been carried out from the perspective of their suitability to measure the extent to which early marriage in Yemen generally causes family disintegration. In other words, priorities were not studied from the perspective of their impact level on the family disintegration state, nor from their relative importance as influential criteria according to certain developmental considerations.

Nevertheless, the proposed framework is fundamental and central to resolving many of the resolution's issues that this study has not been able to address. For example, to prioritize the proposed framework's domains and indicators as benchmarks from different experts' specialized perspectives and according to specific developmental considerations through the use of appropriate techniques such as AHP, F-AHP, BWM, or F-BWM; Conduct an analysis of the causal analysis between indicators, and to understand the different levels of impact results and the logical relationship that links them to each other, with the possibility of studying them from a general perspective, or from multiple specialized perspectives for decision experts through the application of appropriate techniques such as ANP, F-ANP, DEMATEL, or F-DEMATEL.

On the other hand, it could be used to assess and rank the causes of family disintegration in different Yemeni regions from the perspective of members of the community in those areas using a suitable hybrid technique that combines a subjective weighting method or/and objective weighting method with another ranking method such as TOPSIS or F-

TOPSIS; or to carry out structural comparative studies between those indicators in the different Yemeni governorates or areas to propose more effective solutions and treatments. This will help to promote the equity and investment of government resources and budgets on the one hand, and to attract institutions with different directions to implement their social responsibility practices in line with their directions on the other. Based on the foregoing, these applications will constitute the most prominent set of future research directions for researchers in this study.

VII. CONCLUSION

The problem of family disintegration associated with the phenomenon of early marriage is one of the most prominent local issues negatively affecting the stability, prosperity, and development of society. The planning and building of sustainable sound strategies to reduce the negative effects of this problem requires the building of integrated decision support systems, capable of assisting in the implementation of assessments, arrangement, classification, comparison, and other relevant planning functions commensurate with local conditions, environment, and priorities. Also, the effectiveness, quality, and functionality of such systems depend on the validity and efficiency of the evaluation tools used to collect the inputs of such systems, which in turn must include real indicators that have been identified in accordance with the relevant theoretical foundations and principles and through the real participation of experts and specialists, taking into account the requirements and variables imposed by the local environment.

To achieve that goal, the problem was first examined and described as a decision problem. This step was followed by the selection and analysis of a set of relevant literature and theories. At this stage, a total of six social and three health indicators were defined to form the initial social and health indicators of the study. Then, twenty-four local experts were surveyed through a questionnaire tool designed for this purpose. After that, the FDM methodology was applied to study and analyze experts' opinions on the appropriateness of developed indicators. Based on that, eight key final indicators of family disintegration were drawn to represent the main structure of the proposed framework.

By analyzing the study's findings, the following conclusions were reached: (1) Experts focused on the subject of divorce. They believe that divorce arising from cases where the spouses or one of them is forced to marry another without the full conviction or desire to associate with them, to satisfy the family or to fulfill their wishes, is the main indicator for measuring family disintegration in early marriages. (2) Experts focused heavily on the health criterion, with an average assessment of the indicators of this criterion of 0.656, possibly because their concerns were focused on the importance of women's safety and health, which is a key pillar of family stability. (3) Although the average evaluation of health domain indicators was higher than social, the difference was small and did not exceed 0.05, which also underscores the importance of this domain. (4) Experts pay almost equal attention to health indicators, and relatively different to social indicators. The value of the average standard deviation of the

health indicators assessment averages was (0.0028), and that value increased by almost twenty-one times for the social standard indicators (0.059). Despite that, the discrepancy in the importance of social indicators for the group of experts remains relative and ineffective.

In any case, this study reached one final output called the general framework for the evaluation of the family disintegration causes associated with the child marriage phenomenon in Yemen. This framework is characterized by specialization, systematic, and appropriateness, as it was built according to multiple social and health theories, with the participation of local experts who live, influence, and are affected by the surrounding environmental conditions and using a reliable and globally approved decision support technique in order to contribute to solving a specific problem, according to the Yemeni context. Also, it has many real applications, and it can be used as a major component of the assessment, ranking, comparison, classification, and clustering models of the national and social related planning and resource allocation decision support systems.

A Penetration Testing on Malaysia Popular e-Wallets and m-Banking Apps

Md Arif Hassan*, Zarina Shukur, Masnizah Mohd

Center for Cyber Security, Faculty of Information Technology
National University Malaysia (UKM), 43600 UKM, Bangi, Selangor, Malaysia

Abstract—e-Wallets and m-banking apps became more and more popular in the developed world, approaching a point of tipping. This can be due to the global use of big and small merchants of paying equipment and the ubiquity of e-wallet and m-banking apps adoption. Many consumers are using e-wallets and m-banking apps that can be an effective cybercrime option. e-Wallets and m-banking apps allow financial transactions via smartphones that give cybercriminals a lucrative opportunity. Mobile technology has become increasingly mainstream and continually strengthening, with the focus on mobile apps protection and forensic analysis developing. In this paper, the security aspect of five popular e-wallets in Malaysia were analyzed. This paper also provides a security analysis of another five leading m-banking apps. The security analysis is based on a security principle that is recommended by Open Web Application Security (OWASP) under Mobile Security Testing Guide (MSTG) and Mobile Security Threats (MST). The static analysis has been done by using three mobile application-testing tools. This study included a variation of vulnerability scanning, code review and, most significantly, penetration testing. Each app complied with the security requirement, but their security features and characteristics, such as encryption, security protocols, and app services, are different to each other. This study was carried out using a DELL computer with Intel Core i7 CPU, 3.40 GHz CPU, 6 GB RAM. Finally, the results revealed the secure e-wallet and m-banking apps among the selected apps.

Keywords—Electronic payments; e-wallet; m-banking; android; static analysis; security analysis

I. INTRODUCTION

Nowadays, the development of technology advances has brought one of the pioneers of innovation in financial institutions. With the development of Fintech worldwide, there will still be enough challenges for those interested in adopting the technology. As part of their everyday transaction payment choice, several countries have already introduced the use of electronic payments. The payment methods used by consumers have great impacts on the future of the financial system and the business model of a country. Mobile payment services are increasingly popular in the banking world and are capable of replacing cash and becoming the most popular platform in the coming years. Fintech developments have changed payment systems in Malaysia. Malaysia has taken seriously the development of cashless societies in particular. The Central Bank of Malaysia intends to migrate towards a new cashless sector, in alignment with its financial plan 2020, with the intention of increasing efficiency in the financial sector [1]. For current stage, the most commonly used cashless payment methods are credit cards/debit cards, internet banking and

cheques [2]. e-Wallet appears to be a new trend of mobile payment in recent years. In effort to enhance the use of e-wallet in Malaysia, the e-wallet users included in the Malaysia Budget 2020 are granted an RM30 reward [3]. e-Wallet is a modern age of technologies that easily recognizes consumer interest, making our transactions very convenient and efficient [4-5]. Security is among the most crucial factors influencing consumers' determination to use e-wallet apps [6-7]. Cybercrime is a challenge to mobile payment systems, and is obviously not the only concern, although many consider that it is the greatest challenge in the field of mobile privacy. Many e-wallet application developers are financially motivated, and as a result, it is common to overcome challenges quickly in order to save time and money. Cybercrime possibilities are becoming more challenging, hence humans want to share their understanding of certain ways hackers could interfere with e-wallet apps. Those who hope this point of view will help people realize how cyber criminals think, because if everyone know that, then users will continue to defend ourselves by securing certain points of attack.

In addition to the design of the e-wallet apps implementation, it is necessary to preserve the protection and privacy of user data in general [8]. A safety intelligence survey found [9] that 400 leading companies, 40% of them don't even scan their code for security flaws. Besides all these apps, mobile money applications effectively cover high-level private financial and sensitive information, where protection needs to be of the extreme significance as vulnerabilities or risks cannot be tolerated, as absolute protection is necessary. This paper studies e-wallet products associated with e-money issuers listed in National Bank of Malaysia websites, by focusing on its mobile payment feature. There are 42 e-money certificates has issued by Central Bank of Malaysia, including 5 banks and 37 non-banks [10] and [11]. Security in general has become an increasing concern currently, particularly with the evolution of mobile payments, and the almost daily vulnerabilities found in operating systems and applications are what makes it more challenging [12]. This study conduct a penetrating testing using three static analysis tools which is recommended by Open Web Application Security (OWASP). The recommendation of OWSAP related to three static tools are show in Table I.

TABLE I. STATIC TOOLS SECURITY PRINCIPLE

Tools	Security principle	Suggested by
MobSF	OWSAP	Mobile Testing Guide
MARA	OWSAP	Mobile Security Threats
AndroBugs	OWSAP	Mobile Testing Guide

*Corresponding Author.

In this study, our main contributions are as follows:

- We perform a static analysis among five e-wallet and m-banking apps, specifically on security issues targeted for Android applications.
- In order to detect repackaging threats, we evaluate successful solutions and recognize the vulnerabilities.
- We discover the most secure bank and non-banks mobile application among selected application using static analysis tools.

This paper is bifurcated into four sections. Introducing the payments and its related study, which is already discussed above. The second section presented the five bank and non-bank issuers in Malaysia and its association with e-wallet products. Section 3 discussed the proposed methodology of the analysis. Section 4 presented the experimental result of the methods and Section 5, provides the discussion of the findings and finally, the conclusion b presented in Section 6.

II. LITERATURE REVIEW

Electronic payment systems have risen in popularity in the last 20 years because of their significant contribution in modern electronic transactions. Electronic transactions are a financial exchange between buyers and sellers available on the internet [13]. The payment system electronically originally referred to as a payment process through an electronic network [14] which a user may use to make online payments for products and services [15]. Among electronic payment system nowadays, e-wallet and m banking is one of the most famous payment system. The definition and their functionality is described in the next subsection.

A. e-Wallet and m-Banking

e-Wallet is the new invention of finance technology that make our transaction and payment easy and fast. e-Wallet is a virtual storage system [16] that can capture your identity and digital credentials and offer to an electronic gadget or online service that pro-vides a person to commit electronic purchase [17-18]. The e-wallet includes two elements, namely software and information. The software holds all the information contained in a wallet that encrypts confidential personal data. In comparison, the data are all information, such as customer ID, card information and shopping addresses, provided by the customer. There are quite variety of e-wallet services established worldwide.

For the past several years, mobile banking has grown in popularity across many segments of society. M banking is a subcategory of electronic banking that combines both the basics of banking and the distinct features of mobile payment [19]. M banking refers to the delivery and use of banking and financial services using mobile communications de-vices [20]. The range of services available might include the ability to conduct bank and stock market transactions, manage accounts, and obtain personalized data. Mobile banking, often known as m banking, is a terminology for using a mobile device such as a phone to perform balance checks, account transactions, payments, and credit applications. It is the convenient, simple, secure, anytime and everywhere in the world. The functionality

of the apps for each bank and non-bank issuers is listed in Table II and Table III.

- App based system: Application settings are also important since they allow user to personalize the program to his own needs. This will feature profile, payment, and security options, among other things.
- Fingerprint: Fingerprint identification is one of the most well-known and used bio-metric technologies. The fingerprint biometrics is useful and cost effective. Moreover, it can be quickly installed and used under any environmental conditions.
- Bills: This is an important e-wallet function because today's consumers like to pay all of their bills online, including utilities, mortgages, loans, rent, and tuition, to mention a few. e-Wallets are becoming a vital aspect of daily life as digital cash becomes more prevalent, and they should be able to give an easy bill payment option, whether it is a prepaid or postpaid payment service.
- Transfer of money: Transfer money between the payer and payee wallets in seconds rather than hours or days. This function has many advantages, including the ability to make payments at any time and from any location, the ability to make funds available immediately, and the ability to manage personal and business funds.
- Payment history: Any registered member will be able to view all the transaction de-tails in these features. After a successful login, the customer will be able to check order history.
- User account: To carry out a transaction from e-wallet to another e-wallet, the customer must be a user account. The user has been using a registration form. In order to register, the user must fill out all the fields required in the form. The user can access a variety of services using their user account.
- Pin Code: A personal identification number (PIN) is an unique code that must be in-put in order to complete certain banking transactions with a mode of payment. The purpose of a personal identification number (PIN) is to increase the level of security in electronic transactions.
- Top-up: By using these features, users could access the multiple bank list for top-up money. In these features, users need to choose how much they want to update. User chose their favorite bank account whenever. The payment gateway is submitted to the recipient of the application directly. The features help to users to add their balance into their e-wallet.
- QR code: In-store payments can be made using e-wallets using contactless methods such as near-field communication and Quick Response (QR) codes. QR Code is a form of 2D bar codes [21]. The QR code may be readily scanned with a smartphone camera [22]. The barcode is read by the smartphone, which then launches an associated apps or website.

- Open loop: Open loop mobile payment systems allow customers to pay from a centralized e-wallet at many different places. It is easy to comprehend closed payments as a gift card and open payments as a credit card [23].
- Add Money: Add money is used only for the logged-in users. It is connected to a payment gateway. The user can add or choose their bank account before transaction. User can add money with their registered bank account details or debit/credit cards using this function.
- Request money: Anyone may send his or her friend or family member a message to ask him or her to pay his or her money.
- Withdraw money: Users can transfer cash from their account to their connected bank account through the withdraw money functionality. Users may digitally withdraw money from the wallet into any bank account without the inconvenience of paper bills or currency, such as receiving money from sources, collecting money from distributors, in-store or online payments from consumers, or collecting money from sources.
- Voucher: Marketers and merchants are fully aware of the value of coupons and re-rewards. e-Wallets are a great platform for providing these benefits to value customers in a timely manner. As a result, features that make it simple to create and manage coupons, discounts, tickets, and loyalty points are essential for an e-wallet solution and may help e-wallet software stand out in the market.

In the following Table, II and III means- the apps have the properties, whether 0 means the apps do not have the properties. 0 means the apps do not have the properties whether 1 means the apps have the properties.

Table II and Table III revealed e-wallet apps functionality by bank and non-bank issuer where, most of them have same features except Non-Bank5. It shows that there are common and additional properties of e-wallet apps. There are 10 common e-wallet apps functionality by bank and non-bank issuer. They are pin code, fingerprint, bills, transfer of money, top-up, and payment history, add money, and voucher, Request money, and Withdraw money. Each e-wallet playing its own role and position in electronic payment system, several e-wallets such as Non-Bank1, Non-Bank3, and Non-Bank4 focusing on withdraw money from ATM booth, while others focus on online transaction.

B. The Open Web Application Security Project

The OWASP is a non-profit organization that works to improve software security. OWASP relies on an 'open community' concept, that enables anyone to participate in and assist to projects, events, online forums, and other services. Every three years, OWASP identifies the 10 most critical web application security risk types. This "top ten" list shows an agreement on the most serious security problems. The following were the top ten vulnerabilities as reported in OWASP 2017 are:

- 1) A1—Injection (SQL, OS, and LDAP).
- 2) A2—Broken Authentication.
- 3) A3—Cross-Site Scripting (XSS).
- 4) A4— Sensitive Data Exposure.
- 5) A5—Security Misconfigurations.
- 6) A6—Sensitive Data Exposure.
- 7) A7— Broken Access Control.
- 8) A8— Using Components with Known Vulnerabilities.
- 9) A9— Insufficient Logging and Monitoring.
- 10) A10— Insecure Deserialization.

The Open Web Application Security Project guide must be followed in some circumstances while developing web applications. The details of each vulnerability report can be found in [24].

TABLE II. THE FUNCTIONALITY OF BANK ISSUER M-BANKING APPS

Properties	Bank1	Bank2	Bank3	Bank4	Bank5
App based system	1	1	1	1	1
Fingerprint	1	1	1	1	1
Bills	1	1	1	1	1
Transfer of money	1	1	1	1	1
Payment history	1	1	1	1	1
PIN code	1	1	1	1	1
User account needed	1	1	1	1	1
top-up	1	1	1	1	1
QR code	1	1	1	1	1
Open loop	1	1	1	1	1
Voucher	1	1	1	1	1
Request money	1	1	1	1	1
Add money	1	1	1	1	1
Withdraw money	1	1	1	1	1

TABLE III. THE FUNCTIONALITY OF NON-BANK ISSUER E-WALLET APPS

Properties	Non-Bank1	Non-Bank2	Non-Bank3	Non-Bank4	Non-Bank5
App based system	1	1	1	1	1
Fingerprint	1	0	1	1	0
Bills	1	1	1	1	1
Transfer of money	1	1	1	1	0
Payment history	1	1	1	1	1
PIN code	1	1	1	1	0
User account needed	1	1	1	1	1
top-up	1	1	1	1	0
QR code	1	1	1	1	1
Open loop	1	1	1	1	1
Voucher	1	1	1	1	1
Request money	1	1	1	1	0
Add money	1	1	1	1	1
Withdraw money	0	1	1	1	1

C. Android Platform

Android is an open source smartphone operating system that was originally developed by Android Inc. and then acquired by Google with financial support. The first beta edition of Android was launched in November 2007 and the first stable version 1.0 followed in September 2008. Android is the world's most used mobile operating system, dominating the smartphone industry with an 82.8 percent share in 2015 [11]. That is good reason for this paper to perform the study on Android by itself. With the rising number of providers, each with its own Android OS version, the Android environment has been massively decentralized in recent years, ensuring that each has possible different vulnerabilities on top of some android platform problems, which is the total contrast on the IOS side where Apple maintains that a more compact closed ecosystem is accessible. IOS, though, is still suffering from smartphone protection concerns, and the android suffering is even higher. In comparison, being an open source based on Linux, Android makes it even easier to deal with, because it is much easy and popular for Android to remove the source code, scan the files, and include vulnerable code in applications.

D. Static Analysis

We chose static analysis as our vulnerability measurement technique despite reported vulnerabilities for several reasons. Unlike human code review or penetration testing, which results in reported vulnerabilities, static analysis is a purpose, repeatable, and scalable method for evaluating vulnerabilities. Static analysis tools employ a certain algorithms and rule sets every time and may scan a project in hours rather than days or weeks. Vulnerabilities can remain latent in code for years before a researcher discovers and re-ports them, thus the number of reported vulnerabilities is likely to be underestimated by an unspecified amount. Using static analysis, we could investigate the evolution of an application's vulnerabilities details. The number of vulnerabilities we uncovered with our static analysis technique far exceeded the number disclosed for the group of applications. Vulnerabilities of the same type in the same application version must be combined into a single item because of the Common Vulnerabilities and Exposures (CVE) criteria, which explain some differences in performance. Fig. 1 depicts the vulnerability static analysis process.

Fig. 1. Static Analysis Process.

1) *MobSF basic static analysis tools*: Mobile Security Framework that is an automated pen-testing framework capable of performing static and dynamic analysis. The framework also includes REST APIs that enable developers to use continuous integration and continuous delivery (CI/CD) pipelines to test their apps automatically with each build.

MobSF v2.0 is open-source and written in Python 3.7. It is released under the GNU Public License v3.0. The study's installed version was a Docker container provided and maintained by the authors of MobSF. This simplified the installation process and allowed the service to be dismantled or rebuilt on demand. Users can interact with MobSF's graphical user interface by navigating to localhost: 8000 when the Docker container has successfully started up. The security analysis of MobSF is depends on the following properties:

- **Signer Certificate**: A signing certificate encrypts an app, ensuring that the code underlying it is protected and that no one is defrauded.
- **Application Permission**: In Mobile application, several permissions that are classified as dangerous or acceptable. Understanding which permissions can lead to further damage is critical from the perspective of a security analyst. For example, if an application has access to external media and stores essential information on the external media, the files stored on the external media are globally accessible and writable, which might be harmful. Android app permissions can give apps control of users phone.
- **Network Security**: Details on network security issues relating to the application can be found in the network security section. These flaws might lead to critical attacks like man in the middle attack.
- **Android API**: The Android operating system gives a framework API for apps to interface with the Android underlying system.
- **Browsable Activities**: Browsable Activities can control how the device should react when the user clicks on a link in the web browser.
- **Security Analysis**: Details about security issues relating to the application can be found in security. These problems can lead to critical attacks. The security analysis is including Network Security, Manifest Analysis, Code Analysis, Binary Analysis, NIAP Analysis and File Analysis.
- **Manifest Analysis**: Manifest Analysis may extract a variety of data from an Android manifest file, such as which activities are exported, if the app is debug gable, data schemas.
- **Code analysis**: The code analysis part of the MobSF tool is one of the more interesting aspects. MobSF has analyses, evaluated parts of the application's behavior using industry security standard practices such as OWASP Mobile Security Testing Guide (MSTG), and mapped the vulnerabilities using OWASP Top 10. Furthermore, Common Weakness Enumeration and Common Vulnerability Scoring System scores (CVSS) are stated, which might be helpful in different analyst scenarios and make the development of reports a bit more straightforward for developers and analysts.

- **Malware Analysis:** Malware analysis is the domain malware check. MobSF extracts the hard-coding or application-using URLs/IP addresses, presents the malware status, and uses the ip2location to indicate its Geo location. APKiD is used to identify different packers, compilers, and hypocrites.
- **Reconnaissance:** Reconnaissance is used to identify the applications URLs, firebase DB, emails, trackers, and string and hard-coded secrets. This is all done using the decompiled source code.
- **Components:** Components are used to identify the details information regarding activities services. This summarizes the android APK skeleton. The components are including Activities, Services, Receivers, Providers, Libraries and Files.

In contrast to traditional desktop and web apps, mobile applications have unique security challenges. With mobile app security, the MobSF tool is widely employed. According to MobSFs, security score, CVSS and trackers' detection determine the outcome.

- **Security Score:** Security scoring is one of the important features to calculate the overall result. This security scoring is based on, if it introduced an issue to an app that already has higher average CVSS than that issue, app would actually have higher score than before even though it now has more issues. The developer improves the tool's security score. Since the average CVSS score is used, an app with one major issue and several minor ones may score higher than one with only one major issue [25]. Currently, app score is calculated as:

$$\text{avg_cvss} = \text{round}(\text{sum}(\text{cvss_scores}) / \text{len}(\text{cvss_scores}), 1)$$

$$\text{app_score} = \text{int}((10 - \text{avg_cvss}) * 10)$$

- **CVSS:** The CVSS score can be utilized to determine the severity of vulnerabilities found in apps. The CVSS Calculator can be used to calculate the CVSS score. The formulas given in the CVSS specification are used in the calculation [26]. The CVSS Metric Values are shown in Table IV. The details CVSS scores provided by MobSF can be seen in supplementary file (Table I-III) [26-27].
- **Tracker Detection:** Each app may make use of third-party trackers. MobSF analyses the detected tracker in the system's APK using the open source Exodus-Privacy web tool. Tracker analysis can be found in two ways, such as crash reporters and analytics. Crash reporters are those that look into crashes that happen when the program is running normally. Alongside, analytics tracker collects information on how users interact with the app, such as how much time they spend in it, which features they utilize [28].

2) *Reverse engineering:* The method of extracting technology or design information from something man-made is known as reverse engineering [29-30]. The theory behind, it has for centuries been understood that destroying something would help you understand it, evaluate it and even twist it to

achieve another task. In the computer security industry, reverse engineering is commonly used to analyze and exploit viruses and malware, vulnerability detection, binary code auditing, and development [30-31]. In this paper, reverse engineering was introduced after automated security tested as a second part of the static vulnerability analysis.

Reverse engineering is in particular used to see how engineers have constructed this specific system and how they perform essential protective activities and specifications [32]. These are some examples of what we can look for in Android security tests while using reverse engineering: database link, DB name, or DB password, certain hard-coded usernames or passwords that is used to accessing the database [33]. The application's APIs to see whether any of them are compromised, or the API key, and to check for a known vulnerable method after downloading the source code. This section will discuss the tools used in Reverse Engineering, and then the procedure followed to identify vulnerabilities in the selected applications, and will finally go over the results obtained from reverse engineering. During the reverse engineering, the method was initially focused exclusively on the Mobile Reverse Engineering & Analysis framework (MARA) which takes an APK file and delivers the source code in a language that is easily understood in Smali. Fig. 2 indicates the process that follows an application for reverse engineering.

TABLE IV. CVSS METRIC VALUES

No	Metric	Metric Value	Description
1	Attack Vector	Network Adjacent Network Local Physical	The attack vector defines the circumstance in which a vulnerability can be exposed.
2	Attack Complexity	Low High	This metric specifies the conditions that must exist outside the attacker's control in order to exploit the vulnerability. Depends on the situation, unique conditions that need a measurable amount of preparation or execution are necessary for the exploitation of the vulnerability, the metric's score might be low (L) or high (H).
3	Privilege Required	None Low High	The level of privilege necessary to exploit the vulnerability is defined by this metric. Its value is None (N) if the attacker does not need any permission; Low (L) if the attacker just needs basic privileges to change user-owned settings and files; or High (H) if the attacker needs major privileges to affect component-wide configurations and files.
4	User Interaction	None Required	This metric can have the values None (N) or Required (R) depending on whether the vulnerability is exploited with or without user participation.
5	ImpactConf, ImpactInteg, ImpactAvail	High Low None	This metric are refer to the Confidentiality Impact, integrity and availability impact.

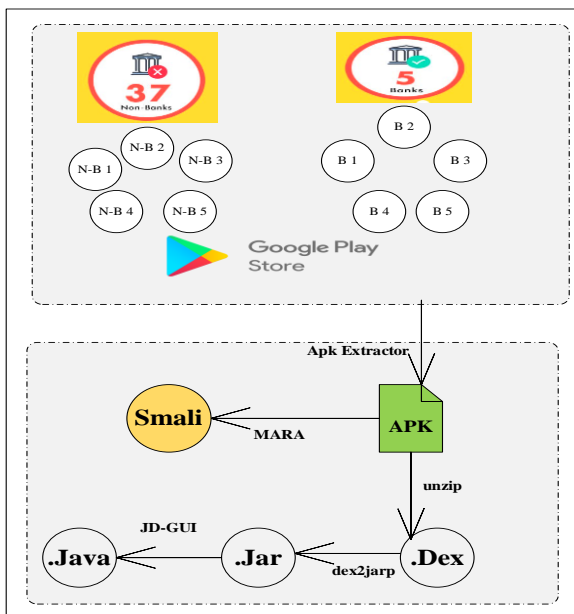

Fig. 2. Reverse Engineering Process [29].

The Mobile Application Reverse Engineering and Analysis (MARA) framework was the technology utilized to execute penetration testing. MARA brings together commonly used reverse engineering and analysis tools for mobile applications to test mobile apps against OWASP mobile security threats and vulnerabilities. MARA is a bash script that combines several prominent android reverse engineering and vulnerability analysis tools everything into solution. The goal was to make the workflow easy to utilize for security researchers and developers. MARA can do dynamic and static analysis requiring no additional post-installation configuration. MARA does not have a graphical user interface; it was created only for terminals. Most of the sub-tools are developed in various Python versions. MARA is evaluated based on six security attributes, which are APK Reverse Engineering, APK Deobfuscation, APK Analysis, APK Manifest Analysis, Domain Analysis, and Security Analysis. Each of the following six security attributes can be found in details [34].

Critical, High, Medium, Low, Info, and Detection issue are the different levels of se-verity [35]. MARA reversed all the chosen applications and retrieved the complete source code. The reverse results obtained by checking the source code individually are provided in Section 4.

3) *Automotive testing*: This segment would present the automated security checks carried out in the chosen banking and non-bank payment methods, processes and outcomes. Automated protection testing is an essential part of the paper's static vulnerability review, which is valuable since it provides a summary of where vulnerabilities can be found in the application. This chapter starts with a summary on chosen tools, and then explains how they are used then shows the results of automatic safety monitoring. All the apps checked for AndroBugs security have received an initial description of where to check for vulnerabilities, while the findings presented by AndroBugs seemed to provide a clear

understanding of the system build and possible vulnerabilities in most instances.

In November 2015, Yu-Cheng Lin released the AndroBugs framework, an open source vulnerability scanner for Android apps. AndroBugs is a Python-based static analysis tool that analyzes for common vulnerabilities in Android apps, it also checks the code is missing best practices and checks dangerous shell commands [29]. AndroBugs seemed to provide a clear understanding of the system build and possible vulnerabilities in most instances. The details of calculated CVSS for AndroBugs can be seen in supplementary file (Table IV) [26]. The possible vulnerabilities can be found in all apps were the following:

- **Runtime Command**: This is because AndroBugs establish in the code a serious function "Runtime.getRuntime ().exec ("...")". This feature allows a user to enter the shell and then modify the commands within it.
- **Fragment Vulnerability**: Since AndroBugs found a 'Fragment' or 'ActionBarSherlock Fragment' in the software, which was vulnerable to Android before 4.4 on phones. Any intruder who runs a code capable of eroding the Android Sandbox, which means access to confidential information not accessible by the application, is vulnerable to using this application on an old Android device.
- **SSL Certificate Verification**: However, this application does not validate the SSL certificate validation, so it causes the self-signed Common Name (CN) certificates for Secure Sockets Layer (SSL) to be expired or to be unacceptable. This is undoubtedly a vital weakness, since it enables attackers to carry out Man in the middle (MITM) attacks.
- **SSL Implementation**: That ensures that such a self-defined application will accept all common names as "HOSTNAME VERIFIER." This allows any attacker with a valid certificate to carry out MITM attacks.
- **Implicit Service**: In other words, this application uses an implicit decision to conduct a service, which is dangerous, since the answering service is not identifiable and the user cannot see which service.
- **Web View Vulnerability**: This implies that AndroBugs find the "addJavaScriptInter-face" method in an application code, which a weakness that JavaScript may use in devices is running android before 4.2 to manage the application.
- **Android Manifest**: This shows that this app has high privileges for AndroBugs. An-droBugs find that the "Mount Unmount FileSystems" android permission is included in this program, which has not been justified as the permission authorization permits removable mounting and mounting of file systems and the Android developer website notes that the application is not used by third party applications. The application is not mounted.

- **Key Store Protection:** AndroBugs therefore find that this application does not adequately secure its Key Store because it appears that it uses byte array and SSL pinning using a hard-coded certificate information. The details of the reverse engineering process are mentioned in Section 2.4, respectively. The existing work and their finding is shown in Table V.

TABLE V. THE EXISTING WORK AND THEIR FINDING

Authors	Method	Country	Finding
Reaves et al. 2015 [39]	Manual analysis	USA	This article completed manual analysis on 7 Android m-banking apps. These apps were tested for SSL/TLS bugs, cryptography, and identity leakage and access control. The findings confirm that the majority of these apps fail to provide the protections needed by financial services.
Filiol and Irolla, 2015 [37]	Static and Dynamic analysis	France	This study executed static and dynamic analysis on 50 Android m-banking apps
Zheng et al. 2017 [38]	Repackaging Attack	Australia	This article examine common security attacks on mobile apps, whether they are performing preliminary tests to determine the effectiveness and complexity of mobile device security attacks using repackaging attacks to obtain victim information.
Chothia et al. 2017 [36]	TLS testing methods	UK	This article presents a security analysis of the 15 m-banking apps issued by leading UK banks. The primary goal was to find the bugs in these apps' TLS implementations.
Chanajitt et al. 2018	Forensic analysis	Thailand	This articles focus on seven Android m-banking apps in Thailand. Several of the applications examined do not perform root device identification, do not encrypted user data, or may be modified and installed as repackaged apps.
Bassolé et al. 2019 [40]	Vulnerability assessments	Africa	This article analyzed the vulnerability of mobile banking and payment applications on Android platforms. This article undertakes vulnerability assessments, allowing for a more informed analysis of the information security and privacy threats that African mobile banking and payment applications face. They specially evaluate login credentials and code vulnerability of these apps in particular to assess the risks of attacks connected to privacy and data confidentiality.
Yang et al. 2019 [41]	Comprehensive analysis	China	This article examines the existing third-party mobile payment ecosystem and identifies possible security concerns by doing an in-depth assessment against China, the world's largest mobile payment market. Aside from that, this

			article also uncovers seven incidences of security rule violations on the Android and IOS platforms.
Verderame et al. 2020 [45]	Static and Dynamic Analysis	Italy	This article describes a unique methodology based on a successful mix of static analysis, dynamic analysis, and machine learning techniques for determining whether a particular app either) has a Google Play privacy policy and ii) accesses privacy. This article also involves examining the compliance of third-party libraries that are incorporated in existing applications.
Majeti et al. 2021 [46]	Cryptographic primitives	India	This article looks at how cryptographic primitives are used in Indian mobile finance apps. They chose 36 apps from three distinct categories and evaluated the flaws separately.
Our study	Static analysis	Malaysia	To perform static analysis of 5 m-banking and non-bank e-wallet apps. The static analysis has been done by using three mobile application-testing tools that is recommended by OWASP.

III. METHODOLOGY OF PROPOSED STUDY

This section presents the methods, processes and results of the automated security tests on the applications pre-selected. The automated safety testing is part of the research paper static vulnerability analysis, with an overview of where vulnerabilities can be found. The analysis is important. This chapter starts with a briefing on selected the analysis tools, and then demonstrates the method and results of the automated security testing. Some of the previous study conducted static or dynamic analyzes among various country leading m-banking apps. The focus of this study is to analyze popular Malaysian e-wallet apps and m-banking apps to identify the security.

A. Information Gathering and Setup

Mobile testing tools can assist organizations in automating Android and iOS testing. The software for mobile application testing can minimize the time required for the test and the probability of human mistakes during testing. Varieties of technologies are available for testers to automate their test scripts nowadays. For the success of the objective, it is essential to choose the right path for particular apps. Various systems may have various risks. The key problem, for example, would be diversion of funds in a bank application.

For object testing, authors utilized a DELL machine with an Intel Core i7 CPU, 3.40 GHz CPU, and 6 GB RAM. The operating system is Windows 10 professional. A virtual machine has been installed name as VMware to create dual boot in the computer. The testing involved the process of first installing Kali Linux, Operating System (OS).

B. Analysis Process and Testing Object

Intruders do the test to evaluate if there are any flaws or weaknesses that can allow the penetration and exploitations during its operation [41]. The e-wallet applications for Android

Redmi 8 are executed to start research, to check if they are running without any error. The study included a variation of vulnerability scanning, code review and, most significantly, penetration testing. AndroBugs is used to automate security-testing tool, where MobSF, used for basic static analysis report. Finally, MARA tools used for reverse engineering checking. In checking mobile apps against the OWASP, MARA builds widely used reverse engineering and research techniques to test mobile applications [42].

The object contains e-wallet applications from leading and growing banks in Malaysia. The platform of Google Play Store, the official site for Android-based smartphone apps downloaded e-wallet applications on the mobile phone. The applications were then transmitted via a universal serial bus serial interface to the computer. A folder was then created with Malaysia e-wallet name, which was then dumped in the e-wallet APK for-mat. APK extension dumped on the desktop. All the selected applications have been security tested by Mobile Security Framework (MobSF), MARA and AndroBugs tool an immediate idea of where weaknesses might be found. The tools findings seem to provide a clear understanding of how the programs are designed and where it could lead to potential vulnerabilities. It was beneficial as a guide for static vulnerability analysis and to know where the weakness available. Fig. 3 shows the selected dataset of e-wallet programs with the analysis process.

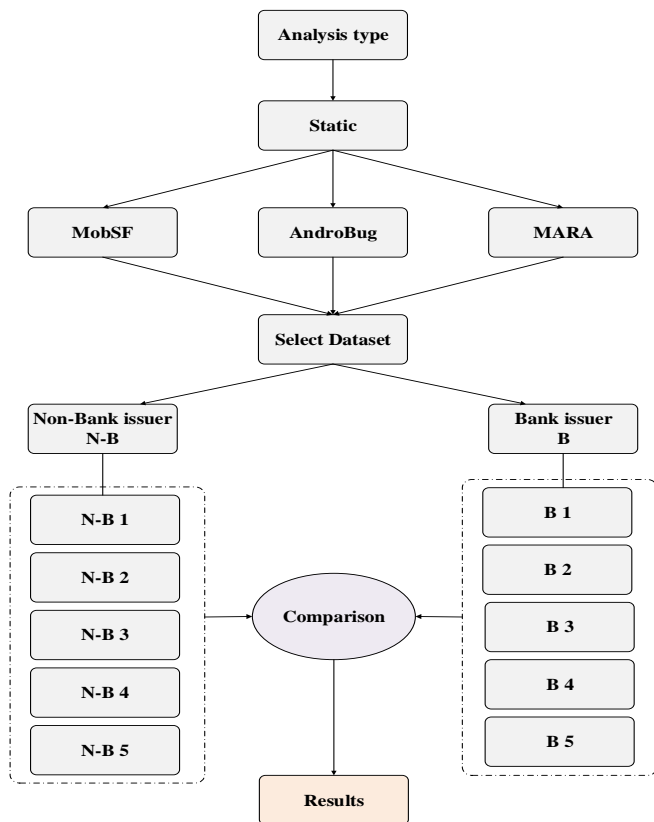

Fig. 3. Selected Testing Object for Analysis.

IV. ANALYSIS RESULT

After installation of the OS, updates and patches for the operating system were then installed from the Linux public repository to update the libraries that used as prerequisites for its installation and operation. The applications were then transferred to the computer via a universal serial bus data cable. The applications were then analyzed one by one tools and reports created and dumped in their respective application folders. The result of non-banks e-wallet apps using MobSF is showing Table VI.

Table VI shows the comparison result of select non-bank e-wallet apps. The analysis report is divided into three categories, such as security score, average Common Vulnerability Scoring System (CVSS) and tracker detection. The security score refers to the overall security results where the CVSS is an open framework for interactive the characteristics and severity of software vulnerabilities. Finally, tracker detection vulnerability checks and evaluates IT network and any device linked to it against thousands of Network Vulnerability Tests (NVTs) [43]. The most active security score in the analysis report is N-B4, which was observed 45 percent of the time, with an average CVSS of 7.0 and 8-tracker detection, which was the top security score APK. The second highest positions security score obtain from N-B3 with 40%, which CVSS rate average 6.4 with 6-tracker detection. From N-B1, N-B2 and N-B5, the same security score has been identified which 10% respectively. Nevertheless, in point of view their CVSS and tracker detection are not similar to their security score. The average CVSS of N-B1 and N-B2 are similar to 6.5 whether N-B5 is 6.9. The tracker detection rates are 6/323, 7/323, 3/323 and 2/323.

Table VII shows the comparison result of select bank issuer mobile apps. The most active security score in analysis report is, B2 with 85%, which average 7.5 CVSS with 0-tracker detection, which was the top security score APK. The second highest positions security score obtain from B1, B3, and B4, with same security score which 10% respectively. Nevertheless, in point of view their CVSS and tracker detection are not similar like their security score. The average CVSS of B1 with 6.7, B3 is 6.6, and B4 is 6.1. Whether the tracker detection rates are 2/319, 3/323, and 3/319. From B5 authors could not find the security score but except Average CVSS 6.8 and Trackers Detection 8/319, respectively. The result of banking apps using MobSF is shown in Table VII. The analysis report of non-banking e-wallet apps is shown in Table VIII.

TABLE VI. RESULT OF NON-BANKS E-WALLET APPS USING MOBSSF

Wallet name	Security Score	Average CVSS	Trackers Detection
N-B1	10/100	6.5	6/323
N-B2	10/100	6.5	7/323
N-B3	40/100	6.4	6/323
N-B4	45/100	7.0	8/323
N-B5	10/100	6.9	2/323

TABLE VII. RESULT OF BANKS APPS USING MOBSEF

Wallet name	Security Score	Average CVSS	Trackers Detection
B1	10/100	6.7	2/319
B2	85/100	7.5	0/319
B3	10/100	6.6	3/323
B4	10/100	6.1	3/319
B5	-	6.8	8/319

TABLE VIII. REPORT OF NON-BANKS APPS USING MARA

Wallet name	Critical	High	Medium	Low	Info	Detection Issue
N-B1	0	-	1	-	-	-
N-B2	0	-	1	-	-	-
N-B3	0	4	2	2	11	19
N-B4	0	6	1	2	11	20
N-B5	0	2	1	2	10	15

Table VIII shows each of the e-wallet application has 0 critical issues. From N-B4 with total 20 detection issues 6 high, 1 medium, 2 low and 11 info analysis report. In N-B3 total 19 detection issues has been collected where 4 high, 2 medium, 2 low and 11 info analysis report which the second highest. The third positions is N-B5 with total 15 detection issues where 2 high, 1 medium, 2 low and 10 info analysis report. N-B1 and N-B2 there is no critical issue but due to system trouble-shoot authors could not get the exact information of both wallet. The result of banking apps using MARA tool is shown in Table IX.

Table IX shows the comparison result of select bank issuer mobile Apps. Each of the banking application has 0 critical issues. From B1 total 19 detection is-sues has been collected where 4 high, 2 medium, 0 low and 11 info analysis report. From B3 and B5 collected a similar value total 17 detection issues where 3 high, 2 medium, 2 low and 10 info analysis report which the second highest, respectively. The third positions is B5 with a total 17 detection issues where 3 high, 2 medium, 2 low and 10 info analysis report. From B4 Apps there is no critical issue but due to system troubleshoot authors could not get the exact information. Finally, B1 has 0 critical issues with high threats, 2 medium and low threats along with 10 info are the most secure application compared to others. The result of banks and non-banks reports using MARA AndroBugs are shown in Table X and Table XI.

TABLE IX. REPORT OF BANKS APPS USING MARA

Wallet name	Critical	High	Medium	Low	Info	Detection Issue
B1	0	4	2	0	11	19
B2	0	0	2	0	6	8
B3	0	3	2	2	10	17
B4	-	-	-	-	-	-
B5	0	3	2	2	10	17

Table X and Table XI shows below, the comparison result of select bank and non-issuer mobile apps using AndroBugs. Each of the application has different kind of critical issue. The analysis report has been categorized into two part parts. From B4 with total 6 issues which is the most critical issue found in the bank issuer analysis report. From B1 and B5 authors collected similar value total 5 issues which the second highest, respectively. The third position is B3 with 3 issues.

TABLE X. RESULT OF BANKS REPORT USING ANDROBUGS

S/n	Properties	B1	B2	B3	B4	B5
1	Runtime Command Checking	No	No	No	No	Yes
2	Base64 String Encryption	No	No	No	No	No
3	SSL Security	No	No	No	No	No
4	Key Store	No	No	No	Yes	Yes
5	Implicit Intent	Yes	No	Yes	Yes	Yes
6	SSL Implementation Checking	Yes	No	No	Yes	No
7	SSL Connection Checking	Yes	No	Yes	No	Yes
8	SSL Certificate Verification Checking	No	No	No	Yes	No
9	<Web View>/Remote Code Execution	Yes	Yes	Yes	Yes	Yes
10	Fragment Vulnerability Checking	Yes	No	No	No	No
11	Android Manifest Critical Use Permission Checking	No	Yes	No	Yes	No

From B2 only single issues have been collected, which is the most secure using AndroBugs analysis. From non-bank, issuer author’s collected total 9 issues from N-B5 which is the most critical issue found in the analysis report. The second highest positions are N-B2, with total 7 issues. From N-B3 and N-B1, similar value has been collected which are total 3 issues respectively. From N-B4, only single issues have been collected, which is the most secure using AndroBugs analysis.

V. DISCUSSION

Mobile apps are growing increasingly, with more consumers being able to access different forms of Android applications availability of a wide range of open Android markets. However, mobile apps threats are developing especially targeted towards mission critical mobile bank applications [44]. This study first analyze five types of bank and nonbank issuer e-wallet products, and then focus on the vulnerabilities and security issues based on static analysis. We evaluate the flaws in protection, critical security, Average CVSS against Malaysian 5 banking and non-banking e-wallet products publicly available. In this section, will present and analyze the outcomes of a data set security evaluation.

TABLE XI. RESULT OF NON-BANKS REPORT USING ANDROBUGS

S/n	Properties	N-B1	N-B2	N-B3	N-B4	N-B5
1	Runtime Command Checking	No	Yes	No	No	Yes
2	Base64 String Encryption	No	Yes	No	No	Yes
3	SSL Security	No	No	No	No	Yes
4	Key Store	No	No	No	No	Yes
5	Implicit Intent	Yes	Yes	Yes	No	Yes
6	SSL Implementation Checking	No	No	No	No	Yes
7	SSL Connection Checking	Yes	Yes	Yes	No	Yes
8	SSL Certificate Verification Checking	No	Yes	No	No	Yes
9	<Web View>/Remote Code Execution	Yes	Yes	Yes	Yes	Yes
10	Fragment Vulnerability Checking	No	No	No	No	No
11	Android Manifest Critical Use Permission Checking	No	Yes	No	No	No

In Fig. 4 presents, the summary of MobSF results of the security tests performed on bank and non-banks e-wallet apps. The most active security score in the analysis report is N-B4, is 45%, which averages 7.0 Common Vulnerability Scoring System (CVSS) with 8-tracker detection, which was the top security score application.

It is clear from the results that N-B4 is quite secure related to the other applications. Table VIII presented the result of banks' apps using MobSF. The most active security score in the analysis report is B2, from which noticed 85%, which average 7.5 CVSS with 0-tracker detection, which was the top security score APK. After the analyzing of Table VIII, found that, N-B5 application have total 15 detection issues where 2 high, 1 medium, 2 low and 01 info analysis report which is quite secure related to the other applications is shown in Fig. 5(a) and Fig. 5(b) shown the high security banking where B3 and B5 are same result, respectively.

On the other hand, the low security low security apps of banking m-apps using MARA tool is B1, which is shown in Fig. 5 (b). Table IX shows the true seeing a report of banks' apps using MARA. Each of the banking application has 0 critical issues. However, the B3 and B5 have 0 critical issue with 3 high threats, 2 medium and low threats along 10 info and 27 detection issues which is the most secure application compared to others. Fig. 5(c) and (d) shown the low security bank and non-bank apps, respectively.

VI. CONCLUSION

Mobile payment applications are very convenient, but the problem is that most mobile payment apps are not exactly appropriate. Companies and developers would need to limit the addition of features and services demand and continue protecting the apps. However, as explained in this paper, it is quite an impossible task to protect the apps, although nothing is 100% secured, but developers at least might make it much more difficult for hackers. This paper covers a security assessment of five non-bank e-wallet apps and five leading banks apps in Malaysian market. The Authors performed a static analysis on three pen-extraction mobile application-testing tools and compared with the Android application among them. The analysis notice that every apps have followed the security standard, but their security features and properties are different in point of view of how their customer demand. Finally, the most secure e-wallet and m-banking apps according to the three different tools, based on their security metrics, have been identified which is not our opinion. This study aims to increase research efforts on the progress of e-wallets and m-banking in Malaysia.

ACKNOWLEDGMENT

This research was funded by the Malaysia Ministry of Education, Universiti Kebangsaan Malaysia, under grants, KKP 2020/UKM-UKM/4/3 and FRGS/1/2021/ICT02/UKM/02/1.

Demand Forecasting Model using Deep Learning Methods for Supply Chain Management 4.0

Loubna Terrada, Mohamed El Khaili, Hassan Ouajji
IESI Laboratory, ENSET Mohammedia
Hassan II University of Casablanca
Mohammedia, Morocco

Abstract—In the context of Supply Chain Management 4.0, costumers' demand forecasting has a crucial role within an industry in order to maintain the balance between the demand and supply, thus improve the decision making. Throughout the Supply Chain (SC), a large amount of data is generated. Artificial Intelligence (AI) can consume this data in order to allow each actor in the SC to gain in performance but also to better know and understand the customer. This study is carried out in order to improve the performance of the demand forecasting system of the SC based on Deep Learning methods, including Auto-Regressive Integrated Moving Average (ARIMA) and Long Short-Term Memory (LSTM) using historical transaction record of a company. The experimental results enable to select the most efficient method that could provide better accuracy than the tested methods.

Keywords—Supply chain management 4.0; demand forecasting; decision making; artificial intelligence; deep learning; Auto-Regressive Integrated Moving Average (ARIMA); Long Short-Term Memory (LSTM)

I. INTRODUCTION

Demand forecasting is one of the crucial challenges of demand planning in the Supply Chain Management that uses historical demands or sales data to predict future costumers' demands and support decision making [1]. It aims to enhance the logistics performance by optimizing stocks' value, minimizing costs and increasing sales to warrant the costumers' satisfaction [2].

The Smart Supply Chain or Supply Chain Management 4.0 (SCM 4.0) is a new paradigm introduced to solve this complexity by the integration of Artificial Intelligence (AI) [3]. AI has been implemented in several stages along the Supply Chain (SC) and showed a huge potential to impact the upstream or the downstream of the SC, to find smart solution to complex problems and deploy the massive amount of data generated at each stage [4].

Artificial Intelligence (AI) and Machine learning (ML) techniques are widely used in several fields. Deep learning (DL) is one of its most used methods, which is deployed mostly for time series problems, for instance: Urban Traffic Control [5], Production and Energy [6] [7], tasks scheduling and e-commerce [8], Smart Cities [9], Healthcare [10], Trading and Stock Price Predictions [11] [12].

The aim of our research emphasizes the role of AI in the Supply Chain by developing a smart demand forecasting

system based on Deep Learning methods to make the SC smart, collaborative and communicative [13].

Many studies have applied multiple types of Neural-Network models, such as Artificial Neural Networks (ANN) and Recurrent Neural Networks (RNN), in different areas, such as inventory management and distribution. However, few studies address the issue of demand forecasting in this context. At the same time, the current trend in methods for calculating forecasts, in many fields of activity, is towards Machine Learning approaches. They demonstrate that these models can dominate statistical methods such as linear regression and Auto-Regressive Integrated Moving Average (ARIMA). As statistical methods are theoretically linear models, they do not cope well with uncertainty and fluctuations in demand. However, few researchers use Long Short-Term Memory (LSTM) in demand forecasting [14] knowing that LSTM has shown relevant forecasting result in many fields.

This paper is structured as follows: Section II "Related work" incorporates demand forecasting of logistics and Supply Chain Management 4.0 in general, we also give an overview on the AI deployed in SCM field. In Section III, we describe the methodology adopted in our forecasting system, more precisely, the proposed models related to LSTM and ARIMA. In this part, we explain all the process and steps followed to define the proposed model. Section IV details an experiment with the proposed method used for comparison between LSTM and other Forecast time series method, such as, ARIMA. Then, we analyze and compare the results obtained in order to validate the most efficient DL method in terms of accuracy and performance. Finally, Section V, conclude the article with a brief overview on our future research perspectives.

II. RELATED WORK

A. Supply Chain Management 4.0: Outlooks

The SCM's principle is to ensure full cooperation and coordination between all the stockholders by developing consistent interactions, collaboration and coordination to achieve overall performance until the final customer [15]. The concept of Supply Chain emerged to warrant products' availability to customers by creating values throughout the whole process. Nevertheless, the SC has always been dealing with several issues such as uncertainty in forecasting and planning, as each stage in the SC requires a high-level accuracy in order to control inventory changes and to avoid

over-stocks and stock-outs. In the literature, this phenomenon is called "Bullwhip effect" [2]. The classic forecasting methods, implemented in many industries, have reached their limits. They are not able to deal with fluctuations in demand or take into account of the complexity of increasingly connected SC networks. Consequently, companies should migrate to intelligent systems and move towards a Smart Supply Chain Management.

According to the literature SCM 4.0 is defined as the interaction between advanced digital technologies and SCM, such as; Big Data, Artificial Intelligence, Cloud Computing, and Blockchain. Researchers have addressed the sustainability challenge through SCM4.0 and showed the impact of digital transformation technologies on SC sustainability to warrant better customers' experiences. Researchers proposed also a SCM4.0 Framework to define the main key topics of this field and the components for its development [3] as shown in Fig. 1.

B. Supply Chain Management 4.0: Challenges

SCM is facing many challenges, such as, demand forecast uncertainty. The latter has a significant effect on planning systems, uncertain demand leads to regular updating of system parameters and regular changing of targets [16]. It can be presented as the range in which the actual demand will continue. The forecast will very rarely be accurate. However, it gives a good idea of the actual demand. Thus, by adding this confidence interval to the forecast, we obtain more accurate information on the likely value of demands. This confidence interval will then be modelled on the product history in order to match reality as closely as possible. Moreover, this error is due to two effects: the quantity or the delay inconsistency. However, both cases have the same consequences: excess stock or shortage. In addition, these consequences can become even more serious when they are amplified by the "Bullwhip effect" [17]. This effect, illustrated in Fig. 2, describes the phenomenon whereby a small variation in demand at customer level will tend to increase throughout the Supply Chain, consequently, their operation inefficiency.

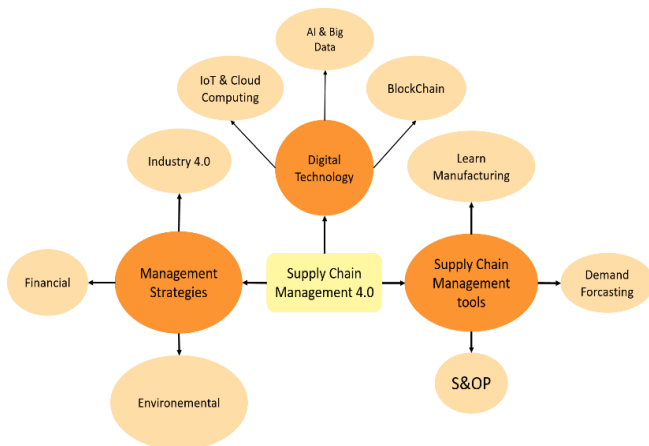

Fig. 1. Supply Chain Management 4.0 Framework.

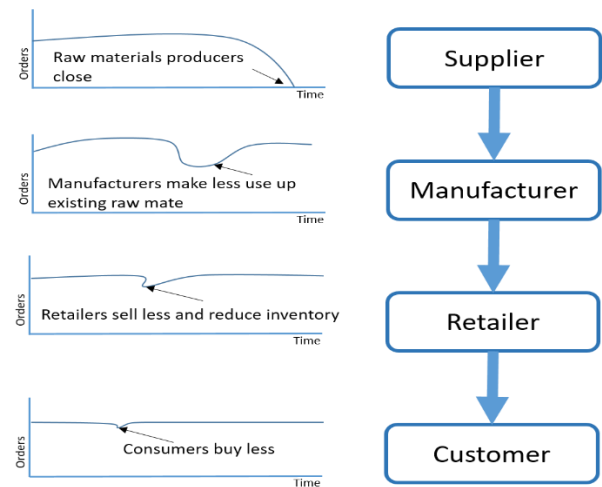

Fig. 2. Demand Distortion in the Supply Chain.

Thus, an intelligent demand forecasting system based on AI is the only solution to deal with the demand variation and then minimize the Bullwhip effect. This phenomenon is due to the Lead-time between the order and the delivery of goods, and Forecast changes that might occur. Each order has to adapt not only to fluctuations in demand during the current period, but also to changes in the level of predicted demand in the lead-time [18].

There are various AI methods used in demand prediction techniques in the literature. Deep Learning shows better performance and results in terms of forecasting comparing to other methods. Although the forecasting based only on the historical data of manufacturing demand is achievable, the accuracy of the prediction results is considerably lower than when taking into account multiple factors [19]. Researchers set up strategies of the exponential forecasting framework for sales forecasting in order to optimize manufacturing planning and inventory [20]. Therefore, our aim is to forecast future demands based on historical data coming from past manufacturer orders and retailers' demands based on customers' requirements, just enough time in advance to compensate for manufacturer Lead-times.

In the literature, researchers used several ML and DL methods to develop the accuracy of demand forecasting. Abbasimehr et al. used multi-layers LSTM method to compare with other time series forecasting methods, such as K-nearest neighbors (KNN), exponential smoothing (ETS), Auto-Regressive Integrated Moving Average (ARIMA), Support Vector Machines (SVM), Recurrent Neural Network (RNN), Artificial Neural Network (ANN) and Long-Short Term Memory (LSTM). The results of this study shows that LSTM method is more efficient compared to the tested methods with regards to performance measures [21]. Zixin et al. used LSTM, and Grey Model (GM) models in order to predict the future values based on historical data and the total industrial value. The Statistical Yearbook of GD was selected to represent the demand of the manufacturing industry. Other indicators are from this statistical yearbook from 2005 to 2020. The experiment shows that LSTM has excellent results in the previous comparative experiments. The GM model is the classic model in the field of Auto-regression. Nevertheless,

it does not give accurate results, which is significantly lower than the forecasting results given by LSTM considering multiple factors [19]. A study conducted by Raizada et al. is based on a comparative analysis of several Supervised Machine Learning algorithms, such as, Support Vector Machine (SVM), Random Forest Regression, K-NN Algorithm and Extra Tree Regression to build a forecasting model for future sales of 45 retail outlets of Walmart store in India. The study shows that that Extra Tree Regression Technique is the most efficient model to predict the sales for the selected dataset; however the predictions obtained from the algorithm may vary based on the variance in training data [22]. Jiaying et al. compared the performance of classical forecasting models and the latest developing forecasting technologies for perishable products and non-perishable items of a large grocery retailer. The Authors made a comparison in terms of performance and accuracy between many algorithms, such as: ARIMA, SVM, RNN and LSTM. The study shows that SVM, RNN and LSTM have a high predictive performance to for perishable products, whereas ARIMA is outstanding in the runtime and LSTM is the most efficient method to deal with non-perishable items due to its advanced prediction performance [23].

There are several ways to apply demand forecasting. In general, the forecasts fluctuations depends on the model used. Using multiple forecasting models could also highlight differences in forecasts. These differences may indicate the need for more research or better data input.

According to the findings, we assume that LSTM and ARIMA are the most efficient Deep Learning methods to warrant a high accuracy level for demand forecasting in the Supply Chain and to deal with its fluctuation to defeat the bullwhip effect.

III. PROPOSED METHODOLOGY

A. Conceptual Framework Description

This paper points out that existing research can provide a rich literature for demand forecasting models in manufacturing, to which we can refer for the selection of the prediction model in this research work.

Furthermore, although RNN algorithms are easier to fit complex non-linear relationships, their accuracy is inherently affected by many factors, such as: vanishing Gradient problem. Therefore, Long Short-Term Memory (LSTM) networks are suitable for demand forecasting in manufacturing, and they are the best to deal with vanishing Gradient problem. To verify the accuracy of the LSTM network, various prediction models are used as comparison models [24]. The selected methods will be used according to the SCM Business Process Model Notation (BPMN) [25] illustrated in Fig. 3. To build our generic model we referred to Supply Chain Operations Reference (SCOR) model and we used BPMN as a tool for modelling. We consider a SC BPM where each process is modelled by a separate pool and process chain as follows: Supplier, Manufacturer, Retailer and Customer. The interactions between the four Agents is managed and submitted to several flows and probabilities. The Agents cooperation, collaboration and coordination are

Crucial in the making-decision process, as efforts will only succeed if internal coordination, information exchange and material flow are effective.

B. Methods and Materials

In this sub-section, we give a brief description forecasting models used in our study.

1) *ARIMA*: Auto-Regressive Moving Average (ARIMA) models include three main procedures: Auto-Regression, Integration and Moving Average [26]. ARIMA can perform modeling of several kinds of time series. However, ARIMA’s limitation is that it assumes that the given time series is linear [21]. This model will be used in our study to be compared with LSTM to evaluate the efficiency of our proposed forecasting system.

In this process, the parameters of the Auto-Regressive Moving Average (ARIMA) model shown in Equation (1) are determined as (p) and (q) , respectively. An ARIMA model is defined as (p, d, q) .

- p : number of Auto-Regressive terms.
- d : degree of differencing.
- q : number of lagged forecast errors in the prediction equation (MA).

$$Y_t = \alpha_1 w_{t-1} + \alpha_2 w_{t-2} + \dots + \alpha_p w_{t-p} + \epsilon_t - \theta_1 \epsilon_{t-1} - \theta_2 \epsilon_{t-2} - \dots - \theta_q \epsilon_{t-q} \quad (1)$$

2) *LSTM*: Long-Short Time Memory (LSTM) method is gradient-based learning algorithm [24]. As illustrated in Fig. 4 [27]. The memory cell’s content is modeled by “Forget Gate”, “Input Gate” and “Output Gate”.

Fig. 3. SCM Business Model Process.

Fig. 4. LSTM Architecture.

LSTM Model notations are as follows:

- $x(t)$: represents the input value.
- $h(t-1)$: represents the output value at time t-1.
- $h(t)$: represents the output value at time t.
- $c(t-1)$: represents the cell state (memory) at time t-1.
- $c(t)$: represents the cell state (memory) at time t.
- $i(t)$: represents the Input Gate.
- $f(t)$: represents the Forget Gate.
- $o(t)$: represents the Output Gate.
- $W1$: represents $\{W_i, W_f, W_c, W_o\}$ weight matrixes.
- $W2$: represents $\{W_{ih}, W_{fh}, W_{ch}, W_{oh}\}$ the recurrent weights.
- b : represents $\{b_i, b_f, b_c, b_o\}$ biases for the gates.
- σ : represents the Sigmoid function.

Based on $x(t)$ and $h(t-1)$ the Forget Gate $f(t)$ can decide what information will be preserved in the cell state using as inputs using Sigmoid activation σ . The Input Gate $i(t)$ uses the input values $x(t)$ and $h(t-1)$ to compute the value of the cell $c(t)$. While the Output Gate $o(t)$ determines the output value $h(t)$ using $h(t-1)$, $x(t)$ and Sigmoid activation σ , whereas, \tanh activation function is used to compute the value of $c(t-1)$ and multiplies it to get $h(t-1)$.

The LSTM cell can be mathematically modelled as follows:

$$i(t) = \sigma(W_{ih} h_{t-1} + W_i x(t) + b_i) \quad (2)$$

$$f(t) = \sigma(W_{fh} h_{t-1} + W_f x(t) + b_f) \quad (3)$$

$$c(t) = f_i \cdot c_{t-1} + i_t \tanh(W_c x(t) + W_{ch} h(t-1) + b_c) \quad (4)$$

$$o(t) = \sigma(W_{oh} h_{t-1} + W_o x(t) + b_o) \quad (5)$$

$$h(t) = o(t) \cdot \tanh(c(t)) \quad (6)$$

Such that \tanh and σ are activation functions. By the evoked iteration and Compute the LSTM output using Equation (2)–(6), with the $x(t)$ Input, the model can compute the future value of the Output $o(t)$.

C. Research Framework

The aim of our research is to select an accurate model for demand forecasting based on the selected Dataset. We deploy the evoked DL methods to select the best time series forecasting model to deal with demand forecasting issues and uncertainty. The proposed methodology is summarized in Fig. 5. The flowchart emphasizes the main steps of our method from the Data collection up to the Output predicted value.

The five main steps of our methodology are detailed in the following sub-sections.

1) *Data collection and pre-processing*: In this research, we use a dataset from Kaggle's competition (<https://www.kaggle.com/code/devswaroop/forecastproductsdemand/data>) which is suits our proposed generic model. Data collection is a crucial step because the quality and volume of data. It's a success factor of the predictive system. In this case, the data used in this study will be the risk factors of Supply Chain components. This will yield us a table of different Features. The more data we collect, the more accuracy we can get while avoiding over-fitting effect [28].

The inputs selection should be in concordance with the system's objective and problem that we need to solve. In our study, we aim to implement a LSTM based forecasting system to predict demand quantities of a specific product based on past values and compare them with the results obtained through ARIMA. The dataset used in our experiment contains demand quantities of several products from 2011 to 2017. Consequently, the neural network's output is the estimated demand and the previous demand quantities with the month' classification implemented as inputs in the input layer. We load our data into a suitable place for pre-processing before using it on our DL models (see Table I).

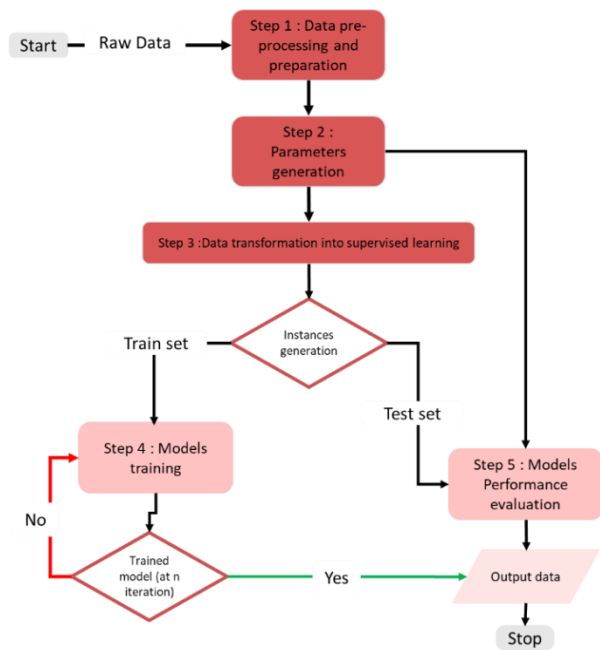

Fig. 5. Our Proposed Methodology Flowchart.

TABLE I. DATASET SAMPLE DEPLOYED DURING EXPERIMENTATIONS

Quantity per Month	Inputs				Output	
	Demand				Warehouse	Demand
Product Category	X1	X2	X3	Xm	Average	Y
Product1	X ¹ ₁	X ¹ ₂	X ¹ ₃	X ¹ _m	Whse_J	Y ₁
Product2	X ² ₁	X ² ₂	X ² ₃	X ² _m		Y ₂
Product3	X ³ ₁	X ³ ₂	X ³ ₃	X ³ _m	Whse_S	Y ₃
Product4	X ⁴ ₁	X ⁴ ₂	X ⁴ ₃	X ⁴ _m		Y ₄
Product5	X ⁵ ₁	X ⁵ ₂	X ⁵ ₃	X ⁵ _m	Whse_C	Y ₅
Product6	X ⁶ ₁	X ⁶ ₂	X ⁶ ₃	X ⁶ _m	Whse_A	Y ₆
Product _n	X ⁿ ₁	X ⁿ ₂	X ⁿ ₃	X ⁿ _m		Y _m

We split the dataset into two subsets: training set (80%) and Test set (20%). Since the dataset was monthly demand data, 1-month-ahead (one-step-ahead), forecasting was performed. Fig. 6 illustrates the time-series evolution of product demand per month.

To prepare the dataset for the training model, we followed the following steps for missing value processing and convert the original data days into months:

- Remove the missing value: remove lines of missing values from the analysis sample.
- Average interpolation: observe the average instead of the missing values.
- High frequency data: refers to time-series data collected at an extremely fine scale. It could be accurately collected at an efficient rate for analysis.

Fig. 6. Order Demand Evolution from 2011 to 2017.

Fig. 7 illustrates the volume of demand for each product category after data cleaning and removing the outliers.

Fig. 7. Demand Volume per Product Category.

2) *Evaluation criteria:* To measure the performance of the proposed method, we used Mean Squared Error (MSE), Root Mean Square Error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE) The LSTM and ARIMA were implemented and trained using Scikit-learn package and Keras in Python. For evaluation, we use MSE, RMSE, MAE and MAPE models defined as follows:

$$MSE = \frac{1}{n} \sum_{t=1}^n \frac{1}{n} (y_t - \hat{y}_t)^2 \tag{7}$$

$$RMSE = \sqrt{\frac{1}{n} \sum_{t=1}^n \frac{1}{n} (y_t - \hat{y}_t)^2} \tag{8}$$

$$MAE = \left(\sum_{t=1}^n \left| \frac{y_t - \hat{y}_t}{y_t} \right| \right) \tag{9}$$

$$MAPE = \left(\sum_{t=1}^n \left| \frac{y_t - \hat{y}_t}{y_t} \right| \right) \frac{100}{n} \tag{10}$$

In Equations (7)-(10), y_t indicates the real value, whereas \hat{y}_t is the predicted value, and n is the number of forecast periods. The model with the lowest standard value obtained using the above metrics should be selected as the most suitable and efficient model for the dataset.

IV. RESULT AND DISCUSSION

In this section, we provide results of our experiment based on the selected dataset.

A. ARIMA Model Findings

ARIMA Model (p, d, q) is implemented using $p [0, 1, 2]$, $d [0, 1, 2]$, $q [0, 1, 2]$ values for the demand data forecasting, and Correlogram test of each of these models were performed apart. Table II indicates the results of several parameters and performance metrics comparison between models. According to the obtained results, the model with a lower error rate is selected as the model with a higher performance level. In this regard, ARIMA (2,2,2) is the model with the lowest MAPE value, thus, it could provide the most accurate forecast among ARIMA models that we performed.

Fig. 8 illustrate the 12 Months forecast data obtained using the model ARIMA (2,2,2) with the lowest error rate value versus actual test data.

TABLE II. ARIMA MODELS CORRELOGRAM RESULTS

Comparison of ARIMA Models				
ARIMA	MSE	RMSE	MAE	MAPE
(1,1,1)	3.70	608840.38	352746.12	2.04
(0,1,0)	4.55	675233.37	420006.19	2.27
(1,0,0)	4.25	652650.05	352531.14	2.28
(1,1,0)	4.53	673113.87	390188.60	2.31
(1,0,1)	4.19	648035.65	356377.35	2.27
(0,0,2)	4.19	647642.11	350322.06	2.24
(2,2,2)	1.67	408946.67	317530.90	0.75

Fig. 8. ARIMA (2, 2, 2) Model and Dataset Comparison Chart.

Fig. 9. ARIMA (0, 1, 0) Model and Dataset Comparison Chart.

Analysis of Fig. 8 and 9 shows that monthly demands values obtained from real data and estimated studies have veering structure and the deviation is not excessive. The efficiency of the model could be seen more clearly in the graph, than the similarity of breakpoint directions and the approximation of the data. The model used here produces values that are very close to the real data with an error of 0.75 MAPE. This situation suggests that the model used in this experiment was compliant.

B. LSTM Model Findings

In the second experiment, LSTM was trained with the dataset, using Python with KERAS. We run the LSTM model on the monthly demands of the products listed between 2011 and 2017, as done in the ARIMA model. We tried different epoch numbers in the training process, thus, we examined the error values results. The error rates obtained from epoch numbers according to the training combinations performed are indicated in Fig. 10.

Fig. 10. Train Plot and Test Loss during LSTM Model Training.

According to the obtained results, LSTM model has managed to provide reliable results with the used data. It produced a lower error value compared to the ARIMA model with Epoch 500 with MSE and MAPE.

C. ARIMA versus LSTM

The time series data used in this experiment is monthly data. The Demand forecasting was performed using different models: ARIMA and LSTM.

Our aim is to train the models to select the best that can provide better accuracy for the used dataset and to compare the models' performance.

In Table III, we indicate the MSE values of ARIMA and LSTM calculated as 1.67 and 1.12 respectively. Considering the MSE and MAPE values, we assume that LSTM is the model suitable to the used dataset and could provide better results in terms of products demand prediction.

In this study, a forecasting was carried out for monthly housing data demand with the selected dataset using the DL methods evoked previously. The data in question was not only computed by being processed in the program just once, but the model was trained multiple times until realistic and reliable values were obtained. According to Table III, the error values that depict the performance metrics, for each method are considerably low. The forecasting accuracy in demand for retailers and manufacturer, with regards to a more balanced supply and demand, will provide reliable information and visibility on the future demand, thus help the Supply Chain stockholders in the making-decision process. The aim is to transform the traditional SCM into Smart Supply Chain Management. In addition, the method and dataset used in our experiment is matching the generic model that we proposed and might be applied by any company despite its size and environment anywhere in the world, because it does not consider a specific situation in the economic environment where the forecasting is made. In this respect, we proposed a generic model which is "oriented-Agent" [29] and also "oriented-process" based on SCOR and using BPMN as a modelling tool. Many different methods could be deployed for forecasting and it may be possible to provide different results from each method [30]. In this purpose, we used two methods in our study and the results obtained from each method were compared in terms of their proximity to the real values. According to the performance metrics of the forecasting models, we deduce that LSTM is more efficient and could provide better results. The demand forecasting is a crucial step in the upstream Supply Chain; it aims to control the Bullwhip effect and also to enhance the Key Performance throughout the Supply Chain from the supplier up to the final customer [31].

TABLE III. PERFORMANCE METRICS COMPARISON BETWEEN LSTM AND ARIMA

Applied method	MSE	RMSE	MAE	MAPE
Auto-Regressive Moving Average	1.67	408946.67	317530.90	0.75
Long-Short Time Memory	1.12	3421527.86	3375479.27	0.65

V. CONCLUSION

In this paper, we focused on one of the main Supply Chain issues related to decision-making, fluctuation and uncertainty of information flow and demand; we have focused on the "Bullwhip effect" phenomenon in order to propose advanced solutions to reduce it. Accurate forecasts are mandatory to improve the performance key indicators of the Supply Chain. Providing a wider range of data, information sharing and collaborative forecasting are crucial in order to enable the supply chain to increase profitability and minimize waste or delays. Similarly, negative data could also lead to downward changes in the statistical forecasts, which could lead to downward changes in forecasting.

In our case study, we deployed two Deep Learning models ARIMA and LSTM, to build our demand forecasting system and to deal with regression problems. We used a dataset collected from Kaggle whose Features correspond best to the generic model of Supply Chain that we proposed which is "Agent-oriented" and "process-oriented". Our experiment and training have shown that multi-layer LSTM gives estimated values closer to reality than those obtained by ARIMA. In particular, LSTM models perform better because they allow better persistence of information compared to classical RNNs and ARIMA, due to the information transmission over time by the hidden state called the "cell state". The aim of our approach is to maintain the balance between the supply and demand in the Supply Chain, thus, incorporate intelligent predicting system using AI, which is a crucial component of Supply Chain Management 4.0.

As perspective of this study, we will propose a Hybrid forecasting model based on ARIMA and LSTM to enhance the performance of our predicting system and improve the accuracy of the results.

Abstract—In this paper, we improve the performance of Deep Learning (DL) by creating a robust and efficient Convolutional Neural Network (CNN) model. This CNN model will be subjected to detecting and recognizing traffic signs in real-time. We apply several techniques; the first is pre-processing, which includes conversion of color space RGB, then equalization and normalization histogram of the image dataset according to Computer Vision (CV) tools. The second is devoted to Artificial Intelligence (AI), which needs the right choice of a neural layer such convolution layer, or dropout layer, with powerful optimizer as Adam and activation functions such as ReLU and SoftMax. Also, we use the technique of augmentation dataset which characterizes by the function of batch size for each epoch. The results obtained is very satisfactory, the prediction at the average is equal to 98%, which encourages this approach to the integration in Intelligent Transportation Systems (ITS) in the automotive sector.

Keywords—Deep learning; convolutional neural network; computer vision; artificial intelligence; traffic sign detection; traffic sign recognition; intelligent transportation systems

I. INTRODUCTION

The detection and recognition of traffic road signs are done in different ways, depending on the methodology or strategy followed by the researcher. In general, the detection and recognition methods can be summarized in three classes. The first method can be based on color segmentation (red, blue, yellow) [1]. In the second method, we can use the geometry of objects (Triangular, Square, Rectangle)[2]. Finally, methods that use artificial intelligence (AI), specifically DL of CNN architecture [3]. For road safety, we use ITS systems [4]. This system is devoted to detecting and recognizing all traffic road signs by identifying them from other objects that existed in environments (a passage, animals, cars, trucks, buildings.....) in real-time[5]. These systems are used in Advanced Driving Assistance Systems (ADAS) [6][7] and are based on a digital camera for perception road environment.

There is a standard technique for detecting and recognizing traffic road signs. For example, the scale-invariant feature transform (SIFT) [8][9], the local binary patterns (LBP) [10], and the histogram of oriented gradients (HOG) [11]. Also, we find advanced techniques to classify a different object, in which the feature vectors are extracted normally from the

training dataset, for example, the support vector machine SVM [12], VGG16 [13], and ImageNet [14]. In recent years, we have been using the CNN model for complex classification situations [15]. The CNN architectures are the best models; they have the same analysis vision as the human being. [16].

To guarantee a reliable and effective model in the decision, most of the research work in the field of AI often plays on the following parameters: optimizer [17], accuracy function [18], loss function [19], dataset [20], architectures [21].

In this paper, we play with several parameters to obtain a robust and efficient model for traffic sign detection and recognition. The first thing we will examine is the effect of normalizing and equalizing the images in the traffic sign dataset on model training. So according to the result of the first step, the second step is choosing an optimal fitting function (Simple, Generator) for deploying the best function between them. Finally, we will use the data augmentation technique by discussing the effect of batch size function during model training. All this is to ensure that the proposed ITS system detects and recognizes signs well in advance so the right decisions can be made as quickly as possible.

In our work, we will test our approach based on Computer Vision (CV) and Artificial Intelligence (AI), for the detection and recognition of the different traffic road signs in real-time. The approach results can be exploited by Intelligent Transport System (ITS) to assist the driver. The paper is organized as follows: Section 1 introduces the most techniques used for the detection and recognition of road signs. Section 2 is dedicated to related work, and then Section 3 presents a general view of the approach proposed. Section 4 is for methodology. Section 5 is devoted to experimentation and evaluation of the approach proposed. Section 6 with Section 7, is for the real-time implementation to recognize traffic road signs. The last section is devoted to the conclusion.

II. RELATED WORK

Most of the developed applications that have high accuracy in object detection and recognition are based on the RNN and CNN architecture [22]. Nevertheless, depending on the available data or the problem to be solved, one type of neural network may be more suitable and used than another for a different problem than the one it is used. Generally, a

Recurrent Neural Network (RNN) is used for text processing and speech recognition as illustrated in Table I. In this regard, convolution networks are applicable for object recognition in images and can specifically identify the shape of objects as illustrated in Table II. In this work, we will use the CNN architecture which is the most efficient neural network model concerning the available dataset.

A. The Constraints of the Traffic Sign Detection and Recognition Algorithms

Detection and recognition based on color segmentation are ranked as one of the fastest methods [41], applied for example to the recognition of road lanes, traffic signs, and vehicle license plates. Most algorithms use this technique to extract regions of interest, by setting specific filters to recognize apparent objects [42]. But this method can meet several problems such as weather conditions (snow, rain...), time of day (morning, night...) which has a great effect on the appearance (light reflection on the signs), or object distance (between the camera and road sign), lead to a false object detection recognition.

Some authors apply a more reliable method, it is the detection and recognition of the geometry of the road signs [43], that the detection is made on the basis of the objects contours in the image. To avoid any overlapping with the objects existing in the road environment by a structural analysis of the road signs [44].

B. Deep Learning and Neural Network

The learning methods are among the techniques that use DL [45], this method has made a revolution in the industrial sector, especially in the embedded systems in the automotive sector [46]. This method is robust in object detection and recognition compared to the geometric and colorimetric methods, which are among the classic methods that suffer from many factors.

The creation of CNN models was based on neural networks. Many hidden layers of the neural network serve to produce CNN. These neuron layers are grouped into a tree category of layers, input layers, hidden layers, and output layers. Firstly, the feature vectors dataset is accepted from the input layer and has a bias neuron. Secondly, the liaison between input and output is hidden layers that use the neuron bias. Finally, the output of neural networks is not used for the bias neuron. The output from a single neuron is calculated according to the following equation (1).

$$f(x, \theta) = \phi(\sum_i(\theta_i \cdot x_i)) \quad (1)$$

- The input vector (x) represents the feature vector.
- The vector θ represents the weights.
- The ϕ is the transfer/activation function.

III. THE APPROACH DESCRIPTION

The approach that will be proposed to integrate it into an ITS system, is essentially based on the creation of a CNN architecture to guarantee road safety for both passengers and drivers of vehicles. Therefore, our approach is based on two processes, the detection process and the recognition of traffic signs as shown in Fig. 1. The detection process uses camera-based CV techniques to receive images to ensure that traffic signs are detected. When the signs are detected, the recognition process is activated using AI techniques. We will use a CNN architecture to extract the characteristics of the road signs. To achieve our objective, the deep training will be done on the German Traffic Sign Recognition Benchmark (GTSRB) dataset. We arrive at the end to identify each detected by the classes that belong to the prediction probability.

The strategy we will follow to have an efficient CNN architecture is summarized in the following points:

- Transformation techniques (equalization and normalization histogram).
- Creation of CNN architecture (convolution layers, and max-pooling layers)
- DL of the CNN architecture with simple fit function and generator fit function.
- Testing the performance of the CNN model in real-time detection and recognition of traffic road signs.

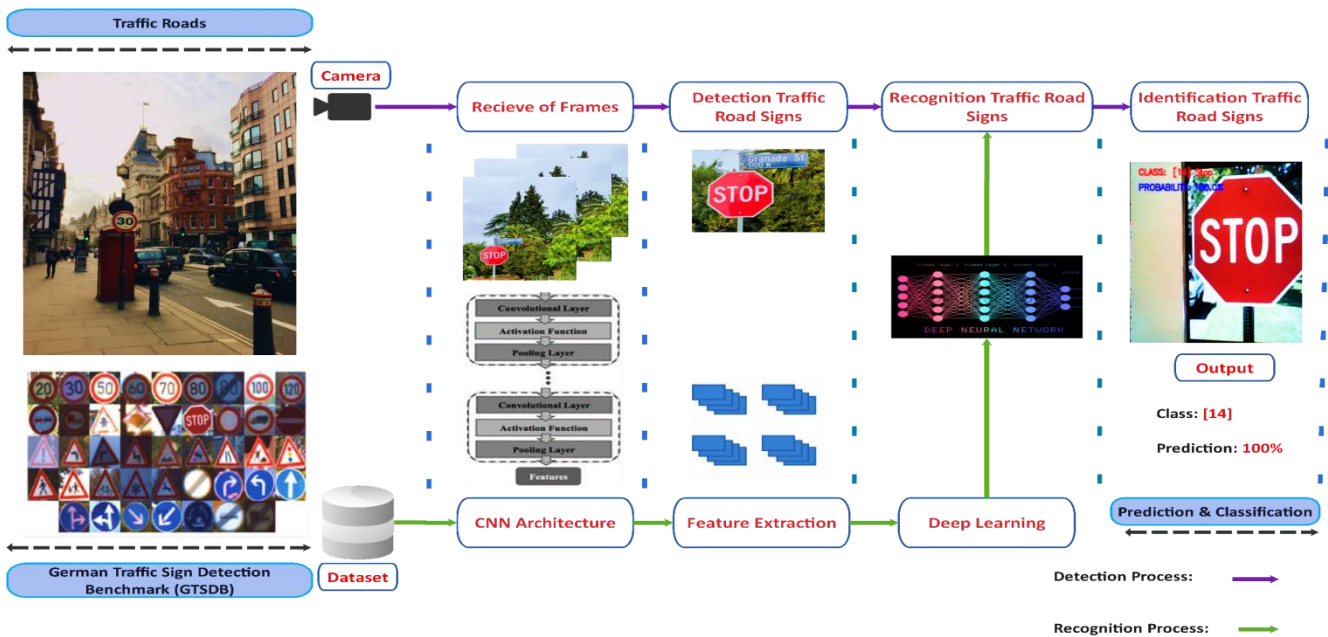

Fig. 1. General View of Approach Applicable for the ITS System.

IV. METHODOLOGY

A. Transformation Techniques for Dataset

a) *Visualization dataset:* For our implementation, we use a dataset of the German traffic sign Benchmark [47], composed of training data, validation data, and testing data. The training set uses 80% of the data and the validation set uses 20%. The GTSD is composed of 43 traffic road sign classes, 34799 images for training data, 4410 images for validation data, and 12630 images for testing data, as illustrated in Fig. 2.

Fig. 2. Visualization of GTSD Training Datasets.

b) *Normalization of a histogram:* Normalizing a histogram is a technique consisting of transforming the discrete distribution of intensities into a discrete distribution of probabilities [48]. To do this, we need to divide each value of the histogram by the number of pixels. In our case, the normalization is done by dividing all pixels in an image by 255.

c) *Equalization of a histogram:* Histogram equalization is an image processing method to adjust the contrast of an image, by modifying the intensity distribution of the histogram [49]. Equalization processing is based on the use of the cumulative probability function. This function is a cumulative sum of all the probabilities in its domain and is defined by equation (2).

$$cdf(x) = \sum_{k=-\infty}^x P(k) \quad (2)$$

The idea of this processing is to give the resulting image a linear cumulative distribution function.

B. Convolutional Neural Networks (CNNs)

Domain CV has been affected by AI mainly by CNNs. The neural network architecture was introduced by LeNet-5 [50]. The next step is the description of each layer type used in the CNN model.

a) *Convolution layers:* The first layer of analysis is the convolution, it allows us to detect the characteristics of each visual element: circles, lines, colors, edges ..., this work is done by internal filters in the layer. If the number of filters is very well brought, they have more features for better accuracy. The filters have a square shape that sweeps over the image from the right to the left. Then there is a very important parameter, which is the width and length of the filter that normally affects the number of features extracted from the images. The single

output matrix of the convolution layer is described in equation (3).

$$M_j = g(\sum_{i=1}^N Img_i * Ker_{i,j} + b_j) \quad \# \quad (3)$$

I_{img} : Input matrix. Ker: Kernel matrix.

b_j : Bias. g : Non-linear activation.

Each set of kernel matrices represents a local feature extractor that extracts regional features from the input matrices. Optimizes neural network connection weights, and can be applied here to train the kernel matrices, biases as shared neuron connection weights.

b) Max pooling layers and dropout layers: Putting the Max-Pooling layers belong after every convolution layer. It serves for re-sizing a picture of 2D in a smaller dimension [51]. Most CNN frameworks implement dropout as a separate layer to avoid the production in DL the overfitting. Dropout layers function like a regular, densely connected CNN layer. The only difference is that the dropout layers will periodically drop some of their neurons during training.

c) Activation function: However, current deep neural networks mainly use the following activation functions, each function has a role to play in a neural network. For the output of the hidden layers, we use the ReLU (Rectified Linear Unit) function [52]. The ReLU function is calculated as follows in equation (4).

$$\phi(x) = \max(0, x) \quad \# \quad (4)$$

The ReLU activation function [53][54] was one of the key improvements in CNN applications, that make deep learning. Unfortunately, the ReLU function is not differentiable at the origin, which makes it hard to use with backpropagation training. ReLU for rectified the feature map, to find the final value positive and deleted the negative value.

The output of classification CNN: We implemented SoftMax. The SoftMax is calculated as follows in equation (5).

$$\phi_i(z) = \frac{e^{z_i}}{\sum_{j \in group} e^{z_j}} \quad \# \quad (5)$$

The SoftMax function is only useful with more than one output neuron. It guarantees that the sum of all output neurons is equal to 1.0. It is therefore very useful for classification, where it indicates the probability that each of the classes is the correct choice.

d) Optimization function: Adam optimizer is very effective [55]. Adam estimates the first mean and second variance moments to determine the weight corrections. Adam begins with an exponentially decaying average of past gradients (m) described in equation (6).

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t \quad \# \quad (6)$$

g_t : the gradient at time t .

This average accomplishes a similar goal as a classic momentum update; however, its value is calculated automatically based on the current gradient (g). The update rule then calculates the second moment (v) in equation (7).

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \quad \# \quad (7)$$

The values m_t and v_t are estimates of the first moment (the mean) and the second moment (the uncentered variance) of the gradients respectively. β_1 and β_2 : are exponential decay rates. Adam is very tolerant of the initial learning rate (η) and other training parameters. Default values of $\beta_1=0.9$, $\beta_2=0.999$, and $\eta=10^{-8}$ [45].

C. CNN Architecture

We have a dataset of dimensions (32,32,3), and we will perform a conversion from RGB color space to gray level. The input images of our architecture will have dimensions (32,32,1). Table III presented the architecture of CNN in detail, type of layers, output shapes, and activation functions. The layers with their corresponding type are shown, denoting the characteristics used. Then implementation of CNN in CPU takes more time because we have a dataset of images that are more difficult to execute. However, the faster implementation we propose to use GPU.

TABLE III. PROPOSED CNN ARCHITECTURE

V. EXPERIMENTATION AND EVALUATION

The results are implemented in ASUSTek Computer, processor intel® Core™ i7-7500 CPU @2.70GHz 2.90GHz, Memory installed (RAM): 8,00 Go, exploitation System 64 bits, processor 64 bits Systems Model: X541UJ, GPU NVIDIA GeForce 920M using the TensorFlow, Keras, and OpenCV libraries.

A. Simple Fit Function

The training of the proposed CNN model requires two essential elements, the training data, and the training labels. For the training, we will use the fit function of the Keras library.

The number of epochs is the number of times the model will run through the data. The more epochs we run, the more the model will improve, up to a certain point. We started our model for 50 epochs with a batch size set to 32. We will also train the dataset with equalization and normalization of the histogram. Thus, the training without equalization and normalization will be noted as Method 1, and the training with equalization and normalization will be noted as Method 2.

We can visualize in Fig. 3 in the accuracy curve, a drop during the training of the data in 2 steps for 50 and 100 epochs. But for the loss curve, we have a huge increase in the error value. So, method (1) leads us to overfit. We can deduct from Fig. 4 that we don't have any underfitting or overfitting in the accuracy curve, we can easily observe that the increase in the number of epochs did not disturb the learning stability. The same thing for the loss curve, we have a very remarkable degradation of the error values compared to the curve of

method (1). Equalization and normalization can be used almost. However, this method (2) shows negligible effect loss and we have the full precision of our network that shows a significant improvement.

A comparison of the performance in Table IV shows accuracy function and loss function. We can conclude from Table IV which contains tests accuracy and loss for Method (1) and Method (2). It is necessary to equalize and normalize. The equalization is served to adjust the contrast in the image's dataset. For the normalization, it allows making training faster and the loss becomes more circular symmetric. The next step is to change the simple fit function by using a fit generator, we visualize if does good predictions and evolution of accuracy with a loss function. The equalization and normalization algorithms result in improved performance of CNN classification.

Fig. 3. Method (1): (a) Training and Validation Accuracy, (b) Training and Validation Loss.

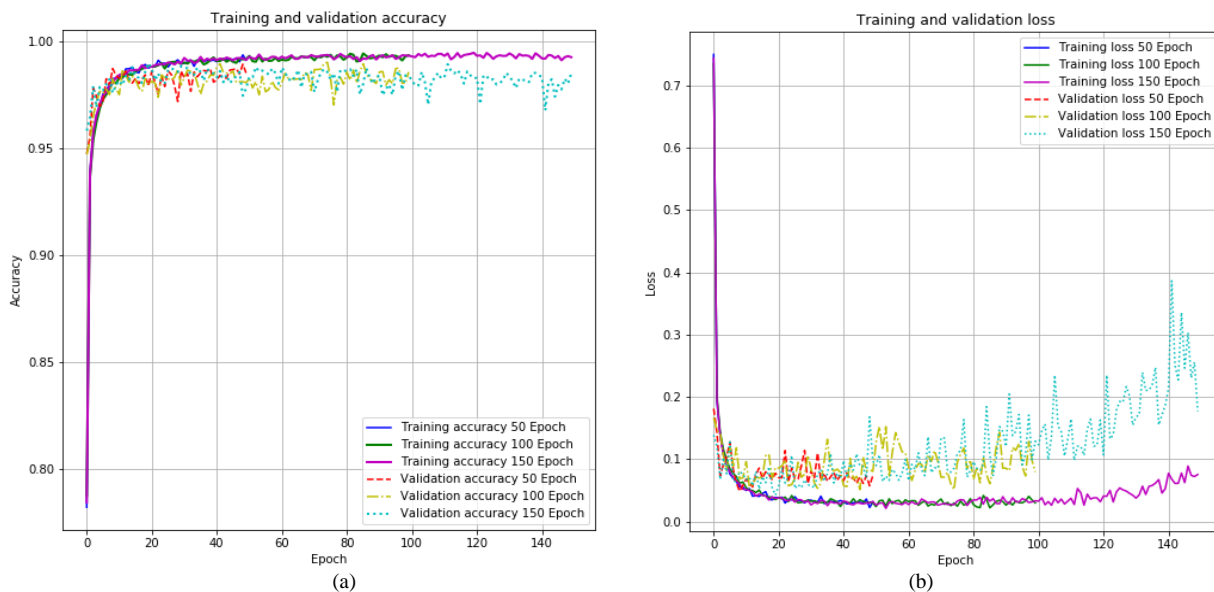

Fig. 4. Method (2): (a) Training and Validation Accuracy, (b) Training and Validation Loss.

TABLE IV. PERFORMANCE COMPARISON OF METHOD 1 AND METHOD 2

Method		Model	Fit Function	Learning Rate	Loss Function	Optimizer	Train Dataset	Epochs	Test Accuracy (%)	Test Loss (%)
Method 1	Without Equalization and Normalization images Datasets	CNN	Simple	10^{-2}	Categorical Cross-Entropy	Adam	34799	50	94.63	44.11
								100	78.21	35.09
								150	64.18	5.76(>100%)
Method 2	With Equalization and Normalization images Datasets							50	96.43	17.65
								100	96.19	25.48
								150	96.52	42.29

B. Fit Generator Function

We propose to use the fit generator function to accept the data sets, perform backpropagation, and update the weights in our model. This function has a hyperparameter, it is the number of steps per epoch, its value as the set of servant landmarks becomes divided by the batch size. It is based on an infinite loop, which must not return empty or exit. However, all researchers calculate the value of steps per epoch as the total number of training data divided by the batch size of training data images.

So, the idea of our experiment is to use method 2 from the previous section. Method 2 will be driven by the generator fitting function with a batch size of 32. We will compare different optimizers (Adam and SGD) and the loss function (Categorical cross-entropy, and Mean squared error). We fixed parameters learning rate in 10^{-2} and epochs in 50.

In Table V, when the loss function uses categorical cross-entropy, we have a high prediction score with a low loss score. Now we improved the model to get the lowest loss score. We got the best scores with the Adam optimizer and the categorical cross-entropy function, for 97.11% accuracy and 11.32% loss. Moreover, the idea is now to improve the accuracy score.

As we can see in Fig. 5, using the fit generator function in the training model the objective is achieved, at 90% we control the situations for not have the overtraining our DL models. The assumptions are therefore correct, we using all of the datasets

at each epoch. We need to choose a batch size and steps per epoch which multiply to give a total number of samples. Usually, it will be a resource. If memory is a problem, we need to reduce the batch size until we can adapt a batch on a GPU. Note that this implementation also allows us to use the multiprocessing argument of a fit generator, where the number of threads specified in workers corresponds to those which generate batches in parallel. A fairly high number of workers ensure that the calculations performed on the GPU are managed efficiently, or in other words, the bottleneck of the whole training process will be due to the propagation operations. In our case, we would probably set batch size the desired amount; we change it only if you want the model to not use all the data for each epoch which deflects the definition of the word epoch.

TABLE V. EXPERIMENT RESULTS OF OPTIMIZER AND LOSS FUNCTION

Loss function	Model	Fit Function	Optimizer	Test Accuracy (%)	Test Loss (%)
Categorical Cross-Entropy	CNN	Generator	SGD	86.74	46.27
			Adam	97.11	11.32
SGD			01.16	02.27	
Adam			97.08	12.12	

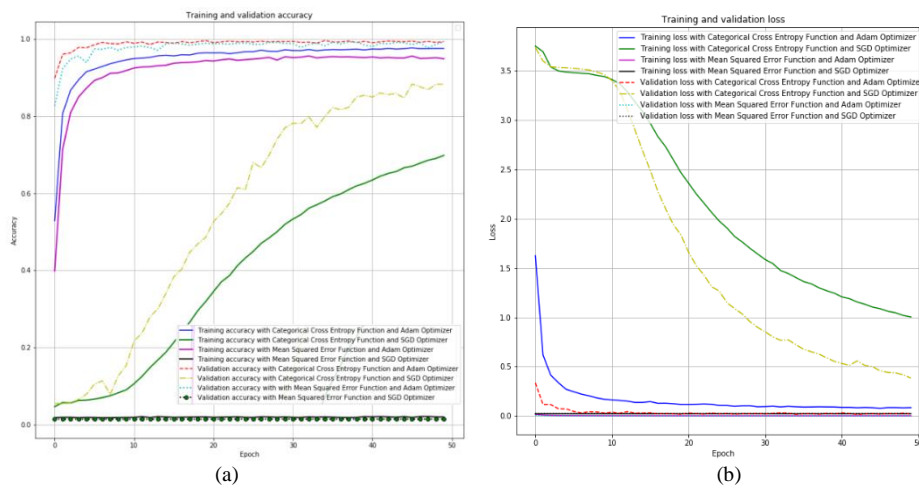

Fig. 5. (a) Training and Validation Accuracy, (b) Training and Validation Loss.

VI. DISCUSSION

We introduce one more technique to improve the model training process data augmentation. This technique creates new data for our CNN model to use during the training process. This is done by taking our existing datasets and transforming or altering the images in useful ways to create new images.

A. Image Data Generator Function

We can have a typical sign image such as this STOP sign image, taking this image and transforming it to create a different image representing the same stop sign. The transformation could be rotation or simply zooming into the image. Also, could even be a combination of both these transformations. These newly created images are referred to as augmented images because they essentially allow us to augment our dataset by adding them. The data augmentation technique is useful because it allows our model to look at each image in our dataset from a variety of different perspectives. This allows it to extract relevant features more accurately and allows it to attain more feature-related data from each training image. This is especially the case for our traffic sign datasets because we have a small dataset (32x32) and a large number of classes. This means that certain classes have very few proximately only 200 training in the Fig. 2. It can benefit our traffic sign recognition model.

We apply the five following transformations with shift range, height shift range, zoom range share, and a rotation range. Five transformations will add sufficient variety to GTSRB datasets and will allow the training process to be much more effective. The first transformation is with shifts, this refers to a horizontal translation in the image which will cause our images to be centered, and this will help our CNN model adapt to test images that aren't necessarily going to be centered. The range can be defined in two ways, if the range value is defined as a number between 0 and 1, then it refers to the fraction of the image that can be shifted. A value of 0.1 would simply imply that the maximum horizontal shift possible is 10 percent of the width of the image. The images with only horizontal translation can be similar. So, to have a difference between the generated, we apply a second technique is a vertical translation. The range value is defined in much the same way and for that reason; the value of vertical translation is 0.1 (10%).

For zoom transformation, can be either zoom out or into the image. The degree of zoom can be defined with a float value between 0 and 1. While the maximum outer zoom is defined by one minus the float value and the maximum zoom is defined by a 1 plus the flow value. We will use a float value of 0.1 which means that we can zoom as far as 0.1 eight's and zoom in as close as 0.2. Next, we have the shear transformation in plane geometry a shear mapping is a linear map that displaces, each point in a fixed direction by an amount proportional to its side and distance. The line that is parallel to that direction, possible in both the x-direction and the y-direction. This transformation is defined using shear intensity which simply refers to the magnitude of the shear, angle in degrees as seen in the image above. We apply a small magnitude of shear to be effective, using a value of 0.1. The last transformation is the rotation; this transformation is a bit more intuitive it simply rotates an image

by a certain value of degrees. This value can be defined using an integer value, in our case, we will use 10. These transformations are simply applied to stop signs as shown in Fig. 6, which will then be applied to the GTSRB dataset.

B. Batch Size Function

First, we declare a batch size is equal to 32 which mean that our image generator will create a batch of 32 images at a time for our CNN model to use our next argument as illustrated in Fig. 7. Also, the steps per epoch this parameter essentially refers to the number of batches. The steps per-epoch argument must specify the number of batches of samples comprising one epoch. In our case, the original dataset has 34799 images and the batch size is 32. Then a reasonable value for steps per epoch when fitting a model on the augmented data might be $\text{ceil}(34799/32)$, or 1087 batches. So, we fix the value of the steps per epoch in 1000.

C. Experimental Results

We are fixed step pre-epochs to 1000, we switch the value of epochs between 50 and 150, we behold augmentation accuracy the same time value loss has diminution. We fit and evaluate all these models in different batch sizes (32, 64, 128, and 256) using the same procedure above of optimizer Adam and the same value of steps pre-epochs with different epochs, found through some minor experimentation. The model is evaluated, reporting the classification accuracy on the test sets between 96.86% and 98.01%. We can specify the results may vary given the stochastic nature of the training algorithm. Table VI demonstrates the effect of batch size, after testing very hard which took an enormous time to find it up to incredible values. When we have for batch size is 256, we have a precision in 50 epochs of 98,01% which is very interesting, and also a remarkable reduction in the function error of 09.15%. The same thing for size 100 epochs has values for the two 97.99% and 09.11%.

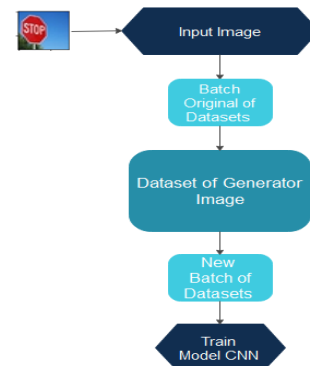

Fig. 7. The Batch of the Training Dataset GTSRB.

TABLE VI. FLOW DATA FOR BATCH SIZE FUNCTION

Batch Size	Optimizer	Step pre-epochs	Epoch	Test Accuracy (%)	Test Loss (%)
32	Adam	1000	50	97.15	10.94
			100	97.11	11.32
			150	96.86	14.16
64	Adam	1000	50	97.18	11.90
			100	97.04	12.28
			150	97.69	09.25
128	Adam	1000	50	97.38	11.02
			100	97.85	10.74
			150	97.94	09.68
256	Adam	1000	50	98.01	09.15
			100	97.99	09.11
			150	97.83	10.84

In Fig. 8, we can see the validation converges to above 99%. A significant improvement is shown over our previous CNN model. This might be our modification that was pretty effective. We have a much smaller gap and training accuracy as well as our validation loss and accuracy, respectively. This demonstrates consistency in our training and a better-trained model and we now finish our model training with a validation accuracy of over 98 % and training accuracy. This is all very good to see and shows our augmentation technique was effective. The model will not learn complex patterns and we can avoid overfitting, we use more dropout layers in our architecture and check its performance. So, the augmentation dataset after performing histogram normalization and equalization, the model learned the data better, and the accuracy of the set improved. Now there is just one more test that our model needs to pass and that is classifying images from the test dataset to predict a couple of them correctly. So, we'll start by testing out the image not seen before for our CNN model.

Fig. 8. Accuracy and Loss Curves of Epochs with a Batch Size of 256.

D. Analyses Performance of a Model Trained

We define several measures based on the confusion matrix, to quantify the performance of a classifier from different points of view: Precision by class, average precision, Recall by class, average recall, F-score by class, and f-score average.

a) *Precision of classification*: The accuracy of a classifier concerning a certain class in other words, about a certain modality of the variable to be predicted, is measured as the proportion of individuals, among all those for whom the classifier predicted this class, who belong to it, exposed in this equation:

$$p_i = \frac{TP}{TP+FP} \quad \# \quad (8)$$

TP : (True Positive) Element of the class correctly predicted.

FP: (False Positive) Element of the class badly predicted.

The overall means of the precision over all the classes i can be evaluated by the macro-average which first calculates the precision on each class i followed by a calculation of the average of the details on the n classes based on this equation:

$$Precision = \sum_i^n \frac{p_i}{n} \quad \# \quad (9)$$

p_i : precision each class i. n : number of classes.

b) *Recall of classification*: The recall of a classifier with a certain class is measured, like the proportion of individuals, among all those who belong to this class, for which the classifier predicted this class.

$$r_i = \frac{TP}{TP+FN} \quad \# \quad (10)$$

The global averages of the recall over all of the classes i can be evaluated by the macro-average which first calculates the recall over each class i followed by a calculation of the average of the reminders over the n classes:

$$Recall = \sum_i^n \frac{r_i}{n} \quad \# \quad (11)$$

r_i : recall each class i. n : number of classes.

c) *F-score of classification*: We can summarize the recall precision measurements to a class in a single indicator, by calculating the harmonic mean:

$$RF - score_i = \frac{2*(p_i*r_i)}{p_i+r_i} \quad \# \quad (12)$$

p_i : precision each class i. r_i : recall each class i.

The average over each class of these indicators gives global indicators on the quality of the classifier.

$$F_{-Score} = \frac{2*(Precision*Recall)}{Precision+Recall} \quad \# \quad (13)$$

Precision: The average precision of all classes.

Recall: The average recall of all classes.

E. Confusion Matrix

The Confusion Matrix identifies the classes of signs and also gives the number of times it gets the confused class to identify the class from another in Fig. 9. Most of the color is diagonal, but there are still some annoying spots somewhere. When we narrowly look at the confusion matrix, we see that the classes [0] have very less respectively all classes, but it's minimized for other classes. The diagonal observations are the true positives of each class and other non-diagonal observations are incorrect classifications of the model.

F. Classifier Metrics

A Classification report is used to measure the quality of predictions from a classification algorithm. We can see in the Table VII, the model has the as recall and precision are calculated for individual classes, have a good score of all the class of traffic road signs. We use macro or micro or weighted scores of recalls, precision, and F1 score of a model for multiclass classification problems have a higher score is 98% this very satisfied.

TABLE VII. CLASSIFIER REPORT FOR THE CNN MODEL

Class names	precision	recall	f1-score	support
Speed limit (20km/h)	0.98	1.00	0.99	60
Speed limit (30km/h)	0.99	1.00	0.99	720
Speed limit (50km/h)	0.99	0.99	0.99	750
Speed limit (60km/h)	0.99	0.94	0.96	450
Speed limit (70km/h)	1.00	0.98	0.99	660
Speed limit (80km/h)	0.95	0.99	0.97	630
End of speed limit (80km/h)	0.99	0.90	0.94	150
Speed limit (100km/h)	1.00	1.00	1.00	450
Speed limit (120km/h)	1.00	1.00	1.00	450
No passing	1.00	1.00	1.00	480
No passing for vechiles over 3.5 metric tons	1.00	1.00	1.00	660
Right-of-way at the next intersection	0.98	0.96	0.97	420
Priority road	1.00	0.99	1.00	690
Yield	1.00	0.99	1.00	720
Stop	1.00	0.99	0.99	270
No vechiles	1.00	0.97	0.98	210
Vechiles over 3.5 metric tons prohibited	0.99	1.00	1.00	150
No entry	1.00	0.97	0.99	360
General caution	0.99	0.89	0.94	390
Dangerous curve to the left	0.98	1.00	0.99	60
Dangerous curve to the right	0.98	1.00	0.99	90
Double curve	0.85	0.78	0.81	90
Bumpy road	1.00	0.93	0.96	120
Slippery road	0.98	1.00	0.99	150
Road narrows on the right	0.99	0.98	0.98	90
Road work	0.98	0.97	0.97	480
Traffic signals	0.91	0.98	0.95	180
Pedestrians	0.89	0.95	0.92	60
Children crossing	0.99	1.00	1.00	150
Bicycles crossing	1.00	0.99	0.99	90
Beware of ice/snow	0.89	0.95	0.92	150
Wild animals crossing	1.00	1.00	1.00	270
End of all speed and passing limits	1.00	0.98	0.99	60
Turn right ahead	0.96	1.00	0.98	210
Turn left ahead	0.99	1.00	1.00	120
Ahead only	1.00	1.00	1.00	390
Go straight or right	0.99	1.00	1.00	120
Go straight or left	0.97	0.98	0.98	60
Keep right	1.00	0.97	0.98	690
Keep left	1.00	0.98	0.99	90
Roundabout mandatory	0.85	0.93	0.89	90
End of no passing	0.98	1.00	0.99	60
End of no passing by vechiles over 3.5 metric tons	0.95	0.87	0.91	90
micro avg	0.98	0.98	0.98	12630
macro avg	0.98	0.97	0.97	12630
weighted avg	0.99	0.98	0.98	12630
samples avg	0.98	0.98	0.98	12630

Fig. 9. Confusion Matrix Epochs 100 and Batch Size 256.

VII. TESTING THE MODEL

A. Test with the Test Dataset

A remarkable performance is illustrated in Fig. 10. Now we'll test for test datasets, we look reaction to our model, to see where the fails. We tried to visualize the class predictions of the test images, it is relevant to have good results, all the images were well classified, and the curve shown next to each image represents the class of the images among the 42 classes, when we have the color blue and a single peak in the curve means the image has been put in the right place without any errors.

B. Testing the Proposed CNN Model in Real-Time

In this section, we will present and evaluate the results of our approach. Traffic road signs that appear in video sequences are often detected. More details on the video sequences are given in Table VIII. In general, for all performance indicators, our proposed approach outperforms other object detection algorithms by achieving up to 100% accuracy. Our CNN model metric value is often higher than in the results of previous work. For the video sequences, our algorithm surpasses the good probability of prediction and classes of Traffic Road signs by the method. This shows that using a robust appearance CNN model achieves better results. It can also be observed that the CNN precision value obtained for the video sequence is higher than that obtained by the approach with a difference between 97.56% and 100%.

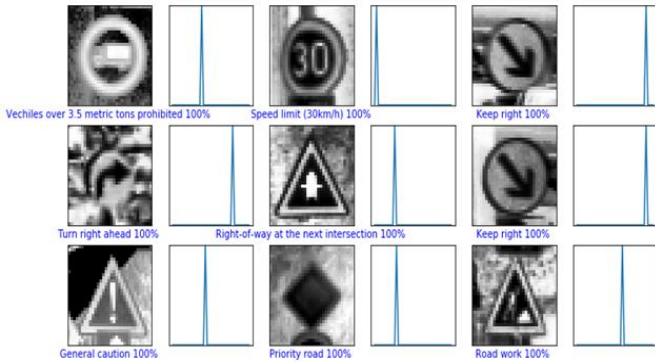

Fig. 10. GRTSB Test Datasets.

TABLE VIII. TEST OF NEW IMAGES IN REAL-TIME

Traffic Road Signs Recognition	Classification	Prediction (%)
	Class Number: [17] No Entry	97.56%
	Class Number: [12] Priority Road	99.15%
	Class Number: [5] Speed limit (80km/h)	98.4%
	Class Number: [14] STOP	100%
	Class Number: [34] Turn left ahead	100%
	Class Number: [33] Turn right ahead	

VIII. CONCLUSION

In this paper, we proposed a methodology for the construction robust CNNs model. We talked about the problems associated with the detection and recognition of traffic road signs in real-time. We also demonstrated how using the right tools and techniques helps us in developing robust CNN models. These CNNs can guarantee road safety in real-time. We also try other pre-processing techniques to further improve the model's accuracy (equalization and normalization histogram). The step of adding augmentation data improved the performance of our deep learning CNN model. We are curious about how much the accuracy can be improved based on adding such simple transformations. We think these results could further be used in the development of automotive systems, such as intelligent transportation systems (ITS). All this is for the safest roads; we try in the future to get better performance and optimistic. It is also very interesting to note that the proposed CNN model reaches 98% accuracy using NVIDIA's GPU processor, which makes them feasible for real-time traffic sign recognition.

In future work, we plan to study other neural network architectures that have been shown to be optimistic for traffic sign detection or classification. In addition, we will attempt to employ these networks in advanced in-vehicle platforms applicable to intelligent transportation systems to reveal valuable information that will help drivers make the right decisions in the real world.

Software College, Liaoning Technical University, Anshan, China⁴

Abstract—Due to the events caused by the COVID-19 pandemic, the education industry is no longer limited to offline, and online classroom education is widely used. The rapid development of online education provides users with more abundant educational course resources and flexible learning methods. Various online education platforms are also constantly improving their service models to give users a better learning experience. However, at present, there are few personalized information recommendation services in student course selection. Students receive the same course selection information and cannot be "tailored" according to their specific preferences. This paper focuses on the integration of collaborative filtering technology into a college course selection system to construct a rating matrix based on students' ratings of the courses they take through correlation between courses and correlation between students. Based on the collaborative filtering algorithm, a predictive rating matrix is generated to produce a recommendation list to achieve intelligent recommendation of suitable courses for students. The experimental results show that, based on the traditional collaborative filtering recommendation technique, the improved collaborative filtering algorithm based on both item and user weighting is used to achieve course recommendation with higher recommendation accuracy. The application of the improved collaborative filtering technique in the course selection recommendation system of colleges and universities is very good at recommending courses for students intelligently, and the recommended courses for students have good rationality and accuracy, and achieve more intelligent course selection for students, which has great practicality and practical significance.

Keywords—Collaborative filtering; course selection system; recommendation; scoring matrix; weighting

I. INTRODUCTION

With the rapid development of the Internet industry, the application of information technology is becoming more and more widespread in the management of academic affairs information, and the online course selection system has become a significance part of the management of academic affairs information. How to quickly find out the course you are interested in among the large amount of optional course information has become one of the research hot-spots of the course selection system. In the course selection system, most of them are based on the system search engine to query course information and take courses [1]. When facing a large number of available courses, students do not have the relevant knowledge as a basis to select courses because they do not know enough about the course information, which will lead to a waste of course resources. Currently, most of the course

selection systems have no recommendation function or low quality of personalized recommendation, so it does not recommend the courses that students may be interested in. However, building a recommendation system based on feedback information such as students' major information and students' ratings of course information can solve these problems [2].

A. The Statement of the Research Problem

Elective courses for college students are courses that students can choose to study independently according to their preferences. Through elective courses, students can expand their knowledge. At present, the course selection system of most colleges and universities lists all the elective courses offered this semester in the system like commodities for students to choose [3]. The relevance and orientation between courses are poor. When college students choose courses, there are the following three problems:

1) *Blindness*: Students do not understand the relevance of courses and the direction of majors, Course selection is arbitrary.

2) *Poor purpose, dealing with errands*: Students only choose some courses that can easily pass in order to complete their credits, regardless of whether the courses they learn are helpful to their curriculum system. As a result, after the course is selected, the learning enthusiasm is poor and the learning effect is not good, which does not achieve the expected effect of elective courses (R. N. Behera and S. Dash, 2016).

3) *Instability and potential risks of course selection system*: The traditional course selection mode has strong time constraint and does not take into account algorithmic fairness, which may often cause peak access and easily cause hidden danger to the security operation of the back-end system.

Therefore, personalized recommendation technology is applied to the course selection system to provide students with personalized elective course recommendations according to their needs and interest preferences, prevent students from choosing courses blindly, and greatly improve the utilization rate of university elective course resources and the operation efficiency of the course selection system.

B. Research Objectives

1) To analyzes and compares several recommendation algorithms, finds out their shortcomings and advantages, and determines the research idea of applying collaborative recommendation technology to course selection system.

2) By understanding the courses that students have taken and their evaluations, analyzing students' preferences, and pushing courses that target students may be willing to take.

3) To apply collaborative filtering technology to the field of students' course selection, and combine it with the basic course selection system to realize an efficient and convenient Personalized Course Selection recommendation system.

C. Research Question

The recommendation algorithm based on collaborative filtering is based on the similarity measure of individual behavioral characteristics. By calculating the similarity between the specified new sample (students) and the original sample in the database, the new sample is clustered, and the individuals with similar behavioral characteristics to the new sample are identified as the nearest neighbor samples (nearest students). After that, the selection set of the nearest neighbor sample is generated, and the selection set is sorted according to preference scores.

Ultimately, course selection recommendations are made to students based on the similarity of the new sample to the nearest neighbor students and the course selection preferences of the nearest neighbor students. There are two important issues that need to be addressed.

1) First, how to calculate the similarity between students through behavioral data, and require that the similarity reflect the interests and learning characteristics of students strengths.

2) Second, after identifying a new sample of near-neighbor students, how to determine the set of recommended courses to be selected based on the near-neighbor students' course selection records.

D. Rationale of the Study

In the field of teaching management practice of colleges and universities, in order to follow up the reform of higher education teaching and meet the demand of society for comprehensive and practical talents, the course selection system of China's colleges and universities has completed the conversion from academic year system to credit system, and schools provide students with a large number of elective courses, and students in colleges and universities are given more options to choose their favorite courses according to their interests. With the diversified development of the society, people are more and more concerned with a wide range of fields, and students' interests show a trend of divergence, so colleges and universities have also opened corresponding courses for students to choose in response to this phenomenon. However, in recent years, there are too many elective courses in colleges and universities, which lead to information overload when students choose courses, and it is difficult for students to choose courses that suit their personal development due to the structural deficiencies of course classification and specialization. This shows that the course selection process of students is not without research value, and there is a pattern of course selection behavior. Moreover, the traditional course selection mode has strong time constraint and does not take into account algorithmic fairness, which may often cause peak access and easily pose hidden risks to the security operation of

the back-end system. Therefore, personalized recommendation technology is applied to the course selection system to provide students with personalized elective course recommendations according to their needs and interest preferences, prevent students from choosing courses blindly, and greatly improve the utilization rate of university elective course resources and the operation efficiency of the course selection system [4].

The "department store" approach of simply improving the quality of teaching resources by simply listing them and letting students "pick and choose" is obviously no longer in line with the current requirements for "personalized learning".

Personalized learning requires adding a number of "shoppers" to the "department store" with a wide range of elective courses to help learners get the right course for them in a timely and accurate manner that is recognized by the learners. This "shopper" is the role that learning paths play in the learning process of learners, aiming to improve the precise guidance of learners, reduce the blindness of learners, and improve the efficiency of course selection [5].

E. Research Gap

At the same time, with the digital reform of higher education, some scholars have started to study the mining of student's one-card data to analyze student behavior. The students' one-card accumulates a large amount of student spending data and daily behavior data. However, there are still many shortcomings in the above-mentioned research on course selection recommendation systems. The recommendation systems based on students' course selection data use very limited course selection data of varying quality, which makes it difficult to accurately mine students' preferences, and they focus too much on the algorithm level, trying to copy the success of recommendation systems in e-commerce and entertainment fields to the education field, using various methods to improve the accuracy of the algorithm, while ignoring the characteristics of the education field itself and the limitations of the scoring matrix itself, resulting in no qualitative improvement in accuracy and hardly satisfactory recommendation results.

Web mining and bibliography mining are the theoretical basis of data mining technology in library user behavior analysis. Based on the research and analysis of library patron behavior composition and acquisition, library user behavior models are constructed by using machine learning and other algorithms. Through these models, we can understand the interest preferences of reader groups. However, there are still many shortcomings in the above-mentioned research on course selection recommendation systems. The recommendation systems based on students' course selection data use very limited course selection data of varying quality, which makes it difficult to accurately mine students' preferences, and they focus too much on the algorithm level, trying to copy the success of recommendation systems in e-commerce and entertainment fields to the education field, using various methods to improve the accuracy of the algorithm, while ignoring the characteristics of the education field itself and the limitations of the scoring matrix itself, resulting in no qualitative improvement in accuracy and hardly satisfactory recommendation results.

This paper proposes a collaborative filtering algorithm-based course selection recommendation system, which no longer pursues excessive algorithmic complexity, avoids the limitations of the scoring matrix itself, and realizes personalized course recommendation.

II. LITERATURE REVIEW

Collaborative filtering is a push technology that is often used to achieve the basic recommendation push function for the system. It is mainly to divide users into different sets by different tendencies, and to push items to target users according to the items that are closer to users' preferences, item's comment information, etc. as the basis for judging.

A. Theoretical Background

Collaborative filtering is to mine a small number of students with similar course preferences to the specified students in a large amount of data, and then designate these similar students as Then, we organize the course preferences of the near-neighbor students into a catalog sorted by preference, and finally recommend courses to the specified students based on the course preferences of similar students.

1) *Similarity measure*: The similarity measure between samples is the basis of cluster analysis. When doing classification, a sample is usually considered as 1 vector in an n-dimensional Euclidean space, so the similarity between 2 vectors in n-dimensional Euclidean space can be measured from the following 2 perspectives. One is from the fish degree of vector distance. Second, from the angle of vectors. In particular, since the Euclidean distance in high-dimensional space still satisfies the triangular inequality of distance, the Euclidean distance is the most common method to measure the vector distance in high-dimensional space [6].

a) *Euclidean distance metric*: In high-dimensional space, the Euclidean distance is a measure of the distance between points in vector space that is closest to the intuitive meaning of distance in three-dimensional space. By introducing the concept of Euclidean distance; the vector space has the concepts of length and angle. Suppose the samples x and y are 2 points in an n ($n \geq 1$) dimensional Euclidean space.

$$x = [x_1, x_2, x_3, \dots, x_n]^T \quad (1)$$

$$y = [y_1, y_2, y_3, \dots, y_n]^T \quad (2)$$

Then the Euclidean distance is calculated as follows.

$$d(x, y) = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \dots + (x_n - y_n)^2} = \sqrt{\sum_{i=1}^n (x_i - y_i)^2} \quad (3)$$

b) *Manhattan Distance Metric*: Manhattan distance is also called city block distance assuming that the sample x and y are 2 points in n ($n \geq 1$) dimensional space, we get equations (1) and (2), then Manhattan distance is calculated as follows.

$$d(x, y) = |x_1 - y_1| + |x_2 - y_2| + \dots + |x_n - y_n| = \sum_{i=1}^n |x_i - y_i| \quad (4)$$

c) *Chebyshev distance metric*: Chebyshev distance is also an important measure to define the distance of points in

vector space, which takes the maximum value of the distance in the component dimension as Chebyshev distance. Specifically, assuming that the samples x and y are two points in an n ($n \geq 1$) dimensional space, equations (1) and (2) are obtained, and the Chebyshev distance is calculated as follows

$$d(x, y) = \lim_{p \rightarrow \infty} (\sum_{i=1}^n |x_i - y_i|^p)^{1/p} \quad (5)$$

d) *Minkowski distance metric*: The Min distance, sometimes referred to as the space-time interval, was first expressed by the Russian-German mathematician H. Minkowski (1864-1909). Assuming that the samples x and y are two points in an n ($n \geq 1$) dimensional space, equations (1) and (2) are obtained, and the Minkowski distance is calculated as follows.

$$d(x, y) = (\sum_{i=1}^n |x_i - y_i|^p)^{1/p} \quad (6)$$

From the calculation formula, Min's distance treats the components as obeying the same distribution, and also disregards the difference of the components in the magnitude.

e) *Standardized Euclidean distance Metric*: Similar to the Min distance, the simple Euclidean distance also suffers from the problem of treating the components as obeying the same distribution, and ignores the differences in the components in terms of mean and variance. By first standardizing the components and then calculating the Euclidean distance, an improved standardized Euclidean distance is obtained. Assuming that the samples x and y are 2 points in an n ($n \geq 1$) dimensional space, equations (1) and (2) are obtained, and the standardized Euclidean distance is calculated as follows.

$$d(x, y) = \sqrt{\sum_{i=1}^n \left(\frac{x_i - y_i}{s_i} \right)^2} \quad (7)$$

f) *Angle cosine metric*: The angle cosine is a measure of the similarity of sample points from the directional point of view, and is widely used in many fields. Suppose the samples x and y are two points in n ($n \geq 1$) dimensional space, and equations (1) and (2) are obtained, then the vector angle cosine is calculated as follows:

$$\cos(\theta) = \frac{\sum_{i=1}^n x_i y_i}{\sqrt{\sum_{i=1}^n x_i^2} \sqrt{\sum_{i=1}^n y_i^2}} \quad (8)$$

From the above equation, the absolute value of the cosine of the vector angle is less than or equal to 1. Its magnitude can reflect the similarity of the two vectors, and the larger the value, the higher the similarity of the two vectors [7]. Moreover, a positive value of the cosine of the vector angle indicates that the two vectors have an isotropic relationship, and vice versa, it indicates that the two vectors. The opposite indicates that the two vectors are negatively related [8]. Considering the similarity measures and the research needs of this paper, the similarity of students is calculated by using the similarity measure based on the cosine of the vector angle.

2) *Student-based collaborative filtering*: In the recommendation system, a sample of 343 senior students and their course selection records from the previous year at Liaoning National Normal College in China was selected as

the basis for this study and the similarity between classmates was calculated by referring to the angle cosine similarity measure. For the purpose of analysis, here is an example of seven students' collaborative over filtering process [9].

Suppose there are seven students, A, B, C, D, E, F and G, who choose the courses they want to take among five courses, a, b, c, d and e. Their course selections are as follows as shown in Fig. 1.

Based on the above students' course selection and the pinch cosine similarity measure, the similarity between students was calculated [10]. For example, the similarity between A and B is shown as below:

$$w_{AB} = \frac{|{a,b,e} \cap {a,d}|}{\sqrt{|{a,b,e}| |{a,d}|}} = \frac{1}{\sqrt{6}} \quad (9)$$

The similarity between A and C is

$$w_{AC} = \frac{|{a,b,e} \cap {c,d}|}{\sqrt{|{a,b,e}| |{c,d}|}} = 0 \quad (10)$$

Similarly, the similarity between A and D is $\frac{2}{\sqrt{6}}$, the similarity between A and E is $\frac{1}{3}$, the similarity between A and F is $\frac{1}{\sqrt{6}}$, and the similarity between A and G is $\frac{2}{3}$

Considering that the above algorithm needs to calculate the similarity between the specified sample (student) and any other sample, in order to improve the computational efficiency of the algorithm, the following improvement scheme is proposed [11].

Step 1: Create a course-to-student reverse lookup table.

Step 2: Build the student's congruence matrix based on the backwards checklist

Based on the selected status of each course in the sample, a backward checklist is created as shown in Fig. 2.

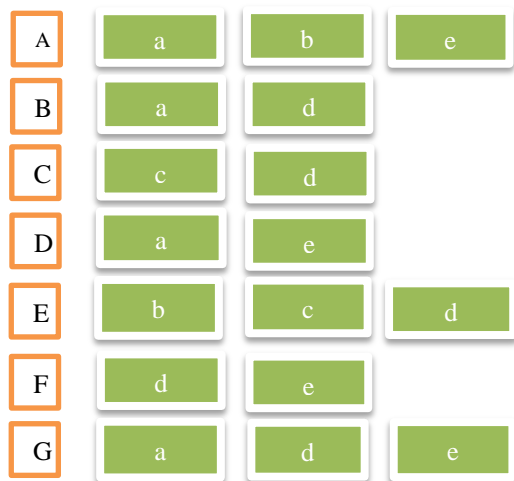

Fig. 1. Sample Student Course Selection List.

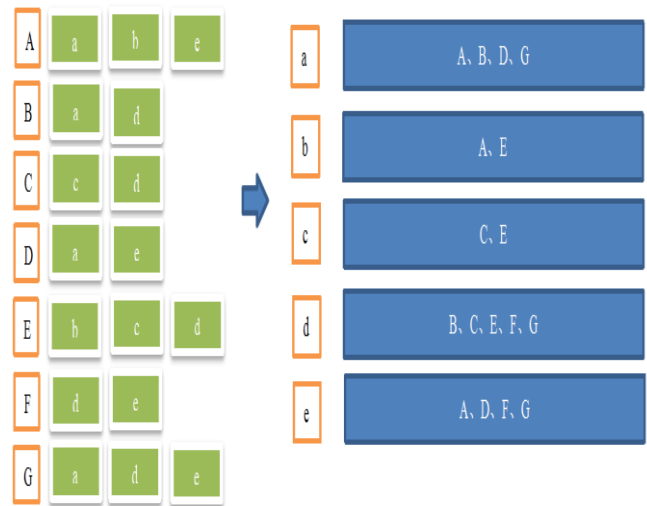

Fig. 2. Sample Student Course Selection Backward Checklist.

Based on the inverted table in Fig. 2, the same present matrix was generated for different students, and the results are shown in Table I.

The co-occurrence table was normalized and the results are shown in Table II.

3) Collaborative course-based filtering: When designing a recommendation system based on collaborative filtering, it is necessary not only to find out the near-neighbor students of a given student based on behavioral data, but also to evaluate the similarity of courses. In evaluating the similarity of courses, the algorithm uses students' ratings of courses to evaluate the similarity between courses [12]. In evaluating course similarity, the algorithm uses students' ratings of courses to evaluate the similarity between courses. To demonstrate the algorithm flow, the analysis is still based on the course selection records of seven students, A, B, C, D, E, F, and G, in five courses, a, b, c, d, and e. The records are analyzed, and their course selections are shown in Fig. 3.

TABLE I. CO-PRESENTATION MATRIX OF THE SAMPLE STUDENTS

	A	B	C	D	E	F	G
A		1		1	1	1	1
B	1		1	1	1	1	1
C		1			1	1	1
D	1	1				1	1
E	1	1					
F	1	1	1	1	1		1
G	1	1	1	1	1	1	

TABLE II. NORMALIZED MATRIX OF THE SAME-PRESENT MATRIX OF THE SAMPLE STUDENTS

	A	B	C	D	E	F	G
A		0.2		0.2	0.2	0.2	0.2
B	0.167		0.167	0.167	0.167	0.167	0.167
C		1			0.25	0.25	0.25
D	0.25	0.25				0.25	0.25
E	0.167	0.167	0.167	0.167		0.167	0.167
FF	0.167	0.167	0.167	0.167	0.167		0.167
GG	0.167	0.167	0.167	0.167	0.167	0.167	

Fig. 3. Sample Student Course Selection Records.

Then, the co-occurrence matrix of the course is normalized. The formula is as follows:

$$w_{ij} = \frac{|N(i \cap j)|}{|N(i)|} \quad (13)$$

The results of the treatment are shown in Table III.

TABLE III. NORMALIZED MATRIX OF COURSE CO-OCCURRENCE MATRIX

	a	b	c	d	e
a		0.33		0.33	0.33
b	0.25		0.25	0.25	0.25
c		0.5		0.5	
d	0.25	0.25	0.25		0.25
e	0.25	0.25		0.25	

After obtaining the students' ratings of the courses, and the similarity between the courses, estimating the preference of students u for the alternative course o [13].

The formula is as follows.

$$p_{u,o} = \sum_{i \in C(0,N)} w_{u,i} p_{u,i} \quad (14)$$

In Equation (14), the measure is the degree of preference of student u for course o . Calculating the degree of preference of a

given student for all alternative courses is the basis for constructing the student course selection recommendation system [14].

In addition, $C(0, N)$ in equation denotes the set of courses similar to the alternative course o , $w_{u,i}$ represents the similarity between the alternative course o and course i , and $p_{u,i}$ is the degree of preference of student u for course i calculated based on the nearest neighbor students [15].

B. Overview of Recommendation Systems

Currently, general education platforms use the course recommendation method based on data statistics, ranking the platform courses based on the number of course selections, and recommending the courses that most platform users are interested in, i.e. the popular course selection list. Among the current recommendation systems, collaborative filtering-based recommendation algorithms are the most widely used [16]. The Recommended methods have their own advantages and disadvantages, in order to better understand their interrelationship and their respective advantages, the two types of algorithms are compared as shown in Table IV.

There are two types of collaborative filtering methods commonly used.

1) user-based collaborative filtering (User-based CF) algorithm, which judges the user's favorite degree of the project through the user's historical behavior, calculates the relationship between users according to different users' preferences for the same project, and recommends the project among users with the same preferences [17].

2) Item-based algorithm focuses on Item, whose similarity is mainly based on its inherent feature values, so it can be classified according to its feature values, calculate the proximity between them, and give suggested results. Since the classification of item is more stable, it can be pushed offline [18].

The comparison of user-based and item-based advantages and disadvantages, and the scope of application have been summarized as shown in Table V.

TABLE IV. COMPARISON OF CLASSIC RECOMMENDATION METHODS

Comparison of Classic Recommendation Methods		
Recommended method	Advantages	Disadvantages
Collaborative filtering recommendations	The ideas are relatively simple and easy to understand; No domain knowledge required; Good comprehension; Can handle unstructured data	Cold start problems; Data sparsity ;
Content-based recommendations	Avoid cold starts and data sparsity;	Difficulty in processing unstructured data Complex feature extraction Recommendation information is prone to over-fitting;

TABLE V. COMPARISON OF USER-BASED AND ITEM-BASED ALGORITHM

Comparison of User-Based And Item-Based Algorithm		
Recommended method	Advantages	Disadvantages
User-based	Push for more socialization. Simply maintain user resemblance Table	Less pronounced specialization. Difficult to provide a push explanation
Item-based	Push specialization. Long-tail item enrichment. Convincing push explanations are available	Unable to adapt to Item updates fast speed

C. The limitation of Previous Studies

The current course selection recommendation system in universities is separate from the online course system. The vast majority of scholars have done a lot of complex work and research in the direction of personalized social network recommendations, e-commerce product recommendations, user emergence mining models, personalized recommendation videos, learning resources, and student user preferences, user profiles, deep recommendation algorithm models, etc.

However, there is very little content related to students' real course selection recommendations, as each school has a different course selection platform. Most schools are concerned about how to complete the task of course selection more easily and quickly, and guarantee the stable operation of the system's course selection platform by randomly drawing lots, or by centrally opening the platform for students to grab courses within a fixed period of time, and do not consider the satisfaction of students' diverse needs through a simple and brutal way.

Algorithms are at the core of personalized recommendation and collaborative filtering techniques. However, how to develop effective and accurate evaluation criteria for the recommendation results of algorithms is an issue that deserves constant attention both for academia and industry. Different evaluation criteria have different focuses, and a single evaluation criterion generally only evaluates a certain aspect of the algorithm, which is more or less deficient. Therefore, how to choose appropriate evaluation metrics to evaluate the recommendation results has a crucial impact on the development of the whole personalized service field [19].

III. METHODOLOGY

Combine course selection function and collaborative filtering and recommendation technology to realize intelligent course selection function. To analyze the trend of students' interest through their information in the system, such as courses taken, grades, ratings, comments, etc., and give them a list of courses. Focusing on the application of pushing process, user-based and item-base are applied to the selection of courses with student and course as the main objects of study. Since the traditional algorithms have some shortcomings, this paper applies item-based weighted and user-based weighted collaborative filtering algorithms to the course selection push system to improve the accuracy. In the design of the course selection push system, consider the major attributes of students,

the relevant attributes of courses and the ratio of students to courses to ensure that the recommendation system can push the set of courses that students are really interested in [20].

A. Data Collection

1) *Selection of data set:* In this paper, we use the data set of the academic system of Liaoning National Normal University to implement the traditional pushing process. A part of the information is extracted as the initial data, and 238 students' evaluation information is obtained. The records were tabulated into students, courses, and ratings tables. Each data file contains the following details.

- Students: Stu-name、Stu-number、Sex、Grade、Score、Zx/Gx (Professional Elective Courses/Public Elective Courses)
- Ratings: Stu-number、Course ID, Rating, and Times.
- Courses: Course-ID、Course-name、Course-category.

The data set is the basis for implementing the course selection push function. Based on the students' course selection and course rating over a period of time, the students' interest level in various elective courses is analyzed and expressed by rank. In this paper, we use a two-dimensional matrix to represent the student's interest in a course, i.e., a $v \times w$ student-course favorite table vw , where v represents the number of students and w represents the number of selected courses. vw value represents the v th student's interest in the w th course. This matrix can be explained by Table VI.

TABLE VI. STUDENT-COURSE GRADING SCALE

	Java	Python	Basketball	H5	Android	PS	Database
student1	5	1	2	1	0	1	4
Student2	2	3	1	2	2	2	5
Student3	2	0	0	4	5	5	2
Student4	3	3	2	3	3	1	3
...
Student N	2	5	0	4	4	4	3

B. Data Description

- Extraction of student attributes and student behavior characteristics:

Define student attributes and behaviors:

student (name、id、sex、grade、Course-name、score、Professional Electives/Public Electives) , For example:Students (Bao Fuyu, 201503, difficult, 21 Computer Applications, Computer Composition, 85, major elective).

- Course Properties

Define course attributes:

Course (course-name, course-id, course-time, score, grade, course-type), such as course (Java programming core technology, F1025, 36 hours 90, 19computer, elective).

C. Research Procedures

The basic framework of intelligent course selection push system is shown in Fig. 4.

Fig. 4. The Framework of the Push System.

The process of Item-based weighting and User-based weighting push is shown in the following Fig. 5.

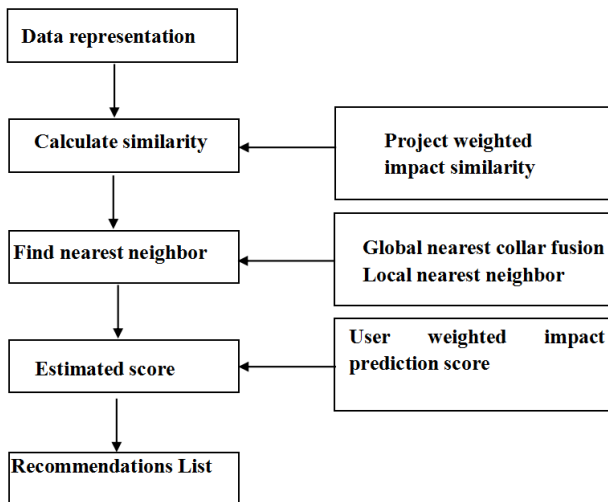

Fig. 5. Item based Weighted and user based Weighted Recommendation Process.

1) *Basic idea:* Consider both course-weighted and student-weighted, and use item-based weighted user cosine similarity and user-based weighted user collaborative filtering to predict the evaluation and improve the accuracy of recommendation [21].

2) *Description of the algorithm process:* Input: target student T, course evaluation form R, course characteristics form A, number of neighbors k;

Output: Top-N recommendation set of target student T;

Step1: Find the set of graded courses of all students, courses and target students T in the system from the course grading table R, and denote them as U_m, I_n, I_T [22].

Step2: The top k students with the highest median value are selected as the closest set of students to student T according to the influence of different course weights to obtain the weighted cosine similarity $N_T = \{j_1, j_2, \dots, j_k\}$.

Step3: For any ungraded course i of the target student T, a weighted approach is used to combine the predicted evaluation of student impact with the predicted evaluation of the student's historical evaluation.

Step4: Select N courses with higher predicted scores as the push result set for target student T.

IV. ANALYSIS AND RESULTS

This chapter is the realization of the system function based on the description and design of the course selection system, then expounds the implementation effect of the recommendation function of the system, and effectively evaluates the recommendation function of the main program of the system according to the evaluation index.

A. Experimental Information

The computer test environment of this machine is shown in Table VII.

TABLE VII. EXPERIMENTAL ENVIRONMENT AND INFORMATION SOURCES

Central processing unit model	Internal Memory (GB)	Operating System	Hard Disk (GB)	Database
Intel(R) Xeon(R) CPU X5650 @ 2.67GHz (12 CPUs)	16GB	Windows11	1TB	Sql Server 2018 R2

B. Data Conversion

The item based weighting and user based weighting recommendation methods are adopted. The item based weighting will affect the proximity value and nearest neighbor selection, and the user based weighting will affect the prediction and evaluation. It is applied to the university educational administration course selection push system to realize the purpose of intelligently pushing elective courses for students. First, get the original data from the database, sort out the original data, retain useful data, delete irrelevant records, and improve the efficiency and accuracy of the algorithm. The data involved in the algorithm studied in this paper are from the educational administration system of Liaoning National Normal University. The data will be processed separately to meet the requirements of the algorithm [23].

From the database, 7 data tables related to students' previous course selection and evaluation data of students' courses are selected. There are 8 tables, from which students' attributes, course selection attributes and students' teaching evaluation information can be obtained. From the interview table collected from students, it can intuitively obtain the students' interest in course in some directions [24]. Obtain the student number, name, course name, major, score, evaluation and other records useful for the algorithm. After re integrating the records, establish the correlation between tables and rewrite them into the database. See Fig. 6 as follows.

Fig. 6. Association Table after Data Conversion.

C. Accuracy Comparison Results

Experiments show that the improved algorithm can improve the push accuracy. During the experiment, the data comes from.

The data of Liaoning National Normal University educational administration system and the information is collected by questionnaire survey. The test set takes three tenths of the information, the training set takes seven tenths of the information and arbitrarily turns it into five parts, which are expressed as data set 1, data set 2, data set 3, data set 4 and data set 5, respectively. The accuracy flow of push algorithm is shown in Fig. 7.

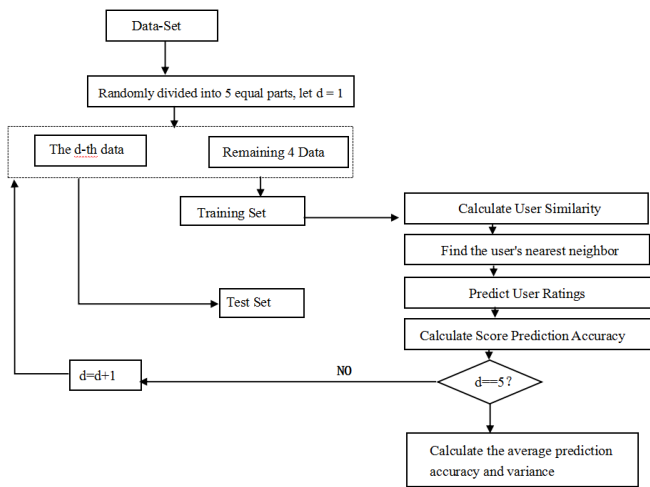

Fig. 7. Accuracy Flow of Collaborative Filtering Algorithm.

V. DISCUSSION

In order to test the prediction accuracy of the recommendation algorithm, the course data set is used for off-line calculation, the student behavior model is established on the training set to predict the student behavior on the test set, and the score prediction accuracy is calculated through the root mean square error RMSE. The detailed experiments are as follows:

- The experimental design uses different data to test the influence of algorithm convergence, and takes the course data set to test, including 343 students and 40 course scores. The data set is divided into two parts: 80% training data and 20% test data.

- Experimental data: under the condition of comprehensive prediction accuracy and efficiency, the experiment carries out three iterative tests of 10K, 100k and 1m data: 5, and 10. The RMSE data is shown in Table VIII.

A. Experimental Analysis

Through the experimental analysis, the following results can be obtained. When the number of iterations increases, the prediction accuracy of RMSE will decrease, and each doubling will decrease by 0.04, indicating that the increase of the amount of data will not significantly reduce the performance of the recommended algorithm, and the increase of the amount of data will make the convergence effect of the algorithm better [25]. At the same time, it can be obtained from the analysis that when the amount of data is the same, the choice of K value affects the prediction accuracy, that is, the smaller the K value, the higher the accuracy, and the larger the K value, the lower the accuracy. Therefore, K is selected as 5 as the number of iterations. The collaborative recommendation algorithm combines the characteristics of User-CF and Item-CF algorithms, and filters the students' information with tags at the initial stage of recommendation, which reduces the search scope to a certain extent. When recommending, filter the initial results of User-CF recommendation, and then make the final recommendation according to the score, so as to make the recommendation effect better, as Fig. 8 and 9.

After many times of verification and improvement, on the whole, the system meets the design requirements. The accuracy of the core algorithm in the recommendation function is evaluated. The experimental results show that the algorithm can produce.

TABLE VIII. RMSE IN DIFFERENT ITERATION DATA

Data-Set	1	2	3	4	5	K
10K	0.9468	0.9411	0.9228	0.9393	0.9265	5
10K	0.9221	0.9254	0.9265	0.9162	0.9232	10
100K	0.8916	0.8870	0.8915	0.8886	0.8891	5
100K	0.8559	0.8671	0.8673	0.8672	0.8655	10
1M	0.8107	0.8382	0.8449	0.8402	0.8322	5
1M	0.8182	0.8182	0.8184	0.8163	0.8153	10

VI. CONCLUSION

In this paper, is used the collaborative filtering algorithm to study students' course selection preferences based on their course selection history data, and build a university course selection recommendation system based on this algorithm. A university course selection recommendation system is built based on this algorithm. The experimental results show that the collaborative filtering algorithm is able to mine and extract the attributes, behavioral characteristics and preferences of students, which can help solve the problems of students' course selection. It can help solve the problem of students' randomness and blindness in course selection, and improve the management efficiency of university education and teaching. In particular, this paper shows that the collaborative filtering algorithm-based student course selection recommendation system can better balance the relationship between student characteristics and course characteristics, and can help achieve the optimal matching between student learning ability and course requirements, student course selection preference and course characteristics, and student ability development and career requirements.

A. Innovation Points

Through the shortcomings of the existing course selection system and the urgent need for an intelligent course selection system, we select the existing course selection system of Liaoning National Normal University and analyze it. Then, introduce collected students' course selection data from Liaoning National Normal University's academic affairs system, pre-processed the data, and compared the user collaborative filtering algorithm based on user weighting with the traditional filtering algorithm through experiments, and the improved way considered the weights of student and course, verified that it can improve the recommendation pushing accuracy in a certain range, and the better pushing result is achieved.

B. Future Work

When looking for nearest neighbors, it can consider the fusion of local nearest neighbors and global nearest neighbors. Global nearest neighbors, local interests are not similar, local nearest neighbors, and global interests are not similar. Through

the optimization algorithm of similarity, the recommendation accuracy can be improved, the data can be used to a greater extent, and the error problem caused by sparse data can be improved. Following problems need to be further studied in the future to supplement and improve the paper: How to make the intelligent course selection recommendation system more accurate and more real-time, and consider the time complexity and space complexity of the algorithm to make the efficiency better?

Abstract—Object recognition method is a computer vision technique for identifying objects in images. The main purpose of this system build is to put an end to blindness by constructing automated hardware with Raspberry Pi that enables a visually impaired person to detect objects or persons in front of them instantly, and inform what is in front of them through audio. Raspberry Pi receives data from a camera then processes it. In addition, the blind will listen to a voice narration via an audio receiver. This paper's key objective is to provide the blind with cost-effective smart assistance to explore and sense the world independently. The second objective is to provide a convenient portable device allows users to recognise objects without touch, having the system determine the object in front of them. The camera module attached in Raspberry Pi will capture image and the processor will then process it. Subsequently, the processed image sends data to the audio receiver narrating the detected object(s). This system will be very useful for a blind person to explore the world by listening to the voice narration. The generated voice narration after processing the image will help the blind to visualise objects in front of them.

I. INTRODUCTION

Physical movement is a challenge for the blind. Visual disability stands out from the many extreme obstacles affecting a person. This is clearly explained in this research study about the visually impaired patients. They face physical and social constraints accrued from their visual loss, and they need to improve on their health and independence [1][2][3]. Designing a gadget to help the blind is not something new. Various technologies exist to help the visually impaired, and as innovations increasingly propelled, ideas appear to provide intriguing measures to help the visually impaired. In any case, designing a device to aid blindness comes with a price and does not come easy, as it is often regarded as a so-called luxurious item in most developing nations.

As indicated by the World Health Organization (WHO) research study, [4][5] it has been estimated that over 1.3 billion people around the world have some form of vision impairment. Roughly, 80% of all kinds of vision debilitation are viewed as avoidable. Additionally, the WHO also mentioned that most visually impaired adolescents would require visual recovery intercessions for self-improvement. Nevertheless, it is most often that visual recovery treatments come with substantial hospital expenses, and with 90% of disabled people living with financial difficulties, visual restoration is not the best alternative for all. For full psychological improvement and better independence without bearing costly bills, blind people require an assistive device that helps them with their daily activities. There exist many assistive devices for visually impaired people and it became the inspiration in the background of this research study. Smart assistance such as a smart and autonomous walking stick, smart glasses/spectacles, or prosthetics [6][7][8][9]. The assistance from another individual is not always accessible, and are unfavoured by visually impaired individuals that search for freedom, without having to bear the cost of such expensive smart assistance equipment as well. We propose an audio receiver for blind people that uses real-time smart assistance interfaces and object recognition technologies as a solution to this occurring issue. Our system mainly consists of two components, Raspberry Pi and Pi camera. The smart assistance audio guidance was developed to assist users to determine objects in front of them and help them visualise the environment around them. The camera in the processor will capture image, then processes that image, and a voice narration will be sent through audio receiver.

The main objective is to provide the blind cost-effective smart assistance to explore and feel the world independently. This enables the blind to visualise their surroundings and afford current technologies. Additionally, we also aim to provide a portable device which is easy to utilise and permits them to recognise objects without touching, and describes the surroundings in front of them.

*Corresponding Author.

This system is used to assist blind people with voice narration, processed by the Raspberry Pi processor. This portable electronic device's purpose is to give voice narration informing what is in front of them. An important objective is to provide a portable device that is simple to use and low cost and affordable smart assistance to blind people. Another goal is to extend the computerised electronic travel aid for the blind by applying real-time object recognition technology. This blind guidance system is solid and financially perceptible. Real-time based smart assistance interfaces the audio receiver for blind people with voice narration by using object recognition methods to provide the blind with cost-effective smart assistance to explore and sense the world independently. Audio guidance helps them to know what is happening around them and it helps them to visualise their surroundings. By using real-time, the system will recognise the objects faster.

The remaining of this paper has been organized as follows: Section 2 discusses the related works. The background of the study is described in Section 3. Section 4 described the system implementation and testing. Section 5 described the results and discussion and finally, the conclusion is described in Section 6.

II. RELATED WORK

There are a lot of assistive devices for visually impaired people to sense the world independently. All these devices rely mainly on ultrasonic sensors and Brailleing.

A. EyeCane and EyeMusic

Maidenbaum et al. [10] designed EyeCane and EyeMusic to improve upon, or likely be within the far distant future, to update the traditional white cane. By applying statistics at visually far distances (5 meters) and greater angles, and most significantly by means of discarding contacts among the cane, and the user's surroundings in cluttered or indoor environments. The EyeCane converts point-distance information into aural and tactile signals. The Prototype of EyeCane and EyeMusic is shown in Fig. 1. The tool can provide distance information to the customer from two different directions at the same time: immediately in advance for long-distance perception and detection of waist-height obstacles, and pointing downward at a 45° angle for ground-level evaluation.

Fig. 1. Prototype of EyeCane and EyeMusic.

B. Blitab

Blitab is a device nicknamed "the iPad for the visually impaired". It appears similar to a digital book, however, its screen utilises smart liquids that protrude tactile pixels to show braille letters, making it conceivable for the blind to see entire pages of braille message at once. Perkins-style keyboard application, text-to-speech yield, and touch navigation provide a completely new user experience for braille and non-braille blind individuals. It empowers the fast conversion of any content into braille. Blitab is a platform for all current and future programming applications for visually impaired people, it is not only a tablet. The Prototype of Blitab is shown in Fig. 2.

Blitab is the world's first real tactile tablet designed specifically for the blind and visually impaired. The device's revolutionary smart liquid technology also allows it to display material images for blind people who do not use braille [11].

C. BrainPort V100

According to Grant et al. [12], BrainPort V100 is an oral electronic vision aid that uses electro-tactile stimulation to help profoundly blind people with direction, mobility, and object recognition. The device is used in conjunction with other assistive devices like a normal white cane or a guide dog.

It deciphers digital data from a wearable camcorder into delicate electrical incitement designs on the outside of the tongue. Users feel moving bubble-like patterns on their tongue then they figure out how to interpret or visualise according to the shape, size, area, and movement of articles in their condition. A few clients have portrayed it as having the option to "see with your tongue". What makes it extraordinary is seeing with your mouth may appear to be outlandish at first, yet with at least 10 hours of one-on-one instructional courses, wearers can figure out how to comprehend the shivers and "see" where objects are found, yet additionally, their size, shape and in the event that they are moving. In a clinical preliminary, 69% of members had the option that effectively recognises protests in an acknowledgment test following one year of preparing with the BrainPort. The Prototype of BrainPort V100 is shown in Fig. 3.

Fig. 2. Prototype of Blitab.

Fig. 3. Prototype of BrainPort V100.

TABLE I. COMPARISON BETWEEN EXISTING SYSTEM

System	Devices needed	Cost	accessibility	purpose
BrainPort V100	Headset, Intra Oral Device(IOD)	Expensive (\$10000)	Controller	To provide oral electronic vision aid
EyeCane& EyeMusic	Infrared emitters, web camera, smartphone, headset	Low cost	Infrared sensors	To provide navigation control and identifies colour, shape and location of objects.
Blitab	Touch screen tablet, Braille lines	Low cost(\$500)	Braille display	Displays tactile images to blind people.
Proposed method	Raspberry Pi 3, Pi camera module, Headset	Cheap (\$100)	Text-to-Speech module	The generated narration will be the final output that is transmitted to the user through a headset.

The difference between existing systems is shown in Table I.

III. BACKGROUND OF THE STUDY

Object Recognition is a method used in image processing to recognise real objects. This method is clearly explained in a

research study about the importance of process that will help blind people to identify their daily items that are commonly used. Our system provides some kind of visual aid that recognises objects dynamically [13]. The algorithm used in this system analyses the object. For instance, a blind person is sitting on his dining table. He has multiple objects in front of him such as bottle, chair, dining table, etc. Therefore, our system will help him by narrating what is in front of them. Text-to-Speech module is used to convert text to speech. The text that is written in text file is the output of object detection. Google API is used for conversion of Text-to-Speech dynamically, provided that the internet connection is stable. This has been studied from a research that explains about Google API that is used for text-to-speech [14]. For example, if the camera captures a book in front of it, it detects the book and converts it into text from the image captured. The text will be written in a text file and then converted to speech by using Google Text-to-Speech. The architecture of this proposed system is the Raspberry Pi board. Raspberry Pi controller controls the system and activates the output and sends the instructions. The detailed specifications of Raspberry Pi 3 B+ consists of: four USB ports, an Ethernet port, forty GPIO pins, SD card slot, SOC (system on a chip), a DSI display interface, HDMI port, LAN controller, audio jack, CSI camera interface, RCA video socket, and 5V micro USB connector [15].

The Block diagram of the object recognition process is shown in Fig. 4.

The Pi camera is connected to a CSI camera interface of Raspberry Pi processor. The processor has an operating system named Raspbian, which process the image, voice narration and other conversions. The headset will connect to an audio jack for audio output. Once the system components activate, the camera module will begin a video stream of its front view, and the image in video will be processed. Before this process starts, the Raspberry Pi will create a video frame, activates "cv" environment, and runs the python script to activate the system. Thereafter, the processed image undergoes object detection for image classification and recognition. Hence, the image in the video will detect through real-time object recognition, and the label of each object will be printed in a text file, which is used for voice narration. The labels in the text file use Google Text-to-Speech for voice narration. The generated narration will be the final output that is transmitted to the user through a headset.

The flowchart of the object recognition process is shown in Fig. 5.

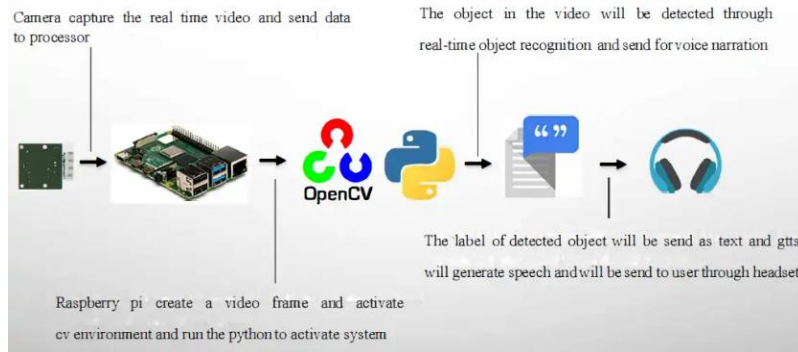

Fig. 4. Block Diagram of the Object Rprocess.

IV. SYSTEM IMPLEMENTATION AND TESTING

A. Hardware Implementation

The necessary components in developing this system consist of a Raspberry Pi and Pi camera. The New Out of Box Software (Noobs) is installed on an SD card to format the Raspberry Pi that will be fixed in the Raspberry Pi, as studied in the manual that was given to study about Raspberry Pi startup [16]. Noobs contain Java SE Platform Products. It is an operating system installer with Raspbian pre-loaded. Once done, this Raspberry Pi will connect to power, start to boot, and be ready to use the operating system, whereas the Pi camera will be configured beforehand. The camera's interfacing option in Raspbian OS will be enabled manually to allow the camera to work with the system. Once the configuration is done, the Raspbian enables the camera. The image captured after configuring the Pi camera is shown in Fig. 6.

B. Software Implementation

The Raspbian operating system is used in the Raspberry Pi 3 model B+ as a platform to run this system; which is, the platform to create, run, and troubleshoot the coding of the software that has been used. Python IDLE software was used to build this system. Python IDLE ran in an OpenCV environment. OpenCV was created to provide a common infrastructure for computer vision applications such as deep learning, optical character recognition (OCR) and object detection, and more as explained in the article [17][18]. OpenCV-Python is the Python API for OpenCV. It's a Python bindings library aimed in solving computer vision challenges. Python has been enhanced with C/C++, enabling programmers to write/express code and develop Python wrappers that can be used as Python modules, as stated in the article named Python. It is packaged as an optional part of the Python packaging with many Linux distributions [19][20]. The actual code will run in the background of the CV environment. To write the necessary codes to run the system, the Python 3.7.3 was used. To capture the image, a Pi camera connected to a Raspberry Pi was used. Furthermore, code will be used to initialise the captured image.

Fig. 5. Flowchart of the Object Recognition Process.

Fig. 6. Image Captured after Configuring the Pi Camera.

V. RESULT AND DISCUSSION

Here is a sample of coding and result for this proposed system. Some discussions are added up as an explanation to understand its function clearly.

A. Coding

Partially applied programming codes are displayed below in Fig. 7 to Fig. 10.

```
ap = argparse.ArgumentParser()
ap.add_argument("-p", "--prototxt", required=True,
                help="path to Caffe 'deploy' prototxt file")
ap.add_argument("-m", "--model", required=True,
                help="path to Caffe pre-trained model")
ap.add_argument("-c", "--confidence", type=float, default=0.2,
                help="minimum probability to filter weak detections")
args = vars(ap.parse_args())
```

Fig. 7. Construction of the Argument Parse.

The preceding code demonstrates how to construct an argument parse to parse the arguments. 'ArgumentParser()' converts the argument value from a string into some other type. The first line sets up an argument parser, followed by three mandatory command-line arguments. Firstly, the 'prototxt' is the path to the Caffe prototxt file which is known as the solver.prototxt, secondly, a configuration file, whereas '— model' is the path to the pre-trained model and thirdly, the '— confidence' is minimum probability threshold when filtering weak detections and it is set to 20% by default.

```
CLASSES = ["background", "aeroplane", "bicycle", "bird", "boat",
           "bottle", "bus", "car", "cat", "chair", "cow", "diningtable",
           "dog", "horse", "motorbike", "person", "pottedplant", "sheep",
           "sofa", "train", "tvmonitor"]
COLORS = np.random.uniform(0, 255, size=(len(CLASSES), 3))

# load our serialized model from disk
print("[INFO] loading model...")
net = cv2.dnn.readNetFromCaffe(args["prototxt"], args["model"])
```

Fig. 8. Initialisation of 'Classes'.

These lines of code initialise 'CLASSES', class labels, and equivalent COLORS, for on-frame text and bounding boxes. Furthermore, the last line loads the serialised neural network model.

```
for i in np.arange(0, detections.shape[2]):
    # extract the confidence (i.e., probability) associated with
    # the prediction
    confidence = detections[0, 0, i, 2]

    # filter out weak detections by ensuring the 'confidence' is
    # greater than the minimum confidence
    if confidence > args["confidence"]:
        # extract the index of the class label from the
        # 'detections', then compute the (x, y)-coordinates of
        # the bounding box for the object
        idx = int(detections[0, 0, i, 1])
        box = detections[0, 0, i, 3:7] * np.array([w, h, w, h])
        (startX, startY, endX, endY) = box.astype("int")

        # draw the prediction on the frame
        label = "{}: {:.2f}%".format(CLASSES[idx],
                                   confidence * 100)
        cv2.rectangle(frame, (startX, startY), (endX, endY),
                    COLORS[idx], 2)
        y = startY - 15 if startY - 15 > 15 else startY + 15
        cv2.putText(frame, label, (startX, y),
                    cv2.FONT_HERSHEY_SIMPLEX, 0.5, COLORS[idx], 2)
```

Fig. 9. Looping the Detection.

This part explains how this system is able to detect numerous objects in a single image. First step is to loop over the detections. The chance of each detection will be checked and tallied with confidence. If the confidence exceeds the

threshold, the prediction will be displayed in terminal and drawn on the frame. Detections will undergo loops and its confidence value is extracted in each loop. Therefore, the class label index is extracted if the confidence level is greater than the minimal threshold, as well as the bounding box coordinates surrounding the detected objects that have been computed too, and a rectangle displaying text is created on the detected object. Labels containing CLASS name and confidence build, and displayed as the processed-colored rectangle created around the object. Finally, the system computes the colored text that was generated onto the frame by using the y-value.

```
from gtts import gTTS
from time import sleep
import os
import pygame

file = open("label.txt", "r").read().replace("\n", " ")
language = 'en'
tts = gTTS(text = 'hi there. i am here to assist you to look the world in front of you, there is' + str(file) + 'in front of you', lang = 'en', slow = False)
tts.save('voice.mp3')
os.system("start /home/pi/Desktop/real-time-object-detection/voice.mp3")
print(file)
```

Fig. 10. Voice Narration.

To enable the Raspberry PI to "talk", the Google Text to Speech (gTTS) module is used in Python is used and also imported into the Raspbian system. This is used to command the system to read the image classification result that has been written after the real time object detection process. To put it simply, this python coding aims to read the text file and then create a voice narration.

B. Result

The system has been tested and its functionality has been demonstrated as per the design. The system has been able to operate as designed, thanks to the combination of software and hardware components. The system interface with Pi camera will capture the front environment and the data will be transferred to the processor to process the image. Object recognition methods will enable image processing, convert it to text, and use Google-Text-to-Speech to create the voice narration and send it to the user through an audio receiver.

The detected objects in frame are shown in Fig. 11.

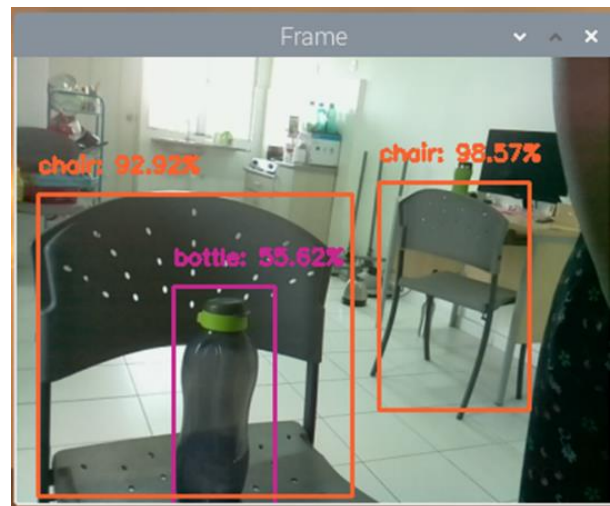

Fig. 11. Shows Objects Detected in Frame and its Confidence Percentage Value of the Detected Objects with its Label of Classes.

Fig. 12. Shows Label Classes will be Printed along with the Detection Confidence Percentage Value.

From Fig. 12, the results from the system are collected and the percentage of confidence value obtained, to show the objects detected along with its confidence percentage value. Confidence value is the probability that a bounding box containing an object and it is predicted by a classifier. The object in the bounding box would return many predictions, but out of those, most of them will have a very low confidence value associated. Hence, only predictions above 20% confidence is reported, as fixed in the python coding itself. That is how the object detection algorithm returns values after confidence thresholding, once the video stream starts in our system. As previously indicated in Fig. 11, the objects in the bounding box are correct, due to the quantifying the predictions.

To confirm the predictions, the correctness value of each object detection should be obtained. The measurement that determines the correctness of the bounding box is the Intersection over Union (IoU). IoU [21][22][23] is the ratio between the intersection, and the union of speculated boxes and ground truth boxes. The IoU's calculation is shown below in Fig. 13.

Consequently, the correct detections will be identified, and then its precision and recall will be calculated. To calculate precision and recall, the True Negatives, False Negatives, True Positives and False Positives will be identified. To obtain True Positives and False Positives, IoU will be used and the detection will be identified to determine whether it is correct (True Positive) or not (False Positive). The used threshold is 0.2, if IoU is > 0.2, it is considered a True Positive. Else, it will be considered as a False Positive. The COCO (Common Objects in Context) evaluation metric suggests measurements through various IoU thresholds.

To calculate the recall, the count of Negatives is required because not every part of the image in the video stream frame detected is an accepted object or is considered a negative. False Negatives will only be measured if the objects detected by our system are missed out. The recall is calculated as the ratio between the number of correct predictions (A) (True Positive) and the missed detections (False Negatives). The correct predictions for each class in the video stream will be commutated after calculation of IoU using the ground truth boxes for each positive detection box that the system has reported. So, with this, the IoU threshold (0.2). Therefore, the formulas will be as below.

$$Precision = \frac{TP}{(FP+TP)} \tag{1}$$

$$Recall = \frac{TP}{(TP+FN)} \tag{2}$$

Subsequently, the Mean Average Precision (mAP) is calculated in Table II. mAP is used in the domains; Information Retrieval and Object Detection. These two domains have separate ways to calculate mean average precision. Object detection of mAP is formalised in the PASCAL Visual Object Classes (VOC). PASCAL VOC provides a common dataset of images and annotations, as well as a standard evaluation to the vision and machine learning communities [24][25]. The average precision for all object types is shown in the table below. The PASCAL VOC dataset's mAP was found to be 0.665. The best mAP value at the moment is reported to be 0.739.

Fig. 13. IoU Calculation.

TABLE II. AVERAGE PRECISION FOR ALL CLASSES

No.	Class	Average Precision
1	Train	0.542
2	Bicycle	0.636
3	Dog	0.818
4	Diningtable	0.534
5	Aeroplane	0.727
6	Chair	0.909
7	Person	0.909
8	Tvmonitor	0.633
9	Bus	0.726
10	Sofa	0.710
11	Bird	0.727
12	Cow	0.632
13	Bottle	0.909
14	Pottedplant	0.359
15	Boat	0.544
16	Car	0.634
17	Cat	0.272
18	Sheep	0.633
19	Motorbike	0.724
20	Horse	0.726

VI. CONCLUSION

The system's goal of providing intelligent help for visually impaired people through real-time based object recognition has been successfully developed. Most of the important details in the general theory of design and execution have also been introduced throughout this article. From the theory to the practical realisation of this category of smart assistance for visually impaired people, these developments involve a variety of technical and coding details. From the testing and result analysis, the designed system's functionality is advanced and helps the visually impaired people to know what is in front of them. According to the data analysis based on Table II, the average precision for all classes is shown. Occasionally, detecting precision is not as precise as it should be, because the object is detected using values assigned by the system. Additional objects of comparable size or shape may also be detected with incorrect predictions. The strength of this system is users are able to listen to the voice narration audio that informs them what objects are in front of them. The Mean Average Precision (mAP) was calculated. The PASCAL VOC dataset's mAP was found to be 0.665. The best mAP value at the moment is reported to be 0.739.

The limitation of this system is it only has one pi camera interfaced to raspberry pi to capture video stream. So the scope only for blind people since the system included with pre-trained model that used for object detection. The most important recommendation for improvement, is about a future work development by implementing the Non-Maximum Suppression, making the regions more accurate. The object detection algorithm is good but not very accurate sometimes, because the regions reduce the ratio of algorithm. Furthermore, the development of this system should include a more pre-trained model in larger numbers. Lastly, the system can be improved by being cloud based, that way, all the data that had been captured will be saved in the cloud, and it will be easy for the user's guardian to acknowledge the details this system has generated, and can include localisation to know the location of the user travelled.

ACKNOWLEDGMENT

The authors would like to thank Centre for Research and Innovation Management (CRIM) for the support given to this research by Universiti Teknikal Malaysia Melaka (UTeM). We thank also those who contributed in any other forms for providing their continuous support throughout this work.

Associate Professor, Department of Computer Science and Applications, Barkatullah University, Bhopal, Madhya Pradesh, India

Abstract—Estimation of reference evapotranspiration (ET_o) is a complex and non-linear problem that is used for the quantification of crop water requirements. In this study, random forest regression based models are developed to predict the ET_o of Bhopal city, Madhya Pradesh, India. The meteorological data is collected from IMD, Pune for the periods of the years 2015-16. Based on the correlation among meteorological variables with observed ET_o, four different random forest regression models are created. Moreover, the effects of three important hyper-parameters of random forest, such as the number of trees in the forest, depth of the tree, and the number of samples at a leaf node are evaluated to estimate ET_o using the proposed models. These hyper-parameters are applied in three different ways to the models such as one hyper-parameter parameter at a time, and combination of hyper-parameters using grid search, and random search approaches. In this study, the result indicates that a random forest regression based model with maximal meteorological input variables exhibits great predictive power in small execution time than minimal input variables. This study also reveals that the model that optimises the hyper-parameters using a grid search approach shows equal predictive power but takes much execution time whereas random search based optimization exhibits the same level of predictive capability in less computation time. Stakeholders can utilize random forest regression models with sufficient meteorological data to estimate crop water requirements, and enhance the food production.

Keywords—Reference evapotranspiration; random forest regression; hyper-parameters; grid search; random search optimization

I. INTRODUCTION

Evapotranspiration is a step of the hydrological cycle and has numerous applications such as water management, irrigation scheduling, etc. Evapotranspiration consists of the evaporation and transpiration process. Evaporation removes water from the soils, ponds, and rivers whereas transpiration removes water from the plants. Reference evapotranspiration (ET_o) is estimated on smooth grassland which is further used to estimate crop evapotranspiration. The FAO-PM56 is one of the standard empirical methods provided by the Food Agriculture Organization of the United Nations [1]. Such an empirical method suffers from complicated calculations. Weather stations at various places are equipped with power full devices that are constantly observing climatic data. Machine

learning based models can be applied to such a huge amount of data to estimate ET_o accurately and efficiently. Many authors have applied various machine learning algorithms to estimate ET_o.

The ability of M5P, RF, RT, REPT, and KStar and neuro-fuzzy inference systems such as ANFIS, ANFIS-GA, ANFIS-DE, and ANFIS-ICA has been tested to estimate evapotranspiration [2]. Feed-forward artificial neural network with the Levenberg–Marquardt (LM) training algorithm has been investigated to predict evapotranspiration [3]. Genetic programming (GP), support vector machine-firefly algorithm (SVM-FFA), artificial neural network (ANN), and support vector machine–wavelet (SVM–Wavelet) have been analyzed to predict reference evapotranspiration [4]. Extreme learning machine (ELM), back-propagation neural networks optimized by genetic algorithm (GANN), and wavelet neural networks (WNNgra) models have been developed to estimate evapotranspiration [5]. Random forest (RF) and generalized regression neural network (GRNN) models have been applied to estimate daily evapotranspiration [6]. Four tree based ensemble algorithms such as random forest (RF), M5 model tree (M5Tree), gradient boosting decision tree (GBDT), and extreme gradient boosting (XGBoost) models have been compared for estimation of evapotranspiration [7]. GRNN, MLP, RBNN, GEP, ANFIS-GP, and ANFIS-SC models have been investigated for modeling evapotranspiration [8]. Genetic (GA) and gene expression programming (GEP) models have been used to estimate reference evapotranspiration [9]. M5P Regression Tree, Bagging, Random Forest (RF), and Support Vector Regression (SVR) have been compared [10]. The performance of kNN k-nearest neighbour, artificial neural network, and Adaptive boosting (AdaBoost) to predict daily evaporation for the potato crop have been investigated [11]. Machine learning algorithms have own hyper-parameters that can be tuned at the training duration. Tuning of hyper-parameters can affect the performance of the algorithm. There are various approaches to tune hyper-parameters. In [12] authors show empirically and theoretically that randomly chosen trails are more efficient than the trails on grid. [13] Performed comparative analysis of various hyper-parameters tuning methods to optimize the accuracy of machine learning algorithms. In [14] hyper-parameters are optimized using weighted random search approaches.

Estimation of ETo plays an important role in water saving and enhancement of food production leading to food security in the world. The selection of machine learning algorithms to estimate ETo is a challenging task because they are not good for all problems. The size and structures of the data affect the performance of the machine learning algorithm. In the current study, the random forest regression algorithm is chosen because of its high performance and handling a complex problem. In this paper, the contribution of works is summarized as follows:

- The reviews of machine learning techniques to estimate reference evapotranspiration and hyper-parameter tuning approaches are done.
- Meteorological data of Bhopal city is collected from IMD Pune. Descriptive analysis is performed on preprocessed data. The correlation coefficient of meteorological data with observed ETo is determined.
- Four different random forest regression based data driven models (based on the correlation among meteorological variables with observed ETo) are developed.
- These hyper-parameters (n_estimators, max_depth, min_samples_leaf) are applied in three different ways ('one parameter at a time, combinations of parameters using grid and random search approaches) to the four random forest models.
- The performances of twenty models are evaluated and compared with FAO-PM56 using six statistical indicators.

II. MATERIAL AND METHODS

A. Study Site

The proposed random forest regression based data driven models are analyzed in this study using meteorological data from Bhopal city of Madhya Pradesh state, India. Daily meteorological data for the years 2015-16 are obtained from the India Meteorological Data, Pune, which includes input attributes such as minimum temperature (Tmin) in 0C, maximum temperature (Tmax) in 0C, relative humidity (RH) in %, wind speed (u) in m/s and mean solar radiation (Rn) in MJ m-2 day-1. Daily mean sunshine hours of Bhopal city are taken from the Daily Normals of Global & Diffuse Radiation report issued by IMD Pune published in the year 2016. Bhopal city has a subtropical humid climate. It has an average elevation of 500 meters and is located at 23.25 oE latitude and 77.42 oN longitude. Descriptions of training and test datasets are summarized in Table I. The monthly variation of ETo at Bhopal city is observed, where the average minimum ETo is 2.33 mm/day in January 2015 and 2.27 mm/day in December 2016 is noted, similarly average maximum ETo is 7.0 mm/day in May 2015 and 7.47 mm/day in May 2016 is noted. The correlation matrix of observed ETo and the meteorological data of Bhopal city is given in Table II. It can be observed that ETo has a positive correlation with temperature, solar radiation, and wind speed parameters whereas a negative correlation with humidity. Hence it can be said that ETo is an energy driven

process and increases as temperature, radiation, and wind speed are increased.

B. FAO-PM56 Equation

The FAO-56 Penman-Monteith equation is provided by the Food and Agriculture Organization of the United Nation and is considered a standard worldwide accepted method to estimate ETo. It is represented as-

$$ETo = \frac{0.408 * (R_n - G) + \gamma \left(\frac{900}{T + 273} \right) u_2 (e_s - e_a)}{\Delta + \gamma (1 + 0.34 * u_2)} \quad (1)$$

Where

ETo = grass reference evapotranspiration in mm day⁻¹

R_n = net radiation in MJ mm⁻² day⁻¹

G = soil heat flux in MJ mm⁻² day⁻¹

γ = psychrometric constant in kPa⁰ c⁻¹

T = mean daily air temperature in °C

u_2 = wind speed at 2m height in m s⁻¹

Δ = slope vapour pressure curve in kPa⁰ c⁻¹

e_s = saturation vapour pressure in kPa

e_a = actual vapour pressure in kPa

$e_s - e_a$ = saturation vapour pressure deficit in kPa

TABLE I. STATISTICAL DESCRIPTION OF METEOROLOGICAL DATA

Climatic parameters	Data set	Minimum	Maximum	Mean	Standard Deviation
T _{min}	Training	5.8	32.1	19.63	6.0
	Test	7.9	31.2	20.25	5.75
T _{max}	Training	15.5	46.7	32.17	5.8
	Test	14.2	45.3	32.84	5.74
RH	Training	12	99	56.85	21.76
	Test	17	98	55.19	23.04
u	Training	0	6.6	1.01	0.65
	Test	0.2	2.9	0.99	0.57
R _n	Training	12.3	26.3	18.83	3.48
	Test	12.3	26.3	19.11	3.65
ETo	Training	1.71	9.5	4.06	1.57
	Test	1.56	8.1	4.15	1.58

TABLE II. CORRELATION COEFFICIENT OF METEOROLOGICAL DATA WITH OBSERVED ETO

	T _{min}	T _{max}	RH	u	R _n	ETo
T _{min}	1					
T _{max}	0.72	1				
RH	-0.054	-0.6	1			
u	0.49	0.22	0.09	1		
R _n	0.36	0.70	-0.74	0.14	1	
ETo	0.71	0.87	-0.60	0.47	0.82	1

ETo is observed by CROPWAT8.0 software in this study, which is a decision support tool and developed by the Land and Water Development division of the Food and Agriculture Organization of the United Nation. Daily minimum temperature (T_{\min}), maximum temperature (T_{\max}), relative humidity (R_H), bright sunshine hours (I_s), and wind speed (u) are applied as input parameters to CROPWAT8.0 software and it returns daily or monthly solar radiation (R_n) and ETo (mm day^{-1}). The FAO-PM56 is considered superior to other methods if reliable and complete meteorological data are available. Huge amounts of meteorological data are recorded at weather stations. Estimation of ETo from such large data using machine learning based models could be an alternative solution that produces accurate and efficient outcomes.

C. Random Forest Regression

Random forest is a supervised machine learning algorithm that is used for classification as well as regression problems. In this study a random forest machine learning algorithm is used to estimate ETo of Bhopal city, which is considered as a function approximation (regression) problem. It works based on the ensemble learning concept, in which instead of making a single model, multiple models are created on randomly selected data. Therefore the outcome of the random forest regression is made based on estimated results of multiple models [15]. Hence it is considered a highly stable model. It removes the overfitting problem of a decision tree. Multiple trees in the random forest lead to higher accuracy. It works well for large datasets with high dimensions. Various hyper-parameters are provided for the random forest. Tuning of hyper-parameters may improve the performance and predictive capability of random forests. Number of trees in the forest ($n_{\text{estimators}}$), the longest path between the root and the leaf node (max_depth), the minimum required samples to split a node in the tree (min_samples_split), the maximum number of leaf nodes in the tree (max_leaf_nodes), minimum number of samples at the leaf nodes (min_samples_leaf), and criteria to split the node in the tree (criterion) are considered some important hyper-parameters of random forest. In the present study, the performance of random forest is evaluated by tuning the three hyper-parameters such as $n_{\text{estimators}}$ (10, 20, 30, ..., 100), max_depth (2, 3, 4, ..., 10), and min_samples_leaf (2, 3, 4, 5). These hyper-parameters are applied in three different ways to the models such as 'one hyper-parameter at a time', and 'combinations of hyper-parameters' using grid search, and random search approaches. In the case of 'one hyper-parameter at a time', the search space consists of one dimensional hyper parameter values. Grid search and random search approaches are used when multiple hyper-parameters are applied to the model. In this case, the search space consists of a grid of hyper-parameter values, and the model is evaluated at each point in the grid. In the case of random search, the model is evaluated on a randomly opted grid point. Grid search is simple to implement and always finds the best combinations of hyper-parameter. It is a time consuming approach due to the exhaustive search nature. Random search exhibits the same performance in less computation time.

D. Model Development

Model development steps are shown in Fig. 1. Initially, the meteorological and geographical data of Bhopal city is taken

into memory. Data preprocessing is a significant step to estimate ETo accurately. It transforms the data in a meaningful way. To obtain the optimum outcomes, missing values are filled in different ways. In the present study, missing values are filled by the mean value of those attributes. Values of all attributes are normalized using the z-score method to make all attributes to the same level of magnitudes so have the same emphasis. Values of ETo are observed using CROPWAT 8.0 software (developed by the Land and Water Development Division of FAO (The Food and Agriculture Organization of the United Nation)) and made as a dependent variable, whereas the remaining attributes (T_{\min} , T_{\max} , R_n , u , R_H) are designated as independent variables. The whole dataset is partitioned into the training dataset (80%) and the test dataset (20%).

Four random forest regression based models such as RFR-Model1, RFR-Model2, RFR-Model3, and RFR-Model4 are created. Different combinations of meteorological input parameters (made based on high correlation coefficient with observed ETo values) are applied to these models. In the RFR-Model1, T_{\min} , and T_{\max} are applied. In the RFR-Model2, T_{\min} , T_{\max} , and R_n are applied. In the RFR-Model3, T_{\min} , T_{\max} , R_n , and u are applied. And finally in the RFR-Model4, T_{\min} , T_{\max} , R_n , u , and R_H are applied. In addition to the input combinations of meteorological parameters, three important hyper-parameters are tuned in each model. These hyper-parameters are tuned and applied to the proposed four models in three different ways: 'one hyper-parameter at a time', and combinations of hyper-parameters are using grid search, and random search optimization approach. Taking into consideration four different models and the applicability of three hyper-parameters to the models produces twenty combinations. Therefore in this study, the performances of twenty models are evaluated. Six different statistical indicators are used in this study to evaluate the performance of the models such as mean absolute error (MAE), mean squared error (MSE), root mean squared error (RMSE), Pearson correlation coefficient (r), r^2 (coefficient of determination), and Nash-Sutcliffe(NS). These models are implemented in Python with the help of Pandas, Numpy, Sklearn and Matplotlib libraries.

E. Performance Evaluation Indices

Predictive skills of RFR-MODEL1, RFR-MODEL2, RFR-MODEL3, and RFR-MODEL4 are evaluated using the following parameters:

Mean absolute error (MAE).

$$MAE = \frac{\sum_{i=1}^n |E_{pi} - E_{oi}|}{n} \quad (2)$$

where

E_{pi} = predicted evapotranspiration.

E_{oi} = observed evapotranspiration.

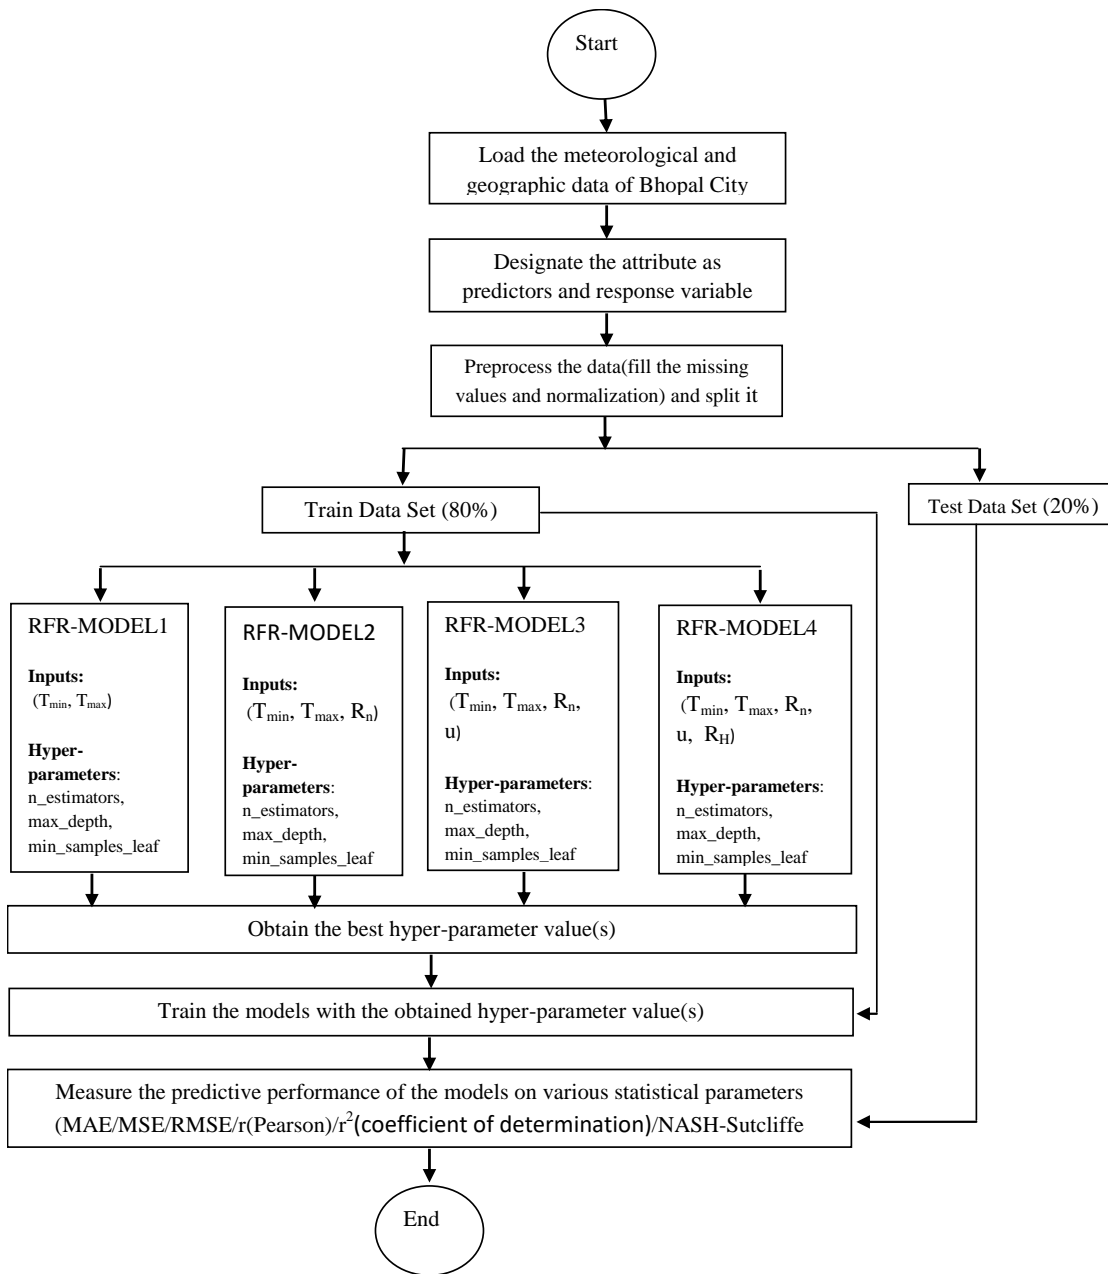

Fig. 1. Flow Chart of Random Forest Regression based Models.

Mean square error (MSE).

$$MSE = \frac{1}{n} \sum_{i=1}^n (E_{oi} - E_{pi})^2 \quad (3)$$

Root mean square error (RMSE) -A small value of RMSE denotes the model fits the datasets strongly.

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^n (E_{oi} - E_{pi})^2} \quad (4)$$

Pearson correlation coefficient shows the strength of the relationship between observed and predicted ET_o.

$$Pearson \text{ correlation}(r) = \frac{\sum_{i=1}^n (E_{pi} - \overline{E_{pi}})(E_{oi} - \overline{E_{oi}})}{\sqrt{\sum_{i=1}^n (E_{pi} - \overline{E_{pi}})^2 \sum_{i=1}^n (E_{oi} - \overline{E_{oi}})^2}} \quad (5)$$

r^2 (coefficient of determination) . A larger value of r^2 indicates the model fits the datasets strongly.

$$Coefficient \text{ of det er min ation}(r^2) = r * r \quad (6)$$

Nash-Sutcliffe efficiency (NS) is used to assess the predictive skills of ANN models.

$$Nash - Sutcliffe\ efficiency(NS) = 1 - \frac{\sum_{i=1}^n (E_{pi} - E_{oi})^2}{\sum_{i=1}^n (E_{pi} - \bar{E}_o)^2} \quad (7)$$

III. RESULT AND DISCUSSION

As stated earlier in the model development section, taking into consideration four different random forest regression based models and the applicability of three hyper-parameters to the models in different ways produces twenty combinations. Therefore in this study, the performances of twenty models are evaluated. The execution time span of each model is calculated from the beginning of the training period to the end of the testing period.

A. Performance of the RFR-Model1

In this model, only two meteorological inputs T_{min} , and T_{max} are applied. The performance of this model is demonstrated in Table III, where it exhibits mae of 0.48, mse of 0.39, rmse of 0.62, r of 0.92, r^2 of 0.85, and Nash-Sutcliffe of 0.85 when the $n_estimators$ hyper-parameter is tuned. Table IV exhibits the performance with mae of 0.45, mse of 0.34, rmse of 0.59, r of 0.93, r^2 of 0.87, and Nash-Sutcliffe of 0.86 when the max_depth hyper-parameter is tuned. Table V exhibits the performance with mae of 0.45, mse of 0.35, rmse of 0.59, r of 0.93, r^2 of 0.87, and Nash-Sutcliffe of 0.86 when the $min_samples_leaf$ hyper-parameter is tuned. Table VI exhibits the performance with mae of 0.46, mse of 0.36, rmse of 0.6, r of 0.93, r^2 of 0.86, and Nash-Sutcliffe of 0.86 when the combination of three hyper-parameters ($n_estimators$, max_depth , $min_samples_leaf$) are tuned using a grid search approach. Similarly, Table VII exhibits the performance with mae of 0.46, mse of 0.35, rmse of 0.59, r of 0.93, r^2 of 0.87, and Nash-Sutcliffe of 0.86 when the same combination of hyper-parameters are tuned using a random search approach. It can be observed that RFR-Model1 shows almost the same predictive capability in all scenarios. The Computation time of this model is represented in Table VIII. It takes 10.5 seconds when the $n_estimators$ hyper-parameter is tuned, 29.38 seconds when the max_depth hyper-parameter is tuned, 70 seconds when the $min_samples_leaf$ hyper-parameter is tuned, 301.33 seconds when a grid search approach is applied, and 11.62 seconds when a random search approach is applied respectively in order to estimate ETo. Regression analysis of the RFR-Model1 is shown in Fig. 2 for all scenarios.

B. Performance of the RFR-Model2

In this model, only three meteorological inputs T_{min} , T_{max} , and R_n are applied. The performance of this model is demonstrated in Table III, where it exhibits mae of 0.29, mse of 0.17, rmse of 0.41, r of 0.97, r^2 of 0.93, and Nash-Sutcliffe of 0.93 when the $n_estimators$ hyper-parameter is tuned. Table IV exhibits the performance with mae of 0.29, mse of 0.17, rmse of 0.41, r of 0.97, r^2 of 0.94, and Nash-Sutcliffe of 0.93 when the max_depth hyper-parameter is tuned. Table V exhibits the performance with mae of 0.29, mse of 0.17, rmse of 0.41, r of 0.97, r^2 of 0.94, and Nash-Sutcliffe of 0.93 when the $min_samples_leaf$ hyper-parameter is tuned. Table VI exhibits the performance with mae of 0.29, mse of 0.17, rmse

of 0.41, r of 0.97, r^2 of 0.94, and Nash-Sutcliffe of 0.93 when the combination of three hyper-parameters ($n_estimators$, max_depth , $min_samples_leaf$) are tuned using a grid search approach. Similarly, Table VII exhibits the performance with mae of 0.29, mse of 0.17, rmse of 0.41, r of 0.97, r^2 of 0.94, and Nash-Sutcliffe of 0.93 when the same combination of hyper-parameters are tuned using a random search approach. It can be observed that RFR-Model2 shows the same predictive capability in all scenarios but higher than RFR-Model1. The Computation time of this model is represented in Table VIII. It takes 11.62 seconds when the $n_estimators$ hyper-parameter is tuned, 31.9 seconds when the max_depth hyper-parameter is tuned, 69 seconds when the $min_samples_leaf$ hyper-parameter is tuned, 321.39 seconds when a grid search approach is applied, and 9.72 seconds when a random search approach is applied respectively in order to estimate ETo. Regression analysis of the RFR-Model2 is shown in Fig. 3 for all scenarios.

TABLE III. MODEL PERFORMANCE WHEN 'N_ESTIMATORS' HYPER PARAMETER IS TUNED

RFR-Model4	12.44	36.8	75.57	329.98	11.12

C. Performance of the RFR-Model3

In this model, four meteorological inputs T_{min} , T_{max} , R_n , and u are applied. The performance of this model is demonstrated in Table III, where it exhibits mae of 0.17, mse of 0.05, rmse of 0.23, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the n_estimators hyper-parameter is tuned. Table IV exhibits the performance with mae of 0.17, mse of 0.05, rmse of 0.23, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the max_depth hyper-parameter is tuned. Table V exhibits the performance with mae of 0.18, mse of 0.06, rmse of 0.25, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.97 when the min_samples_leaf hyper-parameter is tuned. Table VI exhibits the performance with mae of 0.18, mse of 0.06, rmse of 0.25, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.97 when the combination of three hyper-parameters (n_estimators, max_depth, min_samples_leaf) are tuned using a grid search approach. Similarly, Table VII exhibits the performance with mae of 0.19, mse of 0.07, rmse of 0.26, r of 0.99, r² of 0.98, and

Nash-Sutcliffe of 0.97 when the same combination of hyper-parameters are tuned using a random search approach. It can be observed that RFR-Model3 shows almost the same predictive capability with minor variations in all scenarios but higher than RFR-Model1 and RFR-Model2. The Computation time of this model is represented in Table VIII. It takes 11.87 seconds when the n_estimators hyper-parameter is tuned, 33.24 seconds when the max_depth hyper-parameter is tuned, 71.2 seconds when the min_samples_leaf hyper-parameter is tuned, 316.31 seconds when a grid search approach is applied, and 9.48 seconds when a random search approach is applied respectively in order to estimate ETo. Regression analysis of the RFR-Model3 is shown in Fig. 4 for all scenarios.

D. Performance of the RFR-Model4

In this model, five meteorological inputs T_{min} , T_{max} , R_n , u , and R_H are applied. The performance of this model is demonstrated in Table III, where it exhibits mae of 0.15, mse of 0.05, rmse of 0.22, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the n_estimators hyper-parameter is tuned. Table IV exhibits the performance with mae of 0.15, mse of 0.05, rmse of 0.22, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the max_depth hyper-parameter is tuned. Table V exhibits the performance with mae of 0.16, mse of 0.06, rmse of 0.23, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the min_samples_leaf hyper-parameter is tuned. Table VI exhibits the performance with mae of 0.17, mse of 0.06, rmse of 0.24, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the combination of three hyper-parameters (n_estimators, max_depth, min_samples_leaf) are tuned using a grid search approach. Similarly, Table VII exhibits the performance with mae of 0.16, mse of 0.06, rmse of 0.24, r of 0.99, r² of 0.98, and Nash-Sutcliffe of 0.98 when the same combination of hyper-parameters are tuned using a random search approach. It can be observed that RFR-Model4 shows almost the same predictive capability in all scenarios but higher than RFR-Model1, RFR-Model2 and RFR-Model3. The Computation time of this model is represented in Table VIII. It takes 12.44 seconds when the n_estimators hyper-parameter is tuned, 36.8 seconds when the max_depth hyper-parameter is tuned, 75.57 seconds when the min_samples_leaf hyper-parameter is tuned, 329.98 seconds when a grid search approach is applied, and 11.12 seconds when a random search approach is applied respectively in order to estimate ETo. Regression analysis of the RFR-Model4 is shown in Fig. 5 for all scenarios.

It can be observed that RFR-Model1 demonstrates poor predictive performance. The performance of the models is improving gradually when the maximal meteorological input variables are taken into consideration. Grid search based optimization demonstrates the same level of performance but takes much execution time and will not be feasible when size of search spaces increases whereas random search based optimization exhibits better performance than grid search. Computation time is shown in Fig. 6.

IV. CONCLUSION

Estimation of ETo has numerous applications. Irrigation scheduling is one of them. In this study, random forest regression based four different models are developed to estimate ETo. Different combinations of meteorological input variables (made based on high correlation coefficient with observed ETo values) are applied to these models. Moreover, the effects of three important hyper-parameters of random forest regression, such as the number of trees in the forest, depth of the trees, and the number of samples at a leaf node are evaluated to estimate ETo using the proposed models. These hyper-parameters are optimized and applied in three different ways to the models such as one parameter at a time, and combinations of hyper parameters using grid search, and random search. This study reveals that the models with less meteorological input variables demonstrate poor performance than models with maximal input variables (r is of 0.99, r^2 is of 0.98 and Nash-Sutcliffe is of 0.98 in the case of RFR-Model4). Models based on grid search based optimization exhibit the same predictive power but take much computation time. The findings of this study are that random forest regression based models with sufficient meteorological data demonstrate better performance and are useful to the stakeholders such as farmers, engineers for irrigation scheduling and water management. In the future, more hyper-parameter optimization techniques will be applied to estimate accurate ETo for various places in India. This estimated ETo will be used to calculate crop water requirements of Wheat and Maize crops

Abstract—Video surveillance is used for capturing the abnormal events on roadsides that are caused due to improper driving, accidents, and hindrances resulting in transportation lags and life-critical issues. It is essential to highlight the accident keyframes in videos to achieve intelligent video surveillance. Video summarization plays a vital role in summarizing the keyframe for an abnormal event from the stacked video surveillance input. The observed video is converted into frames and analyzed for providing an accurate summarization for accident analysis forecast and guiding the users in avoiding such events. The main issues in summarization arise from the inconsistency between the spatiotemporal redundancies and the classification of sequence verification in video surveillance. This article introduces an Additive Event Summarization Method (AESM) for projecting classified events through a gated recurrent unit learning paradigm. In this process, the gates are assigned for unclassified and active frames for sequence verification. Based on the sequence, the abnormality is classified and summarized with higher accuracy than the state of art techniques. This proposed method relies on heterogeneous features for classifying events with better structural indices. The proposed method's performance is analyzed using the metrics accuracy, false rate, analysis time, SSIM, and F1-Score.

Keywords—Event detection; gated recurrent unit; summarization; intelligent transportation system

I. INTRODUCTION

Road transportation is one of the cheapest and easiest among the other types of the transportation system. Many people around the world are traveling via road to travel from one place to another. Abnormal event detection is one of the critical tasks to perform in transportation systems [1]. Closer circuit television (CCTV) plays a major role in detecting events which are occurred on the roadside. A transport monitoring system plays a vital role in analyzing every detail which is occurred on the roadside and helps to protect people. Accurate abnormal event detection helps to reduce the crime rate and death rate on roadsides [2]. Abnormal events on roadsides are classified based on the physical attributes and behavior, postures, and gestures of the vehicle's position. The abnormal Event detection process is done based on two stages namely classification and video summarization process [3].

The video summarization process is done by analyzing the events which are occurred on the roadside based on certain

keyframes or parameters from the given video clips. Keyframe plays a major role in the summarization process which helps to identify the exact features of the video which is done by comparing it with an important set of features [4]. The classification process is processed by combining both normal and abnormal events which are occurred on the roadside and then it produced a dataset that contains the cause of abnormal events in a detailed manner [5]. The Video Summarization process is used in every monitoring system to enhance the network by understanding the exact cause of events by analyzing the given set of videos [6]. The video summarization process helps to control accidents and crime on roadsides. A keyframe is generated to identify the exact actual cause of the events and it also helps to find out the upcoming events based on people's activities [7]. The machine learning algorithm is mostly used in the summarization process which helps to increase the accuracy rate in the detection process and also helps to reduce the time consumption rate in processing data [8]. A dynamic hierarchical clustering algorithm is used in the summarization process which is done by training the data which are captured by CCTV and producing trained data for further uses. It is done by combining the current clips or data with the previously collected data and generating detailed information which helps to prevent the upcoming accident [3, 9]. A reinforcement algorithm is also used here to identify the keyframes based on features such as gestures, signs, and postures of people and produce sequenced keyframes which help to reduce the crime rate on roadsides [10]. The main disadvantages of the video summarization cause contradiction between the spatiotemporal redundancies and sequence prediction. The proposed Additive Event Summarization Method (AESM) is used for projecting classified events through a gated recurrent unit. The proposed system is used to increase the chances of early classification due to limited state-based classification and summarization. The main advantages of the proposed system are to decrease the computational complexity caused by recurrent replication-based classification and reduce the sensitivity of the output. The experimental analysis of the proposed work is conducted using the dataset of UCSD to find the predominance compared to state of art techniques. The remaining sections of the paper are organized as follows. Section 2 presents the analysis of the related work with the merits and limitations. Section 3 presents the proposed work with a detailed mathematical

analysis of the summarization and classification process. Section 4 describes the experimental analysis of the proposed work. Section 5 concludes the paper with its contributions and the scope of the research.

II. RELATED WORK

Yang et al. [11] proposed an algorithm for the learning model in the real-time event summarization process HRES. The learning model is proposed to capture the information which is stored in the knowledge base (KB) and implicitly the information based on the queries which are given to the users. The proposed HRES method improves the robustness and effectiveness and reduces the time consumption rate.

Wan et al. [12] proposed a long video retrieval algorithm based on a superframe segmentation process for ITS event detection. A long video stream is used to identify the unwanted frames which are present in the database and helps to reduce the unnecessary frame. The segment of Interest (SOI) is generated by using the superframe segmentation process. The proposed method increases the effectiveness by reducing the retrieval time.

Thomas et al. [13] proposed video summarization based on a perceptual model for the roadside event detection process. This method is used to find out the optimal solutions by analyzing the vast number of videos that are captured during accidents time. The surveillance camera is used here to capture video on the roadside. The proposed method increases the accuracy rate in the detection process.

Ji et al. [14,15] proposed a summarization method based on a multi-video by using archetypal analysis on a multi-modal weighted method. To create WAA weight, the multi-modal graph is used which is done based on the query. A multi-modal graph is used to fuse the information which is generated such as the tags, frames, and video clips for the prediction process. The proposed method outperformed the traditional summarization method by increasing the accuracy rate. The proposed method introduced a sparse coding framework for video summarization using query-aware. The proposed framework uses web images for identifying the exact information of the events. Unsupervised multi-graph fusion is used here to find out the keyframes which are available in the database based on the priority of the queries.

Elharrouss et al. [16] proposed multiple human action detection methods for the recognition and summarization process. Human activities are analyzed and generated into sequences to form a dataset. Then the sequence is divided into shots for the detection process. The histogram of oriented gradient (HOG) is framed based on the frames which are generated by based on the given video clips. The proposed method increases the efficiency and accuracy of the recognition and summarization process.

Zhang et al. [17] proposed a method that uses the key contents of the frames from the given video. A discriminator is used to find out the keyframes for the summarization process. The proposed approach increases the efficiency and accuracy rate.

Yang et al. [18] proposed a new framework using a deep neural network to leverage the benefits generated by the systems. It uses LSTM to represent the priority of the queries which are captured by the network. The proposed method increases the accuracy rate.

Gao et al. [19] proposed a key framework for the video summarization process of surveillance videos. Videos are sequenced based on the overlapping maps features. The clustering approach is used to finalize the key frames and generate an accurate set of frames for further use. The proposed method increases the performance and effectiveness of the system.

Lei et al. [20] have introduced a video summarization model using action parsing driven by a reinforcement algorithm. Action parsing is used to divide the videos into a sequenced part which is used in the final stage. The proposed system deals with recurrent neural networks used in the summarization process which selects the frames based on the actions and activities. The proposed method increases the accuracy rate and classification rate of key frames.

Ji et al. [21] have proposed a new video summarization method by combining a deep attentive ad semantic preserving approach. The Huber loss approach is used to replace the error loss which is occurred during summarization. A deep learning approach is used to ensure the security and safety of the keyframes. The proposed framework increases the performance and robustness of the system.

The proposed method is designed for mitigating the inconsistencies in the frame series detection process. In the MWAA process, the graph alignments are based on weights that imbalance the detection due to frame segregation. Contrarily, the sparse representations in the proposed ERA-SS increase the complexity due to multiple superframes. In this process, the computing time is hiked due to frequent switches over. Therefore, these drawbacks increase the difference in pixel representations, resulting in errors.

III. PROPOSED METHOD

The proposed method intakes video inputs for analyzing its sequence and event detection. The input videos are segregated as frames from which distinct features are extracted for analysis and classification. The data from external dataset is used for validating the proposed method. The input is split into different parts for individual processing as presented in the below Fig. 1. Based on the gate assignments for the observed variations are presented for analysis. In Fig. 1, the proposed method's process is illustrated.

Fig. 1. Proposed Method.

In the series assignment (as in Fig. 1), the mixed heterogeneous features namely contrast (∇) and entropy (t°) are analyzed. First, these two features are extracted from the frames as defined in (1).

$$\left. \begin{aligned} \Delta &= \sum_{i=1, j=1}^n d_{i,j}, \text{diff}(i,j)^2 \\ &\text{and} \\ E^\circ &= \sum_{i=1, j=1}^n -\ln(d_{i,j}) \cdot d_{i,j} \\ &\text{such} \\ &i, j \in \left. \begin{array}{l} n \times m \\ \text{even} \end{array} \right\} \text{(or)} \left. \begin{array}{l} m \times n \\ \text{uneven} \end{array} \right\} \end{aligned} \right\} \quad (1)$$

In equation (1) the variables $d_{i,j}$ and $(m \times n)$ represent the pixel density for a frame of size $(m \times n)$. Here i and j balance to m and n for uneven pixel frames or n and n for even pixel frames. The computation $\text{diff}(i,j)$ illustrates the variations between two consecutive pixels. Let T denote the time frame sequence for observing $d_{i,j}$ such that the series assignment is mapped as denoted in (2).

$$\left. \begin{aligned} \forall d_{i,j} \in n \text{ or } m, \Delta = d_{i,j} dT \\ \text{provided } i * j \text{ and } \nabla = 1, \text{ if } i = j \\ \text{and} \\ E^\circ = \begin{cases} -\ln(d_{i,j}) \forall i * j \\ 0 \forall i \neq j \end{cases} \\ \text{Therefore} \\ \nabla :: (i,j) \forall T = \begin{cases} 1 \\ 0, \text{ otherwise} \end{cases} \\ E^\circ :: \text{ or } \forall T = \begin{cases} 1 \\ 0, \text{ otherwise} \end{cases} \end{aligned} \right\} \quad (2)$$

This series assignment as in (3) is used for assigning gates in the learning process. This assignment requires $d_{i,j}$ based assignment in improving the fidelity of summarization. The contrary process of active (sequence) and unclassified is performed. For this purpose, we define current and update gates for state updates. This process is explained in the following subsection.

A. Event Classification

The events are classified by t_o variations in the observed sequences, for which the mapping in equation (2) is used. First, the gates are defined for sequence mapping as in equation (3).

$$\left. \begin{aligned} C &= \tan h \left[\frac{n(i,i)+n(j,j)}{n(i,j)} + \gamma_T \odot \frac{d(i,j)}{n(i,j)} \right] \\ &\text{and} \\ \gamma_T &= \frac{d(i,j)}{n(i,j)} \cdot \frac{n(i,i)+n(j,j)}{n(i,j)} + \int d_{ij} \forall \begin{array}{l} i \in n \\ \text{or } m \\ j \in n \end{array} \end{aligned} \right\} \quad (3)$$

In equation (3), the variables C and γ_T represents the current and update states at time T . Based on the further requirement, the gate states are changed and hence the classifications are performed. In the classification process, the mapping discreteness is observed for detecting active and unclassified series. This detection is performed until the end of the frame. If N is the end of the frame $\forall n, m \in N$, then:

$$\left. \begin{aligned} \Delta_1 &= 1 \\ \Delta_2 &= 1 - \frac{C_1}{n(i,j)} - \frac{C_1}{\gamma_2} \\ &\vdots \\ \Delta_N &= 1 - \frac{C_{N-1}}{n(i,j)} - \frac{C_{N-1}}{\gamma_N} \end{aligned} \right\} \text{for active } N \text{ classification} \quad \left. \begin{aligned} \Delta_1 &= 0 \\ \Delta_2 &= \frac{\gamma_1}{N} + \frac{\gamma_1}{n(i,j)} \times \frac{1}{N} \\ &\vdots \\ \Delta_N &= \frac{\gamma_{N-1}}{N} + \frac{\gamma_{N-1}}{n(i,j)} \times \frac{1}{N} \end{aligned} \right\} \text{for unclassified } N \quad (4)$$

Based on the above classification, the mismatching and detection processes are differentiated. In this process, the E° and ∇ based mismatching for mapped instances as in (2) is performed. The two conditions for ∇ and E° based on T requires multi-feature analysis for a gate assignment. The similarity feature is verified for the stored and acquired features from the mapping as in (3).

$$\left. \begin{aligned} S(x|i, y|j) &= \frac{(2 \times \mu_n \mu_m + k_1)(2 \times \sigma_{nm} + k_2)}{\mu_n^2 + \mu_m^2 + k_1} \frac{(\sigma_n^2 + \sigma_m^2 + k_2)}{\sigma_n^2 + \sigma_m^2 + k_2} \\ &\text{where} \\ \mu &= \frac{1}{n-1} \sum_{i=1}^n (n-i)(m-j) \\ &\text{and} \\ \sigma &= \sqrt{\frac{1}{(n-1)} \sum_{i=1}^n (i-j)^2} = \frac{1}{\sqrt{n-1}} \sum_{i=1}^n (i-j)^2 \forall i \neq j \end{aligned} \right\} \quad (5)$$

This similarity verification is performed for different $(i,j) \in (n,m) \in N$ wherein the mismatch for the above requires an alternate mapping such that C is assigned with a new $n(i,j)$ and γ_T is updated for $(n-1)^{th}$ $d(i,j)$. This means the variations in consecutive pixels are violated in detecting an event. The detection is performed in multiple intervals from 1 to N such that the mismatching $d(i,j)$ are segregated. A contrary part of the abnormal event detection is the synchronization of the $(1 - \frac{S}{N})$ and mapping as in (2) for the different features. In the proposed method, the abnormal events at different T are considered non-cumulative (due to different occurrences). Therefore, the occurrences are synchronized based on $S(x|i, y|j) \forall n$ and m until N is achieved. This is validated for $d(i,j)$ such that the alternating sequences are varied until the end of classification. In Fig.2, the gate assignment and classification processes are illustrated.

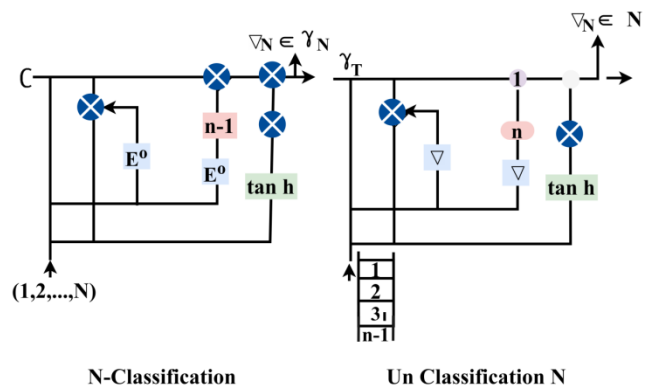

Fig. 2. Classification Process.

In the classification process, as presented in Fig. 2, the "×" and "+" symbols represent the product and sum of the mapping presented in equation (2). First, the product represents the $\nabla \otimes E^\circ \forall T$ in 1 to n (or) 1 to m ; the sum is the joint set of ∇ and E° . For an abnormal event summarization, the $T \notin (\nabla \odot E^\circ)$ is segregated for classifying it as a whole interval. In contrast to the augmenting and mapping processes, the variations are detected for event detection and categorization. Therefore,

$$\left. \begin{aligned}
 d_{i,j} \in T \notin (\nabla \odot E^\circ) \text{ is expected for } T = 1 \\
 \text{rather,} \\
 (i,j) \in n \notin N \forall \nabla \text{ is achieved for } T = 0 \\
 \text{such that} \\
 \Delta_N \in n(i,j) \forall C \text{ and} \\
 \Delta_N \in N \forall \gamma_T \mu \text{ is high}
 \end{aligned} \right\} \quad (6)$$

In equation (6) the abnormal (Post the matching) T is identified for summarization. In the summarization process, the distinct event occurrences are augmented cumulatively. The differences are mitigated without augmenting the Δ_N as classified for $\gamma_T \in N$ and $S(x|i, y|i)$. The summarization process is described below.

B. Summarization Process

In the summarization process, the γ_T that encloses both $\Delta_N \in \gamma_T$ and $s(x|i, y|j)$ (failing) conditions are augmented based on T . This is either discrete/ sequential depending on multiple updates as in E° and ∇ . The process requires unidentified $d(i, j)$ post the gate allocation for maximizing event aggregation. If the event is observed in $T \forall \Delta_N \in \gamma_T$ interrupts, then.

$$\left. \begin{aligned}
 t_{i=1}^T &= |\Delta_N^2 - \max\{C, E^\circ\}|_{i=1 \text{ to } T} \text{ and} \\
 &\text{(or)} \\
 t_{i=T-t}^T &= \left| \frac{\Delta_N}{N} - \min\{E^\circ, \gamma_T\} \right| \forall i = T - t \text{ to } t
 \end{aligned} \right\} \quad (7)$$

In equation (7), the augmenting events classified for $i = t$ and $i - (T - t)$ are identified. Depending on the $\max\{C, E^\circ\}$ and $\min\{E^\circ, \gamma_T\}$ the abnormal classifications is grouped. This is required for projecting $d(i, j) \in T$ and hence the deviations are identified. The proposed method performs a cumulative augmentation of the above observation post $(\nabla \odot E^\circ)$ assessment and hence the summary is an allocation of $d(i, j) \in$ distinct T and $(T - t)$. This is non-recurrent and hence new frames in T and $(T - t)$ (intermediate) are identified without false rates.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section discusses the proposed method's performance assessment using MATLAB simulations. The dataset from UCSD [22] is used for validating the proposed method's performance for accuracy, false rate, analysis time, SSIM, and F1-Score. The inputs are classified based on the available objects; the objects are used as in the dataset labeling. Depending on 4 textural features, the classification is performed; the pixel un-matching inputs are alone mitigated. In this comparative analysis, the identified objects and state updates are varied for the proposed and existing MVS-MWAA [14] and ERA-SS [12] methods. The data set provides

multiple video frames observed at 30fps in 800x480 pixel resolution. A total of 9390 frames are observed in this dataset.

A. Accuracy

In Fig. 3, the accuracy for different objects and state updates is analyzed. The proposed method maximized accuracy by improving the γ_T and E° detection in T and C and Δ_N detection $\forall (T - t)$. This is non-recurrent based on the available $n(i, j)$ in multiple T such that accuracy is maximized. Another detection is the $s(x|i, y|j) \in N$ where multiple pixels with the observed features are validated. This is consistent for different objects identified in the frames wherein accuracy is high.

Fig. 3. Accuracy Analysis.

B. False Rate

The augmentation of $(\Delta \odot E^\circ)$ and $(\nabla \cup E^\circ)$ relies on multiple factors of C and E° such that no error arises. The proposed requires Δ_N classification based on C and γ_T such that in t interference is avoided. In distinct instances, interferences are modeled independently.

The gate updates are non-linear $\forall S(x|i, y|j)$ for unclassified N such that C is high. In this process, the unclassified instances are reduced which achieves less False rate (refer to Fig. 4).

Fig. 4. False Rate Analysis.

C. Analysis Time

The proposed method achieves less analysis time as the proposed method classifies C and $\gamma_T \forall d(i, j)$. In the active classification and (μ, σ) estimation, independent assessments are performed.

These are validated based on the mapping and hence $(T - t)$ and T as independent rather than cumulative and joint analysis. Therefore, the proposed method achieves less analysis time for identified objects and state updates (Fig. 5).

Fig. 5. Analysis Time.

D. SSIM

In Fig. 6, the SSIM for the proposed method is compared for different objects and state updates.

In multiple state updates, the classification is performed under different N . These classifications are performed for $\Delta_N \in \gamma_N$ and $\Delta_N \in N$ for detecting multiple SSIM for $d(i, j)$ such that \forall is achieved in different $(T - t)$.

Fig. 6. SSIM Analysis.

This is unanimously observed for distinct intervals and objects where γ_T is less, maximizing SSIM.

E. F1-Score

For any density of objects and state updates, the F1-score is high for the proposed method (Fig. 7). The proposed method achieves a high F1score by mitigating ($\nabla \cup E^\circ$) instances. This is performed based on the classification and mapping of distinct $d(i, j)$. In the classification process, ($T - t$) and T instances are distinguished for maximizing the F1-score, preventing false rate. The comparative analysis results are tabulated in Tables I and II for different objects and state updates.

Fig. 7. F1-Score Analysis.

TABLE I. COMPARATIVE ANALYSIS RESULTS FOR OBJECTS

Metrics	MVS-MWAA	ERA-SS	AESM	Findings
Accuracy	0.866	0.895	0.907	8.83% High
False Rate	0.122	0.101	0.0884	7.7% Less
Analysis Time (ms)	1436.06	1046.51	580.226	8.88% Less
SSIM	0.832	0.885	0.973	11.45% High
F1-Score	0.886	0.929	0.969	12.3% High

TABLE II. COMPARATIVE ANALYSIS RESULTS FOR STATE UPDATES

Metrics	MVS-MWAA	ERA-SS	AESM	Findings
Accuracy	0.891	0.926	0.951	7.08% High
False Rate	0.096	0.065	0.0396	6.82% Less
Analysis Time (ms)	1420.73	1003.2	541.227	9.22% Less
SSIM	0.818	0.895	0.971	11.55% High
F1-Score	0.893	0.931	0.971	11.8% High

The significance of the proposed method is adaptable for varying objects and computations (state updates). In a video processing, the variations due to objects and computations are practically addressed using this proposed method. The variations are suppressed using the gate assignment and hence the accuracy, SSIM, and F1-Score are improved.

V. CONCLUSION

This article discussed an additive event summarization method for reducing the inconsistencies in video event summarization. The classification events are identified using different state assignments through gated recurrent units. The recurrent unit identifies unclassified and active frames for preventing false rates in event extraction. This classification is performed based on the heterogeneous features over the varying pixel densities over different sequences. From the analyzed sequences, the abnormal feature exhibiting pixels are segregated for providing a summarized output. For the different objects classified, the proposed method achieves 8.83% high accuracy, 11.45% high SSIM, 12.3% high F1-score, 7.7% less false rate, and 8.88% less analysis time. Though the proposed method is reliable in summarizing event related to abnormal occurrences the varying textural features result in pixel errors. Therefore, a spatiotemporal feature classification pre-processing is planned to be integrated in the future work.

Relational Deep Learning Detection with Multi-Sequence Representation for Insider Threats

Abdullah Alshehri

Department of Information Technology
Faculty of Computer Science and Information Technology
Al Baha University
Alaqlq 65779-7738, Saudi Arabia

Abstract—Insider threats are typically more challenging to be detected since security protocols struggle to recognize the anomaly behavior of privileged users in the network. Intuitively, an insider threat detection model depends on analyzing the audit data, representing trusted users' activity streams, on recognizing malicious behaviors. However, the audit data is high dimensional data in that it presents n dependent streams of activities where it establishes a complex feature extraction. In this context, the dependent streams represent user activities where each activity is represented by an ordered set of real variables that pertain to a specific occurrence, such as log-in records. As a result, multiple actions can be represented simultaneously, with one or more values being recorded at each timestamp. Moreover, the relations between dependent streams are typically neglected while detecting the anomaly behavior. Ideally, relation learning is commonly considered to recognize occurrence patterns in streaming data. Thus, the latent relations are thought to have insight for the accurate detection of anomaly behavior concerning insider threats. This study introduces a novel model to detect insider threats by representing audit data as multivariate time series to explicitly learn the existing inter-relations between activity streams using a Recurrent Neural Network (RNN). The model considers learning the latent relationships to effectively extract features for modeling the behavior profile where anomaly behavior can be detected accurately. The evaluation, using the CERT dataset has shown that the proposed model outperforms the comparator approaches to insider threats detection with AUC of 0.99.

Keywords—Insider threats; machine learning; recurrent neural network; user behavior analytic

I. INTRODUCTION

With the rapid advancement and growth in networking technology, cyber threats have become a significant issue for numerous companies and organizations worldwide [1]. A cyber threat can mainly be realized by breaching network security. Ideally, the primary option for malicious intent to breach network security is by using a malware [2]. In this context, the malware contravenes the secured network by an external malicious component such as rootkits, Trojan horses, viruses, and worms [3]. Thus, the ideal solution to secure the network from such external threats is by proposing a perimeter defense, e.g., firewalls, antivirus software, and intrusion prevention/detection systems.

However, a cyber attack can be triggered from an internal source in the network; it is well known as an insider threat [4]. A typical form of an insider threat is that the legitimate user may conduct harmful work at the network, such as

leaking, altering, or disrupting sensitive data. Thus, an insider threat (malicious) is typically realized as an abnormal action, or behavior, in the network flows that is performed by the legitimate user [5]. Fig. ?? shows a conceptual illustration of the internal and external attacks intuition which can affect such a network in cyber space. It can be observed that the external attack is transparent to be prevented/detected by the perimeter defense protocols. On the other hand, the insider attack is commonly deceptive as the perimeter defense can hardly detect attacks conceived from inside the network. Therefore, insider attacks pose a critical challenge in the cyber security domain where the demand to propose practical solutions to detect insider threats remains a desirable solution for a tremendous number of organizations in the market [6].

To detect insider threats, the typical solution relies on developing systems that are capable of analyzing the user's behavior to discover anomalies in the network [7]. The idea is to observe the user's daily activities and tasks where these activities yield frequent network usage patterns. Ideally, the regular activities can underline insightful patterns to map a typical behavior for the legitimate user. In this context, the ideal method to analyze the user's behavior is accomplished using Machine Learning (ML)-based approaches, (see for instance [8], [9], [10], [11]). ML approaches, such as Hidden Markov Model (HMM) and Support Vector Machine (SVM), have been utilized to detect insider threats via modeling the behavioral profile from the audit data (daily activities) such as the log events. Typically, these ML approaches, which are well known as shallow learning methods [12], are subject to attentive feature engineering to model the behavior profile accurately. The reason is that the audit data is composed of a large volume of unstructured, high-dimensional, and sparsity instances, which makes extracting features a non-trivial task. The traditional approaches have modeled the user's behavior by aggregated data consisting of the user's activities within a single day. However, missing some features can cause unpredictable behavior where it imposes unbalanced detection alarms; for example, it can increase the false alarms in the system. Deep Learning (DL), a subset of ML approaches, has been employed to address the drawback mentioned earlier for insider threats detection [13], [4], [14], [15]. DL provides the advantage that features can be represented immediately from unstructured data [16]. Moreover, it has the advantage that features can be extracted sequentially to reduce missing temporal feature learning, a way that is not applicable in the case of shallow learning methods.

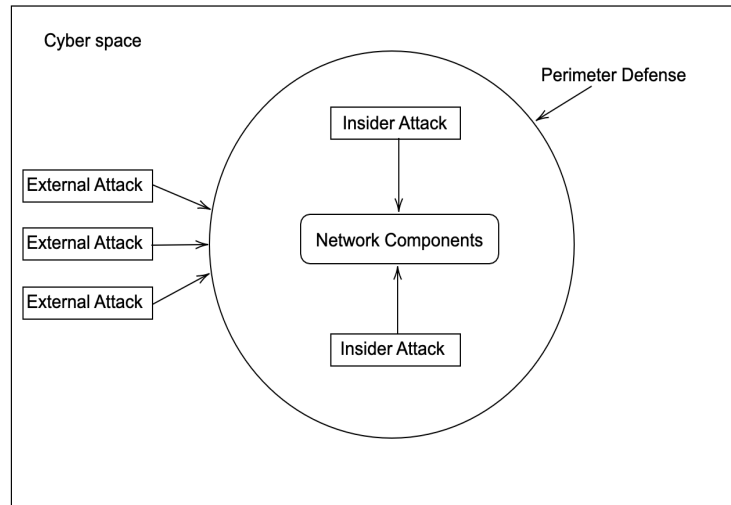

Fig. 1. A Conceptual Illustration Shows the Intuition of External and Internal Attacks in Cyber Space Networks.

Nevertheless, insider threats detection approaches neglect considering the temporal representation of multivariate sequences to model the user's behavior, where this limitation has established a downside to developing an accurate detection model. Intuitively, the user activities are temporally recorded as sequences of dependent variables, i.e., at each timestamp, one or more variables, such as user id and log-in/off time, would be recorded simultaneously. Therefore, incorporating more extensive dependent variables can increase the chance of better modeling the user's behavior. It is worth mentioning that increasing data volume results in improving the learning accuracy as per Bonferonni's principle [17]. This, in turn, brings the motivation to structure the entire audit data as temporal sequences, i.e., multivariate time series representation, which thought it is fruitful to map all possible behavior patterns of the user. Moreover, as the audit data consist of multi-sequential actions, the relations between these sequences are not well considered in previous studies. Thus, the conjecture is that the sequences related to one user would underline strong relations to describe unique user-related patterns used for insider threat detection.

This study proposes a novel model that utilizes DL to learn the user's behavior for insider threats detection using a multivariate representation of audit data. The model represents the user activities as a set of dependent sequences in the temporal domain to where the hidden relations are extracted and learned. In concise, each activity is represented as an ordered set of actual values that refers to some event, such as log-in records. Thus several activities can be represented simultaneously such that one or more values are recorded at each timestamp, i.e. the user activities are represented as multivariate time series streams such that at each time tick, n values are recorded temporally. We then use Recurrent Neural Network (RNN) to learn the existing latent temporal relationships between sequences to map the hidden patterns. Thereafter, the model serves to extract features where the recognized behavior is classified as normal or anomaly, which

indicates a possible insider threat.

The contributions of the proposed work can be summarized as follows:

i) The study has presented a novel method to model the user behavior in a multivariate time series structure. More specifically, the user behavior is represented using all sequences of events that denote the user activities. The intuition is that time series frequencies would present accurate, readable user behavior patterns because they incorporate exclusive features, not only aggregated features.

iii) The developed model has considered learning and extracting the relations between the multivariate sequences to extract patterns in training data. The existing sequences hold latent relations that can be extracted for accurate behavior modeling, leading to the accurate prediction of anomaly behavior.

iii) The proposed model has applied deep learning to extract features from inter-correlation streams that represent audit data of user activities. The importance is that user activities are stochastic and unstructured, so deep learning is ideal for extracting features from unstructured data.

The remainder of this paper is structured as follows. Section II presents an overview of the related work. This is followed by Section III where the proposed model has been introduced. In Section IV, we demonstrate the evaluation and results of the proposed model. Section V provides conclusions and future directions where this study can be extended.

II. RELATED WORK

ML has been increasingly used for cyber threats detection throughout the previous decade [18]. Generally speaking, ML has shown to be advantageous in the identification and classification of anomalous occurrences in the network streams [19], [20]. Insider threat is a well-known type of cyber attack [21] that has received considerable work using ML approaches. The insider attack detection model heavily depends on the user's

daily activities where the behavior is recognized. Typically, the obtained data is unstructured and complex due to the diversity of the user's activities on the network. Thus, modeling the user's behavior is a relatively intricate task. In the literature, most ML approaches for insider threat detection are data-driven in that the user activities are aggregated to underline representative features where the behavior profile is modeled. In this context, insider threat detection would be proposed based on different examples of data instances where the detection model is handled as an anomaly detection problem. Accordingly, various ML methods have been developed for insider threat detection. For example, SVM is used as a one-class detection method for insider attack [22]. The study presented in [9] had proposed an HMM model to map the typical user behavior based on weekly activities. The insider attack is detected by computing a deviation score between sequences; a low probability score could indicate a probable attack. In [8] a set of supervised and unsupervised ML approaches have been evaluated for insider attack detection. The study had used Self Organization Map (SOM), HMM, and Decision Tree to model malicious behavior for anomaly detection. The features were extracted into two categories, including numerical and sequential features. Whatever category was being employed, the features were aggregated to a set of weekly representative instances. Thus the detection model was complex due to the need for extensive feature engineering.

DL methods have been proposed to tackle the issue of requiring feature extraction and handling the large volume of features to be learned in the detection model for insider attacks data. In [5] a comprehensive survey has introduced the state-of-the-art of DL with insider threat detection. In this context, a number of DL applications have been recruited such as deep feed-forward neural network [23], [24], recurrent neural network (RNN) [14], [25], conventional neural network[26], and graph neural network. [13], [27]. Due to the complexity of data structure, the majority of DL approaches have focused on representing sub-sequences, such as one-day activities, for detection granularity. In practice, each session is a subsequence that denotes a series of activities, i.e. "log-in" and "log-off" events. Whenever a subsequence contains malicious activity, the subsequence will be designated as a malicious subsequence where a possible attack could occur. Therefore, detecting abnormal actions is difficult due to the limited information (features) that can be leveraged. Moreover, the relation extraction between sequences is ignored; however, the extraction of latent relations can bring insight for better modeling of user's behavior.

This study addresses the above-mentioned drawbacks by representing all activities (sequences) as multivariate time series streams where the relations between streams are also considered for building the behavior profile. The study also endeavors to leverage the advantage of using RNN for effective feature extraction from the temporal/sequential data. Recall that RNN has shown effective feature learning of the sequential data for anomaly detection [28], [29], [30].

III. PROPOSED MODEL

This section elaborates on the proposed insider threat detection model. Fig. ?? illustrates an overview of the model flows. As it can be seen from the figure that the model

operates in several consecutive steps, including i) user activity representation, ii) sequence activity embedding, iii) latent relations learning, iv) feature learning, and v) anomaly detection. The following subsections give further detail of each step as follows.

A. User Activity Representation

The primary step in the proposed model is to represent the user's activities as multivariate time series. As noted in the introduction to this paper, the user's activities can be structured as a series of temporal activities recorded each tick of time. Several data points (characteristics values) should be recorded at each timestamp, such as log-in/off information, user's id, and HTTP data.

More formally, given a series of a single activity \mathcal{A}_1 it consists of a sequence of an ordered n data points such that $\mathcal{A}_1 = \{p_1^1, p_1^2, \dots, p_1^n\}$, as for a given point p it maps an encoded real value of an event. The entire activities are expressed as a whole series \mathcal{S} which represent set of m activities, i.e. $\mathcal{S} = (\mathcal{A}_1, \mathcal{A}_2, \dots, \mathcal{A}_m) = (\mathcal{A}^1, \mathcal{A}^2, \dots, \mathcal{A}^m)^\top \in \mathbb{R}^{m \times n}$, where $n \in \mathbb{N}$ is the length of time series, i.e. the number of data points in each single activity. Intuitively, \mathcal{S} is structured as a matrix consisting the entire user's activities whose samples are denoted as $p_i^{(t)}$ ($i = 1, \dots, m; t = 1, \dots, n$).

$$\mathcal{S} = \begin{bmatrix} p_1^1, p_1^2, \dots, p_1^n \\ p_2^1, p_2^2, \dots, p_2^n \\ \dots \\ p_m^1, p_m^2, \dots, p_m^n \end{bmatrix}$$

B. Sequence Activity Embedding

The represented activity sequences have a wide range of features that can be related in diverse ways. For example, if we consider the log-in and user id sequences for two different users, the sequences for the same user likely have strong relations. Thus, the idea is to portray each sequence in a flexible fashion that captures the various characteristics that underpin its behavior in a multidimensional manner. To this end, each activity sequence \mathcal{A} has been encoded as an embedding vector \vec{v} such that $\vec{v}_i \in \mathbb{R}^d$, for $i \in \{1, \dots, m\}$. Note that the encoded embedding sequences are randomly initialized before being trained with the remainder of the model. Moreover, sequences with comparable embedding values should have a strong inclination to be connected since similar embedding sequences indicate similar activities.

C. Latent Relations Learning

The subsequent step is to learn relations between the embedded vectors. The optimal method to conduct so is by using direct graph architecture. In this context, given embedded vectors $\mathcal{V} = \{\vec{v}_1, \dots, \vec{v}_{|\mathcal{V}|}\}$, they are mapped to graph structure $\mathcal{V} \mapsto (\mathcal{N}, \xi)$ with nodes and edges; where nodes denote embedded vectors, such that $\vec{v}_i \in \mathcal{N}$ for $i = \{1, \dots, |\mathcal{N}|\}$, and edges represent pairs $\varepsilon_i \in \xi \mapsto \varepsilon_i = \langle \vec{v}, \vec{v}_i \rangle \in \mathcal{N} \times \mathcal{N}$. In this study, we implement direct graph representation for latent relations learning as direct edges $\vec{v} \mapsto \vec{v}_i$ between nodes because the dependency patterns between vectors do not have to be symmetric. Thus, the mapped edges between vectors represent relative dependant relationship in that the first vector

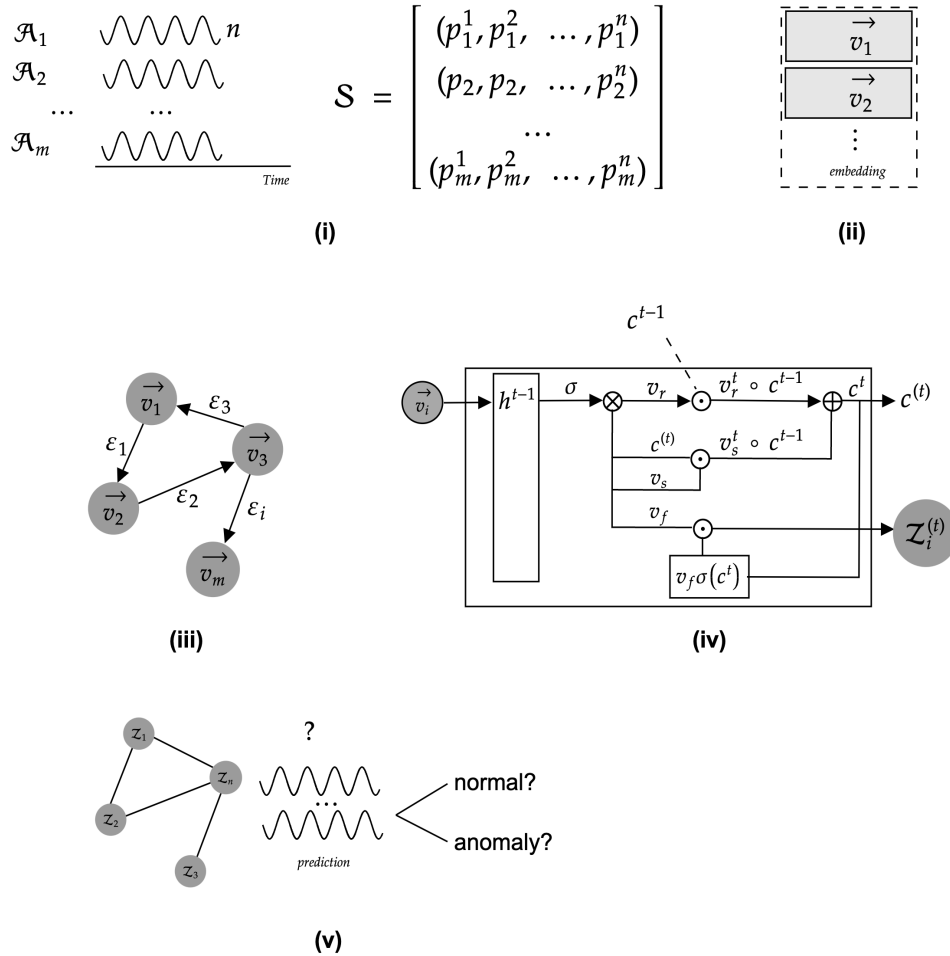

Fig. 2. Illustration of the Proposed Insider Threat Prediction Model.

is used to model the behavior of the second vector. Recall that given a node vector \vec{v} is denoted by $h_{\vec{v}} \in \mathbb{R}^d$. Each node has given a label $\ell_{\vec{v}} \in \{1, \dots, \mathcal{L}_N\}$ that indicates the activity type, e.g. the log-in activities, where the edge has also been given label such that $\ell_{\varepsilon} \in \{1, \dots, \mathcal{L}_E\}$ for each given ε_i .

Note that when an edge connects two vectors, it means the first vector is utilized to underline the behavior of the second vector. The dependency is represented between vectors as a set of candidate relations \mathcal{R}_i for each vector such that $\mathcal{R}_i \subseteq \{1, \dots, m\} \setminus \{\vec{v}_i\}$. The selection of which dependencies related to \vec{v}_i is conducted by the search for the most similar candidate. To this end, we compute the similarity θ between ε_i edge node and the embeddings of its candidate relation $j \in \mathcal{R}_i$ using dot product measure. Equation 1 shows θ similarly measurement.

$$\theta(\varepsilon_i, \varepsilon_j) = \frac{\vec{v}_i \cdot \vec{v}_j}{\|\vec{v}_i\| \cdot \|\vec{v}_j\|} \quad \text{for } j \in \mathcal{R}_i \quad (1)$$

D. Feature Learning

Having represented relations between embedded vectors (graph nodes), the next step is concerned with extracting and learning features. The idea is to establish an abstracted feature space using RNN to fuse a node's information with its neighbors. In the proposed model, feature extraction includes

the vector embedding \vec{v}_i , which describes the various behaviors of various vector kinds. Nevertheless, feature extraction has been accomplished using Long-Short Term Memory (LSTM), a well-known set of RNN architecture. The main benefit of adopting an LSTM unit is that the cell state averages activities over time, which helps to avoid disappearing gradients and better capture long-term time series relationships.

At each tick of time, an individual entry node \vec{v} will map a hidden layer $h^{(t)}$. Each hidden unit has a memory cell $c^{(t)}$ to obtain long-term dependencies. The intuition is that $c^{(t)}$ serves to remember the effect of the prior input layer. In the proposed model, the mapping function use three non-linear gates to manage the access to $c^{(t)}$ cell as follows: i) remember vector v_r , save vector v_s , and focus vector v_f . The following equations express the mathematical notation of gated vector v_r, v_s, v_f respectively (2, 3, 4), memory cell control $c^{(t)}$ (5), and mapping function $h^{(t)}$ (6).

$$v_r = \sigma(W_r[h^{(t-1)}; v^{(t)}] + \epsilon_r) \quad (2)$$

$$v_s = \sigma(W_s[h^{(t-1)}; v^{(t)}] + \epsilon_s) \quad (3)$$

$$v_f = \sigma(W_f[h^{(t-1)}; v^{(t)}] + \epsilon_f) \quad (4)$$

$$c^{(t)} = v_r \odot c^{(t-1)} + v_s \odot \sigma(W_c[h^{(t-1)}; \vec{v}^{(t)}] + \epsilon_c) \quad (5)$$

$$h^{(t)} = v_f \odot \sigma(c^{(t)}) \quad (6)$$

where $[h^{(t-1)}; v^{(t)}] \in \mathbb{R}^d$ is the sum of the prior hidden state $h^{(t-1)}$ and the current vector $v^{(t)}$ along with some bias ϵ , \odot is the element-wise multiplication, and σ is the non-linear Rectified Linear Unite (ReLU) activation function [31]. Here, the resulted output is an aggregated representation \mathcal{Z}_i of hidden layers at time (t) from such input node \vec{v}_i .

$$\mathcal{Z}_i^{(t)} = \sigma(h^{(t)}, \vec{v}_i^{(t)}) \quad (7)$$

where $\vec{v}_i^{(t)}$ is the input for a given node at time t , with ReLU activation σ .

E. Anomaly Detection

When the relations are learned as per the previous subsection, the next step is to determine how the anomaly behavior can be detected accordingly. The idea is to determine how such an unseen behavior deviates from learned relations for each user. Thus, the proposed model attempts to calculate a similarity score Φ between the observed behavior of the user, that has resulted from the learned relations, and the new abstracted stream $\hat{\mathcal{Z}}$:

$$\Phi_i^{(t)} = |\mathcal{Z}_i^{(t)} - \hat{\mathcal{Z}}_i^{(t)}| \quad (8)$$

To assure a robustness calculation of the similarity score, we normalize the score for each input node using the median u of the difference between 1st and 3rd quartiles of distribution α .

$$\varphi_i^{(t)} = \frac{\Phi_i^{(t)} - u_i}{\alpha_i} \quad (9)$$

Recall that the use of inter-quartile range shows an effectiveness calculation of the distribution's spread for anomaly detection in stream data [32]. Then, the anomaly score Anom_{sc} is the max value of φ that is computed at time (t) as follows:

$$\text{Anom}_{sc}^{(t)} = \max(\varphi_i^{(t)}) \quad (10)$$

Hence, the stream is classified as either normal or anomaly activity at some fixed threshold. The user can configure the threshold value; however, in the evaluation of this study, the value is set to max over the validation data. Thus, the stream is labeled as an anomaly whenever the similarity score exceeds the max $\text{Anom}_{sc}^{(t)}$ value.

IV. PERFORMANCE EVALUATION

This section provides the evaluation of the proposed model to determine its efficacy. The main objective of the evaluation is to show the effectiveness of detecting insider anomalous in network flows based on relation-based learning with LSTM. Moreover, the evaluation examines the model's performance under different LSTM parameters tuning to determine how they would affect the detection accuracy. Finally, the evaluation shows how well the performance of the proposed model compared to baseline methods of detecting insider attacks.

A. Evaluation Settings

1) *Dataset*: The evaluation experiments have been conducted over CERT dataset [33]. CERT is a public released insider threat dataset. It consists of activities data for more than 1k users, with 32 million events (log lines) generated over 502 days. There are around 7k log lines representing anomaly actions among the total recorded activities; these logs were manually placed into the data records by specialists. The data pertaining to log-in, log-off, device, and HTTP is stored in the logline. Each user action is parsed into a vector in the experiment, including the id, date, user, computer, and activity type as multivariate time series sequences. The dataset has been splitted to training (70%) and testing (30%) for all conducted experiments.

2) *Metrics*: Confusion Matrix (CM) has been used to compute a number of metrics to evaluate the model's performance. Recall that CM shows the classification performance of the proposed model under different parameters settings and with compared to other comparators baselines. Thus, CM is used to measure: i) F1-score ($F1 = \text{Equation 11}$), Precision ($Pre =$

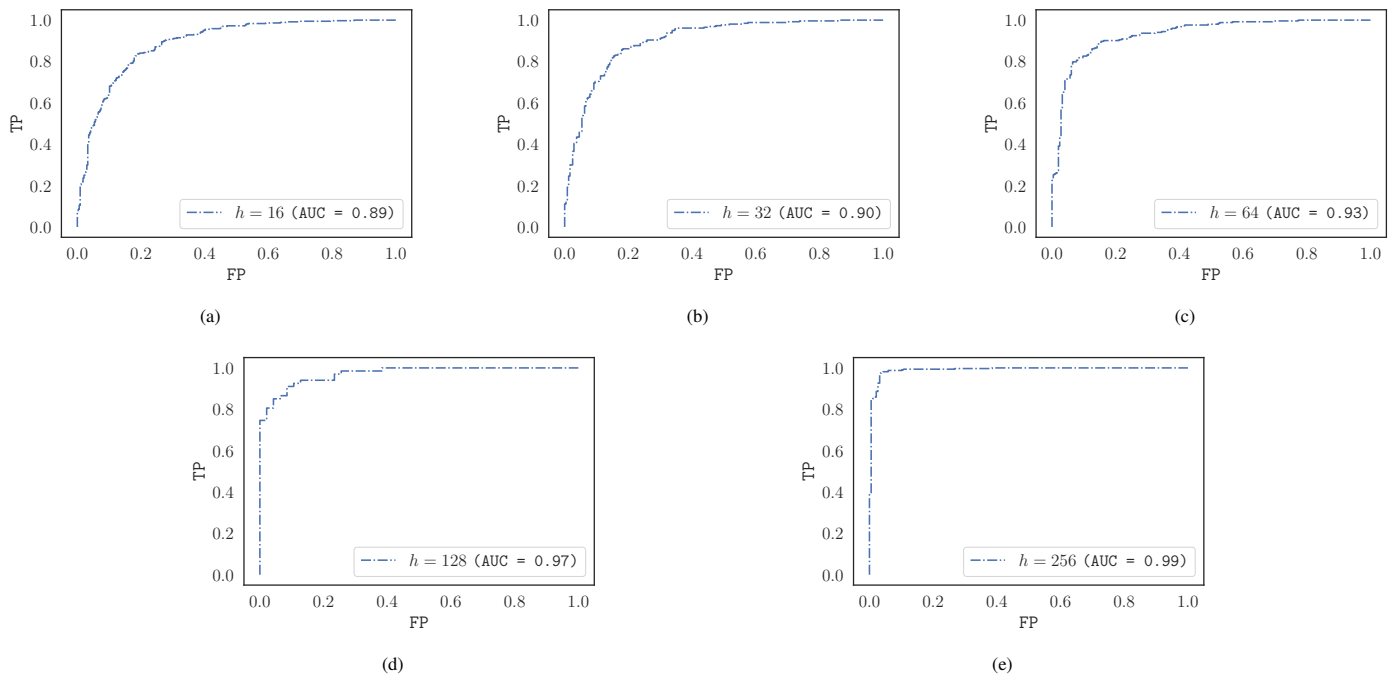

Fig. 4. ROC Curves of the Proposed Model with different Hidden-Layer Size Setting as Follows: (a) $h = 16$, (b) $h = 32$, (c) $h = 64$, (d) $h = 128$, and (e) $h = 256$,

Equation 12), and iii) Recall ($Rec =$ Equation 13), Area Under Curve (AUC), and Receiver Operator Characteristics (ROC) curve.

$$F1 = \frac{TP}{TP + \frac{1}{2}(FP + FN)} \quad (11)$$

$$Pre = \frac{TP}{TP + FP} \quad (12)$$

$$Rec = \frac{TP}{TP + FN} \quad (13)$$

where TP is true positive samples, TN is true negative samples, FP is false positive samples, and FN is false negative samples.

Moreover, Mean Squared Error (MSE) is used to calculate the error rate between predicted values and the actual values. Considering n anomalous sequences inside the dataset, MSE computes the mean of the sum of all the squared errors of each sequence individually (Equation 14).

$$MSE = \sum_{i=1}^n \frac{(a_i - p_i)^2}{n} \quad (14)$$

where a_i is the actual value, and p_i is the predicted value.

3) *Experiment Settings*: The experiments have been conducted using TensorFlow¹. A number of LSTM parameters, including the epochs, batch-size and hidden-layers, have been tested while learning relations and extracting features. Further detail concerning the choice criterion is given in the following section. Recall that batch-size refers to

the size of the embedding vector \vec{v}_i of an activity stream as proposed in the model. The model is trained using Adam optimizer with 0.01 learning rate.

B. Results

The model has been evaluated under different LSTM parameter setting to determine the best performance of relation learning and feature extraction. To this end, we determine the performance of the model under different parameter-setting including epochs, batch-size, and hidden-layer size. To determine the optimal setting for batch-size we conduct a grid search over $\{8, 16, 32, 64, 128\}$. For hidden-layer we also conduct a grid search to tune the best performance over hyper-values of $\{8, 16, 32, 64, 128\}$. The model is run over epochs = 50 and epochs = 100, for the entire grid searches, respectively. Fig. 3 illustrates the performance of the proposed model in terms of MSE value for different parameter setting. The figure shows that epochs = 100 has generally produced better performance than epochs = 50 with different scales of batch-size and hidden-layer. The best results of MSE are recorded with batch-size = 256. It can be seen that the batch-size has an influence on obtaining better results whenever the value get larger although we found that the time complexity is increased accordingly. However, the efficiency on terms of time complexity scale is beyond the scope of this study despite it is interesting for consideration in other simulations such as the case of online feature extraction. Moreover, the model has yield best results whenever hidden-layer = 128 get larger. Figure 4 shows the ROC curves of the proposed model with respect to different hidden-layer sizes. The best result is recorded with AUC = 0.99 at hidden-layer = $h = 256$.

TABLE I. THE RESULTS OF ANOMALY BEHAVIOR DETECTION IN TERMS OF F1, PRE AND REC OF THE PROPOSED MODEL COMPARED WITH BASELINES

Method	F1	Pre	Rec
SVM	0.28	34.20	21.20
HMM	0.35	55.98	49.20
NN	0.74	89.76	58.10
Rel-RNN	0.80	99.12	67.12

Fig. 5. The ROC Curves that Show the Performance of the Proposed Model along with Baseline Methods.

The proposed model has been evaluated to determine the detection accuracy in terms of F1, Pre and Rec compared with baseline methods. The evaluation explores the detection of anomaly behavior with relation-based feature learning of temporal streams, as in the proposed model, and the aggregated features based on statistician abstraction of audit data. We adopt the following baselines: SVM, HMM, and shallow Neural Network (NN). Note that the later considers feedforward structure with one layer of `batch-size = 265` and `hidden-layer = 128`. Table I shows the obtained results of all methods; for clarity, we denote the proposed method as **Rel-RNN**. It can be seen from the table that the **Rel-RNN** has recorded best results with 0.80, 99.12, 67.12 for F1, Pre, and Rec respectively. To further demonstrate the obtained results, Fig. ?? shows the ROC curve for the proposed model compared with baseline methods. It can be observed that the performance of **Rel-RNN** has obtained a better AUC value of 0.99.

V. CONCLUSION

This study has proposed a novel model for insider threats detection. The proposed model structures the audit data, which represents the daily activities, as a multivariate time series covering broader characteristics for better user behavior learning. Thus, the temporal sequence of exclusive events is considered rather than an abstract set of features. The represented sequences are fed into an RNN model to learn hidden relations for feature extraction. The relations between representative features can be learned to identify latent patterns in the

sequences for recognizing malicious behavior. To maintain the consecutive temporal lags between the set of features, LSTM has been used thus to avoid the vanishing gradient problem. The evaluation on the CERT dataset has shown that the proposed model has outperformed the comparator baselines for insider threat prediction. In the future, the plan is to incorporate Spatio-temporal dependencies to determine whether it affects modeling the latent relations to profile the user's behavior. This is desirable when users have the authorization to access the network from different places remotely. This case is observed during the COVID-19 pandemic when most companies and organizations allow employees to access networks from distant locations.

An Improved Label Initialization based Label Propagation Method for Detecting Graph Clusters in Complex Networks

Jyothimon Chandran, V Madhu Viswanatham

Vellore Institute of Technology
Vellore, Tamilnadu, India

Abstract—Community structure is one of the fundamental characteristics of complex networks. Detection of community structure can provide insight into the structural and functional organization that helps to understand various dynamical processes such as epidemics and information spreading. Label propagation algorithm (LPA) is a well-known method for community structure identification due to linear time complexity. However, the communities extracted by the LPA is unstable since it produces different combinations of communities at each run on the same network. In this paper, a novel label initialization method for label propagation algorithm (ILI-LPA) is proposed to detect stable and accurate community structures. The proposed ILI-LPA focuses on more accurate label initialization rather than assigning unique labels thereby reduce the effect of randomness in LPA. The experiments on several real-world and synthetic networks show that the ILI-LPA improves the quality and stability of communities compared to existing algorithms. The results also demonstrate that appropriate label initialization can significantly improve the performance of label propagation algorithms, and the stability has been improved up to 50-78% relative to the standard LPA.

Keywords—Social networks; community detection; graph clustering; edge clustering coefficient; label initialization; triangle count

I. INTRODUCTION

Complex systems can be modeled as networks, with nodes representing entities of the system and links between nodes denoting its relationships [1]. Such networks are usually termed complex networks and can explain the emergence of complex behavior of the system. Examples of such complex networks [2] are biological networks, citation networks, scientific collaboration networks, and social networks. A common and significant characteristic of complex networks is community structure or communities or clusters [3], such as bacterial communities in the microbial ecosystem and community mobility in urban transport systems. Community structure can provide an overview of the system in consideration, explain the underlying dynamics, and reveal the hidden relations among the entities. It is defined as groups of nodes in a network with dense internal connections inside the groups and fewer connections between the groups [4]. An interesting fact about communities is that the nodes that belong to a community exhibit similar characteristics or common properties that define the overall behavior of the network [5]. Detecting community structure has become an integral part of network analysis.

Several community detection algorithms exist in the literature, and they fall into optimization methods or heuristic methods. The optimization methods such as modularity maximization algorithms [6], [7], [8], spectral methods [9], [10], and evolutionary algorithms [11], [12] formulate an objective function and then estimate an optimal value to find community partitions. Modularity maximization-based methods [6], [7], [8] focus on locating the maximum modularity to extract communities. The spectral methods [9], [10] construct the Laplacian matrix of the network from its characteristic vectors by formulating a quadratic objective function to obtain communities. The methods such as whale optimization [11] and genetic algorithm [12] are evolutionary algorithms. They utilize evolutionary computations to evaluate the optimal value of the optimization function to find the communities. However, most of these algorithms are inappropriate for networks of very large in size because of high time complexity. Heuristic methods apply heuristic techniques to identify communities, which are more time efficient than optimization methods. The methods such as Infomap [13], Edge betweenness [3], [14], and Label propagation algorithm [15] are examples of heuristic community detection algorithms.

The label propagation algorithm (LPA) [15] is one of the computationally efficient community identification methods having time complexity linear ($O(n)$). The LPA consists of mainly two steps: label initialization, and label propagation. At the label initialization, unique labels are assigned to every node in the network. Then at the label propagation, node labels of every node are iteratively updated to the label of the maximum of its adjacent nodes. If more than one label satisfies the maximum criteria, then a random selection on the maximal label is considered. This iterative label update process continues until every node label is the same as its adjacent nodes maximum label. According to a random node order, nodes are processed in each iteration. Finally, the communities are extracted with respect to node labels. Due to the low time complexity, the LPA is a better choice for very large networks. However, the communities detected by the LPA on a network differ in each execution, which makes the algorithm unstable. This drawback prevents LPA from being widely used in practice.

A sample network with two communities with few connections between them is shown in Fig. 1. Nodes {1, 2, 3, 4, 5, 6} and the nodes {7, 8, 9, 10, 11, 12} constitute the first and second communities. Two communities are also

Fig. 1. A Sample Network with Two Communities, $C_1 = \{1, 2, 3, 4, 5, 6\}$, and $C_2 = \{7, 8, 9, 10, 11, 12\}$.

connected through edges (1,7), (4,8), and (5,9), and nodes $\{1, 4, 5, 7, 8, 9\}$ are called boundary nodes. Initially, node numbers are considered as node labels. While initiating the label update process, unique label initialization can cause multiple maximum labels for every node. For instance, if node 4 modifies its label with node 8, and node 11 subsequently changes with the label of node 8, and node 1 updates with node 4, then the algorithm returns a single community. In the next run, if the boundary nodes update their label with the label of nodes in their own community, then it produces two different communities. This is the instability problem of LPA.

To improve the stability of LPA, recently, many improvements have been proposed incorporating measures such as network modularity [16], [17], [18], [19], [20], node strength [21], [22], [23], [24], [25], [26], edge strength [27], [28], [29], [30], [31], [32] and other methods such as node attributes, memory constraints, and evolutionary approaches [33], [34]. Most of these LPA improvements assume that the leading cause of instability is the randomness involved in the label update process and the order of node. Hence eliminating the randomness by incorporating an order to the node selection and label update through various measures were received much attention. The modularity-based label propagation algorithms [16], [17], [18], [19], [20] update node labels according to the label of the neighbor node that produces largest modularity when multiple maximal labels exist. Similarly, node strength-based methods [21], [22], [23], [24], [25], [26] perform label selection according to the node strength measures such as node centrality, influence, or importance during the label update. Similarly, edge strength-based algorithms [27], [28], [29], [30], [31], [32] calculate the strength of connections using measures such as edge clustering coefficient, link strength to update the node label. Overall, these methods focus primarily on providing order to label update rule using various measures, thereby improving the stability of LPA. Though these researches have improved the performance of LPA, there still exists improvements in accuracy and stability.

This paper proposes an improved label propagation algorithm called Identical Label Initialization based LPA (ILI-LPA) based on a novel label initialization method for identifying community structure in networks. Instead of eliminating randomness, ILI-LPA focuses on proper label initialization to improve stability and accuracy. The label initialization of ILI-LPA is based on the measure *triangular structural influence (tsi)*, which estimates influence between nodes based on the triangles in the network. The *tsi* helps to find structurally closely connected nodes in the network to assign identical

labels. Once the label initialization is over, the ILI-LPA follows the random label update strategy to extract the communities.

This paper contains the following contributions.

- Introduces *triangular structural influence (tsi)* to estimate the influence between nodes.
- Proposes a novel label initialization method to tackle stability.
- The effectiveness of ILI-LPA is tested on several real-world and synthetic networks.
- The effect of label initialization on reducing the impact of randomness is assessed.

The rest of the paper is organised as follows: Section II outlines the most recent enhancements to the label propagation algorithm that have been made. Section II elaborates the proposed method. Section IV discusses the experimental details such as data sets, baseline algorithms, and evaluation measures. The results and discussion are presented in section V. Section VI provides the conclusion and future works.

II. RELATED WORK

A complex network is represented in this study by an unweighted undirected network $G(V, E)$, with V denoting the node-set and E denoting the edge set. The neighbor set of node u represents $\Gamma(u)$. If an edge connects two nodes, then they are called neighbors. The degree of node u is represented as d_u . If a node u , ($u \in V$), contains a label, then it is denoted as l_u .

Several LPA improvements were proposed to enhance stability. According to the label update strategy, those LPA improvements can be classified into four. They are modularity-based LPA methods [16], [17], [18], [19], [20], node strength-based methods [21], [22], [23], [24], [25], [26], edge strength-based methods [27], [28], [29], [30], [31], [32], and other LPA improvements [33], [34]. These methods focus mainly on eliminating the randomness to improve the stability and accuracy of the communities produced.

A. Modularity-Based LPA Methods

To improve the stability, Barber and Clark [16] developed LPAm treating the LPA as a modularity optimization problem. According to LPAm, the label to be propagated is the label that increases the modularity. Compared to the original LPA, it improves the quality of the detected communities. This approach, however, has the problem of getting trapped in the local optimum, resulting in incorrect partitions. To avoid local maxima, Liu et al. [17] combined many community pairs at once utilizing a multistep greedy agglomerative algorithm and proposed LPAm+. Both LPAm and LPAm+ have a resolution limit problem due to the modularity function, which also increases the time complexity. To address the shortcomings of LPAm+, Le et al. [19] presented an improved LPAm+ algorithm called meta-heuristic-based LPA, which was based on the Record-to-Record Travel algorithm. This algorithm improves modularity prior to community merging. Another improved LPA called Stepping LPA-S was proposed by Li et al. [18] in which labels are propagated based on similarity. The stepping

LPA-S picks the label that results in the highest modularity. A modularity gain acceleration method based on modularity was introduced in [20] by formulating an objective function. The objective function is solved using global and local sum weights. Each node's label transition is computed using local sum and general sum is calculated for each label. However, because of the modularity function, the time complexity of the above-mentioned algorithms is significantly higher than the other LPA improvements. Therefore, these are unsuitable for very large-scale networks.

B. Node Strength-Based LPA Methods

The idea of node strength-based label propagation algorithms is that when multiple labels satisfy the maximum criteria, instead of a random selection, the label of the node with the highest importance is chosen to overcome the instability problem. More crucially, calculating each node's importance in the network is the main task of these methods. Xing et al. [21] put forward the NIBLPA method utilizing the k-shell value to determine which label to update. The influence of nodes is assessed by examining the nodes degree and k-shell value along with its neighbours k-shell values. Subsequently, Zhang et al. [22] proposed LPA_NI, which considers both node importance and label influence. LPA_NI first estimates node importance using both the node's priori influence and the degree and the influence of its neighbors. The algorithm computes the influence of each label and updates the node label with the most influential label. Tasgin and Bingol [23] presented a local approach based on label propagation for detecting communities via boundary node identification. This approach first finds and rank the boundary nodes. Subsequently, the label of the node that has the largest score among its neighbours is spread. A method (NI-LPA) based on node importance was suggested in [24]. The node importance was calculated considering each node's signal propagation capability, Jaccard distance and k-shell value. However, the time complexity is increased to $O(n^2)$. The paper [25] employed label importance and proposed a label importance-based LPA (LILPA). The label update process in LILPA depends on the importance and attraction of nodes and label importance. The LILPA follows a fixed node order in which the nodes are arranged according to node importance, calculated from using closeness and degree of nodes. Incorporating the modularity and node significance, Li et al. [26] presented an enhanced algorithm called LPA_MNI. It begins by initializing each node with a unique community. Following that, a rough community is built for every node based on modularity gain by merging each node with its neighbor community in descending order of node importance until no further improvement is possible. The node strength is quantified using normalized degree centrality.

C. Edge Strength-Based Label Propagation Methods

Some researchers considered the strength of connections between nodes (edges/links) rather than the node importance to identifying community structure in networks. Based on edge strength, Lou et al. [27] introduced LPA_CNP algorithm. To begin, this method calculates the weighted coherent neighborhood propinquity for each pair of nodes to reflect the chance that two vertices are members of the same community. A node's label is updated to the label with the

highest weighted-CNP. The results indicate that LPA_CNP outperforms LPA, particularly in large-scale networks. Zhang et al. [28] suggested an edge clustering-based LPAc algorithm. It first calculates the edge clustering coefficients of every edge in the network. During label propagation, this strategy selects the label of largest edge clustering coefficient edge that connects the neighbor. According to the link influence and node strength, Berahmand and Bouyer [29] presented LP_LPA. This approach initially determines the similarity of links between nodes assuming that nodes within a community share more common neighbors than nodes in other communities. Therefore, node strength is also estimated according to degree centrality, and initial node selection is performed by calculating node strength. Jokar and Mosleh [30] proposed BLDLP, which determines the weight for each edge according to the link density. If nodes' maximum labels are not unique, the largest weight edge label is chosen. Jiang et al. [31] introduced a link similarity measure and proposed LLPA in which node labels were computed from the link weights to identify functional modules. Li et al. [32] studied the network's higher-order properties by determining the most representative triangle motif that encoded the strength of connections and presented a community recognition approach based on Motif-Aware Weighted Label propagation. As a result, a unique voting approach termed NaS is presented to reduce the randomness provided by tie-breaking.

D. Other Label Propagation Methods

Hosseini and Rezvani [33] introduced the AntLP based on ant colony optimization (ACO). The algorithm begins by weighting all the edges employing a combination of similarity indexes. Then, it attempts to spread labels by grouping comparable vertices to optimize modularity of each community according to their similarity of vertices. Berahmand et al. [34] proposed SAS-LP algorithm, an improved LPA algorithm for attributed graphs that addresses issues of instability and low quality while maintaining structural cohesiveness and attribute homogeneity in the detected communities.

Many of the LPA improvements, discussed in Sections 2.3 and 2.4, recommend strategies or techniques on label update procedure and node order, and follow a standard unique label initialization to improve the stability. The significance of label initialization on improving the stability and accuracy still remains an open problem. The aim of the paper is also on evaluating the impact of identical label initialization instead of unique label initialization on the stability and accuracy of LPA.

III. PROPOSED METHOD: ILI-LPA

This section proposes a novel label initialization method for LPA to extract community structure in networks. The proposed algorithm is named Identical Label Initialization based Label Propagation Algorithm (ILI-LPA). Different from the standard LPA and its improvements described in section 2, the ILI-LPA focuses on appropriate label initialization to identify stable and accurate communities.

The effect of an appropriate label initialization is illustrated in Fig. 2. Assume that some of the nodes in each community is assigned with same labels. The label of nodes in each set

Fig. 2. A Simple Network with Two Communities in which the Nodes {3, 5, 6} Share a Common Label, Nodes {10, 11, 12} also Share another Label and the Remaining Nodes have different Labels.

{3, 5, 6} and {10, 11, 12} is same and the remaining nodes ({1, 2, 4, 7, 8, 9}) carries unique labels. Since some of the nodes in each community is assigned with the same labels, the stability of the label propagation improves significantly. This is because the boundary nodes ({1, 4, 5} and {7, 8, 9}) can never update their label to the node labels that lie in other community based on the label propagation rule. One can see that nodes {1, 4, 5} can never update their labels to the label of other community nodes because their maximum neighbors' labels lie within the community. This applies to the nodes {7, 8, 9} also. when the random label update is applied. The main idea of this paper is to find such nodes that possess a high probability of joining a single community and assigning the same labels to them, thereby improving stability and accuracy.

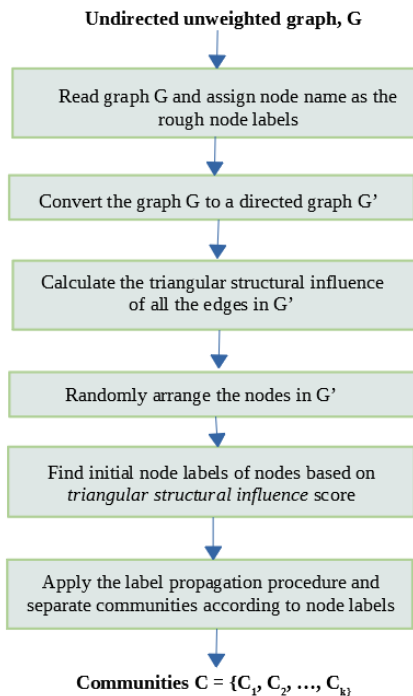

Fig. 3. The Block Diagram the of the Proposed ILI-LPA Method.

The proposed algorithm consists of mainly two phases: identical label initialization and label propagation. At the label initialization phase, ILI-LPA finds structurally closely connected nodes and assigns identical labels to them. When a node is connected with most of the neighbors of a neighbor

node, then the node is said to be structurally closely connected to the neighbor node. To find the nodes that are structurally closely connected, a local measure called *triangular structural influence (tsi)* is introduced from the idea of edge clustering coefficient [36]. Then, according to the *tsi*, the label of the most influential node is given to its structurally closely connected neighbors to initialize node labels. Once the label initialization is over, the ILI-LPA performs the label propagation in which node labels are updated to the neighbors' maximal label. If there exist multiple maximum labels, then a random label selection strategy has opted. Each steps of the proposed ILI-LPA is provided in Fig. 3.

A. Identical Label Initialization

At the label initialization phase, the ILI-LPA aims to assign the same labels to structurally closely connected nodes. It can be measured by estimating the strength of connections between nodes. Several similarity measures exist in the literature that quantifies the connection strength between nodes. These measures quantify similarity considering the network structure or topology to reveal the strength of connections. It includes:

Definition 1: Cosine similarity [35] defined for node i and j is:

$$CS(i, j) = \frac{|\Gamma(i) \cap \Gamma(j)|}{\sqrt{d_i \cdot d_j}} \quad (1)$$

Definition 2: Jaccard Similarity [35] defined for node i and j is:

$$JS(i, j) = \frac{|\Gamma(i) \cap \Gamma(j)|}{|\Gamma(i) \cup \Gamma(j)|} \quad (2)$$

Definition 3: Sørensen Index [35] defined for node i and j is:

$$SS(i, j) = \frac{2 \cdot |\Gamma(i) \cap \Gamma(j)|}{d_i + d_j} \quad (3)$$

Definition 4: Hub Depressed Index [35] defined for node i and j is:

$$HDI(i, j) = \frac{|\Gamma(i) \cap \Gamma(j)|}{\max\{d_i, d_j\}} \quad (4)$$

Definition 5: Hub Promoted Index (HPI) [35] defined for node i and j is:

$$HPI(i, j) = \frac{|\Gamma(i) \cup \Gamma(j)|}{\min\{d_i, d_j\}} \quad (5)$$

Definition 6: Edge clustering coefficient (ECC) [36] is:

$$ECC(i, j) = \frac{|\Gamma(i) \cup \Gamma(j)| + 1}{\min\{d_i - 1, d_j - 1\}} \quad (6)$$

where d_i and d_j indicate degrees of node i and j , $\Gamma(i)$ signifies the neighbors of node i , $|\Gamma(i) \cap \Gamma(j)|$ estimates the number of common nodes. However, these measures are unidirectional, which means that they assume the influence between nodes are equal. In reality, the strength between nodes is bidirectional. Therefore, a new measure is introduced to measure the influence between nodes.

These similarity measures estimate the (structural) strength of connections between nodes accurately. More importantly, it is also known that high similarity value between nodes indicates same community participation of nodes. However, when the (structural) strength of relationship between nodes are considered, one can see that node strength from node i to j and vice versa may not be always same. If an edge that connects a pair of nodes is densely connected by their neighbors, then the edge clustering coefficient of that edge will be comparatively larger. This shows that the nodes exhibit high probability to lie in the same community. From the idea of the edge clustering coefficient, we introduce *triangular structural influence (tsi)* to quantify the node strengths. The *tsi* estimates the strength of the relationship (influence) between nodes based on the triangles associated with each node.

Definition 8: *triangular structural influence tsi(i, j)* denotes the influence the node i exerts on node j . If (i, j) is an edge in the network, $tsi(i, j)$ is the ratio of the actual number of connections from node i to the neighbors of j to the maximum possible connections. Therefore $tsi(i, j)$ is defined as:

$$tsi(i, j) = \frac{1 + |\Gamma(i) \cap \Gamma(j)|}{|\Gamma(j)|} \quad (7)$$

where $\Gamma(i)$ represents the neighbor set of i , $|\Gamma(j)|$ denotes the number of neighbors of node j (degree of j), $|\Gamma(i) \cap \Gamma(j)|$ indicates the number of common neighbors of node i and j , i.e., it represents the number of triangles that connects node i and j . If a node i is connected to all the neighbors of node j , then there exists high influence from i to j .

Similarly, the *tsi* from node i to node j cannot be same as the *tsi* from node j to node i . Therefore $tsi(j, i)$ is:

$$tsi(j, i) = \frac{1 + |\Gamma(i) \cap \Gamma(j)|}{|\Gamma(i)|} \quad (8)$$

The densely connected nodes express high *tsi* than loosely connected nodes. Thus, it is clear that the nodes in a community exhibit higher *tsi* between nodes and less influence between communities.

Once the *tsi* between nodes are estimated, unique rough labels are assigned to every node in the network. Subsequently, in order to assign initial labels (9) is used. During the identical label initialization, each node's label is updated to the label of its neighbors based on the *tsi* using (9).

$$l_j^{init} = \arg \max_{i \in \Gamma(j)} L(l_i, l_j) \cdot f(i, j) \quad (9)$$

where l_j^{init} denotes the initial label of node j , $f(i, j)$ is a function that returns 1 if $tsi(i, j) \geq tsi(j, i)$ and $tsi(i, j) \geq \Theta$. L denotes the label. The Equation (9) can also be interpreted that every node in the network try to update the label of each of its neighbor node with its own label, if $f(i, j)$ is satisfied.

B. Label Propagation

During the label propagation, each node's label is updated asynchronously at random to the label shared by the majority of its neighbors. The proposed method (ILI-LPA) updates the

labels in the same way as the standard LPA does. The every node label is updated using (10).

$$L_i = \arg \max_l |\Gamma^l(j)| \quad (10)$$

where $\Gamma^l(i)$ denotes the neighbors of node i with label l . Communities are formed through an iterative process in which densely connected groups of nodes reach consensus on a single label. Finally, the method converges when there are no more changes to the nodes' labels. If there exists more than one maximal label, the ILI-LPA follows the same LPA strategy, in which ties are broken randomly. Finally, nodes are categorized according to the node labels. That is, nodes with same labels join the same community. The Algorithm 1 describes the procedure of ILI-LPA in detail.

Algorithm 1 The Proposed ILI-LPA

Input: Undirected network $G = (V, E)$, parameter θ

Output: Communities $C = \{C_1, C_2, C_3, \dots, C_k\}$

```

1: procedure ILI-LPA( $G, \Theta$ )
2:   Read network  $G$   $\triangleright$  Phase 1: Label Initialization
3:   Assign rough unique labels to every node in  $V$ 
4:   Convert the network  $G$  to directed network  $G'$  by
   adding directions
5:   for each edge in  $G'$  do
6:     Calculate tsi of the edge
7:     Attach it as edge weights
8:   end for
9:   Arrange the nodes in  $V$  in random order
10:  for each node  $u$  in  $G'$  do
11:    for each node  $v \in \Gamma(u)$  do
12:      if  $tsi(u, v) \geq tsi(v, u)$  and  $tsi(u, v) \geq \Theta$  then
13:        update the label of  $v$  with the label of  $u$ 
14:      end if
15:    end for
16:  end for
17:  Removes the directions and weights of  $G'$ 
18:  Set  $t=1$   $\triangleright$  Phase 2: Label propagation
19:  Arrange the nodes  $V$  in random order and set it to  $V'$ 
20:  for each node  $u$  in  $V'$  do
21:    update its label according to equation (10)
22:    if there exists more than one maximum label then
23:      randomly update to the label of maximum of
   its neighbors.
24:    end if
25:  end for
26:  goto step 27 if none of the node label changes, else
   set  $t = t+1$ , go to step 19
27:  According to the node label, separate the communities.
28:  Return communities  $C$ .
29: end procedure

```

The algorithm first assigns unique rough labels all the nodes. In step 8, it converts the input (undirected) graph to a directed graph by adding directions to all edges. Then, at step 5-8, the *tsi* of each edge is computed using (7) and (8) and attach it as corresponding edge weights. Subsequently, each node tries to spread its label to each of its neighbors and update the neighbor's label with its label if the *tsi* from the node to its neighbor is greater than the neighbor back

to the node. The label spread and label update is performed sequentially in an asynchronous fashion to the entire nodes in the network at once. It is performed in step 18-24. Before that, the algorithm converts the network to an undirected network and remove the edge weights and retain only the node labels. The network contains nodes with identical labels in densely connected regions. This process is followed by the label propagation to find final communities. At step 23, node labels are updated according to the maximum label of their neighbors.

The main steps of ILI-LPA is illustrated in Fig. 4 with the support of a toy network. Fig. 4 (a) shows a network that contains three communities $\{1, 2, 3, 4, 5, 6\}$, $\{7, 8, 9, 10, 11\}$, $\{12, 13, 14, 15, 16, 17, 18\}$. Figure 3 (b) shows the estimated tsi to between nodes and marked at the ends of each edge which represents the tsi to that node. The initial community labels identified by the proposed method by the label initialization is represented in Fig. 4 (c), where the value associated with each node indicates that the node label. Fig. 4 (d) indicates the communities identified after the label propagation. The nodes and their corresponding community labels are given to express the node and its updated nodes label.

C. Complexity Analysis

The ILI-LPA contains mainly two phases. The major steps in phase 1 are unique label initialization and *triangular structural influence* estimation. It takes $O(n)$ time to initialize rough unique labels to every node in the network. The time complexity of estimating the tsi of every edge in both directions is $O(m \cdot d_{avg})$ where d_{avg} and m denote the average degree and the number of edges. The label propagation takes $O(m)$ time. Thus the overall time complexity of ILI-LPA is $O(m \cdot d_{avg}) + O(n) + O(m)$, which is approximately equal to $O(m \cdot d_{avg}) \approx O(n \cdot d)$ ($d \ll n$).

IV. EXPERIMENTAL DETAILS

The performance of the ILI-LPA was tested on synthetic networks and real networks. Experiments were carried out on a 3.4 GHz Intel Core i7 CPU with 16.0 GB of RAM. Python-Networkx was used to develop the algorithm. The algorithm's input parameter θ is set at 0.35 on all the networks.

A. Datasets

1) *Real-World Networks*: The networks considered in this study are: Karate Club [37], Dolphin network [38], Football [3], Polbooks [39], Netscience [40], Email Enron [41], Cond-mat-2003 [41], Cond-mat-2005 [41], DBLP [42], Amazon [42]. The details of these networks are provided in Table I [N_C : actual communities in the network, d_{avg} : average degree, CC : Clustering coefficient].

B. Synthetic Networks

Lancichinetti-Fortunato-Radicchi (LFR) [43] is a popular synthetic network generator to test the performance of community detection algorithms. The community size and degree distributions of generated networks follow power-law distributions. The LFR generator contains the number of nodes

TABLE I. DETAILS OF THE REAL-WORLD NETWORKS

Dataset	Nodes	Edges	NC	d_{avg}	CC
Karate Club	34	78	2	4.58	0.58

LFR_net3	10000	20	1000	1000	2	1	0.05 - 0.75
LFR_net4	20000	20	2000	2000	2	1	0.05 - 0.75

(N), maximum degree ($kmax$), maximum community size (cm_{ax}), average degree (k), degree distribution exponent (t_1), community size distribution exponent (t_2). The most important parameter that sets the character of communities is the mixing parameter μ , which indicates the percentage of linkages between communities and within communities. Table II shows the parameter values given to generate LFR network.

C. Baseline Algorithms

The proposed algorithm was compared with seven existing algorithms. They are Fastgreedy [6], Louvain [7], Infomap [13], LPA [15], NIBLPA [21], LPA-CNP-E [27] and Stepping-LPA [18].

D. Evaluation Metrics

Modularity: For assessing the quality of community partitions, the modularity [44] metric is widely used. Modularity (Q) indicates the percentage of edges within the communities minus the expected percentage of community edges of a random network with same degree distribution. The modularity value of communities C is computed using (11).

$$Q(C) = \frac{1}{2m} \sum (A_{ij} - \frac{k_i k_j}{2m}) \delta(C_i, C_j) \quad (11)$$

where m signifies the total edges, A denotes the adjacency matrix representation of the network, $A_{ij} = 1$ if node i and j are connected, 0 otherwise. The k_i and k_j indicate the degrees of node i and j . The C_i and C_j denote the communities of nodes i and j . The Kronecker delta (δ) yields 1 when nodes i and j belong to a single community, otherwise, it returns 0.

Normalized Mutual Information (NMI): The NMI [45] measures how similar the communities are to one other, by comparing the communities extracted by the community detection algorithm to the actual communities. Let A and B be the actual and detected communities of a given network. The NMI (A, B) is computed using (12).

$$NMI(A, B) = \frac{-2 \sum_{i=1}^{C_A} \sum_{j=1}^{C_B} N_{ij} \log \frac{N_{ij} N}{N_i N_j}}{\sum_{i=1}^{C_A} N_i \log \frac{N_i}{N}} \quad (12)$$

Fig. 4. Details of each Major Steps of ILI-LPA with an Example. a) Input Network, b) Triangular Structural Influence as Weights to each Edge, c) Initial Labels of the Nodes, d) the Final Extracted Communities.

where N_{ij} is the number of common nodes of A's community i and B's community j . The actual and discovered number of communities are denoted as C_A and C_B , respectively. NMI produces its maximum value of 1 if the discovered partition is identical to the actual partitions. If the two partitions are not related, the NMI returns 0.

V. EXPERIMENTAL RESULT AND DISCUSSION

A. Comparing the Modularity of Algorithms on Small Networks

The modularity of the ILI-LPA and the compared algorithms on small networks is presented in Table III. All algorithms were run 100 times, and calculated the average and standard deviation. From Table 3, we can see that ILI-LPA produces significantly better modularity in comparison with baseline algorithms, including the Louvain method on Dolphin and Football networks. On Polbooks network, the ILI-LPA algorithm produces modularity value of 0.526, which is closer to the modularity of Louvain. Though the obtained average modularity of ILI-LPA is only 0.371 on Karate dataset, but still, it is better than standard LPA.

TABLE III. MODULARITY OF ALGORITHMS ON SMALL REAL-WORLD NETWORKS

Algorithms	Karate	Dolphin	Football	Polbooks
Fastgreedy	0.381	0.495	0.568	0.502
Louvain	0.415	0.519	0.604	0.527
Infomap	0.415	0.520	0.563	0.512
LPA	0.357	0.487	0.589	0.511
LPA-CNP-E	0.303	0.463	0.601	0.451
Step-LPA-S	0.371	0.378	0.575	0.496
NIBLPA	0.40	0.43	0.50	0.55
ILI-LPA	0.371±0.00	0.523±0.05	0.604±0.02	0.526±0.002

B. Comparing the NMI of Algorithms on Small Networks

To evaluate the accuracy of algorithms, the NMI is calculated and reported in Table IV. It provides that on Football and Polbooks networks, the NMI score of ILI-LPA is comparatively higher compared to baseline algorithms. Though the modularity value of Dolphin network shown in Table 3 is high, the accuracy is low, with NMI value 0.566. On Karate network, ILI-LPA algorithm yields an NMI score of 0.837, which is just below the NMI of Step-LPA-S and better than other methods, including Louvain. From Tables III and IV, we can say that the ILI-LPA is better than the others on stability and accuracy on small networks.

TABLE IV. NORMALIZED MUTUAL INFORMATION OF ALGORITHMS ON REAL-WORLD NETWORKS

Algorithms	Karate	Dolphin	Football	Polbooks

C. Comparing the Modularity of Algorithms on Large Networks

Table V provides the modularity produced by the algorithms on large networks. As seen on the Table, the modularity value of the proposed algorithm on the network science dataset is 0.921, significantly better than LPA, Step-LPA-S, NIBLPA. On Email-enron network, the ILI-LPA gives 0.562 modularity, which is higher than all the algorithms except the Louvain method. On Cond-mat-2003 dataset, our algorithm is not performing well because the modularity of the detected communities is just 0.632. At the same time, On Cond-mat-2005 network, the modularity of the proposed method is superior to other algorithms except for Louvain. On Amazon, only Fastgreedy and Louvain produces superior modularity than the proposed method. On DBLP network, though our algorithm is inferior to non-LPA-based algorithms, still better than both LPA and NIBLPA. The experiments on large-scale networks compared to LPA-based (LPA, LPA-CNP-E, Step-LPA-S, NIBLPA) and non-LPA-based (Fastgreedy, Louvain, Infomap) algorithms on modularity metric show that the ILI-LPA has better performance on LPA-based algorithms and is closer to non-LPA based algorithms except Louvain. Since Louvain is a modularity optimization method, Louvain can return higher modularity on most of the network. Table 5 demonstrates that the ILI-LPA performs well on large-scale real-world networks.

D. Evaluating the Performance ILI-LPA on LFR Networks

Extensive tests have been carried out on the LFR network in order to validate the performance of the ILI-LPA. It is analyzed on the LFR network in three different aspects: modularity, NMI, and the number of communities. Since the actual community information is available in the LFR network, the actual modularity and number of communities of the corresponding network are considered as GroundTruth value. The algorithms employed for the comparison are Fastgreedy, Louvain, Infomap, and LPA. Since non-LPA algorithms are

better than LPA variants, only these four algorithms are considered for synthetic network evaluation. The results with respect to Modularity (Q) (including the GroundTruth modularity of LFR communities) is illustrated in Fig. 5. With an increase in the mixing parameter (μ), the accuracy of algorithms steadily diminishes. Fig. 5 shows that the modularity of the communities identified by the proposed algorithm is the same as that of the GroundTruth modularity of LFR until reaches 0.70. Though the modularity of Fastgreedy is stable, it is significantly lower than the GroundTruth.

Fig. 5 shows that on all the four networks, the ILI-LPA produces modularity closer to the GroundTruth and better than the other LPA methods. When the μ is less than 0.45, the modularity of detected communities of different algorithms, except the Fastgreedy, is closer to GroundTruth modularity on all four networks. Both LPA and Infomap modularity drastically reduce when at 0.50 and 0.55, respectively. However, ILI-LPA is the same as GroundTruth and Louvain communities until the reaches 0.70. when the modularity of standard LPA drops between 0.40 and 0.50, the proposed improved LPA (ILI-LPA) algorithm maintains the quality of communities till reaches 0.70. In all four networks in Fig. 5, the ILI-LPA shows a similar pattern of modularity and better performance than other algorithms.

The experimental result with respect to NMI is reported in Fig. 6. The results indicate that except the FastGreedy, all algorithms produce good performance on all the four networks until is 0.45. With respect to the increase in the mixing parameter (μ), the difficulty in community identification also increases. Fig. 6 shows that the proposed method produces stable and accurate communities on all the four LFR networks until is less than 0.7. The performance of Fastgreedy and Infomap significantly decreases when is above 0.4, and the performance of LPA also drastically drops when crosses 0.5. The experiments on four LFR networks demonstrate that the ILI-LPA is improved in terms of algorithms than compared algorithms.

Additionally, while evaluating the performance of community detection methods, the number of communities detected is a significant performance metric to consider. In LFR networks, since the actual number of communities is known, the comparison can provide more insights into the performance. The number of communities produced by the algorithms corresponding to four different μ values is illustrated in Fig. 7. In LFR net1, the number of communities of the ILI-LPA is very close to the GroundTruth communities of the LFR network in all the four different μ values. On all four networks, the number of communities of Fastgreedy is significantly low than the GroundTruth values. While μ is greater than 0.4, as expected the both Infomap and LPA yield poor performance. There is only one algorithm that produces an exact number of communities to the ground truth in all the test cases is our proposed ILI-LPA algorithm. Though the Louvain shows high modularity value, the identified community size of Louvain is significantly smaller than that of the actual number of communities. Overall, the experimental results illustrate that the ILI-LPA is stable and accurate in finding communities without consuming much computational time.

Analysis and Discussion The results illustrate that the ILI-LPA improves the stability and accuracy without significantly

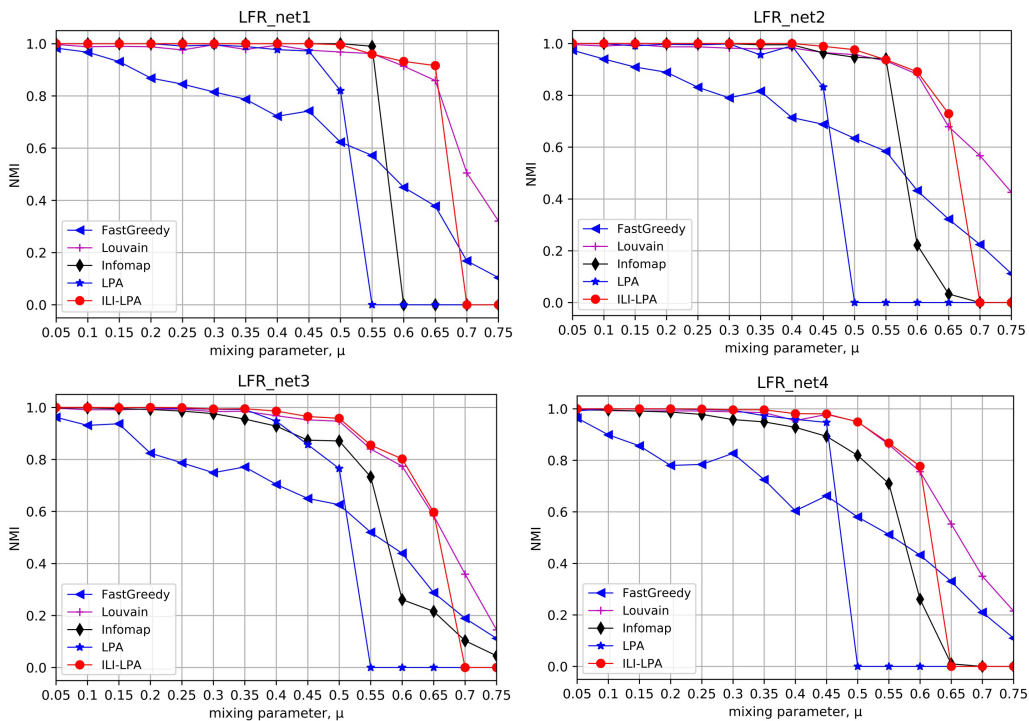

Fig. 6. NMI Produced by the Algorithms on Four LFR Networks.

increasing the execution time. Unlike the standard and other improvements of LPA that assign nodes with unique labels during the label initialization, the ILI-LPA focuses on identical

label initialization where two nodes get the same label if the nodes are structurally closely connected. That is, the two nodes expresses a high probability to continue in a single community

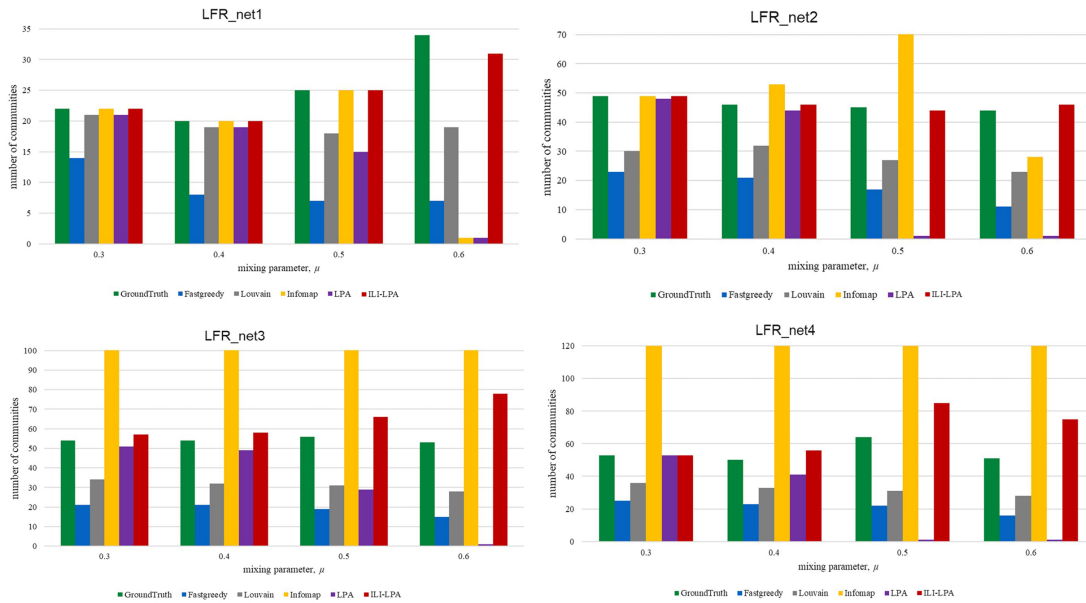

Fig. 7. The Number of Communities Produced by the Algorithms on Four LFR Networks.

from the initialization to the final communities during the label propagation. Real-world and synthetic networks are employed for conducting the experiments. The results prove the importance of more accurate label initialization than the conventional unique label initialization to improve the stability and accuracy of improved LPAs. The main advantage of ILI-LPA is that the identical initialization of labels reduces number of iterations at the label propagation phase. Also, the label initialization helps each node to differentiate its own community neighbors from other neighbors, which solves the instability due to random selection. So that, without eliminating the randomness in LPA and employing proper label initialization, the ILI-LPA achieves better performance.

VI. CONCLUSION AND FUTURE WORK

The LPA is a popular time-efficient community detection algorithm. However, the instability in results is its main drawback. Many of the recent LPA improvements concentrate primarily on eliminating randomness by introducing various measures that provide an order to the label update process. However, these improvements either increase the computational time or reduce the accuracy. This paper presents a novel technique called identical label initialization to improve stability and accuracy and proposes the ILI-LPA. The ILI-LPA finds nodes that are structurally closely connected, then assigns identical labels to them. Our approach focuses primarily on proper label initialization rather than assigning unique labels. The ILI-LPA maintains the random label selection strategy when multiple maximal labels exist to update node labels. The results demonstrate that the proposed ILI-LPA has better performance than the existing algorithms. The results also demonstrate that proper label initialization is also an important factor for improving LPA stability and accuracy. In future, the proposed method can be extended for finding overlapping communities in networks. In addition, the label initialization can be extended to detect evolving communities in dynamic networks.

Natural Language Processing for the Analysis Sentiment using a LSTM Model

Achraf BERRAJAA

Euromed Research Center, Euromed University of Fes, Morocco

Abstract—Over the past decade, social networks have revolutionised the communication between organisations and their customers, and the data provided by customers on social network platforms is having an increasingly important impact on how organisations collect and analyse this data to make better decisions. We have prepared a new dataset that will allow the scientific community to estimate and evaluate new models using nearly the same conditions. Moreover, this dataset represents a recent and interesting sample for the proposed machine learning models to correctly identify the topics or points on which the company should focus to improve customer satisfaction and better meet their needs. Therefore, we have proposed a recurrent neural network (RNN) with Long short-term memory (LSTM) that we will run in the cloud to predict sentiment analysis. The objective is also to define systems capable of extracting subjective information from natural language texts, such as feelings and opinions, with the aim of creating structured knowledge that can be used by a decision support system or a decision maker for better customer management. The proposed neural network has been trained on the proposed dataset which contains 50 000 customer observations. The performance of the proposed architecture is very important as the success rate is 96%.

Keywords—Artificial intelligence; NLP; RNN; LSTM; customer relationship management

I. INTRODUCTION

In recent years, social networks have revolutionised communication between organisations and their customers. The data provided by customers on social media platforms is having an increasing impact on how organisations collect and analyse this data to make better decisions. Natural language processing (NLP) is one of the most promising ways to process data and text from social networks. Developing powerful methods and models to extract relevant information from large amounts of data from multiple sources and languages is a complex challenge. It can be overcome when a powerful pipeline is built to transform this raw data into useful information that we can use.

Information extraction [27], classification and grouping methods [25] are one of the main approaches to leverage raw textual data and transform it into valuable information. In the field of data processing, a robust pipeline is needed to clean this textual data and make it ready for use by different models. To this end, our objective is to propose a data preparation pipeline ranging from data processing and cleaning to digital representation of textual data. The prepared data is intended to be used as training data for machine learning models. A deep learning model is also implemented for sentiment analysis, defined as a system for extracting subjective information from natural language texts, such as feelings and opinions, to create

structured knowledge that will be used by a decision support system or a decision maker.

As far as structure is concerned, this paper is organised as follows: Section 2, presents a literature review on the works related to the different technologies used for natural language processing and their fields of use, namely linguistics and artificial intelligence. Section 3 details the structure of our data preparation pipeline which consists of six modules: data cleaning, tokenization, data normalization, stemming and lemmatization, token categorization and finally data representation. Section 4 is reserved for the creation of machine learning models that are able to classify the observations in our data by assigning them a star score ranging from one to five (Very Satisfied, Satisfied, Fair, Dissatisfied and Very Dissatisfied). In Section 5, a Recurrent Neural Network (RNN) with Long Short-Term Memory cells (LSTM) is implemented for the sentiment analysis of our customers. Section 6 is devoted to the digital experiments. We also discuss and comment on the results obtained and show the effectiveness of our models. Finally, a conclusion that summarises the study and gives some potential perspectives for the developed approach to improve the current results.

II. RELATED WORK

Social networking is a phenomenon that has recently developed worldwide and has rapidly attracted billions of users. The main reason for this phenomenon is the ability of online social networks to provide a platform for users for better communication, as explained in the work of [16]. This form of electronic communication through social networking platforms allows customers to generate their content and share it in different forms, usually in text form. This content is very valuable to the organisations involved. Therefore, automatic natural language processing is formed as an emerging area of research and development [19].

Natural Language Processing can be defined as a field of study using computer science, artificial intelligence and linguistic concepts to analyse natural language. In other words, NLP is a set of tools used to derive meaningful information from textual data and generally used to obtain knowledge and decision support by processing textual data present in web pages, documents, customer reviews [20].

As mentioned earlier, linguistics is an essential part of natural language processing and can be defined as the scientific study of the structure and development of language with particular emphasis on grammar, semantics and phonetics. In other words, linguistics is primarily concerned with the design and evaluation of language rules. If we read this definition

carefully, we realise that natural language is controlled by a set of rules such as grammar and semantics. These rules will be a key factor in enabling the machine to understand the textual data and to process it. The author in [13] present a study that summarises the linguistic research techniques used in automating the analysis of the linguistic structure of language and, at the same time, sheds light on the development of core technologies such as speech recognition, speech synthesis and machine translation using artificial intelligence.

Artificial intelligence (AI) is a branch of computer science that aims to propose and construct systems able of performing tasks that require human intelligence. In other words, any algorithm or computer technique capable of performing sophisticated tasks such as driving a car or diagnosing a disease can be classified as artificial intelligence (for more information, see [24]). Machine learning is a sub-field of artificial intelligence that deals with the development of algorithms capable of learning to perform tasks automatically on the basis of a large number of examples, without being pre-programmed to do so in the case of supervised learning, or with the creation of clusters and grouping of the most similar observations in the case of unsupervised learning. We cite the book *Machine learning algorithms* [8] for more information on machine learning algorithms. On the other hand, Deep Learning refers to the branch of machine learning based on neural network architectures. In [17], the authors summarise the basic principles of deep learning and machine learning to provide a general understanding of the methodical foundations of current intelligent systems. The development of NLP applications relies heavily on machine learning and deep learning methods. Therefore, both disciplines play an important role in the development of this project.

In a natural language processing project, the data is nothing more than text - unstructured data produced by people to be understood by others. Nevertheless, this unstructured data contains patterns or indications that allow it to be analysed by a computer. To put it differently, although text is unstructured data, it is not disordered. On the contrary, text is governed by linguistic properties that enable communication [10]. Thus, our contribution will be to find patterns in the text, and analyse them for better decision making. This approach is similar to that of [20] who proposed a framework for big data analytics in commercial social networks for sentiment analysis and fake review detection for marketing decision making. Furthermore, when working with natural language, we frequently encounter the concepts of syntax and semantics. The syntax of a language refers to the rules that govern the way in which linguistic elements are put together to form phrases, clauses, and sentences. It should be noted, however, that the syntactic rules of a natural language are not as strict as those of computer languages. This means that it is essential that a sentence follows the basic syntactic rules, so that it can be used to enable the machine to process textual data.

Natural language processing is performed on text data ranging from a few words entered by the user for an Internet search to multiple documents to be analysed and from which information needs to be extracted for better decision making. Thus, natural language processing is used in a variety of situations to solve many different types of problems:

- Searching for a string of characters: automatic pro-

cessing of natural language makes it possible to identify specific elements in the text. For example, it can be used to find the occurrence of a word or more generally a string of characters in a document. As an illustration, in the work of [21], a string recognition method based on a lexical search method was proposed. In this method, the string is identified by searching a sequence of segment patterns matching the string in a lexicon.

- Entity recognition: this involves extracting names of places, people, organisations and products from the text. As an application, [26] proposed an NLP pipeline from part-of-speech tagging, through chunking, to named entity recognition of Twitter.
- Sentiment analysis: This technique is used to determine people's feelings and attitudes towards a product or service. It is useful for providing feedback on how a product or service has been perceived. Companies in all sectors are analysing their social network data streams to better understand their customers' opinions. The main challenge is to extract reliable textual reviews from consumers and use them automatically to evaluate the best products or brands. [20] proposed a framework to automatically analyse reviews. Sentiment analysis was used to analyse online reviews on Amazon. Similarly, in the work of Kumar and Sebastian (2012), a hybrid method is proposed, which uses corpus-based and dictionary-based algorithms to define the semantic orientation of opinion words in tweets. In [3], a new method of approaching sentiment classification is proposed based on Twitter data.
- Search engine: Making extensive use of natural language processing for a variety of tasks, such as query understanding, query expansion, question answering, information retrieval, ranking and clustering of results. For example, in [1], a search engine specific to scientific research is proposed, which first collects the information disseminated on the web in the sites of academic institutions and in the personal homepages of researchers. Then, after intensive text processing, it summarises the information in an enriched and user-friendly presentation oriented towards non-expert users. A question answering system has been proposed by [23], which consists of automatically answering a question posed by a human in natural language using a pre-structured database or a collection of natural language documents.
- Electronic messaging: Email platforms use natural language processing to provide a series of features, such as spam classification, inbox priority, auto-completion. As an example for spam classification, [18] proposed a comprehensive spam classification system based on semantic text classification using NLP and URL-based filtering. Similarly, [12] compared various ML algorithms and a convolutional neural network was studied with the objective of creating a powerful and efficient model for correctly classifying emails.

The above use cases are just a sample. NLP is increasingly used in several other applications, and new applications of NLP

are emerging very rapidly. For instance, program synthesis is an ambitious and new field that consists in generating a source code (programming code) from a natural description. The author in [6] proposed an RNN with LSTM cells that generates java source code from a description expressed in natural language.

Several factors make the process of processing text data difficult. The existence of several languages, each of them having different rules [10] is an example of this difficulty. To illustrate, words can be ambiguous and their meaning may depend on their context. A word can also express an action, a feeling, a name or something very different. As textual data belong to the family of unstructured data, it is necessary to go through a set of data preparation operations to make them useful and usable. Despite these difficulties, natural language processing is able to perform complicated tasks in an adequate way and to bring added value in many domains. For example, sentiment analysis can be performed on customer reviews, which can identify potential problems and anomalies with a certain product or service and improve it. In the following, a robust pipeline is used to clean up the textual data and make it ready for use by the various AI models. Postal services have been considered as an application. A pipeline is proposed for data preparation, ranging from data processing and cleaning to digital representation of textual data.

III. DATASET, EXPLORATORY DATA ANALYSIS AND PIPELINE

One of the most important applications where customer service needs to be improved is the postal service. Thus, our goal is to project this application to improve this service.

A. The Dataset

The first step in the development process of any NLP classification system is to collect data relevant to the proposed problem. An initial idea that may arise is to use structured datasets found on sites such as kaggle, but the problem with this approach is that these datasets deal with topics that are not relevant to the business knowledge related to the services offered by the Post. This will result in poor performance for our model. Therefore, we will need to think about retrieving a meaningful and real training dataset for the Post. One way to build a meaningful dataset is to collect reviews from organizations that operate in very similar, if not identical, domains to the Post using a scrapping method. The idea of choosing several organizations instead of one is on the one hand to have a large volume of data and on the other hand, because very often an organization tends to have mainly positive opinions and at the same time some negative opinions (having diffuse opinions).

In order to build the most accurate and robust model possible, it is necessary to have a fairly generalized set of data and to touch as much as possible all categories of reviews. To do so, several datasets from different countries (United States Postal Service, Canada Post and French Post) have been collected. Fig. 1 shows the percentage of observations of the data with a score ranging from 1 to 5 (note that we collect and scrap the data in open source).

Fig. 1. The Percentage of Observations with a Score Ranging from 1 to 5.

Due to the fact that Post France notices are in French. The Google API was used to translate the data observations to obtain standardized observations in one language, English.

B. Exploratory Data Analysis

The idea behind this part (topology of text data observations) is to get an idea of how the data was constructed and if there is some pattern in the way reviews are written by customers, i.e. words used by customers, length of comments, etc. This will help us choose the Hyper-parameters for the Machine Learning / Deep Learning models. We start by visualizing the length distribution of the data observations in Fig. 2. To do this, we can calculate the length of each review and then visualize them using a histogram (Fig. 3).

Fig. 2. Histogram of the Length of Characters per Observations.

We can say that most comments are between 180 and 219 characters long, and as the number of characters' increases, these comments become rarer. On average, a comment contains about 176 characters with a median of 190.

We can see that most of the customer reviews are about 30 to 39 words long, with an average of 32 words per review and a median of 34 and a maximum of 151 words.

This will allow us to have a first interaction with the textual data we have in order to extract indications and a first general

Fig. 3. Histogram Representing the Number of Words per Observation.

view of the available data.

C. Data Preparation Pipeline

At this point, the goal is to clean the data to make it more usable. This task consists of a series of steps to process, clean and normalize the textual data into a form that contains much less noise. The general idea is to remove unnecessary elements that may interfere with decision making or handicap the learning process.

The structure of our data preparation pipeline consists of six modules: data cleaning, tokenization, data normalization, stemming and lemmatization, token categorization and finally data representation.

1) *Data Cleaning*: Regular expressions allow us to create string patterns and use them to find or substitute specific strings in textual data. Python offers a rich module named "re" for creating and using regular expressions [15].

The idea behind this step is to remove characters and symbols that are usually non-alphanumeric characters, which add extra noise to text data. Regular expressions are used to detect non-alphanumeric characters and remove them afterwards.

2) *Tokenization*: Tokenization is the process of dividing a text into "tokens", a token being a significant unit of text, very often a word, that we wish to use to perform an analysis. This step is essential in any natural language processing project, especially with ML models. The importance of this task will become even more apparent when representing textual data in digital format.

We performed two types of tokenization: a) Sentence tokenization is the process of breaking up textual data into sentences. A user review may or may not contain several touching sentences about the same topic, the idea is to try to structure the observation into meaningful sentences. In order to perform tokenization, we will use the *nlk* library using the *nlk.sent_tokenize()* function, which has been pre-trained and gives impressive results. b) Word tokenization is the process of breaking a sentence down into its component parts. A sentence is a collection of words, and with tokenization, we basically break the sentence down into a list of words.

3) *Data Standardization*: In order to make the NLP system more robust, it is essential to go through this step where we will normalize the data by making all the tokens lowercase or uppercase. We can see the value of this step in case we are

looking for patterns in our data, or we are trying to match a certain word, but the main usefulness of this step is seen in the Feature Engineering step, where we will represent our textual data in a digital format. If this step is omitted during the data cleaning process, we will get a very high dimensional vector representation that will handicap the learning models considerably. We apply this process to all data observations using the *lower()* method.

4) *Stemming and Lemmatization*: Stemming and lemmatization ensure that the different forms a word can take, i.e. plurality, gender, cardinality, tense, etc., are treated as single vector components, which reduces the feature space during digital representation and makes the models more efficient during learning.

Stemming is important in the sense that it helps normalize words to their basic root, which facilitates many applications such as classification or any other ML algorithm. This task is performed via the "SnowballStemmer" where we specify an input language which for our project is obviously English, the stemmer removes suffixes and endings from the words and transforms them to their basic form.

A lemma is the basic form of a word. In other words, it is the form in which the word would appear if it were listed in a dictionary. The result of stemming is not always a correct word, but the lemma of a word will always be present in the dictionary. In the application of lemmatization, an additional step is involved where the formed root is compared to the information provided by the dictionary and if and only if the lemma is present in the dictionary it can be taken into consideration. This makes undoubtedly this step much more complex and computationally demanding. The research proposed in [5] is based on comparing the accuracy performance of document retrieval based on language modeling technology, especially stemming and lemmatization. In addition, a baseline ranking algorithm was used to compare the two technologies.

D. Categorization of Tokens

1) *Part-of-Speech Tagging*: Part-of-speech (POS) is a process that determines the grammatical category of each token in the textual data. It labels nouns, verbs, adjectives, adverbs, interjections, conjunctions, singular nouns, plural nouns, proper nouns, etc. All this is done by models trained on datasets containing tokens and the associated tag. This is a crucial step for many NLP applications because by identifying the POS of a word, one can infer its meaning in context, which is used by many machine learning models to better classify textual data. The same token can sometimes be a noun, a verb or adverb. This is where Part-of-Speech tagging becomes of great importance since it allows us to categorize tokens as precisely as possible based on a statistical approach. To add, we use the POS model of the *Spacy* library to categorize the tokens of textual observations.

The same word can have different interpretations. This is why grammatical structure is important. The NLP *spaCy* library uses models that have been pre-trained to best predict the usage of a word in a data observation. When analyzing customer reviews, we want to know what actions customers have performed or undergone in order to get to know them

better and this is where POS tagging comes in, allowing us to easily retrieve all actions performed by the customer.

2) *Named Entity Recognition*: When examining textual data observations, we tend to first identify the key actors in the observation, such as people, places, and organizations. This classification helps us break up data observations into entities and make sense of the semantics of the data observation. The Named Entity Recognition (NER) mimics the same behavior and is used to classify entities (tokens).

Named Entity Recognition (NER) is a process that detects names in textual data, as well as dates, monetary amounts and other types of entities. NER tools often focus on three types of categories: Person, Organization, and Location, drawing on models that have been pre-trained. The Named Entity Recognition process consists of two sub-tasks: entity detection (the token) and entity type determination based on statistical methods, very often supervised models. NER models rely on several parameters, one of which is the POS (part-of-speech-tagging) of the token. It is at this point that we can see a clear relationship between the POS and NER process.

E. Data Representation

Feature engineering is an important step for any machine learning problem. No matter how good the learning algorithm used, if we introduce bad features, we will get bad results.

At this point, we only have cleaned textual data, but we cannot feed it to a machine learning model. Therefore, it is essential to find a way to represent this data so that we can process it with a given model. In other words, we need to transform our textual data into digital form so that it can be passed to ML algorithms.

In this task, the objective was to work on different methods of representing text as vectors in order to choose the best one for our learning models. Several data representations have been used in the field of data science, such as Bag-of-Words [28], TF-IDF [2], Word Embeddings [4] and Word2vec [11]. We chose to use TF-IDF because of its compatibility with this problem.

TF-IDF aims to quantify the importance of a given word relative to other words for each observation in our dataset. The problem with the bag-of-words is that, since the feature vectors are based on the frequency of tokens, some terms may appear frequently in all observations in our dataset and tend to mask the importance of other words in the feature set. In particular, words that do not appear as frequently, but may be more interesting and important as characteristics. A simple way to think about the TF-IDF process is as follows: if a word m appears many times in an observation, but does not appear much in the rest of the observations in the dataset, then word m should have high importance for the observation in question. The importance of m should increase in proportion to its frequency in the observation in question, but at the same time its importance should decrease in proportion to the frequency of the word in the other observations.

Mathematically, TF-IDF is the product of two metrics. TF measures the frequency of occurrence of a word in an observation. Since different observations in the dataset may be of different lengths, a term may appear more often in a

long observation than in a short observation. To normalize this, we divide the number of occurrences by the length of the observation. The IDF measures the importance of a word in the entire dataset. We calculate it by dividing the total number of observations in our dataset by the number of observations containing the term. We do this for each term and then apply a logarithmic scale to the result.

The TF-IDF score is a product of these two metrics. Thus, the TF-IDF score = TF * IDF. And can be represented as follows:

$$W_{i,j} = tf_{i,j} \times \text{Log}\left(\frac{N}{df_i}\right)$$

We apply this same model to our dataset and this numerical representation will be used several times over the prediction models.

IV. CONSTRUCTION OF A REVIEW SCORE PREDICTION MODEL

At this stage, we explored our data, and were interested in the syntax, structure and semantics of the observations in our dataset. We also cleaned our data; then the data was represented in a digital format using the TF-IDF algorithm. The next step is to build models that allow us to take advantage of all the steps seen in the previous tasks. In this step, the task was to create a model that predicts customer ratings with the highest possible accuracy. To do this, a first approach was to understand the objective and how to go about it. The problem addressed, which is the prediction of the star score of reviews, is a classification task that consists of classifying reviews into five categories ranging from a score of one to five based on the specific properties or attributes of each review. The classification of textual data is one of the most complex tasks in automatic natural language processing due to the many factors involved, namely the quality of the data cleaning, the algorithm used to represent the textual data, the quality of the data used to train the model, the prediction model used and its parameters, etc. As we can see, there are many factors and variables and the objective is to optimize each of these factors to obtain the best possible result.

What customers think is important information, it is very valuable knowledge for the organization concerned in the sense that it gives a very clear idea of the quality of a certain product or service and how the public perceives it. While some platforms allow users to give a star rating, most social networks do not offer this possibility of rating on a scale of one to five stars. The objective of this task will be to create a machine learning model that will be able to rank our data observations by assigning a star rating from 1 to 5 (Very Satisfied, Satisfied, Average, Dissatisfied, and Very Dissatisfied).

Once we have a numerical representation of our training dataset, we need to use classification algorithms, which are nothing more than supervised learning algorithms used to classify data observations into different categories. The goal at this point is to train classification models on our training dataset. The classification algorithm will identify patterns based on the characteristics of our training data observations and their corresponding labels, and the result of this identification will constitute our score prediction model. The models are expected to be generalized enough to predict classes for new

data observations (without labels). Thus, having a generalized dataset is essential, as has already been pointed out.

Several learning algorithms were used for this task: SVM, KNN, Decision tree, Random forests and Logistic regression.

The model evaluation is an estimate that can be used to indicate how well you think the algorithm can actually perform. It is not a guarantee of performance since we are talking about a statistical estimate. Once we have estimated the performance of our algorithm, we can re-train the final algorithm on the training data set and prepare it for operational use. The performance of classification models is based on their ability to predict the outcome of new observations. This performance is measured against a test data set, which consists of observations that were not used to train the model. This textual dataset is a real post observation set that represents a real subset (which will be the test dataset of our model). This test dataset contains observations and their corresponding labels. The digital representation of the test dataset is fed into the already trained model and predictions are obtained for each observation. These predictions are then compared to the actual labels to determine the quality or accuracy of the model prediction.

In the result section we will detail the percentage of success of each model. Based on these results, we can observe that most of the models have a good performance, the multinomial logistic regression having the best performance and, on the other hand, the decision tree having the worst predictions.

V. CONSTRUCTION OF A SENTIMENT ANALYSIS MODEL

Sentiment analysis is one of the most active research areas in natural language processing. Sentiment analysis is a field of study that analyzes people's opinions, feelings, evaluations, attitudes and emotions through natural language.

The aim of sentiment analysis is to define a system that can extract subjective information (such as opinions and feelings) from natural language to create structured knowledge that can be used by decision support systems or decision makers. Nowadays, with the advent of social networks, sentiment analysis has gained in value. Their wide diffusion and their role in modern society represent one of the most interesting developments in recent years, attracting the interest of organizations and companies. Not so long ago, sentiment analysis was almost non-existent. Opinions were collected through surveys rather than through observation of textual data because computers were not capable of storing and processing large amounts of data, and there were no algorithms for extracting knowledge from written language.

The explosion of sentiment-laden content on the Internet, the increase in computational power, and advances in data mining techniques have made sentiment analysis a burgeoning research area and a crucial business sector. In this classification, we have implemented a recurrent neural network (RNN) with LSTM cells, where we will apply it on a digital representation of the data represented by One Hot Encoding [9], in order to classify the observations of the Post's customers into Very Satisfied, Satisfied, Average, Dissatisfied, and Very Dissatisfied opinions.

Recurrent neural networks are more effective than traditional neural networks and machine learning algorithms at retaining information from the previous event. The recurrent neural network involves a combination of loop networks. The loop network allows the information to persist. Each network in the loop takes the input and information from the previous network, performs the specified operation and produces an output, and at the same time passes the information to the next network. Some applications only need the most recent information, while other applications may need more information from the past, such as NLP (the meaning of related words). As the gap between the required prior information and the point of application has increased to a large extent, the learning of simple RNN lags behind. But fortunately, long-term memory networks [14], a special form of RNN, can learn such scenarios.

Long-term memory (LSTM) is an alternative architecture proposed in [14]: the traditional architecture of a Recurrent Neural Network (RNN) that is based on a simple activation function is modified in such a way that the vanishing gradient problem is explicitly avoided, while the learning method remains unchangeable. For more information on this architecture [6], [7]. But what are the strengths of LSTM? why the LSTM will be effective to solve the steel continuous casting problem?

A LSTM neuron network is made up of several cell that have not just one activation function but rather three that are represented as an input gate, a forget gate and an output gate. Each cell remembers the state of the problem treat in several time intervals, and the three gates regulate the flow of information in and out of the cell. The LSTM network is very suitable for classification, processing and prediction based on time series data, because there may be lags of unknown duration between important events in the time series. This is what is needed to understand a series of words in a sentence. Also as we explained, LSTM was developed to deal with the explosion and disappearance of gradients that may be encountered when training traditional RNNs.

A. The Proposed LSTM Architecture and Hyperparameter

To define a neural network, it is necessary to establish parameters, such as training data, type of neural network, number of layers, connections, activation functions, propagation rules, etc.

There are several ways to train a neural network to produce a specific output for a specific input. In the current training method (Forward / Backward Propagation), we have error propagation, which involves adjusting the network based on each neuron's contribution to the error, and each neuron adapts the weights by using the gradient of descent. Genetic algorithms are also used to train neural networks [22]. By training these networks on a dataset with known correct outputs, the network will be able to return an approximate result for new data (not seen in the training stage). We trained our LSTM with data from 50,000 use cases (customer observations).

Regarding the architecture, there are several architectures proposed in the neural network language model with some differences between them. The proposed architecture for our application area consists of some basic principles, such as:

The input of our LSTM (the input sequence) is represented by a sentence, it is coded by the code from 1 to K, where K is the length of the client's observation. This involves the use of One Hot Encoding [9] to list individual words. The sequences are generated in 128 batches with 5% diversity (with the goal of avoiding overfitting).

The network topology is represented as follows: An input layer that takes as input the digital representation of the data observations. Five hidden layers have been implemented, each with 256 LSTM units, and each uses the "relu" activation function. For the five hidden layers, a normalization step is added via the Batch Normalization technique, which improves the performance and stability of neural networks. The main idea is to normalize the inputs to each layer so that they have an average output activation of zero and a standard deviation of 1. The regularization is used in the network in the form of an exclusion layer. This form of regularization prevents overfitting of the model. The output layer is composed of five neurons, as we want to perform a five-class classification with a "softmax" activation function that will be used to represent a probability distribution to predict customer sentiment. As shown, the neural network trains by adjusting the weights by comparing the results predicted by the neural network and the actual label of the observations in the dataset.

Now that we have built the model, we will have to train it on the digital representation of the training data. To do so, we will have to define a cost function which measures the difference between the results predicted by our model and the real results. As this is a classification case, we tested several functions but the experimental results show that the categorical function "cross-entropy" is the best for this application domain. So we have a neural network, a cost function to be minimized. To minimize the cost function, we used the gradient descent algorithm and exactly the Adam optimizer which is an optimization algorithm to minimize convex functions. As a learning standard, the used precision of the Adam optimizer is 0.001.

Finally, we define precision as an evaluation metric for our neural network. The following algorithm summarizes the main steps:

VI. EXPERIMENTAL TESTS

In order to evaluate the performance of our models for the two treated part, this part puts forward the performance of the models taking into account the quality of the solution. Note that all the experiments were performed on the google colab under GPU.

A. Assessment of Classification Models

The evaluation metrics used for classifying textual data (observations of data with a star score ranging from 1 to 5) are generally as follows:

Accuracy: is the sum of true negatives and true positives divided by the total number of observations.

$$Accuracy = \frac{TN + TP}{TN + TP + FN + FP}$$

Algorithm 1 : The Proposed LSTM for Better Customer Relationship Management.

- Data preparation pipeline (see section 3).
 - Creation of the LSTM architecture : Creating eight layers, one input layer, five hidden layers each with 256 LSTM units, dropout layer for regularization and final output layer consists of five neurons and "softmax" activation function is used to predict the customer feelings (Very Satisfied, Satisfied, Fair, Dissatisfied and Very Dissatisfied).
 - According to the unified law, the weights are initialized randomly.
 - Codage : list all customer's observations. The One Hot Encoding is used to represent each observation and coded it.
 - The categorical "cross-entropy" is used as cost function.
- while** index \leq Max_iter **do**
1. Five percent of diversity is generated in each batch.
 2. Measuring the difference between the results predicted by our model and the actual results, using cost function.
 3. Adam optimizers is used with a precision of 0,001 in order to minimize the cost function.
 4. Update the weights.
- end while**

Where TN = True Negatives, TP = True Positives, FN = False Negatives and FP = False Positives.

Precision: is the number of real positives on the set of positive cases predicted by the model.

$$Precision = \frac{TP}{TP + FP}$$

Recall: allows the performance of the model to be evaluated from the point of view of the positive class. It indicates the percentage of actual positive cases that the model is able to predict correctly out of the total number of positive cases.

$$Recall = \frac{TP}{TP + FN}$$

F1 Score: a combination of "Precision" and "recall".

we can observe that most of the models have a good performance (a cause of the proposed data processing pipeline), the multinomial logistic regression having the best performance and the decision tree having the worst performance (Table I).

TABLE I. METRICS ASSOCIATED WITH THE APPLICATION OF MODELS ON THE DATA REPRESENTED BY TF-IDF.

Algorithms	Accuracy	Precision	Recall	F1 Score
Random Forst	0.8487	0.7203	0.8487	0.7792
Decision Tree	0.6513	0.7971	0.6513	0.7792
Multinomial Logistic Regression	0.8553	0.8017	0.8553	0.8257
SVM	0.8289	0.7952	0.8289	0.8079

Learning models are parameterized so that their behavior can be tailored to a given problem. Models can have many parameters, and finding the best combination of parameters

can be treated as a search problem. To treat a search problem, we can use different search strategies to find a parameter or a robust set of parameters for an algorithm on a given problem, namely grid search.

Grid search is a parameter tuning approach that allows you to systematically build and evaluate a model for each combination of specified algorithm parameters. To perform Grid Search tuning to find the best parameters, we use the *GridSearchCV* class, but it is important to remember that this task consumes a lot of computing resources and takes a long time to return results.

We specify a few parameters for our model to experiment with, we can choose any values that make sense and the grid search model will return the best set of parameters.

Once our parameters are ready, all we have to do is initialize a gridsearch object and use it. To do this, we execute the parameters we have prepared and also specify the model and the metric that will be used to choose the best model. Once the gridsearch model is ready, we apply it to our data. We repeat this same step for the rest of the models and visualize the results as shown in Fig. 4. We can see that the multinomial logistic regression has the best performance.

Fig. 4. Diagram of the Accuracy Metric of the Models after Applying the Gridsearch.

B. LSTM Network Assessment

To evaluate the RNN model with LSTM cells, we divided our data set (50,000 observations) into two sets, one for training and one for validation, and used cross-validation for training.

1) *The Learning and Validation of LSTM Model:* The learning rate gives an idea on the improvement of the quality of learning on a model. In Fig. 5, we present a graph that represents the learning rate (96%) and the validation rate (89%) of the proposed LSTM.

As can be seen from the model validation accuracy visualization, our RNN model with LSTM cells performed well and the fact that there is not a large discrepancy between the learning accuracy and the validation accuracy allows us to conclude that we do not have an overfitting (Fig. 6). We have also to mention that the learning rate (96%) and the validation rate (89%).

By comparing the accuracy parameters of LSTM with those of machine learning models, we can conclude that the learning rate is higher for LSTM, which will lead to good

Fig. 5. Development of the Training and Validation Score per Epoch.

Fig. 6. Convergence of the Cost Function per Epoch

results. To test our model, we tested it with new and real data (not used in training). For this, we retrieved 1000 new observations (customer reviews with different classes) and compared the predictions with customer satisfaction (target provided by customers). The following confusion matrix (Fig. 7) shows the results of the test where the accuracy mitrics is equal to 94%.

Fig. 7. The Confusion Matrix of the Test Set.

VII. CONCLUSION

In this paper, we have implemented many tasks to propose a data preparation pipeline ranging from data processing and cleaning to digital representation of textual data. We also performed Feature Engineering by digitally representing the text data using different algorithms.

The training data was collected from several companies operating in the same field as the position and the data set had to be balanced as much as possible, which was a challenge. Once the training database was formed, different models were prepared (SVM, KNN, decision tree, random forests, and logistic regression), in order to find the most effective model to rank the observations in our data by assigning them a star score ranging from one to five. After developing the score prediction model, we turned to developing a sentiment analysis model using RNN with LSTM. The performance of the proposed LSTM is very interesting such that the success percentage is 96%.

One of the future works we plan to develop is to generalize the approach on a GPU's cluster platform in order to process more complex documents and not only sentences.

ACKNOWLEDGMENT

The author would like to thank the Editor-in-chief and anonymous reviewers for their comments and suggestions to improve the quality of the paper.

Abstract—A removal nasogastric (NG) tube of a patient is a critical problem especially the patients resist swallowing. To solve this problem, the conventional approach using a personal caretaker is a time-consuming and intense focus on the patient's hands. However, visual technology can decrease the intense focus of a personal caretaker by using image processing to evaluate the patient's gesture and warn the personal caretaker when the patient acts in a risky pose. This work illustrates the feasible solution to prevent a patient with nasogastric tube feeding on removing tube by applied the face detection using Haar and Fiducial markers which consist of color marker and ArUco marker. An image processing can evaluate the patient's gesture and warn the personal caretaker when the subject acts the risky pose. A Raspberry Pi 3 Model B and a Camera module with Python and Open CV package are applied to detect and evaluate the warning gestures with 648 measurements. Six detection methods to evaluate and warn when the patient on bed tries to remove a nasal feeding tube were performed and the results were analyzed. The results show that the detection method using ArUco marker is found to be a good candidate for the alarm system preventing nasogastric (NG) tube removal of a patient.

Keywords—NG tube; image processing; fiducial markers; face detection; Aruco

I. INTRODUCTION

The insertion of nasogastric (NG) tube feeding into the gastrointestinal tract (GI) is very irritating, high risk and it heavily damages the GI tract if the patients resist to swallow [1], [2], [3], [4], [5]. It is typical in the patients with dementia to resist and remove the NG tube. Therefore, a common approach to prevent the NG tube removal by the patients is to tie their hands with the bed or wear hand mittens [6], [7], [8], [9]. The mentioned methods leave many problems like bruises on the patient's wrists, wounds on the patient's finger and palms, or ankylose. The preferred interventions to prevent tube removal or dislodgement are taping the NG tube to the face, application of hand mittens and insertion of nasal loop systems (bridle) [10], [11], [12]. Unfortunately, these are the best practices for keeping NG tube in place. At present these interventions are controversial among patient and relative feeling because of the GI damage, hand restrain, skin exacerbation, diminishing autonomy and justice [13].

According to the FOOD Trials, a family of three multi-centre international randomized controlled trials to address feeding issues for acute stroke patients, the results indicate that stroke patients frequently pulled out their tubes up to 18

times per a patient [14], [15]. The tube removal interrupts their nutrition, hydration or medication. Moreover, dislodging the tube may result in feed fluid entering respiratory tract and causing respiratory tract infections [16]. A long-term study on the accidental removal of endotracheal and nasogastric tubes shows that the patients accidentally remove tubes 13.1 and 41.0 times per 1000 days, respectively [17]. In the aspect of patient numbers, the accidental removal rates are 38 patients out of 289 endotracheal patients and 151 patients out of 368 NG patients. There are many factors involving the incidental removal rate such as age, intervention methods, tube placement position and consciousness level of patients [18]. According to the review, the most used and taught securing technique is using adhesive tape because of its feasibility, convenience and fairly comfortable for the patients. The biggest drawback is the high risk of tube dislodgement or removal and correlates to complications [19]. It is obvious that there is no health system assisting endotracheal or NG patients over conventional interventions.

Recently, Internet of Things (IoT) has been deployed widely in medication, rehabilitation, and intensive caring. There are many applications for autonomous patient monitoring using image processing to evaluate patient status such as postures, facial action units and expressions, head pose variation, and extremity movements [20]. The detection relies mainly on object recognition, objection position and ambient evaluation using sensors. Another example on vision assisted healthcare system is fall detection. There are many techniques used for fall detection like multi-camera systems, monocular systems, infrared and range sensor based systems, and bio-inspired vision sensor based systems [21], [22], [23], [24]. For the monocular camera systems, the camera is mounted on the ceiling or the wall. The 3D space ellipsoid is projected into 2D image plane and the object is tracked with markers [25], [26]. The camera calibration and inverse perspective mapping are performed for the area of interest. Adopting the vision technology, the risky pose can be detected to warn the personal caretaker.

In order to evaluate the risky pose of the subjects, there are many available technologies such as gesture recognition [27], Bluetooth sensors [28], RFID sensors [29], gyroscope [30], [31], face detection [32], [33], [34], and fiducial markers [35], [36]. Each technology has advantages and drawbacks depending on the application. The gesture recognition uses a stereo camera to collect 3D images. Its accuracy and sensitivity are

very high as well as the cost and calculation power. Moreover, the device size is relatively large compared to the patient. Therefore, the installation requires huge space. The Bluetooth and RFID sensors work on calculating the distance between two sensors on the patient's body. They are fast, sensitive and accurate but the sensors carry a certain area and load, approximately 10 cm^2 and 50 g. Both sensor size and weight mostly rely on the battery. In contrast, the gyroscope gives the exact 3D position of the patient. A gyroscope sensor works on the principle of conservation of angular momentum. It works by preserving the angular momentum. Therefore, the position resolution depends on the change in angular momentum and the calibration. In contrast, the image processing method works on an acquired image and algorithms to evaluate the patient's pose. However, the image is sensitive to light condition, image resolution, perspective and background colors. It provides fast, portable and cheap solution.

A face detection using Haar cascades was proposed by Paul Viola and Michael Jones [32], [33]. It is a machine learning based approach where a cascade function is trained from a lot of positive and negative images. It is then used to detect objects in other images. The algorithm needs a lot of positive images (images of faces) and negative images (images without faces) to train the classifier. The image then tested with the trained classifier to give the result. This method requires the full subject face including two eyes, one nose and one mouth. Moreover, it is sensitive the subject face angle to the camera.

Using fiducial markers are an alternative approach to detect the patient's pose. The markers are small and light. They can be attached on the subject face and hands. The color on images can be easily detected and evaluated. The process is to set a certain range of selected color and transform the rest into black. Unfortunately, the detection of color heavily depends on light condition and the background color. Recently, Sergio Garrido and Rafael Muñoz proposed a set of marker library called ArUco to estimate the pose [35], [37], [38]. An ArUco marker is a synthetic square marker composed of black border and inner white binary matrix which determines its identifier (id). The ArUco marker is a fiducial marker designed for pose estimation in many vision applications such as robot navigation and Augmented Reality (AR). Therefore, it is very insensitive to light, image resolution, background noise, nor perspective distortion in 2D or 3D spaces [35], [36].

This work aims to propose an alarm system preventing a patient on bed try to remove a nasogastric (NG) tube which this system can be processed and executed on a small device. This system evaluates the patient's gesture and warns the personal caretaker when the subject acts the risky pose by using visual technology. Therefore a face detection and markers technique was considered in the experiment on Raspberry Pi 3 with a camera module. The contribution of this paper is as follows:

- To detect and evaluate the risky pose of the subjects using visual technology.
- To compare and evaluate detection methods using visual technology.
- To demonstrate an alarm system preventing nasogastric (NG) tube removal of a patient.

II. METHODOLOGY

The subject is equipped with markers to estimate the warning gestures of the subject. The warning gestures are defined as the distance between two markers or the subject's face detection. For the warning using distance, the alert creates when the distance between two nearest markers are less than or equal to the setting value. For the warning using face detection, the alarm creates when the camera cannot detect the subject's face in the frame. Using both warning gestures and different marker types, there are six approaches used to evaluate the warning gestures as follows:

- a) Two ArUco markers (ArucoX2): This method uses ArUco markers to find the distance between two nearest marker centers. One marker is placed on the subject's face and another one is placed on the subject's hand.
- b) Two colors markers (ColorX2): This method uses red and blue markers to find the distance between two nearest marker centers. A blue marker is placed on the subject's face and a red marker is placed on the subject's hand.
- c) Face detection (FaceOnOff): This method identifies the subject's face in the frame by using Viola-Jones framework with Haar features.
- d) An ArUco marker and face detection (FaceAruco): This method finds the distance between the center of the face and a nearest ArUco marker. The ArUco marker is placed on the subject's hand.
- e) A color and an ArUco marker (ColorAruco): This method finds the distance between a selected red marker center and the nearest ArUco marker center. The ArUco marker is placed on the subject's face and the red marker is placed on the subject's hand.
- f) A face detection and a color marker (FaceColor): This method finds the distance between a detected face center and the nearest red center. The color marker is placed on the subject's hand.

The proposed system aims to invent a small device to alarm the risky pose of a patient in the next phase of this research, therefore this work choose a Raspberry Pi with a camera module. A Raspberry Pi 3 Model B and a camera module V2 with Python and OpenCV package are applied to detect and evaluate the warning gestures. In order to find the best detection methods many test conditions are performed and scoring are given to compare the six methods. A list of test conditions is given in Table I.

Five test conditions are selected to represent the performance close to the real environment as follows:

- (i) The subject face angle with respect to the camera is performed to find the limit when the patient turns around. This measurement also represents the perspective distortion on the markers.
- (ii) The subject to camera distance represents many effects such as the perspective distortion, marker size, image resolution and the background disturbance.
- (iii) The marker size is performed to find the optimum marker size. Both ArUco and color markers are prepared as squares on white paper as shown in Fig. 1.
- (iv) The light intensity also affects the detected images mainly on the color properties like shade, tone, saturation and

TABLE I. TEST CONDITIONS FOR THE WARNING GESTURE DETECTION

Condition	Value		
(i) Subject face angle	0°	45°	90°
(ii) Subject to camera distance	30cm	50cm	100cm
(iii) Marker size	1cm ²	9cm ²	25cm ²
(iv) Light intensity	Low intensity	High intensity	
(v) Background color	Monocolor	Multicolor	

hue. Low intensity means the light in a patient's room is off, while high intensity means the light is on.

- (v) The background color on the image usually disturbs the color marker method and sometime misleads the face detection or ArUco marker detection. Therefore, the multicolor background color can provoke the disturbance.

This experiment consists of five test conditions and six approaches, thereby there are 108 measurements times six methods, 648 measurements in total.

During the test, a subject lies on a patient's bed with a camera hung above the patient's head. There are three different face angles in our experiment as shown in Fig. 2. The subject starts with the normal gesture, both hands lie parallel to the body in order to verify the false-positive results. Then, one hand is moved close to the face for the warning gesture. The markers are attached to the subject using a transparent tape. For the monocolor background, bed sheets of green and yellow are used while the multicolor background has at least 7 colors on the bed sheets and subject's clothes. The colors of markers are red and blue. The distance between the camera and subject is measured from the subject's forehead to the camera's lens. During the warning pose, if the method detects the warning, the score of 1 is registered to the performance. Otherwise, the score of 0 is registered.

According to the mentioned before test conditions, four attributes can be extracted from the performances of each method naming speed, accuracy, resolution and tolerance and reliability. A scoring system is used quantified each method. A value of 1 is given for the successful detection and 0 for fail detection. In this study, we neglect the false positive or false-negative results. There are four attributes to measure the performance as follows:

- The speed is acquired from the Frame Per Second.
- The accuracy is calculated from a summation of all test conditions (108 measurements). The accuracy shows how good is the method related the others.
- The tolerance and reliability are acquired under the hardest condition when the marker size is kept at 1 cm² (36 measurements). The score comes from the summation under this condition. It shows the robustness of the detection method.
- The resolution is calculated from the summation of test conditions when the subject face angle is kept at 0° (36 measurements). This attribute compares the effects of image resolution on each method.

The performance representation of each attribute is shown as percentage of the observables over total success cases.

III. RESULT AND DISCUSSION

A set of python codes is implemented on Raspberry Pi 3 to detect the warning gestures under several conditions. The results are recorded and analyzed according to the four attributions to estimate the best method of detection. The experiment was conducted in a patient's room which has two windows near the patient's bed. The performance representation of each attribute is shown as percentage of the observables over total success cases is shown in Table II.

All methods show no difference in the aspect of speed. The average frame per second is 2. The two colors method (ColorX2) is supposed to be the fastest method because it demands the smallest calculation time than others. Surprisingly, the results show no significant difference. The explanation lies in the Raspberry Pi 3 and the camera limits. Moreover, the two colors method (ColorX2) is very sensitive to marker size, subject to camera distance, light intensity, perspective distortion, background noise and subject's face angle which give the lowest score [39], [40]. In general, it is the worst method of detection. The performance of all methods is represented using a radar plot as shown in Fig. 3.

According to the Fig. 3, the overall best performance is assigned to the Face detection method (FaceOnOff). This method has the highest resolution regardless of the image resolution and the highest tolerance to the light intensity and background noise. On the contrary, this method requires the full subject's face including two eyes, one nose and one mouth. Therefore, it is insensitive to the subject's face angle and perspective distortion. These two effects reflect through the relatively low accuracy.

The second place in term of overall performance is the two ArUco markers method (ArucoX2). Though the markers suffer from the image resolution. The image resolution limit is still good, meaning 1cm² markers can be detected only when the distance is 30cm, not detected at the longer distances. In addition, the ArUco markers are very robust to the light intensity, perspective distortion, background noise and subject's face angle which give the highest accuracy.

Another group of detection method is the combination of color markers, ArUco markers and face detection (ColorAruco, FaceAruco, FaceColor). These three methods show relatively similar performances. Unfortunately, the combination does not give the better result than the original because they do not overcome the intrinsic problems on each detection method. They only join those drawbacks and lower the detection performances.

Six detection methods to evaluate and warn when the patient on bed try to remove a nasal feeding tube were

Fig. 1. Three Types of Markers.

Fig. 2. Subject Poses at different Face Angles.

performed and the results were analyzed. The detection method using ArUco markers is found to be a good candidate. This method is robust to any practical disturbances on site and gives good reliability. Only drawback is the minimum marker size. It

is related to the image resolution. Hence, increasing the image resolution can solve this problem by changing the camera or reduce the subject to camera distance. A summary of pros and cons for each method is placed in Table III.

TABLE II. A PERFORMANCE SUMMARY FOR EACH DETECTION METHOD

Method	Performance in Percentage			
	Speed	Accuracy	Tolerance and Reliability	Resolution
a) ArUcoX2	100	70	11	78
b) ColorX2	100	0	0	0
c) FaceOnOff	100	33	33	100
d) FaceArUco	100	26	11	78
e) ColorArUco	100	44	3	58
f) FaceColor	100	20	6	61

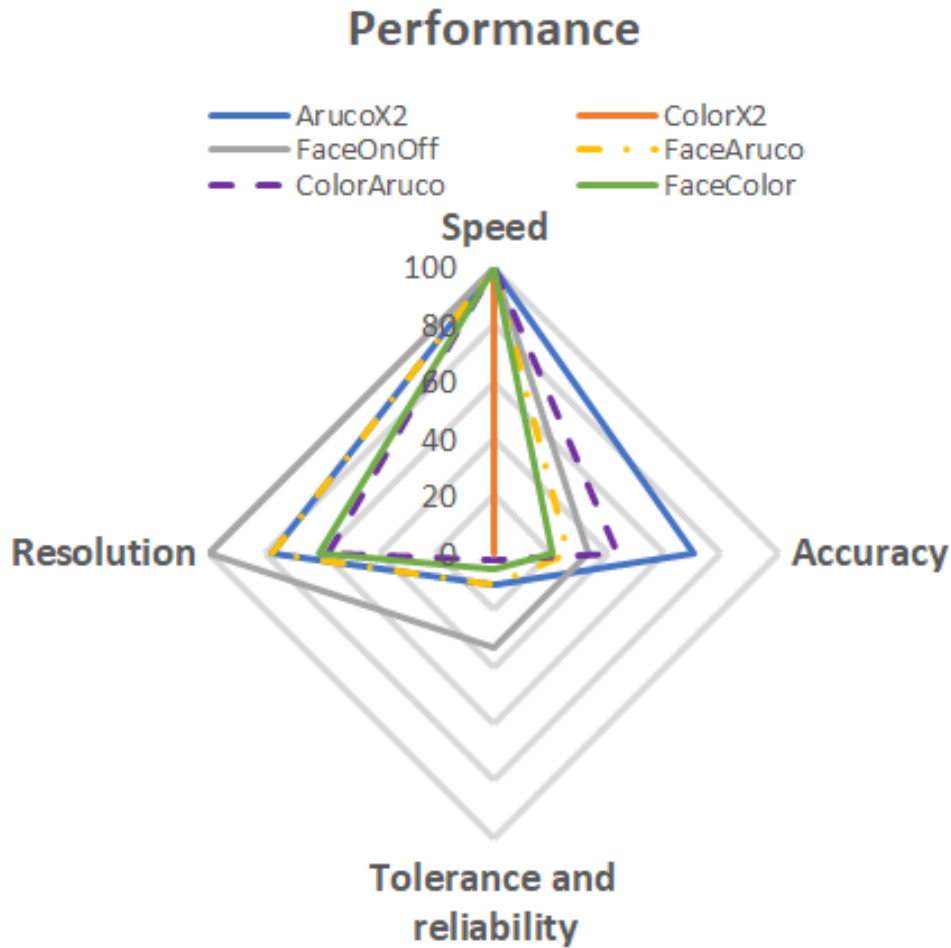

Fig. 3. Performance of Six Detection Methods.

TABLE III. A SUMMARY OF PROS AND CONS FOR EACH METHOD

Method	Pros	Cons
ArUco markers	Robust to any practical disturbances on site	Require good resolution image
Color markers	High detection speed	Sensitive to any practical disturbances on site
Face detection	Independent of image resolution	Critically require full face elements – two eyes, a nose and a mouth

Furthermore, the results also indicate that color markers are the worst method of detection. This is due to the acquired image does not have any color quality correction in order to have the fastest speed as much as possible. An improvement for this is to use image color correction tools to compensate

the light, saturation, tone and hue [41].

IV. CONCLUSION

To prevent a patient on the bed from trying to remove a nasogastric (NG) tube, an alarm system evaluates the patient's

gesture and warns the personal caretaker when the subject acts the risky pose by using visual technology. This system was evaluated a face detection and markers technique on Raspberry Pi 3 with a camera module. This work showed the detection and evaluate the risky pose of the subjects using visual technology, and also showed the comparison and evaluation of detection methods using visual technology. The experiment consists of five test conditions and six approaches, thereby there are 108 measurements times six methods, 648 measurements in total.

The results showed that a color marker method is the fastest method, however, it is very sensitive to marker size, subject to camera distance, light intensity, perspective distortion, background noise, and subject's face angle. A face detection method has the highest resolution regardless of the image resolution and the highest tolerance to the light intensity and background noise. On the contrary, this method requires the full subject's face including two eyes, one nose, and one mouth. An ArUco marker method is very robust to the light intensity, perspective distortion, background noise, and subject's face angle which give the highest accuracy. In contrast, it requires a good resolution image. As a result, The detection method using ArUco marker is found to be a good candidate. This method is robust to any practical disturbances on-site and gives good reliability. The only drawback is the minimum marker size. It is related to image resolution. Therefore, the ArUco marker is appropriate to be used in an alarm system preventing nasogastric (NG) tube removal of a patient.

V. LIMITATIONS AND FUTURE WORK

For the further work, a clinical study is needed to collect data and feedback for the patients with various conditions. In order to implement this work in the clinical study, the correlation between Aruco marker size and the subject to camera distance has to be evaluated. This is the most important factor to determine the warning. These factors can be compensated with high resolution camera. Another crucial issue is the performance under low light and dark conditions. Infrared light source and detectors can handle this issue.

Abstract—Automatic license plate recognition (ALPR) is essential component of security and surveillance. ALPR mainly aims to detect and prevent the crime and fraud activities; it also plays an important role in traffic monitoring. An algorithm is proposed for recognizing license plate candidates. The proposed work aimed to recognize the license plate of a car. Proposed work is designed in multilevel for more accurate License Plate (LP) recognition, At level 1 algorithm produced 93.5% accuracy and in level 3 algorithm gives 96% accuracy. For training and testing purpose, LP images were used from Medialab cars dataset, kaggle car dataset and goggle map images. These images in the dataset is formulated at various angles and illumination. Proposed algorithm for LP recognition is done by using the Block Binary Pixel descriptors (BBPS) and Linear Support Vector Classification (SVC). Proposed algorithm is novel and produces higher accuracy in minimal processing time of an average 0.42 milliseconds with 96% accuracy when compared with state-of-the art methods.

Keywords—BBPS – Block Binary Pixel Sum; ALPR - Automatic License Plate Recognition; ROI - Region of Interest; SVC - Support Vector Classification; LP - License Plate

I. INTRODUCTION

ALPR is a active, popular and interesting topic in image processing [1], development in license plate recognition have received much attention towards English license plate recognition [2]. It also plays an important role in intelligent transport system [3] [4] [5], border control, toll collection, traffic management [6] [7], it is used in information and communication technology [8]. Computer vision plays an major part in extracting ROI from an image [9]; license plate recognition is done by extracting number plate from images [3] where the Region of Interest(ROI) is license plate of an vehicle, the main task is to extract characters from license plate [10], each vehicle number plate carries different font style and size [11].Surveillance camera is fixed everywhere, earlier it is fixed in important places like malls, hospitals and in sensitive places, but now it's fixed everywhere even people prefer to fix surveillance- camera in their places for their safety. Since many algorithms exists for ALPR but still it lags the accuracy due to various factors like images were captured at night time, tilted and blurred images, so there is a need for an efficient algorithm to improve accuracy. Existing algorithms were proposed using various pre-processing steps followed by feature extraction, machine learning and deep learning techniques. Before extracting features from image pre-processing techniques should be applied on image. Preprocessing the input image which includes conversion of input image to a

gray scale image and pre-processing is applied to enhance the details present in the image, in order to highlight the ROI and prune the non-ROI. Then morphological operations like erosion, dilation, tophat, blackhat are applied to enrich input image feature, which supports system proficiency [12]. For recognizing character from image the popular method called optical character recognition with tesseract, an emerging concept is used. ALPR system follows the sequence of steps

- Acquisition of input image
- Localizing license plate
- Segmenting and slicing license plate characters
- Recognizing license plate characters

Since many algorithm exists for ALPR, but it still lags to recognize license plate accurately. So there is a need for an better algorithm to recognize license plate of vehicle accurately even the image captured in uneven lightning, blurred [13]. Proposed work overcomes all those existing disadvantages by recognizing license plate accurately since training of license plate recognition is done by extracting real time license plate images, which tends for more accurate precision. Proposed work is done in multilevel so as to improve the accuracy of proposed algorithm. Many existing algorithm exists for ALPR but its still have many unsolved queries like, it lags to work on images captured at night and dark environment, to recognize license plate of images taken from far distance, to work on skewed and blurred images. It also produces false positive, false negative results for many license plates and existing works fails to predict between characters of similar strokes. So has to solve existing algorithm flaws proposed algorithm is designed in a novel way to overcome all those existing flaws and to recognize license plate accurately from complex backgrounds.

II. RELATED WORK

ALPR plays an important part in border scrutiny, confirming safeguards, and dealing with vehicle-related crime. ALPR system makes use of deep learning techniques using a convolutional neural network (CNN). The CNN assigns significance to numerous features of the image and differentiating them from each other. According to researchers point of view CNN works good for LP character recognition [3]. ALPR received much consideration for the English license plate. ALPR addresses more frightening traffic dealing with scanty road-safety processes. Architecture of ALPR for predicting vehicle LP regions

prior to Vehicle License Plate (VLP) in the ideal is proposed to eliminate false positives causing in higher prediction accuracy of VLP [2]. ALPR plays essential part in current transport organizations such as traffic monitoring and vehicle violation detection. In real-world scenarios, LP recognition faces many contests and is diminished by unrecognized interfering such as weather or lighting conditions. Machine learning based ALPR solutions has been wished-for to resolve such tests in recent years. However, most of the algorithm does not yield convincing results since their consequences are appraised on small or simple datasets that lack varied surrounds, or it require potent hardware to accomplish a practical frames-per-second in real-world solicitations [14]. In ALPR initially, license plate location will be determined. Then, in the second phase, enhancement can be done by applying Gaussian function for filtering. Next, edges in the image located so that LP location can be spotted. Then tilting and plate rotation and affine transformation are applied if the input image was captured in tilted and slanting position or angles. Then by neural network concepts LP characters extracted from LP images [15]. ALPR [16] system plays vital role in Intelligent Transport System (ITS) their major goal was traffic controlling. ALPR for vehicles is a main part of ITS. ALPR send images to a server for LP recognition. To decrease stays and bandwidth usage during images communication, an Edge-AI-based Real-time (ER) ALPR ER-ALPR was proposed, in which an AGX XAVIER entrenched system is embedded on the edge of a camera to attain real-time image input to an AGX edge device and to enable real-time automatic LP candidate recognition. To measure LP characters and styles in a precise setting, the ER-ALPR scheme smears the following methods: (1) image pre-processing (2) You Only Look Once v4-Tiny (YOLOv4-Tiny) [17] for LP prediction; (3) virtual judgment line for determining whether a license plate frame has passed; (4) the proposed modified YOLOv4 (M-YOLOv4) for LP candidate recognition; and (5) a logic ancillary ruling scheme for refining LP recognition. ER-ALPR system was complete in real-life test surroundings in Taiwan. Many state-of-art methodologies exists for recognizing text from various environment, but none of the algorithm recognizes accurately, it lags to differentiate between similar characters, existing algorithm lags to recognize license plate characters from complex environments.

III. THE PROPOSED WORK

The proposed algorithm consists of three levels and each level has different phases

Level 1: Training phase

Input: Load various input font images.

- Initialize the BBPS Descriptor
- Train separately both character and digit classifier using Linear SVC to recognize LP accurately

Output: Dump the character and digit classifier as a file (pickle file).

Testing phase

Input: Load the pickle file (both character and digit classifier) and dataset images.

- Initialize the BBPS Descriptor

Output: Print the license plate text on the image

Level 2: gathering labeled data

This phase is used to train the character and digit classifier for more accurate prediction of LP characters.

Input: Localized license plate images

- Loop over the characters present in each localized LP Images
- Grab each character, create a directory and store it for advanced training

Output: Independent folder created for each character and digits; which is used for advanced training for LP recognition.

Level 3: Advance training phase

Input: Load the sample output generated in level 2 (various segmented image stored in labeled folders)

- Repeat level 1 training phase

Output: Dump the character and digit classifier as a file (advance pickle File). Testing phase

Input: Load the advance pickle file (both character and digit classifier) and dataset images and initialize the BBPS descriptor.

Output: Print the license plate text on the image

A. The Proposed Work (Level 1)

Aim of the proposed work is to propose a powerful algorithm to recognize license plate candidates accurately. Here BBPS descriptor is used to propose an algorithm to extract features of license plate characters. Initially various font images were downloaded from web which is used to train the classifier. Linear SVC is used to train the digit and character classifier separately to obtain higher accuracy. Training dataset were constructed by segmenting LP characters from dataset Images and stored in various labelled folders, which is used in testing phase.

1) *Methodology*: The Objective of the proposed work is to recognize LP images. So a different font style characters and digit dataset images downloaded from web which look alike Fig 1 and used for training the algorithm. For training eight different font style applied image collected from web. Each font displays the characters A-Z and the numbers 0-9. Since we have eight images, we have eight examples for each letter and digit. Proposed algorithm extracts BBPS features from the characters and trained using linear SVC : one for letter recognition and a separate one for digit recognition.

Fig. 1. Training set for License Plate Images

2) *Block-Binary-Pixel-Sum Descriptor(BBPS)*: BBPS descriptor [18], is used for license plate character recognition. BBPS functions by separating an image into non-overlapping $M \times N$ pixel blocks, by applying BBPS descriptor on image ; image will be subdivided on three basis one is 3×3 regions, another one is 2×3 regions and last one is 3×2 sub division as shown in Fig 2. In BBPS target size of the image is fixed, canonical size of ROI is resized so that all images can maintain consistent representation and quantification of each character from dataset images. Input image is converted to a binary image, with pixels corresponding to the character having an intensity > 0 , and pixels corresponding to the background set to 0.

Fig. 2. Example for BBPS Descriptor

3) *Training Classifiers*: License plate has two groups of characters letters followed by digits. In order to obtain better accuracy, both the digit and character classifier should be trained separately. Here linear SVC is used to train a classifier for classification or prediction. Character contains alphabets from string a-z and the digits 0-9. In testing phase all font images will be loaded for training the classifier, convert it to a grayscale image, and threshold operator applied on image so the image look like Fig. 3.

Fig. 3. Training Image after Applying threshold Operator

After thresholding image, contour detection was applied on image to sort our contours from left-to-right, bounding box computed for each of the sorted contours. For each of the sorted contours ROI extracted and passed to BBPS i.e., LP. Training dataset image has characters followed by digits so if value < 26 means it is character otherwise digit. Respective digit and characters updated in appropriate labeled lists. Each character and digit is classified using linear SVC, it will fit the data which is loaded into it will provide, a finest fitting hyperactive plane that rifts or classifies the statistics which feed in to it, linear SVC will dump the data along with its label value as a model. Linear SVC created model will be dumped into pickle file, at the end of training phase two separate pickle file will be created one for character and another for digit. Pickle file which is used for serializing and de-serializing an object structure, which maintains program state across sessions, or transport data over the network. Here we dumped both the classifier in pickle file in order to transmit training data to testing phase. Fig 5 depicts the work flow of level 1 training phase.

4) *Testing Phase*: In this phase two pickle file created in training phase will be loaded along with the testing dataset. From the localized license plate images [12], images were looped over the LP regions bounding box, for each of extracted characters from LP regions [19] applied BBPS descriptor, LP images always carry character followed by digits, So first character classifier is applied to predict features of LP characters followed by digit classifier, length of the bounding box characters were checked if length of the character greater than zero i.e., $\text{len}(\text{chars}) > 0$ and compute the center of LP regions so has to print the detected strings parallel to the LP region. Fig. 6 depicts the work flow of level 1 testing phase.

Fig. 4. License Plate Recognition via Proposed Algorithm

After applying the proposed algorithm, LP image look like Fig 4, proposed algorithm gives a good accuracy and prediction rate. Fig 12 shows the successfull LP recognition in level 1. In Fig 13 LP recognized falsely their character M is wrongly recognized has N since both characters looks similar our proposed classifier lags in differentiating nearest character. In Fig 13 digits were misclassification 1 is recognized has 9 so an enhanced proposed algorithm needed and for such wrong redictions. In order to overcome false prediction characters and to improve accuracy, training classifier were trained using real-time license plate images. License plate characters were extracted and labeled has a sample of license character examples from the license plate dataset, both digit and character classifier has been re-trained on top of the BBPS feature representations from the more “real-world” dataset, testing done with the re-trained classifiers which lead to obtain higher character identification accuracy.

B. The Proposed Work - Level 2

- In order to improvise accuracy training classifier done using real-time license plate images.
- LP characters; extracted and labeled has a sample of license character examples from our license plate dataset.
- Both digit and character classifier will be re-trained on top of the BBPS feature representations from the more “real-world” dataset.
- Testing done with the re-trained classifiers which lead to obtain higher character identification accuracy.

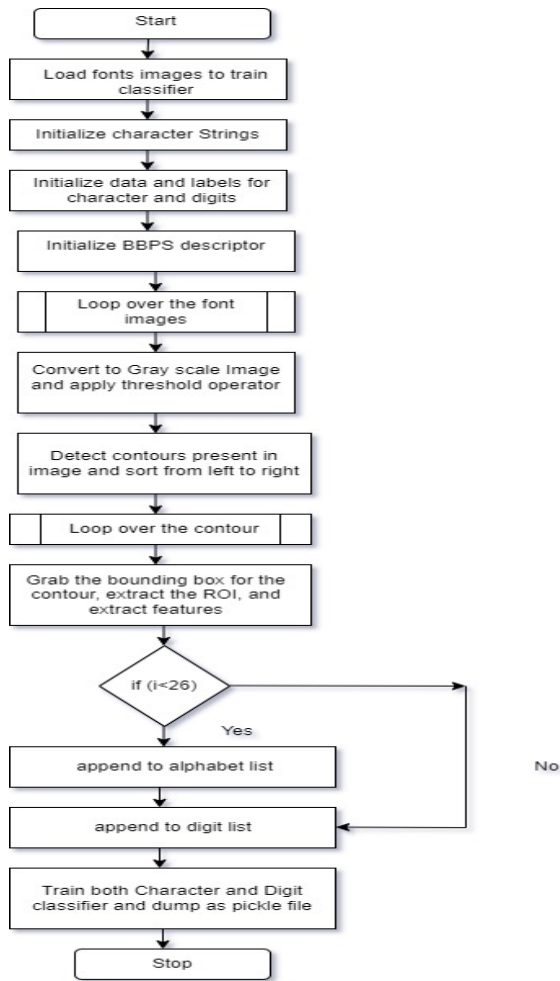

Fig. 5. Flow of Work of Level 1 Training Phase

Fig. 6. Flow of Work of Level 1 Testing Phase

Aim for retraining classifier is to obtain a higher accuracy; here classifier is retrained using real-world character examples using LP dataset. LP dataset which used to training is a real-world LP car image dataset so that it can recognize LP characters of real world vehicles. Fig. 7 depicts the work flow of level 2. From a localized bounding box generated images [12]. In second phase initially will randomly select 50% images for training and 50% images for testing. LP localized image with bounding box will be loaded [12], will loop over the LP region with bounding boxes and extract LP characters [19], in that each of the characters from LP images will be displayed and wait for key press event to manually label each of these LP characters like Fig 8. Once characters extracted from LP, it will wait for key press event. If the '/' (backtick/tilde) key was pressed, proposed work will ignore the character which is built to ignore falsely detected characters or "noise" in the LP image. Other key press represents confirmation of the character without labelled data; meanwhile appropriate key pressed for characters on screen those characters will be stored with correct label like Fig. 9. Once the LP character has been labelled, it will be written in to disk using a directory structure like filename followed by extension like Fig. 10.

Once characters extracted from license plate, once backtick

or tilde key was pressed, proposed work will ignore the character which is built to ignore falsely detected characters or noise in the LP image. Other characters other than other key backtick or tilde key pressed which represents confirmation of the character without labelled data; meanwhile appropriate key pressed for characters on screen those characters will be stored with correct label like Fig. 8. Once the LP character has been labelled, it will be written in to disk using a directory structure like character name/example name.png

By pressing appropriate key while labelling data, character will be saved to folder as like Fig. 10. While comparing with our previous level contrived LP fonts samples these labelled LP characters are certainly representative of real-world LP characters like Fig. 11. In Level 2 labeled characters directory was created with real-time LP images, since web downloaded font image were trained and used in level 1 which lags to give exact recognition at some cases since there is lots of difference between web downloaded image and real LP images, so if training classifier also done with real LP images which gives good accuracy when testing with real LP images. In level 3 from LP dataset images using BBPS extract features, and retrain the character and digit classifier.

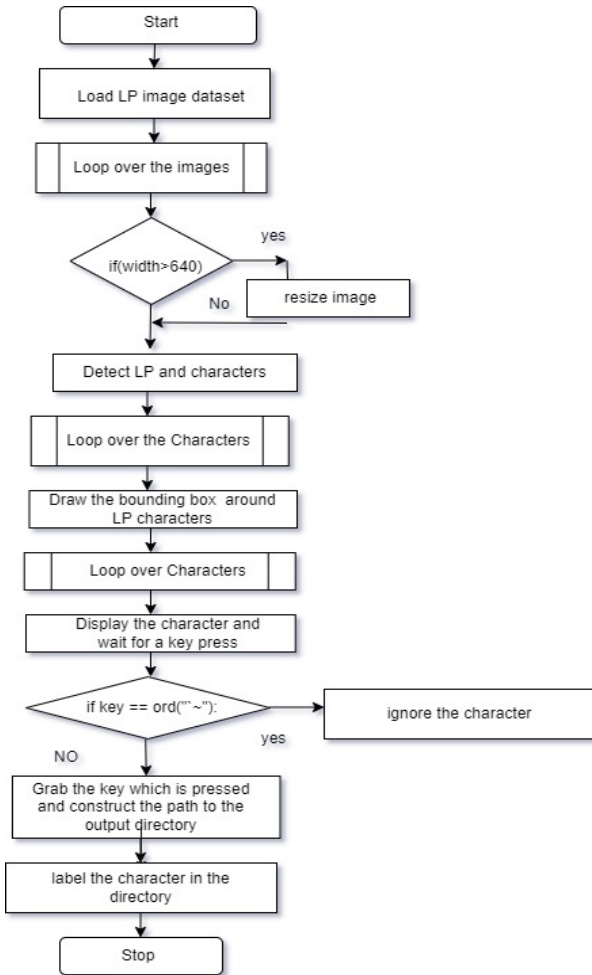

Fig. 7. Flow of Work of Level 2 Gathering LP Characters

Fig. 8. Appropriate Key Press while Labeling LP Characters

Fig. 9. Labeling LP Character Examples

C. The Proposed Work - Level 3

From the gathered labeled directory (o/p of level 2). BBPS descriptor was applied to extract license plate characters. Re-trained letter and digit classifiers were used to re-train

Fig. 10. Output ROI Stored in Subdirectory

Fig. 11. Sample of Labeled LP Characters

classifiers to recognize license plate characters accurately. As a beginning step in level 3, BBPS descriptor will be initialized and sample directory which is created in level 2 will be loaded, each of the images will be loaded, pre-processed and finally BBPS features extracted from those sample images. Accordingly like level 1 digit and character classifier trained and updated and dumped into separate pickle file.

As a beginning step in level 3, BBPS descriptor will be initialized and sample directory which is created in level 2 will be loaded, each of the images will be loaded, pre-processed and finally BBPS features extracted from those sample images. Accordingly like level 1 digit and character classifier trained and updated and dumped into separate pickle file.

IV. DATASET

To recognize LP candidates, large collection of dataset required. Publishing large collections of license plates and any information regarding where the license plates were captured including Global Positioning System (GPS) coordinates, noticeable landmarks, street signs, etc. is actually considered an invasion of privacy in many countries [12]. It's really hard for ALPR standpoint where in google and their street view initiative have amassed one of the largest datasets of license plates in the entire world. The google street view cars have driven countless miles around the world, passing millions upon millions of cars and trucks all with license plates clearly visible; images where blur and license plate characters were looks so smudged [19]. For the proposed work dataset images taken from a popular dataset repository called as medialab which is maintained by a national university in greece, kaggle car dataset and google map images. Proposed work trained and tested with medialab images of 139 combined with kaggle car dataset 55 images and google map images 20, totally 214 images were trained and tested. Dataset images were localized [12], sliced and segmented [19] proposed work is a continuation of previously proposed license plate localization [12], segmentation and scissoring [19].

V. RESULT AND DISCUSSION

The proposed work license plate recognition is done using medialab dataset, kaggle car image dataset and Google map images. Proposed algorithm build using BBPS descriptor implemented in anaconda python. The experiment is done in laptop with intel core i5, 2.70 GHz, 8 GB RAM windows 10-64-bit OS. On execution time all the images were rescaled and maintained the size of 640 pixels with unchanged aspect ratio. Proposed algorithm gives very good accuracy compared to existing works. Proposed work is novel and works better than the state-of-the-art methodologies. Existing works lags to recognize license plate from the blurred, sweked images captured in uneven lightning and fails to recognize license plate characters of images taken from longer distance, proposed algorithm works on all the above cases so its a novel and works better than state-of-the-art methodologies. Proposed algorithm is simple to understand, easy to implement in real time environment which gets executed in 0.42 milliseconds. Proposed algorithm is proposed in such a way to overcome all the flaws of existing methodologies.

Fig. 12 depicts the successful true positive result in level 1. Here license plate were successfully recognized whereas in Fig. 13 in left side image all candidates were recognized correctly except the second character candidate which is recognized has N instead of M. In Fig. 13 all character candidates were recognized correctly except a digit '1' which is recognized has '9'. All these misclassification occur because all these candidates share similar features.

Fig. 12. Successful License Plate Recognition in Level 1

Fig. 13. False Prediction in Level 1

In level 1 training of LP characters were done using different font images downloaded from internet, level 1 yields good accuracy but it fails to recognize a few cases, in order to overcome such flaws, training of classifier is done by gathering characters from dataset images like Fig 14. In Fig. 15 depicts the wrongly predicted license plate images in level 1 which is correctly recognized in level 3.

Fig. 14. Gathering LP Characters in Level 2

Fig. 15. Wrongly Recognized Vehicle LP in Level 1 Predicted Correctly in Level 3

VI. PSEUDOCODE

Level 1: Training Phase

initialize characters string, data and labels for the alphabet and digits

initialize BBPS descriptor

loop dataset images, convert to grayscale

and apply thresholding

detect contours; sort from left to right

loop over contours, grab bounding box of contour

extract ROI

if $i < 26$

it is character

else

digit

train character and digit classifier

dump the character and digit classifier to a file

Testing phase

def testing phase()

load the character and digit classifiers created in training

phase

initialize BBPS descriptor

loop dataset images

```

if width > 640,
    resize(image)
detect the license plates [12] and characters [19]
loop over detected plates and characters
preprocess it
    if i > 3
        call digit classifier
    else
        call character classifier
    update the text of recognized characters
if len(chars)>0
    compute the center of LP bounding box
    draw the characters which are predicted

```

above bounding box

Level 2: gathering LP characters

```

randomly select a portion of the images
loop dataset images
    if width> 640
        resize(image)
    detect the license plate [12] and characters [19]
    draw bounding box around recognized
    license plate
    loop over the characters
    display the character
    if actual != segmented character
        print(ignore)
        continue
    construct the path to the output directory
    if output directory not exist, create directory
    write the labeled character to file

```

Level 3: Advanced training phase

```

initialize the BBPS descriptor
initialize the data and labels for the alphabet and digits
loop over the sample dataset created in level 2
    extract the images
    loop over the images
        load the character, convert it to grayscale
        preprocess it
        if the character is digit
            append digit data and label
        otherwise
            append alphabet data and label

```

train both advanced character and digit classifier

dump the character and digit classifier to file

Advanced testing phase

```

Input: Load advanced character and digit classifier
call testing phase()

```

VII. PERFORMANCE EVALUATION

In the proposed work in level 1 few LP character candidates were predicted wrongly, so to overcome such flaws training images were created using medialab, kaggle car dataset and Google map images. To evaluate the performance of proposed system accurately, here we have trained and tested the proposed system with three dataset images, which has images captured at various angles, various lightning condition. In a Tunisian dataset, [20] which is used for calculating accuracy for LP recognition, which comprised of true positive and true negative divided by true positive, true negative, false positive and false negative boundary boxes. Table 1 depicts different dataset images used, the performance metrics of proposed

system is calculated in terms of measuring precision, recall, f-measure. Proposed algorithm recognize dataset images more accurately than the existing algorithm, it recognizes images captured at challenging environment and angles. Performances of proposed algorithm is produced in table format. If the license plate correctly predicted from license plate images which come under True Positive (TP), if non-license plate region recognized has license plate which called as False Positive (FP). Since the proposed work is done in multilevel performance evaluation has been done for each level independently in Tables 2, 3 and 4 depicts the true positive, false positive values from all the three levels of proposed work.

$$Precision = \frac{TP}{TP + FP} \quad (1)$$

$$Recall = \frac{TP}{TP + FN} \quad (2)$$

$$F - measure = \frac{2 * Precision * Recall}{Precision + Recall} \quad (3)$$

TABLE I. DIFFERENT DATASET IMAGES

Dataset Name	No.of.Images
Medialab	139
Kaggle dataset	55
Google map images	20

TABLE II. CONFUSION MATRIX FOR LEVEL 1

	Predicted Negative (PN)	Predicted Positive (PP)
Actual Positive(AP)	11	17
Actual Negative(AN)	0	204

TABLE III. CONFUSION MATRIX FOR LEVEL 2

	Predicted Negative (PN)	Predicted Positive (PP)
Actual Positive(AP)	0	7
Actual Negative(AN)	0	207

TABLE IV. CONFUSION MATRIX FOR LEVEL 3

	Predicted Negative (PN)	Predicted Positive (PP)
Actual Positive(AP)	3	13
Actual Negative(AN)	0	198

In prediction phase if both the license plate character candidate and predicted character candidate were same means its true positive, if non LP region predicted has LP candidate means its false positive, if non license plate region not recognized has license plate region its true negative, if non license

plate region detected has license plate region means false negative. Equations for precision, recall, f-measure given in eq(1),(2),(3). Precision, recall, f-measure were metrics which is used to test performance of an algorithm. Precision is a measure which can be used when the count of false positive is less. Recall is a metrics which is used to improve the prediction rate when it lag to produce satisfying result in precision phase; this metrics can be used when the value of false negative is less. F1 measure can be used when the accuracy seek the balance between precision and recall, when class distribution is uneven i.e more actual negatives. Table 5 depicts the precision, recall, f-measure score of proposed work. Table 6 depicts the proposed methodology accuracy with existing works.

TABLE V. PRECISION, RECALL, F-MEASURE VALUES

	Precision	Recall	F1-score
Level-1	92.3	94.8	93.5
Level-2	96.7	100	98.3
Level-3	93.8	98.5	96

TABLE VI. COMPARISON WITH EXISTING WORKS

S.no	Author's	Precision	Recall	F-measure
1	Proposed algorithm	93.8%	98.5%	96%
2	Omar et al [10].,	94.43%	92.10%	91.01%
3	Al-Shemarry et al [21].,	91.6%	87.1%	89.33%

Proposed work evaluated with popular dataset like medi-alab, kaggle, and Google map images. All images were used for both training the classifier and testing license plates. Fig. 16 depicts the final outcome by kaggle dataset images and Fig. 17 is a sample output for successful license plate recognition for google map images.

Fig. 16. Successful License Plate Recognition using kaggle Dataset

VIII. CONCLUSION

ALPR is an interesting hot topic, many algorithm exists for ALPR but it still lags on recognizing license plate characters from complex environment, by overcoming all the backdrops in existing system a novel and efficient algorithm produced here to recognize license plate characters accurately from complex environment. In this proposed work, license plate is recognized from media-lab,kaggle car dataset images and

Fig. 17. Successful License Plate Recognition using Goggle Map Images

from Google map images. Many existing algorithm exist for LP recognition but it lags to provide good accuracy due to various factors like images were captured in uneven lightning, taken at tilted position and blurred images. Existing algorithms are tedious, time consuming and it requires labeled data, those were expensive to compute, and highly time consuming. Proposed algorithm is novel, built using BBPS descriptor and linear SVC which is super-fast, run easily in real-time, and its simple to comprehend, its inexpensive to compute, and executes in 0.42 milliseconds. In level 1 proposed work produced 93.5% accuracy, In level 2 gathered training dataset images and which gave 98.3% in recognizing and training dataset images which is used as a input to level 3 . level 3 produced an enhanced better results than proposed level 1 and other existing methodologies. As a future work license plate of regional language images will be recognized.

Genetic Algorithms Applied to the Searching of the Optimal Path in Image-based Robotic Navigation Environments

Fernando Martínez Santa, Fredy H. Martínez Sarmiento, Holman Montiel Ariza
Universidad Distrital Francisco José de Caldas
Bogotá, Colombia

Abstract—This paper describes an optimal-path finding strategy based on Genetic Algorithms, applied to mobile robots in static navigation environments. This strategy starts from an image or plan of the environment and is supported by some different image processing algorithms, mainly the image skeletonization. Three different strategies were tested, changing the domain of the optimization target function for the Genetic Algorithm, the first domain was all the points of the environment image less the obstacles or walls, the second domain was similar but using an image with the obstacles dilated, and the final domain was only the points of the skeleton image. The last tested domain is from 99.4% to 99.6% smaller than the others, that implied reductions from 95% to 96% in the overall execution time of the strategy. Likewise, three skeletonization algorithms were tested in order to use the one with less execution time in this proposal. Finally, the proposed path planning strategy was tested on the same environment changing the initial and final points giving as result a valid and optimized path for the mobile robot in all the tested cases, and an overall average optimization time less than 2 minutes. This last, validates this proposal for robotic navigation applications with static obstacles.

Keywords—Genetic algorithms; optimal path; optimization; robotic environment; mobile robots, image skeletonization

I. INTRODUCTION

Although robotics has been one of the areas with the most ongoing research over the years, today, it continues to expand its fields of application due to the incorporation of automation in daily life. One example of this is mobile robots, which are now looking to help people in daily tasks; this situation implies that mobile robots must be capable of a path in different environmental conditions or grounds. Hence, navigation has become an important robotics process, allowing a mobile robot to know its location and plan and follow a path, preventing collision with obstacles.

According to recent studies [1], there are some approaches to the solution of the navigation problem in robotics based on deterministic and non-deterministic algorithms, which focus on optimal path planning [2] and collision prevention [3]. When reviewing from the path planning point of view, where a route is planned in a given environment reducing the total cost associated with the trajectory, it is necessary to consider whether local path planning [4] or global path planning [5], [6] is being performed. Thus, different methods have been developed, classified into classical approaches and heuristic [1] or reactive approaches [7]. In recent years, heuristic or reactive approaches have been the most used due to their robustness

to handle the uncertainty present in the environment and real-time navigation problems. Some heuristic or reactive methods that have been used are Genetic Algorithm (GA) [8], [9], Ant Colony Optimization (ACO) [10], [11], Particle Swarm Optimization (PSO) [12], [13], [14], [15], Neural Networks (NN) [16], Fuzzy Logic (FL) [17], Dijkstra algorithm [18], A* algorithm [19], among others.

Genetic algorithms (GAs) are part of evolutionary computing, one of Artificial Intelligence techniques that exist today. GA is a meta-heuristic method for solving searching and optimization problems, where a new population is generated from the fitness value of the previous generation. It is based on the phenomenon of natural selection and genetic operations such as mutation and crossover [20]. Some studies have shown that GA is a robust search method that requires little information about the environment to achieve reducing path length and producing smoother path for robot navigation, with some limitations in convergence rate and time-consuming process [21], [22].

Therefore, the aim of this research is to propose a path planning strategy for mobile robots based on digital image processing and Genetic Algorithms. The main idea is exploring the GA as selection and optimization tool for searching a valid and optimized path for a mobile robot in its environment, starting from an image or plan of that environment.

The remainder of this paper is organized as follows. In Section II, a brief description of the robot environment is given, likewise the description of the data flow (pipeline) of the proposed strategy; the pre-processing image operations for the environment image are presented in Sections II-A, II-B and II-C; Section II-D gives the first process of the path planning, the computing of the skeleton of the image. Section II-F describes the application of a GA for finding an optimal path. Section III shows the experiments and results and the Section IV gives our final conclusions.

II. METHODOLOGY

The path planning proposal for mobile robots shown in this document, is supported by digital image processing [23], [24] and it is based on an initial image of the navigation environment, which can be a plan of the room or a photo taken from above. For the scope of this article the initial images are as the one shown in Fig. 1 which represents a plan of a building floor where the mobile robot has to navigate. In that

initial image the floor walls are shown in *black* and the free-navigable space are shown in *white*, likewise the p_s represents the initial or starting point of the robot and p_e the final or ending point.

Fig. 1. Navigation Environment for the Mobile Robot.

The proposed path planning strategy is composed of the following steps: first, a resizing process is applied to the environment image in order to reduce and standardize the input. Second, the resized image is turned into binary to be compatible with the next steps of the process. After, two images are calculated, the first one is an image with the walls expanded (as wide as the radius of the robot), this image will be used to determine possible collisions in the next steps. The other image is the skeleton [25], [26] (medial axis) of the free-navigable space, this one is used for calculating the final path as far as possible to the obstacles (walls). Then, based on the skeleton of the environment image, the array of all the possible navigable points is stored. Finally, a short path is found using a Genetic Algorithm (GA) as optimizing and/or searching algorithm. The GA uses both the image skeleton and the walls dilated image to find the optimal path. The complete pipeline of proposed strategy is shown in the diagram of the Fig. 2. The overall path planning strategy was implemented by using *Python 3* programming language and mainly the *Scikit Image* module for the digital image processing operations. Next subsections show a detailed explanation of each of these steps.

A. Image scaling

In order to reduce the computing time of the overall path planning strategy, the images to work with have to be the small as possible, due to that, the resolution of the input image and therefore all the generated and used images is limited to 700k pixel, specifically images of 1000x700 pixels. This last is very important mainly for the GA, due to some image processing operations are part of the fitness function or target function, that implies it has to be iterated very much times until reach the convergence value. The exponential increasing of the execution time in image processing algorithms where the resolution of the input image increases, will imply a very high execution time for the overall strategy, for that reason is very important to limit the input image resolution. In the scaling or resizing operation that was applied to the input image, no anti-aliasing

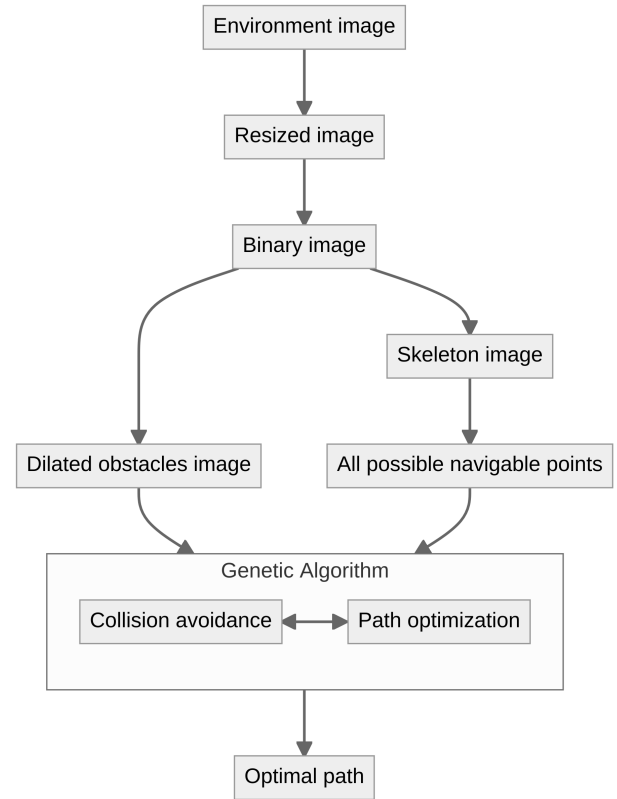

Fig. 2. Pipeline of the Proposed Path Planning Strategy.

method was used in order to not affect the original shape of the border objects in the environment.

B. Image Binarization

Once scaled, the image is normalized and binarized, this is achieved first by turning all the pixel values (bytes) of the image into normalized values from 0 to 1, by means of a simple product. After that, a threshold operation is performed following the eq. 1, where I and J are the maximum dimensions of the normalized image A and the output binary image B , likewise Th is the threshold defined as 0.5. At the end of this process, the image B has the obstacles in *black* (False) and the navigable space in *white* (True), as shown in Fig. 3.

$$\forall i \in I, j \in J : \begin{cases} A_{ij} > Th \rightarrow B_{ij} = True \\ A_{ij} \leq Th \rightarrow B_{ij} = False \end{cases} \quad (1)$$

C. Obstacle Dilation

In order to keep the robot to a safe distance from the obstacles or walls of the environment, that distance is calculated from to the maximum radius (measure from the center to the maximum distance to this one) of the robot following the eq. 2, where r_d is the dilation radius, r_m is the robot maximum radius and Δr is a radius tolerance defined as 10%. The resultant r_d is represented in pixel units and it is rounded to the floor.

Fig. 3. Resized and Binarized Image of the Environment.

$$r_d = \lfloor r_m + \Delta r \rfloor \quad (2)$$

In a binary image, the dilation process is achieved over the *white* objects, so it is necessary to invert the image to obtain the desired *white* obstacles. At the end, the obtained image is inverted again to obtain an image with the dilated *black* obstacles. After inverting the obstacles binary image, a morphology dilation operation is performed by means of using a 2D convolution between that image and a disk shape a radius equivalent to r_d . After that, the image is inverted back, and the result is shown in Fig. 4, where the area of the obstacles or walls are expanded because of the dilation operation. All of this, pretends to avoid collisions between the robot with the walls due to the maximum radius of the robot r_m was taken into account.

Fig. 4. Dilated Obstacles Image.

D. Skeletonization Algorithm

The image skeletonization algorithms pretend to find a medial axis of the shapes on a binary image applying an iterated and controlled image erosion operation until obtained a thin line [27]. This obtained line represents the medial axis of each object in the image. There are some different proposed

algorithms about such as the one proposed by Zhang et al. [28], the Lee's proposal (et al.) [29], and other medial axis operation. For the scope of this paper, three different skeletonization algorithms were tested: the standard skeletonization (Zhang), the Lee's skeletonization and a standard medial axis obtaining algorithm. The main aim is to recognize which of them is the fastest in order to be applied in this proposal. The Fig. 5 shows the resultant execution times of the tested skeletonization algorithms. The tests was applied over an 1000×700 image that contains a possible navigation environment for a mobile robot. A total of 5 tests were done and the average execution time of each algorithm is the shown in Fig. 5. Then, according to those results, for this proposal only the Zhang skeletonization algorithm is applied for obtaining the medial axis points of the environment image, as reference for the navigation.

Fig. 5. Skeletonization Algorithms Execution Times.

The Zhang's skeletonization operation is applied to the resized environment image in order to obtain a thin line in the middle distance between obstacle or walls [30]. The Fig. 6 shows the resultant skeleton (in white) of the environment image, likewise the Fig. 7 shows original environment image plus the inverted skeleton image. This last image was obtained by means of applying logical *not* and logical *and* operations. As shown in the Fig. 7, the skeleton corresponds to the middle distance (medial axis) between halls walls and rooms walls, so it is a good reference for a free-collision navigation of the mobile robot.

E. Navigable Points

Once the environment image skeleton is obtained, all the points of the medial axis E_{ij} are stored in a bi-dimensional array P where each point $P_{k(x,y)}$ is a possible point of the final path. The storage operation of the skeleton set E starts from the skeleton image (see Fig. 6) and looks for the pixels in *white* (True), as the eq. 3 summarizes.

$$\forall k, i \in I, j \in J : E_{ij} = True \rightarrow P_k = (i, j) \quad (3)$$

F. Genetic Algorithm

For calculating and optimizing the path from the navigable points array, Genetic Algorithms (GAs) are used as

Fig. 6. Skeleton of the Environment Image.

Fig. 7. Image of the Navigation Environment Plus its Skeleton.

optimization/searching tool [20] in order to find the shortest path using as reference the navigable points array obtained from the environment skeleton image, and at the same time avoiding collisions with obstacles and walls using the dilated obstacles image previously mentioned.

1) *Collision Avoidance*: The avoidance of possible collisions between each segment of the final path and the obstacles or walls is achieved applying some binary image operations, specifically a binary exclusive disjunction *XOR* between the dilated walls image and the same image with the specific segment drawn in *white* as shown in Fig. 8, where p_1 and p_2 are the points of the path segment. When there is a collision, a white segment line will be down over an obstacle or wall, producing that the two images are different. The eq. 4 has to be accomplished by all the pixels of both images for validating the non-collision condition. Where again, I and J are the valid set of indices in the dilated obstacles image D and the copy of the same image plus the drawn line L .

$$\forall i \in I, j \in J : D_{ij} \leftrightarrow L_{ij} = False \quad (4)$$

2) *Fitness Function*: For starting the searching and optimization process, the starting point p_s and the ending point p_e

Fig. 8. Drawn Line for Testing the Collision with the Obstacles (walls).

are appended to the navigable points array P . Once completed the navigable points array, it is necessary to define the *fitness function* or *target function* to optimize $f(X)$, which depends on the solution set X shown in eq. 5.

$$X = \{x_0, x_1, x_2 \dots x_n\} \quad (5)$$

where each x represents a reading index of the navigable points set P which is based on the skeleton of the environment image. Then, the *fitness function* depends on the summation of the distances of each segment $\overline{p_i p_{(i+1)}}$ from p_s to p_e , that also accomplishes the eq. 4, the complete definition is shown in eq. 6.

$$f(X) = \sum_{i=0}^n |\overrightarrow{p_i p_{(i+1)}}| + d_c \quad (6)$$

Listing 1: *fitness function* Implementation on Python 3.

```
def obj_function(X):
    d = 0

    route_x ,
    route_y = build_route( X,
                           start_p ,
                           end_p )

    for i in range(len(route_x)-1):

        dx = route_x[i] - route_x[i+1]
        dy = route_y[i] - route_y[i+1]
        d += np.sqrt( dx**2 + dy**2 )

        imt = (imd == True)
        rr , cc = line( route_y[i],
                       route_x[i],
                       route_y[i+1],
                       route_x[i+1] )

        imt[rr , cc] = True

    imc = imt == imd
    if sum(sum(imc)) != imd.size:
        d += (max_i + max_j)
```

return d

In the eq. 6, $|\overrightarrow{p_{x_i} p_{(x_i+1)}}|$ is the distance of a segment between two nearby navigable points, and d_c is a penalty distance which is added to the total distance if the current segment produces a collision according to the eq. 4. This penalty distance d_c corresponds to the summation of the image dimension maximum values $A_{x_{max}} + A_{y_{max}}$.

The implementation of the GA *fitness function* in *Python 3* is shown in the listing 1, where the function **build_route** appends the starting and ending points to the rest of points of the path.

3) *Implementation*: The implementation of the GA in this proposal, follows the parameter shown in Table I, where it is important to highlight that the mutation probability was increased to 0.2 in order to accelerate the convergence.

TABLE I. GENETIC ALGORITHM PARAMETERS

Parameter	value
maximum iteration number	None
population size	100
mutation probability	0.2
elitism ratio	0.01
crossover probability	0.5
parents portion	0.3
crossover type	uniform
mutation type	uniform by center
selection type	roulette
max. iteration without improvement	10
dimension	8
variable type	integer
function timeout	5s

The genome of the GA is simply defined as the complete set X , taking into account that $\forall i \in \{0, 1, 2 \dots n\} : x_i \in \mathbb{E}$, where each gene corresponds to each x_i variable, it means $gen_0 = x_0$, $gen_1 = x_1$ etc, being each gene an integer variable.

All the tests of the proposed path planning strategy were done on a simple laptop with the following features: CPU AMD Athlon Gold 3150U @ 2.400GHz with 2 hardware cores, GPU AMD ATI Picasso, RAM 12 GB and main drive SSD. These test were run on the GNU/Linux distribution Ubuntu 20.04.3 LTS x86_64 and Python 3.8.10.

III. RESULTS

As described in the section II-D, three different skeletonization algorithms were tested: the standard one in *Scikit Image* (Zhang's), the Lee's version and the standard *Scikit Image* medial-axis detection algorithm. The Zhang's version showed to take only the 24.6% of the time that the Lee's version took and 80.5% of the time that the medial-axis detection took, as shown in Fig. 5.

The first tested approach applied the GA to search the optimal path directly on the binary image of the plan of the environment, that means that all the pixels of the *white* area in the Fig. 3 (around $617 \cdot 10^3$ points for a 1000×700 image) compose the fitness function domain for the GA. This first approach took around 46 minutes to execute. In the second test, the GA was applied to the obstacles dilated image, reducing

the *white* area therefore the fitness function domain to $465 \cdot 10^3$ points, likewise the execution time was reduced to around 35 minutes. None of those approaches had acceptable execution times, then a third approach was proposed using the skeleton of the image instead of all the possible navigable area. This last approach reduced the domain to just $2.5 \cdot 10^3$ points and the execution time to around 1 minute 46 seconds.

As previously said, the overall algorithm took around 1 minute 46 seconds finding an optimal path with the parameters given to the GA. This time is the median of 10 test done with the same conditions, where only the starting and the ending points were changed.

Four different results are shown in Figures from 9 to 12, where for all the cases the starting point is the same, but the final point was changed to the different rooms in the environment plan. As shown in Fig. 11 it is specifically difficult for the GA to find valid and short paths when the starting and the ending points are near. Fig. 11 shows how the path took king of wrong direction and came back to the correct path, and also taking around 4 minutes to reach the convergence. This strange behaviour probably happens due to the fixed number of points (always 8) configured in the GA, which did not present problems for larger paths because in those there are more space between points.

Fig. 9. Resultant Optimized Image.

IV. CONCLUSION

The speed of Zhang skeletonization algorithm makes it feasible to be applied on environments with moving obstacles, due to the GA would not take very much time recalculating the new image skeleton when any of the obstacles moves.

The execution times of the proposed strategy were reduced from 95% to 96%, reducing the fitness function domain by means of using the image skeleton instead of the original image or even the image with the obstacles and walls dilated. This significantly reduction makes this proposal a hundred percent applicable for static obstacles environments and gets close to real time applications.

As a technical recommendation, the execution time is able to be reduced changing the input parameters of the GA in order to accelerate its convergence, but having the risk to obtain a local minimum (not exactly the "best" as shown in Fig. 11).

Fig. 10. Resultant Optimized Image, Case 2.

Fig. 11. Resultant Optimized Image, Case 3.

Fig. 12. Resultant Optimized Image, Case 4.

As future work, an adaptable and automatic change of the total number of points of the path is proposed in order improve the convergence times and the optimal result when the starting and ending points are close as the example shown in Fig. 11.

Abstract—The proliferation of numerous network function today gave rise to the importance of network traffic classification against various cyber-attacks. Automatic training with a huge number of representative data necessitates the creation of a model for an efficient classifier. As a result, automatic categorization requires using training techniques capable of assigning classes to data objects based on the activities supplied to learn classes. Predefined classes allow for the detection of new items. However, the analysis and categorization of data activity in intrusion detection systems are vulnerable to a wide range of threats. Thus, New methods of analysis must be developed in order to establish an appropriate approach for monitoring circulating traffic in order to solve this problem. The major goal of this research is to develop and verify a heterogeneous traffic classifier that can classify the collected metadata of networks. In this study, a new model is proposed, which is based on machine learning technique, to increase the accuracy of prediction. Prior to the analysis stage, the gathered traffic is subjected to preprocessing. This paper aims to provide the mathematical validation of a novel machine learning classifier for heterogeneous traffic and anomaly detection.

Keywords—Anomaly detection; network metadata; packet analysis; intrusion detection system; machine learning; classification; heterogeneous traffic

I. INTRODUCTION

As part of network forensics, network traffic and event logs are commonly referred to as being sniffed, recorded, acquired, and analyzed to investigate a network security incident. It enables the investigator to study network traffic and records to identify and locate the assaulting system. Computers, smart-phones, tablets, and other network-connected devices continue to grow. As the frequency of assaults against networked systems increases, the criticality of network forensics grows. Most previous studies confront two fundamental issues in extracting external and internal data, making traffic flow prediction a difficult endeavour. Currently, available solutions do not completely use the fundamental properties of short-term nearby and long-term periodic temporal patterns in terms of their various roles. In terms of the extrinsic task, current work has primarily used hand-crafted fusion algorithms to incorporate external inputs, however, there are still challenges with generalization [1].

The examination of a traffic incident is divided into two stages: Appearance check is the initial stage in the process of determining the Bloom filter (period) including an excerpt. To find the flows that conveyed the excerpt, the second phase is termed "flow determination," and it involves combining the excerpt blocks with the flows found by the Bloom filter. It

was key difficulties handled by HBF [2], such as ensuring that blocks were aligned and that they were consecutively placed.

Cybercrime is a constant danger to computer networks. No security mechanism can guarantee complete safety. Even the most advanced network security measures are unable to identify and prevent all assaults, particularly those that are new and unknown. In certain circumstances, preventing cybercrime is impossible. Suppose that confidential information about a company is leaked over its network. How can security specialists track down cybercriminals? Let us consider the following scenario: an organization's internal network has been infected by a worm, and the organization's Intrusion Detection and Prevention System (IDS/IPS) was unable to identify and block the worm's dissemination. How can you track down the person who spreads the virus or the afflicted systems? As a result, in addition to preventative security systems, tools and methodologies for investigating cybercrime after it has occurred are required. This is the function of network forensics and the tools that it provides [2].

Recording and storing raw network traffic is the most basic method of network research. Traffic recording makes it feasible to examine any networking event that occurs. It is possible to scan through the recorded traffic for the leaked information or the worm's signature to determine where it originated and where it ended up. "Attribution" is the term for this operation. The most difficult challenge with this system is the exceedingly costly storing of large amounts of data [3]. In addition, the invasion of privacy is a concern with traffic recording. By monitoring network traffic, it is possible to gain access to the personal information of users. As a result of the increasing difficulty in providing both privacy and network forensics, new Internet designs and protocols have been proposed [4]. However, implementing such modifications would be prohibitively expensive, making them impractical in practice.

In the field of traffic categorization, three groups of methodologies exist port-based, payload-based, and machine learning-based methods [5]. The identification of network traffic based on port numbers is a straightforward process that depends on mapping programs to well-known port numbers. Regrettably, port-based categorization algorithms have grown erroneous as a result of the increased use of dynamic port numbers by numerous apps. Payload-based approaches necessitate the analysis of the payload of each packet. Privacy regulations and encryption, on the other hand, may prevent traffic payloads from being accessed. As a result of this, deep packet inspection (DPI) is expensive in terms of both computation and signature maintenance [6].

II. MOTIVATION

Machine learning-based solutions have the potential to overcome some of the restrictions associated with port- and payload-based systems. More precisely, machine learning approaches can classify Internet traffic based on application-neutral traffic data. When it comes to how long it takes to send and receive a particular message, there are several variables that may be taken into consideration. Furthermore, it has the potential to minimize computing costs while also making it easier to identify encrypted traffic.

There are two main applications for network forensics. The first, which focuses on network security, is keeping an eye out for unusual traffic patterns and spotting breaches. On a hacked system, an attacker may be able to delete all log files. Consequently, network-based evidence may be the sole evidence accessible for forensic investigation in this situation. Law enforcement can also take advantage of network forensics by interpreting human communication represented through e-mails or other forms of electronic correspondence and reassembling transmitted information, looking for keywords, and so on [7].

Today's world is evolving at a rapid pace, and the internet is critical for quicker communication between people or machines, faster transactions, and faster fulfillment of duties (tasks). However, the internet is also a major victim of cybercrime. Transactions over the internet are the main draw for attackers. To do this, we need a forensic technology known as "Network Metadata" to help us identify the perpetrators of cybercrime and their methods of attack. Network Metadata is a sub-field of digital forensics research that deals with computer networks. The collection of network traces from the victim system for examination is a common practice in network forensics, whether the crime has been discovered or after it has been committed. The evidence gathered can be used to bring the perpetrator to justice in a criminal court of law. While digital forensics involves the examination of static data, network forensics involves the examination of volatile and dynamic data [8].

III. RELATED WORK

The study [9] establishes a network intrusion criminal system based on the switching scheme (NIFSTC) that may detect criminality in networked situations and identify digital evidence automatically. The advantage of NIFSTC is that it does not require a standard forensic network to be built, hence it has superior detection performance in practice than traditional approaches. For the most modern network forensic methodologies, the KDD Cup Experiment Series 1999 dataset shows NIFSTC's highest true positive (TP) and lowest rate false positive (FP) .

The authors [10] introduced SPIE (Source Path Isolation Engine) in this regard, which calculates the first eight bytes of the payload and packet digests (i.e. hashes) from the header. A brief period of time is allowed for the digestion of these digests in a bloom filter. If a third-party device, such as an IDS or a firewall, identifies suspicious activity, SPIE can be used to track down the source of a packet.

In the research [11], the focus is on the security risks of the botnet through which DDoS attacks, worms and spam attacks

are implemented. For network security forensic investigation, the researchers recommended the design and implementation of a cloud-based security center. Also, cloud storage is used to store the acquired traffic data, which is then processed utilizing cloud computing.

A tool that explores the architecture of the network forensic is proposed in [12], which is called NetFo (Network Forensic) analysis tool. It captures packets using Winpcap technology and It can be used as a monitoring and management tool. NetFo can discover session information, keywords, bookmarks, hostnames, IP addresses, and other information.

As explained in [13], due to many requirements that were not addressed in this design space, developing a forensic network architecture is a complex task.

The authors [14] present a real-life case study in which they reconstruct a crime scene in relation to a victim's previous Facebook session using digital evidence collected and analysed via access to a desktop computer's RAM, with a focus on some distinct chains that could be used to reconstruct a previous Facebook session.

Huaxin et al. [15] developed a framework for extracting four types of characteristics from real-world Wi-Fi data, as well as supervised machine learning approaches for estimating user demographics. The study was based on Wi-Fi traffic information from 28,158 users during a five-month period. According to the testing results, the best accuracy in predicting gender and education level is 82% and 78%, respectively. Users' demographics may be predicted with a precision of 69% and 76% utilizing HTTPS traffic, even in encrypted transmission (i.e., across the internet). Being forensically prepared increases the degree of security in both cloud and on-premises computing. As a result, research in the fields of cloud and network security may also apply to IoT-centered forensics investigations. After all, traditional computer networks and Internet of Things (IoT) networks are also vulnerable to security flaws. Because IoT systems interact with the physical environment more frequently than traditional systems, they are susceptible to a greater number of physical and digital dangers. As a result, the work introduced in [16] was dedicated for securing the IoT domain.

The authors in [17] provided an overview of forensic advancements related to the IoT as well as the remaining hurdles. They focused on the taxonomy and criteria in the IoT Forensics. However, they did not discuss historical and current frameworks, standardization and certification difficulties in the IoT Forensics.

IV. THE PROPOSED MODEL

The ML models are becoming widespread in recent years because of mitigating a variety of complex relationships and acquiring the most favorable solutions by general evolution. The ML models have the ability to discover nonlinear relationships and complex functions among independent and dependent variables based on processing and classifying the data through training. An ML technique is comprised of algorithms with many models based on artificial intelligence. In this paper, five ML classifiers are used and compared in terms of the highest accuracy.

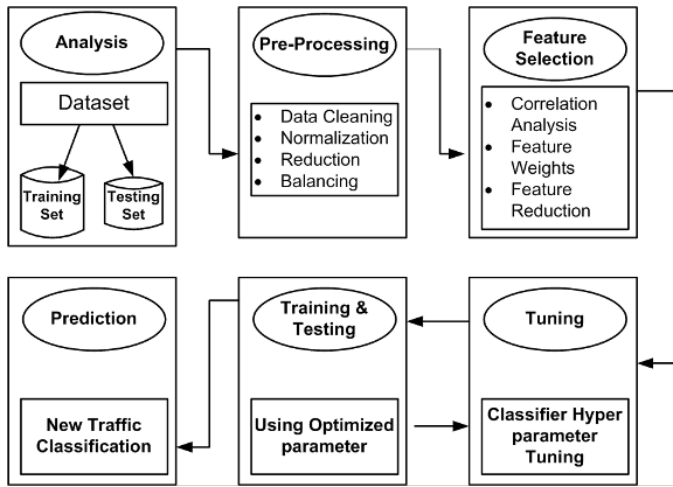

Fig. 1. The Proposed Model based on Machine Learning

Fig. 1 depicts the overall layout of the proposed framework based on machine learning approaches for network anomaly detection. It represents the phases that the model goes through and includes a large number of distinct processes. In the first phase, the dataset is analyzed and split into training and testing sets. For both training and testing, the attribute vectors are sliced in a 70:30 ratio. Next, in the pre-processing phase, the dataset is cleaned, features containing categorical data are normalized, and records including incorrect data are removed. Following, in the feature selection phase, the features are analyzed according to their weights and we choose most important features to define the attacks. Next, in the tuning phase, parameters of chosen classifier are tuned and optimized using a grid search. At the end, the optimized classifier is used for training and testing datasets, which are used for prediction of new traffic records.

A. Dataset

Data are the most valuable asset to develop an efficient intrusion detection system. CICIDS2017 [18] is the most recent intrusion detection evaluation dataset. It was created by the Canadian Institute for Cybersecurity at the University of New Brunswick. The CICIDS2017 dataset was constructed using the Network Traffic Flow analyzer. It was captured over a duration of 5 days over which 83 features and 15 classes were captured [19]. One of these classes represents the normal network traffic (defined as Benign) while the other 14 represent anomaly traffic (called Attacks). The names and numbers of these classes are shown in Table I. Compared to older and traditional datasets, such as KDD-99 [20], DARPA 98/99 [21] and ISCX2012 [22], CICIDS2017 dataset has the following advantages:

- Cover the current trends of attacks.
- Represent real-world data.
- Datasets are labelled.
- Attacks based on many protocols are included, such as HTTP, HTTPS, FTP, SSH, and email protocols.

For these reasons, the CICIDS2017 dataset is selected.

TABLE I. NUMBER OF STREAM RECORDS FOR ATTACK TYPES IN THE CICIDS2017 DATASET

Attack Type	Records
BENIGN	2359087
DoS Hulk	231072
PortScan	158930
DDoS	41835
DoS GoldenEye	10293
FTP-Patator	7938
SSH-Patator	5897
DoS slowloris	5796
DoS Slowhttptest	5499
Bot	1966
Web Attack – Brute Force	1507
Web Attack – XSS	652
Infiltration	36
Web Attack – Sql Injection	21
Heartbleed	11

B. Data Pre-Processing

As explained in the last section, the CICIDS2017 dataset contains 3119345 stream records and 83 features containing 15 class labels (one for normal traffic and 14 for attacks). To ensure that the dataset is ready to be trained, we need to clean and normalize it.

As most of the datasets, CICIDS2017 dataset contains some undesirable elements that must be removed. In CICIDS2017 dataset, because the network traffic was collected using the CICFlowMeter tool, some flag features have constant values (0 or 1), such as “Bwd URG Flags” and “Bwd P SH Flags”. These features were removed from the dataset because they have no impact on model results and to decrease the memory footprint of the dataset. Next step in the preprocessing phase is removing records that have missing class label, missing information, and invalid values such as “NaN” or “Inf”. After examining these records, 288602 records were removed.

If the dataset used for training of a classifier or detector suffers from high class imbalance problem, the classifier biases towards the majority class. As a result, the classifier shows lower accuracy with higher false alarm. Unfortunately, CICIDS2017 data set is prone to high class imbalance, as shown in Table 1. Therefore, to avoid this problem, the normal traffic records have been down sampled. In addition, to improve prevalence ratio and reducing class imbalance issue, few minority classes have been merged, such as Web Attacks. Therefore, the new dataset was partitioned into 70% for training (1571510 records) and 30% for testing (471453) sets.

C. Feature Selection

The goals of feature selection are to identify and remove unneeded, irrelevant and redundant features from the dataset. This help reduce the complexity of the predictive model without compromising its accuracy. Feature selection helps define most important features for detecting attacks on the dataset. First using correlation test, some features are removed from the dataset to reduce its size and enhance the performance.

Fig. 2 shows the correlation matrix, which shows the value of the correlation of variables and features with each other, which negatively or positively affects them. A correlation

Fig. 2. Correlation Matrix

matrix is simply a table that displays the correlation coefficients for different variables. The matrix depicts the correlation between all the possible pairs of values in a table. It is a powerful tool to summarize a large dataset and identify and visualize patterns in the given data. Each cell in the table contains the correlation coefficient between the features that scales from 0 to 1. If the coefficient approaches 1, it means that it is more positive, meaning that both features have an impact on the prediction process, and whenever the value approaches 0, it means a negative correlation that does not benefit us in the process of prediction, and they have no effect.

By analyzing the correlation matrix, we found a strong correlation between the following features: (Fwd IAT Std, BwdIATMean), (Bwd Header Length, Fwd Header Length) and (Bwd Header Length, Subflow Fwd packets). Therefore, we delete the features that are not needed.

After removing correlated features, we still have large number of features. We need to use feature selection methods to determine the importance of a certain features in the detection of anomalous traffic. There are several feature selection methods in the literature, such as Fisher Score, T-Score, chi-squared tests, random forest, or regression. Using these five feature selection methods, each feature is given a weight of importance as to how useful they are. These weights of features are compared and sorted. Fig. 3 shows the most 10 important features that are used for training and testing in the proposed model.

V. RESULT AND DISCUSSION

In this section, the results will be presented and discussed based on the proposed machine learning techniques.

Fig. 3. Important Features

A. Data Classification Methods

In artificial intelligence, machine learning is regarded as a subfield. Automatic classification [[23], [24]] is one of interested subjects for machine learning. In order to handle classification difficulties, automatic learning employs a variety of methods that group homogenous classes of comparable data items together. In order to train the decision rule and develop a classifier, supervised learning is adopted. ML can be used to create a predictive model to detect unknown attacks in network traffic. However, one important problem in ML is to identify and select the most relevant feature characteristics, from which to build a specific model based on training data for a particular classification job [[24], [25],[26]].

Classification is a logical choice for doing predictions with discrete known outcomes when using a machine learning technique such as classification. Items are classified using a classification technique, which is a set of exact rules for categorizing objects based on the quantitative and qualitative factors that characterize the objects. There are a variety of goals for which data categorization is performed, the most prevalent of which is to assist with data security challenges, particularly in anomaly detection [[27], [28], [29]].

In this work, we adopted using five classifiers to categorize the network, which are: the Random Forest, Logistic Regression, Decision Tree Algorithm, SVM, and the k-nearest neighbors. The findings were then compared using performance metrics and classification reports. Through the optimization of the classifier, training and testing process are repeated, where the behavior of the classifier is changed until the intended behavior is accomplished.

B. Performance Measures

To evaluate the performance of the suggested classification methods for anomaly detection, we adopted the following measures: accuracy, recall, precision, and F1 Score. The confusion matrix is utilized to separate the prescient execution of the classification in the test data.

Fig. 4 shows a template for a binary confusion matrix that uses the four kinds of results: (true positives (TP), false negatives (FN), false positives (FP), and true negatives (TN)) along with the positive and negative classifications. The following measurement metrics are used to measure the performance of a dataset:

- 1) Accuracy calculates predicted observation ratios for

		Predicted condition	
		Positive (PP)	Negative (PN)
Total population = P + N			
Actual condition	Positive (P)	True positive (TP)	False negative (FN)
	Negative (N)	False positive (FP)	True negative (TN)

Fig. 4. Confusion Matrix

TABLE II. RESULT OF COMPARE BETWEEN CLASSIFIERS

Algorithm	Accuracy	Recall	Precision	F1 Score
K-Neighbors	95.84	97.51	95.84	97.84
Logistic regression	96.51	97.95	98.45	98.20
SVM	93.69	96.43	96.84	96.63
Decision Tree	97.11	98.31	98.69	98.50
Random Forest	98.63	98.82	99.80	99.31

total observations:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

- 2) Recall is the ability of the proposed model to detect the attacks. Recall can be calculated from the number of detected attacks rather than the number of actual attacks.

$$Recall = \frac{TP}{TP + FN} \quad (2)$$

- 3) Precision is the ratio of predicted positive to total positive observed predictions.

$$Precision = \frac{TP}{TP + FP} \quad (3)$$

- 4) F1 Score is the average of recall and precision values.

$$F1Score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (4)$$

C. Experimental Results

Table II and Fig. 5 show the results of applying five different machine learning techniques for classifying different types of attacks. Fig. 5 shows the confusion matrix for all algorithms. Table II shows the accuracy, precision, recall, F1 Score for each algorithm.

From the Table II, we can notice that the best algorithms are Random Forest and Decision Tree. This is because they have a high accuracy and precision rates. The worst algorithm is K-Neighbors because it had lower accuracy and precision rates.

VI. CONCLUSION AND FUTURE WORK

An intrusion detection system is an important protection tool for detecting complex network attacks. In this work we have developed a new model for network intrusion (anomaly) detection based on machine learning algorithms. The proposed

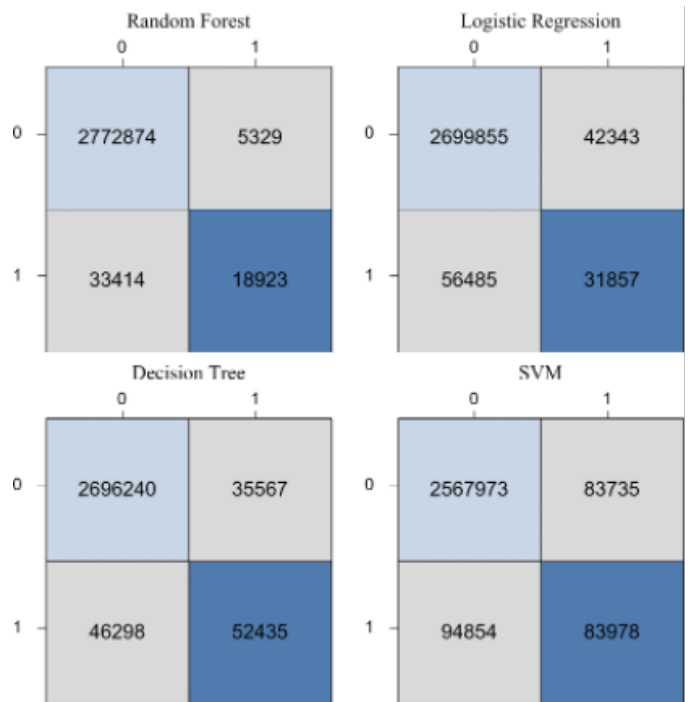

Fig. 5. Confusion Matrix for different Classification Methods

model consists of six phases: dataset analysis, pre-processing, feature selection, parameter tuning, training and testing. Using the proposed model, five machine learning algorithms have been investigated for classification of network anomaly detection, which are: K-neighbors, logistic regression, SVM, decision tree and random forest. The performances of these ML algorithms have been observed on the basis of their accuracy, recall, precision and F1 score. The dataset CICIDS-2017 has been used for training and testing, which consists of seven different types of attacks. According to results, compared to other ML algorithms, the performance of the random forest algorithm is better. This is because it has achieved the highest accuracy and precision rates for classification of anomaly detection, which are 98.63% and 99.80, respectively. Compared to related work, the performance of the proposed model is better. This is because of: (1) The dataset was carefully cleaned by removing noise and outlier data and solving imbalance issues. (2) The proposed feature selection technique removed correlated and irrelevant features from the dataset. (3) Parameters of chosen classifier are tuned and optimized using grid search. As a future work, we will investigate other machine learning and deep learning algorithms for network anomaly detection.

ACKNOWLEDGMENT

The authors would like to thank The University of Tabuk for providing research support and facilities.

Correcting Arabic Soft Spelling Mistakes using BiLSTM-based Machine Learning

Gheith Abandah, Ashraf Suyyagh, Mohammed Z. Khedher
Department of Computer
Engineering
University of Jordan
Amman, Jordan 11942

Abstract—Soft spelling mistakes are a class of mistakes that is widespread among native Arabic speakers and foreign learners alike. Some of these mistakes are typographical in nature. They occur due to orthographic variations of some Arabic letters and the complex rules that dictate their correct usage. Many people forgo these rules, and given the identical phonetic sounds, they often confuse such letters. In this paper, we investigate how to use machine learning to correct such mistakes given that there are no sufficient datasets to train the correction models. Soft errors detection and correction is an active field in Arabic natural language processing. We generate training datasets using proposed transformed input approach and stochastic error injection approach. These approaches are applied to two acclaimed datasets that represent Classical Arabic and Modern Standard Arabic. We treat the problem as character-level, one-to-one sequence transcription problem. This one-to-one transcription of mistakes that include omissions and deletions is possible with adopted simple transformations. This approach permits using bidirectional long short-term memory (BiLSTM) models that are more effective to train compared to other alternatives such as encoder-decoder models. Based on investigating multiple alternatives, we recommend a configuration that has two BiLSTM layers, and is trained using the stochastic error injection approach with error injection rate of 40%. The best model corrects 96.4% of the injected errors and achieves a low character error rate of 1.28% on a real test set of soft spelling mistakes

I. INTRODUCTION

Arabic is one of the world's five major languages with over 290 million native speakers and a total of 422 million world speakers [1], [2]. Arabic is the fourth most common language on the Internet [3], [4] and the fastest growing language online [3]. A recent British Council report [5] ranks Arabic as the fourth needed language for the future based on economic and market factors, diplomatic and security priorities, mobility, tourism, and public interest.

The Arabic language has 28 letters which we show alongside their Unicode encoding in Table I. Of the 44 letters and diacritics listed, eight are letter variants: 0621–0626, 0629, and 0649.¹

Western linguists distinguish between two forms of standard Arabic: Classical Arabic (CA) and Modern Standard

Arabic (MSA). CA is the language of the Quran, ancient religious and liturgical texts, and old Arabic literature. MSA is the modern form that is syntactically, morphologically, and phonologically based on CA. MSA is the primary form of Arabic language used in education, business, media, news, and drafting laws and regulations. The contrast between MSA and CA “is mostly reflected in topic, vocabulary, and style rather than grammatical structure” [7].

Arabic is a diglossic language and Arabic linguists and speakers refer to both CA and MSA as *al-fusha* الفصحى to differentiate between the standard forms and the colloquial variants spoken throughout the Arab world. These dialects are not standardized and vary significantly socially and geographically. Furthermore, they are widely popular in use on social and messaging applications as well on the Internet [8].

The U.S. state department categorizes Arabic among the exceptionally difficult languages to learn for native English speakers [9]. Consequently, it is vital to develop and modernize automated tools that aid native speakers and learners alike in communicating in Arabic using correct grammar and spelling, especially in online communication. To this end, our previous work [10], [11], [12] investigated machine learning and hybrid approaches for Arabic text diacritization with recurrent neural networks (RNN). This novel work investigates Arabic text correction using RNN in contrast to traditional techniques.

Research efforts have normally focused on a subset of the typical spelling and writing mistakes encountered in Arabic texts; usually by addressing one or two at a time. We target in this work the most common type of spelling mistakes, which is the soft spelling mistakes.

A. Soft Spelling Mistakes

Soft spelling mistakes are a special type of lexical and semantic errors that are due to the orthographic variations of some Arabic letters. For example, at the beginning of a word, the Arabic letter *alef* - comes in bare *alef* and *alef with hamza* forms: *alef with madda above*, *alef with hamza above* and *alef with hamza below*. The former bare *alef* shape is called همزة وصل (*hamzaï wasl*) while the *alef* with *hamza* above or below is called همزة قطع (*hamzaï qat*). Replacing one form of *alef* with another is a major case of soft-spelling mistakes [13].

Despite having standard rules for the shape and placement of the *hamza* inside the word, or as known in Arabic الهمزة المتوسطة (*al-hamzaï al-mutawsitaï*); these rules are quite

¹The transliteration used in this paper is Romanization using Glosbe transliteration tools [6].

TABLE I. ARABIC LETTERS AND DIACRITICS IN THE UNICODE ARABIC CODE BLOCK

E	خ	khah			◌◌◌◌◌◌◌◌	fatha		
F	د	dal			◌◌◌◌◌◌◌◌◌◌◌	famma		

complex for natives and learners alike. We can write the middle *hamza* above an *alef* as in the noun ‘head’ رأس (*rās*), or above the letter *waw* as in the noun ‘vision’ رؤية (*rūyāi*), or on a mark نبرة (*nabiri*) as in the noun ‘well’ بئر (*bīr*), or standalone *hamza* form as in the noun ‘reading’ قراءة (*qirāʿai*). We can determine the correct spelling by examining the diacritics of the *hamza* itself and those of the preceding letter. Some exceptions do apply.

Similar Arabic spelling rules dictate how we write the *hamza* at the end of a word, which is called الهمزة المتطرفة (*al-hamzaʿi al-mutaṭarifai*). We can write the *hamza* above an *alef* as in the noun ‘refuge’ ملجأ (*maljā*). We can place it above a *waw* as in the verb ‘to dare’ يجرؤ (*yajrū*) or over the *alef maksura* as in the noun ‘ports’ الموانئ (*al-mawaṅi*). Finally, it can rest alone as in the noun ‘warmth’ دفء (*dif*). Clearly, the shape that the *hamza* takes based on its possible placement within a word could be quite confusing.

There are other notorious examples in the soft misspellings category that are not necessarily related to the *hamza*. These include inserting or omitting the *alef* following a *waw* letter at the end of a word. A common example for the insertion error is adding an *alef* at the end of present tense verbs that end with a *waw*; such as writing the verb ‘to kneel’ as يجثوا (*yajthwa*) instead of يجثو (*yajthw*). We frequently encounter the omission error while spelling conjugated imperative plural verbs. For example, in the imperative sentence ‘Don’t look’ addressing a group of people, the verb can be incorrectly spelled as لا تنظرو (*la tanzurw*) instead of لا تنظروا (*la tanzurwa*).

Furthermore, common soft misspellings include confusing the *teh marbuta* at the end of the word for a *teh*. One example is writing the noun ‘watches’ as ساعة (*saʿai*) instead of ساعات (*saʿat*). The *teh marbuta* is also often confused for the letter *heh* as in the word for library مكتبة/مكتبة (*maktabai/maktabah*).

Finally, due to the similar shapes between the letters for *alef maksura/yeh* written at the end of Arabic words, we can see the letters mistakenly interchanged as in the adjective ‘interactive’

تفاعلي/تفاعلي (*tafaʿuly /tafaʿuly*). The correct shape of the *alef* at the end of a word is dictated by grammatical rules based on the Arabic word root system. Many people forgo the rules, and given the identical phonetic sounds, the *alef maksura* and the *alef* are often written one for the other. To illustrate, the correct spelling for the singular masculine past tense of the verb ‘to cry’ is بكى (*baky*) where it is often misspelled as بكا (*baka*). In contrast, the singular masculine past tense of the verb ‘to forgive’ is عفا (*ʿafa*) and it is misspelled as عفى (*ʿafy*).

Al-Ameri [14] analyzed the frequency of Arabic spelling mistakes in a sample of Teacher Education Institutes attendees. Table II summarizes the most common soft-spelling errors encountered in his study. We notice that the majority of reported errors relate to typographical errors due to phonetic mistranscription (*i.e.*, mistaking a diacritic for a letter or vice versa, phonetically close letters); errors due to *hamza*; and finally confusing the end *alef* or *teh* for other orthographic forms or letters.

It is worth noting that the lack of a common and sufficiently large enough benchmark dataset for Arabic spelling errors has hindered the continuous progress in the field of Arabic spelling errors detection and correction. This holds for both classical and modern standard Arabic sets. Many of the existing sets suffer from the lack of proper and comprehensive annotation, variety, and consistency. For example, within the same set, one can find texts that are fully diacritized while others have minimal or lack diacritization altogether. The lack of annotation makes the tasks of mapping the dataset texts to grammatically sound and misspellings-free texts difficult. Many times, researchers spend cumbersome manual effort in preparing sets for study. Other times, it is easier to introduce artificial mistakes from known correct texts. While this could work most of the time; the injection of artificial errors might not necessarily correspond to the real errors made by language speakers and learners alike.

TABLE II. THE FREQUENCY OF SOFT SPELLING ERRORS ANALYZED IN AL-AMERI STUDY [14]

No.	Spelling Error Type	%	Wrong Spelling	Correct Spelling
1	Writing <i>middle hamza</i> on an <i>alef</i>	73%	قراءة (qirāʾi)	قراءة (qiraʾi)
2	Writing <i>alef maksura</i> instead of <i>alef</i>	71%	عفا (ʿafy)	عفا (ʿafa)
3	Writing <i>alef</i> instead of <i>alef maksura</i>	70%	بكا (baka)	بكي (baky)
4	Omitting <i>alef</i> following a <i>waw</i> at the verb end	67%	لا تنظرو (la tanzurw)	لا تنظروا (la tanzurwā)
5	Writing <i>teh</i> instead of <i>teh marbuta</i>	67%	كثرت (kathrat)	كثرة (kathari)
7	Writing <i>middle hamza</i> on <i>waw</i>	64%	المروؤة (al-murwʾat)	المروءة (al-murwʾai)
8	Writing <i>hamza</i> at the end of the word on <i>alef</i>	51%	أشياء (ʾashyaʾ)	أشياء (ʾashyaʾ)
9	Writing a standalone <i>hamza</i> at the word end	47%	خطء (khatʾ)	خطأ (khatʾa)
10	Writing <i>hamza</i> at the end of the word on <i>yeh</i>	47%	شيء (shayʾ)	شيء (shayʾ)
11	Dropping <i>lam</i> before a “solar letter”	38%	اسماء (asmaʾ)	السماء (al-sāmaʾ)
12	Writing <i>teh marbuta</i> instead of <i>teh</i>	37%	ساعة (saʿat)	ساعات (saʿat)
13	Writing <i>middle hamza</i> on <i>yeh</i>	30%	يتفائل (yatafaʾal)	يتفائل (yatafaʾil)
14	Writing <i>hamzaʾi qaṭʿ</i> instead of <i>hamzaʾi waṣl</i>	28%	ابن (abn)	ابن (abn)
15	Inserting <i>alef</i> after <i>waw</i> at the end of a word	25%	يحيثوا (yajithwā)	يحيثو (yajithw)
16	Confusing <i>teh marbuta</i> and <i>heh</i> at the word end	*	مكتبه (makatabh)	مكتبة (maktabaʾi)

* Common mistake yet not reported in this study

B. Approach and Contribution

In this paper, we propose using a tuned bidirectional long short-term memory (BiLSTM) recurrent neural network to detect and correct spelling mistakes written in either classical or modern standard Arabic. We target a subset of the most commonly encountered spelling mistakes in the Arabic language [14]. Mainly, errors in the soft misspelling category pertaining to *al-hamzat* (الهمزات), the different shapes of *alef*, and the common errors in shaping *teh* at the end of the word. We propose tackling the problem at the character-level and we propose letter conversion scheme that allows one-to-one training of the input sequences against the target sequences.

We propose and evaluate two approaches to train models to correct these mistakes. In the *transformed input* approach, the network is trained to predict correct spelling from transformed unified input. Whereas the *stochastic error injection* trains the network to correct randomly injected spelling mistakes. We recommend best configuration and approach based on evaluation on two training datasets and a sample of real mistakes.

We organize the rest of the paper as follows: In Section II, we survey the state-of-the-art techniques in detecting and correcting spelling mistakes in European, Indo-Iranian and the Arabic languages. In Section III, we review the basic concepts of recurrent neural networks, long short-term memory, and the sequence transcription problem. Section IV details the experimental setup used in this work, the datasets, the used training approaches, and the performance evaluation metrics. Section V presents and discusses the results of our experiments. We provide a summary and conclude the paper in Section VI.

II. RELATED WORK

The natural language processing community has an ongoing interest in spell checking and correction. Traditionally, post-OCR spell check and correction has been a driving force behind research and application. Yet, in the past decade, the proliferation of social media and the high reliance on instant messaging demand more efficient and accurate spell

checkers and on-the-fly accurate correction. The accuracy level of spelling and grammatical mistakes correction varies in maturity between different languages.

It is worth noting that research experiments have been usually evaluated based on artificially-created or proprietary corpora and less so on a corpus of authentic misspellings [15]. Moreover, generic spell checkers (GSCs), such as the ones packaged in popular text editors like Microsoft Word, are designed for native writers and as such fail to detect and correct mistakes commonly introduced by second language learners [16]. In an ever-interconnected world where hundreds of millions of people are bilingual and multilingual, designing accurate spell-checkers is more challenging. In this section, we review some of the most recent works in spelling correction for three world language groups.

A. Spelling Correction for European Languages

Whereas spelling correction for the English language is well-established compared to other languages, most of this research was evaluated on proprietary corpora of native English texts or well-formed texts with artificially injected errors. Yet, spelling correction of non-native speakers is far more challenging as they feature multi-character edits compared to a single-character edit produced by native speakers [17]. To this end, the authors in [15] developed a minimally supervised model based on contextual and non-contextual features. These features include orthographic similarity, phonetic similarity, word frequency, n-grams and word embeddings among others. Notably, they present and use a corpus of real-world learner essays from the TOEFL exam, and further test their model on out-of-domain medical notes. They report an accuracy level of 88.12% on the TOEFL set, and 87.63% on the medical set. The authors in [18] propose a nested RNN model for English word spelling error correction. They generate pseudo data based on phonetic similarity to train the network. Their proposed system has a precision of 71.77%, a recall rate of 61.26%, and an $F_{0.05}$ score of 69.39%.

D’hondt *et al.* [19] employ many-to-many character sequence learning network using LSTM for French text cor-

rection. Their model stacks two LSTM layers: an encoder layer that reads the sequence of characters, and a decoder layer that generates the output. They further use a drop-out layer to enhance performance. They train and evaluate their system on a dataset of OCRed French medical notes using two models that introduce noise and confusion into the text. They report an accuracy rate of 73% for the former and 71% for the latter model. The same authors extended their work by using BiLSTM [20], and used various corpora based on structured English, structured French, and free-text French with artificially corrupted strings. They report accuracy rates no less than 85% for the structured English and French, and 60% for the free-text French. They show that for an original text with a character error rate (CER) of 34.3%, the BiLSTM system reduces the CER to 7.1%.

B. Spelling Correction for Indo-Iranian and Asian Languages

Dastgheib *et al.* [21] introduced Perspell; a semantic-based spelling correction system for the Persian language which is based on an n-gram model. Perspell handles both real-word and non-word errors. The authors' experiments show that for non-word errors, the precision, recall, and F_1 score are 87.7%, 88.9%, and 88.3%, respectively; while for real-word errors, the authors report a precision of 92.4%, a recall rate of 93%, and an F_1 score of 92.6%.

More recently, Yazdani *et al.* [22] use dictionary-based methods to detect word misspells. They rely on a generic Persian dictionary and a specialized medical dictionary as their system is oriented towards health care applications, specifically ultrasound reports. They employ an n-gram model to dictate suggestions based on orthographic and edit distances. They test their system on actual ultrasound free-text reports and achieve a detection performance of up to 90.29% and a correction accuracy of 88.56%.

Salavati *et al.* [23] introduce Rênûs, a spell checker for the Sorani dialect of the Kurdish language. The error detection phase in Rênûs is based on an n-gram frequency model, and the error correction phase is based on the edit distance, as a measure of similarity and frequency. The authors carried out experiments to investigate error correction once with the use of lexicon and another without. They report a correction accuracy of 96.4% for the former and 87% for the latter case.

The work in [24] introduces the SCMIL system which stands for sequence-to-sequence text correction model for Indic languages. SCMIL uses an attention model with a bidirectional RNN encoder and attention decoder. The decoder is trained end-to-end and it has a character-based representation on both encoder and decoder sides. They have synthesized a dataset from the Hindi and Telugu languages with data lists comprised of a maximum of five words. They subsequently introduced errors which include insertion, deletion, substitution, and word fusion. The authors show that SCMIL has an accuracy rate of 85.4% for the Hindi language and 89.3% for the Telugu language.

Zhang *et al.* [25] proposed a system for Chinese spelling error detection which consists of a network for error detection and a network for error correction based on BERT. The two networks are connected to each other through a technique they called soft-masking. For a training set of five million examples,

the authors' error detection system achieved an accuracy of 80.8%, a precision of 65.5%, a recall of 64% and an F_1 score of 64.8%. The error correction system; however, achieved an accuracy of 77.6%, a precision of 55.8%, a recall of 54.5% and an F_1 score of 55.2%.

C. Spelling Correction for the Arabic Language

Most recent works for Arabic spelling detection and correction still use traditional techniques in the field of natural language processing (NLP). For example, the authors in [26] introduced a spell checker which targets both lexical and semantic spelling mistakes. He uses a sequential combination of approaches including lexicon-based, rule-based, and statistical-based methods. He achieves an F_1 score of 67%.

Al-Shneifi *et al.* [27] developed a cascade system called Arib that detects and corrects a range of spelling errors. Errors that are discovered by Arib include: edit, add, split, merge, punctuation, phonological, and other observed common mistakes. They employed two core models: a probabilistic model based on Bayes probability theory and a Levenshtein distance-based model. They further add three extra models; two of which are based on 3rd party error detection tools: MADAMIRA and Ghaltawi, and the third additional module is a rule-based correcter derived from analyzing samples of the QALB database. Overall, Arib has an F_1 score of 57.8%, and precision and recall rates of 66.6% and 51.1%, respectively.

Mubarak and Darwish [28] also used a cascaded approach for word-level errors, followed by punctuation correction. For word-level correction, the authors used a statistical character-level transformation model and a language model to handle letter insertions, deletions, and substitutions and word merges. The author subsequently use a case-specific system aided by a language model to handle specific error types such as dialectal word substitutions and word splits. For punctuation recovery, the authors employ a simple statistical word-based system and a conditional random fields sequence labeler (CRF). For different experiments, the authors were able to achieve a precision rate up to 71.7%, a recall rate up to 60.32%, and an F-measure up to 63.43%.

Bouamor *et al.* [29] introduced another hybrid system that is based on a morphology-based corrector; rule-based linguistic techniques, language modeling, statistical machine translation (SMT), as well as an error-tolerant finite-state automata method. They target common error types which include split, delete, edit, merge, move and add errors based on the 2014 QALB set. They report an F_1 score of 68.4%.

Noaman *et al.* [30] developed a hybrid system based on the concept of confusion matrix and the noisy channel spelling correction model. They automatically detect and correct Arabic spelling errors of the edit and split types based on the QALB dataset. They report a word error correction rate up to 89.7%.

Zahui *et al.* [31] introduced Al-Mossahih tool that detects and corrects one-letter typographical and phonetic transcription errors. Their detection phase is dictionary-based where a collection of around two million words are sorted in alphabetical order. The correction module encompasses four techniques: one is based on a correspondence table between pairs of commonly confused characters, the second is permutation-based where all possible words from the word letters are

generated, the third is a neighborhood module which considers letters whose keys are nearby on the keyboard, and finally a language model that deals with word locations within a sentence. Al-Mossasih tool has a word error detection rate of 74.75% and a correction rate of 80.2%.

Semantic errors have been addressed by few recent works. A major approach is based on confusion matrices, which despite being powerful, they limit the number of errors that can be detected and corrected. Al-Jefri and Mahmoud [32] compiled a corpus of 7.4 million words from the set of words most confused by non-native Arabic speakers and from the set of mis-recognized words by Arabic OCR systems. The authors compiled these words into 28 confusion sets with assigned probabilities. Errors detection only targets words listed in the confusion matrices and error correction is based on picking the word with highest probability using the computed n-gram model. They report an average accuracy of 95.4%.

For non-confusion set-based approaches, Zribi and Ahmed [33] detected semantic errors through the use of four combined statistical and linguistic methods. They have introduced semantic errors on a set of sentences collected from economic articles from the Egyptian Al-Ahram newspaper. The semantic errors were all a single edit away from the correct word. The reported detection performance was 90% and 83% for precision and recall, respectively.

Rokaya [34] introduced a small variation into the previous method by using the power link method instead of traditional frequency to detect and correct semantic errors coupled with confusion sets as a hybrid approach. They only report results for the detection stage where their system achieves 94.35% and 85.57% for precision and recall, respectively.

More recently, Watson *et al.* [35] utilized sequence-to-sequence models and character and word embeddings for Arabic Text Normalization. Azmi *et al.* [36] combine the language model with machine learning in the detection stage. For the correction step, they only use a language model. They have used word n-grams as features which are subsequently fed into a support vector machine classifier (SVM) to detect and mark words with semantic errors. For the correction step, they generate candidate words which are one-edit distance away from the erroneous word. The candidates are ranked and sorted based on the n-gram language model and then they select the best suggestion accordingly. Their system has an F_1 score of 90.7%, and an precision and recall rates of 83.5% and 99.2%, respectively.

Alkhatib *et al.* [37] recently used an LSTM model to detect and correct spelling and grammatical mistakes at the *word-level*. Their model uses word-embeddings and a polynomial classifier. They report an F_1 score of 93.89%, and for morpho-syntactic mistakes pertaining to word form, noun number, verb form, and verb tense, they report a precision of 95.6% and a recall rate of 94.88%. Solyman *et al.* [38] employed CNNs for the automatic correction of Arabic grammar. After fine-tuning their different developed and tested models, the authors achieved a precision of 80.23%, a recall rate of 63.59%, and an F_1 score of 70.91. Kuznetsov and Urdiales [39] proposed a method of performing spelling correction on short input strings, such as search queries or individual words using denoising auto-encoder transformer model to recover the original query.

They used datasets for four languages and achieved an accuracy of 83.33% (Arabic), 91.83% (Russian), 93.97% (Greek), and 94.48% (Setswana).

III. MACHINE LEARNING AND SEQUENCE TRANSCRIPTION

A general definition of sequence transcription is the process of transforming an input sequence into a corresponding output sequence. Within the context of machine learning spelling detection and correction, the input sequence is the set of letters forming the text that may have spelling errors. The corresponding output sequence is the text on which the machine learning algorithm attempted corrections. Sequence transcription is quite common in similar problems in the fields of language translation, voice recognition and diacritizing Arabic texts [12]. In all these applications, we need to infer relationships and provide outputs depending on past input data. Therefore, the need to preserve correlations between data points in the sequence is necessary.

Recurrent neural networks (RNN) provide the capability to learn from data sequences and consequently infer relevant output data. In this section, and for the sake of completeness, we briefly review RNN and a special RNN network cell called long short-term memory (LSTM) that we adopted in this work. We will further provide details of how we handle and process the input sequence prior to its use in the LSTM network.

A. Basic Recurrent Neural Networks

In general, RNN maintain hidden states that are functions of previous input. This enables such networks to infer outputs from past sequences making them quite suitable for applications where we require sequence transcription. A standard RNN cell can be described by two equations that relate the input sequence $x_t \in (x_1, x_2, \dots, x_T)$ to the hidden states $h_t \in (h_1, h_2, \dots, h_T)$ and output sequence $y_t \in (y_1, y_2, \dots, y_T)$. Equations 1 describe the standard RNN model:

$$h_t = \sigma(W_h x_t + U_h h_{t-1} + b_h) \quad (1a)$$

$$y_t = W_y h_t + b_y \quad (1b)$$

where W , U , and b denote the weight and bias matrices. We can clearly observe that the current hidden state h_t depends on both the current input x_t and the previous hidden state h_{t-1} . The model uses a sigmoid function σ to limit the output within a prefixed range. Hyperbolic tangents \tanh , for example, limit the output to between -1 and 1 , whilst logistic sigmoid limits the output to between 0 and 1 . Both functions are often used in RNN among others. In this paper, we strictly use the σ symbol to denote a logistic sigmoid whilst we express the hyperbolic tangent as \tanh . As stated earlier, the hidden state equips the network model with the ability to learn from input sequences, remember past data and infer outputs.

However, if the input sequence is long, and the output data to be inferred depends on a much older (past) input data sequence (*i.e.*, the gap or the distance in sequence between the inferred output and relevant input data is large), RNN in its standard form might not be able to deliver an accurate desired output sequence. To this end, researchers developed the refined RNN cell which they called long short-term memory

Figure 1. Basic Structure of an LSTM Cell [41]

(LSTM) [40]. LSTM can handle much longer sequences as well as avoid an inherent problem in standard RNN: the vanishing gradient problem. The vanishing gradient problem halts the update of network weights when the gradient is too small; thus stopping the learning stage quite early resulting in a poor network model.

B. Long Short-Term Memory Cells

The internal architecture of an LSTM cell vastly improves on the basic RNN cell by incorporating a *set* of gates which govern the operation of each individual cell. These gates equip the cell with the capacity to work with short or long-term contexts. LSTM cells are relatively insensitive to long gaps or large distance between the output to be inferred and relevant old data in the sequence. Figure 1 illustrates the internal architecture of an LSTM cell. An LSTM cell has an *input gate I*, a *forget gate F*, an *output gate O*, and a *cell activation unit C*.

We provide the governing equations of these gates in Equations 2. For each gate type, we use the small letter notation to denote the output of the gate at time t :

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + V_i c_{t-1} + b_i) \quad (2a)$$

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + V_f c_{t-1} + b_f) \quad (2b)$$

$$c_t = f_t \circ c_{t-1} + i_t \circ \tanh(W_c x_t + U_c h_{t-1} + b_c) \quad (2c)$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + V_o c_t + b_o) \quad (2d)$$

$$h_t = o_t \circ \tanh(c_t) \quad (2e)$$

where W , U , V , and b denote the weight and bias matrices and the initial values for $c_0 = h_0 = 0$. The \circ operator denotes the Hadamard (element-wise) product. Similar to the basic RNN cell, an update to a short-term state h_t or long-term state c_t depends on the current input x_t , and previous short-term and long-term memory states h_{t-1} and c_{t-1} .

LSTM is likely to quickly over-fit the training data; thus rendering them less powerful in predicting correct outputs. Dropout is a computationally cheap way that reduces overfitting. It further improves generalization error and model performance in all deep neural networks. Dropout simply

TABLE III. LETTERS CONVERTED TO INTERMEDIATE CODES

implies probabilistically excluding nodes from activation and weight updates while training a network.

The bidirectional LSTM is a version of the LSTM architecture that exploits future contexts as well as past contexts. That is, in sequence transcription problems, it could be beneficial to have access to subsequent (future) sequences to infer correct current outputs. In BiLSTM, we couple the conventional unidirectional LSTM network that works with past sequences with another unidirectional network that works with future sequences. We train the former in a forwards fashion whilst the latter in a backwards fashion. The final output is a concatenation of both the forward and backward LSTM networks.

C. Sequence Processing and Data Encoding

We can classify RNN based on the relationship between the input and output sequence lengths into four types:

- *One-to-one* networks where the length of the input sequence matches the length of the output sequence.
- *Many-to-one* networks where input sequences are transcribed into one final output, for example classification problems.
- *One-to-many* networks where one input vector is used to produce an output sequence.
- *General many-to-many* networks where the number of items in the input sequence differs than that in the output sequence. We use encoder-decoder architectures to tackle these transcription problems by using an intermediary fixed-length vector. The encoder maps a variable-length source sequence to the intermediary fixed-length vector, and the decoder maps the vector representation to a variable-length target sequence.

We can model the Arabic spelling correction problem as a one-to-one problem. Intuitively, this should be straightforward as most soft Arabic spelling errors result from confusing shapes of الهمزات (al-hamzāt) or the similar sounding characters at the end of the word. Simple one-character replacement fixes the misspelled word. However, some of these soft mistakes fall under the addition/omission type. For example, the spelling error in cases 4 and 15 in Table II add or omit the *alef* at the end of the word after a *waw*. Similarly, case one corrects writing *middle hamza* on an *alef* (one letter) by writing it properly following an *alef* (two letters). These particular cases result in differing-length sequences. Ordinarily, the encoder/decoder RNN architecture handles this well, yet with extra cost and overhead.

To mitigate and simplify our approach, we propose a simple yet effective technique that maintains one-to-one sequencing by processing the input sequence stream prior to applying it to the neural network, and then post-processing the output sequence to restore readable Arabic form. We convert some letters and two-letter combinations to intermediate arbitrary codes of English letters, as specified in Table III. The conversion involves letters that are prone to the spelling mistakes under study: the combination *alef-hamza* (ء) and the letters at word ends (و, ه, ت and م). We emphasize that this conversion is positional in nature; that is; we convert the *waw-alef* combination (وا) to an 'A' only when it appears at word endings where the associated error frequently occurs. Should this combination appear in the middle, no conversion is performed. However, we convert the letter combination *alef-hamza* to 'J' wherever it occurs in the word. This combination is susceptible to soft mistakes both in the middle and at the end of the word.

In our machine training approach, we use this converted sequence as the target sequence and a copy of it as the input sequence after injecting some artificial spelling mistakes (refer to Section IV-B). These sequences are stored using the Unicode UTF-8 encoding. However, when presented to the neural network, they are put in 3D ($B \times T \times C$) tensors (dense matrices). Each tensor holds a batch of B sequences of a maximum length $T = 400$ characters. Note that we wrap sequences longer than 400 characters to improve training performance. The third dimension encodes each of the C distinct characters using one-hot encoding.

IV. EXPERIMENTAL SETUP

In this work, we use an experimental setup similar to the one used in our past research [42]. We list the specifications of the experimental platform in Table IV.

A. Machine Learning Model Configurations

We develop our machine learning models using Python deep learning libraries ensuring we use the latest versions of the algorithms. Specifically, we use Keras with TensorFlow at the backend. Given that we tackle the problem of Arabic spelling correction at the character level, we adopt BiLSTM RNN. These networks can handle longer sequences which can be beneficial for correcting misspelled words based on past and future context. We develop and compare three models. The baseline model has only two BiLSTM layers. We add an input masking layer before the two hidden BiLSTM layers, and connect their output to a fully-connected (dense) output layer, as shown in Fig. 2.

The second model maintains the same settings of the previous one but further employs the *dropout* method to reduce or avoid the over-fitting problem. The third and final model has four BiLSTM hidden layers instead of two and also uses *dropout*. We use the same configuration settings for the three models. Each bidirectional layer has 256 cells. We use the *softmax* as the activation function of the output layer and the *RMSprop* optimizer in training. We use categorical cross entropy as the loss function, and a batch size of 64 sequences with a sequence length of 400 while wrapping longer sequences similar to our work in [12]. To combine the forward and backward layers in our BiLSTM layers, we use

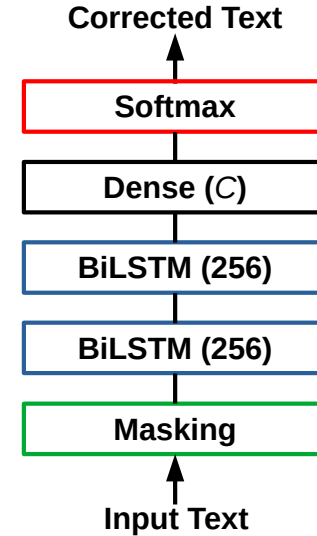

Figure 2. The Base 2-Layer Network Model

concatenation. For the models that use dropout, we use the base settings of dropout = 0.1 and recurrent_dropout = 0.3. We set the training time to a maximum of 50 epochs with early stopping and 5-epoch patience. We show the skeleton code of the 2-Layer model with dropout in Listing 1.

B. Data Sets

We use two widely used datasets for Arabic NLP [43], [44], [45], [46], [47], [48], [49] to train, validate, and test our proposed BiLSTM models. The first is a processed subset of the Tashkeela corpus as extracted in [50]. The second is from the Linguistic Data Consortium's (LDC) Arabic Treebank (LDC2010T08), specifically speaking: the Arabic Treebank Part 3 (ATB3) v3.2 [51]. We will now-forth refer to this dataset as ATB3 in this paper. The major difference between the Tashkeela and ATB3 datasets is the form of the Arabic text they consist of. Tashkeela mainly contains 55K sequences from classical Arabic texts. On the other hand, ATB3 contains samples of modern standard Arabic of 599 distinct news-wire stories from the Lebanese publication An-Nahar. We show in Table V the characteristics of the two datasets in terms of sequence count, word count, character count, average words per sequence, average letters per word, and fraction of sequences shorter than or equal to 400 characters.

In Table VI, we present the Arabic letters and their variations that account for the majority of the soft spelling errors that we presented in detail in Section I and cited in examples in Table II. We break them down in order of their absolute frequency within the dataset texts relative to the character count. We also break them down in terms of their relative appearance to each other within the same texts. This table demonstrates that about one fifth of the characters are involved in the common soft spelling mistakes under study and that the relative frequencies of these letters are highly skewed ranging from 0.13% to 58.23%.

We split the ATB3 dataset as proposed by Zitouni *et*

TABLE IV. EXPERIMENTAL PLATFORM SPECIFICATIONS

```

al. [52] such that we use the first 509 news-wire stories, in *chronological* order, to train the model and use the remaining 90 stories to validate and test the model. This accounts for 22,170 sequences for training and 3,857 sequences for validation. Similarly, we split the Tashkeela dataset into 50K lines for training, 5,000 lines for testing. In our previous work [12], we analyzed the best maximum sequence length to use based on the same datasets. We found that a maximum sequence of 400 characters provides the best speed versus accuracy trade off. We consequently adopt this sequence length in this work as well.

In addition to the above datasets, we test the proposed solutions using samples of real soft spelling mistakes (Test200). These samples were collected in a previous work [8] and are summarized in Table VII. They have a challenging collection of soft spelling mistakes with an average of 6.5 mistakes per sequence.

C. Training Approaches

We have experimented with the following two approaches to train BiLSTM networks to correct the soft spelling mistakes.

- 1) **Transformed input:** This approach trains the BiLSTM network to predict the correct form of the letters under study given unified transformed input. Once the sequences are converted to the intermediary form, as described in Section III-C, we transform the letters that are often confused with each other into one final

form. We show the used mappings of the letters affected by this transformation in Table VIII. All *hamza* forms are transformed to plain *hamza* (ء), the *heh* and *teh* forms at word ends are transformed to *teh marbuta* (ة), *waw-alef* at word ends are transformed to *waw* (و), and *alef* at word ends are transformed to *alef maksura* (ى).

- 2) **Stochastic error injection:** This approach trains the network to correct artificial errors randomly injected in the input sequences. We inject errors in the input sequence by replacing the target letters pertaining to the soft Arabic spelling mistakes. With an *error injection rate* p , a letter belonging to the four groups shown in Table VIII is randomly replaced by one of the letters in its group. For example, we replace *alef maksura* with an *alef* and vice versa (cases 2 and 3 in Table II). We have investigated using multiple error injection rates p as described in Section V. For example, 10% of the letters under investigation are replaced with $p = 10\%$.

D. Evaluation Metrics

We measure and evaluate the performance of BiLSTM networks using their computational time and multiple performance metrics, namely: *accuracy*, *precision*, *recall*, F_1 *score*, character error rate (*CER*), and word error rate (*WER*). These metrics are quite common [36], [50], [53], [54], [37] in evaluating the performance of solutions pertaining to error detection and correction, voice recognition, and similar sequence-based problems.

The first four measures are readily computed and understood through means of a simple confusion matrix that we will explain within the context of our work. At the character level, any character in any sequence can either be correctly spelled or not. When comparing the predicted outcome of our model with the actual (target) sequence, we can thus have four cases that we show in Fig. 3. For a certain character c , the counts of these four cases are:

TABLE V. TASHKEELA AND ATB3 DATASETS CHARACTERISTICS

Criterion	Tashkeela	ATB3
Sequence count	55K	26K
Word count	2,312K	305K
Character count	12,464K	1,660K
Words per sequence	42.1	11.3
Letters per word	4.0	4.6
Sequences \leq 400 chars.	84.1%	99.9%

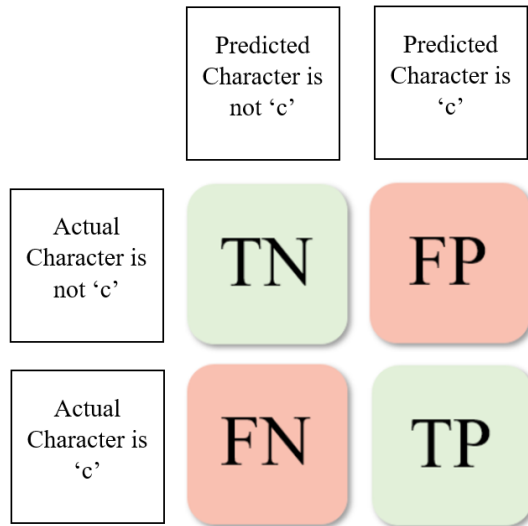

Figure 3. Confusion Matrix of Correct and Erroneous Characters between Predicted and Actual Sequences

- True positive (TP): The number of times character c is correctly predicted as c .
- True negative (TN): The number of times characters other than c are predicted correctly.
- False positive (FP): The number of times characters other than c are incorrectly predicted as c .
- False negative (FN): The number of times character c is incorrectly predicted as another character.

It is evident that we need our model to maximize the correct cases TP and TN (cases shown in green). We desire our model also to keep the incorrectly predicted characters FP and FN to a minimum (cases shown in red). This readily translates to the

TABLE VI. THE SUBSET OF TARGET ARABIC LETTERS (AND THEIR VARIATIONS) UNDER STUDY AND THEIR ABSOLUTE AND RELATIVE FREQUENCIES WITHIN THE DATASETS

Letter(s)	Frequency		Relative Frequency

آ	0.07%	0.08%	0.40%	0.41%
ء	0.07%	0.03%	0.37%	0.13%
ؤ	0.06%	0.14%	0.37%	0.69%
وا	0.04%	0.06%	0.34%	0.28%
Subtotal	17.85%	19.83%	100.00%	100.00%
Other chars.	82.15%	80.17%	0.00%	0.00%
Total	100.00%	100.00%	100.00%	100.00%

definition of the accuracy metric that we present in Equation 3:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

The precision metric is the ratio of correct predictions of character c to total number of characters predicted as c and is given by Equation 4:

$$Precision (P) = \frac{TP}{TP + FP} \quad (4)$$

The recall metric is the ratio of correct predictions of character c to the total count of actual c characters. Equation 5 mathematically defines the recall as:

$$Recall (R) = \frac{TP}{TP + FN} \quad (5)$$

The F_1 score combines the precision and recall metrics into one score by applying the weighted harmonic mean on both giving equal weights to each. We get the F_1 score using Equation 6:

$$F_1 = 2 \times \frac{P \times R}{P + R} \quad (6)$$

We additionally use a new metric (FP/Changes) to assess the prediction error rate with respect to the number of replacements in the input sequence. We divide the number of false positive cases of a letter over the number of times this letter was changed in the input sequence. The accuracy is reported in this work for the entire set of characters. Whereas, precision, recall, F_1 , and FP/Changes scores are reported as weighted averages of the target letters shown in Table VI.

We also evaluate our models using the character error rate (CER) and word error rate (WER). CER is the percentage of letters that are misspelled whereas WER is the percentage of misspelled words. A word is considered misspelled if it has at least one incorrectly spelled letter.

TABLE VII. TEST200 TEST SET OF REAL SOFT SPELLING MISTAKES

Criterion	Count
Sequence count	200
Word count	2,443
Character count	24,002

V. RESULTS AND DISCUSSION

This section presents the results of evaluating alternative network topologies and the two training approaches proposed above. This section also presents and discusses the detailed performance evaluation results.

A. Network Topology

We started by evaluating three network topologies: the base network of two BiLSTM layers, another that adds the dropout technique to the base network, and a third that extends the second network to having four BiLSTM layers instead of two. These three alternatives are inspired by experience from previous work, e.g., [42]. In this initial evaluation, we use the *transformed input* training approach. For each of these three networks, we use the Tashkeela and ATB3 sets to separately train two separate instances of the BiLSTM network; one trained for classical Arabic, and another for MSA Arabic. We repeat this procedure for the three networks using the same training sequences and compare their performance in terms of *accuracy*, *precision*, *recall*, and F_1 score on the test set.

In Fig. 4, we show these metrics for the networks trained with the Tashkeela set. Despite the results being marginally close, we concur that networks with the *dropout* technique employed perform generally better than the one without. We observe that there is no large difference between the performance of the 2-layer and 4-layer networks with dropout, with only a slight edge towards the 2-layer network. Fig. 5 similarly illustrates the same metrics but for the case when we evaluate the BiLSTM networks using the ATB3 set. We notice that our observations and conclusions for the Tashkeela set carry over to the ATB3 set. However, the accuracy with the ATB3 set is generally lower than the accuracy on the larger Tashkeela set.

We notice also that the accuracy is higher than the other three metrics because it is calculated for the entire character set while the other metrics are weighted averages of the target letters only. For the remaining experiments, and given the

slight performance edge and lesser complexity of the 2-layer BiLSTM network with dropout used, we conduct and evaluate the remaining experiments and report their results based on this model only.

B. Training Approach

In this section, we present the performance of the adopted 2-layer network on the two proposed training approaches: *transformed input* and *stochastic error injection*. The error injection rate p correlates with the network’s ability to correct errors. Therefore, we experimented with multiple rates, e.g., 2.5%, 10%, and 40%, alongside the transformed input approach.

For this evaluation, we show the results also in terms of *accuracy*, *precision*, *recall*, and F_1 score. Recall that these metrics are found not only from the letters that we actually changed, but also include the whole letters in the subset under study. Therefore, we expect that the inclusion of all the letters that could possibly be changed and those actually changed dilutes the results. For example, for the case when the error injection rate is 2.5%, we already know that a high percentage of the remaining 97.5% letters are correct and match the target output.

Despite the expected result dilution, we have to present these results for in most cases the analysis and the interest is in the overall output character sequence and that it should be error free. Given these disproportional ratios between unchanged letters and error-injected letters, we expect better performance with lower error injection rates. We indeed observe these results in Figures 6 and 7. The best performance appears here for the network with the smallest error injection rate of $p = 2.5\%$.

It is difficult to make solid conclusions about the two training approaches from the previous data alone. So we compare the two training approaches using the *FP/Changes* ratio. This allows us to observe more insights that we could not deduce from the diluted results in Fig. 6 and 7. We present

Figure 6. Performance of the Transformed Input and Stochastic Error Injection Training Approaches on the “Tashkeela” Set using the 2-Layer with Dropout Network. Three Error Injection Rates are Investigated.

Figure 8. The *FP/Changes* Ratio of the Two Training Approaches on the Tashkeela and ATB3 Sets.

Figure 7. Performance of the Transformed Input and Stochastic Error Injection Training Approaches on the “ATB3” Set using the 2-Layer with Dropout Network. Three Error Injection Rates are Investigated.

In Fig. 9 and 10, we show the character and word error rates for the proposed training approaches. These two metrics are global metrics similar to the accuracy. Therefore, they are generally low because most characters in the input are correct and only need to be passed to the model output as is. We present these metric as any application will handle entire sequences with possible spelling mistakes and attempt to provide an error-free version. Essentially, CER and WER are related so we expect a similar pattern for both. We expect this pattern to resemble that for the analysis presented in above, specifically, $1 - accuracy$. This is due to the ratio of already correct and unchanged characters that are in the input, predicted, and target sequences. Despite this, we observe that for both experiments on the Tashkeela and ATB3 datasets that in the worst case the CER did not exceed 0.36% while the WER did not exceed 1.88%. Referring to the analysis of the datasets that we show in Table V, we note that the average number of letters per word is 4.0 and 4.6 for the Tashkeela and ATB3 sets, respectively. The results we show for WER in Fig. 10 are approximately five times than those for CER in Fig. 9. This is in line with the letters per word statistic for these datasets under consideration.

this ratio in Fig. 8 for the Tashkeela and ATB3 sets. In this analysis, we easily see that increasing the error injection rate helps train the network to better detect and correct errors. For example for Tashkeela, we observe a decrease of the percentage of false positives from 14.4% to 3.6% as we increase the error injection rate from 2.5% to 40%. Despite the more errors introduced, the network was able to handle them well. In the case of transformed input, we even observe better performance. This is because transforming the most confused characters into one form is another way of introducing different errors into the network training.

C. Test200 Results

The above results are not conclusive about which training approach is best. Therefore, we used the BiLSTM models trained on the two training approaches to correct the mistakes in the Test200 set. We use the networks which we trained using the Tashkeela and ATB3 sets here. We report the CER of the predicted Test200 sequences on the eight training configurations shown in Fig. 11. Except for the 2.5% error injection rate, the two training sets provide results within 0.2% for each other. Yet, we note that despite that the reported CER for this external set is quite low, it is an order of magnitude higher than that reported for the test sequences of the Tashkeela and ATB3 datasets. This is because the BiLSTM models were trained using artificially injected errors that might not necessarily always correspond to errors committed by real-users. This

Figure 9. Character Error Rate of the Two Training Approaches on the Tashkeela and ATB3 Sets.

Figure 11. CER of the Two Training Approaches on the Test200 Set for Models Trained on the Tashkeela and ATB3 Sets.

Figure 10. Word Error Rate of the Two Training Approaches on the Tashkeela and ATB3 Sets.

stresses the need for a large Arabic corpora collected from real users, annotated, and corrected by linguistic experts to enrich the Arabic NLP research domain.

Fig. 11 shows also that training on the larger Tashkeela set gives better results and the transformed input and error injection with 40% rate are better than lower rates. The best results with only 1.28% CER is for the case when training using Tashkeela set and 40% error injection rate. To test whether increasing the error injection rate beyond 40% would further decrease CER, we experimented with higher rates (50%, 70%, and 100%). Fig. 12 shows that the model with $p = 40%$ performs best and yielded the least character error rate. Therefore, we recommend using error injection training approach with $p = 40%$. We further analyze the results of this approach in the following subsection.

Figure 12. CER of Test200 Set for Models Trained with the Stochastic Error Injection Approach and the Tashkeela Set as a Function of the Error Injection Rate p .

D. Confusion Matrix Results

Fig. 13 shows the confusion matrix for the predicted against actual of the Tashkeela test set of the letters under investigation. We present here this matrix for the best trained model (error injection with $p = 40%$) and Tashkeela set because it is the largest set we use. This matrix allows us to analyze the letters that our machine learning model mostly confuses with each other. While the majority of the letters are correctly classified and corrected (diagonal), most confusion occurs within the three terminal letters: *heh* (هـ), *teh* (تـ), and *teh marbuta* (ةـ), and *alef with hamza above* (أ) and *alef with hamza below* (إ).

		Predicted Letter													
		وا	ه	اء	و	ت	ء	آ	أ	ؤ	إ	ئ	ا	ة	ى
Actual Letter	وا	264	0	0	3	0	0	0	0	0	0	0	0	0	0
	ه	0	14,699	0	0	66	0	0	0	0	0	0	0	102	0
	اء	0	0	1,083	0	0	0	0	3	0	0	2	7	0	0
	و	9	0	0	3,888	0	0	0	0	0	0	0	0	0	0
	ت	0	123	0	0	2,242	0	0	0	0	0	0	0	30	0
	ء	0	0	0	0	0	381	0	0	0	0	0	0	0	0
	آ	0	0	0	0	0	0	359	25	0	2	0	2	0	0
	أ	0	0	3	0	0	1	20	13,660	19	79	6	31	0	0
	ؤ	0	0	0	0	0	0	0	15	315	0	17	4	0	0
	إ	0	0	0	0	0	0	6	75	0	5,358	1	3	0	0
	ئ	0	0	2	0	0	2	0	4	5	0	957	4	0	0
	ا	0	0	2	0	0	1	6	63	1	3	3	48,505	0	40
	ة	0	151	0	0	46	0	0	0	0	0	0	0	6,881	0
	ى	0	0	0	0	0	0	0	0	0	0	0	107	0	3,735

Figure 13. Confusion Matrix for the 40% Error Injection Training Approach on Tashkeela Test Set.

We list Examples 5, 12, and 16 of these common mistakes in Table II. For example, out of $(151 + 46 + 6,881 = 7,078)$ *teh marbuta* letters, 151 and 46 are wrongly predicted as *heh* and *teh*, respectively.

E. Model Timing

Finally, we report the timing metrics (training time and number of training epochs) of six selected configurations in Fig. 14 and 15 for Tashkeela and ATB3, respectively. In all cases, the training time for the Tashkeela set is between two to five times more than that for the ATB3. It took the longest to train the 4-layer network for both sets; 48.5 hours for Tashkeela and ATB3 using the transformed input approach, respectively. When training the network using variable error injection rate, we observe that the training time *generally* increases as this rate increases.

In these experiments, we set the maximum number of training epochs to 100. Yet, all models converged before half the set number of epochs. In contrast to the number of hours parameter, we observe that in some cases it took from $\frac{2}{3}$ to twice the number of epochs to train the same model for the two datasets.

VI. CONCLUSION

In this work, we addressed the problem of correcting common Arabic soft spelling errors. We developed variant configurations of bidirectional LSTM networks with either two or four hidden layers, while using or forgoing the dropout technique. We use sequences of Arabic texts that are either written in classical Arabic (Tashkeela set), or MSA Arabic

Figure 14. BiLSTM Timing Metrics under different Configurations for the Tashkeela Set.

Figure 15. BiLSTM Timing Metrics under different Configurations for the ATB3 Set.

(ATB3 set) to train and validate our models. The 2-layer network with dropout had the highest F_1 score of 98.7% on Tashkeela test set using the transformed input training approach.

We also experimented with a second training approach where we introduce stochastic errors and train the BiLSTM network to correct them. We deliberately varied the percentage of injected errors in the input sequence to assess the BiLSTM network performance and sensitivity given how well it can learn from lower or higher injected error rates. Networks trained with higher error rates (from 2.5%, 10%, through 40%) have worse accuracy, precision, recall, F_1 score, CER, and WER. However, they are more capable of correcting errors as reflected by their *FP/Changes* ratio. Noting that injecting more errors in the input stream beyond 40% does not improve the

network performance in correcting soft spelling mistakes.

The transformed input training approach has better *FP/Changes* ratio than that of the stochastic error injection approach. However, the latter approach is better in correcting the soft spelling mistakes in the Test200 test set with error injection rate of $p = 40\%$. The best result on this test set is an CER of 1.28%. This lowest error rate is for the network trained on Tashkeela set and $p = 40\%$.

For future work, we consider expanding beyond the class of soft Arabic spelling errors. Further, a much larger annotated and pre-processed dataset will open doors to improving accuracy. We could possibly handle Arabic spelling correction and letter diacritization in one problem space.

Prediction of Presence of Brain Tumor Utilizing Some State-of-the-Art Machine Learning Approaches

Mitrabinda Khuntia, Prabhat Kumar Sahu, Swagatika Devi

Dept. of Computer Science and Engineering, ITER, S'O'A University, Bhubaneswar, India

Abstract—A brain tumor is a kind of abnormal development caused by unregularized cell reproduction and it is increasing day-by-day. The Magnetic Resonance Imaging (MRI) tools are the most often used diagnostic tool for brain tumor detection. However, ample amount of information contained in MRI makes the detection and analysis process tedious and time consuming. The ability to accurately identify the exact size and proper location of a brain tumor is a tough task for radiologists. Medical image processing is an interdisciplinary discipline in which image processing is a tough research. Image segmentation is the prime requirement in image processing as it separates dubious regions from biomedical images thereby enhancing the treatment reliability. In this regard, our article reviews eight existing binary classifiers to compare their results for designing an automated Computer Aided Diagnosis (CAD) system. The proposed classification models can analyze T1-weighted brain MRI images to reach at a conclusion. The classification accuracy advocates the quality of our work.

Keywords—Brain tumor classification; MRI; SVM; decision tree; random forest; CAD

I. INTRODUCTION

The proper diagnosis of some crucial information is a key challenge in the field of bioinformatics or medical research. Many diagnostic and research institutions include a wealth of medical diagnosis data. It is barely essential to categorize them in order to automate and speed up illness diagnosis.

A continuous progression in cancer research has been carried out during the previous decades [1]. Scientists used a number of approaches, including very early-stage screening, to identify the disease before symptoms appeared. They have also developed noble methods for detecting the disease therapy results early on [16]. As a result of the advent of new medical technology, large amounts of cancer data have been gathered and made available to the clinical research community. Hence, medical researchers are exclusively employing popular machine learning techniques which can discover patterns and connections from massive datasets and anticipate future cancer outcomes with high accuracy.

The automated segmentation and categorization of medical images is crucial in brain tumor diagnosis, prognosis of tumor development, and therapy. Early diagnosis of a brain tumor predicts a faster response in therapy, which improves patient survival rates. Manual procedures used in normal clinical work to find and categorize brain tumors in large medical image collections incur considerable effort and time costs. It is desirable and beneficial to have a procedure for automatic detection, localization, and classification. Any disruption may intimate disease and injury. The identification of brain tumors is crucial in biological applications. Several procedures, like

as preprocessing, feature extraction, and classification, are required during the classification process.

Various medical imaging modalities are utilized to give tumor related information that is required for detection [2]. Prime methods include computed tomography (CT), single-photon emission computed tomography (SPECT), positron emission tomography (PET), magnetic resonance spectroscopy (MRS), and magnetic resonance imaging (MRI). MRI collection produces numerous 2D picture slices with strong tissue contrast while taking benefit of no ionising radiation [2]. T2 images are more suitable for identifying the borders of edoema areas. Brain tumors are identified and classified using MRI image processing.

II. LITERATURE SURVEY

Iftekharruddin et al.[5] used fractal wavelet characteristics as input to a Self Organizing Map (SOM) classifier and attained an average accuracy of 90%. Based on histogram study of temporal Magnetic Resonance Image (MRI) data, Manikis et al [14] developed a unique paradigm for monitoring tumor alterations. The proposed method detects tumor distribution and quantitatively predicts its development or decrease, possibly benefiting clinicians in objectively analysing tiny changes throughout therapy. Roy et al. [15] proposed an investigation towards automated brain tumor identification and classification using brain MRI. Brain tumor segmentation was a critical method for collecting information from complex MRI images of the brain. Sindhushree K.S et al [6] created and tested a strategy for segmenting brain tumors using two-dimensional MRI data. Discovered tumors are also shown in three dimensions. To identify malignancy, high pass filtering, histogram equalization, thresholding, morphological methods, along with segmentation employing linked component labeling were used. The recovered 2D tumor pictures were rebuilt into 3D volumetric data, and the tumor volume was determined.

Havaei et al.[6] designed a semi-automatic method using kNN classifier. They used the well-known BRATS 2013 dataset and done both whole and core tests, with Dice similarities of 0.85 for the total tumor region and 0.75 for the core tumor area. Sachdeva et al.[3] semi-automatically constructed the tumor contour and then calculated 71 features using the intensity profile, co-occurrence matrix, and Gabor functions. The classifiers Support Vector Machine (SVM) and Artificial Neural Network (ANN) were compared. Similarly, Kaur[4] presented autonomous brain tumor classification approach with ten features and a Back Propagation Neural Network as the classifier, which had a 95.3% accuracy.

Mohsen et al. [9] suggested a deep learning based classifier paired with discrete wavelet transform (DWT) and principal

components analysis to categorize a dataset including three distinct brain tumors (PCA). Four other deep learning-related research with equivalent goal employ the same dataset as we used in this study, which is crucial for comparing and evaluating the proposed model's performance outcomes. Pashaei et al. [11] suggested two approaches for classification: the first employed a CNN model for classification, while the second used CNN characteristics as inputs to a KELM methodology. The KELM algorithm is a learning algorithm composed of hidden node layers. A two-layer CNN design was introduced by Abiwinanda et al. [10]. A CNN with 16 convolution layers was proposed by Sultan et al. [12]. In another work, Anaraki et al. [13] introduced a hybrid approach for network design enhancement that combines the usage of CNNs with genetic algorithm (GA) criteria.

III. BRAIN TUMOR DIAGNOSIS

Brain is a centralized processing unit in humans that senses, controls, and runs all of our bodily functions. Neurons and Galilean cells are the two types of cells that make up the brain. Brain tumor refers to an unexpected proliferation of brain cells in the brain. Brain tumors can be either malignant or non-cancerous. The examination of tumors in the identification of malignant characteristics is a tough work owing to the variable nature of the tumor and its similarity to other regions of the brain. Early discovery of this impact has a higher possibility of recovery than late diagnosis. However, in today's world, the vast majority of tumors are identified at a late stage. As a result, early stage detection is a critical necessity.

IV. PROPOSED FRAMEWORK

A. Dataset Used

Benign cases are classed as positive in our study, whereas malignant ones are classified as negative as shown in Fig. 1 and fig. 2. Linear correlations are straight-line correlations between two variables with values ranging from -1 to + 1, where -1 represents the ideal negative relationship and + 1 represents the ideal positive relationship. By identifying the relationship between nine aspects of benign and malignant classes, the Pearson correlation between positive and negative classes is presented.

B. Block Diagram of the System

Before training the model, we collected images, partitioned the dataset, and investigated augmentation alternatives. The model is fine-tuned, and the outcomes were enhanced. The confusion matrix, model loss, and model accuracy have all been proven to show the loss and accuracy change with epoch. The proposed block diagram displays the whole classifier system in the simplest way possible as presented in Fig. 3. Decision making is a key component of this scheme and serves an important role in the research.

C. Data Preprocessing

Data preprocessing is used to fill in blanks, locate and eliminate outliers, and resolve self-contradiction. The sample code number has been removed from the dataset since it has no effect on illnesses. Vectors are created by resizing images.

They are then scaled to fit the training method [17]. The following step is to transform each image in the collection to an array. The image is used as a preprocessed input by MobileNetV2. The final level is coding. The tagged dataset is converted into a numerical label, which can then be understood and evaluated. Furthermore, random selection is used in the dataset to guarantee that the data is adequately disseminated.

D. Training and Testing

The training phase extracts properties from the dataset, while the testing phase assesses how well the appropriate model predicts. The dataset is divided into two sections. This is the time for training and testing. In K fold cross-validation, a single fold is utilized for testing and k-1 folds are used for training in a cyclical method. To avoid over fitting, cross-validation is performed. In this paper, we partition data using a five-fold cross-validation strategy, with four fold used for training and one-fold used for testing in each iteration.

E. Performance Measurements

Following the labeling of all pixels I_j in the input slice, P_{ij} as illustrated in equation (1) and (2). From vector f_l , $l = 1, 2, 3$, the classification function predicts the label l_p , that pinpoints the kind of tumor in a slice. The classification function determines the link between predicted label sizes, l , $P_{ij} == 1$, and the overall prediction, $P_{ij} > 0$. The projected label, l_p , will be the label with the largest capacity connection i.e. greater than the confidence threshold's minimum size relation, $\zeta_c \in [0, 1]$.

$$P_{ij} = \begin{cases} = 0, & \text{if (i,j) is healthy position} \\ = 1, & \text{if (i,j) is meningioma tumor} \\ = 2, & \text{if (i,j) is glioma tumor} \\ = 3, & \text{if (i,j) is pituitary tumor} \end{cases} \quad (1)$$

$$f_l = \begin{cases} \frac{P_{ij} == 1}{P_{ij} > 0} > \zeta_c \\ 0 \end{cases} \quad (2)$$

F. Image Classification Performance Metrics

Several metrics, including accuracy, precision, recall, F1-score, and AUC, were employed to evaluate performance of our scheme.

V. MACHINE LEARNING TECHNIQUES

When using traditional Machine Learning approaches, a preprocessing stage aimed at feature extraction is included in the segmentation pipeline [8]. The recovered attributes are then passed on to the classification or segmentation stage [7]. The ML inquiry would inquire whether or not the tumor is likely to be malignant (1=Yes, 0=No). Some important techniques to improve the performance of ML approaches are discussed below:

- 1) dimensionality reduction
- 2) feature selection
- 3) feature extraction

A. Support Vector Machine Algorithm

SVM or Support Vector Machine, may be employed for regression along with classification applications. SVMs offer much greater search accuracy than typical query refinement techniques after only 3 to 4 rounds of relevance feedback, according to simulated data. The SVM algorithm is frequently used in clinical and other disciplines. We will be utilizing the brain tumor dataset to develop our SVM method.

The F1-score for healthy and brain tumor categorization is 86% and 92%, respectively in Fig. 4. We can see from the

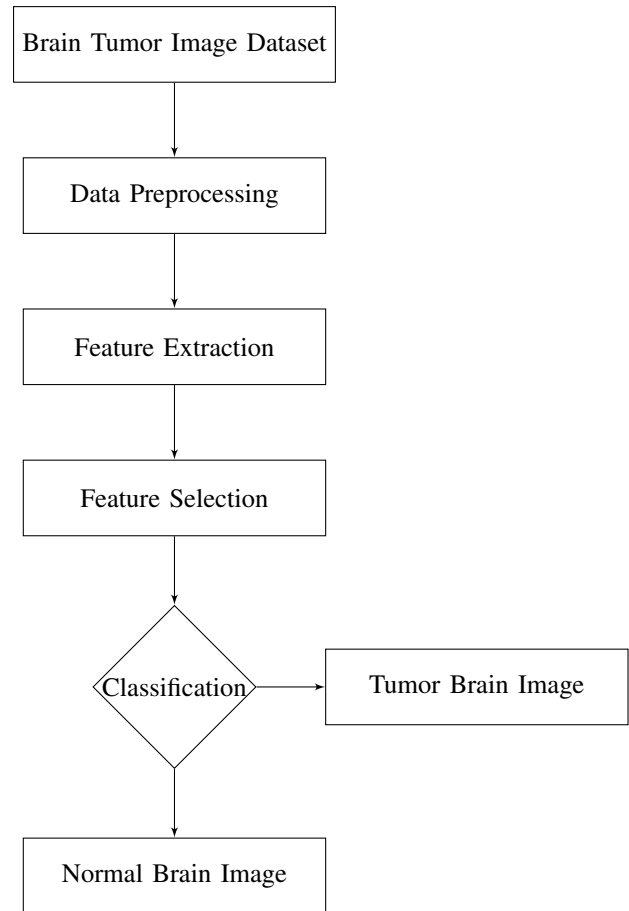

Fig. 3. Block Diagram

output of Fig. 4 that there were some inaccurate predictions; thus, if we want to determine the number of correct and incorrect predictions, we must utilize the confusion matrix. The confusion matrix is shown in the output graphic in Fig. 5, with 4+1=5 wrong guesses and 16+30=46 right predictions.

Fig. 8. Classification Metrics for DTREE Classifier

The graphical depiction of the results in terms of ROC and micro-average ROC curve is shown in Fig. 6. We will draw a graph for the SVM classifier in Fig. 7 to illustrate the training set outcome. The classifier will determine whether a brain tumor is malignant or benign.

B. Decision Tree

Decision Tree (DTree) is a Supervised learning approach and tree structured that can be utilized to solve classification problems. Here the internal nodes represents attribute, branch represent rules and leaf node specifies conclusion. It is a

graphical depiction of solutions to a problem depending on specific criteria.

The F1-score for healthy and brain tumour categorization is 70% and 83%, respectively in Fig. 8. We can see from the output of Fig. 8 that there were some inaccurate predictions; thus, if we want to determine the number of correct and incorrect predictions, we must utilize the confusion matrix. The confusion matrix is shown in the output Fig. 9, with 4+7=11 inaccurate guesses and 13+27=40 right predictions.

Fig. 6. ROC for SVM Classifier

Fig. 9. Confusion Matrix for DTREE Classifier

Fig. 10. ROC for DTREE Classifier

Fig. 11. Visualizer for DTREE Classifier

The graphical depiction of the results in terms of ROC and micro-average ROC curve is shown in Fig. 10. The above output is completely different from the rest classification models. We will plot a graph for the decision tree classifier in Fig. 11 to view the training set outcome. The classifier will determine whether a brain tumor is malignant or benign.

C. Gaussian Naive Bayes

Gaussian Naive Bayes is the name given to the generalization of naive Bayes. The normal distribution (Gaussian distribution) is simpler to use as it can estimate mean and standard deviation very quickly from the training data. A Gaussian distribution is assumed if the input variables are real-valued. This may need the removal of outliers.

The F1-score for normal and brain tumor categorization is 81% and 87%, respectively which is represented in Fig. 12. The confusion matrix is shown in the output Fig. 13, with 3+5=8 inaccurate guesses and 17+26=43 right predictions.

The graphical depiction of the results in terms of ROC and micro-average ROC curve is shown in Fig. 14. We will draw

	precision	recall	f1-score	support
0	0.77	0.85	0.81	20
1	0.90	0.84	0.87	31
accuracy			0.84	51
macro avg	0.83	0.84	0.84	51
weighted avg	0.85	0.84	0.84	51

Fig. 12. Classification Metrics for Gaussian NB Classifier

Fig. 13. Confusion Matrix for Gaussian NB Classifier

a graph in Fig. 15 for the Gaussian NB classifier to show the training set outcome. The classifier will determine whether a brain tumor is malignant or benign.

D. Random Forest

Random forest chooses observations at random, creates a decision tree, and uses the average result. Random Forest classifiers can handle both categorized as well as continuous variables in an effective manner. It outperforms other algorithms in categorization tasks. It is capable of handling binary,

	precision	recall	f1-score	support
0	1.00	0.85	0.92	20
1	0.91	1.00	0.95	31
accuracy			0.94	51
macro avg	0.96	0.93	0.94	51
weighted avg	0.95	0.94	0.94	51

Fig. 16. Classification Metrics for Random Forest Classifier

continuous, and categorical data.

The F1-score for healthy and brain tumor categorization is 92% and 95%, respectively in Fig. 16. The confusion matrix is constructed in the output image Fig. 17 to identify the accurate and wrong guesses, which contains 3+0=3 erroneous predictions and 17+31=48 correct predictions.

The graphical depiction of the results in terms of ROC and micro-average ROC curve is shown in Fig. 18. The above output is completely different from the rest classification

models. We will create a graph for the Random Forest classifier to view the training set results in Fig. 19. The classifier will determine whether a brain tumor is malignant or benign.

E. Multinomial Naive Bayes Classifier

Multinomial Naive Bayes can be treated as a probabilistic process and is extensively utilized for categorical training set. It helps in obtaining highest likelihood. Normally, the multinomial distribution requires integer feature counts.

The F1-score for normal and brain tumor categorization is

	0	0.78	0.70	0.74	20
1	0.82	0.87	0.84		31
accuracy				0.80	51
macro avg	0.80	0.79	0.79		51
weighted avg	0.80	0.80	0.80		51

74% and 84%, respectively in Fig. 20. In Fig. 21, a confusion matrix is used to determine the correct and incorrect guesses, with $6+4=10$ incorrect forecasts and $14+27=41$ accurate predictions.
