Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

***Abstract*—Machine learning is widely used in the data processing including data classification, data regression, data mining and so on, and based on a single type of machine learning technology, it is often difficult to meet the requirements of data processing; in recent years, the machine learning based on fusion has become an important approach to improve data processing effect, and at the same time, corresponding summary study is relatively limited. In this study, we summarize and compare different types of fusion machine learning such as ensemble learning, federated learning and transfer learning from the perspectives of classification, principle and characteristics, and try to explore the research development trend, in order to provide effective reference for subsequent related research and application; furthermore, as an application of fusion machine learning，we also conduct a study on the modeling optimization for car service complaint text classification.**

Keywords—Machine learning; fusion; ensemble learning; federated learning; transfer learning

I. INTRODUCTION

In recent years, machine learning research has developed rapidly and achieved widespread attention; with the expanding and deepening of the development, it is found that traditional machine learning methods often fail to meet the needs of data modeling for certain scenarios; therefore, fusion-based machine learning has become a research hotspot, and relevant research has involved the fields of agriculture, geology, environment, machinery, communication, medicine and so on. This study summarizes and compares the fusion-based machine learning methods from multiple perspectives, it is expected that this study could provide support for effectively obtaining a general understanding for the research progress of the machine learning based on fusion, and explore the research development trend based on summary and analysis.

II. MACHINE LEARNING BASED ON FUSION

Fig. 1 summarizes the main fusion-based machine learning methods from the perspectives of classification, principles, and characteristics.

Fusion-based machine learning involves technology fusion and data fusion.

The technology fusion includes horizontal fusion and vertical fusion. The horizontal fusion mainly refers to ensemble learning, the ensemble strategies include bagging, blending, stacking and so on. The vertical fusion mainly refers to different types of neural networks stacking to form multiple neural networks, and also includes other multi-layer information processing methods based on the stacking of different types of basic technologies.

The Data fusion mainly refers to federated learning which is based on distributed model training; and the method of transfer learning shares model training results through parameters between the models trained based on different parts of data, which could be understood as another kind of machine learning based on data fusion.

A. Ensemble Learning

Ensemble learning commonly uses multiple algorithms to train individual models independently of each other, and then combines the training results through certain strategy to form a comprehensive model based on model horizontal combination to improve the modeling effect.

Different types of machine learning technologies commonly have different characteristics, applicability and limitation, and ensemble learning could effectively combine the advantages of multiple machine learning technologies to optimize the effects of machine learning modeling. In recent years, ensemble learning has received extensive attention, related research had involved agriculture, geology and so on [1-2].

The basic technologies used in the individual model training mainly include the classic technologies such as random forest, support vector machine, ridge regression, and the technologies based on neural network such as bidirectional long short term memory neural network, error back propagation neural network and so on; the ensemble strategies mainly include bagging, blending and stacking.

The bagging ensemble strategy is mainly based on the idea of voting, for classification issue, the calculation results from the individual models could be regarded as votes, and the prediction category with the most votes could be took as the classification prediction output of the overall ensemble model, for regression issue, the weighted average of the outputs from multiple individual models could be computed as the output of the overall ensemble model.

Funding Project: Promote the Classification Development of College-Construction of Professional Degree Sites of Electronic Information (Computer Technology) (5112211038).

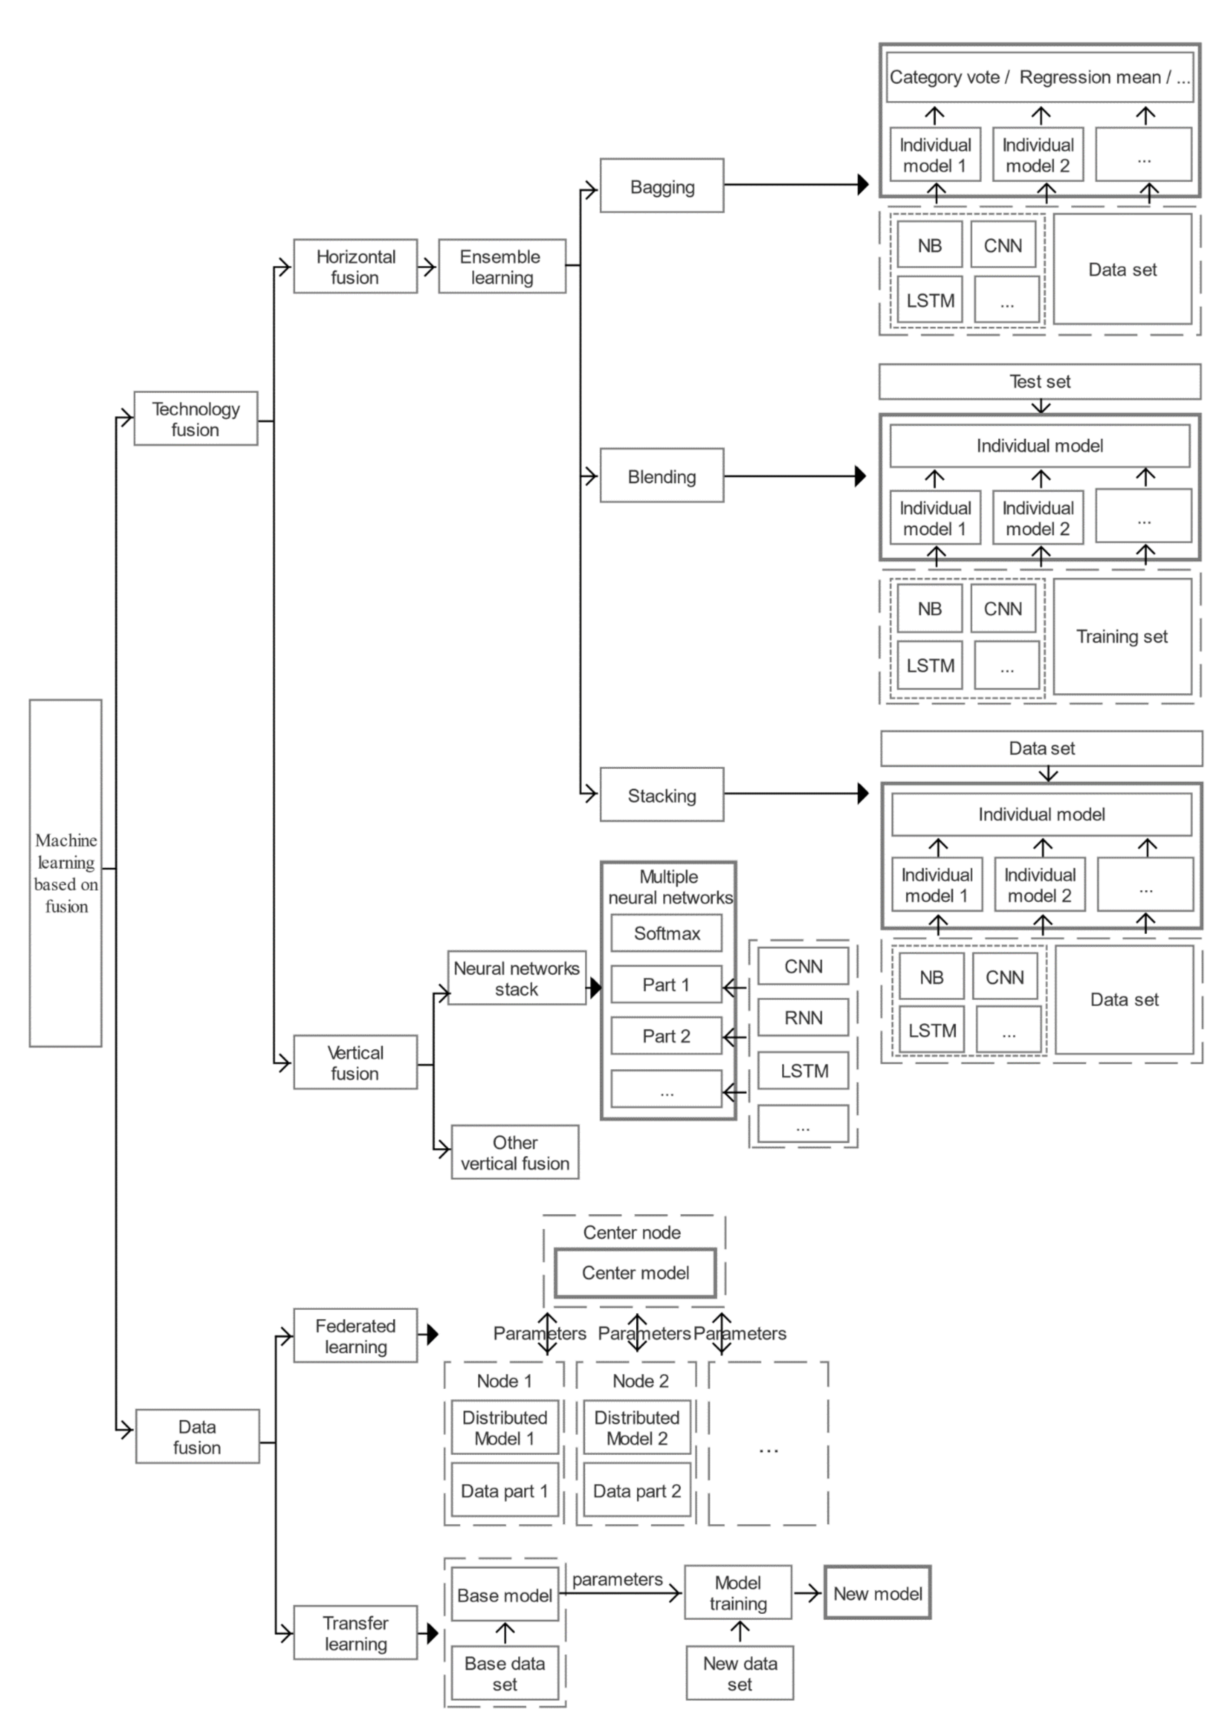

Fig. 1. Machine Learning based on Fusion.

The blending ensemble model usually consists of two layers, the first layer is commonly a plurality of individual models trained independently, the second layer is another individual model, which operate prediction based on the outputs of the first layer, and the predicted result from the second layer would be used as the final output of the ensemble model; to build a blending ensemble model, the dataset is commonly divided into a test set and a training set firstly, and then the model training of first layer is performed based on the training set, and the model training of second layer is performed based on the test set.

The stacking ensemble model commonly includes two layers too, the first layer consists of multiple individual models; and the second layer is another individual model, which conducts prediction based on the outputs of the multiple individual models of the first layer; the stacking ensemble strategy is similar to the blending ensemble strategy, the main difference lies in the data segmentation in the model training, in stacking model training, the data used for the first-layer model training and the second-layer model training is consistent, and in the training of blending model, the training data of the second-layer does not intersect with the training data of the first-layer.

Table I generally summarizes and compares the research examples for the ensemble learning from the aspects of ensemble strategy, basic technology, etc.

B. Transfer Learning

Transfer learning commonly initializes new model training based on pre-trained model parameters, and through little applicability adjustment, achieves quickly and effective data modeling [3-6]. The transfer learning methods used in related research are mainly based on neural network, which commonly redesigns the fully connected layer and freeze the other layers of the pre-trained model, or freeze part layers and adjust the other layers.

Transfer learning provides an effective alternative approach mainly for two kinds of scenarios, one is the data modeling based on a limited amount of data, by transfer learning, effective modeling could commonly be achieved through fine-tuning based on a pre-trained model trained based on enough data; the second is the scenario where the machine learning model training takes too much time, through transfer learning, the pre-trained model could be used as basis to quickly realize the modeling for a new dataset, which could effectively reduce the training time and reduce the timeliness constraint of the model use.

Transfer learning is commonly based on convolutional neural networks, and related methods mainly include four categories, including the methods based on AlexNet, the methods based on VGGNet, the methods based on ResNet and the methods based on DenseNet. Table II generally summarizes and compares the research examples for different kinds of transfer learning from the aspects of research method, benchmark method and so on.

TABLE I. FUSION STRATEGIES OF ENSEMBLE LEARNING AND THE RESEARCH EXAMPLES

No.	Integration strategy	Research method	Research object	References
1	Bagging	Individual learning: KNN (k-nearest neighbor), BP (error back propagation neural network), GBDT (gradient boosting decision tree), RF (random forest); using improved weighted voting strategy	Electricity theft detection	[7]
		Individual learning: DT (decision tree)	Personal credit evaluation	[8]
		Individual learning: DT	Character recognition	[9]
		Obtaining different datasets based on the bootstrap sampling method and training multiple BP models separately	Water bloom prediction	[10]
2	Blending	Individual learning: GBDT, linear-SVM (linear support vector machine), RBF-SVM (radial basis function-support vector machine), Fusing: linear-SVM	Infrared spectroscopy data analysis	[11]
3	Stacking	Individual learning: LR (logistic regression), KNN, RF, GBDT Fusing: GBDT	Strains classification of Anoectochilus roxburghii	[12]
		Individual learning: RF, XGBoost, LightGBM Fusing: LR (linear regression)	Gaseous nitrous prediction (in air)	[13]
		Individual learning: RF, GBDT, SVM (support vector machine), RR (ridge regression) Fusing: RR	Estimation of summer corn fractional vegetation coverage (based on drone multispectral image)	[14]
		Basic method: KNN, SVM, RF, GBDT	Classification of rice phenomics entitie	[15]
		Basic method: KNN, RF, adaptive boosting	Estimation of nitrogen contents in citrus leaves	[16]
		Basic method: RF, LDA (latent dirichlet allocation), LIBSVM	Classification of black Goji berry	[17]

TABLE II. CATEGORIES OF TRANSFER LEARNING AND THE RESEARCH EXAMPLES

No.	Category	Research method	Contrast method	Research object	References
1	AlexNet	AlexNet	SVM (support vector machine, BP (error back propagation neural network), VGG-19, GoogLeNet Inception v2	Image recognition of cotton leaf diseases and pests	[18]
		AlexNet	CNN (convolutional neural network)	Flotation performance recognition	[19]
2	ResNet	ResNet-101	ResNet-50	Intelligent lithology identification	[20]
		TL-SE-ResNeXt-101 (based on improved deep residual network SE-ResNeXt-101)	ResNet-50, VGG-16, DenseNet-121, GoogLeNet	Crop disease classification	[21]
		CDCNNv2 (based on residual network ResNet-50)	ResNet 50, VGG16, VGG19, DenseNet 121, Xception	Crop diseases detection	[22]
		MPDE-VMD+DTL (multiple population differential evolution-variational mode decomposition, deep transfer learning)	BP, ResNet, migration component analysis	Mechanical fault diagnosis	[23]
3	VGGNet	VGG-16	AlexNet, ResNet 50, Inception v3	Grape leaf disease detection	[24]
		Grape-VGG-16 (a kind of grape leaf disease identification model)	New learning	Grape leaf disease recognition	[25]
4	DenseNet	DL–T (based on DenseNet and LSTM)	RNN–T	Speech recognition	[26]
		DenseNet-GCForest (based on DenseNet and deep forest)	CNN	Wafer map defect recognition	[27]

C. Federated Learning

Federated learning commonly does not centralize training data, but is based on distributed model training, independent partial model training is performed on multiple terminals based on different parts of the data, and the partial training result parameters would be centralized, based on which the central model parameters could be updated through certain strategy, so as to achieve the purpose of integrating multi-source data to improve the machine training effect.

The characteristics and advantages of federated learning mainly include three aspects, firstly, it is not necessary for federated learning to centralize raw data from different sources or terminals, which could effectively protect the data security and user privacy; secondly, federated learning could be combined with the idea of edge computing, and a large amount of data processing workload would be distributed to terminals, which could effectively relieve the computational pressure of the central node and improve the performance of the overall machine learning system; finally, under the condition of multi-node computing, since the data transmission between the terminal nodes and the central node does not involve the transmission of original data but only a small amount of data such as training parameters, the data transmission pressure could be significantly reduced and the performance of the machine learning system could be further optimized.

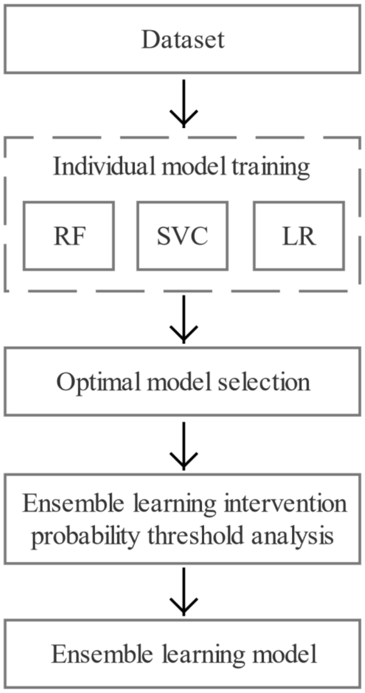
With the rapid development and wide application of information technology, as the disadvantage side of the double-edged sword of the technology, data security and privacy security risk are gradually being highlighted; at the same time, the application of the internet of things is becoming more and more extensive, and there are always more and more big data processing scenarios; therefor, federated learning has become a hot topic. Related researches have involved the fields of communication, medicine, multimedia and so on. In the field of communications, Wang Jia Rui et al. (2021) proposed a clustered wireless federated learning algorithm for the scenario of high-speed internet of vehicle, the test based on handwriting recognition model show that under the condition in which the channel state is poor and the user transmit power is greatly limited, the convergence value of the loss function could be effectively reduced based on this method, compared with traditional centralized algorithm [28]. Jing Xing Hong et al. (2021) proposed a LTE-V2X (long term evolution-vehicle to everything) channel estimation algorithm based on federated learning, which estimates the time-varying channel based on CNN-LSTM-DNN (convolutional neural network-long short term memory-deep neural network), and allocates the required computation to vehicle users, research result show that the method could effectively track the time-varying channel in the high-speed mobile scene of vehicle user, which only lose a small amount of performance compared with the centralized learning algorithm [29]. In medical field, Wang Sheng Sheng et al. (2021) proposed a kind of federated learning method based on improved RetinaNet and attention mechanism for the privacy protection requirements in the model training for medical image target detection, and research result show that compared with centralized learning method, the model performance is slightly lower and the training speed is accelerated to a large extent [30]; moreover, Wang Sheng Sheng et al. (2021) proposed a kind of machine learning method based on federated learning and blockchain for the data protection requirements in the model training for the segmentation of new coronary pneumonia chest CT image [31]. In multimedia field, Zhao Yu et al. (2020) proposed a kind of federated learning method based on lightweight neural network and sub-scenario model training for the problem of high latency in video surveillance, and research result show that the method could improve the accuracy and training speed compared with the benchmark method [32].

III. Application of Fusion Machine Learning

As an application of fusion machine learning in natural language text classification, this section studies the modeling of car service complaint text classification based on ensemble learning.

The research data of this section is from the Beijing Car Quality Net Information Technology Limited Company, and the dataset used includes 7 classes of car service complaint text data，the total data amount is 2100，and the data amount of every class is 300.

The technology route is shown in Fig. 2



Dataset
Individual model training
RF
SVC
LR
Optimal model selection
Ensemble learning intervention probability threshold analysis
Ensemble learning model

Fig. 2. The Technical Route of Ensemble Learning.

In previous research foundation, we have conducted research on the classification modeling of car service complaint texts based on RF method and formed corresponding academic paper; this section mainly focuses on the modeling optimization based on ensemble learning. We take the RF model as a basic, and when the highest predicted probability of the RF model for different classes is less than the threshold, select the class corresponding to the highest predicted probability of the RF model, SVC model, and LR model as the output of the integrated learning model; the comparison of the model prediction effects under different threshold conditions is shown in Table III.

TABLE III. Prediction Comparison under Different Intervention Threshold Conditions

No.	Threshold	Accuracy	Recall	F1-score
1	0.1	0.8476	0.8476	0.8495
2	0.2	0.8476	0.8476	0.8495
3	0.3	0.8524	0.8524	0.8539
4	0.4	0.8571	0.8571	0.8597
5	0.5	0.8476	0.8476	0.8498
6	0.6	0.8429	0.8429	0.8447
7	0.7	0.8429	0.8429	0.8447
8	0.8	0.8381	0.8381	0.8397
9	0.9	0.8381	0.8381	0.8397
10	1.0	0.8381	0.8381	0.8397

Comparison of the prediction effects from different models is shown in Table IV. The research results show that the ensemble learning model has the optimal effect, which could effectively classify the car service complaint texts.

TABLE IV. Comparison of the Prediction Effects from different Models

No.	Method	Accuracy	Recall	F1-score
1	RF	0.8476	0.8476	0.8495
2	SVC	0.8000	0.8000	0.8022
3	LR	0.8381	0.8381	0.8408
4	Ensemble learning (Threshold: 0.4)	0.8571	0.8571	0.8597

In general, the threshold-based ensemble learning is an effective approach to improve the modeling effect of natural language text classification, and the methods based on fusion enrich the machine learning to a great extent.

IV. Conclusion and Outlook

Generally, different kinds of fusion methods have corresponding advantages, applicability and limitation, the rapid development of fusion machine learning has built a better foundation for further data science research. For the technological development trend, in terms of basic research, the innovation in the model integration strategies for ensemble learning and the innovation in the parameter fusion strategies for federated learning would be of great significance; in terms of application, the development of fusion machine learning has enriched the data modeling methods greatly, and follow-up related research could take the characteristics of specific scenario as basis to comprehensively consider the applicability of traditional machine learning methods and different types of fusion machine learning methods to achieve high-quality data modeling. In particular, the effective combination of federated learning and edge computing would make important social value in the fields of big data processing and privacy protection.

In order to provide convenient reference for relevant researchers, we have sorted up the research reports cited in this paper according to the research field, research object and fusion strategy, as shown in Table V, it is expected that subsequent researchers could make quick reference based on the reference table or take it as the basis for further improvement.

Abstract—**Premature ventricular contraction (PVC) is a very common arrhythmia that can originate in any part of the ventricle and is one of the important causes of sudden cardiac death. Timely and rapid detection of PVC on dynamic electrocardiogram (ECG) recording for patients with cardiovascular diseases is of great significance for clinical diagnosis. Furthermore, it can facilitate the planning and execution of radiofrequency ablation. But the dynamic ECGs can be easily contaminated by various noises and its morphological characteristics show significant variations for different patients. Though the deep learning methods achieved outstanding performance in ECG automatic recognition, there are still some limitations, such as overfitting, gradient disappearance or gradient explosion in deep networks. Therefore, a residual module is constructed using the squeeze-excitation method to alleviate the problems. A 20-layer squeeze-extraction residual network (SE-ResNet) containing multiple squeeze-extraction modules was designed for real-time PVC detection on 12-lead dynamic ECG. The algorithm was evaluated using the dynamic 12-lead ECGs in INCART database (168,379 heartbeats in total). The experimental results show that the test accuracy of the method proposed in this paper is 98.71%, and the specificity and sensitivity of PVC are 99.12% and 99.59%, respectively. Under the same dataset and experimental platform, the average recognition accuracy of our proposed method is increased by 0.73%, 1.55%, 2.9% and 1.65% compared with the results obtained by CNN, Inception, AlexNet and deep multilayer perceptron, respectively. The proposed scheme provides a new method for real-time detection of PVC on dynamic 12-lead ECGs. The experiment results show that the proposed method outperforms state-of-the-art methods, and has good potential for clinical applications.**

Keywords—Dynamic ECG; squeeze-excitation; residual network; premature ventricular contraction

I. Introduction

Premature ventricular contractions (PVCs) are the most common type of arrhythmia and, under certain conditions, can lead to life-threatening heart disease. Electrocardiogram (ECG) is not only a noninvasive and economical tool for routine cardiovascular examination, but also an essential monitoring device in surgical procedures and intensive care units. It is more clinically significant for the diagnosis of PVC. However, it is time-consuming and arduous for cardiologists to analyze many long-term dynamic ECG. Therefore, the automatic detection of PVC on body surface dynamic ECGs can not only improve cardiology workflow efficiency and timely prevent cardiac diseases such as arrhythmia, but also accurately locate the occurrence time and source localization of ventricular premature beats, and then guiding the surgical process such as radiofrequency ablation, etc.

Dynamic ECG is susceptible to various background noises, such as power-line interference, inotropic noise, baseline drift and motion artifact, and its morphological characteristics show significant variations for different patients and under different temporal and physical conditions. Even experienced specialists cannot accurately determine the type of arrhythmias. Machine learning methods such as deep neural networks can more accurately detect arrhythmias such as PVC, and have shown good clinical applications [1].

Deep learning has experienced great breakthroughs in the past decade in many fields, such as image recognition and natural language processing. With the popularity of deep learning and outstanding performance in other fields, researches use deep learning to monitor arrhythmias such as PVCs [2-5]. They transform ECG as one-dimensional time-series signals or two-dimensional signals such as multi-lead ECG beats or time-frequency images as the input of the convolution neural network (CNN). Then conduct layer-by-layer feature extraction and classification. In 2017, Acharya et al.[6] proposed a 9-layer deep CNN to discriminate 5 types of ECG heartbeats and achieved 94.03% accuracy using MIT-BIH arrhythmia database. In 2018, Yildirim et al. [7] designed a new 1D convolutional neural network model (1D-CNN) to recognize 17 different types of long-time dynamic ECG signals. Using the MIT-BIH database, they achieved an overall accuracy of 91.33% for the 17 type arrhythmias. In 2019, Andersen et al. [8] proposed a convolution combined cyclic convolution model, which could search for atrial fibrillation heartbeats from 24-hour dynamic ECG signals, and achieved good results. In 2020, Ullah et al. [9] proposed a two-dimensional (2-D) CNN model to recognize eight types of ECG signals. The model was evaluated on the MIT-BIH dataset and the classification accuracy reached 99.11%. With the deepening of deep network structure, the accuracy of the neural network model will decrease. That is the degradation of neural network. To overcome the problem, deep CNN model with residual structure is developed for ECG arrhythmias detection, which improves classification accuracy [10]. In 2019, Brito et al. [11] proposed a deep learning model based on ResNet architecture. They conducted experiments using MIT-

BIH arrhythmia database and achieved an accuracy of more than 90%. In 2020, Li et al. [12] classified arrhythmias based on deep residual network. The experiments applied to the MIT-BIH arrhythmia database and showed high classification performance with an accuracy of 99.38%. Deep learning has made some achievements in the classification and recognition of PVCs [13, 14]. It has good performance on small evaluation samples and static ECGs, but the accuracy decreases for clinical dynamic 12-lead large data especially for non-equilibrium dataset. Therefore, the evolutionary model and method is crucial to improve the efficiency and effects of PVC detection which will promote the further clinical applications.

Although there are many studies on arrhythmia detection in the literature, there are still various problems such as difficult convergence of deep networks, training cost, and computational complexity. Furthermore, in the literature, most models are trained on relatively clean open-source ECG datasets such as the MIT-BIH database. In this study, considering the advantages and disadvantages of existing technologies, a squeeze-excitation module is constructed which embedded in a residual structure to improve the convergence of the deep network. It aims to improve the non-linear fitting ability of the deep network by reconstructing the hyperplane parameters through the squeeze-excitation operation. The network model uses a feature rescaling strategy, where the importance of each feature channel is automatically obtained by learning, and then the useful features are promoted and the less useful features are suppressed according to its importance. The network model can fully consider the weight of each lead and main wave of ECG signals, and provide a new idea for deep feature extraction of arrhythmia heartbeats. Based on the SE-ResNet model, the performance of the model was evaluated by 168379 12-lead heartbeats from the St Petersburg INCART 12-Lead (INCART) arrhythmia dynamic ECG database. The effectiveness of this method is evaluated by experiments.

The remainder of this paper is organized as follows. Section II described the related work and methods for this study. In Section III, a novel SE-ResNet for detection of premature ventricular beats was implementation. Experimental results are also described. Section IV is discussion and Section V concludes the paper.

II. Method

A. Convolutional Neural Network

CNN is a deep learning algorithm based on artificial neural network structure, trained by a gradient-based optimization algorithm. In contrast to traditional machine learning algorithms, CNN architecture does not need to manually extract features from raw data. Feature extraction and classification are embedded in the architecture, so robust features can be automatically identified from the input data [15]. In general, a CNN consists of multiple back-to-back layers connected in a feedforward manner. As shown in Fig. 1, in the CNN architecture, the main layers are including convolutional layers, pooling layers and a fully-connected layer. Convolutional and pooling layers are responsible for feature extraction, while fully-connected layer is responsible for classification.

B. Squeeze-excitation Residual Network

Bioelectric signals are characterized by individual variability, strong interference, and multi-lead characteristics. Individual variability is reflected in the ECG morphology of different patients with the same disease, and even the difference and translation of characteristic wave directions. In addition, the same patient will also have certain differences in different times and environments. Different leads of the ECG signal reflect the potential transformation of cardiac activity in different parts of the body. The waveforms corresponding to each lead has great difference, and each lead is relatively independent. CNN improves performance by deepening the network structure as much as possible. However, with the increase of CNN depth, namely, the number of network layer increases, the performance of the model tends to saturate and even decline rapidly, which makes the training of deep networks more difficult.

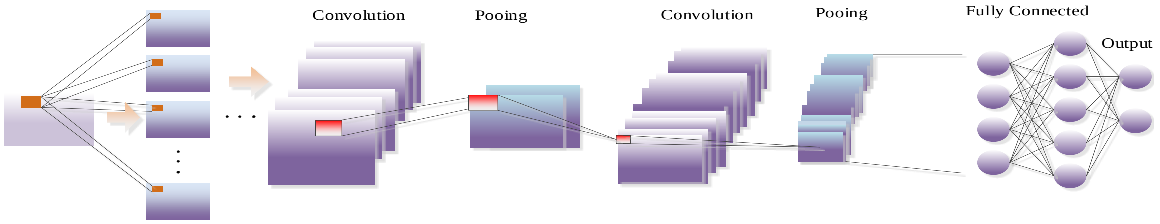

Fig. 1. CNN Architecture.

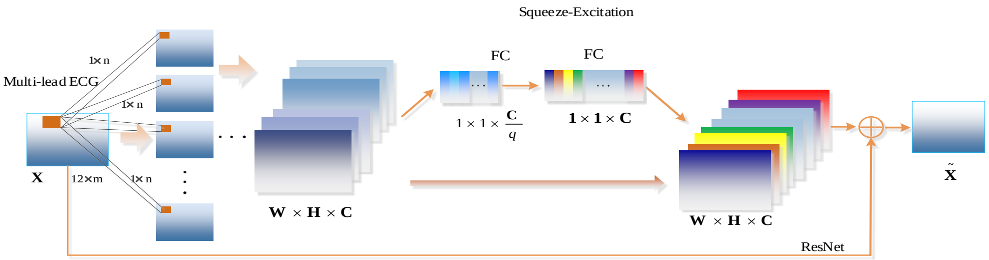

Fig. 2. SE-ResNet Architecture.

Aiming at the above problems, this paper adopts the SE-ResNet model, a deep network architecture with stronger nonlinear fitting ability. The model constructs a squeeze-excitation module which embedded in a residual structure. The network model adopts a feature recalculation strategy, namely, the importance of each feature channel is automatically obtained by learning, and then the useful features are improved and the features that are not useful for the current task are suppressed according to the importance. As shown in Fig. 2, in the squeeze layer, for inputs X = [x_1,x_2, ⋯ ,x_c], where $\mathrm{x_c} \in R^{H\times W}$, the simplest aggregation technique, global averaging, is used to generate channel statistics. Formally, the statistic $z \in R^{c}$ is generated by reducing X by reducing its spatial dimension H × W, and the c-th element of z is calculated by the following equation (1):

$$\mathrm{z_c} = \frac{1}{H\times W}\sum_{i=1}^{H}\sum_{i=1}^{W}\mathrm{x}_c(i,j) \tag{1}$$

Among them, the H and W represent the height and width of the feature map, respectively, and C represents the number of feature map channels.

In the excitation layer, two fully-connected layers (FC) are used to achieve channel scaling with a reduction rate of q. The dimension of feature data changes from 1 × C to 1 × C / q, and then playback to 1 × C. Finally, the sigmoid activation function is used to scale the data back to the previous data dimension. Since we want to ensure that multiple channels are allowed to be emphasized, a simple gating mechanism with sigmoid activation in equation (2) is employed:

$$s = \sigma(g(z,W)) = \sigma(W_2\sigma(W_1 z)) \tag{2}$$

where σ is the sigmoid function, $W_1 \in R^{\frac{c}{q}\times C}$ and $W_2 \in R^{C\times\frac{\mathrm{c}}{q}}$. Here q is a scaling parameter. The final output of the block is obtained by rescaling X with the activations s, as shown in Equation (3) below:

$$\tilde{\mathrm{x}}_c = s_c \times \mathrm{x}_c \tag{3}$$

Where $\tilde{X}$ = [$\tilde{\mathrm{x}}_1$,$\tilde{}$ $\tilde{\mathrm{x}}_2$,…,$\tilde{}$ $\tilde{\mathrm{x}}_c$] and the channel multiplication between the index quantity sc and the feature map $\mathrm{x_c} \in R^{H\times W}$.

Reconstructing hyperplane parameters by squeeze-excitation operation can alleviate the problems of the difficulty tuning of deep network and the nonlinear fitting ability of deep network. The architecture can effectively avoid the effect of traditional ECG signal feature extraction on the subsequent classification accuracy.

III. Detection of Premature Ventricular Contractions based on SE-ResNet

A. Data Sources and Evaluation Metrics

In this experiment, the 12-lead dynamic ECGs from the open INCART Arrhythmia database were used for evaluating the algorithm. The INCART Dynamic Arrhythmia ECG database contains 75 records, sampled at 275 Hz. Each record is about half an hour long and has 12 leads. The original ECG data were collected from patients who were examined for coronary artery disease, and most of them had premature ventricular contractions [16].

Since V6 lead is missing in 102 ECG record, V3 lead is missing in 103 record, and V4 lead is missing in 158 record, the above three ECG records were deleted in consideration of the lead consistency. All heartbeats from the remaining 72 records were used in this experiment. According to our statistics, the data in INCART database included 168379 heartbeats. In order to test the recognition effect of premature ventricular contractions, all cardiac heartbeats were divided into three types: normal heartbeats (N), premature ventricular contractions (V) and other heartbeats (O). The number of normal heartbeats was 143,260, the number of premature ventricular contractions was 19,640 and the number of other heartbeats (premature atrial contractions, supraventricular premature heartbeats and right bundle branch block, etc.) was 5479.

In this study, three metrics were used to evaluate the performance of the proposed classification method: accuracy ($A\mathrm{cc}$), sensitivity ($S\mathrm{e}$) and specificity (Sp), which were defined in formulas (4), (5) and (6) respectively. The calculations are made based on the statistical results of multiple experiments.

$$Acc = \frac{TP+TN}{TP+TN+FP+FN} \tag{4}$$

$$S\mathrm{e} = \frac{TP}{TP+FN} \tag{5}$$

$$S\mathrm{p} = \frac{TN}{TN+FP} \tag{6}$$

Among them, TP, FP, TN and FN are true positive, false positive, true negative and false negative, respectively [17, 18].

B. Pre-processing

In contrast, dynamic ECG signals have stronger interference from noise such as motion artefacts, due to factors such as poor skin-to-electrode contact, the effects of breathing and poor contact with the power lines of electrical equipment, et al. Therefore the signal characteristics are chaotic, non-linear and multi-channel. Noises in the ECG signal distort some of its morphological characteristics, which make diagnosis more difficult. So reasonable filtering is very important for subsequent recognition. The useful part of the frequency in the ECG signal mainly ranges from 1 to 40 Hz, and the interest signal is easily submerged in the background noises. The main noise sources include baseline drift, power frequency interference, motion artifact and myoelectric interference [19]. In addition, the low-frequency part of ECG signal contains indicators of malignant arrhythmias such as S-T segment abnormalities, and the high frequency part reflects the amplitude information of main complex wave. In order to keep the morphological characteristics of ECG signal as completely as possible, a wavelet adaptive threshold filtering method is proposed. The algorithm includes three steps: wavelet decomposition, adaptive threshold de-noising and reconstruction. The selection of threshold is adaptive to the signal; therefore, the inherent morphological characteristics of the ECG signal are preserved as much as possible.

The INCART dynamic ECG database contains long-term ECG records with complete annotation of heartbeats. Before applying the model, segmentation of the heartbeat was performed, dividing the long ECG record into heartbeat segments that represent different types, namely, N, V and O. Each heartbeat segment was extracted by selecting a window of 300 samples around the R-peak, which formed by taking 92 points in front of the R-peak and 137 points behind the R-peak, respectively. As each heartbeat segment consists of 230 samples, and the ECG signals are 12 leads, so the size of each beat sample is 12 * 230.

C. SE-ResNet Network Modeling

The architecture of the SE-ResNet network pay more attention to the weights of each lead, and can fully extract the morphological features of the multi-lead ECG waveform. Since the number and complexity of network layers will have a great impact on the training results, we designed SE-ResNet models with different layers and structures, and performed several cross-validation experiments and comparisons. Fig. 3 is the experimental results of the accuracy for each epoch training using the SE-ResNet networks with 8, 12, 16, 20, and 24 layers. As shown in Fig. 3, the 20-layer SE-ResNet achieved better training and testing results, and the 24-layer network performance was comparable to the 20-layer network. Considering computation efficiency and the real-time implementation, especially performed on the embedded processor, we select a 20-layer network for PVC recognition in the following experiments.

In order to optimize the model, we selected the Sgd optimizer, with an initial learning rate of 0.05. To improve the performance of the neural networks, the negative log-likelihood loss (NLLLoss) function and cross-entropy loss (CrossEntropyLoss) function were compared, and the results were shown in Fig. 4. The figure represents the convergence performance for 30 epoch training iterations using different loss functions. As is shown in Fig. 4, using the CrossEntropy loss function, the neural network has more robust stability and better convergence of the training process. Therefore, the CrossEntropyLoss function was selected as the loss function in the following experiments.

In this work, the model architecture of the 20-layer SE-ResNet was designed, as is shown in Fig. 5. The main difference between the proposed network and the original SE-ResNet on ImageNet is that the proposed network uses 1D convolutions instead of 2D convolutions. The input ECG heartbeat is a sample of 12*230 size, and after a convolutional layer with a kernel size of 1*3, followed 9 residual blocks. The residual blocks of the network have 16, 32, and 64 channels respectively. Among them, the first three residual blocks have 16 channels, the second three residual blocks have 32 channels and the remainder three residual blocks has 64 channels.

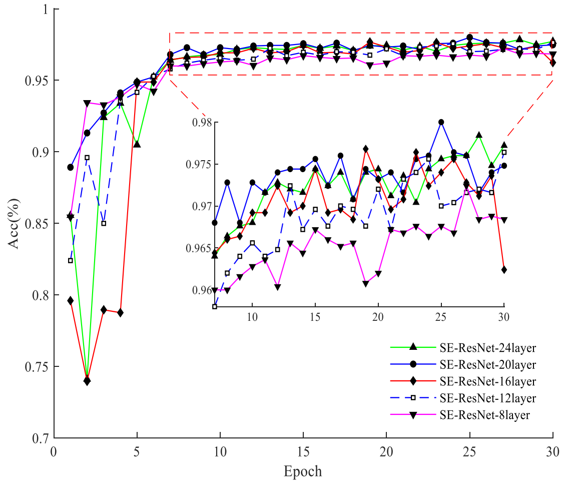

Fig. 3. ECG Recognition Results of different Network Architecture.

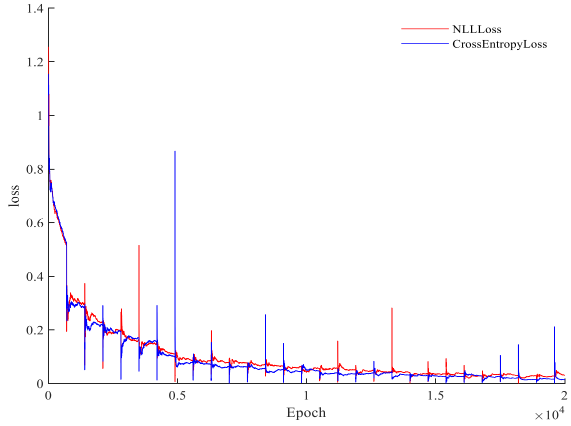

Fig. 4. Comparison of Convergence in Training Process with different Loss Functions.

Each residual block is embedded with squeeze-excitation modules, so a total of 3+ 3+3=9 residual blocks are designed in Fig. 5. In order to accurately extract information from each channel of the ECG heartbeat signal, each residual (short-connect connection) is embedded with a squeeze-excitation module that automatically captures the weight information of each feature channel of the ECG heartbeats in a learning manner, effectively enhancing the features of the useful channels and suppressing information that is not sufficiently useful for the current classification recognition task. Take the first three residual blocks (short-connect) of 16 channels as an example, as shown in Fig. 5, in order to make the best use of the contextual ECG feature information of each channel, channel-level statistics are generated by global averaging pooling. The excitation layer is implemented using two fully-connected layers (FC) for channel scaling, the reduction rate is taken as 4, the dimension of the feature data is changed from 1* 16 to 1* 4 and then replayed as 1* 16. Finally, use the sigmoid activation function to rescale the data back to the dimensions before squeezing. It is equivalent to map the data associated with the input to a set of channel weights, so that the channel features are not limited to the local perceptual field of the convolutional network. Therefore, the context information can be easily understood, and different weights are assigned to the channels. Residual architecture can improve the parameter adjustment ability of the network, namely, the optimization ability. As shown in Fig. 5, there are three 16-channel SE-ResNet modules in total, and each module has two layers of convolution. There are three 32-channel SE-ResNet modules in total, and each module has two layers of convolution. Similarly, there are three 64-channel SE-ResNet modules in total, each with two layers of convolution. Through 19 layers of network transmission, deep feature extraction is completed. Finally, the feature is fed into a fully-connected layer, so the network model has a total of 20 parameter layers.

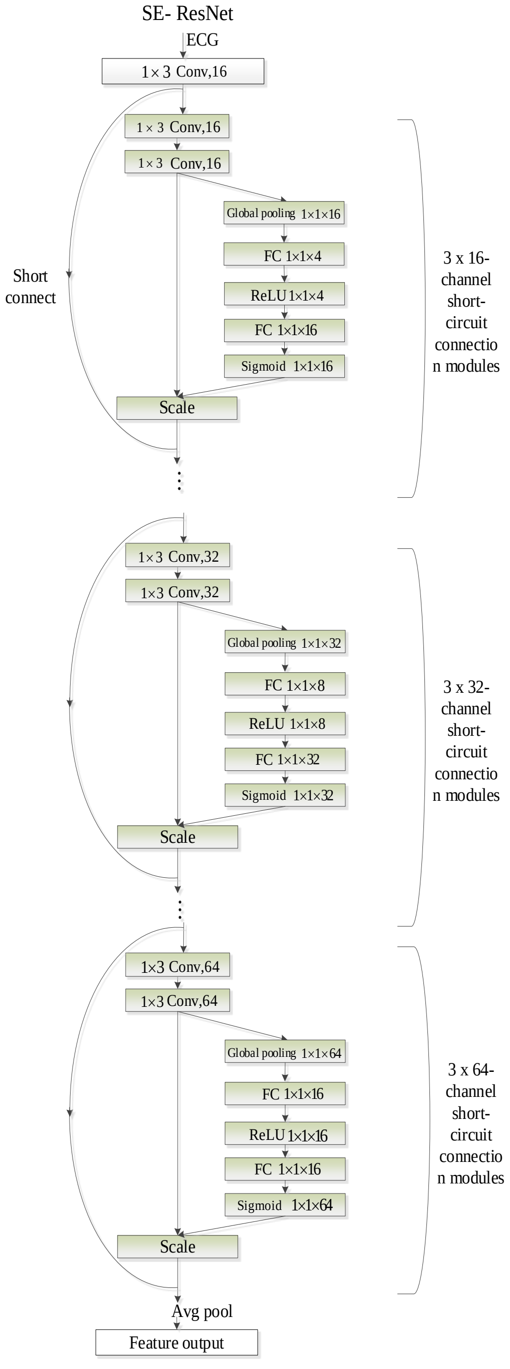

Fig. 5. SE-ResNet Network Model.

D. Analysis of Experimental Results

In order to evaluate the recognition effect of the proposed SE-ResNet model for PVCs recognition based on the INCART dynamic ECG database, this experiment employed a wavelet self-adapting filter to preprocess all 72 lead-consistent ECG records, and segmented 168379 heartbeats according to the R-peak position. We randomly selected 3000 normal heartbeats, 3000 PVCs and 1000 other type heartbeats, respectively from the total 168,379 heartbeats which include 143260 normal heartbeats, 19640 premature ventricular contraction and 5479 other heartbeats. So the total training samples is 7000. Similarly, 1000, 1000 and 500 heartbeats were randomly selected from the remainder data, which were used for cross verification. The remainder 158,879 heartbeats were used for the final evaluation. The classification results were expected to be affected by the heartbeat sample size, and the ratio of training to testing sample size. In general, the lower the ratio of training samples to total samples, the greater the generalization ability of the classifiers. In order to evaluate the network's performance and avoid the occasionality of random sampling, we carried out three random sampling experiments, and the confusion matrix was calculated from the average value of the three experiment results. Then, CNN, Inception, multi-layer perceptron (MLP) and Alexnet of the same complexity were designed. In these experiments, the parameters of the networks were regulated to be best fitted in the classification task. The five networks were trained 30 epochs using the same training samples, and the test results were also compared. The confusion matrix and evaluation metrics are shown in Table I.

Since the experiments were performed three times, three trained models were obtained with exactly the same training dataset. When testing the 12-lead ECG signal, the predicted probabilities of the three models were averaged and finally got the final classification results. The confusion matrix and three different statistical indices, such as Sensitivity (Se), Specificity (Sp), and Accuracy (Acc) were summarized in Table I. As is shown in Table I, it can be seen that the algorithm designed in this paper achieved an accuracy of 98.71% for the detection of the arrhythmias, and the sensitivity (Se) and specificity (Sp) for PVC recognition are 99.12% and 99.59%, respectively. The experimental results showed that the accuracy of the designed SE-ResNet algorithm was improved by 0.73%, 1.55%, 1.65% and 2.9% over CNN, Inception, MLP and AlexNet networks, respectively. The PVC sensitivity (Se) value of the SE-ResNet test was 98.71%, and the sensitivities (Se) of the CNN, Inception, MLP, and Alexnet tests were 92.17%, 97.74%, 94.62, and 95.97%, respectively. It can be seen that the sensitivity of PVC has been significantly improved.

E. Compare Results with other Methods

The PVCs detection results of our proposed method were compared with the recent published research results. These published results on the same dataset are shown in Table II. The detection results were expected to be affected by the heartbeat sample size, the number of classes for classification, and the ratio of training to testing sample size. In general, the lower the ratio of training samples to total samples, the greater the generalization ability of the classifiers, and the fewer the types for classification, the higher the recognition accuracy. In one study, Al Rahhal et al. [20] proposed an electrocardiogram

(ECG) technique based on multi-lead signals and a deep learning architecture. Automatic identification of ECG signals was performed using INCART Arrhythmia Database, which automatically recognized three types: normal heartbeats, PVC and other heartbeats. The overall classification accuracy reached 98.6%, but the sensitivity (Se) of PVC was 91.4%. In a study, Allami [21] used three morphological features and seven statistical features, and also employed the artificial neural network (ANN) classifier for PVC and non-PVC ECG heartbeats recognition. Using 75 ECG records, the classification accuracy and the sensitivity (Se) of PVC they achieved was 95.8% and 93.9%, respectively. In another, Malek et al. [22] developed an improved template matching technique for PVCs and normal heartbeats detecting, by analyzing the maximum value and the correlation coefficients of the maximum and minimum value. The classification accuracy rate was 97.91%, and the sensitivity (Se) and specificity (Sp) of PVC detection were 91.14% and 98.82%, respectively. In general, the proposed SE-ResNet residual network has achieved superior performance on the PVCs recognition experiments using the 12-lead dynamic ECGs. It demonstrates great clinical application prospects.

F. Discussion

Dynamic 12-lead ECG is the gold standard in the detection of arrhythmias. Multi-lead dynamic ECG has strong background noise; there are correlations of ECG leads. Different arrhythmias have corresponding lead characteristics, and the main wave morphological characteristics of some leads are more distinguishable for the specific arrhythmia. Squeeze-excitation network introduces attention mechanism that the importance of each feature channel is automatically obtained by learning. That the useful features are promoted and the less useful features are suppressed according to its importance. The network model can fully consider the weight of each lead and main wave of ECG signals. Therefore, the model can fully extract the morphological features of multi-lead and its main waves, and improve the robustness and generalization ability of the network.

In this work, we analysis the characteristics of the long-time dynamic 12-lead ECGs and introduce the squeeze-excitation ResNet model to the real-time PVCs recognition on 12-lead dynamic ECGs. Which is to overcome the and fully extract the multi-lead and multi-dominant complexes. Reconstructing hyperplane parameters by squeeze-excitation operation can alleviate the problems of the difficulty tuning of deep network and the nonlinear fitting ability of deep network. In addition, we considered the influence of SE-ResNet models with different layers and structures on the training results, and through experiments, a 20-layer network was selected as the recognition model. At the same time, the results of two different loss functions under the 20-layer network model are also compared. Finally, the CrossEntropyLoss function was selected as the loss function. The test accuracy of the method proposed in this paper is 98.71%. Under the same dataset and experimental platform, the recognition accuracy of this method is improved compared with CNN, IncexNet and deep multilayer perceptron. The proposed SE-ResNet residual network has achieved superior performance on the PVCs recognition experiments using the 12-lead dynamic ECGs. It demonstrates great clinical application prospects. Then, the PVCs detection results of our proposed method were compared with the recent published research results. Experimental results show that our method has better precision and accuracy than previous studies. Which perform Demonstrate its practical application potential in the medical field.

Although the research results of this paper has achieved good performance, there are still some challenges and study values. First, Bioelectric signals are characterized by individual variability, strong interference, and multi-lead characteristics. The same patient will also have certain differences in different times and environments. Real-time identification of multiple arrhythmias using clinical big data is a challenge work and is of great value in clinical diagnosis. Therefore, we will extend the proposed method to multiple types of arrhythmias on long-term dynamic ECGs, which is of great significance for collecting more clinical ECG data from different patients under different conditions. This also puts forward higher requirements on the robustness and generalization ability of the recognition network. Second, because of the fast and slow changes in heart rhythm, it is not always desirable to use a fixed beat length. It is necessary to study adaptive beat size segmentation to meet different. Third, to achieve higher accuracy, many studies focus on the deep learning trend of making networks deeper and more complex. However, many real-world studies must be performed on computationally limited platforms. We need to consider the computational speed and the computational complexity of the model, as well as its accuracy. Finally, as catheter ablation is an effective therapy for treatment of symptomatic PVCs. And it is important to estimate the targeted anatomic ablation site that prior to the procedure. Based on this study, the localization of the site of origin of a PVCs using 12-lead ECGs is still an interesting and challenge work. Therefore, the further study of us will focus on the location of PVCs. It is important for the planning and execution of the electrophysiological procedure for the catheter ablation and has great clinical application values.

IV. Conclusion

In this study, a 12-lead dynamic ECG PVCs recognition algorithm based on squeeze-excitation residual network is proposed. The squeeze-excitation module is constructed and embedded in the residual structure to improve the performance of the deep network. The hyperplane parameters are reconstructed by squeezing-excitation operations to improve the nonlinear fitting ability of deep networks. A SE-ResNet model based on 20 layers is designed, which overcomes the degradation problem caused by the increase of the network layers when the deep neural network approximates the identity mapping, and ensures the smooth convergence of the network. Experiments of PVCs recognition was performed using 168,379 heartbeats from the INCART dynamic 12-lead ECG database. In the same experimental samples, several popular deep neural network algorithms were compared. The experimental results show that the proposed method effectively improves the overall PVC recognition accuracy on the INCART 12-lead dynamic ECGs, as well as the sensitivity and the specificity have achieved. In the future, we intend to improve the performance of this work with further advanced deep learning techniques. Additional datasets will be added to test the performance of the model to further verify the robustness of the method used. Furthermore, we will further study the localization of the site of origin of a PVC, which is important for the planning and execution of the electrophysiological procedure for the catheter ablation.

Personality Classification Model of Social Network Profiles based on their Activities and Contents

Mervat Ragab Bakry[1], Mona Mohamed Nasr[2], Fahad Kamal Alsheref[3]
Information Systems Department, Beni-Suef University, Egypt[1, 3]
Information Systems Department, Helwan University, Egypt[2]

Abstract*—Social networks have become an important part of everyday life, especially after the latest technologies such as smartphones, tablets, and laptops have become widespread. Individuals spend a lot of time on social media and express their feelings and opinions through statuses, comments, and updates which could be a way to understand and classify their personalities. The personalities in psychological science are divided into five classes according to the Big-five model (Openness, Extraversion, Consciousness, Agreeableness, and Neurotic). This model shows the key features with their weights for each personality. In this paper, a proposed model is developed for detecting the personality features from users' activities in social networks. In this model, machine learning techniques are used for predicting the personalities with a score for each Big-five model type and sorting them in descending order. The personality classification model will be useful in developing a better understanding of the user profile and specifically targeting users with appropriate advertising. Any social media network user's personality can be predicted by using their posts and status updates to get better accuracy. The experimental results of the model in this study provide an enhancement because it can predict the precise score of one user in each factor of the Big-five. The proposed model was tested on a dataset extracted from Facebook and manually classified by experts, and it achieved 89.37% accuracy.

***Keywords*—Psychological personality; machine learning techniques; big-five; LinearSVC**

I. Introduction

In recent years, social media has surpassed email as the most extensively utilized method for communication and engagement between people [1]. As people increasingly choose to connect informally through smartphones, face-to-face engagement is becoming less common. As a result, determining a person's personality is challenging. However, because individuals spend a lot of time on social media and express their feelings and opinions through statuses, comments, and updates, what is published on social networks can help to receive the information needed for this study.

Users on Facebook typically express their views and ideas through status updates or comments. Despite the fact that Facebook is now more extensively used to post photographs and videos, this study focuses on the linguistic element of Facebook users' status updates. There is a link between a person's personality and his or her language conduct, according to studies in the field of psychology [2] and [3]. Using a natural language processing technique, this association may be successfully evaluated and shown. As a result, the purpose of this study is to develop a system that can automatically estimate a user's personality based on their Facebook behaviors.

Big Five Personality, MBTI (Myers-Briggs Type Indicator), and DISC are some of the personality models used to predict personality (Dominance Influence Steadiness Conscientiousness). However, after some thought and a literature search, Big-five personality was chosen for this paper since it is the most common and accurate method of determining a person's personality qualities. Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism are the traits in this paradigm.

The corpus used in this study consists of a one dataset which contains 100 Facebook profiles with their 27,182 posts classified over 38 categories. The rest of this paper is organized as follows. Section II gives background information about used concepts and techniques. Section III discusses related work. Section IV describes the proposed model for personality classification model. In Section V, the case study and its findings are discussed and the conclusion in Section VI.

II. Background

Several methodologies, such as the Personality model and other classification algorithms, are employed in the proposed model, as discussed in the following sections.

A. Personality Models

Personality is a persistent tendency and attribute that governs how an individual's psychological behavior is similar and different (thoughts, emotions, behaviors). In other words, personality reflects patterns of human behavior, thought, and interpersonal communication, and has a significant impact on a variety of elements of life, including happiness, taste, and physical and mental health [3] and [4]. There are other psychological personality models, but the Big Five (shown in Fig. 1) is the most often utilized.

1) Big-five model: Many academics nowadays believe that there are five basic personality traits [5]. For several years, evidence of this notion has been growing, beginning with D. W. Fiske's (1949) research and later elaborated upon by other researchers such as Norman (1967), Smith (1967), Goldberg (1981), and McCrae & Costa (1983). (1987).

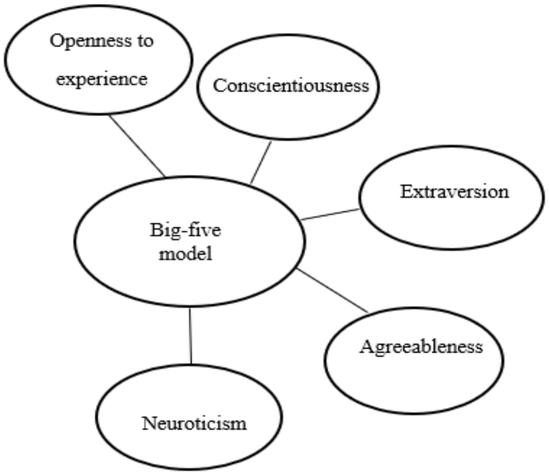

Fig. 1. Big-Five Model [5].

The big five personality traits are broad categories of personality traits are:

- Openness: Imagination and insight are two features of this attribute [5]. People with a high level of this attribute also have a diverse set of interests. They are curious in the world and other people, and they are eager to learn new skills and have a better understanding of new concerns. People with a high level of this characteristic are more likely to be daring and creative. People with low levels of this component are more traditional and may have difficulty thinking abstractly [6].
- Conscientiousness: High levels of thinking, effective impulse control, and goal-directed activities are all common aspects of this component [5]. People that are very conscientious have a propensity to be structured and detail oriented. They consider the consequences of their activities and are mindful of deadlines [6].
- Extraversion: Excitability, sociability, talkativeness, decisiveness, and extensive use of emotional emotions are all characteristics of extraversion [5]. People with a high level of extraversion are friendly and have a proclivity to gain power in social situations. Being in the company of others helps them to feel empowered and happy. People with a low level of extraversion are more likely to be timid and have less ability to consume in social contexts [6].
- Agreeableness: Characteristics like confidence, altruism, humanism, love, and other prosocial behaviours are included in this personality component [5]. People who score high in agreeableness are more helpful, whereas those who score low are more competitive and, at times, cunning [6].
- Neuroticism: Sadness, moodiness, and emotional unpredictability are all symptoms of neuroticism [5]. People with high levels of this component are more likely to experience mood swings, concern, irritability, and disappointment. People who score low on this characteristic are more emotionally balanced [6].

B. *Classification Algorithms*

As mentioned in section I, there are 38 categories and the collected posts and comments are classified on them, so in this study the several classification algorithms are used to classify new entries into the predefined categories or classes.

The selected classification algorithms are:

- Linear Support Vector Classification (LSVC)
- Logistic Regression (LR)
- The multinomial Naive Bayes classifier (MNB)
- Random Forest Classifier (RFC)

The accuracy is calculated for each algorithm to find the highest accuracy algorithm; the results exist in Section V.

III. Related Work

Many researchers have advocated extensive customization of user personality traits and other social traits in recommender systems, and in this section, a literature survey on personality traits is presented. Personality traits are used in many areas to improve recommender systems, and many researchers have advocated extensive customization of user personality traits and other social traits in recommender systems.

Gozde et al [7], collect data from 99,217 participants from 41 countries as part of the COVIDiSTRESS worldwide survey in order to better understand the numerous relationships between COVID-19 psychological outcomes and the "big-five" personality traits. Multigroup confirmatory factor analysis and a multilevel regression model were used to examine the data. The findings revealed that throughout the pandemic, the big-five personality characteristics were strongly linked to feelings of stress and loneliness, while some of the links were weak. Their research aids in the identification of susceptible individuals and the optimization of psychological therapy during and after the COVID-19 pandemic, where neuroticism is a role in stress and loneliness vulnerabilities, particularly during disasters.

Jose et al in [8] try give a complete knowledge of the primary user privacy problems that influence DDI. The methodology used in this study is divided into three phases: (i) a systematic literature review (SLR); (ii) in-depth interviews on user privacy concerns framed through the lenses of UGD and DDI; and (iii) topic modelling using a Latent Dirichlet allocation (LDA) model to extract insights related to the object of study. They identify 14 areas linked to the research of DDI and UGD techniques based on the findings. In addition, 14 future research topics and 7 research propositions for the study of UGD, DDI, and user privacy in digital marketplaces are offered and it finished with a discussion of the importance of user privacy in DDI in digital markets. And therefore, raised the importance of understanding the personality of users, forecasting user behaviour, and evaluating their actions.

Kamal et al in [9] offered a new deep learning-based personality prediction and classification model that combines data and classifier-level fusion. Using prominent pre-trained language models such as Elmo, ULMFiT, and BERT, this approach gained from transferring learning to natural language processing. The suggested model indicates the effectiveness of the strategy as a potential personality prediction model. Their proposed model proved to be more accurate than previous ones with 1.25 per cent and 3.12 per cent, respectively.

Valanarasu in [10] proposed a new machine learning method for predicting people's personalities based on the digital footprint of social media. During COVID-19, the suggested model may be verified for each job seeker by registering online for each organization. The suggested algorithm uses dynamic multi-context information, such as account information from Facebook, Twitter, and YouTube, among other sites. Personality prediction was more accurate than other available approaches. Even though human reasoning changes seasonally, the suggested algorithm regularly outperforms other current traditional techniques to predicting human cognition.

Masud [11] surveyed a chosen number of Facebook users based on the Short Dark Triad (SD3) model. Random Forest, Support Vector Machine, and Nave Bayes algorithms were used to categorize dark triads like Machiavellianism, Self-Centricity, and Psychopathy in this study. Compared to Random Forest and SVM, Nave Bayes produced superior results. However, showing psychopathy and self-centeredness is more difficult to detect than Machiavellianism, according to their research.

Yang Li et al in [12] proposed a new multi-task learning framework that predicted personality traits and emotional behaviours at the same time, based on the well-known correlation between personality traits and emotional attitude. It also empirically evaluated and described various information exchange mechanisms between the two tasks.

Fatemeh et al in [13] proposed a deep learning-based method for the detecting personalities from text. Convolutional neural networks (CNNs) were utilized, which have previously been found to be effective in natural language processing and personality recognition. A series of tests were used to validate their suggested technique using an essay dataset, and the empirical findings indicated that it outperformed machine learning and deep learning methods for personality detection tasks.

Ghina in [14] proposed a model to predict the personalities of Twitter users with better performance than other prediction systems. It was done by an online poll utilizing the Big-five Inventory (BFI) survey, which was sent to 295 Twitter users and collected 511,617 tweets. The suggested model employed a Support Vector Machine (SVM) to test two alternative semantic approaches that combined SVM and BERT. The results reveal that combining these two approaches yields an accuracy score of 79.35 percent, with LIWC deployment improving the accuracy score by up to 80.07 percent.

Jianshan et al in [15] proposed a new way to formalize personality as a digital twin model by observing content postings and user preference behaviours. The deep neural multitask learning network model uses two forms of data representation to estimate a user's personality. Experiments suggest that integrating the two forms of data can increase personality prediction accuracy.

Junaid et al in [16] proposed a model to classify the input text into psychopathic and nonpsychopathic features. The majority of prior work on psychopath identification has been done in the realm of psychology, employing conventional methodologies like the SRP III method and small dataset sizes. As a result, they are motivated to create advanced computer models in the field of text analysis to detect psychopaths. This study investigates sophisticated deep learning approaches, such as attention-based BILSTMs, for expanding dataset size and effectively classifying input text into psychopath and nonpsychopath classes in order to discover psychopaths.

At the conclusion of this section, it must be affirmed that understanding personality is critical to target users with appropriate advertising, detect the dark side of the personality, and assist in the recruitment process, in which some companies require understanding personality prior to employment process acceptance in order to determine whether or not a candidate has aggressive behaviour. In this project, machine learning techniques will be utilized to create a model that predicts psychological personality scores based on user-generated content utilizing the Big-five model's multiple elements and metrics. The study's hurdles include gathering data and estimating a single user's precise score in each of the big-five factors.

IV. Proposed Model

Fig. 2 shows the suggested methodology. User-generated material (posts) is sent to the preparation phase, which includes data cleaning, data transformation, and text conversion to vectors so that the algorithms can develop a prediction model, manage missing values, and remove stop words. Model of this study has two main phases Machine learning phase and personality prediction phase. The dataset of users' posts contains two main characteristics (post and post category), as shown in table I. The features are then passed on to the machine learning methods phase, which uses 80% of the dataset for training and 20% for testing.

Then move to the personality prediction phase After building the classification model, which used to predict the category of the posts for each user. The result of this phase is a new csv file with post, predicted post category, and five new columns containing discrete values for each of the big-five traits for each post category; values from 0 to 5, which 0 means that a specific big-five trait does not meet that category and 5 means that a specific big-five trait strongly meets that category, a snap shot of the csv file is shown in Fig. 3.

Finally, the model can detect the user personality between the big-five by classifying his posts and then calculating the score as shown in Table II. Table II displays an example of personality prediction results for one user posts.

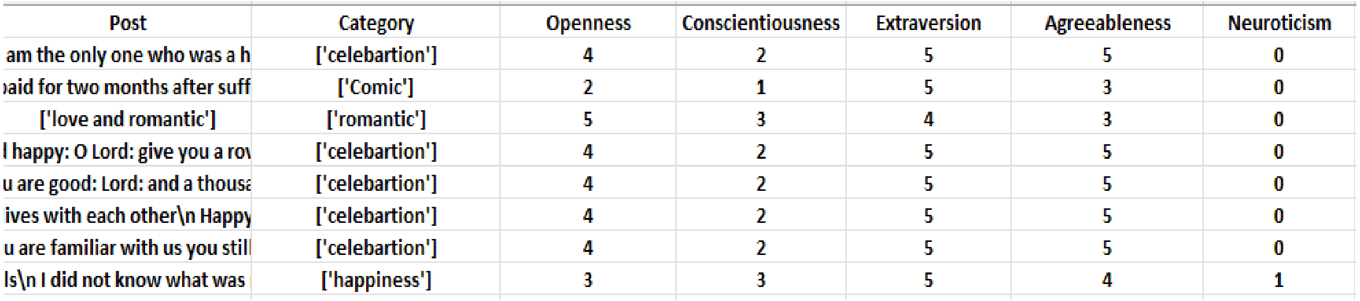
Post	Category
['Eman Tuhami: I swear if I said all the words of the world I cannot give you your place. During the four years college: with the feeling that I am your daughter happiness and happy day.\n Thousand million Congratulations my beloved makes us a good husband for you.']	['celebration']
['When you get paid for two months after suffering of waiting']	['Comic']



Post	Category	Openness	Conscientiousness	Extraversion	Agreeableness	Neuroticism
am the only one who was a h	['celebartion']	4	2	5	5	0
›aid for two months after suff	['Comic']	2	1	5	3	0
['love and romantic']	['romantic']	5	3	4	3	0
l happy: O Lord: give you a ro\	['celebartion']	4	2	5	5	0
u are good: Lord: and a thous:	['celebartion']	4	2	5	5	0
ives with each other\n Happy	['celebartion']	4	2	5	5	0
u are familiar with us you stil	['celebartion']	4	2	5	5	0
ls\n I did not know what was	['happiness']	3	3	5	4	1

Fig. 3. CSV File with Big-Five Scores.

TABLE II. EXAMPLE OF PERSONALITY PREDICTION FOR ONE USER

Big-five Trait	Score
Openess to Experience	23.859386686611817 %
Conscientiousness	20.269259536275243 %
Extraversion	23.78459237097981 %
Agreeableness	23.036649214659686 %
Neuroticism	9.050112191473449 %

TABLE III. MACHINE LEARNING ALGORITHMS ACCURACY

Model Name	Mean Accuracy
Linear SVC	89.37%
Logistic Regression	87.11%
Multinomial NB	78.81%
Random Forest Classifier	54.44 %

V. EXPERIMENTAL RESULTS

Gathered dataset comes from the user's Facebook profile, post data, and medium post titles, and is based on a merged dataset. The final dataset comprises all of the Facebook postings as well as their categories. Dataset has 38 categories that assist in obtaining more precise findings. The total number of postings in the final dataset is 27,182. The categories are verified by the psychologist Dr. Noha Gamal.

Then the model applied the machine learning algorithms LR, MNB, LSVC, and RFC for predicting the post category for each post. The results shows that LSVC achieved the highest accuracy with 89.37% while the RFC got the lowest accuracy with 54.44%, the other results are shown in Table III, Fig. 4 and Fig. 5.

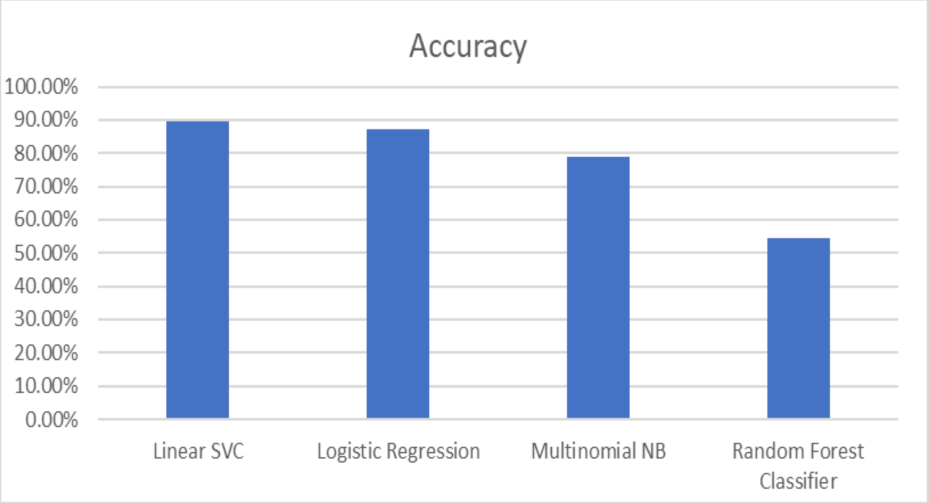


Fig. 4. Comparison of Model Performance.

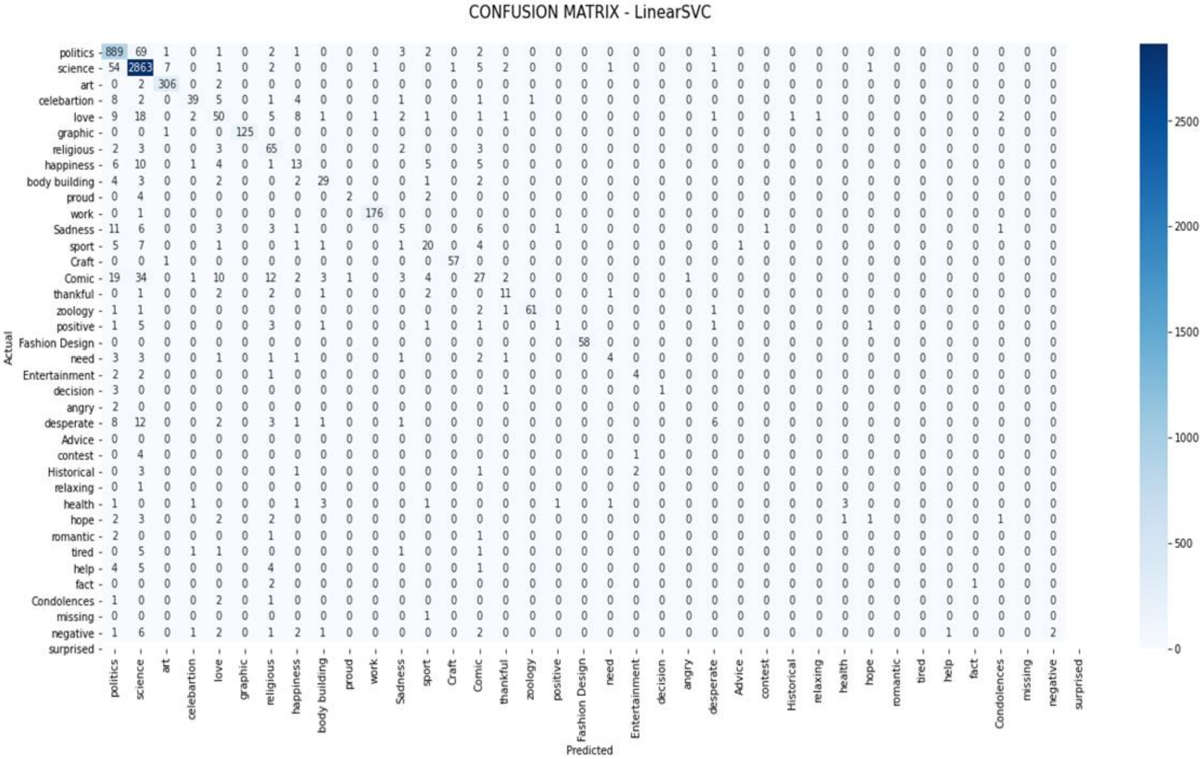

Fig. 5. LSVC Confusion Matrix.

Our achieved accuracy proves the success of the proposed model by achieving more accuracy than previous work mentioned in the previous section.

The classification results are presented and explained in this section, and Table III shows a comparison of model performance. To forecast each user's personality traits, each user's postings are sent to the model as a distinct document, and the results identify the user's personality of the big-five.

VI. Conclusion and Future Work

Understanding personality qualities is vital for appropriately treating everyone based on his or her personality traits. The proposed model can be used to target users with appropriate advertising, detect the dark side of the personality, and aid in the recruitment process, in which some companies need to understand personality before accepting the employment process to know if this person has aggressive behaviors or not. The proposed model provesc the success of identifying user’s personality according his actions and contents in social networks. The experimental results of this study represent an improvement because it can estimate the precise score of one user in each of the big-five factors. The proposed model, LinearSVC, has an accuracy of 89.37 percent. In future work, the proposed model is planned to use deep learning to improve accuracy.

***Abstract*—We propose a method for customer profiling based on Binary Decision Tree: BDT and k-means clustering with customer related big data for sales prediction; valuable customer findings as well as customer relation improvements. Through the customer related big data, not only sales prediction but also categorization of customers as well as Corporate Social Responsibility (CSR) can be done. This paper describes a method for these purposes. Examples of the analyzed data relating to the sales prediction, valuable customer findings and customer relation improvements are shown here. It is found that the proposed method allows sales prediction, valuable customer findings with some acceptable errors.**

Keywords—Customer profiling; binary decision tree: BDT; corporate social responsibility (CSR); k-means clustering; sales prediction; valuable customer findings

I. Introduction

When "analyzing customer data", it must be understood what kind of data exists, firstly. In addition, since the data in the database is used for various purposes, it is not always stored in a format suitable for analyzing customer data. Therefore, the first thing to do is to get an overall picture of customer data by profiling. Here, we propose to assume a certain data format and think based on that data format.

This is a data retention format that is generally used as target data for data mining. The retention format is a simple table with customer numbers in the vertical rows and all possible customer attributes and indicators in the horizontal columns. This table may be physically created as a database table, or it may be considered as an image when starting the analysis work just by assuming such a format.

Since the target of the analysis is the customer, first, this format is used so that the information about each customer is listed in each line. On the other hand, the attributes and index values arranged in the column are called variables. It is a "variable" meaning a "changing numerical value" because it takes a different value for each customer. The variable means the standard for looking at the customer and defines "from what point of view the customer is understood".

To perform profiling, let's look at each variable independently. Each variable is classified as either a quantitative variable or a qualitative variable. In the case of quantitative variables, understand the characteristics of variable values by using representative values such as average value, minimum value, and maximum value. Also, by understanding the distribution, it becomes possible to understand how the variable values are concentrated / distributed.

Once we understand the characteristics of each variable by profiling a single variable, the next step is to understand the relationships between the variables. A scatter-like visualization of each customer in dots makes it possible to understand whether the two variables are in direct proportion, inversely proportional, or completely random. When deciphering the relationship between variables, it is necessary to proceed with the analysis with a certain purpose, not just a visual and intuitive grasp. Data mining can be considered as one of the methods.

Large analytical datasets are vertically compressed by age group. In other words, customers are classified based on a single variable (here, age), and the tendency of each classification (= segment) is grasped. In addition to this, we have added a row for the population and a new index for the number of customers. This allows us to compare with the whole customer and understand the size of each segment. At this time, since each row to be analyzed is aggregated from customer (single customer) to segment (multiple customers), the variables to be used are average value, minimum value, maximum value, total value, composition ratio, etc. It will be converted into an index and compared. And the difference in the index value is the characteristic of the segment.

If it can be understood what kind of products it is contracting / purchasing for each segment, what kind of channel it is using, what kind of usage pattern it is using, etc. It can be understood whether it has such characteristics. With this, the profiling work is almost completed, and we have grasped what kind of variable characteristics each customer group has. The next task is analysis for "behavior". Considering that the target of analysis is the customer, the "behavior" here is an action to the customer, specifically a campaign activity.

Although there are many methods for customer profiling, performance is not good enough. Also, it is rare the method which allows prediction of sales based on the customer profiling. In this paper, we intend to improve the customer profiling performance and to propose a method for sales prediction based on Deep Learning.

There are prediction related research works as follows,

Probabilistic cellular automata-based approach for prediction of hot mudflow disaster area and volume is proposed [1]. Also, new approach of prediction of Sidoarjo hot mudflow disaster area based on probabilistic cellular automata is proposed [2]. These prediction methods are expanded to GIS based 2D cellular automata approach for prediction of forest fire spreading [3].

Cell based GIS as Cellular Automata: CA for disaster spreading prediction and required data systems is proposed [4]. The method is applied to hot mudflow prediction area model and simulation based cellular automata for LUSI and plume at Sidoarjo East Jawa [5].

Comparative study between Eigen space and real space-based image prediction methods by means of autoregressive model is conducted [6]. Also, comparative study on image prediction methods between the proposed morphing utilized method and Kalman filtering method is conducted [7].

Another prediction method for time series of imagery data in Eigen space is proposed [8] together with image prediction method with non-linear control lines derived from Kriging method with extracted feature points based on morphing [9]. Cell based GIS as cellular automata for disaster spreading predictions and required data systems are developed [10].

Prediction method of El Nino Southern Oscillation: ENSO event by means of wavelet-based data compression with appropriate support length of base function is proposed [11]. On the other hand, Question Answering: Q/A for collaborative learning with answer quality prediction is created [12].

Wildlife damage estimated and prediction using blog and tweet information is conducted in [13]. Meanwhile, prediction method for large diatom appearance with meteorological data and MODIS derived turbidity as well as chlorophyll-a in Ariake Bay area in Japan is proposed [14].

Method for thermal pain level prediction with eye motion using SVM is proposed in [15]. Meanwhile, prediction method for large diatom appearance with meteorological data and MODIS derived turbidity and chlorophyll-a in Ariake bay area in Japan [16].

Smartphone image based agricultural product quality and harvest amount prediction method is proposed [17]. On the other hand, data retrieval method based on physical meaning and its application for prediction of linear precipitation zone with remote sensing satellite data and open data is proposed and validated with the actual data [18].

Recursive Least Square: RLS method-based time series data prediction for many missing data is proposed [19]. Meanwhile, prediction of isoflavone content in beans with Sentinel-2 optical sensor data by means of regressive analysis is proposed and validated with the actual data [20].

In this connection, we propose a method for customer profiling based on Binary Decision Tree: BDT and K-means clustering with customer related big data for sales prediction and valuable customer findings as well as customer relation improvements. The scikit-learn of BDT[1] is used in the study. K-means clustering of scikit-learn[2] is also used.

The following section describes research background followed by the proposed method. Then example of the experimental actual data of sales is described as a validation of the proposed method followed by conclusion with some discussions.

II. Research Background

A. Importance of Customer Profiling

Customer profiling is important for improving sales environment and customer relation. In order to create customer profiles, customer clustering is needed, first. Then valuable customers could be found. These activities help customer need surveillance together with customer satisfaction as shown in Fig. 1.

Customer Needs Satisfactio

Fig. 1. Importance of Customer Profiling.

B. Parameters for Customer Profiling

There are 7 layers of the parameters for customer profiling as shown in Table I. In the layers, typical data labels as shown in Fig. 2 must be considered.

The parameters in each layer are shown in Fig. 2, the parameters in Fig. 2 shows all the possible parameters, some of them are influencing to sales prediction. The first layer includes customer information while the second layer includes demographics information. Meanwhile, the third layer includes geographic information while the fourth layer includes information on customers' preference and interest. On the other hand, the fifth layer includes shopping pattern while the sixth layer includes brand affinity. The seventh layer includes purchase action related information such as risk to lose, propensity to buy, predicted date to come.

III. Proposed Sales Prediction Method

A. Sales Prediction

Fig. 3 shows the proposed process flow of sales prediction. The customer profile, including the information on gender, age, address, occupation, education etc. must be made available first. Then it is followed by segmentation. After that, AI models are created, and finally total sales is going to be predicted.

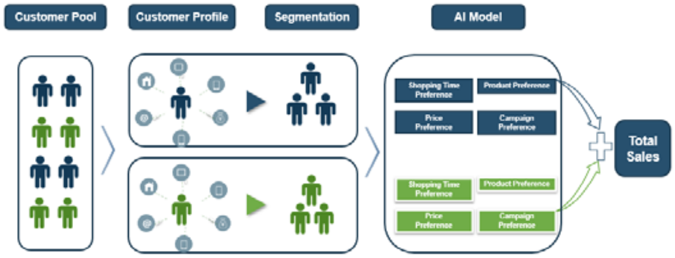

Fig. 3. Proposed Process Flow of Sales Prediction.

Fig. 4 also shows the details of sales prediction targets. The next visit date, types of sales products and sales are predicted with the AI models. Time, product, price preferences are modeled by AI through learning processes of deep learning.

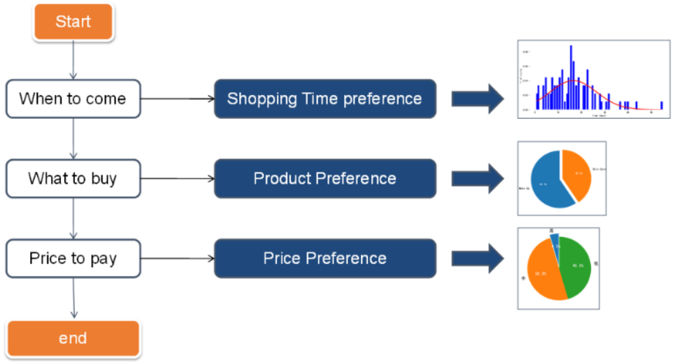

Fig. 4. Details of Sales Prediction Targets.

B. Sales Prediction with Deep Learning

Fig. 5 shows the preferences of the time, the product, and the price for the specific customer. The customer is specified through the previous processes with deep learning. All the preferences are obtained from the sales information such as shown in Table II. This is a just example of the specific customer's sales data. Total sales can also be predicted through the learned deep learning. In the proposed Deep Learning, TensorFlow Keras is used. Two hidden layers are implemented with the number of neurons of 250. Also, ReLU is used for activation function together with the fully connected layer with SoftMax function.

(c)Price Preference.

Fig. 5. Preferences of the Time, the Product and the Price.

IV. Experimental Results from Sales Prediction

A. Preparation of Data for Deep Learning

The first thing we must do is to check the missing data in the customer information. Fig. 6 shows the percentage ratio of the missing data by item by item. The customer rank is the most frequently missing data item followed by e-mail addresses of the customer. Therefore, we must conduct deep learning processes without the missing data. The second thing we must do is to standardization of sales data. The ranges are different from each other so that the sales data are standardized with mean and standard deviation so as to adjust the mean and standard deviation are 0 and 1 after the standardization.

Fig. 7 shows the percentage ratio of the missing data in the sales data. As shown in Fig. 7, the highest percentage ratio of the missing data about sales is motivation to visit the shop followed by the staff ID who made services to the customer. These missing data of customer related information and the sales data must be care about in the learning processes.

TABLE II. Sales Data for the Specific Customer

Customer ID	Product ID	Product Price	No. of Sales
133034	32	Skin Care	1
133034	48	Skin Care	1

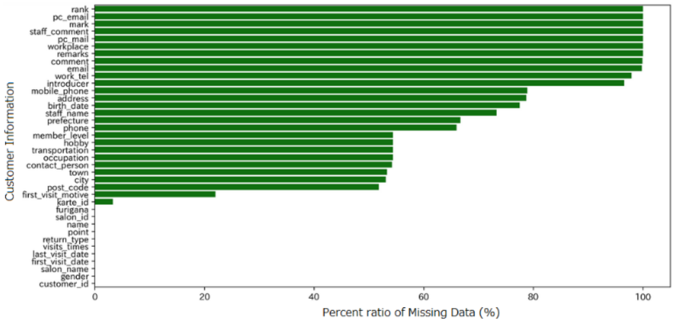

Fig. 6. Percentage Ratio of the Missing Data in the Sales Data.

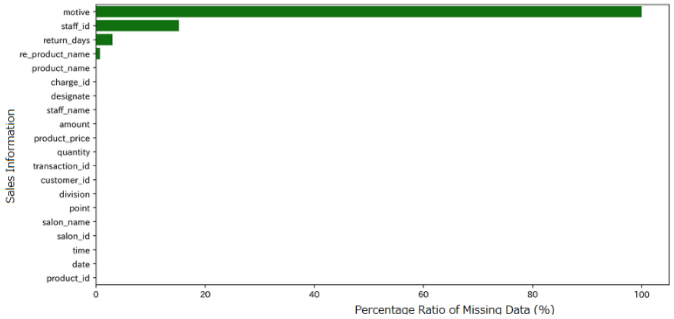

Fig. 7. Percentage Ratio of the Missing Data in the Sales Data.

Fig. 8 shows rating results of the percentage ratio of the sales type (Product name). The highest sales type is the adult hair cut (sales type No.1) followed by the gray hair dyeing (sales type No.2).

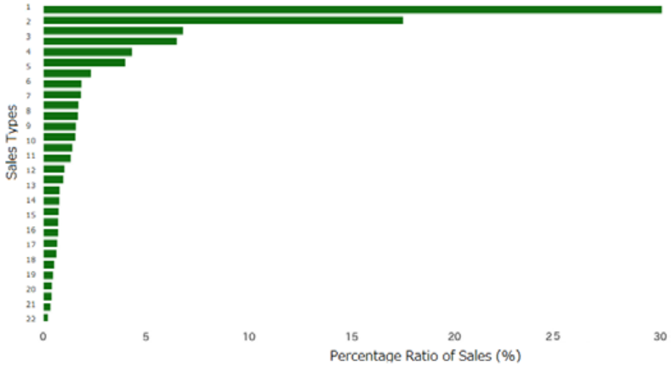

Fig. 8. Rating Results of the Percentage Ratio of the Sales Type (Product Name).

Monthly sales can also be calculated from the sales data. Fig. 9 shows the monthly sales for the specific hair salon for the period from September of 2010 to December of 2021.

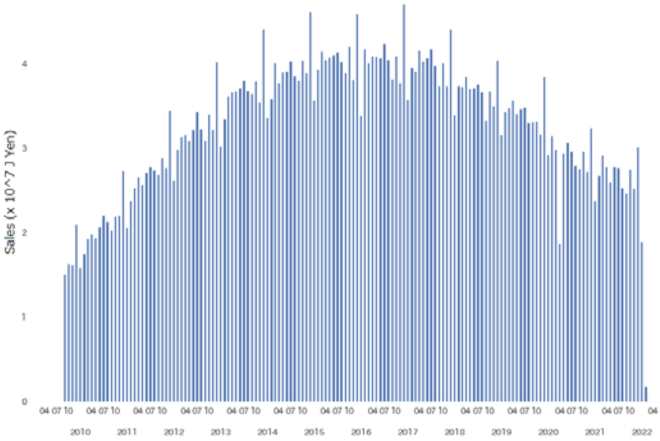

Fig. 9. Monthly Sales for the Specific Hair Salon.

Fig. 10 shows the revisit day interval (repeat cycle) for the specific hair salon.

As shown in Fig. 10, highest frequency ranges from 30 to 60 days. Therefore, it is found that the customer visits the specific hair salon every month to two months. Also, histogram of customers' age distribution is shown in Fig. 11. There are two peaks at around 15 to 20 years old for both male and female customers and 45 to 85 years old for female customers. This is the second layer of the customer profile, demographic information. The other layer data are also calculated from the sales data.

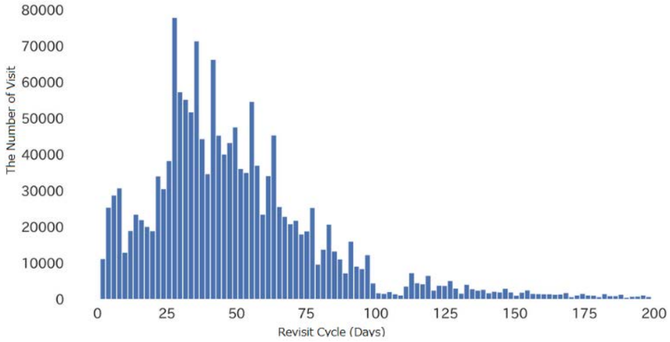

Fig. 10. Revisit Day Interval (Repeat Cycle) for the Specific Hair Salon.

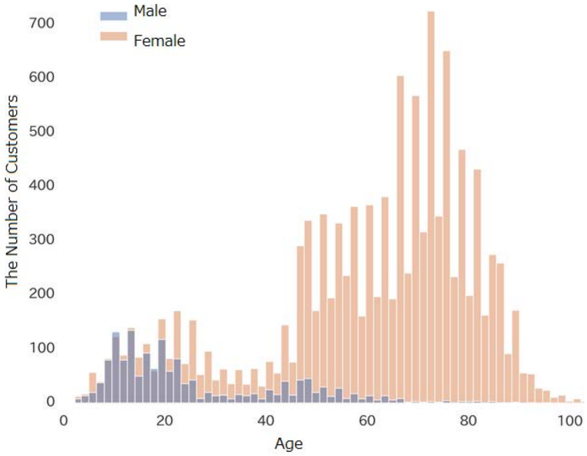

Fig. 11. Histogram of Customers' Age Distribution.

B. Customer Clustering

The number of visits to the specific hair salon is investigated as one of the parameters (feature vector) of the customer clustering.

Fig. 12 shows relation between the number of visit and the number of customers (green bars) as well as percentage ratio of revisit customers (red solid line). More than 95% of customers are repeat customers as shown in Fig. 12.

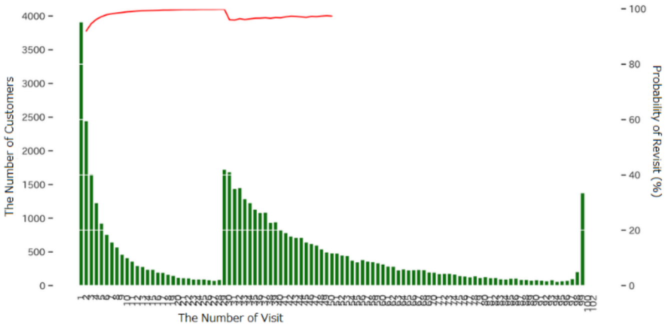

Fig. 12. Relation between the Number of Visit and the Number of Customers as well as Percentage Ratio of Revisit Customers.

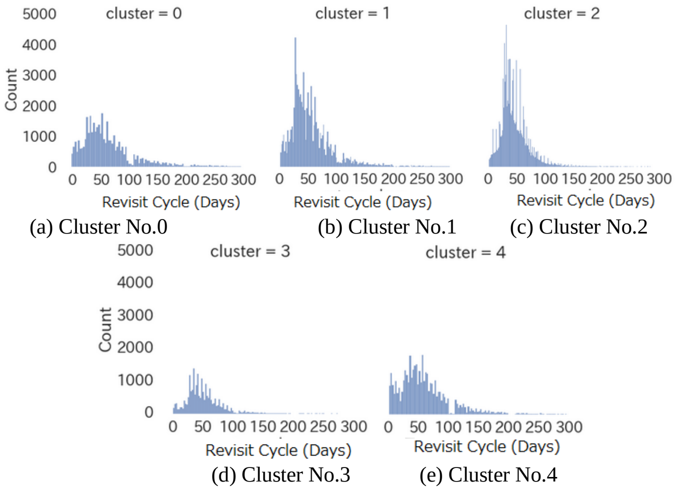

(a) Cluster No.0 (b) Cluster No.1 (c) Cluster No.2

(d) Cluster No.3 (e) Cluster No.4

Fig. 13. Histogram of the Revisit Cycle (Days).

Then K-mean clustering is applied to the sales data with the number of clusters is five. Histogram of the revisit cycle (days) is shown in Fig. 13. This is one of the results from the clustering. Also, the learning processes are done with deep learning for each cluster. The cluster No. 0 is resembling to the cluster No. 4.

TABLE III. NUMBER OF CUSTOMERS FOR EACH CLUSTER

Cluster No.	The_Number_of_Customers
1	1833
4	1439
2	1360
0	1316
3	564

There is the peak of the histogram at the revisit cycle around 50. On the other hand, the cluster No. 1 is like the cluster No. 2 the peaks of the histograms of the cluster No. 1 and 2 are much higher than that of the cluster No.0 and 4 as well as the cluster No.3. The number of customers for each cluster is shown in Table III.

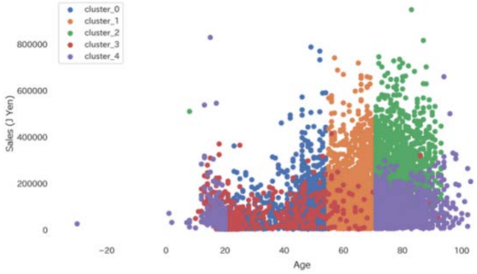

Fig. 14. Relation between the Sales Amount and Age.

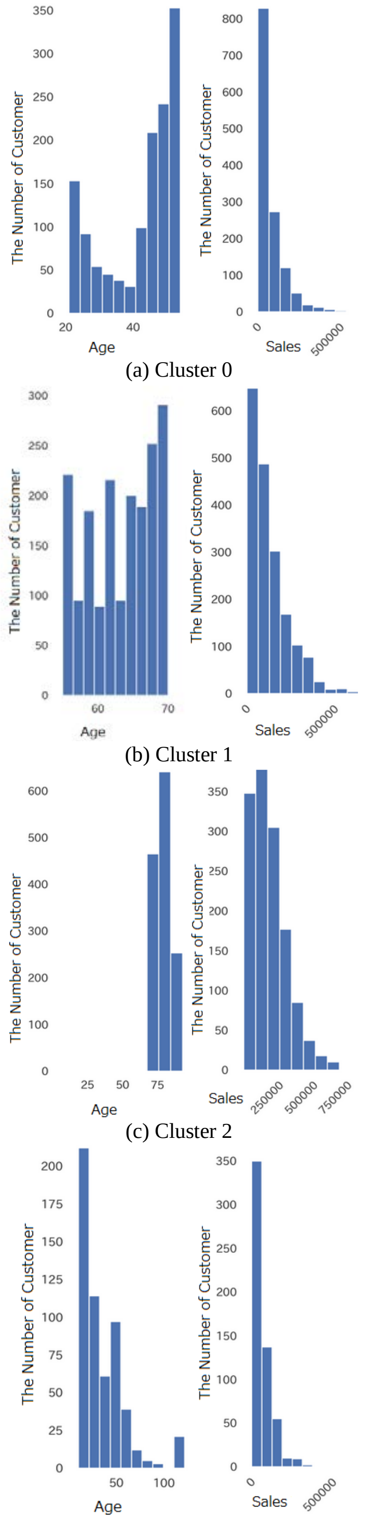
C. Clustering Results

One of the clustering results is shown in Fig. 14 (relation between the age and the sales amount) for each cluster. Also, Fig. 15 shows the relations between the number of customer and age as well as sales for each cluster. As shown in Fig. 14 and 15, all the customers are divided into five clusters clearly and these clusters are well characterized with their profiles.

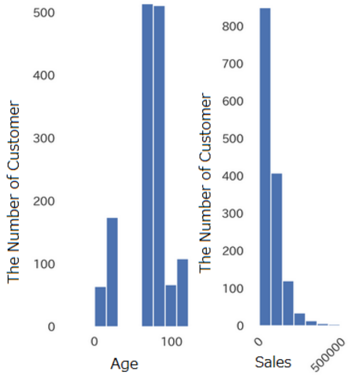


(a) Cluster 0

(b) Cluster 1

(c) Cluster 2

(d) Cluster 3



(e) Cluster 4

Fig. 15. Relations between the Number of Customer and Age as well as Sales.

Fig. 16 shows the sales amount for each cluster. The sales amount of the cluster No. 2 is highest followed by cluster No. 1. Also, there is the big dip at the late of 2019 since the number of customers is getting down by the influence due to the COVID-19.

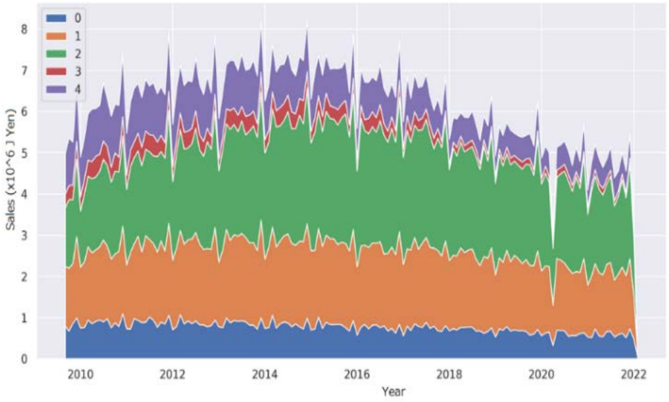


Fig. 16. Shows the Sales Amount for each Cluster.

D. Deep Learning

After the clustering, all the customers are divided into five clusters. Then the customers are segmented. Also, the number of transactions (visit), the sales amount is investigated. TensorFlow of deep learning is used for sales prediction. The training sample data is the sales data of the year from 2010 to 2013 and the validation data is the sales data of the year of 2014. The four years learning processes are conducted and then validation is done for the year of 2014. The validation result is shown in Fig. 17.

As shown in Fig. 17, prediction accuracy is not good enough (Root Mean Square Error: RMSE= 17.04: 21.25%) since the training sales data is not enough for deep learning. Also, customers’ behavior is changed by year so that the different customers’ behavior between 2010 to 2014 and 2014 induces such prediction error.

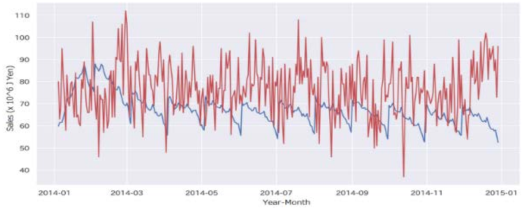

Fig. 17. Sales Prediction Result for the Year of 2014 with the Learning Processes during 2010 and 2013.

V. Conclusion

We proposed a method for customer profiling based on Binary Decision Tree: BDT and K-means clustering with customer related big data for sales prediction and valuable customer findings as well as customer relation improvements. Through the customer related big data, not only sales prediction but also categorization of customers as well as Corporate Social Responsibility: CSR can be done.

This paper describes a method for these purposes. Examples of the analyzed data relating to the sales prediction, valuable customer findings and customer relation improvements are shown in this paper. It is found that the proposed method allows sales prediction, valuable customer findings with some acceptable errors (21.25% of RMSE).

VI. Future Reaesrch Work

Further investigations are required for improvement of prediction accuracy.

Acknowledgment

During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 77 books and published 670 journal papers as well as 500 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

A New Hybrid-Heuristic Approach for Vertex *p*-Median Location Problems

Hassan Mohamed Rabie[1]
Institute of National Planning
Egypt

Said Salhi[2]
Kent Business School, University of Kent
Canterbury CT2 7FS

***Abstract*—In this paper, a new hybridization of a Myopic and Neighborhood approaches is proposed to solve large-size vertex *p*-median location problems. The effectiveness and efficiency of our approach are demonstrated empirically through an intensive computational experiment on large-size instances taken from TSPLib and BIRCH datasets, with the number of nodes varying from 734 to 9,976 for the former and from 9,600 to 20,000 nodes for the latter. The results show that the new approach, though relatively simple, yields better solutions compared to the ones in the literature. This demonstrates that a simpler approach that takes into account the advantages of other methods can lead to promising outcome and has the potential of being adopted in other combinatorial optimization problems.**

Keywords*—*P-median; discrete location problems; myopic heuristic; neighborhood heuristic

I. Introduction

The *p*-median location problem is one of the oldest discrete location problems. The objective of the vertex *p*-median location problem is to find the location of *p* median facilities among *n* demand points to minimize the sum of the distances between customers and their nearest median facilities. This problem is also known as the minisum vertex location problem [1]. In the uncapacitated type, each median facility is not restricted by the number of demand points/customers to serve, however, in the capacitated *p*-median location problem each median facility has a fixed capacity. In this paper, we are interested in addressing the former for the case of large-scale instances where exact methods may not be suitable. This type of location problems has many applications such as, locating the locations of the ambulances, schools, firefighters and hospitals among others [2-5].

The problem was first introduced in [6, 7], and has been proved to be an NP-hard optimization problem [8]. For large-size location problems, optimal solutions may not be reached, therefore, heuristic and metaheuristic approaches are usually the best way forward for solving these vertex *p*-median location problems [9, 10]. For more information on the vertex *p*-median location problems, see [11-13]. The vertex *p*-median location problem was formulated by ReVelle and Swain in [14] and its implementation was enhanced by Rosing et al. in [15]. The following notation is used.

Let I be the set of nodes (demand points), J the set of potential sites, and C_{ij} the distance between site i ($i \in I$) and demand point j ($j \in J$).

Let p the number of median facilities to be located and let y_i and x_{ij} the following decision variables with:

$$y_i = \begin{cases} 1, if\ a\ facility\ is\ located\ at\ candidate\ site\ i \\ \qquad\qquad 0, otherwise \end{cases}$$

and x_{ij} the fraction of the demand of customer j that is supplied from facility i.

The p-median location problem can be formulated as follows:

$$minimize\ \sum_{i \in I} \sum_{j \in J} c_{ij} x_{ij} \tag{1}$$

$$subject\ to\ \sum_{i \in I} x_{ij} = 1\ \forall\ j\ \in J \tag{2}$$

$$\sum_{i \in I} y_i = p \tag{3}$$

$$x_{ij} - y_i \leq 0\ \forall\ i\ \in I\ ;\ j\ \in J \tag{4}$$

$$y_i\ \in \{0\ , 1\}\ ;\ \forall\ i\ \in I \tag{5}$$

$$x_{ij}\ \geq\ 0\ ;\ j\ \in J \tag{6}$$

Equation (1) is the objective function which minimizes the sum of the total distances, (2) states that all demand at demand site (*j*) must be satisfied, (3) guarantees that exactly *p* median facilities are to be located. Equation (4) ensures that demand nodes can be only assigned to the open median facilities, (5) specifies that the location variables have to be binary, and finally, (6) requires that the assignment variables have to be non-negative.

Though there exist heuristic approaches dedicated for the vertex *p*-median location, there is no recent research that has concentrated on comparing the performance of the heuristic approaches with the state-of-the-art techniques. In this paper, we aim to fill that gap.

A. Contribution and Organization of the Paper

Here, the basic Myopic construction and Neighborhood improvement approaches are first outlined. A new Hybrid-heuristic that integrates the two above techniques is also proposed. In other words, the contribution of this study is three folds:

- Introduce a new Hybrid-heuristic approach which integrates Myopic and Neighborhood for solving large-size vertex *p*-median problems,

- Compare the performance of heuristic approaches versus the performance of recent existing approaches, and
- Generate new best solutions for large instances that can be used for benchmarking purposes or even as bounds for exact methods if need be.

The paper is organized as follows. The next Section presents a brief review of the related literature. The third Section describes some vertex *p*-median heuristic approaches, with an emphasis on the new proposed approach. In Section 4, an illustrative example is presented followed by the computational results in Section 5. The final Section outlines our conclusion and highlights some research avenues.

II. Literature Review

The difficulty of solving large-size vertex *p*-median location problems led several authors to investigate alternative approaches and techniques [16-18]. This section provides a brief overview of some work on recent large-size vertex *p*-median location problems. See [19, 20] for a review on this topic.

In [16], Avella et al. presented a Branch-and-Cut-and-Price approach, which yields reasonable solutions for instances with demand points/customers (*n*) less than 3,795. They applied their approach on the OR library instances, namely, the TSP-Lib instances [21]: Fl1400, PCB3038 and Rl5934, and the Optimal Diversity Management (ODM) instances BN1284, BN3373 and BN5535. In [22], Hansen et al. used a Variable Neighborhood Search (VNS) to find a solution for the clustering problem as a large-size vertex *p*-median location problem. They reported the results for two large-size datasets, where each dataset consists of *p* groups (clusters) of two dimensional data points generated in a square. The datasets consist of BRICH I instances and BRICH III instances [23]. The size of each dataset ranged from 10,000 demand points to 89,600 demand points. The TSP-Lib library is used to choose the second set of instances from [21]: PCB3038, RL5915, RL5934, RL11849, USA13509, IT16862, SW24978, and BM33708, where the number attached to each instance title indicates the number of demand points (*n*) in that instance. In [24], Avella et al. introduced a new Lagrangean relaxation heuristic to solve large-size *p*-median location instances. The algorithm consists of three main components: (1) Subgradient column generation, (2) Core heuristic, and (3) Aggregation procedure. The authors reported the solution of instances from BRICH (two of type BRICH I and two of type BRICH III), and also two instances from the TSP-Lib library [21], namely PCB3038 and USA13509. In [25], Irawan et al. introduced a multiphase approach that includes three parts; (1) demand points aggregation, (2) Variable Neighbourhood Search and (3) an exact approach to solve large-size unconditional and conditional *p*-median location vertex problems. The approach consists of four phases (stages). The first phase solves several aggregated problems using a ‘‘Local Search with Shaking’’ procedure to generate candidate solutions which are then used to solve a reduced location problem in Phase two using Variable Neighbourhood Search or an exact method. The new candidate solution set is then introduced as an input for the iterative learning process to tackle the aggregated *p*-median location problem in Phase three. Finally, Phase four is a post optimization phase applied to solve the original problem using a local search, starting from the best solution obtained in the previous phase. This multiphase approach is tested on three well-known datasets. The first is the BIRCH datasets (BIRCH I and BIRCH III), the second is based on the TSP-Lib library [21] which includes IT16862, SW24978, BU33708 and CH71009 whereas the third is the Circle dataset, which is a newly geometrically generated by the authors to guarantee optimal solutions and hence provides a strong comparison with the heuristic produced. In [26], Irawan and Salhi further designed a hybrid technique based on clustering and VNS with the aim to find a solution to large-size *p*-median location problems. The new approach is a multi-step methodology in which learning from previous steps is taken into account when tackling the next step. Each step consists from sub-problems which are solved by a fast procedure to produce good feasible solutions. Within each step, the solutions are grouped together to produce a new promising subset of potential medians/facilities. This is similar in principle to data mining and heuristic concentration developed by Rosing and ReVelle [27]. The proposed approach is tested on BIRCH datasets. In [3], Janáček and Kvet studied the public service system design which is formulated as a *p*-median location problem, through focusing on the approximate radial approach using dividing points. The approximate approach can be implemented using any commercial integer programming solver. The proposed approach is tested on TSP-Lib instances; RL1304, FL1400, U1432, V1748, D2103, and PCB3038. In [28], Vasilyev and Ushakov proposed a new modified hybrid sequential Lagrangian heuristic that uses a shared memory parallel implementation which can be used in suitable technology. They integrate their Lagrangian relaxation approach with a sub gradient column generation and a core selection method in combination with a simulated annealing to identify the sequences of lower and upper bounds for the optimal value. The proposed approach is also tested on BIRCH datasets. In [29], Vasilyev et al. addressed a general fault-tolerant version of the p-median location problem. The authors adapted their earlier method to determine the upper and lower bounds. They tested the proposed method on large-scale problem instances taken from TSPLIB library: JA9847, USA13509, IT16862, and SW24978.

In summary, due to the importance of the vertex *p*-median location problem and its real-life applications, a considerable amount of *p*-median location approaches have been proposed such as Branch-and-cut-and-price, Variable neighborhood search, Lagrangean relaxation, among others. Though the above approaches are promising, they are not easily and widely applicable. We therefore believe there could still be the need to propose a simple but powerful and effective heuristic-based approach.

III. Heuristics Approaches for the *p*-Median Problem

This section outlined two classes of heuristic approaches: the Myopic approach, and the Neighborhood Search approach. The Myopic approach is a construction method that builds a good solution from scratch, while the neighborhood search approach is an improvement algorithm. More details can be found in [19, 20, 30]. This will then be followed by the new hybrid myopic-neighborhood which we propose.

A. *Myopic Approach*

Myopic is the simplest greedy add (i.e., construction) heuristic approach. The Myopic method starts with an empty set of medians (vertices/points) and successively adds the candidate vertex (point) that yields the best decrease in the minisum objective function value. The process continues until the solution includes *p* median facilities [19]. The Myopic Approach is simple to understand and to implement. However, it suffers from the fact that once a facility is added, it is not removed in subsequent iterations and therefore will restrict the search space. Fig. 1 shows the commonly used Myopic pseudocode. Let us define the function $Z(J,X) = \sum_{j\in J} min_{m\in X}\{c_{mj}\},$; where X is the current set of candidate solutions. The function depends on both the set of demand nodes to be considered and the candidate locations to be used.

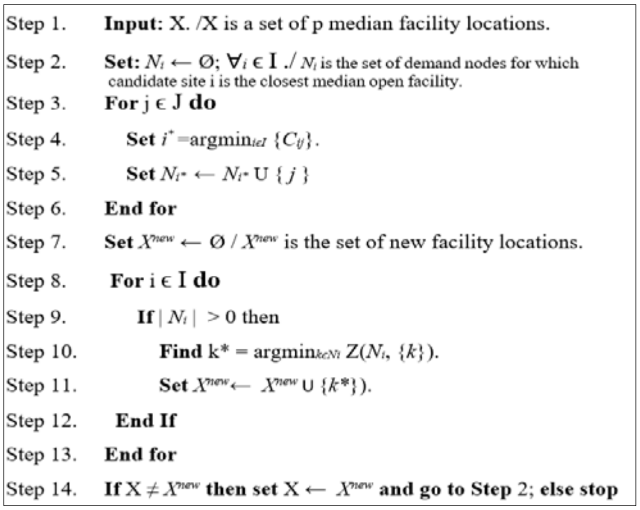
```
Step 1. Let X ← Ø. /Where X is the set of locations, starting with an empty set.
Step 2. Find $i^*$ =argmin$_{i\epsilon I}$ {Z(J, X U{i}x)}. / the best node to add to the
        solution set.
Step 3. Set X ← X U { $i$* }./ Adds that site to the solution.
.       If |X| < P, go to Step 2; else stop.
```

Fig. 1. Myopic Algorithm Pseudocode [20].

Step 1 starts by initializing the set of candidate solutions to an empty set. Step 2 relates to the best vertex (point) to be added to the candidate solution set. Step 3 adds that vertex/point to the candidate solution set. Step 4 checks if less than *p* median facilities have been added to the solution set. If so, the Myopic approach continues with Step 2; if not, the search terminates. According to Daskin [30], the solution obtained using Myopic method may not be optimal as outlined earlier. This is because once a site is chosen, it remains there which restricts the search making the solution suboptimal as the optimal solution may not necessarily have the additive property. In other words, there is no guarantee of optimality for the Myopic approach, unless we are locating only a single median facility [20].

B. *Neighborhood Approach*

Neighborhood approach attempts to improve a given solution made up of *p* candidates. It can be considered as one of the most-widely and oldest improvement mechanism [19, 30]. The approach starts with any feasible candidate solution to the vertex *p*-median location problem (For example, it could begin with the solution set identified by the Myopic approach), then the approach assigns each demand vertex to its nearest median facility. Then the one median location problem within each neighborhood is selected through examining each candidate demand point. If the solution of the one median location results in a new location for the median facility, the approach reallocates all demand points to the nearest open median facility. Otherwise (i.e., if no change for the median facility locations), the approach stops. If there is no new assignments, the approach also stops; otherwise, the search continues [20]. Fig. 2 shows the pseudocode of the Neighborhood search approach. Note that this approach was initially developed for the Weber problem (i.e, the *p*-median problem but on the plane) by [31] which is known as the locate-allocate method.



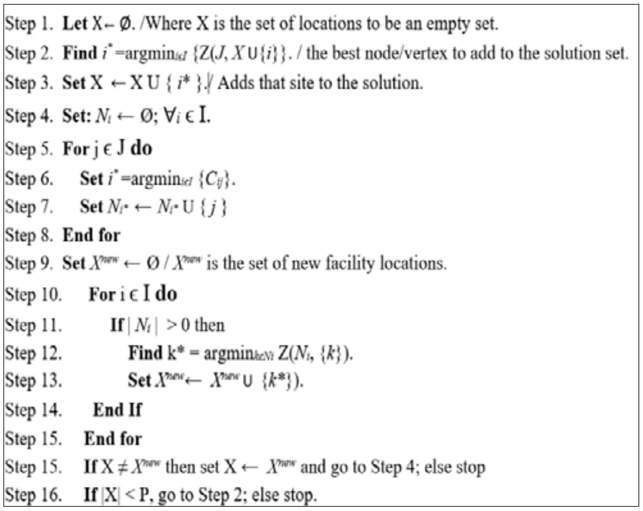
```
Step 1.   Input: X. /X is a set of p median facility locations.
Step 2.   Set: $N_i$ ← Ø; ∀$_i$ ϵ I ./ $N_i$ is the set of demand nodes for which
           candidate site i is the closest median open facility.
Step 3.   For j ϵ J do
Step 4.       Set $i^*$ =argmin$_{i\epsilon I}$ {$C_{ij}$}.
Step 5.       Set $N_{i^*}$ ← $N_{i^*}$ U { $j$ }
Step 6.   End for
Step 7.   Set $X^{new}$ ← Ø / $X^{new}$ is the set of new facility locations.
Step 8.    For i ϵ I do
Step 9.         If | $N_i$ | > 0 then
Step 10.            Find k* = argmin$_{k\epsilon Ni}$ Z($N_i$, {$k$}).
Step 11.            Set $X^{new}$← $X^{new}$ ∪ {$k$*}).
Step 12.     End If
Step 13.  End for
Step 14.  If X ≠ $X^{new}$ then set X ← $X^{new}$ and go to Step 2; else stop
```

Fig. 2. Neighborhood Search Approach Pseudocode [20].

Step 1 starts by initializing the solution with any set of *p* median facilities. Step 2 to Step 6 initialize and set the vertices/points neighborhood. Step 7 initializes a new candidate set of median facility locations. Step 8 to Step 13 the new candidate locations is found. Step 10 calculates the 1-median location problem within each neighborhood and adds that vertex/point to the solution set in Step 11.

C. *The Proposed Hybrid Myopic-Neighborhood Approach*

This section outlines the new Hybrid Myopic-Neighborhood. The main idea of the proposed approach is that, at each iteration of the Myopic and after determining the next point (vertex) to be added to the current solution; the Neighborhood approach is used as many times as possible till there is no improvement in the current candidate solution. In other words, this embedded local search acts as a filtering mechanism during the search process as the open set of facilities is augmented. Fig. 3 shows the pseudocode of the Hybrid Myopic-Neighborhood approach.



```
Step 1.  Let X← Ø. /Where X is the set of locations to be an empty set.
Step 2.  Find $i^*$ =argmin$_{i\epsilon I}$ {Z(J, X ∪{i}}. / the best node/vertex to add to the solution set.
Step 3.  Set X ← X U { $i$* }./ Adds that site to the solution.
Step 4.  Set: $N_i$ ← Ø; ∀$_i$ ϵ I.
Step 5.  For j ϵ J do
Step 6.      Set $i^*$ =argmin$_{i\epsilon I}$ {$C_{ij}$}.
Step 7.      Set $N_{i^*}$ ← $N_{i^*}$ U { $j$ }
Step 8.  End for
Step 9.  Set $X^{new}$ ← Ø / $X^{new}$ is the set of new facility locations.
Step 10.     For i ϵ I do
Step 11.         If | $N_i$ | > 0 then
Step 12.             Find k* = argmin$_{k\epsilon Ni}$ Z($N_i$, {$k$}).
Step 13.             Set $X^{new}$← $X^{new}$ ∪ {$k$*}).
Step 14.      End If
Step 15.    End for
Step 15.    If X ≠ $X^{new}$ then set X ← $X^{new}$ and go to Step 4; else stop
Step 16.    If |X| < P, go to Step 2; else stop.
```

Locate: First facility at optimal 1-median location using total enumeration
Have all P Located?
Yes
Locate: Next facility at optimal location using total enumeration, holding the locations of other facilities fixed
Find: Neighborhoods for each median/facility
Find: Optimal 1-median in each Neighborhood
Did any facility sites change?
No
Find: Neighborhoods for each median/facility
Yes
Did any Neighborhoods change?
STOP

Fig. 4. A Simple Flowchart of the New Hybrid Myopic-Neighborhood Approach.

For completeness, we also provide Fig. 4 as a flowchart for the Hybrid Myopic-Neighborhood approach.

IV. Numerical Example

This section introduces a small example to illustrate the new Hybrid Myopic-Neighborhood approach to solve vertex location problem. For simplicity let us consider an example from Daskin [30] with Table I shows the distance matrix.

For the first median (*p*=1), using total enumeration, the location of the 1st median is located at vertex (point) 9.

For the second median (*p*=2), (1) applying Myopic: The location of the 2nd median is located at vertex 7 and the set of solution X= {9, 7}. According to the Myopic, we should proceed by adding a new third vertex which yields the lowest objective function value, however, the new Hybrid approach proposed applying Neighborhood approach; (2) applying Neighborhood, no change has been happened in the solution set, therefore, go to next median (i.e., *median* # 3).

For the third median (*p*=3), (1) applying Myopic, the location of the 3rd median is located at vertex 6 and the set of solution X={9,7,6}. (2) applying Neighborhood, The new location set, X^{new}={11,7,6}, a change happened at site 9 and swapped with site 11, therefore, go to step 4, and apply again Neighborhood. Now, there is no median facility changed; go to Next median, and so on. The detailed calculations can be found in Appendix A.

It is clear that using the new Hybrid approach improves the objective function value of the Myopic, which considered an added sequence approach. The best solution at *p* is not necessarily the best solution at *p*-1 with adding an additional vertex. This is because the additivity property is not satisfied. This observation was also taken advantage of when applying the ‘drop’ method instead of the ‘add’ method, as demonstrated by the flexible drop method, known as subdrop, originally developed by Salhi and Atkinson [32]. Also, it is worth noting that the new Hybrid either improves the objective function value of the Neighborhood or retain that value but never worsen it, since the Hybrid keeps starting from a better intermediate initial solution.

Table II compares the results of using the new Hybrid approach to solve the example in Table I, versus the results of Myopic, Neighborhood, Exchange, and Lagrangian approaches in [30]. The table shows that the new Hybrid Myopic-Neighborhood outperformed other heuristics, namely, Myopic, Neighborhood, and Exchange heuristics approaches. The Hybrid approach achieved optimality at all levels of medians (*q*=1,…,*p*), such as the Lagrangian exact approach. However, the new Hybrid approach is very simple to understand and relatively easier to implement in practical setting.

V. COMPUTATIONAL RESULTS

To assess the performance of the new Hybrid Myopic-Neighborhood approach to solve large-size vertex *p*-median location problems, an extensive computation experiment using two frequently types of datasets is carried out. These datasets consist of the TSP-Lib, and BIRCH instances. Computational results of the vertex *p*-median instances are listed in Table III, Table IV, Table V and Table VI. This section reports the computational results on a subset of large-size instances which have previously been used in [22, 24, 25, 28]. Computational experiments were carried out on a processor Intel(R) Core(TM) i7-8550U CPU@1.80GHz 1.99 with 8 GB of RAM, under Windows 10, 64-bit. The code was written and executed in MATLAB.

A. TSP-Lib Instances

The first dataset of instances is taken from the TSP-Lib, a travelling salesman library [21]. There are 11 instances (UY734, ZI929, MU1979, CA4663, TZ6117, EG7146, YM7663, EI8246, JA9847, GR9882, and KZ9976), where each instance is solved with *p* varying from 25 to 75 with an increment of 5. The number attached to each instance name indicate the number of demand points (*n*) of that instance. For example, UY734 contains the coordinates of 734 cities in the Uruguay. The instances are ranged in size from *n* = 734 to 9,976.

1) Comparison vs Neighborhood "NBHD" and Myopic: The computational results for the new Hybrid approach on the TSP-Lib dataset are presented in Table III alongside those obtained by the Neighborhood "NBHD" and Myopic approaches, with 'Bold' showing the best solutions. For clarity, the items in Table III are as follows:

a) n is the number of demand points,

b) p is the number of median facilities to be located,

c) z is the minisum objective function obtained by the three approaches,

d) Deviation(%): The percentage gap between a given solution and the best solution. It is computed as: *Deviation*(%)= 100*(Z_H-Z_{Best})/Z_{Best}), where Z_H and Z_{Best} correspond to the *Z* value obtained with heuristic '*H*' and the best *Z* value respectively. 'Bold' values in the table refer to the best solutions [25].

e) Time (*Sec*); Time in seconds. We should notice that the time of Neighborhood "NBHD" is significantly small since the approach starts by the candidate solution obtained by the Myopic approach and apply one pass of improvement instead of repeated ones in earlier steps.

Generally speaking, the new Hybrid approach provides better results than Neighborhood and Myopic approach, for all TSP-Lib instances listed in Table III. This means that the new Hybrid approach outperforms both the Neighborhood and Myopic approaches of the vertex *p*-median location problem.

2) Comparison vs. existing techniques: Table IV compared the performance of the Hybrid Myopic-Neighborhood versus the performance of two versions of Variable Neighborhood Search approach called Var1 and Var2 presented in [25]. The results are given in Table IV which shows the value of the objective function (*Z*), the deviations in % and the CPU time in seconds for the Hybrid approach. The notations in the table are the same as the ones given earlier for Table III.

To our surprise, the results demonstrated that the new Hybrid provides better solutions compared to Variable Neighborhood Search on all TSP-Lib instances listed in Table IV. The Hybrid approach yields new benchmarking solutions for all of the instances by producing 11 new best solutions which can be used for further benchmarking.

B. BIRCH Instances

BIRCH is a generated-synthetic dataset suggested by Zhang et al. [23]. Each BIRCH dataset contains *p* two-dimensional clusters demand points (data points) generated in a square. Dataset of type I is the easiest to solve while datasets II and III are harder [22]. Type 1 and Type 3 instances results are reported in this paper; these are the most frequently used types in the vertex *p*-median literature. The largest problem instance generated in this category contains 20,000 demand points. The number of medians (clusters) *p* is ranged from 25 and 100 as shown in Table V which also shows the results of the 24 BIRCH instances.

9976	75	**6172025.46**	6378764	6340439		3.35	2.73
Average						**4.94**	**4.28**

1) Comparison vs. Neighborhood “NBHD” and Myopic: The computational results for our new Hybrid approach on the BIRCH dataset are presented in Table V, where the summary results of the three approaches (Hybrid, Neighborhood “NBHD” and Myopic) are shown. Here, we have the obtained objective function (*Z*) of the three approaches, the deviation (%) of the NBHD and Myopic form the Hybrid, and the run time (in seconds). On the BIRCH instances of Type 1 and Type 3, the Hybrid approach, as shown in earlier experiments, provides again better solutions compared to Neighborhood “NBHD” and Myopic approaches.

2) Comparison vs. existing techniques: The results of our computational experiments on the BIRCH I and III datasets are also compared with the results obtained by Hansen et al. [22], who presented a primal–dual variable neighborhood search (VNS) algorithm; and Avella et al. [24] who introduced a Lagrangean relaxation approach, which consists of three components: (1) subgradient column generation; (2) core heuristic; and (3) an aggregation procedure. The two approaches are referred to as VNS and CH respectively. The results of the VNS and CH approaches are taken from [24].

The computational results of the new Hybrid approach on the BIRCH dataset are presented in Table VI versus the results of the other two approaches (VNS and CH). For the BIRCH I instances the new Hybrid provides better solutions compared to VNS and CH. The Hybrid approach yielded the same results as the best-known results with deviation equal to (0.000), while VNS and CH yielded (0.039) and (3.674) respectively. On the BIRCH III instances, Hybrid outperforms VNS and CH where Hybrid found three best solutions and yielded the smallest deviation (0.002). As stated in [22] our experiments also show that the BIRCH instances of type 3 are harder to solve compared to type 1 instances. Also, Table VI shows that not only the Hybrid approach yielded better results than VNS and CH, but also requires relatively less computational burden compared to its nearest competitor in terms of quality, namely, the VNS metaheuristic. This reduction in computational time is even more significant in those larger instances where the hybrid consumes only approximately 15% of the time spent by the VNS.

VI. Conclusion

This paper introduces a new Hybrid heuristic to solve large scale vertex *p*-median location problems varying in size ranging from 734 to 20,000 demand points. Many Heuristics, Meta-heuristics and Exact approaches have been developed for this purpose. This paper presented a new Hybrid-heuristic approach which integrates two heuristic approaches, namely, the Myopic approach as a construction method to find the solution of each q ($q=1,..,p$) median facility; while the Neighborhood approach improves this solution as much as possible at each level of q. By embedding the Neighborhood approach into the Myopic heuristic within the search and not put in a sequential manner as a post optimizer at the very end, as usually applied, excellent results have been produced which are highly competitive with the state-of-the-art approaches on large-size instances with up to 20,000 demand points. This can be seen to act as a continuous filtering mechanism to guide the search.

The new Hybrid approach was tested on the TSP-Lib instances (n = 734−9976) and outperformed the ones by [25]. In addition, the new approach was assessed on several large-size BIRCH instances (n = 9600−20000), each instance is solved with p ranging from 25 to 100. The results show that our method gives better solutions compared to [24] and [22] results.

In brief, the results show that the new approach gives in general better solutions which can be then used for benchmarking purpose in the future. This demonstrates that a simpler approach that takes into account the advantages of other methods can lead to promising outcome besides having the potential to be adopted in tackling other combinatorial optimization problems.

Appendix A

For the first median (p=1) Set X=Ø, Table 7 shows the calculations of the total enumeration by summing the entries in each column in Table 1, to obtain the values of $Z(J,X)$. Finding i^* =argmin$_{i\epsilon I}$ { $Z(J,X)$}. The smallest value is 4772, i^*=9 and X={9}.

TABLE VII. The Total Enumeration (P=1)

I	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
Z	**7816**	**7913**	**5855**	**6457**	**5784**	**5760**	**6936**	**5971**	**4772**	**6886**	**5576**	**6371**

For the second median (p=2), (1) applying Myopic approach by finding i^* =argmin$_{i\epsilon I}$ {Z(J, X U{i})}. Table 8 shows the results of this computation, to obtain the values of $Z(J,X)$. The minimum sum value is 3145, corresponds i^*=7 and X={9,7}.

TABLE VIII. The Results of the Myopic Approach (P=2)

X	9	9	9	9	9	9	**9**	9	9	9	9	9
i	1	2	3	4	5	6	**7**	8	9	10	11	12
Z	3845	3725	3943	4296	3696	4268	**3145**	3655	4772	3563	3858	4392

According to the Myopic, we should proceed by adding a new third point (vertex/median) in the same manner, however, the new Hybrid Myopic-Neighborhood approach proposed applying the Neighborhood approach. By finding N_1 and N_2, where N_i is the set of demand nodes which i median is the closest open median facility to it. Here $N1$ ={3,4,5,6,9,11,12} and $N2$ ={1,2,7,8,10}. Then find k^* =argmin$_{k\epsilon Ni}${$Z(Ni$,{k})}; k^*=9,7 and X^{new}={9,7}. No median facility changed; Go to Next median (p).

For the third median (p=3), (1) applying Myopic, by finding i^* =argminiϵI {$Z(J$, X U{i})}. Table 9 shows the results of this computation to obtain the values of $Z(J,X)$. The minimum value is 2641, corresponds i^*=6 and X={9,7,6}.

TABLE IX. The Results of the Myopic Approach (P=3)

X	9	9	9	9	9	**9**	9	9	9	9	9	9
	7	7	7	7	7	**7**	7	7	7	7	7	7
i	1	2	3	4	5	**6**	7	8	9	10	11	12
Z	2695	2770	2647	2689	2929	**2641**	3145	2845	3145	2661	2718	2765

(2) applying Neighborhood, by finding N_1, N_2 and N_3. Here N_1 ={3,5,9,11,12} N_2 ={1,2,7,8,10}, and N_3 ={4,6}. Then find k* =argmin$_{k\epsilon Ni}${$Z(N_i$,{k})}; k^*=11,7,6 and X^{new}={11,7,6}, the new value of Z is 2535. Median facility changed; go to step 4.

finding N_1 , N_2 and N_3. N_1 ={8,10,11,12}, N_2 ={1,2,5,7} and N_3 ={3,4,6,9}. Then find k^* =argmin$_{k\epsilon Ni}${$Z(N_i$,{k})}; k^*=11,1,6 and X^{new}={11,1,6} the new value of Z is 2438. Median facility changed; go to step 4.

finding N_1 ,N_2 and N_3. N_1 ={8,10,11,12} N_2 ={1,2,5,7} and N_3 ={3,4,6,9}. Then find k^* =argmin$_{k\epsilon Ni}${$Z(N_i$,{k})}; k^*=11,1,6 and X^{new}={11,1,6} No median facility changed; Go to Next p median and so on.

Annotated Corpus with Negation and Speculation in Arabic Review Domain: NSAR

***Abstract*—Negation and speculation detection are critical for Natural Language Processing (NLP) tasks, such as sentiment analysis, information retrieval, and machine translation. This paper presents the first Arabic corpus in the review domain annotated with negation and speculation. The Negation and Speculation Arabic Review (NSAR) corpus consists of 3K randomly selected review sentences from three well-known and benchmarked Arabic corpora. It contains reviews from different categories, including books, hotels, restaurants, and other products written in various Arabic dialects. The negation and speculation keywords have been annotated along with their linguistic scope based on the annotation guidelines reviewed by an expert linguist. The inter-annotator agreement between two independent annotators, Arabic native speakers, is measured using the Cohen's Kappa coefficients with values of 95 and 80 for negation and speculation, respectively. Furthermore, 29% of this corpus includes at least one negation instance, while only 4% of this corpus contains speculative content. Therefore, the Arabic reviews focus more on negation structures rather than speculation. This corpus will be available for the Arabic research community to handle these critical phenomena[1].**

Keywords*—Arabic NLP; negation; speculation; uncertainty; annotation; annotation guidelines; corpus; review domain; sentiment analysis

I. Introduction

Negation and speculation are commonly used linguistic phenomena, providing information on factuality and the polarity of facts [1]. Negation is a linguistic property shared by all human languages [2], which denotes the absence of something; therefore, negation affects the contextual polarity of words. On the contrary, speculative language is used to convey uncertainty about an event or idea. It means there is not enough evidence in the text to prove whether the information is 100% true. Consequently, sentences including negation or speculation may misclassify the opinionated phrases [3] or inaccurately identifying the medical terms [4], [5]. In order to efficiently identify instances of these phenomena, it is necessary to find those words expressing negation and speculation and then their scope, such as the tokens within the sentence that are affected by these cues [6]. Since negation and speculation are language-dependent, they must be addressed in all-natural languages [7]. Therefore, many studies addressed them to enhance the performance of Natural Language Processing (NLP) tasks and applications in various languages such as Sentiment Analysis (SA) [8], Machine Translation (MT) [9], and Information Extraction (IE) [5]. These studies addressed the negation and speculation scope detection using rule-based [10] and sophisticated supervised learning methods [11], [12].

Arabic Natural Language Processing (ANLP) has gained unprecedented interest in the age of big data and social media platforms, making it one of the most important research topics, especially in North Africa and the Gulf Area [13]. Classical Arabic (CA), Modern Standard Arabic (MSA), and Dialectal Arabic (DA) are the three primary forms of Arabic [14]. The Qur'an and ancient literature are written in the CA form. The MSA is mainly used in education, the official written reports like newspapers, and formal TV programs. Conversely, the DA includes all current forms of Arabic spoken, written on social media platforms, and reviewed applications and websites where it varies nationally and internationally depending on location [15]. Since the DA has no syntactic rules and multiple forms of the same word, ANLP tasks are challenging.

Negation frequently occurs in the Arabic language and is one of the dominant linguistic methods for changing the text polarity, so negation detection is highly considered in the Arabic Sentiment Analysis (ASA) [3]. However, the presence of negation words in a sentence does not imply that all the sentimental words are inverted. Still, there are odd cases where the presence of negation terms may confirm the polarity of the following lexeme [16]. In the implicit form of negation, a sentence can be negated without using negation words. The level of speculative content increases or decreases the certainty of polarity classification [17]. Few Arabic studies have addressed the impact of negation and speculation using simple rules. Hamouda and El-Taher considered the frequency of negation terms in the ASA task as a classification feature, but the effect of the negation feature on the sentiment classification was not clearly mentioned [18]. In 2015, Duwairi and Alshboul defined six handcrafted rules to handle negation in the Modern Standard Arabic (MSA) texts in the review domain to enhance the performance of the ASA [19]. Even though they addressed the MSA, which follows well-defined rules, the simplistic approach has proven inadequate for a syntactically and morphologically rich language like Arabic. El-Naggar et al. considered several valences to build a negation-aware classifier for ASA in MSA and the Egyptian dialect [20]. Later, Assiri et al. formulated four rules to handle negation in the Saudi dialect

[1] https://github.com/amahany/NSAR

[21]. In addition, Kaddoura et al. have proposed a system that inverts the polarity of a sentence's clause if a negation term precedes a positive or negative pattern [3]. Regardless of the improvement in performance in these systems' experimental results [3], [20], [21], none handled the implicit form of negation frequently used in Arabic. Simple rule-based algorithms cannot handle all the negation and speculation cases for the various Arabic language forms and dialects [14]. According to the findings of our earlier work, the treatment of negation scope detection utilizing supervised based learning is promising [12]. To the best of our knowledge, there are no available Arabic corpora annotated with negation or speculation in various domains including the review, newswire and medical domains. Furthermore, speculation detection in ASA has not been studied in any research work.

In the last decade, there has been a growing interest in detecting negation and speculation. Nevertheless, the available open-access corpora for low-resource languages, such as the Arabic language [22], are limited compared to the English and the Spanish languages [7]. Speculation corpora are even more scarce than those for negation, with the majority focusing on the biomedical domain. Since negation and speculation are language-dependent phenomena, the negation- and speculation-aware models from other languages, such as English, cannot be applied to the Arabic text because the syntactic structure of negation in Arabic differs from that in English. Therefore, developing an annotated corpus with negation and speculation for the Arabic review domain is required. It is very important to know that negation- and speculation-aware systems improve the overall systems performance [9], [11].

The rest of the paper is organized as follows: Section II shows the different sources for our corpus. Section III details the annotation guidelines we build for the negation and speculation texts in the Arabic review domain. The annotation process and its result including the agreement analysis of the annotators and the discussion are presented in IV and V. Finally, Section VI concludes the paper and suggests the future work.

II. Corpus Collection

This section demonstrates the overall characteristics of the Negation and Speculation Arabic Review (NSAR) corpus, as well as a brief description of the texts that compromise it. Furthermore, general statistics are presented regarding each source's size and polarity distribution. The NSAR corpus is comprised of texts extracted from three well-established and benchmarked Arabic review corpora: Large Scale Arabic Book Review (LABR) [23], Large Arabic Multi-domain Resources (LAMR) [24], and Multi-domain Arabic Sentiment Corpus (MASC) [25]. Table I shows the distribution of randomly selected positive and negative sentences from each source, with 2,312 positive reviews accounting for approximately 77% of our corpus. Each topic has a different number of sentences, but the average number of words per sentence is nearly the same. The LABR corpus contains 63K book reviews, with ratings ranging from 1 to 5 stars [23]. Aly and Atiya considered the reviews with 4 or 5 stars with positive polarity and those with 1 or 2 stars with negative polarity. The authors collected these reviews from the best Arabic books listed in the social network for book readers [2]; hence, most of the randomly selected reviews are positive reviews, as per Table I. The LAMR corpus is the second source for NSAR corpus, and it consists of 33K reviews scrapped via Scrapy framework [3] from various reviewing websites, Souq [4], TripAdvisor [5], Elcinema [6], and Qaym [7], including reviews for various items and services [24]. Each sentence includes the review text and normalized rating that could be positive, negative, or mixed polarity. The third source, MASC [25], includes 8,860 reviews on different topics such as shopping, restaurants, and software applications written in multiple Arabic dialects. These reviews were obtained primarily from Jeera [8], Qaym, Google Play, Twitter, and Facebook. The majority of the reviews from LAMR and MASC were composed in Egyptian, and Gulf areas' dialects. On the contrary, most of the LABR samples were written in the MSA form. The review texts in the NSAR corpus are collected from various sources to ensure that it captures the diversity of dialectical language usage in the review domain.

TABLE I. Corpus Statistics

Corpus	Topic	Positive	Negative	Total
LABR	Books	879 (84.52%)	161 (15.48%)	1,040
LAMR	Touristic Attractions	102 (94.44%)	6 (5.56%)	108
	Hotels	74 (100%)	0 (0%)	74
	Products	684 (75.58%)	221 (24.42%)	905
	Resturants 1	248 (74.47%)	85 (25.53%)	333
	Restaurants 2	114 (81.43%)	26 (18.57%)	140
MASC	Software	210 (52.50%)	190 (47.50%)	400
	Products	1 (9.09%)	10 (90.91%)	11
Total		**2,312 (76.79%)**	**699 (23.21%)**	**3,011**

III. Annotation Guidelines

Negation and speculation phenomena are interrelated and have similar characteristics: they both have a scope, so they affect the part of the text denoted by the presence of negating or speculative keywords. Furthermore, both of them have two types: implicit and explicit. In the case of the explicit type, the phenomenon cue is written in the sentence, whereas being understood in the case of the implicit one without a cue. Sentences including a negation cue are not necessarily annotated for negation; however, they may have speculative content. Therefore, the annotators should read sentences containing negation cues carefully. In most cases, the keywords influence their scope, aligned from the left to the end of the clause or the sentence.

The following subsections list the general principles, negation, and annotation guidelines. Furthermore, the special

[6] https://elcinema.com/
[7] https://www.qaym.com/
[8] https://www.jeeran.com/

or complex cases for both phenomena are demonstrated. In order to illustrate examples in the annotation guidelines, the negating cues are surrounded by a negation symbol (¬), the speculative cues are surrounded by an uncertainty symbol (∓), and their scope boundaries are surrounded by parenthesis.

A. General

When annotating the negation and speculation, several general rules must be followed, which are adapted from the BioScope annotation guidelines [6], then modified to the Arabic language and review domain. Sentences with some instance of negative or speculative language will be only considered. In addition, the min-max strategy should be followed during the annotation. The minimal unit (single word) that expresses the negation or speculation will be marked as a cue. Nevertheless, in some cases, a cue may include more than a single word which is called a complex cue. The maximum number of words affected by a cue will be marked as the scope for negation or speculation. The scope usually starts after the keyword and ends at the end of the phrase, clause, or sentence. However, the scope may include a word or a statement preceding it. The below list summarizes the general rules for both negation and speculation:

- A sentence may contain more than one cue instead of only one keyword; in this situation, each cue should be annotated separately.
- Structures of negation and speculation can be annotated in a single sentence.
- The cue is not included in the scope, but it may be included in complex cases and in the scope that includes words preceding and following a cue.
- If a sentence contains a cue that appears at the end of the sentence, the phenomenon's scope is limited to the cue.
- Due to the improper use of spaces in the informal Arabic text, a cue+verb/noun may be concatenated without a space; in this case, the verb/noun will be included in the negation/speculation cue.
- The coordinating conjunctions و (and) extend the scope.
- Annotators will only annotate the cue and leave the scope for the linguist expert if the annotator is unsure about the scope.
- There is an annotation element called the ‘undecided’ used if the annotator is unsure what type the keyword should be assigned.

Additionally, each type of a negation or speculation structure is depicted with an example where the transliteration and English translation of these examples are listed in Appendix I.

B. Negation Structures

- لا (*no*) is the most used negating Arabic word, which is used to deny the occurrence of a verb in the past and present tenses, as well as to deny a nominal sentence. Therefore, the scope begins with the negative cue and ends at the end of the sentence.

1) أحلام اجمل الايام كانت هناك و (ذكريات ¬ لا ¬ تنسى) مكان رائع يجمع الكل فى حركه و ضحك وحياه

- ما (*did not – does not*) interfere with past or present verbs in dialectal Arabic and the formal Arabic forms in the nominal sentences. It is most often found in a pre-verbal state. To ensure that ما with a verb in the past is working, replace it with لم (*does not*) followed by the same verb in the present.

2) لو كان سعره اقل وفيه فلاش كنت قيمته اكار من كدا فشل واضح من سوني انها ¬ ماحطتش ¬ (ليه فلاش)

- لم keyword is used with a verb in the present tense to deny a truth that occurred in the past. In exceptional cases, it may affect something in the present or future.

3) جهاز جبار ويتفوق علي نظرائة من الايباد والسامسونج بجد رائع بس ¬ لم ¬ (ياخذ حجم الدعايه المطلوبه)

- لما (*Lamma*) is used before a verb in the present to deny something in the past and may deny something in the future. However, if it comes with a verb in the past, it does not deny anything after it.
- لات (*no*) cue is used only in the classical Arabic form.
- إن (*Inn*) affects nouns, past, or present verbs. إن will be effective if it gets replaced with another cue and reverses the polarity. There is a distinction between إن و أن (*Ann*) where أن is not a negating cue. Furthermore, إن و إن may be written ان without همزة (*Hamza*) in the dialectical Arabic. Therefore, it is necessary to read the sentences carefully to determine the correct form in accordance with the context of the sentence.
- لن (*will not*) is used with a verb in the present tense to deny something in the future.

4) 7 روايات في رواية ، تهكم وسخرية وأدب وأشياء اخرى ¬ لن ¬ (تمل منها)

- ليس (*Not*) is a verb in the past tense, extending the negation to the end of the sentence. The origin of ليس is لا+ايس which means no + existing. It has different forms like لست – ليست – ليسا – لسنا – لسن – فلست

5) يستاهل لانه دعم اللغة العربية لكن ياريت يثبت البرنامج على رقم المستخدم ¬ وليس ¬ (على حساب)

- عدم (*None*), عدا (*Except*), and دون (*Without*) keywords are used to deny a noun or nominal sentence.

6) الذي فاجئني وزعجني هو ¬ عدم ¬ (وجود ريموت فيها) بالمقارنة مع السعر

- مش (*Mesh*) keyword and the pattern of م + verb + ش are mainly used in the Egyptian dialect to deny a verb.

7) تطبيق رائع وفيه خصوصيه ¬ محدش ¬ (يعرف دخلت امتي خرجت امتي) انت حتي لو بتكتب (اللي قدامك ¬ مش ¬ بيعرف)

- مفيش (*Not*) used in the Egyptian dialect to deny nouns

8) فكرني بفلاش و سماش والحاجات دي بس ¬ مفيش ¬ (كلمات متقاطعة (

- مو (*Not*) keyword used in the Gulf/Levant countries to deny a verb, noun, or an event.

9) مرررررره حلو وعصيراته فرش ⌐ ومو ⌐ (حاطين له لاسكر ولا مويه كله فرش)

C. Speculation Structures

- There are many Arabic adjectives or adverbs that indicate speculation such as, محتمل – احتمال – ممكن – مرجح – شكاك – أحيانا –

10) نصيحتي ان (في محلات فطاير تانية في حدايق حلوان ∓ ممكن ∓ تكون أفضل كتير)

- Some other adjectives, if get preceded by a negation cue, it indicates a speculative content, such as غير مؤكد

11) اول روايه اقرأها لباولو كويلهو ∓ ولااعتقد ∓ (انها الاخيره)

- This list of verbs, but not limited, indicates speculation - يعتقد - يظن - يمكن – توحى – يبدو – تظهر – تشير – يفترض – يشك. In addition to, the noun form for some of these verbs like الشك – الظن – فرضية – الافتراض

12) ⌐ لم ⌐ (استسيغ نزار فى شعر الفصحى) ∓ اعتقدوا ∓ فى الشعر الحر اكثر ابداعا)

- These Arabic particles لو – قد – ربما – لعل –ما بين indicate speculative content.

13) فندق مريح صراحة اسعارة جيدة ∓ ما بين ∓ (150 الى 300 ريال الليلة) ونظيف جدا

- Conjunction keywords such as أو (*or*) have the scope of elements ranging from the right to the left side of the conjunction. However, in instances where the conjunction is composed of two or more words like أو, إما (*Or*), سواء (*Whether*), the scope does not change.

14) أنصح بيه أي حد بيدرس (هندسة كهربية ∓ أو ∓ عايز يدرسها) هتوفر عليه جنون كتير

- Sentences starting with a question that should be annotated as speculative.

- If the speculation cue is present at the start of the sentence, then the scope extends to include the whole sentence.

15) ∓ربما ∓ (يكون الكتاب جيداً ولكن بروز شخصية الكاتب المتملقه تفسد ذلك؟)

D. Negation Complex Cases

The presence of a negation keyword does not automatically negate a sentence as follows:

- For example, إن that assures something.

16) ⌐ ما ⌐ إن رأيت ولا سمعت بمثله

- Example for ما used for wonderment.

17) ⌐ ما ⌐ هذه الرومانسية الحالمة ⌐ وما ⌐ هذا الاسلوب الناعم الجميل هذه الرواية من اجمل ⌐ ما ⌐ قرات على الاطلاق

- Question marked withليس reverts the sentence from being negated to being proven

18) ⌐ أليس ⌐ هذا بالحق

- If a sentence consists of ما then إلا, the negation is canceled

19) ⌐ مَا ⌐ هَٰذَا بَشَرًا إِنْ هَٰذَا إِلَّا مَلَكٌ كَرِيمٌ

- Two consecutive negating cues like ما cancels the effect of negation.

- غير sometimes used in the Gulf countries to express something unique.

20) جدة ⌐ غير ⌐

- غير in some cases means change but not a negation cue

21) كتاب ⌐ غير ⌐ مجرى تفكيرى خلاه اوسع خلانى أثق اوووى فى العلامات

- مش بس is used to assure something

22) تجنننننن انا بصراحه ⌐ مش ⌐ بس الفندق جميل كل حاجه زورتها كانت جميله قوي قوي قوي قوي

- Verb in forms of ما + أفعل

23) أجمل ⌐ ما ⌐ فيه هو إفطاره

In some other cases, the negation is implied in the sentence without any negating cue while understood from the context of the text.

- The sentence implies denial without any negative cues such as

24) كتاب خفيف و واقعي و ⌐ بعيد ⌐ (عن المبالغة تماما) كل شيء فيه حقيقي

- Negating the not obvious

25) (وَتَرَى النَّاسَ سُكَارَىٰ وَمَا هُم بِسُكَارَىٰ)

E. Speculation Complex Cases

Certain speculation cases are marked using few keywords.

- For example, قد can express speculative content only if the verb following it is in the present tense form, as in point 25. However, the content in point 26 is not speculative and comes with a verb in the past tense.

26) الكلمة ∓ قد∓ (تفعل فى الانسان ما لم تفعلة الادوية القوية) لك كل قدير

27) السلعة ليست بالجودة المطلوبة ∓ وقد ∓ اشتخدمتها لمرة واحدة فقط ولم ارجع لاستخدامها مرة ثانية

- When used at the end of a sentence, the negation cue ما indicates speculation.

28) جلسات رائعة جلسات المطعم الخارجية رائعة خصوصا في فصل الربيع والشتاء اما (الاكل فجيد) ∓ نوعا ما ∓

- Most of the cases that use لعل do not express speculation; however, it represents hopefulness.

29) وَجَعَلَ لَكُمُ السَّمْعَ وَالْأَبْصَارَ وَالْأَفْئِدَةَ ۙ لَعَلَّكُمْ تَشْكُرُونَ

- In some cases, speculation cues may be used to imply an affirmation.

30) الَّذِينَ يَظُنُّونَ أَنَّهُم مُّلَاقُو رَبِّهِمْ وَأَنَّهُمْ إِلَيْهِ رَاجِعُونَ

IV. NSAR Annotation

This section describes the procedure followed in the annotation process of the NSAR corpus. Initially, the guidelines are created based on the negation rules of the formal Arabic language in addition to the commonly used slang negating cues in the Egyptian and Gulf countries' dialects. Then, a list of Arabic keywords for the speculation is built which would indicate speculative content, and subsequently, these rules are applied to annotate a sample of the corpus and extract any additional cases from the corpus to enhance these rules for the annotation process.

There is a need for a tool for the annotation process to build and develop NSAR corpus. There are many available annotation tools for this purpose. Based on an evaluation of the well-known annotation tools in this study [26], WebAnno[9] is selected, which achieved the highest score [27]. WebAnno is an open-source web-based annotation tool that provides full functionality for both semantic and syntactic annotations. Furthermore, it supports adding user-defined annotation layers as we did for the negation and speculation. The user-defined layers are only supported in TSV3 format, where there is an open-source Python library to extract the annotations written in TSV[10]. As in Section II, NSAR corpus is collected from three different Arabic corpora from the review domain labeled as positive or negative and written in CSV file format. Therefore, we transformed the input files from CSV to TSV file format. Five user-defined labels associated with the WebAnno project: sentiment, negation, speculation, bad, and undecided are created. The sentiment has one feature called ‘polarity’ with ‘negative’ or ‘positive’ values, used with the transformation from CSV to TSV for the sentiment labeling. For the negation and speculation labels, every label has a tag set with two different values ‘cue’ and ‘scope’ which are associated to each other using two user-defined relations ‘NegRel’ and ‘SpecRel’. The other two labels ‘bad’ and ‘undecided’ are used to highlight any inappropriate or hateful content in the text or the annotator cannot take a decision about a sentence.

The annotation process was implemented in three phases: the first phase was to describe the annotation guidelines and train the annotators on using WebAnno, then the annotators carried out the annotation to measure the inter-annotator agreement (IAA), and finally, a linguist expert resolved the disagreements between them. Two independent Arabic native speakers carried out this process; one is an experienced annotator with a solid background, and the second is a well-trained person. Each file has been annotated by both annotators.

V. Results and Discussion

In this section, we explore the result of the annotation process. The Cohen’s Kappa coefficient [28] is used to measure the quality of the annotation process. Cohen’s Kappa of value 0.95 for the negation and 0.8 for speculation are obtained. These values demonstrate that the speculation annotation is more complex than the negation in Arabic. Table II shows the NSAR corpus, which includes 862 negated sentences out of 3,011, and only 121 sentences containing at least one speculative content.

The disagreements between the two annotators were revised by a linguist expert [6]. The majority of disagreement cases in negation are caused by common human errors, such as one of the annotators forgetting to relate the negation cue to its scope using the relation layer. Since a single sentence may contain multiple negation structures [29], this layer is added and should be specified for each annotation. The speculation cases, on the contrary, are ambiguous and may lead the annotator to consider it a negation or speculation [7]. Therefore, it had a higher level of disagreement than the negation. These cases involve an issue within the scope of speculation, such as the non-inclusion of a word. In addition to the undecided label, the disagreements have been curated by the first author and the linguist expert.

Table II shows that 29% and 4% of total sentences have at least negation and speculation structures, respectively; however, these percentages vary from topic to topic. For instance, MASC sub-corpus includes high rates of negating and speculative content.

TABLE II. NSAR Statistics

Corpus	Topic	Size	Negation	Speculation
LABR	Books	1,040	248 (23.85%)	46 (4.42%)
LAMR	Touristic Attractions	108	20 (18.52%)	1 (0.93%)
	Hotels	74	7 (9.46%)	2 (2.70%)
	Products	905	284 (31.38%)	30 (3.31%)
	Resturants 1	333	98 (29.43%)	10 (3%)
	Restaurants 2	140	33 (23.57%)	3 (2.14%)
MASC	Software	400	166 (41.50%)	28 (7.00%)
	Products	11	6 (54.55%)	1 (9.09%)
Total		**3,011**	**862 (28.63%)**	**121 (4.02%)**

The subject types in Arabic sentences change the form of most Arabic words, such as verbs ذهب (He went) and ذهبت (She went). There are other various forms of negation in Arabic that have the same meaning in English. This example shows the negation difference between the MSA and Egyptian dialect where ملكشى in the Egyptian dialect is derived from لا شىء لك or ليس لك شىء in MSA form, where all of them means (you do not own anything). Another example, مكنتش in the Egyptian dialect, which is derived from لم تكن or لم أكن in MSA, means (I do not + verb) or (She does not + verb) according to the context. However, removing a single character from this word as مكنش will change the meaning to be (He does not + verb). These examples demonstrate the complexity of negation in Arabic, especially in the dialect Arabic. Furthermore, the spelling rules are not followed in dialectical Arabic, resulting in tokenization issues such as in الكتابةلاتظهر (The written text does not appear) [3]. There is no space between the three words that should formally be used. Other instances in the dialect of Arabic include different forms for the same Arabic word with the same meaning as in مافيش and مفيش (None-existence). Therefore, we normalized the commonly used negation and

[9] https://webanno.github.io/webanno/

[10] https://github.com/neuged/webanno_tsv

speculation cues, as depicted in Table III and Table IV. The Negator لا and speculative cue لو account for approximately 45% of the negation and speculation cues, respectively.

TABLE III. THE COMMON NEGATING CUES IN NSAR

Normalized Negation Cues	Frequency
لا	455
ما	161
لم	129
غير	84
مش	78
لن	20
دون	25
مو	30
ليس	74
عدم	21
عدا	7

ملهاش - معجبتنيش - الا	3
محدش - مقدرتش	2
مبتستاهل	2
مكنتش - مكنش - ماكنتش - معجبنيش - معجبتنيش - مفهمتش - مفهمتهاش - مبقتش - مابقتش - معرفش - معرفتش - ميستحقش - ميخلكش - ملوش - مفيهوش - ماينفعش - متتبعتش - معتش - مبقتش - مبيضحكش - منبسطش - محستهاش - متعميلهاش - بلاش - عديم - معاد - مب	1

TABLE IV. THE COMMON SPECULATION CUES IN NSAR

Normalized Speculation Cues	Frequency
لو	41
اعتقد	11
كانت	8
او	6
قد	6
اظن	5
ممكن	5
ربما	4
يمكن - لااعتقد - معظم - احيانا	3
اتمنى - ولا - تقريبا - لاادرى - إذا	2
مما يثيرالشك - بالرغم من الشكوك - فعلا كان - نوعا ما - لا اظن - ما بين - غالبا - ياريت - تبدو - تاكد - ان - لما	1

Table V displays the average, minimum, and maximum scope lengths for both negation and speculation for each topic. For the negation scope, the minimum and average scope lengths are nearly identical, but there is a notable variation in the maximum scope length for each topic. This notice in books and software topics usually negate the longest part of the sentence. Table V also shows that the speculated words within a sentence are longer than the negated words because the speculation structures usually affect the whole sentence, as described in the annotation guidelines.

TABLE V. NSAR NEGATION AND SPECULATION SCOPE LENGTH

Corpus	Topic	Negation Scope			Speculation Scope		
		Max	***Min***	***Avg***	***Max***	***Min***	***Avg***
LABR	Books	66	2	22	82	2	32
LAMR	Touristic Attractions	45	3	21	13	13	13
	Hotels	33	7	17	23	21	22
	Products	56	3	22	65	12	35
	Resturants 1	50	2	17	86	10	35
	Restaurant 2	44	3	26	48	10	27
MASC	Software	60	2	20	62	8	32
	Products	40	5	30	52	52	52
All		**66**	**2**	**21**	**86**	**2**	**31**

Table VI presents the distribution of negated and speculated sentences based on the overall polarity of the sentence. On average, the number of sentences with negation structures and positive polarity is the same as negative polarity. Nonetheless, the number of negation cases in the software topic with negative polarity is more than the cases with positive polarity. In addition, the speculative contents within positive polarity account for 66% of the corpus speculation cases as it is the majority in the books and software topics. According to our observation, the book's topic includes most negation and speculation cases, which are typically used to cancel something negative about the books. Furthermore, most of the software advantages or features are negated or speculated.

Fig. 1 and Fig. 2 demonstrate the number of negation cases in each sentence within the three sub-corpora. The number of negated sentences that include more than two negation scopes in one sentence is 173, accounting for 20% of the negation cases in the NSAR corpus. However, there are only three sentences with two speculation scopes. This finding further proves that the speculative content in the review domain includes the entire sentence as long as the polarity.

TABLE VI. NEGATION AND SPECULATION SENTENCES PER POLARITY

Corpus	Topic	Negation		Speculation	
		Pos	***Neg***	***Pos***	***Neg***
LABR	Books	165	83	29	17

VI. Conclusion and Future Work

The DA texts are used in people's day-to-day conversations on social media platforms and review websites. Many research groups worked on the sentiment analysis task, and some of them considered the negation linguistic feature and highlighted its significance using simple rules. However, researchers still have challenges in addressing various structures of the negation phenomenon as long as the speculation. This paper presented the first Arabic corpus in the review domain annotated with negation and speculation (NSAR) to tackle these challenges using supervised learning techniques. This corpus was annotated by two Arabic native speakers who adhered to strict annotation guidelines that were reviewed by a linguist expert. The Cohen's Kappa coefficients were used to measure annotator agreement and obtained 95 and 80 for negation and speculation, respectively. The results show that the annotation guidelines were written clearly. NSAR will be made available, which will contribute to the detection of negation and speculation, as well as the sentiment analysis task. The future work includes extending the corpus by annotating the events element as long as the negation focus. In addition, we plan to apply the recent deep learning techniques on this corpus to study the impact of negation and speculation on various ANLP tasks.

APPENDIX I

TABLE VII. ANNOTATION GUIDELINES EXAMPLES

No.	Arabic Text	Transliteration*	English Translation
1	أحلام اجمل الايام كانت هناك و ذكريات لا تنسى مكان رائع يجمع الكل فى حركه و ضحك وحياه	Aḥlām ajmal al-Ayyām kānat hunāk wa Dhikrayāt lā tunsá makān rā'i' yajma'u al-Kull fī ḥrkh wa ḍaḥika wḥyāh	The most beautiful days were spent there with unforgettable memories; it is a wonderful place that brings everyone together in liveliness, laughter and life.
2	لو كان سعره اقل وفيه فلاش كنت قيمته اكار من كدا فشل واضح من سوني انها ماحطتش ليه فلاش	Law kāna si'ruhu aqall wa-fīhi Flāsh Kunt qymth akār min kdā fashal Wāḍiḥ min Sūnī annahā māḥṭtsh Līh Flāsh	If it had a lower price and had a flash, it would have been worth a lot more than this. It is a clear failure from Sony that they didn't add a flash.
3	جهاز جبار ويتفوق علي نظرائة من الايباد والسامسونج بجد رابع بس لم ياخذ حجم الدعايه المطلوبه	Jihāz Jabbār wytfwq 'Alī nẓrā'h min alāybād wālsāmswnj bi-jadd rāá' Bass lam yākhdh ḥajm ald'āyh almṭlwbh	This an excellent device that outperforms its counterparts from iPad and Samsung which is really great, but it did not receive enough publicity.
4	7 روايات في رواية ، تهكم وسخرية وأدب وأشياء اخرى لن تمل منها	7 Riwāyāt fī riwāyah, thkm wskhryh wa-adab wa-ashyā' ukhrá lan tml minhā	This book has seven novels in a novel: sarcasm, irony, literature and other things that you will not get bored of.
5	يستاهل لانه دعم اللغة العربية لكن ياريت يثبت البرنامج على رقم المستخدم وليس على حساب	Ystāhl lānh Da'm al-lughah al-'Arabīyah lākin yāryt yuthbatu al-Barnāmaj 'alá raqm al-mustakhdam wa-laysa 'alá ḥisāb	It is worth it because it supports the Arabic language, but I hope that I can register with my mobile number not my account number.
6	الذي فاجئني وزعجني هو عدم وجود ريموت فيها بالمقارنة مع السعر	Alladhī fāj'ny wz'jny huwa 'adam wujūd rymwt fīhā bi-al-muqāranah ma'a al-si'r	What shocked and annoyed me was the lack of a remote control in it compared to the price.
7	تطبيق رائع وفيه خصوصيه محدش يعرف دخلت امتي خرجت امتي انت حتي لو بتكتب اللي قدامك مش بيعرف	Taṭbīq rā'i' wa-fīhi khṣwṣyh Maḥaddish ya'rifu dkhlt amty kharajat amty anta ḥattá Law btktb Illī qdāmk mish by'rf	This is a wonderful application that protects your privacy; no one knows when you logged in or logged out. Even while typing, the person in front of you will not know that you are typing.
8	فكرني بفلاش و سماش والحاجات دي بس مفيش كلمات متقاطعة	Fkrny bflāsh wa smāsh wālḥājāt Dī Bass mfysh Kalimāt mutaqāṭi'ah	It reminded me of 'Flash and Smash' and these things, but this one does not have crossword puzzles.
9	مررررره حلو وعصيراته فرش ومو حاطين له لاسكر ولا مويه كله فرش	Mrrrrrh Ḥulw w'ṣyrāth farsh wmw ḥāṭyn la-hu lāskr wa-lā mwyh kullahu farsh	It is extremely delicious, and its juices are fresh, and they do not add sugar or water; it is all fresh.
10	نصيحتي ان في محلات فطاير تانية في حدايق حلوان ممكن تكون أفضل كتير	Naṣīḥatī an fī maḥallāt fṭāyr tānyh fī Ḥadāīq Ḥulwān mumkin takūn afḍal kitīr	My advice is that there are other pastry shops in Hadyaa Helwan that could be much better.
11	اول روايه اقرأها لباولو كويلهو ولااعتقد انها الاخيره	Awwal riwāyah aqr'hā lbāwlw kwylhw wlāā'tqd annahā alākhyrh	This is the first novel I read for Paulo Coelho, and I don't think it will be the last.
12	لم استسيغ نزار فى شعر الفصحى اعتقدوا فى الشعر الحر اكثر ابداعا	Lam astsygh Nizār fī shi'r al-fuṣḥá a'tqdwā fī al-shi'r al-Ḥurr akthar abdā'ā	I did not like Nizar in classical poetry. I think in free verse he is more creative.
13	فندق مريح صراحة اسعارة جيدة ما بين 150 الى 300 ريال الليلة ونظيف جدا	Funduq mryḥ ṣrāḥh as'ārh Jīdah mā bayna 150 ilá 300 Riyāl al-laylah wa-Naẓīf jiddan	It is a comfortable hotel, frankly; it has good prices, between 150 to 300 riyals per night, and it is very clean.
14	أنصح بيه أي حد بيدرس هندسة كهربية أو عايز يدرسها هتوفر عليه جنون كتير	Anṣḥ Bīh Ayy ḥadd bydrs Handasat khrbyh aw 'āyiz ydrshā htwfr 'alayhi Junūn kitīr	I recommend it to anyone who studies electrical engineering or wants to study it; it will save a lot for him.
15	ربما يكون الكتاب جيداً ولكن بروز شخصية الكاتب المتملقه تفسد ذلك؟	Rubbamā yakūn al-Kitāb jayyidan wa-lakin Burūz shakhṣīyah al-Kātib almtmlqh tufsidu dhālika?	The book may be good, but the author's fawning character spoils it.
16	ما إن رأيت ولا سمعت بمثله	Mā Inna ra'aytu wa-lā sami't bi-mithlih	I have neither seen nor heard of anything like it.
17	ما هذه الرومانسية الحالمة وما هذا الاسلوب الناعم الجميل هذه الرواية من اجمل ما قرات على الاطلاق	Mā Hādhihi al-rūmānsīyah al-ḥālimah wa-mā Hādhā al-uslūb al-Nā'im al-jamīl Hādhihi al-riwāyah min ajmal mā qrāt 'alá al-iṭlāq	What is this dreamy romance, and what is this soft and beautiful style? This novel is one of the most beautiful novels I have ever read.
18	أليس هذا بالحق	Alīs Hādhā bi-al-Ḥaqq	Isn't that right?
19	مَا هَٰذَا بَشَرًا إِنْ هَٰذَا إِلَّا مَلَكٌ كَرِيمٌ	Mā haādhā basharan in haādhā illā malakun karīm	This is not a man; this is none but a noble angel **
20	جدة غير	Jiddah ghayr	Jeddah is different/unique.

21	كتاب غير مجرى تفكيرى خلاه اوسع خلانى أثق اوووى فى العلامات	Kitāb ghayr majrá tfkyrá khlāh awsaʻ khlāná athq awwwá fī al-ʻalāmāt	This book changed my way of thinking; it broadened my mind and made me trust the signs strongly.
22	تجننننن انا بصراحه مش بس الفندق جميل كل حاجه زورتها كانت جميله قوي قوي قوي قوي	Tjnnnnnn anā bṣrāḥh mish Bass al-Funduq Jamīl kull ḥājh zwrthā kānat Jamīlah Qawī Qawī Qawī Qawī	Amazing! Not only is the hotel beautiful but also everything I visited there was very very very very beautiful.
23	أجمل ما فيه هو إفطاره	Ajmal mā fīhi huwa ifṭārh	The best thing about it is its breakfast.
24	كتاب خفيف و واقعي و بعيد عن المبالغة تماما كل شيء فيه حقيقي	Kitāb khafīf wa wāqiʻī wa baʻīd ʻan al-Mubālaghah tamāman kull Shay’ fīhi ḥaqīqī	This is a light and realistic book which is absolutely far from exaggeration; everything in it is real.
25	وَتَرَى النَّاسَ سُكَارَىٰ وَمَا هُم بِسُكَارَىٰ	Watará alnnāsa sukāráā wamā hum bisukāráā	You will see the people [appearing] intoxicated while they are not intoxicated [**]
26	الكلمة قد تفعل فى الانسان ما لم تفعلة الادوية القوية لك كل قدير	al-Kalimah qad tfʻl fī al-insān mā lam tfʻlh al-adwīyah al-qawīyah laka kull qdyr	The effect of a word may be stronger than the effect of medicines.
27	السلعة ليست بالجودة المطلوبة وقد اشتخدمتها لمرة واحدة فقط ولم ارجع لاستخدامها مرة ثانية	Alslʻh laysat bāljwdh al-maṭlūbah wa-qad ashtkhdmthā li-marrah wāḥidah faqaṭ wa-lam arjʻ lāstkhdāmhā marrah thānīyah	The item is not of the expected quality, and I only used it once and did not use it again.
28	جلسات رائعة جلسات المطعم الخارجية رائعة خصوصا في فصل الربيع والشتاء اما الاكل فجيد نوعا ما	Jalasāt rā’iʻah jalasāt almṭʻm al-khārijīyah rā’iʻah khṣwṣā fī Faṣl al-Rabīʻ wa-al-shitā’ amā alākl fjyd nwʻā mā	The atmosphere of the outdoor restaurant is wonderful, especially during spring and winter, but the food is not that good.
29	وَجَعَلَ لَكُمُ السَّمْعَ وَالْأَبْصَارَ وَالْأَفْئِدَةَ ۙ لَعَلَّكُمْ تَشْكُرُونَ	Wajaʻala lakumu alssamʻa wāl’abṣāra wāl’af’idata ۙ laʻallakum tashkurūn	He [Allah] made for you hearing and vision and intellect that perhaps you would be grateful [**]
30	الَّذِينَ يَظُنُّونَ أَنَّهُم مُّلَاقُو رَبِّهِمْ وَأَنَّهُمْ إِلَيْهِ رَاجِعُونَ	Alladhīna yaẓunnūna annahum mmulāqū rabbihim wa’annahum ilayhi rājiʻūn	Who are certain that they will meet their Lord and that they will return to Him [**]

Drought Prediction and Validation for Desert Region using Machine Learning Methods

Azmat Raja, Gopikrishnan T
Department of Civil Engineering
National Institute of Technology, Patna, India

***Abstract*—Drought prediction serves as an early warning to the effective management of water resources to avoid the drought impact. The drought prediction is carried out for arid, semi-arid, sub-humid, and humid climate types in the desert region. The drought is predicted using Standardized precipitation evapotranspiration index (SPEI). The application of machine learning methods such as artificial neural network (ANN), K-Nearest Neighbors (KNN), and Deep Neural Network (DNN) for the drought prediction suitability is analyzed. The SPEI is predicted using the aforesaid machine learning methods with inputs used to calculate SPEI. The predictions are assessed using statistical indicators. The coefficient of determination of ANN, KNN, and DNN are 0.93, 0.83, and 0.91 respectively. The mean square error of ANN, KNN, and DNN are 0.065, 0.512, and 0.52 respectively. The mean absolute error of ANN, KNN, and DNN are 0.001, 0.512, and 0.01 respectively. Based on results of statistical indicator and validations it is found that DNN is suitable to predict drought in all the four types of desert region.**

Keywords—Drought; SPEI; machine learning; water resources; prediction

I. Introduction

Drought is a recurring natural phenomenon characterized by prolonged water crisis driven by below-normal precipitation over a considerable length of time ranging from months to years [11]. Because of its complex nature and extensive occurrence, it is difficult to describe drought and identify its characteristics [16]. For sustainable agricultural activity and water resource management, accurate drought prediction and management are critical. The duration, frequency, intensity, and geographic distribution of rainfall, as well as the water needs of humans, animals, crops, and the region's vegetative cover, assess the severity of the drought. Drought is divided into four categories based on its effects: meteorological drought, agricultural drought, hydrological drought, and socioeconomic drought [8] [25]. Drought can reduce food production and have an impact on a community's socioeconomic viability [32].

Agricultural drought analysis and forecasting are more important than other types of drought in India since it is an agrarian country with 68 percent of the population dependent on agriculture. Due to a lack of water, anomalous rainfall, and harsh climatic conditions, the dry region of western India is at risk of severe droughts. The state of Rajasthan in India comprises of desert region which is classified as arid, semi-arid, sub-humid, and humid. Rajasthan is vulnerable to drought due to harsh climate. Drought is unavoidable, but it can be minimized by careful planning and preparation. Effective drought responses do not come from simply understanding the situation. While resources should be invested in enhancing the accuracy of drought monitoring and early warning systems, equal or more emphasis should be placed on upgrading drought governance structures to ensure a more effective division of responsibilities between national and local governments. As a result, numerous studies have been conducted in order to provide an objective and quantitative assessment of drought severity. Drought indices, which are proxies based on climate data and assumed to appropriately characterize the degree of drought hazard, are commonly used to quantify the effects of drought.

Drought indices have been developed in large numbers and are widely used in drought evaluation, monitoring, and forecasting. The standardized precipitation evapotranspiration index (SPEI) [36] is a developed form of standardized precipitation index (SPI) [27] by taking monthly climatic water balance. The SPEI's multi-scalar properties allow it to distinguish between different drought types and impacts, which is a significant advantage over the most generally used drought indices, which assess the effect of potential evapotranspiration on drought severity [5].

Machine learning is the subset of artificial intelligence. Machine learning (ML) algorithms are a set of commands that allow systems to learn and improve from prior data without requiring complex programming. ML techniques have been used to implement prediction or forecasting of drought. These algorithms work by simulating a model from input datasets known test sets, and then using the model findings to forecast, predict, or make various types of judgments in various application domains. K-Nearest Neighbors (KNN), Artificial Neural Network (ANN), and Deep Neural Network (DNN) machine learning techniques are extensively used in prediction of drought [1]-[4], [7], [9]-[10], [12]-[15], [17]-[24], [28]-[31], [33]-[35].

KNN is also called Lazy Learner. It does not require any training. It stores the training dataset and only uses it to make real-time predictions. As a result, the KNN method is much faster than other algorithms that require training. KNN is a simple algorithm to use. KNN can be implemented with only two parameters: the value of K and the distance function. ANN have a number of advantages, including the ability to detect complex nonlinear relationships between dependent and independent variables, the ability to recognize all potential relationships between predictor factors [10]. ANN is suitable for both large and small data sets. Deep learning is significantly responsible for the current boom in artificial intelligence (AI) usage. DNN has the biggest advantage in that it learns high-level features from data in a gradual manner. DNN gives the high quality results over other traditional methods. Overfitting is a major problem in neural networks which can be easily handled in DNN using dropout layer.

Various studies have used machine learning approaches to predict the drought using SPEI. For drought estimation, we take into account all climatic parameters that influence evapotranspiration. All of the activation functions are used to determine the best activation function for drought prediction. In this study we use SPEI drought indices to measure drought in western Rajasthan from 1979 to 2013. Drought prediction and selection of acceptable methodologies for drought measures in dry regions utilizing ANN, KNN, and Deep Neural Network machine learning algorithms.

II. Materials and Methods

The computation process of the drought prediction using both SPEI drought indices and machine learning techniques is shown in work flow diagram (Fig. 1). The working procedure start from the data collection and end at accuracy assessments of machine learning models.

A. Study Area

Rajasthan is located in north-western India between latitudes of 230 N and 300 N and longitudes of 690 E and 780 E. Fig. 2 depicts the study area in western Rajasthan, which consists of 12 districts in the state of Rajasthan. Due to insufficient rainfall and vast desert, the 12 districts are at risk of drought. Jaisalmer and Bikaner are in the arid region; Ganganagar, Hanumangarh, and Jodhpur are in the semi-arid region; Jalor, Jhunjhunu, Pali, and Sikar are in the sub-humid region; and Barmer district is in the humid region.

B. Data Collection

Daily and monthly weather data for all 12 districts in western Rajasthan for 24 weather stations were retrieved from global weather data (https://globalweather.tamu.edu/) from 1979 to 2013. Maximum and minimum temperatures, precipitation, wind speed, humidity, and solar radiation are all included in the weather data.

C. Standardized Precipitation Evapotranspiration Index (SPEI)

Vicente et al. [36] created SPEI, which is derived from SPI and uses both precipitation and potential evapotranspiration (PET) as input parameters to calculate the monthly climatic water balance.

$$D = P - PET \qquad (1)$$

Where D is a simple aggregation of water shortages or excess over a period of time, P is the precipitation in mm, and PET is potential evapotranspiration in mm. The PET is computed using penman- Monteith (PM) equation using meteorological data [5-6].

The SPEI value can be calculated using the standardized values of F(x) [36].

$$SPEI = W - \frac{C_0 + C_1W + C_2W^2}{1 + d_1W + d_2W^2 + d_3W^3} \qquad (2)$$

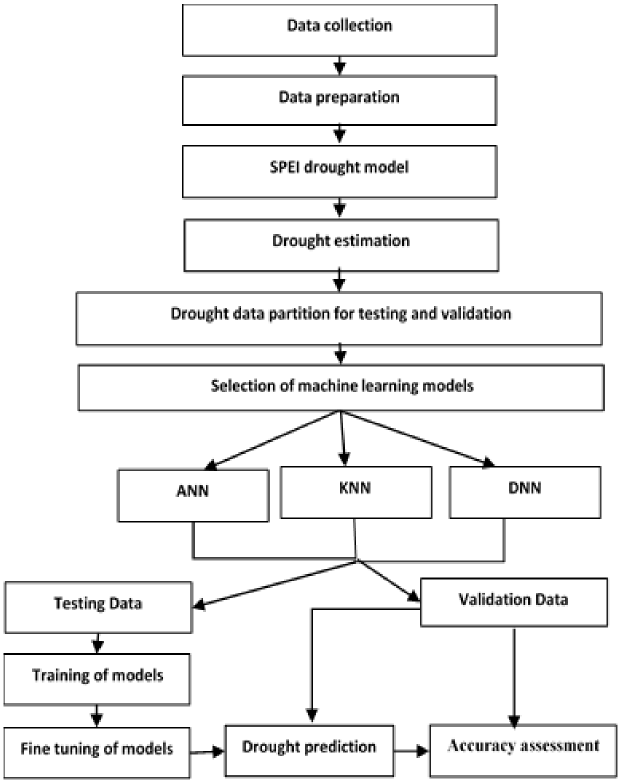

Fig. 1. The Workflow Diagram.

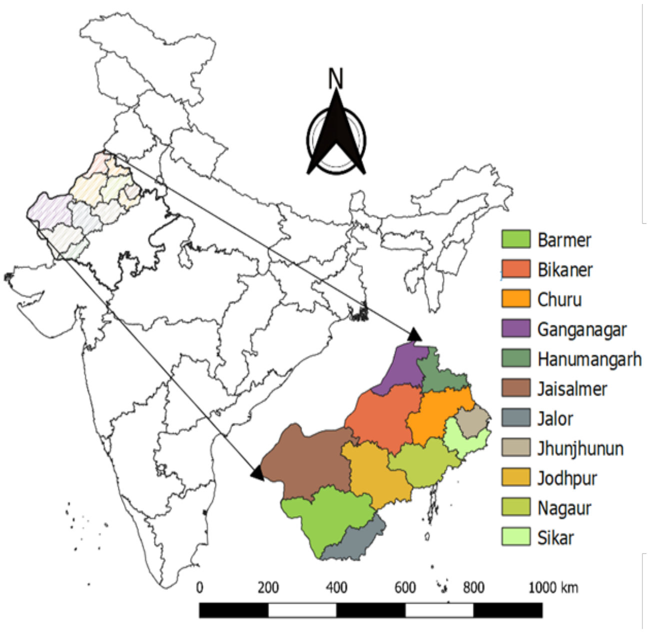

Fig. 2. The Map of the Study Area.

Where, $W = \sqrt{-2lnp}$ for P ≤ 0.5 and P is the probability of exceeding a determined D value, P =1-F(x). If P > 0.5, then P is replaced by 1 - P and the sign of the resultant SPEI is reversed. The constants are C_0= 2.515517, C_1 = 0.802853, C_2= 0.010328, d_1 = 1.432788, d_2 = 0.189269 and d_3= 0.001308.

According to the classifications of [27] [5] the SPEI can be classified mainly in five classes as shown in Table I.

TABLE I. SPEI DROUGHT CATEGORY CLASSIFICATION

Drought class	SPEI
No-Drought	Greater than -0.5
Mild	-0.5 to -0.99
Moderate	-1 to -1.49
Severe	-1.50 to -1.99
Extreme	Less than -2

D. Machine Learning Methods

Artificial neural network (ANN): McCulloch and Pitts [26] created the technique in the 1940s, and it has since evolved alongside developments in calibrating methodologies. One of the benefits of the ANN method is that the simulation is not required to completely characterize the intermediate relationships [10], [12], [21]. An ANN consists of a series of input layers, hidden layers, and output layers, each with its unique weightage as shown in Fig. 3. In this study we used 7 inputs variables and two hidden layers (first hidden layer consists eight nodes and second hidden layer consists five nodes) to compute the SPEI at output node.

1) K-Nearest Neighbors (KNN): The K-Nearest Neighbors (KNN) algorithm is a supervised machine learning algorithm that can be used to address classification and regression problems. The KNN is successfully applied in drought forecasting globally [13]-[14] [17] [28]. The basic logic behind the KNN is computing the Euclidean distance, the other alternative distance can be used are Manhattan distance, Hamming Distance, and Minkowski distance. The outcome of a KNN regression is the mean of the k closest data points. We choose odd numbers as k as a rule of thumb. KNN is a lazy learning model in which only runtime computations are performed. KNN has advantage over ANN as neural networks need large training data. The importance of meteorological data and PET on drought prediction is shown in Fig. 4.

2) Deep Neural Network (DNN): Deep learning has risen in popularity in recent years as a result of its superiority in prediction when compared to traditional machine learning approaches. Deep learning takes a lot of data because the network learns on its own. Traditional machine learning is just a set of algorithms for parsing and learning from data. The DNN has been successfully used for prediction in the past with positive results [7], [18], [21], [23], [33]-[34]. We used Keras and tensor flow package in R which is based on deep learning. The high-level interface and the automatic differentiation feature of TensorFlow make simple to implement the algorithm in an efficient manner [24]. The process of computation involved in prediction is shown in Fig. 5.

Relu, Selu, Tanh, and Sigmoid are the most common activation functions utilized in DNN. As stated in Table II, we used all four activation functions as well as their combinations. The DNN has a high prospect of overfitting the model in most cases. We used 20% of the training data for validation, as indicated in Fig. 6, to avoid overfitting the model.

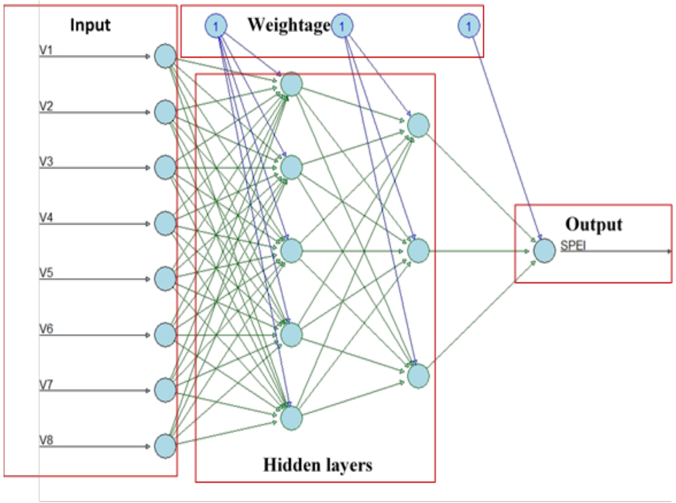

Fig. 3. The Components of ANN.

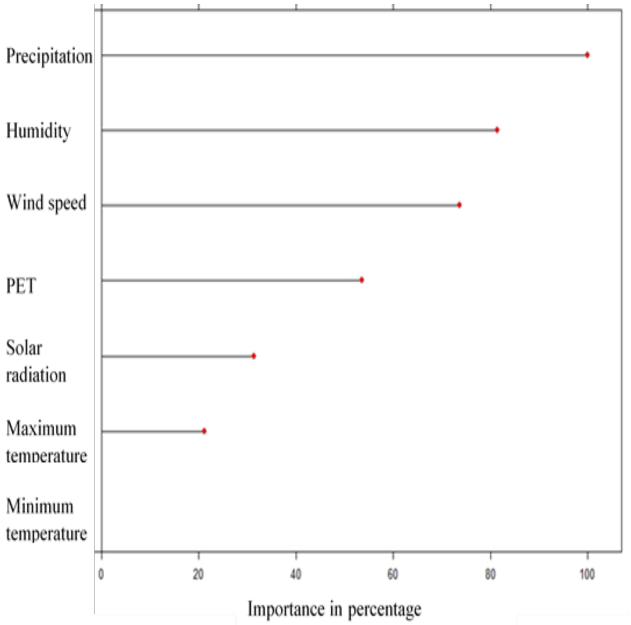

Fig. 4. The Importance of Meteorological Parameters on Drought Prediction using KNN.

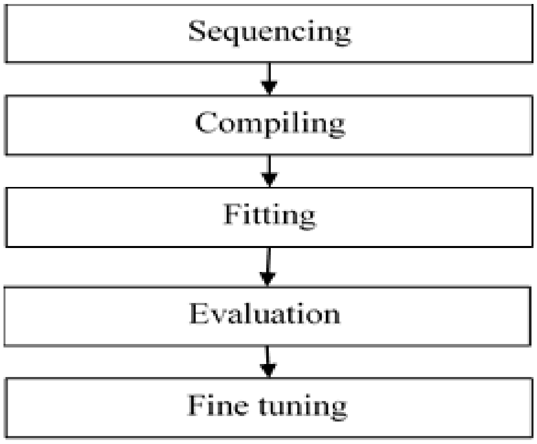

Fig. 5. Computation Process of Drought.

TABLE II. ACTIVATION FUNCTION USED IN DNN MODELLING

Activation function	Abbreviation
Relu without fine-tuning	M
Relu	M1
Selu	M2
Tanh	M3
Sigmoid	M4
Combination of Relu, Selu, and Tanh	M5
Combination of Relu, Selu, Sigmoid, and Tanh	M6

3) Performance assessment: The mean absolute error (MAE), root mean square error (RMSE), and coefficient of determination (R^2) are three typical performance indicators used to assess the models performance.

$$MAE = \frac{1}{N}\sum_{i=1}^{N} |Actual - Predicted| \quad (3)$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(Actual - Predicted)^2} \quad (4)$$

$$R^2 = 1 - \frac{Squared\ sum\ error\ of\ regrssion\ line}{Squared\ sum\ error\ of\ mean\ line} \quad (5)$$

Where, N is the number of samples.

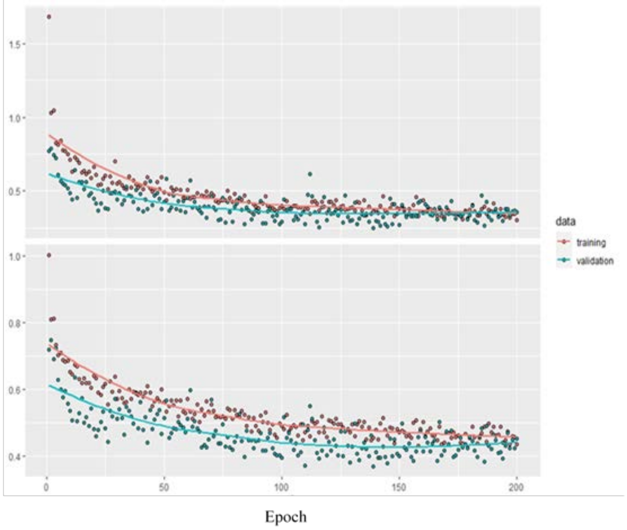

Fig. 6. Validation Spilt to avoid Overfitting of the Model.

III. RESULT AND DISCUSION

A. Temporal Variation of SPEI

The temporal variation of SPEI from 1979 to 2013 for different regions of western Rajasthan is shown in Fig. 7. The variation of drought pattern is varying with climatic condition. Each region observed severe to extreme drought in the year 1987, 1999, 2002, 2006, and 2009. The arid and semi-arid region showed more vulnerable to drought than the humid and sub-humid region Due to their location in the driest section of the Rajasthan, the districts of Jaisalmer and Bikaner experienced severe drought whereas other districts had moderate drought. Drought is less of a concern in Barmer, but it is more of a problem in Jaisalmer.

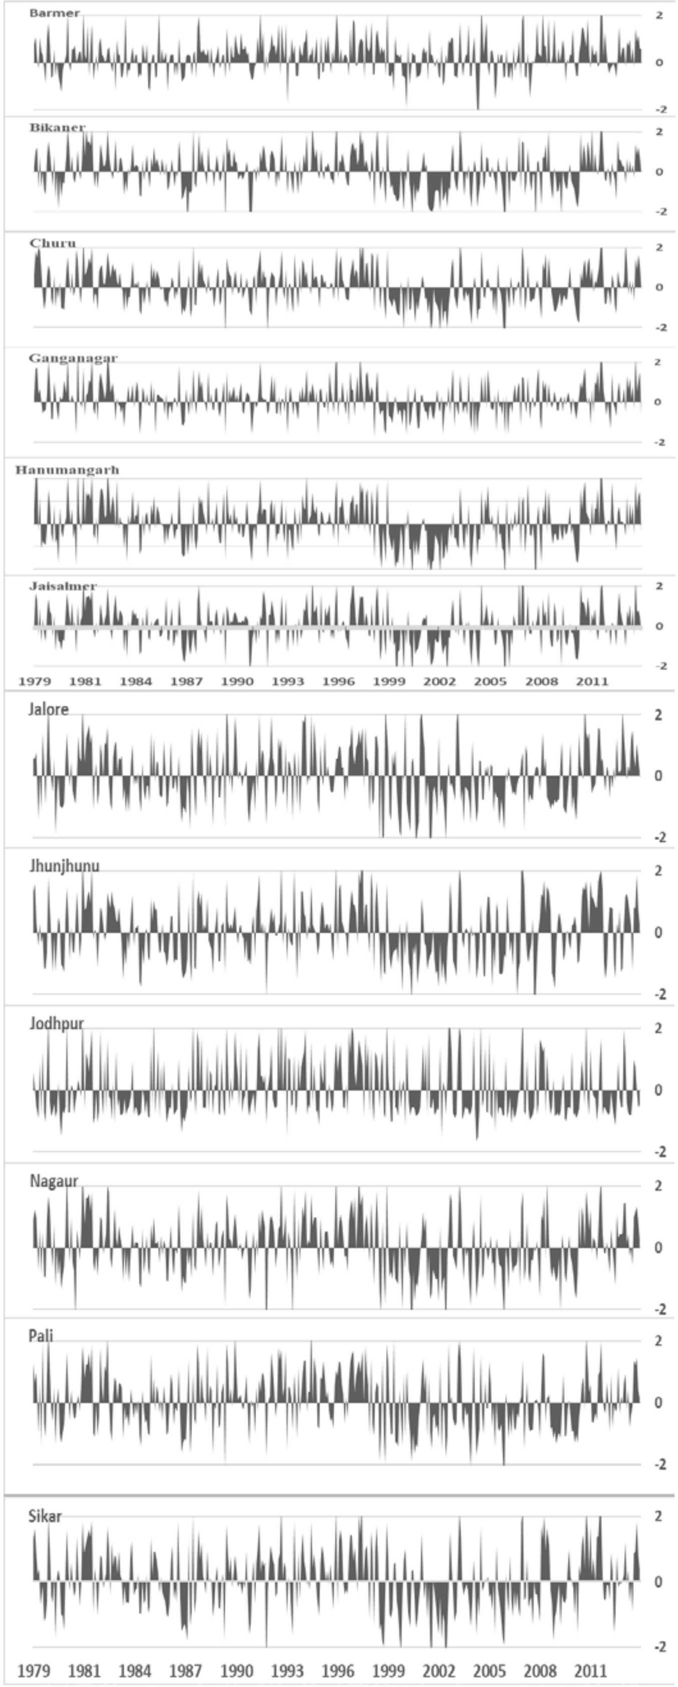

Fig. 7. Temporal Variations of SPEI over the Years 1979-2013.

B. Validation of ANN Drought

The variation of drought predicted by ANN for four different meteorological conditions is shown in Fig. 8. With slightly high or low SPEI values, the predicted values showed a similar pattern of variation as the test target. All of the regions showed good results, although the humid zone produced slightly better results. We used normalized data because there is always a problem with convergence with ANN when dealing with large data sets.

C. Validation of KNN Drought

The variation SPEI values predicted by KNN is shown Fig. 9. All the region showed similar kind of variation. The ANN showed slight better variation than KNN with target SPEI values. For sub-humid and humid locations, the K-NN based SPEI values best matched lower test target SPEI values, indicating that K-NN is better suited for drought prediction in humid regions.

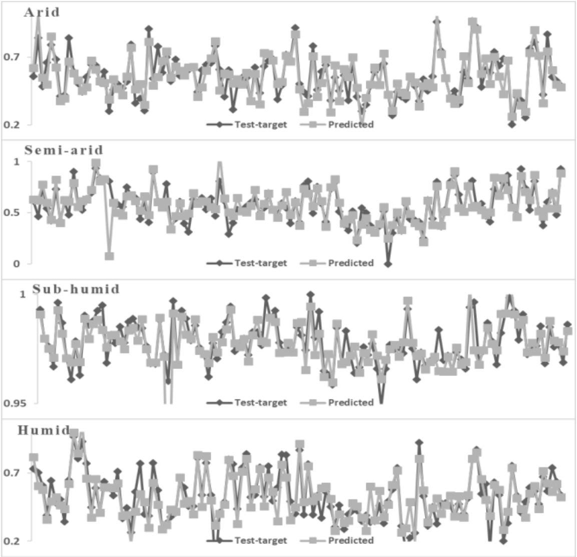

Fig. 8. Comparison of ANN Predicted and Test Target SPEI.

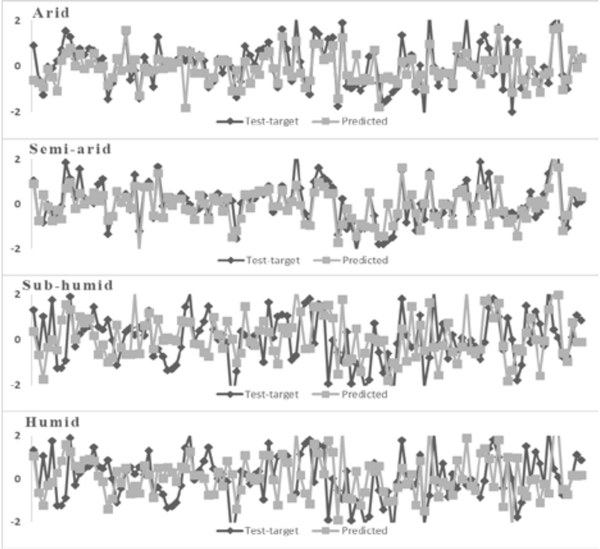

Fig. 9. Comparison of KNN Predicted and Test Target SPEI.

D. Validation of DNN Drought

The variation SPEI values predicted by DNN using a fine-tuned relu activation functions shown Fig. 10. The variation of SPEI values predicted by the DNN showed similar pattern of variation as target value with almost same SPEI values. The results of DNN is better than the both ANN and KNN for all the regions. The predicted values do not exceed the target values because the DNN has overfitting control. All the activation functions and their combinations showed good results.

E. Performance Assesment

Three different statistical indicators are used to evaluate the drought prediction models' performance: coefficient of determination, mean square error, and mean absolute error. The performance statistics of the ANN, KNN, and DNN is shown in Fig. 11, Fig. 12, and Fig. 13 respectively for arid, semi-arid, sub-humid, and humid regions. After fine-tuning, both ANN and DNN showed considerable improvements in statistical parameters, however KNN did not show any substantial improvement. In ANN and DNN, the coefficient determination is higher, whereas in KNN, it is slightly lower but still satisfactory. The highest coefficient of determination of ANN, KNN, and DNN are 0.93, 0.83, and 0.91 in semi-arid, sub-humid, and semi-arid region respectively. All the three models resulted in low MSE and very low MAE values. All of the activation functions in DNN worked well, however Relu and the combination of activation functions worked very well. The fine-tuning of the model improves the results, but it can also lead to overfitting, therefore when fine-tuning is applied we need to examine the pattern and similarity of predicted values with target values. The activation function Relu after fine-tuning showed highest agreement in arid and humid region with R^2 values 0.87 and 0.89 respectively. The highest agreement observed in semi-arid and sub-humid region by fine-tuned Selu with R^2 values 0.91 and 0.87 respectively.

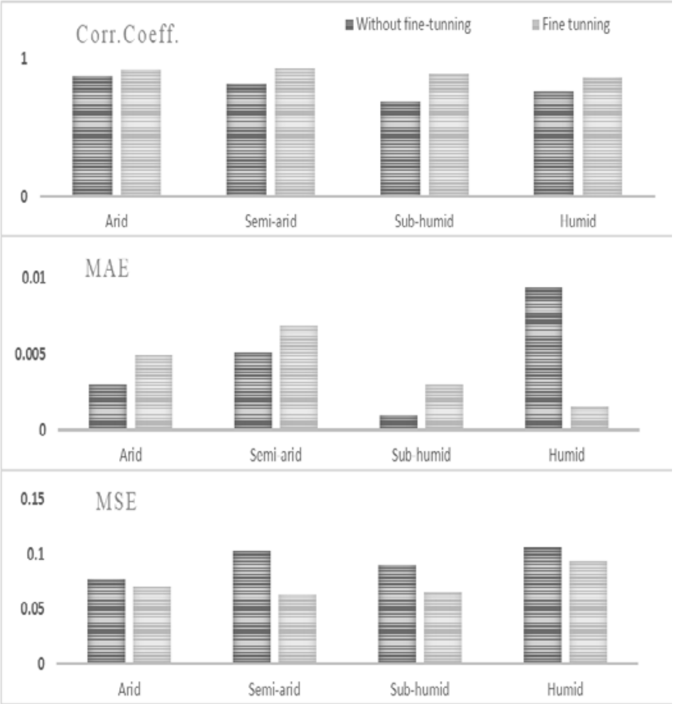

Fig. 11. Statistical Indices of ANN for different Climatic Condtions.

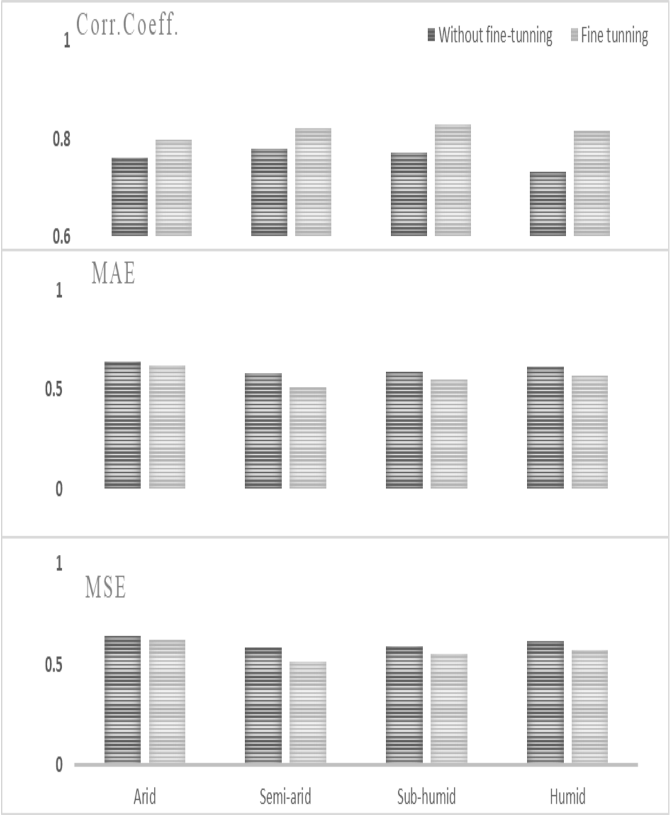

Fig. 12. Statistical Indices of KNN for different Climatic Condtions.

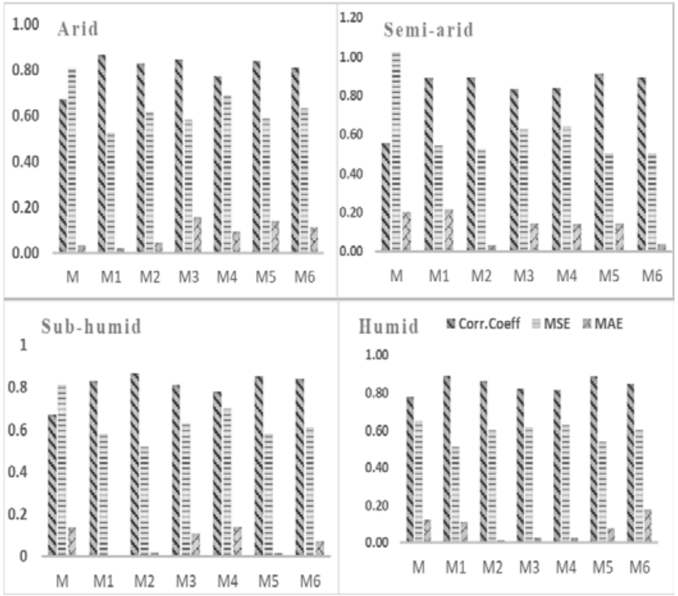

Fig. 13. Statistical Indices of DNN for different Climatic Condtions.

IV. Conclusion

The ANN, K-NN, and DNN are used to predict the drought in arid, semi-arid, sub humid, and humid conditions for the years 1979 to 2013. The KNN is one of the oldest machine learning algorithms but it is still in use for comparison to other machine learning methods. The DNN performed better than the both ANN and KNN for predicting drought in all the climate conditions. The ANN predicted better results than the KNN. It is also observed that both the ANN and KNN showed very similar results to the SPEI prediction in humid region. In all climatic conditions, DNN and ANN have larger coefficients of determination, whereas KNN has a comparatively lower coefficient of determination. The activation Relu showed best results compared to other activation function. Based on the results DNN can be used for drought prediction of any climatic condition with large data sets.

***Abstract*—Detecting Distributed Denial of Service (DDoS) attacks has become a significant security issue for various network technologies. This attack has to be detected to increase the system's reliability. Though various traditional studies are present, they suffer from data shift issues and accuracy. Hence, this study intends to detect DDoS attacks by classifying the normal and malicious traffic. The study aims to solve the data shift issues by using the introduced Decision Tree Detection (DTD) model encompassing of Greedy Feature Selection (GFS) algorithm and Decision Tree Algorithm (DTA). It also attempts to enhance the proposed model's detection rate (accuracy) above 90%. Various processes are involved in DDoS attack detection. Initially, the gureKddcup dataset is loaded to perform pre-processing. This process is essential for removing noisy data. After this, feature selection is performed to select only the relevant features, removing the irrelevant data. This is then fed into the train and test split. Following this, Software Defined Networking (SDN) based DTA is used to classify the normal and malicious traffic, then given to the trained model for predicting this attack. Performance analysis is undertaken by comparing the proposed model with existing systems in terms of accuracy, MCC (Matthew's Correlation Coefficient), sensitivity, specificity, error rate, FAR (False Alarm Rate), and AUC (Area under Curve). This analysis is carried out to evaluate the efficacy of the proposed model, which is verified through the results.**

Keywords—Distributed denial of service attack; greedy feature selection; decision tree algorithm; software defined networking; cloud and decision tree detection

I. Introduction

Cloud computing led to the development of technologies due to its services like resource pooling, measured service, broad network access, rapid elasticity, and on-demand self-service. But, security challenges have a dominant issue in cloud computing development. In cloud computing, security requirements include integrity, availability, privacy preservability, confidentiality, and accountability. Among these, availability has been vital, as the main functionality of cloud computing has been to afford on-demand service at various stages. DDoS (Distributed Denial of Service) and DoS (Denial of Service) have been the fundamental techniques to minimize cloud computing availability. SDN (Software Defined Network) has evolved as a novel network paradigm as the SDN characteristics afford the requirement of flexibility, reliability, and secured future networks that could alter the traditional networks. As SDN possesses abilities like decoupling the control plane from the corresponding DP (Data Plane) and centralized controller, traditional networks could be altered with SDN for easy and early detection of DDoS attacks [1]. Clouds and SDNs explore identical designs with three-layered architecture composing an infrastructure layer and computational resources controlled through a control layer that has been controlled through API (Application Program Interface) by applications in the application layer, as presented in Fig. 1.

SDN has been used to deal with DDoS attacks. However, SDN's issues explore the fact that the overall network gets compromised when a specific controller has been flooded with several attacks. The DDoS attack intends to attack the SDN controller through overflowing FT (Flow Table) in the respective DP, as explored in Fig. 2. Cost and limited memory have made FT in DP to be minimum. Hence, whenever a request with an unknown record in FT arises, DP switches forward all the requests directly to the SDN controller, which checks its FT. If it is a legitimate request, it answers with a legal flow. If the requests received have been more at a specific time, the controller takes more time to look at the FT. In addition, the response also enhances that exhausts the controller's resources and makes it unavailable to deal with legitimate requests. Hence, before forwarding a request to the corresponding DP, it is essential to check if the particular request is normal or an attack. In addition, SDN installation would permit novel security issues [2] in SDN as the centralized SDN controller is the bottleneck and turns out to be an SPF (Single Point Failure) in SDN. Attackers will also concentrate on the DDoS attacks, particularly on the SDN controller for flooding the network traffic in the controller. This controller could no longer reply to the elements of DP, like network routers and switches. This collapses the overall network and makes all the cloud services not accessible to end-users through resource exhaustion, resulting in reputation and economic loss.

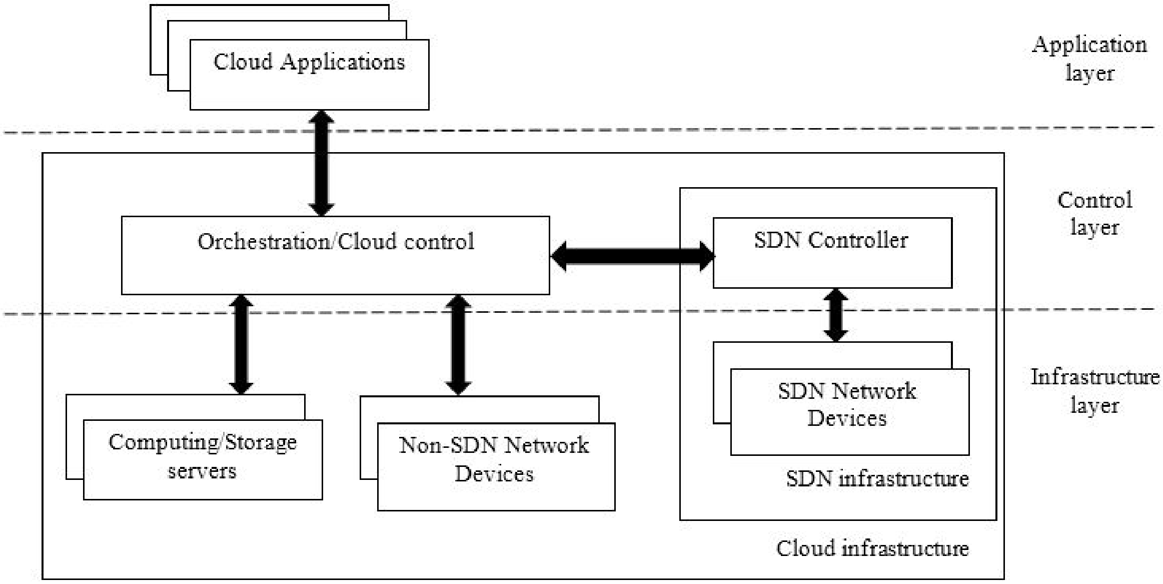

Fig. 1. The Architecture of SDN based Cloud.

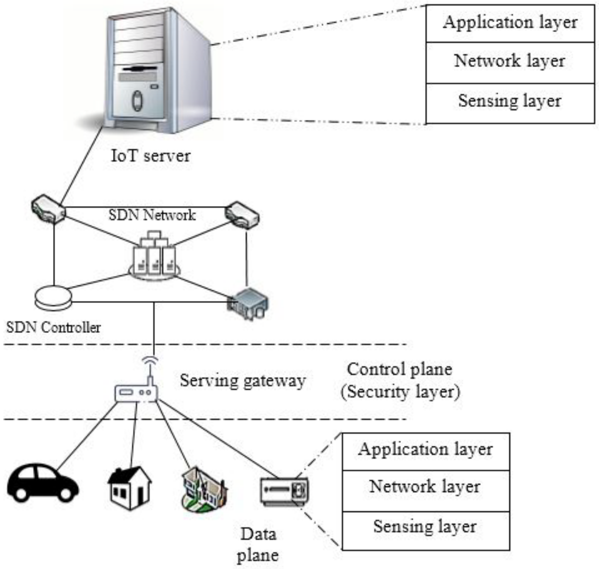

Fig. 2. DDoS Attack Detection in SDN.

Though some efficient studies have been undertaken to detect DDoS attacks in conventional computing environments, these attacks are turning out to be highly occurring in cloud computing environments [3]. The study [4] introduced a design that can detect DDoS attacks in the cloud environment on execution in the real world. Under this design, three ML classification models, RF (Random Forest), LR (Logistic Regression) [5], and SVM (Support Vector Machine), are trained on the CICDDoS2019 dataset. The introduced algorithm chooses the effective classifier for attack prevention, relying on the traffic rate. RF has been found to show better outcomes with 97% accuracy. In addition, a practical and lightweight alleviation method has been introduced for protecting the SDN framework in contradiction to DDoS flooding, confirming an efficient and secure networking environment based on SDN [6]. The proposed system enhanced the DP with a mitigation and classification module to analyze all the new incoming packets and classify all the normal requests from SYN-flood attacks. Subsequently, it performs suitable countermeasures. Simulation outcomes represent that the introduced defending method might effectively deal with DDoS attacks in downstream servers and SDN [7]. The DDoS attack detection in SDN is shown in Fig. 2, which comprises IoT server, SDN controller, serving gateway, data plane, and control plane. Typically, an IoT sensor shall comprise three layers: an application, network, and sensing layer.

The end-user software like email clients and web browsers utilize the application layer. It allows the software to send and receive information and present essential data to the users. The network layer affords the telecommunication resource operations that allow data transfer amongst the systems. PDN (Public Data Network) might provide real-time telecommunication services and have been defined as sub-networks. The sensing layer shows the data type arriving from specific data sources like web services, conventional WSN (Wireless Sensor Networks), and PSNs (Pervasive Social Networks).

Hence, DDoS attack detection is accomplished in SDN, where the SDN controller manages the overall flow control to improve application performance and network management. This platform usually utilizes protocols to inform switches by directing the path for sending the data packets and runs on the server.

Various researches have been carried out to detect DDoS attacks. An approach based on anomaly intrusion has been introduced in the hypervisor layer to minimize the DDoS attacks amongst VMs (Virtual Machines). The evolutionary neural network has been employed to execute the proposed system that integrates PSO (Particle Swarm Optimization) with NN (Neural Network) to detect and classify traffic exchanged amongst VMs. Analysis of the system showed the efficiency in classifying these attacks with high accuracy and a low false alarm rate [8]. However, the dataset used handles only the traffic exchange amongst VMs; hence, traffic arriving from the outside host could be researched in further studies. As this system relied on soft computing methods, a probable future work has to be chosen as the alternative technique to accomplish a high detection rate and minimum computation time. Similarly, ML (Machine Learning) based system has been recommended to detect DDoS attacks. This system makes inferences by the signatures extracted earlier from network traffic samples. Experimentations have been performed through four benchmark datasets, and the outcomes exhibited an accuracy rate of 96.5%. However, the accuracy rate has to be further improved to enhance the detection rate [9], [10]. However, accuracy and dataset shift issues are common in existing methods. Hence, the present study intends to detect DDoS attacks in the SDN-based cloud environment through the proposed Decision Tree Detection (DTD) model.

The objectives of this study are 1) to address the dataset shift issue efficiently through the proposed Decision Tree Detection (DTD) model comprising Greedy Feature Selection (GFS) algorithm and Decision Tree Algorithm (DTA). 2) To enhance the detection accuracy above 90% using the introduced Decision Tree Detection (DTD) model. 3) To evaluate the performance of the proposed system by comparing it with traditional ML methods concerning detection rate, error rate, FAR (False Alarm Rate), specificity, sensitivity, MCC (Matthew's Correlation Coefficient), and AUC (Area under Curve).

A. The Significant Contribution of the Proposed Study

The proposed model contributes to increasing the security in the cloud system with high accuracy. The proposed system employed GFS in the feature selection process, which reduces the overfitting issues, the accuracy range was improvised, and the model training was accomplished faster. The proposed system then used a DTD algorithm for classification, which forms in a tree structure. Further, it breaks down the dataset into smaller subsets, whereas the related decision tree is incrementally developed at the equivalent period. The system also efficiently performs data shifting. Various studies implemented with DTA and GFS in cloud environments were viewed. Therefore, the system can effectively and efficiently detect DDoS attacks in the SDN-based cloud system.

B. The Motivation of the Proposed Model

Though various studies have been implemented in the DDoS attack detection over the SDN-based cloud system with the DT approach, they still fail to enhance the accuracy range. The Decision tree provides an efficient approach for decision-making because it results in lay for the problems, thus that all choices might be challenged. Consents to estimate all the conceivable magnitudes of a decision. Affords an architecture for enumerating the standards of results and the possibilities of accomplishing them. Then, the Greedy algorithm results elucidation for small illustration of the complications can be forthright and easy to understand. The greedy feature selection process results in both forward and backward selection; in the proposed model, the backward selection is employed. Thus, these factors motivate implementation of an SDN Based Decision Tree Detection (DTD) Model for Detecting DDoS Attacks in a Cloud Environment.

C. Paper Organization

The paper is organized in the following way. Section I explores the SDN-based cloud's basic ideas in DDoS attack detection. Followed by the existing works related to this context are analyzed in Section II. Then, the proposed DTD model is described in Section III. The results obtained from the proposed system are discussed in Section IV. Finally, the overall study is summarized in Section V.

II. Review of Existing Work

Various existing studies that correspond to DDoS (Distributed Denial of Service) attack detection in SDN-based cloud are analyzed, and the outcomes are presented. The common problems encountered in these existing systems during this review are also explored in this section.

The SDN (Software Defined Networking) encompasses various management, control, and configuration functionalities from the server. This SDN is partitioned into the control and DP method. From the recent data centers that maintain massive data every moment with servers possessing large data volumes, the SDN driver has increased. Components needed in this technique are costly. This process also consumes more time, and configuration turns out to be manual. Through central and management control, this issue has been solved in SDNs. However, SDN has a weak structure in various threats where DDoS attacks dominate. The main recent disruptions in all security systems have been because of DDoS attacks. These attacks mainly intend to collapse the user's access path to another server or network source. It occurs by integrating the server and host. Because of this, resources like CPU, memory, and traffic disappear from the host. Hence, this issue occurs when data transfer happens between authentic users and servers. Supplementary attacks could be resolved through rebooting. However, this merging model or flooding is complex. The DDoS attack detection has been analyzed based on entropy in SDN for detecting and controlling the impact of the SDN controller. DDoS attack traffic has been incorporated into typical traffic by a setup of twenty-five and fifty percent of traffic intended towards a host in the SDN network. Simulation has been carried out, and the outcomes explore the threshold value selected to find an effective DDoS attack. Future studies include simulating chi-square to find the attack traffic incorporated with the typical traffic [11]. Similarly, a method based on $\mathrm{Inf}_{\mathrm{dis}}$ (Information distance) has been used to detect this attack in SDN based cloud environment. Subsequently, ABA (Adaptive Boosting Algorithm) framework has been employed with SDN features to detect DDoS attacks. Finally, experimentations revealed the effectiveness of ABA in detecting this attack in SDN based cloud. Despite various merits in utilizing SDN in the cloud, it makes the cloud system susceptible to multiple novel security attacks like FTO (Flow-Table Overloading) DDoS attacks [12]. The FTS (Flow Table Sharing) method has been used to protect SDN-based clouds from FTO DDoS attacks to prevent this attack. This method uses idle FT of supplementary OFS (Open Flow Switches) in-network to protect the FT of switches from overloading. The proposed method enhances the cloud system's resistance against DDoS attacks with minimum engagement of the SDN controller. This leads to minimum communication overhead. The proposed approach has been highly supported by many experiments based on simulation. This shows the efficacy of the proposed system. It is also significant to classify abnormal and normal traffic [13].

Ensemble classification methods comprising SVM (Support Vector Machine), ELM (Extreme Learning Machine), and K-Nearest Neighbour (K-NN) have been suggested for the detection of DDoS attacks through the classification of the traffic as abnormal and normal. The analytical results explored that the proposed K-NN shows an accuracy rate of 76.9%. ELM and SVM classifier performs less or more identical to one another, with an accuracy of 96.4% and 92.7%. The overall decision is undertaken through a max-vote methodology [14], [15]. Various existing methods used different techniques for detecting this attack. The distributed blockchain method has been employed to detect and prevent DDoS attacks on SDN's centralized control plane. The proposed system has been simulated through the use of the AnyLogic simulator. The outcomes revealed the efficiency of the introduced system more than traditional systems, as it adds only minor overhead. Results explored that the controller's overhead was minimized up to thirty-five percent. This also substantially minimized the SDN controller's DDoS attack risk and overhead. A HIDS (Host-based Intrusion Detection System) has been presented to monitor the intrude's activity. The host machine would permit the administrator to monitor the attacker and their activities and alert the data owner in the cloud [16]. The proposed method has enhanced efficacy over the overall system's performance [17], [18].

Similarly, TEHO-DBN (Taylor Elephant Herd Optimization-Deep Belief Network) has been used to detect DDoS attacks in the cloud computing environment. This proposed classifier determines if the particular user is normal or an attacker. Simulation has been undertaken, and it could be summarized that the introduced TEHO relying on DBN has enhanced the performance with an accuracy of 83%. Though the accuracy is better, it has to be further improvised for efficient detection of DDoS attacks [19]. Hence, a Bi-fold SDN-based solution has been recommended using a covariance matrix and genetic algorithm (GA). Traffic data (real-time) has been gathered from an analyzer tool named Tshark network. The Bi-fold method has been employed to distinguish the abnormal traffic. GA takes an initial decision regarding the abnormal and normal attacks. The covariance matrix has been used for refining decisions. Empirical outcomes confirmed the efficiency of the introduced method with better sensitivity, specificity, and accuracy. But, the consumption of time to detect attacks is higher, but it is tolerable simultaneously. In addition, minimizing biased data is also significant in enhancing the attack detection rate [20].

The article [21] examined all the features extracted from SDN traffic, minimizing bias data from the dataset. The traffic features have been assessed through a tenfold-cross validation method. The efficiency of the proposed dataset has been assessed through comparison with the supplementary dataset, for instance-KDDCUP99 (Knowledge Discovery and Data mining tools Competition) dataset. The outcomes revealed that the introduced dataset could be efficiently used for SVM on SDN. A live traffic analysis technique has been provided with the NN (Neural Network) [22]. The proposed TFC-NN (Traffic Flow Classifier-Neural Network) has been trained by a labeled dataset built from under traffic and regular traffic of SDN. A live reduction process has also been integrated with TFC-NN relying on detecting DDoS. The recommended method has been deployed and assessed on SDN architecture relying on various performance metrics under different scenarios of DDoS attacks. Through TFC-NN, Classification has been accomplished with Global accuracy (96.13%). SDN and fog computing has been integrated as a mitigation method to accomplish better outcomes [23]. It also considers the IP spoof an excellent way to detect DDoS attacks. Proposed IP-spoof detection has been undertaken near the attacker source in this study to enhance the attack trace. In addition, a model has been introduced for detecting and mitigating all the DDoS attacks in the cloud environment [24], [25]. The introduced model needs small storage and the ability for fast detection. Empirical outcomes explored the power of the system to ease many attacks. Processing time and detection accuracy were the performance metrics used to assess the proposed model's performance. From the outcomes, it has been clear that the proposed system accomplished high accuracy of 97% with reduced false alarms [26], [27]. Similarly, issues have been solved by introducing an effective system named Prodefense to detect and mitigate DDoS attacks. It also includes criteria that are application-specific for the corresponding threshold of the network traffic. This allows the execution of customizable measures to detect DDoS attacks [28].

Likewise, a modular and flexible architecture has been suggested to alleviate and detect LR-DDoS (Low Rate DDoS) attacks in SDN-based clouds. Notably, the IDS (Intrusion Detection System) has been trained in the suggested architecture through the use of six ML (Machine Learning) models such as RF (Random Forest), SVM, MLP (Multilayer Perceptron), RT (Random Tree), and J48 to assess their performance through the use of CIC (Canadian Institute of Cybersecurity) DoS dataset. Evaluation findings reveal that the introduced method accomplished a 95% detection rate, irrespective of the complexity of detecting LR-DoS attacks. Simulation has been carried out equivalent to real-world production through the usage of the ONOS (Open Network Operating System) controller that has been running on MVM (Mininet Virtual Machine), which showed better outcome. Fast attack detection is also another significant parameter to be considered [29]. For this purpose, a DDoS attack alleviation architecture has been recommended to combine a programmable network observance to permit flexible controlling structure and attack detection for specific and fast attack reactions. To manage the structure, an attack detection system based on a graphic model has been introduced that could handle the dataset shift issue [30]. Simulation outcomes revealed that the suggested architecture could efficiently and effectively solve the security issues caused by the novel network paradigm. It has also been concluded that the proposed attack detection could efficiently state several attacks through real-world cases. Empirical analysis of ML methods has been carried out for detecting Botnet DDoS attacks [31].

Evaluation has been carried out on KDD99 and UNBS-NB 15 datasets for detecting Botnet DDoS. Typically, ML methods such as SVM, NB (Naïve Bayes), USML (Unsupervised Machine Learning), ANN (Artificial Neural Network), and DT (Decision Tree) have been analyzed concerning FPR (False Positive Rate), AUC (Area under Curve), accuracy, FAR (False Alarm Rate) and MCC (Matthews Correlation Coefficient). Analytical results revealed that the KDD99 dataset's performance was better than UNBS-NB 15. This substantiation has been crucial in network security and other relevant areas [32].

Various problems identified through the review of different existing methods for DDoS attack detection in SDN-based cloud environments are discussed below,

- Only a few parameters have been taken into analysis that encompasses the FPR (False Positive Rate) and attack detection rate [12], [16]. In addition, the current work [14], [20] considered only accuracy, specificity, and sensitivity. The present study considers many performance metrics for comparative analysis, such as detection rate, error rate, FAR (False Alarm Rate), specificity, sensitivity, MCC (Matthew's Correlation Coefficient), and AUC (Area under Curve), which explores the effective analysis of the proposed system.

- The traditional research [14] used K-NN, ELM, and SVM for DDoS attack detection, and the accuracy rate of K-NN was found to be 76.9%, ELM-96.4%, and SVM-92.7%. The existing system [19] used TEHO-DBN to detect this attack, and the accuracy was 83%. In addition, the article [22] accomplished an accuracy rate of 96.13% through the use of the proposed TFC-NN. Similarly, the paper introduced methods like HIDS with an accuracy of 97 per cent. Only two parameters are considered [24]. Likewise, the article [29] used ML-based methods, and accuracy was 95 per cent. However, accuracy has to be improved further in all these cases for efficient DDoS attack detection. Hence, this article intends to improve the detection accuracy through the proposed DTD model. Its efficiency is confirmed through the results.

- The existing work [22] has not executed and deployed the NIDS (Network-Based Intrusion Detection System) in SDN. However, the present study intends to detect DDoS attacks in SDN based cloud environment.

- Introduced model of the traditional systems performs fast execution. But, these works hardly suffer from performance loss regarding dataset shift issues [30] and detection accuracy [31]. The proposed system aims to solve these issues through the proposed DTD model.

- The traditional system [32] aimed to compare the introduced methods with other ML methods through many evaluation metrics in the future. But, the present work performs comparative analysis in terms of several metrics by considering various ML methods, such as SVM, NB, DT, USML and deep learning (DL) algorithm - ANN.

- Though various studies [31], [32], [28], [23] have been implemented in the DDoS attack detection, it fails to focus on the data shifting issues.

III. Proposed Methodology

The research introduced a model named DTD (Decision Tree Detection), comprising two algorithms such as Greedy Feature Selection (GFS) and Decision Tree Algorithm (DTA), to detect DDoS attacks in SDN based cloud environment. Various techniques and methods exist to detect this attack. In the proposed model GFS is employed for feature selection, which reduces the complexity and selects features faster. Followed by this, the classification is performed with DTA that enhance the accuracy range in class. However, all these methods possess common drawbacks. The data shift issues are not efficiently handled, and detection accuracy is also minimal [30]. To resolve this drawback, this study proposed a DTD model comprising two algorithms such as GFS and DTA, where GFS is used to perform feature selection. For this purpose, the gureKddcup dataset is used, which includes 48 features. In addition, DTA (Decision Tree Algorithm) is used for classification. The overall process of the proposed system is presented in Fig. 3.

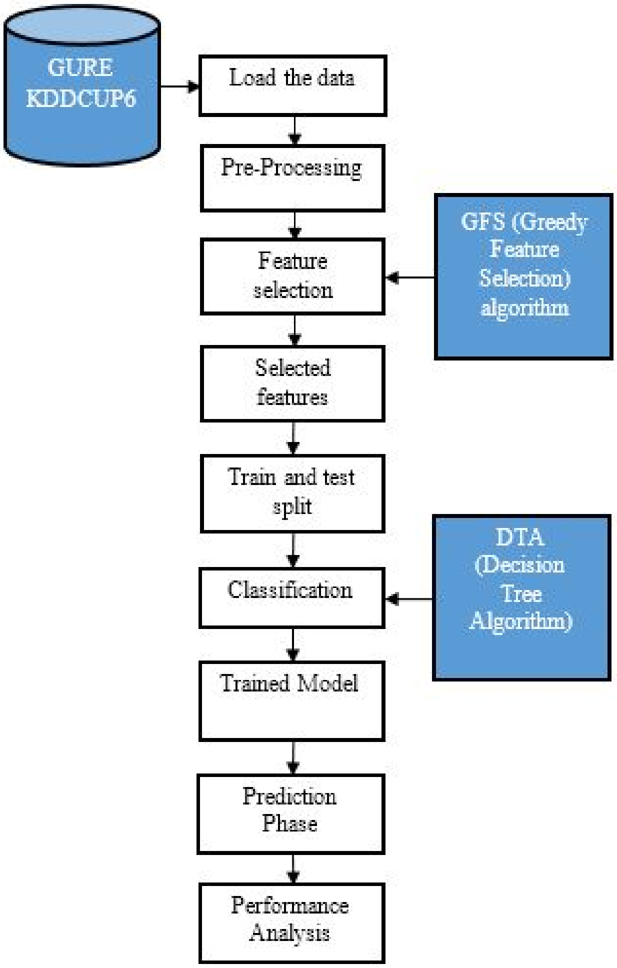

Fig. 3. Dataflow Diagram of the Proposed DTD Model.

Various processes are involved in detecting DDoS attacks. At first, the dataset is loaded, and then pre-processing is performed for noise removal. After this, the feature selection is performed by the GFS algorithm, which filters only five features from all the features available in the dataset; these features are then fed into DTA, one of the efficient classification algorithms that classify non-malicious (normal) and malicious attacks. Here, one portion of the dataset is used for training. The other portion is used for testing. Training data is labeled as local. At the same time, the testing data is labeled as global. After training, the proposed model can detect DDoS attacks effectively, which is proven through results. Finally, performance analysis is undertaken to evaluate the efficiency of the proposed system.

A. GFS (Greedy Feature Selection) Algorithm

GFS is a mathematical method that is simple, easy to implement, and provides solutions to complex issues by making practical decisions [33]. This algorithm operates by recursively building object sets from minimum probable constituent elements. It either selects the best features individually (forward selection) or removes all the worst features individually (backward selection). In the proposed model, the backward selection is employed. The dataset is loaded for pre-processing and feature selection using the GFS algorithm. It performs various steps to accomplish this process, and those steps are presented,

Step 1: Initialize the dataset and its source with the attack features.

Step 2: Generate the objects for the evaluator, search algorithms, and attribute selection.

Step 3: Initiate a Greedy backward search with a filter in accordance with the search algorithms and evaluator over a particular dataset.

Step 4: Measure the error of LOOCV (Leave One Out Cross Validation) of DT classification for the current population set of features of the current search iteration. This is the fitness cost $f(x_{iter})$ for the input set of features of the current iteration x_{iter}.

Step 5: Apply filter to perform greedy operations in a stepwise way. Evaluate it to optimize the search filters.

Step 6: Obtain the count of classes and their attributes. Map the class indexes and update their weight for a pre-defined count of instances.

Step 7: Repeat step 2 to 7 for maximum search iterations.

Step 8: Save and update the minimum fitness cost as $f_{min}(x) = \min f(x)$.

Step 9: Final optimal solution of GFS comprises the significant features from the dataset.

The fitness cost $f(x)$ serves as the parameter to decide on the selection of significant features since it is the evaluation measure of the feature set x. The GFS is executed until the $f_{min}(x)$ is obtained as the optimal solution. Hence, after implementing all these steps through GFS, the dataset comprising 48 columns gets reduced to 5 columns with only relevant and specific features. Feature selection must be made efficiently as it affects the accuracy rate. Implementing GFS for feature selection undergoes the seven steps to select the best features effectively. Finding an issue's solution is typically easier with the GFS algorithm than with other algorithms. Hence, implementing it will enhance the detection accuracy proven through outcomes.

B. DTA (Decision Tree Algorithm)

DTA pertains to the group of SLA (Supervised Learning Algorithms) [34]. It is a tree-based classifier where the internal nodes show the dataset features, individual leaf nodes show the results, and branches show decision rules. Unlike other SLAs, DTA can be used for classification and regression issues. DTs are efficient kinds of algorithms that rely on several learning techniques. It possesses various advantages by boosting the accuracy of prediction models, stability, and straightforward interpretation. DTA is an efficient classification algorithm that exhibits data records into corresponding classes. It utilizes the recursive partition method for data exploration. The DTA components include roots, leaves, and branches. This study pursues a directed tree, which means roots don't have edges. Other components possess a single edge. In addition, the interior nodes show nodes without flow edges. Other nodes are leaves which show the decisional or terminal nodes. The Interior node partitions the space decision into many subspaces based on minimized feature sets. As numeric attributes are considered, attribute spaces are termed conditional ranges. Leaf nodes hold target values to attain their corresponding classes. Under the conditional values, the arrangement of interior nodes occurs from the root node to the leaf nodes. Hence, DTA is used for feature classification based on the below steps.

Step 1: Initialize the tree with a root node (R) that comprises the overall dataset.

Step 2: Determine all the best attributes in the dataset through ASM (Attribute Selection Measure).

Step 3: Determine all the best attributes in the dataset through ASM (Attribute Selection Measure) using information gain I. Information gain is the criterion for estimating the information comprised by each feature attribute. It can be expressed as,

$$I = E_R - (A_R * E_x)$$

Where, E_R is the entropy of the dataset, E_x is the entropy of the feature x, and A_R is the weighted average of the dataset. This measure of entropy helps in the identification of redundant or unnecessary information in an attribute and in the specification of randomness in the data.

Step 4: Generate the node of DT that comprises the best attributes.

Step 5: Recursively make new DTs using dataset subsets developed in step 3. Iterate this process until a particular stage is met, where further classification of nodes cannot be performed. These final nodes are the leaf nodes.

Hence, all the features selected using the GFS algorithm are fed into DTA, which classifies the features based on the above five steps. The attacks are classified as malicious or non-malicious through the overall proposed DTD model. The efficacy of the proposed system is confirmed through the outcomes, which are discussed in the subsequent section.

IV. Results and Discussion

A. Experimental Setup and Dataset Description

The research considered the dataset to evaluate the proposed model for detecting DDoS attacks. It is described in this section. The proposed system also attempts to solve the data shift issue, a common problem in the existing system. A comprehensive analysis of data shift is also explored in this section.

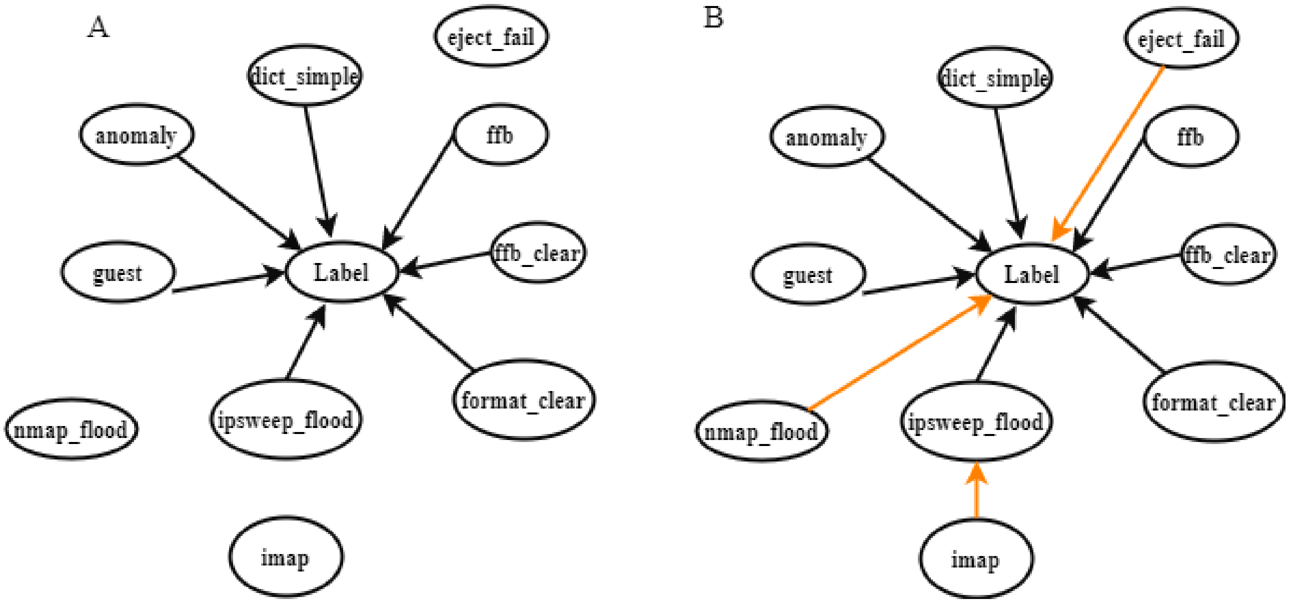
1) Experimental setup: The proposed system is developed and implemented in a system having configurations, as shown below.

Hardware details of the introduced module: Windows 10 pro processor: Intel (R) Core ™ i5-4210U CPU @1.70GHz installed memory, RAM: 4GB, System type: the 64-bit operating system.

2) Dataset description: This study used the gureKddcup dataset [35] to assess the performance of the proposed algorithms, which is one of the widely utilized datasets. It is created regarding the association of Kddcup99 (UCI repository database) and incorporates its payload into individual connections. This dataset helps extract all the information directly from a separate connection's payload to be effectively used in ML processes. In this study, the gureKddcup dataset is used to detect DDoS attacks that consist of 48 attributes which are later reduced to five through the proposed GFS algorithm.

3) Data shift: The data shift issue handles the information association in two subsets of data and assists in predicting a subset, thereby taking into account the data in the supplementary subset. This issue happens when the data generation relies on a model P y1/x1 P(x1), where P(x1) indicates the data distribution or changes amongst the train and test split. It usually occurs when data from a particular class is selected spontaneously compared to a supplementary class. Hence, a large dataset is needed to accomplish high accuracy in this case. During data classification and dataset partitioning in training and testing split, the training dataset is termed Local. The testing dataset is termed Global. It is shown in Fig. 4. As per Fig. 4, it could be seen that a data shift issue occurs in network traffic when a model is constructed using a training dataset. In the proposed method, when new traffic arrives, only some existing data is used as training data (Global). This shows that the proposed detection model keeps updating its training data according to the data received in real-time. Hence, it could always get new observations, afford accurate outcomes, and solve data shift problems. The proposed model nearly functions in real-time and thus solves data shift issues. This infers that the proposed model is not limited or constrained to any particular dataset. To prove the robustness of the model, its performance is compared with the performance of existing datasets.

4) Performance metrics: The performance of the proposed system is analyzed concerning detection rate (accuracy), error rate, specificity, sensitivity, FAR (False Alarm Rate), AUC (Area under Curve), and Matthew's Correlation Coefficient (MCC). Each of the performance metrics is discussed in this section.



(A): Local Update

(B): Global Update.

Fig. 4. Comprising A and B, explores how the Introduced Model Efficiently Handles Data Shift Issues. It is also essential as it affects the Proposed Model's Accuracy. Hence, the Proposed System Efficiently Solves Data Shift Issues, enhancing the Accuracy Rate above 90%.

Accuracy in detecting the attacks can be described as the proportion of detected attacks to the overall attack counts. It is given by the following equation 1.

$$\text{Accuracy} = \frac{\text{Count of detected attacks}}{\text{Overall attack count}} \qquad (1)$$

a) Error rate: The error rate is the proportion of attack counts not detected by the overall attack count and is given by equation 2.

$$\text{Error rate} = \frac{\text{Count of attacks not detected}}{\text{Overall attack count}} \qquad (2)$$

b) Sensitivity: It is defined as the number of true positives correctly predicted and given by equation 3.

$$\text{Sensitivity} = \frac{\text{True Positive}}{\text{True Positive+False Positive}} \qquad (3)$$

c) Specificity: The state/quality of being specific/unique to an individual or a group. It is mathematically represented as per equation 4.

$$\text{Specificity} = \frac{\text{True Negative}}{\text{True Negative+False Negative}} \qquad (4)$$

d) AUC (Area Under Curve): It could be stated as the correct curve integral that explores differences in classification and is given by equation 5.

$$\text{AUC} = \frac{1}{2}((\frac{\text{True Positive}}{\text{True Positive+False Negative}})+(\frac{\text{True Negative}}{\text{True Negative+False Positive}})) \qquad (5)$$

e) FAR (False Alarm Rate): It is defined as the ratio in which FA occurs in contradiction to true alarms.

f) MCC (Matthew's Correlation Coefficient): A highly static and reliable rate would afford a high score if detection attained good outcomes in all four confusion matrix classes (True Positive, False Positive, True Negative, and False Negative). It is given by equation 6.

$$\text{MCC} = \frac{\text{True Positive}*\text{True Negative}-\text{False Positive}*\text{False Negative}}{\sqrt{\text{(True Positive+False Positive)(True Positive+False Negative)(True Negative+False Positive)(True Negative+False Negative)}}} \qquad (6)$$

B. Experimental Results

The proposed DTD model is implemented, and the results are shown in this section. Initially, the dataset is uploaded. The dataset used in the study is gureKddcup. After the dataset is uploaded, the dataset is viewed. The overall count of instances or records is 10000, and attributes (features) are found to be 48. The proposed evolution of the proposed model is stated in Table I with respect to the class and considered performance metrics. Initially, in class normal, the true positive is 0.985, the false positive is 0.043, Precision is 0.999, recall is 0.985, F-measure is 0.992, and the ROC area is 0.972. In the class warezclient, true positive is 0.965; true negative is 0.015, Precision is 0.428, recall is 0.965, F1-measure is 0.593, and ROC area is 0.996. Similarly, in the class dict, the true positive is 0.961, the true negative is 0, Precision is 0.98, recall is 0.961, F1-measure is 0.97, and ROC area is 0.999. Therefore, in class warezmaster, the true positive is 0, the true negative is 0, Precision is 0, recall is 0, F1-measure is 0, and ROC area is 1. For class teardrop, the true positive is 0.982, the true negative is 0, Precision is 1, recall is 0.982, F1-measure is 0.991, and ROC area is 1. In syslog class, the true positive is 0, the true negative is 0, Precision is 0, recall is 0, F1-measure is 0, and ROC area is 0.499. Similarly, in land class, the true positive is 0, the true negative is 0, Precision is 0, recall is 0, F1-measure is 0, and ROC area is 0.499. In the guest class, the true positive is 0, the true negative is 0, Precision is 0, recall is 0, F1-measure is 0, and the ROC area is 0.489. Similarly, in class imap, the true positive is 0, the true negative is 0, Precision is 0, recall is 0, F1-measure is 0, and ROC area is 0.489. In the weighted average class, the true positive is 0.984, the true negative is 0.043, Precision is 0.992, recall is 0.984, F1-measure is 0.987, and ROC area is 0.976.

The confusion matrix is the performance evaluation of ML classification issues. The output could be two or many classes, a table with four varied combinations of actual and predicted values. The confusion matrix for the proposed model is done as shown in Table II. As per Table II, the diagonal values show the correct prediction rate. Finally, the correct and incorrect classified instances are determined as per Table III.

From Table III, the correctly classified instances are 98.42%, and the incorrectly classified instances are 1.58%. In addition, the kappa statistics, MAE (Mean Absolute Error), RMSE (Root Mean Square Error), RAE (Relative Absolute Error), and RRSE (Root Relative Squared Error). The experimental results show that the proposed system shows high accuracy with a low error rate. The proposed system is compared with the existing system to prove the efficacy of the introduced system over other systems, which is explored in the next section.

TABLE I. PERFORMANCE ANALYSIS

TP Rate	**FP Rate**	**Precision**	**Recall**	**F-Measure**	**ROC Area**	**Class**
0.985	0.043	0.999	0.985	0.992	0.976	normal
0.965	0.015	0.428	0.965	0.593	0.996	warezclient
0.961	0	0.98	0.961	0.97	0.999	dict
0	0	0	0	0	1	warezmaster
0.982	0	1	0.982	0.991	1	teardrop
0	0	0	0	0	0.499	syslog
0	0	0	0	0	0.499	land
0	0	0	0	0	0.489	guest
0	0	0	0	0	0.489	imap
0.984	0.043	0.992	0.984	0.987	0.976	Weighted Average

TABLE II. CONFUSION MATRIX

a	**b**	**c**	**d**	**e**	**f**	**g**	**h**	**i**	**<--classified as**
9627	142	1	0	0	0	0	0	0	a=normal

TABLE III. CORRECTLY AND INCORRECTLY CLASSIFIED INSTANCES

Correctly classified instances	98.42
Incorrectly classified instances	1.58
Kappa statistics	0.7281
Mean absolute error	0.0035
Root mean squared error	0.0587
Relative absolute error	34.0313
Root relative squared error	82.7176
Total number of instances	10000

C. Comparative Analysis

The proposed system is analyzed by comparing it with other algorithms concerning seven performance metrics. The existing algorithms considered for analysis include SVM (Support Vector Machine), DT (Decision Tree), NB (Naïve Bayes), ANN (Artificial Neural Network), and USML (Unsupervised Machine Learning). At first, the comparison is made by considering the existing and proposed model's detection rate and error rate over the corresponding input dataset. It is shown in Table IV.

TABLE IV. COMPARATIVE ANALYSIS OF THE PROPOSED AND TRADITIONAL SYSTEMS [30]

Parameter	**Local**		**Global**	
	[30]	**DTD (Proposed work result)**	**[30]**	**DTD (Proposed work result)**
Detection rate	86.56%	88.80%	89.30%	98.42%
Error	13.44%	11.20%	10.70%	1.58%

From the comparative analysis, as shown in Table IV, it is found that the proposed DTD model shows an 88.80% detection rate in local data and an error rate of 11.20%. In comparison, the existing system [30] shows a detection rate of 86.56% and an error rate of 13.44% in local data. The proposed DTD shows a detection rate of 98.42% and an error rate of 1.58% in Global data. In contrast, the traditional system [30] offers an 89.30% detection rate and 10.70% error rate in Global data. It is also graphically presented in Fig. 5. Hence, the introduced model affords more effective accuracy than traditional systems in both local and global data. In real-time, the attackers don't send similar attack patterns each time, which might vary. As the experimental outcomes show the efficiency of the proposed system in testing data with high accuracy, the introduced model can also be utilized in real-time.

In addition, a comparative analysis is undertaken by comparing the proposed DTD model with the existing methods, such as SVM, NB, ANN, DT and USML in terms of accuracy, sensitivity, specificity, FAR, AUC and MCC. The obtained results are shown in Table V and Fig. 6.

The comparative analysis explores that the proposed DTD model shows an accuracy rate of 98.42%, existing SVM shows a 91.55% accuracy rate, DT of 93.30%, NB of 96.74%, ANN of 97.44%, and USML offers 98.08%. From this comparison, the proposed system shows high accuracy rate than the existing systems. The proposed system also shows high AUC, MCC, sensitivity, and specificity than the traditional systems. The FAR of the proposed system is 1.58%, which is minimum than the existing methods, revealing that the introduced system shows only a minimum error rate with high accuracy. Hence, it can be concluded that the presented system is more effective than the traditional systems in terms of all the considered metrics.

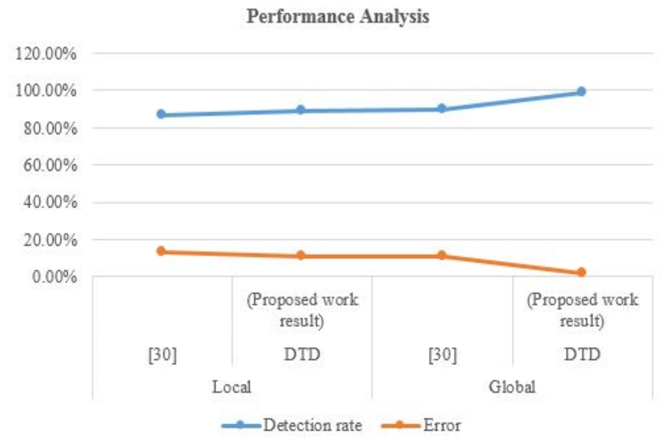

Fig. 5. Comparative Analysis in Terms of Detection Rate and Error Rate [30].

TABLE V. COMPARATIVE ANALYSIS IN TERMS OF VARIOUS METRICS [31]

Performance metrics	**SVM**	**DT**	**NB**	**ANN**	**USML**	**DTD (Proposed work result)**
Accuracy	91.55%	93.30%	96.74%	97.44%	98.08%	98.42%
FAR	8.45 %	6.70 %	3.26 %	2.56 %	1.92 %	1.58%
Sensitivity	90.13%	93.14%	98.21%	84.89%	91.88%	98.84%
Specificity	9.87 %	6.86 %	1.71 %	15.11%	8.12 %	94.30%
MCC	10.46%	5.48 %	10.42%	14.46%	1.48 %	90.26%
AUC	89.54%	94.52%	89.58%	85.54%	98.52%	98.90%

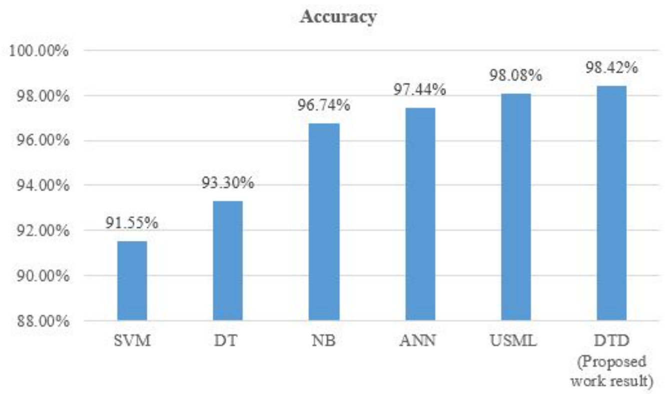

Fig. 6. Comparative Analysis in Terms of Accuracy [31].

V. Conclusion

The study detected DDoS (Distributed Denial of Service) attacks through the use of the proposed DTD (Decision Tree Detection) model that is composed of the GFS (Greedy Feature Selection) algorithm for selecting relevant features and DTA (Decision Tree Algorithm) for classifying these features. The proposed model was assessed by comparing it with traditional algorithms such as SVM (Support Vector Machine), DT (Decision Tree), NB (Naïve Bayes), ANN (Artificial Neural Network), and USML (Unsupervised Machine Learning) concerning significant metrics such as accuracy, MCC, sensitivity, specificity, error rate, FAR and AUC. The outcomes explored that the proposed system showed a high accuracy of 98.42% in testing data. As the proposed system showed high accuracy in testing data, it can be employed in real-time and is expected to get efficient results in detecting DDoS attacks. The proposed approach is also more effective than traditional methods, which are confirmed through the outcomes. Hence, these merits show the efficacy of the proposed system in classifying the malicious and normal attacks, thereby efficiently predicting. This results in the proposed model being employed in real-time to enhance the security in the cloud environment. The proposed model is evaluated with only Gurekddcup6 dataset; it can also be evaluated with other datasets. In the future, various other algorithms and hybrid approaches can improve detection accuracy further and perform DDoS attack mitigation.

Mono Camera-based Human Skeletal Tracking for Squat Exercise Abnormality Detection using Double Exponential Smoothing

Muhammad Nafis Hisham[1], Mohd Fadzil Abu Hassan[2]*, Norazlin Ibrahim[3], Zalhan Mohd Zin[4]
Universiti Kuala Lumpur, Malaysia France Institute, Bangi, Selangor, Malaysia[1, 2, 3, 4]
UniKL Robotics and Industrial Automation Center (URIAC), UniKL MFI, Bangi, Selangor, Malaysia[2, 3, 4]

Abstract—**Human action analysis is an enthralling area of research in artificial intelligence, as it may be used to improve a range of applications, including sports coaching, rehabilitation, and monitoring. By forecasting the body's vital position of posture, human action analysis may be performed. Human body tracking and action recognition are the two primary components of video-based human action analysis. We present an efficient human tracking model for squat exercises using the open-source MediaPipe technology. The human posture detection model is used to detect and track the vital body joints within the human topology. A series of critical body joint motions are being observed and analysed for aberrant body movement patterns while conducting squat workouts. The model is validated using a squat dataset collected from ten healthy people of varying genders and physiques. The incoming data from the model is filtered using the double exponential smoothing method;the Mean Squared Error between the measured and smoothed angles is determined to classify the movement as normal or abnormal. Level smoothing and trend control have parameters of 0.8928 and 0.77256, respectively. Six out of ten subjects in the trial were precisely predicted by the model. The mean square error of the signals obtained under normal and abnormal squat settings is 56.3197 and 29.7857, respectively. Thus, by utilising a simple threshold method, the low-cost camera-based squat movement condition detection model was able to detect the abnormality of the workout movement.**

Keywords—Abnormality movement; double exponential smoothing; skeletal tracking; mediapipe; squat exercise

I. Introduction

Human activity recognition is a critical application in the computer vision community. Human activity recognition is comprised of two primary components: body tracking and action recognition [1]. These two components have garnered considerable attention in recent years as a result of their multiple applications in areas such as health tracking, sign language recognition, and video surveillance.

Human body tracking can be utilised to tackle a range of problems. This includes avoiding injury during physical body exercise routines (aerobic, anaerobic, or agility training) by monitoring and predicting the person's body's vital points through each frame of a video stream [2]. Injury-free is essential during physical exercise. Thus, computer-assisted self-training systems for sports and exercise can help participants improve their performance and avoid injuries [3]. Besides human body monitoring can be used to solve several issues. Injuries can be avoided during physical training (aerobic, anaerobic, or agility training) by monitoring and predicting body vital points through video streams [2]. Injury-free exercising is crucial and computer-assisted self-training systems for sports and exercise can help athletes increase their performance while avoiding injury [3]. Determining the fundamental cause of postural, balance, and total body coordination difficulties can also be done through corrective exercise.

Action recognition can also benefit the living. During the COVID-19 pandemic, Malaysians were advised to stay at home and avoid routine visits. This may harm older people who were not accompanied by youngsters. Due to health difficulties, most elderly people are in danger of falling and fainting. Seniors may also face security issues such as robbery. Moreover, a study found that Malaysian healthcare has improved, accelerating the "Silver tsunami" of population ageing [4]. Thus, eldercare should focus on this population. Using machine learning and contemporary computer vision techniques, we can detect things of interest more accurately than humans [5]. Hence, an automated eldercare system should be considered for good monitoring.

Additionally, numerous studies have demonstrated that commercially available devices such as the Microsoft Kinect Sensor, the PlayStation Eye, and the Wiimote are successful at sensing and analysing human joint motion in many applications [6]. However, these researcher tracking studies necessitated the use of a 3-Dimensional (3D) sensor and additional expensive visual and wearable sensors. As a result, a low-cost mono camera equipped with a MediaPipe algorithm is proposed for determining pose landmarks and monitoring action motion in daily routine human activity.

II. Literature Review

Human skeletal tracking consists of tracking several key points from different parts of the human body, such as the body joints, eyes, nose, and ears depending on the purpose of tracking. The key points are connected creating a human skeletal form. Generally, the tracking of human motion can be done through visual information like images from video or extraction data through camera sensors. From the human skeletal features, Human Pose Estimation (HPE) and Human Action Recognition (HAR) can be applied. HPE is widely

*Corresponding Author.
Short Term Research Grant (Str19023) UniKL

applied to solve various problems such as bad posture correction, sports movement monitoring, fall detection, etc., [7]. HAR can be used to recognize daily life activities such as running, jumping, squatting, etc. which are recognized from video sequences using the vectors extracted [8]. The goal of HAR is to study and recognize the nature of action from unknown video sequences automatically [9].

A. Human Body and Movement Tracking

Human movement detection predicts and tracks an entity's position and orientation within an image/video frame. Previous researchers have investigated various techniques for detecting human movement. Certain detecting methods make use of wearable sensors. The Inertial Motion Unit (IMU) sensor is one of the most frequently used wearable sensors [10]. IMU technology is used in conjunction with a machine learning (ML) technique to precisely locate body key points and deliver accurate orientation measurements. However, relying exclusively on wearable sensors may impose significant limits, particularly for home-based monitoring. In addition, the implementation of the environmental sensor leads to high costs due to the use of professional external sensors [11].

In comparison to prior systems, some researchers use depth cameras such as the Kinect sensor, a low-cost consumer-grade 3D camera, to extract key points on the human body [12]. This technology can contribute to the provision of several human action characteristics, such as depth, colour differentiation, and human skeletal structure [13]. The x and y coordinates, as well as the confidence value, were recorded for each body key point, and a 2-Dimensional (2D) human movement estimate can be performed using the OpenPose algorithm [14]. Human movement detection can also be performed with an RGB stereo camera as a result of enhanced advances in in-depth imaging technology [6].

B. Machine Learning Framework

A framework represents an interface algorithm that makes the work of the machine learning model easier and faster. [7] apply six machine learning frameworks; OpenPose, Tflite, Pifpat, Tfjs (mobileNet), Tfjs (Resnet 50), and BlazePose for pose estimation and correction of fitness training dataset since the goal was to find the fastest and most accurate methods that work in real-time. Besides that, the use of a Kinect sensor to extract the skeletal features has also been used to determine the abnormality of squat exercise from a dataset [12]. In addition, [15] and [16] suggested the use of the OpenPose framework to extract the keypoints coordinates from the RGB data for pose detection of fall action. In comparison, the BlazePose framework that was used by the MediaPipe model presented a topology with 33 human body keypoints, which is more than OpenPose and Kinect topologies, which only provide 17 human body keypoints [2].

MediaPipe is an open-source ML model purposely for live and streaming media and provides direct and customizable Python solutions as a prebuilt Python package [17]. The primary use of MediaPipe is the quick creation of perceptual pipelines with any models and other reusable components [18]. MediaPipe offers several solutions such as MediaPipe Face Detection, MediaPipe Hands, MediaPipe Pose, MediaPipe Object Detection, etc. MediaPipe Hands tracking solution offers an ML pipeline that includes two different models that act in tandem; Palm Detection Model and Hand Landmark Model [19].

Furthermore, The MediaPipe Pose model, which was inspired by Leonardo's Vitruvian man, can identify the human body by predicting the midpoint of the human's hip, the radius of a circle circumscribing the full body, and the inclination angle of the line linking the shoulder and hip midpoints [18]. In [7] the author applied the MediaPipe Pose solution, which can predict 33 3D human body landmarks for human pose assessment and correction with an emphasis on fitness training. The MediaPipe Pose solution was also used during the pre-trained pose estimate for data collection of various yoga poses [20].

C. Rehabilitation Exercise

Physical therapy and rehabilitation programs are critical for persons who participate in sports, are accident victims, or are senior citizens. Nowadays, rehabilitation programs are conducted prior to the occurrence of any sports injury in order to prepare the athletes for the next level of physical demands [21]. The rehabilitation approach will involve exercises to increase muscle and joint range of motion. To ensure a consistent recovery outcome, patients are urged to complete a series of prescribed home-based physiotherapy sessions.

Squats are a well-known rehabilitation exercise, particularly for people with knee difficulties or injuries. This exercise is ideal for a home workout program because it does not require any extra equipment. Squat exercises require the patient's knee and hip joints to flex and extend to develop the body part's flexion and extension strength [22]. Hip, knee, and ankle movements must be synchronized correctly to ensure efficient muscle function and avoid damage throughout the activity [23]. The squat exercise cycle is performed as followed:

Step 1: Stand straight, open your feet align with the shoulder, and stretch out your arms to the front;

Step 2: Bend down your knees slowly until you reach a half-crouched position while maintaining your chest upward and back straight;

Step 3: Hold the previous step position for approximately one second while maintaining your feet flat on the floor;

Step 4: Slowly stand up to the initial position and one cycle is completed;

Step 5: Repeat steps 1 to 4.

All of the procedures above must be followed precisely to guarantee that the exercise's objective is met and that undesired injury is avoided. The training and testing phases of this paper make use of a similar squat dataset from [14]. The dataset was created by video recording squat exercises performed by ten healthy volunteers of varying gender and body build using Microsoft Kinect. The dataset is divided into two distinct categories: normal and aberrant. The normal condition dataset contains somewhat slow squatting movements to mimic the patient's gradual movement during rehabilitation. While the abnormal dataset was conducted with the same group of volunteers performing a comparable squat exercise with only one leg. This is done to mimic the same level of discomfort experienced by some patients during therapy.

III. Methodology

The goal of this research is to identify the abnormality of squat exercise by a single human using a single camera image. Training and testing datasets for classifiers were acquired from a set of ten subjects with different genders and physical body postures performed half-squat exercise. The diversities of human squat exercise were classified into two categories; normal condition squat and abnormal condition squat as shown in Fig. 1.

The normal condition squat consists of ten videos of the different subjects performing double legs half-squat exercise as shown in Fig. 1(a). On the other hand, the abnormal condition squat videos consist of ten videos of a similar subject in normal condition squat performing single legs half-squat exercise as shown in Fig. 1(b). Each subject conducted the exercise separately, and it was captured from front viewpoint angles in normal lab lighting. In this study, the distance between the 3D image sensor and subjects is fixed in the range of 2.5-3 meters.

A. *Human Skeletal Tracking-MediaPipe Pose*

MediaPipe Pose is the current solution for human pose assessment i.e. fitness training [12] which can predict 33 3D human body landmarks as shown in Fig. 2. By using the MediaPipe Pose model, this study is improvised and able to track the subjects' lower body (from hip to ankle) of the squat exercise dataset without the use of any marker on 2D images.

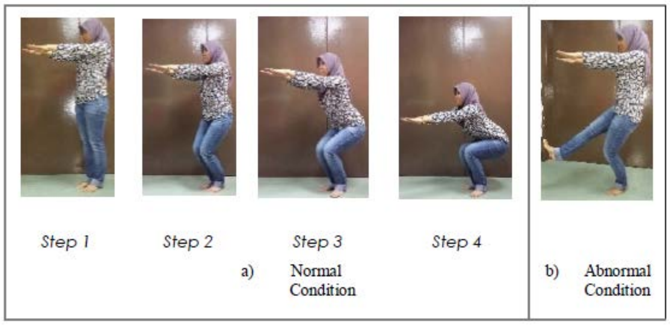

Fig. 1. Normal and Abnormal Squat Exercise Posture Steps [10].

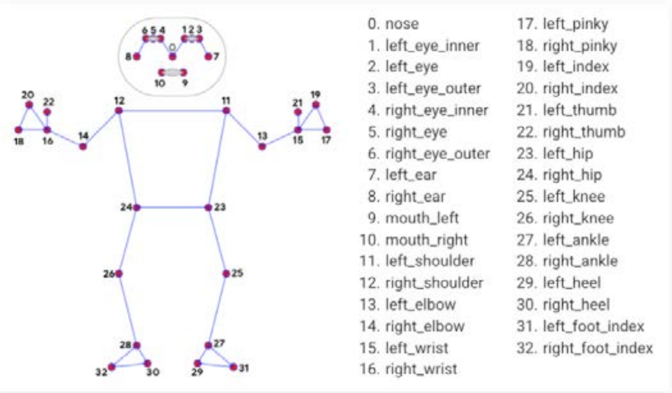

Fig. 2. Thirty-Three Human Skeletal Landmarks of MediaPipe Pose Model.

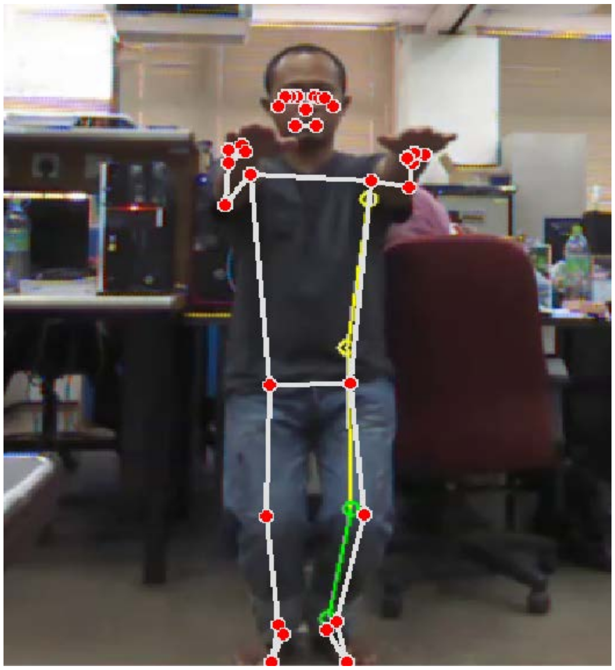

Fig. 3. Thirty-Three 3D Body Landmarks-MediaPipe Pose on 2D Image.

The study focuses on the hip-knee-ankle of a subject performing the half-squat exercise. The MediaPipe Pose model is capable to predict the essential human body landmarks as shown in Fig. 3.

B. *Joint Angle Tracking*

The angle was generated in 3D space based on the joint's coordinates as shown in Fig. 4. Euclidean distance is computed to evaluate the distance between two joints; hip-knee joint, knee-ankle joint, and knee-hip joint [24] using (1)-(3) below:

$$d_{HL,KL} = \sqrt{(x_{HL}-x_{KL})^2+(y_{HL}-y_{KL})^2+(z_{HL}-z_{KL})^2} \quad (1)$$

$$d_{KL,AL} = \sqrt{(x_{KL}-x_{AL})^2+(y_{KL}-y_{AL})^2+(z_{KL}-z_{AL})^2} \quad (2)$$

$$d_{AL,HL} = \sqrt{(x_{AL}-x_{HL})^2+(y_{AL}-y_{HL})^2+(z_{AL}-z_{HL})^2} \quad (3)$$

From the distance calculated, the knee angle (θ), is determined by using the Law of Cosines in (4) as stated below:

$$\theta_K = \cos^{-1}\left(\frac{d_{HL,KL}^2 + d_{KL,AL}^2 - d_{AL,HL}^2}{2d_{HL,KL}d_{KL,AL}}\right), 0 \leq \theta_K \leq \pi \quad (4)$$

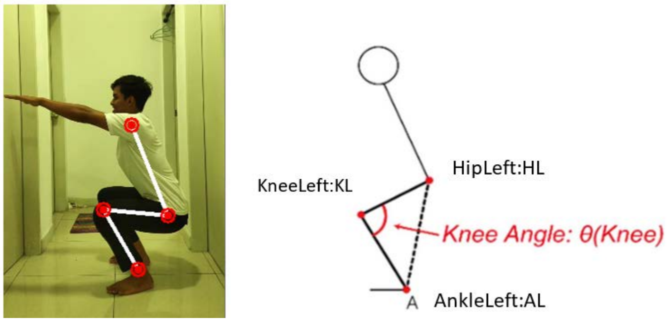

Fig. 4. Illustration of Tracking Lower Body Joints and Joint Movement.

C. Signal Filtering

From the result of the hip-knee-ankle angle extracted from the skeletal features, it is discovered that there was some unwanted noise presented. This random noise might occur due to the image parameter such as illumination disturbance, random shadow, subject pose, etc. from the dataset [12]. Therefore, an algorithm is applied to filter the incoming data image for the elimination of the noise before proceeding to the next process.

Double Exponential Smoothing (DES) was chosen for the following task as suggested by [25] to predict the trend for forecasting. Generally, DES is approached in economic data analysis to predict the immense range of noise, to forecast a trend, and give high forecasting accuracy level. DES also has been proven to run 100 times faster than the extended Kalman Filter [26]. The (5)-(6) are applied as stated below which are related to DES:

$$S_t = \alpha y_t + (1-\alpha)(S_{t-1} + b_{t-1})\,,\alpha\ \in [0{,}1] \qquad (5)$$

$$S_t = \alpha y_t + (1-\alpha)(S_{t-1} + b_{t-1})\,,\alpha\ \in [0{,}1] \qquad (6)$$

where:

y_t = original measured angle.

α = level smoothing parameter.

S_t = smoothed value.

b_t = trend control parameter.

β = trend smoothing parameter.

Equation 5 is applied for adjusting the new smoothed value (S_t) by totaling the previous smoothed value (S_t-1) with the previous trend control (b_t-1). Equation 6 is responsible for updating the new trend control (b_t) by calculating the difference between current S_t with S_t-1. In this study, the initial value of S_t and b_t are $S_1 = y_1$ and b1 = $y_2 - y_1$; similar to the method applied by [10]. All the angles' data of the 10 samples are recorded and smoothed using DES. Fig. 5 represents one of the examples of DES application on the original angle data and the result of the smoothed value. It shows that smoothed using DES is able to reduce the random noise due to environmental constraints.

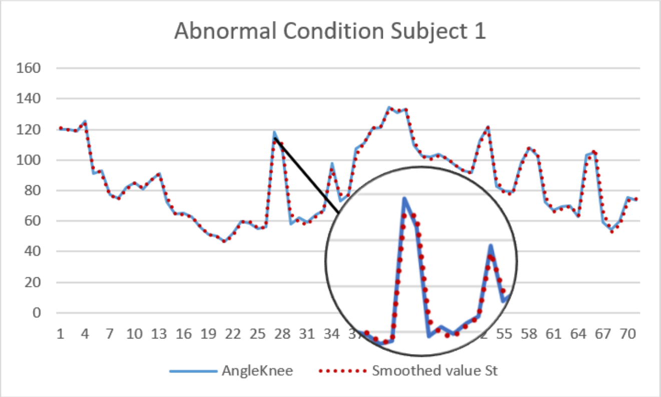

Fig. 5. Original Angle Vs Smoothed Angle Data.

Next, the mean squared error (MSE) is calculated from the smoothed value of the knee angle by the DES method [25]. The MSE method is used to determine the values of constant that minimizes the error size and how close estimations or forecasts are to actual data. The MSE formula can be defined in (7) below:

$$\mathrm{MSE} = \frac{1}{n}\sum e_t^2 \qquad (7)$$

Where the error, e, is derived from the difference of values between the current period of the original measured angle (yt) and the previous period of smoothed value (S_{t-1}) as shown in (8).

$$e_t = y_t - S_{t-1} \qquad (8)$$

In this study, to calculate the MSE value for all samples of the normal and abnormal conditions, the average value is calculated. The optimum α and β values of 0.8928 and 0.77256 respectively are reused based on performance results obtained by [10].

IV. Result

Based on the experimental setup explained in Section II, Fig. 6(a) shows the half-squat exercise in normal conditions, while Fig. 6(b) shows half-squat exercise in abnormal condition performed by subject 1. The hip-knee-ankle angle was extracted from the squat exercise performed by subject 1 in normal conditions (Fig. 7) and abnormal conditions (Fig. 8).

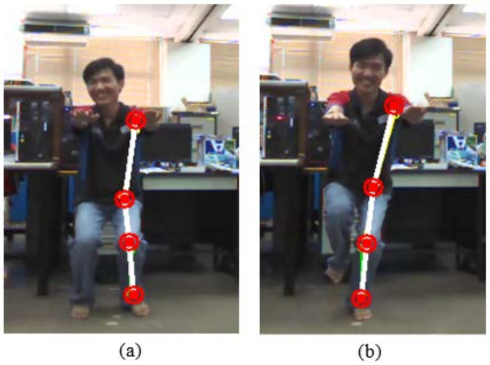

Fig. 6. Half-Squat Exercise in Normal (a) and Abnormal (b) Conditions.

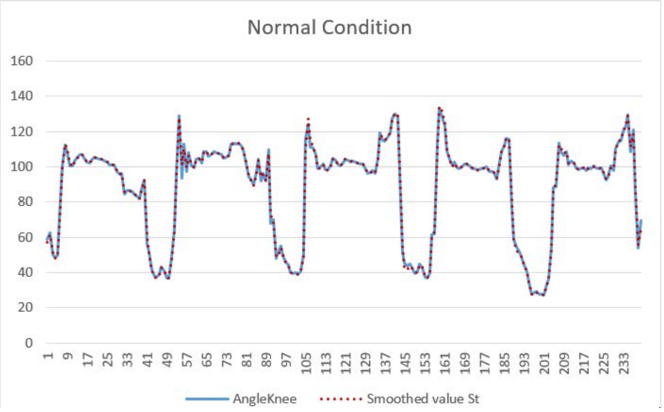

Fig. 7. Knee Angle Captured from Normal Squat Exercise for Subject 1.

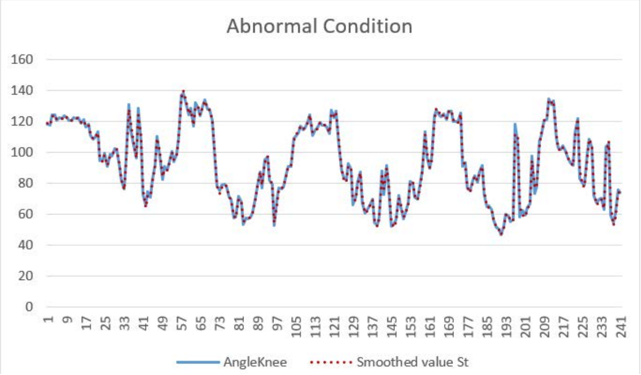

Fig. 8. Knee Angle Captured from Abnormal Squat Exercise for Subject 1.

Based on the data that have been collected from the dataset in Table I, there is a significant difference between the result of MSE of the normal and abnormal conditions. The average of MSE from 10 normal exercise data is 50.63, for the specified constants: α = 0.8928 and β = 0.7726. In contrast, the average MSE for ten abnormal exercise data sets is 84.69.

The comparison of MSE normal and abnormal conditions, the difference between MSE, and the average of MSE among the subjects are presented in Fig. 9. From the figure, subjects 4 and 8 performed adequate accurate movements during both normal and abnormal squat exercises in comparison to the other subjects. This shows that their positions are balanced during both normal and abnormal exercise. In contrast, squat exercise movement of subjects 5 and 10 can be considered mediocre based on the difference between the MSE of normal and abnormal. The threshold value of 67.66 (mean MSE) meets as a dividing boundary between the normal and abnormal conditions for all subjects except subjects 1, 4, 6, and 8.

TABLE I. THE PERFORMANCE RESULT FOR EACH SUBJECT

Subject No.	**Mean Squared Error**			
	Normal	***Abnormal***	***Difference***	***Average***
1	116.40	151.83	35.43	134.11
2	40.94	86.45	45.51	63.69
3	43.25	92.61	49.36	67.93
4	50.13	62.12	11.99	56.12
Subject No.	**Mean Squared Error**			
	Normal	***Abnormal***	***Difference***	***Average***
5	54.18	106.29	52.16	80.24
6	27.14	58.48	31.33	42.81
7	49.73	71.50	21.77	60.62

Min	**27.14**	**52.25**	**11.99**	**42.81**
Max	**116.40**	**151.83**	**52.12**	**134.11**

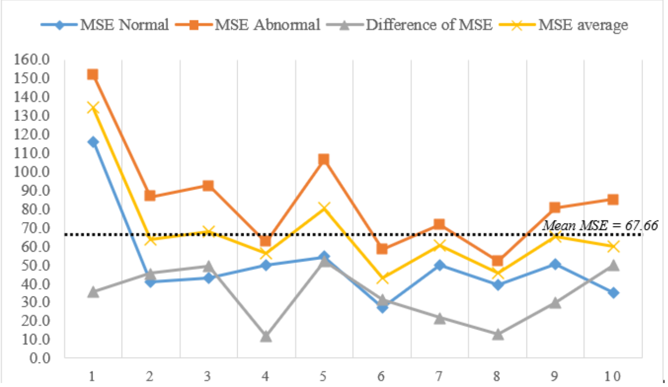

Fig. 9. MSE for Normal Vs Abnormal Squat Condition.

V. Discussion

From Fig. 7 and Fig. 8, the trend in MSE of the normal condition has a lower frequency of vibration compared with the abnormal condition. This showed that the subject was able to maintain a better squat form while performing the exercise in normal conditions compared to an abnormal condition. This proves that MSE is a suitable measurement for evaluating the performance of the system [27]. The smoothed value also helps in evaluating the data by reducing the noise. Thus, the simulated result shows that the DES method has been proven as one of the methods to reduce random noise from the original data of the dataset based on the computed results [28]. As a result, from Table I, the average MSE for normal condition squat exercise is lower and better than the abnormal condition. This shows that the MediaPipe Pose model able to predict the 3D body landmarks of subjects efficiently [12].

Fig. 9 shows that their positions are balanced during both normal and abnormal exercise. In contrast, squat exercise movement of subjects 5 and 10 can be considered mediocre based on the difference between the MSE of normal and abnormal. The threshold value of 67.66 (mean MSE) meets as a dividing boundary between the normal and abnormal conditions for all subjects except subjects 1, 4, 6, and 8.

There are some limitations of the model observed in this research that need to be considered and further addressed. Firstly, beside its high ability to perform human detection of squat action, MediaPipe Pose algorithm has so far only managed to detect a single person per frame. It may not be not suitable to be used for human detection of squat action when multiple humans present in the image frames. In addition to that, the model faces difficulties if there are obstacles blocking the camera's view of human upper body. This will affect the human detection confidence level. To address this issue and to have better detection performance, it is advisable to ensure that no foreign object block the camera view. Lastly, like other vision system issues, the performance of human detection might be affected due to the lack of proper illumination.

VI. Conclusion

This paper introduced the use of the MediaPipe Pose model for human movement tracking on a 2D frame-frame video dataset. The MediaPipe Pose model is a powerful model which can predict thirty-three 3D human body landmarks and can be used to perform a human virtual skeletal model for features extraction. Skeletal pose features will contain all of the necessary information to comprehend the action's results. This model can be applied to a rehabilitation center or self-monitoring exercise at home. DES method was able to minimize the random noise from the tracked angle data that might be due to the image parameter such as illumination, shadow, pose, etc. Next, MSE is applied to evaluate the movement cycle for squat exercise. Finally, the mean MSE was used as the threshold value to differentiate the posture movement for squat exercise between the two conditions.

ACKNOWLEDGMENT

The authors would like to express their gratitude to UniKL MFI for giving support in conducting this research and the financial support from Short Term Research Grant (Str19023) UniKL.

Solving the Imbalanced and Limited Data Labeled for Automated Essay Scoring using Cost Sensitive XGBoost and Pseudo-Labeling

Marvina Pramularsih[1], Mardhani Riasetiawan[2]*

Universitas Gadjah Mada, Yogyakarta, Indonesia

***Abstract*—There are two main problems on forming the Automatic Essay Scoring Model. They are the datasets having imbalanced amount of the right and wrong answers and the minimal use of labeled data in the model training. The model forming based on these problems is divided into three main points, namely word representation, Cost-Sensitive XGBoost Classification, and adding unlabeled data with the Pseudo-Labeling Technique. The essay answer data is converted into a vector using the trained word vector fastText. Furthermore, the classification of unlabeled data was carried out using the Cost-Sensitive XGBoost Method. The data labeled by the classification model is added as training data for the new classification model form. The process is carried out iteratively. This research is about using the combination of Cost-Sensitive XGBoost Classification and Pseudo-Labeling which is expected to solve the problems. For the 0th iteration, the dataset having a ratio of the amount of "right" labeled data with the amount of "right" labeled data is close to 1, in other words a balanced dataset or a ratio that is more than 1 produces a model with better performance. Thus, the selection of training data at an early stage must pay attention to this ratio. In addition, the use of the Hybrid Method on these datasets can save labeled data 56 times compared to the AdaBoost Method. Hybrid model is able to produce F1-Measure more than 95.6%, so it can be concluded that the Hybrid Method, which combines the XGBoost and Pseudo-Labeling Cost-Sensitive Classification with Self Training, is able to overcome the problem of unbalanced datasets and data limited label.**

***Keywords*—Imbalanced data; limited labeled data; automated essay scoring; cost sensitive XGBoost; pseudo-labeling**

I. Introduction

Pusat Asesmen dan Pembelajaran (PUSMENJAR), Ministry of Cultural, Education, and Research Technology, Republic of Indonesia conducts a mapping program of educational attainment to monitor the quality of education nationally or locally, called AKSI (Asesmen Kompetensi Siswa Indonesia). Learning evaluation is carried out based on the results of the questions tested on students. PUSMENJAR distinguishes question packages into two, those are literacy and numeracy. There are eight packages of literacy questions and eight packages of numeracy questions that will be used to simulate the exam. In the sixteen question packages, there are six types of questions, namely true or false, check box, matching, sorting, multiple choice, and essay. For the process of correcting true or false, check boxes, matching, sorting, and multiple choice can be done by matching the answer keys. However, the process of correcting essay answers cannot always be done by matching an answer with the answer key. In addition, essay answers scoring manually takes longer than answers for multiple choice questions and short answers [1]. Therefore, we need models for scoring essay answers automatically.

Herwanto et al. [2] sees correction of the essay answer as a classification of a true or false answer using AdaBoost Classification Method. Another Automated Essay Scoring (AES) model has begun to be researched to develop a model for automatically correcting essay answers in Indonesian [3]. However, the models that have been developed have not paid attention to the effect of the large number of manually labeled data on model performance and have not paid attention to whether the dataset is a dataset that has amount of the right and wrong labeled data and is balanced or not.

The exam simulation of high school level questions obtained ten datasets of essay answers. After manual labeling by experts, it is known that the dataset is an imbalanced dataset between correct and false answers. Therefore, a classification algorithm which is capable of handling imbalanced data characteristics is needed. Fernandez et al. [4] and He and Ma [5] state that the approach taken to solve imbalanced data problems is divided into three points, namely methods at the data level, methods at the algorithm level, and methods at the hybrid level. The method at the algorithm level is the easiest method to apply [6]. Wang et al. [7] and Xia et al. [6] classify imbalanced data using the Cost-Sensitive XGBoost method. The use of the XGBoost algorithm is due to the fact there are many teams wining the competition using this algorithm [8]. In addition to the imbalance problem in the dataset, there is another problem that is forming a model with good performance with less training data than the current number of labeled data. The number of labeled data provided is currently around 6,000 data and will be used to correct approximately 330,000 uncorrected answer data. This problem can be overcome, one of which is by implementing Pseudo-Labeling with Self Training as was done by Babakhin et al. [9].

II. Automated Essay Scoring

Research on Automated Essay Scoring (AES) began since Page [10] conducted research on essay assessment using computers. AES research on answers to essays in Indonesia has begun to be developed from various points of view. One of them views the problem of essay assessment as a problem of classifying right or wrong answers [2], [3].

Herwanto et al. [2] conducted research on the AES Model for answers to essays in Indonesia. The dataset used is three datasets of student answers from the Program for International Student Assessments (PISA). The word representation used is Bag-of-Words (BoW) and character ngrams. The classification algorithm used is Adaptive Boosting (AdaBoost). The AES model formed has a F1-Score of 97.69% for the Machu Picchu dataset, 67.2% for the jacket dataset, and 71.74% for the bicycle dataset. Riasetiawan et al. [3] conducted research for essay answers on clustering and classification. The dataset used is a dataset of essay answers from the Indonesian Ministry of Education and Culture (Kemendikbud). The clustering algorithm used is K-Means, while the classification algorithm used is Convolutional Neural Network (CNN). Prior to clustering and classification, the word representation stage was carried out using GloVe. The answer classification model yields an accuracy above 85%.

In supervised learning, not all labeled datasets are balanced datasets. To solve the problem of unbalanced datasets, it can be done using data sampling methods [11], cost-sensitive algorithms [6], or a combination of data sampling methods and cost-sensitive algorithms [12]. The use of the data sampling method has weaknesses, namely, in addition to choosing a suitable classification method for the dataset, there is a need for further analysis of what data sampling method is more suitable for the dataset before entering the classification model training stage. In a cost-sensitive algorithm, there is no need to add these steps, so this method is the easiest of the other two methods to be applied to an unbalanced dataset.

Xu et al. [11] conducted research on the classification of sentiments and emotions on an unbalanced dataset. By using the Support Vector Machine (SVM) and Word Embedding Compositionality with Minority Oversampling Technique (WEC-MOTE), it can increase the precision by 29.3%. Xia et al. [6] conducted research on the classification of borrowers in peer-to-peer lending. By using the Cost-Sensitive XGBoost (CSXGBoost), the highest Area under the ROC Curve (AUC) value was obtained when compared to all trials compared by Xia et al. [6], which is 74.85%. The use of cost-sensitive is the easiest way to deal with unbalanced datasets [6]. Le et al. [12] conducted research on the classification of bankruptcy companies. Using CBoost and SMOTE-ENN, the highest AUC values were obtained from all the trials compared by Le et al. [12], which is 87.1%. Pseudo-Labeling is a technique used to increase the amount of labeled data by utilizing the unlabeled data that is owned. There are several learning algorithms used in Pseudo-Labeling, namely Self-Training [9], Co-Training [13], and Cluster-then-label [14]. In the Co-Training algorithm, the features used must be divided into two. Meanwhile, in cluster-labeling, there is a clustering stage before labeling. The clustering stage in the Cluster-then-label algorithm has its own challenges, namely making a good cluster. Based on the three algorithms, namely Self-Training [9], Co-Training [13], and Cluster-then-label [14], the Self-Training algorithm is the easiest algorithm to be implemented.

III. Hybrid Method

This research uses eight pairs of datasets, namely eight labeled datasets and eight unlabeled datasets [15], shown in Table I. Each dataset uses the .xlsx format. The datasets are from the PUSMENJAR. The datasets are the answers to the simulation of AKSI questions. For each pair the dataset will be analyzed and the model with the best performance is sought based on the experiments carried out.

Data pre-processing is necessary being used in the next process. The pre-processing consists of Lower-Case Folding, Filtering, and Tokenization, fastText pretrained word embedding for Indonesia. Pre-trained word vectors are trained on Wikipedia using fastText. The model is trained using skip-gram, dimension 100, subwords size 3-6 characters, epoch 5, and learning rate 0.05. To increase the chances that the machine can produce the best labels, the best-performing classification model is needed before it is used to predict answers on the unlabeled dataset. This is done by training the model with several combinations of different parameter values and selecting the model with the highest F1-Measure. Fig. 1 shows the Cost-Sensitive XGBoost modeling development for the research.

TABLE I. DATASET DESCRIPTION

IV. Result and Discussion

Pseudo-Labeling (Fig. 2) testing is seen based on two things, those are the amount of initial data and the amount of data added per iteration. This experiment is repeated until the third iteration. Fig. 3 (a)-(h) are the results of testing the initial data for Pseudo-Labeling. Based on Fig. 3, it is found that in the 0th iteration, the F1-Measure model with N0 = 100 is always lower than the model with more initial data. However, after iterating until the third iteration the F1-Measure of the model increases. On the Dataset 2, 4, 5, and 6, the F1-Measures of the models are able to exceed the models using a bigger amount of manual labeled data. In the Dataset 7, F1-Measure of the model with N0 = 100 is 0%. Although, it has been done for some iterations, but cannot improve the F1-Measure of the model. In this case, the number of “true” labeled data is 1, while the “false” labeled is 99. For the extreme case of the Dataset 7, the Pseudo-Labeling technique has not been able to improve the F1-Measure of the model. Furthermore, the amount of additional data tested are 50, 100, 150, and 200. Fig. 4 (a)-(h) are the results of testing additional data for Pseudo-Labeling using 100 labeled data as initial data. Based on Fig. 4, the selections of the amount of additional data per iteration that have been tried always increase F1-Measure of the models when compared to F1-Measure of the models in the 0th iteration, except for the Dataset 7 which only has 1 “true” labeled data and 99 “false” labeled data. Furthermore, the selection of additional data which is 50 (half of the number of initial data) is always lower than the others (equal to or higher than the initial data).

Fig. 4. Performance Comparisons for Cost-sensitive XGBoost.

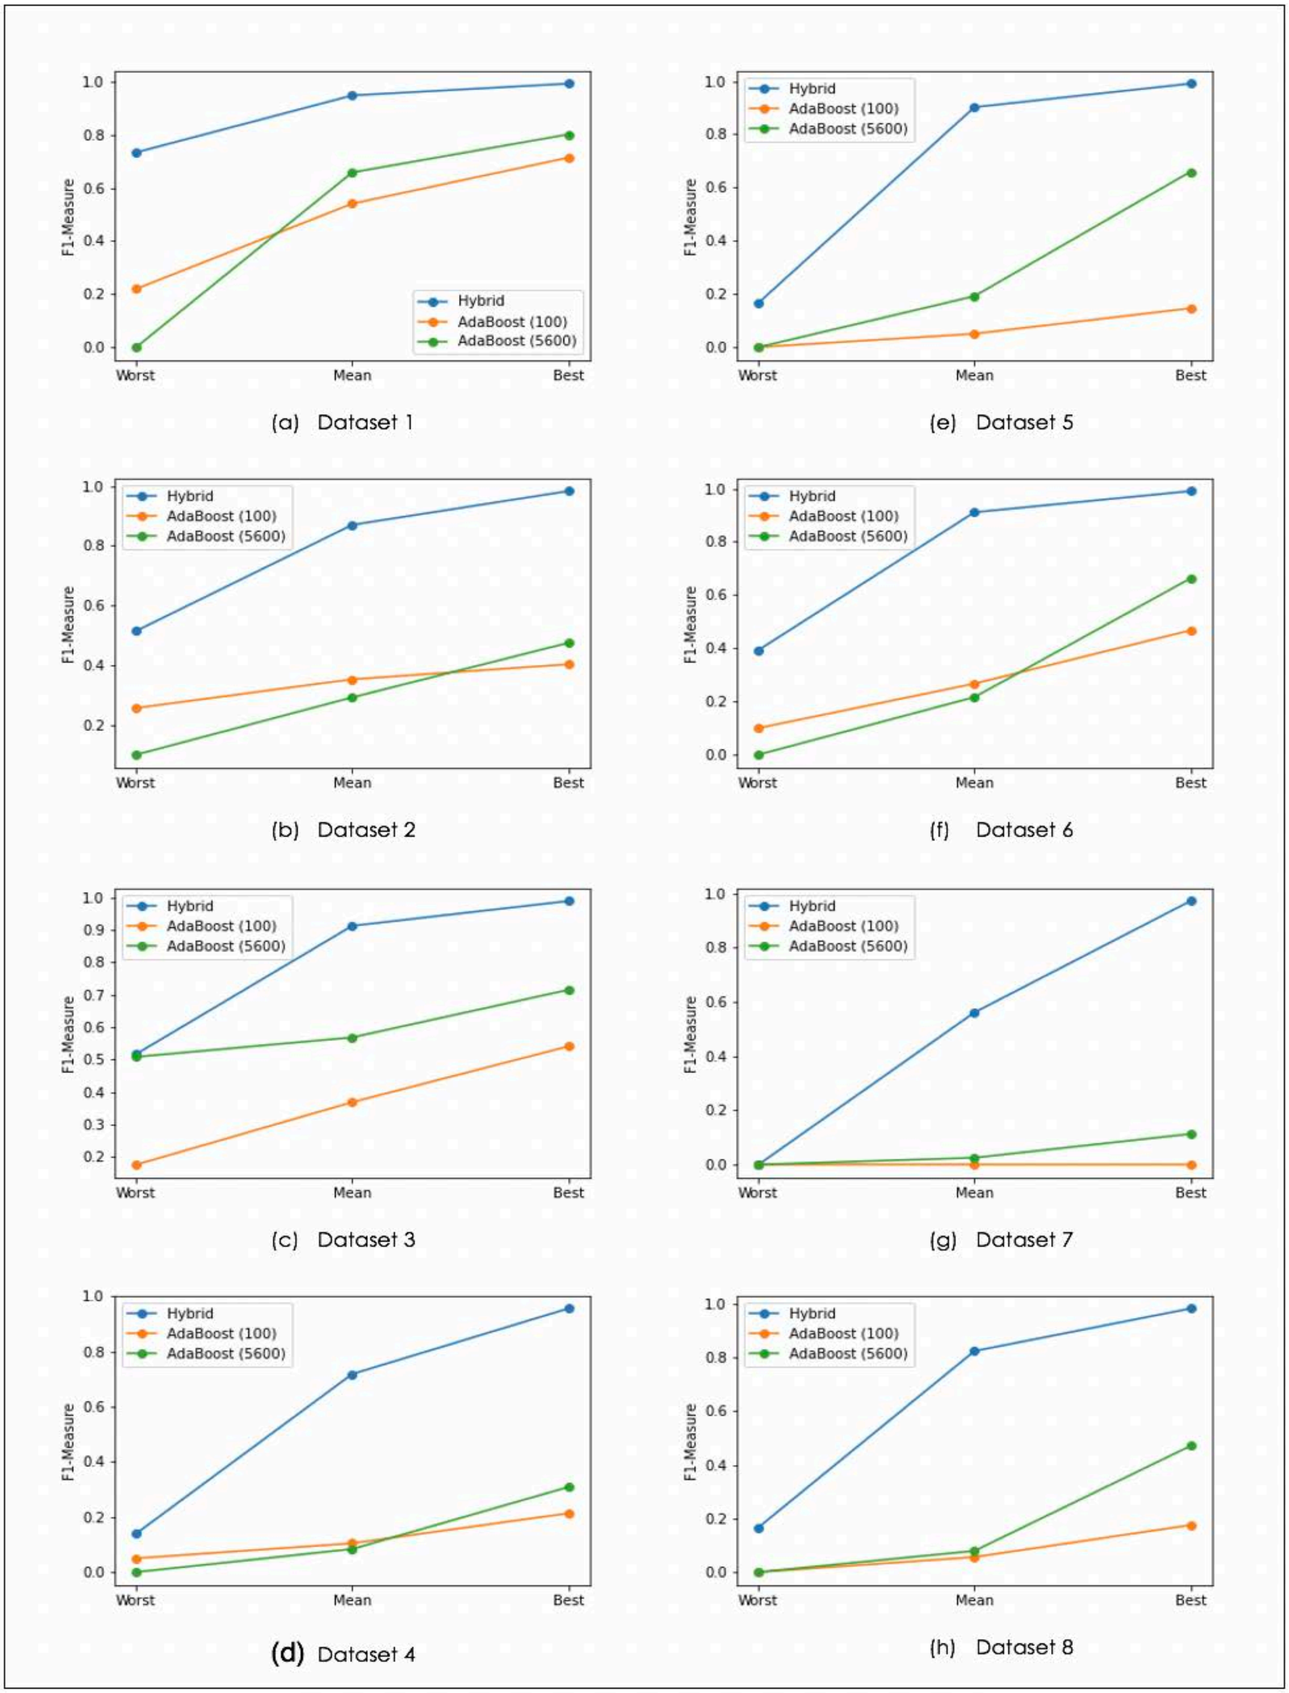

Fig. 5. Performance Comparisons for Hybrid and AdaBoost.

Fig. 5 (a)-(h) are graphs comparing three models, namely the Hybrid Model using 100 labeled data, the AdaBoost Model using 100 labeled data, and the AdaBoost Model using 5600 labeled data. In this comparison, three F1-Measure values are compared for each case, namely the best, mean, and worst F1-Measures that can be obtained from the use of these algorithms.

Based on Fig. 5 (a)-(h), it is found that the best and mean F1-Measure of the Hybrid Model is always higher than the two AdaBoost Models. Overall, the worst F1-Measure of the Hybrid Model is also higher than the two AdaBoost Models. There is only one worst F1-Measure value of the Hybrid Model which is lower than the AdaBoost Model using 5600 labeled data, namely the Dataset 3, but the difference in F1-Measure values is less than 6%. By saving 5500 data labeling, the difference between the F1-Measure values can be neglected. Overall, even though one of the AdaBoost Models already uses 56 times more data, it still cannot compete the F1-Measure of the Hybrid Model.

V. Conclusion

For the 0th iteration, the dataset having a ratio of the amount of "right" labeled data with the amount of "right" labeled data is close to 1. In other words, a balanced dataset or a ratio that is more than 1 produces a model with better performance. Thus, the selection of training data at an early stage must pay attention to this ratio. In addition, the use of the Hybrid Method on these datasets can save labeled data 56 times compared to the AdaBoost Method. The positive class weight parameter has no effect on the performance of the resulting model. The Pseudo-Labeling process with Self Training is able to handle the problem of limited training data, except for the Income Dataset Residents who have F1-Measure with a value of 0% both before and after the Pseudo-Labeling process with Self Training. Hybrid model which is able to produce F1-Measure more than 95.6%, so it can be concluded that the Hybrid Method combines the XGBoost and Pseudo-Labeling Cost-Sensitive Classification with Self Training is able to overcome the problem of unbalanced datasets and data limited label.

Acknowledgment

This work is supported by Pusat Asesmen dan Pembelajaran (PUSMENJAR), Ministry of Cultural, Education, and Research Technology, Republic of Indonesia for providing datasets. The paper is part of the Master Thesis by the 1st author in Magister of Computer Science, Faculty of Mathematic and Natural Sciences, Universitas Gadjah Mada.

***Abstract*—The quality of instructors' performance mainly influences the quality of educational services in higher educational institutions. One of the major challenges of higher educational institutions is the accumulated amount of data and how it can be utilized to boost the academic programs quality. The recent advancements in Artificial Intelligence techniques, including machine and deep learning models, have led to the expansion in practical prediction for various fields. In this paper, a dataset was collected from UCI Repository, University of California, for the prediction of instructor performance. In order to find how effective the instructor in the higher education systems is, a group of machine and deep learning algorithms were applied to predict instructor performance in higher education systems. The best machine-learning algorithm was Extra Trees Regressor with Accuracy (98.78%), Precision (98.78%), Recall (98.78%), F1-score (98.78%); however, the proposed deep learning algorithm achieved Accuracy (98.89%), Precision (98.91%), Recall (98.94%), and F1-score (98.92%).**

I. Introduction

Machine learning is a subclass of artificial intelligence (AI) [1, 2]. It is concerned with the teaching computers how to learn from different types of data and to enhance with experience without programming explicitly to do that [3]. In machine learning, models are being trained to look for correlations and patterns in huge datasets and be able to make predictions and decisions according to its analysis [4]. Applications of machine learning are improved with usage and become more precise when there are more data at hand. Machine learning applications are everywhere –in our offices, our supermarkets, our social media, and our hospitals [5].

Deep learning are subclass of Machine learning. Deep learning are networks with a great number of layers [6]. These layers can process broad quantities of data and find the weight of associated link in a network; such as, in an image of bird species recognition, part of the layers in the network can detect singular features in the bird's face, such as beak or eyes, whereas another layer could tell if the features in some way designate bird face [7]. Deep learning emulates how human brain operate. A few examples of deep learning are self-driven cars, medical diagnoses through sounds, classification of fish species, detection of different diseases from the eyes of the person [8]. If a network has more layers, these layers can perform complex tasks. Deep learning algorithms need high computer power to be able to produce results [10, 13].

Higher education systems claim new methodologies that increase the achievement, quality and efficiency [14, 15]. Typically Machine and Deep learning algorithms are applied in higher education for examining the effect of educational approaches on students, and in what way students comprehend the course material [11, 22]. The academic performance of students usually is based on some features like the Cumulative Grade Point Average (CGPA), economic situation, demographic data, family background and the models for prediction. Therefore the majority of the research in this field depends on the attributes that are related to the students [12, 21].

This paper is an attempt to analyze the data associated with the evaluation of the student for instructors to enhance the quality of higher educational systems and specify the factors that impact the performance of the students. Student performance prediction is largely associated with the quality of teaching.

In this study, various data prediction techniques are carried out on the student evaluation dataset for the prediction of student accomplishment, inspect instructors' performance, and discover the best technique for classification in line with these measures: Accuracy, Precision, Recall, F1-score and time performance [16].

II. Literature Review

It is required to measure the instructors' performance to boost the effectiveness of teaching and enhance the knowledge of students in the field of higher education. It is done by using feedback gathered from the students.

Agaoglu [1] measured the performances of instructor dependent on view of student using questionnaire of a course evaluation using four techniques: Support Vector Machines, Decision Tree algorithms (C5.0, CART), Discriminant Analysis and Artificial Neural Networks (ANN-2QH, ANN-3QH, ANNMH). The performance measurements applied were recall, precision, accuracy, and specificity. Also, feature importance was done to eliminate the irrelevant features. At last this work indicated the expressiveness and adequacy of models of data mining in higher education. Dataset was collected from Marmara University, Istanbul, Turkey. The dataset contains 2850 records, 25 features, and one class name. Among various strategies C5.0 achieved high accuracy of 92.3%.

The research in Ahmadi and Ahmad [2], inspected the attributes of instructors training performance utilizing two techniques: stepwise regression and decision trees. The dataset in that study was collected from learners of MIS department during the time of 2004-2009. Factor investigation was applied to reveal free factors influencing the overall performance of instructors. Stepwise regression model was created using SPSS and decision trees were built using Answer Tree.

Ahmed et al. [3] inspected the parts which are mainly influencing the success of learners for predicting the performance of instructors to upsurge the quality of the educational system using several techniques like Multilayer Perception (MLP), J48 Decision Tree, Sequential Minimal Optimization (SMO) and Naïve Bayes (NB). The Dataset was collected from (UCI) Repository. There were 32 features collected from Q1 to Q28 asked with responses from 1 to 5. Features were assessed utilizing R, eight features were chosen with high impact. Algorithms were applied with all features and with strongly affected features only. J48 achieved 84.8% with all the features and SMO achieved 85.8% for chosen features.

Ola and Sellapan [16] examined the feedback from students about the instructors to form Instructor Evaluation framework using WEKA tool. Data collected from 830 undergraduate studies around 104 records with five attributes. Decision tree algorithm applied and the outcomes were utilized by the educationalist to distinguish whether specific instructor is proceeded to the following semester or not. The researchers used an intelligent approach for the assessment of instructors' performance in higher institutions and proposed an optimal machine learning algorithm to design a system framework. Formative and Summative assessment methods applied to assess the instructor's performance to increase the quality.

Kumar and Saurabh [17] created a framework to predict the performance of instructors utilizing their assessment, checking the classes and performance assessment of instructors. The strategies utilized in that system was Naive Bayes, ID3, LAD tree and CART in WEKA tool. Three years of data gathered from post graduate students with 14 attributes. The precision created by ID3 was 65.14%, 72.32% by CART, 75.00% by LAD Tree and the most accuracy 80.35% produced by NB classifier.

In the study of Vijayalakshmi et al. [19] some of the machine learning algorithms were applied like "Naïve Bayes, K-Nearest Neighbor, Random Forest, Support Vector Machine, and Decision Tree". The implementation language is R programming language for data mining apps. Various implementation measures were applied to assess the system such as accuracy, precision, recall, specificity, sensitivity. The highest accuracy attained was by SVM. It was better than other models using the dataset at hand.

Yahya et al. [20] examined the practicality of applying Data Mining techniques to distinguish the practicality of instructors. Data was gathered, nine methods were applied such K-Nearest Neighbors (KNN), Naive Bayes (NB), Support Vector Machine (SVM), RA, J48, JPip, AdaBoost, BN, Random Forest among these Random Forest (RF) and SVM showed prominent implementation.

A. *Summary of the Previous Studies*

In Table I, a summarization of the above discussed previous studies in terms of Machine Learning methods, best method, tools used, accuracy of each method used, and the size of the dataset and number of attributes.

Therefore, in the current, the same dataset as in [3] which was collected from UCI Machine Learning Repository from the University of California for the prediction of instructor performance [18] was used.

III. Methodology

This section will present the methodology of our study which includes Data Collection, Data Preprocessing, Explanation of the proposed models used for analysis and prediction.

A. *Dataset*

Dataset used in this study was collected from UCI Repository for the prediction of instructor performance [18]. It has 5820 with 33 features.

The features in the dataset: "instr code, class level, number of repeating the course, attendance, difficulty level, and 28 question (Q1 to Q28). Q1-Q28 are all Likert-type, meaning that the values are taken from 1-5, where 1,2,3,4,5 represents 'Poor', 'Fair', 'Good', 'Very Good', and 'Excellent' respectively for Q1 to Q28. Furthermore, there is one class variable (Performance). Performance was calculated by taking the average of the 28 Question values. The calculated values of these questions are in the form {1, 2, 3, 4, 5}, where 1,2,3,4,5 represents the 'Poor', 'Fair', 'Good' 'Very Good', and 'Excellent' respectively." [18]

B. *Data Analysis*

The class (performance) variable predicts the performance of the instructor. The possible values for performance are 'Poor' (888 Observations),".Fair" (996 Observations), Good" (2073 Observations), "Very Good" (1275 Observations), 'Excellent' (588 Observations). The class (performance) variable distribution is shown in Fig. 1.

C. *Data Preparation*

All of the 33 features and the Performance class of the dataset are already label encoded. The class (Performance) balancing was checked and found that the class is not balanced as in Fig. 1. So, Smote function was used to balance the class (Performance). The Smote function increases the number of samples of the low counts to be the same as the higher count.

D. *Dataset Splitting*

The dataset was split into 3 datasets: (Training, testing and validating datasets). The ratio of splitting was (60%, 20%, and 20%).

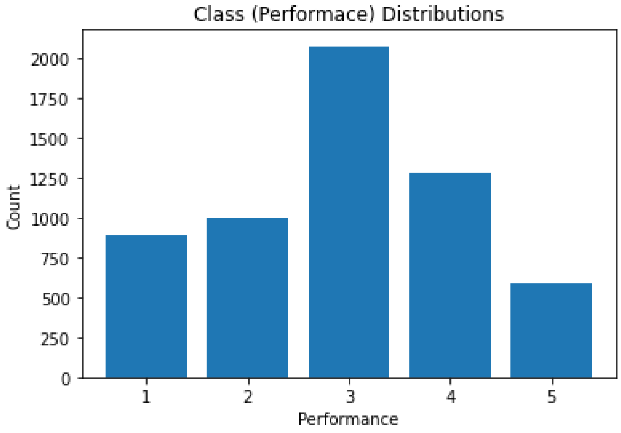

Fig. 1. Class (Performance) Distribution.

E. *Description of Models used in the Study*

There are many algorithms of ML that can be used in the prediction of instructor Performance level. ML algorithms were trained and tested using the current dataset with 18 various features. The algorithms that were used for prediction and analysis belong to 10 categories of Machine Learning [9] including:

- Naive_Bayes (GaussianNB).
- Neighbors (NearestCentroid, KNeighborsClassifier).
- Linear_model(LogisticRegression,LogisticRegressionCV , LinearRegression).
- SVM (SVC).
- Tree (ExtraTreeClassifier, DecisionTreeClassifier).
- XGBoost (XGBClassifier).
- Ensemble (GradientBoostingClassifier, GradientBoostingRegressor, AdaBoostRegressor, Extra TreesRegressor, BaggingClassifier, RandomForest Classifier).
- Neural_Network(MLPClassifier, MLPRegressor).
- Lightgbm(LGBMClassifier).
- Semi_supervised(LabelPropagation).

Furthermore, a deep learning model was proposed to predict instructors' performance in higher education systems. The DL proposed model consists of seven Dense layers: one input layer (33 features), five hidden layers (256,128, 64, 32, and 16 neurons), and one output layer with five classes and softmax function as can be seen in Fig. 2. The reason for using five hidden layers is the high accuracy. The structure of the DL model gave the best accuracy compared to four, three, or two hidden layers.

The steps of the methodology used in the study for predicting instructors' performance in higher education systems are summarized in Fig. 3.

IV. Result and Analysis

In the following sections, a discussion of the result achieved by the deep learning model and the machine learning models will be presented. The first section talks in detail about the Performance Evaluation and the second section presents the Performance Analysis of all models used in this study.

V. Performance Evaluation

Different machine and deep learning measurements can be applied on the various model used in the current study. The most popular measurements are: Accuracy, F1- score, Recall and Precision are the most important criterion used to assess a models performance. The value of the confusion matrix which is generated during the testing of the model is considered to calculate these measurements as illustrated in equation 1, 2, 3 and 4.

$$\text{Accuracy} = (TP + TN) / (TP+TN+FP+FN) \quad (1)$$

$$\text{Precision} = (TP / (TP+FP) \quad (2)$$

$$\text{Recall} = (TP / (TP+FN) \quad (3)$$

$$F1 = 2 \text{ x } (\text{Precision x Recall}) / (\text{Precision} + \text{Recall}) \quad (4)$$

Where TP = True Positive, TN = True Negative

FP = False Positive, FN = False Negative

VI. Performance Analysis of Applied Models

In this study, 18 machine learning algorithms to predict instructors' performance in higher education systems were used. Furthermore, a deep learning model was proposed to predict instructors' performance in higher education systems. The aim of this study was to get a more efficient predictive model by making a comparison between the different deep and machine learning models. 60% of the dataset for training, 20% of the dataset for validating and the remaining 20% of the dataset were used for the testing.

TABLE II. PERFORMANCE OF THE MACHINE AND DEEP LEARNING ALGORITHMS

Model Type	Model Name	Accuracy	Precision	Recall	F1-score	Time in Sec
Machine Learning	Extra Trees Regressor	**98.78%**	**98.78%**	**98.78%**	**98.78%**	2.70

	Gradient Boosting Classifier	95.95%	95.95%	95.95%	95.95%	5.55
	MLP Classifier	95.80%	95.80%	95.80%	95.80%	11.37
	Bagging Classifier	95.75%	95.75%	95.75%	95.75%	0.25
	Logistic Regression	94.64%	94.64%	94.64%	94.64%	1.93
	Extra Tree Classifier	93.83%	93.83%	93.83%	93.83%	0.02
	Decision Tree Classifier	93.39%	93.39%	93.39%	93.39%	0.03
	Label Propagation	93.25%	93.25%	93.25%	93.25%	2.02
	Gaussian NB	92.47%	92.47%	92.47%	92.47%	0.02
	K Neighbors Classifier	91.66%	91.66%	91.66%	91.66%	0.41
	SVC	91.66%	91.66%	91.66%	91.66%	0.61
	Linear Discriminant Analysis	91.27%	91.27%	91.27%	91.27%	0.07
	Ada Boost Regressor	91.16%	91.16%	91.16%	91.16%	2.12
	Nearest Centroid	90.79%	90.79%	90.79%	90.79%	0.02
Deep Learning	Proposed Deep Learning Model	**98.89%**	**98.91%**	**98.94%**	**98.92%**	**2.00**

To evaluate the models performance, five sorts of assessment measures were engaged: "Recall, Precision, Accuracy, F1-Score and time needed for each model to run are shown in Table II. It is observed that the best machine-learning algorithm was "Extra Trees Regressor" with an Accuracy (98.78%), Precision (98.78%), Recall (98.78%), and F1-score (98.78%); however, the proposed deep learning algorithm achieved an Accuracy (98.89%), Precision (98.91%), Recall (98.94%), and F1-score (98.92%).

VII. RESULT AND DISCUSSION

All previous studies reviewed in the section of literature review except one used different datasets; thus the results of these studies cannot be compared with the result obtained in the current study.

The previous study that used the same dataset as in the current study is Ahmed et al. [3]. The following table compares their results with the current proposed model's results.

As it can be seen in Table III, the results of the current study are much higher than the results obtained in the previous study.

TABLE III. RESULTS COMPARISON WITH PREVIOUS STUDIES

Model Name	**Previous study (Ahmed *et al.* [3])**	**Proposed Models of the Current Study**
Decision Tree Classifier (DT)	84.80	93.83
Gaussian NB	83.30	92.47
Extra Trees Regressor (ETR)	84.50	98.78
MLP Classifier	82.50	95.80

The reason for the high accuracy of the current study is the pre-processing the handling of the dataset.

VIII. CONCLUSION

In this study, 18 different Machine Learning algorithms and one deep learning algorithm for predicting instructors' performance in higher education systems were used. The dataset was collected from UCI Repository for the prediction of instructor performance. The dataset was preprocessed, the class (performance) was balanced using smote function. Each algorithm was trained, tested and its performance was noted. Furthermore, the proposed deep learning model was trained, validated and tested using the same dataset and its performance was noted. Among all the machine learning models used, the best machine-learning algorithm was Extra Trees Regressor with an Accuracy (98.78%), Precision (98.78%), Recall (98.78%), F1-score (98.78%); however, the proposed deep learning algorithm achieved an Accuracy (98.89%), Precision (98.91%), Recall (98.94%), F1-score (98.92%). Even though, the accuracies of the best machine learning algorithm and the proposed deep learning algorithm were close; the proposed deep learning algorithm was slightly better.

These discoveries are helpful to educationalist to improve their performances.

Application-based Usability Evaluation Metrics

Hanaa Bayomi[1], Noura A.Sayed[2], Hesham Hassan[3], Khaled Wassif[4]
Faculty of Computers and Artificial Intelligence, Cairo University, Cairo, Egypt[1, 3, 4]
Faculty of Computers and Artificial Intelligence, Akhbar El Youm Academy, Cairo, Egypt[2]

***Abstract*—Testing is one of the vital stages in the software development life cycle (SDLC). Usability testing is a very important field that helps the applications be easily used by the end-users. Because of the importance of usability testing, a metrics has been developed to help in measuring the usability through converting the main qualitative usability attributes in ISO to quantitative steps that provide the developer a framework to follow in developing to achieve usability of their applications and helps the tester with a checklist and a tool to measure the usability percentage of their application. The framework provides a set of steps to achieve the usability attributes and answers the question of how you could measure this attribute with the defined steps. The framework results in a 95% average accuracy in the high-rate application and a 59% average accuracy in the low-rate application. Finally, the framework is programmed in a tool to measure the usability percentage of the application through a checklist and provides a scheme to help the developer achieve the best results in usability.**

***Keywords*—Usability; human-computer interaction; evaluation; quantitative attributes; testing**

I. Introduction

Testing is one of the important stages of the SDLC. Usability testing is one of the non-functional testing types [1]. Usability is one of the quality dimension that evaluates the quality and usefulness of applications [2]. Usability is a quality attribute that determines how easily and simply user interfaces can be used. So, usability is the interface’s necessary condition for application’s survival [3]. If an interface is difficult to use and the users get lost, they will leave. No user would be bothered with reading a manual first before using an interface or a website. Therefore, usability is a very vital element of an application interface.

Accordingly, a framework has been developed to convert the qualitative usability attributes into qualitative steps to help the developer to have simple steps to achieve the highest usability and helps the tester to have a checklist to easily evaluate the application usability. According to Nielson, usability can be defined as a method for improving the design process [4]. Usability is assessed based on six dimensions, which include learnability, memorability, efficiency, effectiveness, error rate, and user satisfaction. [5]. Usability testing uses the black box testing technique [1]. Our framework can be performed by the tester at the system and acceptance levels. As well, usability is one of the nonfunctional requirements of any software, which is one of the core areas of research in the field of human-computer interaction [6].

Now-a-days, both Web and mobile applications are considered the most two popular types of applications. Usability has been defined as a key component in the overall quality of a software product, and research shows that usability can determine the success or failure of a software system [7]. Usable software systems are not only more efficient, accurate, and safe, but also much more successful and several studies have shown the benefits of incorporating usability evaluation in the process of software development. Therefore, usability evaluation has become an important research field [7].

The remainder of this paper is organized as follows: Section II is related work, which provides background information about usability and testing techniques; Section III is methods, which describe how the research is designed and carried out; Section IV is usability attributes, which describe the attributes in well-defined steps; Section V is testing references and questions, which describe the usability attributes in testing questions; and Section VI is results, which describe the findings.

II. Related Work

Nielsen (1994) defined usability as a quality attribute that measures how user interaction can be used as a method for improving ease-of-use, efficiency, and satisfaction [4]. Standard ISO 9241-11 defines usability as "the extent to which a product can be used by specific users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [7]. It was further elaborated that there are other important concepts related to usability, such as user, goal, effectiveness, efficiency, satisfaction, and context of use [8].

Usability of software applications is one of the core areas of research in the field of human-computer interaction. There were many methods to inspect, test, and inquire about an application's usability [7], [9].

Making the application usable doesn’t mean that it will be easy. Some applications must be a little bit difficult to use to help in reaching the target of the application's usage for example e-learning applications [10]. The e-learning applications' difficulty must be specified according to the learning level of the student to meet the target of increasing the student's learning curve [11]. One of the very effective ways of evaluating the e-learning applications’ usability is the heuristic evaluation method [12], [13]. Heuristic evaluation can also be used to measure other types of applications because it has been shown to be effective in inspecting errors [14], [15], [16].

Before evaluating any application, the latest issues must be reviewed and the most commonly occurring errors arise related to your application type [17]. To change the qualitative attributes to quantitative, the quantitative attributes must be revised [18]. Mobile and web applications are the most commonly used types of applications today. Both of those types can be accessed via mobile, which is the most convenient device to hold most of the time, so we must concentrate on mobile application usability [19], [20], [21], [22], [23].

Most of the papers focus on updating the usability attributes by adding some new attributes or deleting some of existing attributes or changing the way of the attribute evaluation [24]. Some of the papers are updating the usability main categories introduced in the ISO/IEC 25022 [3], [6]. Some papers are creating new modules to be remotely evaluating the applications through user usage [25]. Some papers focus on one of the usability evaluation techniques [26] [27]. Some papers focus on analyzing the Human computer interaction or usability attributes according to a specific application type [28], [29]. There is some approaches and frameworks that improve issues tracking [30], [31], [32].

According to the ISO, those are the documented standards presented in Table I [6].

TABLE I. ISO USABILITY ATTRIBUTES REFERENCES

ISO reference number	Usability attribute category
ISO 9241-11	Usability Definitions and concepts, replacing the 1988 version of ISO 9241-11
ISO 9241-220	Processes for enabling, executing and assessing human-centered design within organizations, replacing the earlier ISO TR 18529
ISO/IEC 25066	Common industry Format for Usability — Evaluation Reports
ISO/IEC 25022	Measurement of quality in use, (includes measures of effectiveness, efficiency and satisfaction), replacing ISO TR 9126-4
ISO/IEC 25023	Measurement of system and software product quality, (includes measures for usability attributes), replacing ISO/IEC TR 9126-2 and ISO/IEC TR 9126-3

This research highlighted the following usability gaps: first, there is a problem in evaluating the usability of the application's interface. Second, developers do not focus on the simplicity of the interface as they focus on the functionality of the application because the functionality is easy to develop as there are no clear guidelines for evaluating the interface usability. Third, there is no balance between user experience and interface simplicity. For example, learning applications mustn't be so easy or so difficult to meet the goal of increasing the learning curve. Finally, there is no clear qualitative borderline to be applied by the developer and tested by the tester. To fill those gaps, a framework has been developed to describe the usability attributes in fine steps and helps in achieving the best usability of the application.

III. METHODOLOGY

To convert usability attributes in the ISO from qualitative to quantitative steps, this is done by searching for how the developer could achieve each attribute in well-defined steps and asking usability experts what the points they take into consideration to make the application usable enough for the user. The 20 developers and testers were asked about the frequently repeated problems that they face while developing and testing the applications. After collecting the required data, usability attributes have been chosen from the ISO Usability standards. Some of those attributes were merged and some have been added to create an effective usability framework. In the framework, the qualitative chosen attributes have been converted to detailed steps to help the developer and the tester in their practical work. Then, one or two questions is assigned for every attribute to be asked by the tester for evaluation and tested on the application to measure the usability.

The results have been developed by choosing two applications, one with a high rate (amazom) and the other with a low rate (waradly) to test the effectiveness of the framework developed. The first is Amazon, which has a global web application and also a mobile application with a rate of 4.3 out of 5, and the other is Waradly, which is an Egyptian e-commerce site with an intermediate rate, but they don't have a mobile application. To test our framework, three main tasks have been chosen that are performed by any e-commerce application, which are searching, seeking product data, and purchasing.

Finally, a tool has been developed using our framework to measure the usability percentage of the application through a checklist and provide a scheme to help the developer to achieve the best results in usability (http://abuem.com/).

IV. USABILITY ATTRIBUTES

Accordingly, steps have been assigned for each attribute in each category to be measured quantitatively, merging, and adding some attributes to them.

A. *Effectiveness*

1) Tasks completed and objectives achieved: The applications mainly provide the user with services or products. To complete the task, you have to use a scale from 1 to 10 according to the feasibility analysis conducted by the business analyst. To achieve effectiveness in tasks completed and objectives achieved, set reasonable objectives according to each business environment, choose the best developing environment to achieve these objectives (desktop, mobile, or web application), set tasks, specify for each task input and output, specify for each task severity and priority, and order the tasks according to the scale set by feasibility analysis. Here is an example to calculate the rest %. Subtract the finished tasks from the number of all tasks to give you the rest of the tasks. Then divide the result by the number of all tasks and multiply by 100 to give you the whole percent of the rest of the tasks.

2) Errors in a task: To achieve effectiveness in errors in a task attribute, the errors that may arise at each task individually must be predicted; choose an efficient programming language to minimize the predicted errors, fix the unpredicted errors, and document them with their solution to be fixed automatically if they arise again, according to the literature.

3) Tasks with errors: To achieve the effectiveness in tasks with errors attribute, make sure that the errors in each stage will be solved individually, don't move to the next task unless the previous task is clear of any errors, and after testing, the total number of errors mustn't exceed 25% of all the tasks to deliver the system to the end-user.

4) Task error intensity: To achieve the effectiveness in task error intensity attribute, task errors must be classified according to task complexity, error intensity must be set from 1 to 5 based on the severity and priority set by a tester, and the factors that cause the error must be identified in order to solve it or give the user a hint on how to deal with it in order to reduce the intensity of its existence.

B. Efficiency

1) Task time: To achieve the Efficiency in Tasks time attribute, the developer must set the shortest way for the user to make the task to achieve the goal in the easiest way**, s**et the minimum developing time for a task according to its complexity without the existence of any errors**, s**et the maximum developing time for a task according to its complexity with the existence of all errors that could happen, and complete each task within the maximum and minimum of it.

2) Time efficiency: To achieve the Efficiency in Tasks efficiency attribute, the developer must choose a task at a time to set its input and desired output. Set the best programming language to achieve your target and choose the best algorithm according to its big O to achieve the best time efficiency.

3) Cost-effectiveness: To achieve the efficiency in cost-effectiveness attribute, a feasibility study must be developed based on the hardware and software needs (developing and testing environment) and choose the best platform to satisfy user needs, including user supplies to support most of the devices he can afford in software and hardware.

4) Productive time ratio: To achieve efficiency in the productive time ratio attribute, the developer must develop a timing strategy for ending the project and create criteria to set time for each feature based on the employee performance to achieve the optimal standard above and more quantity.

5) Unnecessary actions: To achieve the efficiency in unnecessary actions attribute, after finalising your code, all of the code must be revised to make sure that you choose the best development path and choose the quickest way to make the function with the minimum number of steps.

6) Fatigue: To achieve the Efficiency in Fatigue attribute, the developer must be aware of the problems that occur while developing that affect the deadlines and add them to the delivery date, and be prepared for the cases that make the system load slowly or go down.

C. Satisfaction

1) Overall satisfaction: To achieve satisfaction in the overall satisfaction attribute, the project must be delivered before the deadline, have well-defined requirements that have one meaning, and involve small prototypes to involve the users while developing.

2) Satisfaction with features: To achieve the satisfaction with features attribute, continuous messages must be displayed to inform the user of the current processing, block all the expected errors, and minimize the needed resources for working.

3) Discretionary usage: To achieve the Satisfaction in Discretionary usage attribute, the developer must think about all the cases where the user needs to use the application, and according to each case, the developer must satisfy the user's needs, satisfy the client's needs, and satisfy the market's needs. Finally, the developer must develop all the ways to achieve each target, for example, adding a speech-to-text feature and chatting to enter data.

4) Feature utilization: To achieve the satisfaction in feature utilization attribute, each feature must be explained to the user, choose the simplest way to develop each feature; they must choose the shortest number of steps to end a task; and the page must contain at most one objective or task.

5) Proportion of users complaining: To achieve satisfaction in the overall satisfaction attribute, the application must be too clear to reduce user inquires, provide a chat pot as a supporter in any problem, and provide quick support in a large problem.

6) Proportion of user complaints about a particular feature: To achieve the satisfaction in the overall satisfaction attribute, the application must help the user at the beginning by giving him a demo for each feature, giving the feature a definition and descriptive logo, and making the feature complete on one page with fine input and several steps. Then put the main features on the home page and their shortcuts on other pages. Finally, try to use AI in the application to tell the user if he is making the wrong decision.

7) User trust: To achieve the satisfaction in the overall satisfaction attribute, the application must: get permission from the user before saving or using his data, give a full explanation for why their data is needed as audio or text, solve all the user's problems most simply; then support the user with all the knowledge he may need; and involve the user as much as possible while developing to see the prototypes.

8) User pleasure: To achieve the satisfaction in user pleasure attribute, the application must develop every single task easily with fewer errors, give users continuous explanations and motivation messages, choose cheerful designs and colors to make the user happy, and ask the user for their feedback continuously.

9) Physical comfort: To achieve the satisfaction in physical comfort attribute, a backup must be taken for all your work to make the user feel safe, use UPS to assure that the data will be safe, and use the simplest way to develop the application.

D. Appropriateness Recognizability

1) Readability: To achieve the appropriate level of recognizability in the readability attribute, the icons must be readable to allow the other attributes like learnability, accessibility, and so on to be achieved. So, the font of the icon must be as big as you can to minimize the number of objects that exist on one page, whether it is a mobile or a web application.

2) Description completeness: To achieve appropriateness recognizability in the description completeness attribute, user stories must be wisely described to satisfy the developer and have one meaning based on the user's point of view, market needs, and recommendation of the best way to develop (interface architecture).

3) Demonstration coverage: To achieve the appropriateness recognisability in demonstration coverage attribute, the developer should develop many application types and many targets of applications at the same field to be aware of all the vulnerabilities of developing, and while developing, the developer must study all the pros and cons of any way related to developing.

4) Entry point self-descriptiveness: To achieve the appropriateness recognizability in the entry point self-descriptiveness attribute, requirements must be determined based on user stories that describe each scenario that could happen by the user to make the most effective decision while developing, and each feature must be described in the simplest way to make it easy to develop by a beginner developer.

E. Learnability

1) User guidance completeness: To achieve the learnability in user guidance completeness attribute, the project mustn’t be launched until the user manual is available in the form of steps.

2) Entry fields defaults: To achieve the learnability in entry fields defaults attribute, the right option must be very clear to the user to avoid errors in data entry fields.

3) Error message: To achieve the learnability in an error message attribute, every problem in every step the user can do, an error message must be designed to clarify the error and help him avoid it.

4) Understandability: To achieve the learnability in the understandability attribute, every step must be clear and mustn’t have a double meaning as possible.

5) Self-explanatory user interface: To achieve the Learnability in Self-explanatory User Interface Attribute, interface parts must be mapped to the objects used in our lives to be easy to understand, recognize, and recall.

F. Operability

1) Operational consistency: To achieve operability in the operational consistency attribute, the page mustn’t contain many tasks or any other information that doesn’t relate to the main task (each page for one purpose).

2) Message clarity: To achieve the operability in the message clarity attribute, any message that appears to the user must be very clear, and if the developer has time, he must add an option to let the user see the last message again when it disappears.

3) Functional customizability: To achieve the operability in the functional customizability attribute, the application must have fewer mandatory fields in each task as much as possible for less time consumption and make a detailed manual consisting of steps to make the application very easy.

4) User interface customizability: To achieve the operability in the user interface customizability attribute, flexibility must be given to the user to change the places of the objects on the interface as well as the colors to make the application more comfortable.

5) Monitoring capability: To achieve the operability in the monitoring capability attribute, the application must provide the user with an indication when he gets closer to the end of his task and provide the user with full statistics of the application usage and resource consumption. Then, inform the user about memory and resource usage, help the user to reduce memory consumption, and don't ask the user for too much data to be saved or user in one task.

6) Undo capability: To achieve the operability in the undo capability attribute, the user must have the ability to go back with clear action and help them to recognize it in many situations.

7) Understandable categorization of information: To achieve operability in understandable categorization of information attributes, the application must provide the user with a thorough explanation of the input data and why it is required, and then inform the user if his data will be used.

8) Appearance consistency: To achieve operability in the appearance consistency attribute, the system must have one design on every page, stick to simple and realistic symbols and designs to relate them to our lives, avoid attaching unrelated things to the application, and avoid putting too many details on one page even if they are related to the same task.

9) Input device support: To achieve the operability in the input device support attribute, the application must work on cheap resources, don’t make the application need many hardware devices to work properly, and try the application before delivery to the customer on different category devices according to the budget.

G. User Error Protection

1) Avoidance of user operation error: To achieve user error protection in the avoidance of user operation error attributes, the application mustn’t allow the user to input wrong data and must give a full explanation for the user's errors.

2) User entry error correction: To achieve user error protection in the User entry error correction attribute, the application has to give the user a full description of the error type and reason for its happening and give the user suggestions to correct his error.

3) User error recoverability: To achieve user error protection in the user error recoverability attribute, the application must allow the user to go back one step to make the user feel safe, give the user a description for each step he makes to increase awareness, and provide the user with a short manual that explains all the steps of the application.

H. User Interface Aesthetics

To achieve user interface aesthetics in the appearance aesthetics of user interfaces attribute, the developer has to choose the best comfortable color for the eye, the uploaded pictures must be of high resolution and minimum size to decrease the time of loading and increase the font of the data as much as possible to satisfy the user.

I. Accessibility

1) Accessibility for users with a disability: To achieve user interface aesthetics in the appearance aesthetics of user interfaces, the developer must be aware of all the types of users that will use the application and their disabilities, like color blindness, wheelchairs, etc.

2) Supported languages adequacy: To achieve user interface aesthetics in **s**upported languages adequacy attribute, the application must support the global language and the regional language, and in the future, you can add the most important languages ordered by priority.

V. TESTING REFERENCES AND QUESTIONS

Some will need to be revised from the requirements documentation, while others will need to be tested on the application. Here is a table that identifies which attributes need to be tested from the application only and which attributes need to be revised from what has been approved in the requirements documentation and sets some suggested questions for each attribute described in Table II.

TABLE II. DESCRIPTIVE QUESTION OF USABILITY ATTRIBUTES

Attributes	**Requirements documentation or Application usage**	**Questions to ask for an evaluation**
Tasks completed and Objectives achieved	Requirements documentation	Are all the system tasks according to the system requirements is done? Do you achieve all the objectives of the system according to the required documentation?
Errors in a task	Application usage	Do you have any errors in any tasks? Then try it
Tasks with errors	Application usage	After testing each task, is all the tasks that have errors exceed 25% of all the tasks?
Task error intensity	Application usage	Is the task error frequently happening?
Task time	Application usage	Is each task takes the minimum time it must take?
Time efficiency	Application usage	Do you develop each task to be done at the minimum processing time?
Cost-effectiveness	Requirements documentation	Are you stick to the feasibility analysis you made before starting?
Productive time ratio	Requirements documentation	Is every second in the application is useful to the user?
Attributes	Requirements documentation or Application usage	Questions to ask for an evaluation
Unnecessary actions	Application usage	Is every step in each task a must and has a specific target?
Fatigue	Application usage	Taking into consideration the maximum number of users at a time works with stability?
Overall satisfaction	Application usage	Dose all the usability requirements tested to achieve high satisfaction?
Satisfaction with features	Application usage	Does the simplicity of each feature exist?
Discretionary usage	Application usage	Can you use the system anytime anywhere?
Feature utilization	Application usage	Do all the features the system support are mandatory?
The proportion of users complaining	Application usage	Will the user need to call customer support or see the manual many times while usage?
The proportion of user complaints about a particular feature	Application usage	Does every feature need to be seen first from a manual?
User trust	Application usage	Does the system makes the user feel that he/ she is secure enough to trust the system?
User pleasure	Application usage	Does the system make the user pleased by the system?
Physical comfort	Application usage	Does the system allow comfortable positions while usage?
Readability	Application usage	Do all the pages is seen clearly by higher ages?
Description completeness	Application usage	Do you make a user manual to explain the system in steps or develop a demo to help the user to see the steps of any task?
Demonstration coverage	Application usage	Does the system has an explanation coverage?
Entry point self-descriptiveness	Application usage	Is every step described in its meaning, target, and how to the user without using the manual?

User guidance completeness	Application usage	Do you create a manual to help the user in explaining the system?
Entry fields defaults	Application usage	Do you explain the default inputs to the user?
Error message	Application usage	Do you give messages every time the user could make an error?
understandability	Application usage	Is the system easy to use and helps user memory to recover quickly?
Self-explanatory user interface	Application usage	Is the interface explain itself by mapping the tasks to the user knowledge?
Operational consistency	Application usage	Does the page contain many tasks?
Message clarity	Application usage	Does the information in all the messages that appears to the user clearly described?
Functional customizability	Application usage	Do all the fields in every step are mandatory?
User interface customizability	Application usage	Does the user have the flexibility to change the interface appearance?
Attributes	Requirements documentation or Application usage	Questions to ask for an evaluation
Monitoring capability	Application usage	Do the system support monitoring for the user errors to help him in the long run?
Undo capability	Application usage	Do you allow the user to go back whenever he wants?
Understandable categorization of information	Application usage	Do you inform the user of the structure of the data and why the application uses it?
Appearance consistency	Application usage	Do the system parts have consistency?
nput device support	Application usage	oes all the input devices available to the user while working with the system?
voidance of user operation error	Application usage	o you take into consideration all the errors that can be done by the user and block them?
User entry error correction	Application usage	Do you design error messages to help the user with their errors?
User error recoverability	Application usage	Do you allow the user to solve the errors he/she made?
Appearance aesthetics of user interfaces	Application usage	Does the interface explain every step?
Accessibility for users with a disability	Application usage	Is the system helps users with different disabilities to use it easily?
Supported languages adequacy	Application usage	Do the system support many languages mainly the global language and the user's first language?

VI. Results and Discussion

A. Results

Three main tasks have been chosen according to their importance to any e-commerce users which are search, seek product data and purchase to test them on two applications one with high rate (amazom) and the other with low rate (waradly). Assume that the attributes that need to be revised from the requirement documentation are all true. The results have been calculated by testing framework attributes on the two application simultaneously through asking the previous questions of each attribute. The answers will be true or false. If answer is true, so the attribute is applied on the application. If answer is false, so the attribute is not applied on the application. Every true will be converted to 1 grade and every false will be converted to 0 grade. Finally, all the grades of all the attributes are added, then divided by the total number of attributes which are 44, and multiplied by 100 to get the usability percentage of each task usability. For example, after testing the searching task on amazon application by opening the application and answer all the usability attributes on the searching task to check the existence of every attribute, the result was 42 attributes were true from total 44 attributes. The result was calculated by calculating total true attributes, divided by total number and multiply 100 (42/44*100) to give the result 95%. All the final results are presented in Table III after testing all the usability attribute on every e-commerce task then compare the usability results of every application to proof that the framework can differentiate between the usability of the high rate and the low rate applications.

TABLE III. Usability Testing Results

E-commerce Task	Results after checking the attributed existence on every e-commerce task	
	High rate Application(*Amazon*)	Low rate Application(*Waradly*)
Searching	95 %	49 %
Seeking product data	100 %	61 %
Purchasing	95 %	59%

B. Discussion

Most of the previous work papers focus on updating the needed attributes that is used in testing the applications and test them to proof their idea or taking an existence framework and upgrade the way of evaluation to get better results. But in this research, the framework focus on describing all the usability attributes from qualitative title into quantitative detailed steps that helps the developer and tester on their daily work.

VII. Limitations of the Study

For future improvement, this research contains some limitations as setting usability attributes for each application type according to the application categories. Also, differentiating between the general attributes that could be applied on all applications and the specific application types.

Finally, setting weights for each attribute to clarify the importance of each attribute and order them according to the attribute weights.

VIII. Conclusion

After testing the framework on two e-commerce applications, one with a high rate and the other with a low rate on three main tasks, which are searching, seeking product data, and purchasing, our framework proves that a high rate (Amazon) resulted in 95% in the searching task while a low rate (Waradly) resulted in 49%. Also, it proves that a high rate (Amazon) resulted in 100% in the seeking product data task while a low rate (Waradly) resulted in 61%. Finally, a high rate (Amazon) resulted in 95% in the purchasing task while a low rate (Waradly) resulted in 59%.

So that means our framework proved that Amazon has a high rate and Waradly has a low rate, which means it can measure the usability percentage and categorises the application usability. The testers can use the framework in testing their applications of any type as the attributes are generic, which means they can measure any type of application.

Acknowledgment

First and foremost, I feel always indebted to Allah the Most Beneficent and Merciful. Words can never suffice to reflect my sincere appreciation and gratitude to Prof. Dr. Hesham Hassan, Prof. Dr. Khaled Wassif, and Dr. Hanaa Bayomi.

***Abstract*—The World Health Organization (WHO) declared the COVID-19 pandemic on 12 Mar, 2020, due to the growth in the number of cases worldwide. WHO advises wearing a face mask and practicing social distancing, which has played a crucial role in prevention and control measures that can prevent the spread of COVID-19. Thus, this paper presents the process through which face mask box is equipped with a voice reminder and sensor. It is made with the help of an Arduino Uno board to give awareness or reminder whenever a person is alerted with a voice reminder to wear a face mask before going outside. It can be helpful, especially in the pandemic era, as a new norm of practice in wearing a mask.**

***Keywords*—Face mask box; COVID-19; Voice reminder; Arduino; New norm**

I. Introduction

The World Health Organization (WHO) declared COVID-19 as a pandemic on 12 Mar, 2020 due to the growth in the number of cases worldwide [1]. The Covid-19 pandemic has had a negative impact on health, education, economy, finance, and others, resulting in the introduction of the Movement Control Order for many countries. People were advised to stay at home, work from home, limit their movement outside the house, wear a mask to cover their nose and mouth, regularly wash their hands, establish social imprisonment, and so on as precautions to stop this pandemic [2]. So, all people need to carry and adapt to daily life with the new norm; as a prevention and control measure to limit the spread of COVID-19, WHO advises wearing a face mask and practicing social distancing [3]. Mask has played a crucial role in prevention and control measures to prevent the spreading of some respiratory diseases and COVID-19. The use of masks and frequent hand hygiene, social distancing, and other Infection Prevention and Control (IPC) measures should be followed to prevent the spread of COVID-19 [4].

One significant benefit of wearing face masks is to protect the people around us, especially if we have been exposed to someone carrying the virus or work in a crowded place. Therefore, wearing masks is a critical habit everyone should be applying since this simple step could significantly reduce the risk of transmission [5]. Hence, it is a pressing need to design and develop a face mask reminder with a low-cost material that can be easily made since there is also none of this product available in the market to date.

II. Background and Previous Related Work

A. Motivation and Problem Statement

Coronavirus Disease 2019 or known as COVID-19, has become the latest threat to global health [6]. It is an infectious disease [7] that causes severe acute respiratory syndrome (SARS) [6]. The symptoms of the infection consist of fever, cough, nasal congestion, fatigue, and other signs of upper respiratory tract infections [8]. The condition can cause severe disease or death; as a prevention and control measure to limit the spread of COVID-19, the WHO advises wearing a face mask and practicing social distancing [3].

Recently, it seems like some people are starting to disregard the WHO order to practice social distancing and wear a face mask whenever they leave the house or are in a crowded place. Thus, to address these problems, every country affected by COVID-19 has made it mandatory for people to wear face masks in public, especially in crowded places. The new normal must be continued depending on our awareness level, attitudes, and habits. For this project, the problem focuses on the attitude and practices of wearing face masks. Thus, to solve the issues stated, this project developed a face mask reminder to give awareness of the importance of face masks. A person will be alerted with a voice reminder to wear a face mask before going outside through the project.

For this project, the problem focuses on the attitude and habits of wearing face masks. Thus, to solve the issues stated, this project developed a face mask reminder to give awareness of the importance of face masks. A person will be alerted with a voice reminder to wear a face mask before going outside through the project.

B. Previous Related Work

Based on the literature review of the previous works, the ideas of face mask boxes and voice reminders are considered to develop an awareness system toward the importance of face masks. The difference from previous related work is through the project, a person will be alerted with a voice reminder to wear a face mask before going outside.

1) Build your own COVID-19 face mask reminder using Arduino: The project designed and made by The Assembly Production addressed how people always forgot to wear a face mask when going outside [9]. The emergence of COVID-19 has made the entire world obey the rules on social distancing and wear face masks to prevent the spread of COVID-19.

Thus, the Assembly Production designed a face mask reminder using Arduino Uno, PIR sensor, buzzer, LCD, and keypad. The PIR sensor detects the motion of a person going through the device, and the buzzer will make a noise to alert the person to wear a face mask before going outside [9]. The device also has an LCD to display the number of face masks and a keypad to enter the number of face masks in the box. Fig. 1 shows the device produced by the Assembly where the user can store the face mask in the designated container. The face mask's material was a paper box, which was low in cost.

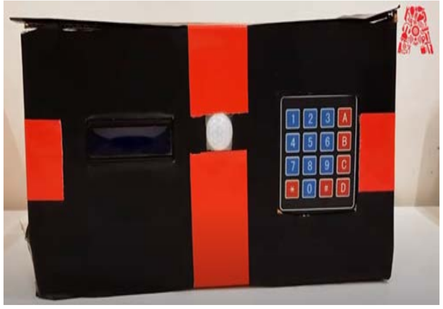

Fig. 1. Face Mask Reminder Device.

2) Contact-free hand wash dispenser with voice assistance: The Assembly Production The project designed and made by Neutrino addressed how to use a hand wash without making any contact while taking the hand soap, as illustrated in Fig. 2 [10]. It is designed using Arduino Pro Mini, DF Player, PIR sensor, DS1307 Tiny RTC, SD Card module, and speaker. The intelligent hand wash dispenser reminds a user with a message after every 2 hours to wash hands. The PIR sensor detects the motion of a person by putting their hands next to the hand soap. Then, the signal is sent to the DF player, and voice assistance will help them wash their hands.

Fig. 2. Contact - Free Hand Wash Dispenser.

III. Development of Face Mask Reminder Prototype

A. Methods

The face mask reminder is designed to alert the person to wear a face mask before going out. Fig. 3 shows the flowchart for project planning.

To assure the project runs smoothly, systematic action was taken to analyze the face mask reminder's performance. The project flow is divided into four phases: Research, Design and Modelling, Prototype, and Result and Analysis.

For Phase 1: Research, the project begins with a detailed study on a literature review about voice reminders and motion detection. Based on the previous related works, [9] designed a face mask reminder box to noise to alert the person to wear a face mask before going outside. While [10] developed a contact-free hand wash dispenser with a voice reminder feature. The project will also focus on the simulation and coding to implement motion detection and voice reminder.

For Phase 2: Design and Modelling, the project followed by designing the device for a better experience. In this phase, some research was done on hardware and software compatibility and suitability for the proposed system. Every system is a combination of hardware and software, mainly hardware or software [11].

For Phase 3: Prototype, the prototype's functionality is tested after the simulation and design is done. The design was done using Fritzing to determine the hardware connection of each component. At the same time, the simulation of hardware connection was done by using Proteus software.

For Phase 4: Result and Analysis, the result obtained from testing the prototype was analyzed to monitor the system's performance. The analysis was done on the device's performance and improvement on other parts.

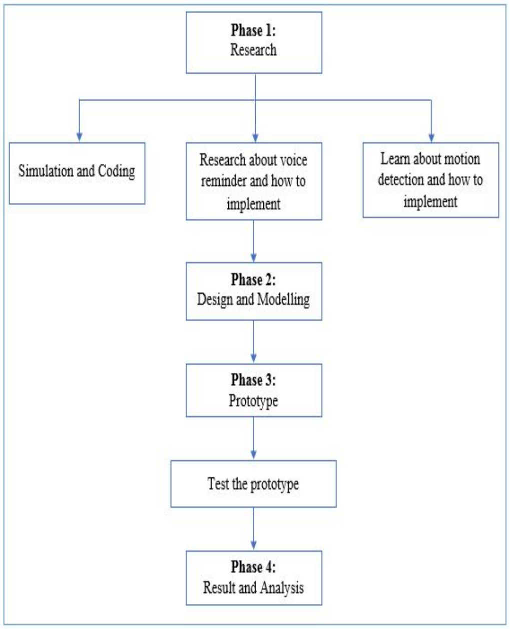

Fig. 3. Flowchart of the Project Planning.

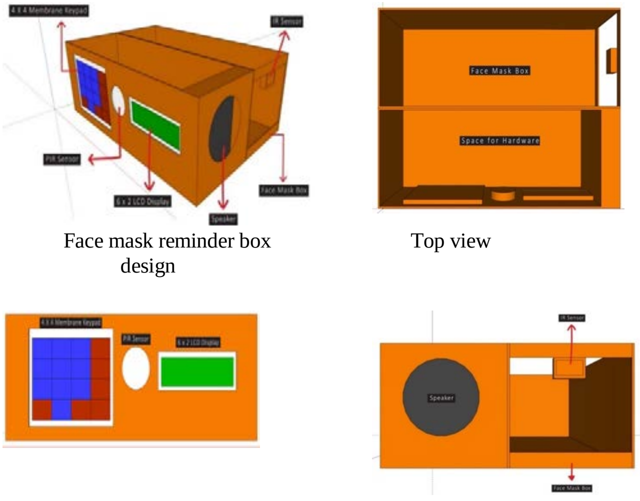
B. Face Mask Reminder Box Design

To assure the project runs smoothly, systematic action was taken to analyze the face mask reminder's performance. The project flow is divided into four phases: Research; the Face Mask Reminder is designed on Sketch Up software based on the requirements.

The prototype design includes space for hardware and a face mask box. Fig. 4 shows the face mask reminder box's design using SketchUp software. SketchUp has a lot of possibilities and needs a low amount of pre-knowledge to get started. This software shows some knowledge about models, building and using models can be getting through its help. There might be a few doubts for the new users, but this can be solved easily with help and demonstrated videos. There are tools for selection, drawing, component, view, and sharing the drawing designs [12]. The sketching shows the sides to be used to place all the hardware with each part labeling. The 4x4 keypad membrane, PIR sensor, and 16x2 LCD display are placed side by side for the front side. For the right side, the speaker and IR sensor are also placed side to side.

Hardware space is for placing the Arduino UNO and power supply; the suggested power supply to be used is a power bank. Arduino is used as an open-source computing platform that is used for constructing and programming electronic devices. It can also act as a mini-computer, like other microcontrollers, by taking inputs and controlling the outputs for various electronic devices [13]. At the same time, the face mask box is for the user to put the face mask in the box up to 100 pieces of face mask. The IR sensor function will detect a person's hand that takes out the face mask, and the number displayed on the LCD will be reduced. Then, the PIR sensor will detect a person's movement through the box and play a voice reminder: "Please wear a face mask before going out" using a speaker. So people will become more alert during going out.



Face mask reminder box design

Top view

Front view

Right Side View

Fig. 4. Design of Face Mask Reminder Prototype using SketchUp Software.

C. Mask Reminder Box Fabrication

The face mask reminder is designed to alert the person to wear a face mask before going out. As shown in Fig. 4, the face mask reminder box design is divided into two parts. The first part is for hardware connection space, where all the hardware will be placed in this space. This box comes with a small hole for power supply purposes. The second part is for a face mask box where a user can store up to 100 face masks in this space.

The material used for the box is Acrylic or Perspex. Acrylic is a transparent plastic material with outstanding strength, stiffness, and optical clarity. Acrylic is also a material with properties such as transparency and durability. It is now being used in a wide range of applications such as lenses of glasses, tail lights, and various other instruments in a vehicle to reduce cost and productivity [14]. It is highly resistant to variations in temperature and humidity. Thus, it is helpful in outdoor applications as well. Fig. 5 shows the top view of the box. The box has a lid that can be opened to check the hardware connection and fill in the face mask. The cover can be opened and closed quickly.

Fig. 6 shows the front view of the face reminder box. The 4x4 membrane keypad and 16x2 LCD keypad with I2C are placed side to side on the front side. The keypad is used to key in the number of face masks in the box. The LCD display presents the actual number of face masks in the box. On display, it will show the exact number of masks and the maximum number that can be entered. The maximum number of face masks that can be placed in the box is 100 pieces. The device can be used easily if the hardware is connected.

Fig. 7 shows the left side view of the face reminder box. The speakers, PIR, and IR sensor are placed side to side on the left side. In addition, on the right is a face mask box where the user can place a face mask. The speaker is used to alert "Please wear a face mask before going out" to anyone passing through the box. PIR sensor is used to detect a person's motion. When it detects a motion, the speaker will sound an alert. At the same time, an IR sensor is used to detect a hand motion of a person. If a person removes a face mask from the box, the number displayed on the LCD will be reduced.

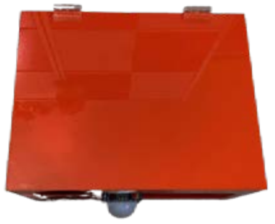


Fig. 5. Top View of Face Mask Reminder Box.

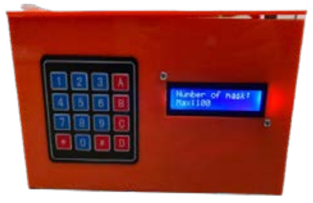

Fig. 6. Front View of Face Mask Reminder Box.

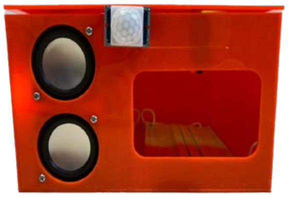

Fig. 7. Left Side View of Face Mask Reminder Box.

Fig. 8. Right Side View of Face Mask Reminder Box.

Fig. 8 shows the right-side view of the face reminder box. There is only a tiny cutout of acrylic sheet for connecting the hardware to the power supply on the right side. But, since the power supply is a small 20000mAH power bank, it is just placed inside the box. Fig. 9 shows the backside view of the face mask reminder box.

Fig. 9. Backside View of Face Mask Reminder Box.

IV. Development of Face Mask Reminder System

A. *Circuit Design of Face Mask Reminder*

The hardware component for the prototype is Arduino UNO with PIR and IR sensor, LCD with I2C, Keypad, SD card module, and Speaker. Fig. 10 shows the circuit connection using Fritzing application.

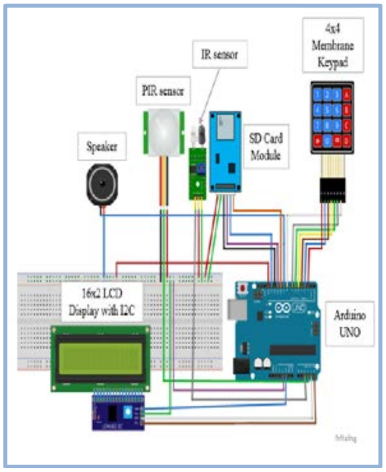

Fig. 10. Hardware Connection of Face Mask Reminder using Fritzing.

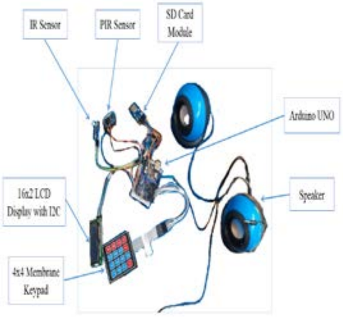

Fig. 11. Hardware Connection of Face Mask Reminder.

The prototype consists of only hardware parts tested to assure the device's functionality. Fig. 11 shows the hardware connection of the face mask reminder. Arduino UNO acts as a microcontroller and holds all of the other components. The power supply is a 20000mAH power bank to keep the hardware active.

V. Implementation of Face Mask Reminder

A. *Testing the Face Mask Reminder Box*

The face mask reminder box was tested to get its functionality in this part. The test was done in a living room near a door. A hardware component is connected to the 20000mAH power bank that acts as a power supply to keep the box active through the testing. The audio of different voice alerts is stored on an SD card in waveform audio file (WAV) format [15].

A person passed through the box, and the speaker sent an alert with a voice reminder, "Please wear a face mask before going out." Next, the box reminds the person to wear a face mask before going outside to prevent exposure to the virus COVID-19. Then, the person takes out a face mask from the box and decreases the number of face masks shown on the LCD display.

On the other hand, the person refills the face mask in the box. After that, he keys in the actual amount of face mask added using the keypad. Thus, the exact number of face masks in a box appeared on the LCD.

The result obtained in this project is analyzed according to the related part. It has been proved that the face mask reminder box works systematically according to the working principle and based on the testing phase. As a result, the face mask reminder is successfully implemented.

B. *Manual to Key in Quantity of Face Mask*

Fig. 12 shows that the keypad matrix with 16 push buttons [16] is used to key in the number of face masks in a box. This type of keypad has four rows and four columns where the overlapping rows and columns are the keys [17]. To key in the number of face masks, the user can follow the instruction below.

1) Press any number from 1 to 100.
2) Press "#" to enter.
3) The number will be shown on the LCD.
4) To backspace, press "A."

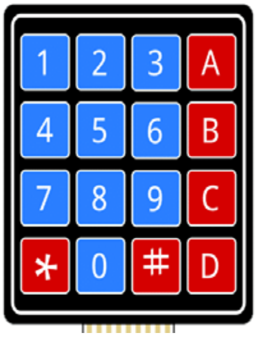

Fig. 12. 4x4 Keypad Membrane.

Users can only enter numbers 1 to 100 because the system only allowed face masks up to 100 pieces. If a user enters more than 100, the LCD will show "Invalid number," and it must key in the number again. If the user enters a wrong number, press keypad "A" during the process to backspace.

VI. Overall System Architecture

The overall system architecture of the developed Face Mask Reminder system is illustrated in Fig. 11 and Fig. 13. The system design consists of one central part: hardware. The hardware components are Arduino UNO, PIR and IR sensor, 16x2 LCD with I2C, 4x4 membrane keypad, SD card module, and speaker.

Firstly, Arduino UNO acts as a microcontroller that integrates with the PIR sensor to detect any motion within the range [11]. When the sensor detects a person's movement, a speaker will alert with a voice reminder from the SD card module. It will be a warning for a person to wear a face mask before going outside. Secondly, Arduino UNO is a microcontroller that integrates with an IR sensor to detect the hand motion of someone taking a face mask from the box [18]. When the sensor detects a hand motion, the number displayed on the LCD will be decreased. Lastly, the keypad is used to enter the number of face masks in the box.

The flowchart of the system operation mechanism is shown in Fig. 14. The application starts with the face mask reminder box attached next to the door or somewhere close to the door. Then, a user can fill in the face mask in the box and key in the quantity of the face mask using the keypad membrane. The actual number of face masks in a box is shown on the LCD.

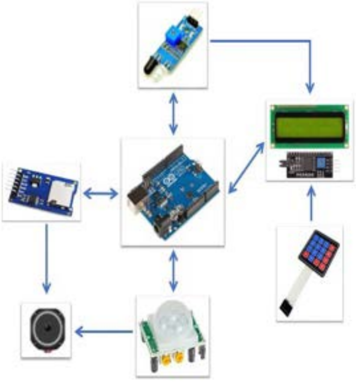

Fig. 13. Face Mask Reminder System Architecture.

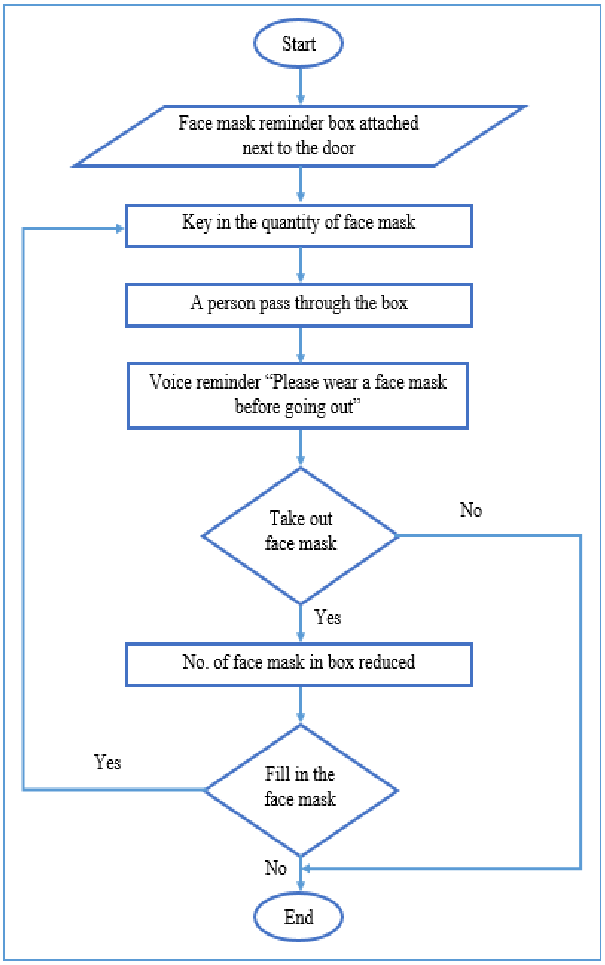

Start
Face mask reminder box attached next to the door
Key in the quantity of face mask
A person pass through the box
Voice reminder "Please wear a face mask before going out"
Take out face mask
No
Yes
No. of face mask in box reduced
Yes
Fill in the face mask
No
End

Fig. 14. Flowchart of Face Mask Reminder Application.

When a person passes through the box, the PIR sensor detects a motion and sends a signal to the speaker [19]. A voice reminder alerts the person with a warning, "Please wear a face mask before going out." If a person takes a face mask from the box, the IR sensor senses a hand motion into the face mask box [20]. Then, the number of face masks in the box was reduced. Thus, if a user fills in the face mask in the box, they must key in quantity, and the actual number appears on the LCD [21]. If a person does not make a face mask or fill in the face mask, they can continue their way out. The complete supplementary files for the Facemask Reminder coding algorithm can be found in the link here: https://tinyurl.com/facemaskbox reminder

VII. Conclusion and Recommendation

The design of the proposed system only consists of hardware parts. The hardware implementation used Arduino UNO, PIR and IR sensor, LCD Display, Keypad, Speaker, and SD Card Module. It is used to develop the Face Mask Reminder, which provides a face mask box with a voice reminder. The Face Mask Reminder box capabilities provide a voice reminder as an alert or warning to a person to wear a face mask before going outside. To reduce the problem of people who recently forgot to wear a face mask, the box comes with a space to place a face mask up to 100pcs. The sensors increased accuracy in detecting a person's motion when it passed through the box and taking a face mask out of the box. The performance of the box is tested in the living room, and it shows an excellent result that can be used for a face mask reminder. The Face Mask Reminder box is built successfully. However, this system could be upgraded better by using more accurate sensors. PIR sensors depend on motion detection, with the motion sensitivity declining as the user's distance from the sensor increases [22]. While IR sensor is highly accurate, they are highly fragile in nature [23].

***Abstract*—The area of video technology is rapidly growing owing to advancements in intelligent video systems in sensor operations, higher bandwidth capacity, storage, and high-resolution displays. This led to the proliferation of video-based computing modeling to perform specific tasks on video sequences to gain more insight from the data. Visual tracking of events is a core component in video visual surveillance systems that classify and track moving objects to describe their behavioral aspects. The prime motive behind intelligent video systems is to perform efficient video analytics to meet the specific requirements of the user/use-cases. It involves a self-directed paradigm to understand event sequences, reducing the computational burden of characterizing the activities. The study incorporates a block-shift feature algorithm and introduces a novel computational research method for unusual event tracking in video sequences. The formulated approach employs a framework combining operational blocks to compute sequential operations such as block-matching from the dictionary of motion estimations. Before applying the learning model, the subsequent analysis procedure adds feature lexicon and dominant attributes to make the execution computationally efficient. Further, it uses a sparse-non negative factorization approach to organize the informative details into k possible finite clusters. The event detection outcome from the training datasets of video sequences shows better experimental results than the traditional highly cited related approach of unusual object detection and tracking.**

Keywords—Object detection; tracking; learning models; video sequence analysis

I. Introduction

The ever-increasing surveillance process adopted in every walk of life leads to the video sequence databases' reposit. If these databases are not analyzed, it is just a kind of dead data. The analysis of textual data is quite simple as the basic terms construct it. In contrast, the video sequences contain various sensitive pattern features and information. Its interpretation requires suitable and efficient algorithms to deal with its analysis so that multiple applications can be built based on this analysis, and real-time decisions can be taken. The advancement of the computing platforms with the CPU and GPU functioning provides the right ecosystem to explore the possibilities of automatically tracking an object in the video sequences. In the computer vision domain, detecting and tracking the objects within video sequences plays an essential role in many applications [1]. Some of the examples of such applications include i) event tracking in video surveillance [2], ii) dynamic road traffic management [3], iii) intruder tracking [4], and iv) robotics vision [5]. The individual image sequences in the video are popularly known as a frame in video processing. These frames contain both the static and moving object into it. The structure's static part is termed the background, whereas the moving objects are known as the foreground [6]. The task of tracking objects in the video frames or sequences includes detecting moving objects of interest, then classifying them and following them from frame to frame.

In the process of object detection, the pixels of the object in interest are clustered, which is generally performed by various methods, including i) frame differences, ii) subtraction of the background, and iii) optical flow computation [7]. The object classification occurs only after the object detection based on the high-level features, including one or combinations of color, shape, texture, or sometimes motion. However, the tracking of an object is to gain specific information on the object utilizing its orientation, activity, occlusion, etc., using three popular approaches i) silhouette [8], ii) kernel [9], and iii) point-based tracking [10]. Point-Based Tracking (PBT) is significant for tracking small objects in the video sequences; however, it does not perform well in occlusion and provides false detection [11]. The PBT is broadly classified into i) Kalman filtering (KF) [12] and ii) Particle filtering (PF) [13]. The typical working process of the KF is to perform prediction of the current state variables and correction recursively. Since KF handles the noisy input data in recursion, it can track single objects in a real-time scenario [14]. Though the PF also performs the prediction and correction similar to the KF, it overcomes the state variable's approximation constraints by re-sampling.

PF generates many possible models for the current variable before moving to the following state variable. The PF exploits feature sets like {color, contour, texture}[15]. The Kernel-Based Tracking (KBT) uses shapes like rectangles or ellipses to keep the object of interest outside the shape and background to detect rigid objects. The typical classification of the KBT includes i) Simple Template Matching (STM), ii) Mean Shift (MS), iii) Support Vector Machine (SVM), and iv) Layer Matching (LM) [16]. The STM is applicable for tracking a single object in partial occlusion conditions. It verifies the video sequences with a reference frame, and only motion transformation is possible in this method. Simultaneously, the MS method uses chamfer distance transformation, the Bhattacharya coefficient for distance, and color distribution transformation among the region of interest in windows to windows to improve the accuracy. However, it cannot track high-speed moving objects and only single object tracking [17]. However, the SVM-based method tracking the object in video sequences tracks only the positive samples. This method also handles tracking a single object and limits its applicability to partial occlusion [18]. The LM- method is used along with the KB method to track multiple objects, even in the complete occlusion condition [19]. The complex object containing a composite shape is well followed using the Silhouette-based method, which is further categorized into i) contour tracking (CT) [20] and ii) shape matching (SM) [21]. In CT, the object's motion and shape are considered using a state-space model. Then, the contour energy is minimized using gradient descent for computing the next frame's contour in iteration from the previous frames. This method helps track objects with irregular shapes. However, the shape-based process is the same as SMM without classifying the objects, and it uses the edge templates and occlusion utilizing Hough transformations.

This paper proposes a moving object tracking with satisfying background conditions using a block-matching method from the dictionary of the motion estimations. The contribution and potential benefits of proposed approach are as follows:

- The presented model introduces a learning-based approach, initially incorporates-video sequence exploration, followed by block-wise feature lexicon extraction, updates the dictionary of feature lexicon with dominant attributes.
- The system also includes a novel feature engineering schema and workflow modeling to compute feature elements with lexicon vector.
- The study model discusses about a novel sparse non-negative factorization (S-NNF) technique that factorizes data organization into k possible finite clusters.
- The study further applies a simplified learning-based systematic approach to faster tracking moving objects from the video feed of frame sequence.
- The system is analytically represented with numerical analysis, which subjects to the dictionary-based learning operation towards tracking the moving object anomaly.
- The study also simulates the devised numerical models with the systematic workflow execution for evaluating the performance. The outcome clearly shows the effectiveness of the block-shift feature algorithm in terms of different classification parameters.

All the above mentioned contribution are implemented in a sequential way. The organization of the paper is as follows: Section II discusses about existing methodologies while its identified problems are briefed in Section III. Section IV discusses about the system model while result discussion is carried out in Section V. The summary of the paper in form of conclusion is briefed in Section VI

II. Review of Literature

Various strategies are evolving to improve the video tracking system's operation and performance. To develop an effective video tracking system, the existing approaches consider selecting multiple parameters, e.g., points, primitive geometric shape, contour, Silhouette of an object, articulated shape, and skeletal models. Such conventional approaches are usually modeled using standard features, e.g., color, edges, optical flow, and texture. However, the video tracking system has recently introduced various unique techniques. The existing approach offers importance to extracting the semantic factor associated with capturing essential features for performing the track. Boukhers et al. [22] have discussed a probability-based model for obtaining trajectories of a three-dimensional object from two-dimensional video feeds. The model can estimate the object depth from the calculated focal length. The technique also uses a particle filtering method based on the Markov chain Monte Carlo process to stabilize the video better feeds with reduced time consumption for detecting an object. However, the majority of the video tracking application emphasizes more on human as an object. The challenge in this field is to differentiate the object from the background based on appearance and color. This issue is sorted out by Damotharasamy [23] by using a sparse representation that is not affected by any variations caused due to illumination. Apart from this, the issue associated with occlusion is addressed using subspace learning that extracts the visual features during the dictionary's updating process.

Further work also performs sophisticated video tracking of moving objects and recognition of specific actions. Studies using a similar methodology were also encountered in the literature using the discrete tracking mechanism by Kong et al. [24]. This approach has considered the localization of coordinates of a moving object using compressive tracking. The study has contributed to refining the scaling factor and recovering the occlusion issue. A convolution network is used in this study for recognizing the action of the moving object based on pre-defined information of the actions and extracts potential features considering the static data of an object.

Existing studies have also witnessed a video tracking system from multi-feeds that offers more elaborated information of the same scene event captured from multiple cameras mounted in different locations. A similar concept has been modeled by Lee et al. [25], where segmentation and tracking multiple objects using dual forms of the feature are applied. Feedback with multi-kernel is used for detecting local objects while performing a video track with a single camera. At the same time, the contextual information and appearance are integrated to carry out multi-camera tracking. The study also used an unsupervised learning method to improve the scalability factor. However, the study is all about tracking a single object. A unique variant of this approach was seen in Liu et al. [26], capable of tracking multiple objects. Independent from any specific object model, this approach can differentiate two similar objects based on the trajectory generation. The system uses a neural network and graphical model for tracking with a correlation between the targets. Another part of the literature on video tracking has been carried out considering detecting abnormalities present within it.

Adopting the Gaussian mixture is proven to improve the video tracking system effectively, as seen in Ratre and Panchapakesan [27]. The model offers a better classification of an object and the decomposition concept's usage using tucker tension. The study also uses cosine similarity to compare the attributes of decomposition considering the mobility-based feature, i.e., speed and shape of an object, to track the event from the video feed. Existing studies also include the text as another representation of an object from the web video for exhibiting the video tracking mechanism. Tian et al. [28] further works in this direction and come up with a Bayesian-based algorithm model for object detection and tracking from a complex video form. A similar kind of tracking of the object is also carried out by Yang et al. [29] by addressing its multi-orientation. The study uses multiple frames using dynamic programming for performing video tracking over various scenes.

Literature has also witnessed the implication of the identification and classification of a different number of objects for a video feed, as seen in the work of Wong et al. [30]. The author has developed a model independent of any apriori information of the object to perform tracking. At the same time, the classification is carried out using the learning approach of the neural network. There are specific unique categories of studies on video tracking. Existing literature has also seen the usage of super-pixels to extract fluctuation of an object's appearance with the monitoring, as seen in the work of Cheng et al. [31]. Using a deep residual network, the classification performance is improved using a correlation filter in tracking. The concept of facial recognition for automated identification of a specific human as an object is presented by Khan et al. [32]. The study also uses location information and time to carry out the tracking process. The adoption of infrared modalities and Red, Green Blue content (RGB) was used to develop a video tracking system for industrial surveillance systems, as explored in Lan et al. [33]. Adopting machine learning has addressed the issues associated with modalities' discrepancies. Another unique implementation is carried out by Liu et al. [34] and Benthem et al. [35]. A stochastic nature grammar is used over a decomposed graph to manage different attributes of the signal feeds. A learning-based approach is delivered for training this grammar model. This work addresses various possibilities of error in object recognition from the video feed. Therefore, multiple methods have been evolved to brief the associated issues in the next section.

III. Research Problem

A review of existing approaches towards improving video tracking performance shows various procedures in recent times and also outlines their limitation factors. However, a closer look into existing systems shows its emphasis on identifying a single mobile object. The studies also offer minor inclusion of contextual attributes connected with objects' mobility patterns. Various studies using trajectories are not meant to evaluate the dynamic environment over the scene. This could be a more significant challenge when tracking an object with dynamic mobility patterns in the crowd. Irrespective of approaches using the extraction of particular objects, the studies lack the consideration of other similar objects moving along with the target object, which could generate a significant number of outliers in its detection process. Although this challenge is somewhat solved using a machine learning-based approach, it should be noted that such systems are computationally complex when it relates to their practical operation of video tracking. Simultaneously, dependencies of trained feeds will also include many resources to store and process them. Such a phenomenon will lag in the bounding box's appearances over the tracked target presence within a scene. Therefore, there is a potential need for research to be carried out to extract contextual information about the target object from the video feed scene to improve accuracy. Learning-based approaches are a potential solution to overcome this challenge; however, such methods also require the smart amendment to balance the spontaneity in tracking performance and computational complexity.

IV. System Model

This study continues our prior works in [36], [37]. The formulated system model consists of various sub-computational units as i) video sequence explorer: where the training and testing data are visualized to get an intuition about the scene, ii) Dictionary feature lexicon blocks: where the dictionary based on the blocks are made, iii) Feature engineering modeling with feature element and lexicon vector computation, followed by iv) Design and development of a cost-effective learning model to estimate learning-based features which help in identifying the unusual moving object from each frame of the input video sequence and v) Exploration of the numerical outcome to justify the performance of the proposed modeling. The consecutive sections illustrate the rational description corresponding to the system modeling concept with mathematical notions.

A. Video Sequence Exploration

The system model provision to select the reposit location (R_l) of the training dataset (D_t), which consists of 'n' video sequences (Vs). The explicit function $f_1([R_l, D_t] \rightarrow$*:* Sc[Vs.(N)], the typical elements of the structure set Sc={Na, D, S}, where Na = video sequence name, D=date of creation that may trace the event's date in the surveillance system, and **S**= memory space. The statistical description of the dataset is given in Table I.

The dataset typically consists of '44' independent folders consisting of '8800' video sequences in totality, divided into 77.28 % as training data and 22.72 % as testing data. Few random video sequences from both training data and the testing data are shown below in Table II.

TABLE I. Statistics of the Dataset

Sl. No	Data Description	No of the video sequences
1	Training Data	6800
2	Testing Data	2000

B. Dictionary Feature Lexicon Block

The computational block for obtaining the 'Dictionary of Feature Lexicon' (DFL) takes three input sets {D_t, R_l, Sc[Vs.(n)]}, the detailed operations are given in the algorithm -1.

```
Algorithm 1: Block wise Feature Lexicon
Input: $D_t$ , $R_l$ , Sc[Vs(n)]
Output:DFL
Process
Start
Initiate: BS← [ n x n x n ]
        F1←Sc[Vs(n)], n=1
        B←Convert F1 into a column of block n x n
        Create Dictionary Size:
                nR←$n^3$ and nC← q [no. of columns(B)]
                oBS← $n^2$
                Cs← with Size [ $n^3$,q , D= $\frac{\lfloor N(Vs)_t \rfloor}{n}$ ]
Compute: Mean of B as $\vec{M}$
$V = \frac{B_j - \vec{M}}{\|B_j - \vec{M}\|}$

Update DFL with V
End
```

The computing model initiates a block size (BS) of [n x n x n], and the entire sequence (Vs) is arranged in columns of BS with the size n x n, as shown below:

$$\begin{bmatrix} p_{1,1} & p_{1,k} & p_{1,n} \\ \cdots & \cdots & \cdots \\ p_{m,1} & p_{m,k} & p_{m,n} \end{bmatrix} \rightarrow \text{f(BS):[B1,B2,B3,....Bq]} \rightarrow [\text{B}]_{1 \text{ x } q}$$

The vector size for storing the lexicon blocks in the dictionary is n^3 x q. The observation block size (oBS) is defined as [n x n]. The container size (Cs) for the dictionary feature lexicon is Cs [n^3, q, D], where D is the dimension as in equation (1) if D n ≤ 0.49 and as in equation (2) if D ≥ 0.49

$$D = \frac{\lfloor N(Vs)_t \rfloor}{n} \tag{1}$$

$$D = \frac{\lceil N(Vs)_t \rceil}{n} \ldots \tag{2}$$

For∀ Vs.∈ Sc, an empty vector $\vec{f}$ of the number of rows and columns as of Vs. The dimension of 'n' is created, and the pixels of ∀ Vs.∈ Sc is stored in all the nul1 matrices of $\vec{f}$. The Lexicon block dictionary for ∀ Vs.∈ Sc as a null matrix of size [n^3, q,]. The mean of the B is computed as $\vec{M}$ and further, the normalized Vector (V) is computed as in equation (3).

$$V = \frac{B_j - \vec{M}}{\|B_j - \vec{M}\|} \ldots \tag{3}$$

The dictionary for the feature lexicon gets updated with the corresponding values of the V.

C. Feature Engineering

The multidimensional array for the Lexicon of 'Vs' dictionary as $\vec{\boldsymbol{L}}$(m x n x d) is an input vector for the feature engineering process. The 'Fs' A structure for storing the feature vectors ($\overrightarrow{\boldsymbol{Fv}}$).

```
Algorithm-2: Feature Engineering
Input: $\vec{L}$
Output: $\overrightarrow{Fv}$
Start
for∀ n ∈ $\vec{L}$, compute $\overrightarrow{Lt}$(m,1, d)
        initiate, X[0](m x 1)
        for ∀ d ∈ $\overrightarrow{Lt}$
                [val](m x d) ←$\overrightarrow{Lt}$(d)
    end
check for noise (NAN)
        $\vec{X}$ [0:NAN]←NAN: (Algorithm-3)
Define the number of clusters: k
        Invoke, f $_{Non-NLS}$ (): (Algorithm-4)
        {features}←NNLS($\vec{X}$,k)
Updates, $\overrightarrow{Fv}$({features}
End
```

This phase of the study incorporates an efficient feature engineering modeling to normalize the lexicon attributes $\vec{L}$(m x n x d) ∈ $'$Vs.$'$ dictionary. The prime underlying motive of the feature engineering modeling in this research phase is to speed up the calculations during the execution phase of the empirical decomposition model. A matrix structure 'Fs' is further created to update the trainable extracted features for the feature vectors ($\overrightarrow{Fv}$). The algorithm finally yields a vector of computed ($\overrightarrow{Fv}$). The computation steps exhibit that it initially computes and creates a structure corresponding to the lexicon attributes of the dictionary feature set. Here, for each lexicon attribute of the dictionary feature matrix, the process computes each column corresponding to $\vec{L}$ Moreover, further computed in a decomposed form as: $\overrightarrow{Lt}$(m,1,d) ∈ $\vec{L}$(m x n x d). The matrix decomposition process makes the computational process efficient from the execution and memory "S" viewpoint. Here the computation takes place with one column vector from the matrix. The analytical algorithm also initializes another form of the matrix: X[0](m x 1), and for each individual d, the process workflow computes dominant and significant attributes of the Lexicon from $\overrightarrow{Lt}$(d) and further store it into [val](m x d). The dimensionality (∂) of computed feature elements gets reduced from $O(d^3) \rightarrow O(d^2)$. The execution workflow of this Algorithm 2 further checks for the noise elements (NAN) in the feature set and also performs correction of feature attributes by replacing the elements of $\vec{X}$ [0:NAN]←NAN by 0. The process of computing the adjusted and normalized feature matrix is shown with simplified execution steps below.

```
Algorithm-3: Normalization of the [val](m x d) ←$\overrightarrow{Lt}$(d)

Start
    1. Create one structure: Feature Set
    2. For each column of $\vec{L}$
        a. $\vec{L}$(m x n x d) →$\overrightarrow{Lt}$(m,1,d)
        b. X(m,1)=[0]
        c. X[val](m x d) ←$\overrightarrow{Lt}$(d)
        d. Check for NAN if found, replace it by 0, X [0:
           NAN]←NAN
End
```

Algorithm-3 computationally executes the normalization of the feature lexicon from the dictionary attributes, making them suitable to train the proposed model with higher efficiency and optimized computation. Here, the appropriate feature lexicons also improve the learning-based performance towards the accuracy of event detection. In this computing stage, the proposed model also incorporates another cost-effective approach of feature lexicon approximation by defining several clusters in k. Here the system invokes a functional segment $f_{\mathbf{NNLS}}$ (): to be operated on the normalized feature lexicon vector X[val] (m x d). Finally, the computed factorize multivariate lexicon blocks of learning-based features are evaluated by the functional component of the non-negative least square approach, which optimizes the non-negative factorization of the lexicon block matrix. The executable functional segment of $f_{\mathbf{NNLS}}$ () is further discussed in the subsequent section. The computed trainable lexicon vector features are then stored in a structure called $\overrightarrow{\mathrm{Fv}}$*({features}* and it is updated. The raw form of Lexicon features Vector $\vec{X}$ (Fig. 1) before NNLS-based lexicon factorization is visualized as follows:

D. The NNLS Algorithm

The explicit function, sparse-"non-negative factorization" as S-NNF, effectively handles multivariate for the depreciation of massive matrix computation's computational resources. The algorithm for S-NNF takes the matrix of the feature vector $\overrightarrow{Fv}$. The dictionary features lexicon block as a mixed-signal to factorize organized as samples in the column and features in a row with clusters (k).

```
Algorithm-4:The NNLS Algorithm
Input:$\overrightarrow{\boldsymbol{Fv}}$ , k
Output: $(\overrightarrow{\boldsymbol{Fv}})\boldsymbol{res}$
Process:
Start:
$\vec{Y}$← Matrix with random value
        for each iteration
                $\vec{A}$← (Moore-pseudo inverse $\vec{Y}$) x $\overrightarrow{\boldsymbol{Fv}}$
                Update normalized ($\vec{A}$)
                $\vec{Y}$←$f$(Ae,$(\overrightarrow{Fv})o$) // function for solution of least square
                        Initialize, a large value of Xp
                        $(\overrightarrow{Fv})c$←$\vec{A}$ x $\vec{Y}$
                        $(\overrightarrow{Fv})f$←$f((\overrightarrow{Fv})p - (\overrightarrow{Fv})c)$ // function for the Frobenius norm
                        Update$(\overrightarrow{Fv})p$←$(\overrightarrow{Fv})c$
                        $(\overrightarrow{Fv})res$←‖$\overrightarrow{Fv}$ - $(\overrightarrow{Fv})c$ ‖
        end
End
```

The NNLS(): The $\vec{X}$ as $\overrightarrow{Fv}$contains -ve elements; therefore, directly non-negative factorization(NNF) is not applicable as in NNF, all $\vec{X}$ and its factors $\vec{W}$ and $\vec{H}$ Shall be having non-negative elements. Therefore, Semi-NNF is used. The semi-non-negative matrix factorization is a technique that learns a low-dimensional dataset representation that lends itself to a clustering interpretation.). A vector $\vec{Y}$as a matrix to hold the coefficient initially consist of random values with the number of rows is equal to the number of clusters(k) and the number of the columns as the number of columns of $\overrightarrow{Fv}$ and another vector $\vec{A}$ As a base matrix. In each iteration of computation, the Moore-pseudo inverse of the Vector $\vec{Y}$ updates the value of $\vec{A}$ after multiplying to the $\overrightarrow{Fv}$ and gets normalized $\vec{A}$. The parameter Ae and $(\overrightarrow{Fv})o$ is taken as an input argument to an algorithm for the solution of the NN-constraint least square problem (LSP) [AR]. With the value of the $\vec{A}$ based on the Ae and $(\overrightarrow{Fv})o$, this algorithm solves for the optimal value of the K in a least-square using equation (4).

$$\mathrm{Ae} = (\overrightarrow{Fv})o \times \mathrm{K} \tag{4}$$

In the problem of Min ‖ Ae - $(\overrightarrow{Fv})o$ x K ‖ such that K≥ 0 for a given Ae and $(\overrightarrow{Fv})o$. A considerable value of the previous fit value $(\overrightarrow{Fv})p$and the current fit value $(\overrightarrow{Fv})c$ = $\vec{A}$ x $\vec{Y}$ provides the Frobenius norm to give the fittest result $(\overrightarrow{Fv})f$ and the current fit value is updated as a previous fit value, and finally, the final residual $(\overrightarrow{Fv})res$ is gets updated using equation (5).

$$(\overrightarrow{Fv})res \leftarrow \| \overrightarrow{Fv} - (\overrightarrow{Fv})c \| \tag{5}$$

The updated value of the final residual as $(\overrightarrow{Fv})res$ at every iteration are computed where the proposed NNLS algorithm optimizes the factorization approach and computes the learning based-features of lexicon blocks in $(\overrightarrow{Fv})res$ after the completion of the training. The proposed system further extracts the test data (GT←$\mathrm{D}_{\mathrm{test}}$) from the repository location (R_1). The process also checks for the GT dimension and converts it into greyscale form with the dimension of (∂). Here the study invokes an explicit function f_{t}(x) to test the S-NNF of the least square, which is obtained as $(\overrightarrow{Fv})res$. The study further discussed the explicit functions of ground truth (GT) computation solution considering the formulated approach.

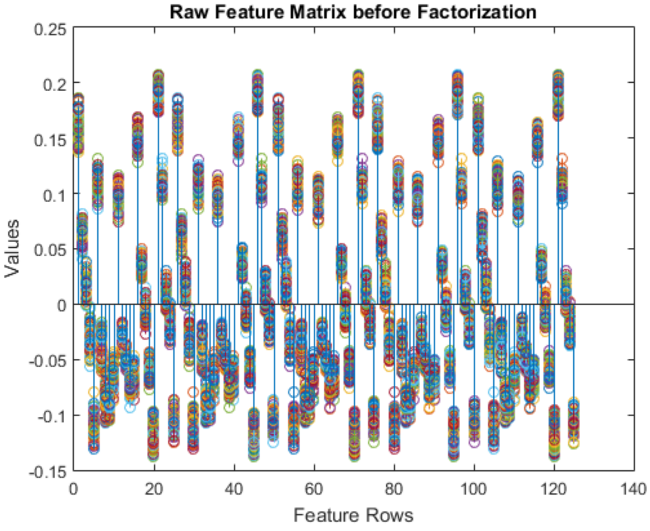

Fig. 1. Visualization of Feature Elements of the Lexicon Vector $\vec{X}$.

Explicit $f_t(x)$ to test the S-NNF of least square with GT

```
Input: GT, $bw$ ←DFL{} , $(\overrightarrow{Fv})res,\ d$
Output: Updated $bw$ ←DFL{}, $d$
Process start:
        Initialize: GT, $bw$ ←DFL{} , $(\overrightarrow{Fv})res,\ d$
        $p \leftarrow R(GT)$
        $C \leftarrow con(1, p)$
        $if\ C \rightarrow$ []
                $Compute: c1 \rightarrow C(row, 1)$
                $Normalize \rightarrow range(\ C1)$
                $Compute: c2 \rightarrow C(row, 2)$
                $Normalize \rightarrow range(\ C2)$
                $update: bw \leftarrow\ Obj(bw)$ $[func\_in: bw, c1, c2]$
        $else$
                $update: bw \leftarrow\ Z[size(GT)]$
        $end$
        $perform\ gt \leftarrow\ bwMO(GT)$
        $bw \leftarrow\ bw \times gt$
        $update: bw \leftarrow DFL(d)$
End
```

In this process, the system initially computes the GT as a binarize form of the D_{test} from the greyscale matrix. The approach here also considers the lexicon properties of DFL for the test sequence generation. Initially, the function computes the region properties from the centroid matrix corresponding to the GT. Further, the function $f_t(x)$ also performs concatenation on the centroid factor of computed region properties and stores the numerical values into a vector *C*. Further algorithmically, the computational process also assesses a conditional check on this computed Vector C. If it finds C as an empty matrix, it computes the 1st column values corresponding to *C* and stores it into another variable, *c1*. The range of *c1* is also get adjusted for ease of computation. Further, the system also computes another variable, c2, from the second column of *C* and adjusts the range of *c2*. Here the function f_t(x) invokes another function to identify the objects in the binary form of an image that overlaps with the pixel attributes (pi). The function here considers bw, c1, and c2 for the execution purpose. Else the process constructs a vector of zeros for bw with the size of the matrix GT. Finally, the computational process applies morphological operations on the pixel of the binary image to identify the Obj and update the bw matrix form. In the ground truth (GT), the contiguous region is considered a connected component, sometimes known as blobs. An example of a label matrix containing the blobs is as in the following Table II:

TABLE II. LABEL MATRIX

1	1	0	2	2	0	3
1	1	0	2	2	0	3

It returns a [1 x n] vector that specifies the center of the region's area. The very first element of the centroid is the x-coordinate and the second element is the y-coordinate. The study further incorporates another functional module, *f_m(x),* to compute the Moore-pseudo inverse $\vec{Y}$ concerning $\overrightarrow{Fv}$ as shown in the above algorithm-4 for NNLS computation and optimization procedure. This explicit function computation is discussed as follows.

Explicit $f_m(x)$ to compute Moore-pseudo inverse $\vec{Y}$

```
Input: $\vec{Y}$ , $\overrightarrow{\boldsymbol{Fv}}$ , $\delta$
Output: $\vec{A}$
Process start:
        Init: $\vec{Y}$ , $\overrightarrow{\boldsymbol{Fv}}$ , $\delta$
        Compute: [$row$, $col$] ←size( $\vec{Y}$) matrix form
        Check: func: input $arg$
        If $arg$ <2
                If ($row$ < $col$)
                        $\vec{A} \leftarrow \frac{(\overrightarrow{\vec{Y}' \times \vec{Y}})}{\vec{Y}'}$
                Else
                        $\vec{A} \leftarrow \frac{\vec{Y}'}{(\overrightarrow{\vec{Y}' \times \vec{Y}})}$
        End
        If ($row$ < $col$)
                $\vec{A} \leftarrow \frac{1}{\delta} \times \sum \mathrm{I(col)}, \vec{Y}'/\vec{Y}' \times \vec{Y}$
        Else
                $\vec{A} \leftarrow \frac{\vec{Y}'}{\frac{1}{\delta} \times \sum \mathrm{I(col)}, \vec{Y}' \times \vec{Y}}$
        End
```

The above function for Moore-pseudo inverse computation is analytically modeled in such a way that it takes $\vec{Y}$, $\overrightarrow{Fv}\ \delta$ as inputs here δ refers to a scalar parameter that produces a stable outcome during the computation, and its value should be tremendous. Further, the process computes the size of the matrix form of $\vec{Y}$ and according to the conditional check, it executes the numerical computation of pseudo-inverse and stores it into $\vec{A}$ in the inverse computed form. The system was further subjected to compute another functional module $f_{norm}(x)$ for the Frobenius norm computation considering $(\overrightarrow{Fv})c$ as input which is the normalized form of the computed Vector $\vec{A}$. The following eq can obtain the computation of the Frobenius norm. (1).

$$\overrightarrow{Fv} \leftarrow \sqrt{\sum\sum(\overrightarrow{Fv})c^2} \qquad (6)$$

The system computes the Frobenius norm during the execution of the proposed NNLS algorithm to strengthen the feature computation and training procedure. It also applies another functional strategy of fast combinatorial to deal with the optimization problem of least square execution mode in NNLS. The function $\boldsymbol{f_O(x)}$ here adjusts the least square problem in $\vec{A}$e and computes a solution matrix k in the form of $\vec{Y}$ During the execution mode of NNLS. For an optimal matrix of $\vec{Y}$ computation, the function $\boldsymbol{f_O(x)}$ takes the input parameters $\vec{A}$e and defined coefficient matrix from $(\overrightarrow{Fv})o$. The optimization problem for the function $\boldsymbol{f_O(x)}$ is formulated as:

$$Min\ f_O(x) \rightarrow ||\vec{A}\mathrm{e}-, (\overrightarrow{Fv})o \times k \qquad (7)$$

$$subjected\ k \geq 0\ for\ given\ \vec{A}\mathrm{e}(\overrightarrow{Fv})o,$$

The proposed solution in $\vec{Y}$ in the form of k obtained from minimizing the function $f_O(x)$, the study here also checked whether the proposed NNLS algorithm converged properly toward the optimality of $\vec{Y}$. The formulated learning model based on NNLS also computes a scalar *K* for linear kernel computation. It constructs a function $f_K(x)$ to compute K, that is, kernel vector concerning column vectors of $c1, c2$. The function $f_K(x)$ is explicitly designed as follows:

Explicit $f_K(x)$ to compute linear kernel matrix

```
Input: $c1, c2$
Output: $K$
Process start:
        Init: $c1, c2$
        If size (c1) >1
                $c1 \leftarrow m(c1,3)$
                $c2 \leftarrow m(c2,3)$
                $c1 \leftarrow c1'$
                $c2 \leftarrow c2'$
        End
        $K \leftarrow c1' \times c2$
End
```

The function here computes a linear kernel matrix to ease the identification of unusual objects during the tracking phase. The formulated approach computes two distinct column vectors and performs normalization of column vectors with a function $m(x)$. Finally, the product of $c1'c2$ are stored into K as a linear kernel matrix. The study constructs another function, $f_{KM}(x)$, to compute the kernel matrix for different kernel functions. Finally, for the computation of the kernel function, the $f_{KM}(x)$ evaluates the kernel function to retain the value of K. The next segment of the study discusses the experimental outcome obtained for different random test instances during the model evaluation and validation phase considering test sequence exploration concerning GT and the context of tracking unusual events.

V. Result Analysis

The study performs an extensive numerical analysis by investigating the outcome of a block-shift feature algorithm-based learning model for tracking unusual object movement from a video sequence. Every functional module associated with the formulated approach is evaluated with numerical modeling and a systematic execution flow. The optimized version of the proposed NNLS algorithm for S-NNF converges towards a fixed point. It helps in efficient and faster tracking of the motion patterns associated with the non-pedestrian entities. The study refers to the dataset in [38] for the block-shift feature-based framework's entire design and numerical analysis phase.

A. Analysis of the Dataset for the Experiment

The dataset contains a set of training videos and testing videos as GT for validation, and also it consists of cumulatively 5000 frame sequences for videos. Here, each video data was captured through a camera installed on the roadside to record pedestrians' feeds and the non-pedestrian pattern of movement, which is also considered an unusual movement in this study. Here, during the numerical modeling and computation of scene sequences and dictionary lexicon block extraction, it is realized that each of the moving scene sequences is composed of a set of people walking on streets and moving in two directions. Among the crowd of people, the prime role of the formulated NNLS-based approach is to track significant unusual events in the form of the non-pedestrian pattern of movement and dynamic movement of the pedestrian. The dataset of video sequences also consists of metadata annotation and a GT set of sequences in test data form. Here the annotation form of metadata indicates binary flags for each video scene. The prime intention here is to objectify the significant events to be tracked. Here unusual event tracking belongs to a cart between pedestrians, a wheelchair rolling in sideways, skaters moving in between the walking way, and a biker). The numerical modeling-based framework assesses different training and test instances to validate the performance of an NNLS-based formulated unique event tracking algorithm. It also assesses the algorithm's capability to differentiate the significant events (i.e., unusual events) from normal circumstances (i.e., pedestrians walking on the road). The visualization of the outcome for the video sequence exploration phase partially has already been shown in Fig. 2 above for training and testing sequences of random video scenes. Fig. 2 shows the unexpected visual outcome for feature block extraction during the extended video sequence exploration phase.

Fig. 2 shows the random visuals of scenes involving pedestrians on the road for a different set of training sequences in the event tracking dataset. The data of random visuals are generated during the execution of algorithm-1 for the lexicon block extraction process and feature selection modeling processes. Every algorithm modeling is analytically simplified so that the formulated learning model based on the NNLS algorithm does not encounter convergence problems during the feature evaluation process during run-time. The dataset computed post feature extraction process subjected the NNLS optimization procedure to converge towards optimal DFL with properly trained classes. During the training procedure, the visuals of unusual events are learned, tracked with the appropriate feature modeling, and reposited and indexed with the composition of a matrix set in the subsequent computation process. The proposed system of NNLS-based computation results in a single form of matrix composition with the outcome of training, making the evaluation and validation process computationally faster during run-time. The visuals of the unusual tracing of objects using the block shift feature algorithm are as follows in Fig. 3.

Fig. 3 shows the tracking visuals of the unusual movement of an object using the proposed NNLS algorithm. The validation phase is carried out concerning the computed GT, generated with the explicit function ft(x). To measure the effectiveness of the proposed tracking algorithm, the performance parameters are compared with a highly cited related study by Fang et al. [39], in which the learning model is designed based on deep learning. The comparative outcome in figure xx shows that the formulated approach attains better unusual event tracking accuracy concerning the performance parameters such as recall factor, precision score, specificity score, F1-score, and algorithm execution time. The interpretation of figure xx clearly shows that the formulated NNLS attain a significantly lesser processing time for execution, approximately 0.266621 sec.

(b) Color map of the tracked scene

Fig. 3. Tracking Visuals for Training Data-1 in different Frame Instances with the Colormap.

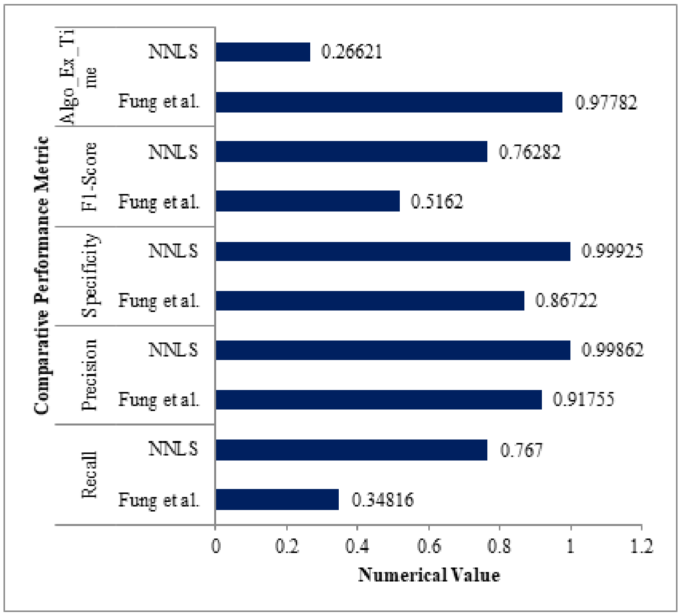

Fig. 4. Comparable Outcomes for the Effectiveness Measure in Comparison with Fang et al. [39].

In contrast, the deep learning-based model in Fang et al. [39] takes a comparatively higher computing time execution of approximately 0.97782 sec. The numerical assessment for the comparative analysis is performed in a similar test environment. The relative performance outcome is shown in the following Fig. 4.

The prime reason behind the effectiveness of the outcome corresponding to the formulated approach NNLS is that it has a lower dependency on the computational resources, unlike the deep learning models. The deep learning-based models have a more considerable dependency on the quantity of the training data set, which can attain accuracy but compromise the computational performance. However, the formulated NNLS-based tracking approach intelligently extracts features and poses lower dependency on the training images with faster execution in run time, making it suitable for real-time video tracking applications.

VI. Conclusion

This paper introduces an efficient scheme of unusual movement tracking from video sequences considering a novel block-shift feature and NNLS algorithm. The study finds a standard dataset of different video sets where the scenes comprise crowd and pedestrian movements. The underlying motive behind this research study is to track the unusual dynamics associated with a mobile object that differs from the pedestrian movement pattern. The proposed research introduces an efficient feature extraction algorithm with a block-wise feature lexicon. It optimizes the NNLS algorithm to optimize the computing and training performance of the learning model. The extensive performance outcome shows that the formulated NNLS-based approach involves training for the learning model, which doesn't include many dependencies on the computational resources and the video feeds, unlike other traditional learning models. Most conventional training models demand a comparatively larger size of trained data to accomplish better tracking accuracy. The NNLS design is optimized so that it can efficiently train with even low or medium training data and performs with higher accuracy in identifying unusual events. The formulated approach's faster and timelier execution makes it highly applicable in a practical environment.

***Abstract*—Breast cancer is mostly a female disease, but it may affect men as well even at a considerably lower percentage. An automated diagnosis system should be built for early detection because manual breast cancer diagnosis takes a long time. Doctors have lately achieved significant advances in the early identification and treatment of breast cancer in order to decrease the rate of mortality caused by the latter. Researchers, on the other hand, are analysing large amounts of complicated medical data by employing a combination of statistical and machine learning methodologies to assist clinicians in predicting breast cancer. Various machine learning approaches, including ontology-based Machine Learning methods, have lately played an essential role in medical science by building an automated system that can identify breast cancer. This study examines and evaluates the most popular machine learning algorithms, besides the ontological model based on Machine Learning. Among the classification methods investigated were Naive Bayes, Decision Tree, Logistic Regression, Support Vector Machine, Artificial Neural Network, Random Forest, and k-Nearest Neighbours. The dataset utilized has 683 instances and is available for download from the Kaggle website. The findings are assessed using performance measures generated from the confusion matrix, such as F-Measure, Accuracy, Precision, and Recall. The ontology model surpassed all machine learning techniques, according to the results.**

Keywords—Machine learning; prediction; ontology; semantic web rule language; decision tree; breast cancer

I. Introduction

In 2020, 2.3M women were identified with breast cancer, with 685 thousand fatalities worldwide. By the end of 2020, there will have been 7.8M women diagnosed with breast cancer in the previous five years, making it the most frequent kind of cancer in the world. Breast cancer claims more DALYs from women than any other kind of cancer worldwide. Breast cancer affects women of all ages after puberty in every country throughout the world, but at a rising rate in the latter stages of life. From the 1930s through the 1970s, there was minimal change in the breast cancer death rate. In nations where early diagnosis systems are available in conjunction with various treatment options to remove intrusive illnesses, life expectancies started to get better as in 1980s.

Machine learning (ML) is one of the most constantly evolving areas of computer science, with a wide range of applications [1], [2]. It is the process of obtaining usable information from a big quantity of data [3]. Marketing, Industry, Medical diagnosis, and other scientific domains all make use of ML approaches. ML algorithms are well-suited for medical data analysis since they have been frequently employed in medical datasets. ML comes in several forms, including classification, regression, and clustering. Each form has a particular consequence and influence depending on the problem that we are attempting to address. We focus on classification algorithms in our work because of their high accuracy and performance in classifying a given dataset into predetermined categories and predicting future events or information from that data. In the medical field, classification algorithms are often utilized, particularly in the diagnosis of illnesses such as breast cancer. As a result, regularly used machine learning classification methods such as Support Vector Machine (SVM), k-Nearest Neighbours (KNN), Artificial Neural Network (ANN), Naive Bayes (NB), Logistic regression (LR), and Decision Tree (DT) are utilized to detect patients with breast cancer at an early stage.

Several researches have been conducted, and various machine learning models have been implemented, to identify and predict breast cancer diagnoses [4]. For example, this study [5] sought to identify the most accurate machine learning approaches for predicting patients with breast cancer. Various supervised machine-learning algorithms, including RF, KNN, DT, AdaboostM1, LR, and ANN [6], were used and their performance was compared. The authors of this study [7], examined linear discriminant analysis with support vector machines in terms of specificity, F-Measure, accuracy, and sensitivity to see which method is better for classifying breast cancer datasets. The results reveal that the support vector machine outperforms the linear discriminant analysis, with a 98.77 percent accuracy rate. [8] This study covers the whole Bayesian technique to assess the predicted distribution of all classes using three datasets and three classifiers: naive bayes (NB), bayesian networks (BN), and tree augmented naive bayes (TAN). The outcomes showed that the BN method performed the best, with an accuracy rate of 97 percent.

Breast cancer diagnosis and prediction has garnered a lot of attention in recent years, and numerous ways have been taken to address this issue [9]–[12]. The present focus is on machine learning and the semantic web. The Wisconsin Breast Cancer Dataset was used in this study [13]. The authors' purpose is to study the dataset and assess the efficacy of several ML algorithms for predicting breast cancer. Several machine learning methods have been developed to differentiate benign and malignant tumors. To predict whether breast cancer is malignant or benign, [14] the authors used machine learning and computer vision to extract features and construct an optimized model by varying hyper-parameter values. The

*Corresponding Author.

analysis is carried out using a support vector machine, and several quality indicators are produced, with the observed findings being notable. [15] The goal of this study is to evaluate the classification algorithms' prediction accuracy in terms of efficiency and effectiveness. The authors conduct a rigorous comparison of classification algorithms such as SVM, DT, NB, and RF in terms of prediction accuracy utilizing WEKA and a 10-fold cross validation approach on the Wisconsin Diagnostic Breast Cancer dataset. In this study [16], two machine learning algorithms, Decision Tree Classifier, and Logistic Regression, were implemented for breast cancer prediction on the "Breast Cancer Wisconsin (Diagnostic) Data Set," and their accuracies were compared and the Decision Tree Classifier is the most suited-algorithm for prediction since it has a precise prediction accuracy.

Recently, researchers published a significant quantity of research utilizing machine-learning algorithms to diagnose breast cancer [17]–[20]. In this comparison study [21], 4 machine learning (ML) algorithms were used: DT classifiers, SVM, KNN, and RF, and the results show that Support Vector Machine has the highest accuracy of 97% among them for the classification of breast tumors in women. On the Wisconsin Breast Cancer dataset, [22] the authors examined five supervised machine learning algorithms: LR, RF, KNN, ANN, and SVM. The metrics of the confusion matrix are used to assess the study's performance. According to the results, the ANNs had the greatest accuracy score of 98.57 percent.

Furthermore, ontology has been one of the most widely used techniques to managing, organizing, and extracting data throughout the last few decades. It is a way of data representation that has been effectively utilized in a number of domains, particularly the medical domain. It is significant in computer science because of its ability to express many concepts and their relationships across fields. In reality, no single ontology is sufficient to meet today's expanding healthcare demands, and ontologies must be combined with machine learning algorithms to facilitate data integration and analysis. The authors in [23] created and explored an ontology-based decision tree model able to predict diabetes, [24] then compared the findings to numerous ML techniques, and discovered that the ontology model outperforms all other classifiers.

In this research, we intend to compare seven prominent classification approaches with the Ontological Model using carefully chosen criteria obtained from the confusion matrix, such as F-Measure, Accuracy, Precision, and Recall. The rest of this paper is organized as follows: Section II describes the methodologies utilized in this comparison analysis. Section III summarizes the findings and discussion. Section IV concludes and discusses future work.

II. Methods and Evaluation

The approaches and materials employed, as well as the experimental methodology, dataset description, machine learning algorithms, ontology model, and evaluation metrics, are all included in this section. Fig. 1 depicts the process flowchart for this comparative study.

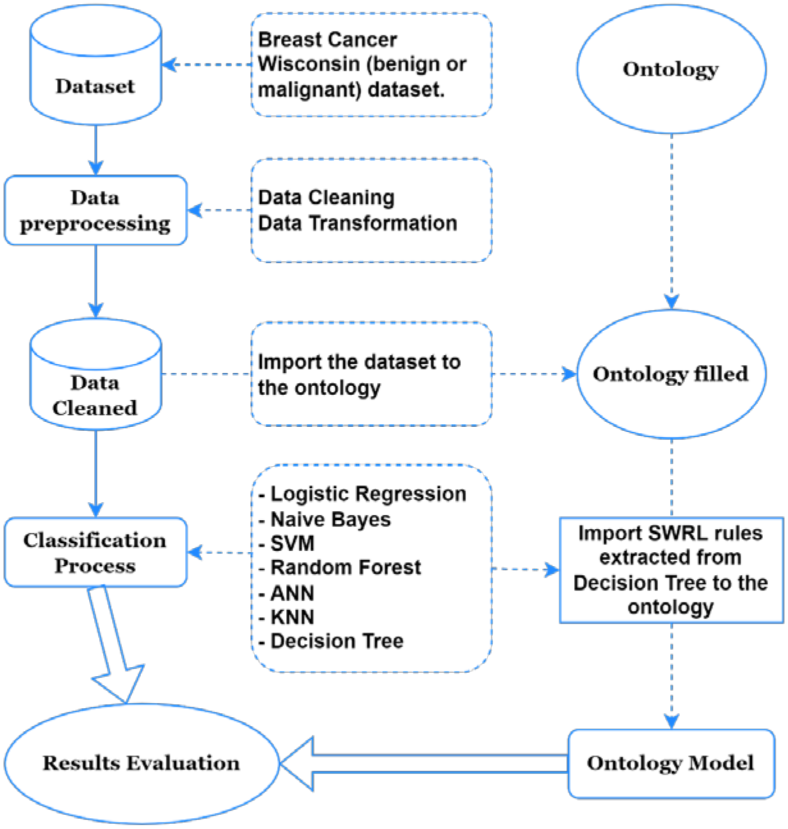

Fig. 1. Experimental Workflow.

A. *Data Preprocessing*

The dataset used is Breast Cancer Wisconsin - benign or malignant from Kaggle website, it consists of 683 instances and 10 features (9 attributes and the last one is a target). A full description of all dataset attributes is provided in Table I.

To build an effective machine learning classifier, we should always start with data cleaning, normalization of features, transformation of features, and even creation of new features from the dataset. The dataset contains 234 similar instances, after removing duplicated instances the remaining is 449 instances, where 213 represent benign cancer cells and 236 represent malignant cancer cells. We would like to inform you that in order to provide a fair comparison of the classification results obtained, we did not use any feature selection or performance-boosting methods.

B. *Machine Learning Algorithms*

We have used Weka software for all machine learning algorithms to predict whether the cancer cells are benign or malignant. Weka comprises tools for data classification, clustering, visualization, preparation, association rules mining, and regression [25].

We used the seven most classifiers used to classify datasets (Decision Tree, Random Forest, Logistic Regression, Artificial Neural Network, Naïve Bayes, Support Vector Machine, k-Nearest Neighbours). In addition, we employed two modes of test options: 10-fold cross validation and percentage split (split 50% train, remainder test) for the reason of enriching the study.

C. *Ontological Model*

This section presents the technologies used to create the ontology, besides the approach used to build the ontology model with the help of rules extracted from DT. This methodology has been referred to in this research for more details [26], which we recommend reading for more information. We'll go through some specifics shortly here.

1) Ontology construction: The ontology was built using the Protégé software, which is an open-source platform that provides a set of tools to a growing user community for constructing domain models and knowledge-based applications with ontologies. The ontology was created manually; the main classes are Diagnostic and Patient. The graphical representation of the ontology is shown in Fig. 2.

TABLE I. DATASET FEATURE'S INFORMATION

Attribute	**Description**
1- clump	Clump Thickness: Benign cells often form monolayers, whereas malignant cells frequently form multilayers.
2- ucz	Uniformity of Cell Size: Cancer cells differ in size.
3- ucp	Uniformity of Cell Shape: Cancer cells differ in form.
4- adhesion	Marginal Adhesion: Adhesion loss is an indication of cancer.
5- epithelial	Single Epithelial Cell Size: Is connected to the previously mentioned uniformity. Significantly expanded epithelial cells may be cancerous cells
6- bare_nuclei	Bare Nuclei: These are common in benign tumors.
7- bland_chromatin	Bland Chromatin: In benign cells, the nucleus has a homogenous texture.
8- normal_nucleoli	Normal Nucleoli: In normal cells, the nucleolus is generally quite tiny, if at all detectable. The nucleoli grow more visible in cancer cells.
9- mitoses	-
10- Class	Predicted class (2 for benign, 4 for malignant).

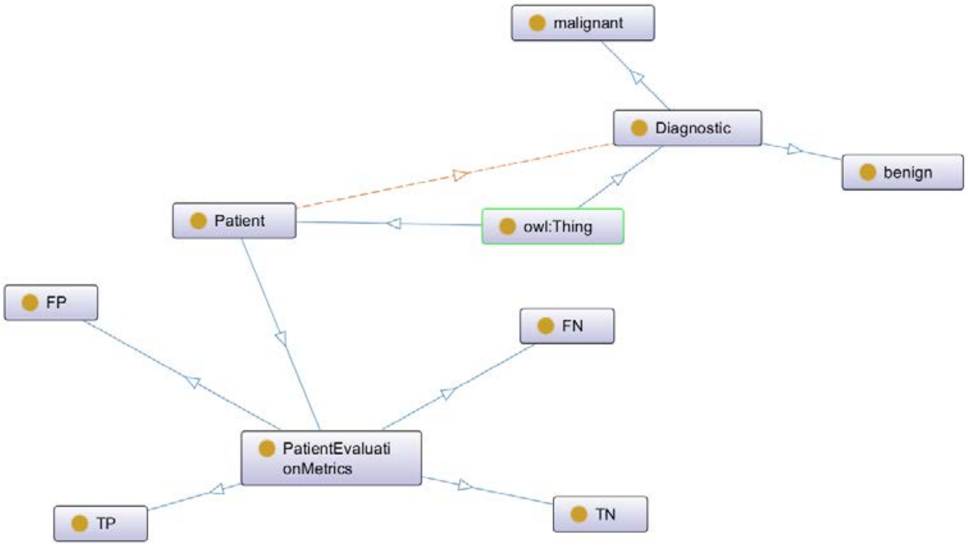

Fig. 2. The Ontology Graph.

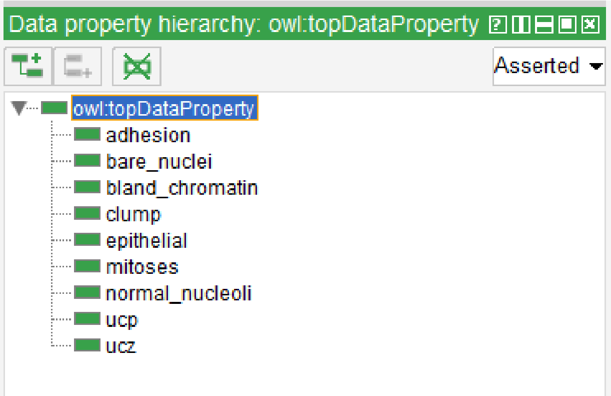

Data property hierarchy: owl:topDataProperty

- owl:topDataProperty
  - adhesion
  - bare_nuclei
  - bland_chromatin
  - clump
  - epithelial
  - mitoses
  - normal_nucleoli
  - ucp
  - ucz

Fig. 3. Data Properties.

2) Data properties and instances: The data properties used in the ontology are the same attributes presented in Table I which are used to build models of machine learning algorithms. Fig. 3 illustrates the data properties. A plugin among the Protégé software plugins called Cellfie is used to import the same dataset used in Weka.

3) Semantic web language rules and pellet reasoned: Following the creation of classes, data properties, and instances in the ontology. We need to establish the SWRL reasoning rules. To achieve this, we used the SWRLTab plugin, we retrieved created rules from the DT algorithm, and imported them into Protégé. The collected rules from the DT algorithm are converted using the Java programming language, with each leaf of the tree extracted as a single SWRL rule. For instance/

<u>A leaf from the DT algorithm</u>
If ucp > 2 && ucz ≤ 4 && bare_nuclei ≤ 2 && adhesion ≤ 3 THEN put the patient in benign

<u>SWRL resulted</u>
Patient(?P) ^ ucp(?P, ?UCP) ^ swrlb:greaterThan(?UCP, '2'^^xsd:decimal) ^ ucz(?P, ?UCZ) ^ swrlb:lessThanOrEqual(?UCZ, '4'^^xsd:decimal) ^ bare_nuclei(?P, ?BN) ^ swrlb:lessThanOrEqual(?BN, '2'^^xsd:decimal) ^ adhesion(?P, ?A) ^ swrlb:lessThanOrEqual(?A, '3'^^xsd:decimal) → benign

To execute SWRL rules and infer new ontology axioms we utilized another plugin from Protégé software named Pellet [27], which includes capabilities for checking ontology coherence, deals with SWRL rules, computing the classification hierarchy, deals with OWL, explaining inferences, and answering SPARQL queries. It uses the Ontology and SWRL rules to initiate the inference and then determines if the cancer cells are benign or malignant. The ontology classifier's results are reported in the next section.

D. Evaluation

ROC Area, F-Measure, Root mean squared error, Recall, Accuracy, Root relative squared error, Precision, Kappa statistic, and other performance measures are employed to assess ML algorithms. We employed two test modes (split-test and K-fold cross-validation) using several metrics including Recall, F-Measure, Accuracy, and Precision to analyze our experimental results, which are presented below and in Fig. 4. Furthermore, the same criteria are utilized to assess the validity of this comparison research including ML classifiers and the ontological model.

$$\mathrm{ACC} = \frac{\mathrm{TP+TN}}{\mathrm{TP+TN+FP+FN}} \quad (1)$$

$$\mathrm{PREC} = \frac{\mathrm{TP}}{\mathrm{TP+FP}} \quad (2)$$

$$REC = \frac{TP}{TP+FN} \quad (3)$$

$$\text{F-Measure} = 2 * \frac{PREC * REC}{PREC+REC} \quad (4)$$

Other metrics, such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE), are available but are most commonly employed in regression issues. As a result, owing to classification issues imposed by the dataset and techniques employed.

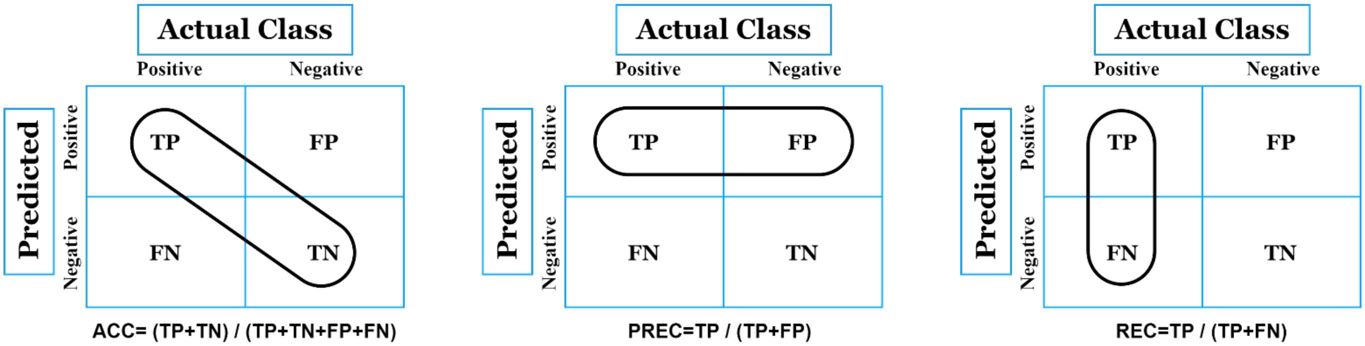

Fig. 4. Performance Metrics.

III. Results and Discussion

In this section, the results of the evaluation of the various classifiers that were used in this study are presented. The statistics and results of the ontological model are also shown in Tables II, III, and Fig. 5 illustrates the performance metrics of the ontology model.

The results of this study provide a visual representation of the various metrics that are used in this research, such as precision, F-measure, Recall, and Accuracy, as shown in Fig. 6-9. Table IV also shows the results of the various classifiers that were used in this research.

TABLE II. 10-Fold Cross-Validation for Ontological Model

Confusion matrix		Actual class	
		positive	Negative
Predicted class	positive negative	TP : 207 FN : 9	FP : 5 TN : 228

- TP (207)

(a) 10-fold cross-validation

Individuals by type (inferred):

- benign (278)
- FN (3)
- FP (6)
- malignant (171)
- TN (117)
- TP (98)

(b) 50% split mode validation

Fig. 5. Results of Inferred Concepts.

Accuracy:

The ontological model achieved the maximum value of 96.88% and Random Forest with rate of 96.00%, and 95.30 % for both Support Vector Machine and Logistic Regression in terms of 10-fold cross-validation, according to Fig. 6 and Table IV.

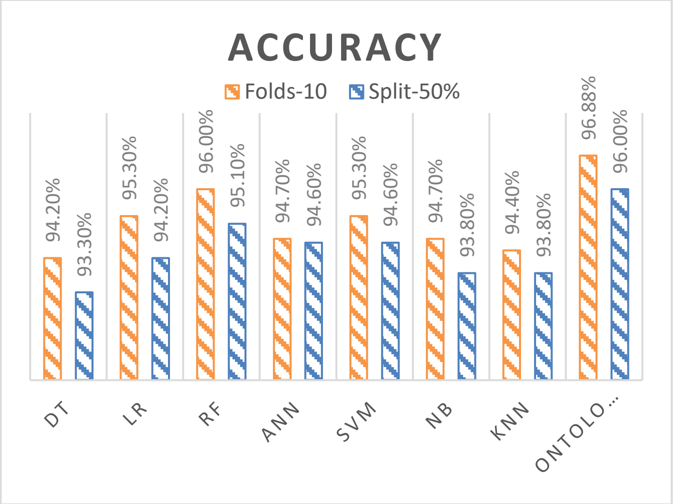

Fig. 6. Comparison Results of Accuracy.

Almost the same results using split test mode, we obtained 96.00%, 95.10% for Ontology and Random Forest consecutively, and 94.60% for both Support Vector Machine and Artificial Neural Network.

Precision:

The ontology classifier has the highest Precision of 97.64% in terms of 10-fold cross-validation mode, followed by Random Forest and Naïve Bayes. Concerning split test mode, the highest Precision value of 97.00% goes for ANN. More details are shown in Table IV and Fig. 7.

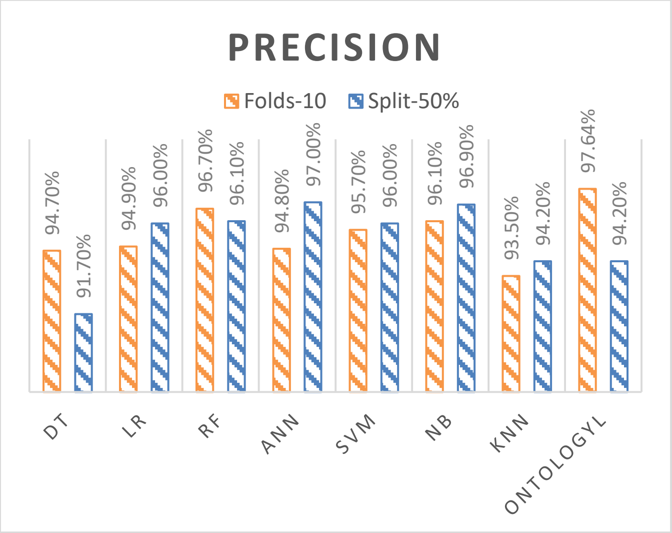

Fig. 7. Comparison Results of Precision.

Recall:

According to Fig. 8 and Table IV, the ontological model has the highest Recall values of 95.83 % and 97.00 % for both test modes, followed by RF, LR, and KNN for 10-fold cross-validation mode, and Decision Tree and Random Forest for split test mode.

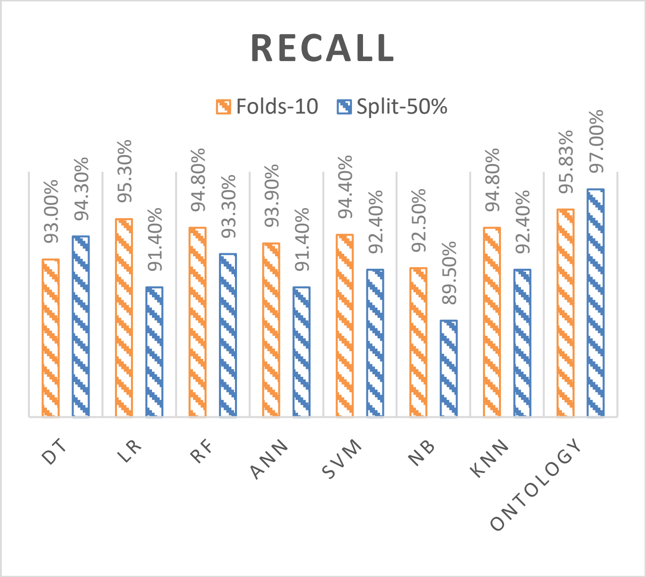

Fig. 8. Comparison Results of Recall.

F-Measure:

According to Fig. 9 and Table IV, the ontology model had the greatest value of 96 % in both test modes, followed by Random Forest in the second position and Support Vector Machine in the third position.

The experimental findings reveal that the ontology model has the highest accuracy of 96.9 %, followed by the Random Forest at 96.00 % and both Logistic Regression and Support Vector Machine at 95.30 %. In terms of the data stated above, we see no significant difference between 50%-Split and 10-Folds test modes. We conclude that the ontological model can aid by extending the scope machine learning model. They can comprise any data kind or variation, and each diver data can be assigned to a certain job. Combining the ontological model with machine learning may provide well outcomes. The ontological model achieves results that are comparable to machine learning classifiers. Humans may interpret the findings, and the rules can be modified or added as needed. Furthermore, it supports unstructured, semi-structured, and structured data formats, allowing for more seamless data integration. It can comprise all aspects of the data modeling process, starting with schemas at the most basic level. As a result, they can handle the massive amounts of data utilized as input for machine learning training or output as outcomes. Furthermore, ontology matches any organization's aim, which might be mathematical, logical, or semantic-based. To the best of our knowledge, this is the first comparative study of the ontological model and ML in which we have integrated the ontology with ML, especially in the area of breast cancer detection. As a result, no significant comparison can be done.

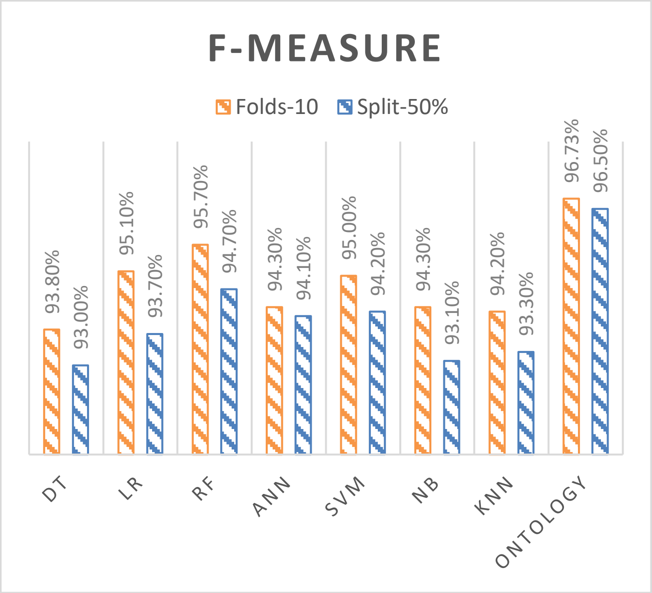

Fig. 9. F-Measure Comparison Findings.

TABLE IV. ONTOLOGICAL MODEL AND MACHINE LEARNING CLASSIFIERS RESULTS

	Accuracy		**Precision**		**Recall**		**F-Measure**	
	Folds-10	Split-50%	Folds-10	Split-50%	Folds-10	Split-50%	Folds-10	Split-50%
DT	0.942	0.933	0.947	0.917	0.93	0.943	0.938	0.93

Ontology	0.969	0.960	0.976	0.942	0.958	0.970	0.967	0.965

IV. Conclusion

ML methods are widely employed in all scientific disciplines and have revolutionized industries all over the world. The use of machine learning techniques and algorithms in healthcare has recently advanced significantly. These approaches have shown success and may be valuable in the treatment of enduring diseases such as breast cancer. Furthermore, the Semantic Web has proven its usefulness and effectiveness in a multitude of areas, including health. As a Semantic Web component, ontology has the capability to treat concepts and relationships in the same way that humans view connected concepts.

In this research, we provided seven machine learning algorithms and an ontology model, as well as a comparison of their performance. Furthermore, two test modes are employed: 10-fold cross validation and percentage split, and several performance measures such as Accuracy, F-Measure, Precision, and Recall are employed to assess the outcomes. The findings show that the ontological model has the uppermost accuracy even when no feature selection is used. This brings us to a new search area, to which we advise and urge academics to participate and produce new insights in the same context, in order to provide additional outcomes and analysis, in order to make a forecast, recommendation, or decision, and so on. In future work, we want to improve this comparison analysis by adopting new ways to incorporate ML rules with the ontological model method, as well as regression machine learning algorithms.

An Intelligent Transport System in VANET using Proxima Analysis

Satyanarayana Raju K[1], Dr. Selvakumar K[2]
Department of Information Technology, Annamalai University, Chidhambaram, India

***Abstract*—There is no proper structure for Vehicular ad hoc networks (VANETs). VANET generates several mobility vehicles that move in different directions by connecting the vehicles and transferring the data between the source and destination which is very useful information. In this system, a small network is created with vehicles and other devices that behave like nodes in the network. Sometimes for better communication, VANET uses suitable hardware for improving the performance of the network. Reliability is one of the significant tasks that perform the needful operations and methods based on the conditions at a specific time. To disturb the VANETS, the attacker tries to hit the server and that causes damage to the server. This paper mainly focused on detecting the falsification nodes by analyzing the behavior of the models. In this paper, an improved intelligent transportation system (ITS) Proxima analysis is introduced to find the accurate falsification nodes. The proposed approach is the integration of KNN and RF with Proxima analysis. The main aim of the Proxima is to analyze the falsification nodes within the network and improve the mobility of the vehicles by sending source to destination without any miscommunication.**

Keywords—Vehicular Ad hoc Network (VANET); intelligent transportation system (ITS); KNN; RF

I. Introduction

VANETs is a very fast-growing field in wireless technology. VANET is considered as a sub-class of MANET in which the moving vehicles are considered as nodes or routers which are used to exchange the messages between the vehicles or access points. All the vehicles in this network are connected within the range of 100 to 900 meters by using 802.11p. This network will support both vehicles to a vehicle (V2V) and vehicle to infrastructure (V2I) for better communication within the network. The proposed approach ITS is used to increase road safety and provides a better travel experience for driver and passengers [1], [2].

Generally, VANET can increase traffic safety and effectiveness. Before starting the VANET network, privacy and security are two issues that are addressed before starting the network and data transmission [3]. In security, authentication is one of the significant tasks to provide privacy for the nodes present in the VANET network. With anonymous authentication, the network has to face challenges in verifying the vehicles in the network. This leads to a loss of data and communication between the vehicles [4]. This also fails to verify the huge data per second in VANETs. In VANETs, several advantages for routing protocols are identified based on the nature of the vehicle movements. A lot of research has been done on the issues of routing protocols such as scalability and reliability around the urban VANETs [5]. Nowadays Intelligent transportation systems (ITSs) are becoming more popular for connecting vehicles very efficiently and with better coordination. ITS's is the internal part of the VANET. This technique is mainly used to transfer the data between the nodes to improve security, efficiency, and reliability. VANETs are the sub-domain in the mobile ad-hoc networks (MANETs) and these are the integral parts of the ITSs. Strongly interconnected vehicles are used to sense the data and transfer the data based on location, traffic, environment, and urgent services [6].

VANET is showing attention because of several significant applications that are related to road safety and control of traffic. VANET mainly focused on improving road safety and controlling traffic. In smart cities, a lot of problems occur due to the heavy traffic due to the falsification nodes or vehicles. Falsification nodes create a lot of network damage that will lose the data which is transferred by the vehicles. By detecting the falsification nodes the Intelligent Transportation System (ITS) will improve the routing in the network. Based on the behavior of the vehicles falsifications vehicles are detected.

Fig. 1 shows the sample vehicles in the VANET's by using the SUMO simulator. All the yellow vehicles are normal vehicles that are having mobility. Fig. 2 shows the process of visualizing the VANET network by applying the proposed approach and its functionalities.

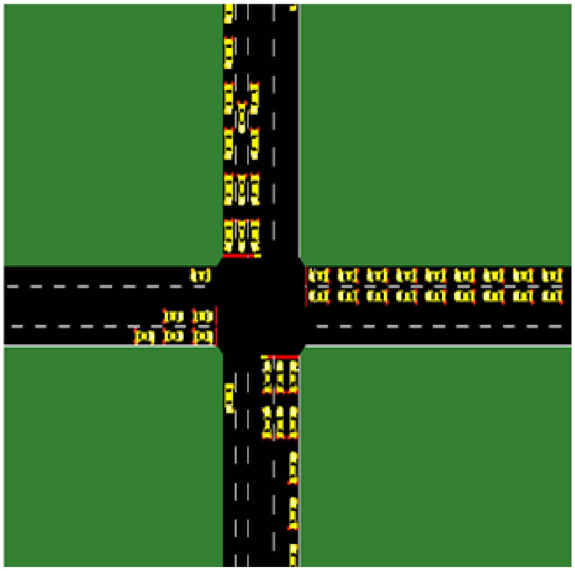

Fig. 1. Shows the Mobility of the Vehicles according to the Signals.

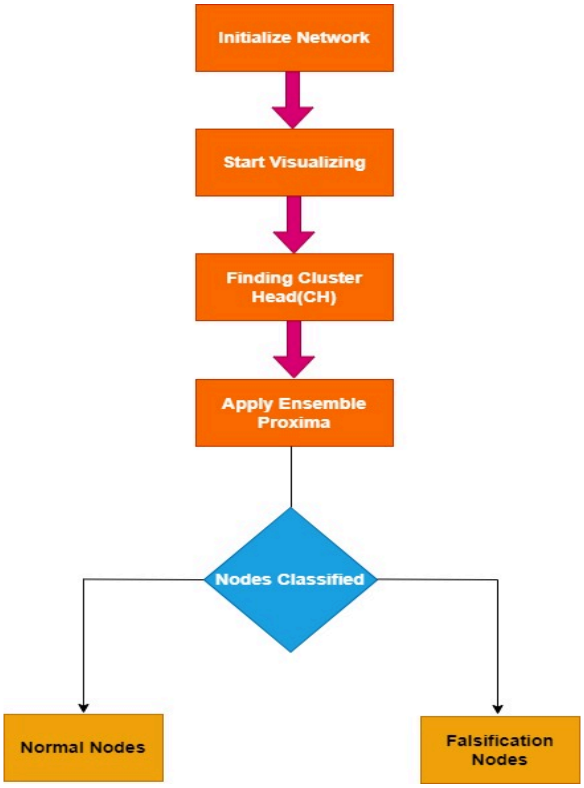

Fig. 2. Steps for Processing of Improved Intelligent Transportation System (ITS) Proxima Analysis.

II. Literature Survey

Over the last few years, Intelligent Transportation Systems (ITS) is showing an improvement in the movements of vehicles on the roads. The aim of the ITS is to provide better and more comfortable driving for the VANET vehicles that are present in the network by updating the information about the roads. Over the past many years, many researchers developed several approaches that are discussed in this section.

A. Ullah et al., [7] presented the location-based routing (LBR) protocol which is used to present the taxonomy. This approach is focused on analyzing the parked vehicles that are nearer to the junction for the selection of the path. This approach supports only less packet delivery, delay, and data transmission time and is more expensive. Abu Talib et al., [8] presented various security issues and solutions for the various issues and challenges in VANETs. This article also discussed the various types of attacks and various solutions that are implemented by solving several threats and shows the performance.

Abdul Quyoom et al., [9] proposed the ITS which is integrated with multifunctional system that collects a huge amount of data from several resources: Vision-Driven ITS (the sample data is collected from various visual sensors and utilized the vehicle and pedestrian detection); Multisource-Driven ITS (inductive, laser and GPS detectors); Learning-Driven ITS (this will reduce the collisions between the vehicles); and Visual-Driven ITS (this is used to find the abnormal traffic patterns and take required measures).

J. Cui et al., [10] introduced the adaptive approach that controls the traffic based on the communication among the cars. This system reduces the waiting time of the vehicles that are interacted with the decrease in queue length. To increase this system, clustering is adopted by utilizing the intersection of vehicles. By using this approach, the density of vehicles that are present in the cluster is calculated by using the clustering approach. The DBCV approach is used to increase the accuracy of the results. This approach is a combination of cluster and strategic diffusion methods which is utilized and collects the density information. Based on the movement and directions the clusters are formed within the region. By using the GPS and maps the direction of the vehicles is measured.

Saif Al-Sultan et al. [11] control the systems that are based on the other vehicles' data. Every vehicle is designed with a short communication device that controls the nodes that are combined with traffic lights. The node that controls this system plays the adaptive signal system. VANETs characteristics makes security and trust management as challenging issues. Different types of security threats and attacks persist in VANET [12].

III. Several Types of Attacks that Occur at the Simulation Time

Denial of Service (DoS) is an attack that can occur in the network [13]. There are two types of attackers, inside attacker and outside attacker. An inside attacker can jam the network by transmitting fake messages and stopping the network connections. The outside attacker continuously circulates the fake messages with fake signatures that use the bandwidth or other resources of a targeted vehicle. With this attack, VANET loses the ability to give services to the actual vehicles [14]. The main aim of this attack is to send the fake message to TSU and also to the actual vehicle to create a jam in the network.

The malicious nodes in the black hole attack [15], try to have the best route for the destination node and show that the data should transfer from this route by transferring the fake route information. A malicious node in this attack mainly drops or misuses the stopped packets without sending them to anyone [16]. This attack mainly creates the black hole area that creates the number of malicious vehicles and they are not interested to receive the messages from the actual vehicles [17].

Malicious vehicles in Wormhole attack [18], received the data at one point and replay it with another malicious vehicle by utilizing a wormhole high-speed link (tunnel) and data transfer from source to destination continuous by using malicious vehicles. This attack shows the huge impact on preventing finding the valid routes & menaces the security by transferring data packets. In this attack, the tunnel is used to broadcast the secret information by using two malicious vehicles.

The malicious vehicles in the sinkhole attack telecast the dummy routing information within the network [19]. This can easily attract the network traffic towards routing. This attack shows the huge impact on the network that complicates and reduces the performance by changing the data packets or dropping the packets [20]. The malicious vehicles in this network drop the data packets that are received from the authorized vehicle & telecast the fake routing info to the authorized vehicles on backside [21].

The malicious vehicles in the Sybil attack create a huge number of fake signatures that take overall control of VANET and insert the fake data in the network to threaten the legal vehicles. This attack will create the illusion among the multiple vehicles that creates a huge impact on the VANET network. This attack shows the huge impact on the network because of spoofing the signatures or places of other vehicles in the vehicular network [22]. This attack aims to create the fake identities of multiple vehicles and generates huge vehicles on the network [23].

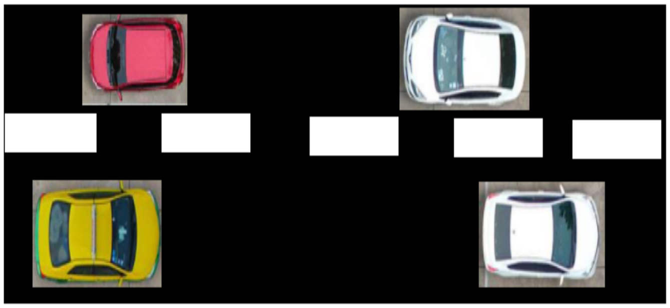

Fig. 3. In this Network Red Color Vehicle is considered as Malicious Node and other Vehicles are Normal Vehicles.

A. Random Forest (RF) for Detecting the Falsification Nodes

Random Forest (RF) is one of the hybrid approaches that follows the rule of bagging. It is an ensemble approach. Fig. 3 shows the normal nodes and malicious nodes by representing the malicious node with red color and normal vehicles are represented with white and yellow. This approach is a continuation of the decision tree (DT). DT is used to develop the information gain technique represented in Equation 1 and Equation 2.

To calculate the entropy value at every vehicle the equation (1) is given below:

$$\mathrm{E(s)} = \sum \mathrm{p_i log_2 p_i} \tag{1}$$

After entropy is calculated, the information gain is measured at every attribute to get the better decision for the vehicles.

$$\mathrm{Gain(S, A)} = \mathrm{Entropy(S)} - \frac{\Sigma_{\mathrm{v \in values(A)}} |\mathrm{S_v}|}{|\mathrm{S}|\mathrm{Entropy}} (\mathrm{S_v}) \tag{2}$$

Based on the entropy value the vehicles are classified according to the behavior.

The output of the random forest is given as an input to the KNN approach for filtering the falsification nodes according to the distance measure.

B. Applying KNN for RF Output Vehicles

KNN is one of the significant approaches used to classify the complex dataset. This is one of the better approaches for detecting the falsification nodes. Better training is given to the system for effective output. This approach analyzes the behavior of the vehicles in the real-time network. Based on the distance and direction the training generates better properties from the nodes. From the moving vehicles, the test runs are measured when the vehicles are in the same direction, different directions, and the location of vehicles are collected. For training, the dataset is utilized for the KNN model. If any abnormal behavior is identified among the vehicles, the distance and directions are identified as an input to the KNN classifier. The outputs of the KNN are represented as 0 or 1. 0 indicates the dangerous node and 1 indicates the safe. The KNN Algorithm Pseudocode:

```
1. Training and testing data is loaded
2. K-value is selected.
3. Every point in test data:
    ➢ Euclidean distance is used for training data points
      such as (a, b) and (-a, -b).

$d = \sqrt[2]{(a^2 + b^2}$                                   (3)

    ➢ List of Euclidean distances are stored and sorted.
    ➢ First k points are chosen.
    ➢ Based on the majority the class is assigned.

4. End
```

Above algorithm represents, K=5 i.e. five nearest neighbors are compared for every instance that requires to be classified. Hence it is known that the nearest vehicles are considered as normal vehicles and other vehicles are falsification vehicles based on the distance.

C. Measuring the Falsification Vehicles in the VANETs

In this paper, the proposed approach mainly focused on measuring the optimized routing by using proxima analysis. This approach considered the output of the KNN for proxima analysis. Proxima analysis is mainly focused on measuring the distance among the vehicles in the network. In this scenario, a proximity sensor plays the major role in detecting the distance among the vehicles and analyses the movement of vehicles. Here, the clustering head plays the major role to detect the abnormal vehicle.

- If the vehicle is having abnormal behavior then the vehicle drops or fakes the data packets received to create congestion in the network and mislead the vehicles and damage the malicious messages for their purpose.

- Truthful nodes forward the correct messages to the several nodes in the network and create the accurate messages for transmission.

- The main aim of this system is to monitor the behavior of the network. The monitoring process of the vehicles is called as “verifier” vehicles. Verifier is smaller or equal to Td compared with the Td of vehicle V, and this is placed inside the region z (V, Cluster Head (CH)). The intersection region is created for both vehicles named as V and CH.

By using these steps, the verifiers are monitored with V are send reports to CH [24]. The CH is equal to its transmission range and the V is obtained from the region and it is represented with Equation (4).

$$\text{Area (V)} = \text{TR(V)} - T_f(S_{max} - S_{min}) \tag{4}$$

Where,

S_{max} - Legal maximum speed of the vehicle. S_{min} - Legal minimum speed of the vehicle.

T_f – Packet Latency.

CH – Cluster Head.

Thus this will improve the routing of the vehicles by using proxima analysis.

Algorithm Steps for Proxima Analysis

```
Input: Nodes in the network Vehicles)
Output: Malicious Nodes (Vehicles)
Initialize variables N-Network, n-nodes or vehicles, r-region.
Step 1: $N_{mob}$-telecast the messages from all the vehicles.
Step 2: if ($N_{mob} \geq 2$)
Step 3: the mobility started it indicates presence of multiple nodes //Explains the status of the mobility
Else
Mobility not started.
Step 4: Calculate Euclidean distance by using Equation (3)
Step 5: arraylist [nearest nodes $N_n$] //Store the nearest nodes in arraylist.
Step 6: By using the given function nd_malv(Packet *p) the malicious vehicle is detected based on behavior.
if(mal==true)
{
drop(p,DROP_RTR_ROUTE_LOOP);
}
By showing the packet dropping rate the malicious nodes are identified.
Step 7: Malicious nodes are detected.
```

Table I shows the malicious and normal nodes. It is observed that in the existing approach there are missing nodes that are not considered by the existing approach. Compare with existing system approach the proposed approach detect very less missed vehicles.

TABLE I. SHOWING THE MALICIOUS AND NORMAL NODES

Total No of Nodes	Malicious Nodes		Normal Nodes	
	ES	PS	ES	PS
50	13	23	28	35
100	26	36	45	59
150	38	99	48	99
200	37	138	53	144

IV. Performance Metrics

A. Area under ROC Curve (AUC)

The overall proportion of true positives (malicious nodes accurately classified as malicious) compare with the proportion of false positives (not malicious and it is wrongly classified as malicious).

This is one of the efficient approaches that measures the following equation, Where t = (1 – specificity) and ROC (t) is sensitivity.

$$\text{AUC} = \int_0^1 \text{ROC(t)dt} \tag{5}$$

B. Accuracy

In machine learning, this is one of the significant metric that shows the overall accuracy of the data transmission and the performance of proposed approach. The overall accuracy is calculated by using below equation:

$$\text{Accuracy} = \frac{\text{TN+TP}}{\text{TP+TN+FP+FN}} \tag{6}$$

C. Precision

Precision is one of the significant factors in analyzing the results. High precision represents the low false positive rate.

$$\text{Precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{7}$$

D. Recall or Sensitivity

Recall is also one of the parameter to analyze the results. High recall relates to a low false negative rate.

$$\text{Recall} = \frac{\text{TP}}{\text{TP+FN}} \tag{8}$$

E. Specificity

This measures the overall proportion of original negatives (Falsification Nodes), where the results are predicted as negative.

$$\text{Specificity} = \frac{\text{TN}}{\text{TN+FP}} \tag{9}$$

F. F1-Score

This is one of the measures that scores the weighted average of Precision and Recall. This will consider the false positives and negatives from the account. This will also show the uneven distributed classes.

$$\text{F1} - \text{Score} = \frac{2*(\text{Precision}*\text{Recall})}{(\text{Precision}+\text{Recall})} \tag{10}$$

Results and graphs were obtained with the following parametric values shown in Table II.

TABLE II. PARAMETRIC ENVIRONMENT

Metric	Values
Total No of Nodes	50-200 Nodes
Average Node Speed	50 m/s
Simulation Time	90-100 Sec

Table III and Fig. 4 show the performance of existing approaches by showing the AUC curve performance for 50, 100, 150 and 200 nodes. Among this the proposed approach Ensemble Proxima achieved the better results.

TABLE III. PERFORMANCE OF MACHINE LEARNING (ML) ALGORITHMS SHOWING AUROC

Total No of Nodes	KNN	KNN_RF	Ensemble Proxima
50	0.73	0.78	0.89
100	0.74	0.76	0.91
150	0.75	0.76	0.91
200	0.75	0.76	0.92

V. CONCLUSION

In this paper, the proposed approach focused on finding the falsification vehicles by using integrated Proxima analysis. The proposed approach is the combination of RF and KNN that helps to detect the falsification nodes based on the behavior of the vehicles. Falsification vehicles attack the network and cause breaking traffic rules such as over-speeding and wrong-way driving. It also provides a GUI which can be used by the traffic department to monitor roads and send help in case of an accident. The proposed method was cautiously evaluated in a traffic simulation environment, SUMO. The performance of the proposed approach has improved the performance in terms of the accuracy of AUROC. In future, an improved learning approach is combined with the various heuristic approaches to get the better detection of malicious nodes.

***Abstract*—Background: Virtual reality (VR) technology is an effective, interactive and immersive type of communication since it produces greater interest and attention in the user, thereby allowing greater understanding and comprehension than with more traditional methods. On the other hand, not much information is known about the application of this novel technology in the context of social acceptance as far as the mining sector is concerned; our approach and methodology were based on scoping review (Prisma-SrC, Daudt et al., Arksey, and O'Malley). The research terms were also planned before, with the aim of carrying out three posterior screening levels, among which was the use of EndNote 20 and the PICO framework. Exhaustive research was carried out in nine databases. We obtained n=2 research articles of n=923 initially found, all of which went through three levels of filtering. The chosen articles were evaluated according to Hawker et al. 's methodological rigor, to be included in the review. This scoping review could be the starting point for a series of further investigations that would fill the gap in the literature on this topic, emphasizing experimental articles to confirm the impact of virtual reality technologies on the communities within the sphere of influence of a mining project.**

***Keywords*—Mining projects; social acceptance; virtual reality; interaction; mining communities**

I. Introduction

Nowadays, virtual reality (VR) is present in a wide range of research fields, such as medicine, aviation, military activities and space engineering, architecture, entertainment, leisure, and mining, etc. [1-3]. According to a study of twenty years of research on virtual reality, its basic characteristics have evolved considerably, improving the interactivity produced between the user and the system human-computer interaction (HCI), in addition to perfecting the feeling of immersion that the user perceives while in the virtual world [4, 5]. Furthermore, virtual reality can be performed with exceptionally high quality, reproducing images and changing data three-dimensionally [6] providing a highly realistic simulation of the real world [7] and its continued development would facilitate the possibility of applying powerful new tools to influence the user's perceptual psychology [5].

On the other hand, social acceptance is related to the degree of tolerance that a community surrounding a mining project has for said project and whether or not the mining company can carry out its operations. This is considered very important since, without prior acceptance, the Social License to Operate (SLO) [8] would not be issued and, therefore, it would not start operations [9], generating economic losses to the company and the loss of benefits delivered to communities by mining companies [10] (mining taxes and royalties, direct and indirect employment).

Currently, energy and mining companies tend to justify their projects to the surrounding communities through the use of traditional methods and tools [11] which are usually represented by 2D images, plans and static drawings [6]. However, this does not guarantee either effective or convincing transmission of information with the community, which could create tension and conflicts due to misunderstandings among the stakeholders [10, 12]. A digital visualization of a landscape could stimulate public participation and allow for broader input regarding questions related with industrial projects [7].

The objective of this scoping review was to carry out an exhaustive investigation with the aim of determining the opportunities that the application of virtual technology could provide in support of mining projects and, based on the eventual findings, to identify gaps in the literature to help the planning and implementation of future research [13, 14].

A. Virtual Reality (VR)

This is defined as the hardware-software binomial, which works in the interaction with the user through effective synchronous communication [7], and it has the capacity for isolation from real life and immersion in a virtual life [15,16]. Virtual reality could also solve even more complex problems [15].

Immersive Virtual Reality (IVR) is defined directly with the concept of emphasizing the act of being present in the virtual environment, where the quality of immersion is directly proportional to the effectiveness of the experience [16], which may raise public awareness more effectively and result in a higher rate of acceptance of diverse projects [7]. In more simple terms, in order to obtain optimum results, you must work under the Triangle matrix of Virtual Reality (Interaction-Imagination-Immersion) [2, 3].

II. Materials and Methods

For the purposes of this study, a PRISMA extension methodology for scoping reviews was employed (PRISMA-SrC) [13], as well as the methodology of Arksey and O'Malley [17] and Daudt et al. [18]. Furthermore, to provide added value to the scoping review, step six by Arksey y O'Malley [17] who considered the exercise of additional inquiry was carried out (Daudt et al. [18] y Levac et al. [19] discuss and consider it mandatory). As argued by Daudt et al. [18], too many people in a research group involves a risk that there will be several diverse interpretations during a scoping review; so it was decided to carry out this article with only four participating researchers.

A. Search Plan

First of all, before search criteria were developed, for which a variety of compiled tasks were carried out in August 2021 from nine distinct online databases: Scopus, Web of Science, IEEE, EBSCOhost and ScienceDirect ACM Digital Library, ERIC, SciELO, Google Scholar. The researcher (KV) supervised the means of obtaining data, as well as the use of Boolean operators and thesauri. The following link shows Table I detailing the databases and their search criteria.

TABLE I. Search Criteria According to Database used

Electronic Databases	Search Strategy
IEEE	(("All Metadata":interact* OR "All Metadata":acceptance) AND ("All Metadata":publics OR "All Metadata":public OR "All Metadata":communit*) AND ("All Metadata":project* OR "All Metadata":compan* OR "All Metadata":mining) AND ("Document Title":"virtual reality" OR "Document Title":VR))
ScienceDirect	Title, abstract, keywords: (interact OR acceptance) AND (public OR publics OR community) AND (project OR company OR mining) Title: ("virtual reality" OR VR)
Scopus/Web of Science	Title, abstract, keywords: (interact* OR acceptance) AND (public OR publics OR communit*) AND (project* OR compan* OR mining) Title: ("virtual reality" OR VR)
EBSCOhost	Title, abstract, keywords: (interact* OR acceptance) AND (public OR publics OR communit*) AND (project* OR compan* OR mining) NOT (patient* AND rehabilitation) Title: ("virtual reality" OR VR)
ACM Digital Library	[[All: interact*] OR [All: acceptance]] AND [[All: public] OR [All: publics] OR [All: communit*]] AND [[All: project*] OR [All: compan*] OR [All: mining]] AND [[Publication Title: "virtual reality"] OR [Publication Title: vr]]
ERIC	(interact* OR acceptance) AND (public OR publics OR communit*) AND (project* OR compan* OR mining) Title: ("virtual reality" OR VR)
SciELO	((interact* OR acceptance) AND (public OR publics OR communit*) AND (project* OR compan* OR mining)) AND (title: (("virtual reality" OR VR))))
Google Scholar	CON TODAS LAS PALABRAS (interact acceptance public community project company mining) CON LA FRASE EXACTA (intitle:virtual intitle:reality)

The search criteria were limited to journals, conference papers, and reviews, with only publications in English from 2010 to 2021 taken into account. Subsequently, the search results were imported into EndNote 20 software, which is a reference manager that allowed us to proceed with the second filter. Later, the screening process was performed, and was based on the PICO framework (Population-Intervention or Exposure-Comparison-Results) [14].

B. Screening Criteria

The second review was carried out by two researchers (AA & JR), who used EndNote 20 to delete the duplicated articles. Additionally, the researchers identified, verified, and removed irrelevant articles manually. The third filter was performed under the PICO framework [14], with the aim of finding articles related to this research project. Each aspect of the eligibility criteria is detailed in Table II. Screening was carried out by performing manual searches in which all researchers participated (AA, KV, MB, PL, JR).

TABLE II. Type of Screening used for Selection of Studies

Electronic Databases	Search Strategy
Population Communities in general.	Homogeneous communities, Clients, Patients
Intervention or Exposure Virtual Reality Technology (VR), Immersive Virtual Reality Technology (IVR), Cinematographic Virtual Reality Technology (CVR)	Non-Immersive Reality Technology (NIVR), Augmented Reality (AR) Technology, Smartphone Applications, 2D simulation technology.
Comparison Pre-test, Post-test.	If it lacks any evidence mentioned in the Inclusion Criterion, then it is discarded.
Results If it lacks any evidence mentioned in the Inclusion Criterion, then it is discarded.	If the approach is not related to Social Acceptance, then the article is discarded.

C. Methodological Rigor

The evaluation proposed by Hawker et al. helps to enhance the quality of this article in order for it to be useful and subsequently disseminated for future research [18]. The research articles that passed the three levels of filtering were evaluated according to the methodology of Hawker et al. [20] by two reviewers (AA, JR), according to the following evaluation criteria: "Good", "Fair", "Poor", and "Very Poor". This design framework allows us to evaluate a wide range of research methods. For this reason, we considered the parameters of Appendix D regarding to the methodological rigor analysis [20].

III. Results

Table III, which contains the results of the evaluation of methodological rigor [20], resulting in the approval of the quality of both articles for the development of this scoping review.

TABLE III. RESULTS OF EVALUATION OF METHODOLOGICAL RIGOR APPLIED IN THE SELECTED STUDIES

Methodological Rigor Analysis	**Worth a thousand words: Presenting wind turbines in virtual reality reveals new opportunities for social acceptance and visualization research**	**The 3D Immersive Virtual Reality Technology Use for Spatial Planning and Public Acceptance**
1. Abstract and title: Did they provide a clear description of the study?	Good	Good
2. Introduction and aims: Was there a good background and clear statement of the aims of the research?	Good	Good
3. Method and data: Is the method appropriate and clearly explained?	Good	Good
4. Sampling: Was the sampling strategy appropriate to address the aims?	Good	Good
5. Data analysis: Was the description of the data analysis sufficiently rigorous?	Good	Good
6. Ethics and bias: Have ethical issues been addressed, and what has necessary ethical approval gained? Has the relationship between researchers and participant been adequately considered?	Good	Good
7. Results: Is there a clear statement of the findings?	Good	Good
8. Transferability or generalizability: Are the findings of this study transferable (generalizable) to a wider population?	Good	Good
9. Implications and usefulness: How important are these findings to policy and practice?	Good	Good
General Perception	Good	Good

Using the search criteria, n=923 articles were found, possibly related to the aim of the present research. Then, the information was screened until n=2 articles, according to their methodological rigor evaluation, as shown in Fig. 1.

A. Research Summary

An article selected and included in the present investigation emphasized its experimental objective by demonstrating that the use of technologies such as Immersive Virtual Reality (IVR) can be of great benefit to companies, mainly to provide a competitive advantage in the market [21]. The study was based on the range and variety of problems that wind energy projects go through before and during the construction process and it was demonstrated that the methods used to establish communication with the public are usually ineffective. Two tests were carried out before and one after the experimentation with 70 participants, where 50% were from the male population and the remainder from the female population. Additionally, the article highlights that 21.4% of the participants were over 28 years of age. The research findings showed an 8.6% increase in the post-test concerning the change in the participants' attitudes towards the proposed technology's general acceptance. Likewise, 40% of participants changed their perception in the pre-test, since the post-test results showed that 62.8% considered the project harmful to animals and the environment. On the other hand, 97.1% of the participants affirmed that immersive virtual reality technology was essential to change their attitude about energy projects, helping to better understand what they wanted to teach. On the other hand, only 38.6% of the participants considered 2D technology significant. The results found in this research show that the existing gap in communication between companies and people is reduced when implementing 3D IVR. It was also revealed that the use of this technology should play a more significant role in companies since it can unify the level of understanding between participants who are experts in a subject and those with less experience [21].

Fig. 1. Filter Stages and Selection of Studies.

Another article developed in the United States [11], investigates how the interaction, between the study population and the wind turbine represented by cinematographic virtual reality (CVR), influences the expectations and perceptions of wind energy projects. Specifically, it studies the relationship between personal appreciation of energy projects and changes in opinions after interacting with CVR. The population was recruited for the student-based experiment, all of whom were eligible to participate in the project, and the study group only knew about the subject from the mentions made by the recruiter, so it was considered a "naive population for the purposes of the study" (For this reason the authors include this article as part of the final filter of the quality review). A total of 101 students (47 women and 54 men) carried out an entrance survey to determine the population’s knowledge of before energy technologies. The questions are divided into seven categories: support and opposition, personal feeling, overall impact, impact on wind farms, attitude, knowledge, and visual and acoustic questions. 74% of the participants had never seen a wind turbine before, 54% had already experimented with virtual reality at some point in their lives, and 30% of the participants felt they knew enough about wind energy before experimentation. Afterwards, the participants underwent a test phase where they spent two minutes immersed in a virtual reality video to acclimatize and prepare the population. Participants who had never seen a wind turbine, and who did not know about it, were the ones who presented the most significant changes in their attitudes and opinions after the experiment. The experience turned out to have a high level of immersion and ecological validity, reducing erroneous beliefs about the different impacts of wind turbines- It can be assumed, therefore, that virtual reality can be profitably used to communicate more clearly the development of wind projects to the public in general, especially if the population's has poor knowledge of the subject. It goes on to propose that developers and politicians take such technological advances into account these since these are new tools which enable more effective interaction(s) with the population. A higher quality of image and audio in the presentation of a proposed project through virtual reality will help the public become more aware of and better understand the real impacts of the project and therefore will have greater influence in its acceptance [11].

You can see Table IV specifying the main characteristics of both articles.

TABLE IV. OUTSTANDING CHARACTERISTICS OF SELECTED STUDIES

Article	**Worth a thousand words. Presenting wind turbines in virtual reality reveals new opportunities for social acceptance and visualization research**	**The 3D Immersive Virtual Reality Technology Use for Spatial Planning and Public Acceptance**
Research Aim/ Objective	Examine how a multimodal and cinematographic virtual reality (CVR) experience with a wind turbine affects the expectations and perceptions of wind power projects. Specifically, we investigated the relationship between personal opinions about (renewable and non-renewable) energy sources, and variations in perceived impacts.	The objective is to evaluate the use of 3D virtual reality to support innovative SMEs in addressing issues related to spatial planning and corresponding public acceptance.
Outcomes	Students completed the experiment and approximately half (54%) had previously experienced virtual reality. Three quarters of the participants (74%) had never seen a wind turbine up close. About a third of all participants (30%) felt they were well informed about wind energy prior to the study. The CVR experience provided a high level of immersion and ecological validity. The CVR experience corrected previous erroneous beliefs regarding the expected visual and acoustic impacts of wind turbines.	There was a significant change in the perception of the participants before and after the session. For example, there was an increase of approximately 8.6% of the participants who positively changed their perception about the appearance of wind turbines. It also increased by almost 40% of participants who considered wind turbines as "bird friendly". The preference of people in 97.1% with respect to immersive virtual reality was also observed, tripling the result obtained in 2D technology.
Conclusions	In many cases, participants who had not seen a wind turbine before or who had felt less informed had greater changes in attitudes and opinions after the CVR experience. The participants felt immersed in the scene. Most of the participants considered that the wind turbine had a neutral or positive impact on the scene, although we cannot reject the null hypothesis that men and women reported feeling equally knowledgeable about wind energy. After the CVR experience, visual concerns about offshore wind farms having negative impacts on the landscape decreased. Taken together, these results suggest that CVR can be leveraged to more clearly communicate wind project development plans to the general public, especially when prior audience knowledge and experience with wind turbines is limited. We recommend that developers and managers, as well as politicians consider the proposed multimodal virtual experiences with wind turbines as a new tool to interact with the public. Accurately representing the visual and auditory characteristics of a proposed project through immersive visual and auditory simulations can help the public understand what to expect regarding project impacts, potentially allowing communities and developers to interact with one another more significantly.	The gap produced between companies and the public can be drastically reduced due to the implementation of 3D IVR As an SMEs. McCamley's management first reported a positive impact on the implementation of innovative 3D IVR within both its internal and external decision-making process. Internally, the company enriched its knowledge of the importance of technology in supporting engineering and management decisions, promotional events, and discussions with investors. In addition, dynamic simulation in the 3D IVR environment provides the public and the authority with a better understanding of the product. This allowed public support for one of the key product features; that of it being bird friendly. The commercial importance of the brand and color becomes a clear management decision because it can broaden public acceptance in terms of turbine appearance and shorten the payback

Article	**Worth a thousand words. Presenting wind turbines in virtual reality reveals new opportunities for social acceptance and visualization research**	**The 3D Immersive Virtual Reality Technology Use for Spatial Planning and Public Acceptance**
		period for investors. The company endorses the value of technology by integrating immersive 3D virtual reality into diverse management processes.
Methods and Methodology	The entry survey asked participants a series of questions about their opinions on different energy technologies in general and wind energy in greater detail. These questions were divided into seven categories: support and opposition, personal feeling, general impact, wind farm impact, attitude, knowledge, and visual and acoustic questions. During the testing phase, participants spent two minutes in a virtual museum in order to (a) acclimatize them to virtual reality, and (b) prepare them to put themselves in their place. A group asked about the visual and acoustic elements of the scene, including the volume and how well the wind turbine fit into the scene. Another group evaluated participants' previous experience with virtual reality and self-reported level of immersion in the scene using selected elements from Witmer and Singer.	A prior survey was conducted to measure the perception of 70 participants on wind energy projects. 10 sessions were held, and each session involved the participation of 5 to 9 people. After that the participants experienced 3D IVR, once the participants finished the experience, they carried out subsequent questionnaires to determine their changing perceptions.
Study Population	Participants were recruited between November 2018 and May 2019 and were compensated ($ 10 or course credit) upon completing the experiment. Participants were naive of the purpose of the study, although recruitment materials did mention wind energy. A total of 101 (47F, 54M; Age 19.5 years, SD Age 1.44 years) students completed the experiment and approximately half (54%) had previous experience of virtual reality. All students were eligible to participate in the study.	70 participants, of whom 50% were men, and 50% women. 21.4% were over 28 years old, 64.3% were participants with a history.

B. Stakeholder Views

According to a professional in mining operations, virtual reality would be an improved alternative when dealing with affected communities. This technology can surpass conventional methods in supporting mining projects within the surrounding areas and communities. Consideration should also be given to providing information and training through the application of virtual reality technology since it allows real time simulations similar to real experience, reducing risks, negative impacts and operating costs. He also commented that human-computer interaction (HCI) offers adequate retention, similar to mining training. A second professional (GP) said that this technology is used in shovels and mining trucks, claiming that it was a success. He argues that everyone in large mining projects invests in technology and virtual reality. He proposed to perform visual modeling of wind direction so that members of the surrounding communities can understand how controls are carried out in operational units such as blasting and loading, which are generators of particulate material. HS, involved in the agricultural sector further assured that the use of virtual reality to support mining projects would show the proposed execution of said projects would be undertaken in a more refreshing and convincing way.

IV. Discussion

Individual differences were found in aspects of the selected articles. This does not mean that they have a low methodological rigor [16], but these differences can make them more complementary. For example, the type of virtual reality technology used by Cranmer et al. [11] was different from that of Abulrub et al. [21], cinematographic (CVR), and immersive (IVR) respectively. Despite such differences, both results were positive, because these technologies are effective for their purpose, so it can be logically assumed that human-computer interaction is effective [22]. The interaction between virtual reality technology and the user has the most significant impact on those who have little or no experience with said technology [11]. Therefore, it is believed that virtual reality could be efficient in the communities lying within the sphere of influence of a mining project since most of them do not have any (previous) access to Information and Communication Technologies (ICT) [23], as highlighted in a 2018 study which stated that the use of virtual reality technology could be considered to be the main and most effective means of communication with the public due to its immersive capacity [7].

Due to the few articles found in the databases specified in the methodology, it is possible to argue that this research could be the first scoping review that refers to the use of virtual reality technology to generate a new opportunity for the social acceptance of mining projects. When performing an in-depth and exhaustive investigation into the databases mentioned in the methodology, very few articles were found related to the use of virtual reality for the social acceptance of mining projects. Indeed, no articles at all were found which were directly associated with the last variable. As a consequence, it was decided to analyze the experience with wind-energy projects, since both these and mining projects have a common problem: dealing with social acceptance [10] and reducing the gap in understanding and communication between the project and local communities [24]. Although it is possible to extract valuable information on the social acceptance of renewable energy (RE) projects, the appreciation is not the same since their operations do not have the same impact [25], For this reason, more experimental research is needed to know more precisely what the appreciation of the communities towards mining projects is and how HCI with virtual reality could reduce the understanding-communication gap [2, 21]. It is worth mentioning that Cranmer et al. [11], carried out his experimentation with a student community. Nevertheless, it was decided to include this article as part of the scoping review, since it shares the technological objective of this research and the results of the opinions were similar to those of the population from Massachusetts.

According to the research included for review and analysis, conventional 2D methods are still used currently to support projects [6], although it is stated that these traditional methods do not have enough interaction, nor the same understanding produced by experimenting with virtual reality technology [11,21], even though these technological methods are extraordinarily superior to traditional ones [1-3,6,11,15,21-22].

ICTs have been continuously improving over the years, and these tools can concretely and effectively support the teaching and learning process [26] that occurs when presenting a mining project to a specific population to achieve its acceptance and implementation. The use of ICT can be used by the personnel in charge of informing the public about the mining project, since these are flexible, accessible, affordable and without limitations in terms of time and space, so that the population with the mine's sphere of influence can have a good understanding of the mine's operations, activities and intentions [27].

The professionals' opinion provide us with support for the benefit acquired by using virtual reality technology as well as providing us with additional ideas to support mining projects, such as the idea proposed by (GP) on the creation of a visual model of wind management. In that way, the impact minimization plan [28] will practically be shown to residents, seeking to demonstrate that the benefit that the community will obtain by accepting the project will be higher than the cost of the impacts generated, as long as the corresponding legislation of the country where it would operate [10]. The idea of a professional in mining operations about the use of virtual reality technology, would surpass the understanding and understanding of conventional methodologies, coinciding with the opinion of (HS) an agricultural representative of a community within the sphere of a mining project, who believes it would improve understanding and, likewise, reduce the uncertainty of the local population [11,21,29], (HS) affirming that it would be a different and novel way of explaining the aspects of a mining project regarding its benefits, stages, operational processes and mitigation plan specified in the Environmental Impact Study. In this case, the farmer's point of view is highly important, since a social conflict between mining and agriculture is often generated.

The authors believe that the use of virtual reality can improve the planning of a mining project with the participation of the surrounding community, thereby ensuring a common benefit and reaching mutual agreement, as specified by Yu et.al [7], where public participation makes wind projects more acceptable.

V. Conclusion

The accessibility to the UCSM virtual library allowed us to do our research freely without any restrictions regarding different international databases, such as those mentioned in the methodology. Also, the opinion that was obtained from the interested parties was considered a strength. A limitation was the scarcity of existing research regarding the interaction of the local community with virtual reality in the context of social acceptance of mining projects. The current situation (SARS-CoV-2) is also considered as a difficulty to obtain more data or opinions from professionals and people close to a mining project.

We conclude that we have little scientific research information regarding the use of virtual reality in the interaction of neighboring communities for the social acceptance of mining projects.

Based on the experimental experiences from the selected articles, we conclude that immersive virtual reality (IVR) as well as cinematographic virtual reality (CVR) provides better communication and understanding between the user and the company in comparison to the traditional methods, improving the acceptance percentage of the proposed project.

The authors trust that this scoping review article will be the starting point to begin the experimental research and the future systematic reviews to contribute the use of virtual reality technology for the development of effective and interactive communication.

Acknowledgment

The authors declare that there is no conflict of interest. We thank the Universidad Católica de Santa María for providing us the easy access to scientific databases. We thank the professionals consulted in the mining sector: Eng. Milton Trujillo Espinoza, Eng. Giancarlo Pinto Guerra, and the farmer Helbert Samalvides for their important points of view on this research.

***Abstract*—In terms of data formats, codecs, and storage capacity, the previous two decades have seen a phenomenal progress. Rather than needing to adjust to one's application demands to the restricted storage solutions available in the past, there is now a wide range of options to pick from in order to best satisfy an application's needs. As a result, there is massive volume of data available in many forms and formats that, when linked and searched together, may yield significant knowledge and insights. We offer data warehouse as a solution and Big data as a solution in this study in order to handle heterogeneous data. However, both of these techniques have drawbacks when it comes to handling diverse data. Afterwards we propose another framework (Squerall), which relies on the ideas of Ontology-Based Data Access (OBDA) to allow querying of diverse heterogeneous sources using a single query language, SPARQL. In Squerall original data is queried on the fly, with no prior data materialization or modification. Squerall, in particular, enables the distributed aggregate and combining of massive data sets. It comes with five data sources out of the box, and it may be programmatically expanded to include other sources and query engines. The framework includes user interfaces for creating required inputs and for assisting non-SPARQL specialists through the process of writing SPARQL queries. It declares data mappings and transformations using RML and FnO, and employs Spark and Presto as query engines. The initiative underscored the importance of developing in this framework, technologies, and processes that enable for decentralized Big Data administration. Furthermore, demonstrating the feasibility and usefulness of OBDA on top of the growing NoSQL movement has a beneficial impact on Semantic Web principles acceptance. This demonstrates Squerall's importance and contribution to the organization.**

Keywords—Heterogeneous data; data warehouse; big data; presto; spark; squerall

I. Introduction

According to former Google CEO Eric Schmidt, "every two days today we produce as much content as we did from the birth of global civilization up until 2003, it's more like five Exabyte of data" [1]. In 2011, 300 million new websites were added, bringing the total number of websites to 555 million [2], resulting in a wide variety of data sources, each with its own structure and framework. User-desired quantitative approach remains an issue that must be understood and addressed as soon as possible. With the rapid rise of heterogeneous data, big data presents new challenges for extracting information from it. Scholars have acknowledged the usefulness of information that comes through interactions on social networks for many years. It is necessary to comprehend and use this information, as well as to evaluate the massive quantities that are increasing day by day [3]. These sources of information can contain structured, semi-structured, or unstructured data; that is, the records are in a variety of different formats such as relational model, HTML/XML file format, and so on, and different volumes raise key challenges in analytics on leveraging data features existing from multiple databases.

Higher education institutions, such as universities, also face similar challenges in dealing with massive amounts of data from a variety of sources for accreditation purposes, including data generated from online transactions, mobile phone applications, and data stored on multiple operating systems and repositories. This data is typically saved, categorized, retrieved, and evaluated in a standard style to fulfil accreditation criteria [4]. On the other hand, traditional database systems and technologies are incapable of effectively processing enormous volumes of data. Currently, developing software and methods for storing, managing, and manipulating enormous volumes of data is one of the most significant and hardest tasks in software systems research [5]. In addition, much of this information is kept in an unstructured way, utilizing a variety of languages and formats. Traditional techniques to data management are ineffective due to the data's vast quantity and complexity.

To deliver relevant insights, the analytical models require access to one or more data sources. Because of the differences in data type and amount, it is difficult to run any analytical model that can only function on a one data source. As a result, there is a need for a unique system that can execute analytic models using input from many data sources.

Heterogeneous data is unstructured information that is never presented in a structured fashion. Processing this unstructured data in a standard relational database is challenging. As a result, we favour a variety of techniques for dealing with diverse data. Data warehouse, big data, and Squerall-like systems are among these solutions. The former two, on the other hand, have their own set of repercussions when it comes to efficiently handling this diverse set of data

[6]. As a result, in this research, we use the Squerall architecture, which can handle unstructured data with billions of rows and millions of columns efficiently. Our research objective aims us to gain a better understanding of how diverse data is handled and how it varies with time.

The following section (Section II) deals with the backdrop of the current study, followed by Section III, which deals with the solution employing data warehouse and big data, as well as the limitations of each. A brief introduction to the Squerall algorithm is provided in Section IV, and the basic design and implementation are defined in Sections V and VI, respectively. The result analysis is covered in Section VII, as well as the overall operation of the approach employed in this study. Finally, Section VII wraps up the report with some recommendations for the future.

II. Literature Survey

Transforming and combining them into a single data source is a widely used approach for handling data heterogeneity issues [7-10]. When all of the data sources are combined into a single data source, the storage capacity need rises to that of a data warehouse, and some information may be lost as a result of lexical, syntactic, and geometrical discrepancies that occur during data integration.

S. A. Catanese [11] et al. described the collecting and analysis of massive data representing the linkages between online social network participants. They took two different approaches, both of which are well-defined and have been tested in practice against the popular social network Facebook. They presented two algorithms for data crawling: the BFS crawler and the Uniform crawler. For data integration, there are a variety of ways based on ontology. Bellatreche et al. [12] present the a priori approach, which is an ontology-driven data integration method. It is assumed that all data sources refer to a common ontology, which they may extend by adding their own concept specializations. There are two algorithms presented: 1: when sources add specific classes and properties to the shared ontology 2: when the shared ontology is extended by sources, but the occurrences are reflected into the shared ontologies before being exchanged.

Cruz et al. [13-14] presents a layered architecture for the integration of networked data that is syntactically, schematically, and semantically heterogeneous. They employ a global ontology to bridge the gap between the schemas of various data sources. A query is given in one of the data sources or the global ontology, and the mappings sharing of common lexicon are used to translate it into queries in other data sources.

Hashim [15] et al. present a cognitive integration framework that is integrated, mediated, and data warehouse-based. To guide the integration and handle syntactic, structural, and semantic heterogeneity, they use two types of ontologies: local and global ontologies.

Cur´e [16-17] et al. provides a mapping language to express access linkages to NoSQL databases for non-ontology-based access. It proposes an intermediate query language for converting SQL to Java methods for NoSQL database access. Query processing, on the other hand, is neither defined nor evaluated.

According to Gadepally [18] et al., data can be shifted across various databases at query time to improve calculation performance; the appropriate database is determined on a case-by-case basis. Although it has been demonstrated that using one database improves overall performance and data transportation, this has not been confirmed to be true with enormous data.

Support for a wide range of data sources is restricted or non-existent in all of the examined solutions. Only a few data sources [19-22] appear to be supported, and wrappers must be manually built or hard-coded. Squerall, on the other hand, does not invent the wheel and instead makes use of the numerous wrappers for existing motors. As a result, it is the solution with the most Big Data Variety support in terms of data sources.

III. Towards Solution

A. Data Warehouse as a Solution

"A data warehouse (DW) is a collection of data that has been arranged to be utilized as a decision support system," with data grouped by topics or subjects [23]. For instance, production, sales, and marketing. This arrangement enables for the collection of all relevant information on a given issue in order to aid decision-making. Users are less likely to modify or remove data in a warehouse since it is primarily used for consultation; this preserves the traceability of information so that analysis may be performed across time [24]. When data is put into a DW, data integration removes any conflicts of representation, resulting in a uniform representation of data.

The overall architecture of a DW is depicted in Fig. 1. It holds information from a variety of diverse and dispersed sources. Databases, data files, external sources, and other sources are examples of these sources. Data sources must be cleansed before being saved. The cleaning procedure involves selecting and purifying data in order to eliminate errors and resolve semantic disparities. The data will be integrated into the warehouse once it has been cleansed.

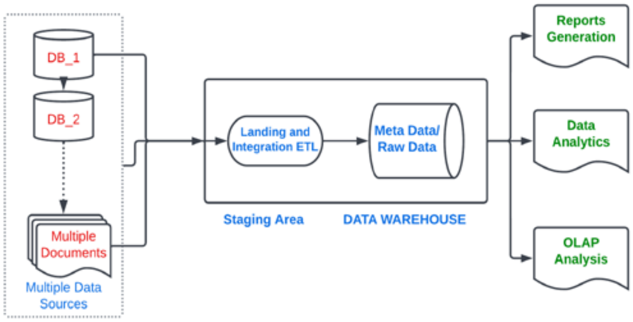

Fig. 1. Data Warehouse Architecture.

To integrate data from different sources, the ETL (extract, transform, and load) procedure must be employed, and data sources must be loaded at the logical warehouse schema transformations [25]. There are three steps to this: (1) Extraction is the process of retrieving data from several sources. To maintain data integrity, this stage necessitates synchronization of the extraction process. (2) Transformation is the process of formatting the extracted data using a set of rules to conform to the target warehouse schema. Assigning semantics to data sources and integrating source fields with target fields are two examples. (3) Loading is the process of transferring data from a source database, data warehouse, or data mart into a destination database, data warehouse, or data mart for analysis. A separate directory in the warehouse stores information on the warehouse's establishment, management, and use. This "metadata" information includes details on the schema sources, associated data, integration schema, refresh rules, user profiles, and user groups [26]. A data warehouse can be made up of many data marts. They are extracts from the warehouse that are tailored to a certain group of consumers and address a specific need. They work on OLAP (Online Analytical Processing) analysis and decision-making. OLAP delivers multidimensional representations of data to assist decision-making tools.

1) Limitations: Various data warehouses have been created in various sectors [26-27]. Today's DWs, on the other hand, confront fresh scientific obstacles. Indeed, today's data sources are diverse, self-contained, scalable, and dispersed. Traditional data warehouses face some limitations as a result of these challenges, which [28] summarizes as "Lack of scalability due to processing complexities coupled with inherent data issues and limitations of the underlying hardware, application software, and other infrastructure," and which we detail as follows:

- Data essence: New semi-structured and unstructured data models and formats have necessitated their integration and usage by modern data warehouses, yet classic DWs cannot manage semi-structured unstructured data [29].
- Data availability: The inability to obtain data at the proper time has an impact on the institution's decision-making use and implementation.
- Storage method and design: in the data warehouse, utilizing the same set of discs and controllers has a significant impact on both availability and performance analysis.

Because analytic and ad-hoc searches are non-deterministic, they have the largest influence on total query performance, data access, and processing, including data movement via the network [30]. Queries may call for a significant amount of data to be accessed from various storage regions, or a large amount of data to be accessed from a smaller storage area [31].

B. Big Data as a Solution

The fast creation of data by various technologies and people has reached enormous quantities that hardware and human capacities to interpret and modify cannot handle [32-33]. As a result, there is a common trend in the literature to conceive Big Data in terms of data volume. However, there is limited consensus on what defines Big Data in terms of volume among academics in many fields outside of education.

1) Limitations: Operating with Big Data systems necessitates the use of a high-speed computing infrastructure capable of handling vast amounts of data, which can be costly in terms of data acquisition, storage, analysis, and visualization [34]. Despite the fact that many academic institutions are already collecting numerous types of data, this information is stored in many databases, making analysis challenging. Furthermore, the absence of connectivity among institutional data systems makes gathering data from various systems for analysis difficult [35]. Additionally, the lack of data sharing agreements and data governance rules might act as a barrier to cross-institutional data integration and comparability [36]. Other key difficulties in Big Data systems include concerns about preserving personal and organizational privacy through verification and security.

Moreover, because much of the data already exists in institutional databases, current requirements for getting participants' consent in Big Data research are difficult to meet. Another ethical issue with utilizing Big Data for study is ensuring research integrity when using publically accessible data, because persons who created the data may not be willing to consent to its use, or such individuals may no longer be available for the study. Table I summarizes the full conclusion of the above-mentioned concerns.

Because the two viable solutions presented so far each have their own set of restrictions. Therefore, in addition to this, we need to discover a better solution that will address all of the difficulties that may occur in the future.

TABLE I. BIG DATA ISSUE SUMMARIZATION

Issues	Limitations
Management	Switching the entire company to a new infrastructure may be costly and time-consuming.
Storage	One Exabyte of data requires 25,000 gigabytes of disc space, which is difficult to manage and time-consuming to upload to the cloud.
Processing	Processing zettabytes and even Exabyte's of data appears to be a problem.
Heterogeneity	Big Data is frequently developed by combining many data sources belonging to various subpopulations. Each subpopulation may have some characteristics that are not shared by others. Data points from tiny subpopulations are often characterized as 'outliers' in traditional contexts when the sample size is small or moderate, and it is difficult to properly model them due to inadequate observations.
Noise Accumulation	When analyzing Big Data, we must concurrently estimate or test a large number of factors. When a decision or prediction rule is based on a large number of such factors, estimate mistakes accrue. In large dimensions, this noise accumulation effect is extremely severe, and it can even overwhelm real signals. The sparsity assumption is generally used to deal with it.

IV. Solution Beyond Data Warehouse and Big Data: Semantically Query all -- Squerall

Relational data management has been the dominant paradigm for storing and managing structured data for more than two decades. However, the introduction of really large-scale applications exposed relational data management's shortcomings in flexibly and horizontally extending the storing and querying of vast volumes of data. This sparked a paradigm change, requiring a new breed of databases capable of managing enormous data quantities while decreasing query expressivity and consistency constraints without compromising query efficiency.

By 2008, a slew of so-called non-relational or NoSQL (Not simply SQL) databases have popped up (e.g., MongoDB, Neo4j). One of the key Big Data difficulties is variety, which is exacerbated by heterogeneity. The fundamental rationale for the development of semantic technologies during the last two decades has been the integration of diverse data. Local data schemata are mapped to global ontology terms using defined mapping languages for a variety of popular data forms, such as relational data, JSON, CSV, or XML [37]. Heterogeneous data may therefore be accessed uniformly via queries written in SPARQL, a standardized query language that uses words from the ontology. Ontology-Based Data Access (OBDA) is the term used to describe this type of data access.

Three issues arise when implementing an OBDA architecture on top of Big Data:

- Translation of a query: SPARQL searches must be converted to the query languages of the various data sources. It's difficult to achieve a general and dynamic data model translation.
- Execution of federated queries: Because nonselective searches with big intermediate results are prevalent in Big Data settings, joining or aggregation cannot be executed on a single node but must be dispersed over a cluster.
- Information barriers: Data from a variety of sources can be linked to produce new insights, and it might not be easily 'joinable'.

Squerall, an extensible framework for querying Data Lakes, was built to address the above - mentioned issues [38].

- It enables ad hoc querying of massive, diverse data sources without the need for data integration or transformation.
- It enables the execution of distributed queries, particularly the combining of different heterogeneous sources.
- It allows users to describe query-time modifications that change join keys, allowing data to be joined.
- Squerall combines Apache Spark and Presto, two cutting-edge Big Data engines, with RML and FnO, two semantic technologies.

V. Squerall Architectural Framework

The OBDA principles [39] are used to build Squerall (Semantically query all). Most of these were designed to retrieve relational data but have no restrictions on the type or scale of data they may handle. We apply them to a Central Database, which contains massive and diverse data sources.

To help guide future debates, we will define the following concepts first:

- All notions used by data sources to characterize a single recorded datum, are represented by Data Attribute.
- A data entity, also known as a relevant entity, is a notion that data sources use to bring together related data, such as a table in a tabular database or a collection in a document database. There are one or more data characteristics associated with an object. If an entity includes information that matches a component of the query, it is relevant to the query.
- In response to a query, the Parallel Operational Area (POA) is the parallel distributed environment where ParSets are loaded, combined, and modified. It has an internal data structure that ParSets must follow.
- Any storage media, such as basic file storage or a database, is referred to as a data source.
- A data lake is a collection of many data sources where data is kept and retrieved in its original state and format, without being transformed beforehand [39].

A. Squerall Architectural Components

Squerall is made up of four primary parts (Fig. 2). We will utilize the generic ParSets and POA notions instead of Squerall's underlying corresponding concrete words, which vary from machine to machine, because of Squerall's extensible architecture.

1) Decomposer: Query Decomposer is a programme that decomposes queries. OBDA and query federation systems frequently use this component. The query's Basic Graph Pattern is decomposed into topic variables here. Because the focus of query execution is on bringing and merging entities from several sources, rather than retrieving a specific known item, query decomposition is subject-based (varying subjects). In a pre-processing phase, retrieving a certain entity, i.e., topic is constant, necessitates full-data parsing and index creation. This goes against the Data Lake notion of being able to access original data without having to go through a pre-processing stage. Nonetheless, a specific entity may be found by filtering on its properties.

2) Entity extractor: Relevant Entity Extractor is a programme that extracts relevant entities. This component searches the Mappings for entities with attribute mappings to each of the extracted star's characteristics for each extracted star.

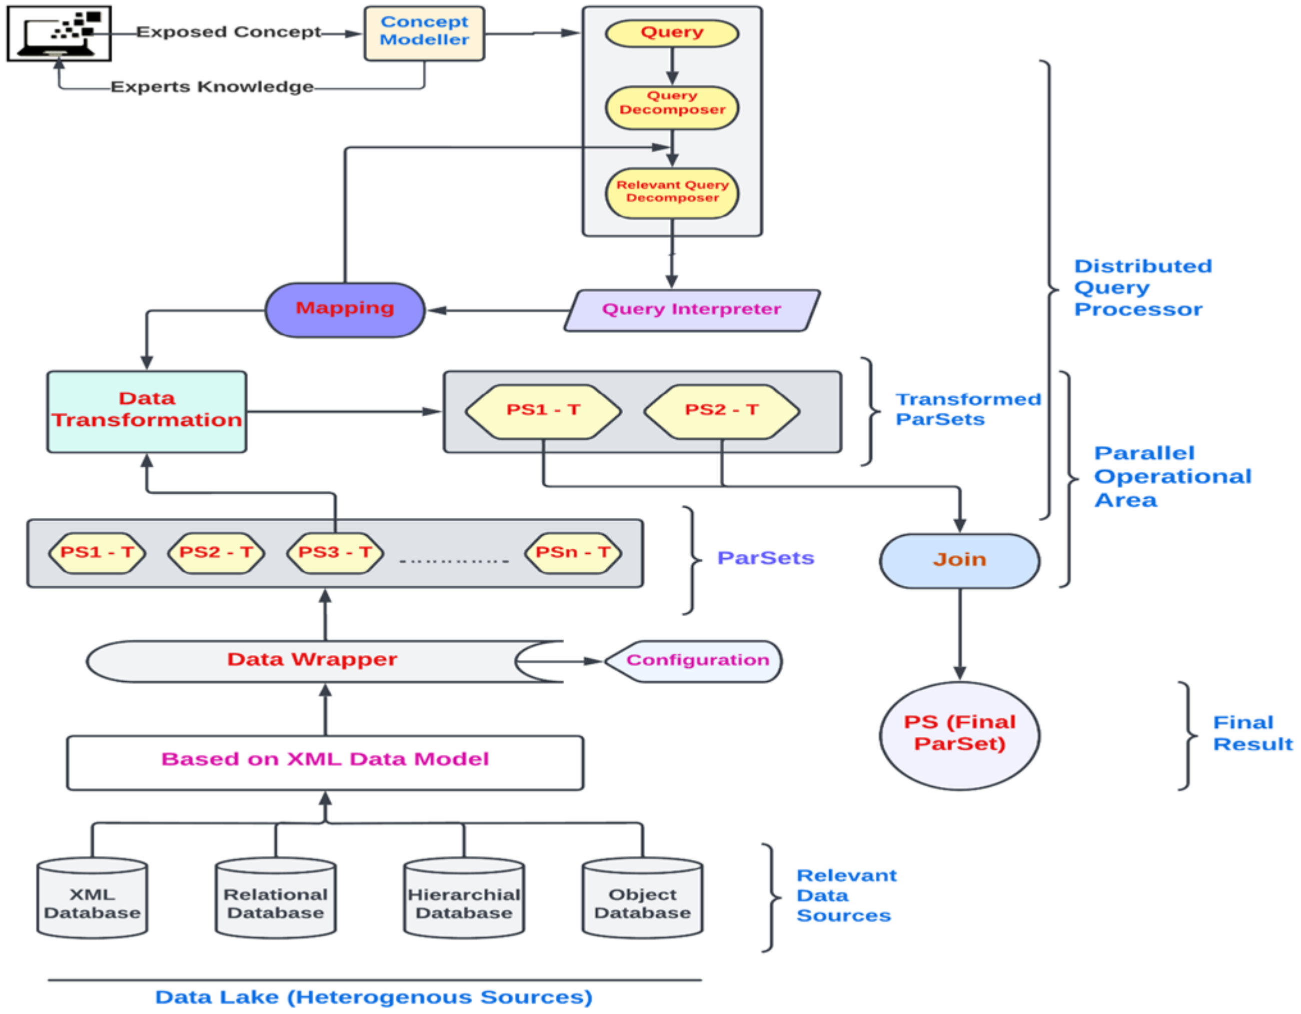

Fig. 2. Basic Squerall Architectural Components.

3) *Data wrapper:* The SPARQL query must be translated to the query language of the relevant data sources in the traditional OBDA. In the very varied Data Lake environments, this is difficult to implement in practice. As a result, a number of recent papers have recommended for the adoption of an intermediate query language. The intermediary query language in our example is POA's query language, which is determined by its internal data structure. At query time, the Data Wrapper creates data in POA's data structure, allowing for the concurrent execution of costly operations such as join. Wrappers must exist to transform data entities from the source to POA's data structure, either completely or partly, depending on whether parts of the data may be sent down to the original source.

4) *Distributed query processor:* The final results are formed by joining ParSets together. In the POA, ParSets may be subjected to any query action, including as selection, aggregation, and ordering. However, because we are interested in querying several data sources, we will concentrate on the join process.

VI. Squerall Implementation

Scala is used to write Squerall. It declares data mappings and transformations using RML and FnO, and employs Spark and Presto as query engines.

A. Mapping

Squerall allows RML entity and attribute mappings, which extends the W3C R2RML mapping language to facilitate mapping of diverse sources.

The rml:logicalsource fragment, which specifies the entity source and type, is anticipated.

rr:subjectMap is used to obtain the entity ID.

rr:predicateObjectMap, which is used for all entity attributes and translates an rml:reference to an ontology word through rr:predicate.

We extend RML with the NoSQL: store attribute from our NoSQL ontology, which allows you to define the entity type, such as Cassandra, MongoDB, and so on.

B. Information Transformation

Users can specify transformations in Squerall to provide data join ability. There are two conditions that must be met:

1) The transformation specification must be divorced from the technical implementation.

2) Transformations must be done on-the-fly at query time, as defined by the Data Lake definition.

We employ the Function Ontology, which abstracts away the particular technology used to describe machine-processable high-level functions [40-42]. We utilize *FnO* in combination with RML in the same way as the *DBpedia* Extraction Framework does. We do not, however, build RDF triples physically; instead, we apply *FnO* operations on-the-fly at query time.

When a transformation declaration is satisfied, Squerall examines the mappings at query time and initiates appropriate Spark and Presto actions over the query intermediate results [43]. A map () transformation is employed in Spark, whereas equivalent string or number SQL operations are used in Presto.

C. Querying and Wrapping

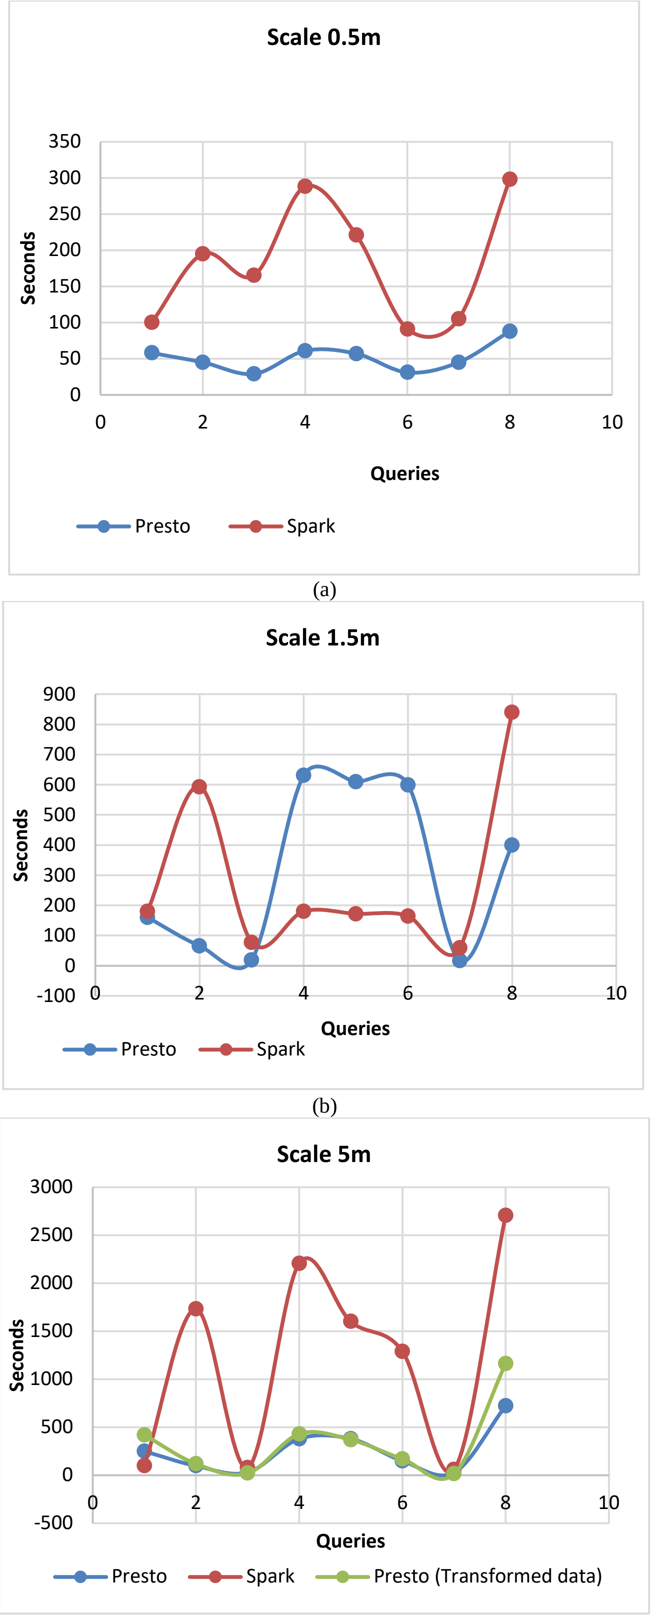
We use two popular frameworks to build the Squerall engine: Apache Spark and Presto. Spark is a general-purpose processing engine, while Presto is a distributed SQL query engine for active querying. Both rely on memory for their operations [44-45]. We use the connector idea in Spark and Presto, which is a wrapper that can import data from an external source into their internal data structure (*ParSet*), flattening any semi representations [46]. DataFrame is Spark's internal data structure, which is a tabular format that can be queried programmatically in SQL. Their structure is the same as the *ParSet's*, with one column per star predicate.

VII. Result Analysis and Discussion

We assess the correctness of the results as well as the query's performance. We compare query results to a centralized relational database (MySQL) for correctness, since it reflects data at its most consistent level. We test query execution time against the three created scales to determine performance. The influence of the number of joins on query time is highlighted in detail. We determine the mean value of each query after running it three times. The timeout value is set to 3600 seconds.

In the absence of a similar study that allows to query all five data sources and SPARQL fragments that Squerall supports, we compare the performance of Squerall's two underlying query engines: Spark and Presto.

In case of Accuracy measure, Squerall provided the same amount of returns in all scale 0.5m queries as MySQL, indicating 100 percent accuracy. We evaluated the effectiveness of the various engines after MySQL timed out with data of scale 1.5m, and the results were likewise similar.



(a)

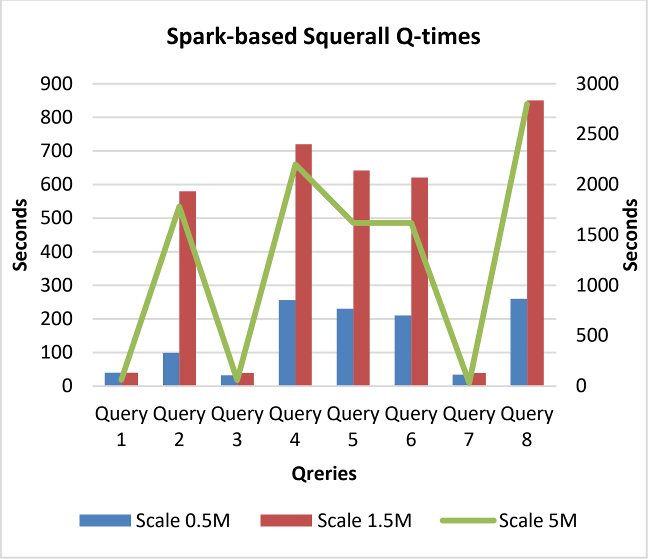
(b)

(c)

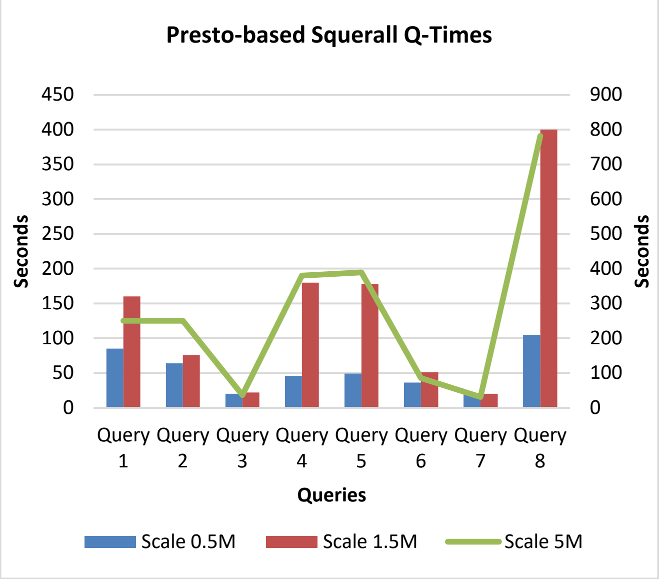
Fig. 3. Query Execution Time based on Presto, Spark on different Scales (0.5m, 1.5m & 5m).

While as, the findings imply that Squerall performs rather well across a wide range of queries, i.e., a large number of them. Filtering and sorting of joins, with and without filtering Squerall, located in Presto, is on display. Up to an order of magnitude greater performance than Spark-based solutions. Query performance is higher across the board with the 0.5m [Figure 3(a)] data scale. There was a rise of up to 800% in the number of inquiries. Presto-based models come in 1.5m [Figure 3(b)] and 5m scales [Figure 3(c)]. With a rise of up to 1300 percent in all inquiries except Query 1, is outstanding. Thus, a variety of elements contributes to greatness.

Query performance did not suffer as data size increased; query times were roughly proportional to data size (Fig. 4) and stayed below the threshold. We purposely add modifications to the data so that it becomes unjoinable in order to test the effect of the query-time data manipulations.



(a)



(b)

Fig. 4. Percentage differences between the Scales (Presto-based and Spark-based).

The findings reveal that in the vast majority of cases, the cost is insignificant. This is due to the fact that both Spark and Presto use RAM to do computations. These transformations in Spark (figure 4a) only use the map function, which is done locally and does not require any data movement. Only a few queries out of 5 million in Presto-based Squerall [Figure 4(b)] had expenses that were evident but not significant. We only add the results of the processing cost at the scale 5M due to small variances and to improve readability. Our findings might be viewed as a comparison of results between Spark and Presto, which is a rare occurrence.

VIII. Conclusion and Future Strategies

We described Squerall in this paper as a framework for achieving the Semantic Data Lake, or querying diverse and huge data sources using Semantic Web approaches. It lets users to describe changes that enable joinability on-the-fly at query time, and it conducts distributed cross-source join operations. Squerall is designed with Spark and Presto, two cutting-edge Big Data technologies. Squerall removes users from handcrafting wrappers by relying on the latter's connectors to wrap the data—a fundamental bottleneck in supporting data variation across the literature. It also allows Squerall to be readily extended. Squerall may also be dynamically modified to use different query engines thanks to its modular code design. We want to enable more SPARQL operations in the future, such as OPTIONAL and UNION, as well as take use of the query engines' own algorithms to improve query performance. Finally, there is a natural necessity to maintain provenance at the data and query results levels in such a diverse setting.

***Abstract*—This article presents an evaluation of 2D Animation of Learning Numbers and Letters for Children with Verbal Apraxia. The developed application provides some knowledge and encourage children with verbal apraxia to learn and know about numbers and letters. An experimental testing was conducted to evaluate the usability of the developed application, aimed as a therapy for the children who suffer this apraxia across all age. Five important evaluation components such as learnability, usability, accessibility, functionality, and effectiveness were included in this testing to investigate the user engagement and satisfaction of the proposed medical and educational learning system. Online questionnaires were distributed as a method to collect user testing outputs. A total of 33 respondents from multimedia designers, practitioners, psychologists, and parents were involved in this survey. The results of the testing indicate that majority of respondents are satisfied with the outcomes of the 2D animation video. The results presented may facilitate improvements in the teaching syllabus for students with speech and language disorder and produce a great visual animation treatment to the users.**

***Keywords*—Childhood apraxia of speech; verbal dyspraxia; speech and language disorder; 2D animation; visual animation treatment; evaluation**

I. Introduction

Childhood Apraxia of Speech (CAS) is a speech condition in which a child's brain struggles to coordinate the complex oral motions required to create sounds into syllables, syllables into words, and words into phrases. An evaluation of the child's expressive and receptive language abilities is required as part of a diagnosis of childhood apraxia of speech; many children with this disorder have language deficiencies. This article focuses on the testing phase of the 2D animation of Learning Numbers and Letters for Children with Verbal Apraxia. The objective of this paper is to present a comprehensive usability evaluation of visual animation named "2D animation of Learning Numbers and Letters for Children with Verbal Apraxia". There are five evaluation components included in the testing to evaluate the user engagement and satisfaction of the 2D animation learning system. It is envisaged the proposed product would assist in providing a visual therapy to patients with Apraxia of Speech in the form of 2D animated video. The contribution of this study is obvious as the resulting outcomes can be capitalised as guidelines to increase an awareness about Verbal Apraxia to the public.

II. Literature Review / Previous Work

There have been several studies in the literature reporting on the usage of animation, particularly in teaching and learning purpose [1-3]. In addition, there are some products which are related to the proposed visual animation for verbal apraxia of speech. For example, Speech Therapy Songs Animation by Barefoot Books [4] and Alphabets and Numbers Verbal Therapy by Terapi Autisme Online [5]. However, these products are limited for general, autism and spectrum disorder use. Besides, these applications are not interactive and the syllabus is outdated.

Hence, a 2D Animation of Learning Numbers and Letters for Children with Verbal Apraxia [6] is developed. This application is focusing on visual therapy to patients with Apraxia of Speech using an animation element. The comprehensive explanation on the design and development phases of the application; 2D Animation of Learning Numbers and Letters for Children with Verbal Apraxia is presented in [6]. The comparison of the existing products with the proposed application is also presented in [6]. Fig. 1, Fig. 2 and Fig. 3 present the screenshots of the developed 2D animation of Learning Numbers and Letters.

Fig. 1. Screenshot of the Main Page.

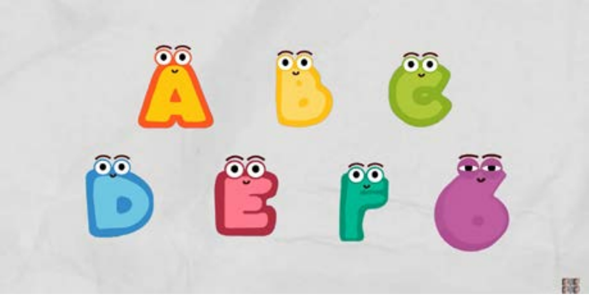

Fig. 3. Screenshot of the Alphabet Module Page.

Usability is described as a product's or service's ability to provide maximum satisfaction, efficiency, and effectiveness when utilised by various types of users as described in [7]. The usability has been investigated by many researchers in [8-13]. In recent years, there has been an increasing amount of literature on usability testing [14-15].

This paper presents an extension of the work reported earlier in [6] with emphasis on the evaluation of the proposed application. Also, this paper elaborated five components which are used as evaluation components for the system testing purpose; they are learnability, usability, accessibility, functionality, and effectiveness.

III. Methodology

The methodology section presents about the testing and outcomes. The test plan comprising of the test user, test schedule, test strategy and test implementation and eventually test results are elaborated in this section.

In this research work, the main target user is children who suffers from Verbal Apraxia of Speech from the age of 5-10 in Autism Therapy Center in Edufa Pekanbaru, Indonesia. The practitioner who guides the children will also be the target user as they will be observing the children’s behavior while checking the content of the application to make sure it is according to the children’s method of study. Table I shows the details of respondents that involved in this testing.

1) Multimedia expert: A multimedia expert is a specialist in the field of multimedia and information technology who has extensive knowledge and expertise. Graphic Designer, Animator, Videographer, and Lecturer were chosen to take the test. This test is performed at the end of the development process and before the product is released. They will test the application with a focus on interface, interactivity, design, integration of multimedia elements, and content layouts in the application.

2) Subject matter expert: A subject matter expert is an individual that has a specialties and background of medical that help improve the application before and after the testing method. The practitioners, therapists, and psychologists were chosen to take the test. They will independently test the application and give an input about the application with medical terms and medical point of view.

3) Parents: The children with autistic and verbal apraxia of speech are the main target user of this research work. Since the testing was conducted online, the device setup and supervision were assisted by their parents. This category is addressed to the parents, who will explain the questionnaire to their children with their own way. Basically, this category is answered by their children assisted by the role of parents.

During the testing phase, test implementation will outline how the testing will be implemented to a certain target user. The relationship between the test description and the test data is carried out in accordance with the test strategy.

A. Test Description

The total number of respondents for the testing procedure is 33 people. After receiving an explanation of the research work, each respondent will conduct the testing independently. They are required to answer all of the questionnaire questions. Each of the respondent is required to respond and provide comments regarding the application in their perspective.

B. Test Data

The test data for the user testing will be explained in Table II, while Table III, Table IV and Table V represent the respondents of subject matter expert, multimedia expert and parents, respectively.

TABLE I. TESTING RESPONDENTS

	Multimedia Expert	**Subject Matter Expert**	**Parents**
General Information	Practitioners who teach in Autism Center, and Doctor who expert in Autism	Multimedia Designer who works and experienced in multimedia field	Parents of children with Apraxia of Speech
Description	To evaluate the usage and the effectiveness of multimedia elements in the animation	To identify the content validity, provides understanding related to subtopics	To identify the effectiveness of the animation as a therapy

TABLE II. TEST DATA FOR USER TESTING

General Information	**Number of Respondents**
Practitioners who teach in Autism Center, and Doctor who expert in Autism	16
Multimedia Designer who works and experienced in multimedia field	11
Parents with autistic children, especially for children with verbal apraxia of speech	6

TABLE III. DETAILS OF SUBJECT MATTER EXPERT

Respondents	Gender	Age	Occupation
Respondent 1	Female	28	Practitioner at Palembang Therapy Center
Respondent 2	Male	26	General Practitioner at Eka Hospital Pekanbaru
Respondent 3	Female	34	Lecturer at Sriwijaya University
Respondent 4	Female	29	Teacher at Palembang School with Special Needs
Respondent 5	Female	23	Assistant Psychologist at Magna Penta
Respondent 6	Female	25	General Practitioner at Palembang Therapy Center
Respondent 7	Female	27	Therapist at Clemira Therapy Center
Respondent 8	Female	25	Therapist at Clemira Therapy Center
Respondent 9	Female	23	Psychology Student, Intern at Palembang Health Department
Respondent 10	Female	23	Psychology Student, Volunteer at Palembang Autism Parenting 2020
Respondent 11	Female	32	Psychologist, Psychotherapy at Optime Palembang
Respondent 12	Male	22	Psychology Student, Volunteer at Hari Peduli Autisme
Respondent 13	Male	28	Child Therapist at Dian Selaras Konsultan Psikologi & Klinik Hipnoterapi
Respondent 14	Female	22	Psychology Student at Sriwijaya University
Respondent 15	Female	23	Psychology Student at Sriwijaya University
Respondent 16	Female	22	Psychology Student at Sriwijaya University

TABLE IV. DETAILS OF MULTIMEDIA EXPERT

Respondents	Gender	Age	Occupation
Respondent 1	Male	24	Graphic Designer at RAGBI MALAYA RESOURCES
Respondent 2	Male	21	Animator at KINARYA COOP, Film and Animation Student at Binus University
Respondent 3	Male	21	Freelance Videographer at Tanjak Studio
Respondent 4	Male	21	Freelance Filmmaker, Broadcasting student at Ahmad Dahlan University
Respondent 5	Male	22	Video Editor Intern at Sinemalis Studio
Respondent 6	Male	22	Deputy Coordinator of Multimedia Bureau at PPI Malaysia
Respondent 7	Female	24	Web Developer Intern at Sma Maahad As-Syakhsiah Tahfiz Sains, Pulau Pinang
Respondent 8	Male	23	Project Manager at PT. Kreatif Media Industri
Respondent 9	Female	24	Lecturer at University of Mataram
Respondent 10	Female	24	Master of Computer Science at Universiti Teknikal Malaysia Melaka
Respondent 11	Female	25	Graphic Designer at DigitalBrain SDN BHD

TABLE V. DETAILS OF PARENTS

Respondents	Gender	Age
Respondent 1	Female	43
Respondent 2	Female	42
Respondent 3	Male	36
Respondent 4	Male	41
Respondent 5	Female	32
Respondent 6	Male	40

C. *Chart Results and Analysis*

Diagrams and charts will be displayed in this analysis based on the results of the overview and testing measures. This is an examination diagram of the assessment testing that was conducted. A few charts have been created based on the information obtained from the testing results to summarize the outcome of the assessment.

1) Multimedia expert: Eleven multimedia experts, including animators, graphic designers, videographers, filmmakers, lecturers, and multimedia students, took part in the testing phase. The multimedia experts were asked to assess the usage of the multimedia features in the animation video, which include content, audio, video, and interface design. The collected data will be analyzed and compiled into a bar chart.

a) Chart of Learnability for Multimedia Expert: Fig. 4 shows the testing results from multimedia expert for the learnability aspect. For the information and messages outcome, we can see that 63.6% of multimedia experts strongly agree that the information and message in animation are simple and straightforward, this is because animation is aimed at children, who do not like watching long videos that make them feel bored.

There are about 72.7% of multimedia experts who strongly agree that the content of the animation is very easy to understand because the animation displays eye-catching and easy-to-understand visuals for the viewers.

It is indicated that there are 54.5% experts agreed that the instructions in the video can guide users because the instructions are easy to follow and understandable, but parental assistance is needed to be able to help children to always follow the instructions until the end.

b) Chart of Usability for Multimedia Expert: Fig. 5 shows the testing results from multimedia expert for the usability aspect. Although 45.5% agree, 9.1% disagree that the text and graphics are readable and clear because some experts feel that these graphics need to be improved, so that they are easily seen by the viewer's eyes.

More than 50% of experts agree that users do not need help with instructions outside of the video because the instructions in the video itself are very clear to understand and follow.

As illustrated in Fig. 5, the finding revealed that 54.5% of experts agree that the use of animation gains a better understanding of the content of the animated video because of the interaction of the host and the movement of the animation to the viewer.

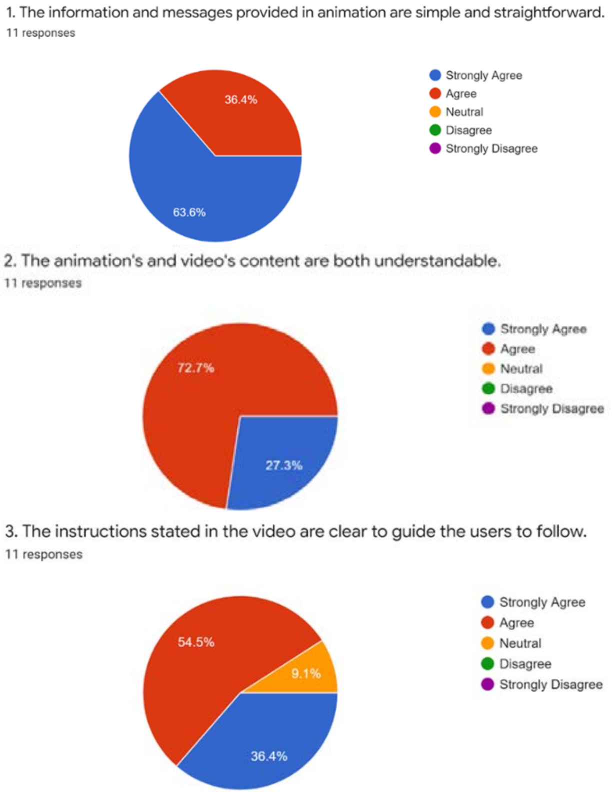

Fig. 4. Result of Learnability by the Multimedia Experts.

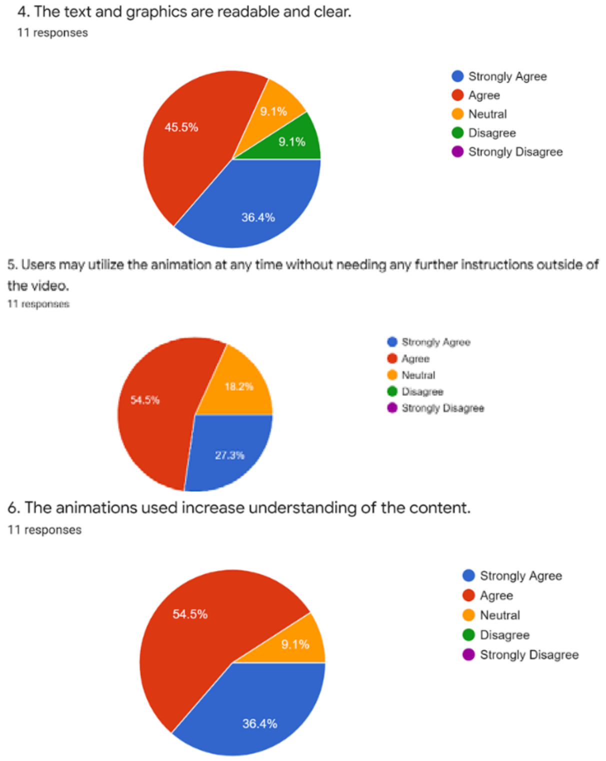

Fig. 5. Result of Usability by the Multimedia Experts.

c) Chart of Effectiveness for Multimedia Expert: Fig. 6 shows the testing results from multimedia expert for the effectiveness aspect. Fig. 6 shows more than half experts agree that integration between multimedia elements can help users obtain information effectively because multimedia instruments work together to help deliver information.

About 72.7% of experts agree that the layout of the content increases the effectiveness in conveying information as illustrated in Fig. 6 because the arrangement in the preparation of the layout is considered by the creators before being applied to the video.

Findings in Fig. 6 highlight 72.7% of experts agree that the information has an impact on the user as stated in Fig. 12 because they believe that the instructions and interactions will help children in verbal apraxia therapy through visual interactions.

d) Chart of Accessibility for Multimedia Expert: Fig. 7 shows the testing results from multimedia expert for the accessibility aspect. Fig. 7 clarifies that although seven respondents agree that audio used is suitable, it turns out that there is one respondent who thinks that the audio used is not clear to hear because indeed the device in using audio recording does not use a special microphone for voice over, but only an ordinary cellphone headset.

Surprisingly two experts believe that the graphics used are not too attractive. This is because there is still a lot of potential that can be developed from the animation, such as designs that are more attractive to children than the existing ones.

Fig. 7 shows that almost as many as a quarter of experts believe that the use of color in this animation is appropriate and attractive because the purpose of this animation is for children, so the animation must be made as interesting as possible.

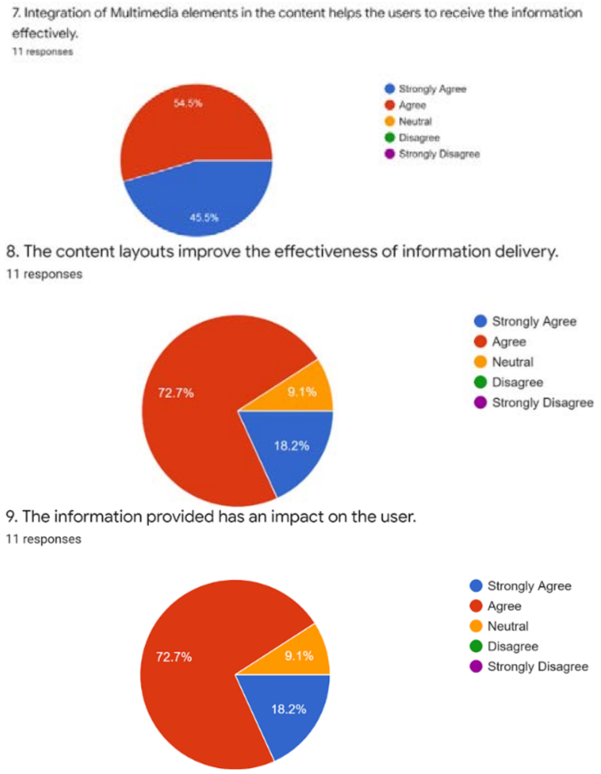

Fig. 6. Result of Effectivess by the Multimedia Experts.

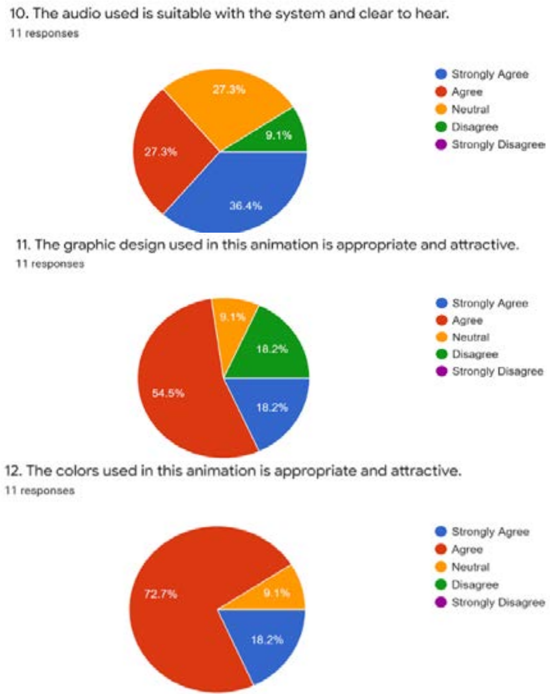

Fig. 7. Result of Accessibility by the Multimedia Experts.

e) Chart of Functionality for Multimedia Expert: Fig. 8 shows the testing results from multimedia expert for the accessibility aspect. Fig. 8 illustrates that there are four experts who strongly agree, and four others also agree with the statement that the animation is smooth and can be seen clearly. This is because according to their proposal, the use of visual aspects is very critical in making an animation video.

This study indicates that 63.6% experts agree that the user will be able to catch the message from the host quickly as presents in Fig. 8, this is because of the influence of good delivery and interaction from the host which makes the message will be conveyed well to the users.

Summary for Multimedia Expert responses are summarises in Table VI.

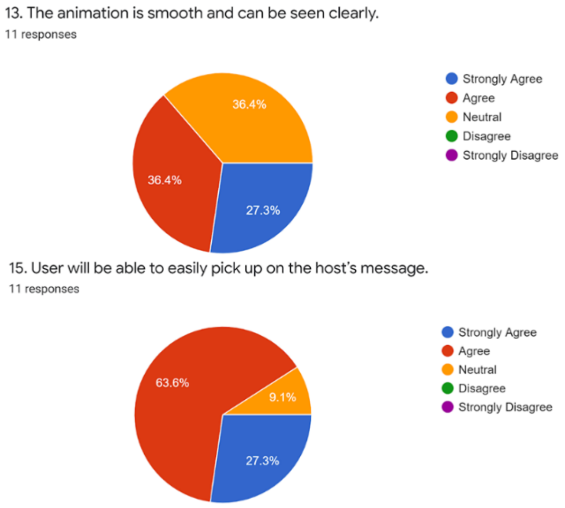

Fig. 8. Result of Functionality by the Multimedia Experts.

f) Suggestion for Improvement from Multimedia Expert: Based on the questionnaire to the multimedia experts, below are the suggestion for improvement:

i. Font for animation (numbers and alphabets) can be improved if the font used is a more familiar font. For example, the number 0 looks like a dot, because the hole is not so visible. The shape of the numbers/letters are not clear.

ii. The main problem regarding handwritten text animation could be improved a lot so that the kids understand how they should write it, especially given with the font choice that should be suitable enough for using that effect.

iii. Regarding about the sound quality coming from the speaker, it would be better to use a camera instead of using laptop or personal computer due to the sound quality would be bad for the kids to listen. With an alternative way to get the sound right, using a phone for sound recording while using a camera for visual recording will make the quality better, including for getting a good interactive feeling.

iv. The animation wise could be better by not making it the same all the time, but should be at least different, no matter how simple it is.

v. The animation could be better by not making it the same all the time, but should be at least different, no matter how simple it is.

vi. The video is good and informative, the quality is fine, but the audio can be improved, maybe by using more prepared tools, because audio is one of the important instruments.

vii. Instead of using numbers and letters animations that uses bold and thick type of font, the application might seek other font type alternatives that gives a clearer identification and distinguish between each alphabet/number. This suggestion is based on the personal difficulty to identify zero due to the unclear shape of font and animation flow. Hence, other appropriate font type and animation could be suggested to give audience a clearer understanding.

2) Subject matter expert: There are 16 subject matter experts, including practitioners, therapists, psychologists, lecturers, and psychology students who took part in the testing phase. The subject matter expert was asked to assess the content of the animation from the medical point of view. Then the collected data will be analyzed and compiled into a bar chart.

a) Chart of Learnability for Subject Matter Expert: Fig. 9 shows the testing results from subject matter expert for the learnability aspect. The finding highlights 56.3% experts agree that the user will be able to catch the message from the host quickly as displayed in Fig. 9, this is because of the influence of good delivery and interaction from the host which means the message will be conveyed well to the users.

TABLE VI. RESULT SUMMARY FOR MULTIMEDIA EXPERT

Question type	Strongly Disagree	Disagree	Moderate	Agree	Strongly Agree	Total
Leamability	-	-	3%	55%	42%	100%
Usability	-	3%	12%	52%	33%	100%
Effectiveness	-	-	6%	67%	27%	100%
Accessibility	-	9%	15%	52%	24%	100%
Functionality	-	-	23%	50%	27%	100%
Average		2%	12%	55%	31%	100%

Fig. 9 also shows that our finding revealed that most of the respondents agreed that the application animation and content are easily understandable.

There are ten experts agreed that the instructions in the video were clear to follow as stated in Fig. 20 because the instructions from the host were very clear and delivered straight to the point without wasting time.

b) Chart of Flexibility for Subject Matter Expert: Fig. 10 shows the testing results from subject matter expert for the flexibility aspect. The finding provides evidence that eight experts agree that the content provided can promote positive behavior between children and parents as mentioned in Fig. 10. It is because it takes good cooperation and synergy between them to be able to apply the knowledge learned from the effects after watching the animated video.

Fig. 10 also presents that all experts agree that this content about learning numbers and letters is very suitable for users such as children because in general at this age the syllabus is used in the field of education in schools is general.

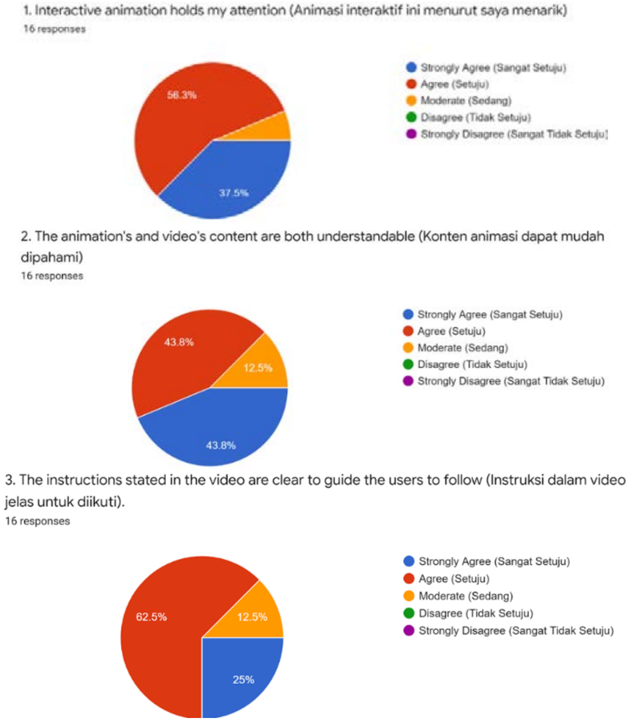

Fig. 9. Result of Learnbility by the Subject Matter Experts.

In addition, Fig. 10 stated that half of the experts agree and even the rest strongly agree that this animation will improve understanding of the content presented because children need content that is appropriate for their age such as numbers, letters, objects, colors, and so on.

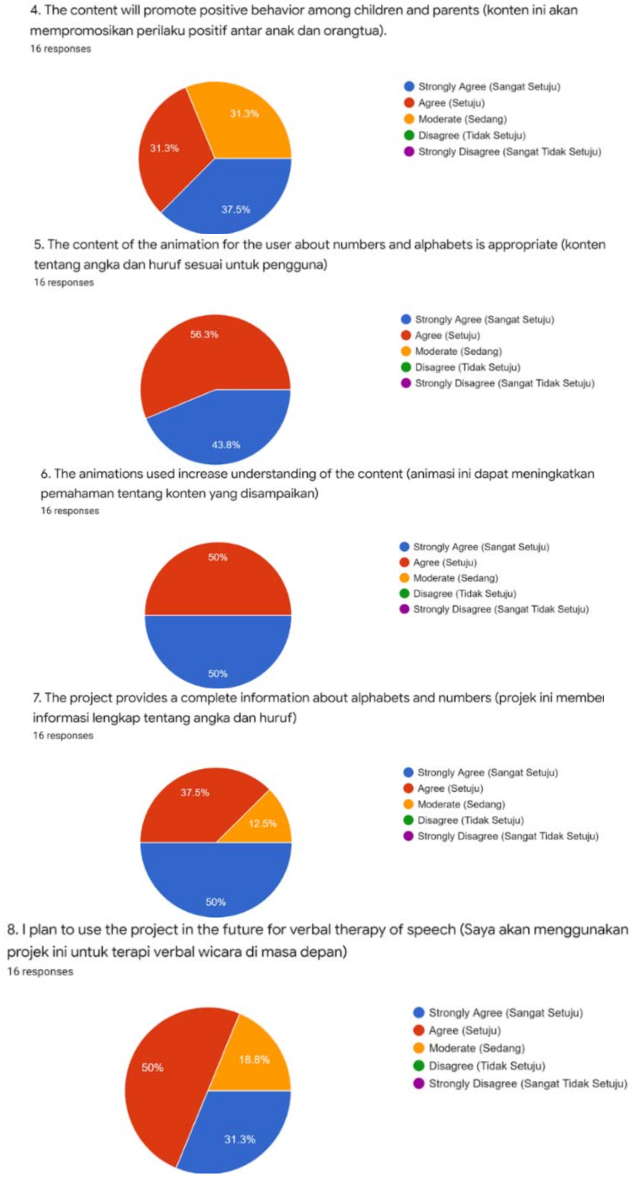

Fig. 10. Result of Flexibility by the Subject Matter Experts.

This study indicated that eight out of 16 experts strongly agree that this application provides a complete information about alphabets and numbers as mentioned in Fig. 10. This kind of syllabus is very easy to understand and remember because it will always be used in everyday life by children who watch this animated video.

Fig. 10 shows about 50% of the experts will use this application for verbal speech therapy in the future, because they believe they will be able to use it easily and without special instructions.

c) Chart of Effectiveness for Subject Matter Expert: Fig. 11 shows the testing results from subject matter expert for the effectiveness aspect. This study indicates that nine experts strongly agree that the integration of the use of multimedia elements in the animation helps users get information effectively as stated in Fig. 11 because they have used such a good, appropriate, and quite interactive elements and instruments.

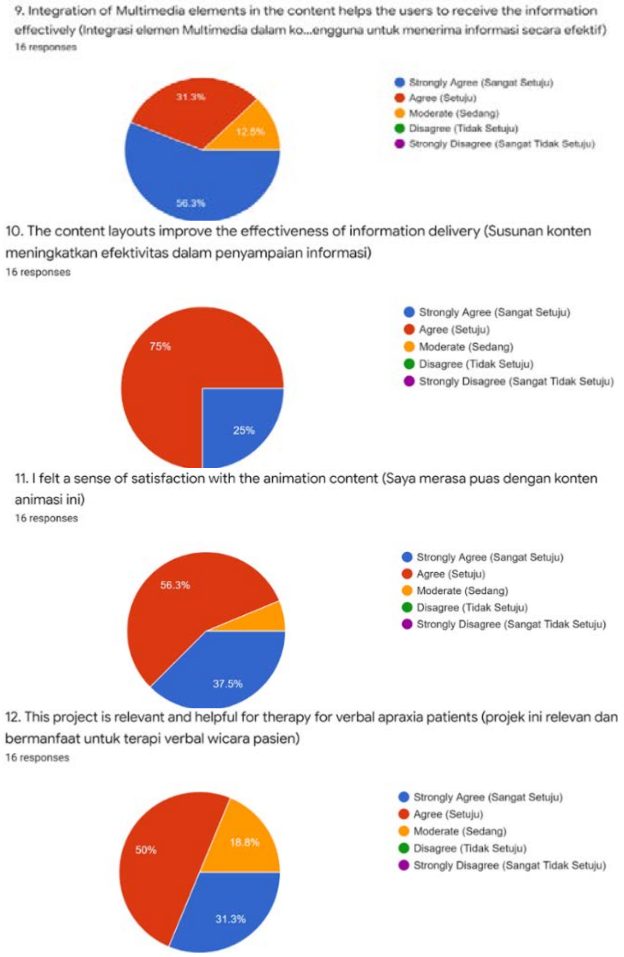

Fig. 11. Result of Effectivess by the Subject Matter Experts.

Fig. 11 presents that our finding revealed that 75% or almost all of the experts agree that the layout of this content increases the effectiveness of delivering information. This is because the arrangement is in accordance with the needs of users, namely the placement of letters, numbers, and images that are not too flashy and the selection of colors that are not monotonous makes it easy for children to remember shapes and colors different in their memory.

There are nine out of 16 experts who were satisfied, even six of them were very satisfied with this animated content as mentioned in Fig. 11. They believed it would be a good therapy for children with verbal apraxia, enabling them to learn from the animated visual interactions of the video.

Fig. 11 displays eight experts agree and five others strongly agree that this application is very relevant and believed to be useful for humans in the fields of health and education, especially for verbal speech therapy patients.

Table VII summarises test findings for subject matter experts.

d) Suggestion for Improvement from Subject Matter Expert: Based on the questionnaire provided to the subject matter expert, below are the suggestion for improvement:

i. Videos are made more colorful to help children visually receive learning.

ii. Made suitable for children to be able to guess the numbers or letters that have been learned.

iii. The material is good, only in the selection of fonts for letters, otherwise use a simple font (without an accent of beauty) so that it is easier for children to imitate.

iv. Children with special needs require less time in learning activities. A long enough duration can interfere with the child's concentration in receiving the material presented.

v. Children with disorders need more visual acuity so that animated animations can be added that can provoke cognitive thinking in children to accept learning.

vi. The background used is trying to be more dynamic, so as not to disturb the audience's focus on the back sound.

vii. This video is quite interesting, where the media used in learning is technology. As we know that children with autism disorder like new things that are not too monotonous. With interesting videos full of colors and animations, it can increase children's motivation in understanding the material presented. However, this video has a long enough duration which can interfere with the concentration of children in receiving learning. The suggestion is that this video can be divided into two sessions, where the children can first be given a break and have a moment to rest in receiving the next material.

TABLE VII. RESULT SUMMARY FOR SUBJECT MATTER EXPERT

Question type	Strongly Disagree	Disagree	Moderate	Agree	Strongly	Total
Leamability	-	-	11%	54%	35%	100%
Flexibility	-	-	12%	45%	43%	100%
Effectiveness	-	-	9%	53%	38%	100%
Average	-	-	10%	51%	39%	100%

3) Parents: There are six parents of children with verbal apraxia took part in the testing phase. They assist the testing phase to run well by explaining the questionnaire to their children with their own way.

a) Chart of Learnability for Parents: Fig. 12 shows the testing results from parents for the learnability aspect. Fig. 12 shows most parents agree and the rest strongly agree that this animation is able to attract the attention of their children because most of them acknowledge that their children are interested in interesting audio as well as cute and easy to remember animated pictures.

Half of the parents agree and the other half strongly agree that this animation is easy for their child to understand as illustrated in Fig. 12, because it contains clear instructions and keeps them focused.

There are four parents who agree and two others who strongly agree that the instructions in this video are clear for their children to follow as represented in Fig. 12 because the instructions and directions from the host are very clear with clear words and voices for the user who follows.

Fig. 12 interprets about 66.7% of parents (4 respondents) agree that learning with animation really helps their children for better understanding of numbers and letters. It is more interesting and attractive for children, as children like and are happy when there are moving pictures that resemble shapes and have eyes image to teach them how to memorize letters and numbers.

b) Chart of Effectiveness for Parents: Fig. 13 shows the testing results from parents for the effectiveness aspect. Fig. 13 depicts that four out of six chose “strongly agree” that animated interactions involve their children as a whole from the beginning of learning to completion of learning, so that children are 100% involved in the learning process through the animated visuals.

The finding highlight 100% of parents agree that this application has a good impact on their children as shows in Fig. 13. It makes children happy with the animations given and able to repeat songs and read letters and numbers, also making them easily remember the concepts learned.

Fig. 13 illustrates that our finding revealed that 66.7% of parents agree this application can promote positive behavior in children because it can make children to be more focused on something, be patient in seeing things and understand things slowly and well.

Also, Fig. 13 shows that four people agree and two others do not really agree with the statement that by using 2D animation is more effective than watching other learning videos. It is because not all children like animation, some only like the audio or the visual, not both.

c) Chart of Accessibility for Parents: Fig. 14 shows the testing results from parents for the accessibility aspect. There are five people who agree that the layout of the content increases the effectiveness in delivering information as stated in Fig. 14 because behind a neat layout, a structured pattern will appear so that the video goes according to the specified plan.

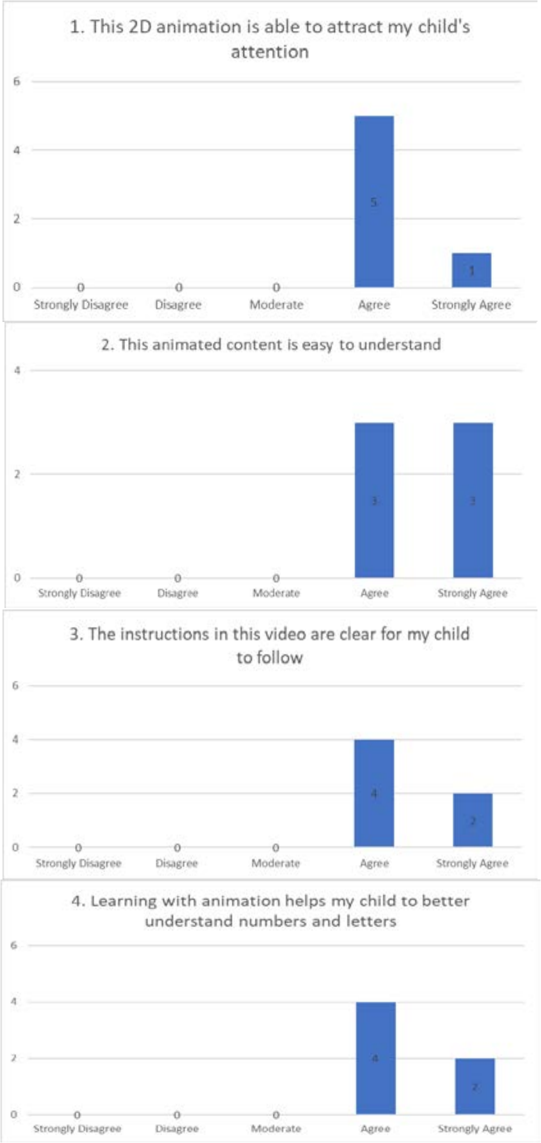

Fig. 12. Result of Learnability by the Parents.

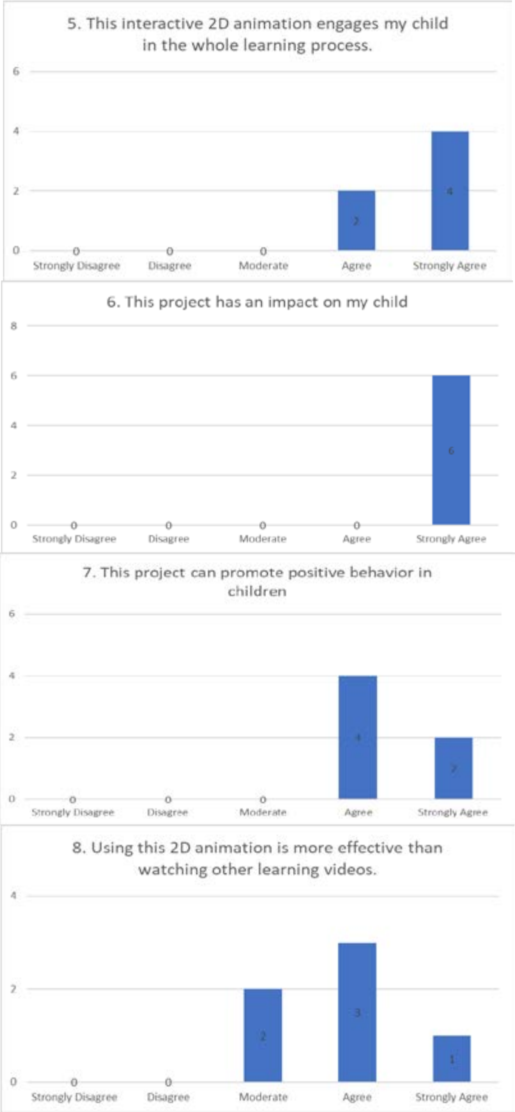

Fig. 13. Result of Effectivess by the Parents.

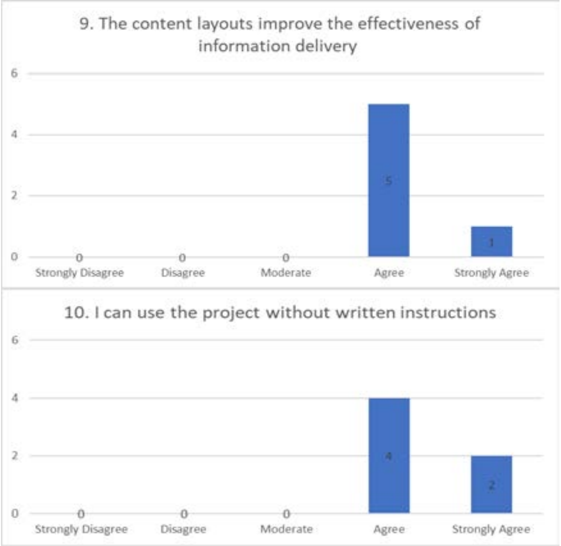

Fig. 14. Result of Accessibility by the Parents.

This study indicates that 66.7% of parents agree this application can be used easily, without written instructions as mentioned in Figure 14. This animation ran smoothly and without issue. The host and the character along with the transitions both flows well to the end. The sounds and text are both clear and smooth.

Table VIII summarises the testing summary for parents.

TABLE VIII. RESULT SUMMARY FOR PARENTS

Question type	**Strongly Disagree**	**Disagree**	**Moderate**	**Agree**	**Strongly**	**Total**
Leamability	-	-	-	67%	33%	100%
Effectiveness	-	-	8%	66%	26%	100%
Accessibility	-	-	-	75%	25%	100%
Average	-	-	8%	69%	23%	100%

d) Summary for Improvement from Parents: Based on the questionnaire distributed to the parents, below are the suggestion for improvement:

i. Videos are made more colorful to help children visually receive learning.

ii. It is suggested for this application to add the numbers up to 20 or 100, for the letters it can go up to A-Z. The rest is good and the child loves this video.

iii. Suggestion for the video, not just number and letters, but can talk about shapes, colors, animals, food and others.

iv. Quite good, and quite interesting. The child is happy with the video as the child watched it three times because the child really liked the song.

v. Do not make the video too long, suggested for two or three minutes. The rest is interesting and educational.

vi. The child may be a little annoyed with a rather long duration but enjoys.

IV. DISCUSSION

It is recommended that further improvement be undertaken such as the professional recording equipment where the equipment like voice recorders and cameras play an important role in overcoming visual and hearing problems. It is suggested to use proper equipment which can help solve the audio problem. Besides that, duration of the video also needs to be shortened which will make the audience feel less bored. Thus, dividing the topics into separate video parts and not putting them in the same video will help solve the problem. In addition, the other contents or topics of the animation should be added like types of colors, shapes, plants, human body, and other topics which is still in line with the children's learning syllabus.

The contribution of this study is obvious as the resulting outcomes can be capitalised as guidelines as verbal apraxia therapy for children with verbal apraxia of speech. The findings of this study will help demonstrate the aid for children with verbal apraxia of speech in their learning. This research work promotes children and society by providing therapy for children with verbal apraxia. It can enhance the way to conduct therapy with a new method for kids, and hopefully can be used for adults too. Furthermore, this animation includes essential knowledge that is simple to comprehend for children. This animation also provides an excellent view for children to learn about topics, such as numbers and alphabets. This application encourages children to listen to and comprehend the messages, as well as to memorize them.

V. Conclusion

The purpose of the current study was to determine the usability of the proposed application; 2D animation for Learning Numbers and Alphabets. One of the more significant findings to emerge from this study is that the proposed application received positive feedbacks from the target users. These findings suggest that in general the application is accepted and greatly contributes to the verbal apraxia children. The animation has been successfully developed and run for the target users; children with verbal apraxia. This research work also meets the objectives, which is to develop an animation video as a therapeutic solution for children with verbal apraxia, and to evaluate the effectiveness of this animation. It is very useful and could be an alternative for therapists, instructors, doctors, and parents who have children who suffer verbal apraxia, for them to learn things by a new learning method with fun and entertainment. The children are entertained by the visuals of the animation, which motivates them to learn and study new things; if this application is developed carefully with more research in accordance with the criteria recommended by medical experts, multimedia experts, and parents, this research work will have a major impact on science and education if developed carefully. The 2D animation application was developed for the society and can reach out other scopes like social, community and even science and technology.

Acknowledgment

This research is part of Final Year Project in Information and Communication Technology, presently being carried out at the Faculty of Information and Communication Technology, Universiti Teknikal Malaysia Melaka (UTeM). We are thankful to UTeM and all respondents who took part in the final survey and testing phase, and we would like to express our thoughtful appreciation to them.

An Evaluation Method for Service-Oriented Architecture Maturity Model

Mohd Hamdi Irwan Hamzah, Ezak Fadzrin Ahmad Shaubari
Faculty of Computer Science and Information Technology
Universiti Tun Hussein Onn Malaysia
86400, Parit Raja, Johor, Malaysia

***Abstract*—SOA maturity model was used to clarify and provide a common definition of SOA inside an organization. The model provides an abstract overview of SOA adoption by characterizing evolutionary levels. However, this study found that there is a lacking on how the previous models were evaluated to show that the model is conforming to the specification and can be implemented in the real-world environment. Therefore, this study aims to provide the evaluation method for the SOA maturity model through the verification and validation process. The Integrated Adoption Maturity for Service-Oriented Architecture (IAMSOA) model was chosen and the verification process is being performed through expert review where the study identifies the experts, determines the verification criteria, and collects and analyzes the feedback; while the validation was performed through case study by identifying the organization, determining the validation criteria, brainstorming, and collecting and analyzing the feedback. The verification results show that the evaluated model is comprehensive, understandable, accurate, and well-organized. Moreover, the validation results reveal that it is feasible and practical to be executed in the real environment. Conclusively, this study has successfully evaluated one of the SOA maturity models and shows the verification and validation process in detail which can be re-enacted in different projects and settings.**

Keywords—Maturity model; model evaluation; model validation; model verification; service-oriented architecture

I. Introduction

Google, Microsoft, and Facebook, among others, have grown increasingly reliant on cyberspace for everyday operations. As a result of COVID-19's rapid global spread, demand for internet services has urged in lockstep with the issue [1] [2]. The volume of service requests has increased dramatically in comparison to previous years and some of the firms have taken several significant initiatives, including the adoption of Service Oriented Architecture (SOA). A successful SOA implementation requires a well-defined SOA roadmap that details the plans, milestones, techniques, and desired outcomes. Adopting SOA is a major project that requires numerous organizational changes. Typically, businesses begin by wrapping traditional systems in web services and utilizing SOA as a means of achieving business benefits through total business transformation [3]. The most effective method for handling this shift is to divide it into phases. Adopting a maturity model is the simplest way to implement the transformation roadmap [4].

Additionally, the frequently divergent perspectives of IT, business managers, and organization leaders on SOA maturity adoption and delivery could be the result of unstated assumptions about where and why SOA should be adopted [5]. Furthermore, auxiliary work in SOA metrics is also required. Researchers are encouraged to continue developing maturity models using a combination of qualitative and quantitative metrics. A model of SOA maturity must consider both perspective and execution maturity. Progress must also be accomplished in a three-dimensional environment, with the shift from an IT-driven to an enterprise-transformation perspective — encompassing governance, performance indications, drivers, and even nomenclature, which therefore will likely eclipse execution enhancements inside a given perspective.

Nevertheless, even though numerous scholars contributed to the development of the SOA maturity model, there is still a dearth of effort in evaluating the model at the time of writing. This study has found that it is important to evaluate the model to show that it conforms to the standard specifications and is suitable to be implemented in a real-world setting. Moreover, based on the previous literature, this study has identified various SOA maturity models that have been constructed, such as SOAMM, SOASMM, Governance Maturity for SOA, and IT Risk Management Maturity Model for SOA [6, 7, 8, 9]. Yet, most of the previous models did not discuss in detail how they evaluate their models to prove they are of high quality and can produce reliable results. Based on the literature reading, the IT Risk Management Maturity Model for SOA is one of the few models that highlights the importance of evaluating the model through a case study approach. A similar finding has also been mentioned in other maturity models set up in the Global Software Development (GSD) domain, where they state that the case study approach is a powerful evaluation tool that can provide valuable real-world information [10].

However, relying solely on the case study approach to determine that the developed model conforms to its specifications and that all of the required components are present in sufficient quantity is inadequate [11]. It is critical to obtain the domain expert's approval and feedback before sanctioning the developed model [12]. Therefore, this study proposed including both the expert review (verification) and case study (validation) approach within the evaluation process. In realizing this approach, it was determined that one of the SOA maturity models should be evaluated to determine whether the constructed model meets the specifications, captures the requirements needed, and can be implemented in a real-world environment. Accordingly, the Integrated Adoption Maturity for Service-Oriented Architecture (IAMSOA) model was chosen and evaluated through the verification and validation approaches. This study is structured as follows: Section 1 covers the introduction and is followed by Section II (the background of the study). Section III discusses the methodology applied in this study and Section IV presents the results. Section V discusses the verification and validation results and Section VI summarizes the study.

II. Background of the Study

SOA maturity models provide an abstract overview of SOA adoption by characterizing evolutionary levels [13] [14]. They can be thought of as a collection of critical process areas that work together to optimize a well-defined business and IT architecture. They also can be used to regulate and measure the progress of SOA adoption [15]. In addition, SOA maturity is one of the most pressing challenges of SOA adoption issues in the SOA lifecycle [16]. However, theoretically sound, methodologically rigorous and empirically evaluated SOA maturity models are extremely rare [17]. As a result, this study determined the importance of reviewing and discussing many of the most widely used SOA maturity models presented by the industry and academia. The aim of the study is to determine how the current researchers evaluate their proposed SOA maturity model.

The SOA Maturity Model (SOAMM) was published in 2005 based on the feedback from around 2000 architects and developers [6]. SOAMM maturity levels were evaluated through a single evaluation dimension that incorporates various perspectives, including prime business benefits, scope, critical technology success factors, critical people success factors, organizational success factors, and selected relevant standards. Based on these perspectives, they presented a guide for establishing SOA vision and a benchmark for measuring progress by including the goals, characterization of the scope, business benefits, important industry standard, key practices, and critical success factor. Despite this, SOAMM never explained how they evaluate their model in depth.

In 2012, Welke et al. [14] proposed an SOA maturity model based on the capabilities of maturity model integration (CMMI). Welke's model first interpreted their maturity model as a capability orientation model, and then they specified that as SOA becomes more mature, the SOA ability should be fully realized in order to contribute to business operations and organization's service orientation as a whole. Furthermore, the researcher proposed an SOA maturity cube that introduces the idea of a multidimensional view for SOA maturity. The first dimension is for the organization to identify their current levels of SOA maturity according to six defined SOA criteria, which are the infrastructure efficiency, reuse, composition and integration, business process and analytics, enterprise flexibility and agility and enterprise transformation; the second dimension is to determine what to do in order to reach the next maturity, which are the benefits and metrics, business involvement, methodology, service sourcing and governances. However, their study also does not include a comprehensive discussion on the evaluation method.

Inspired by the introduction of the SOA maturity model in 2005 [6] and the maturity cube concept by Welke et al. [14], Hamzah et al. [18] first presented that the SOA should have prioritized on both information technology (IT) and business benefits. Then, continuing their work, they mentioned that the SOA maturity level should be based on the Adoption of Innovation theory to cater for SOA adoption issues and that the GQM approach should have been included within the evaluation matrix to provide a structure and systematic evaluation [19] [20]. Additionally, they did an exploratory study in 2019 to bolster and enhance their findings, which subsequently lead to the introduction of the IAMSOA model. Nonetheless, their work is incomplete, as they emphasize the importance of evaluating their model to conform that it can accomplish the desired objective and being employed in a real-world setting.

Coincidentally, within the same year of 2019, another researcher has performed a systematic literature review on the SOA maturity models to identify research opportunities and areas where the SOA maturity model can be improved [21]. A total of 20 unique SOA Maturity Models were investigated and reviewed in detail. Their findings reveal that although all SOA Maturity Models propose an assessment framework, only a few SOA Maturity Models are guided in prioritizing the improvement process. Furthermore, in line with this study's interest, they also mentioned that empirical research on the in-depth analysis and evaluation of SOA Maturity Models is sparse. They also further acknowledged that there is minimal effort in evaluating the SOA maturity model and it is critical for future research to work on this issue.

Recently in 2021, Azevedo et al. [9] constructed an IT Risk Management Maturity Model for SOA. This work presents a risk management maturity model, formed by the union of good information technology risk management practices and existing maturity models, to be applied in an SOA. The model aims to support the assessment process of identifying the level of risk management maturity within the SOA domain. To evaluate the proposed model, the scenario of a health organization was used, and the results indicated that the level of IT risk management maturity based on SOA was measured, providing a holistic view of risk management on the dimensions of people, processes, and technology. They stated unequivocally that it is important to validate the SOA maturity model through a real-world scenario in which their results show the risks maturity level and the importance of managing risks properly.

As a result of earlier literatures, this study concluded that it is important to perform the evaluation on the SOA maturity model, particularly through the implementation in a real-world environment. The proposed evaluation method through the verification and validation process is expected to provide an organized guideline for other researcher to evaluate their developed SOA maturity model. This study will build on the work of [20] by conducting an evaluation of the IAMSOA model via the verification and validation process. The approach utilized in this study to evaluate the IAMSOA model is described in the next section.

III. THE EVALUATION METHOD FOR SERVICE-ORIENTED ARCHITECTURE MATURITY MODEL

Based on the literature reading, this study has found that the evaluation for SOA maturity model should be performed through two main phases which are the verification and validation phases. Fig. 1 shows the proposed evaluation method for SOA maturity model and the components require to perform the evaluation process. They are discussed further in the next subsection.

A. Verification Stage

The verification should be performed to check whether the SOA maturity model conforms to its specification [22] and ensures that all required components are present in the right quantity [23]. This study found that the verification stage was intended to verify i) the maturity level, ii) evaluation dimension, and iii) evaluation matrix. To accomplish these aims, the expert review should be used because it has been accepted as a significant way to detect and remove defects [24]. Basically, there are three activities involved in verifying the SOA maturity model which are i) identifying the expert, ii) determining the verification criteria, and iii) analyzing the feedback. These activities are discussed in the following subsections.

1) Identifying the expert: The experts should be chosen among the academicians (knowledge experts) by following the characteristics of experts as suggested by Hallowell and Gambatese [25]. The characteristics include i) currently attached to the field of the study under examination, ii) hold an advanced degree (PhD.), iii) faculty members at an accredited university, iv) authorship, and v) have at least five years of experience. Additionally, as the SOA maturity model is intended to be used by the SOA practitioners, therefore, they should be included as the domain experts to perform the verification as well as to give their insights from the real-life environment point of view. The characteristics of the domain experts are that they should have at least three years of experience in SOA implementation.

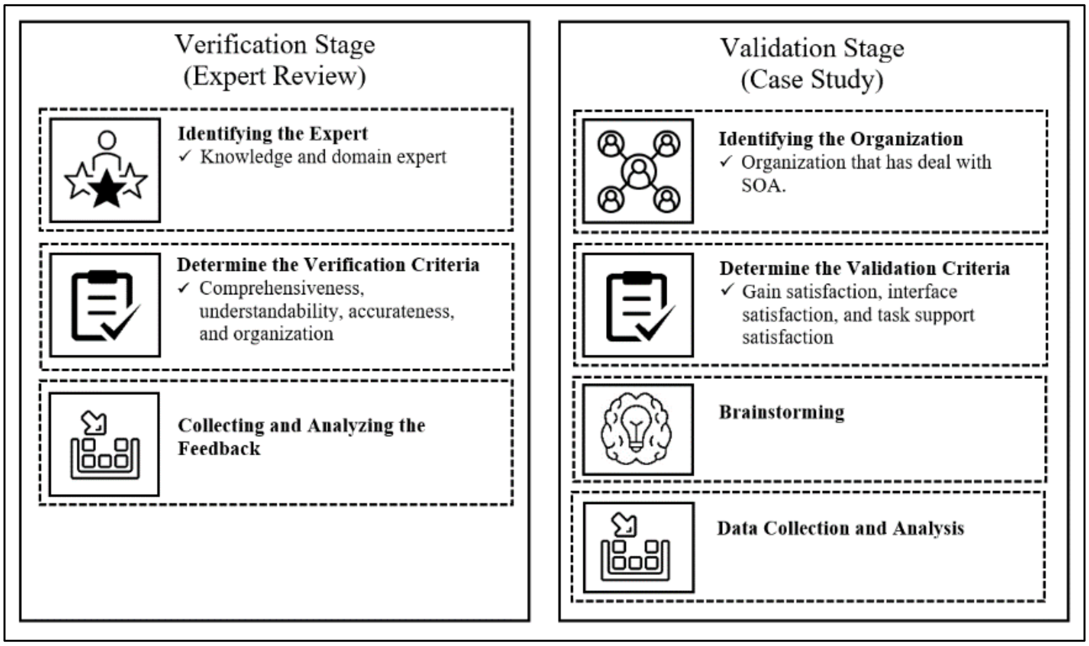
2) Determine the verification criteria: The study has identified that the major components of the SOA maturity model are the maturity level, evaluation dimension, and the evaluation matrix. These components should be verified for their comprehensiveness, understandability, accurateness, and organization. These criteria were based on the previous studies where it was appropriate and has been successfully used to verify their model or framework [26] [27]. The questions that were asked to verify and measure these criteria were adopted from Salah [28].

3) Collecting and analyze the feedback: The knowledge expert's feedbacks should be collected and analyzed for further improvements.

B. Validation Stage

Models validation is a fundamental process to confirm that the models are of sufficiently high quality [29]. In this context, the validation process was performed to prove that the SOA maturity model have high quality and can be re-enacted in other projects or settings. This study performed the validation process through the case study approach. The details activities for the validation process are discussed in the next subsection.

1) Identifying the organization: The organization should be selected based on their dealing with SOA, the available projects related to the SOA, and their willingness to apply the model. The study also identified that it is appropriate to select the organization according to their expertise in dealing with SOA where the organization needs to be competent in SOA-based applications. This enables the testing of the feasibility and practicality of the model in different settings.



Verification Stage
(Expert Review)
Identifying the Expert
✓ Knowledge and domain expert
Determine the Verification Criteria
✓ Comprehensiveness, understandability, accurateness, and organization
Collecting and Analyzing the Feedback
Validation Stage
(Case Study)
Identifying the Organization
✓ Organization that has deal with SOA.
Determine the Validation Criteria
✓ Gain satisfaction, interface satisfaction, and task support satisfaction
Brainstorming
Data Collection and Analysis

Fig. 1. The Proposed Evaluation Method for SOA Maturity Model.

2) Determine the validation criteria: The validation criteria for the SOA maturity model were determined by adapting them from the study of [25] which can reveal the success of the proposed model. Kitchenham and Pickard [30] stated that the evaluation criteria should include three main criteria which are, gain satisfaction, interface satisfaction, and task support satisfaction. These common criteria had then been used by several researchers such as [20] and [19] in evaluating their model or framework which were carried out in the field of software engineering.

3) Brainstorming: After the identification of the validation criteria, the validation process should be performed. The brainstorming session should be conducted where it is to introduce the SOA maturity model to the organization. The purpose of implementing the SOA maturity model should be explained to the organization who participate in this validation process.

4) Data collection and analysis: The data collection and analysis can be performed by giving out and collecting the data based on two evaluation forms which are: i) the proposed instrument in order to evaluate the maturity of SOA adoption for the organization and ii) the evaluation form to validate the proposed model. Based on the feedback from the organization, the data should be analyzed and the evaluated SOA maturity model should be improved.

IV. The Implementation of the Proposed Evaluation Method for Service-Oriented Architecture Maturity Model

This section is going to discuss the result of implementing the proposed evaluation method tos the IAMSOA model.

A. *Result for Verification*

This section illustrates the experts' answers and suggestions for the IAMSOA verification. There are three major components of the IAMSOA model which need to be verified by the experts which are the evaluation dimension, maturity level, and evaluation matrix. These components were verified based on their comprehensiveness, understandability, accurateness, and organization. These criteria were adapted from previous studies [24] [26].

The experts provided their feedbacks by filling in the checklist form. The experts were asked to rank the level of these criteria achievement. The Six Likert scales were used to describe the level of achievement of the items. The results were calculated by getting the mean score for each criterion and selecting the appropriate interval that represents the actual mean. Table I shows the mean interval presentation and the achievement level adapted from ISO 15504 while Table II reveals the verification results for the evaluation dimension components.

Results in Table II show that three out of four criteria gained "fully achieved" for the evaluation dimension which are comprehensiveness, understandability, and well-organized. The accuracy is the only criteria that gained 'largely achieved'. Most of the experts stated that the evaluation dimension is well defined and acceptable.

TABLE I. Representation of Achievement Levels (Adapted from ISO/IEC 15504)

Mean Interval Presentation	Achievement level
From 0 to 0.8 (0%-15%)	Not achieved
From 0.9 to 2.9 (>15%-50%)	Partially achieved
From 3 to 5 (>50%-85%)	Largely achieved
From 5.1 to 6 (>85%-100%)	Fully achieved

TABLE II. Verification Results for the IAMSOA Evaluation Dimension

Item	Mean	Overall Mean	Achievement Level
Comprehensiveness			
The required criteria for evaluating the SOA IT and business benefits are included.	5.3	5.3	Fully Achieved
The required sub-criteria for evaluating the SOA IT and business benefits are included.	5.3		
Accuracy			
The IT and business benefits criteria and sub-criteria are correctly assigned to maturity levels.	4.9	5	Largely Achieved
There is no overlap detected for the descriptions of IT and business benefits criteria and sub-criteria.	5.1		
The sub-criteria for IT and business benefits are correctly assigned to IT and business benefits criteria.	5		
Understandability			
The IT and business benefits criteria and sub-criteria are understandable.	5.2	5.2	Fully Achieved
The IT and business benefits criteria and sub-criteria descriptions are understandable.	5.2		
Well-Organized			
The IT and business benefits criteria are well organized.	5.3	5.25	Fully Achieved
The IT and business benefits sub-criteria are well organized.	5.2		

Expert F mentioned that at the 'Optimized' level, the organization should be looking at the agility and flexibility for optimization and transformation to be ahead of the competition. Furthermore, another expert (Expert C) stated that the proposed model needs to consider a few KPAs such as Configuration Management. In short, all of the experts agreed with the evaluation dimension of the IAMSOA by stating that the proposed dimension is acceptable and can be applied to measure the IT and business benefits. As for the IAMSOA maturity level verification, the results are listed in Table III.

TABLE III. VERIFICATION RESULTS FOR THE IAMSOA MATURITY LEVEL

Item	Mean	Overall Mean	Achievement Level
Comprehensiveness			
The number of maturity levels are adequate and appropriate.	5.2	5.08	Fully Achieved
The maturity levels description is sufficient.	5.3		
The maturity levels are sufficient to represent all maturation stages of the domain.	5		
The Key Process Area (KPA) for each maturity level covers all aspects for evaluation of the domain.	4.8		
Accuracy			
There is no overlap detected between descriptions of maturity levels.	5	5.13	Fully Achieved
There is no overlap detected between each Key Process Area (KPA) of maturity levels.	5		
The Key Process Areas (KPAs) are correctly assigned to their respective maturity level.	5.4		
Understandability			
The maturity levels are understandable.	5.3	5.2	Fully Achieved
The maturity levels description are understandable.	5.2		
The Key Process Areas (KPAs) for each maturity level are understandable	5.1		
Well-Organized			
The maturity levels are well organized.	5.2	5.15	Fully Achieved
The Key Process Area (KPA) for each maturity level are well organized.	5.1		

As shown in Table III, the maturity level gained "fully achieved" for all the criteria. Based on the expert review, majority of the experts satisfied with the proposed maturity level. One of the experts mentioned that the maturity level for the IAMSOA model is derived from a well-defined standard in software engineering practices such as CMMI and it is well understood. Another expert also stated that the maturity level is well organized and understandable. Conclusively, all the experts agreed that the IAMSOA maturity level is well-defined, organized, and appropriate to be used as a benchmark for measuring the SOA maturity and adoption. Table IV presents the results of the IAMSOA evaluation matrix verification.

TABLE IV. VERIFICATION RESULTS FOR THE IAMSOA EVALUATION MATRIX

Item	Mean	Overall Mean	Achievement Level
Comprehensiveness			
The model is sufficient to determine the SOA adoption maturity	5	4.92	Largely Achieved
The model is sufficient for conducting SOA adoption process improvement	5		
The model is sufficient to track the SOA adoption issues	4.7		
The model is sufficient and practical to be used in industry	4.9		
The model is useful to be used in industry	5		
Accuracy			
The overall evaluation matrix are constructed correctly	5.1	4.98	Largely Achieved
The evaluation goals are constructed correctly	5		
The evaluation questions are constructed correctly	4.9		
The evaluation metrics are constructed correctly	5.1		
The evaluation process are constructed correctly	4.8		
Understandability			
The evaluation matrix is understandable	5.3	5.2	Fully Achieved
The evaluation process is understandable	5.3		
The implementation guideline is understandable	5		
The scoring scheme is understandable	5.2		
Well-Organized			
The structure of evaluation matrix are well organized	5.4	5.3	Fully Achieved
The evaluation process are well organized	5.2		

Based on Table IV, two out of four criteria for the IAMSOA evaluation dimension gained "fully achieved". The criteria that obtained "fully achieved" are understandability and well-organized, while the comprehensiveness and accuracy criteria "largely achieved". Expert E commented that detail descriptions for the achievement scale (not achieved, partially achieved, largely achieved, and fully achieved) are required and the coverage for the evaluation needs to be included. Moreover, Expert A mentioned that the evaluation matrix needs to include specific steps such as an evaluation flow for the evaluation matrix to be clearer and understandable. Another expert (Expert C) also stated that there are a few steps in the assessment process that need to be rearranged where some of the steps should appear at the beginning of the assessment process. Nevertheless, despite some of their comments, all the experts agreed that the evaluation matrix for IAMSOA is well structured and can be applied in the real-world environment.

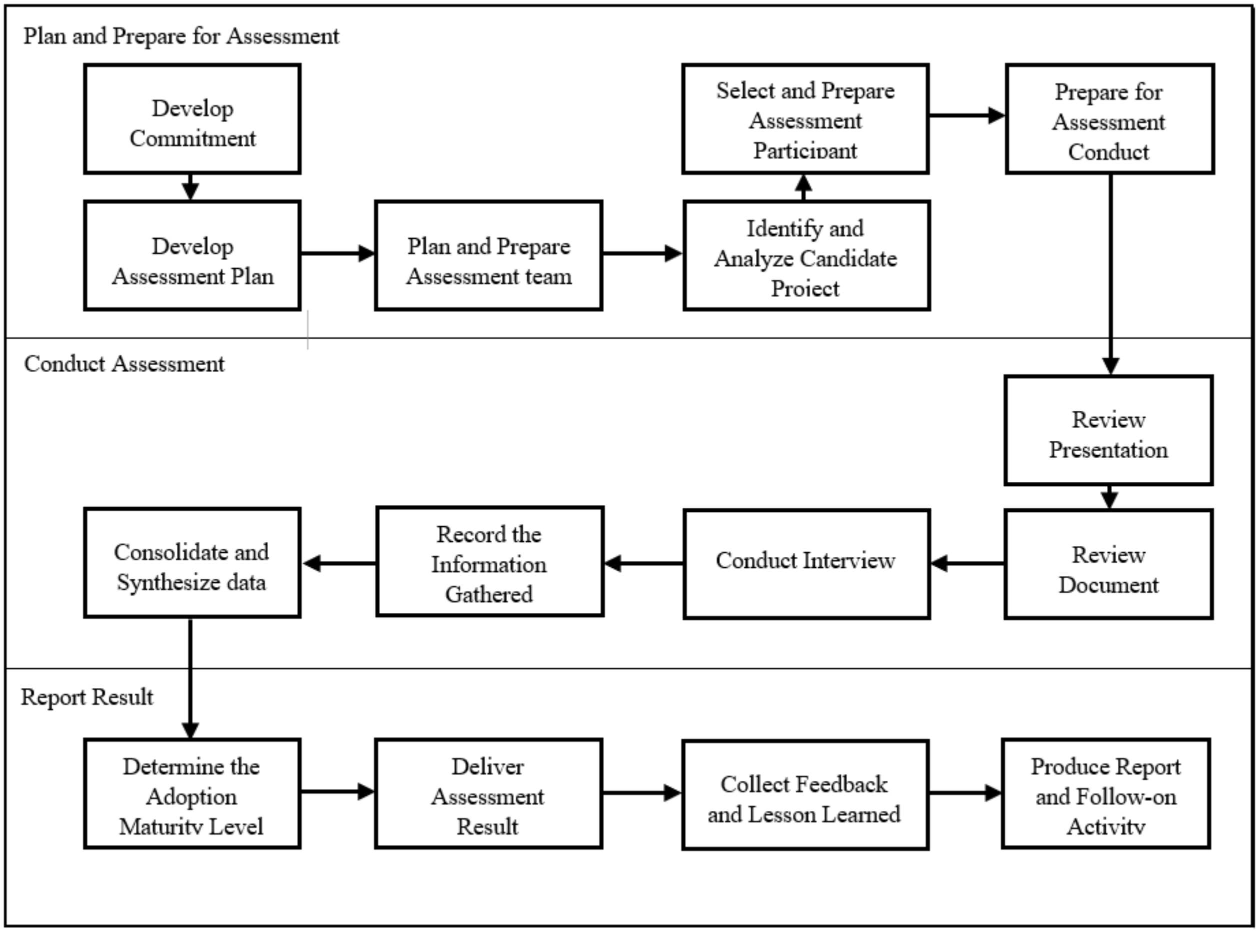
Overall, all experts gave general reviews of the proposed IAMSOA model. They concluded that IAMSOA is a good model and can benefit the industry. Majority of the experts agreed that IAMSOA is a flexible model that can be extended to cater other related SOA domains. Finally, once the evaluation dimension, maturity level, and evaluation matrix have been verified, the validation process were performed and is presented in the next subsection.

B. *Result for Validation*

The aim of the validation process is to evaluate the effectiveness of the IAMSOA model. In this study, the validation was performed through case study. This section presents the results of the case study conducted in one of the software companies in Malaysia. The aim is to validate the IAMSOA model and show its applicability and added benefits. Fig. 2 shows the assessment process flow for SOA maturity model.

The case study was performed by assessing the Product Inspection System by Company A. Detail discussions for the case study are presented in the following subsection.

1) Organization profile: Company A is an in-house solution provider. Its main client is an electric utility company that represents one of the large semi-government sectors in Malaysia. Apart from providing a centralized, one-stop center for technical solutions and innovation, Company A has developed some solutions under a variety of applied research projects. Recently, Company A needed to ensure that only qualified equipment is employed by their parent company. In order to provide this service, a Product Inspection (PI) Management System was developed by the company. This signifies that the PI has an enormous job coordination. To handle such big volumes, a flexible architecture is necessary to ensure that the PI Section is able to manage various PI related works. Hence, the SOA has been adopted in developing the PI Management System. In addition, a mechanism to measure the quality of the SOA-based application is required to ensure the delivery of high-quality services to the IT and business people in the company. Having the SOA-based application, it is obvious that the IAMSOA model can help in determining the level of adoption and maturity. After contacting and discussing with the company's ICT Research Unit, the proposed IAMSOA model was used to assess the SOA adoption maturity for the PI Management System. The subsequent sections describe the details of the IAMSOA model related processes in evaluating and assessing the SOA adoption maturity in the company.



Plan and Prepare for Assessment
Develop Commitment
Develop Assessment Plan
Plan and Prepare Assessment team
Identify and Analyze Candidate Project
Select and Prepare Assessment Participant
Prepare for Assessment Conduct
Conduct Assessment
Review Presentation
Review Document
Conduct Interview
Record the Information Gathered
Consolidate and Synthesize data
Report Result
Determine the Adoption Maturity Level
Deliver Assessment Result
Collect Feedback and Lesson Learned
Produce Report and Follow-on Activity

Fig. 2. SOA Maturity Model Assessment Process Flow.

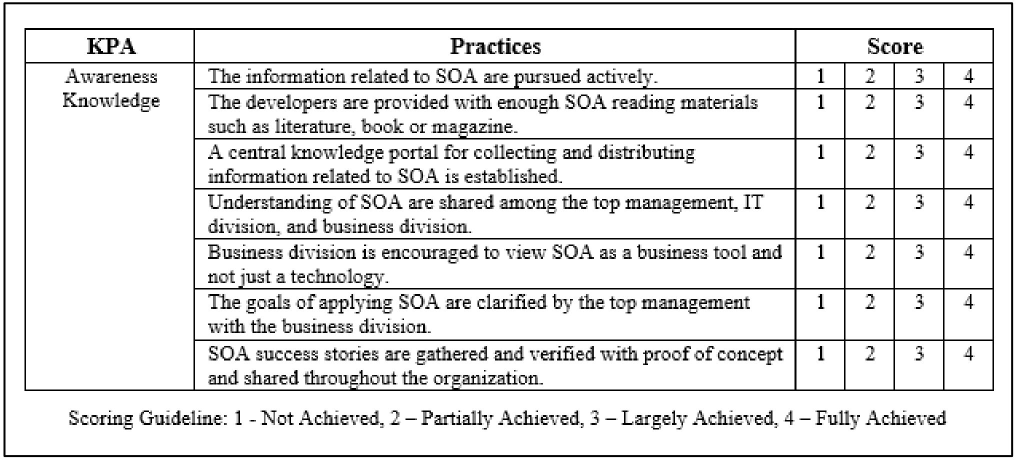
2) Plan and prepare for assessment process: There are six activities involved in the planning and preparing for the assessment process; i) developing commitment, ii) developing assessment plan, iii) planning and preparing assessment team, iv) identifying and analyzing project candidate, v) selecting and preparing assessment participant, and vi) preparing assessment conduct. During this phase, the assessment team in Company A started to plan and prepare for applying the IAMSOA model. The phase started by defining the objectives, constraint, and scope for appropriate assessment design as well as establishing an organization leader commitment. Then, the team prepared a document for guiding and defining the execution of the assessment. The lead assessor, conducted a briefing session to the team to familiarize them with the assessment plan, IAMSOA model, and assessment process. After the briefing, the team continued with a meeting among its members to discuss whether the assessment can be conducted or not. After they agreed to proceed with the assessment, each staff was appointed a specific role.

3) Conduct assessment process: After finishing the first activity, the assessment team continued to conduct the assessment. The assessment processes include i) reviewing presentation, ii) reviewing document, iii) conducting interview, iv) recording the gathered information, and v) consolidating and synthesizing data.

This phase began when the assessor started to collect the data by participating during the staff/developer's presentation regarding SOA project. The assessor then assessed the documents produced during the development of the project. The assessor also interviewed the top management, project manager, and developers to obtain information about the project/system and clarify on any information that could not be acquired through document review. Then, the assessor produced a document that records all the gathered information. After obtaining all the required data, the assessor went on to calculate the score for individual and overall performance qualities of the SOA project by using the IAMSOA assessment form as shown in Fig. 3.

4) Report result process: The final phase is about reporting the results that involved four activities; i) determining the adoption maturity level, ii) delivering assessment results, iii) collecting feedbacks and lesson learned, and iv) producing report and supporting follow-on activity. At the beginning of this phase, the SOA adoption maturity level for Company A was determined based on the score extracted from the IAMSOA assessment form. The results of the maturity level for the PI Management System is presented in Tables V, VI, VII, and VIII. Table V shows the score for the PI Management System at Maturity Level 1 is 95% which indicates that the PI Management System has successfully achieved maturity level 1.

Table VI shows the score for the PI Management System at Maturity Level 2 of 91.5%. This indicates that the PI Management System has successfully achieved maturity level 2.



KPA	Practices	Score			
Awareness Knowledge	The information related to SOA are pursued actively.	1	2	3	4
	The developers are provided with enough SOA reading materials such as literature, book or magazine.	1	2	3	4
	A central knowledge portal for collecting and distributing information related to SOA is established.	1	2	3	4
	Understanding of SOA are shared among the top management, IT division, and business division.	1	2	3	4
	Business division is encouraged to view SOA as a business tool and not just a technology.	1	2	3	4
	The goals of applying SOA are clarified by the top management with the business division.	1	2	3	4
	SOA success stories are gathered and verified with proof of concept and shared throughout the organization.	1	2	3	4

Scoring Guideline: 1 - Not Achieved, 2 – Partially Achieved, 3 – Largely Achieved, 4 – Fully Achieved

Fig. 3. Example of the IAMSOA Model Assessment Form.

TABLE V. MATURITY LEVEL 1 FOR THE PI MANAGEMENT SYSTEM

Key Process Area	Key Practices	Individual Quality	Overall Quality	Achievement
SOA Knowledge Gathering (SOAKG)	Awareness Knowledge (AK)	85%	95%	>85% Achieved Maturity Level 1
	How-to Knowledge (HK)	90%		
	Principle Knowledge (PK)	100%		
New Functionality (NF)	Perform New Service (PNS)	100%		
	Develop Pilot Project (DPP)	100%		

TABLE VI. MATURITY LEVEL 2 FOR THE PI MANAGEMENT SYSTEM

Key Process Area	**Key Practices**	**Individual Quality**	**Overall Quality**	**chievement**
SOA Adoption (SOAA)	SOA Adoption Decision (SOAAD)	100%	91.5%	>85% Achieved Maturity Level 2
	SOA Infrastructure Management (SOAIM)	85%		
	SOA Best Practices Management (SOABPM)	95%		
	SOA Project Planning (SOAPP)	87%		
Service Integration (SI)	Service Modularity (SM)	95%		
Service Scalability (SS)	Service Migration (SMi)	87%		
Cost Reduction (CR)	Time Management (TM)	87%		
	Cost Management (CM)	96%		

Table VII shows the score for the PI Management System at Maturity Level 3 of 93.5%. This shows that the PI Management System has successfully achieved maturity level 3.

TABLE VII. MATURITY LEVEL 3 FOR THE PI MANAGEMENT SYSTEM

Key Process Area	**Key Practices**	**Individual Quality**	**Overall Quality**	**Achievement**
SOA Implementation (SOAI)	Technical Assistance Resolution (TAR)	96%	93.5%	>85% Achieved Maturity Level 3
	Service Analysis (SA)	87%		
	Service Design (SDES)	89%		
	Service Development (SDEV)	93%		
	Service Monitoring (SMo)	100%		
Service Reusability (SR)	Service Publicity (SP)	100%		
	Service Conformance (SC)	100%		
	Service Comprehensibility (SCo)	100%		
	Service Understandability (SU)	100%		
Service Integration (SI)	Service Availability (SAv)	91%		
Service Flexibility (SF)	Service Reliability (SRe)	91%		
Service Agility (SA)	Service Modifiability (SMod)	100%		
Service Scalability (SS)	Service Replication (SRe)	100%		
IT/Business Alignment (ITBA)	Orchestration Management (OM)	91%		
	Resources Alignment (RA)	85%		

Table VIII shows the score for the PI Management System at Maturity Level 4 of 77.4%. This indicates that the PI Management System has not achieved maturity level 4.

TABLE VIII. MATURITY LEVEL 4 FOR THE PI MANAGEMENT SYSTEM

Key Process Area	**Key Practices**	**Individual Quality**	**Overall Quality**	**Achievement**
SOA Performance Evaluation (SOAPE)	Service Level Agreement (SLA)	95%	77.4%	<85% Not Achieved Maturity Level 4
	System Testing (ST)	100%		
Service Reusability (SR)	Service Discoverability (SD)	83%		
	Service Commonality (SCom)	92%		
	Service Composability (SComp)	75%		
	Service Portability (SP)	62.5%		
	Service Adaptability (SAd)	62.5%		
Service Flexibility (SF)	Service Interoperability (SInt)	42%		
	Service Changeability (SCh)	55%		
Service Agility (SA)	Service Evolvability (SEv)	75%		
Business Quality (BQ)	QoS Assurance (QoSA)	95%		
	Security Management (SM)	92%		

Results from the evaluation show that the PI Management System has achieved "Maturity Level 3". Maturity level 5 Key Process Area was marked with 'pending' once the Company A failed to achieve Maturity Level 4. Based on Table VIII, Company A can instantly identify at which Key Process Areas and Key Practices that they have been lacking off. Therefore, it is important for Company A to be able to measure the relative maturity within each Key Process Area to identify areas that are lacking.

As presented in Table VIII, at maturity level 4, the PI Management System partially achieved the Service Flexibility, and largely achieved the Service Reusability and Service Agility. Thus, Company A needs to give more attention and work on these Key Process Areas to achieve the next level which is Maturity Level 4. Once the lagging Key Process Areas have been identified, it is possible to come up with solutions and eventually improve the success of the overall SOA initiative.

Based on the results presented in Tables V, VI, VII, and VIII, Company A can determine which goal that the PI Management System has already achieved according to the IAMSOA model. The goal achievement is important to identify the areas that are already fulfilled and those that need improvement. After determining the SOA adoption maturity, the assessment results were immediately presented to the company's ICT Research Unit to get an agreement on the outcomes. In addition, based on the results, recommendation on future improvements were proposed. Company A has to improve three main service areas, namely Flexibility, Reusability, and Agility in order to achieve Maturity Level 4 and to progress to the next level Maturity Level 5.

V. Discussion

The results indicate that Company A has achieved maturity level 3 and implies that Company A is competent in applying the SOA based-application. Moreover, an interview session was conducted with the assessment team leader for Company A to validate the IAMSOA model. The team leader answered the validation form that was constructed based on a set of evaluation factors. These factors are gain, interface, and task support satisfactions. Each factor includes various related items or statements. These statements were answered by the assessment team members by deciding whether to AGREE or DISAGREE. This type of answers format signifies a practical measurement [31] that can directly capture the respondent's intention effectively. Table IX displays the validation results form.

From Table IX, the first criterion or factor to be evaluated during the validation process is "gain satisfaction" that measures the benefit of the IAMSOA model to the real-life environment. The measurement items for this factor include decision support satisfaction, comparison with the previous model, clarity, and task appropriateness. The results from the interview point out that the assessment team from company A stressed that the model achieved decision support satisfaction by helping the organization to decide on well-defined processes. The assessment team also agree that the model is very clear and understandable where each process presents the required input, outputs, methods and activities.

TABLE IX. Validation Results

Item	Company A
Gain satisfaction	
Decision support satisfaction: The IAMSOA model helps the management to take a well-defined decision based on the processes.	Agree
Comparison with the previous SOA model: The IAMSOA is better than the old model that you used in terms of structure and achieved results.	Agree
Clarity (clear and illuminate the process): The IAMSOA process is clear to the development team, where each phase clearly presents the required inputs, outputs, methods or practices, and activities.	Agree
Task Appropriateness: The phases and activities presented in the IAMSOA model are appropriate for adopting and implementing SOA in your company; and the flow of the process is presented in a systematic and effective way.	Agree
Interface satisfaction	
Internally consistent: The IAMSOA model is internally consistent.	Agree
Organization (well organized): The components of the IAMSOA model are well organized and structured which makes the process easy to perform.	Agree
Appropriate for audience: The IAMSOA model is appropriate for the audience. Those audiences are referred to the development and the monitoring team in the software firms.	Agree
Presentation: The results presented by performing the IAMSOA process are produced in a readable and useful format.	Agree
Task support satisfaction	
Ability to produce expected results: The IAMSOA model is able to produce expected results.	Agree
Completeness (adequate or sufficient): The IAMSOA model is adequate and sufficient for adopting and implementing SOA in your organization.	Agree
Ease of implementation: The process of the IAMSOA model is easy to implement.	Agree
Perceived usefulness	
Using IAMSOA model enables you to accomplish your tasks more quickly.	Agree
Using IAMSOA model improve the performance of your work.	Agree
Using IAMSOA model makes performing your tasks easier.	Agree
IAMSOA model is useful to your work.	Agree
Using IAMSOA model increases your productivity.	Agree
Perceived ease of use	
Learning the IAMSOA model is easy for you.	Agree
Do you find it easy to use IAMSOA model to do what want to do?	Agree
The IAMSOA model is flexible to interact with.	Agree
Your interactions with the IAMSOA model are clear and understandable.	Agree
It is easy for you to become skillful in using the IAMSOA model.	Agree
The IAMSOA model is easy to use.	Agree

The “interface satisfaction” represents the second criterion or factor that measures the IAMSOA model in terms of interface presentation, format, and processing efficiency. Pertaining to this factor the assessment teams emphasized that the model is internally consistent whereby each component complements one another. The team also agreed that the IAMSOA components are well organized and structured by sorting all the processes, activities, and roles in a clear and understandable manner. The model is also declared to be appropriate for the audience as the team members comprised of those with variety of skills. The team also satisfied with the readable and useful results format produced based on the IAMSOA model.

To ensure that the IAMSOA model can achieve its intended purpose and satisfies the assessor, the “task support satisfaction” factor is used as the third measurement factor. The team also agreed that the IAMSOA model can produce the expected result because it provides a well-defined sequence of activities and a wide variety of evaluation criteria such as the SOA adoption, maturity, IT, and business benefits. In addition, the model was found to be adequate and sufficient in determining the level of SOA adoption maturity that focuses on the IT and business benefits. Consequently, based on the responses relating to perceived usefulness and ease of use, it can be concluded that the IAMSOA model is useful, easy to use, effective, and feasible to be used in Malaysian organizations.

VI. Conclusion

This study has presented the evaluation method for the SOA maturity model through the verification and validation stages. The significance of the proposed evaluation method within the domain of the study is to provide a guideline for other researchers who want to ensure that their SOA maturity model conforms to the specification and can be implemented in the real-world environment. The IAMSOA model was chosen as a case study to implement the proposed evaluation method for the SOA maturity model. In the verification stage, the IAMSOA model has been verified by five knowledge and five domain experts. The experts were asked to verify the IAMSOA evaluation dimension, maturity level, and evaluation matrix. Next, the validation stage was performed using the case study approach, and the findings reveal that the IAMSOA model is feasible to be implemented in the real world based on several real-life applicability evaluation criteria such as gain satisfaction, interface satisfaction, task support satisfaction, perceived usefulness, and perceived ease of use. Conclusively, this study has successfully evaluated one of the SOA maturity models through the verification and validation process. Moreover, this study has contributed to explaining how to perform the expert review and case study to evaluate the SOA maturity model. The detailed process, methods, results, and discussion have been presented, and this can guide other researchers to perform the evaluation of their models in other settings.

Nevertheless, this study also identified that there is a limitation to the proposed evaluation method, which requires future work towards enhancing this study. The limitation is that the proposed method involves collaborative assessment where organizations form a team to assess the maturity of their SOA-based applications. Based on the assessment results, Company A achieved maturity level 3 in their first assessment. The achievement of maturity level 3 for the first assessment is considered high compared to the CMMI assessment (third-party assessment). The high achievement might relate to the collaborative assessment whereby the assessment was performed by its own staff, which may cause biased assessment. Another reason may relate to the practices for the assessment being too general. Thus, in the future, a third-party assessor can be brought in, and the practices should be changed to make the results more reliable and high-quality.

Acknowledgment

The authors would like to thank the Ministry of Higher Education Malaysia for supporting this research under Fundamental Research Grant Scheme Vot No. FRGS/1/2020/ICT03/UTHM/03/1 and partially sponsored by Universiti Tun Hussein Onn Malaysia.

***Abstract*—As machine learning is growing rapidly, creating art and images by machine is one of the most trending topics in current time. It has enormous applications in our current day to day life. Various researchers have researched this topic and they try to implement various ideas and most of them are based on CNN or other tools. The aim of our work is to generate comparatively better real-life fake human faces with low computational power and without any external image classifier, rather than removing all the noise and maximizing the stabilization which was the main challenge of the previous related works. For that, in this paper, we tried to implement our generative adversarial network with two fully connected sequential models, one as a generator and another as a discriminator. Our generator is trainable which gets random data and tries to create fake human faces. On the other hand, our discriminator gets data from the CelebA dataset and tries to detect that the images generated by the generator are fake or real, and gives feedback to the generator. Based on the feedback the generator improves its model and tries to generate more realistic images.**

Keywords—Generative adversarial network; fake human faces; generator; discriminator; CelebA dataset

I. Introduction

Fake images can be used by police to track down people who are involved in adultery. As we know nowadays child and underage pornography is alarming. To catch such people we can use computer generated fake faces, that will be more ethical than using real images [11]. As we can see nowadays creating fake or edited images is very easy. To identify these kinds of images, we can build a model. For this model to be trained we can use the computer generated images to identify the real and fake images. We use the fake computer generated images in visual art and the advertising industries. These images have a huge role in computer games. In computer and mobile games along with play station games, these images can be used. As augmented reality and virtual reality are growing rapidly, we can use these computer generated fake images.

II. Literature Review

There are many fake image generation models created or updated by the researchers which generate pretty good images. Zhang et al. [1] in 2020 discussed an algorithm that can improve the quality of generated images as the quality of the fake images generated by the conventional GAN is limited. Wang et al. [2] in 2016 tried to simplify the overall process of generative models which gave them more realistic high resolution images as well as highly stable and robust learning procedures. Ghatas et al. [3] in 2020 proposed a method of building a complex modular pipeline using previously trained models to generate the kin image. They tried to build such a model where it changes the way of approaching GAN problems.

Hamdi et al. [4] in 2019 proposed a new GAN that uses the K-nearest neighbor for selective feature matching in a high level space and they named their work as K-GAN. Tolosana et al. [5] in 2020 tried to recognize fake news, fake images, fake media, and face manipulation using their method. They provided a thorough review of digital manipulation techniques which were applied to facial content due to the huge number of possible detrimental applications.

Karras et al. [6] in 2019 proposed a method that re-designs the generator architecture so that we can understand the various aspects of the image synthesis process. Though GAN has seen rapid improvement in recent years, we still have a very poor understanding of the properties of the latent spaces. They tried to understand the inner workings of the latent spaces. Their work starts learning from constant input and tries to adjust the “Style” of the image on each layer. Their method was tested on Flickr-Faces-HQ and FFHQ datasets.

Zhao et al. [7] in 2019 proposed an image translation network by exploiting attributes with the generative adversarial network. It can remarkably contribute to the seven authenticity of the generated face by supplementing the sketch image with the additional facial attribute feature. The generator and discriminator both use skip-connection to reduce the number of layers without affecting network performance. In the underlying feature extraction phase this network is different from most attribute-embedded networks. They divided their networks into two parts as sub-branch A and sub-branch B, which takes a sketch image and attribute vector to extract low level profile information and high level semantic features.

In recent years, Generative Adversarial Networks have achieved extraordinary results for various applications in many fields especially in image generation because of their ability to create sharp and realistic images. In this paper, Shirin Nasr Esfahani et al. [8] discussed five areas of image synthesis based on different techniques of GAN. They are: Text to Image Synthesis, Image to Image translation, Face Manipulation, 3D Image Synthesis and Deep Master Prints. In this paper they have actually tried to focus on the applications of the above techniques and discussed their merits and demerits and future applications. An Introduction to Image Synthesis with Generative Adversarial Nets is proposed in [10]. This model is working well for the simple dataset, for the complex dataset the model does not work well.

Though there are many fake image generation models, what we have tried to do in our work is that we have tried to generate the images using low computational power and without any external image classifier. We have used two neural networks in our model. One is Generator and the other is Discriminator. Generator creates fake human faces and Discriminator detects the faces generated by the generator if this is fake or real. If the face generated by the generator is detected as fake then the discriminator gives feedback to the generator. And based on the feedback of the discriminator, the generator improves itself and tries to generate better quality faces. This process goes on until the generator creates better quality fake human faces. From detecting fake news, fake images to data misclassification, fake human face generation helps us to be used in all of these areas. And generative adversarial network model is one of the best one to create better real life fake human faces.

Rest of the paper is organized as follows. The proposed method is explained in Section III. In Section IV, the experimental results are presented. The paper is concluded in Section V.

III. Proposed Method

A. Methodology

In our model we have tried to implement generative adversarial networks in a very classic way with new and latest tools and technologies. We have tried to implement a generative adversarial network to generate fake human faces from random noise with low computational power and without any external image classifier, rather than removing all the noise and maximizing the stabilization which was the main challenge of the previous related works. We know that for implementing generative adversarial network we have to set a generator whose work will be to generate fake faces from the noise and update its own model after receiving the feedback from the discriminator and we also have to implement a proper discriminator to identify the real and fake image, so that it give the right feedback, means it says true to real image and false to fake image and based on its feedback the generator will change its model in such a way that eventually it will create almost real like images.

That’s how we are trying to implement our generative adversarial network to generate fake human faces. Our generator and discriminator will use the keras’s classic sequential modeling.

We proposed to use two sequential models, one as a generator and another one as a discriminator to implement our generative adversarial model. For implementing the generator, as we can see from the workflow diagram, we have used random noise as input data for the generator. We have also used the Batch Normalization technique and the Reshape module from the keras to resize the data and normalize to train the generator properly. In our generator we have used a total of five layers, one is an input layer with 128 nodes, starting with three more dense layers 512, 1024 and 2048 nodes respectively with each layer and lastly the output layer. We have used the Leaky ReLU activation function for all the layers except the output layer; in the output layer we have used the tanh activation function for the output layer. We have also used the loss function as the binary cross-entropy for our generator model. Our generator will receive feedback data from the discriminator and based on the received feedback our generator will be updated.

On the other hand, our discriminator is also implemented with the sequential model. However, the main difference between our generators is that after each epoch it does not learn, meaning it will not update or train after each epoch. Our discriminator’s main purpose is to identify the real and fake image and give the feedback to the generator, so that we will use the sequential model. In our discriminator’s input data we have used both the generator produced data and the real image from the CelebA dataset and it takes both images and tries to identify the real and the fake image. Here, the model uses a total of four layers. As an input layer we have taken the generated data and the real image data and there are also two hidden dense layers along with an output layer which produce binary values. Other than the output layer we have used the Leaky ReLU activation function in our model and as our output will be classification type, so in the output layer we have used the sigmoid function. For the loss function in our model we have used the binary cross-entropy function.

B. Overall Workflow

In Fig. 1 the diagram we have shown the overall workflow of our proposed model, and later in this paper we have also explained how our generator, discriminator and the fully connected sequential model work [12] [13].

C. Generator

We have proposed two sequential models, one as a generator and another one as a discriminator to implement the generative adversarial model. We have used random noise as input data in the generator model. The input data is actually a layer which has 100 nodes. Then we have used four hidden layers where we have used Leaky Relu as our activation function. The hidden layers have 128, 256, 512, 1024 nodes respectively. We have used the Tanh activation function in our last layer. We have also used Batch Normalization to normalize the data. At last, we have reshaped the nodes into (48, 48, 1) size. The Adam optimizer has been used as our optimizer. During the compilation of the model, binary cross-entropy has been used as our loss function. The generator will produce some fake human faces and it will improve itself by the feedback from the discriminator. The flow diagram of the generator is presented at Fig. 2.

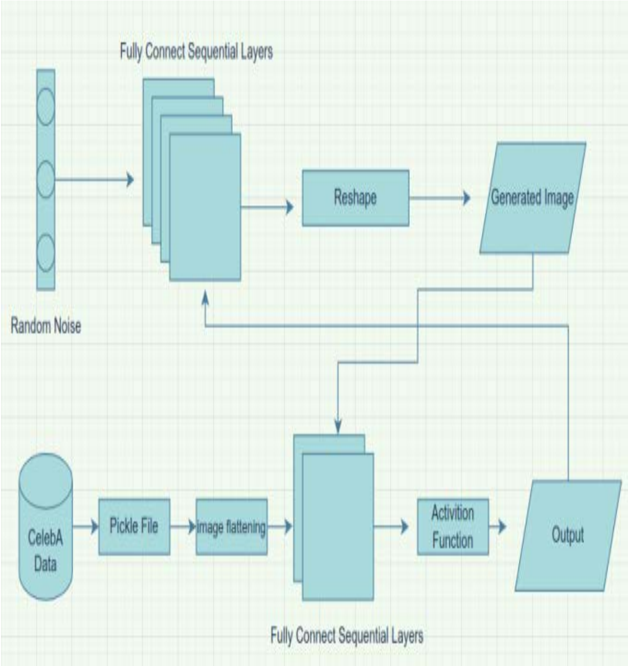

Fig. 1. Overall Workflow Diagram.

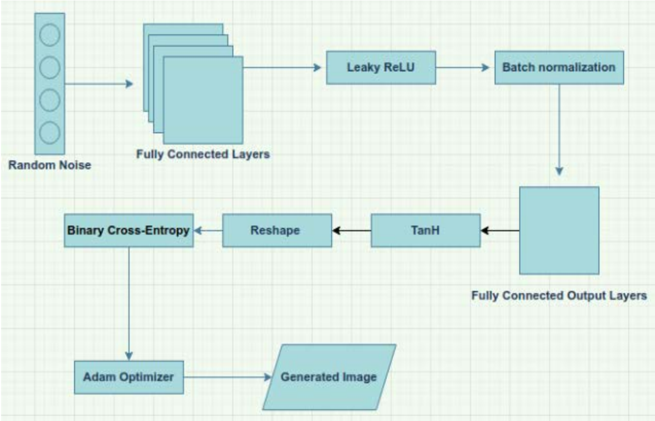

Fig. 2. Generator.

D. Discriminator

Discriminator is our second sequential model which we have used in our generative adversarial model. At first we used the flatten operation to make the data one dimensional. After that there are two dense layers. The first hidden layer has 48*48 nodes and the second hidden layer has half of the first hidden layer, which means 1152 nodes. Leaky ReLU has been used as the activation function in those two dense layers having the learning rate as 0.2. In the output layer the sigmoid activation function has been used as the activation function. We have used binary cross-entropy as the loss function and Adam as the optimizer during the compilation period. The discriminator will receive images from both the actual data from the celebA dataset and fake data from the generator and it will give feedback to the generator if the images generated by the generator are fake or real. The generator will receive feedback from the discriminator and improve itself. The flow diagram of the discriminator is presented in Fig. 3.

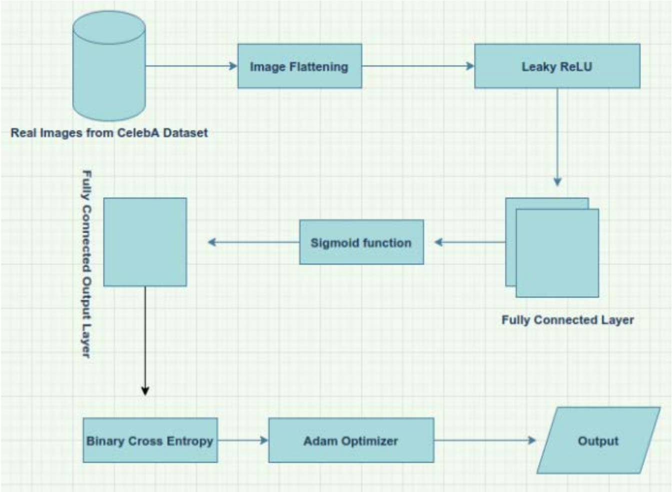

Fig. 3. Discriminator.

In our proposed model we have used two fully connected sequential models, one as a generator and another one as a discriminator. The generator receives a random noise and tries to train it as a human face and then our discriminator receives data from the CelebA dataset and tries to match the faces with the generator's fake faces, and give feedback to the generator, and based on the feedback our generator learns and tries to create comparatively better fake human faces after each training.

IV. Experimental Results

In this section, we have presented a detailed overview of the experiments of our presented model based on the CelebA dataset. We have shown how our model worked during different scenarios of the dataset. We have changed the size of the data multiple times to see how the model works each time. And we have got different results each time. We have described how the results differ and improve over the time.

A. Dataset and Experimental Settings

We have used the CelebA dataset for our model. In our CelebA dataset there are more than 200k data. At first, we ran our model on this whole dataset but we used the size of images as 48*48. We ran 100000 epochs on the model to get a good result. Normally in generative adversarial models we have to run a lot of epochs to get a good result. Generative adversarial models generally generate new images according to the task given. So, it requires a lot of time to generate the new images. That's why we ran the model 100k epochs [14].

B. Experimental Tools and Environment

We have used different tools and environments for preprocessing the data and running the model so that we can have good results from our model.

C. Programming Language

Tensorflow and Keras, which are the two libraries of the Python programming language, have been used in our model. Nowadays Python is the most popular programming language for implementing Machine Learning and Deep Learning models as it has many collections of packages which are very helpful to implement the different Machine Learning and Deep Learning models. Python is also the most preferred language because it is very easy to learn and implement. Python has many free and open source libraries for Machine Learning and Deep Learning models. Tensorflow is one of them. Keras is an open source software library which supports a Python interface for artificial neural networks. Keras plays the role as an interface for the Tensorflow library.

D. Result

The four images shown in the Fig. 4 were generated by the same model after 52000, 65000, 81000 and 97000 epochs respectively. In the first image two faces could not be generated properly. Rest of the faces of the first image were generated but still there were a lot of noises which actually prevented us from understanding the faces properly.

Compared to the first one, the second image is slightly a little bit better but there are also one or two faces which could not be generated properly and contained a lot of noise. Almost all of the images were generated properly in the third image containing some noise, though it was comparatively better than the first two images. In the fourth image, this image performed quite well. In the fourth image all of the faces were generated and had a small noise. After receiving the images from the CelebA database we first flatten the images then we run the sequential model with the Leaky ReLU. Then in the output layer we use the sigmoid function to return the true or false type result value. Then in the discriminator we use the binary cross entropy as the loss function along with the Adam optimizer. This output from the discriminator then goes to the generator as a feedback and based on the feedback of the discriminator, the generator tries to create new images. So, after the above discussion we can say that there are still noises in the generated faces at the end of the model too, though the results of the latter part of the model performed comparatively better.

The four images shown in Fig. 5 were generated after 52000, 63500, 81500 and 99500 epochs respectively. After the 52000 epochs, two faces could not be generated properly, which we can see from the first image above. Some faces are not perfect though some faces are generated properly with little noise. In the second image which was generated after 63500 epochs, all of the faces were almost properly generated with some noise. After 81500 epochs and 99500 epochs, the faces which were generated, that we can see from the above third and fourth images, are much better. The interesting fact is that if we observe the faces properly we can see that almost all of the faces are different from one another.

After the above discussion what we can observe is that the faces became better as the time went on. And at the last phase of the model the faces became more and more clear and understandable. Another interesting fact is that as the time went on all of the faces were generated by which we can understand that the model was improving over time. And we can also see the faces were different from one another which is also a very positive output of this model.

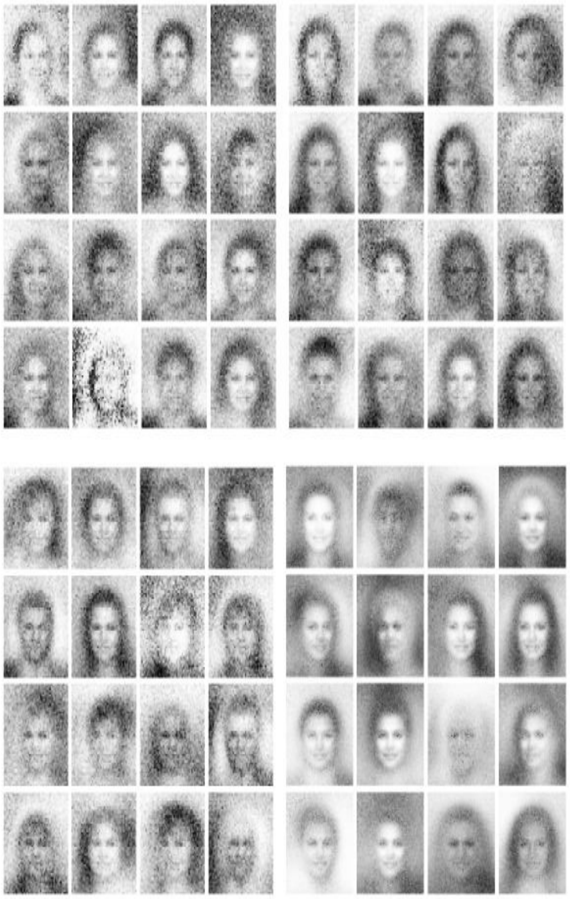

Fig. 4. Generated Data of 48*48 Size (CelebA Dataset).

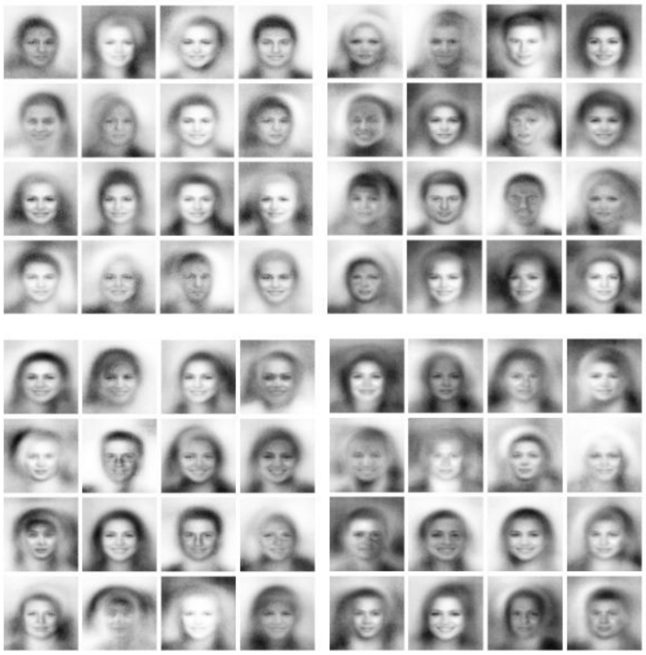

Fig. 5. Generated Data of 100*100 Size (CelebA Dataset).

E. Loss Function

Here, in the Fig. 6, we can see the loss function of the discriminator. We ran our models at about 100000 epochs. If we see the graph we can see most of the loss value between 0 to 1, which is pretty good value for the discriminator. And as the discriminator is an un-trainable model we see the loss value maintains the same ranges between the whole 100000 epochs. Now we can see some spike in the loss value of our graph. If we try to separate the high spike by trying again and again to visualize the diagram without the high spike of the loss value in our (48 x 48) size images, we can then easily see our loss value is somewhere between 0 and 1.4. And if we calculate the high spike, we can see there are 771 high spikes between 100000 epochs which is around 0.77% high spike and other 99.23% are the average, means 0 to 1.4 ranges. This is pretty good value for our model.

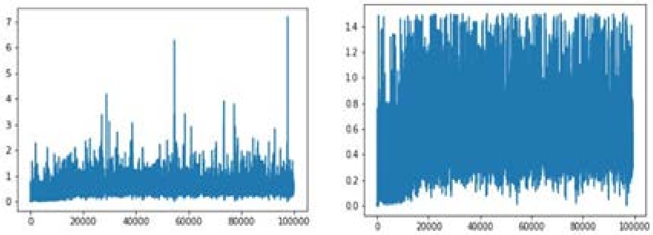

Fig. 6. Loss Values.

F. Comparative Analysis

Zeliha Dogan [9] et al. proposed a model titled “Baby Face Generation with Generative Neural Networks”, where they tried to generate fake baby faces using comparatively low computational power. We have chosen this paper for comparison because both this paper and our work follow almost the same objectives. Both this paper and our model mainly tried to generate fake faces using comparatively low computation power. Below in this section we have tried to compare our work with this paper, and show where our proposed method stands out and why. We have also tried to show our drawbacks and possible ways to overcome this drawback.

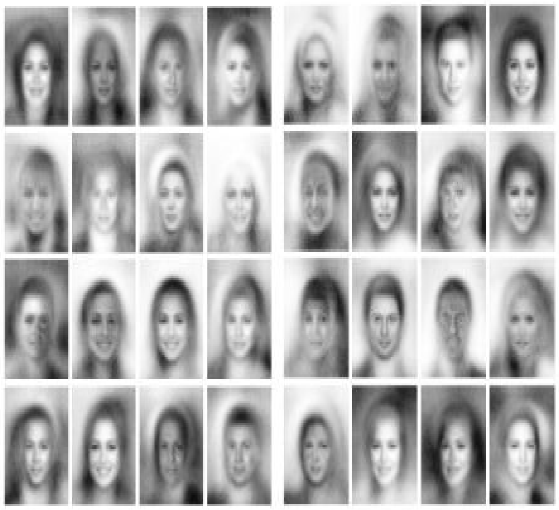

Fig. 7. Sample Output Images of the Proposed Model.

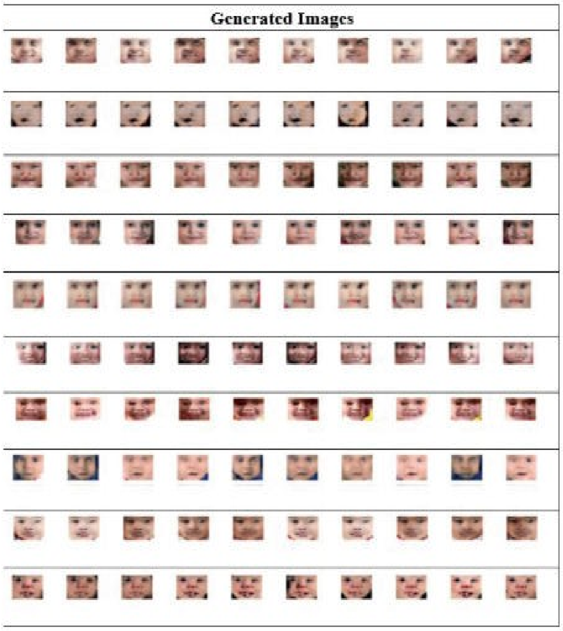

Fig. 8. Sample Output Images of the Baby Face Generation Model.

For sample output we have shown two figures. One is the Fig. 7 which is the generated output of our proposed model and another is the Fig. 8 which is the generated output of the baby face generation paper. At first glance we may think that both of these papers are very different. However, if we think clearly that both of those images are generated by a computer. And the objectives of those image creations are the same, which means creating fake human faces. If we see the baby face generation model images, they clearly lack the uniqueness of their faces. These images look like they were created with some other faces. It’s more like editing rather than creating or generating fake faces. On the other hand if we see our generated images we can clearly see that these images are not like those. And surely we can’t figure out if these images are created by mixing some other faces. It’s more like generating from the ground. Other than that we can clearly see that our image has more sharpness in eyes, nose and faces. But we have drawbacks in color and hair.

In the Table I, we can see that the different aspects of two models. In our model we have used black and white data with three different sizes of images 48*48, 100*100 and lastly 150*150. On the other hand, Baby face generation paper uses RGB images with 200*200 sizes. They ran only 200 to 300 epochs whereas our model ran about 100000 epochs. In our dataset we use 10k to 203k images on the other hand baby faces use only 623 images.

Now we can clearly see that though the sizes of images are smaller, we have used a lot of images with more epochs without the color of the image which can be trained in comparatively low computational power. Though we need more computer power than the baby face generator paper, using this extra computational power we can with proper scaling of the images create better images with sharper faces.

TABLE I. COMPARISON TABLE

Model	Image Type	Image Size	Number of Epochs	Da-taset	Size of Dataset used	Generator Loss	Output
Our Model	Black & white	48*48, 100*100, 150*150	100000	CelebA	230K, 50K, 10K	0.0-10.0	Overall better quality image, sharp Face
Baby Face Generator Model	RGB	200*200	200-300	UTKFace	623	1.0-2.0	Low quality image, RGB image

So after comparing with the baby face generation paper, we can say that in our paper using some extra computation power with proper image scaling we generated much better human faces which are more realistic and sharper. But we also have some drawbacks and our main drawback is that we have used comparatively more computational power than the baby face generation paper and our resulting images are black and white and our model needs comparatively more training data.

G. Discussion

In this paper, we try to create fake human faces. Our main focus was to create as much as a good image with low computational powers without any external image classifier. As we discussed above we used two sequential layers and a CelebA dataset to create fake human faces.

From our result and the loss function, we can see that, we successfully created human faces from random noises using limited computational power. However, the images are not as good as the real life images, so there is lots of scope in our paper to improve. However, we can see from the result that we have successfully created fake human faces from the random noise data. This is one of our main focuses.

Overall, using our low computational power we have tried to generate real life fake human faces. For comparing this model's results and to see how it reacts with different sizes of images we have tested it with three different sizes. At first, we tested it using 48 * 48 sizes. At that time, the model did not give that much good result though it generated fake human faces having noises. And then, to improve the quality we used 100*100 sizes. This time, the model performed quite well, where it gave quite a good result. When we used 100*100 sizes of the generated images were very clear and understandable. To get a better result, we then used 150*150 images. This time the model gave comparatively better results than the previous two models. Each time we ran our model at 100000 epochs.

V. CONCLUSION

In this work, a generative adversarial network model is proposed to generate fake human faces with low computational cost. The proposed generative adversarial network model generates comparatively better real life fake human faces with respect to the present state-of-the-art. We have also shown how we can only use two fully connected sequential models, one as a generator and another one as a discriminator to generate fake human faces. Though there are a lot of improvement areas in our proposed method, we can say that using our proposed model we have successfully produced pretty good fake human faces comparatively using very low computation power. In future, we can develop model to generate the images that can be used by police to track down people who are involved in adultery. We can also develop models for generating fake computer generated images in visual art, for the advertising industries and computer games.

***Abstract*—With the ease of use of smart devices, most data is now kept and exchanged in digital forms such as images, diaries, calendars, movies, and so on. Digital forensic investigation is a new technology that emerged from criminals' who extensively use computers and digital storage devices to commit different types of crimes. To address this issue, a new domain called Online Social Networks Forensic (OSNF) was created to investigate these dynamic crimes perpetrated on social media platforms. OSNFI seeks to obtain, organise, investigate, and visualise user information as direct, objective, and fair evidence. Considering the millions of individuals using social media to share and communicate, they are becoming increasingly relevant for criminal investigations. In forensics investigation of online social network, there are currently major problems such as: lack of structured procedures, the lack of unified automated methods, and the lack of a theoretical context. The use of non-uniform and ad hoc forensic techniques and procedures not only reduces the effectiveness of the process, but also affects the reliability and creditability of the proof in criminal proceedings. As a result, this paper will provide a method derived from the software engineering domain known as metamodelling, which will integrate OSNFI knowledge into an artifact known as a metamodel.**

***Keywords*—Online social networks forensic; online social networks forensic investigation; metamodelling; metamodel; model**

I. Introduction

Most organisations are now heavily reliant on digital media for information storage as digital media is used to create, process, store, and share the majority of information. Computer crimes and frauds are on the rise as the number of people using digital media grows and the law enforcement agencies faced several challenges as a result of the growing fraud and security threats. OSNs have received a lot of forensics investigation due to their widespread use and availability of supporting application interfaces. Furthermore, the number of criminal acts involving OSNs is increasing on a daily basis. It is vital to comprehend and evaluate online social network crimes and attacks in order to avoid illegal activity, discover malevolent users, and solve criminal cases. Furthermore, OSN users' safety should be enhanced to the greatest extent possible.

There are a variety of digital forensic investigation models available. However, most of them use similar methodologies and ignore the essential differences and special needs of online social networks. The main challenge is the use of a non-uniform and ad-hoc forensic techniques in the existing DFIM's [1]. The employment of non-standard and ad hoc forensic techniques and processes not only diminishes the effectiveness of the process, but it also undermines the dependability and creditability of the evidence in criminal cases.

Furthermore, while most of the created models focused more on a certain platform or content than the entire OSN [2], some still required manual treatment and could reduce the dependability and trustworthiness of evidence in criminal proceedings [3].

Therefore, there is the need to create a metamodel (a conceptual framework) for a domain which will assist many newcomers and stakeholders of the domain to have clear understanding and views of the relationship between concepts in the domain. Therefore, this is where this research will contribute in unifying the knowledge and all the processes of the OSNFI domain.

The remaining sections of this paper are organized as follows. Section II discusses on the concept of OSNFI. The OSNFI issues and challenges are presented in Section III. Section IV discusses the metamodelling approach. The preliminary results of the OSNFI metamodel development steps are presented in Section V. Sections VI and VII contain the conclusion and future work respectively.

II. Online Social Networks Forensic Investigation

The Scientific Working Group (SWG) defines Digital Forensic as the application of systematically developed and established methodologies for the safeguarding, gathering, validation, identification, analysis, interpretation, documentation, and presentation of digital evidence produced from digital sources [4]; to ensure the correct presentation of crime evidentiary data in court [5], primarily by protecting the data's credibility and ensuring a strict chain of custody. The ultimate aim of digital forensics is to gather evidence in order to answer questions like: What transpired, Who was involved, When did it take place, Where did it take place, Why did that happen, and How an incident occurred [6]. According to [7], the prevalence of computers and other devices has caused a proliferation in the quantity of incidents and amount of digital information in society. Previously, digital forensics was primarily handled by government agencies, but has recently become more frequent in the commercial sector.

According to [5], there are many reasons to justify why digital forensic investigation models need to be developed. Among which are: *(*i). the avoidance of future malicious events against the intended target, (ii). The successful tracing of the circumstances which lead to the crime and the identification of the parties involved, (iii). Identifying and apprehending the culprits of the crime, (iv). Improving present prevention procedures in place to avoid such an event from happening again, (v). Improving corporate security experts' usage of standards to secure their respective corporate networks, and (vi). How everyone connected into this digital world can become more aware of current vulnerabilities and preventive measures. However, multiplicity, measure cloud resources, secure of digital evidence, confidentiality, hiring, training, and development are some operational challenges faced by digital forensic [4].

Forensics is utilized on social networking networks such as Facebook, MySpace, Twitter, and LinkedIn. It is well known as social media forensics, and it's a subset of digital forensics and network forensics [8]. OSNs are web-based services which allow users to create a public or semi-public profile within a limited system [3], articulate a list of other individuals that they share a link, display and navigate their list of connections as well as those created within the system by others [9]; [10]. Different SNSs, like Facebook, Twitter, and LinkedIn, are used to connect people and enable them to communicate with one another [11]. People build personal profiles from various social networking sites to share their thoughts, photographs, images, emails, and instant messaging [12], as well as to find old friends or people with common interests or problems through various social networking sites [13].

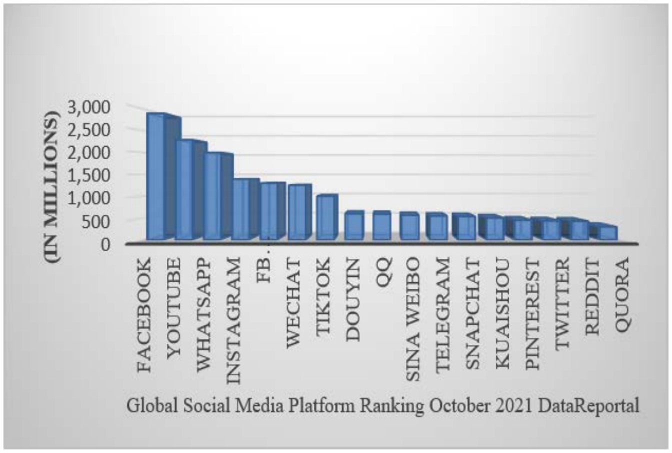

Fig. 1. Global Social Media Platform Ranking October 2021 DataReportal [14].

Facebook is managing 2,895 million users around the globe, whatsApp managing 2,000 million users, instagram managing 1,393 million users, and twitter managing 436 million users as of October 2021 as shown in Fig. 1. With the proliferation of mobile phones, the use of social network services (SNS) has skyrocketed, this SNS stores a variety of data, including user conversations, user location information, personal networks, and user psychology which can be valuable evidence in a digital forensics investigation of an incident [15]. Other uses of social networking sites include, general chatting, broadcasting breaking news, setting up a date, tracking election results, planning disaster response, humour, and serious analysis [12].

III. OSNFI Issues and Challenges

Investigators and legal practitioners are currently finding it difficult to examine social networking sites for evidence [16]. In order to discuss on the challenges associated to this explicitly, the method of the investigation are categorized into two: Conventional and Automated/Semi-automated OSN digital forensic investigation.

A. Conventional OSN Digital Forensic Investigation

Conventional OSN digital forensic investigation is a manual way of collecting and analysing all relevant information which can be considered as evidence. The following are some of the challenges associated with this technique:

1) Traditional digital forensic procedures include seizing and gathering everything that may be considered evidence. Nevertheless, this level of complete data extraction and preservation cannot be possible on online social network because of the extremely dispersed nature of social networks, their enormous scale, and mutual proprietorship of data.

2) Gathering data from people connected to the subjects (i.e., suspects or victims) lacking a reasonable suspicion of wrongdoing is virtually impossible and legally prohibited under confidentiality acts.

3) The evidence-collection process on social media sites is a process that is sometimes iterative. Therefore, the investigators will be required to gather more information if the examination subsequently identified other suspect [17].

B. Automated / Semi-automated OSN Digital Forensic Investigation

1) It can dumb down the profession because expert expertise cannot be derived solely from the field; it must also be derived from ongoing formal and informal research [13].

2) Digital forensics automation is more than just a technological issue; it also has legal and even political implications. Therefore, automation should be used only in specific phases and under expert supervision [13].

3) There are limited available automated tools that can be used in the investigation as a result of the heterogeneity of online social network and the non-existence of standardization [17].

4) Digital investigation training, practitioner training was a major concern, with 73 percent of respondents believing they don't get enough, especially in digital forensics, online investigations, and computer and network security as contained in a report by in a report by the High Technology Crime Investigation Association (HTCIA).

C. Current Issues of OSN Digital Forensic Investigation

Five relevant current issues of OSN forensic investigation as presented in Fig. 2 are discussed in this section as follows:

1) Increase in cyber-criminal activity in OSN: When creating a profile on many OSN sites, users can include their complete name, pictures, date of birth, up-to-date location, contact numbers, residential address, and office address (amongst others) [3]. Such profiles can aid in the connection of users. Users may choose to keep their profiles private, limiting their contacts, or make them public, allowing everyone to access and contact them.

Criminals may use all of the details available in these profiles to identify a specific person [18]. By their very nature, social networks have certain inherent properties that make them suitable for an adversary to manipulate. The following are the most critical of these characteristics: (i) a huge and extremely distributed user- base, (ii) clusters of users having the same social interests, developing trust with one another, and pursuing access to the same resources, and (iii) platform openness for deploying fraud resources and applications that trap users to install them.

Undoubtedly, these characteristics are the causes why cyber criminals believe there is a large chance to use online social network as a platform to commit crimes [3]. Among other illegal activities that have become a significant threat to OSN includes; Website phishing, Online sexual predators, OSN as vehicles for reaching an international audience, soliciting funding, recruiting new members, and disseminating propaganda.

2) Anti-Forensic techniques: Technical difficulties make obtaining data from the OSNs difficult. Criminals use anti-forensic techniques to hide evidence or to distract attention away from the investigation. Encryption, steganography, covert channelling, storage space data hiding, and residual data wiping are all methods used to conceal evidence [19].

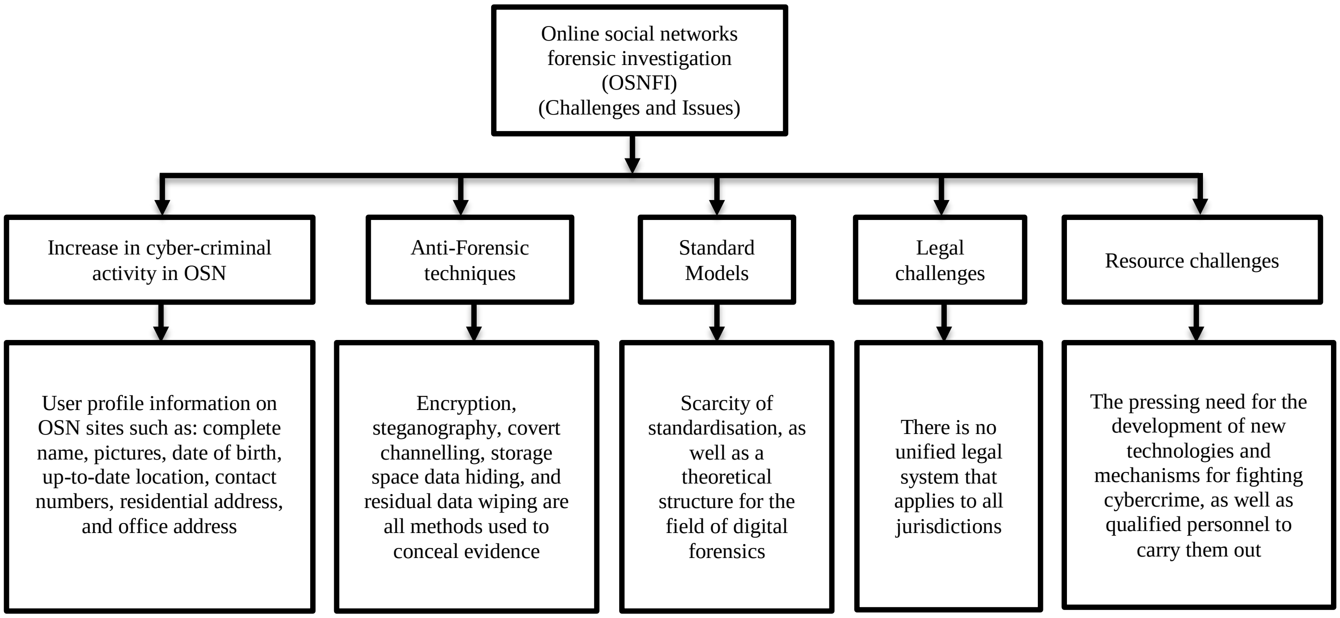
3) Standard models: A scarcity of standardisation, as well as a theoretical structure for the field of digital forensics, is one of the most serious issues that investigators are currently facing [20]. A such, the use of ad hoc methods and tools for eliciting digital evidence may limit the evidence's reliability and legitimacy, particularly in criminal cases where both the evidence and the processes used to gather it can be contested [3].

4) Legal challenges: The complications in investigations as a result in scarcity of commonly established rules and criteria governing the field are referred to as legal challenges. There is no unified legal system that applies to all jurisdictions. Despite the fact that internet use has risen globally. Many countries formulate policies in accordance with their regulatory structure, which differs from country to country [19].

5) Resource challenges: Advances in cybercrime, strategies in propagating them and evading investigations are made possible by technical development. The volume of data accessible for assessments for OSNs is normally enormous. The DFIs must classify the most relevant data without jeopardising the evidence's consistency. As a result, there is a pressing need for the development of new technologies and mechanisms for fighting cybercrime, as well as qualified personnel to carry them out [19].

D. Crimes Involving OSNs

Online Social Network is a database of information that criminals can use to commit various forms of crimes such as malware distribution, fraud, harassment, grooming, Assault, burglary, domestic violence, kidnapping and so on [21]. Therefore, OSN-related crimes are divided into two categories: Classical crimes and Digital crimes as presented in Fig. 3.



Online social networks forensic investigation (OSNFI) (Challenges and Issues)
Increase in cyber-criminal activity in OSN
Anti-Forensic techniques
Standard Models
Legal challenges
Resource challenges
User profile information on OSN sites such as: complete name, pictures, date of birth, up-to-date location, contact numbers, residential address, and office address
Encryption, steganography, covert channelling, storage space data hiding, and residual data wiping are all methods used to conceal evidence
Scarcity of standardisation, as well as a theoretical structure for the field of digital forensics
There is no unified legal system that applies to all jurisdictions
The pressing need for the development of new technologies and mechanisms for fighting cybercrime, as well as qualified personnel to carry them out

Fig. 2. OSNFI Challenges and Issues.

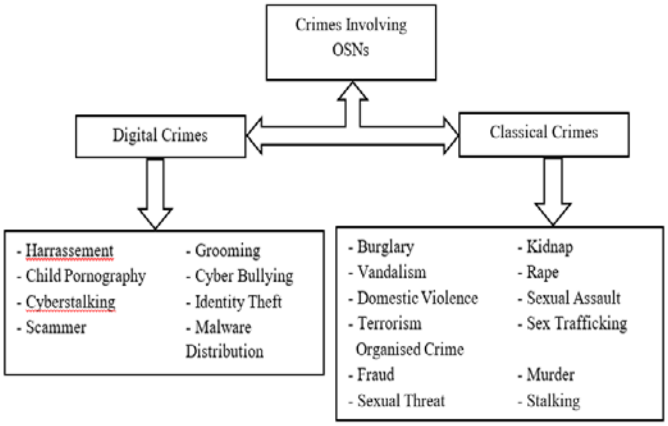


Fig. 3. Crimes Involved in OSNs [21].

1) *Classical crimes:* Online social network is referred to as a location where criminals can commit traditional criminalities. For example, social media users can update their status by posting their current whereabouts, the time they will be absent from home, and what they will be doing, giving possible criminals enough time to break into their home. This is one of several incidents that have been reported in the media [21]. Other crimes may include: vandalism, domestic violence, terrorism organised crime, fraud, sexual threat, kidnapping, rape sexual assault, sex trafficking, murder and stalking.

2) *Digital crimes:* Any criminal activity involving an information technology infrastructure, such as unauthorised or illegal entry, surveillance, and so on, is referred to as digital crime. The most common OSNs digital crimes are: cyber-based, and social engineering which is one tool that can be used to commit these crimes [21]. Other crimes may include: drug network, street gang, bombing, harassment, child phonography, cyberstalking, scammer, grooming, cyberbullying, identity theft, and malware distribution as presented in Fig. 4.

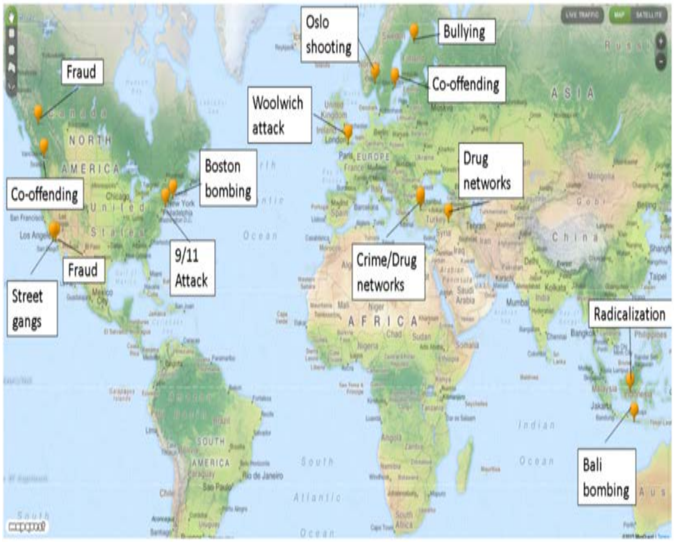

Fig. 4. Global Map of Sample Crime Analysis [22].

E. *Necessity for OSN Digital Forensic Investigation Metamodel*

SNS stores a variety of information about its users which in an investigation case, the suspect's personal data stored on a social media site will support in a variety of ways, including identifying living habits, determining geographical location, and assessing ideas and mental state. *However*, by simply collecting data from an SNS user's personal information section, it is difficult to gather useful data for a case investigation [15]. In order to address these flaws, OSN requires the establishment of a standardised forensic investigation procedure which can help investigators in an investigation. These procedures are presented in Fig. 5.

IV. Metamodelling Approach for Online Social Networks Forensic

Metamodelling is the process of developing metamodels [23]. Modelling and metamodelling are both talking about model creation but the only difference between them is in how they are interpreted.

There are numerous digital forensic investigation models available. However, the majority of them employ comparable approaches and disregard the crucial distinctions and unique requirements of online social networks.

In [17], proposed a seven phase semi-automated forensic investigation model for online social networks. These phases are: Pre-Investigation, Incident specification, Extraction, Preservation, Analysis, Iteration and Presentation. A WhatsApp Messenger Smartphone Forensic Investigation Analysis Against Web-Based WhatsApp was proposed by [24] which comprises of six phases, namely: Identification, Preservation, Collection, Examination, Analysis and Presentation. A four-phase Framework Analysis of IDFIF V2 in WhatsApp Investigation Process on Android Smartphones was proposed by [25]. The phases are: Preparation, Incidence response, Laboratorium process and Presentation.

A Framework for the ForensicAnalysis of User Interaction with Social Media was proposed by [26] which has four phases: Acquisition, Triage, Analysis and Presentation. A four-phase Digital Forensic Investigation Model for Online Social Networking was proposed by [21] which has: Preliminary, Investigation, Analysis and Evaluation phases.

The fundamental issue is the employment of ad hoc and non-uniform forensic techniques in the current DFIMs. The use of ad hoc and non-standard forensic procedures reduces not only the efficiency of the procedure but also the dependability and credibility of the evidence in criminal proceedings. Consequently, this is where the research will help to standardise the OSNFI domain's operations.

A. *Models and Metamodels*

A model is a representation of real-world phenomena [27]. It is a description of something [28], which are used to reason about a problem domain and design a solution in its domain [29]. Models are essential for comprehending and disseminating information about complex systems [30]; [31]. They have been and continue to be crucial in many scientific contexts as a large branch of philosophy of science is centered on models.

Models can be used for different purposes. They can come in form of graphical, mathematical or textual. Models can be used for descriptive, prescriptive or for defining the method by which a system will be implemented. Descriptive is simply describing a system's or a context's reality while Prescriptive is to determine the extent and depth of a problem's investigation [32]. On a philosophical level, one can concur that "everything is a model," because nothing can be managed by human mind unless it is "modelled." As a result, it's not astonishing that models have become crucial in technical fields like mechanics, civil engineering, and, eventually, computer science and engineering [33]. According to [34], models can be categorised into; conceptual versus data models, viewable and executable models, active and passive models, static and dynamic models in the study of information systems. Identifying concepts terminologies, meaning, definition and interconnections are some of the challenges encountered in model development; this is because concepts terminologies are too inconsistent and too ambiguous.

Metamodel is a model that describes/prescribes models [35]; [23]; [32]. It is a collection of *concepts* and *relations* that define the syntax of a model, and they are described using a model description language [36]. Metamodel is an abstraction that highlights properties of the model itself just as how a model is an abstraction of real-world phenomena [27]. It describes a collection of concepts and their relevant relationships, and it used as an abstraction filter in a specific modelling activity [37]. A modelling language is used in the creation of a metamodel and this language is termed as Metamodeling language [38].

In Model-Driven Engineering, metamodels are widely used to specify available model elements and structures. Nevertheless, metamodels are likely to evolve during development for a variety of reasons, such as changing requirements or evolving domain expertise [39]. Metamodeling is among the significant components of MDD; its main importance include the creation of a modelling language that will be utilized to accurately define metamodels [40] and is used to ensure the consistency of models during transformation [41]. Metamodelling is the study of processes, development of frames, production rules, constraints, models, and theories that can be used to extended models of intelligent software and information systems [23]. The basic goal of metamodeling is to represent data in such a way that it becomes self-contained and allows for the extension and alteration of its structure. Metamodeling must adhere to its own set of rules, which are as follows: Suitability, Completeness, Dynamic, Openness, Compatibility, Consistency, Reusability, and Simplicity.

B. *Step-by-Step of OSNFI Metamodel Development.*

A uniform representation of language is frequently required to reflect shared understanding in a consistent manner that fulfills the needs of the various parties involved. This method discovers specific domain characteristics, gathers domain concepts, and divides domain problems into sub-domain problems. The steps in the procedure are as follows:

1) Step 0: Identification of common phases of domain.
2) Step 1: Models collection and classification.
3) Step 2: Extraction of concepts.
4) Step 3: Identification of common concepts.
5) Step 4: Short-listing and reconciliation of definitions.
6) Step 5: Classification of common concepts: Concepts are assigned to one of the OSNFI phases: preliminary, acquisition/preservation, analysis, or presentation.
7) Step 6: Identification of relationships.
8) Step 7: Metamodel validation (*is not covered in this paper*).

To achieve the goal of creating a universally applicable OSNFIM, a broad coverage across concepts is required. Looking at the coverage measure alone, as shown in Table I, it gives a rapid indication of the supplied model's applicability. If a model can cover all of the stages of OSNFI, it is said to have a high coverage value. If the model just describes a single OSNFI phase, the coverage value of the model is lower.

TABLE I. OSNFI PROCESS MODELS

Models		**Coverage**	**Coverage of Model (according to phases)**
1	A Digital Forensic Investigation Model for Online Social Networking [3]	0.2	Preliminary, Analysis and Presentation
2	Online Social Networks As Supporting Evidence: A Digital Forensic Investigation Model and Its Application Design [9]	0.2	Preliminary, Analysis and Presentation
3	A Framework for the Forensic Analysis of User Interaction with Social Media [26]	0.2	Acquisition, Analysis and Presentation
4	Forensic Imaging for Online Social Networks [11]	0.2	Preliminary, Analysis and Presentation
5	A Review of Using Online Social Networks for Investigative Activities [21]	0.2	Acquisition, Analysis and Presentation
6	A comprehensive digital forensic investigation process model [42]	0.3	Preliminary, Acquisition, Analysis and Presentation
7	WhatsApp Messenger Smartphone Forensic Investigation Analysis Against Web-Based WhatsApp [24]	0.2	Acquisition, Analysis and Presentation
8	Framework Analysis of IDFIF V2 in WhatsApp Investigation Process on Android Smartphones [25]	0.2	Acquisition, Analysis and Presentation
9	Forensic investigation of cross platform massively multiplayer online games: Minecraft as a case study [2]	0.2	Preservation, Analysis and Presentation
10	A semi-automated forensic investigation model for online social networks [17]	0.3	Preliminary, Acquisition, Analysis and Presentation

V. The Resultant Online Social Networks Forensic Investigation Metamodel (OSNFIM)

In Fig. 5, the preliminary results of developing OSNFIM are represented by twenty-two key concepts that were collected from nineteen and filtered based on the four phases (Preliminary, Acquisition/Preservation, Analysis, and Presentation). Disparities between definitions are addressed in this process. All of the definitions listed in this process are taken into account when picking or synthesizing the common concept definition to be used as presented in Table II.

Although OSNFI is no longer widely used in research, the precise meaning of important terminology and phrases used in its concepts can often still differ among the few academics who are familiar with it. This can be a result of the researchers having different backgrounds and viewpoints. If two or more sources employ concept definitions in conflict, a technique to harmonize and fit the definition in the metamodel is necessary. In some circumstances, some models don't participate in the reconciliation procedure because they don't describe some of their concepts explicitly.

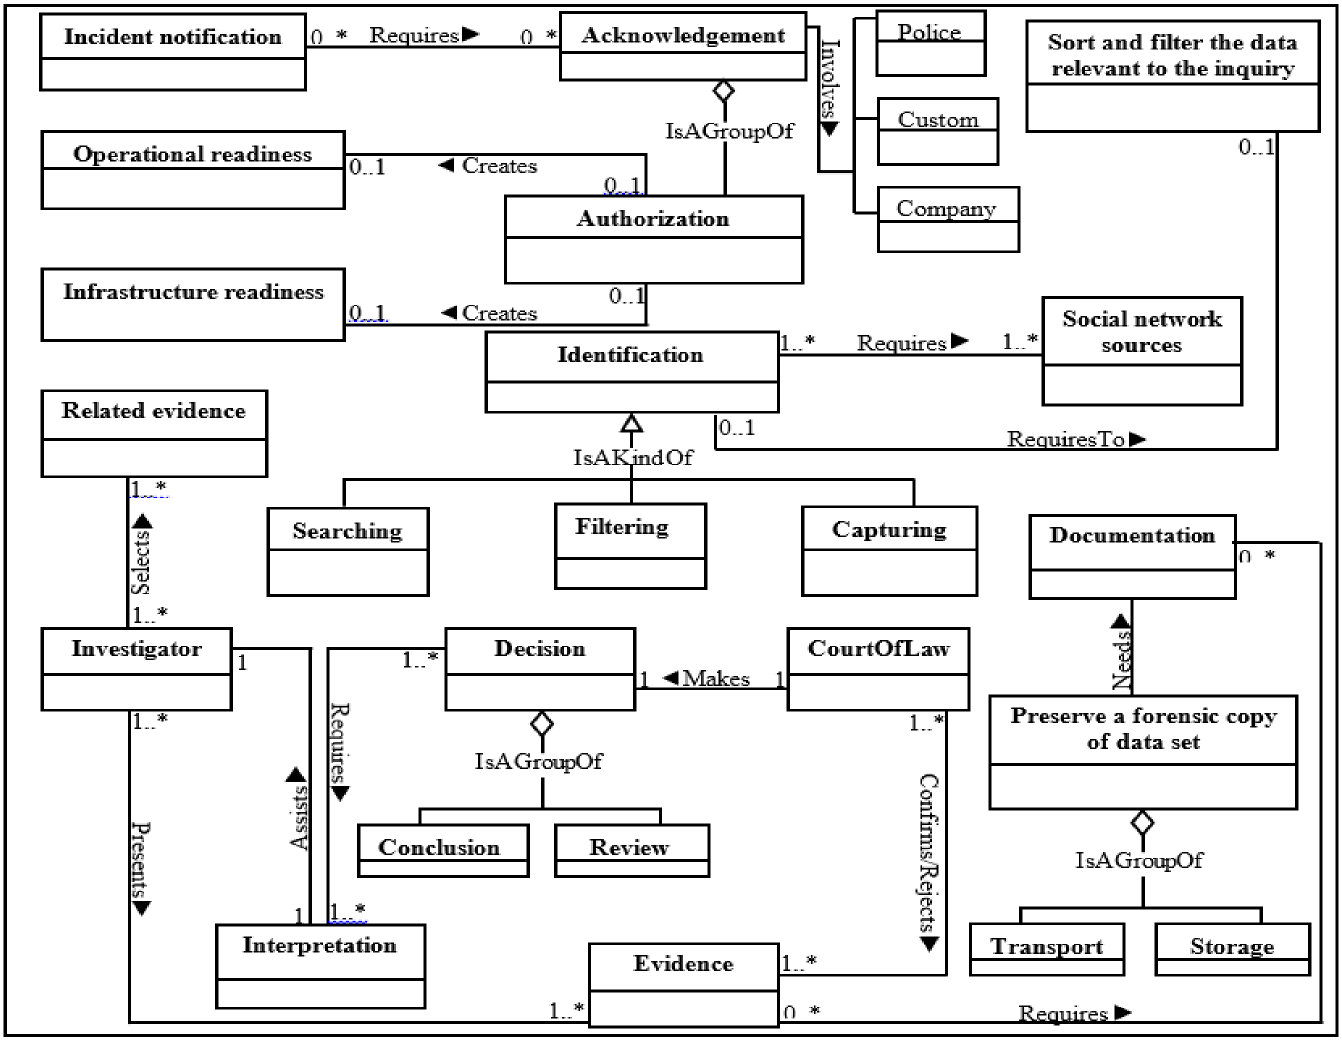

Fig. 5. The Initial Result of Online Social Networks Forensic Investigation Metamodel (OSNFIM).

TABLE II. CONCEPTS AND THEIR DEFINITIONS

S/No.	CONCEPT	DEFINITION
1	Operational readiness	This is a proper initial policy and procedure documents before a successfully launch of an effective digital forensic investigation.
2	Infrastructure readiness	Infrastructure readiness component is determined by elements external and internal to the organization which is critical to test them before implementation so that they are ready for use when needed.
3	Incident notification	Explicitly specifying the incident under investigation.
4	Authorization	Stages to gain access to evidence and legal status of the inquiry process.
5	Acknowledgment	This is the first step of an online social network forensic investigation where a case or an audit is requested from an external organisation such as the police, customs, or a company.
6	Identify Social Network sources	A way of identifying the social network involved by Initialize the SN source.
7	Identification	A process of identifying any evidence or supporting information that might be available in an online social network.
8	Searching	This is a process of discovering relevant data automatically based on the relevant data gathered from the investigation process.
9	Filtering	An activity which will scale down and focus the investigation on relevant information and discard any irrelevant information.
10	Capturing	Information collected through filtering will be captured in the best way to ensure the integrity of the data is sustained.
11	Transport	This is the process of moving digital evidence from the scene to the forensic digital laboratory.
12	Storage	A process of keeping potential digital evidence which might be needed if the analysis cannot be performed right away or if there is a legal requirement to keep digital evidence for a certain period of time.
13	Preserve a forensic copy of Data Set	Safeguarding the integrity of the original digital evidence.
14	Sort and filter the data relevant to the inquiry	The investigators must examine the results in the context of a given incident.
15	Conclusion	Investigators will conclude their examination in this stage. They may confirm their hypothesis, or they might need to find more information related to the entities involved in an investigation to credit or discredit a theory.
16	Select Relevant Evidence	The investigators will select the evidence that is relevant and appropriate for presenting in court.
17	Present the Evidence	To show anything you see, experience, read, or hear that leads you to assume something is true or has actually happened
18	Decision	A decision or resolution reached after careful consideration
19	Interpretation	To use scientifically proven methods to explain facts discovered throughout the analysis process within the context of the investigation.
20	Documentation	Documentation of all activities that have been done from the beginning of the investigation process to the end of the analysis process in the forensic laboratory.
21	Investigator	A person who conducts a formal investigation or inquiry
22	CourtOfLaw	A group of individuals presided over by a judge or judges who operate as a tribunal in civil and criminal proceedings

VI. CONCLUSION

Online social networks forensic investigation domain is a new, but extremely important and a high demand domain. The number of crimes increases on daily basis due to the advancement in technology and the use of smart devices. The problems with the OSNF domain which are addressed in this paper are: lack of uniformity in the procedures for the OSN investigation, increase in cyber-criminal activity, anti-Forensic techniques, standard models, legal and resource challenges. Hence, the OSNF investigation metamodel proposed will aid in the proper investigation of digital crimes through various processes.

VII. FUTURE WORK

The future work will be to validate the proposed Metamodel based on two relevant metamodel validation technique: (i) Comparison to other models and, (ii) Frequency-based Selection validation techniques.

ACKNOWLEDGMENT

The authors would like to express their gratitude to Yobe State University (YSU), Damaturu, Nigeria and the Tertiary Education Trust Fund (TETFund) of Nigeria for funding this research.

***Abstract*—Recommendation systems aim at providing the user with large information that will be user-friendly. They are techniques based on the individual's contribution in rating the items. The main principle of recommendation systems is that it is useful for user's sharing the same interests. Furthermore, collaborative filtering is a widely used technique for creating recommender systems, and it has been successfully applied in many programs. However, collaborative filtering faces multiple issues that affect the recommended accuracy, including data sparsity and cold start, which is caused by the lack of the user's feedback. To address these issues, a new method called "GlotMF" has been suggested to enhance the collaborative filtering method of recommendation accuracy. Trust-based social networks are also used by modelling the user's preferences and using different user's situations. The experimental results based on real data sets show that the proposed method performs better result compared to trust-based recommendation approaches, in terms of prediction accuracy.**

Keywords—Recommendation systems; collaborative filtering; trust; social networks

I. INTRODUCTION

The platforms with thousands of items will support the users to be able to know how to connect to the right content, which is relevant to their interests and concern. To help users, the systems of recommendation emerge as a great solution to personalize the content presented to the users in the form of techniques and software tools that provide personalized suggestions and recommendations for items in order to boost the users' competencies [1, 2]. Even though several types of methods have been proposed to build systems of recommendation, the collaborative filtering method remains one of the greatest widely used and adopted techniques to generate recommendations. It is far from ideal in terms of predictive performance. As, it suffers from countless inherent problems [3, 4]. The most important thing of these is data sparsity and cold start, which affects the recommender's accuracy of the system [3]. To address these issues and model the user's preferences more accurately, the additional information can be incorporated into the collaborative filtering method to compensate for insufficient rating information, such as social media information, including friendship, belonging, and trusting relationships [1, 5, 6].

The relationship which is based on trust is one of the most crucial types of social relationships, as it gives its power and good positive association with similarities between the users [1], and several studies have shown great efficiency in improving predictive accuracy compared with the traditional recommendation techniques. Additionally, collaborative filtering is one of the most common approaches in systems of recommendation. As it does not depend on additional data, only the history of interactions, it becomes quite simple to be reproduced in various real applications and increase its popularity. The recommendation based on collaborative filtering was developed from the observation that people tend to adopt other people's recommendations. Someone who has the intention to purchase a certain product, for example, s/he looks for opinions and points of view from the other people who have already purchased and bought the same product before deciding to purchase. This happens frequently in the daily lives of people with different yet varied situations. The selection of a certain movie, a book, among many other [2]. Several trust-based systems of recommendation that employ these models to solve data sparsity and cold-start problems have also been proposed to combine the impacts and the great influences of social trust with different strategies. However, the previous work which is proposed in this field failed to systematically model the reciprocal effect between the users. It cannot model how and to what extent the user's preferences are affected by trustees and at the same time to what extent it influences the same user by trustors, where the user preferences as trustee or trustor can be distinct from each other [7]. Therefore, when predicting a user's preferences for an item, it does make more sense to consider both the trustor's preferences and the trustee's performances at the same time. However, in the previous studies, the methods modelled the users using a single case [8], or by separately considering the two user cases [7]. In other words, no distinction is made between different cases of the user as trustee or trustor in the ratings generation process.

Regardless of the learning approach adopted by the systems of recommendation, there must be a past set of interactions that describe the users' relationships with the items of the system. Past interactions between a user and an item are traditionally called feedback, and they can be either explicit or implicit. Most of the existing methods depend on an explicit trust bond between the users, based on which users display their preferences as trustors or trustees, except those users who may not explicitly interact with others, but rather implicitly. We note that most of the methods found in previous studies are effective and efficient in modelling explicit relationships. However, they do not consider the discovery and modelling of implicit interactions between two users who may be similar but not connected in the network of trust. The local perspective of social relations reveals the relationship between the user and their neighbors, while the global perspective of social relations reveals the reputation of the user in the social network [9]. Users around the world are more likely to seek suggestions from their local friends. Yet, they may also be tempted to solicit suggestions from high-reputation users, indicating that public and local opinions based on social relations might be exploited to improve the performance of systems of recommendation.

As a suggestion, a model called "GlotMF" (Global Local Trust with Matrix Factorization), that exploits both the global and local social context of trust relationships for recommendations. This work introduces a new strategy for merging ratings data and trust data by sufficiently exploring how to generate known ratings under the influence of the trust behaviors of users that are intertwined in their trust network, rather than simply combining two types of data, as most previous studies did, to express the mutual influence of users more logically on each other's opinions. The proposed method uses a matrix factorization technique to model user preferences for trust-based recommendations, and the preferences of the two different cases of users are learned by modelling the explicit and implicit interactions between them. Specifically, the preferences of the trustees and trustors are estimated to be distinctly suitable for the explicit ratings and explicit trust relationships of existing methods that measure the association of two users based on only the links between them. It is also being taken advantage of the structure of Local Trust Network Links to assess links between trustees and trustors users, as the structure of these links is used to model the user's implicit interaction with other users in terms of both trustees' and trustors' preferences. Experiments conducted on a real dataset demonstrate the effectiveness of our method in terms of predictive accuracy, and the results confirm that our method achieves promising recommendation performance, especially by dint of its effectiveness for Cold-Start and sparsity data compared to its counterparts.

II. Literature Review of Related Work

The merge of model-based collaborative filtering methods with trust relationships to improve the accuracy of recommendations has recently become a very popular research topic, especially using the matrix factorization technique due to its high precision and ease of use contribution to alleviating the problem of sparsity data better than other techniques [3, 8]. Many researchers have exploited this technique to learn about latent features of users and well-known ratings items, and to merge social relationships between users with rating data using different techniques. The researchers proposed in [8] a "SoRec" model which integrates a social network database into a probability matrix factorization model by simultaneously analyzing the rating matrix and the social trust matrix by sharing the matrix of features latent to a user [10]. Their empirical analysis shows that their method is superior to the basic matrix factorization model and other memory-based methods that take advantage of trust relationships, but that true recommendation processes are not reflected in this model. Thus, to model the information of confidence in a more realistic way, the same researchers proposed in a model "RSTE"[11], which interprets the user's decision to rate like a balance between his own tastes and those of his neighbor's trustees. Their experiences shows that their model outperforms the basic matrix factorization method and existing trust-based methods, but in their model, the vectors of features of user's immediate neighbors influence his ratings rather of influence his vector of features, and this model does not deal with the diffusion of trust.

The researchers reinforced in [12] this model by allowing the diffusion of trust and built a "SocialMF" model, which integrates the social impact by making the latent features of each user depend on the latent features of their immediate neighbors in the social network. Moreover, to effectively use the information of social networks when there is no trust information available, the researchers proposed in [13, 14] a "SoReg" model that performs matrix factorization while exploiting social regularization defined based on both user-item matrices and positive social relations. This work is different from previous studies in the field of trust-based recommendation since it recognizes the difference between the relationship of trust and the relationship of friendship, as well as it forces the preferences of the user to be closer to the preferences of their friends in the social network.

The methods "SoReg", "SocialMF", "STE" and "SoRec" in general have the same goal [15, 16], while the most important work relevant to our work, which is "TrustMF", in this paper is the preferences of different cases are learned independently to guess the ratings. However, in this paper, it is said that it makes more sense to consider both the preferences of the trustee and the preferences of the trustor at the same time in the learning process since the assessment is generated from the two cases. In addition, the "TrustMF" model cannot capture the implicit relationship between the confident user and the trusted user when they are not socially related, nor does it consider the trust of the public, which will be addressed in our proposed model[17].

III. A GlotMF: A Model-based Method

A. *Problem Description*

A recommender system that involves m users and n items is introduced to introduce some notations used to model the recommendation problem in this work. Let $U = \{u_1, u_2, \ldots, u_n\}$ and $V = \{v_1, v_2, \ldots, v_m\}$ be two groups of users and items respectively, where n is the number of users and m is the number items. Let $R \in R^{nxm}$denotes the user-item rating matrix which represents the numerical scores given by the users on the items, and $R_{i,j}$ represents the rating of item v_j given by user u_i, where each user evaluates a subset item with certain values from a rating field predefined by the recommendation system. Let $\Omega = \left\{(\boldsymbol{i}, \boldsymbol{j}) \colon \boldsymbol{R_{i,j}} \neq \boldsymbol{0}\right\}$ denotes the locations of observed ratings in the rating matrix R.

$T \in R^{nxn}$ is the user's trust relationship matrix, where $T_{i,k}$ is a real number in the domain [0, 1] describing the strength of the relationship between users u_i and u_k . Let $\psi = \left\{(i, k) \colon T_{i,k} \neq 0\right\}$ denotes the locations of observed trust relations in trust network matrix T. Since we use in this paper a matrix analysis technique to build the proposed model, let $B_i \in R^k$ be the K-dimensional preference vector of the trustor and $E_i \in R^k$the K-dimensional preference vector of trustee for the useru_i. $V_i \in R^k$ is a k-dimensional feature vector of the element v_j. So, we can formulate the recommendation problem in this paper as follows: by giving a set of user ratings on R's items and a set of trust values T for users by other users who also rated a group of items, and by using the matrix analysis technique to study how to learn the preferences of the different states of the users and the features of the items to guess the rating given by the target user u_i on the target item v_j plus precisely.

B. *Matrix Factorization Model*

The matrix factorization model assumes that some latent factors influence a user's rating behaviors and that the vector of user preferences is determined by how each factor is applied to that user [18]. This hypothesis makes it possible to discover missing ratings in the rating matrix from known ratings. This technique decomposes the rating matrix R into two matrices of lower order K which are the matrix of the latent features of the user U and the matrix of the latent features of the item V that is to say $R \approx U^T V$ (as shown in Fig. 1), where the low dimension U and V matrices are unknown and must be predicted. Thus, the goal of the matrix factorization technique is to learn the matrices of latent features U and V and to use them thereafter to provide predictions of missing ratings by solving the following optimization problem [19]:

$$\min_{U,V} \sum_{i=1}^{n} \sum_{j=1}^{m} W_{i,j} \left(R_{i,j} - U_i^T V_j\right)^2 + \lambda(\|U\|_F^2 + \|V\|_F^2) \quad (1)$$

$U_i \in R^k$denotes a vector of the latent features of user's preferences u_i, and $V_j \in R^k$ denotes a vector of latent features of the preferences of the item v_j, K is the number of latent features, λ is the regulation parameter which controls the complexity of the model to avoid relevance with training data (over-fitting) by introducing the term $\lambda(\|U\|_F^2 + \|V\|_F^2)$ where $\|.\|_F^2$ This is the "Frobenius norm". Conversely, $W \in R^{nxm}$ is the weight matrix where $W_{i,j}$ is the weight of the rating given by the user u_i on the item v_j. The common way to define W is $W_{i,j} =$ 1 if $R_{i,j} \neq$ 0, but a matrix of weight W can also be used to process implicit opinions and encode secondary information such as the similarity between users and items or user reputation. This factorization is illustrated in Fig. 1.

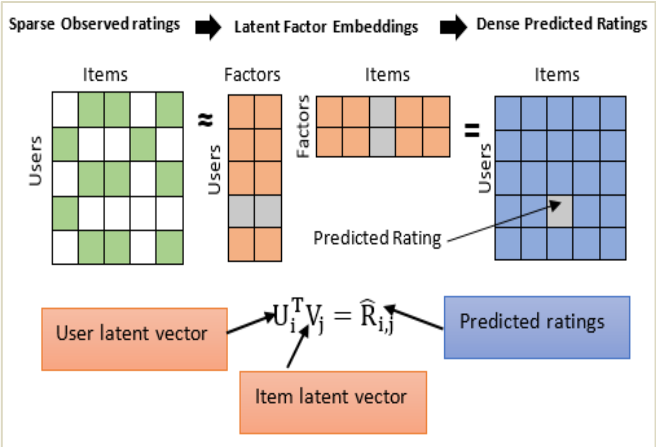

Fig. 1. Operating Principle of the Matrix Factorization Technique.

C. *Steps of the Construction: The Proposed Model*

1) Modeling of global information in social networks: The information contained in social networks represents the reputation of the user in the network, where reputation is a type of case that gives additional powers and capabilities to recommendation systems. There are many algorithms to calculate the reputation value of social network nodes based on their connections. In this work, we rely on one of the most popular algorithms, "PageRank" to calculate user reputation values. We first apply the "PageRank" algorithm to rank users by exploiting the general view of social networks, assuming that $r_i \in$ is the reputation rank of u_i so that $r_i = 1$ indicates that u_i has the highest reputation in the entire social network, then we set the reputation value w_i to u_i according to the reputation value r_i according to as follows:

$$w_i = f(r_i) = \frac{1}{1+log(r_i)} \quad (2)$$

So long as the function (f) constrains the reputation value w_i in the interval [0, 1] is a decreasing function for r_i, that is, higher rank users have high reputation values. So, to model the information in social networks, we can use the reputation values of the users to weigh the significance of their recommendations by modifying the previous equation (3) so that it becomes as follows:

$$\min_{B,E,V} \sum_{(i,j)\in\Omega} w_i \left(R_{i,j} - g(\alpha B_i^T V_j + (1-\alpha) E_i^T V_j)\right)^2 + \lambda(\|B\|_F^2 + \|E\|_F^2 + \|V\|_F^2) \quad (3)$$

During this matrix factorization, the large value of w indicating the high reputation of u_i , will force the term $(\alpha B_i^T V_j + (1-\alpha) E_i^T V_j)$ to fit tightly into the evaluation of $R_{i,j}$, while the small value ofw_i will make the term $(\alpha B_i^T V_j + (1-\alpha) E_i^T V_j)$ approximate $R_{i,j}$.

2) Modeling of local information in social networks: Local information represents preferences of the two different states of the user as a trustee and a trustor which are learned by modelling the explicit interactions between users. The preferences of the trustor and the preferences of the trustee are calculated to account for explicit ratings and explicit trust relationships. The local trust network link structure is used to assess the links between trustees and trustors, as the structure of these links is exploited as organizational boundaries to model the user's implicit interaction with other users in terms of the preferences of the trustors and the preferences of the trustees.

3) Modeling of explicit interactions between users: In this part, there is a description of how to generate ratings and trust relationships from the perspective of different user cases as shown in Fig. 2, where the social impact of user ratings can flow in both ways. That is to say, the user's rating is not influenced only by trustees, but also by trustors and this is what is confirmed by the researchers in [20], which indicates that the influence of trustors in predicting rating may be equal to that of trustees, and therefore may provide added value to predict ratings more accurately.

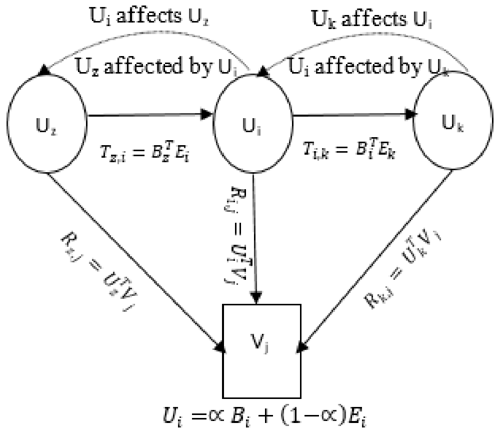

Fig. 2. The Influence of Trusters and Trustees on the Prediction of the Rating for the Target user on the Target Item.

Fig. 2 shows the proposed trustor model that can characterize how a user U_i's ratings are affected by other users they trust by means of $B_i^T V_j$, and as it does show the proposed trustee model that is able to characterize how a user U_i's opinions affect the decisions of others who trust U_i by means of $E_i^T V_j$.

a) Trust modeling: In addition to the rating data, there is a huge user-generated trust network also available on product showcases on the Internet. Following user preferences are affected by the preferences of the trustees through browsing activities and comments (For example, presenting ratings and reviews of users who trust products) and affect the trustors themselves. Along with the relationship between user preferences and trust, we can also model user preferences on the known trust database using a matrix factorization technique as shown in [18, 21]. When users are mapped to the same k-dimensional vector space, we can model each already known trust value $T_{i,k}$ as the internal product of B_i and E_k, i.e., the expected strength of the trust relationship between u_i and u_k is given by:

$$\hat{T}_{i,k} = B_i^T E_k \tag{4}$$

Considering only the trust data, we can learn the feature matrices $B \in R^{k \times n}$ and $E \in R^{k \times n}$ by solving the following optimization problem:

$$\min_{B,E} \sum_{(i,k) \in \psi} \left(T_{i,k} - g\left(\hat{T}_{i,k}\right) \right)^2 + \lambda (\|B\|_F^2 + \|E\|_F^2) \tag{5}$$

Thus, by performing the above matrix factorization, anyone can learn the user's preferences in terms of the latent features vectors of the trustee, and the latent features vectors of the trustor from the known trust data.

b) Rating modeling: Given the assumption that different user cases influence rating generation differently [6, 20], each known rating should be determined by the preferences of the trustor as well as the preferences of the trustee. Based on this, the rating is predicted by user u_i on the v_i item as follows:

$$\hat{R}_{i,j} = \propto B_i^T V_j + (1 - \propto) E_i^T V_j \tag{6}$$

Given α is the parameter to control the contribution to the evaluation of the different cases of the user. So, by considering only the rating data, we can learn the feature matrices $B \in R^{k \times n}$, $E \in R^{k \times n}$, $V \in R^{k \times m}$ by solving the following optimization problem:

$$\min_{B,E,V} \sum_{(i,j) \in \Omega} \left(R_{i,j} - g\left(\hat{R}_{i,j}\right) \right)^2 + \lambda F \tag{7}$$

where $\mathrm{F} = (\|B\|_F^2 + \|E\|_F^2 + \|V\|_F^2)$ This is the "Frobenius norm".

Given that g(x) is the logistic function suggested by the researchers to link the internal product of feature vectors latent in the interval [0, 1] is given by the relation $g(x) = 1/(1 + e^{-X})$ To learn the parameters more conveniently, we map the raw rating $R_{i,j}$ to the interval [0, 1] using the function $(x) = 1/(1 + e^{-X})$, where Rmax is the maximum value of the ratings defined in the recommender system. After training the model and learning the feature matrices, the prediction of the rating can be obtained from user u_i at item v_i by the relation $g\left(\hat{R}_{i,j}\right)$ x R_{max} Thus, by performing the previous matrix factorization technique, a person can learn the user's preferences in terms of their latent feature vectors in both cases as trustee and trustor from already known rating data.

Modeling of implicit interactions between users: In this section, we describe how to model the implicit interactions between two trustees and between two trustors by incorporating the local binding structure of the trust network to restrict the objective function.

c) The implicit influence of the trusters: Two trustors are alike if they share many out-links in a trusted network. In other words, they are jointly chatting with several trustees. So, by taking all the user's trust links with other users, and instead of relying on a single link, we can achieve a more precise and robust link between two trustors even if they are not explicitly linked. Therefore, to capture the similarity between two trustors users u_i, u_k depending on the structure of the links coming out of it, we adopt the following "cosine similarity" scale[22]:

$$S_{i,k}^B = \frac{\sum_{f=1}^n T_{i,f} T_{k,f}}{\sqrt{(\sum_{f=1}^n T_{i,f}^2) \ x \ (\sum_{f=1}^n T_{k,f}^2)}} \tag{8}$$

In our experiment, we have used a binary value for the trust $T_{i,k}$ (0 or 1), and here B denotes the similarity between two trustors. With this similarity, we can model the implicit effect of the trustors by minimizing the following term:

$$\sum_{i=1}^n \sum_{k=1}^n S_{i,k}^B \|B_i - B_k\|_F^2 \tag{9}$$

The large value of $S_{i,k}^B$ indicates that the trustor u_i and the trustor u_k share several external bonds, and we, therefore, enforce their preference vectors to be as close as possible, while a small value of $S_{i,k}^B$ indicates that the distance between the two preference vectors must be large. Therefore, by presenting this structure-dependent analogy, the vectors of the preferences of the trustors are linked in the learning process.

d) The implicit impact of trustees: Two trustees are alike if they share many in-links in the trust network. That is, they are jointly trusted by many trustors. Thus, the similarity between two trustees u_i and u_k based on the structure of the links entering them can be captured by the following scale:

$$S_{i,k}^{E} = \frac{\sum_{f=1}^{n} T_{f,i} . T_{f,k}}{\sqrt{(\sum_{f=1}^{n} T_{f,i}^{2})\ x\ (\sum_{f=1}^{n} T_{f,k}^{2})}} \tag{10}$$

Given that E here denotes the similarity between two trustees, as in modelling the implicit influence of the trustors, we model the implicit influence of the trustees by minimizing the following term:

$$\sum_{i=1}^{n} \sum_{k=1}^{n} S_{i,k}^{E} \, \|E_i - E_k\|_F^2 \tag{11}$$

4) The proposed model standardized framework: As shown above, the explicit interactions and the implicit interactions between the trustors and the trustees. Moreover, we have presented how to model the information represented by the reputation of the users in the trust networks. We then propose the following merged model which considers all the previous information and find a solution for the following objective function:

$$\mathcal{L} = \frac{1}{2}\Big(\sum_{(i,j)\in\Omega} w_i \left(R_{i,j} - g(\hat{R}_{i,j})\right)^2 + \sum_{(i,k)\in\psi} \left(T_{i,k} - g(\hat{T}_{i,k})\right)^2 + \lambda_B \sum_{i=1}^{n} \sum_{k=1}^{n} S_{i,k}^{B} \|B_i - B_k\|_F^2 + \lambda_E \sum_{i=1}^{n} \sum_{k=1}^{n} S_{i,k}^{E} \|E_i - E_k\|_F^2 + \lambda \mathrm{F}\Big) \tag{12}$$

λ_B and λ_E are respectively parameters to control the extent of the influence of the implicit interactions between the trustors and those between the trustees. To reduce the complexity of the model, we experimented with λB = λE. The former term of the previous equation is the regulation parameter used to avoid large adaptation to the training data, while λ is the regulation parameter.

D. *Learning the Model*

To get the minimum term of the previous objective function, and, thus, learn the feature matrices V, E and B and use them to predict unknown ratings, we use the Stochastic Gradient Descent method, which generally works efficiently for recommender systems.

Fig. 3 shows instructions of the algorithm for learning the model. There are several parameters taken as input, including the rating matrix R, the trust matrix T, the regulation parameters E, B, and A, the parameter controlling the rating contribution of the different cases of the user ∝, the initial learning rate μ, and the number of latent factors K.

In the first place, the researchers randomly generate the latent feature matrices V, E and B with small values. Secondly, we continue to train the model until the objective function converges to L. More precisely, we calculate the derivatives of the variables V, E and B then we modify them using the Stochastic Gradient Descent method. Finally, we obtain a latent feature vector of the trustor and a latent feature vector of the trustee and the latent feature vector of the item, and we use them to compute the prediction of the target user on the target item.

1) A learning algorithm for the proposed model

R : Rating matrix,

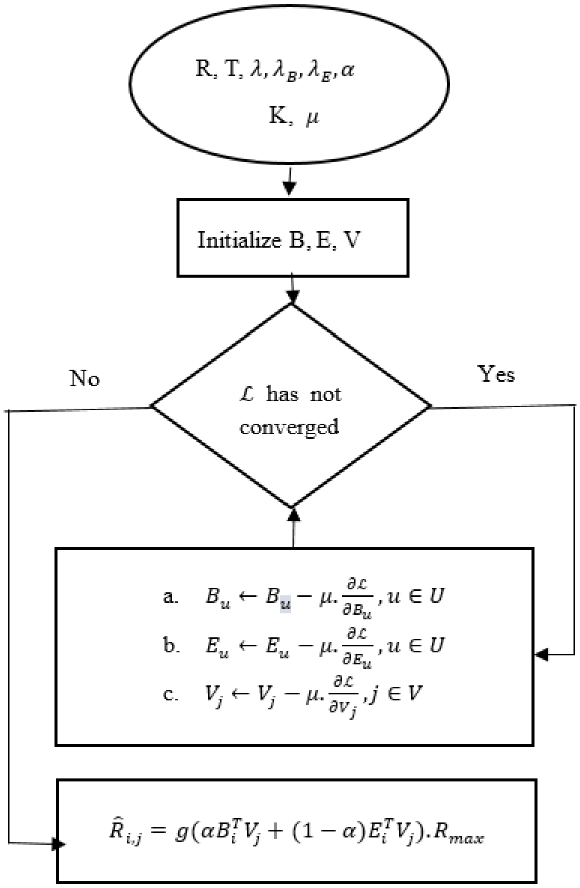
T : social matrix,

$\lambda, \lambda_B, \lambda_E, \alpha$ and K: hype-parameters

μ : learning rate

B and E: Features matrices for users with roles of truster and trustee,

V: Feature matrix for items with implicit and explicit feedbacks.



R, T, $\lambda, \lambda_B, \lambda_E, \alpha$
K, μ
Initialize B, E, V

IV. Experimental Evaluation

A. *Description of the Dataset*

Epinions is considered a real-world dataset, publicly available, and widely used to evaluate recommender systems in the literature. Epinions contains users' ratings on items and explicit trust/distrust relationships between users, which is necessary to validate our model. The "Epinions" database used in our experiments was compiled by Paolo Massa in a five week "crawling" process (October / December 2003) for Epinions.com [23] , Table I presents statistics of this database.

TABLE I. DATABASE USED IN EXPERIMENTS

Feature	**Epinions**
Items	139 738
Users	40 163
Ratings	664 824
Trusts	487 183
Trusters	33 960
Trustees	49 288
Intervalle	[1-5]

We have also noticed through a set of experiments that have been carried out that the distributions of trustors and trustees of the "Epinions" database correspond to the "Power-Law" distribution, as is the case. In many social networks, and this is illustrated in the Fig. 4, where only a few trustees have many trustors, while most trustees have only a few trustors. This indicates that there is a significant dislocation in the confidence data provided by users.

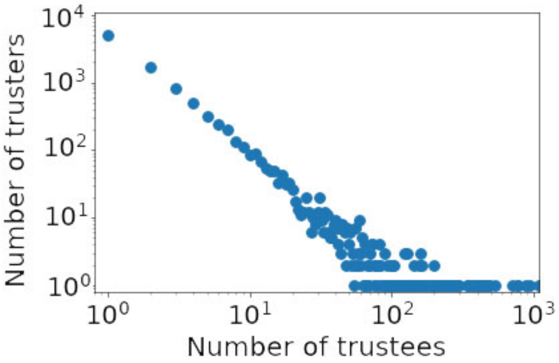

Fig. 4. Distribution of Trustees Relative to Trusters.

B. *Ratings Measures*

To measure the predictive quality of the proposed method compared to collaborative filtering and other methods based on trust, we use two measures [7, 20, 24]:Mean Absolute Error (MAE): it measures the mean absolute differences between the real ratings $R_{i,j}$ given by the user and the ratings predicted by the recommendation system R and is illustrated by the following relation:

$$MAE = \frac{1}{N}\sum_{(u_i,v_j)\in TestSet}\left|\hat{R}_{i,j} - R_{i,j}\right| \quad (13)$$

Where N is the number of ratings we want to test, the lower the MAE measurement value is, the higher the prediction becomes.

RMSE (Root Mean Absolute Error) measures the square root of the mean square of the differences between the actual ratings $R_{i,j}$ given by the user and the ratings predicted by the recommendation system, and is explained by the following relation:

$$RMSE = \sqrt{\frac{1}{N}\sum_{(u_i,v_j)\in TestSet}(\hat{R}_{i,j} - R_{i,j})^2} \quad (14)$$

The lower the RMSE measurement value is, the higher the prediction becomes.

In addition to the ratings measures, it is also necessary to choose the technology in which the recommendation system will be rated. In this paper, we use the technique of "Five-Fold cross-validation" for training and testing, in which the database is divided into two parts. The former part concerns model training, while the latter is concerned with testing for its rating. Specifically, the database is randomly divided into five parts, one part is kept as test data, and the remaining four parts are used as training data. This process is repeated five times. Each of these five parts is used as test data only once, and at the end, the results are averaged to obtain the exact result. In our experiments, in each part, we use 80% of the data as training data and the remaining 20% as the test data, which means that we randomize 80% of the ratings in the "Epinions" database as training data to predict the remaining 20% of ratings.

C. *Experimental Parameters*

To show the performance improvements of the proposed method, we compare it with the traditional matrix analysis method and with a few confidence-based methods found in previous studies that are relevant to our present study.

TABLE II. THE PERFORMANCE OF PROPOSED METHOD

Methods	**Rationale**	**Optimal Parameters**
PMF[25]	The basic matrix analysis method uses the rating matrix only for recommendations, without considering social relationships between users.	$\lambda_u = 0.001$ $\lambda_v = 0.001$
SoRec[8]	The method analyses the rating matrix and the users' social trust matrix by sharing the same space of latent features.	$\lambda_c = 1$ $\lambda_u = 0.001$ $\lambda_v = 0.001$ $\lambda_z = 0.001$
RSTE[11]	The method models users' ratings as a balance between their own preferences and those of their trustee's people.	$\alpha = 0.4$ $\lambda_u = 0.001$ $\lambda_v = 0.001$
SocialMF[12]	The method in which the diffusion of trust is considered when modelling trust relationships between users.	$\lambda_t = 1$ $\lambda_u = 0.001$ $\lambda_v = 0.001$
SoReg[13]	The method in which the trust relations are modelled by supposing that the distance between the latent features of the trustors must be minimal.	$\beta = 0.001$ $\lambda_1 = 0.001$ $\lambda_2 = 0.001$
TrustMF[24]	The method in which users are questioned at two spaces of latent features, the space of the user as trustor and the space of the user as trustee, by analyzing the trust network.	$\lambda_t = 1$ $\lambda = 0.001$
GlotMF	Our proposed method in which the general and the local social context of trust relationships between users is exploited, where local information represents the preferences of the two different states of users (trustee and trustor) which are learned by modelling the explicit and implicit interactions between users, while the general information represents the reputation of the user in the social network.	$\alpha = 0.6$ $\lambda_b = 0.1$ $\lambda_e = 0.1$ $\lambda = 0.001$

To check all the methods that are compared with the methods we use, we define our own optimization parameters according to the corresponding references that are based on our experiments, as shown in the Table II. To compare these methods fairly, we define the dimension K of the latent feature space, for example, five and ten. In reference to all the methods, we adopt the same initialization strategy, which randomly initializes all the latent feature matrices with a distribution uniform in the domain [0, 1].

In this test, we will focus on two user's points of view to measure the performance of the different methods compared:

- Perspective of All Users: users who have at least one rating.
- Perspective of Cold-Start Users: Users with less than 5 ratings.

D. *Experimental Results*

the results of our experiments that we carried out on the "Epinions" database for the "All Users" and "Cold-Start Users" perspectives on the "MAE" and "RMSE" measurements used in the process of evaluation and with different parameters for the dimension of the latent factor space (k = 5, k = 10). The experimental results of our proposed method and the methods we compared with, are presented in the Table III and Table IV.

TABLE III. RECOMMENDATION PERFORMANCE COMPARISONS ON EPINIONS DATA SET, THE CASE OF "ALL USERS"

Metrics	**MAE**		**RMSE**	
	K=5	K=10	K=5	K=10
PMF	0.979	0.909	1.290	1.197
RSTE	0.950	0.958	1.196	1.278
SoRec	0.882	0.884	1.114	1.142
SoReg	0.994	0.932	1.315	1.232
SocialMF	0.825	0.826	1.070	1.082
TrustMF	0.818	0.820	1.069	1.095
GlotMF	0.804	0.805	1.043	1.044

TABLE IV. RECOMMENDATION PERFORMANCE COMPARISONS ON EPINIONS DATA SET, THE CASE OF "COLD-START USERS"

Metrics	**MAE**		**RMSE**	
	K=5	K=10	K=5	K=10
PMF	1.451	1.153	1.770	1.432
RSTE	1.051	0.981	1.266	1.313
SoRec	0.892	0.846	1.138	1.180
SoReg	1.398	1.139	1.735	1.437
SocialMF	0.884	0.857	1.133	1.152
TrustMF	0.891	0.853	1.125	1.176
GlotMF	0.868	0.868	1.105	1.108

1) *Analysis and discussion of the results*

- The performance of the traditional "PMF" method is lower than the performance of other compared methods based on a matrix analysis which, in our opinion, benefits from the relationships of trust in the two perspectives "All Users" and "Cold-Start Users" which underline the importance of trust in improving the performance of model-based recommendation systems.
- From an "All Users" perspective, the TrustMF and GlotMF models perform better than other trust-based models that map users to a single latent feature space. In addition, our proposed model "GlotMF" outperforms the "TrustMF" model among all models compared by 1.4% and 2.6% respectively when K = 5, and by 1.5%, 5.1% when K = 10 in terms of "MAE" and "RMSE" respectively.
- From a Cold-Start User perspective, there is no single model that works best among trust-based models. In general, our suggested model performs better than the others. Although, with a few noted exceptions in terms of MAE, our model is more robust in terms of RMSE. Since all confidence-based models aim to improve the squared errors between predicted values and actual values. Whereas, the "RMSE" measurement is more significant than the "MAE" measurement (where "RMSE" calculates the square of the differences between the actual ratings and the predicted ratings, thusly, penalizing large errors more than the "MAE"), and, therefore, our model always has the best performances, surpassing the "TrustMF" model the best among the compared models at the level of the "RMSE" measure when K = 5, and the "SocialMF" model the best at the level of the "RMSE" measure when K = 10.
- In addition, we notice that the "GlotMF" model achieves better performance in both perspectives, which confirms the efficiency of taking the implicit links between the users beside the explicit links in improving the performance of the recommendation, as well as exploiting the general social context of users contributed to our model outperforming other models based on trust.
- Although the percentage of relative improvements in our model compared to other compared models is small, these improvements are significant, as researchers in [4, 26] noted that even small improvements in MAE and RMSE measurements can lead to significant differences in the recommendations. As evidence to the above-mentioned result, a million-dollar award was submitted to the Netflix Prize competition in October 2006 for a 10% improvement in the RMSE metric over traditional sponsorship methods.

2) Checking the performance of the proposed model on users with different degrees of confidence: other series of experiments to verify the performance of the proposed model for users with different degrees of trust relationships was carried out to compare our method with other trust-based methods and test the possibilities of these different methods by benefiting trust data for the recommendation. The degrees of trust relationships can be defined as the total of the trustees' neighbors of the user and the trustors' neighbors of the user themselves. To conduct our experiments, we first group all the users into several groups (up to seven groups) according to their degrees of trust, these groups are "1-5", "6-10", "11-20 "," 21-40 "," 41-100 "," 101-500 ", and "> 500 "as used by the researchers. Then, we calculate the predictive error in each group respectively in terms of measures" MAE "and" RMSE "when the number of latent features is equal to five and ten, the results of these experiments are shown in the Fig. 5, Fig. 6, Fig. 7, and Fig. 8.

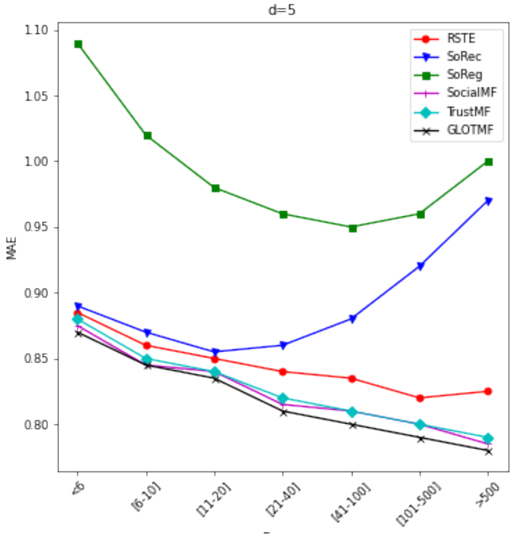

Fig. 5. The Predict Error on users in different Methods when d=**5** (MAE).

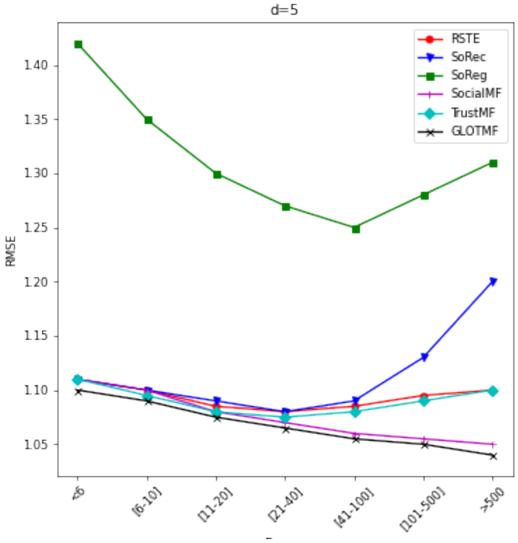

Fig. 6. The Predict Error on users in different Methods when d=**5** (RMSE).

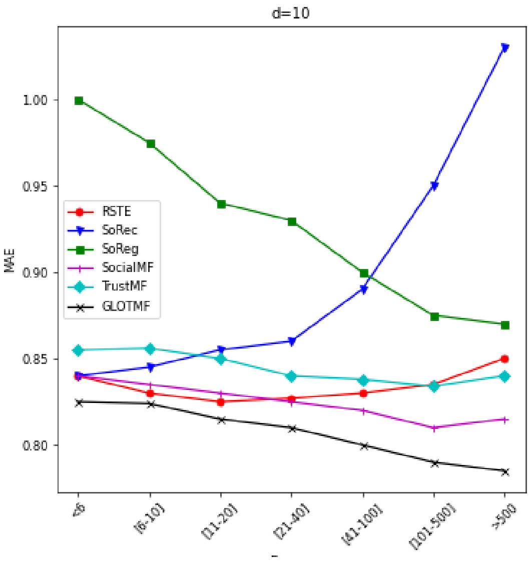

Fig. 7. The Predict Error on users in different Methods when d=10 (MAE).

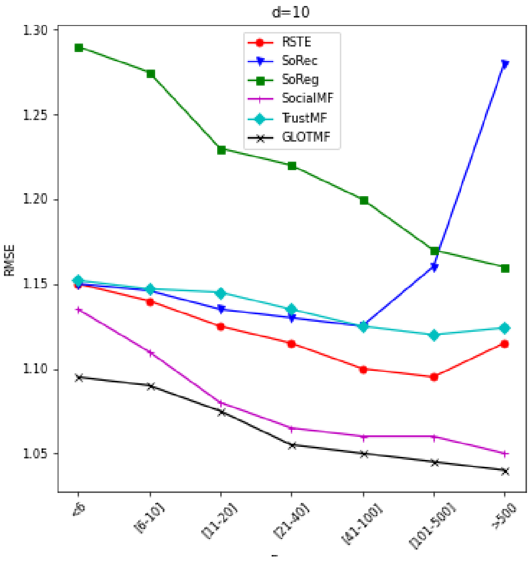

Fig. 8. The Predict Error on users in different Methods when d=10 (RMSE).

The results obtained show that the performance of the six compared methods differ to some extent from the different trust groups, and our "GlotMF" model works stable and shows the best quality for most groups, especially for the group with five relationships of maximum trust (about 63.4% of users), and for the group of 6 to 10 trust relationships (about 11.6% of users) on the MAE and RMSE measures in the two dimensions five and ten. This strongly suggests that our model can benefit from dispersed trust data more effectively than other trust-based collaborative filtering methods.

V. Conclusion

The Research tried to present our proposal to improve the accuracy of recommendations in the model-based collaborative filtering method by taking advantage of trust relationships between users. This is done by presenting a new data fusion strategy rating and trust data to express users' mutual impact on their opinions more logically, and, thusly, predict the unknown values of user ratings on items more accurately and efficiently. In our proposed method, local information represents the preferences of the two different user states trustee and trustor which are learned by modelling the explicit and implicit interactions between users. While general information represents the reputation of the user in the social network. Experiments were performed on a real database, "Epinions", and in two user perspectives, "All Users" and "Cold-Start Users". The results of these experiments showed that the suggested method brought up significant improvements in terms of predictive accuracy, and its effectiveness in alleviating data dispersion and cold start problems compared to other methods based on models that take advantage of trust relationships to improve the accuracy of recommendations. Current work relies on the explicit trust granted explicitly by users, but the user might refute to share or disclose this information, for example, due to privacy concerns. Moreover, many of these available datasets contain explicit trust information. Therefore, implicit trust values can be inferred from user behaviors to improve the generalizability of proposed method. In future work, we intend to improve the proposed model, and it will be interesting to study more extensions.

***Abstract*—Determining an impervious surface is one of the most important topics of remote sensing because of its great role in providing information that benefits decision-makers in urban planning, sustainable development goals, and environmental protection. In recent years, a great development in this field has occurred due to the huge improvement in the algorithms and techniques that are used to map impervious surfaces. In this paper, the deep learning technique has been implemented to investigate the extraction of impervious surfaces in Marrakesh city, based on Landsat images. 9000 polygons and 13840 points have been taken to prepare label data by random forest in Google Earth Engine (GEE). In addition, all preprocessing steps for remote sensing images have been implemented in GEE. An artificial neural network (ANN) has been used to determine impervious surfaces. After training and testing the proposed network on Landsat image datasets, precision, accuracy, recall, and F1-score matrix scores were 0.79, 0.98, 0.87, and 0.82, respectively. The experimental results show that this method is efficient and precise for mapping the impervious surfaces of Marrakesh city.**

***Keywords*—Deep-learning; remote sensing; artificial neural network ANN; impervious surface**

I. Introduction

Impervious surfaces are a prominent indicator of human presence and are characterized as land covers that have been contained by manmade structures that restrict water penetration into the soil, such as building roofs, roadways, and parking lots [1]. The growth of impervious surfaces and urban areas causes a variety of problems, including environmental risks and sociopolitical consequences [2, 3]. In order to achieve sustainable development goals, urban planning, and environmental protection, it is necessary to provide all details and specific information that cover the long-term dynamics of impervious surfaces [4, 5]. Since the 1970s, remote sensing instruments have been widely employed to monitor the Earth. Everywhere across the world, day or night, these satellites gather data at a low cost or for free. With this, the quantity of data that can be used to research impervious surfaces has increased significantly [6-8]. In order to successfully extract information from such a massive volume of data, high-performance processing skills, such as machine learning and cloud computing platforms, are required. These algorithms and technologies have been shown to be extremely efficient [9-12].

Remote sensing has been widely utilized to identify impervious surfaces. Several articles have been published describing the state-of-the-art of this topic [13-21]. Earlier, statistical remote sensing indices including the Normalized Difference Built-up Index (NDBI) [22], Normalized Difference Impervious Surface Index (NDISI) [23], modified NDISI [24], and perpendicular impervious surface index(PISI) [25] , biophysical composition index (BCI) [26] , and the normalized difference vegetation index (NDVI) have been developed to map impervious surfaces. Scholars and researchers have moved their focus to machine learning techniques such as Random Forest [27], Support Vector Machine (SVM) [28], and Classification and regression trees (Cart) [29], among others. Similar to our earlier study, this is a continuation of that work [30]. In recent years, deep learning algorithms and cloud computing infrastructures have witnessed tremendous development, resulting in significant advancements in image processing applications such as classification, segmentation, and change detection [31-33]. As a result, the remote sensing community is attempting to modernize remote sensing image preprocessing and processing in order to keep up with this development.

One of these major accomplishments is the Google Earth Engine cloud computing platform, which is free and combines a multi-petabyte catalog of satellite imagery and geospatial datasets with planetary-scale analysis capabilities, as well as its community [34, 35]. This is constantly updated and has many scientists, researchers, and developers working on it to develop remote sensing and environmental applications. Despite the fact that deep learning has unique automatic feature learning capabilities and strong nonlinear complex function expression and fitting capabilities, and it can combine low-level features to form more abstract high-level representations and attribute categories or features, it requires significantly more training data than conventional machine learning supervised classifications [36].

In this work, deep learning techniques have been proposed to determine impervious surfaces of Marrakesh city, based on Landsat images to take advantage of the large archive owned by this satellite (1972–now) [37, 38]. 6787 polygons have been extracted from the cadastral plan, and 13122 labeled points have been chosen carefully from high resolution images to prepare label data images by random forest in the Google Earth engine (GEE). In addition, all preprocessing for remote sensing images for training and testing images has been implemented in GEE. An artificial neural network (ANN) has been used to implement this task. The remainder of this paper is organized as follows: Section II discusses the pieces that are related to this topic. The proposed methodology for predicting impervious surfaces for the city of Marrakech has been illustrated in Section III. Section IV describes the experimental results and their evaluations. The conclusion is found in Section V.

II. Related Work

In general, the literature on remote sensing techniques for detecting impervious surfaces is divided into three categories: statistical-index based, machine learning based.

1) Statistical-index based: In this subsection, index-methods will be discussed briefly. These statistical indicators have been modeled by calculating two or more bands in order to improve the spectrum of specific features of the target areas, such as NDBI, modified NDISI, NDIS, PISI, and BCI. The computing formulas for some of these indicators are presented below:

$$NDBI = \frac{SWIR1 - NIR}{SWIR1 + NIR}$$

$$\mathrm{MNDWI} = \frac{\mathrm{G - SWIR1}}{G + SWIR1}$$

$$\mathrm{NDISI} = \frac{\mathrm{Tb + (MNDWI + NIR + SWIR1)/3}}{\mathrm{Tb - (MNDWI + NIR + SWIR1)/3}}$$

$$\mathrm{PISI} = 0.8192 * \mathrm{B} - 0.5735 * \mathrm{NIR} + 0.075$$

$$NDVI = \frac{NIR\ - RED}{NIR\ + RED}$$

where:

- SWIRI is the band of shortwave infrared waves (Landsat 8 band 6).while.
- Tb indicated to the temperature of the TIRS1 thermal band's brightness.
- NIR refers to the near-infrared band pixel values (Landsat 8 band 5).
- RED, G, and B represent the red, green and blue canals on Landsat 8, also known as Bands 4, 3 and 2 respectively.

Despite these statistical-based algorithms being obvious and simple to use, they faced a few restrictions in their performance. For example, in regions with large concentrations of topsoil, NDBI does not work well because it cannot distinguish between urbanized areas and vegetation. On the other hand, the NDISI relied on land-surface temperature, which might fail in zones where the heat island effect is less prominent. Furthermore, the Tb band is also problematic since it is not present in all sensors. In general, it's hard to use these indicators alone to predict the impervious surface because the threshold interval changes from zone to zone and hasn't been adjusted yet [25].

a) Texture-based methods: Previously, scholars and researchers have extracted the impervious surface using various methods based on spectral analysis and mixed pixel decomposition to examine the variations in reflectance features of impervious surface areas using medium-to-low-resolution remote sensing images, such as Landsat [39, 40].

b) Machine learning based: Machine learning algorithms have been extensively conducted to model impervious surfaces, such as the maximum likelihood classifier, support vector machines (SVM), classification and regression trees (CART) algorithm, and random forest. In spite of the fast development of these approaches, they need vast quantities of labeled training and assessment data. Nonetheless, the gathering and generation of this quantity of labeling data by visual interpretation is regarded as time-consuming and cost-intensive [28]. In addition, the machine learning approach has been challenged by the spectral and textural complexity of impervious surface area (ISA) in mixed pixels, including different combinations of ISA and other land cover types [41].

III. Research Methodology

Marrakesh is one of the most important Moroccan cities, it is located at 31° 37′ 48″ N 8° 0′ 32″ W, and has a surface area of more than 230 km²; It suffers from the effects of migration from the surrounding countryside to it; it was chosen by the atlas project (www.atlasofurbanexpansion.org/) to study urban expansion from 1985 to the present; and it was also chosen in our previous work [30]. This paper will determine the impervious surface of Marrakesh city using deep learning technique.

A. Database Preparation for Learning and Testing the Proposed Model

Cloud computing is very important for deep learning applications since it provides unlimited storage, provisioning, and updating, as well as guaranteed privacy and security [42, 43]. Users of cloud services can also improve server usage, dynamic scalability, and reduce the time for creating new applications [44]. The Google Earth engine platform (GEE) is utilized to implement all steps for training and testing the deep learning model.

In this study, our goal is to use deep learning techniques to extract the impervious surface of the city of Marrakech based on Landsat images. 6787 polygons and 13122 points have been chosen to prepare labeling data by using random forest in GEE. These points had been collected using visual interpretation analysis, which is based on our power to match patterns and colors in an image to real-world features, from high resolution images from different resources such as (Google earth, Sentinel-2 OSM). According to the polygons, they were taken from plan cadastral of Marrakesh city. Then these data are uploaded to GEE cloud platform as a form of features collections. After that, a sampling operation was performed to link the features (Landsat image datasets 8 bands: B2, B3, B4, B5, B6, B7, NDVI, and NDBI of each point and polygon with the corresponding pixels in the target image (Marrakesh city image).

In the present study, random forest algorithm has utilized to produce labeled data image as it is the best obtained result in our previous study [30]. Fig. 1 shows the resulted image from random forest, the white pixels represent the impervious surface of Marrakesh city.

Random forest is composed of many decision trees. Furthermore, it employs randomness to improve accuracy and avoid over fitting, which can be a significant problem for such a complex algorithm. These methods generate decision trees from a random sampling of data and extract predictions from each tree. Following that, they vote on the most possible solution. The use of random forest (RF) for image classification has gained popularity due to its ease of use (e.g. relatively insensitive to classification parameters) and generally high accuracy [45]. This algorithm works as follows: Assuming the dataset has "m" features, the random forest will select "k" features randomly, where k < m. The algorithm will now select the node with the biggest information gain among the k features as the root node. The algorithm then divides the node into child nodes and continues the procedure "n" times more; a forest with n trees is obtained. Finally, bootstrapping, which entails combining the outcomes of all of the decision trees in random forest, will be performed. Because it is based on the functionality of decision trees, it is definitely one of the most complicated algorithms[46].

After obtaining our labeled image, it is necessary to prepare the database (the labeled image) to be the input of the ANN model. The steps for preparing the database are as follows:

- First step is to flattening the data shape from multi-dimensions (Landsat image datasets eight layers: b2, b3, b4, b5, b7, b7, NDVI, NDBI) into two dimensions array. This is a very important step because Flatten makes the serialization of a multidimensional tensor apparent (typically the input one here eight layers). The mapping between the (flattened) input tensor and the first hidden layer is now possible. Each member of the (serialized) input tensor will be linked with each element of the hidden array if the first hidden layer is "dense". The way the input tensor is mapped into the first hidden layer would be unclear if you didn't utilize Flatten. Fig. 2 shows the result of the flatting operation.
- The second step is data cleaning, by removing no-data pixels from the arrays.
- The third is to divide the data by 60 percent for training and 40 percent for validation accordingly.
- The fourth stage is normalization, which is required by many machine learning methods, including NNs. This indicates that the histogram has been stretched and scaled to meet a particular range of values (here, 0 to 1). We will normalize our features to fulfill this requirement. Normalization can be performed by subtracting the minimum value and dividing it by the range. Because the Landsat 8 data is a 16 bits data (216= 65536 values), the lowest and highest values are 0 and 65536. Fig. 2 also shows the result of the normalization operation.
- Reshaping the features from two to three dimensions, such that each row represents an individual pixel, is another pre-processing step. Fig. 3 indicates the result of converting the features from two to three dimensions.

B. Architecture of the Proposed Model

In recent years, an artificial neural network (ANN) has gotten a lot of attention because of its ability to solve complicated nonlinear problems in domains like computer vision, image processing, natural language processing, and so on. For this reason, an ANN deep learning model has been implemented to improve impervious surface extraction for Marrakech, Morocco.

The basic architecture of an ANN model consists of input and output layers as well as hidden layers with various weights. Then, these several layers are connected by neurons. Every single neuron is inspired by a biological neuron, and produces a single output, and is known as a perceptron.

0.268	...	...	...	...	...	...	...		0

Fig. 3. Reshaping.

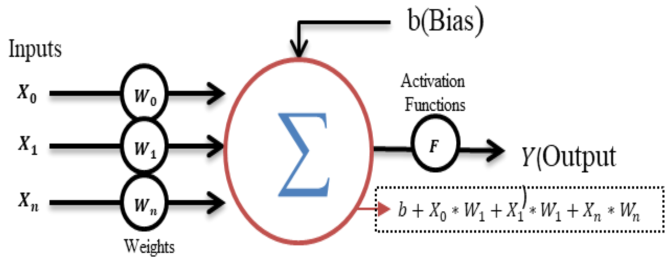

Fig. 4. Basic Architecture of ANN.

The perceptron's basic architecture is illustrated in the diagram above (Fig. 4). Initially, X0, X1,... and Xn indicate inputs. The inputs (X0, X1,.. and Xn) are multiplied by a connection of weights (W0, W1,.. and Wn) and then summed with the bias value b (which permits the activation function to be shifted up or down). To obtain the output of the perceptron, the output of the summation operation is applied to the activation function. If no activation function is used, the output signal is just a linear function, and the model will be unable to learn and model complex data (such as images, videos, audio, speech, and so on). A neural network needs to learn and represent anything, as well as any arbitrarily complicated function that links an input to an output. Therefore, a neural network has to use a non-linear activation function to perform this task.

C. Implementation of ANN

In our model, the input variables are Landsat 8 image bands from Band 2 – Blue to Band 7 – SWIR 2, NDVI, and NDBI. We chose the additional bands (NDVI and NDBI) to increase the amount of data, which leads to improving the performance of our model.

The proposed model has two hidden layers; the first layer contains 32 neurons, while the other contains 16 neurons, followed by an output layer with two classes, impervious and non-impervious pixels, as shown in Fig. 4. The Softmax activation function is used because it is the most suited function for our situation to estimate impervious surface pixels.

IV. Results and Discussion

The impervious surface classification results will be discussed in this section. To detect the impervious surfaces, a series of preprocessing steps have been implemented, as already mentioned in the previous section. We utilized an ANN model to implement the detection of impervious surfaces. This model was trained and tested using a dataset, which is taken from the Landsat-8 archive. This dataset has been corrected, filtered, and exported in the form of a Geographic Tagged Image File Format (GeoTIFF) Image (Fig. 1) in GEE. This image contains eight bands with 30 meter spatial resolution, and its dimensions are 961 pixels in height and 2476 pixels in width. To train and test the proposed model, the database is split into two parts; the first contains 60% of the database, which is used to train the model, while the other part is used for testing the model.

A. Performance Accuracy Assessment of ANN Model

At this stage, the proposed model has been implemented on the Google Colaboratory Cloud platform. This platform facilitates the training of deep learning models online by providing a lot of computing power, better than our local machines. After training and testing our model, we obtained the confusion matrix's components as shown in Table I. The explanation of the confusion matrix is as follows:

- True Positive means that the pixel is predicted as an impervious surface pixel and it's true.
- True Negative represents the pixels that are not impervious surface pixels, and it's true.
- False Positive means that the pixel is predicted as an impervious surface pixel, but it’s false.
- False Negative means that the pixel is predicted as a non-impervious surface pixel, but it’s false.

Table I indicated that, our model has very high performance as the positive impervious surface detection is very high and the wrong detection is low. To quantitatively evaluate our model performance, four measurements are utilized, namely accuracy, recall, precision, and F1-score.

Accuracy: The discernment required to distinguish between impervious and non-impervious surfaces. The percentage of all assessed instances that are true positive and true negative is derived to assess a test's accuracy. It can be expressed mathematically as:

$$\text{Accuracy} = \frac{(TN + TP)}{(TN + TP + FN + FP)}$$

TABLE I. THE OBTAINED RESULTS OF OUR MODEL

confusion matrix		
Output -predictable image	***Actually Positive(1)***	***Actually Negative(0)***
Impervious surface Class - 1	True positive (TP) **916106**	False positive (FP) 6778
Non-Impervious surface class -0	False negative (FN) 3873	True negative (TN) 25018

That is the total number of assessments divided by the number of correct assessments. Additionally, precision, recall, and F1 score are used to assess the proposed methodology of performance. Precision is defined as the proportion of accurately predicted positive observations to all positive observations. A low proportion of false positives is associated with high precision. It can be expressed as follows:

$$\text{Precision } = \frac{\text{TP}}{\text{TP} + \text{FP})}$$

Recall: The recall is the proportion of correctly foreseen positive observations to all of the actual class observations. To put it another way, it can be expressed as.

$$\text{Recall } = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

F1 Score: This is the recall and precision weighted average. As a result, both false positive and false negative numbers are taken into account. In situations where the distribution class is unbalanced, F1 is more helpful than accuracy. The formula for this is F1.

$$\text{F1 Score} = \frac{2(\text{Recall} * \text{Precision})}{(\text{Recall} * \text{Precision })}$$

Table II shows the obtained results of the four measurement parameters that have been chosen.

TABLE II. THE OBTAINED RESULTS OF THE FOUR MEASUREMENTS STATISTICAL

Accuracy	*Precision*	*Recall*	*F1 Score*
0.98%	0.79%	0.87%	0.82%

It can be noted from Table II that our method has high performance in all measurement parameters (accuracy, precision, recall, and F1-score) as their values are higher than 0.79%. This is because of the good design of our model architecture and the large amount of data that is used for training and testing our model.

The evaluation of our ANN model has been applied to a dataset subset covering 124 km on the western side of Marrakesh city, and its dimensions are 589 pixels in height and 1104 pixels in width. Fig. 5 shows the original image of the target area. Fig. 6 presents the output predicted image of our ANN model. Fig. 7 presents the high-resolution image from Sentinel-2 for the same area as the impervious surfaces are clearly monitored. It is noted in Fig. 6 that the impervious surfaces are represented by white pixels. In comparison with Fig. 7, we notice that the impervious surfaces are classified and detected well. Our ANN model has a high accuracy in detecting impervious surfaces.

To assess and analyze the benefits and drawbacks of the suggested model and obtain a comprehensive overview of our research region, high-resolution images from Sentinel-2 have been brought, with true color composited. Fig. 8 displays this image, which describes urbanized Lands located at the end and fringes of the city, the western side of the image, and some settlements in the south of the image.

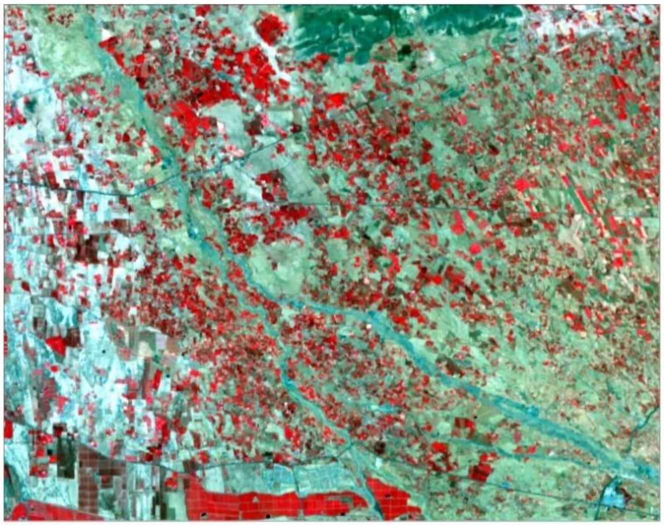

Fig. 6. Marrakech Original Image with Near-Infrared (NIR) Composite Landsat.

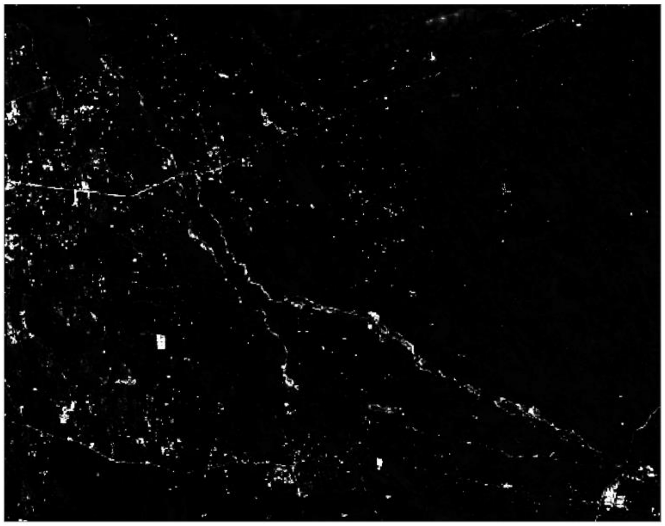

Fig. 7. Output - Predicted Image.

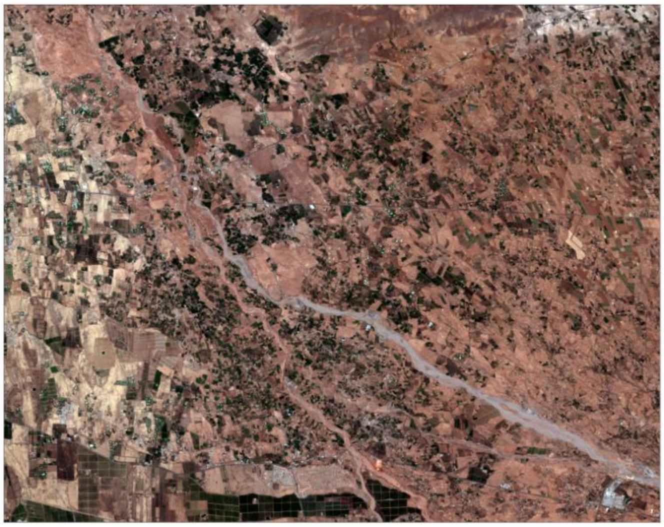

Fig. 8. Subset from Sentinel-2 Image for the Same Area.

V. Conclusion

In this paper, an artificial neural network deep learning model has been used to predict impervious surfaces in Marrakech city; the model is trained and tested using Landsat images. The experimental results show that our model has an accuracy of 81.80% in the precision matrix and 83% in the recall. This is because of the good design of our model architecture and the large amount of data that is used for training and testing our model. In the future, our goal might be to extend the proposed model to a large database containing many cities over many years. Therefore, increasing the amount of data will improve the accuracy of the model.

E-AHP: An Enhanced Analytical Hierarchy Process Algorithm for Priotrizing Large Software Requirements Numbers

Nahla Mohamed[1], Sherif Mazen[2], Waleed Helmy[3]
Department of Information Systems, Faculty of Computers and Artificial Intelligence, Cairo University, Giza, Egypt

***Abstract*—One of the main activities of software requirements analysis is requirements prioritization. The wrong requirements prioritization is risky as it leads to many software failures. The current requirements prioritization techniques can't deal with large requirement numbers efficiently, which is considered one of their main issues. Many researchers have agreed that the analytical hierarchy process (AHP) is one of the best prioritization techniques as it produces highly accurate results. AHP has two main problems: scalability and inconsistency. These problems have motivated us to propose an improved version of AHP for software requirements prioritization, namely Enhanced AHP (E-AHP). A performance evaluation has been done for the conventional AHP, E-AHP, and one of the recent algorithms that also try to solve the AHP scalability problems, namely removing eigenvalues and introducing the dynamic consistency checking algorithm into AHP (ReDCCahp) algorithms The evaluation shows which algorithm takes the least time, uses the least memory, produces the most consistent and accurate results, and has the highest scalability. The three algorithms have been evaluated by running their codes using different numbers of requirements ranging from 10 to 500. The results show that E-AHP is more scalable, takes the least time, uses the least memory, and produces the most consistent and accurate results compared to the other two algorithms. That becomes remarkable when the number of requirements increases. Therefore, E-AHP is suitable to be applied in large software projects, as it can deal efficiently with the large software requirements numbers.**

Keywords*—*Requirements engineering; analytical hierarchy process; software engineering; requirements prioritization techniques

I. Introduction

Requirements engineering is a critical part of software engineering [1]. It is the process of gathering the requirements and understanding them deeply to ensure that they are correct, complete, and consistent [2]. If the requirements engineering process has not taken enough time, it will affect the overall project [3], [4]. The requirements engineering process consists of five activities: requirements elicitation, requirements analysis, requirements specification, requirements validation, and requirements management. The prioritization of requirements is one of the critical activities in the requirements analysis process [5], [6]. When the requirements number increases, analysts must organize them to implement the most important ones in the early stages to avoid the high cost of system transformation and rework and achieve user satisfaction according to a pre-specified budget, time, and resources [7].

There are three requirements prioritization technique types [8], [9]: nominal scale techniques, ordinal scale techniques and ratio scale techniques. In the Nominal scale prioritization techniques [7], [10], the users assign each requirement to a priority group, and all requirements in the same group have the same priority [8]. One of the well-known techniques is the Numerical Assignment technique, which categorizes the requirements by distributing them into groups [11]; each group has a number that describes its rank or order among all groups. And the number of groups equals the scale range [9], [12]. Top Ten Requirements is another well-known nominal scale technique. It has only one group that contains the most ten critical requirements [9]. Another technique is MoSCow, which distributes the requirements into four main groups [8]: Must-Have, Should-Have, Could-Have, and Will-Not-Have [5], [12]. These techniques are simple, easy, and fast [10]. But their results are not accurate in most cases as they don't give specific priority value to each requirement [13] and cannot deal efficiently with large requirements numbers [11].

The Ordinal scale techniques produce an ordered requirements list [10], [12], and each requirement has a specific priority [8]. They are more accurate than nominal scale techniques [9]. One of the well-known ordinal scale techniques is the Priority group [11]. It is like the Nominal scale techniques but has only three groups: High, Medium, and Low. The users prioritize and classify the requirements within the same group into another sub-group; users repeat that looping until each group has only one. Bubble sort is another well-known ordinal scale technique [11]. In this technique, the user should list the requirements and then compare every adjacent two [9]. If the second one has less priority than the first, the user swaps the order of these two requirements. The user should repeat this process for each element in the requirements list until it becomes sorted in ascending order.

Binary Search Tree (BST) is another well-known ordinal scale technique. It depends on node structure. In BST, each node represents a requirement [14] .The root node is in the first level. The last level is the ordered requirements list. BST works as follows: the user first selects one requirement to represent the top node (the root node) [8]. After that, the user iterates on the requirements list; if the requirement in the root node is more important than the requirement in the current node, the user should search in the left sub-tree to place it. Otherwise, the user searches in the right sub-tree. The user repeats this process until putting each requirement in the right place in the tree based on its priority. The ordinal scale techniques have medium scalability, consume more time, and are less easy to use than nominal scale techniques [9].

The Ratio scale techniques are similar to the Ordinal scale prioritization techniques [6], [10]. In addition, they show relative importance among all the requirements, which means they give the requirements priority values [8]. In these techniques, the users know to what extent each requirement is more important than the others [9]. Cumulative Voting (CV) is a well-known ratio scale technique that depends on the users' voting; each user has 100 points [9] and distributes the points among the requirements based on their priority [15]. Hierarchical Cumulative Voting (HCV) is a new modification of the CV technique [2]. The main difference is that HCV also prioritizes the detailed requirements (prioritizes requirements and their sub-requirements hierarchically).

Analytical Hierarchical Process (AHP) is multi-criterion decision-making and mathematical method used in many fields, including requirements prioritization [6], [9]. It selects the best decision based on pairwise comparisons among all decisions concerning many criteria [8], [13] (note that AHP will be explained in detail in section three; because the proposed algorithm is based mainly on it). It is good to use one of these techniques when the project is critical, and it is necessary to know the exact difference of importance among all the requirements [11].

Most of the prioritization techniques can’t deal with large requirements numbers and produce accurate results at the same time [2], [5], [9], [11], [13], [14], [15]. Researchers [2], [7], [9], [11], [12], [14], [15] agreed that AHP is the most accurate prioritization technique, as it is a mathematical-based method and produces highly accurate results. But they found that AHP is suitable to be used only if the requirements number is small; otherwise, it is not good as it is not scalable and sometimes suffers from inconsistency problems. Scalability means the ability of a technique to deal with a large number of requirements efficiently, and inconsistency means it sometimes produces elements that are semantically conflicting and not compatible with each other. The limitations of AHP can be summarized as follows:

- Sometimes, the results of AHP may be inconsistent because of the high human involvement [13], especially with large requirements numbers [5].
- AHP is not fast; it takes much time to work [8], [13].
- It is not easy for users to use as it needs an excellent mathematical base. It also needs time to understand how it works [13], [4].
- AHP performs n*(n-1)/2 comparisons [4], [9]where n is the number of requirements ; that means when the requirements numbers increases, the pairwise comparisons number will increase exponentially [11], which indicates it does not work well with a large number of requirements and is not scalable [3], [13].

The previous AHP limitations have motivated us to search for new ways to enhance it to deal efficiently with large requirements numbers.

The main contributions of this paper can be summarized as follows:

- Proposing a new algorithm that tries to solve the scalability problem that faces the conventional AHP and minimizes inconsistent and inaccurate results.
- An experiment that compares the proposed algorithm against the AHP and one of the best recent algorithms introduced to solve the scalability problem of AHP, namely removing eigenvalues and introducing the dynamic consistency checking algorithm into AHP (ReDCCahp), is conducted. The experiment aims to test the three algorithms' scalability, complexity, results' accuracy, and consistency.

The rest of the paper is structured as follows: Section II presents the related works on the recent techniques introduced to solve the scalability and inconsistency problems of the conventional AHP and other prioritization techniques. Section III is the research background; it explains the conventional AHP (as the proposed algorithm is a modification of AHP). Section IV presents the proposed requirements prioritization algorithm. Section V presents an experiment that compares the proposed algorithm against the AHP and ReDCCahp algorithms. Section VI presents the experimental results and discussion. Section VII is the conclusion of the paper. Section VIII is the limitations and future works.

II. Related Work

Many researchers introduced several approaches and techniques to prioritize a large number of requirements efficiently. This section will briefly explain most of them. Market-Driven Requirement Prioritization Model (MDRM) [16] is an AHP modification model introduced to deal with large requirements numbers by reducing the number of pairwise comparisons. The main idea of MDRM is to divide all the requirements into bins and prioritize all these bins by AHP. The main limitations of this technique are that it can’t consider the dependencies and conflicts among the requirements [3] and cannot deal with large requirements number efficiently [13].

NAcAHP is another technique introduced to prioritize a large number of requirements [17]; it combines the AHP technique with the Numerical Assignment technique to reduce the time that results from the pairwise comparisons [12], [11]. There are three main priority groups: Optional, Standard, and Critical. AHP works only on ones in the Critical group. One of the main limitations of this technique is that it works well only if at least 80 % of all requirements are critical (because users can't know their priorities until completing the prioritization process) [18], [19]. Other limitations [2], [3] are that it does not do consistency checking for the results, and it has not been evaluated on large data sets [17].

Fuzzy AHP [20] is another approach introduced to solve the scalability issue that faces AHP [11]. The main idea of Fuzzy AHP is to use fuzzy scales [21], and the pairwise comparison matrix consists of fuzzy triangle numbers. It provides flexibility and efficiency to get benefits from the decision-maker's preferences. This approach also addresses the uncertainty in human judgment that AHP cannot address [3], [18]. Fuzzy AHP has many limitations. One of them is that it is not reliable [8], couldn't solve the scalability problem as it can't deal with large requirements numbers and takes much time to work [13]. Another limitation [22], [23] is that it doesn't consider requirements dependencies. And also, fuzzy systems are highly dependent on human expertise, have no systematic problem-solving approach, and need a lot of validation and testing. Researchers [22] proposed a goal-based requirements prioritization technique. It depends on giving weights to the requirements based on the different project's goals [3]. But this technique is not scalable [13], suffers from the data vagueness and uncertainty problems as it heavily relies on user involvement, and does not consider the dependency relationships among the requirements [22].

The Interactive Genetic Algorithm-based (IGA) technique [24] was introduced to solve the scalability problem by combining pairwise comparisons IGA [18]. This technique uses the IGA to reduce the pairwise comparisons number [3], [14], it’s working on extracting from the user the relevant knowledge, and each user provides his preference values. IGA algorithms don’t require much information about the problem. But they have many limitations [2], [5]. Un-Scalability is a major one, as the search space increases exponentially when the number of problem elements increases [25]. Another is that the experts choose the best solution only after comparing it to the others, has no stopping criteria, and designing the objective function and getting the correct operators and representation needs effort [9].

Researchers [9] introduced an expert system, namely the Priority Handler (PHandler), to solve the scalability issue. It combines three approaches, Value-based Intelligent Requirement Prioritization (VIRP), the Back Propagation Neural Network (BPNN), and AHP. PHandler predicts the values of the requirement priorities by applying the BPNN, and then AHP. It can deal with large requirements numbers [13]. The main challenge of this system is choosing professional business analysts because a strong analyst's knowledge is necessary to estimate accurate values of requirements classification factors. One of the main limitations [13] of this system is that it neglects the dependency relationship among requirements. And the expert systems do not explain the logic behind taking a decision, cannot easily automate complex processes, and have no common sense when making a decision.

Fuzzy AHP ANN [21] is an artificial intelligence decision support system proposed to deal with large requirements numbers [18]. It integrates the Artificial intelligence Neural Network (ANN) with AHP to select the best alternatives. It determines the priority weights for the requirements using a program, namely PECAR. After that, a supervised ANN is trained (by applying a feed-forward back-propagation algorithm) using results from the PECAR program. And the decision-makers can apply different scenarios using the PECAR program by entering several input parameters into it and then observing the difference among the results. The main challenge of this system is that it needs high experts’ involvement in the prioritization process. One of the main limitations of this system [13] is that it does not produce consistent results. Another limitation is that large neural networks consume a high processing time, need a lot of data to work, cannot specify a single solution for the problem, and not scalable [2].

Researchers [26] introduced a graph-based approach to prioritize a large number of requirements. It represents the requirements as a directed graph; each node represents a requirement and can be a pre-request for or dependent on other nodes. The dependency relationships among nodes are represented as directed arrows. After that, all spanning trees are generated from the graph. In the end, requirements priorities values will be calculated based on the number of requirements dependent on them (the dependent requirements will have lower priority than the pre-requisite requirements). The main limitation of this approach [27] is the large memory consumption. It is also hard to be implemented by users; its representation is not structured, and has no specific spanning concept [26]. Researchers [4] introduced an iteration model for implementing large numbers of requirements. The main idea is to implement the requirements in phases and not all at one time. It uses the graph-based approach. One of the main limitations of this model is it does not implement all the requirements as it implements the critical ones only [4]. Another limitation is that system architecture issues will appear as all the requirements have not been gathered together, it needs more resources, and it doesn't consider the dependency among the requirements.

Researchers [19] introduced another technique based on AHP, namely, ReDCCahp. The main idea of ReDCCahp is to put every pair of adjunct requirements from the requirements list in one group and make the pairwise comparison among these groups to reduce the number of pairwise comparisons and matrix size. It is fast, simple, and does not need a strong background in math, data science, or data structure; to understand it. So it is easy to use and understand by users and more effective than AHP when dealing with a medium number of requirements. But this technique is not highly accurate as it randomly groups the adjacent requirements in the list, which means it does not have a specific requirements grouping method, which is considered its main limitation [19]. It also can deal with only small and medium requirements numbers [13] and doesn’t consider the requirements dependencies. Because ReDCCahp is one of the easiest and best new requirements prioritization techniques, the proposed algorithm tries to solve its limitation besides AHP limitations by introducing an efficient method for requirements grouping. A comparison has been made among the proposed algorithm, the conventional AHP, and the ReDCCahp algorithms.

III. Background: The Conventional AHP

This section explains the conventional AHP; because the proposed algorithm is based on it. AHP is a multi-criterion decision-making method developed by Saaty (1980) [28], [29] to solve social science domain problems. It had been used in many other fields, one of which is requirements engineering. AHP is a mathematical technique based mainly on pairwise comparisons; it selects the best decision based on comparisons among all decisions concerning many criteria. It is one of the efficient and best techniques for dealing with complex decisions. AHP consists of two phases: 1. Construct the reciprocal matrix and get the priority vector (PV). 2. Checking the consistency of the results.

In the first phase, an n × n reciprocal matrix is constructed (where n is the number of requirements) from the pairwise comparisons among the requirements by letting the user choose a value from a specified scale in AHP (each value in the scale refers to a specific importance degree) between each pair of requirements as follows: the user will put 1 in the cell(i, j) and cell(j, i) in the matrix when the requirements i and j have the same importance, and if i has more priority than j, the user should put the value he chooses from the scale in cell (i, j), and put the reciprocal of this value in cell (j, i) and vice versa. Table I shows the pairwise comparison scale in AHP.

TABLE I. PAIRWISE COMPARISON SCALE IN AHP

Intensity of importance	**Description**	**Reciprocal value**
1	Equal importance	1
2	Equal to moderate difference in importance	1/2
3	Moderate difference in importance	1/3
4	Moderate to strong difference in importance	1/4
5	Strong difference in importance	1/5
6	Strong to very strong difference in importance	1/6
7	Very strong difference in importance	1/7
8	Very strong to extremely difference in importance	1/8
9	Extreme difference in importance	1/9

Then, each element in the matrix should be divided by the sum of its columns to get a normalized matrix. After that, the user should sum elements of each row in the matrix to get the eigenvector. The last step is normalizing the eigenvector by dividing each cell by the requirements number. The normalized eigenvector is the PV, which describes the relative weights among the requirements, and the summation of all values in PV should equal one. After finishing these steps, user goes to the second phase, the Consistency checking. It means that if there are three requirements: R1, R2, and R3. R1 is more important than R2, and R2 is more important than R3, then R1 should be more important than R3. That check is called the Transitivity check. So the user should ensure that all the elements in the matrix are transitive (the matrix is a correct reciprocal matrix). The percentage of inconsistent results is high as the matrix produced by AHP is made by humans.

Professor Saaty defined a measure for consistency checking called Consistency Index (CI), which is calculated using the formula (λmax-n) / (n-1), where λmax means the maximum eigenvalue of the matrix [30], and n is the number of pairwise comparisons. To ensure that the matrix is consistent, CI should equal zero (λmax should equal n), which means there is no deviation or difference between the excepted reciprocal matrix and the resulting one. But in real-life ideal cases rarely happen, so; how much inconsistency is acceptable? Professor Saaty put a specified percentage; if the error didn't exceed it, then the matrix is consistent (there is a minimum acceptable ratio for the inconsistency).

Saaty defined this ratio as Consistency Ratio (CR), which is a guide to checking whether the matrix is consistent or not. If CR is more than 10%, then the matrix is inconsistent, and users should repeat the process from the beginning, but if the CR value is equal to or less than 10 %, then the matrix is consistent. CR value is the value of CI divided by Random Index (RI), where RI is the average CI value of several comparison matrices sizes.

IV. E-AHP: THE PROPOSED ALGORITHM

Ma [31] has found that the user's effort in the prioritization process should be reduced to solve the AHP's scalability problem. And that can happen by reducing the time pairwise comparisons take. This section introduces an AHP-based algorithm namely, Enhanced Analytical Hierarchal Process (E-AHP). Which increases the scalability of AHP by reducing the time AHP takes to construct a reciprocal matrix; its main idea is to group similar requirements using a specific method. It also decreases the inconsistent results by giving scores to the requirements groups. E-AHP consists of five main steps that will be explained in the following subsections.

A. Gathering the Requirements

First, the analysts should gather all the functional and non-functional requirements, ensure they are consistent, discover any dependencies among them [2] and make sure they are clear and specific.

B. Scoring and Sorting the Requirements

In this step, each user assigns a score to each requirement, and the score scale will equal the total requirements number. More than one requirement can have the same score if they have the same priority to the user. After finishing the scoring process, the algorithm sorts the requirements in descending order by their scores. For example, if there are three requirements: R1, R2, and R3, in this case, the score scale will be from 1 to 3. If the user assigns scores 1 to R1, 3 to R2, and 2 to R3, then the algorithm will sort them in descending order, and the sorted requirements list will be 1. R2, 2. R3, 3. R1.

To sort the requirements' scores list, a hybrid algorithm of insertion sort algorithm [19] and merge sort algorithm [32] is applied. The main idea of the hybrid algorithm is to divide the list of requirements scores into chunks. The chunk is an ascending or descending sorted sub-list that has the following patterns: $a_i > a_{i+1} > ... > a_n$ or $a_i < a_{i+1} < ... < a_n$ where a is the score of the requirement in position i, and n is requirements number. For example, if there is a list {1, 5, 6, 4, 3, 2} then the first chuck will be {1, 5, 6} (ascending order), and the second chunk will be {4, 3, 2} (descending order). After that, the algorithm reverses the first chunks to be sorted in descending order. A minimum size for each chunk is defined. For example, if the list is {2, 3, 1, 4, 5, 6} and the minimum pre-specified chunk size is 3, then the first chunk should be {2, 3, 1} not {2, 3}, although the element 1 breaks the chunk's pattern. After that, the algorithm does an insertion sort in descending order to this chunk to be {3, 2, and 1}. That algorithm fastens the sorting process (the complexity of the best case is O (n)) as it benefits from the already existing sorted sub-lists. In the end, the merge sort is applied to all these sub-lists to make a final sorted list.

C. Grouping the Similar Requirements

After sorting the requirements list, the algorithm will group all requirements that have the same score, or the difference among their scores is <= MaxDRS. Where the MaxDRS variable is the Maximum Difference of Requirements Scores in the same group; and it is pre-specified by the user. The user also specifies the value of MaxNR, which is the Maximum Number of Requirements in one group. For example, if there are five requirements: R1, R2, R3, R4, and R5. R1 and R2 have a score of 1, R3 has a score of 2, R4 has a score of 5, R5 has a score of 6, and MaxDRS = 1. Then the algorithm will put R1, R2, and R3 in one group and R4; and R5 in another group. And if MaxNR = 5 and seven of them have a score <= the specified MaxDRS, in this case, only five of them will be in the same group, and the rest two will be in another new group. To assign a score for one group, the algorithm calculates the average score of all its requirements. For example, if a group has three requirements: R1, R2, and R3, and the score of R1, R2 is 1, and the score of R3 is 2, then the score of their group will be (1+1+2)/3 =1.3.

The different values of MaxNR and MaxDRS influence the results, because there are negative relationships between the values of MaxNR, MaxDRS, and time, and between them and accuracy. If users aim to decrease the time taken, the MaxNR and MaxDRS values should be increased, which reduces the accuracy and vice versa. The best choice is to choose the values of MaxNR and MaxDRS based on the total number of requirements in the project. If the requirements number is large, it's better to choose large values for them and vice versa.

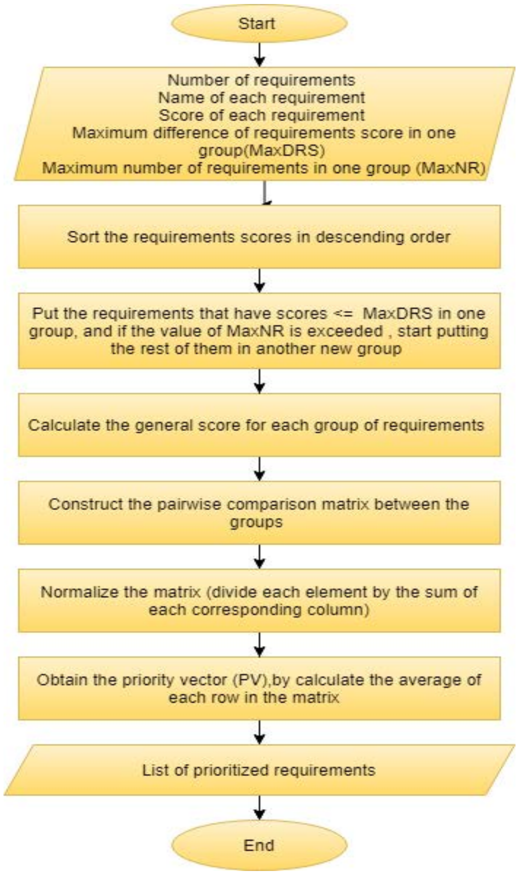
D. Constructing the Reciprocal Matrix

In these steps, E-AHP constructs the reciprocal matrix like AHP, but in E-AHP, the rows and columns of the matrix are the requirements groups, and the matrix's elements are the difference between the scores of the requirements groups. For example, if the score of G1 is 4; and the score of G2 is 2, then the element in the intersection of row G1, column G2 will be 2. And will be -2 between row G2 and column G1. After that, E-AHP normalizes the elements in the matrix and does the same mathematical calculations in AHP to get the PV. The flow chart in Fig. 1 and Algorithm I explain the steps to get the PV in E-AHP.

Algorithm I. Construct PC matrix and get the PV

```
Input: N - number of requirements
Input: RN - the requirements names list
Input: RS - the requirements scores list
Input: MaxDRS - maximum difference of requirements
scores in one group
Input: MaxNR - maximum numbers of requirements in one
group
Output: List of prioritized requirements
Initialize: R      // list of requirements objects
Initialize: G      // One group of requirements
Initialize: GL     // One group length
Initialize: AG     // List of all groups
Initialize: NG     // Number of all groups
Initialize: Sum    // Counter
Initialize: M      // The Reciprocal matrix
Initialize: CS     // List of column sum
Begin
for i in N do
    requirement ← new Requirement()
    requirement.name ←RN[i]
    requirement.score ← RS[i]
    requirement.ingroup ← false
    R.append(requirement)
end for
R ← sort(R by names, reverse=true)
for i in R.length do
    if R[i].ingroup == true then
        skip to next iteration
    G.reqList.append(R[i])
    R[i].ingroup ← true // R[i] is assigned to a group
    for j in R.length do
        if R[j].ingroup == true
        or (R[j].score - R[i].score) > MaxDRS
        or G.length > MaxNR then
            skip to next iteration
        else
            G.reqList.append(R[i])
            R[i].ingroup ← true
        end if
        G.reqList ← []
        G.avScore ← 0.0
    end for
    AG.append(G)
end for
NG ← AG.length
for i in NG do
    if AG[i].length == 1 then
        AG[i].avScore←AG[i][0].score
    else
        GL ← AG[i].length
        for j in GL do
            AG[i].avScore ←AG[i].avScore +
            AG[i].reqList[j].score
        end for
        AG[i].avScore←AG[i].avScore / GL
    end if
end for
for i in NG do
    for j in NG do
        if AG[i].avScore == AG[j].avScore then
            M[i][j] ← 1
        else if AG[i].avScore > AG[j].avScore then
            M[i][j]←AG[i].avScore - AG[j].avScore
        else
            M[i][j] ←1 / (AG[i].avScore -
            AG[j].avScore)
        end if
    end for
end for
Sum ←0
for j in NG do
    for i in NG do
        Sum ← Sum + M[i][j]
    end for
```

```
        CS[j] ←Sum
        Sum ← 0
    end for
    for j in NG do
        for i in NG do
            M[i][j] ← M[i][j] / CS[j]
        end for
        Sum ←0
    end for
    for i in NG do
        PV[i] ←PV[i] / NG
    end for
    for i in NG do
        for j in AG[i]
            print(AG[i].reqList[j].name "has relative weight
            : " + PV[i])
        end for
    end for
    End
```



Start
Number of requirements
Name of each requirement
Score of each requirement
Maximum difference of requirements score in one group(MaxDRS)
Maximum number of requirements in one group (MaxNR)
Sort the requirements scores in descending order
Put the requirements that have scores <= MaxDRS in one group, and if the value of MaxNR is exceeded , start putting the rest of them in another new group
Calculate the general score for each group of requirements
Construct the pairwise comparison matrix between the groups
Normalize the matrix (divide each element by the sum of each corresponding column)
Obtain the priority vector (PV),by calculate the average of each row in the matrix
List of prioritized requirements
End

Fig. 1. A Flowchart shows Steps to Get the PV in the E-AHP Algorithm.

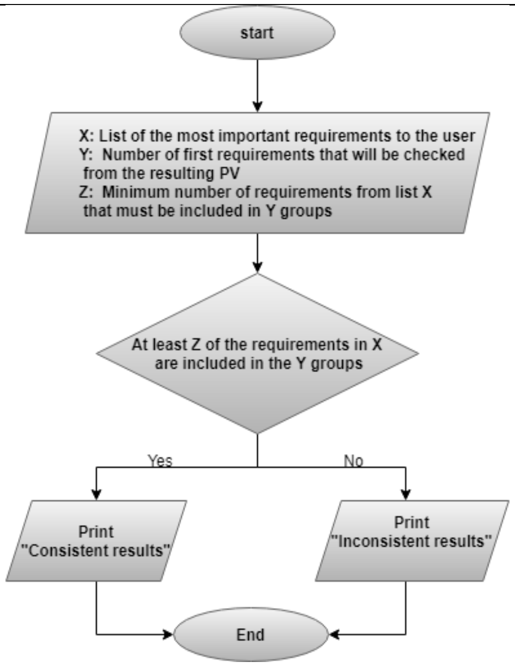
E. Consistency Check of the Results

In this step, a new consistency check algorithm is applied to ensure that the results are consistent. This step has three inputs: X, Y, and Z. X is a list of the most critical requirements to the user, and Y is the number of first groups from the resulting PV that will be checked. And Z is the minimum acceptable number of requirements in the list X that must be in the Y groups. The user fills the list (X), and to prove consistency, the algorithm checks that at least (Z) of them are in the (Y) groups from the resulting PV; otherwise, the result is inconsistent. And users should repeat the prioritization process from the beginning and re-evaluate their preference judgments. For example, if the size of the list X =5, Y=6 and Z=3, which means the user will choose the most critical five requirements for him, and then to prove the consistency of the results, the algorithm must find at least three of these requirements in the first sex groups from the resulting PV. These variables influence the results as the more the values of X, Z and the less the value of Y, the more accurate the results will be.

The flow chart in Fig. 2 and Algorithm II explain the consistency check step in E-AHP.

Algorithm II. Consistency checking of the results

```
Input: X - list of most important requirements
Input: Y - number of requirements for check
Input: Z – minimum accepted number of found requirements
Input: PV - priority vector result from phase 1
Output: print whether the results are consistent or not
Initialize: XL // length of most important requirements list
Initialize: nXF // number of important requirements found
Begin
nXF ← 0
for i in XL do
    for j in Y do
        if X[i] == PV[j] then
            nXF ← nXF + 1
        end if
    end for
end for
if nXF >= Z
    print ( "Results are consistent")
else print ("Results are not consistent")
end if
End
```



start
X: List of the most important requirements to the user
Y: Number of first requirements that will be checked from the resulting PV
Z: Minimum number of requirements from list X that must be included in Y groups
At least Z of the requirements in X are included in the Y groups
Yes
No
Print "Consistent results"
Print "Inconsistent results"
End

Fig. 2. A Flowchart shows the Consistency Check Step in the E-AHP Algorithm.

V. An Experiment Comparing the Proposed Algorithm (E-AHP) Against AHP and ReDCCahp Algorithms

This section will explain the experiment that compares the E-AHP against the AHP and ReDCCahp. It will mention the experiment objectives, variables, and setup.

A. *Experimental Objective*

This experiment aims to validate that E-AHP (the proposed algorithm) is better than AHP and ReDCCahp; by proving that it solves the scalability, inconsistency, and accuracy problems (as AHP suffers from scalability and inconsistency problems, and ReDCCahp suffers from accuracy problems). The experiment has compared the three algorithms (AHP, ReDCCahp, and E-AHP) against each other to test which one can deal with large numbers of requirements efficiently.

The research aims to answer the following questions:

- Which algorithm among the three algorithms takes the least time?
- Which algorithm among the three algorithms uses the least memory?
- Which algorithm among the three algorithms produces the most consistent results (produces results with minimum CR value)?
- Which algorithm among the three algorithms is the most scalable?
- Which algorithm among the three algorithms produces the most accurate results?

B. *Experimental Variables*

The experiment has three independent variables: AHP, ReDCCahp, and E-AHP, and three dependent variables: time, memory, and CR value. A brief definition for these dependent variables is given below.

- Time: representing the time each algorithm takes to prioritize the requirements (completion time of each algorithm), and it is measured in minutes.
- Memory: representing the memory needed for each algorithm to prioritize the requirements, and it is measured in megabytes (MB).
- CR: is the main criterion to check whether the results are consistent. It is calculated in the experiment by the same equation used in AHP (CI / RI) [28], [29].

C. *Experimental Setup*

The time consumption, memory usage, and CR values are evaluated by implementing and running the algorithms' codes and comparing their results. They have been written in the JAVA programming language and run on a machine with a Processor: Intel(R) Core(TM) i7-6500U CPU @ 2.50 GHz 2.60 GHz, and Installed Memory (RAM): 8.00 GB and System type: 64-bit operating system, x64-based processor.

Researchers [9], [31] considered the requirements numbers small when they are less than 20; medium when they are between 20 and 50; Otherwise, large. Several data set sizes (small, medium, and large) that range from 10 to 500 requirements are used in the experiment to prove the efficiency of E-AHP over AHP and ReDCCahp when dealing with various requirements numbers. The input will be a list of requirements objects (R1, R2, and R3…Rn), where n is the requirements number. Each requirement object has the name and score of the requirement. The requirements names are according to their order in the list. To consider the different scores for the requirements, the codes of the three algorithms have run ten times, each with different scores values, and then the average results are taken. Only the requirements numbers and their scores are important in the experiment, and it doesn't matter about their meaning.

VI. Discussion and Results

A. *Discussion*

This section presents and discusses the experiment results; it compares the performance of AHP, ReDCCahp, and E-AHP. It will show the time taken, memory used, and CR values of the algorithms after running their Java code with different numbers of requirements ranging from 10 to 500. Tables II and III present the average time taken and memory used by AHP, ReDDCahp, and E-AHP, respectively. Table IV presents the CR values of the AHP, ReDCCahp, and E-AHP results.

TABLE II. THE AVERAGE TIME TAKEN (IN MINUTES) BY THE AHP, REDDCAHP AND E-AHP ALGORITHMS

Number of requirements	**AHP**	**ReDDCahp**	**E-AHP**
10	2.501	1.391	0.297
25	9.647	3.675	0.972
50	17.533	6.988	2.326
100	27.091	13.962	4.955
150	49.081	22.491	6.883
200	74.718	28.541	13.481
300	109.981	46.846	25.236
400	136.345	61.932	36.766
500	161.709	95.961	45.152

TABLE III. THE AVERAGE MEMORY USED (IN MB) BY THE AHP, REDDCAHP AND E-AHP ALGORITHMS

Number of requirements	**AHP**	**ReDDCahp**	**E-AHP**
10	0.0681	0.0344	0.0293
25	0.2133	0.0939	0.0845
50	0.3312	0.1997	0.1497
100	0.5508	0.3138	0.2349
150	0.7019	0.4609	0.2911
200	0.9402	0.5011	0.3278
300	1.3082	0.7443	0.4026
400	1.8708	0.9952	0.5133
500	2.8937	1.1960	0.6479

TABLE IV. THE AVERAGE CR VALUE OF THE AHP, REDCCAHP AND E-AHP ALGORITHMS' RESULTS

Number of requirements	AHP	ReDDCahp	E-AHP
10	0.0791	0.0504	0.0193
25	0.1944	0.0905	0.0337
50	0.2908	0.0981	0.0617
100	0.3873	0.1649	0.0729
150	0.4521	0.2591	0.0801
200	0.5091	0.3287	0.0896
300	0.6099	0.4926	0.11091
400	0.7011	0.6608	0.1482
500	0.8019	0.7492	0.1615

Charts in Fig. 3 and Fig. 4 visualize results in Table II and Table III, respectively. Chart in Fig. 5 visualizes results in Table IV. Tables II, III, Fig.3, and Fig. 4 show that ReDCCahp and E-AHP take less time and memory than AHP. When the requirements number is from 10 to 50, the difference between the time taken and memory used by the algorithms is small, larger when the number of requirements becomes > 50, and significant when > 150. That happens because they apply the grouping method, which decreases their matrix size (when the matrix size decreases, the memory and time needed to complete the operations to get the final PV decreases).

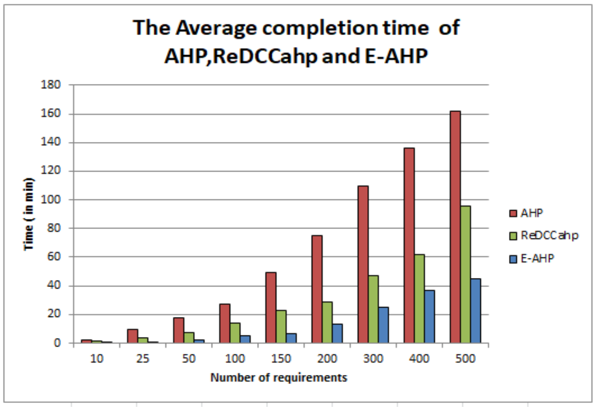


Fig. 3. The Average Time taken by the AHP, ReDCCahp and E-AHP Algorithms.

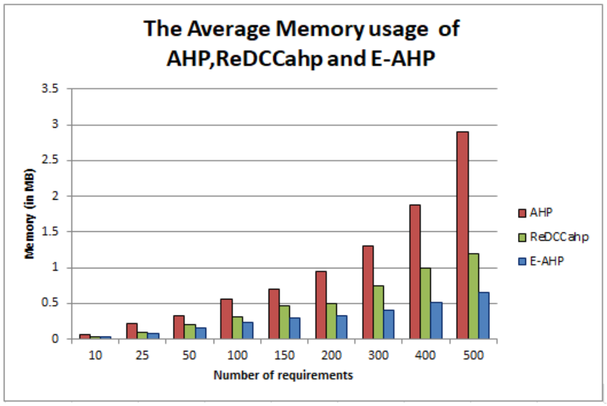

Fig. 4. The Average Memory used by the AHP, ReDCCahp and E-AHP Algorithms.

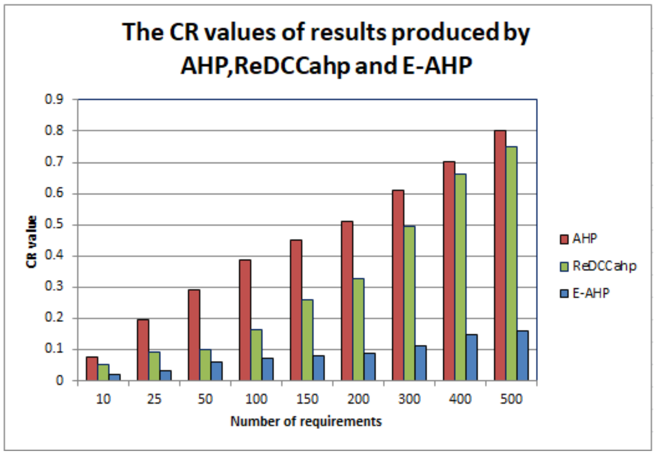

Fig. 5. The Average CR Value of the AHP, ReDCCahp and E-AHP Algorithms' Result.

It also can be noticed that E-AHP takes less time and memory than ReDCCahp, especially when the requirements number is > 100 (large). Because, in ReDCCahp, the group size is fixed (each group has only two requirements), but in E-AHP, the group size is variable (one group can have any requirements number). So in most cases, E-AHP produces less number of groups than ReDCCahp, which makes its pairwise comparison matrix size smaller than ReDCCahp.

Table IV and Fig. 5 show that the results of AHP becomes inconsistent (CR > .1) when the number of requirements is > = 25. That happens because it requires the users to make pairwise comparisons among all requirements; not among requirements groups, which increases the human error proportion; and hence decreases the results consistency. ReDCCahp produces consistent results when the number of requirements is < =50, and E-AHP produces consistent results when the requirement number is < 300. Although E-AHP and ReDCCahp both group the requirements, E-AHP produces more consistent results than ReDCCahp. That happens because E-AHP uses the scoring method instead of the pairwise comparisons, which decreases the human error proportion and increases results consistency. Moreover, the scoring method takes less time than the pairwise comparisons method, as the pairwise comparisons increase the time exponentially when the requirements number increases.

B. Results

The results that can be concluded from the experiment are as follows:

- AHP consumes more time than ReDCCahp and E-AHP, and E-AHP uses the least time among the three algorithms.
- AHP uses more memory than ReDCCahp and E-AHP, and E-AHP uses the least among the three algorithms.
- AHP produces less consistent results than ReDCCahp and E-AHP, and E-AHP produces the most consistent results among the three algorithms.
- AHP has less scalability than ReDCCahp and E-AHP, and E-AHP is the most scalable algorithm among the three algorithms.

- AHP produces less accurate results than ReDCCahp and E-AHP, and E-AHP produces the most accurate results among the three algorithms.

So among the three algorithms, E-AHP is the best one as it takes the least time, uses the least memory, has the highest scalability, and produces the most consistent and accurate results. All of that becomes remarkable when the number of requirements increases.

VII. Conclusion

This research proposes a new software requirements prioritization algorithm to solve the scalability and inconsistency problems faced by the AHP, namely E-AHP. A performance evaluation of the E-AHP algorithm against the AHP and ReDCCahp algorithms (ReDCCahp is one of the best recent algorithms that try to solve the AHP problems) was done to prove the effectiveness and efficiency of E-AHP. The java codes of the three algorithms have been implemented and run on the same machine with various requirements numbers ranging from 10 to 500 (small, medium, and large). The time taken, the memory used, and CR values of the results are measured. Results show that E-AHP takes much less time, uses less memory, and produces more consistent and accurate results than AHP and ReDCCahp, especially with large requirements numbers, which means that E-AHP has high scalability. So E-AHP is better than AHP and ReDCCahp as it can deal efficiently with large numbers of requirements.

VIII. Limitations and Future Work

Some cases will reduce the speed and accuracy of the E-AHP algorithm: first, if the difference among most of the requirements scores is more than the MaxDRS value, in this case, most of the groups will have one requirement, and the number of groups will increase (will almost equal to the requirements number), which will cause a scalability problem. Second, if the difference among most requirements scores is the same, then each group will have many requirements, which will decrease the accuracy of the results. The negative effect is reduced in these cases by choosing small values for MaxDRS and MaxNR. So in the future, we plan to enhance the E-AHP algorithm to deal with the previous cases efficiently. We also plan to conduct an experiment using a large number of software analysts as participants to validate the applicability and usability of the proposed algorithm on large real-life software projects.

***Abstract*—In this work, we investigated the effectiveness of adopting Human-in-the-Loop (HITL) aimed to correct automatically generated labels from existing scoring models, e.g. SentiWordNet and Vader to enhance prediction accuracy. Recently, many proposals showed a trend in utilizing these models to label data by assuming that the labels produced are near to ground truth. However, none investigated the correctness of this notion. Therefore, this paper fills this gap. Bad labels result in bad predictions, hence hypothetically, by positioning a human in the computing loop to correct inaccurate labels accuracy performance can be improved. As it is infeasible to expect a human to correct a multitude of labels, we set out to answer the questions of "What is the smallest percentage of corrected labels needed to improve prediction quality against a baseline?" and "Would randomly selecting automatic labels for correction produce better prediction than specifically choosing labels with distinct data points?". Naïve Bayes (NB) and Decision Tree (DT) were employed on AirBnB and Vaccines public datasets. We could conclude from our results that not all ML algorithms are suited to be used in a HITL environment. NB fared better than DT at producing improved accuracy with small percentages of corrected labels, as low as 1%, exceeding the baseline. When selected for human correction, labels with distinct data points assisted in enhancing the accuracy better than random selection for NB across both datasets, yet partially for DT.**

Keywords*—Human-in-the-loop; few labels; sentiment polarization

I. Introduction

Sentiment is used in an array of applications, from sentiment analysis to customer intelligence. Two primary sentiment polarities are "positive" and "negative". In the absence of any sentiment, a "neutral" polarity would be given. To date, additional polarities have been introduced to include the element of intensity. They are "strongly positive" and "strongly negative". Typically, the approach to determining polarity is via a hand-crafted lexicon of sentiments. Words in the lexicon were earlier identified to express positive or negative opinions about a particular subject of interest. This approach is limited to the list of collected words. Continuous enrichment must occur to sustain an ever-expanding vocabulary, especially on social media platforms with the existence of new words e.g., "Google" and "tweet". On its own, this approach may not be perpetually effective when more data are added.

Evolving from this approach is the use of machine learning (ML) algorithms trained on a dataset labelled with polarity. Through this approach, the algorithms learn from the labels and predict the polarity of newly unseen data points. This frees arduous efforts in the upkeeping of a lexicon. However, the performance of this approach relies considerably on a large number of good-quality labels which usually are produced with the assistance of human annotators. Several downsides of this technique are human annotators can be scarce in some domains, the quality of the annotators can differ depending on their level of knowledge and experience, not all datasets can be annotated, engaging human annotators are costly and they are incapable of annotating a tremendously large number of data points.

Recent works [1]–[5] show the implementation of a hybrid solution where a lexicon is used to automatically label a dataset which is then used as a training set by a ML algorithm. The assumption made is the produced labels are close to the ground truth, thus reliable. Our work investigates this assumption based on two lexicon-based scoring models of different types – a valence-based lexicon, SentiWordNet, and a rule-based lexicon, Vader. Human annotators were employed to examine the generated sentiment polarity of two public datasets (AirBnB and Vaccines) when the resulting labels conflict with one another. We found that Vader identifies polarity more like a human annotator than SentiWordNet. We extended this finding to further explore the effect Human-in-the-Loop (HITL) has on accuracy. By having a human expert in the loop, incorrect labels that compromised quality can be emended. Consequently, the ML algorithm learns the correction and updates its knowledge space, resulting in enhanced accuracy. As human annotators would not be able to correct a multitude of labels, we added another component to this experimental setting, i.e., few labels, which is counterintuitive to many ML algorithms as they often need numerous labelled data.

In this work, we determined the quality of sentiment labels from SentiWordNet and Vader based on a human's opinion. We constructed a HITL experimental framework and addressed two important questions. 1) What is the smallest percentage of corrected labels needed to improve prediction quality against a baseline? 2) Would randomly selecting automatic labels for correction produce better prediction than specifically choosing automatic labels with distinct data points?

This paper is outlined as follows. The literature review is covered in Section II. In Section III, we describe our proposed HITL methodology and formulated two research questions to be addressed via experiments. The results of the experiments are presented and discussed in Section IV. Finally, in Section V, we conclude this paper.

II. Literature Review

A. Sentiment Labelling

Traditional sentiment labelling requires human annotators to label data. Although this is known to produce gold standard datasets, unfortunately, it can be error-prone, time-consuming, labour intensive and infeasible with big data [6]. Automatic labelling comes into the picture to overcome this limitation. As of late, a scoring model such as SentiWordNet [7] or Vader [6] has been employed for this task. SentiWordNet works by utilizing a lexicon of synonymous English words clustered together a.k.a. synset. It contains 147,306 synsets labelled with the polarity of positivity, negativity and neutrality. An advantage of SentiWordNet as compared to older lexicons, e.g., Linguistic Inquiry and Word Count (LIWC), is its account of sentiment valence to assist in portraying sentiment intensity [6]. Nonetheless, SentiWordNet also shares the disadvantages of other lexicons: a shortage in coverage, where essential features tend to be missed and costly maintenance [6]. Conversely, Vader is newer and leverages rules to decide on the polarity and intensity of sentiments [6]. Vader adopted the same human-validated sentiment lexicons as LIWC, Affective Norms for English Words (ANEW) and General Inquirer (GI) yet appended more features specific to social media text, making it sensitive to their nuances. The cornerstone of Vader is the adoption of the wisdom-of-the-crowd to determine sentiment valence and the leveraging of Grounded Theory to formulate rules customized to generalize across an array of grammatical and syntactical functions for sentiment polarity decision-making.

B. Human-in-the-Loop (HITL)

HITL is not a new idea. Including feedback from a human during a computer-related process to improve effectiveness has been earlier proposed – e.g., harnessing paid feedback in crowdsourcing via Amazon Turk [8]. Another example is in the Pay-as-You-Go dataspace where users supply feedback to assist in resolving entities during data integration [9]. The HITL idea is also adopted in Few-Shot Learning [10], Active Learning [11], Transfer Learning [12] and User Guidance [13]. The underlying notion is performance can be enhanced even with a small amount of data from humans, especially for datasets that are too large to the extent of being infeasible to manually annotate [14].

C. Machine Learning Algorithms

Naïve Bayes and Decision Tree are popularly used in numerous sentiment analysis literature. To date, they include [1], [15]–[19].

1) Naïve Bayes (NB) when used for sentiment prediction is simple and intuitive yet highly accurate [20]. To predict, NB leverages the concept of conditional probability. Its advantage is it does not require a large training set [21]. However, a primary disadvantage is its tendency to theorize linguistic features to be independent under soconditionsion [20]. The argument put forth is the nature of words is co-occurring and are joined by syntactic as well as semantic dependencies, hence, NB may produce unfavourable performance.

2) Decision Tree (DT) is hierarchical in its natural form. Rules are generated for the task of predicting target terms. Each leaf node contains a word feature of the sentences in a corpus. DT was reported to have a great deal of adaptability to large datasets as compared to other ML algorithms [21]. A larger dataset triggers the formulation of additional rules, permitting the construction of higher quality trees with a larger pool of attributes available [22]. Nonetheless, this can be disadvantageous in a setting with few labels.

III. Research Methodology

A. Automatic Sentiment Production

In this step, we produced labels on each data point using automatic techniques. Two popularly used techniques are SentiWordNet and Vader scoring models. We applied both techniques to AirBnB[1] and Vaccines[2] public datasets. AirBnB contains 142,114 reviews on various premise owners in Asheville, North Carolina, United States, while the Vaccines dataset consists of 24,075 tweets related to opinions of Covid-19 vaccines worldwide. Both techniques' output is a pair of polarity confidence values for each data point; one for positive sentiment and the other for negative sentiment. The higher confidence value between the two becomes the final suggested sentiment. E.g., the positive polarity confidence for data *X* is 25% whereas the negative polarity confidence is 75%. Therefore, data point *X* will have a negative polarity.

When the set of sentiment labels is placed in tandem, three sets of results exist. The first is where both models scored positive sentiments on each data point. The second set contains only negative sentiments, and the last set has contradicting sentiments. For example, Vader scored a positive sentiment whereas SentiWordNet scored a negative sentiment on the same data point *Y*. The earlier two sets are not interesting in this study since both techniques produced the same result. We assume there is strong evidence to support the generated degree of confidence which led to the same result and thus it is more worthwhile to bring our focus to the contradicting set as this would allow us to discriminate between the two scoring models. For AirBnB, the size of the contrasting set was 3,967. For the Vaccines dataset, a total of 3,055 tweets were found.

B. Human Labelling

Next thing is to determine which contradicting labels are correct, Vader's or SentiWordNet's. Known as the ground truth, this task must be performed by the participation of a human. We employed two human annotators to evaluate each suggested sentiment in the contradicting set. The annotators are not English native speakers but have more than five years of writing and speaking English at a university level. We aim to investigate which model is less aligned with a human's

[1] http://insideairbnb.com/get-the-data.html

[2] https://www.kaggle.com/gpreda/all-covid19-vaccines-tweets

judgement. This model is then used to discover the role of HITL with few corrected labels in improving the performance of prediction.

The result in Table I displays Vader produced 85.73% labels that match with human labels from the AirBnB dataset. From the Vaccines dataset, 22.37% of Vader's labels match with human labels. In contrast, for the AirBnB dataset, SentiWordNet obtained 2.14% matches and 4.45% for the Vaccines dataset. In summary, SentiWordNet scored the farthest to a human's perception of sentiment on both datasets. Additionally, for the conflicting set, we discovered that SentiWordNet tends to score text as negative sentiment more than positive, whereas Vader was the opposite. This could be due to Vader's capability to handle social media features as the datasets contain online reviews of that nature. Furthermore, both the datasets are general, and thus it would be interesting to use an inherently negative dataset in the future, for example from the mental health domain, to see how both models would behave. Therefore, with these two datasets, Vader produced better scores compared to SentiWordNet.

TABLE I. SCORING MODELS MATCH WITH HUMAN LABEL

AirBnB		***Vaccines***	
Vader	**SentiWordNet**	**Vader**	**SentiWordNet**
85.73%	2.14%	**22.39%**	4.45%

C. Calculate Baseline Effectiveness

Since SentiWordNet and Vader show contradictory results to human labels, we then proceed to calculate baseline effectiveness i.e. the accuracy that could be achieved. Fig. 1 shows the processes involved. Each label set from SentiWordNet and Vader was used to train two popularly used ML algorithms, Decision Tree and Naïve Bayes. Cross-validation of five folds was employed. Afterwards, predictions of each dataset were generated. To know the accuracy of these predictions, we compare them against human labels.

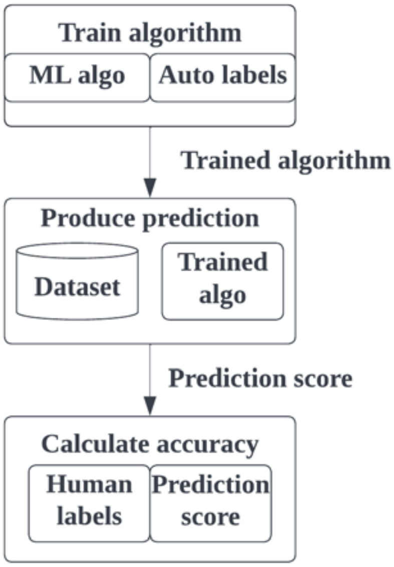

Fig. 1. Process of Calculating Baseline Effectiveness.

TABLE II. ACCURACY VALUES OF BOTH SCORING MODELS WITH SENTIWORDNET CHOSEN AS THE BASELINE

	Decision Tree (DT)		***Naïve Bayes (NB)***	
	AirBnB	**Vaccines**	**AirBnB**	**Vaccines**
SWordNet	**1.34%**	**0.00%**	**0.00%**	**0.00%**
Vader	86.54%	26.84%	87.88%	26.84%

Table II displays the baseline accuracy values. SentiWordNet labels produced substantially low accuracy across both datasets and both ML algorithms with values of 0.00% and 1.34%. Conversely, Vader labels achieved good accuracy for the AirBnB dataset of 86.54% (DT) and 87.88% (NB); the average for the Vaccines dataset with 26.84% (both DT and NB). To conclude, SentiWordNet's low-quality labels are less effective in a prediction task.

From the findings, it is interesting to learn the effects on prediction accuracy when a human expert is present to provide explicit feedback in the form of corrections to automatic labels. Hence, we performed several experiments to investigate.

D. Experimental HITL Framework Construction

To conduct this experiment, we developed a basic HITL framework and adapted it to incorporate human explicit feedback (Fig. 2). Our study did not lean towards any specific variants of HITL, alternatively, our interest is in exploring the generic idea of including humans in the labelling process to correct a small number of labels and observe the outcome. The framework consists of five layers: data, automatic label generation, algorithm training, prediction performance evaluation and label correction.

In the first layer, datasets are introduced into the framework. From these datasets, the scoring models will automatically generate labels. These scoring models are in-built with their own lexicon and thus do not require any annotated data point. Then, a human expert checks a small number of the produced labels and corrects them, if deemed necessary. By choosing to correct the labels or otherwise, the expert inadvertently injects explicit feedback into the framework. The output, a set of labels, becomes the training set for one or more machine learning algorithms. Once trained, the algorithms will produce predictions. The quality of these predictions, in the form of accuracy, is calculated to measure the effectiveness of the corrected automatic labels. A threshold of preferred accuracy is checked and if this threshold was not reached, the predicted labels are presented to the human expert for correction. Several iterations would occur until the threshold is met. Alternatively, if the human expert decided not to continue correcting anymore labels, the loop would end. This manifests the role of a human in the prediction loop; thus, the term human-in-the-loop framework.

The following questions are addressed in this work and the answers are explained in the next section.

Q1: What is the smallest percentage of corrected labels needed to improve prediction quality against a baseline?

Q2: Would randomly selecting automatic labels for correction produce better prediction than specifically choosing automatic labels with distinct data points?

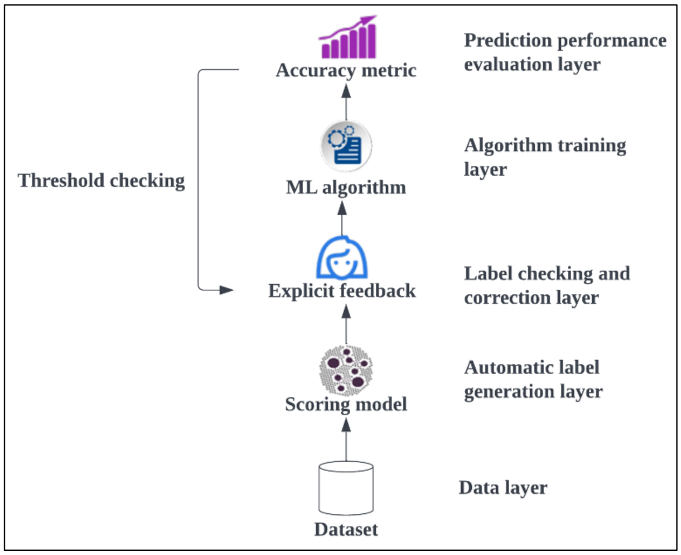

Fig. 2. Experimental HITL Framework.

IV. Result and Discussion

In this section, we describe the experimental setup and present as well as discuss the results and findings of our study. RapidMiner and Orange were employed as the simulation platform for these experiments.

A. *Experiment 1*

Aim: This experiment aims to answer Q1 where we want to determine at what percentage of corrected labels introduced in the loop would enhance accuracy. The threshold accuracy values are based on the baseline results in Table II. Since SentiWordNet yields accuracy values worse than Vader, therefore, it was used as the scoring model in this study.

Setup: We experimented with different percentages of human labels. Very small percentages of 10% and below were tested, followed by percentages of 20% and 35%. The labels were randomly selected. Two classic ML algorithms were used, Decision Tree (DT) and Naïve Bayes (NB). Cross validation of 5 folds was employed.

Result: Referring to Table III and Fig. 3, we found the following:

1) *Baseline test:* Only NB exceeded the baseline accuracy for both datasets (NB AirBnB – 99.14; NB Vaccines – 69.56). DT surpassed the baseline accuracy for the Vaccines dataset at 73.16, however, failed for AirBnB, reaching the highest accuracy of only 1.34 which is at par with the baseline.

2) *Small percentages test:* NB was able to achieve improvement in accuracy at even 1% of corrected labels for both AirBnB and Vaccines datasets. In contrast, DT did not improve for AirBnB but showed marked improvement (i.e. 73.16) only when 35% of corrected labels were supplied.

In summary, not all ML algorithms are suitable for HITL with few corrected labels. Nevertheless, with the right algorithm, a percentage of corrected labels as small as 1% can be effective in significantly enhancing accuracy. Depending on the characteristics of the dataset, further increment of accuracy beyond the initial value can occur early as witnessed from AirBnB when NB is employed. A jump in accuracy of 46.63 from 12.13 was attained at 9%. To note, these labels were chosen randomly, therefore, an interesting alternative is where a more deliberate strategy is tested. Experiment 2 explores this idea.

B. *Experiment 2*

This experiment investigates if by carefully choosing automatic labels with distinct data points would yield better accuracy than when the labels were picked randomly. The result of this experiment answers Q2. Distinct data points represent unique cases within the data space of a particular domain. This approach trains ML algorithms using a set of "small data" [23]. Small data supports the notion of quality over quantity. Here, a small number of high-quality data points that represents the majority of a population is more preferred than a large, primarily uniformed, collection of data points. Such uniformity can cause the algorithm to become blindsided and thus focuses only on a specific case, limiting its learning experience.

TABLE III. SentiWordNet Accuracy Values

	Decision Tree (DT)		***Naïve Bayes (NB)***

35%	1.34%	**73.16%**	**99.14%**	**69.56%**

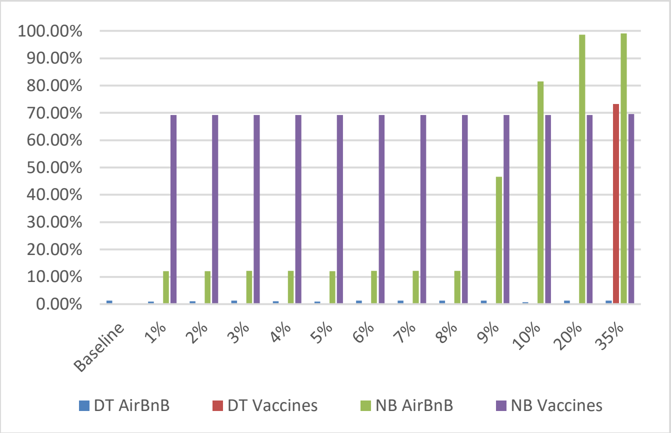

Fig. 3. SentiWordNet Accuracy Values Visualized with Bars.

To reflect the distinct nature of the data points, four techniques to calculate the distance between a pair of text were used and compared. They are Cosine, Euclidean, Jaccard and Manhattan. Afterwards, the resulting similar texts were clustered together. A dendrogram was formed and a cutting point was determined based on the production of a cluster set with a size of approximately 30 to 40 clusters. The rationale behind this condition is to produce an approximate minimum number of data points as in Experiment 1 for reasons of comparison fairness. In other words, 1% of AirBnB and Vaccines datasets, each. These data points and their labels were used to train both DT and NB. Stratification was included in this experiment to understand its possible influence on effectively producing better accuracy when there are very few human-corrected labels. Therefore, a combined total of 8 techniques were used. They are Non-Stratified Cosine (NSC), Non-Stratified Euclidean (NSE), Non-Stratified Jaccard (NSJ), Non-Stratified Manhattan (NSM), Stratified Cosine (SC), Stratified Euclidean (SE), Stratified Jaccard (SJ) and Stratified Manhattan (SM).

Setup: Alike Experiment 1, we experimented with different percentages of human labels. Very small percentages of 10% and below were tested, followed by percentages of 20% and 35%. The labels were obtained from across the derived cluster set to consist of as many unique representations as possible. Two classic ML algorithms were used: Decision Tree (DT) and Naïve Bayes (NB). Cross validation of 5 folds was employed.

Result: The following were discovered.

1) Baseline test: Generally, the results exhibit a similar pattern as found in Experiment 1, but with enhanced accuracy values in a majority of the cases. Table IV and Fig. 4 show the average accuracy of all eight techniques when no stratification was used with distinct data points. The result shows no difference in the accuracy of AirBnB when applied to DT where in both random and distinct data, DT did not surpass the baseline. In contrast, for Vaccine dataset, a higher accuracy was obtained at 78.00 while random data achieved only 73.16. With NB, it attained accuracy higher than the baseline for both datasets (NB AirBnB – 99.77; NB Vaccines – 77.79) and better than random data in Experiment 1.

When we compare to see if stratification of data can contribute to the improvement of accuracy, we found that this is true for NB but not for DT. Accuracy for AirBnB remained similarly low as the baseline i.e. 1.34 in DT. In addition, DT achieved only a slightly higher accuracy i.e. 78.07 with Vaccines dataset as compared to random data i.e. 78.00. Conversely, NB reached better accuracy in AirBnB and Vaccines datasets with stratification (NB AirBnB – 99.94; NB Vaccines – 77.85). Table V and Fig. 5 show the average accuracy for distinct data points with stratification applied.

Thus far, we can observe that in this HITL framework, taking advantage of distinct data points can produce better accuracy than just randomly selecting data for a human expert to check and correct. Additionally, applying stratification can further improve the produced accuracy. To understand the performance of each of the eight techniques, we selected the best values they produced against the baseline and the result is displayed in Table VI.

TABLE IV. AVERAGE ACCURACY FOR DISTINCT DATA POINTS WITHOUT STRATIFICATION APPLIED

SM	1.34%	75.90%	98.66%	75.67%

NSC-Non-Stratified Cosine; NSE-Non-Stratified Euclidean; NSJ-Non-Stratified Jaccard; NSM-Non-Stratified Manhattan; SC-Stratified Cosine; SJ-Stratified Euclidean; SJ-Stratified Jaccard; SM-Stratified Manhattan

None of the eight techniques successfully excelled over the baseline when DT was applied to the AirBnB dataset, but when NB was applied all surpassed the baseline for both datasets (Table VI). Furthermore, the top values from all the techniques were also generated when NB was used with AirBnB, even reaching 100% accuracy. For the Vaccines dataset, both DT and NB produced comparable accuracy values between 75 and 79, indicating generalization occurred well here. Jaccard, despite having stratification or otherwise, continually churned good accuracy in both AirBnB and Vaccines datasets (DT Vaccines – 78.88; NB AirBnB – 100; NB Vaccines – 78.68), but performed better with stratification.

2) Small percentages test: Similar to the result in Experiment 1, DT did not produce better accuracy for Vaccines dataset at 1% corrected labels. Nevertheless, using distinct data points resulted in the need of a smaller percentage i.e. 20% as compared to random selection i.e. 35%. Furthermore, better accuracy was obtained in this experiment i.e., 78.00 (Table IV) from 73.16 in Experiment 1 (Table III) with the same percentage of corrected label of 35%.

As with Experiment 1, NB showed better accuracy from baseline even at 1% of corrected labels for both datasets (Table IV). For AirBnB, the accuracy at 1% is identical to Experiment 1 (i.e., 12.12), yet, the improvement of accuracy occurred faster at 8% in contrast to 9% in Experiment 1. Unfortunately, this came with a cost of reduced accuracy i.e. 20.79 (Table IV). Applying stratification did not result in needing a smaller percentage different from without stratification.

In summary, supplying corrected labels with distinct data points can help in obtaining higher accuracy if coupled with a ML algorithm suitable for HITL as proven with NB on AirBnB and Vaccines datasets. Although both have different characteristics, indicating a generalized effect, more datasets will need to be tested to ascertain this. Overall, the role of stratification in affecting accuracy was positive, depending on the combination of a ML algorithm and dataset chosen. Applying an ensemble of similarity techniques can yield better result.

V. CONCLUSION

In this paper, we have investigated the effectiveness of using human-in-the-loop (HITL) to improve prediction accuracy by correcting automatically generated labels from existing scoring models such as SentiWordNet and Vader. As more recent work adopted the use of these scoring models in place of a training set, we took the initiative to understand if their inherent assumption of these labels being gold-standard-worthy is plausible. We experimented using two public datasets, AirBnB and Vaccines, in combination with two ML algorithms, Naïve Bayes and Decision Tree, where we discovered that Naïve Bayes produced better accuracy than Decision Tree at small percentages of corrected human labels. We also discovered that selecting labels with distinct data points to be corrected helps to enhance accuracy for Naïve Bayes but partially for Decision Tree.

Fuzzy Clustering Analysis of Power Incomplete Data based on Improved IVAEGAN Model

Yutian Hong*, Jun Lin
Guangdong Electric Power Information Technology Co., Ltd.
Guangzhou, Guangdong 520000 China

***Abstract*—The scale of data generated by the complex and huge power system during operation is also very large. With the data acquisition of various information systems, it is easy to form the situation of incomplete power data information, which cannot guarantee the efficiency and quality of work, and reduce the security and reliability of the entire power grid. When incomplete data and incomplete data sets are caused by data storage failure or data acquisition errors, fuzzy clustering of data will face great difficulties. The fuzzy clustering of incomplete data of the power equipment is divided into the processing of incomplete data and the clustering analysis of "recovered" complete data. This paper proposes an IVAEGAN-IFCM interval fuzzy clustering algorithm, which uses interval data sets to fill in the incomplete data, and then completes the clustering of interval data. At the same time, the whole numerical data set is transformed into a complete interval data set. The final clustering result is obtained by interval fuzzy mean clustering analysis of the whole interval data set. Finally, the algorithm proposed in this paper and other machine learning training data sets is made for experimental analysis. The experimental results show that the algorithm proposed in this paper can complete incomplete data sets with high precision clustering. Compared with other contrast methods, it shows higher clustering accuracy. Compared with the numerical clustering algorithm, the clustering accuracy is improved by more than 4.3%, and it has better robustness. It also shows better generalization on the artificial data sets and other complex data sets. It is helpful to improve the technical level of the existing power grid and has important theoretical research value and engineering practice significance.**

Keywords—Power system; power equipment; incomplete data; fuzzy clustering; mining algorithm

I. Introduction

With the development of the economy, along with the construction of the smart grid and smart distribution network informatization, the level of automation and interactive are raised. The IoT degree of mutual penetration and integration of power distribution networks as a direct link between the user and the power grid is also improved. The safe and stable operation of the distribution network is directly related to the electricity quality and reliability of power use. The reliability of the distribution network system is particularly important [1]. Due to the massive increase of all kinds of power data and the increase of complexity, the data processing speed and processing capacity are greatly improved with the help of computer clustering analysis, and it is widely used in many key parts of power [2].

Distribution network equipment will produce a large amount of data in operation, because in the whole distribution system, there are many equipment from different manufacturers. Their models are mostly different because these distribution equipment and background monitoring system will use their own transmission protocol communication, resulting in the existence of many communication methods. Due to the conversion of various interfaces and transmission protocols, it is inevitable to cause problems such as slow data transmission rate and loss of some data information. If these missing data are not effectively analyzed, the maintenance efficiency will be low, and the equipment operation status cannot be timely, accurately and finely evaluated. Finally, it will affect the operation quality and efficiency of the large power grid.

With the in-depth study of incomplete data attribute imputation algorithm, it is further found that interval data samples can better express the ambiguity of incomplete data and improve the accuracy and robustness of clustering [3]. In the fields of pattern recognition, image processing, fuzzy control, and clustering analysis, there were some relevant researches [4]. Scholars in China and abroad have proposed many improved algorithms and applications for interval fuzzy sets. Zhang and other scholars proposed an improved BP neural network interval filling incomplete data clustering algorithm, which uses a neural network to fill the interval range of missing attributes [5]. Li et al. proposed an interval kernel function fuzzy clustering algorithm, which uses the nearest neighbor rule to determine the missing attribute interval, and uses the kernel function fuzzy C-means to map and cluster the samples in high dimensions [6]. The above research content has obvious advantages for dynamic data and big data, but it is prone to complex and difficult computing problems in model construction. Trang and other scholars proposed an interval fuzzy co-clustering algorithm, which applies interval data to co-clustering to make the clustering results more accurate [7]. Reference [8] uses mutually exclusive maintenance, simultaneous maintenance, power grid security, resources and other constraints to constrain interrelated equipment, which comprehensively considers the status of power grid equipment, and power grid operation, and uses a tabu search algorithm to optimize the starting period of power transmission and transformation equipment maintenance in the whole network. The calculation methods in references [7] and [8] are relatively simple, but the accuracy of estimation needs to be further improved. The above research content does not fully tap the potential value of incomplete data, and the effective information is not fully utilized. The data processing of distribution network equipment operation big data will mainly

*Corresponding Author.

study the incomplete data objects in the distribution network equipment operation big data. The vector data repair technology based on genetic nearest neighbor clustering will study the data repair technology-oriented to the distribution network operation big data to facilitate the filling and repair of incomplete distribution network operation data objects [9].

To solve the problem of data loss in large-scale data, a deep learning generation model based on the conditional generation antagonistic network is designed according to the data characteristics. An optimization function is proposed according to the data characteristics. The replacement of training data is optimized, and the optimization constraints are proposed to make the interpolation model more effective. Based on the IVAEGAN-FCM algorithm, this paper proposes an IVAEGAN-IFCM interval fuzzy clustering algorithm, which uses interval data sets to cluster incomplete data. This study is closely related to the operation status of power equipment, which is conducive to improving the safe operation efficiency of power grid enterprises.

The main innovations of this paper are as follows:

1) A certain estimation error exists in the estimation of the missing attribute through the IVAEGAN model. The average value of all errors is taken as the interval size range of the interval type data to construct an interval type data set.

2) Calculate the extreme value of the attribute of the nearest neighbor sample of the incomplete data to restrict the interval size of each data.

3) Calculate the local density of the sample in the adjacent area of each sample, and further constrain the size of the interval through the local density of the sample.

4) Convert the whole numerical data set into a complete interval data set. To improve the accuracy of incomplete data clustering, the interval fuzzy C-means (IFCM) clustering analysis is carried out on the whole interval data set.

The main contents of this paper are as follows:

1) This paper introduces the importance of equipment data integrity in the power system operation.

2) In the related work, the power system equipment data and the IVAEGAN model are introduced.

3) The construction of the IVAEGAN interval model and the calculation of data integrity by the fuzzy clustering algorithm are done.

4) The IFCM algorithm is improved by using the IVAEGAN model.

5) The accuracy and effectiveness of the proposed algorithm are verified by experimental simulation analysis.

6) Finally, the research contents and results of this paper are summarized.

II. Related work

A. Analysis of Data Sources for Typical Power Equipment

Power grid automation helps power grid dispatchers to grasp the operating conditions of the power grid under their jurisdiction in real-time so that dispatchers can make correct dispatching decisions. At the same time, it can also provide data support such as load forecast for short-term and medium-term power grid production and development plans [10]. The centralized control mode of the substation is established to realize more and more automation systems with different functions. To improve the reliability, efficiency, and power supply quality of distribution network operation, the distribution automation system has been developed. At present, the dispatching automation system, substation integrated automation system, and distribution automation system have become the main components of the power grid automation system [11]. The power data studied in this paper takes the distribution equipment data as an example, and carries out data resources according to the equipment material information, as shown in Table I.

B. IVAEGAN Value Estimation Principle

1) An IVAEGAN model performs estimated value filling on missing attributes x_{ik} in an incomplete data set. Since the IVAEGAN model also performs estimated value calculation on data with complete attributes in a training process, an absolute error exists between an expected estimated value and an actual value, and the absolute value of an error average value is used as the interval size of the estimated value of the missing attributes. The left and right endpoints of the valuation interval are: x_{ik}^{-} , x_{ik}^{+} respectively. Then the incomplete data can be expressed in the form of interval, namely $\left[x_{ik}^{-}, x_{ik}^{+}\right]$;

For the complete data x in the incomplete data set, its complete attribute value x_{ij} also needs to be converted into the form of interval data, that is $\left[x_{ik}^{-}, x_{ik}^{+}\right]$, where $x_{ij}^{-} = x_{ij} = x_{ij}^{+}$. Therefore, the complete attribute of the complete data is also expressed in the interval type, and the left and right interval endpoints of the interval attribute are equal to the attribute value [12].

TABLE I. Power Cable Index System Table

part	First class indicator	Secondary indicator (state)
power cable	Cable body	Line load, Insulation resistance, Exterior, Fire fire flame retardant, Depth, filthy
	Cable terminal	
	Cable middle head	
	Cable channel	
	Auxiliary facilities	

Through the training process of the IVAEGAN and the evaluation process of incomplete data, the average evaluation error of the training process is determined as the range of interval size. The evaluation of incomplete data attributes is determined as the median of the interval to determine the evaluation interval of the incomplete data [13]. And then the complete numerical data set after the valuation "recovery" is transformed into a complete interval data set. Finally, the complete interval data set is subjected to fuzzy clustering analysis through the IFCM clustering algorithm, and the clustering result is obtained [14].

III. IVAEGAN Fuzzy Clustering Algorithm for Interval Estimation

A. IVAEGAN Model Construction

VAE (Variational autoencoder) is fused as the generator of GAN (Generative Adversarial Network), and the fused model is improved to obtain the IVAEGAN model. The IVAEGAN network is proposed to better estimate, predict and fill the missing data attribute values contained in the incomplete data set [15]. The core idea of the IVAEGAN network proposed in this paper is to feedback the difference between the predicted value of the incomplete data through the network generator and the discriminator to the input layer so that the network can obtain more information, and thus can better realize the estimation filling of missing attributes in incomplete data. This can make the filling value of missing attributes more reasonable, thus improving the effectiveness of clustering analysis. The topology of the improved model is shown in Fig. 1:

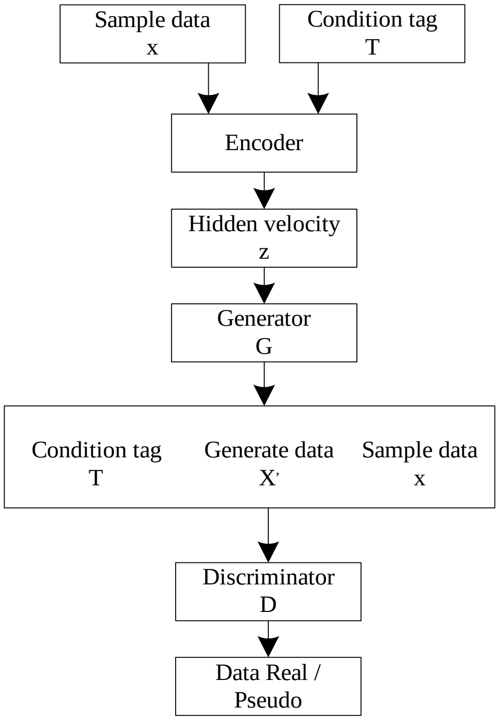

Fig. 1. IVAEGAN Model Structure.

The integration of variational learning and adversarial learning provides strong support for learning and reasoning in generative models, and these methods are used to establish new hybrid reasoning methods.

B. Interval reconstruction of numerical incomplete data set

Interval data $x=[x^-,x^+]$ and interval data $y=[y^-,y^+]$: the addition operation of interval type is expressed as: $x+y=\left[x^-+y^-,x^++y^+\right]$. Similarly, the definition of subtraction operation of interval data is expressed as: $x-y=\left[x^--y^-,x^+-y^+\right]$ [16]. Euclidean distance is commonly used in calculating relative distance, and the Euclidean distance formula for interval data is:

$$D(x,y)=\sqrt{(x^--y^-)^2+(x^+-y^+)^2} \tag{1}$$

The density of samples in a local area reflects the degree of clustering of samples, and also reflects the similarity between samples. The greater the density of samples in a local area, the closer the attribute values are. In this paper, the regional density of sample points is used to calculate sample density a, and the obtained attribute estimation interval $[\min,\max]$ is constrained to obtain a new interval: $\left[\min+\frac{a(\max-\min)}{2},\max-\frac{a(\max-\min)}{2}\right]$.

The calculation formula for the distance between samples x_p and other samples is shown in (2):

$$d_{pq}=\left\|x_p-x_q\right\|_2^2 \tag{2}$$

Let the attribute dimension be the s-interval dataset $\overline{X}=\{\overline{x}_1,\overline{x}_2,\cdots,\overline{x}_n\}$. The data $\overline{x}_i=[\overline{x}_{1i},\overline{x}_{2i},\cdots,\overline{x}_{si}]^T$, for any $\overline{x}_{ji}=\left[x_{ji}^-,x_{ji}^+\right]$, the objective function formula of the interval fuzzy C-means algorithm is shown in (3):

$$J_m(U,\overline{V})=\sum_{i=1}^{c}\sum_{k=1}^{n}u_{ik}^m\left\|\overline{x}_k-\overline{v}_i\right\|_2^2 \tag{5}$$

$$\sum_{i=1}^{c}u_{ik}=1,k=1,2,\cdots,n \tag{4}$$

$$\left\|x_k-v_i\right\|_2^2=\sqrt{(x_k{}^--v_i{}^-)^T(x_k{}^--v_i{}^-)+(x_k{}^+-v_i{}^+)^T(x_k{}^+-v_i{}^+)} \tag{5}$$

$\overline{v}_i$ represents the ith cluster center. $\overline{V}$ is the cluster center matrix, and is expressed as: $\overline{V}=\left[\overline{v}_{ji}\right]=[\overline{v}_1,\overline{v}_2,\cdots,\overline{v}_c]$, $\overline{v}_{ji}=\left[v_{ji}^-,v_{ji}^+\right]$, $i=1,2,\cdots,c$, $j=1,2,\cdots,s$ 。

The minimum condition of Equation (5) is:

$$v_i{}^-=\frac{\sum_{k=1}^{n}u_{ik}^m x_k^-}{\sum_{k=1}^{n}u_{ik}^m},i=1,2,\cdots,c \tag{6}$$

$$v_i^+ = \frac{\sum_{k=1}^{n} u_{ik}^m x_k^+}{\sum_{j=1}^{n} u_{ik}^m}, i = 1, 2, \cdots, c \tag{7}$$

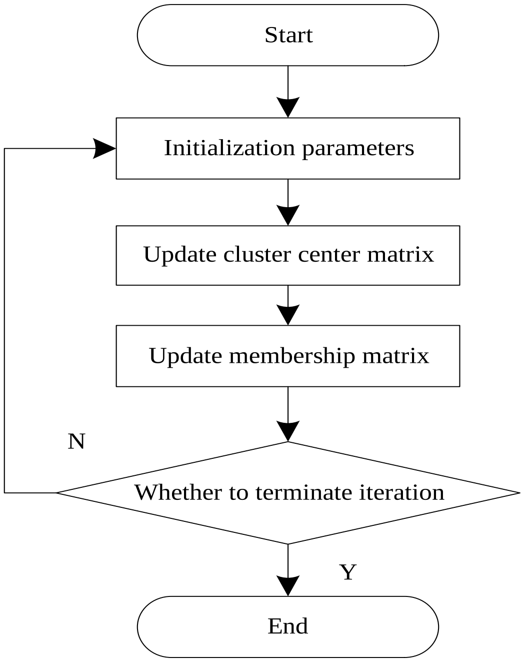
If there is an interval type data sample $\overline{x}_k$ within the interval value of a cluster center, its membership degree is set to 1; otherwise, its membership degree is 0 and it does not belong to this category. The formula is as follows:

$$u_{ij} = \begin{cases} 0, i \neq h \\ 1, i = h \end{cases} \tag{8}$$

Otherwise：

$$u_{ij} = \left[\sum_{t=1}^{c} \left(\frac{\left\| x_j - v_i \right\|_2^2}{\left\| x_j - v_t \right\|_2^2} \right)^{\frac{1}{m-1}} \right]^{-1}, i = 1, 2, \cdots, c; j = i = 1, 2, \cdots, n \tag{9}$$

The basic steps of IFCM algorithm are shown in Figure 2:



Start
Initialization parameters
Update cluster center matrix
Update membership matrix
N
Whether to terminate iteration
Y
End

Fig. 2. IFCM Algorithm Process.

1) Initialize algorithm parameters, namely set an iteration stopping threshold ε, a fuzzy clustering parameter m. The number of clustering is $c(2 \leq c \leq \sqrt{n})$ and the maximum iteration number is G. Initialize the membership degree matrix $U^{(0)}$.

2) Update a clustering center matrix: when that iteration time reach the $l(l = 1, 2, \cdots)$ time, update the clustering center matrix $U^{(l-1)}$ by using the clustering prototype calculation formulas (6) and (7) in combination with the membership degree partition matrix $\overline{V}^{(l)}$.

3) Update the membership degree matrix: update the partition membership degree matrix $U^{(l)}$ by using formulas (8) and (9).

4) Iteration termination condition of the algorithm: when the number of iterations reaches the maximum, or $\forall i$, k, $\max\left|u_{ik}^{(l)} - u_{ik}^{(l-1)}\right| < \varepsilon$, the iteration is stopped, then the IFCM algorithm stops and outputs the partition matrix U and the clustering prototype matrix $\overline{V}$; otherwise $l = l + 1$, return to step (2) [18].

C. The Autoencoder Algorithm Normalization Flow

The basic flow of the auto-encoder algorithm is as follows:

1) Input normalization. All the attributes of the input data is transformed into the number between [0, 1] to improve the flexibility of the model and eliminate the difference between the orders of magnitude of each attribute.

2) Initialize the auto-encoder model parameters. The parameters include the node number of input layer, the layer number of hidden layer, the node number of each layer of hidden layer, the encoder weight matrix, decoder weight matrix, center vector, maximum training times, and the model self-learning rate and parameters.

a) Input data. Sample points are drawn from the data set.

b) Random sampling in noisy data.

c) The SGVB gradient estimation.

d) Update parameters and weight.

e) Judge whether that parameter are converged.

f) Determination of termination. When the model is completely converged or reaches the maximum training times, the training is ended; otherwise, the step (3) is repeated.

IV. IVAEGAN-IFCM ESTABLISHMENT OF ALGORITHM

To solve the problem of incomplete data fuzzy clustering, an interval fuzzy clustering algorithm based on the IVAEGAN estimation (IVAEGAN-IFCM) is proposed to cluster the incomplete data sets. Through the IVAEGAN model, the incomplete data set is "restored" into a complete numerical data set, and the complete numerical data set is converted into an interval data set according to the interval rule proposed in this paper, and then the interval data set is analyzed by fuzzy clustering [19].

The specific algorithm flow of the IVAEGAN-IFCM algorithm is shown in Fig. 3.

1) Construct a nearest neighbor sample set for an incomplete data sample. The nearest neighbor samples are selected according to the nearest neighbor rule, and the nearest neighbor sample set of incomplete data is constructed.

2) Construct an attribute nearest neighbor sample interval of incomplete data. According to the interval rule proposed in this paper, the maximum and minimum values of missing attributes are determined in the nearest neighbor sample set of incomplete data to construct the nearest neighbor interval of attributes.

3) Determine the density of data samples in the neighborhood of incomplete data samples [20].

4) Input sample normalization. All data are converted into numbers between intervals$^{[0,1]}$, thus eliminating the difference of orders of magnitude between dimensions.

5) Initialize the IVAEGAN model. Initialize the network parameters in the IVAEGAN model, weight, bias value, maximum number of iterations, and training error.

6) Train the IVAEGAN model. The IVAEGAN model was trained on the complete data.

7) Fill in the missing attributes. The IVAEGAN model proposed in this paper estimates and predicts each missing data attribute in incomplete data, and at the same time obtains the estimation error of the IVAEGAN network for the complete attributes in the data set.

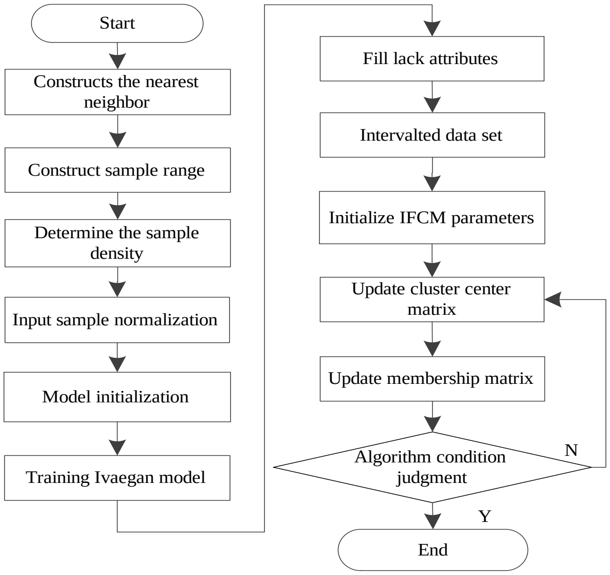
8) Interval data set: according to the interval type transformation rule proposed in this paper, all the data in the numerical data set are transformed into interval type, and then the interval type matrix is constructed.

9) Initialize the IFCM algorithm parameters. Initialize the membership degree matrix, and set the number of clustering categories, the number of cycles, the termination threshold and the fuzzy index.

10) Update the cluster center matrix. Update the clustering center matrix $V^{(l)}$ according to the clustering center matrix$U^{(l-1)}$.

11) Update that membership matrix. The statement $V^{(l)}$ updates the membership degree matrix$U^{(l)}$.

12) Algorithm condition judgment: when the number of iterations reaches the maximum, or $\max\left|U^{(l+1)} - U^{(l)}\right| \le \varepsilon$, the algorithm stops iterating; otherwise $l = l+1$, it returns to (10).



Start
Constructs the nearest neighbor
Construct sample range
Determine the sample density
Input sample normalization
Model initialization
Training Ivaegan model
Fill lack attributes
Intervalted data set
Initialize IFCM parameters
Update cluster center matrix
Update membership matrix
Algorithm condition judgment
N
Y
End

Fig. 3. IVAEGAN-IFCM Algorithm Process.

V. Experimental Analysis

A. Experimental Preparation

Aiming at the problem that the FCM clustering algorithm cannot directly use incomplete data for clustering analysis, this paper proposes a numerical incomplete data fuzzy clustering algorithm based on the IVAEGAN estimation. The missing attributes in the incomplete data are estimated and filled by the IVAEGAN model, and then the complete data set after recovery is analyzed by fuzzy clustering using the FCM clustering algorithm.

B. Construct the Artificial Dataset

In this experiment, the effectiveness of the algorithm is verified by artificial data sets, which are generated by the methods in the literature. Two artificial data sets are obtained. The artificial data set Test 1 contains two types of data. Each type has 1000 data samples, and the total number of samples is 2000 [21]. The artificial data set Test 2 contains three types of data, each type of data contains 800, 1000 and 2200 samples respectively, and the total number of data sets is 4000. Two artificial data sets subject to independent two-dimensional normal distribution are generated according to the above literature, and the conditional expectation and variance are as follows:

$$u = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} \quad \Sigma = \begin{bmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{bmatrix}$$

Where, the data generation parameters of manual data sets Test 1 and Test 2 are shown in Table II:

TABLE II. Artificial Datasets

	u_1	u_2	σ_1^2	σ_2^2
Test 1	3	3	2	2
	7	9	2	2
Test 2	28	24	6	6
	38	30	9	11
	50	42	17	20

According to the above generation method and parameter settings, generate a series of artificial data sets, in which the distribution of Test 1 is shown in Fig. 4, and the distribution of Test 2 is shown in Fig. 5.

In Fig. 4, the data in Test 1 is generated based on the first set of parameters. The two types of data are generated in equal quantities, and the data are evenly distributed, but the obvious differences of the data categories are maintained.

In Fig. 5, due to the different distribution and data amount of the three types of data, the first type of data is more concentrated, while the second and third types of data are more dispersed. The three types of data can still maintain relative independence, which is suitable for the validity verification of clustering algorithm.

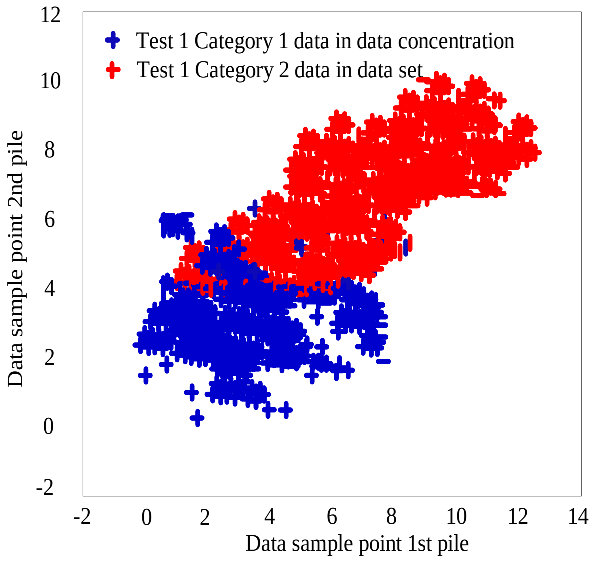


Fig. 4. Artificial Dataset Test 1.

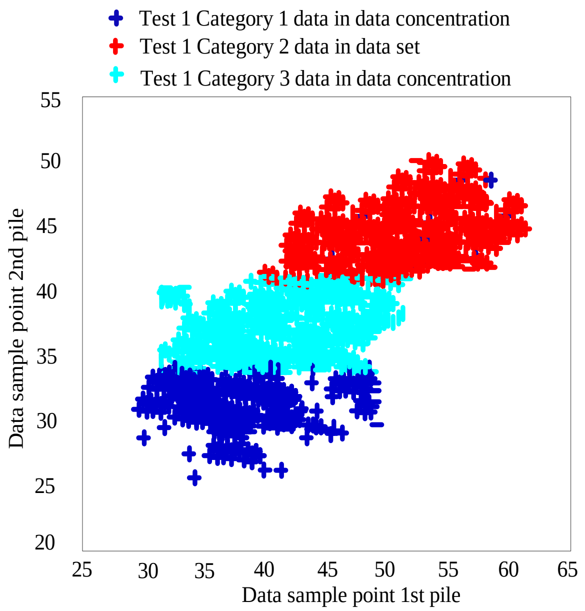

Fig. 5. Artificial Dataset Test 2.

C. *Incomplete Data Generation Rules*

In the whole data processing process, in order to make the incomplete data generated in the experiment closer to reality, the incomplete data set is generated by randomly discarding the data and randomly losing the complete data in different proportions set manually. In an incomplete data set, the missing attribute of the data sample is denoted by "?" to represent. The rules for generating data missing attributes of the incomplete data sets are as follows:

1) In an incomplete data set, the attribute values of a sample data cannot be completely lost, that is, if the data set is n-dimensional, the incomplete data in it can lose at most attributes, and at least one attribute of an incomplete data must exist.

2) In the incomplete data set, any one-dimensional attribute has at least one complete attribute value, that is, the attribute column of the data set cannot be empty to ensure the reliability of the valuation.

In the algorithm comparison experiment of this paper, the complete data strategy fuzzy C-means clustering algorithm (whole data strategy fuzzy C-means clustering) WDS-FCM) and the local distance strategy fuzzy C-means clustering algorithm (partial distance strategy fuzzy C-means clustering, PDS-FCM) are rejection methods [22].

The remaining two comparison algorithms optimize the complete strategy fuzzy c-means clustering algorithm (optimal completion strategy fuzzy C-means clustering, OCS-FCM) and the nearest prototype strategy fuzzy C-means clustering algorithm (Nearest Prototype Strategy fuzzy C-means clustering, NPS-FCM) belong to the valuation method [23].

The IVAEGAN-IFCM algorithm proposed in this paper uses the IVAEGAN model to estimate the incomplete missing attributes. The IVAEGAN model performs feature extraction and data generation on the incomplete data set. Meanwhile, the model combines the median of the neighbor data as the conditional label to make the estimation range more accurate and efficient. After the IVAEGAN model performs estimation filling on the incomplete data set, the obtained complete data set completes the fuzzy clustering, which improves the clustering accuracy [24]. Iris, Bupa and Breast data sets are used in the experiment. Each data set contains 500 samples, 11 feature categories and 9 attributes.

According to the average number of iterations in Tables III to V, the algorithm in this paper can converge stably after multiple iterations under different missing rates of each data set. Compared with other clustering algorithms, the algorithm does not achieve the best results, but it can still achieve stable results after a certain number of iterations.

TABLE III. AVERAGE ITERATION TIMES OF IRIS

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	25.1	25.3	27.5	27.8	30.5
10	25.9	26.3	27.9	28.2	30.8
15	26.1	26.7	28.6	29.3	31.4
20	26.8	27.1	28.8	29.7	31.8

TABLE IV. AVERAGE NUMBER OF ITERATIONS OF BUPA

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	33.7	36.2	36.6	36.7	36.5
10	35.6	37.4	39.1	37.7	39.3
15	37.3	35.9	38.6	38.9	42.4
20	38.6	36.5	36.8	40.3	46.2

TABLE V. AVERAGE ITERATION TIMES OF BREAST

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	15.3	15.2	16.4	15.6	18.4
10	15.9	16.3	16.8	15.7	18.9
15	16.1	16.8	17.2	16.3	22.3
20	16.9	17.4	18.6	17.2	24.6

According to the experimental results, the algorithm in this paper is relatively better, in the case of small data loss, such as 15% loss, the clustering effect of the numerical estimation method is better, which is obviously better than other algorithms.

From the standard deviation of clustering error scores in Tables VI to VIII, the algorithm in this paper can maintain a low standard deviation of clustering error scores under different missing rates of different data sets, which reflects the stability of the algorithm. In some cases, such as the case of less missing rate, the optimal solution cannot be obtained, and in other cases, the best results can be obtained.

TABLE VI. STANDARD DEVIATION OF IRIS CLUSTERING ERROR SCORE

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	1.24	1.56	2.02	1.86	2.03
10	2.15	1.75	1.95	1.78	1.78
15	2.08	1.89	2.04	169	1.93
20	2.09	1.92	2.01	2.07	2.04

TABLE VII. STANDARD DEVIATION OF BUPA'S CLUSTERING ERROR SCORE

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	2.03	2.36	2.12	2.36	2.04
10	1.83	1.89	2.05	2.04	2.12
15	2.51	1.38	1.89	2.01	2.23
20	2.18	1.94	1.95	1.98	2.64

TABLE VIII. STANDARD DEVIATION OF BREAST CLUSTERING ERROR SCORE

Missing rate /%	WDS-FCM	PDS-FCM	OCS-FCM	NPS-FCM	Algorithm
5	3.54	3.12	3.45	2.89	4.31
10	3.57	2.92	3.23	2.96	4.56
15	3.26	3.02	3.21	3.25	4.89
20	3.58	3.08	3.04	3.12	4.97

Test results show that the algorithm in this paper is better than other algorithms on the whole. Compared with other algorithms, the performance of our algorithm is improved by 4%. 3% when the missing rate of the data set is low, such as the missing rate of 5% and 10% of the small data loss. With the increase of the missing rate, the test performance of the sample is also gradually improved. It is proved that the algorithm proposed in this paper can fully show the uncertainty of incomplete data estimation by using interval data, and has superior performance in the process of missing data filling and clustering analysis.

The WDS-FCM algorithm eliminates all the incomplete sample data in the data set and only performs fuzzy clustering on the complete sample data. The clustering accuracy of the algorithm will be greatly affected when the proportion of incomplete samples increases. The PDS-FCM algorithm replaces the Euclidean distance in FCM with the local distance formula, and only adds the iterative operation to the complete attributes in the processing of incomplete sample data, without considering the missing attribute information of incomplete samples, which does not give full play to the information value of incomplete samples. Therefore, both the WDS-FCM and the PDS-FCM do not make full use of the effective information value of the mining incomplete data. The IVAEGAN-FCM algorithm proposed in this paper does not delete and abandon incomplete data, but reconstructs the model to fill in the missing data, so that the data set can be "restored" to a complete data set. The training samples are used to train the IVAEGAN model, and the missing attributes of each incomplete attribute are estimated and filled to obtain the "recovered" complete data set, and then the complete data set is subjected to fuzzy clustering.

VI. CONCLUSION

In this paper, according to the incomplete data formed in the power system, a numerical incomplete data fuzzy clustering algorithm based on the improved IVAEGAN estimation is proposed to solve the problem that the traditional clustering algorithm cannot directly use the incomplete data. A new fusion model is constructed by combining VAE and GAN to estimate and fill the incomplete data. The main work includes:

1) Fill the incomplete data attributes to realize the estimation clustering. A fuzzy clustering algorithm for numerical incomplete data based on the improved IVAEGAN estimation is proposed.

2) Construct a nearest neighbor sample set for that incomplete data according to the nearest neighbor rule, generating a model VAE and a model GAN, and constructing an IVAEGAN model.

3) Construct a missing attribute label by using that median value of the attribute of the nearest neighbor sample set so that the IVAEGAN model can obtain more effective information, and the estimation accuracy is improved.

4) UCI data sets and two artificial data sets are used for comparative experiments to verify the effectiveness of the algorithm, and the effectiveness of the algorithm is summarized in depth.

The model in this paper uses the gradient integral to update the parameter values, which is fast and has high computational complexity, and has obvious effect on improving the training speed. Compared with other models, this paper uses the attributes of the nearest neighbor sample set to construct condition variables, and other construction methods of condition variables are more effective, which further optimizes the space and improves the theoretical and practical basis of data integrity research. The research results of this paper are very important to fully mine the effective information in the incomplete data of power system, and play an important role in ensuring the normal operation of power system.

In the future work, more optimization methods will be used to optimize the parameter update, such as the wolf pack optimization algorithm. The GAN model is prone to the phenomenon of gradient explosion, center collapse and training non-convergence to further enhance the space for improvement.

MCBRank Method to Improve Software Requirements Prioritization

An Empirical Investigation

***Abstract*—Software Requirements Prioritization is an important issue that has a more profound effect on the overall quality of software development. Application of software requirements prioritization provides benefits to minimize risks in software development so that the most important and most impactful requirements are given priority. This paper presents a proposed software requirements prioritization method named MCBRank, which incorporates renowned MoSCoW Method and Case-Based Ranking to improve prioritization correctness. It elaborates on the implementation of MCBRank in an empirical investigation to determine software requirements prioritization for a potential e-library system. The investigation allows the software requirements prioritization process to be implemented by using the proposed MCBRank method. A role-playing empirical investigation with 30 respondents prioritized 31 software requirements, and the results were measured by Cohen Kappa. The kappa results show that MCBRank achieves a better agreement towards the Gold Standard with kappa value of 0.60. Therefore, the investigation results support that MCBRank improves the importance of ranking correctness, representing the stakeholders' wants and the organization's actual needs for the potential e-library system.**

***Keywords*—Requirements prioritization; requirements engineering; software engineering; empirical software engineering**

I. Introduction

Requirements play an essential part in software development as they lay a foundation for a system to be developed [1]. Among many factors influencing the success or failure of software development, prioritization seems vital as it is responsible for determining the value of various requirements proposed by many stakeholders based on specific criteria defined from their usefulness for the final software product [2]. Thus, requirements prioritization is an essential part of requirements management. It is responsible for identifying the subset from many candidate requirements to maximize the fulfilment of various limitations such as resources availability, constrained timeline, and budget.

Thus, the main objective of the prioritization is to ensure that the customers get the software system that satisfies their needs with utmost value within limited resources. This is supported by a study [3] that stated Software Requirements Prioritization (SRP) could affect several factors in software development such as value, time to market, cost, and, most importantly, user satisfaction. Using SRP, the requirements will be prioritized based on human choices and by analyzing several factors that can be the reason for a product to fail or succeed.

The importance of having the correct prioritized requirements which fulfil the stakeholders' needs [4] and the difficulty of getting a good set of requirements that satisfy the business value motivate this research to propose an enhanced MoSCoW prioritization method called MCBRank. The proposed method incorporates renowned MoSCoW method and Case-Based Ranking method to improve the prioritization correctness. In this paper, an empirical method is adapted to evaluate the MCBRank effectiveness to prioritize software requirements. Therefore, this paper presents the empirical investigation of the MCBRank prioritization method based on a case study. The empirical result showed that the MCBRank method improves the software requirements prioritization correctness which represent the stakeholders' wants and the organization's actual needs for the potential e-library system.

Following the introduction, Section II presents the literature review. Next, Section III presents the proposed prioritization method, and Section IV explains the empirical investigation methodology. This is followed by Section V that discusses the empirical investigation results. Finally, Section VI concludes the paper.

II. Literature Review

Requirements prioritization refers to the process of choosing the correct set of specifications from a mass of overlapping and contradictory demands from various stakeholders involved in a software development project. Prioritization is one of the critical steps in system development to make meaningful decisions to scrutinize essential requirements for realization. This is supported by a study which stated that requirements prioritization has an enduring partnership with several other important technical practices such as interaction with the requirements analysis, requirement engineering, and general software engineering practices [5].

Gilb and Maier [6] stated that "priority is the relative right of a requirement to the usage of restricted (or scarce) capital." In this description, "capital" includes all kinds of capital, including time, money, and human capital. In other terms, we can have anything of the infinite system; then, there is no need to consider the requirements. However, ventures usually face finite capital such as short deadlines, restricted budgets, limited human capacity, and fixed technologies. Consequently, proposals sometimes include more requests than what can be executed in one release period. Thus, requirements prioritization enables the project planners to choose the final requirements to be implemented under resource constraints.

Various requirements prioritization techniques exist, but using the same technique to assign requirements for multiple stages may result in restricted benefits [7]. Different requirements prioritization techniques involve various properties, and therefore selecting the most optimal technique will optimize the gains gained at specific points [8]. These techniques enable the software development team to prioritize software requirements with high priority [9]. According to a study [5], there are many methods used to classify requirements. These prioritization methods may be classified as nominal scale, ordinal scale, ratio scale, machine learning, and hybridization, as shown in Fig. 1.

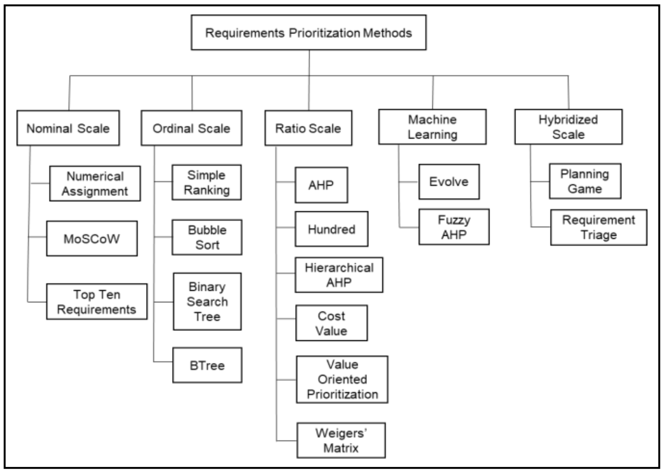

Fig. 1. Requirements Prioritization Method [19].

Other than methods, the elements being considered during the prioritization process are also essential. Hujainah et al. [10] provide a comprehensive investigation of the interrelated elements that need to be considered to formulate practical requirements prioritization technique. The findings reveal four interrelated elements that should be considered in developing RP techniques to secure an effective prioritization process. These elements are criteria for requirements, stakeholders, procedures, and implementation, which play important roles in prioritizing requirements. To incorporate the interrelated elements for prioritization, further research [11] proposed a semi-automated scalable prioritization technique to improve the prioritization efficiency for a large-scale project.

The fact that stakeholders’ preferences need to be considered is also supported by Yaseen et al. [12]. It is noted that large numbers of requirements are likely to be developed based on the customers' preferences stated in the early stage of the requirements engineering phase. However, diverse stakeholders need to be considered since specific requirements are important for particular customers but not others [13]. Furthermore, customers may generally understand what they want but do not have a specific picture of precisely what is needed for a well-functioning software system. Therefore, requirements prioritization may assist the development team in shortlisting the requirements because essential requirements should be presented to the stakeholders as quickly as possible. In addition, should conflicting requirements surface, requirements prioritization can be performed to resolve the conflicts. This is also supported by Ma [7], who stated that requirement prioritization refers to the process of choosing the correct set of specifications from a multitude of overlapping and contradictory demands from various stakeholders involved in a software development project.

Achimugu et al. [14] performed a systematic review of 48 Software Requirements Prioritization methods and found that MoSCoW is the most cited and utilized prioritization method. Miranda [15] noted that the MoSCoW is a more straightforward method of obtaining information from customers, meaning that customers better understand what is being asked of them and thus provide the development team with more meaningful and valuable information. Moreover, the MoSCoW is suitable for iterative development such as "agile software development" [16, 17, 18], which allows collaborative requirements prioritization between stakeholders [19]. This collaborative effort provides the customers with a product of a maximized business value [20]. On the other hand, the MoSCoW needs more time as detailed information is required to provide a relative value for each requirement. Besides MoSCoW technique is a numerical assignment technique that needs more effort to solve conflicts between analysis and stakeholders' viewpoints [21].

Meanwhile, Avesani et al. [22] proposed a framework called Case-Based Ranking that can reduce the acquisition effort by combining human reference elicitation and automatic preference approximation. The result shows improvement in requirement prioritization accuracy and a trade-off between experts’ elicitation efforts. During the requirements analysis process on deciding which requirements to develop, different methods are used to select the correct requirements due to the system development team's preferences and work nature.

While MoSCoW and CBRank have received a great deal of attention in the literature, MCBRank method is designed to emphasize the strength of both techniques to improve software requirements prioritization.

III. The Proposed Method

According to Yaseen et al. [23], it is necessary to recognize requirements' importance and priority to assist the developers in expediting the system development process. MCBRank enables two-layer prioritization to improve the correctness in terms of importance ranking. In this research design, the importance is represented by the key stakeholders’ cumulative needs for the best of the system to be developed. Fig. 2 gives an overview of the MCBRank. Firstly, all candidate requirements which come from multiple stakeholders are listed. Then the key stakeholders are required to classify each requirement based on the adapted MoSCoW method on five points scale. The MoSCoW classification of M (Must have), S (Should have), C (Could have), and W (Would have) are assigned with numbers as listed below. ‘Must not have this’ is added into the scale to allow stakeholders to indicate the requirements they do not want to be realized.

5 - Must have this.

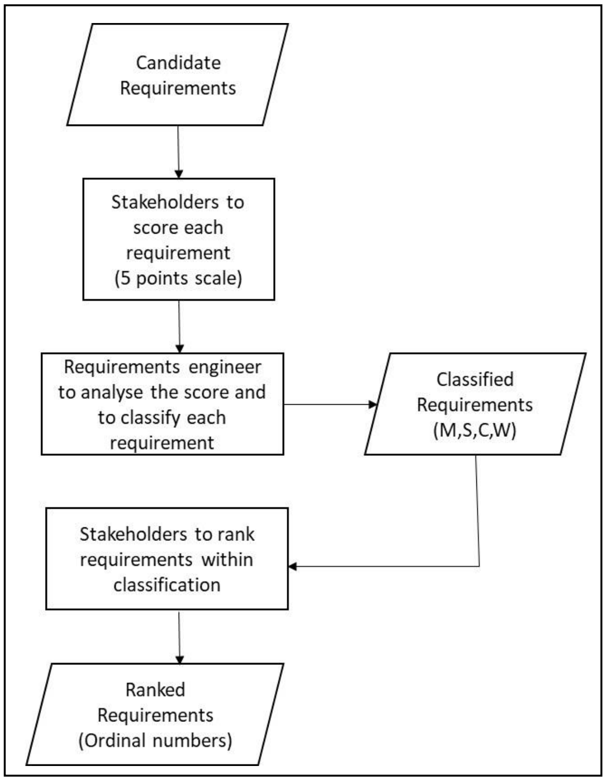
4 - Should have this if at all possible.

3 - Could have this if it does not affect anything else.

2 -Will not have this time but would like in the future.

1 - Must not have this.

Following that, the classification score based on the scale will be used to classify all the requirements into M (Must have), S (Should have), C (Could have), and W (Would have). At this point, the unwanted requirements will be discarded.



Candidate Requirements
Stakeholders to score each requirement (5 points scale)
Requirements engineer to analyse the score and to classify each requirement
Classified Requirements (M,S,C,W)
Stakeholders to rank requirements within classification
Ranked Requirements (Ordinal numbers)

Fig. 2. Overview of MCBRank.

Next, within the classification, each requirement will be ranked using ordinal numbers. The majority rank will be the position of the requirement. If the majority rank is the same for two or more requirements, a smaller accumulative score given by the participating stakeholders will be in a higher rank. Finally, a new ranked requirements list is produced.

This ranking allows stakeholders to prioritize the requirements, delineate and narrow the scope of work to acquire focus. Priorities make it possible to measure how important the stakeholders feel about each requirement concerning a software solution to meet their needs. The prioritized requirements successfully narrow the focus, which helps in group agreement. Through priority [12], if it is impossible to develop all project requirements, it is feasible to discriminate the most critical requirements to the stakeholders. This means that a project that does not meet all of its requirements can still be of high value if it meets the stakeholders' most important requirements.

A. *An Example*

Assume that there are ten requirements proposed by three key stakeholders numbered as Req. 1 until Req. 10.

Step 1: The key stakeholders to score the listed requirements based on importance (5 points scale).

Requirements	**Stakeholder 1**	**Stakeholder 2**	**Stakeholder 3**
Req 1	5	5	4
Req 2	4	4	5
Req 3	5	4	5
Req 4	5	3	5
Req 5	3	3	4
Req 6	4	5	5
Req 7	5	2	1
Req 8	3	4	3
Req 9	2	3	3
Req 10	1	2	1

Step 2: The requirements engineer to analyze the score and to classify each requirement. In order to do this, the requirements engineer need to analyze the requirements and take into consideration the technical knowledge on top of just importance classified by the stakeholders. This is required to ensure the essential services for the said system is not neglected.

Req.	**Stakeholder 1**	**Stakeholder 2**	**Stakeholder 3**	**Group**
Req 1	5	5	4	M
Req 2	4	4	5	S
Req 3	5	4	5	M
Req 4	5	3	5	M
Req 5	3	4	4	S
Req 6	4	5	5	M
Req 7	5	2	1	W
Req 8	3	4	3	C
Req 9	2	3	3	C
Req 10	1	2	1	discard

Step 3: Within each classification group, the key stakeholders to rank requirements based on ordinal numbers. The majority will be the rank of the requirements. Note that, the ordinal number will follow through based on classification group priority. For example, Req 2 is ranked as 1 within Group S, then the number must be after the last number in the group M. Therefore, Req 2 is ranked as 5.

Group	**Req**	**S 1**	**S 2**	**S 3**	**Rank**
M	Req 1	2	1	2	2
	Req 3	1	2	1	1
	Req 4	3	4	3	3
	Req 6	4	3	4	4
S	Req 2	1	2	1	5
	Req 5	2	1	2	6
C	Req 8	2	2	1	8
	Req 9	1	1	2	7
W	Req 7	1	1	1	9
-	Req 10	-	-	-	-

IV. Empirical Investigation methodology

An empirical investigation method was carried out to evaluate the effectiveness of the proposed MCBRank Method. It is a role-playing investigation to test if the requirements prioritization is improved following the implementation of MCBRank.

A. The Underlying Concept

The underlying concept includes an explanation and rationale for the terms and approaches applied.

- Stakeholders are terms that refer to any person or group directly or indirectly affected by the system. Stakeholders include end-users who interact with the system and everyone in the organization who may be affected by its installation. Other system stakeholders may be engineers who develop or maintain related systems, business managers, domain experts, and union representatives. These stakeholders are the key people representing the interests of their group. They may include end-users, system owners, and managers who work together and are actively involved in decision-making to reach mutually satisfactory agreements. However, it is neither appropriate nor possible to have all system stakeholders in acquiring requirements. Therefore, during the role-play investigation, this project will involve key stakeholders to represent users and administrators.

- The Gold Standard (GS) is a term used to describe the theoretical idea of the best requirements set that can exist for a system. In this requirements prioritization study, the 'ideal' set represents the right ranked requirements based on importance, representing the cumulative key stakeholders' needs and the actual need of the organization. This is because a sound system should fulfill what the stakeholders want and what the customers describe is what they want and what the organization needs from the system to be developed. However, there is no way to test this benefit in the short term. That is why this study presents the GS to represent a set of right ranked requirements based on importance from the domain experts' point of view. The domain experts are familiar with the crucial need of the system to fit the system's purposes of existence and understand the system's business value. The GS is determined by the candidate requirements and the collaborative efforts of researchers and several domain experts in the field. The experts are library practitioners ranging from thirty-five to fifty years old, with more than ten years of experience working in the library for Universiti Teknikal Malaysia Melaka. It is established as a benchmark for the best possible requirements with the correct importance rank for the particular case study; e-library system. The results from the investigations that will be carried out will be measured against the GS.

B. Gold Standard Formulation

This subsection describes how the researcher obtained the Gold Standard (GS). The GS is an ideal set of ranked requirements based on importance from the point of view of domain experts. The GS is obtained through an expert judgment technique that involves a group of domain experts. GS is a term used to describe the theoretical idea of the ideal set of well-ranked requirements based on importance for a system. GS was developed carefully by identifying some requirements that contain all the primary requirements required for the system. Researchers are aware that it is impossible to find a precise solution, but estimates can be determined based on the analysis of several experts.

Subjects involved in determining GS are experts who are library practitioners with criteria aged 30-50 years, have more than ten years of experience in related fields, and come from the Universiti Teknikal Malaysia Melaka. The procedures carried out are:

- In the first step, the researcher prepares a set of instruments containing an introduction, instructions, e-library scenario description, and a decision form that contains 31 candidate requirements to collect expert opinions.

- In the second step, screening and determining experts based on predetermined demographic components were conducted. This study involved six experts in determining GS.

- In the third step, the experts were given three days to examine the GS determination instrument to get familiar with the introduction, instructions, descriptive scenario, and a list of candidate requirements. Experts will get an overview of the background system from which the requirements were obtained through descriptive scenarios. Then the experts were asked to provide a rating with a Likert scale of 1-5 on the decision form. The scale of the assessment technique used in this study was adapted from the MoSCoW method.

Following the three steps above, the researcher gets the results of the requirements that have been ranked according to the highest to lowest rated. These properly ranked requirements are determined as GS. The value of each requirement is obtained from the total rate given by the six experts. Sorting has no problem when a requirement has different total values and does not get an equal value. For the first and second ranks, there were no obstacles. As for rank three and four, the total value for requirements R6 and R29 are the same, but since R29 has a higher number of five-point rating which means that more people rate R29 as 'Must have, R29 is placed in the third rank followed by R6 in the fourth rank. This also applied to the requirements R7, R5, and R22; R9 and R27; R17 and R23. As for requirements R26 and R12, which have the same total value and the same number of five-point ratings, R26 was decided to be in a lower rank than R12 because there exists a lower point rating for R26. Fundamentally, for the rest of the requirements, if the total value is the same and if the five-point rating is the same, then a lower point rating, if it exists for one of the requirements, will determine the ranking of the said requirements.

The formation of the GS in this investigation was done carefully since the GS represents an ideal set of requirements with the right importance ranking (theoretically represents both the stakeholders' wants and the organization's needs). The right rank of importance will determine the most crucial requirements to be realized to reduce the timeline or budget shortage. Thus, the output of the MCBRank will be measured against the GS to evaluate its effectiveness.

C. Investigation Method

1) Investigation materials: The candidate requirements are derived from the e-Library descriptive scenario. Ideally, the candidate requirements are proposed by independent stakeholders (or by a group of stakeholders) [24], represented by participants who play roles as a system's stakeholders in this investigation. However, the investigation focuses on the requirements prioritization effort with the proposed method and the researchers' candidate requirements prepared in advance. Requirements are built on the experience of researchers in using the system. They are improved by academics who previously have years of experience in developing systems and working on requirements. For prioritization purposes, candidate requirements are constructed to represent the interests and needs of various stakeholders. Candidate requirements include essential system features and additional features with a mix of quality values. In addition, the requirements also meet SMART concept; (S)pecific, (M)easurable, (A)greed, (R)ealistic, and (T)ime-bonded [3]. The number of candidate requirements is balanced and adjusted to the interests of specific key stakeholders. This is generally based on the purpose of the investigation. The number of candidate requirements was set for the experiment considering its time to rank effectively.

2) Population and sample: The investigation was carried out with 30 people, and the role-playing technique was exercised. Each was given a role as a user (students, lecturers, university staff) and administrators (librarians). Participants who carried out the investigation had a background in software engineering knowledge and were between 20 to 30 years old. Several of them have work experience in software development. To avoid bias, the roles they played in the investigation were randomized. Also, role-playing investigations always attend to whether the participants are actually playing a role or are merely including their judgments. It is expected that each participant will be more committed to individual priorities. Participants are given an exact role to minimize that possibility and given instructions and guidelines on playing system stakeholders' positions. Since participants may also have limited knowledge to precisely rank all candidate requirements concerning their impact on the acceptance of the software system [19], scenario descriptions and candidate requirements have been given to them in advance. This reading material is helpful because the scenario description describes the system needs and concerns of different stakeholders. In addition, the candidate requirements are carefully tailored to the needs of specific stakeholders.

3) The investigation protocol: For investigation, participants were divided into two groups. Each group consisted of thirty participants to rank candidate requirements based on the role they were playing. One group was a control group to exercise the MoSCoW prioritization method, and the other group exercised the MCBRank prioritization method. The results of the investigation are a prioritized list of software requirements.

Initially, during the investigation process, all participants were given scenario descriptions of potential e-libraries. Furthermore, a briefing was conducted on the experimental background knowledge through online communication. This is followed by instructions supported by an overview of examples of step-by-step activities. The assignment of participants is tailored to the role that will be played during the investigation. The participants were given a day to understand the roles and descriptions of the scenario prepared for them. The next day, participants were given a google form link and asked to prioritize the candidate requirements based on the MoSCoW method and MCBRank method. The participants' prioritization effort was then collected and analyzed. When all the participants had completed the assignment, a feedback form was given to them to learn about the strengths and weaknesses of the investigation for future references.

D. Justification of Results Measures

A study [25] introduced the concept of a perfect set of requirements (here termed the 'Gold Standard'), and measurements of progress towards such an ideal are made. Cohen's Kappa [26] is used to measure agreement between two assessors. Cohen's Kappa is an inter-rater reliability index commonly used to measure the level of agreement between two sets of dichotomous ratings or scores. It is generally a more robust measure than simple percent agreement calculation since it considers the agreement occurring by chance. Here, Cohen's Kappa is used to measure the agreement between requirements prioritized using MCBRank and the Gold Standard. The two raters are the group exercising the MCBRank and the domain experts who provide the Gold Standard. Kappa values show the movement of the agreement towards the Gold Standard. The nearer the agreement to the Gold Standard, the better quality it is. Therefore, the suitability of this metric is discussed, and its relevance to this study is stated.

Each participant prioritizes each requirement by using the MoSCoW or MCBRank methods. The prioritized requirements resulting from both methods were evaluated against the GS using the Cohen Kappa. Cohen's Kappa is used to measure the distance or degree of agreement between the GS and a set of requirements obtained through the application of the MCBRank in the investigation. If the agreement between results from the MCBRank and GS is better than the agreement between MoSCoW and GS, then the MCBRank method has succeeded in improving the level of correctness in requirements prioritization.

V. Results and Discussion

The empirical investigation evaluates whether the enhanced MoSCoW method named MCBRank can improve software requirements prioritization in terms of the correct rank of importance. Role-playing technique as key stakeholders to the e-library system was exercised in this study where the participants were to prioritize the candidate requirements using the proposed method. The purpose of this study is to evaluate the MCBRank method.

A control group was formed to exercise the MoSCoW method to be compared with the proposed method (MCBRank). The results obtained from the MoSCoW method and MCBRank method were both calculated. The level of agreement of both methods with GS was calculated using the Cohen Kappa formula.

The formula to calculate Cohen's kappa for two raters is:

$$k = \frac{P_{o-}\, p_e}{1 - \ p_e}$$

where:

P_o = total number of requirements that have the same rank position in GS.

p_e = total number of expected similarities that would occur if the observers were statistically independent.

Cohen's kappa measures the agreement between two raters who classify several items into several mutually exclusive categories. Landis and Koch [27] mention that labels with appropriate kappa ranges should be used to maintain consistent terminology when describing the relative agreement strength associated with kappa statistics. Table I presents the agreement strength based on Cohen Kappa.

The prioritized requirements obtained from the MoSCoW method were calculated, and the agreement to the GS is presented in Table II.

Based on the guideline adapted from Landis & Koch [27], a kappa (κ) of .067 represents a poor strength of agreement. Furthermore, since p = .042 (which means p > .0005), our kappa (κ) coefficient is not statistically significant. Meanwhile, Table III presents the measure of agreement between prioritization obtained from the MCBRank method and GS.

Meanwhile, a kappa (κ) of .600 represents a moderate strength of agreement. Furthermore, since p = .000 (which means p < .0005), our kappa (κ) coefficient is statistically significant.

Kappa values show the movement of the agreement towards the Gold Standard. The nearer the agreement to the Gold Standard, the better quality it is. The investigation was carried out to determine whether there was an agreement between the prioritized requirements achieved through the MoSCoW method to the GS and those achieved through the MCBRank to the GS. There is a poor agreement between the MoSCoW method and the GS, κ = .067, p> .0005. On the other hand, the kappa value shows a moderate strength agreement between the MCBRank method and the GS, κ = .600, p <.0005. Through the investigation, this research demonstrates that the set of prioritized requirements obtained using the MCBRank method moves closer towards the ideal Gold Standard compared to the prioritized requirements obtained using the MoSCoW method. Therefore, requirements prioritization in terms of the correct ranked requirements based on importance is better achieved through MCBRank.

A. Limitations

The research was conducted in a limited time frame, and therefore there are several limitations in the investigation conducted as stated below:

- It is ideal to have candidate requirements proposed by the participants. However, due to limited execution time and the need to focus on the prioritization exercise, the researchers carefully prepared the candidate requirements based on a specific case study. Ample time is given for the participants to understand the requirements before the prioritization activity.
- It is best to have a complete set requirement for at least an industrial small size system to investigate the requirements prioritization performance [28]. However, the candidate requirements were reduced to allow sufficient time to exercise prioritization activity. The researchers carefully selected the right combinations of requirements which consist of importance variety to allow the requirements prioritization activity to happen.

TABLE I. Strength of the Agreement based on Cohen kappa

Kappa Statistic	Strength of Agreement
<0.00	Poor
0.00-0.20	Slight
0.21-0.40	Fair
0.41-0.60	Moderate
0.61-0.80	Substantial
0.81-1.00	Almost Perfect

TABLE II. Symmetric Measures of GS and MosCoW Method

		Value	Asymptotic Standard Error[a]	Approximate T[b]	Approximate Significance
Measure of Agreement	Kappa	.067	.055	2.033	.042
N of Valid Cases		31

VI. CONCLUSION AND FUTURE WORK

An enhanced method is commonly understood to provide better results, but it is merely an assumption if scientific data does not prove the claim. Therefore, this paper presents an empirical investigation to show that an enhanced MoSCoW method named MCBRank improves software requirements prioritization. The empirical results showed that the requirements could be better prioritized closer to the Gold Standard and represent cumulative importance values from multiple stakeholders of a software system.

Further investigation can be done on various requirements elements and attributes that influence the prioritization for future work. Besides, techniques to be embedded for automation are worth exploring to expedite the prioritization process to improve performance. However, careful measures to include a variety of stakeholders' perspectives must be taken care of.

***Abstract*—Breast Cancer (BC) is one of the leading cause of deaths worldwide. Approximately 10 million people pass away internationally from breast cancer in the year 2020. Breast Cancer is a fatal disease and very popular among women globally. It is ranked fourth among the fatal diseases of different cancers, for example colorectal cancer, cervical cancer, and brain tumors. Furthermore, the number of new cases of breast cancer is anticipated to upsurge by 70% in the next twenty years. Consequently, early detection and precise diagnosis of breast cancer plays an essential part in enhancing the diagnosis and improving the breast cancer survival rate of patients from 30 to 50%. Through the advances of technology in healthcare, deep learning takes a significant role in handling and inspecting a great number of X-ray, Magnetic Resonance Imaging (MRI), computed tomography (CT) images. The aim of this study is to propose a deep learning model to detect and classify breast cancers. Breast cancers has eight classes of cancers: benign adenosis, benign fibroadenoma, benign phyllodes tumor, benign tubular adenoma, malignant ductal carcinoma, malignant lobular carcinoma, malignant mucinous carcinoma, and malignant papillary carcinoma. The dataset was collected from Kaggle depository for breast cancer detection and classification. The measurement that was used in the evaluation of the proposed model includes: F1-score, recall, precision, accuracy. The proposed model was trained, validated and tested using the preprocessed dataset. The results showed that Precision was (97.60%), Recall (97.60%) and F1-Score (97.58%). This indicates that deep learning models are suitable for detecting and classifying breast cancers precisely.**

Keywords—Breast cancer; deep learning; xception

I. Introduction

Breast Cancer is considered one of the most common type of cancers and is taken as the second, to cause death in women worldwide. In 2002, it was the second most common cancer globally, by means of exceeding of one million new cases. Despite the enhancements in early detection and knowing of the molecular foundations of the biology of the breast cancer, nearly 30% of the patients with “early-stage” breast cancer have disease recurred.

Determining the most real and least toxic therapy, molecular and clinical features of the tumor in certain need of inspection. General treatment of breast cancer comprises hormonal agents, immunotherapy and cytotoxic. These medications are used in adjuvant, transitional, and neoadjuvant modes. Overall, systemic agents are vigorous at the start of management in 90% of main breast cancers and 50% of metastases. Though, after a flexible period of time, progress does follow. At the present, opposition to treatment is not only popular but anticipated [7, 9].

Diagnosing BC early is the most important features of its treatment. Amongst the diverse types of diagnosing technique of BC, imaging is the main diagnostic method that can make offer important data on the patients of BC. It was revealed that a few techniques of imaging e.g.: “Magnetic Resonance Imaging (MRI), Single-Photon Emission Computed Tomography (SPECT), mammography, Computerized Tomography (CT), and Positron Emission Tomography (PET)” can be put into use for the identifying and observing of the patients of BC in diverse stages. Moreover, techniques of imaging, and the use of biomarkers of biochemical e.g.: “proteins, mRNAs, DNA, and microRNAs” can be used as an innovative analytic and therapy gears for BC patients [12, 13 and 14].

Deep Learning (DL) as a type of Machine Learning method has its working mechanism inspiration from the way human brain neurons process information. The most basic element of the DL networks are small nodes known as artificial neurons , which are usually arranged in layers wherein each neuron has connections to every neuron in the subsequent layer via weighted connections. Recently, the rise of DL technique has encouraged different areas of study to solve complex problem or enhance performances of existing study using the new technology. Example of application of DL includes machine translation, speech recognition, sentiment analysis, image recognition, face recognition, signal processing, etc. [17].

The current trend of applying DL technique in medical applications has reaped great success with the potential of DL technology to perform faster analysis with higher accuracy when compared with human practitioners. To give an example, a notable study by Google on the diagnostic classification of diabetic retinopathy has shown remarkable performance that exceeds the capabilities of domain experts [22]. In addition, the application of transfer learning techniques can be seen in several studies. As opposed to training a model from scratch, transfer learning method allowed the use of weight s trained previously on a specific task to be reused as the starting point for a model on another task.

It comes with the benefits of shorter training time and is possible to deliver better results. CNN models such as Alex Net, VGG, ResNet, and Xception are the most dominant models applied in transfer learning approach. Generally, there are two ways of applying transfer learning technique; First, pre-trained model with weights trained on ImageNet dataset can be used as feature extractor; Second, fine-tuning of pre-trained model on a new problem. Study utilized transfer learning technology with Xception neural network to speed up the training of model for distinguishing subjects [6].

II. Literature Review

Many researchers have employed artificial intelligence, expert systems, and neural networks in the diagnosis of BC to increase the screening accuracy. Usually hospitals use x-rays for diagnosis of BC, but lately, hospitals have been using mammography images as a substitute of x-rays, due to their easiness in analyzing and studying through intelligent models, which have increased the efficiency and accuracy of BC diagnosis.

A number of models and methods were proposed for increasing the efficacy of the diagnosis of BC. These methods include: “Linear Regression (LR), Artificial Neural Network (ANN), K-Nearest Neighbors (KNN) search, Softmax Regression, and Support Vector Machine (SVM), and Convolutional Neural Network (CNN)”.

The authors in [3] and [18] collected their datasets from Kaggle depository. They proposed a prediction model to predict whether or not a person has breast cancer and to provide awareness or diagnosis about it. The authors of these studies made a comparisons using accuracy of each results of the SVM, random forest (RF), Naive Bayes classifier, and logistic regression on the dataset to deliver a precise model for breast cancer prediction. The outcome of their experiments indicated that the techniques of machine learning models that were applied in their studies predicted breast cancer disease with an accuracy between 52.63% and 98.24%.

In these studies, the authors propose new KNN models for the need for early diagnosis and precise diagnostic procedures that clinicians can use to classify whether cancer is benign or malignant. The main objective of their study was to compare the results of supervised learning classification algorithms and to combine these algorithms using a classification technique called voting. Voting was a grouping method because they could combine multiple models to achieve higher classification accuracy. The datasets were collected from the University of Wisconsin. [8] achieved 98.90%, [16] achieved an accuracy of 97.60%, [17] achieved 97.13%, [10] achieved 99.9%, [27] achieved 98.10% [28] achieved 98.23% and [6] achieved 83.45%.

In the following studies like [15, 21, 29, 30, 31] the authors argued that early detection and prevention can significantly reduce the chances of passing away. An important fact about breast cancer prognosis was to improve the likelihood of cancer recurrence. Their studies aimed to find the probability of breast cancer recurrence using different machine learning techniques like SVM. The authors presented new approaches in order to improve the accuracy of these models. Cancer patient data were collected from the Wisconsin Dataset of the UCI Machine Learning Repository. The dataset contains a total of 35 attributes in which they applied the Naive Bayes, C4.5 Decision Tree and SVM algorithms and measured their prediction accuracy. The efficient feature selection algorithm helped them improve the accuracy of each model by reducing some lower-order features. Not only are the contributions of these traits much lower, but their addition also misleads the classification algorithms. After careful selection of higher-order attributes, they significantly improved accuracy rate for all algorithms.

The study of [4, 10, 11, 24, 25, 26, 32] proposed method that uses CNNs which is a particular type of deep learning, feedforward network, and some preliminary experiments used the deep learning approach to classify breast cancer mammography images from BreaKHis, which is a public dataset. Method based on the extraction of image patches for training the CNN and the combination of these patches for final classification. All their convolutional network technique for categorizing screening mammograms reached good accuracies. The finest performance on an independent test set of digitized film mammograms from the Digital Database for Screening Mammography was 0.88%, (the sensitivity: 86.2%, the specificity: 80.2%).

The aim of the studies [1, 2, 5] was to develop methods for classifying cancers into specific prognostic categories based on gene expression signatures using artificial neural networks. ANN were trained to use small round blue cell tumors (SRBCTs) as a model. These cancers belong to four distinct diagnostic classes and often present diagnostic dilemmas in clinical practice. ANN properly classified all samples and recognized the genes most related to the classification. The experimental results suggested that the new strategies were able to improve the stability of the selection results as well as the sample classification accuracy. The new algorithms achieved accuracy of classification about 99%.

A. Previous Studies Summary

The previous studies aim was to detect if an image has breast cancer or not. The current study’s aim is to classify eight types of breast cancers. A summary was made of the studies discussed in the previous section in terms of the following criteria: Machine Learning methods used, programming language used, best result attained, best method, and source of the dataset used in Table I.

There are numerous studies and suggestions that put on to deal with breast cancer. Each suggestion or study has a different way of detecting or dealing with it. Some of the studies use methods that rely on image processing and the use of systems for this purpose and other studies that address the form of the breast and observe any changes in it. Some studies have enhanced the quality of algorithms that exist for detecting the disease. All these studies concentrate on the detection of whether breast cancer exists or not. None of these studies classified the eight different classes of the breast cancer. In the current study, the concentrate will be on the classification of the eight classes of breast cancers: “benign adenosis, benign fibroadenoma, benign phyllodes tumor, benign tubular adenoma, malignant ductal carcinoma, malignant papillary carcinoma, malignant mucinous carcinoma, and malignant lobular carcinoma”.

III. METHODOLOGY

The methodology that was used in the study consists of dataset collection, dataset preparation, dataset splitting, create the proposed model, model training, validating and testing as can be seen in Fig. 1.

A. Dataset

The dataset has been collected from Kaggle depository. The Breast "Cancer Histopathological Image Classification" (BreakHis) consists of 7909 microscopic images of breast cancer tissue gathered from 82 patients using various magnifying factors (40X, 100X, 200X, and 400X). It contains 2,480 benign and 5,429 malignant samples (700X460 pixels, three-channel RGB, eight-bit depth in each channel, PNG image format). This dataset was built in collaboration with the P&D Laboratory – Pathological Anatomy and Cytopathology, Parana, Brazil"

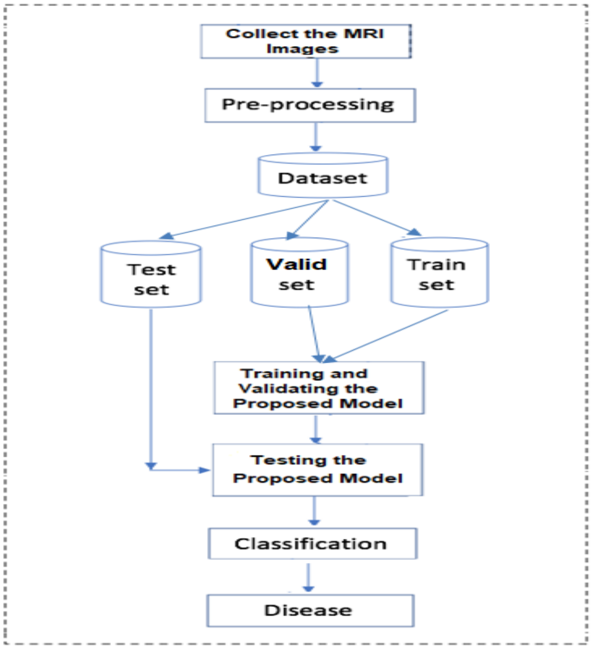

Fig. 1. Methodology Flowchart.

B. Data Perpetration

The number of images in the original BreakHis dataset has 7,909 images. This number of images is considered low and thus one can use new methods to generate more images to boost the dataset called Generative Adversarial Networks" (GANs). GAN is an algorithmic constructions that utilizes two NNs, fighting one in contradiction of the other (consequently the 'adversarial') to be able to produce new, fake instances of images that can pass as real images. They are very popular in image generation, voice generation, and video generation [19, 20, 23]. By using GAN the dataset was increased to 10,000 images. Each class of the eight classes has 1250 images. Sample of the eight classes are shown in Fig. 2.

C. Data Splitting

The dataset has been split into three datasets: training, validating, and testing datasets. The ratio of splitting is 60%, 20%, and 20% respectively.

D. Performance Measures

The most popular measurements were used in the performance of the proposed model: Accuracy is represented in (1), Precision is represented in (2), Recall is represented in (3) and F1-score is represented in (4).

$$\text{Accuracy} = (TP + TN) / (TP+TN+FP+FN) \quad (1)$$

$$\text{Precision} = (TP / (TP+FP) \quad (2)$$

$$\text{Recall} = (TP / (TP+FN) \quad (3)$$

$$\text{F1-score}= 2x(\text{Precision x Recall})/(\text{Precision}+\text{Recall}) \quad (4)$$

Where TP = True Positive, TN = True Negative

FP = False Positive, FN = False Negative

E. Proposed Model

A pre-trained Deep Learning model called Xception was proposed to be fine-tuned for the detection and classification of breast cancer. Xception model is considered to be among the beast pre-trained model of all classical Deep learning models due to its high accuracy in classifying the1000 natural images of ImageNet [17].

To be able to use a pre-trained model in the current dataset, it must be fine-tuned. In the current dataset, there are eight classes only. That means the top layer has to be removed from the Xception model which is called the classifier and to be replaced with the current classifier of the eight classes as illustrated in Fig. 3.

F. Model Training and Validating and Testing

The newly customized Xception model was trained with the prepared training dataset and cross-validating it with the validation dataset for 120 epochs. During the training, Learning Rate (0.0001), Batch Size (128), and the Optimizer is Adam were used. Furthermore, data augmentation was used during training to overcome the problem of overfitting. Fig. 4 and Fig. 5 shows the loss and accuracy of the training and validation of the xception model.

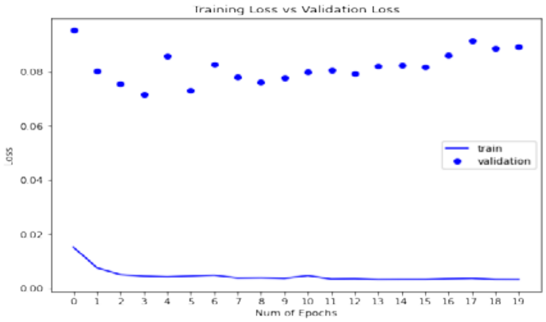

Fig. 4. Training and Validation Loss.

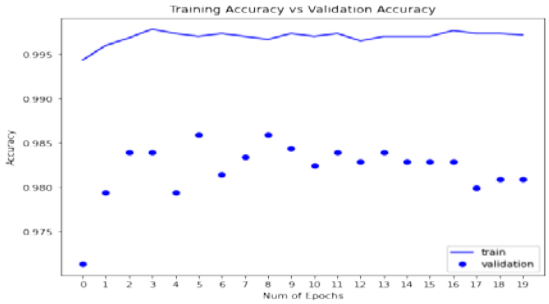

Fig. 5. Training and Validation Accuracy.

After the training was finished and validating the customized Xception model, it was tested with the testing dataset and the different performance measures were recorded.

IV. Result and Discussion

The model achieved Training Accuracy (99.78%), Validating Accuracy (98.59%) and Testing Accuracy (97.60%). In the customized model Training Loss was (0.00315), Validating Loss (0.07326), Testing Loss (0.09518). In terms of the time required for training and testing, the Xception model needed 2944 seconds for training and 5.32 seconds for testing.

Table II shows the precision, Recall, F1-Score of each class in the dataset in terms of the eight classes that the models are used for classifying: benign adenosis (BA), benign fibroadenoma (BF), benign phyllodes tumor (BPT), and benign tubular adenoma (BTA), malignant lobular carcinoma (MLC), malignant mucinous carcinoma (MMC), and malignant papillary carcinoma (MPC), malignant ductal carcinoma (MDC). The customized model achieved average Precision (97.60%), Recall (97.60%) and F1-Score (97.58%). Furthermore, the ROC Curve measure for each class in the dataset reached 100% as shown in Fig. 6.

TABLE II. Xception Precision, Recall, F1-Score of each Class in the Dataset

Measure	**BA**	**BF**	**BPT**	**BTA**	**MLC**	**MMC**	**MPC**	**MDC**	**Model AVG**

V. Conclusion and Future Work

Breast Cancer is the top cause of deaths worldwide. About ten million people died globally from cancer in the year 2020. Breast Cancer is a fatal disease among women worldwide. With technical advances in healthcare, machine learning and deep learning play an important role in processing and analyzing a large number of medical images. The objective of this study is to propose a deep learning model for detecting classifying Breast Cancer. Xception model was used and customized to fit our current breast cancer eight classes dataset. The Dataset was collected from Kaggle and boosted using GAN. The dataset was split into three datasets: training, validating and testing. The customized Xception model was trained, validated, and tested. The mode achieved Precision (97.60%), Recall (97.60%) and F1-Score (97.58%).

In future work, other techniques of generating images will be used and the Xception model will be tested with newly generated images. Furthermore, other pre-trained model will be tested and compared with the current results.

Improved POS Tagging Model for Malay Twitter Data based on Machine Learning Algorithm

Siti Noor Allia Noor Ariffin[1], Sabrina Tiun[2]
Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia

***Abstract*—Twitter is a popular social media platform in Malaysia that allows for 280-character microblogging. Almost everything that happens in a single day is tweeted by users. Because of the popularity of Twitter, most Malaysians use it daily, providing researchers and developers with a wealth of data on Malaysian users. This paper explains why and how this study chose to create a new Malay Twitter corpus, Malay Part-of-Speech (POS) tags, and a Malay POS tagger model. The goal of this paper is to improve existing Malay POS tags so that they are more compatible with the newly created Malay Twitter corpus, as well as to build a POS tagging model specifically tailored for Malay Twitter data using various machine learning algorithms. For instance, Support Vector Machine (SVM), Naïve Bayes (NB), Decision Tree (DT), and K-Nearest Neighbor (KNN) classifiers. This study's data was gathered by using Twitter's Advanced Search function and relevant and related keywords associated with informal Malay. The data was fed into machine learning algorithms after several stages of processing to serve as the training and testing corpus. The evaluation and analysis of the developed Malay POS tagger model show that the SVM classifier, as well as the newly proposed Malay POS tags, is the best machine learning algorithm for Malay Twitter data. Furthermore, the prediction accuracy and POS tagging results show that this research outperformed a comparable previous study, indicating that the Malay POS tagger model and its POS were successfully improved.**

Keywords*—*Informal Malay; Malay Twitter corpus; Malay POS tagging; Malay POS tagger model, Malay social media texts; Malay POS machine learning

I. Introduction

In general, POS is a classification system for words that classifies them according to their usage and function in sentences [1]. Similarly, a POS tagger is a component of software that reads the text in multiple languages and assigns appropriate words to each word (or other tokens) in the text. Malay has four leading POS tags, namely nouns, verbs, adjectives, and word tasks [2]; however, these leading POS tags are more suitable for tagging standard Malay text than informal Malay text such as Malay Twitter data.

Twitter is a microblogging service that combines social networking websites and instant messaging technologies to create a network of users from all walks of life who can communicate throughout the day via 280-character [3][4] short messages called tweets. Additionally, users can use Twitter's Trending features to follow specific topics. Tweets can range from jokes to current events to dinner plans, yet they cannot exceed Twitter's characters limit [5].

Twitter's Application Programming Interface (API) simplifies the process of collecting Twitter data. However, Twitter imposed specific fees and requirements for data access. Clearly, according to [6], collecting tweets using a standard Twitter API account is limited to the most recent seven days of data, and collecting and accessing tweets older than those seven days requires a premium Twitter API account efficiently cost hundreds of dollars. On top of that, Twitter provides an Advanced Search feature that enables users to refine search results based on date ranges, people, and more. Hence, this study collects tweets written in informal Malay, incorporates various dialects, conversational slang languages, and mixed languages via Twitter's Advanced Search feature [1][6][7], rather than the costly and limited API [6]. However, this data collection limited to the words contained in tweets due to other tweet features, such as user information (full name & username), hashtags, URLs, and timestamps, are considered superfluous. Hence, this study purposefully ignored and omitted it.

Malay (ISO 639-3; MSA) is a formal language spoken by Malaysians, Indonesians, Singaporeans, and Bruneians of all races. On the contrary, informal Malay is a dialect of Malay that Malaysians use in everyday conversation. Informal Malay encompasses a diverse range of informal terms, such as accent (or dialect) words, slang, titles (e.g., hang, mek), sounds (such as words written to express sounds like laughter, cat sounds, and knocking sounds), and mixed languages. Firstly, the term 'regional dialect or language' refers to a group of people who speak a country state's language, resulting in word variation. In comparison, slang is understood by a minuscule percentage of the population. Following that, 'mixed language' refers to the simultaneous use of a foreign language and Malay. For instance, when users write on social media to share feedback, express an opinion or stories, they frequently use every day conversational language to convey a friendly, casual, and easy-going image to other users.

Moreover, numerous research papers have been published in recent years on the Malay Twitter corpus and the prediction and POS tagging of Malay Twitter data; however, there has been a dearth of information in various areas, which requires improvement. For instance, Malay Twitter data normalization techniques [5], Malay POS tagger explicitly tailored for such data [1], and supervised machine learning algorithms that best suit the mentioned data. According to [8], one way for improving the quality of language processing on social media data is to automate non-standard terms to their corresponding standard tokens using normalization methods. Hence, this study chose to utilize [5]'s improvised normalization techniques for Malay Twitter data, dubbed Malay Text Normalizer. Furthermore, their Malay Text Normalizer demonstrated acceptable performance with POS tagging on a normalized tweets test corpus.

Besides, Malay Twitter data can be tagged with POS in numerous ways. Using supervised machine learning algorithms to build a POS tagging model is one of the most widely used methods. According to [1], developing a Malay POS tagging model specifically for Malay Twitter data is difficult due to the presence of dialects, grammatical and typographical errors, and abbreviations. Nevertheless, they have successfully developed a Malay POS tagger that can tag Malay Twitter data using a supervised machine learning algorithm, QTAG, a language-independent probabilistic tagger by [9]. In addition, their Malay QTAG tagger produces exceptional results on both normalized and unnormalized test corpora. Therefore, in this study several different supervised machine learning algorithms such as SVM, NB, DT, and KNN classifiers will be employ. This technique has been applied to a wide variety of research fields. The primary reason for using these supervised machine learning algorithms in this study is that it has demonstrated satisfactory results in other languages and is underutilized in informal Malay Twitter data. Thus, it is critical to investigate how well these supervised machine learning algorithms perform on such data.

This study aims to enhance existing Malay POS tags by [1] to make them more compatible with the newly created Malay Twitter corpus and develop a POS tagging model specifically for the Malay Twitter corpus using the previously mentioned machine learning algorithms. Throughout this paper, this study has successfully made several significant contributions, such as collecting and extracting Malay Twitter data by employing informal Malay terms as keywords, tagging the Malay Twitter corpus with newly proposed improvised Malay POS tags, and analyzing the corpus data with the newly developed data Malay POS tagging model. Nonetheless, until the data's copyright is enforced, this Malay Twitter data collection will be inaccessible to the public or future research.

The following is how the rest of this paper is organized: Section II summarizes relevant works, Section III discusses the methodology of this study, Section IV discusses the discussion of this study, Section V presents the results and analysis, and Section VI summarizes the study as well as several suggested future works.

II. Related Work

Malay POS tags are a type of Malay POS used to tag words in this language. As stated previously, Malay has four primary POS tags; however, this POS tag is insufficient for tagging words in the Malay Twitter corpus. For this reason, this study decided to create new Malay POS tags by referencing Malay formulas and grammar by [2]. Furthermore, this study modified the newly created POS tags to meet the Malay Twitter data criteria by comparing the word classes discovered in [2] and [10], as well as some previous findings on social media texts [1].

Additionally, a study by [11] created several new POS tags to meet their research requirements. This study discovered that several of [11]'s newly developed POS tags are suitable for categorizing words in the Malay Twitter corpus. Consider the FOR and NEG POS tags, for example. The FOR POS tag is used to classify words in foreign languages found in the study corpus. Similarly, the NEG POS tag identifies words with negative connotations, such as those that refer to swearing. Therefore, this study chose to use [11]'s two newly developed POS tags, namely FOR and NEG POS tags, as the Malay Twitter data writing demonstrates that Malaysians enjoy combining words from multiple languages in tweets and using negative words to express emotions or disapproval of situations. In addition, removing a foreign language from the corpus alters the author's intended meaning and the structure of the tweets' writing. This change will result in an error when auto annotations and annotators attempt to tag the POS tags. In that case, this study will not exclude foreign language terms, slang terms, or informal Malay expressions that adhere to this principle—instead, a unique POS tag designed for this type of word tagging. Moreover, by referencing to [11], this study generated several new Malay POS tags, namely LD, SL, GL, and BY POS tags. Firstly, the LD POS tag is used to indicate words with an accent (or dialect). Secondly, the SL POS tag is used to indicate slang language. Following that, the GL POS tag is used to indicate words referred to nicknames, and lastly, the BY POS tag used to indicate words that express sounds. Besides, this study also combined two POS tags that contained the same word into a single POS tag, such as the GDT-KTY POS tag, which comprises the POS tag for self-query pronouns (kata ganti nama diri tanya) and the POS tag for query word (kata tanya). Finally, another newly developed Malay POS tag was created by combining several prominent POS tags with sub-POS tags for shortened words, accents (or dialects), and negative particles. For instance, the term 'iols' is an abbreviation for a foreign language term. Therefore, the appropriate POS tag for this term combines the foreign language primary POS tag (FOR) and the shortened word sub-POS tags (KEP).

Malaysians, particularly teenagers, are incredibly inventive in writing and developing new words [12]. As a result, Malay social media text, such as Malay tweets, is saturated with informal Malay and peppered with mixed-language phrases and derogatory terms. POS tagging is exceptionally complicated, time-consuming, and energy-intensive for this type of corpus. If a word is not suitable to any existing POS tags, researchers will need to find alternative initiatives to either remove the word or tag it with any existing POS tags that they deem appropriate. This technique, however, is impractical due to the researchers' manipulation of study data. Thus, this study took the initiative to create new Malay POS tags that are compatible with Malay Twitter data to avoid confusion and expedite the POS tagging process; this study not only added and used the FOR and NEG POS tags from [11] and created several new Malay POS tags, but also added six additional Malay POS tags from [1]. With these numerous newly crafted Malay POS tags, this study's total number of POS tags has increased to 45 tags. As stated earlier, Malay POS tags were explicitly created to tag words in Malay Twitter data, saving researchers and annotators time to tag words with the correct POS tags.

This study conducted prediction and Malay POS tagging using the Malay POS tagger model developed based on four different machine learning algorithms from similar past studies [1], namely SVM, NB, DT, and KNN classifiers. Firstly, SVM is a widely used classifier in this type of research using machine learning algorithms, as it can accurately predict and tag POS tags [13]. Additionally, SVM predicts the POS tags for unknown words [14][15] and is considered one of the most efficient and accurate classification techniques for POS tagging [16]. According to [14], this classifier is based on sub-words, contextual information, and environmental context tagger, and [16] noted that this classifier could be used to classify sentences, ambiguity classes, and word length. Secondly, the NB classifier generates documents using the Bayes rule theory. NB classifier is extensively used in research related to predicting and tagging POS tags [17], as it can estimate the probability of each word feature before building the classification model. Five classification techniques are included in the NB class: Gaussian, Multinomial, Complement, Bernoulli, and Categorical. Following that, DT is a highly simple-to-understand and interprets machine learning class. DT works by developing predictive models for target variables. This classifier requires only a tiny amount of configuration data to operate and supports two distinct data types: numeric and categorical. DT can be validated using statistical tests and perform well, even if the data model occasionally rejects the resulting prediction. This classifier can overcome the information breakdown problem by obtaining accurate estimates of the probability of change [18] and can be used to tag unknown words with POS tags based on their word endings, word forms, and context information. Lastly, because the KNN classifier relies on POS tags associated with the test corpus, it does not generate a clear declaration representation; however, it estimated the new word POS tag by comparing it to words in the training set.

Generally, this study evaluated and quantified the prediction accuracy and POS tagging using these four-evaluation metrics: precision, recall, F1-score, and accuracy. Firstly, the precision evaluation metrics quantify machine learning algorithms' ability to avoid predicting and tagging negative samples as positive. Secondly, the recall evaluation metric assesses a machine learning algorithm's ability to re-identify positive samples. These terms refer to whether the predictions made by such machine learning algorithms are appropriate for external assessment or not. Following that the F1-score evaluation metrics can be interpreted as a weighted harmonic mean for precision and recall evaluation metrics. Furthermore, this study discovered that Malay social media text's prediction accuracy and POS tagging could be evaluated and quantified using all four-evaluation metrics. In addition, this study also discovered that the computation value for each evaluation metric could be easily generated via the classification report's evaluation metrics [19]. Classification reports are evaluation metrics that present computation values for each of the four-evaluation metrics in a classification report table. Thus, this study chose to evaluate and quantify the prediction accuracy and POS tagging using the sklearn library's evaluation metrics for classification reports [20].

III. Methodology

This study aims to improve existing Malay POS tags to fit the new Malay Twitter corpus better and develop a tagging model tailored to the new Malay Twitter corpus using the previously mentioned machine learning algorithms. The proposed methodology entails data collection and pre-processing as shown in Fig. 1. As stated previously, this study's data was compiled using Twitter's Advanced Search feature. It conducts the search using the provided keywords. Pre-processing of data includes data normalization and annotation. After that, vectorization is then applied to the data, preparing it for use by the machine learning algorithms: SVM, NB, DT, and KNN classifiers. This study vectorizes the data using the sklearn library's vectorization techniques [20], converting them to numbers, as machine learning algorithms operate exclusively on numbers. Then, to effectively use these algorithms, they must be trained to extract both word characteristics and their POS from the data. This procedure generates a model upon which Malay tweets can be automatically tagged with the Malay POS tags based solely on their context. The following sections go into details about each process.

A. Data Collection

This study gathered data manually by focusing on keywords associated with informal Malay and restricting the date ranges to February 2019. The keywords were selected following a review of the literature on informal Malay and structure. Table I contains a sample of keywords derived from previous studies and used to collect data. As stated earlier, the standard method of collecting Twitter data is through their API, enabling developers and researchers to collect data quickly; however, the API comes with a slew of restrictions, including a seven-day limit on tweets and a limit on the number of requests made to the Twitter server [6]. As a result, this study chose to manually collect data using Twitter's Advanced Search feature, rendering the limitations mentioned previously obsolete.

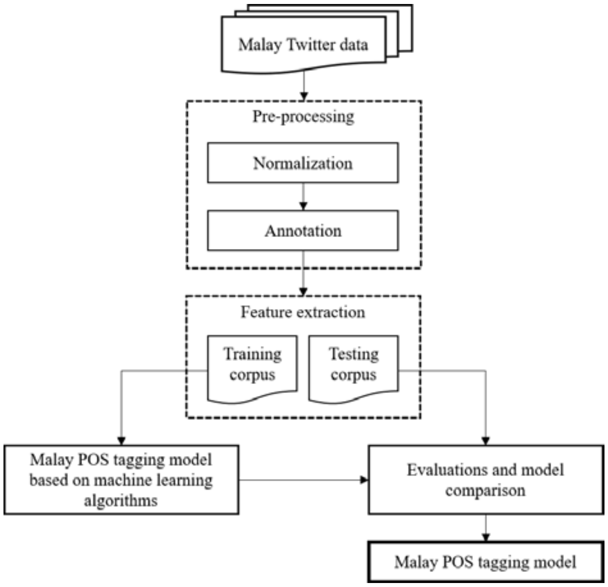

Fig. 1. Architecture of the Malay POS Tagging Model.

TABLE I. THE FOLLOWING ARE SOME OF THE KEYWORDS ASSOCIATED WITH SLANG TERMS [17] USED TO COLLECT DATA

Slang Word	Meaning in Malay	Meaning in English	Slang Form
bro	*awak, kamu, abang*	you, brother	Pronouns
gua	*saya, aku*	me	Pronouns
korang	*awak semua, kamu semua*	all of you, you all	Pronouns
pastu	*selepas itu*	after that	Expression
kekadang	*kadang-kadang*	sometimes	Expression
tetibe	*tiba-tiba*	out of the blue, suddenly	Expression
heran	*hairan*	astonished	Expression
takpe	*tidak mengapa*	it's okay	Expression
takleh	*tidak boleh*	can't	Expression
citer	*cerita*	story, tale	Expression
sesama	*bersama-sama*	together	Expression
jeles	*cemburu*	jealous	Foreign language
terer	*pandai*	clever	Foreign language
kaler	*warna*	colour, tone	Foreign language
hensem	*kacak*	handsome	Foreign language

This study focuses entirely on a single criterion for tweet inclusion: tweets must be written in informal Malay. As noted previously, informal Malay is replete with colloquial terms such as dialect, slang, titles, sounds, and mixed languages. Eventually, this study used only keywords derived from previous research findings to ensure that the chosen tweets were appropriate and accurately reflected this study's objective. On the contrary, there are currently no exclusion criteria for tweets as this study compiled a list of all tweets returned in response to the keywords entered. However, as explained earlier, several additional tweet features were purposefully overlooked and omitted, as the study's goal is to collect only informal Malay text. Therefore, this study ignores all other characteristics to focus exclusively on textual characteristics and the frequency with which informal Malay terms were used in social media texts.

B. Data Pre-processing

As previously stated, the data for this study will be pre-processed using two well-known pre-processing steps: data normalization and annotation. The pre-processing of the data begins with data normalization. The data normalization process strips Malay Twitter data of all ambiguous signs, symbols, and spellings. This normalization process is required for accurate POS tagging; however, accurate POS tagging is only possible after informal terms in the data are converted to their standard form (spellings). Therefore, this study's data were normalized using Malay Text Normalizer, a rule-based normalizer designed to normalize only Malay, Romanized Arabic, and English words [5] in the corpus. Subsequently, in the next pre-processing steps: data annotation, the normalized data will be annotated with POS. The data annotation process needs to ensure that each word in the data is appropriately tagged with the correct POS tags. For this reason, this study's data were manually annotated [1] using the newly proposed Malay POS tags. The final dataset contains 1,791 tweets in various languages relevant to informal Malay and related to the previously mentioned keywords.

C. Feature Extraction and Model Training

Following data collection and pre-processing, the final dataset is divided into two corpora: training and testing. The training corpus contains 70% of the data from the final dataset and is used to train these machine learning algorithms on extracting valuable features from words and their contexts using [21] features extraction method. This study extracted ten significant features, including the preceding and following words, the prefix of each word (limited to the first three alphabets of the word), the suffix of each word (limited to the last three alphabets of the word), the word's length, and the presence of a digit in the word. These features were extracted to aid the POS tagging model in automatically assign the correct POS to each word in the corpus, based on its context alone.

Additionally, as previously explained, the training corpus is vectorized before being fed into machine learning algorithms. Vectorization converts data from a textual to a numerical format, as these algorithms only work with numbers. Hence, this study leverages [20]'s sklearn library by vectorizing the training corpus using its vectorization technique. After that, all machine learning classifiers are trained using this vectorized training corpus by incorporating it into the classifier's code in the sklearn library. The sklearn library by [20] used in this study because it includes all necessary algorithms [22], such as machine learning classifiers and vectorization techniques, and evaluation methods. Besides, the library is simple to use, as the algorithms are invoked via the provided code. Finally, the accuracy of these machine learning classifiers will be evaluated using the sklearn library's evaluation metrics for classification reports and tested using the testing corpus, which contains the remaining 30% of the final dataset's data. Table II contains a summary of the features used in this phase.

TABLE II. LIST OF FEATURES USED IN THIS STUDY

Categories	Feature Description
Word Prefixes & Suffixes	Prefix 1 (first letter) Prefix 2 (first two letters) Prefix 3 (first three letters) Suffix 1 (last letter) Suffix 2 (last two letters) Suffix 3 (last three letters)
Token (Word) Context	The previous word Next word Word length Does the word contain digits

The features listed in Table II were chosen because:

1) According to [21], the word before it and its POS tag serves as a guideline for identifying the appropriate POS tag for the word after it.

2) Author in [21] also stated that the presented algorithm tags the current word with the appropriate POS tags based on the word information and surrounding POS tags.

3) The letter at the beginning and end of each word refers to the letter's size and position in the word. This feature, according to [23], has the potential to influence the effectiveness of POS tagging.

4) The length of each word is a binary feature that determines its size [23], [24].

5) The author in [23] defines digit features as features based on the presence of digits (numbers) and symbols in words.

6) According to [23] and [24], the context of words in a sentence influences the tagging value of unigrams in the corpus.

IV. Discussion

This study gathered tweets written in informal Malay from numerous Malaysian users through relevant and related keywords associated with informal Malay language. The keywords searched was done by using the same method used by [1][6][7] which is through Advanced Search Twitter function located at the Twitter main homepage. The collected data then was normalized using a Malay normalizer by [5] and annotated with the newly created Malay POS tags in the pre-processing process. Additionally, this study extensively used the sklearn library code by [20] to implement the classifiers algorithm, vectorization techniques, and evaluation method. Following that, this study vectorized the data to prepare it for the machine learning algorithms as the classifiers can only read data in numerical format. Finally, this study used the sklearn library [20] to develop a Malay POS tagger model based on these machine learning algorithms, namely SVM, NB, DT, and KNN, and evaluate each classifier's results.

V. Results and Analysis

This study developed a Malay POS tagger models using a training corpus and machine learning classifiers code from the sklearn library in previous sections. Therefore, this section will evaluate the developed Malay POS tagger models using the test corpus to determine its functionality. The evaluation of POS tagging by Malay POS tagger models employs metrics for classification reports from the sklearn library to determine the accuracy of POS tagging across all four machine learning algorithms. Table III summarizes the algorithms' evaluation results using the prepared testing corpus and the details mentioned previously.

Based on the table above, this study discovered that the SVM classifier achieved a relatively high predictive accuracy and Malay POS tagging at 94%, and the DT classifier had the second-highest score at a rate of 93%. Besides, the SVM and DT classifiers also rated the highest POS tagging evaluation results on the same scoring metric, i.e., F1-score (0.92 & 0.89). In other words, this evaluation demonstrates that both classifiers generate nearly identical predictive outcomes and POS tagging. The reason for this is that while the SVM classifier is computationally simple to implement, it has a high computational cost [14][15], whereas the DT classifier is capable of handling sparse data problems and still produces the best results when tested on small size data [25][26].

TABLE III. The Following Summarized the Classification Reports for POS Tagging Generated by All Four Machine Learning Classifiers

Machine Learning Classifier	**Classification Reports**			
	Precision	***Recall***	***F1-score***	***Accuracy***
Support Vector Machine (SVM)	0.93	0.91	0.92	0.95
Naïve Bayes (NB)	0.74	0.57	0.60	0.85
Decision Tree (DT)	0.89	0.88	0.89	0.93
K-Nearest Neighbor (KNN)	0.85	0.87	0.85	0.90

This study examined the algorithms' functionality using extensive data collection, resulting in up to 95% accuracy. Based on this result, the developed Malay POS tagging model is ready to predict and tag Malay Twitter data using the newly created Malay POS tags. The evaluation and analysis results indicate that the SVM classifier is the optimal machine learning algorithm for Malay Twitter data and that the Malay POS tags used are also optimal for such data. Furthermore, this study's prediction accuracy and POS tagging score are higher than those of a similar previous study, indicating that this study successfully improved the Malay POS tagger model and its POS.

A. Model Comparisons

As stated earlier, this study was based on an earlier study by [1]. The author in [1] investigated the prediction and tagging of Malay POS by developing Malay POS tagger models based on the Hidden Markov Model (HMM) trigram machine learning algorithm, the QTAG model. As a result, this study took the initiative to conduct comparable studies using various machine learning algorithms, including SVM, NB, DT, and KNN classifiers. The purpose of this study was to determine which machine learning algorithms are best suited for processing Malay POS predictions and tagging, particularly Malay Twitter data.

While both studies used the same data type, the pre-processing of the data was significantly different. For instance, this study normalized the data using the Malay Text Normalizer by [5], whereas [1] used only a few simple data pre-processing steps such as the removal of punctuation marks, symbols, and numbers. Following that, the Malay POS tags used in the annotation process of the two studies are distinct, as each study developed its own Malay POS tags that correspond to the content of its study data. Finally, by comparing the prediction accuracy and POS tagging results from these two studies, the results obtained by this study were significantly higher, with a difference of 0.29% from [1]. Eventually, the results and analysis demonstrate that the SVM classifier is the optimal machine learning algorithm for predicting and tagging Malay POS in Malay Twitter data and that the newly proposed Malay POS tags are appropriate for use as POS in such data. The distinction between this study and [1] is summarized in Table IV.

TABLE IV. THE FOLLOWING TABLE COMPARES [1] TO THIS STUDY

Studies	[1]'s study	This study
Objectives	Malay POS tagger	
Corpus	Informal Malay tweets	
Technique	Machine learning	
Algorithms	HMM (QTAG)	SVM, NB, DT, & KNN
POS Size	38	45
No. of Tweets	300	1,791
No. of Words	5,513	38,714
Accuracy	94.60%	95.00%

VI. CONCLUSION AND FUTURE WORK

In general, this study aims to improve on [1], work by developing a POS tagging model tailored to Malay Twitter data using a variety of machine learning algorithms, including SVM, NB, DT, and KNN classifiers. The collected data, as well as the newly developed Malay POS tags and Malay POS tagger model, are expected to be of assistance to researchers and developers, particularly those with expertise in informal Malay and related Natural Language Processing fields. This study can be improved further by collecting more non-standard Malay words in the training corpus, preferably more than 10,000 tweets specific to a specific domain such as food or health, rather than general domain. This enhancement is proposed to ensure that the training corpus contains enough data for the subsequent processing process.

ACKNOWLEDGMENT

This research work is funded by The Ministry of Higher Education Malaysia under research grant code: FRGS/1/2020/ICT02/UKM/02/1.

Dept. of Computer Science, Faculty of Computing and AI, Helwan University, Cairo, Egypt[2]

***Abstract*—This article proposes framework for determining the optimal or near optimal locations of physical internet hubs using data mining and deep learning algorithms. The framework extracts latitude and longitude coordinates from various data types as data acquisition phase. These coordinates has been extracted from RIFD, online maps, GPS, and GSM data. These coordinates has been class labeled according to decision maker's preferences using k-mean, density based algorithm (DB Scan and hierarchical clustering analysis algorithms. The proposed algorithm uses haversine distance matrix to calculate the distance between each coordinates rather than the Euclidian distance matrix. The haversine matrix provides more accurate distance surface of a sphere. The framework uses the class labeled data after the clustering phase as input for the classification phase. The classification has been performed using decision tree, random forest, Bayesian, gradient decent, neural network, convolutional neural network and recurrent neural network. The classified coordinates has been evaluated for each algorithms. It has been found that CNN, RNN outperformed the other classification algorithms with accuracy 97.6% and 97.9% respectively.**

I. Introduction

Choosing the location of storage warehouses is one of the most important steps facing supply chain officials, if not the most important step. This step has gained importance because of its impact on the entire supply chain. It also affects transportation operations and determines the speed of response to customer requests. Therefore, it was necessary for many researchers and specialists in supply chains to use all available means and techniques to determine the best location for these warehouses. With the rapid development of communication technologies and their overlap with the Internet of Things, large amounts of data became available for analysis and to give accurate mathematical alternatives to solve the problem of choosing the locations of those repositories. There are devices to track the movements of cars and their various effects along the supply chain. These devices also show the time of movement and waiting for these cars in an accurate and round-the-clock manner. There were many ways to analyze this data to reach the optimal location for these repositories. Classification processes are one of the most used methods to reach the most accurate solutions. The researchers also used other methods, such as relying on the global positioning system technology to track trucks in various places. From this standpoint, the research team decided to use the available data from that technology, taking into account the waiting hours, to determine the best places for these warehouses. But before proceeding in detail in this research, some concepts related to the topic of research must be presented, including first the different data collection techniques and the reason for choosing some of them over the other. Second, the methods of data analysis and the algorithms used to analysis that data. Third, the research team will address the new phenomenon in the field of supply chains, namely the physical Internet (PI), and the extent of its expected impact in the near future, in context of what has been published on this subject in some international scientific journals. Fourth, a detailed overview of deep learning techniques in the context of the research topic will be illustrated.

First vehicles tracking [1] Global Positioning System, The Global Positioning System (GPS), formerly known as Navstar GPS, is a satellite-based radio navigation system owned by the US government and maintained by the US Space Force. The GPS does not require the user to send any data, and it works independently of telephonic or Internet reception, however both technologies can improve the accuracy of GPS positioning data. Military, civic, and commercial users all across the world rely on the GPS for crucial positioning. The US government designed, maintains, and administers the system, which is publicly accessible to anybody with a GPS device. Based on data received from several GPS satellites, the GPS receiver estimates its own four-dimensional position in space-time. Each satellite keeps a precise record of its position and time, which it sends to the receiver which in our case is attached to trucks.

On other hand, Radio Frequency Identification (RFID) is a passive wireless technology that allows an item or person to be tracked or identified. Tags and readers are the two main components of the system. Radio Frequency Identification (RFID) relies on a small electrical device, generally a microchip, to store data. These devices are usually quite small, about the size of a grain of rice, and can store a lot of information. Some contain a stored power source or batteries, even if they don't always emit electricity. The scanners that are used to read these devices can also offer enough power to read the microchip. The technology has a variety of applications, but it is most typically used to track objects.

Global System for Mobile Communication (GSM) based tracking system is presented that uses a mobile phone text message system to keep track of a vehicle's location and speed. The technology may send text notifications for speed and location in real time. One of the disadvantages of this technology is that it bears an additional cost and weak or no signals in some places during the supply chain.

On other hand, researcher used computer vision approach for latitude and Longitude coordinates extraction [2]. A lot of data is required for computer vision. It repeats data analysis until it detects distinctions and, eventually, recognizes images. To teach a computer to recognize automotive tires, for example, it must be fed a large number of tire photos and tire-related materials in order for it to understand the differences and recognize a tire, particularly one with no faults. Computer vision enables procedures to be automated, saving time and reducing the pressure on a limited labor supply. Computer vision has been used to unload inventory trailers with increased efficiency. Vehicle departure times must be carefully synchronized with the loading periods of other trucks, trains, or planes.

The motive that motivated the research team to conduct such a study is the lack of a single framework that can deal with different types of data, whether classified or unclassified data. The team believes that by creating a single framework that integrates many data sources and provides different mining and machine learning algorithms and techniques, it can provide an addition in supply chain and physical internet operations, especially in the current and future period.

This article is divided into several parts. The first part provides solid overview of the main concepts of physical internet and deep learning techniques. It also, provides a brief summary of some related researches in the logistics industry. The second part discusses in detail the proposed framework. The last part demonstrates the experiments and results.

II. Theoretical Background

The following section discusses briefly the main concept of physical internet and deep learning. Some related studies will be discussed in section.

A. *Physical Internet*

The physical internet (PI) was developed in response to the inefficiencies and unsustainable nature of current logistics and supply chain management strategies. It was proposed to address issues that make current logistics practices unsustainable, such as limited space utilization for road, rail, sea, and air transportation, empty travel being the norm rather than the exception; poor working conditions for truck drivers, products sitting idle, inefficiency of product distribution, inefficient use of production and storage facilities, mediocre coordination within distribution networks, and high inefficiency of multimodal transportation [3].

The primary goal of the PI is to change "the way physical goods are handled, moved, stored, realized, supplied, and used, with the goal of improving global logistics efficiency and sustainability." The PI intends to coordinate physical commodities transit in the same way as data packets are carried via the digital Internet. The movement of commodities will be optimized in terms of cost, speed, efficiency, and sustainability by pooling resources such as vehicles and data and constructing transit centers that enable smooth interoperability. The PI establishes common and generally agreed-upon standards and protocols to promote horizontal and vertical cooperation amongst businesses in order to achieve this optimization.

The PI does not directly manipulate physical items, but rather manipulates and maintains the transportation containers that house them, just as digital Internet packets store embedded data. Many factors must be coordinated for the PI to become fully functional, including tangible items such as PI modular containers or PI transit centers, as well as more abstract notions such as legislation and business models. Previous research, which concentrated on performing simulations with a small number of participants in specific industries, has demonstrated that the application of the PI, even if it is partial, can result in significant advantages [4].

As shown in Fig. 1, according to ALICE [5] The Physical Internet contemplates the transformation of Logistics Nodes into Physical Internet nodes with standardized service definition and operations. Services at PI nodes are visible and digitally accessible to businesses, and they cover planning, booking/transactions, execution, and information exchange. The Physical Internet is based on a comprehensive and systemic consolidation of flow and network of networks principles. The Physical Internet promotes full consolidation of logistics flows from independent shippers in logistics networks (e.g., extended pooling). The Physical Internet promotes pooling resources and assets in open, connected, and shared networks (i.e. connecting existing (business) networks, capabilities, and resources) so that network users and partners can use them easily. It is predicted that by pooling demand and resources to meet that demand, resource utilization will be more efficient. Transport, storage, and physical handling procedures of load units such as containers, swap-bodies, pallets, boxes, and so on are included in the Physical Internet, as is any other resource required for a freight transport and logistics operation [5].

B. Deep Learning

Deep learning is a machine learning technique that trains computers to do what people do instinctively. Deep learning is a major technology underpinning a lot of applications such as automated driving, medical research, voice control, text, inventory management and other critical fields [6]. Deep learning has received a lot of attention recently, and for good reason. It is attaining results that were previously unthinkable. Deep learning models can attain cutting-edge accuracy, sometimes outperforming humans. Models are trained utilizing a huge quantity of labeled data and multi-layered neural network architectures [7] Fig. 2 demonstrates architecture of deep learning network layers. Deep learning has several known algorithms such as convolution neural network (CNN), recurrent neural network (RNN), long short term memory networks (LSTM) and generative adversarial networks (GANs). CNN and RNN are the main concern in this research. CNNs are multilayer perceptron that have been regularized. Multilayer perceptron are typically completely connected networks, in which each neuron in one layer is linked to all neurons in the following layer. Because of their complete connectedness, these networks are subject to data over fitting. Regularization, or preventing over fitting, is commonly accomplished by punishing parameters during training (such as weight decay) or reducing connectivity (skipped connections, dropout, etc.) CNNs use the hierarchical pattern in data to assemble patterns of increasing complexity utilizing smaller and simpler patterns imprinted in their filters. As a result, CNNs are at the lowest end of the connectivity and complexity spectrum [8]. RNNs are a form of neural network capable of modeling sequence data. RNNs, which are generated from feed forward networks, behave similarly to human brains. Simply said, recurrent neural networks are capable of anticipating sequential data in ways that other algorithms are not. RNNs feature a Memory that retains all calculation information. It uses the same parameters for each input because doing the same task on all inputs or hidden layers yields the same result.

It uses the same parameters for each input because doing the same task on all inputs or hidden layers yields the same result.

C. Related Work

Several studies have been published to determine the best locations for supply chain warehouses using a number of different methods. Some of these researches used mathematical models to determine the locations and others used data mining techniques. In this section, the results of some of these studies, pointing out their advantages and disadvantages will be reviewed.

In [9], the researchers proposed an integrated Multi-Objective Hybrid Harmony Search-Simulated Annealing (MOHS-SA) algorithm to find the trade-off between the total cost of operating facilities, and the cost of CO2 emissions. The research presented a number of alternatives to warehouse locations, but it lacked any possibility of self-learning or determining the optimal location for these warehouses.

On other hand, in [10] the researchers examined a case study at a company that works in the Fast Moving Consumer Goods (FMCG) area and was undertaking a market test for its new alternative tobacco products using the B2C distribution system. The goal of this research is to identify both the number and location of warehouses that provide the lowest total logistics costs for the B2C process, while the company is still employing company-owned B2B warehouses. The number and location of these warehouses are determined using Agglomerative Hierarchical Clustering with Evolutionary Solver, where clustering is based on the shortest distance. One of the important effects that resulted from this research is that he was able to determine the number of warehouses based on the minimum costs, whether operating or transportation costs, in line with customer requests. The weak point of this research is that it locates warehouses based on cost only, without looking at other dimensions such as the environmental dimension, increased demand, or the introduction of other types of products. On other words this research is not the optimal solution for general case study.

In 2020 [11] proposed a mathematical model to allocate the warehouse centers in Far East of Russia based on population, trade turnover and volume of goods manufacturing. This research divided the warehouses to three categories federal, regional, and local centers. These logistics centers have been located in different cities regardless of the exact geographic information of these centers.

Using Lingo solver software [12] the researchers proposed a solution to locate warehouse based on linear programming. The decision in this research has been taken on cost of moving material, frequency trips of material, and the distance of location. This research suffered from the lack of the possibility of self-learning, as it relied entirely on linear mathematical equations without exposure to the non-linear nature of this problem.

In [13], the researchers proposed a solution to determine the optimal location of supply chain distribution centers using k-near neighbor clustering algorithm. They used spatial dataset in their case study. They have demonstrated the ability of this algorithm to divide geographical areas and locate warehouses. The defect of this algorithm was the necessity to determine the number of warehouses before starting the process of clustering the spatial data.

The authors of this paper [14] proposed a two-step clustering approach. In the first stage, they extract the frequent GPS trajectory halt locations. The second stage is to use a density-based clustering method to determine the nearest locations. Because it starts clustering from extracted points, the suggested approach saves time.

In [15], the authors proposed a clustering model using automatic identification system and DBSCAN algorithm to spot the location of ships using the navigation GPS latitude and longitude. The residence point of each ship is identified according to the ship speed and course change. This research uses only GPS data and lacks of self-learning possibility.

III. Proposed Framework

In this part, the proposed framework for solving the problem of locating supply chain repositories in context of the physical internet phenomenon will be presented. The proposed framework consists of four phases, data acquisition, data labeling, classification and testing. During data acquisition and selection phase, data from many sources is combined into a single data repository, resulting in a target dataset containing intriguing variables or data samples for discovery.

Due to the lack of classified data in many cases in actual supply chain applications and to maximize the effectiveness of the proposed framework, the research team performed a preliminary clustering of the collected data as data labeling phase. The clustering stage will be done using three known algorithms K-mean, density based algorithm (DB Scan) and hierarchical cluster analysis (HCA) to satisfy most of the decision-makers requirements. For example, when using k-mean algorithm, the decision maker can determine the number of PI hubs according to the available resources and future plans of the organization such equipment, transportation and workers. Decision makers can use the DB Scan algorithm to cluster the data without specifying a specific number of Hubs, due to the nature of the work of this algorithm. It divides the data into any number of groups so that the differences between the points of the same group are reduced to a minimum. If it is expected that there will be groups with arbitrary shapes, the decision maker can use DB Scan algorithm. The decision makers can use HCA to cluster the latitude and longitude coordinates according to regions or cities. The most significant aspect in hierarchical clustering is the linkage mechanism, which determines how the distances between clusters will be calculated. It has a significant impact on not just the clustering quality but also the algorithm's efficiency. The k-centroid link method has been chosen in our implementation. The output of this phase is labeled training dataset.

The clustering distance matrix used in the proposed framework is haversine formula. The haversine formula is a very accurate method of estimating distances between two places on the surface of a sphere given the two points' latitude and longitude. The haversine formula is a re-formulation of the spherical law of cosines; however the haversine formulation is more useful for tiny angles and distances. The central angle (θ) between any two points on a sphere is:

$$\theta = \frac{d}{r}$$

where:

d is the distance between the two points along a great circle of the sphere.

r is the radius of the sphere.

The haversine formula allows the haversine of θ (that is, hav(θ)) to be computed directly from the latitude (represented by φ) and longitude (represented by λ) of the two points:

$$hav(\theta) = hav(\varphi_2 - \varphi_1) + \cos(\varphi_1)\cos(\varphi_2)\, hav(\lambda_2 - \lambda_1)$$

where:

φ1, φ2 are the latitude of point 1 and latitude of point 2,

λ1, λ2 are the longitude of point 1 and longitude of point 2.

Finally, the haversine function hav(θ), applied above to both the central angle θ and the differences in latitude and longitude, is

$$hav(\theta) = sin^2\left(\frac{\theta}{2}\right) = \frac{1 - \cos(\theta)}{2}$$

In the third phase, the proposed framework presents the possibility of using a number of well-known classification algorithms to classify data, such as: decision tree, Naïve Bayes, random forest, gradient descent, k-nearest neighbors, support vector machine (SVM), CNN, and RNN. Although some of these algorithms are lazy learning algorithms, they classify data accurately in many cases. The proposed framework uses CNN and RNN deep learning algorithms to add self-learning nature.

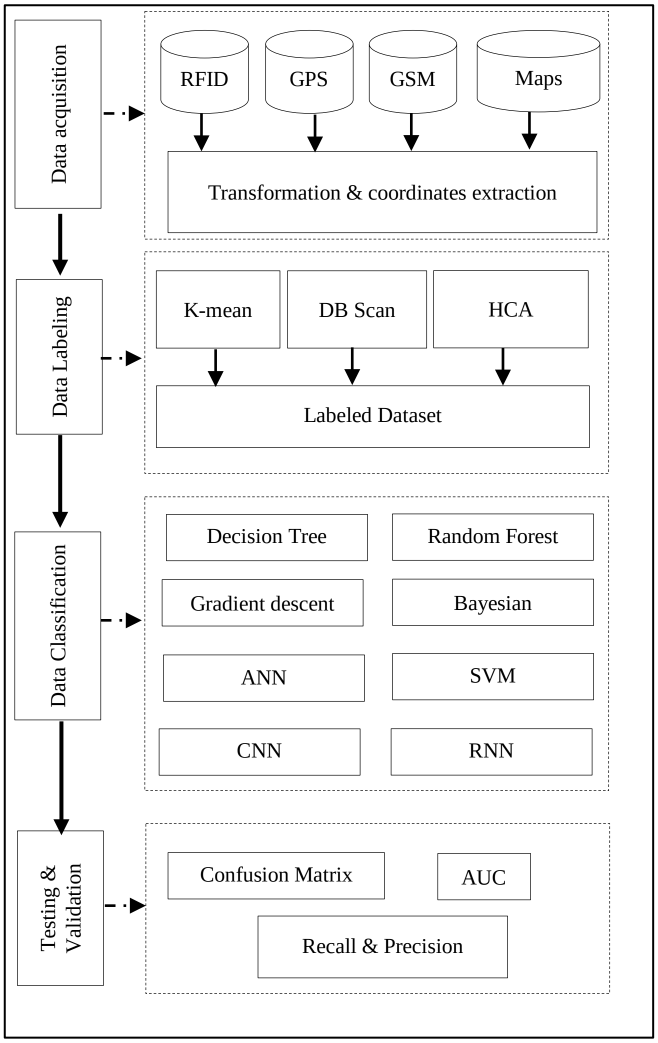

Fig. 4. Physical Internet Hubs Locating using Latitude and Longitude Classification.

Testing and validation is the fourth phase. At this phase, the results of all classification algorithms that have been used in the proposed framework are evaluated to find out the optimal outcomes within standardized testing criteria. In this phase the area under curve (AUC), confusion matrix and precision have been used to calculate the framework accuracy.

As in Fig. 4 the framework extracts latitude and longitude coordinates from four major resources (RFID, GPS, GSM, and maps) at data acquisition phase the framework has been developed to handle all of these data types. It is not necessary to use all data types in real case scenarios; any user can customize this step according to his application.

IV. Experiments and Results

This section discusses in detail the performed experiments. All experiments were carried out using Spain's coordinate's dataset on the Kaggle website [16]. The frame work has been implemented with python3 environment. Table I illustrates the Spain's coordinate's dataset main features.

All null features (city, district, & region) and missing instances have been dropped as preprocessing phase. The reset 975000 instances will be divided as 70% for training and 30% for testing and validation for the classification purposes after the preparation phase.

The dataset was divided into 15 class labeled groups using k-mean algorithm as data preparation phase. The number of groups was chosen to reduce distances to a minimum in order to reduce the time and cost of transporting goods between points which achieves sustainability. Then this labeled dataset has been fed to the proposed framework for classification as 3rd phase. The architecture implementation of CNN algorithms was as the following: 1 Conv. layer, 5 dense layers and the used activation function was Relu. The RNN implementation also as the following; 1 RNN layer, 4 dense function using tanh activation function. Table II shows the evaluating comparison of the used classification algorithms.

As shown in Table II, the Bayesian algorithm classification accuracy was 86.2%. The Random forest algorithm achieved 90.2% accuracy. CNN and RNN algorithms made the classification with 97.6%, and 97.9% respectively. On other hand SVM classified the dataset with accuracy 95.1%. The previous results have been calculated with confidence level 95%. The results showed also, that RNN outperformed the classification rather than other algorithms.

TABLE II. THE PROPOSED FRAMEWORK ACCURACY COMPARISON

	AUC	**CA**	**Precision**	**Recall**
Bayesian	0.8956	0.862	0.885	0.890
Random Forest	0.9145	0.902	0.903	0.912
CNN	0.9806	0.976	0.971	0.978
RNN	0.9812	0.979	0.982	0.989
SVM	0.9342	0.928	0.913	0.922
ANN	0.9564	0.951	0.934	0.946
Gradient descent	0.9012	0.899	0.891	0.898
Decision tree	0.9102	0.909	0.906	0.904

V. CONCLUSION

The proposed framework consists of four major phases. The first phase is data acquisition. In this phase the latitude and longitude data extracted from different data sources such as: RFID, GSM, GPS, and maps. This data has been class label using one of three clustering algorithms (k-mean, DB scan, & HCA) as second phase. The third phase is classification phase. In this phase, the decision makers can choose from one or more classification algorithms such as: Bayesian, decision tree, random forest, SVM, ANN, CNN and RNN. The performed experiments showed that RNN classified the data better than other algorithms with accuracy 97.9%. According testing results, the research team believes that it is preferable to locate the physical internet hubs by one of deep learning algorithms especially CNN or RNN rather than other classification techniques. This study can be extended in the future by adding new deep learning algorithms or using different activation functions.

Development of Adaptive Line Tracking Breakpoint Detection Algorithm for Room Sensing using LiDAR Sensor

Deddy El Amin, Karlisa Priandana, Medria Kusuma Dewi Hardhienata
Computer Science Department, Bogor Agricultural University (IPB University), Bogor, Indonesia

***Abstract*—This research focuses on the use of Light Detection and Ranging (LiDAR) sensors for robot localization. One of the most essential algorithms in LiDAR localization is the breakpoint detector algorithm which is used to determine the corner of the room. The previously developed breakpoint detection methods have weaknesses, such as the Adaptive Breakpoint Detector (ABD), could generate dynamic threshold values. The ABD results, on the other hand, still require Line Extraction to obtain the corner breakpoint. Line Extraction method, e.g. Iterative End Point Fit (IEPF), is used to categorize data, resulting in the generation of a line pattern as an interpretation of a wall. The computational method for obtaining the corner breakpoint becomes longer as the line is extracted. To address this issue, our algorithm proposes a new threshold area in the form of an ellipse with the threshold value parameter obtained from previously identified room size and sensor characteristics. As a result the corner breakpoint detection becomes more adaptive. The goal of this research is to create an Adaptive Line Tracking Breakpoint Detector (ALTBD) approach that will reduce the computing time required to detect corner breakpoints. Furthermore, the Line Extraction method required for corner breakpoint detection is modified in the ALTBD. To distinguish between the edge of the wall and the corner of the room, the boundary value is increased. The ALTBD method was tested in a simulation arena comprised of multiple rooms and halls. According to the results, the ALTBD computation time is faster in detecting corner breakpoints than the ABD IEPF method, also the accuracy for determining the position of the robot was improved.**

Keywords—LiDAR; breakpoint detector; robot localization; corner detection; line segmentation

I. Introduction

Robot localization which is a method to acquire information about a robot's direction and position in its working environment is required by every autonomous robot in order to move and accomplish its task. Three types of robot localization are global localization, predictive localization, and local localization [1]. When the robot is outside, global localization works relatively well [2]. Whenever the robot is indoors, it uses probabilistic localization, local localization, or a combination of the two [3]. Our research leads to probabilistic localization, which determines the robot's position and orientation based on sensor measurement data combined with prior knowledge in the form of a map of the arena in the room.

Several papers have been written about the sensors used in localization and probabilistic localization methods, including encoder sensors [4][5], magnetic compass [6], magnetic anomalies map [7], low-cost gyro [8], ultrasonic sensors [9] [10], RFID [11] to the Light Distance and Ranging (LiDAR) sensor. Sensors such as encoder disc sensors, magnetic compasses, low-cost gyros, and ultrasonic sensors require significant movement before the robot can identify its position. If time is of the essence in accomplishing the objective of the robot, the sensor is not the first option to be installed in the robot. As a result, this research utilizes a LiDAR sensor capable of identifying the position and surroundings without requiring the robot to move, improving the robot's movement more effective.

Previous research has widely proposed the LiDAR sensor since it has excellent spatial accuracy, fast data renewal, and does not rely on object illumination or reflectance [12]. This research focuses on determining the form of the room using the LiDAR sensor measurement results. The issue is determining how to identify the geometry of the space based on its corner position. Breakpoint detection is one way for determining the corner of a room. This method detects the room's corner points and the edge of the wall by verifying the discontinuity between the two points scanned consecutively by the LiDAR sensor [13].

Breakpoint detection method that combines Successive Edge Following (SEF), Line Tracking (LT), and Iterative End Point Fit (IEPF) was developed by Siadat et al. [14]. However, all three methods have a weakness: finding a consistent threshold value to detect a breakpoint between two consecutive sensor scan points is challenging. The observed breakpoints can take the form of room corners or the edge of a wall. The breakpoint detection threshold value should be dynamic, based on the distance between the sensor and the object being scanned [13].

Several researchers have indicated determining dynamic threshold values. The threshold value in Lee et al. [15] research is based on the current and prior measurement distance values. The DIET method, which takes the measurement angle into account when establishing the threshold value, was developed by Dietmayer et al. [16]. The method by including the virtual wall angle parameter as an estimate of the detected wall slope angle was improved by Santos et al. [17]. The threshold value in their Adaptive Breakpoint Detector (ABD) method as well developed by Borges and Aldon [13]. They use auxiliary angles to determine the point of intersection and use it as a reference for the threshold value, and Certad et al. [18] also adjusted the threshold value in the ABD. They modify the measurement distance value in the ABD equation with the shortest distance value from either the current or previous distance. In his research on the ABD method, Su Young et al. [19] identified the lack of a line cluster perpendicular to the sensor as a problem. The challenge was then solved by combining the ABD and LT methods to create the Dual Breakpoint Detector (DBD), and Weerakoon et al. [20] also used ABD in their research. In order to increase the feature extraction rate value, Weerakoon et al. [20] research suggests taking the measurement error value and the longest distance value into consideration. The corner breakpoint was determined in three phases in this investigation. The first stage is ABD, which is used to segment the data depending on a threshold value. The following stage is Line Extraction with IEPF. Line Extraction is a method for organizing data based on line patterns that can be formed as an interpretation of a wall. The intersection of the two lines obtained by the IEPF two-segment linear regression is then used to locate the corner breakpoint in the third phase. Dingyao et al. [21] research's to determine the corner breakpoint included one more phase into four phases, i.e. point feature matching to compare angles and distances. The second, third and fourth stages of Corner Breakpoint Detection render the algorithm's computational process worthless.

To overcome these issues, The Adaptive Line Tracking Breakpoint Detector (ALTBD) method is developed in this research. The ALTBD method is a variation of the Line Tracking (LT) and Adaptive Breakpoint Detector (ABD) algorithms that introduces a new threshold area to improve corner breakpoint detection. By using established room sizes, this method also solves the challenge of finding the threshold. The breakpoint detection threshold value is made dynamic in this method by taking into consideration the difference between the sensor measurement distance and the projected virtual wall distance. Furthermore, the Line Extraction method required for corner breakpoint identification is improved in the ALTBD to reduce computational time. To distinguish between the edge of the wall and the corner of the room, the boundary value is increased.

This paper outline is as follows: The next section reviews some relevant works on LT and ABD method. Section III defines the proposed adaptive line tracking breakpoint detector method. Section IV provides the methodology that used to in this research, and Section V shows the results and analysis, whilst the conclusion is presented in the final section.

II. Related Work

In this section, several methods are discussed as the basis for the proposed method, namely Line Tracking (LT) and Adaptive Breakpoint Detector (ABD) method.

A. Line Tracking Method

Line tracking (LT) is a method of detecting breakpoints or segmenting line data that use linear regression and works in Cartesian coordinates. The following pseudo code [22] describes the working principle of this method:

1) Begin with two points of measurement, then draw a line between them.

2) Insert the next point to make a new line model.

3) Reprocess the line's parameters.

4) If the result of the generated line is satisfactory, continue (repeat to step 2).

5) If the result is not satisfactory, make the last point the line segment's end point, re-process the line's parameters, and make it as one line segment.

6) Go back to step 2 after completing the next two points.

The difficulty in defining the threshold value (D_{max}) to determine the breakpoint between the two measures is this LT's disadvantage [13]. Fig. 1 depicts two segments of data generated by LT when $d_5 > D_{max.}$

B. Adaptive Breakpoint Detector Method

The Adaptive Breakpoint Detector (ABD) method to address the issue of a fixed threshold value at LT was proposed by Borges and Aldon [13]. This method performs on the same principles as the LT method, which utilizes a threshold to detect breakpoints. The distinction is that there is no linear regression in this method, and the threshold value is made dynamic by utilizing the angle difference between the two measurement results. The ABD method is illustrated in Fig. 2 along with the parameters utilized. In ABD, breakpoints are detected by creating a border circle with a radius of D_{max} and a center at p_{n-1}. A breakpoint is detected if the current scan point (p_n) is found to be outside the circle. As a result, the previous scan point (p_{n-1}) is considered the end point of the current segment, whereas p_n is considered the beginning point of the following segment.

The adaptive breakpoint detector (ADB) method has the advantage of having a threshold value (D_{max}) that can change depending on the previously created distance (r_{n-1}) and a difference in the angle of measurement ($\Delta\phi$). This value is used as a comparison (border value) to distinguish between two segments of line data.

Equation (1) [13] describes the data terms stated as breakpoints:

if $\|p_n - p_{n-1}\| > D_{max}$ then k^b_n := TRUE and k^b_{n-1} := TRUE
(1)

Where, $\|p_n - p_{n-1}\|$ represents the distance between the p_n point and the p_{n-1} point. D_{max} is the breakpoint threshold whose value is determined by the sensor's distance to a measurable object (r_n). The current measured position is p_n, while the previous measured point is p_{n-1}. Fig. 2 depicts this ADB method. Detection is accomplished by drawing a dividing circle with the center point at p_{n-1} and a radius of D_{max}.

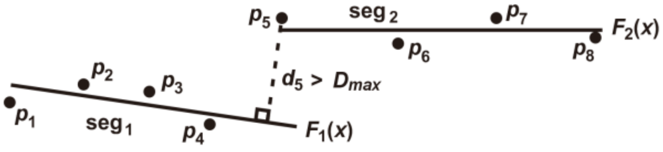

Fig. 1. Line Tracking Method [14].

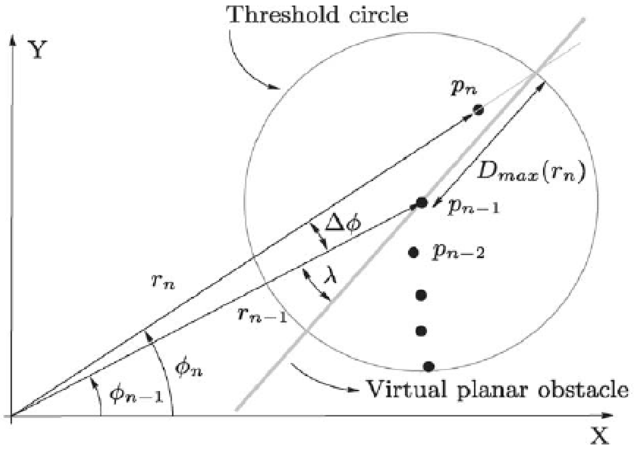

Fig. 2. Adaptive Breakpoint Detector Method [4].

If the current scan point (p_n) is found to be outside the circle, $p_{n\text{-}1}$ is considered the endpoint of the current segment and p_n is determined the start point of the following segment. Equation (2) [13] describes its mathematical function:

$$\|p^h{}_n - p_{n\text{-}1}\| = r_{n\text{-}1}.\ (\sin(\Delta\phi)/\sin(\lambda\text{-}\Delta\phi)) \qquad (2)$$

$\|p^h{}_n - p_{n\text{-}1}\|$ as the breakpoint testing threshold value Equations (3) and (4) are provided a real implementation of the threshold formula with [13]:

$$D_{max} = \|p^h{}_n - p_{n\text{-}1}\| + 3\sigma_r \qquad (3)$$

$$D_{max} = r_{n\text{-}1}.\ (\sin(\Delta\phi)/\sin(\lambda\text{-}\Delta\phi)) + 3\sigma_r \qquad (4)$$

Where, σ_r is the laser scanner manufacturer's parameter and λ the angle between the virtual line and the line connecting the object point to the laser scanner ($r_{n\text{-}1}$).

1) Line extraction: The ABD method generates breakpoints only at the ends of segments, which we refer to as terminal breakpoints in our research. As a result, another algorithm, Line Extraction, is required to reprocess existing data into new segments that can represent a line. As a result, the ABD computation time exceeds the LT in determining the angular breakpoint. Linear Regression [23], Split and Merge algorithm [24], Iteration End Point Fit [25], RANSAC algorithm [26], Hough Transform algorithm and Expectation-Maximization algorithm are some line extraction algorithms that can be used [27]. The Iteration End Point Fit (IEPF) method is discussed in this chapter as a comparison to the new method developed.

The IEPF algorithm [25] is a recursive Line Extraction method. Data checks are performed repeatedly for each segment base due to its recursive nature. The IEPF method is depicted in Fig. 3 by truncating one segment of data resulting from ABD into three data segments that form three lines. First, the initial data (p_1) and final data (p_{n}) are connected to form a straight line. The distance between the second data and the line is then calculated orthogonally. This is repeated for the third data point, and so on until all members of the segment have been checked. The maximum orthogonal distance ($d_i{}^m$) of the result will be compared to the limit value (d_{thd}). The limit value is the comparison value that was declared at the beginning. If the maximum value ($d_i{}^m$) is greater than the limit value, the segment will be halved at the maximum distance point. Fig. 9 illustrates how the first cut of a segment (Z_1 = { p_1,.., p_n}) into two segments (Z_2 = {p_1,..., p_i} and Z_3 = {p_i,..., p_n}) occurs at the p_i point. The initial data (p_1) and final data (p_i) of the Z_2 segment are then connected to form a straight line. The distance between all of the data points in the segment Z_2 is then calculated orthogonally to the line. The result's maximum orthogonal distance ($d_h{}^m$) will be recompromised by the limit value (d_{thd}). One line segment has been checked because the maximum orthogonal distance ($d_h{}^m$) is less than the limit value (d_{thd}). The segment is a Z_2 made up of p_1 to p_i. The Z_3 segment is treated similarly. However, the maximum orthogonal distance ($d_j{}^m$) in the Z_3 segment {(p_i,..., p_n)} is greater than the limit value (d_{thd}), so the segment must be cut in half with the intersection point at the p_j. The maximum orthogonal distance between the segments {p_i,..., p_j} and {p_j,..., p_n} is then calculated and compared to the limit value (d_{thd}). The data grouping on the Z_1 segment is complete because the maximum orthogonal distance of each segment is less than the limit value (d_{thd}). Through IEPF on the Z_1 segment, the final result is three line segments, namely S_1{p_1,..., p_i}, S_2{p_i,..., p_j}, and S_3{p_j,..., p_n}.

Weerakoon et al. [20] research's describes examples of ABD and Line Extraction implementation. The ABD threshold value equation was modified to Equation (5) in the research [20].

$$D_{max} = min\{r_n,r_{n+1}\}(1 - 3\sigma_r)(\sin(\Delta\phi)/\sin(\lambda\text{-}\Delta\phi))$$
$$+ 3\sigma_r.max\{r_n,r_{n+1}\} \qquad (5)$$

The ABD method has a disadvantage in that the angle value generating the threshold value is obtained based on the results of the experiment and requires Line Extraction to detect the corner breakpoint.

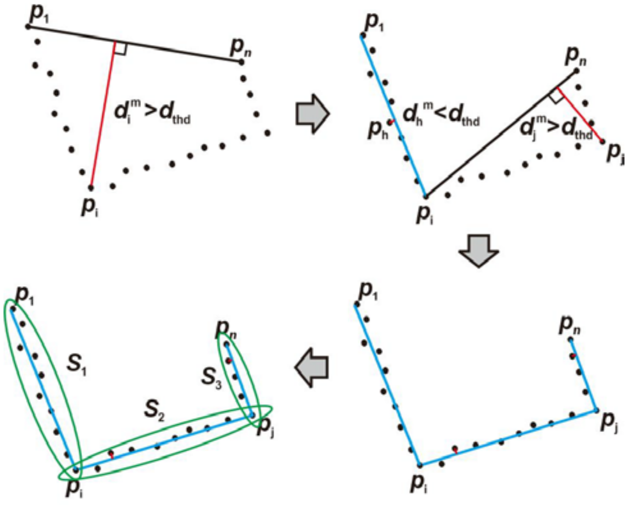

Fig. 3. IEPF Algorithm Working Principle.

III. THE PROPOSED ADAPTIVE LINE TRACKING BREAKPOINT DETECTOR METHOD

A. Propose a New Method (Adaptive Line Tracking Breakpoint Detector)

The Adaptive Line Tracking Breakpoint Detector (ALTBD) method we propose is a combination of the Line tracking (LT) and Adaptive Breakpoint Detector (ABD) methods. The existing breakpoint detector (ABD) obtains coverage in the form of a circle with a threshold value diameter, whereas ALTBD obtains coverage in the form of an elliptical area with an elliptical center point from the prediction point. The LT method calculation yielded the prediction point. Although elliptical shapes require more complicated equations, they depict a point spread rather than a circle. The threshold value on ABD is determined by the virtual angle derived from the experiment, whereas in ALTBD, the parameter producing an elliptical area, which is a minor value, is made adaptable by taking the measurement error of the LiDAR sensor into consideration.

The linear equation $F'_n(x)$ generated by LT is used to predict the next point of measurement, as shown in Fig. 4. The point's polar angle value (θ_{n+1}) is then used as an input to calculate the equation of the line $F_{n+1}(x)$. The predictive point p'_{n+1} is then obtained by intersecting the two equations of the line. The prediction point p'_{n+1} is defined as a point (0,0) or the center point of the elliptical area, with the x-axis representing as the major axis and the y-axis representing as the minor axis. The length of the major axis ($qmax_{n+1}$) is determined by the distance between the points p_n and the prediction line $F'_n(x)$ at the point of intersection. Minor axis length ($hmax_{n+1}$) is determined by calculating using orthogonal regression against the prediction line and the error values at the previous points. Fig. 4 and 5 depict the parameters used in the ALTBD method. The ALTBD algorithm's flow is described in detail:

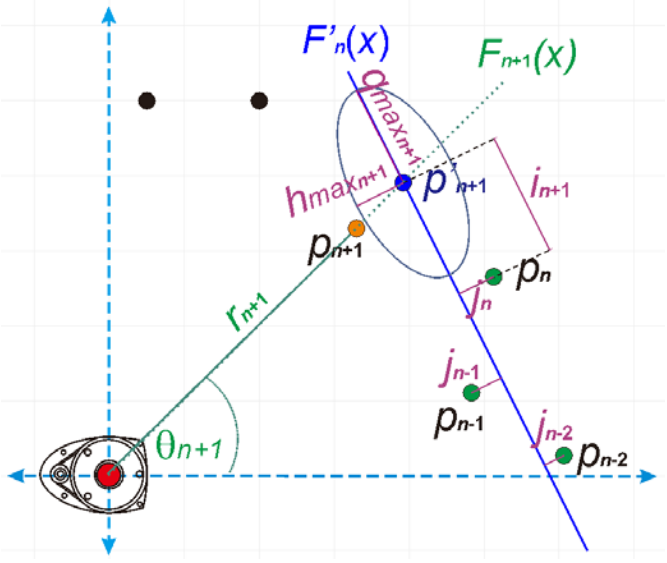

Fig. 4. ALTBD Method.

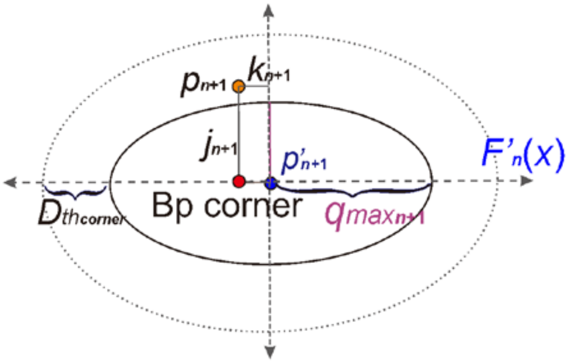

Fig. 5. Corner Detection ALTBD.

Algorithm for Detecting Breakpoints in Adaptive Line Tracking:

1) Determine the linear regression equation from three starting points (p_{n-2}, p_{n-1}, p_n) and transform it into a predictive line ($F'_n(x)$).
2) Determine the difference between the starting point (j_{n-2}, j_{n-1}, j_n) and the predicted line ($F'_n(x)$).
3) Using the equation $\boldsymbol{\varepsilon}_n = |j_n|/r_n$, calculate the percentage error ($\boldsymbol{\varepsilon}_{n-2}$, $\boldsymbol{\varepsilon}_{n-1}$, $\boldsymbol{\varepsilon}_n$) relative to the distance to the sensor (r_n).
4) Determine the average error percentage, $\sigma_n = (\Sigma^n_{i=n-2}\boldsymbol{\varepsilon}_i)/3$
5) Determine the minor axis limit, $hmax_{n+1} = \sigma_n + \sigma_{offset}$.
6) Verify out the next angle data (θ_{n+1}).
7) Create an equation using the angle gradient (θ_{n+1}) and the line ($F_{n+1}(x)$) that passes through the point (0,0).
8) Make the intersection point of the prediction line ($F'_n(x)$) and the scan line ($F_{n+1}(x)$) the prediction point (p'_{n+1}).
9) Calculate the distance between the prediction point (p'_{n+1}) and the last scan point (p_n) parallel to the prediction line ($F'_n(x)$), and set it as the major axis limit ($qmax_{n+1}$).
10) Read the next data set (p_{n+1}).
11) Transform the predicted point (p_{n+1}) to new coordinates, with the predicted point (p'_{n+1}) as the origin (0,0) and the predicted line ($F'_n(x)$) as the x-axis.
12) Calculate the new position of the point (p_{n+1}), and update x by k_{n+1} and y by j_{n+1},
    $k_{n+1} = \cos(\theta).(xp_{n+1} - xp'_{n+1}) + \sin(\theta).(yp_{n+1} - yp'_{n+1})$
    $j_{n+1} = -\sin(\theta).(xp_{n+1} - xp'_{n+1}) + \cos(\theta).(yp_{n+1} - yp'_{n+1})$
13) Enter the minor axis boundary ($hmax_{n+1}$), the major axis boundary ($qmax_{n+1}$), and the new measurement point position (k_{n+1}, j_{n+1}) into the ellipse equation,
    $e\_result = ((k^2_{n+1})/(qmax_{n+1})) + ((j^2_{n+1})/(hmax_{n+1}))$
14) If $e\_result > 1$, a breakpoint has been detected. Then, determine whether the position of the point (p_{n+1}) is within the tolerance range of the corner (Dth_{corner}).
15) If it is within the corner's tolerance limit, set the point (k_{n+1},0) as the corner breakpoint and transform it back to the original coordinates.
16) If it is not within the corner's tolerance range, use the following three measurement points (p_{n+2}, p_{n+1}, p_n) as the starting point and return to step 1.
17) If $e\_result \leq 1$, then calculate the difference between the measurement points and the prediction line (j_{n+1}).
18) Recalculate the percentage of error, $\boldsymbol{\varepsilon}_{n+1} = |j_{n+1}|/r_{n+1}$
19) Recalculate the minor axis limit, $hmax_{n+1} = \sigma_{n+1} + \sigma_{offset}$
20) Repeat step 6.

IV. Methodology

A. Materials and Tools

This research was performed out with the following hardware and software: The RpLidar A1 module, Beaglebone Black Wireless, Intel i5 2.5 GHz RAM 4GB Win32bit Laptop, and Jupyter Notebook.

B. Stages of Research

The seven research stages in the development of the Adaptive Line Tracking Breakpoint Detector (ALTBD) method are as follows: data acquisition, LiDAR data noise model design, LiDAR data generator module design with simulation, data processing using the ALTBD method, data processing using comparison methods (ABD Line Extraction and LT), testing the ALTBD algorithm, and analysis and evaluation. Fig. 6 depicts the flow of the research method.

Because the data utilized in the test will use simulation data from the LiDAR data generator module, the first stage of this research is LiDAR data acquisition, which is done in real time to obtain a noise sensor model. The purpose of this data acquisition is to determine the noise characteristics of the RpLidar data and to validate the noise characteristics of the sensor manual document. Observations were taken on a straight wall with no obstacles that was greater than 5 meters long.

1) LiDAR data acquisition: The next stage is LiDAR data acquisition, which is done to create a LiDAR sensor noise model. The distance between the LiDAR sensor and the wall was varied from 15 to 225 cm with 5 cm intervals to obtain appropriate data. For each distance variation, data were collected five times.

2) Design of noisi model for the RpLiDAR A1: The simulation module use the noise model to verify that the generated data is as close to the real LiDAR data as possible. Residual noise will be added at random and generated using a normal distribution. The model is built using a polynomial regression method on the outcomes of LiDAR data collecting. Linear or polynomial interpolation is used to approximate the values of the element variables.

3) Design of a LiDAR data generator simulation module: The arena simulation module is used to test the ALTBD method. A square-shaped arena with four rooms and multiple tunnels is used for simulation testing. That's the 2.4 m by 2.4 m arena for the Indonesian Fire Extinguisher Robot Contest (KRPAI 2019). In the KRPAI guide document [28], the position of the doors in rooms 3 and 4 distinguishes four distinct room layout combinations. This simulation module is made up of five blocks, as depicted in Fig. 7. This module takes as input the robot's position (x,y) and direction (azimuth), as well as the choice of space combinations 3 and 4. This module generates level 3 scan data with angle and distance attributes.

4) Testing: The tests were analyzed by comparing three Breakpoint Detector methods: the one we developed (ALTBD), the LT method, and the ABD IEPF method from the Weerakoon et al. [20] research. In this research, the computing time, percentage of distance inaccuracy, and position difference between the Breakpoint Pattern Recognition results will be sought from each method. Computational time is measured beginning with level 3 scan data, which is processed in each method to produce an output in the form of a corner breakpoint. The percentage of distance measurement error is calculated by subtracting the results of the Breakpoint Detector from the position of the reference breakpoint.

The difference is then compared to the sensor's distance from the reference breakpoint. But first, the Breakpoint Detector data must pass through the Breakpoint Extraction module to enable determining the reference breakpoint point easier. This research will investigate the position difference between the Breakpoint Pattern Recognition results and the actual global position. On the LiDAR data generator simulation module, the global position is the input sensor location in the arena. Fig. 8 depicts the test diagram.

a) Breakpoint Extraction: This module sorts breakpoints, namely corner breakpoints, corner breakpoint terminal points, and other points that form only one side of the wall. This module also removes breakpoints that are overlapping. The breakpoint extraction module is required to support and facilitate the pattern matching process, allowing it to be developed as needed to achieve the best results.

b) Breakpoint Pattern Recognition: The closest or adjacent star methodology is used in this research's breakpoint pattern identification method, which is based on the concept of a star pattern recognition algorithm using a satellite star sensor [29]. The method's star pattern is replaced with a breakpoint pattern. The main catalog and the sub-catalogue are the two catalogs. The primary catalog contains IDs for all breakpoints, as well as two attributes: position in Cartesian coordinates and type (x,y). The sub catalog contains all of the neighboring breakpoint point IDs, as well as the distance between the breakpoints. The main idea behind this method is to compare each distance between the three observed breakpoint points to a catalog of previously defined space mappings.

V. Result and Discussion

A. Noise Data Model Design of RpLidar A1

The Rplidar A1 noise data model is made up of three conditions: 0-60, 60-100, and 100-225 cm at the point nearest to the sensor and the wall. The first condition is approximated by 6-order polynomial regression, while the values of the variables in the equation are approximated by 3rd order polynomial interpolation. The regression used is appropriate to utilize 2nd order polynomials in the range of 60 to 225, but the range of 60 to 100 values of the element variables is produced by 3rd order interpolation. The range of 100 to 225 is then estimated using linear interpolation.

B. Adaptive Line Tracking Breakpoint Detector (ALTBD)

The measurement inaccuracy (σ_{offset}) percentage value utilized is 0.04. This value is the average of the percentage of errors obtained from data collection results in the first stage of the research. The tolerance value as the corner breakpoint limit (Dth_{corner}) is 23 cm, which is half the door distance of 46 cm. Fig. 9 depicts one of the ALTBD module's results and Fig. 10 depicts one of the ABD IEPF module's results.

The ALTBD results show the detection of several corner breakpoints generated by the 18 mm thick side wall. Because the detected side is close to the sensor, the number of scanning points created is sufficient to make a segment with more than four points. Breakpoints that should be designated corner breakpoints by the IEPF method are regarded terminal breakpoints, in contrast to ABD IEPF. This is due to the fact that the required threshold distance is not met on that side.

C. Adaptive Breakpoint Detector (ABD) and IEPF

The threshold value equation utilized is consistent with the results of the Weerakoon et al. [20] research. The residual error is 0.0038, whereas the angle (λ) is 8º. The extraction line used is an IEPF with a limit value of 46 cm. The intersection of the two lines generated by the IEPF two-segment linear regression is used to determine the corner breakpoint.

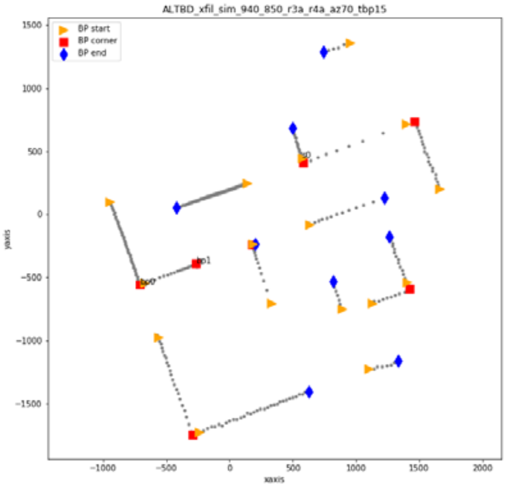

Fig. 9. Breakpoint Detector Results of ALTBD.

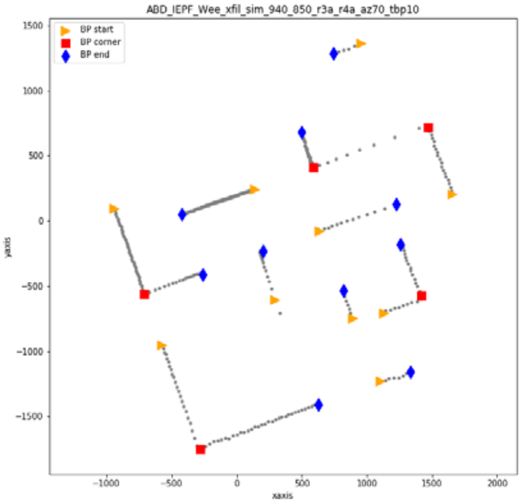

Fig. 10. Breakpoint Detector Results of ABD IEPF.

D. Testing

Fig. 11 depicts a comparison of the computing times of the three Breakpoint Detector methods. The comparison of the ALTBD, ABD IEPF, and LT methods reveals that the LT method computes faster than the ALTBD and ABD IEPF methods. The average computation time for the LT technique is 59,87 ± 1,94 ms, whereas the ALTBD and ABD IEPF methods require 101.61 ± 2.63 ms and 175.4 ± 10.13 ms, respectively. Although LT has the shortest calculation time, the resulting corner breakpoints are not as precise as ALTBD and ABD IEPF. If the accuracy of the LiDAR sensor's position in the room is a major priority in robot localization, this will be a disadvantage of the LT method. The ALTBD method has the second fastest computation time. Despite the fact that the ALTBD calculation is more sophisticated, each data point is only processed once. Unlike the IEPF ABD, the data is processed at least twice in this method. This method processes data twice, once using the ABD method and once using the IEPF method. The theory behind the significant difference in computational time is that the LT, ABD, and ALTBD methods are linear search algorithms with a time complexity of O(n), whereas the IEPF method is a linear recursive algorithm with a time complexity of $T(n) = 2T(n/2) + O(n)$, with the worst-case complexity being O(n^2). Table I presents the detailed results of the computational time comparison.

According to the test results, the IEPF's disadvantage is the recognition of an inaccurate corner breakpoint. This takes the form of a four-sided space, as illustrated in Fig. 10. This is due to the fact that the IEPF seeks the greatest deviation from the line connecting the starting and finishing points. Furthermore, there is a lot of noise at that point. This type of room is said to be unfavorable for detecting corner breakpoints using the IEPF method.

E. Breakpoint Extraction

The results of the tests show that the IEPF method has weaknesses, including the inaccuracy of recognizing corner breakpoints in the form of a four-sided room, as illustrated in Fig. 12. Table II indicates that the ALTBD method detects corner breakpoints with only two errors out of 43 position samples tested, but the ABD IEPF detects them with ten. When compared to ALTBD and ABD IEPF, the LT method has the most detection errors. If there are only two corner breakpoints on one side of the wall, the accuracy of the corner breakpoint is declared correct. It is still considered a corner breakpoint detection error if there are more than two corner breakpoints, even if they are close to one other.

The IEPF method is inaccurate in recognizing corner breakpoints because it looks for the greatest difference between the start and finish lines. Furthermore, there is a lot of noise at that point. When using IEPF, this type of room will result in an inaccurate corner breakpoint. In addition, ALTBD generates an inaccurate a corner breakpoint. Because the erroneous corner breakpoint is typically located distant from the LiDAR sensor, it has little effect on the location results of the Breakpoint Pattern Recognition, as illustrated in Fig. 13. However, with the spatial pattern depicted in Fig. 12, the resulting corner breakpoint position in the IEPF is not quite close to the LiDAR sensor. The Breakpoint Pattern Recognition method will not produce the right position if these two spots are not actual corner breakpoints. Some corner breakpoint detection problems in the LT method occur when the incorrect position is close to the sensor and the distance to the other reference corner breakpoint is within the Breakpoint Pattern Recognition tolerance limit, as illustrated in Fig. 14. As a result, the Breakpoint Pattern Recognition procedure is unable to locate a pattern match in the database.

F. Breakpoint Pattern Recognition

There are three stages to the breakpoint pattern recognition process. The first step is to look for a pattern match for the three initial reference points, which are the three breakpoints nearest to the sensor. The results of the search throughout the sub-catalogues are saved. Step two must be completed if there is more than one possibility. The second stage is to find a match against the original three reference points on the remaining corner breakpoints and terminal breakpoints in all sub-catalogues. The match of the nearby breakpoint points with the most points that determines the three initial patterns is eligible for selection. If stage two yields two or more results, stage three will be carried out. Stage three follows the same principles as stage two, with the exception of the matching point. This is the last of the breakpoints on the list (points that form a line). If step three is completed, all breakpoints have been verified.

TABLE I. COMPUTATIONAL TIME RESULTS

Location	**Num. sample**	**Computational time in ms**		
		ALTBD	***ABDiepf***	***LT***
Room 1	9	103,3 ± 8,0	198,9 ± 11,0	62,4 ± 0,0
Room 2	8	103,8 ± 8,0	208,6 ± 8,0	58,5 ± 7,2
Room 3	10	99,5 ± 8,0	157,9 ± 15,5	56,5 ± 8,0
Room 4	8	101,4 ± 8,0	169,0 ± 11,7	62,4 ± 0,0
Street	8	100,3 ± 8,0	135,9 ± 21,5	60,2 ± 5,9

TABLE II. CORNER BREAKPOINT DETECTION RESULTS

Location	**Num. sample**	**Corner breakpoint**					
		ALTBD		***ABDiepf***		***LT***	
		True	***False***	***True***	***False***	***True***	***False***
Room 1	9	33	0	34	3	36	4
Room 2	8	32	0	32	0	32	6
Room 3	10	30	0	32	3	36	3
Room 4	8	28	1	28	2	26	3
Street	8	34	1	32	2	45	7

Furthermore, the major catalog should be summarized in order to limit the number of candidate positions generated. In fact, one wall has four sides: two long sides and two wide sides, or what is generally referred to as the thick side. The wall has four breakpoints at first, which are then combined into two breakpoints with the condition that the wall thickness is included in the tolerance limit value. The main catalog, which originally had 40 points, was reduced to 19 points. Similarly, the sub-catalog averaged 19 nearby breakpoints at the end. The reduced number of neighbors in the reference point accelerates the matching process.

Fig. 15, 16, and 17 shows that the position generated by ALTBD is more accurate than ABD IEPF through the pattern recognition process using the closest breakpoint method. This is due to the fact that the reference points for position computations are only the two closest corner breakpoints. ALTBD produces the closest corner breakpoint more precisely than ABD IEPF.

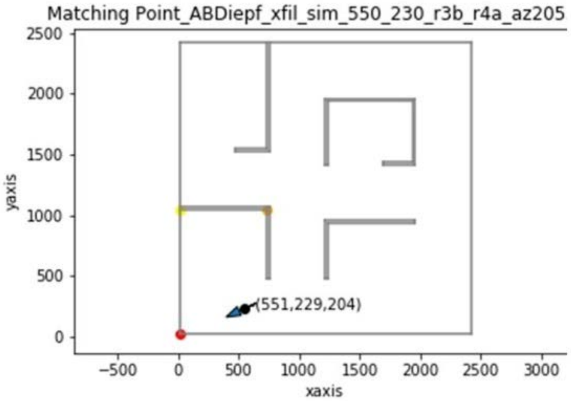

Fig. 17. Breakpoint Pattern Recognition Results of ABD IEPF.

VI. CONCLUSION

This research was successful in developing a new algorithm for breakpoint detection called the Adaptive Line Tracking Breakpoint Detector (ALTBD). This method modifies the Line Tracking (LT) and Adaptive Breakpoint Detector (ABD) algorithms by introducing a new threshold area in the shape of an ellipse, resolving corner breakpoint detection more adaptive and fasting. Algorithm testing was done by apply the ALTBD and ABD algorithms with Iterative End Point Fit (ABD IEPF) to detect the position of the robot in the room.

The results of the tests prove that the ALTBD computation time is faster in detecting corner breakpoints than the ABD IEPF method. The average computation time for the ALTBD method is 101.61 ± 2.63 ms, while the ABD IEPF is 175.4 ± 10.13 ms. The corner breakpoint detection error in the ALTBD method is only two errors out of 43 position samples, whereas the ABD IEPF method has ten detection errors. Furthermore, the ALTBD method is more accurate in determining the position of the robot than the ABD IEPF method, with a distance difference of 9.72 ± 1.55 mm, instead of 11.2 ± 2.14 mm in the ABD IEPF.

ACKNOWLEDGMENT

The authors would like to thank the Head of the Satellite Technology Research Center (BRIN) and Lembaga Penelitian dan Pengabdian kepada Masyarakat (LPPM) IPB University for their support in completing this research. This research is partially sponsored by the Ministry of Research and Technology of the Republic of Indonesia (RISTEK-BRIN) through Penelitian Dasar Unggulan Perguruan Tinggi (PDUPT) research grant number 3626/IT3.L1/PT.01.03/P/B/2022.

***Abstract*—Information systems help organizations manage their entities with innovative technologies. These entities are often very different in nature. In this paper, we consider a business process level based on a set of Business Process Model and Notation (BPMN) models and a software system level based on a Unified Modeling Language (UML) class diagram. The differences between these entities make them difficult to align. In addition, an organization's BPMN models may be designed by different teams, which can cause syntactic and semantic heterogeneities. We present the first step of our proposed approach for aligning a software system level with a business process level without conflict (redundancy and lost information). Syntactic and semantic rules based on ontologies and other resources for comparing BPMN models are described, as well as a process for transforming BPMN models into UML model.**

***Keywords*—Information system alignment; business process; software system; Business Process Model and Notation (BPMN); Unified Modelling Language (UML); class diagram; ontology; semantic aspects**

I. Introduction

As organizations increase in number, competition between them intensifies. In order to compete, organizations adopt innovative strategies, seek high quality human resources, follow best practices, and use the most efficient technological tools. Developing an efficient and cost-effective information system is crucial for an organization's ability to compete. For this reason, alignment is vital for organizations. Indeed, alignment can provide solutions to problems associated with the diverse changes that may occur in an organization's entities. Business/IT alignment has been the topic of several previous studies [1]–[5]. The approach proposed in this paper is relevant in various situations. An information system with aligned levels may experience changes in one of its levels due to a revision of goals or other factors. This causes the levels to become misaligned. In addition, different levels of an organization's information system may be modelled by different teams. Each team perceives the system from a different perspective, which can also result in misaligned levels. Similarly, when two organizations with levels of different natures merge, the levels of the resulting information system will likely be misaligned as well. In this case, the resulting information system will contain misaligned levels. Further, most organizations include several BPMN models at the business process level, all built independently of each other. This can cause conflicts during alignment, due to heterogeneities between the models. In fact, existing approaches considering a set of BPMN models align models syntactically. However, they only test identity. They do not detect other correspondences, such as inclusions, abbreviations and acronyms. Moreover, none of these studies takes semantic aspects into account (synonymy, homonymy or hyponymy). These heterogeneities can cause conflicts when models are aligned and may introduce problems and inconsistencies in the resulting UML model. Indeed, if alignment approaches based on identity only consider two BPMN elements to be different when they are equivalent, they will introduce a false difference and, therefore, redundancy in the UML model. Worse, considering two elements as equivalent when they are different will introduce a false equivalence, resulting in information loss in the resulting UML model. A generalisation relationship between hyponymic elements is also missing in the UML model.

In all these situations, an effective alignment approach is required to obtain a successful information system. Additionally, it is necessary to ensure that alignment is achieved without conflicts (i.e. without loss or redundant information).

The different approaches described in previous studies concerning business process and software system levels are analysed in this paper. Following that analysis, we propose an alignment approach that resolves syntactic and semantic conflicts. The first step of the proposed approach includes a set of rules for comparing BPMN models to detect equivalencies and differences as well as a transformation process for converting a set of BPMN models into a UML class diagram [6]. The second step provides a method for preserving software system level information.

This paper is organised as follows: Section II presents the background of the topic; it introduces the concept of alignment and ontology. Section III provides a brief overview of related work, while the proposed approach is presented in Section IV. Section V presents a case study. Finally, the conclusion outlines our objectives for future work.

II. BACKGROUND

A. The Concept of Alignment

In the literature, various expressions have been used to describe the term alignment. Chan [7] refers to alignment by fit and synergy. Henderson and Venkatraman [8] use the terms fit, integration, and interrelationships. Reich and Benbasat [9] use the word linkage. For Ciborra [10], alignment is defined as a bridge. Smaczny [11] describes it as fusion. Luftman [12] employs the term harmony, while Nickels [13] uses congruence. Alignment between business and IT is defined by Ullah and Lai [5], as “the optimized synchronization between dynamic business objectives/processes and respective technological services provided by IT”. According to Luftman [12], business-IT alignment concerns the application of IT in a timely and a suitable manner, in harmony with business strategies, goals and needs. For Luftman [12], this definition considers the way IT is aligned with the business, and the way the business should or could be aligned with IT. In present work, we define alignment of a target level with a source level as a method that ensures the continued operation of the target level, while remaining suitable to the source level.

B. Ontology

Ontology is defined as an “explicit specification of a conceptualization” [14]. Domain ontologies are ontologies built on a particular knowledge domain. There are many domain ontologies such as MENELAS (in the medical domain) [15] and TOVE (in the business management domain) [16]. The domain ontology is a semantically rich model (it can express equivalence, inverse, disjunction, symmetry, transitivity, etc.), and is defined as an exhaustive list of concepts (ontology class) and relations between these concepts describing a particular domain (e.g. Medicine, Business, E-Government).

III. RELATED WORK

In a previous work [17], we proposed a pattern system as a guideline, to help organizations apply the alignment. In addition, a systematic literature review was conducted [18] to present various approaches to the alignment of business requirement, business process and software system levels, that use different modelling languages.

In this study, we focus on UML and BPMN languages, because they are standards defined by the Object Management Group (OMG). More precisely, we focus on a business process level modelled by BPMN and a software system level modelled by a UML class diagram.

BPMN and class diagrams are subjects of interest in different approaches. Amr et al. [19] propose an MDA approach for transforming a BPMN source model into a UML class diagram, using a set of transformation rules. Brdjanin et al. [20] present an approach for the automated generation of a conceptual database model represented by a UML class diagram from a single BPMN model. Brdjanin et al. [21] take a set of business process models into account. Khlif et al. [22] describe an approach to transform a business process model into a class diagram, based on aspects descriptions. Rhazali et al. [23] suggest a set of rules for transforming a BPMN model into a use case, state and class diagrams. Cruz et al. [24] propose an approach to obtain a data model from a business process model. Cruz et al. [25] present rules to transform a set of business process models into a data model. Kriouile et al. [26] describe an approach to transform a BPMN model into a domain class model. Bousetta et al. [27] propose an approach for building a domain class diagram based on a BPMN model, using a set of business rules.

In organizations, models of both levels usually exist. An analysis of existing approaches makes it clear that all existing approaches propose transformation from the source level into the target level. However, an approach-based transformation is not always sufficient to apply alignment when business process and software system models exist. In fact, these approaches can cause a loss of information. Fig. 1 presents the result of applying one of the existing approaches. M1 represents the business process level model, while M2 represents the software system level model.

Let X, Y and Z be three models belonging to business process level (M1). X contains elements A, F, K and I. Y contains elements B and J, while Z contains elements G and H. Model M2 contains elements D and E. The existing approaches can generate a new UML class diagram (M2’), containing T(A), T(F), T(K), T(I), T(B), T(G) and T(H), which represent the results of the transformation of elements A, F, K, I, B, G and H respectively.

We note that M2’ differs from model M2. Therefore, information D and E associated with the existing UML class diagram, will be lost after alignment (TABLE I, column 2). None of the existing approaches consider all BPMN elements frequently used in organizations (complete metamodel), which provide a detailed description of the models and which belong to the latest BPMN 2.0.2 specification [28], such as all task types or all data types (TABLE I, column 3). The majority of approaches take a single model at the source level into consideration. Only two existing approaches ([21] and [25]) have achieved transformation using a set of BPMN models as a source (TABLE I, column 4).

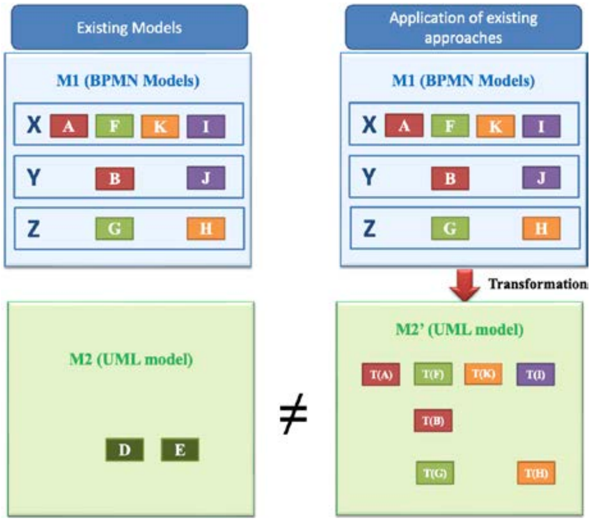

Fig. 1. Application of Existing Transformation Approaches.

TABLE I. SYNTHESIS OF APPROACHES

Ref.	Preserving information	Complete BPMN MM	Set of BPMN models	Syntactic aspect				Semantic aspect		
				Id	Inc	Ab	Ac	S	Hp	Hm
[19]	-	-	-	-	-	-	-	-	-	-
[20]	-	-	-	-	-	-	-	-	-	-
[21]	-	-	x	x	-	-	-	-	-	-
[22]	-	-	-	-	-	-	-	-	-	-
[23]	-	-	-	-	-	-	-	-	-	-
[24]	-	-	-	-	-	-	-	-	-	-
[25]	-	-	x	x	-	-	-	-	-	-
[26]	-	-	-	-	-	-	-	-	-	-
[27]	-	-	-	-	-	-	-	-	-	-

Because models X, Y and Z are usually created independently, they include many types of heterogeneity. All approaches considering a set of BPMN models align models elements syntactically. However, they only test identity: the string equality of elements. They do not detect other correspondences, such as inclusions (e.g. element A, “Medical Office” in X and element B, “Office” in Y), abbreviations (e.g. “Qty” and “Quantity”) and acronyms (e.g. "UOM" and "Unit Of Measure") (TABLE I, column 5). Moreover, none of these studies take semantic aspects into account (TABLE I, column 6). They do not detect synonymy (e.g. element F, "Doctor" in X and element G, "Medical Practitioner" in Z), homonymy (e.g. element I, "Invoice" (of Patient) in X, and element J "Invoice" (of Supplier) in Y), or hyponymy (a semantic relationship between terms where the meaning of one is included in another, more general term) (e.g. element K, “Patient” in X and element H, “Diabetic” in Z).

As shown in Fig. 1, these heterogeneities can cause conflicts when models are aligned and may introduce problems and inconsistencies in the resulting UML model. Indeed, if alignment approaches based on identity only consider two BPMN elements (belonging to X and Y) to be different when they are equivalent, they will introduce a false difference and therefore redundancy in the UML model. For example, we can find both T(A) “Medical Office” and T(B) “Office” in the UML model. Worse, considering two elements (belonging to X and Y) as equivalent when they are different will introduce a false equivalence, resulting in information loss in the resulting UML model. For example, only T(I) “Invoice” (of Patient) can be found in the UML model, and not “Invoice” (of Supplier). A generalisation relationship between hyponymic elements is also missing in the UML model. For example, the generalisation relationship between element T(K) “Patient” and element T(H) “Diabetic”.

We synthesize the existing approaches in TABLE I according to the following criteria: preserving information, considering complete BPMN metamodel (MM), considering a set of BPMN models, considering syntactic aspects (we note syntactic comparison, the comparison strings of model elements’ letters. It indicates if the approach detects identity (Id), inclusions (Inc), abbreviations (Ab) and acronyms (Ac)), and considering semantic aspects (we note semantic comparison, the comparison of the meaning associated with the model’s elements). It indicates if the approach detects synonymy (S), hyponymy (Hp) and homonymy (Hm). In TABLE I, “**x”** indicates that a criterion is considered.

This analysis of existing approaches reveals the need for an alignment approach that preserves existing information, uses a set of BPMN models and considers most used BPMN elements. Moreover, our objective is to propose how to find real equivalences and real differences and how to get UML result model without conflicts.

IV. PROPOSED APPROACH

A. *Overview of the Proposed Approach*

The aim of the proposed approach is to align the software system level with the business process level, without losing information and without conflict.

We present an alignment system in Fig. 2 that takes a set of BPMN models as input and outputs the resulting UML model. It encompasses two steps:

1) *Step 1: Comparison and transformation*

a) Comparison of BPMN models: Our goal is to provide a semantic comparison approach that also integrates syntactic aspects. The model comparison subsystem takes BPMN models as input and returns (1) a comparison table containing the correspondence between elements (equivalent, different and hyponymic elements) and (2) isolated elements (those without equivalent, homonym or hyponym in another model). It is a syntactic and semantic rules-based system (presented in section IV.C.1), driven by a comparison process. We use strategies based on semantic properties to take semantic aspects into account. Therefore, our system refers to a domain ontology that will provide semantically relevant information for decision-making during the comparison (example: two ontology classes are semantically equivalent, two elements are hyponyms presented by an ontology class and its ontology subclass, etc.).

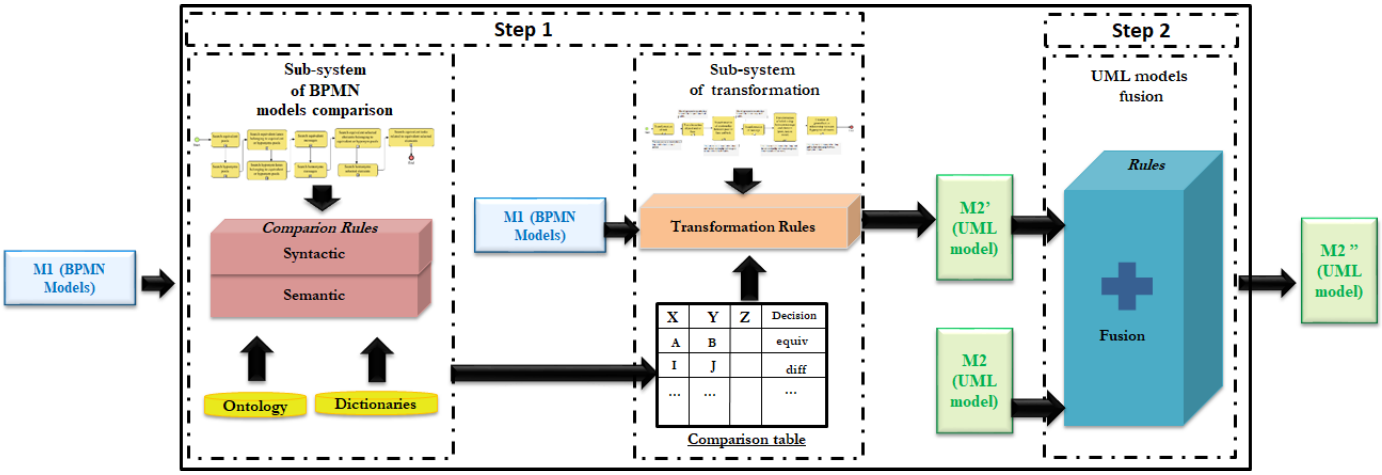

Fig. 2. Representation of Our Alignment Approach.

In addition, our system relies on several other resources to complete these comparisons. We use an acronym dictionary[1], an abbreviation dictionary[2], and a dictionary of synonyms[3].

b) Transformation of BPMN models into a UML model: This subsystem consists of the application of rules to transform a set of BPMN models (M1) into a generated UML class diagram (M2'), based on a comparison table and following a transformation process. Transformation rules based on MDA are presented in our previous work [29]. In the present work, we update the transformation process from BPMN models into a UML model, considering syntactic and semantic aspects (presented in section IV.C.2)).

By applying the rules of syntactic and semantic comparison, we can detect real equivalences and real differences, and thus obtain a UML result model without conflicts (Fig. 3). By identifying F and G as semantically equivalent, we are left with only one element, T(F), and therefore do not have redundancy in UML diagram M2'. Additionally, identifying A and B as syntactically equivalent results in only one element T(A), and thus no redundancy in M2'. Identifying I and J as homonyms produces two result elements, T(I) and T(J), in M2'. Finally, identifying K and H as hyponyms produces a generalisation relationship between the two resulting elements T(K) and T(H) in M2'.

2) Step 2: Fusion: This step consists of creating a fusion between the UML class diagram (M2') generated in step 1 and the existing UML class diagram (M2). We have previously demonstrated the results of this phase; the comparison and fusion meta-models were published in [30]. This solution also takes into account the syntactic and semantic aspects of the two class diagrams elements.

The result is a final UML class diagram (M2"). By applying the two steps illustrated in Fig. 3, the target level is completed, as it contains the information related to the existing class diagram (M2) as well as the information related to the generated class diagram (M2').

B. Example of BPMN Models

This approach can be applied to several BPMN models such us collaboration or process diagrams. In this section, we present a set of BPMN collaboration diagrams. To illustrate our approach, we use an example representing the business process level of a medical field.

A collaboration diagram can contain several elements: pool, lane, event, task, gateway, message flow, message, sequence flow, data, data association, artifact and association. A pool can refer to a process or can be a black box. A lane is a sub-partition within a pool; it can contain a set of events (facts that occur during the process), tasks (atomic work performed in a process), or gateways (controlling the convergence or divergence of flows in a process). A task can appear as a send task, a receive task, a service task, a user task, a manual task, a business rule task, or a script task. A message flow may contain a message (in the present work, we suppose that a message flow contains a message), and links source and target elements (pools, events, or tasks). A sequence flow connects a source and a target element (events, tasks, or gateways). Data provides information about what tasks need to be performed and/or what they produce. There are four types of data: data object, data store, data input or data output. A data association links source data or target data to a task. An artifact can be in the form of a group or a text annotation. It aims to provide more clarity to the process. An association links an artifact with a BPMN element.

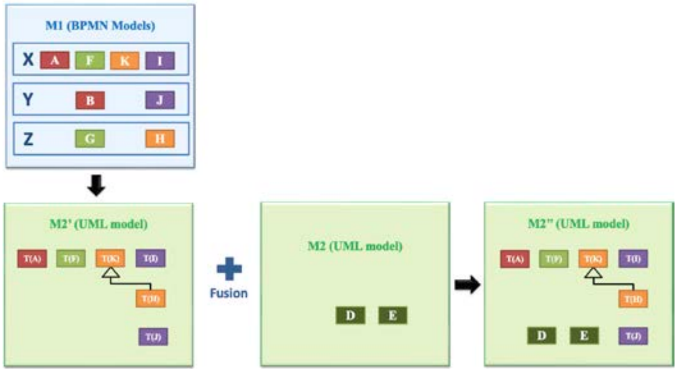

Fig. 3. Result Model without Conflicts or Information Loss.

[2] http://theleme.enc.sorbonne.fr/dico.php
[3] http://wordnet.princeton.edu/

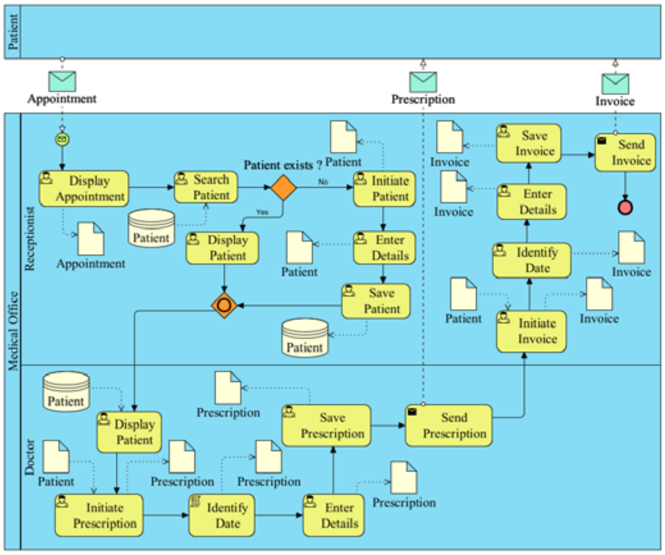

Fig. 4. Model X - Patient Consultation in a Medical Office.

Fig. 4 can illustrate the collaboration diagram (model X) for a patient consultation in a medical office. It is composed of two pools: “Patient”, which is a black box and “Medical Office”, which contains the lanes “Receptionist” and “Doctor”. The diagram begins when a patient arrives at the medical office. The receptionist performs the first task, “Display Appointment”, which has a data object “Appointment” as output. The receptionist then searches for the patient in a patient list. If a patient file exists, the receptionist displays the patient’s information. If not, the receptionist initiates the patient file, adds details and saves the file. The doctor then displays the patient file and initiates a prescription. The date of the prescription is identified. Then, the doctor enters details, saves the file, and sends the prescription. Next, the receptionist initiates an invoice, and its date is identified. The receptionist then enters details, saves the file, and sends the invoice.

Fig. 5 can represent the second collaboration diagram (model Y) placing orders with suppliers. It contains two pools: “Supplier”, represented as a black box, and “Office” which contains two lanes (“Assistant” and “Doctor”). The first task is “Initiate Purchase Order” performed by the assistant. It has as an output the data object “Purchase Order”. Then the date of the purchase order is identified. Next, the assistant adds details, and saves the purchase order. Then, the doctor displays, modifies and validates the purchase order. Next, the assistant sends the purchase order and then receives the invoice from the supplier.

Fig. 6 can illustrate the third collaboration diagram (model Z), for monitoring patients with diabetes. It contains two pools: “Diabetic”, represented as a black box, and “Medical Office”, which contains two lanes (“Assistant” and “Medical Practitioner”). The first task is “Search Patient File” executed by the assistant. Its input is the data store “Patient File”. If the patient is diabetic, the patient file is exposed. If the patient needs an appointment, the assistant initiates the appointment, adds details, saves and sends the appointment to the diabetic. Then the medical practitioner exposes the appointment.

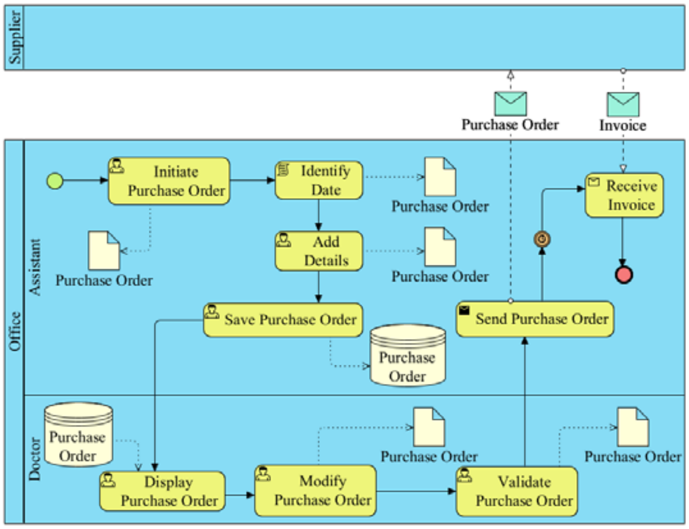

Fig. 5. Model Y - Ordering from Suppliers.

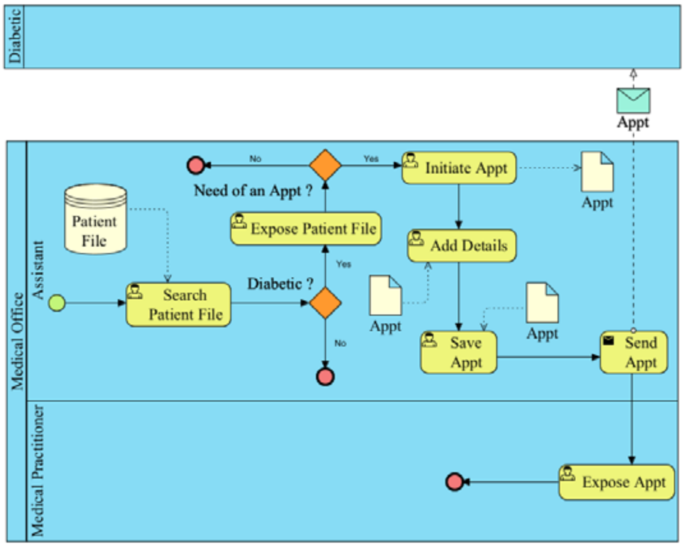

Fig. 6. Model Z - Monitoring Diabetics.

C. Comparison and Transformation Subsystems

In this section, we present the details of our approach. We first present the comparison of BPMN models, then the transformation of those BPMN models into a UML class diagram.

1) Comparison of BPMN models: Our goal is to compare BPMN models syntactically and semantically. To do so, we follow the model comparison process detailed in Section IV.C.1)a), which applies the BPMN element comparison rules described in Section IV.C.1)b).

a) Comparison process: We apply a comparison between each two models. To create a UML class diagram, we create classes before their operations. To do this, we first compare BPMN elements that will be transformed into classes: 1) *Pools, 2)* lanes, 3) messages and 4) data of non manual task and direct object (DO) of all types of task (except manual task) without data, send task that have a data in its input and receive task that have a data in its output). We call the fourth category of elements: “selected elements”. Next, we compare BPMN elements that will be transformed to operations: tasks related to equivalent selected elements.

The BPMN elements that will be transformed to associations, aggregations, attributes, and multiplicities [presented in Section IV.C.2)] are not concerned by comparison, because they are not named elements and therefore cannot be compared syntactically and semantically. The elements events, gateways, manual tasks, data related to manual tasks, sequence flows, and artifacts are not considered also in this comparison, because they will not appear in the resulting UML model (they do not have an equivalent in the UML class diagram).

In order to compare BPMN models, we follow the steps of the comparison process (Fig. 7), in this order: search equivalent pools, search hyponym pools, search equivalent lanes belonging to equivalent or hyponym pools, search hyponym lanes belonging to equivalent or hyponym pools, search equivalent messages, search homonym messages, search equivalent selected elements belonging to equivalent or hyponym pools, search homonym selected elements, and finally search equivalent tasks related to equivalent selected elements.

Pools are not concerned with homonymy because BPMN models are designed for the same domain. For example, if “office” is found in the first model meaning medical office, and "office" is also found in the second model, it will refer to a medical office there as well, and not, for example, a lawyer's office. The same is true for lanes: two homonymic lanes cannot belong to equivalent pools.

b) Comparison rules: We define a mathematical framework to express formally our approach. We present the comparison rules by the predicate language. So, we needed to express, in predicate logic, BPMN model (representing input of system), ontology and other resources (representing the system references). For that, we realised transformations, in the Model Driven Architecture (MDA) context:

i) The first transformation concerns BPMN model into logical model that generates a set of predicates representing BPMN elements to compare:

- Element(e,M): The element Pool or Lane “e” belonging to the model “M”.
- Pool(P,M): The pool “P” belonging to the model “M”.
- Lane (L,P,M) : The Lane “L” belonging to the pool “P”and the model “M”.
- Message (m, SourceP, TargetP,M): The message “m” relating the source Pool “SourceP” and the target Pool “TargetP”, belonging to the model “M”.
- SelectedElement(E, P, M) : The selected element “E”, belonging to the pool “P” and the model “M”.
- Task (T, in, out, L, P, M) : The task “T”, with the input data “in”, and the output data “out”, belonging to the Lane “L”, the pool “P” and the model “M”.

ii) The second transformation concerns OWL ontology (conform to an extract of OWL metamodel [31]) into logical model. The transformation generates a set of predicates representing OWL ontology, such as:

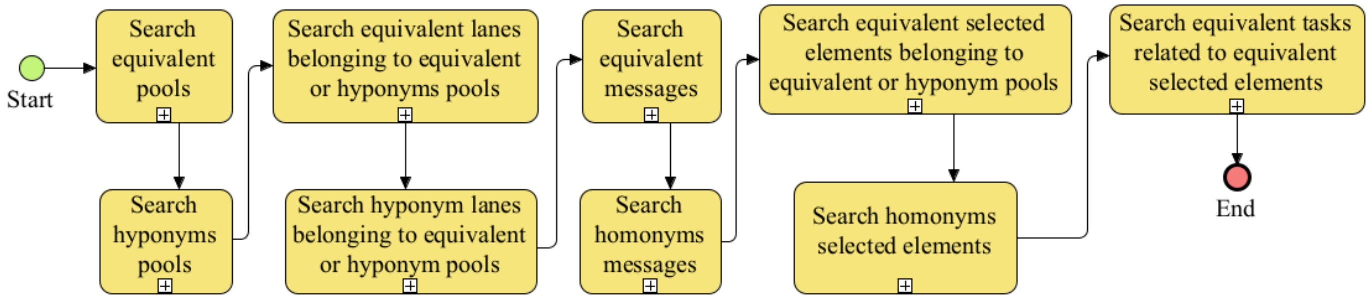
- equivalentOntoClass(C1, C2): The ontology classes “C1” and “C2” are equivalent.
- OntoSuperClassOf(C1, C2): The ontology class “C1” is subclass of the ontology class “C2”.

Other system references are presented as follows:

- DicAcronyms(elt1,elt2): “elt1” and “elt2” are acronyms.
- DicAbbreviation(elt1,elt2) :“elt1” and “elt2” are on abbreviation relation.
- DicSynonymy(elt1,elt2) :“elt1” and “elt2” are synonyms.

To complete rules expression, we define a set of facts from programming languages, such as equality of two strings, and inclusion of two strings:

- String(elt) : “elt” is a character string.
- InclusionString(s1,s2) : means that the character string “s1” is included in the character string “s2”.
- EqualString(s1,s2): The two strings “s1” and “s2” are equal.



Start
Search equivalent pools
Search hyponyms pools
Search equivalent lanes belonging to equivalent or hyponyms pools
Search hyponym lanes belonging to equivalent or hyponym pools
Search equivalent messages
Search homonyms messages
Search equivalent selected elements belonging to equivalent or hyponym pools
Search homonyms selected elements
Search equivalent tasks related to equivalent selected elements
End

Fig. 7. Comparison Process.

Our system is based on a set of comparison rules which are characterized by a name and it is composed of a set of parameters (e.g. elements to compare, first model and second model) that have a name. A rule can call one or more other rules.

We present the comparison rules of models below.

- CR1 : Rule of syntactic identity of elements

$$\mathrm{Syntactic\_Identity}(\mathrm{elt}_i, \mathrm{elt}_j) \Leftrightarrow \mathrm{EqualString}\ (\mathrm{elt}_i, \mathrm{elt}_j)$$

Two elements elt_i and elt_j are syntactically identical if and only if they have the same name.

Example: The pool “Medical office” in X and the pool “Medical office” in Z.

- CR2: Rule of syntactic equivalence of elements

$$\begin{array}{l}
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, \mathrm{elt}_j) \Leftrightarrow [\mathrm{Syntactic\_Identity}\ (\mathrm{elt}_i, \mathrm{elt}_j) \lor \\
\mathrm{InclusionString}\ (\mathrm{elt}_i, \mathrm{elt}_j) \lor \mathrm{InclusionString}\ (\mathrm{elt}_j, \mathrm{elt}_i) \lor \\
\mathrm{DicAcronyms}(\mathrm{elt}_i, \mathrm{elt}_j) \lor \mathrm{DicAbbreviation}(\mathrm{elt}_i, \mathrm{elt}_j)]
\end{array}$$

Two elements elt_i and elt_j are syntactically equivalent if and only if they are identical, or if there is a relationship of inclusion, acronym or abbreviation of them (according to dictionaries).

Example: The pools “Medical Office” in X and “Office” in Y.

- CR3: Rule of semantic equivalence of elements

$$\mathrm{Equivalence\_Semantic\_Elements}(\mathrm{elt}_i, \mathrm{elt}_j) \Leftrightarrow$$

$$\begin{array}{l}
[(\mathrm{DicSynonymy}(\mathrm{elt}_i, \mathrm{elt}_j) \lor (\exists e\ \mathrm{String}(e) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, e) \land \mathrm{DicSynonymy}(e, \mathrm{elt}_j)) \lor \\
(\exists c\ \mathrm{String}(c) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, c) \land \\
\mathrm{DicSynonymy}(c, \mathrm{elt}_i)) \lor (\exists e\ \mathrm{String}(e) \land \exists c\ \mathrm{String}(c) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, e) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, c) \land \\
\mathrm{DicSynonymy}(e, c)))
\end{array}$$

$$\begin{array}{l}
\lor (\mathrm{equivalentOntoClass}(\mathrm{elt}_i, \mathrm{elt}_j) \lor (\exists e\ \mathrm{String}(e) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, e) \land \mathrm{equivalentOntoClass}(e, \mathrm{elt})) \lor \\
(\exists c\ \mathrm{String}(c) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, c) \land \\
\mathrm{equivalentOntoClass}(c, \mathrm{elt}_i)) \lor (\exists e\ \mathrm{String}(e) \land \exists c\ \mathrm{String}(c) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, e) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, c) \land \\
\mathrm{equivalentOntoClass}(e, c)))]
\end{array}$$

Two elements elt_i and elt_j are semantically equivalent if and only if one of these conditions is satisfied:

- elt_i (or a character string syntactically equivalent to elt_i) is synonymous with elt_j (or a character string syntactically equivalent to e_j), according to a synonym dictionary.
- there are two classes in the domain ontology with the same names of elt_i and elt_j (or a character string syntactically equivalent to elt_i and elt_j), which are equivalent.

Example: The lanes “Receptionist” in X and “Assistant” in Y.

- CR4: Rule of hyponyms of elements (Pool or Lane)

$$\begin{array}{l}
\mathrm{Hyponym\_Elements}(\mathrm{elt}_i, \mathrm{elt}_j, M_i, M_j) \Leftrightarrow [\mathrm{Element}(\mathrm{elt}_i, M_i) \land \\
\mathrm{Element}(\mathrm{elt}_j, M2) \land (\mathrm{OntoSuperClassOf}(\mathrm{elt}_i, \mathrm{elt}_j) \lor (\exists e\ \mathrm{String}(e) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, e) \land \mathrm{OntoSuperClassOf}(e, \mathrm{elt}_j)) \lor \\
(\exists c\ \mathrm{String}(c) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, c) \land \\
\mathrm{OntoSuperClassOf}(\mathrm{elt}_i, c)) \lor (\exists e\ \mathrm{String}(e) \land \exists c\ \mathrm{String}(c) \land \\
\mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_i, e) \land \mathrm{Equivalence\_Syntactic\_Elts}(\mathrm{elt}_j, c) \land \\
\mathrm{OntoSuperClassOf}(e, c)))\ ]
\end{array}$$

An element (Pool or Lane) elt_i is a hyponym of an element elt_j if and only if, in a domain ontology, one ontology class with the same name of elt_i (or a character string syntactically equivalent to elt_i) is an ontology subclass of elt_j (or a character string syntactically equivalent to elt_j).

Example: The pool “Diabetic” in Z is a hyponym of the pool “Patient” in X.

- CR5: Rule of Equivalent Pools

$$\begin{array}{l}
\mathrm{Equivalence\_Pools}(P_i, P_j, M_i, M_j) \Leftrightarrow [\mathrm{Pool}(P_i, M_i) \land \mathrm{Pool}(P_j, M_j) \land \\
(\mathrm{Equivalence\_Syntactic\_Elts}(P_i, P_j) \lor \\
\mathrm{Equivalence\_Semantic\_Elements}(P_i, P_j)\ )]
\end{array}$$

Two pools P_i and P_j are equivalent if and only if they are syntactically or semantically equivalent.

Example: The pool “Medical Office” in X and the pool “Medical Office” in Z.

- CR6: Rule of Equivalent lanes

$$\begin{array}{l}
\mathrm{Equivalence\_Lanes}(L_i, L_j, M_i, M_j) \Leftrightarrow [\mathrm{Lane}(L_i, P_i, M_i) \land \mathrm{Lane}(L_j, P_j, M_j) \land \\
(\mathrm{Equivalence\_Syntactic\_Elts}(L_i, L_j) \lor \\
\mathrm{Equivalence\_Semantic\_Elements}(L_i, L_j))]
\end{array}$$

Two lanes L_i and L_j are equivalent if and only if they are syntactically or semantically equivalent.

Example: The lane “Doctor” belonging to the pool “Medical Office” in X and the lane “Medical Practitioner” belonging to the pool “Medical Office” in Z.

- CR7: Rule of Equivalent messages

$$\begin{array}{l}
\mathrm{Equivalence\_Messages}(m_i, m_j, M_i, M_j) \Leftrightarrow \\
[\mathrm{Message}(m_i\ \mathrm{SourceP}_i, \mathrm{TargetP}_i, M_i) \land \\
\mathrm{Message}(m_j, \mathrm{SourceP}_j, \mathrm{TargetP}_j, M_j) \land \\
(\mathrm{Equivalence\_Syntactic\_Elts}(m_i, m_j) \lor \\
\mathrm{Equivalence\_Semantic\_Elements}(m_i, m_j)) \land \\
((\mathrm{Equivalence\_Pools}(\mathrm{SourceP}_i, \mathrm{SourceP}_j, M_i, M_j) \lor \\
\mathrm{Equivalence\_Pools}(\mathrm{SourceP}_i, \mathrm{TargetP}_j, M_i, M_j) \lor \\
(\mathrm{Hymonym\_Elements}(\mathrm{SourceP}_i, \mathrm{SourceP}_j, M_i, M_j) \lor \\
\mathrm{Hymonym\_Elements}(\mathrm{SourceP}_j, \mathrm{SourceP}_i, M_i, M_j)) \lor \\
(\mathrm{Hymonym\_Elements}(\mathrm{SourceP}_i, \mathrm{TargetP}_j, M_i, M_j) \lor \\
\mathrm{Hymonym\_Elements}(\mathrm{TargetP}_j, \mathrm{SourceP}_i, M_i, M_j))) \land \\
(\mathrm{Equivalence\_Pools}(\mathrm{TargetP}_i, \mathrm{SourceP}_j, M_i, M_j) \lor \\
\mathrm{Equivalence\_Pools}(\mathrm{TargetP}_i, \mathrm{TargetP}_j, M_i, M_j) \lor \\
(\mathrm{Hymonym\_Elements}(\mathrm{TargetP}_i, \mathrm{SourceP}_j, M_i, M_j) \lor \\
\mathrm{Hymonym\_Elements}(\mathrm{SourceP}_j, \mathrm{TargetP}_i, M_i, M_j)) \lor \\
(\mathrm{Hymonym\_Elements}(\mathrm{TargetP}_i, \mathrm{TargetP}_j, M_i, M_j) \lor \\
\mathrm{Hymonym\_Elements}(\mathrm{TargetP}_j, \mathrm{TargetP}_i, M_i, M_j))))]
\end{array}$$

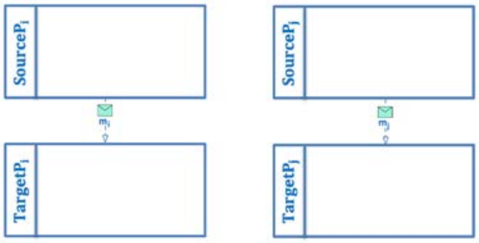


Fig. 8. Representation of Two Messages Mi and Mj.

Two messages m_i and mj (Fig. 8) are equivalent if and only if:

- they are syntactically or semantically equivalent.
- and their source and target pools are equivalent or hyponyms.

Example: The message “Appointment” connecting the pools “Medical Office” and “Patient” in X and the message “Appt” connecting the pools “Medical Office” and “Diabetic” in Z.

- CR8: Rule of homonym message

$$\begin{aligned}&\text{Homonym\_Messages}(m_i, m_j, M_i, M_j)\\ &\quad\Leftrightarrow [\text{Message}(m_i\ \text{SourceP}_i, \text{TargetP}_i, M_i)\\ &\quad\wedge \text{Message}(m_j, \text{SourceP}_j, \text{TargetP}_j, M_j)\\ &\quad\wedge \text{Equivalence\_Syntactic\_Elts}(m_i, m_j)\\ &\quad\wedge (\neg\text{Equivalence\_Pools}(\text{SourceP}_i, \text{SourceP}_j, M_i, M_j)\\ &\quad\vee \neg\text{Equivalence\_Pools}(\text{SourceP}_i, \text{TargetP}_j, M_i, M_j)\\ &\quad\vee \neg\text{Equivalence\_Pools}(\text{TargetP}_i, \text{SourceP}_j, M_i, M_j)\\ &\quad\vee \neg\text{Equivalence\_Pools}(\text{TargetP}_i, \text{TargetP}_j, M_i, M_j))]\end{aligned}$$

Two messages m_i and m_j (Fig. 8) are homonyms if and only if:

- they are syntactically equivalent.
- if at least one of their source or target pools are not equivalent.

Example: The message “Invoice” in X and the message “Invoice” in Y.

- CR9: Rule of equivalent selected elements.

$$\begin{aligned}&\text{Equivalence\_SelectetElements}(e_i, e_j, M_i, M_j)\ \Leftrightarrow\\ &[\text{SelectedElement}(e_i, P_i, M_i) \wedge \text{SelectedElement}(e_j, P_j, M_j) \wedge\\ &(\text{Equivalence\_Syntactic\_Elts}(e_i, e_j) \vee\\ &\text{Equivalence\_Semantic\_Elements}(e_i, e_j)) \wedge\\ &(\nexists m_i \text{Message}(m_i, \text{SourceP}_i, \text{TargetP}_i, M_i) \wedge\\ &\text{Equivalence\_Syntactic\_Elts}(e_i\ , m_i)\ \wedge\\ &\nexists m_j \text{Message}(m_j, \text{SourceP}_j, \text{TargetP}_j, M_j) \wedge\\ &\text{Equivalence\_Syntactic\_Elts}(e_j\ , m_j) \wedge\\ &\text{Homonym\_Messages}(m_i, m_j, M1, M2))]\end{aligned}$$

Two selected elements e_i and e_j are equivalent if and only if:

- they are syntactically or semantically equivalent.
- and there is no homonyms messages with the same name of selected elements.

Examples: The selected element “Patient” in X and the selected element “Patient File” are equivalent.

- CR10: rule of Homonyms selected elements

$$\begin{aligned}&\text{Homonym\_SelectetElements}(e_i, e_j, M_i, M_j)\ \Leftrightarrow\\ &[\text{SelectedElement}(e_i, P_i, M_i) \wedge \text{SelectedElement}(e_j, P_j, M_j) \wedge\\ &((\exists m_i \text{Message}(m_i, \text{SourceP}_i, \text{TargetP}_i, M_i) \wedge\\ &\text{Equivalence\_Syntactic\_Elts}(e_i\ , m_i)\ \wedge\\ &\exists m_i \text{Message}(m_j, \text{SourceP}_j, \text{TargetP}_j, M_j) \wedge\\ &\text{Equivalence\_Syntactic\_Elts}(e_j\ , m_j) \wedge\\ &\text{Homonym\_Messages}(m_i, m_j, M_i, M_j)) \vee\\ &((\text{Equivalence\_Syntactic\_Elts}(e_i, e_j) \wedge\\ &(\neg\text{Equivalence\_Pools}(P_i, P_j, M_i, M_j)) \vee\\ &\neg\text{Hymonym\_Elements}(P_i, P_j, M_i, M_j))]\end{aligned}$$

Two selected elements e_i and e_j are homonyms if and only if:

- there are homonyms messages with the same name of selected elements.
- or, they are syntactically equivalent and belong to non-equivalent and non-hyponym pools.

Example: The selected element “Invoice” in X and the selected element “Invoice” in Y.

- CR11: Rule of Equivalent tasks

$$\begin{aligned}&\text{Equivalence\_Tasks}(T_j, T_j, M_i, M_j) \Leftrightarrow [\text{Task}(T_i, \text{type}_{ti}, \text{dIN}_i, \text{dOUT}_i, L_i, P_i, M_i)\\ &\wedge \text{Task}(T_j, \text{type}_{tj}, \text{dIN}_j, \text{dOUT}_j, L_j, P_j, M_j)\\ &\qquad\wedge (\text{Equivalence\_Syntactic\_Elts}(T_i, T_j))\\ &\qquad\vee \text{Equivalence\_Semantic\_Elements}(T_i, T_j)]]\end{aligned}$$

Two tasks T_i and T_j are equivalent if and only if are syntactically or semantically equivalent.

Example: The task “Display Appointment” in X and the task “Display Appt” in Z.

c) Comparison table: We apply the process and the comparison rules on the examples of BPMN models presented in section IV.B, by referring to an ontology of the medical field as well as dictionaries. We choose OWL (Ontology Web language) ontology because it is a W3C[4] recommendation, and the metamodel OWL was defined by Ontology Definition Metamodel specification of OMG. To compare these models, we can find in ontology of medical domain several information. For a reason of space, we present bellow two information: Two equivalent ontology OWL classes, and the ontology OWL class “Patient” and its sub class “Diabetic”:

```
<owl:Class rdf:ID="Doctor">

<owl:equivalentClass rdf:resource="#Medical Practionnar"/>

   </owl:Class>

<owl:Class rdf:ID="Diabetic">

      <rdfs:subClassOf rdf:resource="#Patient"/>

</owl:Class>
```

[4] www.w3.org

TABLE II. COMPARISON TABLE

	X	Y	Z	Equiv syn/sem	Hypo	Hom	Decision	RCX	RCY	RCZ
Pools	Medical Office	Office	Medical Office	Yes	-	-	Equivalent	Medical Office	Medical Office	Medical Office
	Patient	-	Diabetic	-	Yes	-	Hyponymy	Patient	Diabetic	-
Lanes	Receptionist	Assistant	Assistant	Yes	-	-	Equivalent	Receptionist	Receptionist	Receptionist
	Doctor	Doctor	Medical Practitioner	Yes	-	-	Equivalent	Doctor	Doctor	Doctor
Messages	Appointment	-	Appt	Yes	-	No	Equivalent	Appointment	Appointment	-
	Invoice	Invoice	-	Yes	-	Yes	Different	Invoice_Patient	Invoice_ Supplier	-
Selected Elements	Invoice	Invoice	-	Yes	-	Yes	Different	Invoice_Patient	Invoice_ Supplier	-
	Appointment	-	Appt	-	-		Equivalent	Appointment	Appointment	-
	Patient	-	Patient File	Yes	-	No	Equivalent	Patient	-	Patient
Tasks	Display Appointment	-	Expose Appt	-	-	-	Equivalent	Display Appointment	-	Display Appointment
	Display Patient	-	Expose Patient File	-	-	-	Equivalent	Display Patient	-	Display Patient
	Search Patient	-	Search Patient File	-	-	-	Equivalent	Search Patient	-	Search Patient

We obtain the comparison table (TABLE II), after the elimination of duplicate elements. The first four columns present the elements of the models X, Y and Z to be compared, the fifth column presents whether or not the elements are syntactically or semantically equivalent. The sixth column shows whether or not the elements are hyponyms. The seventh column presents whether or not the elements are homonyms. The eighth column presents the final decision (equivalence, hyponymy or difference).

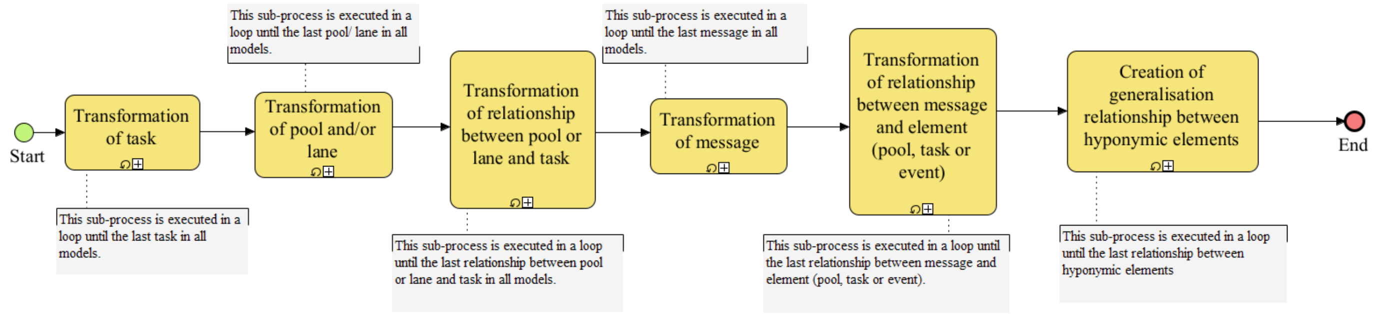
In order to choose the appropriate name of UML result elements (in the second subsystem of transformation), we base on the decision of column 8 to rename elements in the three last columns called RCM$_i$ (M$_i$ represents X, Y or Z), as following: (1) If the decision is "Equivalent", we rename the elements of model X, Y and or Z using the name of the first column. (2) If the decision is "Hyponymy", we keep the same name of the elements of the model. (3) If the decision is "Different", we use the name of the element and we add "_the name of the pool that is different to the pool of the other element".

2) Transformation of BPMN models into UML class diagram: In order to transform BPMN models into a UML class diagram we apply a transformation process (Fig. 9) based on the comparison table presented in section IV.C.1)c). This process is based on 18 transformation rules presented in detail in our previous work [29]. This process is presented in the form of a series of steps based on BPMN notation as follow (Fig. 9):

- Transformation of task: this sub-process is based on 12 rules related to tasks (considering their types and if they are linked to data or not) and call one other rule related to data. At the end of this step, the UML class diagram can be constituted of classes, attributes, operations, associations and multiplicities.
- Transformation of pool and/or lane: this sub-process generates classes, attributes, and aggregations after this step.
- Transformation of relationship between (pool or lane) and task: it generates associations and multiplicities.
- Transformation of message: it generates classes and attributes.
- Transformation of relationship between message and element (pool, task or event): it generates associations and multiplicities.

For those first fifth sub process, we:

- Identify an element "i" of a model M$_i$
- Apply the corresponding rule (according to the element identified). If the element belongs to the column M$_i$ in the comparison table, the name of the element (class or operation) that will be used corresponds to the RCM$_i$ column. In addition, a check is performed to determine whether an element (class, operation or association) of the class diagram has already been created by another rule. If it has:
    - o All the instructions associated with that rule are applied, except creation of the element.
    - o If an association already exists, such that the multiplicities are different, the existing association is kept, and the union of multiplicities is applied for each end of the association.



Start
Transformation of task
Transformation of pool and/or lane
Transformation of relationship between pool or lane and task
Transformation of message
Transformation of relationship between message and element (pool, task or event)
Creation of generalisation relationship between hyponymic elements
End
This sub-process is executed in a loop until the last task in all models.
This sub-process is executed in a loop until the last pool/ lane in all models.
This sub-process is executed in a loop until the last relationship between pool or lane and task in all models.
This sub-process is executed in a loop until the last message in all models.
This sub-process is executed in a loop until the last relationship between message and element (pool, task or event).
This sub-process is executed in a loop until the last relationship between hyponymic elements

Fig. 9. The Transformation Process.

- Creation of a generalisation relationship between hyponymic elements. In this sub-process, we:
  - o Identify hyponymic elements.
  - o Create a generalisation relationship between elements. When transforming an element "i" of model Mi, if the element belongs to the column Mi in the comparison table, the name of the element class that will be used corresponds to the RCMi column.

V. Case Study

In order to illustrate the application of the first step of our proposed approach, the three BPMN models represented in section IV.B, are transformed into a UML class diagram (Fig. 10) by applying our transformation process and rules and by referring to the comparison table. Resulted model represents the output of step 1 (M2' UML model).

We note that there is no redundancy in the classes. Indeed, for example, we find only the class "Medical Office" instead of having in addition the class "Office", only the class "Doctor, instead of having in addition the class "Medical Practitioner", only the class "Receptionist" instead of having in addition another class "Assistant", a single class "Appointment" instead of having in addition the class "Appt". Moreover, we don't find redundancies in class operations. In fact, for example, we find a single "displayAppointment()" operation, and not a second "exposeAppt()", we also found a single "displayPatient()" operation, and a single "searchPatient()" operation. Also, we don't find a loss information by finding the two classes "Invoice_Patient" and "Invoice_Supplier". Finally, we find a generalisation relationship between the "Diabetic" and "Patient" classes.

We present the resulted elements of the first step of transformation process (classes, attributes, associations, multiplicities) by black color. At the second step, the resulted elements (classes, attributes, aggregations, multiplicities) are illustrated using blue color. The resulted elements (associations and multiplicities) after the third step are mentioned using green color. After the fourth step, we didn't add new element because they were created in the previous steps. After the fifth step, the added or modified elements (associations, multiplicities) are illustrated by red color. Finally, we illustrate the resulted generalisation relationship, using yellow color.

To create the result UML model M2", we merge (by applying the fusion subsystem, already developed in our previous works), M2 model which can represent the existing software level in medical field and this M2' resulted model.

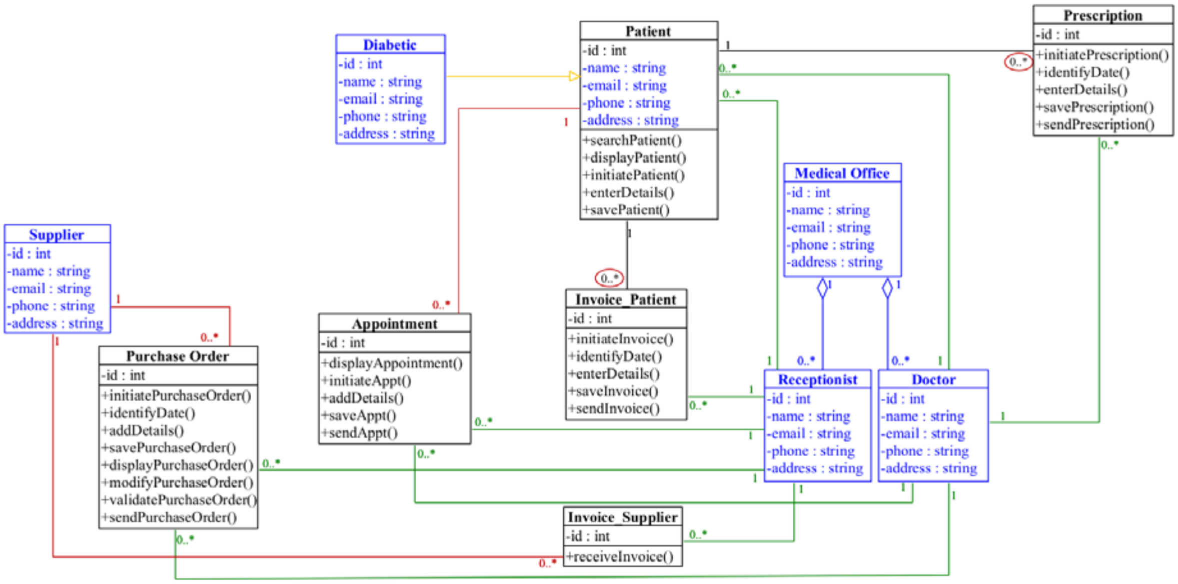


Fig. 10. Resulted Class Diagram UML Model M2'.

VI. Conclusion

In this paper, we propose a method for aligning software system level with business process level without conflicts, by considering a set of models at the source level.

We responded to the limitations of existing work. In fact, by applying the rules of syntactic and semantic comparison, we can detect real equivalences and real differences, and thus obtain a UML result model without conflicts. Indeed, by identifying two elements as semantically equivalent, we are left with only one element, and therefore do not have redundancy in UML diagram; additionally, identifying two elements as syntactically equivalent results in only one element, and thus no redundancy in result model. Identifying two elements as homonyms produces two result elements in UML model. Finally, identifying two elements as hyponyms produces a generalisation relationship between the two resulting elements in result model.

We have implemented a first version of our approach, which allows us to facilitate and automate the transformation phase. This was accomplished using the Java programming language in the Eclipse development environment. The tool takes a set of xpdl files as input. Each file is a representation of a BPMN model. An xmi file is generated from this input, which is later converted into a UML class diagram. It is tested through a case study in the field of telecommunications. Our intent is to update this module by considering syntactic and semantic aspects. We aim also proposing the alignment of BPMN models with UML model to realise a more complete alignment.

The syntactic and semantic comparison of BPMN models resulted in our work can be used in the first step of a research theme, which is the fusion of the BPMN models, in the context of organizations’ merge.

Multi-Task Reinforcement Meta-Learning in Neural Networks

Ghazi Shakah
Software Engineering Department, Faculty of Information and Technology
Ajloun National University, P.O. Box 43, Ajloun 26810, Jordan

***Abstract*—Artificial Neural Networks (ANN) is one of the main and widespread tools for creating intelligent systems. And, they are actively used for data analysis in many areas such as robotics, computer vision, natural language processing, etc. The learning process of ANN is one of the most labor-intensive stages in ANN. There are many different modifications of ANNs and methods for their training. Currently, deep neural networks are becoming one of the most popular methods of machine learning due to their effectiveness in areas such as speech recognition, medical informatics, computer vision, etc. It is known that ANN training depends on the type of input data. In this paper, reinforcement learning is considered, as popular method used in cases where information is reinforced by signals from the external environment with which the model interacts. The purpose of this paper is to develop a reinforcement meta-learning algorithm that would be efficient in terms of quality and speed of learning. However, despite the significant scientific progress in deep learning, existing algorithms are not efficient enough to solve problems in the real world. In addition, such algorithms require a significant amount of learning time, which complicates the development process. To solve these problems, the use of meta-learning or "learning to learn" algorithms has recently been especially relevant. The paper proposes an approach to reinforcement meta-learning using a multitasking weight optimizer. experimentally shown that the proposed approach is more efficient than the known MAML (Model-Agnostic Meta-Learning) algorithm. The proposed MAML SPSA-Track method shows an improvement in efficiency by an average of 4%, and MAML SPSA-Delta by 8%, respectively. Moreover, the last algorithm spends on average 2 times less time on push-v2 and pick-place-v2 tasks.**

***Keywords*—Multitasking; meta-learning; reinforcement learning; neural networks; optimization**

I. Introduction

Humans have an innate ability to learn new skills quickly and easily. For example, we can look at one instance of a knife and distinguish all knives from other cutlery such as spoons and forks. Our ability to learn new skills and quickly adapt to a new environment based on a small number of examples is not just limited to identifying new objects, learning a new language, or figuring out how to use a new tool; our possibilities are much more diverse. [1], [2]. In contrast, machines—specifically, deep reinforcement learning algorithms—generally learn quite differently [3]. They require very large amounts of data and computational resources to achieve acceptable performance. The reason why people can learn quickly and adapt to a new environment is that they use the knowledge gained from previous experience to solve new problems. Similarly, meta-learning uses little experience gained from data to solve new problems quickly and efficiently. Through this method, it is possible to significantly speed up the training of neural networks with reinforcement significantly. Neural networks with reinforcement require quite large amounts of training data and computational resources. Creating such datasets is costly, especially when you need to involve a domain expert. While pre-training is useful, these approaches become less efficient for domain-specific problems, which it still requires large amounts of task-specific labeled data to achieve good performance. In addition, some existing problems are characterized by a wide and unbalanced distribution of data, which can make it difficult to collect training examples [4]. On the other hand, it is possible to use a pre-trained network from another task and then finish training it on the current small training set. However, depending on the specifics of the problem, this is not always possible, especially if the task on which the neural network was trained is significantly different. It is important to note that the ability to quickly learn new tasks during model inference is something traditional machine learning approaches do not attempt. This is what makes meta-learning especially attractive. Meta-learning is particularly interesting and can be used for the following reasons [5].

- The ability to learn from just a few examples.
- Quick adaptation to new tasks.
- The ability to create more versatile systems.

Meta-learning is especially successful in situations where a large amount of data is required; for example, robots are tasked with learning new skills in the real world and often encounter new environments [6].

Finally, the task was formally set to develop a meta-learning algorithm with reinforcement of a machine learning model that would be efficient in terms of learning.

II. Literature Review

Meta-learning tries to gain general knowledge about the target area by learning the set of tasks belonging to it [7]. The idea of meta-learning is to train the model by showing it only a few examples for each class and [8] then test it on new examples from the same classes that were taken from the original dataset.

The author in [9] proposed a formal description of the few-shot learning task as meta-learning. The data set of each class is randomly divided into a support set and a query set. The support set consists of labeled examples that are used to predict classes of untagged examples from the query set. The set of classes at the training stage does not intersect with the set of classes at the testing stage.

The author in [10] introduced a multitasking loss function based on maximizing the Gaussian likelihood with a task-dependent uncertainty. The proposed single model for all tasks outperformed separate models for each task.

Subsequently, a multitasking approach was applied in [11] to solve the problem of character recognition from a small number of examples, which led to an improvement in the overall recognition efficiency compared to the base model.

The author in [12] established a close relationship between the optimization problems of multitask learning and optimization-based meta-learning. Different from existing works, this paper focuses on improving the meta-learning stage. Only inductive methods that use a meta-learning process without prior training are considered. To do this, MAML was chosen as an example of the use of optimization-based learning, since the works describing this method are among the most cited in this field.

III. Material and Method

A. The Task of Reinforcement Meta-Learning

Reinforcement learning (RL) is one of the methods of machine learning, the purpose of which is to find an optimal strategy for the behavior of the model in the environment and maximize the reward received from the environment throughout the entire time the model interacts with the environment. The main concepts in RL are the agent and the environment: The environment represents the world in which the agent lives and interacts. In Fig. 1, at each interaction step, the agent observes (perhaps only partially) the state of the environment [3]. While the agent then decides what action to take. The environment changes when the agent acts on it, but it can also change by itself. The agent also receives a reward from the environment, a number that tells him how good or bad the current state of the world is. Accordingly, the agent's goal is to maximize his total reward, called profitability. Reinforcement learning methods are approaches by which an agent can learn the desired behavior to achieve a goal [13].

Reinforcement meta-learning is meta-learning in the field of reinforcement learning. Usually, training and test problems are different, but they are taken from the same family of problems.

Let's we have a distribution of tasks, each of which is The Markov Decision Process (MDP).

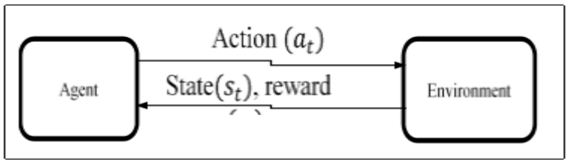

Fig. 1. The Cycle of Interaction between the Agent and the Environment [3].

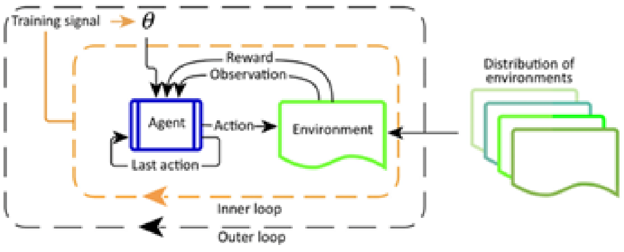

Fig. 2. A Meta-RL representation Containing Two Optimization Loops [4].

$M_i \in M$, where M_i is defined by the set $\langle S, A, P_i, R_i \rangle$. In Fig. 2, at each iteration of the external cycle, a new environment is selected and the parameters that determine the behavior of the agent are adjusted using the metal earning algorithm. In the inner loop, the agent interacts with the environment and maximizes the reward using a reinforcement learning algorithm [4], [14]. Note that the general state S and action space A, so the stochastic policy is:

$\pi_\theta: \mathrm{S} \times \mathrm{A} \rightarrow \mathrm{R}_+$

Will receive input data that is compatible with different tasks. Test items are selected from the same or slightly modified distribution M. In general, reinforcement meta learning is very similar to regular reinforcement learning, except that the last reward r_{t-1} and the last action $a_{t-1}$are also included in the observation in addition to the current state. s_t:

- In reinforcement learning $\pi_\theta(s_t) \rightarrow a$
- In Reinforcement Meta-learning $\pi_\theta(a_{t-1}, r_{t-1}, s_t) \rightarrow a$

This is done so that the policy will learn the changes between states, rewards and actions in the current MDP and can adjust its strategy accordingly. This is done so that the policy can assimilate the changes between states, rewards and actions in the current MDP and can adjust its strategy accordingly.

IV. Development of the Training Method

A. MAML Meta-Learning Algorithm

Reinforcement meta-learning uses two optimization loops: external and internal. During the outer loop, a meta-learning algorithm is applied. It is important to note that MAML is compatible with any model that can be trained using gradient descent, which is its main advantage. There aren't any restrictions on the loss function. The algorithm is applicable to such a wide range of problems as regression, classification, and reinforcement learning. MAML does not change the structure of the learning model, but only changes the network parameters in such a way that a small number of gradient descent steps are required on a small training dataset of a new problem to obtain a good generalization ability on this problem [15]. However, this algorithm requires taking second-order derivatives, which is the main disadvantage of this algorithm.

B. Method Formulation of the Problem

Despite the fact that there are a number of algorithms that do a good job of this kind of task, the speed of learning these algorithms, even on the most productive equipment, takes an extremely long time. Moreover, due to the dynamism and variety of tasks in the real world, the quality of the solution on new test problems can be much worse than the quality of training ones. So, the goal of this thesis is to develop a reinforcement meta-learning algorithm that would be effective in terms of quality and speed of learning. Also, during the execution of the work, the following tasks were set:

- Modify the basic MAML (Model-Agnostic Meta-Learning). An algorithm based on a multitasking approach.
- The tasks of deep learning, reinforcement learning, meta-learning, multitasking learning, and reinforcement meta-learning have been described.
- The main approaches to meta-learning were analyzed - based on models, metrics and optimization, and modern meta-learning algorithms for each approach.
- Compare the efficiency of the modified and unmodified algorithms.
- The common problem of low efficiency for these methods was analyzed in terms of both data and time resources spent on training the model.
- Formally, the task was to develop a meta-learning algorithm with reinforcement of a machine learning model that would be effective in terms of quality and speed of learning.

V. Software Implementation of the Console Application

A. Architecture and Composition

The console application was developed in the popular Python programming language for further experiments. Fig. 3 describes the standard process for developing a strategy model, along with the important modules associated with solving the problem.

Meta-World's ML1 environment was used as an environment for the agent. To implement the neural network of the agent, the torch.nn module of the well-known PyTorch framework was used. [16].

To realize the basic MAML algorithm and the proposed SPSA-Delta and SPSA-Track algorithms, the modules were optim and torch. Autograd was used, which presents various standard optimization algorithms for training neural networks. The training results were written to the hard disk using the torch.utils.tensorboard module. PyTorch is one of the most popular open-source machine learning frameworks in the Python programming language.

The main PyTorch modules that are used in the software implementation are: torch.nn, torch.optim, torch.autograd, torch.utils.tensorboard. The torch.nn module defines computational graphs and works with gradients, which makes it easy to build neural networks. The following module torch.optim introduces various optimization algorithms for training neural networks. The torch.autograd module implements the automatic differentiation method. The torch.utils.tensorboard module helps to save and visualize the results.

The first step in any deep learning project involves loading and processing training data. Reinforcement learning of a model consists of its interaction with the simulated environment. Meta-World allows you to design environments according to the Env interface of the Gym framework. First, we need to create the desired test, and then an instance of the environment. A task is assigned to the environment using the set_task() method from the corresponding already defined training and test tasks of the created test. In the current project, a function was described that returns an instance of the environment given the benchmark test and the task name task name.

The process of creating the environment of the Meta-World framework for the subsequent training of the model is shown in Fig. 4. The agent's interaction with the environment is implemented through the environment's step() method. For the convenience of interacting with the environment, the Runner class was described, an instance of which receives from the model the action to be performed, passes it to the simulated environment and receives from it information about the current state, the value of the reward, success rate and other metadata. Then, an instance of the ReplayMemory class collects all the received information about states, actions, etc. into the corresponding tensors in order to further transfer it to the main MAML algorithm for processing. The strategy is presented as a neural network. To create it, PyTorch uses the corresponding torch.nn module. It provides the implementation of all commonly used neural network components such as fully connected and convolutional layers, activation layers and associated loss functions.

The neural network representing the main strategy consists of one hidden layer with a size of 128 neurons and an activation function nn.Tanh() between the layers Fig. 5.

The input of the neural network is a vector of length 39 about the state of the ML1 Meta-World test environment, at the output the neural network gives a vector of length 4 about the next action by the agent in the environment.

            nn.Tanh()
        ).to(device)
```

Fig. 5. The Strategy Neural Network Initialization.

For each iteration of the meta-learning stage 10 training tasks were selected to obtain the needed data. The number of adaptation steps of the MAML algorithm was equal to 1, i.e. during testing, adaptation to a new problem occurred in one step of the gradient descent algorithm. The maximum length for a single task in the environment was 500. The maximum length for a single task in the environment was 500. The reward discount factor was 0.99.

During the adaptation phase, the weights of the neural network were changed with a learning rate factor of 1×10^{-4}, during the meta-learning phase 1×10^{-3}. The optimization method TRPO was used as a meta-optimizer with a maximum number of steps for linear search of 15 and a step of 5×10^{-3}.

The neural network was trained for 600 epochs for environment with reach-v2, pick-place-v2 tasks and 1200 epochs for push-v2. Also, the multitasking weight optimizer only started optimization after 50 epochs so that the model had time to adjust the initially randomized weights according to the task and environment.

B. General Description of the MetaWorld Environment

Meta World is an open-source simulated test for reinforcement meta-learning and multitasking learning, consisting of 50 different environments with robotic manipulations [17]. Task T in Meta World is defined as a set consisting of a reward function, an object's starting position, and its target position. Metal-earning makes two important assumptions:

1) Meta-training and meta-testing tasks have a common distribution $p(T)$.

2) The task distribution $p(T)$, has a general structure that can be used to effectively adapt to new tasks.

If $p(T)$, is defined as a family of variations within a specific problem, as in previous works [6], [10], then it is unreasonable to hope for a generalization to completely new problems. For example, an agent has little chance of being able to quickly learn to open a door without ever hitting a door before if it has only been trained on a set of uniform and narrow tasks during meta-learning. Thus, in order to allow reinforcement meta-learning methods to adapt to completely new tasks, a sufficiently large set of tasks is needed, where continuous changes in parameters cannot be used to describe the differences between tasks. In Meta World, all tasks are performed by a robotic arm. The action space is a set of two elements, consisting of changing the 3D space of the gripper.

Actions in this space range from -1 to 1. The observation space is represented as a set of 6 3D Cartesian positions of the gripper, a normalized measurement of how open the grip is, the 3D position of the first object, the quaternion of the first object, the 3D position of the second object, the quaternion of the second object, all previous measurements in the environment, and finally 3D position of the target. If there is no second object or the target is not supposed to be included in the observation, then the values corresponding to them are set to zero. The state space is always 39-dimensional. The reward functions for all tasks have the same value, which is in the range from 0 to 10, where 10 always corresponds to the fact that the task was solved. It should be noted that all tasks were implemented using the MuJoCo physics engine [18], [19], which allows to simulate the physical laws of the real world quickly and efficiently. The Multi-world interface [20] and interfaces of the popular OpenAI Gym environment [21] were taken as the basis, which makes this framework quite easy to use.

VI. Experimental Methodology

As an applied task for solving and evaluating the efficiency of the developed algorithms, we consider the ML1 test in the Meta-World environment. ML1 is aimed at evaluating the adaptation of the algorithm in several steps to change the goal within the same task. ML1 uses separate Meta-World tasks, where training tasks correspond to 50 random initial positions of objects and targets, and testing tasks correspond to 50 held positions. Algorithms are evaluated on three tasks from Meta-World:

- reach-v2.
- push-v2.
- pick-place-v2.

where either the position to be reached or the target position of the object varies. Target positions are not specified in world states, which forces reinforcement meta-learning algorithms to adapt to the target through trial and error.

In the reach-v2 task, the robotic arm needs to reach a target position, which is given randomly. The next push-v2 challenge is to push the puck towards the net. In the pick-place-v2 problem, it’s important to take and place the puck in the goal. The positions of the puck and the goal in the tasks are set randomly.

Since the reward values do not directly indicate the success of the chosen policy, Meta-World defines an interpretable success metric for each task, which is used as the main criterion. Since all tasks involve the manipulation of one or more objects in the target configuration, this success metric is usually based on the distance between the task-relevant object and its final target position, i.e.,$||o - j|| < \varepsilon$, where ε is the threshold, for example, 5 cm. The software implementation was carried out in the Python programming language version 3.8. The environment was modeled using the Meta-World framework version 2.0 together with the OpenAI Gym framework version 0.19. As noted earlier, MetaWorld contains ready-made implementations of various environments for meta-reinforcement learning and agent testing. To build models of neural networks, the PyTorch framework version 1.10 was used, which contains implementations of various layers and algorithms for optimizing neural networks.

VII. Analysis of Results

Fig. 6 shows the maximum success rate, averaged over 5 runs, in the ML1 Meta-World test environment. Based on the results obtained, all 3 algorithms do an excellent job of solving the reach-v2 problem both at the training and testing stages. On more complex push-v2 and pick-place-v2 tasks, the MAML SPSA-Delta algorithm is the most efficient among all those considered. The improvement relative to the basic algorithm was 17% at the training stage and 21% at the testing stage on the push-v2 task, 8% and 3% on the pick-place-v2 task, respectively. However, on the pick-place-v2 problem, the ability of the MAML SPSA-Delta method to generalize is not much higher than the MAML SPSA-Track algorithm (60% for MAML SPSA-Delta and 59% for MAML SPSA-Track). The following figures show examples of the moving average success rate for the reach-v2 task over 6×10^7steps in a test environment (Fig. 6 is the training phase, Fig. 7 is the testing phase). For all constructed charts, the moving average coefficient is 0.8. As can be seen from the graph, the modified MAML algorithms solve the problem no worse than the original MAML algorithm environment (Fig. 7 is the training phase; Fig. 8 is the testing phase). For all constructed charts, the moving average coefficient is 0.8.

As can be seen from the graph, the modified MAML algorithms solve the problem better than the original MAML algorithm. Now let's look at the moving average success rate plots for the following push-v2 task over 2×10^8steps in a test environment (Fig. 9 is the training phase, Fig. 10 is the testing phase). Compared to other tasks, the SPSA-Delta MAML algorithm took significantly longer to adapt to the environment and overtake the basic MAML method. The SPSA-Track algorithm also shows good results, but they do not differ significantly from the results of the unmodified MAML algorithm. Finally, let's analyze the constructed plots of the moving average success rate for the last pick-place-v2 task over 6×10^7 steps in the test environment (Fig. 11 is the training phase, Fig. 12 is the testing phase). It follows from the graph that both MAML algorithms with modifications are significantly more efficient at the testing stage than the original MAML algorithm.

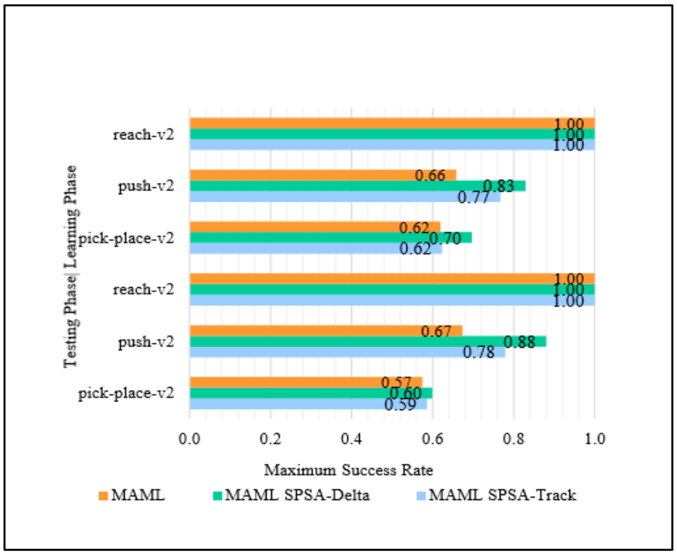

Fig. 6. The Maximum Success rate of Algorithms in the ML1 Meta-World Test Environment.

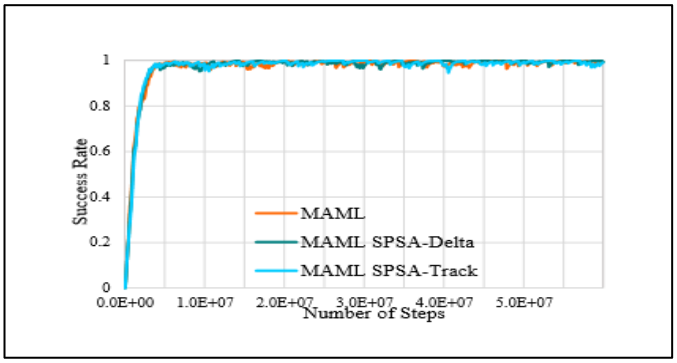

Fig. 7. Average Success Rate of Algorithms on the Reach-v2 Problem at the Training Stage.

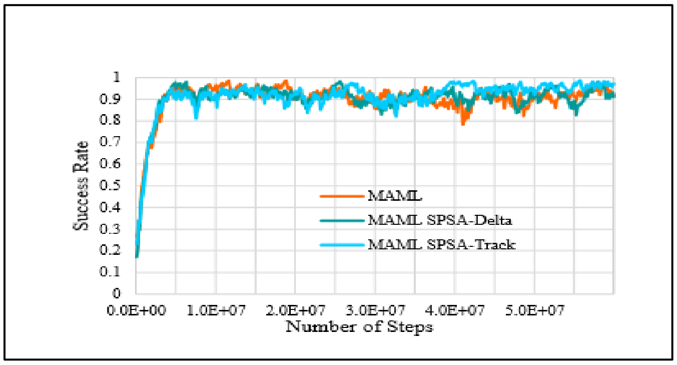

Fig. 8. Success Rate of Algorithms on the Reach-v2 Problem at the Testing Stage.

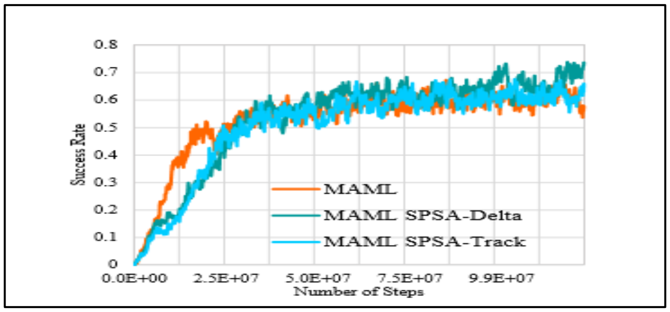

Fig. 9. Success Rate of Algorithms on the Push-v2 Problem at the Training Stage.

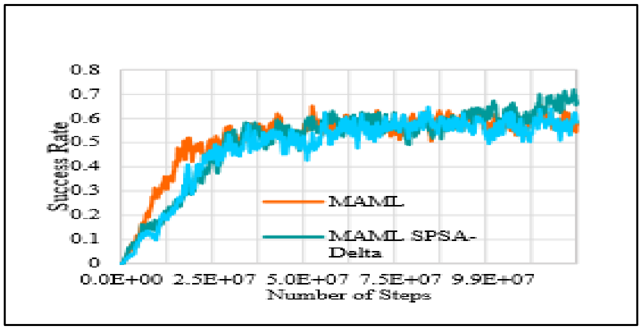

Fig. 10. Success Rate of Algorithms on the Push-v2 Task at the Testing Stage.

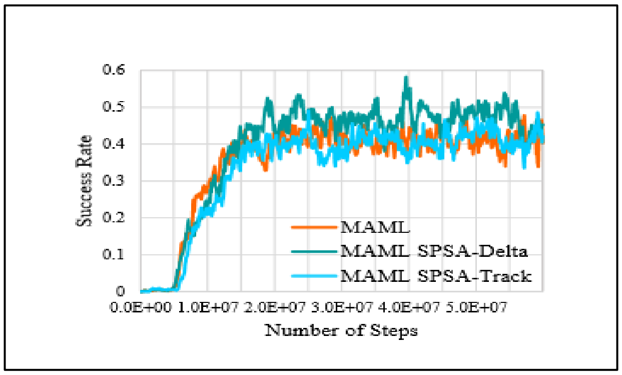

Fig. 11. Success Rate of Algorithms on the Pick-place- v2 Problem at the Training Stage.

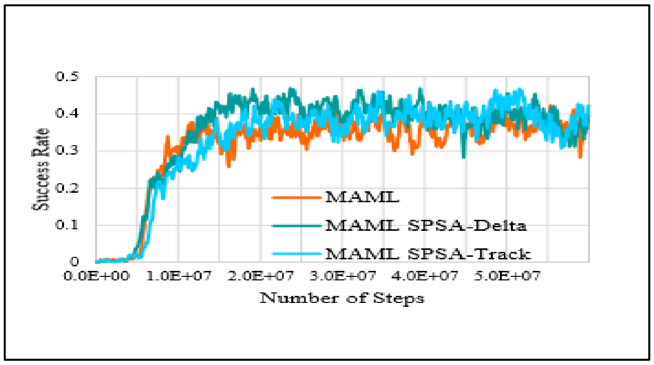

Fig. 12. Success Rate of Algorithms on the Pick-place-v2 Task at the Testing Stage.

Moreover, the MAML SPSA-Delta and MAML with SPSA-Track algorithms achieve the same high success rate, but the first algorithm learns 2 times faster than the second.

Consider the average maximum success rate achieved by each algorithm in the ML1 Meta-World test environment, information about which is shown in Table I.

Based on the results of experiments in the ML1 MetaWorld test environment with three different methods of deep reinforcement meta-learning: the original MAML algorithm, MAML SPSA-Delta, MAML SPSA-Track, the proposed MAML SPSA-Track method shows an average efficiency improvement of 4%, and MAML SPSA-Track Delta by 8%, respectively. Moreover, the latter spends on average 2 times less time for training on push-v2 and pick-place-v2 tasks. According to the obtained results, it is safe to say that the use of a multitasking loss function and its stochastic approximation with simultaneous perturbation can significantly improve the efficiency of deep reinforcement learning algorithms.

TABLE I. MAXIMUM SUCCESS RATE AVERAGED OVER ALL TASKS IN THE ML1 META-WORLD TEST ENVIRONMENT.

Algorithms	**Learning Phase**	**Testing Phase**
MAML	**76%**	75%
MAML SPSA-Delta	84%	83%
MAML SPSA-Track	80%	79%

VIII. CONCLUSION

Based on the tasks of deep learning, reinforcement learning, meta-learning, meta-learning with reinforcement and multitasking learning and their relevance are described.

After making comparison of the basic MAML algorithm with the proposed MAML SPSA-Delta and MAML SPSA-Track by conducting computational experiments to train the agent on reach-v2, push-v2, pick-place-v2 tasks in the ML1 Meta World test environment, it was concluded that the MAML SPS-Track algorithm is on average 4% more efficient compared to the original MAML method, and the MAML SPSA-Delta algorithm is 8% more efficient. Moreover, the last algorithm spends on average 2 times less time on push-v2 and pick-place-v2 tasks.

Data Fusion Model of Road Sensors based IoT Feature Clustering

Hua Yang*
Civil Engineering Department
Guangxi Vocational Normal University, Nanning, China

***Abstract*—The collection of traffic data can play a role in analyzing and predicting highway design, planning, and real-time traffic management. The accuracy requirements for road dynamic data collection are low, and the accuracy is usually 3%-5%. However, it is required that vehicles can pass at high speed and obtain traffic information such as vehicle classification and vehicle speed. The prerequisite for the application of Internet of Things (IoT) technology to road information monitoring lies in the research and development of sensor technology in the perception layer and communication technology in the network layer, so that can obtain a large amount of perception data to serve the development and application of algorithms. To achieve the goal of low-cost and long-term monitoring of comprehensive traffic information and road service status information, this paper constructs a road vibration monitoring system, carries out road vibration monitoring under complex road environments, and proposes a traffic information monitoring method driven by road vibration data. By deploying the pavement vibration monitoring system in the actual road, the original signal of pavement vibration under the action of vehicle moving load is obtained. Through smooth processing and eigenvalue extraction, the monitoring of vehicle speed, wheelbase driving direction, vehicle load position and traffic flow is realized. The experimental results prove that the analysis of the road dynamic response under working conditions, as well as smoothing processing and eigenvalue extraction, the numerical modeling method in this paper realizes the monitoring of the position of the vehicle load and the traffic flow. The calculation error of vehicle speed and wheelbase is within ±4%, which is helpful to find the characteristic index of road vibration signal for evaluating road service status, and provides a reference for the application of road vibration response in road damage early warning and scientific maintenance.**

Keywords*—Traffic data; Internet of Things (IoT) technology; perception sensors; vibration monitoring; k-means++ algorithm

I. Introduction

The road is the infrastructure for all kinds of trackless vehicles and pedestrians. Road transportation can realize the reasonable allocation of production materials, integrate various resources, promote the flow of materials, talents, information and funds between regions, and ultimately promote economic development [1]. Due to factors such as heavy traffic, heavy-axle trucks, high tire pressures, and harsh weather conditions, many roads have developed fatigue cracking, loose materials, rutting and other diseases, which are likely to cause traffic congestion and accidents. It also severely shortens the service life of the road and reduces the driving efficiency [2]. How to extend the service life of roads and improve the efficiency of transportation under the actual driving load and the external environment has always been a hot issue of concern to the academic and industrial circles at home and abroad. Therefore, it is necessary to establish a comprehensive, intelligent and long-lasting road dynamic response monitoring system to understand the road dynamic response under vehicle load in time. Furthermore, real-time monitoring of road service status and road traffic conditions is carried out to realize scientific road maintenance and intelligent traffic control [3].

Many road information monitoring projects have been carried out at home and abroad. For example, more than 400 sensors are embedded in the test section of the intelligent highway in Virginia, USA to collect data such as stress and strain, temperature and humidity, and traffic volume [4]. Literature [5] develops a stress-based analytical model of pavement performance by burying strain gauges inside the pavement, and points out that the impact of temperature and water on pavement performance should be considered. Literature [6] acquires the lateral and longitudinal strain information of the road surface under different vehicle loads under various working conditions by embedding stress and strain sensors, and establishes the relationship function between the pavement structure modulus and the stress and strain. These works have made many contributions to road dynamic response monitoring. However, because the road structure is different from other building structures, its distribution area is wide, and it is affected by vehicle load and environmental factors for a long time. These will lead to some shortcomings in the existing embedded monitoring system [7], such as the large size of the sensor, which destroys the original road structure after being buried. A large amount of on-site data collection is difficult to process in real time, causing communication jams and data redundancy problems. The data acquisition system is complex and heavy, with high energy consumption, which causes a lot of inconveniences when placed on site. The installation and maintenance cost of the monitoring system is too high. The monitoring data is affected by many factors, and the error of the system monitoring results may become larger as time changes [8]. However, most of the MEMS sensors for stress, strain and displacement monitoring are still in the experimental stage. There are many challenges in applying MEMS sensors to actual road monitoring. Short-term effects such as high temperature, humidity and corrosive environment in construction and long-term effects such as freeze-thaw cycle and vehicle load in actual road structure must be considered. The communication and energy supply of the sensors must also be considered.

*Corresponding Author.

To effectively solve the above problems, this paper uses the IoT technology to monitor the dynamic response information of the road under the action of the moving load of the vehicle, and realize the monitoring of the traffic and structure service status. The road acceleration sensing node collects and analyzes the road vibration response data under the moving load of the vehicle, and carries out the numerical simulation of the road dynamic response, so that can obtain the comprehensive traffic analysis of the impact of the road vibration data under the moving vehicle load on the results. Eventually, intelligent traffic control and scientific road maintenance will be realized, which can improve driving efficiency and extending road service life. It will not only significantly reduce the cost of the monitoring system, but also contribute to the popularization and application of the system.

The innovations of this paper are as follows:

1) A method for road vibration data monitoring is proposed, and a sensor node for road vibration monitoring based on the Internet of Things is developed.

2) Clustering is based on the characteristics of road vibration data, and comprehensive information monitoring methods are used to construct monitoring indicators.

3) The k-means++ algorithm is used for clustering analysis, and the vibration data indicators are domesticated, which improves the accuracy of the algorithm.

II. Related Work

A. Monitoring Technology of Road Vibration

Now, acceleration sensors have been used in the health monitoring of bridge structures. Research and practice show that vibration information can reflect the health of the structure. In the field of road engineering, the application of accelerometer is in the experimental research stage, but it shows a broad application prospect. It can be used not only for traffic information monitoring, but also for road structure state monitoring [9].

There are still many challenges in the application of acceleration sensors to road information monitoring. Due to the complex road driving environment, embedded acceleration sensors often experience data packet loss under wireless transmission. Embedded installation may cause the accelerometer battery power to be difficult to meet the long-term monitoring requirements. If the battery capacity is increased, the volume of the package node will increase and the original road structure will be destroyed. The vibration signal of the road surface under the moving load of vehicles is affected by many factors, such as axle load, vehicle speed, load acting position, node embedding depth, road structure, pavement material, vehicle suspension system, and road surface smoothness. The traditional empirical model is difficult to clarify the relationship between the vibration signal and the load on the road. Moreover, the amplitude of road vibration under vehicle load is very small. How to obtain accurate measurement values in complex interference environments, such as traffic noise, traffic in adjacent lanes, etc. How to ensure that the signal processing algorithm is simple and efficient to achieve real-time data processing and energy saving. How to package and protect the sensor so that it can withstand vehicle loads and the long-term impact of harsh environments [10]?

B. IoT Technology

With the development of time, especially with the development of computer communication technology, Internet technology, and sensor technology, the concept of the IoT has undergone considerable changes. The IoT is a kind of network that connects various networks through sensor equipment in accordance with the agreed protocol to exchange and communicate information, which can realize intelligent identification, positioning, tracking, monitoring and management [11].

It can be seen from the concept of the Internet of Things that the Internet of Things has the following characteristics: The first is a comprehensive perception, which uses RFID (Radio Frequency Identification), sensors or other sensing technologies to collect dynamic information of objects in real time. The second is to transmit the sensed information reliably in real time through various communication networks. The third is intelligent processing, using computing and other technologies to intelligently store and process massive amounts of information to realize communication between people-to-people, people-to-things, and things-to-things. These three characteristics correspond to the three-layer typical architecture of the IoT, namely, the perception layer, the network layer and the application layer. The perception layer provides perception data in the physical world, the network layer provides a link between information transmission and terminal communication, and the application layer provides diversified IoT applications [12].

Now, there are relatively few researches on the application of IoT technology to road information monitoring. The premise of the application of IoT technology to road information monitoring lies in the research and development of sensor technology in the perception layer and communication technology in the network layer, so that can obtain a large amount of perception data to serve the development and application of algorithms [13].

III. Establishment of Finite Element Model for Pavement Structure

A. Model Parameter Setting

1) Structure and material parameters: A three-dimensional finite element model of the structure and materials of the expressway is established. The pavement is mainly composed of an asphalt surface, a semi-rigid base, a sub-base and a soil base [14]. "Code for Design of Highway Asphalt Pavement" (JTGD50-2006) is referred to obtain the material parameters of each pavement structure, as shown in Table I.

The material parameters of AC-30 are estimated by referring to the lower limit value of AC-25 material parameters. Rayleigh damping is used to simulate material viscosity. The damping ratio of the pavement structure is generally between 0.02 and 0.2, and is set to 0.05 [15].

TABLE I. PAVEMENT STRUCTURE AND MATERIAL PARAMETERS

Material	Layer	Thickness of layer (cm)	Elastic Modulus Mpa	Poisson's ratio	Density kg/m^3	Damping ratio
SMA-16	Upper	4	1400	035	2400	0.05
AC-25	Middle	5	1200	0.35	2400	0.05
AC-30	Lower	7	1000	0.35	2400	0.05

2) Model size: The size of the road model (x, y, z) is 9.0m x 6.5m x 4m, the X-axis is the longitudinal direction of the road, the Y-axis is the lateral direction of the road, Z is the vertical direction of the road, and the driving direction is along the positive direction of the X-axis. The road model uses an eight-node linear reduced integral equal-parametric unit (C3D8R), and the road model is divided into 119016 units by the grid [16]. When dividing the grid, the grid in the load movement area is dense, and the distance gradually becomes sparse, as shown in Fig. 1.

The grid length*width of the load movement area is 2cm*2cm. The SMA, AC-25, and AC-30 in the surface layer are divided into two layers of grids in the vertical direction. The model is fixed around the normal direction, and the bottom is fixed in three directions. The contact between the surface layer and the base layer is completely continuous. Due to the small deformation of the soil foundation, the sub-base layer and the soil foundation are bound by Tie binding, which can appropriately reduce the number of grids and improve calculation efficiency [17]. The load movement area is the middle of the model, and the distance from the boundary is at least 3m, which reduces the influence of boundary conditions on it. The boundary conditions of the model and the load movement area are shown in Fig. 2.

B. Random Non-uniform Moving Load Setting

1) The size of the load changes with time: According to the established vehicle model, the road surface level is set as B-level road surface, and the vehicle speed is 10m/s. The random dynamic load of the vehicle on the road is obtained, as shown in Fig. 3.

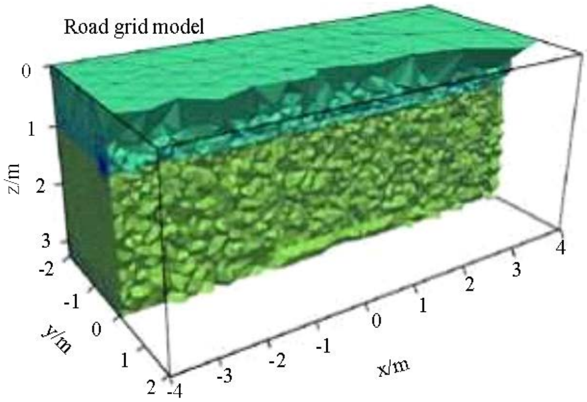

Fig. 1. Grid Road Model.

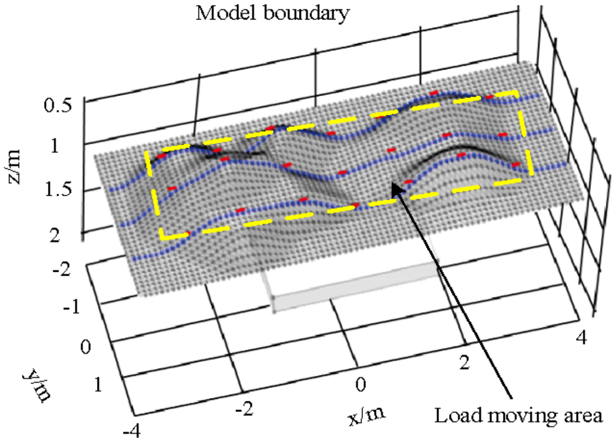

Fig. 2. Model Boundary Conditions and Load Moving Area.

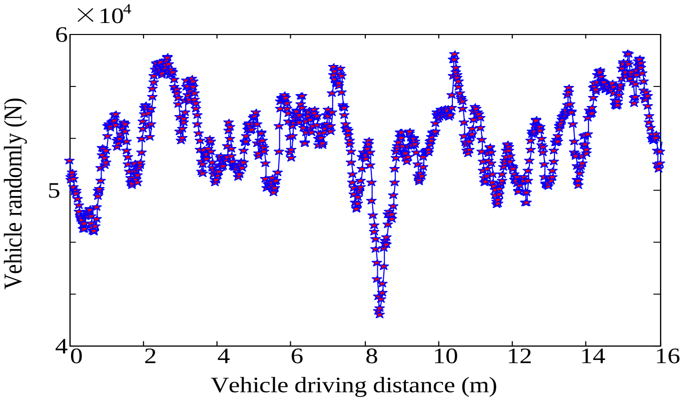

Fig. 3. Random Dynamic Load of the Vehicle.

2) The load size is distributed with space: To obtain a more realistic road dynamic response, it is necessary to consider the randomness and spatial distribution characteristics of vehicle load. After clarifying the dynamic load of the vehicle, by considering the actual contact between the tire and the road surface, a more realistic contact force distribution can be obtained. The contact between the vehicle tire and the road surface is surface contact, and its loading area can be simplified as a rectangular area [18]. In the rectangular area, the load distribution is affected by the tire tread, and the size changes with space. Fig. 4 shows the tire contacting the ground curve. The loading area of the tire on the road is a rectangular area of 20cm*18cm, which is affected by the tire pattern and forms five strip-shaped loading areas.

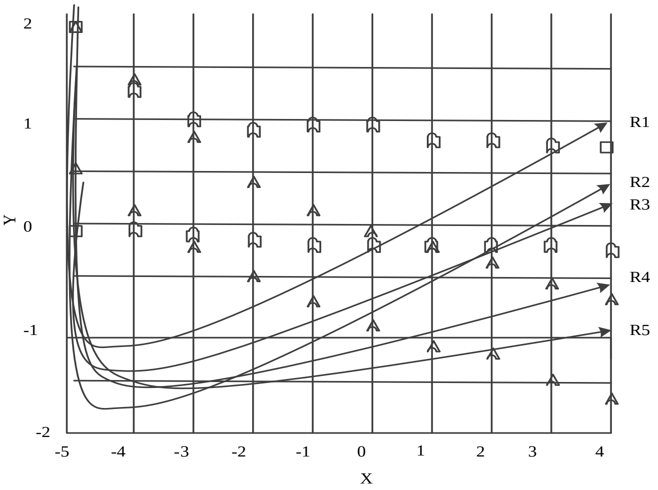

Fig. 4. The Actual Contact between the Tire and the Road.

When the vehicle moves in a straight line at a constant speed, the load amplitude ratio of the central area (R3), the side areas (R2, R4) and the edge area (R1, R5) are about 1:0.9:0.5. Moreover, in each rectangular area, the spatial distribution of the vertical load along the driving direction can be simplified to a half-sine function [19].

3) Application of Random non-uniform moving load: To simulate the moving random non-uniform load, the secondary development of the DLOAD subroutine was carried out based on the finite element software ABAQUS. Parameter analysis is as follows:

a) Sensitivity. The sensitivity of acceleration sensing node refers to the variation of sensor output voltage corresponding to the change of unit acceleration during static measurement. Therefore, the sensitivity of the acceleration sensing node can be obtained by calculating the relationship between the given acceleration and the output voltage.

b) Noise. Due to the inevitable existence of the external vibration and interference, the output signal of the sensing node includes not only the device noise of the sensing structure and the electrical noise of the signal processing module, but also a large part of the output signal is caused by external vibration and interference. Analyze the output voltage data when the sensitive axis of the acceleration sensing node is in the horizontal position.

c) Resolution. The resolution of the sensing node is the minimum variation of the acceleration that can be detected under certain conditions. The resolution can be obtained from the sensitivity and noise.

The specified coordinate function COORDS(*) and time function TIME(1) are applied to define the loading area and realize the movement of the load [20]. Equation (1) indicates that the loading area moves at a constant speed along the X-axis, and the positive direction of the X-axis is defined as the driving direction.

$$X = COORDS(1) - V \times TIME(1) - X_0 \tag{1}$$

Where COORDS(1) is the X-axis coordinate value of the integration point in the load movement area, X_0 is the initial X coordinate value corresponding to the load, V is the vehicle speed, and TIME(1) is the value of the step time [21]. Therefore, X is the X-axis coordinate value of the integration point in the load movement area corresponding to the moving coordinate system.

Equation (2) represents the spatial distribution of the load at time t, which is simplified to a half-sine function along the direction of travel.

$$Y = COORDS(2) - Y_0 \tag{2}$$

Where COORDS(2) is the y-axis coordinate value of the integration point in the load movement area, the direction of the y-axis is perpendicular to the driving direction, and Y_0 is the initial Y coordinate value corresponding to the load. $abs(X) \le \frac{b}{2}$ defines the length of the load application area, $abs(Y) \le \frac{c}{2}$ defines the width of the load application area, and α is the ratio of the load amplitude [22]. R3 is set to 1, R2 and R4 are set to 0.9, R1 and R5 are set to 0.5. b is the length of the load action area along the direction of travel, R3 is 18cm, and R1, R2, R4 and R5 are 16cm. c is the width of the load action area perpendicular to the driving direction, and the width of each small rectangle is set to 3cm. S is the actual contact area, which is the sum of the areas of R1 to R5. It is the pressure set at the integration point in the load action area corresponding to TIME(l), and is the random load value generated by the two-degree-of-freedom vehicle model [23].

The random non-uniformly distributed moving load is realized by Equation (3).

$$\begin{aligned} &If\ \ abs(X) \le \frac{b}{2} ab(Y) \le \frac{c}{2} \\ &Then\ P(t) = a \times \frac{F(t)}{S} \times \sin\frac{\pi}{b} \times X + \frac{\pi}{2}) \end{aligned} \tag{3}$$

The vehicle speed is set to 10m/s, and the length of the load movement area is set to 3m.

Therefore, the total duration is 0.3 seconds. The increment time is set to 0.001s, which is consistent with the random load sampling frequency (1000Hz). If the loading time is short enough, it can be considered that the applied load is a continuously moving load.

IV. Feature Clustering of vehicle data collection

Feature clustering is used to analyze the data of similar vehicles, which can find out the abnormal vehicle weight among similar vehicles.

1) Feature clustering: The goal of feature clustering is to find k cluster centers for the data set, so that the sum of squared distances from each point to its nearest cluster center is the smallest. Since k-means clustering randomly selects the initial cluster center, and the location of the initial cluster center will affect the clustering result. Therefore, the k-means++ algorithm is used to avoid the influence of random initialization on the result. The steps of the feature clustering algorithm are:

Step 1: A sample from the data set X is randomly selected as the initial cluster center c_I .

Step 2: A new cluster center c_I is taken, and the shortest distance is calculated between each sample $x \in X$ and the existing cluster center, that is, the distance to the nearest cluster center, denoted by $D(x)$. Calculating the probability $\frac{D(x)^2}{\sum_{x\in X} D(x)}$ that each sample is selected as the next cluster center.

Step 3: Repeating step 2 until k cluster centers are selected.

Step 4: For each sample xxx in the data set, its distance is calculated to the k cluster centers, and classified into the cluster corresponding to the cluster center with the smallest distance.

Step 5: For each category c_I , recalculating its cluster center that is the centroid $c_I = \sum_{x\in X}\frac{1}{|c_I|}$ of all samples belonging to that category.

Step 6: Repeating steps 4 and 5 until the position of the cluster center no longer changes.

2) Analysis of abnormal vehicle weight: In this paper, the cluster analysis of the two types of car models is carried out to find outliers. The analysis steps are as follows:

Step 1: Vehicle speed, temperature, and amplitude are normalized, its range is (0,1).

Step 2: K-means++ algorithm is used for clustering analysis. Because it is the same type of vehicle, the category is set to category 1.

Step 3: The coordinates of the center point are obtained, and the distance is calculated between each sample point and the center point.

Step 4: The sample points far from the center point are found out, that is, the outliers in this category.

Step 5: Since the vehicle weight is positively correlated with the amplitude, the sample point with the larger amplitude in the outlier is the point with the larger vehicle weight in the sample data.

The clustering method can be used to find outliers in the data set, which not only improves the efficiency of overweight vehicle inspection, but also reduces the energy consumption of the monitoring system. With the increase of training sample data, the accuracy of the system will be further improved, which can improve the inspection efficiency of overweight vehicles. Moreover, the camera-equipped in the system can be used as a controlling executive. When the system judges that the vehicle is abnormal, it can trigger the camera to start taking pictures instead of real-time video recording or taking pictures of all passing vehicles, which can improve the pertinence and save system energy.

3) Sensor network architecture: Using a fixed threshold for classification will increase the computational complexity and reduce the computational fault tolerance. Therefore, using the ANN (Artificial Neural Networks) for vehicle classification is easy to establish a nonlinear system model, and its programmed calculation method can reduce the complexity of the model, which is conducive to model deployment.

The ANN model has a three-layer structure, including input layer, hidden layer and output layer, as shown in Fig. 5.

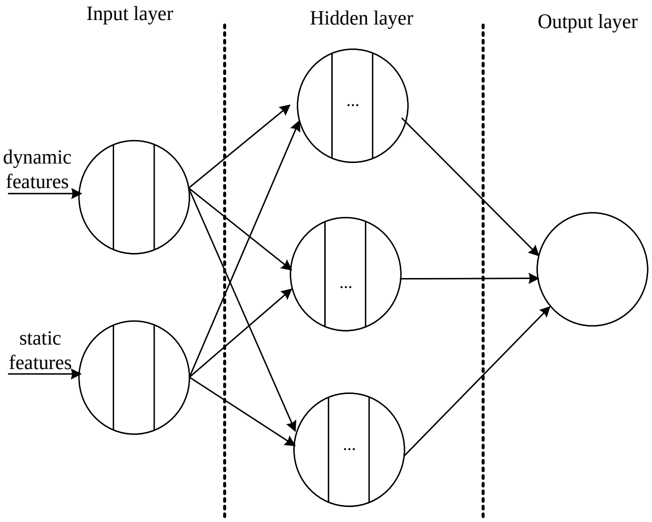

Fig. 5. Sensor Network Architecture.

The input layer contains 10 input parameters, and the vibration amplitude is the sum of the amplitude of each node in the third group. The output layer has only one node; the number of nodes in the hidden layer is set as P; to determine the optimal P value, the network with different P values is trained. When the accuracy of the trained network output is the highest, the P value is considered to be the optimal value.

V. Model Validation

To verify the rationality of the road model, the simulated data are compared with the measured data. The measured strain data comes from the fiber Bragg grating (FBG) sensor embedded on the Beijing Sixth Ring Expressway. The FBG sensor is used to measure the three-way strain response of the road surface under the moving load of the vehicle. The measured vibration data comes from the road vibration monitoring on the G320 highway. Compared to the verified monitoring points, monitoring point A is selected for comparative analysis of strain and vibration response, and monitoring point B is chosen for comparative analysis of strain response.

Wireless data transmission is also possible when the sensor platform is embedded in asphalt and concrete structures. Due to power constraints, the range of RF data transmission is limited to 40 feet. The data is transmitted through an RF wireless link located about 4 meters away from the monitoring point. The ratio of analog data to actual data is 1:100.

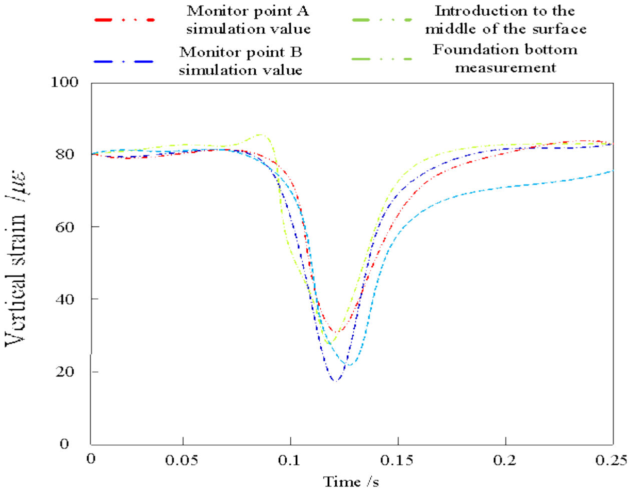

Fig. 6. Comparison of Simulated Data and Measured Data.

Fig. 6 compares the simulated data with the measured data.

It can be seen from Fig. 6 that the simulated and measured strain data match well in trend and size, and the maximum difference between the two is only about 15%. There is a deviation between the two curves, one is due to the inevitable difference between the simulated material parameters and the measured material parameters, and the other is the randomness of the vehicle dynamic load.

A. *The Stress Extreme Value Distribution in the Longitudinal Monitoring Area*

Under the situation of random non-uniform load and constant non-uniform load, the distribution of extreme longitudinal stress for pavement structure is compared. The constant non-uniform load considers the influence of tire pattern, and its contact area is the sum of the areas of R1 to R5. However, regardless of the randomness of the load, the rated load of the vehicle is adopted, and the size is 4900kN. The monitoring area is shown in Fig. 7.

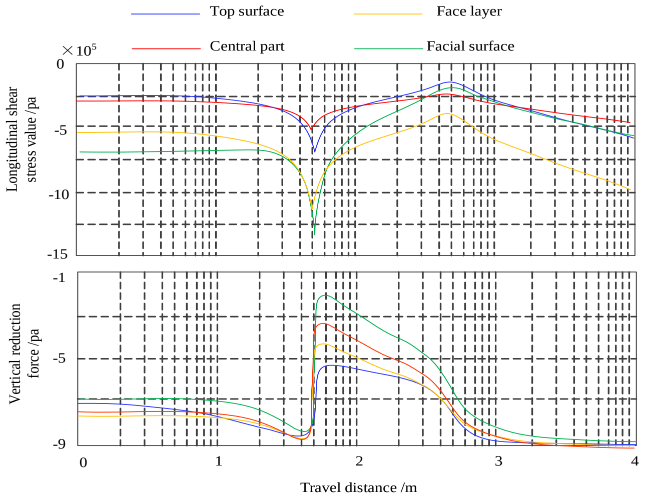

Fig. 7. The Stress Extreme Value Curve of the Longitudinal Monitoring Area of each Layer for the Pavement.

Fig. 7 shows that under the action of random non-uniform load, the extreme stress of each layer of the road surface is constantly changing, and its change characteristics are similar to the change characteristics of the vehicle's random dynamic load. However, under the action of constant non-uniform load, the extreme stress of each layer of the pavement remains unchanged. Under the action of random non-uniform load, the pavement stress fluctuation characteristics become less obvious with the increase of pavement depth. It can be seen that the random non-uniform load has a greater impact on the upper pavement structure. Moreover, under the action of random non-uniform load, the maximum stress of each layer of the pavement structure is greater than the stress extreme under the action of constant non-uniform load. And the damaging effect of random non-uniform load on the pavement is greater than that of constant non-uniform load.

B. *Distribution of Stress Extremes in the Lateral Monitoring Area*

The vertical stress extreme value is the largest when the vehicle travel distance is X=0.46m. The stress extreme value distribution of the lateral monitoring area at this position is analyzed. The horizontal monitoring area is shown in Fig. 8.

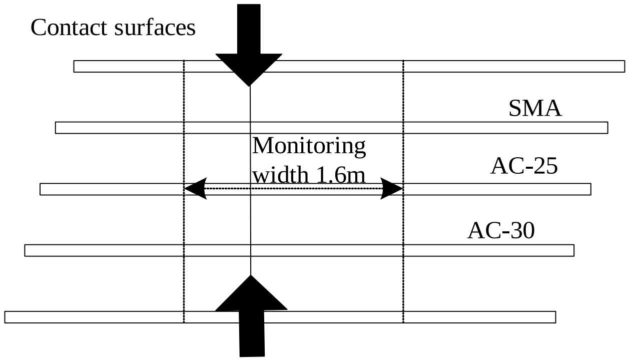

Fig. 8. Schematic Diagram of Lateral Monitoring Area at X=0.46m.

The six areas, such as the middle of SMA, the middle of AC-25, the middle of AC-30, the top of the base, the middle of the base, and the top of the base, are selected. The width of the monitoring area is 1.6m. The distribution of extreme vertical stress in the monitoring area under random non-uniform load, constant non-uniform load, and constant uniform load are compared and analyzed. For a constant uniform load, regardless of the tire pattern, the contact area is rectangular 18cm*20cm, and the rated load of the vehicle is used, and the size is 4900kN. Fig. 9 shows the distribution curve of the extreme vertical stress in the lateral monitoring area.

In comparison with Fig. 9, the uniform load has no stress concentration characteristics, while for non-uniform load, the vertical stress extreme value distribution on the road surface layer is obviously affected by the tire tread pattern. The stress distribution law is similar to the tire pattern distribution law, and the maximum stress is at the center of the tire. Secondly, there are obvious stress peaks at the stripes on both sides. As the depth increases, the overall vertical stress becomes smaller, and its spatial distribution is less affected by the tire tread. It can be seen that the spatial distribution of the load has a greater impact on the upper pavement structure.

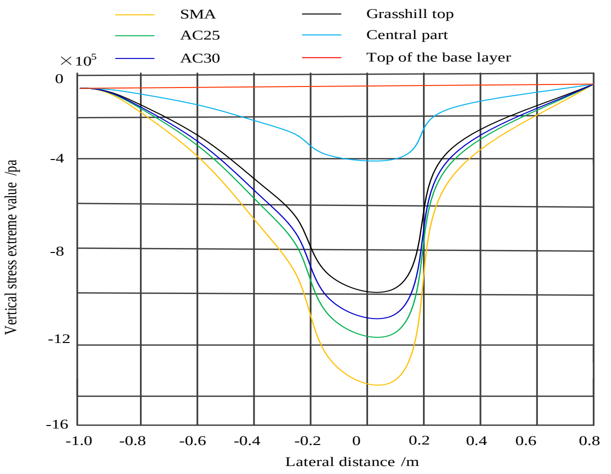

Fig. 9. The Distribution Curve of the Extreme Vertical Stress in the Lateral Monitoring Area.

Fig. 10 compares the maximum vertical stress extremes in each monitoring area.

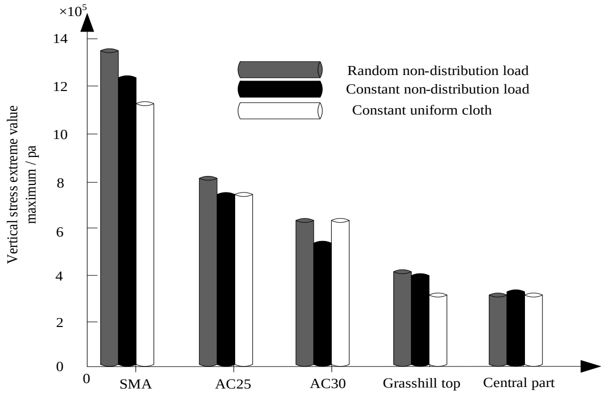

Fig. 10. The Maximum Value of the Extreme Vertical Stress in Each Lateral Monitoring Area.

Fig. 10 shows that in the middle of the SMA, the maximum stress extreme value under random non-uniform load is 32.75% higher than the maximum stress extreme value under constant uniform load. In the middle of AC25, the maximum stress extreme value in the random non-uniform load is only 11.25% higher than the maximum stress extreme value in the constant uniform load. And below the AC30 structural layer, the maximum stress extreme value of the constant uniform load is the highest, but its value is only 1.94% higher than the maximum stress extreme value under the random non-uniform load. It can be seen that as the depth increases, the difference between the maximum stress extremes for the three types of loads continues to decrease. Since the influence of the tire pattern of the vehicle, the stress distribution of the road surface layer is uneven. When the pressure is transferred to the base layer through the surface layer, the uneven stress gradually transforms into the uniform stress. In a word, if the spatial distribution characteristics of the vehicle load are ignored, the damaging effect of the vehicle load on the road surface will be underestimated.

VI. Conclusion

This paper studies the road perception nodes of road vibration monitoring based on the IoT technology, collects road vibration signals under the action of vehicle moving loads, and analyzes the characteristics and influencing factors of road vibration signals to carry out on-site monitoring. The dynamic response of the road surface under the action of random and non-uniformly distributed moving loads is simulated, and the characteristics of the road surface vibration signal under different working conditions are analyzed, and the characteristic evaluation index of the road service state is found. Finally, after the experimental analysis of the model, it is proved that different dynamic loads, surface materials and structural integrity will have a significant impact on the road vibration, and the characteristics of the road vibration signal are significantly different. In which vibration amplitude, time-domain signal waveform and frequency distribution can be used as potential evaluation indicators of road service status. Main research contents are as follows:

1) A road acceleration sensing node used for the road vibration monitoring is developed, which not only has the sensing function, but also can process, store and transmit data. The node resolution can reach 0.199 mg, can withstand the pressure of more than 67.54 Mpa, and has good waterproof packaging.

2) The road vibration amplitude is affected by the vehicle speed, vehicle weight and load position. The vehicle speed and vehicle weight are positively correlated with the road vibration amplitude, and the load position is negatively correlated with the vibration amplitude. Once the load position deviates from the monitoring point, the vibration amplitude at the monitoring point will rapidly attenuate.

3) By simulating and analyzing the dynamic response characteristics of pavement under actual loads, a method for characterizing the service state of pavement based on vibration data is proposed.

This paper realizes the road vibration monitoring under the moving load of the vehicle, and solves some technical problems of the application. In future work, the road vibration IoT monitoring prototype system can be further improved, which includes the self-powered design and performance optimization of the front-end sensing node. Its packaging and installation methods can be compatible with the characteristics of the road structure and construction technology. Through more experimental tests, the obtained monitoring results can be calibrated, and the distributed calculation and real-time processing of data can be realized.

***Abstract*—A protection platen is a vital component in relay protection systems. The manual inspection of protection platen states is long-term repetitive work with low efficiency and imposes a heavy burden on workers. In this work, we propose a new system to automatically detect the states of multi-type protection platens in images. This system can classify two protection platen categories and further recognize the states of protection platens. For the classification of protection platen types, we propose a new algorithm that automatically detects two protection platen types based on HSV (Hue, Saturation, Value) color space weighting operators. The proposed operators quantify the color variation in the protection platen and reduce the influence of environmental factors. With respect to the state recognition of protection platens, the Type-I protection platen states are automatically classified by the YOLOv5 (You only look once version 5) network. Since the Type-II protection platen has three primary states and more complicated structures, we investigate a new parallel multi-decision algorithm to recognize the states of Type-II protection platens based on the newly proposed watershed-color space difference-shape feature (W-CD-SF) method and the YOLOv5 network. The W-CD-SF technique can segment the protection platens and extract their shape features automatically. This multi-decision mechanism improves the robustness and generalization of state recognition. Experiments were conducted on the collected protection platen images containing 8,969 protection platens. The recognition accuracies of protection platen states exceed 95%. This system can provide auxiliary detection and long-term monitoring of protection platen states.**

Keywords—Protection platen; parallel multi-decision; YOLOv5 network; watershed-color space difference-shape feature

I. Introduction

Relay protection systems ensure the security and stability of power system operation. A protection platen is a vital component in relay protection systems [1,2]. Protection platens require manual inspection during the operation process, and such inspection is long-term repetitive work with low efficiency, which places a heavy burden on workers [3,4]. An automatic tool can help relieve the aforementioned burden on and improve inspection efficiency. With this objective, image processing techniques can be adapted to provide auxiliary detection and long-term monitoring of protection platens.

There are many types of protection platens in relay protection systems. The most commonly used types, defined as Type-I and -II protection platens are illustrated in Fig. 1. The Type-I protection platens are shown in Fig. 1(a) while the Type-II protection platens are figured in Fig. 1(b). Type-I protection platens have two categories of states, i.e., “on” and “off,” while Type-II protection platens have three categories of states, i.e., “on,” “off,” and “standby.”

In existing studies, most researchers have conducted experiments based on the images of Type-I or -II protection platens. The relevant details of previous works are the following.

1) Image processing methods for recognizing different protection platen states: Gao Jian et al. [5] eliminated the influence of shadows in images caused by illumination based on the improved Otsu threshold method and adopted the Graham algorithm to detect the states of Type-II protection platens. They achieved a detection accuracy of 96.5% for 200 shadow images. Yao Jingyan et al. [6] used the RANSAC method to restore the highlight area and evaluated the state of the Type-II protection platen by calculating the dip angle of the plate’s edges. They tested their method with 200 images and achieved an accuracy of 93%. Zhenhan et al. [7] proposed a method of automatic recognition of protection platen states based on improved sparse representation. First, they detected highlight areas in images by evaluating the maximum distances between two classes and eliminated the detected highlight areas by the improved sparse algorithm. Then, the protection platen states were recognized by their calculated minimum external rectangle. The detection accuracy of Type-II protection platens in 240 images reached 97.92%. Chen Yueqing et al. [8] proposed an improved image searching algorithm that used the background-difference and optical flow methods to extract foreground objects and recognized the Type-I protection platen switch states based on extracted edges. However, this study does not provide recognition results for specific samples. Li Tiecheng et al. [9] automatically recognized the Type-I protection platen and its corresponding text label based on an image processing technique. Combined with a model clustering and matching algorithm, the protection platens’ row number and column number in images are obtained. The recognition accuracy is obtained by comparing the calculated locations and the manually labeled locations. Fu

Wenlong et al. [10] recognized the Type-I protection platen states based on morphological processing. They applied their method to the images collected from different places, and most of the protection platen states could be detected. The specific detection results were not given in their research.

2) Deep-learning networks for recognizing different protection platen states: Yuan Tuolai et al. [11] used the RPN algorithm to generate a detection box and delimit the search range and then used the trained fast RCNN algorithm to detect the valuable features in this range. The accuracy of detecting the Type-I protection platen states exceeded 94%. Based on the YOLOv5 algorithm, Shi Baohua et al. [12] proposed the EYOLO algorithm, designed the local residual aggregation module, globalized the local residual characteristics, and embedded the spatial attention mechanism into the residual block to maximize the role of the local residual module. The recognition accuracy of the Type-I protection platen states reached 94.07%. Chen Xiang et al. [13] proposed an improved target detection algorithm based on a lightweight perception-v3 network. The protection platen switch states are recognized based on the migration learning strategy. The experiment was conducted on 48 Type-I protection platen images. Yang Qianwen et al. [14] proposed a bilinear fine-grained recognition method. They integrated an attention mechanism to realize end-to-end recognition of Type-II protection platen states.

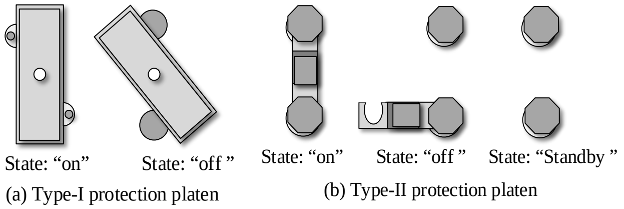

Fig. 1. Illustration of (a) Type-I and (b) Type-II Protection Platens.

The above studies illustrate that image processing methods and deep-learning networks can effectively detect protection platen states. However, these studies still have some limitations in practical applications. To overcome these limitations, we propose a new automatic state recognition system of multi-type protection platens based on the YOLOv5 and parallel multi-decision algorithms. The contributions of this work are as follows.

1) The existing studies can only recognize the states of one type of protection platen, namely a Type-I or -II protection platen. However, there are various types of protection platen in the actual operating environment. To solve this problem, we propose a new system that can classify multiple protection platen types and further recognize the states of protection platens automatically.

2) The proposed protection platen classification algorithm automatically detects two protection platen types based on HSV color space weighting operators. The proposed operators quantify the color variation in the protection platen region of interest (ROI) and reduce the influence of environmental factors through the operator weight settings of the H, S, and V color vectors.

3) A new parallel multi-decision algorithm is proposed to recognize the states of a Type-II protection platen in which parallel multi-decision is achieved by the newly proposed watershed-color space difference-shape feature (W-CD-SF) method and the YOLOv5 network. The W-CD-SF technique can segment the protection platens and extract their shape features automatically. The W-CD-SF with a support-vector-machine (SVM) classifier and YOLOv5 network classify the Type-II protection platen states in parallel, and then a fusion scheme is proposed to obtain the final detection results. This mechanism improves the robustness and generalization of the Type-II protection platen states recognition system.

II. Methods

Automatic protection platen states recognition can help relieve the burden on workers, improve inspection efficiency, and provide long-term monitoring. In this section, we detail a new system that can classify two protection platen categories and further recognize the protection platen states automatically. First, two types of protection platens are classified by the newly designed HSV color space weighting operators. Second, two states of a Type-I protection platen are automatically classified using the YOLOv5 network. Compared with the Type-I protection platen, the Type-II protection platen has three basic states and more complicated structures. In this work, a parallel multi-decision algorithm is proposed based on the proposed W-CD-SF method and the YOLOv5 network. The structure of this system is depicted in Fig. 2.

A. Automatic Classification of Protection Platen Types based on HSV Color Space Weighting Operators

Automatic protection platen states classification is an important part of power protection system inspection. There are two commonly used protection platen types, and to detect protection platen states the types of protection platens are classified first. Based on the HSV color space, an automatic classification of the protection platen category algorithm is proposed in this work, and the method is shown in Fig. 3.

1) ROI exaction of the protection platens: As shown in Fig. 3, the ROI of each protection platen is segmented in the images using the morphological method. The Sobel operator is used to calculate the image edges. Filtering and threshold processing are applied to binarize the image edge. Based on the binary image edge, the smaller connected components are removed, and the bounding box of each protection platen connected component is extracted. Through the corresponding position of the bounding boxes, the ROI of each protection platen is segmented from the original images.

2) Classification of protection platen types based on HSV color space weighting operators: To classify the types of protection platens, HSV color space weighting operators are proposed in this work. The proposed HSV color space weighting operators quantify the overall color variation degree of the ROI. The color vectors H, S, and V in the HSV color space represent hue, saturation, and value, respectively.

Environmental factors, especially illumination, have the greatest influence on value variation, second-greatest on saturation variation, and least-greatest on hue variation. In this work, the color variation degree quantization operators are proposed for the above three vectors. To reduce the influence of environmental factors on color variation quantification, the operator weights are set as follows: The operator weight of hue is set to the maximum, followed by saturation, and the weight of value is set to the minimum. The structure of each operator is shown in Fig. 4. The color variation degree quantization operators for Hue, Saturation, Value vectors are illustrated in Fig. 4(a), (b) and (c), separately.

Fig. 4. Structure of Each Color Variation Degree Quantization Operator: Color Variation Degree Quantization Operator for (a) H, (b) S, and (c) V Vectors.

The length of each color variation degree quantization operator is consistent with the number of ROI rows. Each ROI column is traversed using the proposed operators, and the traversal sum of all columns is the calculated ROI color variation degree. The calculation formula of the ROI color variation degree (cv_{all}) is as follows:

$$cv_{all} = \sum_{j=1}^{n}\sum_{i=1}^{m} f_H(i,j)\cdot cell_H(i) + \sum_{j=1}^{n}\sum_{i=1}^{m} f_S(i,j)\cdot cell_S(i) + \sum_{j=1}^{n}\sum_{i=1}^{m} f_V(i,j)\cdot cell_V(i) \tag{1}$$

where $cell_H$, $cell_S$, and $cell_V$ denote the color variation degree quantization operator for the H, S, and V vectors, respectively. $f_H(i,j)$, $f_S(i,j)$, and $f_V(i,j)$ represent the corresponding pixel values of the point with coordinates (i,j) in the ROI. m and n represent the index of rows and columns of the ROI, respectively.

The mean value of cv_{all} of all ROIs in the image is the calculated color variation. Based on the quantified color variation, the protective panel images are divided into two categories combined with the SVM classifier.

B. Automatic Detection of Type-I Protection Platen States based on YOLOv5

In this work, the deep-learning network YOLOv5 is used to detect the states of Type-I protection platens, which have two categories of states: “on” and “off.”

In practical applications, multiple protection platens are densely distributed on the protective panel. The target detection of the protection platens belongs to small target detection because each protective panel experimental image has many small protection platens. The YOLOv5 network uses mosaic data enhancement [15], adaptive anchor box calculation [16], and adaptive image scaling at the input layer to improve the detection ability of small targets [17]. The small target detection ability of YOLOv5 is suitable for automatic protection platen detection in this work. In addition, the lightweight structure of YOLOv5 ensures the real-time detection requirements of protection platens in practical applications.

Regarding the overall framework of YOLOv5 shown in Fig. 5, the YOLOv5 network inherits the YOLOv4 structure, including the input layer, backbone network, neck, and prediction layer. It rescales the Type-I protection platen images to 608×608 size at the input layer. The rescaled input is divided into grids, and in each grid, the coordinates of the target boxes and their confidences are predicted. The confidence of the target box can be expressed as.

$$p = \Pr(Object) * IoU_{pred}^{truth} \tag{2}$$

Each target box carries the information of (x, y, w, h, p) , where (x, y) is the relative coordinate of the normalized center point of target box, and (w, h) represents the width and height, respectively. The network outputs the corresponding prediction boxes according to the conditional probability values of the target boxes.

The input goes through the four kinds of modules of Focus, CBL, SSP, and CSPX_1 in the backbone network [18,19]. In the Focus module, the input is sliced, and then the sliced results are concatenated. The output of the Focus module is

$$Out_{Focus} = Concat(Slice(I_1, \cdots, I_n)) \tag{3}$$

where $Slice$ represents reshape operation, the input image (A, B, C) is reshaped into $(A/n, B/n, C\times n\times n)$.

The output of the CBL module is

$$Out_{CBL} = \mathrm{Re}\,LU(BN(Conv(Input_{CBL}))) \tag{4}$$

where $Conv$ represents the convolution, BN is the batch normalization, and $\mathrm{Re}\,LU$ is the activation function Leaky-ReLU.

In the CSPX_1 module, the input of the CSPX_1 module is shortcut connected:

$$Out_{CSPX\_1} = CBL(CBL(Input_{CSPX\_1})) + Input_{CSPX\_1} \tag{5}$$

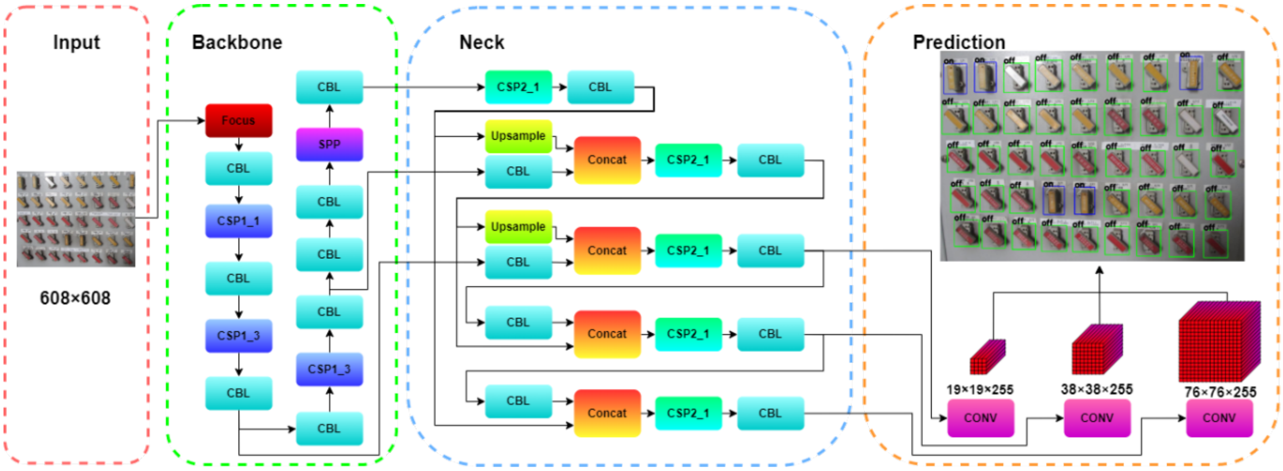

Fig. 5. Architecture of YOLOv5 for Automatic Recognition of Type-I Protection Platen States.

There are two operations in the SSP module, i.e., max-pooling and concatenation. The outputs of the SSP module are obtained as follows:

$$Out_{\mathrm{SSP}} = Concat(Maxpool(Input_{\mathrm{SSP}_1}, \cdots, Input_{\mathrm{SSP}_n})) \tag{6}$$

Through the backbone network, the feature maps of 20×20, 40×40, and 80×80 are obtained. The three sets of feature maps are combined by Neck (the structure combining FPN and PAN) for feature fusion detection. Neck outputs three feature map tensors, and the tensors are combined and passed to the prediction layer [20,21]. The prediction layer uses generalized intersection over union (GIoU) loss as the loss function and filters the target box through non-maximum suppression to obtain the final detection result. The GIoU loss is calculated as [22].

$$GIOU_{Loss} = 1 - IoU_B^A + \frac{\lfloor C(A \cup B) \rfloor}{|C|} \tag{7}$$

where A and B represent ground truth and predictions, respectively. C is the minimum closed area of A and B. Two states of Type-I protection platens are detected using the YOLOv5 network.

C. Parallel Multi-decision Algorithm for Type-II Protection Platen States Detection

The geometry and shooting background of Type-II protection platens are more complicated than those of Type-I protection platens. To achieve an accurate measurement, a parallel multi-decision algorithm is proposed based on the proposed W-CD-SF method and YOLOv5. First, the protection platens images are pre-processed to eliminate the highlight areas. Second, each protection platen is segmented based on the watershed method and color space difference information. The shape features are extracted from the segmented protection platens. Then, the states of the Type-II protection platens are automatically recognized using the proposed parallel multi-decision algorithm. The general overview of the proposed parallel multi-decision algorithm for type-II protection platen states detection is illustrated in Fig. 6.

1) Pre-processing: In this task, the quality of collected images is affected by the lighting, shooting distance, shooting angle, and other environmental factors. The highlights have a considerable influence on the protection platen segmentation. We adopt a method to detect and repair the highlight area. The details of this method are listed below.

a) Highlight area detection based on the proposed adaptive kurtosis threshold method: The detection and restoration of highlight areas are important in protection platen state detection. We propose an adaptive kurtosis threshold method to obtain a binarized mask image of the highlight areas automatically. The diagram of the proposed adaptive kurtosis threshold method is shown in Fig. 7.

Since the grey values of highlight areas differ greatly in adjacent regions of the protective panel images, the probability density curve of a grey image is adopted to evaluate the distribution of grey pixels. Generally, the highlight area is located at the back of the probability density curve due to its larger grey values. The probability density curve contains multiple peaks. The grey value corresponding to the rightmost peak is set as the adaptive threshold T_h. Based on the adaptive threshold; the binarized mask image of the highlight areas is calculated.

b) Highlight area restoration by using the fast march algorithm: The fast marching algorithm [23] is adopted to restore the detected highlight areas. The algorithm repairs the highlight areas from the boundaries of the non-zero regions in the mask image and updates the changes in the original image dynamically [24].

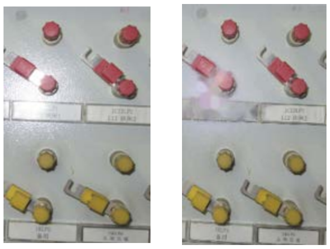
The fast marching algorithm fills the highlight area with pixels in its neighborhood [25]. To ensure natural filling, the weight function is adopted to distinguish the importance of different pixels in the neighborhood. The calculation formula of pixels to be filled is

$$I(p)=\frac{\sum_{q\in B_{\varepsilon}(p)}\omega(p,q)[I(q)+\nabla I(q)(p-q)]}{\sum_{q\in B_{\varepsilon}(p)}\omega(p,q)} \tag{8}$$

where $B_{\varepsilon}(p)$ denotes the neighborhood of the current pixel to be filled. $\omega(p,q)$ is the corresponding weight of neighborhood pixels, which is calculated as

$$\omega(p,q)=dir(p,q)\cdot dst(p,q)\cdot lev(p,q) \tag{9}$$

where $dir(p,q)$, $dst(p,q)$, and $lev(p,q)$ represent direction factor, geometric distance factor, and level set distance factor, respectively. The set of the above three factors ensures that the pixels closest to the normal, those closest to the pixel to be filled, and those closest to the contour of the highlight area to be repaired have the highest importance.



(a) (b)

Fig. 8. Illustration of Highlight Area Restoration in Protective Panel Images. (a) Original Images with Highlight Areas. (b) Restored Images.

When all the nonzero regions in the mask image are repaired, the highlight areas in the original image are also restored. An example of the highlight area restoration is shown in Fig. 8.

It is observed in Fig. 8 that the differences between the highlight area and its surrounding area are reduced.

2) Segmentation and feature extraction using the proposed W-CD-SF method: There are many protection platens in a protective panel image. To segment these protection platens, we propose a W-CD-SF method. The details of this method are introduced below.

a) Preliminary segmentation based on a watershed algorithm: The watershed algorithm is adopted to obtain the preliminary segmentation results of the protection platen. This algorithm is a transformation defined on a grayscale image. This transformation treats the image as a topographic map, with the brightness of each point representing its height, and finds the lines that run along the tops of ridges [26-29]. In this segmentation, we adopt this algorithm to obtain a continuous and close edge of each protection platen. Based on the close edge, each protection platen region can be extracted.

b) Irrelevant area elimination based on color space difference: In the second stage, we propose a new method to eliminate the irrelevant areas from segmented regions based on color difference. The irrelevant areas are mostly caused by uneven illumination and noise interference. There are color differences between the ROI and the irrelevant areas. In this method, the RGB color space is adopted to quantify the color differences. Fig. 9 shows the diagram of the proposed irrelevant area elimination method.

i) *Classification of sub-regions based on color distribution features:* Each image is divided into several 4 × 4 sub-regions. For each sub-region, the pixel value variances in the R, G, and B channels are calculated separately. The sum of the calculated pixel value variances in the three channels reflects the color distribution difference of the sub-region. Owing to the color difference between irrelevant areas and the ROI, the overall color distribution difference in the sub-region in which interference exists is greater than that in which interference does not exist. Based on the quantified color distribution difference, the sub-regions with irrelevant points are distinguished.

ii) *Interference points removal:* The pixels are arranged by their corresponding pixel value, and the first-order difference of the sorted pixel sequence difference is calculated to qualify the pixel value difference. In this work, the pixels with corresponding differences greater than the difference mean value are considered as interference points and removed.

c) Shape features extraction: To detect the states of Type-II protection platen, we extract the shape features of these segmented protection platens. These features are calculated based on the circumscribed rectangle of each protection platen's connected domain. The length h and width w of the circumscribed rectangle are obtained and illustrated in Fig. 10. Fig. 10(a), (b) and (c) correspond to the circumscribed rectangle for the state "on", "off" and "standby", respectively.

The bounding boxes of the Type-II protection platen obtained using the W-CD-SF method can be classified into two parts: protection platen region and noise. To eliminate the influence of noise and recognize the states of the Type-II protection platen more accurately, we propose the three following features with which to evaluate the shape of each bounding box:

$$HWR=\frac{h}{w} \tag{10}$$

$$CRA=h\times w \tag{11}$$

$$CRA_{mean}=\frac{\sum_{i}^{n}h_{i}\square w_{i}}{n} \tag{12}$$

Fig. 9. Diagram of Proposed Irrelevant Area Elimination Method.

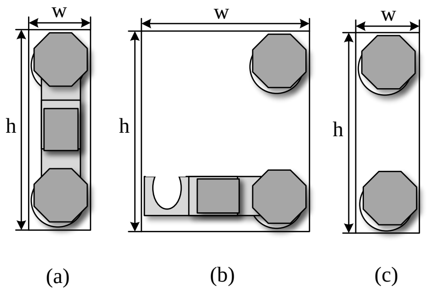

Fig. 10. Parameters Calculated from Each Connected Domain Circumscribed Rectangle: (a) State ”on,” (b) State ”off,” and (c) State ”Standby.”

where HWR is the ratio of h to w, CRA is the area of the circumscribed rectangle, and CRA_{mean} is the average area of a circumscribed rectangle of all detected objects. Finally, the Type-II protection platen states can be recognized using the segmentation masks and shape features combined with the SVM classifier.

3) Parallel multi-decision scheme based on W-CD-SF method and YOLOv5 network: The recognition result of Type-II protection platen using the W-CD-SF method is represented as A_i, which consists of the state category S_{A_i} (including states “on,” “off,” or “standby”) and the bounding box region R_{A_i}. In addition, the state recognition result of the Type-II protection platen using YOLOv5 is represented as B_i, which is also composed of the state category S_{B_i} (including states “on”, “off,” or “standby”) and the bounding box region R_{B_i}. The final state recognition result is the fusion of A_i and B_i.

Specifically, given the results of the W-CD-SF and YOLOv5 method, we can obtain the final states recognition result using the following rule:

$$E_i = \begin{cases} S_{A_i}, R_{A_i} \cap R_{B_i} = \varnothing \\ S_{B_i}, R_{A_i} \cap R_{B_i} \neq \varnothing \end{cases} \tag{13}$$

In this rule, if there is overlap between R_{A_i} and R_{B_i}, the final result is dependent on S_{B_i}, otherwise S_{A_i}.

III. Experimental Results and Analysis

The protection platen is an essential part of a relay protection inspection system. In this work, we propose a method to automatically detect the states of a protection platen. This method is composed of three parts: automatic protection platen type classification based on HSV color space weighting operators, Type-I protection platen state recognition based on YOLOv5, and Type-II protection platen state recognition based on the proposed parallel multi-decision mechanism. To evaluate the effectiveness of the proposed method, we conducted experiments on a protection platen image dataset. In this section, the dataset details, experimental settings, experimental results of automatic protection platen state recognition, along with the details of comparative experiments, are introduced and analyzed.

A. Dataset

The experimental data used in this work were collected by the State Grid Hebei Electric Power Company. There are two protection platens usually used in practical applications, i.e., Type-I and Type-II protection platens. In this work, the protective panel images containing these two types of protection platens are shot in various environments and include 3,625 Type-I protection platens and 5,344 Type-II protection platens.

B. Experimental Settings

This work achieves the automatic recognition of protection platen states. To evaluate the performance of the proposed method, the 10-fold cross-validation method is applied. The performance of the system is evaluated in terms of accuracy, false positive rate (FPR), and false negative rate (FNR). Accuracy is the proportion of correctly predicted samples to total samples. FPR is the proportion of negative samples predicted to be positive to total negative samples, which reflects the probability of negative samples being misclassified. FNR is the proportion of positive samples predicted to be negative to total positive samples, which reflects the probability of missing detection of positive samples. The calculation formulas of accuracy, FPR, and FNR are respectively, where TP denotes the number of actually positive samples predicted to be positive samples, TN represents the number of actually negative samples predicted to be negative samples, FP is the number of actually negative samples predicted to be positive samples, and FN is the number of actually positive samples predicted to be negative samples.

$$\text{Accuracy}=\frac{TP+TN}{TP+FP+TN+FN} \tag{14}$$

$$\text{FPR}=\frac{FP}{FP+TN} \tag{15}$$

$$\text{FNR}=\frac{FN}{FN+TP} \tag{16}$$

The experiments were implemented based on the PyTorch framework. The YOLOv5 network was trained using batch size 8 for 300 epochs. The initial learning rate was set to 0.01, and the warmup technique was used for training YOLOv5. The learning rate warmup was set to 0.1. Adam was used as the optimization algorithm with a momentum of 0.8.

C. *Experimental Results of Protection Platen States Recognition*

The automatic recognition of protection platen states is a challenging task. The Type-I and -II protection platens have varied shapes. For one specific type, there are different colors of protection platens, and some protection platens and their protective panels are similar in color. Moreover, the shooting angle and distance are not the same, and the image quality is affected by lighting and shooting conditions, resulting in difficulties in recognizing the states of protection platens.

In this work, we propose utilizing the YOLOv5 network to recognize the Type-I protection platen state. Different from the Type-I protection platen, the shape of the Type-II protection platen is more complicated. To improve the recognition accuracy, in this work we propose a parallel multi-decision method combining the advantages of the proposed W-CD-SF method and YOLOv5 network.

The state classification results of Type-I and -II protection platens are listed in Tables I and II, respectively.

Table I shows that for the automatic state recognition task of Type-I protection platens the recognition accuracy, FPR, and FNR for the state "on" are 98.77%, 0%, and 1.23%, respectively. The recognition accuracy, FPR, and FNR for state "off" are 99.15%, 0%, and 0.85%, respectively. It can be seen from the results that the protection platen recognition accuracy of Type-I protection platens is over 98%, meeting the needs of practical applications.

TABLE I. TWO STATES RECOGNITION RESULTS OF TYPE-I PROTECTION PLATENS USING YOLOV5

State of protection platen	Number of protection platens	Accuracy	FPR	FNR
on	897	98.77%	0%	1.23%
off	2,728	99.15%	0%	0.85%

TABLE II. THREE STATES RECOGNITION RESULTS OF TYPE-II PROTECTION PLATENS USING PARALLEL MULTI-DECISION METHOD

State of protection platen	Number of protection platens	Accuracy	FPR	FNR
on	1,615	99.55%	8.90%	0.45%
off	2,391	96.98%	5.00%	3.02%
standby	1,338	95.33%	4.50%	4.67%

Table II lists the state detection results of Type-II protection platens using the parallel multi-decision method. It is observed that there are 5,344 Type-II protection platens, of which 1,615 are in the "on" state, 2,391 are in the "off" state, and 1,338 are in the "standby" state. As shown in Table III, for the automatic state recognition task of Type-II protection platens the recognition accuracy for the state "on" is 99.55%, that for FPR 8.90%, and that for FNR 0.45%. The recognition accuracy for state "off" is 96.98%, that for FPR 5.00%, and that for FNR 3.02%. The recognition accuracy for state "standby" is 95.33%, that for FPR 4.50%, and that for FNR 4.67%. These results show that the recognition accuracy of Type-II protection platens in three states is above 95%.

D. *Experimental Results of Type-II Protection Platen without Multi-decision Scheme*

In this work, we propose a new parallel multi-decision technique to recognize the states of Type-II protection platens. To evaluate the effectiveness of this new parallel multi-decision method, the classification results using the single-decision method with the W-CD-SF or YOLOv5 network are listed in Table III.

Table III lists the automatic state recognition results of Type-II protection platens using the single-decision method with the W-CD-SF or YOLOv5 network. As shown in Table III, for the state "on," the recognition accuracy using W-CD-SF is 93.12%, that for FPR 7.68%, and that for FNR 6.88%. The recognition accuracy using YOLOv5 is 98.88%, that for FPR 9.46%, and that for FNR 1.12%. For state "off," the recognition accuracy using W-CD-SF is 89.54%, that for FPR 10.85%, and that for FNR 10.46%. The recognition accuracy using YOLOv5 is 91.61%, that for FPR 6.19%, and that for FNR 8.39%. For state "standby," the recognition accuracy using W-CD-SF is 92.85%, that for FPR 12.08%, and that for FNR 7.15%. The recognition accuracy using YOLOv5 is 93.06%, that for FPR 11.06%, and that for FNR 6.94%. It is shown that for three states the recognition performance of each single-decision method is poorer than that of the proposed parallel multi-decision method (shown in Table II). The results indicate that the parallel multi-decision method improves the recognition accuracies by 0.68%, 5.86%, and 2.44% for “on,” “off,” and “standby” states of the protection platen, respectively.

E. Comparison Experiments

To evaluate the effectiveness of the method proposed in this work, we compared the performance of Faster-RCNN and single-shot multi-box detector (SSD) networks with YOLOv5 for Type-I and -II protection platen states recognition tasks.

Faster-RCNN is a two-stage network used for object detection tasks, especially for small objects. It has high detection accuracy and has been widely used in industry [30], [31]. The SSD network is a one-stage network that is based on regression and region proposal algorithms. It can directly predict the position and category of bounding boxes [32,33]. The results of these two deep-learning methods and our proposed method with the YOLOv5 network for recognizing protection platen states are shown in Table IV.

Table IV shows the automatic state recognition results for Type-I and -II protection platens. For Type-I protection platens, the recognition accuracy of state “on” using Faster-RCNN is 96.54% and that using SSD is 89.63%, which are both lower than the accuracy using YOLOv5 (98.77%). The recognition accuracy of state “off” using Faster-RCNN is 92.25% and that using SSD is 90.58%, which are both lower than the accuracy using YOLOv5 (99.15%). For Type-II protection platens, the recognition accuracy of state “on ” using Faster-RCNN+W-CD-SF is 97.52%, and that using SSD+W-CD-SF is 90.43%, which are both lower than the accuracy using YOLOv5+W-CD-SF (99.55%). The recognition accuracy of state “off” using Faster-RCNN+W-CD-SF is 95.46% and that using SSD+W-CD-SF is 93.65%, which are both lower than the accuracy using YOLOv5+W-CD-SF (96.98%). The recognition accuracy of state “standby” using Faster-RCNN+W-CD-SF is 96.38% and that using SSD+W-CD-SF is 89.75%, which are both lower than the accuracy using YOLOv5+W-CD-SF (95.33%). The comparison of experimental results indicates that the YOLOv5 is more suitable for automatic protection platen state classification in this work.

The experimental data were collected under various shooting environments and conditions, leading to difficulties in accurately discriminating protection platen state. The methods proposed in this work combine the advantages of YOLOv5 and image processing algorithms and perform well in the state recognition task of two protection platen types.

TABLE III. STATE RECOGNITION RESULTS OF TYPE-II PROTECTION PLATENS USING A SINGLE-DECISION METHOD WITH W-CD-SF OR YOLOV5 NETWORK

State of protection platen	Accuracy		FPR		FNR	
	W-CD-SF	YOLOv5	W-CD-SF	YOLOv5	W-CD-SF	YOLOv5
on	93.12%	98.88%	7.68%	9.46%	6.88%	1.12%
off	89.54%	91.61%	10.85%	6.19%	10.46%	8.39%
standby	92.85%	93.06%	12.08%	11.06%	7.15%	6.94%

TABLE IV. COMPARISON OF EXPERIMENTAL RESULTS

State classification accuracy of Type-I protection platen			State classification accuracy of Type-II protection platen			
Network	State of protection platen		Method	State of protection platen		
	On	off		on	off	standby
Faster-RCNN	96.54%	92.25%	Faster-RCNN +W-CD-SF	97.52%	95.46%	96.38%
SSD	89.63%	90.58%	SSD+W-CD-SF	90.43%	93.65%	89.75%
YOLOv5	98.77%	99.15%	YOLOv5 + W-CD-SF	99.55%	96.98%	95.33%

IV. CONCLUSION

An automatic protection platen state detection method was proposed in this work. In most previous research, experiments were conducted for only one type of protection platen; this was not helpful in practical applications since there are different protection platen types in the natural environment. To solve this problem, we proposed a new system that could classify multiple protection platen types and recognize each protection platen state automatically. First, the automatic classification of Type-I and -II protection platens was realized by the proposed HSV color space weighting operators. Second, the YOLOv5 network was used to detect the Type-I protection platen states. The detection accuracy for two states of Type-I protection platen was over 98%. Then, an automatic state detection system for the Type-II protection platen was presented based on the proposed parallel multi-decision method, combining the proposed W-CD-SF method and the YOLOv5 network. The recognition accuracies of the three states of Type-II protection platen (“on”, “off” and “standby”) exceeded 95%. Experimental results showed that our newly proposed system could classify multiple protection platen types and recognize each platen state automatically. In addition, the proposed system had good robustness and generalization due to the combination of a deep-learning network and image processing techniques. Future work will focus on the practical application of the proposed system and the classification and identification of other types of protection platens.

ACKNOWLEDGMENT

We thank all our participants for their contributions.

***Abstract*—There has been a recent explosion in the number of mobile network payment gateways that enable users to access services through a variety of devices. Mobile payment gateway security is complicated by a number of difficult-to-solve issues. As digital technology has progressed over the last decade, mobile payment mechanisms have gained a lot of interest. In the internet industry, these standards might have a significant impact on service quality. However, the most important aspect to consider when using these systems is their accountability, which assures confidence between the parties engaged in the financial transactions. Mobile payments may be easy, quick and secure. On the other hand, they may be rather pricey and are still susceptible to problems caused by technology. Specifically, mobile payments won't be able to go through at all if there are any problems with the host phone. For this reason, in this article a mobile payment mechanism that uses secure bilinear dual authentication. Using Bullet hash Maximum distance separable (MDS) and the mutate Hellman algorithm, our payment protocol incorporates all of the essential security characteristics to establish confidence between the parties. To put it another way, accountability is assured by mutual authentication and non-repudiation. Conflicts that may emerge in the course of a payment transaction may be resolved using our strategy. Scyther is used to test our suggested protocol's empirical performance.**

Keywords*—*Mobile payment; transaction protocol; bullet hash maximum distance separable; mutate Hellman algorithm

I. Introduction

Mobile smart devices (such as smartphones or laptops) have become more common in everyday life as a result of the development and widespread usage of mobile communication technology [1]. This results in an ever-increasing amount of online service requests. Online services such as Ali Pay, Apple Pay, We Chat Pay and so on rely on mobile payments, which are attracting a lot of attention. These online transaction programs let customers to purchase a wide range of goods and services from wherever they have internet access. A user's private identifying information is often made available to retailers when an online transaction is initiated in order to verify the transaction's authenticity. The unreliability and avarice of merchants may lead them to offer items that the user does not need or merely to sell the identity of the user for economic gain to other parties. There must be an ability to validate a transaction message's legality and validity, so that the merchant may ensure that products or services are given by the proper user. [2] Verification of transaction messages may also prevent users from claiming that they didn't acquire the products and services they claimed to have purchased. Many cryptographic primitive-based protocols for mobile payments have been developed to meet these security requirements. Their protocols meet security standards such as user anonymity and unforgivability. The identity of any merchant or opponent cannot be linked to a transaction message when a protocol maintains anonymity for the users involved [3]. Unforgeability, on the other hand, implies that the sender of a message can be identified and that anybody attempting to forge the transaction message of another party will be caught [4]. A mobile payment system must take efficiency into consideration in addition to security considerations. As a result, it is important that a payment protocol only need a minimal amount of processing power and storage space to be implemented on low-powered gadgets. Traditional transaction protocols provide user public key certificates through a public key infrastructure (PKI) [5, 6]. Verifying the authenticity of a public key may be done with the help of a trusted certificate authority. Because of the need for extra resources to manage certificate revocations, distribution, and storage, the use of PKI significantly raises the costs of both communicating and storing data. As a result, there is a contradiction between PKI and the capabilities of mobile devices with limited processing and storage. It is still difficult to build a mobile transaction protocol with minimal resource requirements in terms of computation, network traffic, and data storage. Addressing the aforementioned issue, a novel mobile payment system was created that simultaneously guarantees secrecy, immutability, and minimal resource usage. The following is a brief summary of its most important contributions:

1) First, the dual authentication payment transaction method was provided.

2) A mobile payment mechanism based on our suggested approach is demonstrated. Furthermore, Pay Platform serves as a trusted proxy for users when they want to securely communicate with Merchant Server. As a result, users can rest easy knowing that they won't be sending or receiving private messages from merchants. Since most calculation takes place on Pay Platform, user resource utilization is lowered as well. Unforgeability is ensured by the use of certificate less public key cryptography and signatures on every piece of transaction data.

3) It is important to maintain the Pay Platform and Merchant Server as lightweight as possible, despite the fact that they must do computations for each transaction, in order to solve the scalability problem. When processing a payment on the Pay Platform or the Merchant Server, the signature verification process is by far the most time-consuming step.

4) The protocol was implemented to test the using the Bullet hash MDS, a mutated version of the Hellman algorithm, and various mobile payment protocols. Comparison reveals that our protocol is viable and efficient in terms of secure payments.

Rest of the paper has been divided into sections. Section II focuses on other studies in this field. The problem statement is presented in Section III. Section IV demonstrates the suggested technique's terminology in action. Section V focuses on experiments and implementation. Towards the end of the article, the conclusion is reached.

II. Related Work

Mobile payment systems have been the focus of a number of researches in recent years aimed at strengthening their security. Many of these efforts have been directed to developing foundations for the establishment of new electronic payment systems, as well. Username and passwords, symmetric and non-symmetric and elliptic curve encryption, smart cards, 2D bar codes, and biometric technologies have all been tried for electronic payment system authentication. All sorts of authentication techniques and protocols are based on these notions. Symmetric and asymmetric signatures fail in M-commerce despite being frequently utilized for authentication. In [7], mobile payment solutions based on durable certificate-less signatures and bilinear pairing are proposed. [7] To make the suggested mobile payment system acceptable for mobile devices with low processing capacity, they smartly improve it. Security and performance testing of the suggested mobile payment system on the Raspberry PI have demonstrated its feasibility. Anonymous and untraceable payments have never previously been feasible on a mobile device according to a novel payment technique explained in [8]. Because mobile devices have limited computing capacity, the proposed protocol depends on a Pay Platform to handle the majority of the computational burden (which is almost usually equipped with lots of processing power) (which is almost always equipped with plenty of processing power). Batch-verification has been implemented to lessen the overhead for millions of users on the Pay Platform and Merchant Server because the Pay Platform and Merchant Server must run calculations for each transaction. In terms of cloud security and privacy, one of the most pressing challenges is whether or not sensitive information may be accessed by other parties. The researchers [9] have presented cloud service providers with an intelligent encryption solution that secures cloud service providers' access to the incomplete data. Dispersed cloud servers are recommended for data storage after the data file has been partitioned. SA-EDS is a notion and an algorithm that underpins the Secure Efficient Data Distribution (SED2) Method, the EDCon Methodology, and the Alternative Data Distribution (AD2) Algorithm. ZeroMT is a method presented in [10] that enables several simultaneous covert balance transfers. This method ensures that the balances in all accounts and the amounts transferred remain private." "Since all transfers are contained within a single transaction, there are fewer transactions to verify on the main chain. Off-chain, they are the standard building block for a multi-transfer transaction that is undetectable by unauthorised parties but can be validated by smart contract infrastructures. NFC devices and payment terminals connect with each other using this protocol, which is based on the EMV standard [11]. EMV's weaknesses will be solved by adding an extra layer of security and beefing up the core EMV communications, according to the protocol. Due to the lack of a reliable third party, security features such as the detection of double spending and the prevention of brute force attacks are still in development. In order to make secure mobile payments, NFC-enabled cellphones may be utilised, as stated in [12]. Abughazalah's protocol has the potential to address issues of privacy and security. In order to ensure the security of this protocol, a one-time password (OTP) system was implemented. The OTP mechanism is preinstalled in NFC-enabled smartphones. However, without a trusted third party, this protocol lacks essential security features like the ability to prevent double spending and ensure all participants are treated fairly. According to [13], mobile vouchers for NFC-enabled phones are safe to use. The suggested strategy focuses largely on the collection and redemption of loyalty points. However, there are still several potential security holes in this system, including those related to message privacy, mutual authentication, and detecting duplicate spending. This results in an inherently unfair implementation of the protocol. An EMV-compliant near-field communication (NFC) mobile payment system was presented by the author in [14]. Data and digital signatures are secured by cryptographic methods like symmetric key encryption and public key encryption in their proposed protocol. Unfortunately, this protocol is vulnerable to a wide range of attacks despite the fact that it is not fair and cannot rely on a neutral third party to ensure its security. In [15], the author presented a secure contactless NFC payment system using NFC bank cards and an internet connection with a respectable organization. Client payment devices limited to NFC bank cards that do not need Wi-Fi or 4G. Due to the absence of a reliable third party, this protocol is not yet capable of detecting duplicate spending or protecting against brute-force attacks, and it is therefore not yet fair. An NFC mobile payment system with cloud-based security was shown in [16]. The usage of NFC radio waves in a public setting makes it more secure than the EMV standard. Other security flaws, such the ability to spot double spending, may be exploited even in the absence of a third party that can be trusted. The au's anonymous mobile payment system, which was introduced in [17], has increased the safety of mobile commerce data. They assert that their protocol satisfies all of the necessary conditions for non-repudiation, anonymity, and unlinkability. However, there is no safeguarding against message corruption or brute-force attacks in this protocol [18-21]. The trustworthy third party's knowledge of sensitive transaction data like payments and invoices also poses a security risk. Using key distribution, the author of this research presents [22] a cloud-based efficient authentication system for mobile payments. Our innovative certificate-less proxy re-signing approach for mobile payments not only protects your privacy, but also simplifies your data storage needs. Using the Secure Authentication Protocol, [23] suggests a mobile payment system (SAP). By using cryptographic methods, it was able to create a reliable solution that can identify fake servers and clients. While the use of mobile devices in the payment industry continues to rise, the proposed method ensures the safety of user accounts and individual privacy. Smart mobile device makers and mobile data users both have a role to play in resolving this problem so that mobile payments may continue to be used in public communication networks that are not always secure. They provide a secure business strategy for mobile payments in the e-healthcare application by making use of key distribution cryptographic techniques. In [24], a novel, effective trust model for secure, dynamic group communication across distant networks is presented. The concept of a hierarchical attribute-based encryption was introduced by the author in [25]. A single encryption key may secure a whole directory's worth of data. The computational and storage requirements of their attribute-based hierarchical file encryption method are less than those of prior research. A novel index model, the data vector (DV) tree, based on a crossover genetic process, was developed with the help of soft computing. The file's term and inverse document frequencies, together with any other features included in the file, are used to build the DV tree. Their new key generation, encryption, and decryption tool is an extra bonus for anybody using their data. The authors of [26] proposed a machine learning algorithm to identify malicious uniform resource locators by combining URL lexical selections, payload size, and python supply parameters. A Chaotic Hopfield Neural Network combined with an adaptive encoding approach may provide a more secure model for keeping private information; the proposed approach enhances the safety of a shared key among any number of nodes [27-32].

A. Research Gap

Consequently, the existing solutions for mobile payment protocols lacked both substantial data security and fairness. There is no credible third party under the constraints of such procedures. To avoid wasting time and money in the event of a disagreement, no one gathers and records all transactional data. This means that the processes at play cannot ensure a fair outcome. As a result, there is potential for a variety of attacks, including physical force, man-in-the-middle, and double spending. In this work, a strategy for resolving these issues is demonstrated. That is to say, the proposed protocol simultaneously guarantees both high levels of fairness and critical data security. The offline session key generation and hashing features are used for further security and mobility. Basically, it was impossible to stop repetition or brute-force attacks by never reusing the session keys that are created for each and every transaction.

III. Problem Statement

No one will trust m-commerce until there is a secure method of exchanging business information and conducting electronic financial transactions over mobile networks. Secure connections and transfers are essential for M-payment systems, which send sensitive data. As a result, high levels of perceived and technological security are required for m-payment systems to be widely used and widely accepted by customers. M-commerce has seen the implementation of a number of different mobile security and payment mechanisms. Cryptography techniques are essential to satisfy the above-described transaction security standards. The security of mobile payments done via networks with little or no physical protection is greatly enhanced by these devices.

IV. Proposed Work

Client, Merchant, Acquirer, Issuer, and Payment Gateway are all parts of the BDAPTP architecture was developed (which is in turn based on the Client Centric model) (all of which were described earlier). Below are three examples of simple Payment transactions that illustrate the Client Centric approach in action.

- When a customer completes a purchase, the money is transferred to the shop owner.
- With Value Subtraction, the Client's funds are deducted by the Payment Gateway (on behalf of the Issuer).
- The Acquirer's Payment Gateway sends funds to the Merchant's Value Claim account. When using a Payment Gateway, you may get in touch with an Acquirer straight away (an entity that provides infrastructure for a Merchant to take credit card and other kinds of electronic payment). The suggested method has no need for communication between the merchant and the acquirer. A wireless or cellular network provided by a mobile phone provider is used to create an Internet connection between the Client and the Payment Gateway. The overall illustration of the suggested methodology was depicted in the Fig. 1.

A. BDAPT Protocol

There are a variety of processes for payment transaction depicted in Fig. 2. An individual identification number was assigned to each mobile phone. If an IMEI number is placed on a blacklist by a wireless network operator, GSM, it is used to identify legitimate devices on the network and to prevent ongoing usage of a phone that has been blacklisted from using the network. Different aspects of the suggested mobile payment security were identified in this article. The stages involved are:

1) Registration phase: Users and merchants must register on the payment gateway in order to get legitimate credentials, such as a mobile PIN for login and the encryption key, which must be generated.

2) Transaction phase: To make a payment, a user must first send a payment request to the merchant, which the merchant must confirm by verifying the user's payment information and personal information.

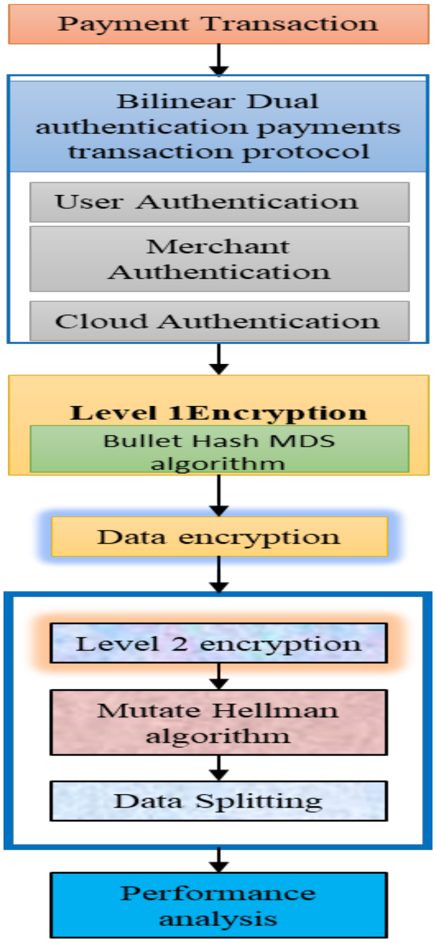

Fig. 1. Schematic Representation of the Suggested Methodology.

3) *Authentication phase:* The Issuer and Acquirer calculate the trust value to authenticate the payment credentials and approve the payment via the confirmation from the merchant module, which is then executed on the payment gateway.

It shows the process of the merchant server authentication using the proposed protocol. Merchant and admin servers must agree to the process of generating and disseminating a secret key for data encryption and decryption during authentication in order for the suggested method to operate. The Merchant Server employs "bank number" and a secret key to authenticate the admin server, creating a basic ciphertext when the authentication process is complete. The cipher text formula for merchant server authentication is:

$$\text{Merchant Server Authentication (MSA)} = \text{bankno (xor) trust value} \quad (1)$$

In order to avoid a session hijacking on the buyer's end, each authenticating demand should be issued a distinct private key.

$$\text{Admin Server Authentication (ASA)} = \text{MSA (xor) trust value} \quad (2)$$

$$\text{Admin server trust value (ASV)} = \left(g^{bankno}\right) \quad (3)$$

$$\text{Merchant share value(MSV)} = \left(g^{H(bankno_{no})}.g\right)^{bankno} \quad (4)$$

Whenever a client sends a payment, ask for the customer's transaction number in the cloud. Processing the request data requires the use of a trapdoor-creating method for the simple reason that if the payment requests were transmitted over the plain text, we run the risk of them being tracked and attacked. As a result, enhancing security and preventing the attack may be accomplished via the trapdoor design process.

$$\text{Patient Number Request (PNR)} = \left(g^{H(bankno_{no}).pn}, g^{pn}\right) \quad (5)$$

where $PN1 = g^{H(bankno_{no}).pn}$ and $PN2 = g^{pn}$

The cloud should now check and validate the merchant data and the mobile user request, as shown below, after it has received the whole request, trusted cloud exchanged between merchant server and mobile user across a distribution channel.

$$\text{Cloud payment request matching} = e\ (PNR, MSV) \quad (6)$$

$$= e\left(\left(g^{H(bankno_{no})}.g\right)^{bankno}, g^{pn}\right) \quad (7)$$

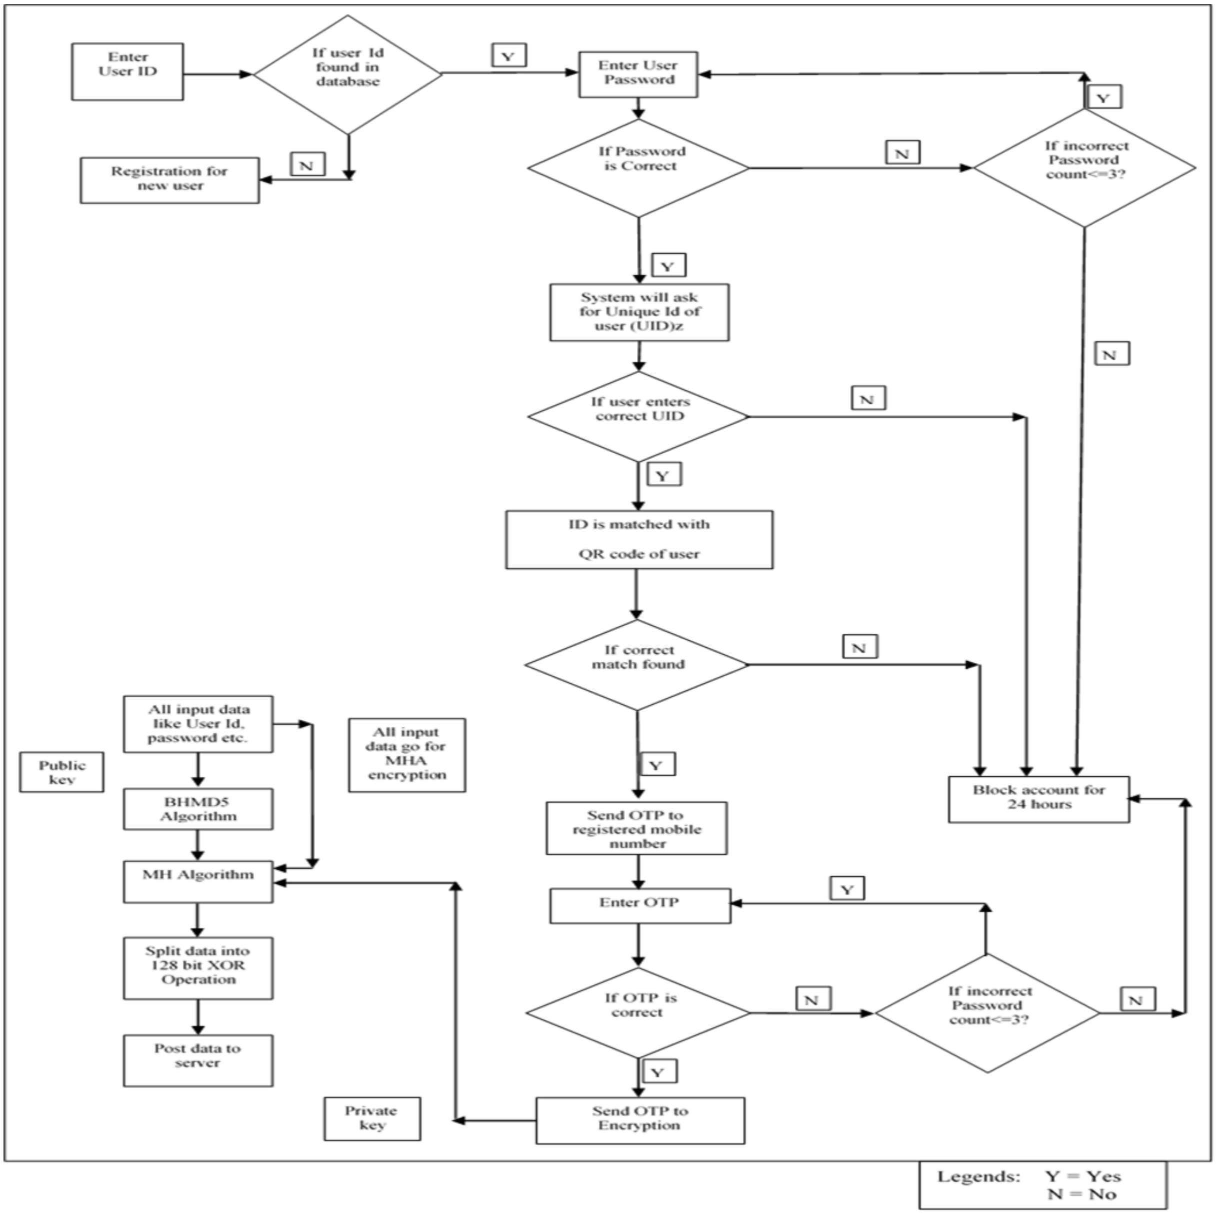
$$= e(g,g)^{(H(bankno_{no})+1).bankno.pn} \quad (8)$$

$$= e(g,g)^{H(bankno_{no}).bankno.pn}.e(g,g)^{bankno.pn} \quad (9)$$

$$= e\left(g^{H(bankno_{no}).pn}, g^{bankno}\right).e\left(g^{bankno}, g^{pn}\right) \quad (10)$$

$$e\ (PNR, MSV) = e(PN1, ASV).e(ASV, PN2) \quad (11)$$

A user's User Id is required before they may initiate a cloud transaction. The system will direct the user to the registration page if they have not previously done so. Once a user's id is found in the bank's database, the next step is to have them input a password. It is verified and if found to be inaccurate, the user is led back through the process, or if it is correct the user will be sent to a new step in which the system will ask for a unique identification (UID). For 24 hours, the user's account will be suspended if the incorrect UID is entered. If the user's UID and QR Code are matched, an OTP will be sent to the user's registered cellphone number; if the user's UID and QR Code are not matched, the user's account will be blocked for 24 hours. Once the OTP has been entered, the following step is to verify that the OTP entered is accurate. If the OTP is accurate, the key is kept secret throughout the encryption step. For 24 hours, the account will be blocked if the OTP entered is wrong. If the OTP is entered correctly three times, the system will send you to the right OTP entry procedure. All input is encrypted using the Bullet hash MD5 algorithm, a public key cryptosystem that provides a hash key. To further increase the degree of security in the suggested technique, the asymmetric public key cryptosystem modify Hellman algorithm was used to generate the hash key. Data is subsequently divided into 128-bit XOR operations and sent to the server for further processing.



Enter User ID

Fig. 2. Process of Transaction.

B. Units Cryptographic Transaction

1) Bullet hash MD5 algorithm: Integrity security is mostly provided via hash functions. Authentication is also provided when they are used in conjunction with digital signature and message authentication code (MAC) techniques. As an example of an important family of hash functions, consider the SHA-2 family, which has the same basic functional structure but varies in internal operations, message length and security bits.

A message is fed into one of these algorithms, which performs repetitive, one-way operations to produce a digest of the message. Blocks of 512-bit messages and 256-bit hash values expressed as eight 32-bit words are processed 64 times by the BHMD5 algorithm (C, D, ..., I). The hash message is 256-bits in length.

The following are some possible descriptions for the system:

$$\begin{cases} \dot{z} = l(t - z) \\ \dot{t} = xz - t - zm \\ \dot{m} = zt - vm \end{cases} \quad (12)$$

Where, z, t, and m represent the current state of the system, whereas l, v and x represent its parameters. A system enters chaos when a, b, and c are all equal to 10.

The BHMD5 was utilized to generate a 256-bit secret key J in the suggested cryptosystem. No matter how minor a difference there is between two photos, their hash values will be different. Thus, a 2256-complexity cryptosystem can withstand a brute-force attack without being breached. Accordingly, J may be represented as follows: 256-bit secret key split into 8-bit blocks (j_u).

$$J = j_1, j_2, j_3, \dots, j_{32} \quad (13)$$

The initial values can be obtained as follows.

$$z_0 = z_0' + \frac{(j_1 \oplus j_2 \oplus j_3 \oplus \dots \oplus j_{11})}{256} \quad (14)$$

$$t_0 = t_0' + \frac{(j_{12} \oplus j_{13} \oplus j_{14} \oplus \dots \oplus j_{22})}{256} \quad (15)$$

$$m_0 = m_0' + \frac{(j_{23} \oplus j_{24} \oplus j_{25} \oplus \dots \oplus j_{33})}{256} \quad (16)$$

Where, z_0', t_0' andm_0' are the initial given values.

Four elements make up the suggested encryption algorithm. Transaction data is first encrypted using the hash technique to create J and the Lorenz system's starting values. Encryption rules are then applied to the original data sequence J. Finally, decipher the series of numbers. Encrypted data is the product of the process.

Step 1: For each row and each column, enter the data in the form of O(n,b), where n is the number of rows.

Step 2: Generate the starting values of J and the key sequence (z_0', t_0',m_0') of the Lorenz system.

Step 3: The matrix N_j (n, b ×8) may be generated by repeating the binary sequence $J_{v,r}$ times where $r = \frac{n\times b\times 8}{32}$. Encode N_j with the same encoding rule and N_{jw} was obtained.

Step 4: According to XOR operation, Oe' = Oe XOR N_{jw}, Of'= OfXOR N_{je} and Ov' = OvXOR N_{jw}.

Step 5: The chaotic sequences are generated as z_b, t_bandm_b and its length is n× b× 4 by using the Lorenz system will having the initial values z_0', t_0' andm_0'.

Step 6: Prepare the chaotic sequences z_b, t_bandm_b as follows:

$$\begin{cases} (kz, dz) = sort(z) \\ (kt, dt) = sort(t) \\ (km, dm) = sort(m) \end{cases} \quad (17)$$

where (•, •) = sort (•) a new sequence after rising to an index value z is the new sequence, and the index values for this new sequence are the index values for this new sequence.

Step 7: The binary matrices should be converted $Oe', Of'$and$Ov'$to three vectors Ce (n× b× 4), Cf (n× b× 4) and Cv(n× b× 4), respectively.

$$\begin{cases} Ce'(u) = Ce(kz(u)) \\ Cf'(u) = Cf(kt(u)) \\ Cv'(u) = Cv(km(u)) \end{cases} \quad (18)$$

Step 8: Convert $\mathrm{Ce}', \mathrm{Cf}'$ and $\mathrm{Cv}'$to matrices Ew(n, b× 4), Fw(n, b× 4) and Vw(n, b×4), respectively. Decode Ew, Fw and Vw using a same rule Rule_{dec} and get three binary matrices Ev, Fv and Vv.

Step 9: Finally, recover data that is the encrypted one

Decryption is the opposite of encryption in that it is a reverse operation. In order to decode the encrypted data, the receivers must get secret keys from the sender. Following is a step-by-step breakdown of the decryption procedure.

Step 1: Having Rule_{dec}, Components of the ciphered data are encoded. Three matrices were given as a input in total. Ew, Fw and Vw, as well as their vectorization into three $\mathrm{Ce}', \mathrm{Cf}'$ and Cv'.

Step 2: $\mathrm{Ce}', \mathrm{Cf}'$ and $\mathrm{Cv}'$are the vectors. For obtaining the non- vectors Ce, Cf and Cv, step 8 of the encryption method is reversed as a result:

$$\begin{cases} Ce(u) = Ce'(kz(u)) \\ Cf(u) = Cf'(kt(u)) \\ Cm(u) = Cm'(km(u)) \end{cases} \quad (19)$$

Where, kz, kt and km It is addressed in the encryption procedure in stages 6 and 7.

Step 3: Convert the three vectors Ce, Cf and Cv in the form of the matrices Oe', Of'andOv'.

Step 4: According to XOR operation the invert process was done then the encryption algorithm as follows:Oe =Oe' XOR N_{jw}, Of = Of' XOR N_{je} and Ov = Ov' XOR N_{jw}, where N_{jw} utilizing the key sequence J, as described in encryption step 5, yields the desired result.

Step 5: Oe, Of and Ov are the three matrices for the sequence. Using the rule, the decoding was done (Oe, Of, and Ov)to extract the E, F, and V components of the data.

Step 6: Finally, the original data was recovered.

Before the data can post to the server it can be splitted to improve the second level of the security, for that the MHA was used.

Hellman Fibonacci sequence D_b can be defined as follows.

$$D_b = \begin{cases} 0 \; b = 0 \\ 1 \; b = 1 \\ D_{b-1} + D_{b-2} \; otherwise \end{cases} \quad (20)$$

Equation (20) is used to construct the Fibonacci sequence, which consists of the integers. Using any four consecutive terms of the Fibonacci numbers, a 2 x 2 matrix may be created that can be used to scramble data. The definition of a generalized Fibonacci mask is as follows:

$$\begin{bmatrix} \dot{z} \\ \dot{t} \end{bmatrix} = \begin{bmatrix} d_u & d_{u+1} \\ d_{u+2} & d_{u+3} \end{bmatrix} \begin{bmatrix} z \\ t \end{bmatrix} \bmod (b) \quad (21)$$

Where z, t, $\dot{z}$, $\dot{t}$ ∈ 0,1,2,3,4, … ,b−1 , du is the u^{th} term of the Fibonacci series, and b is the overall data size z, A crammed dataset has a new coordinate for the original data, which is t. Scan the whole data horizontally and vertically so that the data may be scrambled into new information.

Y orthogonal matrix of size n×n, C orthogonal matrix of size b×b and A diagonal matrix of size n×b are all singular value decomposition matrices for any given matrix L ∈ $E^{n\times b}$ where u≠h.

$$L_{nb} = Y_{nn} A_{nb} C_{bb}^{R} \quad (22)$$

Where $Y^T Y=I$, $C^T C=I$ and $a_{11} \geq a_{22} \geq \cdots a_{oo} \geq 0$, where o = min {n, b}. The columns of **Y** are orthonormal eigenvectors of LL^T, the columns of **C** are represented as a orthonormal eigenvectors of L^TL, where A is a diagonal matrix that contains the square root of Eigenvalues from Y or C in decreasing order. This is what matrix N would look like if it was 5 by 3.

$$N = Y \times A \times C^T \tag{23}$$

$$\begin{bmatrix} n_{11} & n_{12} & n_{13} \\ n_{21} & n_{22} & n_{23} \\ n_{31} & n_{32} & n_{33} \\ n_{41} & n_{42} & n_{43} \\ n_{51} & n_{52} & n_{53} \end{bmatrix} = \begin{bmatrix} y_{11} & y_{12} & y_{13} & y_{14} & y_{15} \\ y_{21} & y_{22} & y_{23} & y_{24} & y_{25} \\ y_{31} & y_{32} & y_{33} & y_{34} & y_{35} \\ y_{41} & y_{42} & y_{43} & y_{44} & y_{45} \\ y_{51} & y_{52} & y_{53} & y_{54} & y_{55} \end{bmatrix} \begin{bmatrix} a_{11} & 0 & 0 \\ 0 & a_{22} & 0 \\ 0 & 0 & a_{33} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix}^T \tag{24}$$

The following are the measures that will be taken:

1) First, need to take a look at the data in the form of a matrix Z.

2) Using Hellman Fibonacci Transform, randomize the elements of matrix Z to get matrix V.

3) Apply the SVD transformation to the matrix V to create three new matrices.

$$[Y, A, C] = SVD(V) \tag{25}$$

4) L and O are Diagonal matrices that contain only integer and fractional parts of A values, respectively.

$$A = L + O \tag{26}$$

5) The receiver already has the same keys (big and small) that may be utilized for the data reversing operation.

C. Equations

The attack success rate is done in a Scyther. Here$\alpha < \beta + \gamma$, the probability decreases exponentially with an increasing R_x . In this analysis, the hash power (G) will dominate the mining race in R_x time. When predicting how many blocks will be mined over the course of a certain period of time, the Poisson distribution may be used.

A double-spending assault happens when the opponent makes a second payment that is more than the previous payment. O_{sa} may be calculated by adding up all possible double spending attacks.

$$O_{so} = \sum_{J_1=0}^{+\infty}[O_1(J_1, R_x) \sum_{J_2=J_1+1}^{+\infty} O_2(J_2, R_x)], \tag{27}$$

Where, $O_1(J_1, R_x)$ and $O_2(J_2, R_x)$ are defined in Equation (27) and Equation (27), respectively.

It is the payee of the double-payment assault who has got the first payment and is trying to get a second one from Arbitrator. It is the payer's goal to defeat the payee in arbitration so that the arbitrator does not make a second payment to the latter. Hash power is used to create Non-Payment Proof in the double-payment attack βG and PaymentChallenge is generated with hash power $(\alpha + \gamma)G = (1 - \beta)G$ By the similar analysis as O_{sa}, the probability of double-payment attack O_{so} is given by.

$$O_{so} = \sum_{J_1=0}^{+\infty}[O_1(J_1, R_x) \sum_{J_2=J_1}^{+\infty}[O_2(J_2, R_x)], \tag{28}$$

Where, $O_1(J_1, R_x)$ and $O_2(J_2, R_x)$ are dened in Equation (27) and Equation (28), respectively. If Non-Payment Proof and Payment Challenge have the same length, then Arbitrator decides in favor of the payee, and there is no other difference in the computation of O_{so} and O_{sa}. With rising R_x, O so decreases exponentially. It is therefore possible to minimize the O so double-payment chance significantly by raising the parameter R_x by using the proposed procedure.

V. Performance Analysis

Mobile payment transactions between smartphones and payment terminals will be made more secure thanks to a new protocol were introduced in this paper. It provides an extra layer of cryptographic protection to address payment security flaws. It safeguards: the integrity and confidentiality of banking information, as well as the mutual authentication and non-repudiation of those data; and the validity of those data that are not. Using the Scyther tool, the suggested methodology was tested.

Humans still have a hard time proving that a security protocol is correct and safe. So, Scyther tool was used, which has been used in both research and teaching environments, to check the suggested protocol. Scyther enables security protocols to be analyzed in a formal manner by detecting possible attacks and weaknesses. When compared to other security verification methods, the results from Scyther's researchers are impressive. Unrestricted sessions and assured end-of-life are the hallmarks of Scyther's protocol analysis service. It generates a graph describing an assault if it discovers one that matches a certain claim. Protocols in the Scyther tool are implemented using the Security Protocol Description Language (SPDL). All Scyther statements that no attacks have been detected on Banking Data are supported by the protocol, as shown in Fig. 3. Definitions based on official sources are provided below.

The proposed Logical Diffie Hellman algorithm may be shown to be successful by comparing it to the [20] in order to demonstrate its efficacy.

	Claim	Status		Comments
BDAPT Protocol	Secret BankData	Ok	Verified	No attacks.
BDAPT Protocol	Secret BankData	Ok	Verified	No attacks.
BDAPT Protocol	Secret BankData	Ok	Verified	No attacks.
BDAPT Protocol	Secret BankData	Ok	Verified	No attacks.

Fig. 3. Protocol Efficiency Analysis.

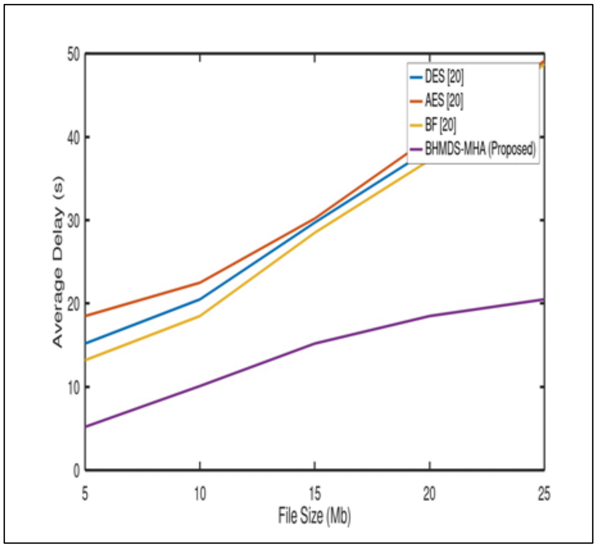

Fig. 4. File Size Vs. Average Delay.

Errors are more likely to occur during a switchover if the information used is inaccurate, imprecise, or confusing. Processing, queuing, transmission, and propagation delays are the four most common types of delays in packet switched networks. The quality and timeliness of a product are threatened by delays in communication (Transmission). Some of the probable repercussions include longer wait times, delays in discharge and poor decision-making. The delay ratio is shown in Fig. 4. The suggested method has a much lower delay ratio (20.5) than earlier procedures.

Fig. 5 and 6 depicts the time it takes to encrypt and decode a message in milliseconds, and the performance of the method is calculated. The suggested approach is compared to existing algorithms as BF, DES, and AES in terms of time differences.

It is shown in Fig. 7 that the proposed technique consumes less energy than other well-known encryption algorithms such as BF and DES.

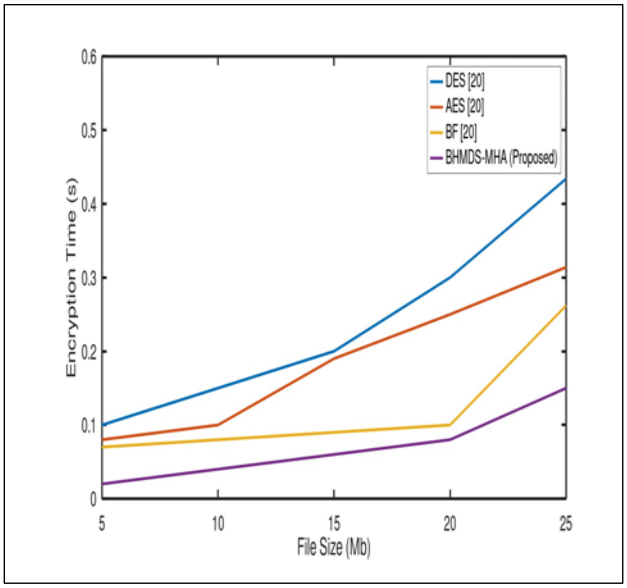

Fig. 5. File Size Vs. Encryption Time.

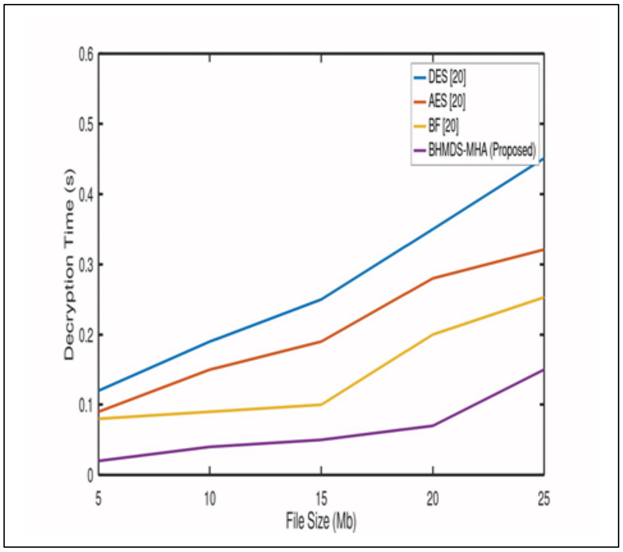

Fig. 6. File Size Vs. Decryption Time.

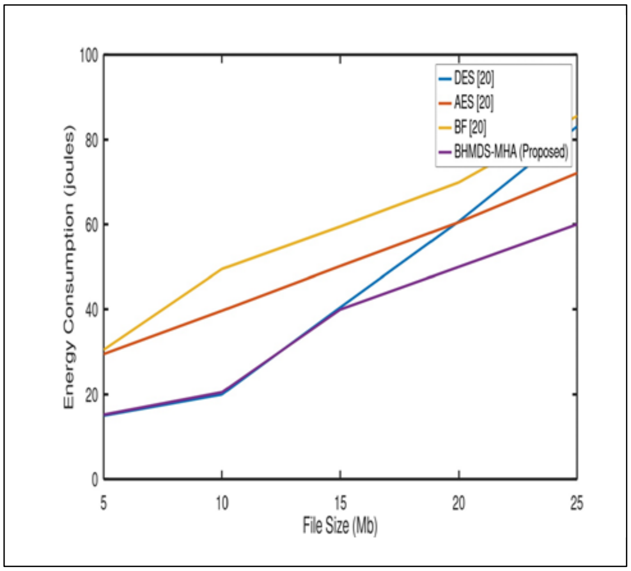

Fig. 7. File Size Vs. Energy Consumption.

Fig. 8 compares the proposed method to existing ones like DES BF and AES and shows how much faster it is in terms of throughput (in kbps). Fig. 5 to 8 show how the suggested method is tested. They look at things like average delay, throughput, encryption time, energy consumption, and decryption time to see how well the method works. BF, DES, and AES are used to figure out BHMD5-MHA, which takes into account things like average delay and throughput. BF is a competitor in near vicinity that ensures the privacy and integrity of user data. Although it seeks to reduce key complexity, its security is sometimes unreliable. BHMD5-MHA improves security for secure and successful financial transactions while also reducing the likelihood of fraud.

A secured mobile payment system was created here in this study by first employing the BHMD5-MHA method, which saves encrypted blocks of data and then links them together. An evaluation of the proposed mechanism's level of security is carried out. The proposed BHMD5-MHA algorithm is compared against existing methods as DES [18], RSA [19], and AES [21].

Various encryption algorithms are compared and contrasted in Fig. 9 to show how secure they are in comparison. The existing DES, RSA, AES methodologies are compared with a new one called BHMD5-MHA. The security level is 82% TDH, 78% DES, 77% RSA, and 73% AES for files less than 20 MB. Security is also evaluated for file sizes as large as 40 MB and as little as 1 MB. When compared to various encryption algorithms, the graph shows that the BHMD5-MHA is the most secure. According to the data, the proposed technique beats other currently used procedures when it comes to ensuring transaction security.

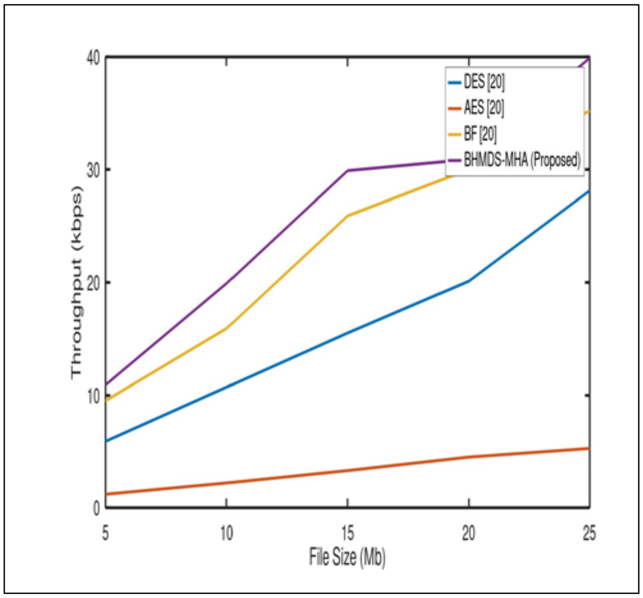

Fig. 8. File Size Vs. Throughput.

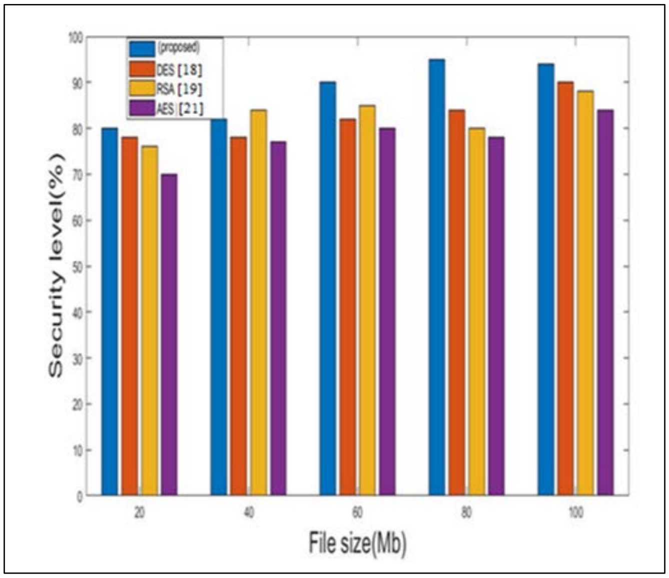

Fig. 9. File Size Vs. Security Level.

VI. Discussion

Based on the outcome that was achieved, our protocol meets the transaction security requirements listed below: 1) Symmetric encryption and the secret are used to guarantee the authenticity of the parties involved. 2) Transaction privacy is ensured by encryption, 3) Transaction integrity is ensured by the suggested protocol, and 4) Non-repudiation of transactions is also ensured in that the merchant is able to provide a non-repudiable evidence to prove to other parties that the client has originated the message. The encryption ensures that either the client or the merchant has originated the message and authenticates the client. Because the keys that are communicated between parties in our proposed protocol need to be updated on a regular basis or in response to specific requests, another worry that emerges relates to the distribution of keys. In the normal course of events, every time a new key is released, even if it is done so in an encrypted form, it is still feasible for an adversary to obtain it. Because it is possible to enlist the information in a coded form, our protocol does not need the customer to provide their card information. A participant in any transaction should not place their faith in other parties until those other parties can demonstrate that they can be trusted. Because the issuer is the one who provides the client with a credit card, our protocol specifies the trust connection that exists between the client and the issuer rather than the trust relationship that exists between the client and the payment gateway.

VII. Conclusion

The novel protocol and cryptographic techniques have been clearly addressed in this study. The Scyther compliance with standards and guidelines is used to demonstrate the model. An analogy of the key length is provided, as well as an analytical look into cryptography approaches for real-time use Due to the magnitude of the BHMD5's key, it has been demonstrated to be the most secure. As a second degree of protection, the MHA scrambles the original data. According to other symmetric key algorithms, this approach is the most secure (96 percent) and uses the least processing time. According to the findings, the proposed method could help in deal with the growing security issues that come with online transactions.

***Abstract*—Ad-hoc network usability extends the application for Dedicated Short-Range Communication. This type of ad-hoc network technology is non infrastructure and due to this fact, it can be used for Direct Short Range Communication System to provide the quick and real time message to the vehicular operator to prevent the damage and fatality of life by meeting accidents and crashes. In this paper, we present a holistic approach to estimate the number of vehicles in specified range of one KM distance. The designed system for vehicle number estimation is based on the Time Division Multiple Access mechanism which further estimates the number of reserved slots by vehicular nodes. This estimation methodology is tested under the digital simulator and approximately 34 number of vehicles for 24 seconds are defined to test the slot reservation. We found that in case of vehicular nodes greater than 20, slot reservation accuracy is 95% and when the vehicular nodes are less than 20 then the slot reservation is 100%.**

Keywords—Vehicular ad hoc networking; hidden vehicle; visible vehicle; time division multiple access; dedicated short range communication

I. Introduction

Dedicated short range communication (DSRC) structure was specially developed for the vehicular communication technology. A bunch of wireless methodologies are available for the primary medium of communication to DSRC. The major needs of wireless system under ad-hoc network for vehicular environment is that the latency should be 20 mili seconds or less than it, throughput should be high, and it cover the communication range up to one kilometer. There should also be support of diverse schemes of communication with the wireless technology. The important one is support of one-way in both uplink and downlink communication allowing the vehicular nodes to dissipate a broadcast message. The second important communication requirement is two-way that allows two vehicles to establish the dialog between them. Third important one communication requirement is point to point and point to multipoint. The point to point communication supports the message delivery to specific location or vehicular node, and point to multipoint communication the message is sent to many locations or vehicular nodes.

It is much important to evaluate the wireless technologies to determine which particular meets the DSRC requirements. A modified version of IEEE 802.11a with Time Division Multiple Access (TDMA) methodology equipped Physical layer is considered to be best suitable for DSRC communication [1]. Also, the other evaluated wireless technologies are not suitable so that these technologies are unacceptable with many different reasons. The cellular and satellite communication systems provide huge bandwidth but these two technologies have high latency. Due to this fact cellular and satellite technologies are suitable only for some of applications of DSRC. The cellular technology does not support the message broadcasting and it is a costly communication system. Similarly, satellite communication system is costly and is not suitable for DSRC applications. The wireless technology under the DSRC applications should be free of cost and must be based on ad-hoc communication. Also, the cost pertaining to the infrastructure must be cheaper than that of the satellite and cellular communication system.

Vehicular ad hoc network (VANET) becomes a challenging task to implement in real world scenario. Ad-hoc network in vehicular environment is a type of mobile ad hoc network where the computing nodes are being implemented on vehicles with modern technique of communication devices. The communication of information from vehicle to vehicle or vehicle to roadside and vice versa is performed with the active help of fast computing environment. The clear scenario for feasible vehicular communication for the different categories of applications is either related to public safety or general, such as internet accessibility based upon the various factors of vehicular ad hoc networking. One of the major problems related to estimate the number of vehicles in a lane with respect to the coverage area of an antenna established at roadside. The roadside installed antenna is also equipped with modern fast computing devices. The major role of roadside installed station is to provide the information related to vehicle safety along with structural aspect of road and highway. The estimation of number of vehicles in the specified range of the road or highway is very challenging task due to dynamic nature of vehicles.

II. Literature Review

Different forwarding methods based on the broadcasting are infrastructure less node to node communication. It is facilitated by ad hoc network under vehicular environment. The broadcast contention control provides the reliable and low latency multi-hop connection. Algorithm behind the broadcast contention control optimizes the back off distribution and provides the priority to forward the information related to the location of the node [2].

Ad-Hoc network under the vehicular environment provides the connection among the vehicular nodes of vehicles on the road. This is considered an important and valuable concept to improve the safety of the transportation system with elegant efficiency. Time division multiple access relies on slotted frame structure having the good quality of service framework. This has low scalability and complex synchronization mechanism. The vehicle number estimation according to the slot reservation is not always be optimal due to the delay and less quality of service having interference and the speeds of the nodes running on the vehicle [3].

Ad-Hoc network under the vehicular environment is more vulnerable to the Denial-of-Service attack [4]. One the most common Denial of Service Attack is Jamming attack which leads to the interference with the used wireless ad-hoc network service and creates the network congestion. Once the Jamming attack progresses, the quality of service of the ad hoc network degrades and the optimal service cannot be achieved. Due to this fact the vehicle number estimation fails and this causes the failure of the overall network service of ad hoc network in vehicular environment.

A cross layered Medium Access Control having clustering mechanism supports the propagation of the broadcast message in ad hoc network under vehicular environment [5]. Distributed dynamic clustering frames, and the dynamic virtual backbone in the ad hoc network are the building blocks of the cross layered Medium Access Control. The members associated and connected with the ad-hoc network in vehicular environment are responsible to implement the efficient message propagation to utilize the slot and count the numbers of allocated slots in the vehicle number estimation. This fails when the vehicle's speed goes beyond the defined threshold value and the performance of this method degrades.

III. Proposed Method for Vehicle Numbers Estimation

In case of vehicular ad hoc networking there are two different categories of vehicles on road or highways. These two categories of vehicles are either visible or hidden vehicles. To estimate the number of vehicles, it should be first determine the estimation method for both hidden and visible vehicles. The hidden vehicle is considered hidden because this type of vehicles has not joined the coverage area of roadside antenna. The estimation of visible or hidden vehicles are taken with the help of reservation of slots under Time division multiple access (TDMA).

A. Visible Vehicle Numbers Estimation

The intensity of vehicles with respect to specified time in a given direction is estimated by the number of occupied slots of TDMA channel by sequence numbers from beginning to end [6]. The specific beacon frame containing message indicates by adding an additional field into the frame format. This estimation of number of vehicles is performed with every regular interval of time by roadside station with broadcasting to all vehicles in the coverage range of station. These visible vehicles become under the control of regulation. The determination of visible vehicles is shown with Fig. 1.

In accordance with Fig. 1, it is very clear that the road is only two-lane structure. For left side running vehicles in a lane under same direction reserves the slots of TDMA from left to right [7]. The vehicles running into right side in other lane under opposite direction on road reserve to slot of TDMA in reverse direction. The sequence numbers of reserved slots are not repeated in any case. Hence, the sum of highest sequence numbers of both lanes TDMA slots forward and reverse directions gives the total number of visible vehicles on the coverage area of roadside station.

B. Hidden Vehicles Number Estimation

Roadside installed stations checks the number of hidden vehicles with regular interval of time by beaconing itself. The beacons with additional parameters are listening to all the vehicles but vehicles avoid this which is already connected into the network with specified group. An additional sub field that contains the connecting request information for the vehicle node is attached under the beacon frame. There is specified number of two slots under the TDMA slots which depict the beaconing for estimating the hidden vehicles. These two slots cannot be probed and reserved by any vehicles in any direction. These slots are indicated by special identifier Hidden Vehicles (HV) [8]. Under this slot interval any vehicle probing is observed then it is concluded that this is hidden vehicles and roadside unit add one in hidden vehicles number and subsequently broadcast the message to all groups about the hidden vehicle. The TDMA slots are reserved for HV predicted under Fig. 2.

The TDMA channels slots of Fig. 2, shows that the first HV is in a forward direction and second in the reverse direction of vehicles.

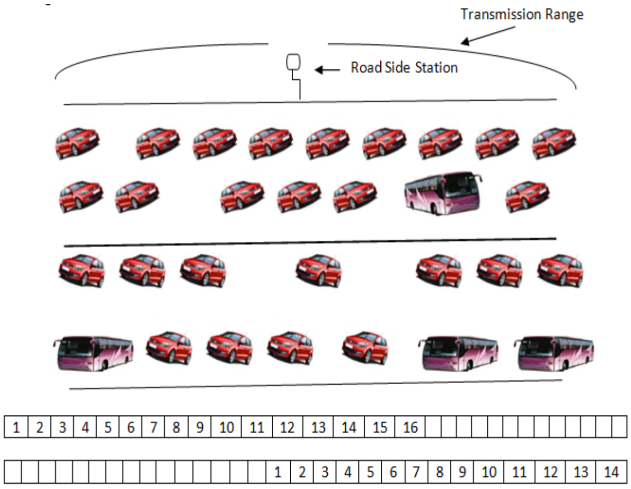

Fig. 1. Visible Vehicles having Ad-Hoc Network Node.

1	2	3	4	5	6	8	9	10	HV	
HV	1	2		3	4	5	6	7	8	9

Fig. 2. TDMA Slots with Hidden Vehicles.

Suppose that the probability is p of hidden vehicle which transmit HV frames under the TDMA slots and n is the total number of hidden vehicles in both directions of vehicles in two lanes of given road. Again, let, n1 be the number of vehicles in one direction and n2 be the number of vehicles in opposite direction. Also, let m be the total number of hidden vehicles under the communication range of a roadside station, we can derive the probabilities of the different status of HV Channel slots.

Probability that HV slot is ideal

$I = (1 - p)^{m}$

Probability that HV frame is successfully received from a hidden vehicle in a direction is

$DP_1 = n_1p(1 - p)^{m-1}$

Probability that HV frame is successfully received in opposite direction hidden vehicle is

$DP_2 = n_2p\ (1 - p)^{m-1}$

Therefore, the total number of estimated hidden vehicles in each same and opposite directions are calculated as,

$$n1 = \frac{s1}{I}\left(\frac{1-p}{p}\right)$$

$$n2 = \frac{s2}{I}\left(\frac{1-p}{p}\right)$$

After getting the probabilities values of vehicles in each direction we can further smooth the values by exponential moving averages by smoothing factor VHAlpha, which is a system parameter [9].

IV. Designed System Simulation

The estimation of hidden and visible vehicles simulation is performed with the above-mentioned criteria with total number of 30 vehicular nodes. The vehicles that are under the vehicular ad-hoc network environment must have the digital map under the designed simulator application. We have used constructed files as a digital map to simulate the VANET. The constructed files contain detailed geographical information about the road. The data which digital map contains comes in the form of geographical coordinates (latitude, longitude) for the road [10]. The constructed files based on the selected road specify the end points, having the intermediate points those are required. In case, when the road is straight, then there is not any intermediate points. This is so because the intermediary points are calculated by the help of interpolation. Further, in case of the road having curves, there are very huge numbers of intermediate points, so that the map is considered accurate.

The traffic simulator that takes actions of each of the vehicle under the given scenario is a digital simulator, as opposed to those digital simulators that use the global measure like density of traffic on road to describe the evolution of traffic. The dynamics of the traffic can be better understood with help of the digital simulator and appropriate design of facilities related to road traffic such as lanes, lights, closure of lanes and corners [10].

A. Digital Traffic Simulator

A digital traffic simulator is an application used to simulate the traffic behavior with respect to the wireless ad-hoc network communication message. Each of the vehicles which are taken under the vehicle has the computing node and is able to send and receive the wireless signals to the others. Simulating in digital traffic simulator there is requirement of setup of the vehicles and road with trajectories and intermediary point. The vehicle behavior with respect to the requirements to fulfill the order of traffic is observed in the process of simulation.

With above facts, there is requirement of high level of details to study the suitability of wireless ad-hoc network in vehicular environment. To solve this, we have designed a digital traffic simulator based on a model of behavior of driver. This designed driver behavior model is presented in Fig. 3. There are many traffic simulators such as ‘VISSIM’ and others that use this type of designed driver behavior model for the simulation of vehicular environment. Basically, VISSIM’s purpose is to model and forecast the traffic flow of vehicles, addition of new lane, making of the study of traffic closure to lane and creating the overpass and many more. Also, it is true that this type simulators are very difficult to integrate with the network simulator as these types of simulators are commercial products [12] [13].

Thereafter, we have made the description of the driver behavior model which we have deployed. The assumptions are taken under the driver behavior model are ‘free driving’, ‘following’, ‘braking’, and ‘approaching’.

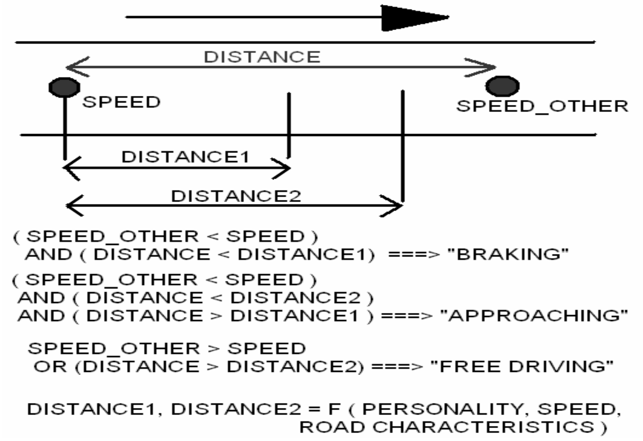
Driver model with ‘free driving’ states that there is no influence by preceding vehicles under the same lane of the vehicles. Thus, the drivers have to maintain the desired speed. Although, the speed and acceleration depend on the driver and the features of the road on which the vehicles are driven.

Driver model with ‘approaching’ states that the preceding vehicle is slower in speed. In this case the driver has to de-accelerate the speed to make the same speed of preceding vehicle. Basically, de-acceleration is treated as a function of distance between preceding and approaching vehicles, their speed and other parameters in same lane of road.

Driver model with ‘following’ states that the speeds of preceding and following vehicles are equal or same. In this case the drivers of both of the vehicles maintains the same speed and constant acceleration can be maintained.

Driver model with ‘braking’ states that the slower preceding vehicle is close to front of following vehicle. In this case, the following vehicle driver has to deaccelerate by braking the vehicle to avoid the crash.

The rules defined for driver to determine the driver mode is presented by Fig. 2. Two thresholds are taken, where ‘distance1’ is first and ‘distance2’ is second, when the preceding vehicle is closer to ‘distance1’ and slower than the just following vehicle.



DISTANCE
SPEED
SPEED_OTHER
DISTANCE1
DISTANCE2
(SPEED_OTHER < SPEED)
AND (DISTANCE < DISTANCE1) ===> "BRAKING"
(SPEED_OTHER < SPEED)
AND (DISTANCE < DISTANCE2)
AND (DISTANCE > DISTANCE1) ===> "APPROACHING"
SPEED_OTHER > SPEED
OR (DISTANCE > DISTANCE2) ===> "FREE DRIVING"
DISTANCE1, DISTANCE2 = F (PERSONALITY, SPEED, ROAD CHARACTERISTICS)

Fig. 3. Designed Digital Traffic Simulator.

In case of ‘braking’ mode, when the slower preceding vehicle is under the ‘distance1’ and ‘distance2’, then the mode is considered ‘approaching’ then the current vehicle definitely deaccelerates [14]. When the preceding vehicle is away from distance2, then there is no influence to current vehicle by any means, and it is taken under ‘free driving’ mode. Also, the defined thresholds ‘distance1’ and ‘distance2’ are not fixed. These depend on the driver driving style and speed of the vehicle [15] [16].

B. Simulation Data

The simulation data is based on the number of vehicles taken under simulator, lanes defined under the simulator, time specified for simulation and vehicle flow per second. The whole data is presented in Table I.

TABLE I. SIMULATION DATA

No. of Vehicles	No. of Lanes	Time (Sec.)	TDMA Slot Reserved

C. Simulation Result

The scenario of simulation provides the estimation of vehicles having node connection with station and slot reservation under the range within 24 seconds. The result shows that maximum 5% deviation in case of the heavy traffic (No. of vehicles 30 or more), and in case of the vehicular nodes less than 20 the vehicle estimation is 100% in both visible and non-visible scenarios. The simulation result is presented in Fig. 4.

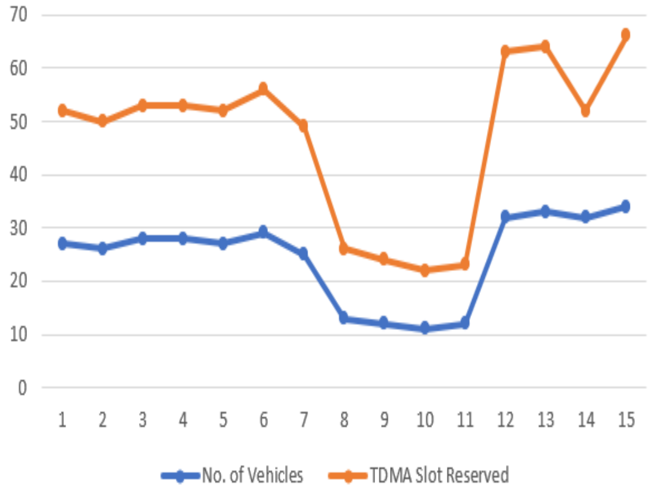

Fig. 4. Simulation Result of Vehicles Number Estimation.

The mentioned data is gathered from real time environment of the roads having two lanes under the simulator to simulate the performance. According to the simulation setup as per the given parameters the time is obtained. The TDMA slot reservation is based on the vehicles on both of the lanes under the simulation environment. Finally, the result of the simulation under the Fig. 4, is well presented.

V. CONCLUSION

The carried research work is performed to enhance safety of the living beings while travelling via vehicles like car, bus and others by employing the ad-hoc network and nodes on the vehicles. In this research work we have done the design of the digital traffic simulator and used various parameters such as approaching, distance to generate the warning message to the operators through the ad hoc network nodes to driver screen. TDMA slot allocation is used to estimate the total number of vehicles in the pre-defined range of road having single and double lane in the city scenario. The number of vehicle estimation and its results show that during the more load of vehicles, means vehicle nodes > 20 the correctness is 95% for estimation and if the number of vehicles having ad -hoc nodes < 20 then correctness is about to 100%

Virtual Tourism and Digital Heritage: An Analysis of VR/AR Technologies and Applications

Muhammad Shoaib Siddiqui, Toqeer Ali Syed, Adnan Nadeem, Waqas Nawaz, Ahmad Alkhodre
Faculty of Computer and Information Systems, Islamic University of Madinah
Madinah, Kingdom of Saudi Arabia

***Abstract*—During the time of the pandemic, travel restrictions have impacted the tourism industry with an estimated loss of more than a trillion USD; however, at the same time, we have seen a significant increase in profits for the industries which empower remote connectivity. Various studies have identified the positive impact of virtual tourism, in which tourists can be attracted by providing a VR/AR-based experience of the destination. Similarly, virtual, mixed, and augmented realities are being used to enhance user experience in digital heritage and its preservation. With emerging technologies and increasing demand for e-tourism (due to travel restrictions), there is a need to review the technological changes and analyze user requirements with respect to virtual tourism. This paper provides a literature review of the latest technologies and applications that can potentially benefit the virtual tourism and digital heritage industry. We also provide an analysis of its impact on user experience, awareness, and interest, as well as the pros and cons of virtual experiences, which may benefit the research community about the current spectrum of virtual tourism and digital heritage.**

Keywords—Virtual tourism; digital heritage; virtual reality; user experience

I. Introduction

Virtual Reality (VR) [1] is the art of envisaging the imagination capabilities of the human mind. People can visualize and interact with imaginary objects in a fantasy environment. They can pretend to live, roam, and interact in ideal, purpose-built, or inventive worlds. In general, it is non-trivial to define limits on human imagination, however, it is possible to create human-inspired imaginary worlds with the state-of-the-art technologies in computer-based systems [2]. With the advent of technology, the imagination of the virtual world can be diversified with the real world to provide more realistic experiences. This field is known as Mixed Reality (MR) [1], in which a mixture of real world and virtual objects and scenes can be emulated to provide a better and more realistic experience. Similarly, the real world can be augmented with virtual assets and entities for providing past and future experiences, in-depth infographics, and supplementary details. This type of environment is termed as Augmented Reality (AR) [3].

During the pandemic, most countries posted a ban on traveling, which had an adverse effect on the tourism industry [4]. The tourism industry was estimated to be USD 1.478 billion-dollar industry worldwide [5] before the pandemic; however, due to the COVID restrictions, the severe effects were not limited to internal and external tourism but also propagated to other related industries such as hotels, restaurants, theme parks, travel agencies, etc. Tourism and related industries are estimated to observe a Trillion USD loss in 2021 and 2022 [6].

Virtual Tourism (VT) provides ample opportunity and a substitute for the tourism industry. For the safety of the public, people were advised to keep a distance from each other, which introduced boring and monotonous experiences in everyday life. VT enables a tourism experience within the boundaries and guidelines of the pandemic restrictions. Users can have an immersive experience of a virtual or a real environment using special equipment from the comfortability of their homes. Although the user interaction in a virtual environment is not real and limited, i.e., without the experience of culture and language; however, it provides a cost-effective solution with high-quality graphics and sufficient control on viewing details in a safe and secure environment. Another advantage of virtual tourism is the preservation of cultural and natural heritage from vulnerable environments, due to tourist visits and urbanization, which introduces a potential application of Digital Heritage (DH) [7]. Digital heritage is the use of digital media to understand and preserve cultural or natural heritage. The cultural, historical, scientific, educational, and linguistic resources are converted into digital media to be preserved for later generations. For example, if a historical site is visited more often by many tourists with poor maintenance, it may deteriorate its originality. Similarly, if an ancient book, is given physical access to many people, then the vital piece of history may get destroyed. Therefore, access to these resources should only be through virtual, augmented, and/or mixed realities to provide an immersive experience.

Virtual tourism and digital heritage are enabled by VR/AR/MR technologies and applications. Without the implementation and support of the right tools, this promising industry cannot develop and thrive. In this paper, we have reviewed various technologies and applications related to virtual, augmented, and mixed realities that play a vital role in VT and DH. We have conducted a survey analysis of the perceptions, experiences, and intentions of users of different age groups about virtual tourism and digital heritage. We have also presented an in-depth analysis of commercial technologies and web/mobile applications that would benefit the research community about the current spectrum of virtual tourism and digital heritage.

The rest of the paper is structured as follows. Section II provides a detailed introduction to virtual tourism, and digital heritage and its business value. Section III reviews the

This work is supported by the Ministry of Education under project 20/16, titled: “Virtual journey into the history of the Kingdom of Saudi Arabia”.

concepts, technologies and applications of VR/AR/MR. Section IV presents the analysis of our conducted survey about peoples' perceptions of VR & DH. Section V analyzes the pros and cons of VR & DH. Section VI provides the literature review of the research related to our domain and Section VII concludes the paper.

II. Virtual Tourism and Digital Heritage

The user experience in virtual, augmented, and mixed environments can be classified into non-immersive, semi-immersive, and fully immersive experiences. Due to the everyday interaction with the artificially generated and enhanced media, people do not consider the non-immersive experience as VR/AR/MR. People are accustomed to TV, mobile phones, and computer screens without realizing that they are having a non-immersive experience in the context of VR/AR/MR. This technology provides a computer-generated experience, but still gives users awareness and control of their physical environment. Non-immersive virtual reality systems rely on computer or video game consoles, displays, and input devices such as keyboards, locators, and controllers. Watching movies and playing video games are some examples of a non-immersive VR experience [8].

The semi-immersive environment provides users a more perceptive experience of being connected to the virtual world; however, they can still feel their physical surroundings. Semi-immersive realities use high-end computer graphics to provide a more realistic environment with limited interaction, such as, using tools and simulating to have a hands-on experience using controllers and feedback actuators. The applications of semi-immersive reality are mostly simulations, which partially replicate the design and functionality of real-world mechanisms, for training and educational purposes [8].

The most realistic and attractive experience is provided by the fully immersive realities. It provides the sense of touch using hand gestures and feedback actuators, sense of sound by using stereo-based and motion-based directional audio, and sense of sight by using motion and eye tracking sensors. Head-mounted 3D displays with directional sensors are used to provide a wide field of 360-degree stereoscopic view. This type of VR has generally been adapted for gaming and other entertainment purposes, but its use is also increasing in other fields such as education, training, and virtual tourism. With fully immersive experience, the potential for using VR/AR/MR is endless and only limited by human imagination [8].

All three categories of VR/AR/MR experience can be used to enable virtual tourism and digital heritage; however, they are limited by cost-effectiveness, in-depth design, technological evolution, and user acceptance [9].

A. *Virtual Tourism*

Virtual tourism is a remote application that enables travelers to explore nature, attractions, destinations, ruins, buildings, and other travel destinations without having to physically visit them. It provides a detailed experience made possible by the emerging technology. Virtual tours can include 360-degree photos, guided teleconferencing, virtual reality (VR), augmented reality (AR), video tours, the ability to interact with art and culture experiences, or ancient environments [10].

Virtual tourism is a growing trend around the world and it's not just a response to the COVID epidemic, it is being developed behind the scenes for quite some time. Traditionally used primarily as a marketing tool, virtual tourism has recently become increasingly popular among tourism industry stakeholders. Thanks to technological advances around the world and the use of the Internet, it is deeply rooted in the concept of smart tourism. Worldwide, the VT industry was worth USD 5 Billion in 2021 and it is anticipated to reach USD 24 Billion in 2022 [11], as shown in Fig. 1.

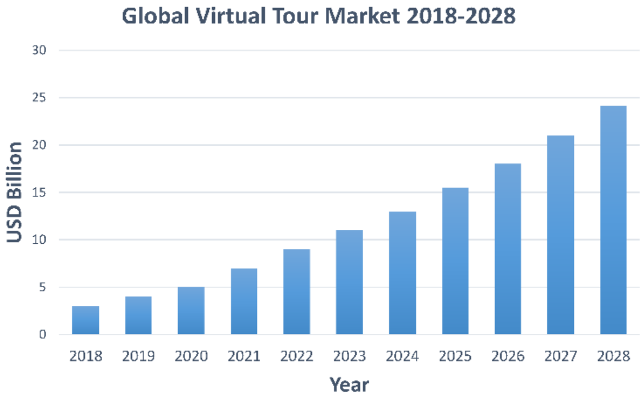

Fig. 1. Market Growth of Virtual Tourism [11].

Virtual tourism takes many forms and offers different levels of technical competence. In its simplest form, virtual tours solely rely on videos of places of interest. A 'tourist' uses speakers and a screen to see pictures. A more sophisticated form of virtual tourism involves immersing yourself in the environment using a headset or simulator. This may involve the use of various technological instruments, the user may need to wear gloves, and may have additional sensors, such as motion, proximity, direction, gestures, feeling (response), and even smell. Virtual tourism covers a wide range of digitally enhanced realities, including virtual reality, mixed reality, and augmented reality. For instance, whether you are a traveler looking for an exotic destination like Forest of Knives in Madagascar, a teacher sharing an experience with your students about the ruins of Machu Picchu, an architectural enthusiast looking for modern design like the Guggenheim in New York, or a wildlife explorer to spot animals from a safari jeep in Tanzania at sunrise, there is a virtual tour available for you.

Moreover, the virtual museum tour at the Louvre [12] provides access to Egyptian Antiquities, the remains of the Louvre's Moat, the Galerie d'Apollon, and famous artworks, such as, the Winged Victory of Samothrace, Mona Lisa, the Coronation of Napoleon, and many more. Dubai 360 provides an immersive awe-inspiring view of Dubai's modern architecture [13]. An interactive journey to the Great Barrier Reef, narrated by David Attenborough is available on YouTube 3D [14]. Users can have a semi-immersive experience of Anne Frank's house, walk through the Great Wall of China [15], indulge in the royal history at Buckingham Palace [16], experience a flight over a Volcano, bewildered by the scenic view of the Yosemite National park [17], imagine the gladiators' battle inside the Colosseum [18], inspired by the 360 view of the Statue of Liberty [19], visit the Holy land of Jerusalem [20] and Mecca [21], climb Mount Everest [22], get lost in the Amazon jungle, or even take a trip to space [23]. From the couch of your living room, you can party in Ibiza, be alone in the clouds in a hot air balloon, dive with fishes in the Georgia aquarium, or fly over the skies of Paris; virtual tourism enables all of this and much more [24].

B. *Digital Heritage*

The Charter on the Preservation of Digital Heritage of UNESCO defines digital heritage as embracing "cultural, educational, scientific and administrative resources, as well as technical, legal, medical and other kinds of information created digitally, or converted into digital form from existing analogue resources" [25]. UNESCO divides digital heritage into two separate groups namely Digital Cultural Heritage and Digital Natural Heritage [25]. Cultural heritage is the preservation and recording of cultural entities through digitization. These are things that are considered culturally important, which can be digitized or presented in physical details. It also includes intangible heritage, such as, traditions, customs, value systems, techniques, traditional dances, food, performances, and other unique features of culture, which are prone to destruction due to urbanization. Digital natural heritage is related to natural heritage objects of cultural, scientific, or aesthetic importance. In this case, digital heritage is used not only to provide access to these objects, but also to monitor changes such as plant and animal habitats over time.

There are several projects and programs which concentrate on digital heritage [27]. Global Digital Heritage (GDH) is a non-profit, private research and educational organization dedicated to documenting, monitoring, and preserving the global cultural and natural heritage [28]. They record, manage and provide immersive experiences to various destinations like Château de La Roche-Guyon in France, Early Christian Basilica of Sofiana in Italy, Archaeological Museum of Aidone in Italy; Bull Ring and Sanctuary of the Virgen de Las Nieves in Spain, Necropolis of Jebel al-Buhais in UAE, and many more [26].

Although a tour to the museum brings a surreal sensation of being in the past and present at the same time, feeling interested, surprised, happy, fantastic, and special because one can learn new things about the history and the art. Google Arts & Culture works with more than 1,200 museums and galleries around the world to provide everyone with virtual tours and online exhibits of the world's most popular museums [29]. Preserving the heritage by digitizing and making it available to the people is the main goal of such initiatives. Google Arts and Culture do not include all the museums and galleries; however, many of the museums, cultural sites, galleries, and even literature sites have created 2D and/or 3D models, which can be experienced through either virtual reality or augmented reality.

Similarly, history enthusiasts are able to visit various sites (Machu Picchu in Peru, stone carved palaces of Petra in Jordan, Taj Mahal in India, Khumbu Valley in Nepal, the Vatican City, etc.) [29], museums (Smithsonian National Museum of Natural History in USA, British Museum, etc.) [30] and read digitized old books at libraries (Library of Congress, British Library and UC Davis Library, etc.) [31] without disturbing the physical environment.

III. VR/AR Technologies and Applications

Virtual Tourism and Digital Heritage are enabled by VR/AR/MR technologies and applications [32] [33]. Without the implementation and support of the proper tools, this promising industry cannot evolve and prosper [34]. Various technologies are required for creating a virtual world, which involves capturing the real world, modelling the assets and scenes, and adding narration and interaction. For experiencing the virtual world, involves immersive displays, movement/motion tracking, environment sensing, and enabling runtime command and control. These technologies can be classified as, display screens, viewing glasses, sensors, cameras, image processing tools, and graphics processors. Furthermore, various software are also required to provide realistic experience, such as graphics engines, AR/VR toolkits, and libraries and APIs. In the following subsections, the models that envisages VT and DH, and some of the enabling technologies and application toolkits are discussed.

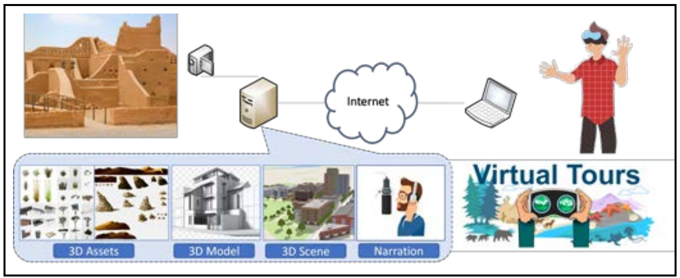

Fig. 2. Conceptual Model of How Virtual Tourism Concept is Created and Experienced.

A. *How VT and DH Works?*

Before the user can have a remote experience, the virtual environment must be created using CGI (Computer Graphics Interface). Fig. 2 shows a conceptual model of how the content is created for a virtual experience. For the non-immersive experience, a simple or 3D camera can be used to capture images and composed them together to create a visual tour using available toolkits and applications. 2D/3D assets are created using graphics tools, transformed into a 3D scene and then a virtual world is created. After that, narration is often added to guide the user.

For semi-immersive experiences, 360-degree cameras can be used which provide a panoramic view of the actual place. A user can connect to this 360-degree camera using the Internet and view it using a head-mounted display with motion sensors. When a user moves the sensors observe the movement and send to the controller, which calculates the viewing angle and direction and changes the display image accordingly. YouTube360 and Metaverse by Facebook are examples of these experiences.

Developers also use extensive CGI to create a 3D model of a place, such as, a palace or a museum, and augment it with the real images captured in real-time [35]. They use both audio and video streams to provide a fully immersive experience. The view in the 3D model is changed according to the movement of the user, which is recorded using gyroscope, magnetometer and accelerometer present in the head-mounted display or the mobile phone. Stereo surround-sound is used to provide directional sounds to the user with the built-in speaker in the head-mounted display. Similarly, for interaction with the environment, users can use a magnetic, ultrasonic, or gesture-based tracking systems to grab, and/or displace objects, actuate menus and/or perform other activities. The system receives the input signals, processes the interaction model, and displays the activities to the user at runtime. Instructions and detailed information about events, places, milestones, and important sites are also augmented in the 2D/3D world for guiding the users about the history or the significance of the place.

B. VR Equipment

1) Display devices: The quality of immersive in VR is defined by the display devices. A common monitor screen can provide a virtual experience; however, it would be a non-immersive impression [45]. A mobile phone can provide a semi-immersive experience, as it has motion sensors, which can detect changes in orientation and direction, and may respond by changing the view for the user [46]. The display devices use split screens to emulate a wide field of 360-degree stereoscopic view. This gives the user an illusion of looking around in the environment. Virtual Box [44] and Google Cardboard [43] are examples of such a device; however, they only provide a casing for the mobile device and help the user mount on the display device [44].

For a fully immersive experience, a range of head-mounted display devices are available, that contain sensors, cameras, location devices and controllers, built-in inside the device. Table I shows the comparisons of some of the famous head-mounted display devices, which are commonly known as VR kits.

As shown in Table I, Google Cardboard, and VRBox and similar devices are very cheap as they provide a method of holding a mobile phone for proper viewing the virtual environment. An elastic band is used to mount the device over user's head, or the user has to hold it using hands which makes it ergonomically infeasible. Some Bluetooth based controllers can be used to provide input; however, the experience in semi-immersive. On the other hand, HTC Vive Pro 2, HP Reverb G2, and Pimax Vision 8K X VR Headsets have ergonomic designs and are very comfortable with adjustable straps, which makes them very expensive. The other factors that make some of these devices expensive, is the display resolution and refresh rate. Pimax Vision 8K X VR Headset has the best display quality, however, high-quality CGI means an expensive GPU is also required. Every headset (in Table I) that is providing a fully immersive experience, requires a fast computer with a high-end GPU device except Oculus Quest 2, which can work as a stand-alone. It has its own processor and memory and can work with or without a computer. Oculus Quest 2 does not require extra devices, such as base stations, to track the headset and/or the controllers and provides flexible mobility using wireless communication. Oculus Rift, HTC Vive Pro 2, HP Reverb G2, HP Windows Mixed Reality, and Pimax Vision 8K X VR Headsets are connected through a wire to the computer; therefore, mobility is limited. However, wireless connectivity is being made available by various vendors to compete with the acceptability of Oculus Quest 2.

TABLE I. A COMPARISON OF VARIOUS HEAD-MOUNTED DISPLAY FOR VR

S. No	VR kit	Characteristics	Experience
1	Oculus Rift [36]	• Resolution 1280x1440, 80 Hz • No computation or memory resources • Accelerometer, proximity, magnetometer, gyroscope • Guardian system for headset and controllers tracking • Buttons and gestures-based input • Stereo speakers, positional audio • No Battery • Inexpensive	Fully immersive
2	Oculus Quest 2 [37]	• Stand-alone, • Resolution 1832x1920 per eye, 80 Hz • Qualcomm® Snapdragon™ XR2 processor with 128/256 GB ROM • Accelerometer, proximity, magnetometer, gyroscope • Guardian system for headset and controllers tracking, camera-based outside tracking, GPS • Buttons and gestures-based input • Stereo speakers, positional audio • 2–3-hour Battery life • Inexpensive	Fully immersive
3	HTC Vive Pro [38]	• Resolution: 2448x2448 per eye, 90/120 Hz, 5K display • 100-degree field of view • No computation or memory resources • G-sensor, proximity, gyroscope, IPD sensor • Guardian system for headset and controllers tracking, infrared camera-based outside tracking • Buttons and gestures-based input • Stereo speakers, positional audio • No Battery • Very Expensive	Fully immersive
4	HP Reverb G2 [39]	• Resolution: 2160 x 2160 per eye, 90 Hz, 2 LCDs • No computation or memory resources • G-sensor, proximity, gyroscope, IPD sensor • Guardian system for headset and controllers tracking and camera-based tracking • Stereo speakers, positional audio • No Battery • Expensive	Fully immersive
5	Sony Playstation VR [40]	• Resolution: 960x1080 per eye, 90/120 Hz • Graphics Controller Box for screen mirroring and sound processing • Accelerometer, gyroscope • Positional tracking with 9 LEDs via PlayStation Camera	Fully immersive

		• Stereo speakers, positional audio • No Battery • Expensive	
6	HP Windows Mixed Reality Headset	• Resolution: 1440 x 1440 per eye, 90 Hz, 2 LCDs • No computation or memory resources • Windows Mixed Reality inside/out 6 DOF motion tracking, gyroscope, accelerometer, and magnetometer • Front-facing camera tracking • Stereo speakers, positional audio • No Battery • Expensive	Fully immersive
7	Pimax Vision 8K X VR Headset [41]	• Resolution: 3840 x 2160 per eye, 60-114 Hz (2560x1440), 170-degree FOV • No computation or memory resources • 9-axis accelerometer • SteamVR tracking • Buttons and gestures-based input • Stereo speakers, positional audio • No Battery • Very Expensive	Fully immersive
8	DPVR Headset [42]	• Resolution: 1280x1400 per eye, 72 Hz, 110-degree FOV • No computation or memory resources • 3 DoF Non-positional tracking • SteamVR platform • No Battery • Very Cheap	Semi immersive
9	Google Cardboard [43]	• Uses mobile phone as a display • No computation or memory resources, • Very cheap	Semi immersive
10	VR Box [44] and similar	• Use mobile phone as a display • No computation resources, No memory, • Bluetooth based input devices are available • Inexpensive	Semi immersive

2) Sensors: A variety of sensor technologies are needed to provide input to VR/AR system. These sensors include object and motion tracking, directional sensing, visual sensing, and audio interfacing [46]. The technology is ever evolving by the introduction of new types of sensors and different types of haptics for touch, smell, and heat-based feedbacks. A conventional VR/AR system uses G-sensors, such as, accelerometer, magnetometer, and gyroscope to detect inertial movement and direction. Indoor and outdoor GPS systems are used to identify the location of the user, directional mics are used to understand what the user is saying or hearing and from where, and cameras are used to identify what the user is seeing. State-of-the-art devices are using more complex sensors, such as, time-of-flight sensors, heat mapping, structured light sensors, etc., which are product of integrated basic sensors mentioned above. Table II provides the details of some common sensors and tracking systems used in AR/VR technologies.

TABLE II. VARIOUS SENSOR USED IN AR/VR SYSTEMS AND THEIR USAGE

S. No	Sensor	Usage
1	Accelerometer	Movement tracking in X, Y and Z dimensions
2	Gyroscope	Sense angular velocity or rotation motion
3	G-sensor	Force of movement in gravitational units
4	Magnetometer	Direction tracking
5	Proximity	Measure distance of object in front
6	Light sensor	Measure the luminescence
7	IR sensor	Senses the invisible light (infrared) for proximity and motion detection
8	Depth sensors	Camera based sensor to detect the depth in the recorded image to identify which object is near and which is far away
9	Eye-tracking	Track the movement of eyes to identify where the user is looking
10	Directional microphone	A pair of mics which can identify where the sound is coming from using Doppler effect.
11	Inertial Measurement Sensor	An integrated accelerometer, gyroscope and magnetometer sensor
12	Time-of-Flight sensor	Laser or IR based distance detection for finding range between object and the camera. Used for robot navigation, vehicle monitoring, people counting, and object detection
13	Object & Gesture Tracking	Camera and image processing-based system used to track objects and user for recognition movement and gestures
14	Ultra-sound sensors	Ultrasound sensors are mainly used to detect proximity and distance
15	Thermal sensor	Helps in detecting heat signatures to differentiate between users and various objects.
16	Ambient light sensor	Helps in detecting heat signatures to differentiate between users and various objects.
17	GPS	Global Positioning System uses satellite-based location calculation and only works in open environments
18	Indoor GPS	To enable indoor location, Bluetooth or Wi-Fi beacon-based solutions are used where a device uses a triangulation method to calculate its own location

3) Cameras: The VR world is artificially created using CGI which can provide a 2D view for non-immersive display or a 3D view, which can be used to provide a fully immersive experience. But to create a whole 3D model, a lot of effort is required, which may not be realistic. To make the world more realistic, it is augmented by mixing the real-world object and scenes. Cameras are used to capture these images and then the virtual world is augmented with these captured images. Hence, the quality of the camera has significance in creating a realistic environment along with the 3D modelling and rendering process.

A simple camera can be used to take pictures of an environment from different angles and the images can be stitched together to provide a 360-degree view, which is time-consuming. These days, cameras are available that take a 360-degree picture of an environment and output a 3D world to be viewed at runtime or to be saved to create realistic mixed realities. A 3D camera is either omnidirectional or composed of many small cameras. It captures multiple images at the same time from different angles. The software, either inside the camera or on a computer or smartphone, orchestrates a spherical image by fusing the images. VR headset can be used to view these spherical images as it allows the user to move inside the image and feel an immersive experience. A comparison of some famous 360-degree cameras is provided in Table III.

TABLE III. COMPARISON OF FAMOUS 360-DEGREE CAMERAS

Q. No	Camera	Features
1	Insta360 One X2	• 2x 5.7K lenses • 6080x3040 360-degree recording • 6-axis gyroscope • 360 directional focus audio • Bluetooth, Wi-Fi, USB connectivity • MicroSD card storage • Less Expensive
2	GoPro Max	• 1x 5.6K lens • 16.6mp 360-degree recording • GPS • 4 channel microphones audio • Bluetooth, Wi-Fi, USB connectivity • MicroSD card storage • Less Expensive
3	Ricoh Theta Z1	• 2x 4K lenses • 23mp 360-degree recording • GPS • 6x microphones audio • Bluetooth, Wi-Fi (web server), USB connectivity • 50 GB internal storage • Expensive
4	Samsung Gear 360	• 2x 15mp lenses • 3840x1920 360-degree recording • Accelerometer, Gyroscope • Bluetooth, Wi-Fi, USB, NFC connectivity • Compatible with High-end Samsung Mobile phones • 1 GB internal storage with 128 GB using MicroSD • Cheap
5	Vuze XR	• 2 x Sony 12MP IMX-378 fisheye lenses • 3840x1920 360-degree recording through Ambarella H2 video processor • Accelerometer, Gyroscope • Wi-Fi, USB connectivity • 4x microphones • Removeable MicroSD card • Cheap
6	Nokia OZO	• 8 2Kx2K ISO 190-degree lenses • 9 Capture up to 12K30 x 12K30 Video/Stills • 500 GB SSD Module for Recording • Automatic stitching • HDMI output • Omnidirectional microphones • Extremely Expensive
7	Gopro Odyssey	• 16 x 2.7K Lenses • MicroSD card storage • Automatic stitching • USB cable for connectivity • 16-mono microphones • Expensive
8	Kandao Obsidian GO 360° 3D VR Camera	• 8 x 6K f/2.8 195° Fisheye Lenses • Capture up to 12K30 x 12K30 Video/Stills • Internal 8TB SSD Module for Recording • 8 x 6K f/2.8 195° Fisheye Lenses • Automatic stitching • Wi-Fi 6, Bluetooth 5, Gigabit Ethernet • 4-directional microphones • Extremely Expensive
9	Panono 360° 108MP Camera	• 6 x 3MP Cameras with 360° 108MP Still Image recording • Image Requires Stitching • Wi-Fi Connectivity • Expensive
10	Z CAM V1 Spherical VR 360 Camera	• 10 fisheye lenses with 190-degree view, each • 7K 360-degree video recording • Automatic stitching • Live video streaming • 4 built-in microphones • Very Expensive
11	Z CAM V1 Pro Cinematic VR Camera	• 9 MFT Lenses with 190-degree view • Automatic stitching • Live video streaming • 4-directional microphones • Extremely Expensive

4) Input devices: As with any system, user interaction is mainly based on the input devices being used. Although in VR most of the input is delivered through sensors; there are many input devices and controllers available for the users. Most of these input devices are only compatible with specific head-mounted displays, but some generic input devices are also available. Table IV presents some of the input devices that are being used by VR users and their classification based on the sensor technology they are equipped with.

TABLE IV. THE FAMOUS INPUT DEVICES OR CONTROLLERS FOR VR/AR KITS

S. No	Input Device	Class	Features
1	Oculus Controllers	Position and Orientation Tracking	IMU sensors, IR-Led- based tracking ring (for fingers) and camera-based hand tracking, HD haptic feedback, buttons and thumbstick
2	HTC Vive Controllers	Position and Orientation Tracking	24 IMU sensors, buttons, multi-function trackpad, dual-stage trigger, IR-based hand tracking, HD haptic feedback and a rechargeable battery
3	HP Reverb Controllers [39]	Position and Orientation Tracking	IMU sensors and active LEDs based tracking and IR camera-based hand tracking, haptic feedback, buttons and thumbstick
4	PlayStation VR Aim Controller [40]	Dual Camera-based Object Tracking	2x cameras, Hand tracking, gesture recognition
5	HP Windows MR Controllers	Position and Orientation Tracking	IMU sensors, multi-function trackpad and IR-led and camera-based hand tracking, HD haptic feedback, buttons and thumbstick
6	Polhemus Fastrak	Magnetic Tracker	3D digitizer and a quad receiver motion tracker, which computes the position and orientation of a small receiver
7	Mattel Power Glove	Acoustic (Ultrasonic) Trackers	Buttons, detects yaw, pitch and roll of hand, uses fiberoptic sensors to detect finger flexure to 256 positions per finger for four fingers. Uses sonics to calculate X, Y and Z location also

8	NAC Eye Mark Eye Tracker	Eye Tracking	Uses Pupil / Cornea Reflection to detect eyeball movement. Provides video footage of the field of view of the user in real-time
9	VPL Data Glove	3D input device: Glove	Camera and image processing-based tracking of the specific-colored glove to detect gestures as input.
10	Virtex Cyber Glove	3D input device: Glove	Uses electronic joint-angle sensors, electro-magnetic position tracker, and virtual hand control software detect gestures as input
11	Joystick based upon 6DOF	3D input device: mouse	Uses force-sensors to detect change in momentum and identify movement in all six directions.
12	Dexterous Hand Master (DHM)	3D input device: Dexterous manipulators	Extremely accurate movement and gesture-detection device used for medical and scientific training. Based on IMU sensors, position trackers and/or visual sensors.

C. Toolkits and Libraries

The tools and technologies are the building block of the virtual experience, and they are evolving with new features every day. They allow the user to have an immersive experience of the virtual or real world and provide a realistic interaction with the environment by constantly sending and receiving data from the devices to the multimedia system and vice versa. Another very important aspect of VR/AR systems is the 3D design and rendering model inside the server or mobile phone that enables this real-time interaction. These 3D realistic models and systems are created by graphic designers and software engineers using various programming frameworks.

To prompt development of 3D object and scene, various application and tools are available for the developers. For modelling object CGI tools, such as, 3D Studio Max, Maya, and Adobe Illustrator, are used. For building the scene and implementing the concepts of physics using complex mathematics of collision meshes, boundary detection, object interaction, differential equations, and fluid dynamics, the need for a support library is eminent. For prompt development, developer make use of 3D graphics engines, such as, Unreal Engine, Unity, Amazon Lumberyard, Unigine, if Tech 5, 3ds Max Design, ApertusVR, etc. These engines provide a VR SDK, which allows them to design, build, and test their VR environments.

Similarly, some toolkits are also available, which provide a quicker way to create VR games and environments [47]. They provide a collection of useful scripts, 3D assets and templates, interaction models, and libraries to interface various sensors, displays and actuators in a VR application.

VRSciT project provides a toolkit to explore new approaches in educational tourism using a VR environment [48]. TIDE Toolkit is a tourism toolkit for European Maritime and Underwater Cultural Heritage [49]. Digital Trail is another toolkit that allows developers to build their VR/AR content as an App and share the App with the users [50]. VITAKI is a toolkit designed to create VR applications and games with specific libraries for interaction with vibration and haptics [51]. VR Mini-Degree is another toolkit that provides tools to build VR games and applications using Unity. Samples of first shooter games, 360-degree space view and other examples are available to reduce the learning time for the developers. The tourism department in Northern Ireland has published a Cultural heritage toolkit for developing Irish cultural heritage experience for the tourists [77]. These are set of guidelines for developing virtual tourism systems. A similar toolkit is also published by Scotland [53] and a set of guidelines are published in [52] for promoting sports tourism.

For developing VR/AR systems, many developers are using VRTK, which is a VR toolkit for Unity Engine [47]. VRTK library consists of numbers of solution or mechanisms, like movement in VR, interaction with object like touching and catching, and 2D and 3D control like button, lever, and another objects. There are various libraries that provide ease in implementing tracking in AR/VR systems, such as, Qualcomm’s Vuforia and ARToolKit, and the BuildAR authoring toolkits.

COLIBRI VR is an open-source VR toolkit for capturing, modelling, and rendering real-world scenes in a VR environment [54]. For visualizing data in an immersive environment, authors in [55] have developed a VR toolkit for building and analyzing datasets and processed results. OVR toolkit provides a desktop view in a VR experience by augmenting a VR environment with real-life desktop objects [56]. VR performance toolkit [57] provides models and algorithms to improve performance in VR-based games. POV’s VR toolkit provides 3D assets and pre-build environments to create VR Apps in a matter of hours. Vrui VR toolkit provides functionalities, such as, portability, scalability, and fast development for VR applications. XR Interaction toolkit provides a cross platform, input, haptics, interaction, and feedback procedures for the VR environment. BlocklyXR is another toolkit which provides a visual programming environment for implementing realistic interactions in developing digital storytelling VR applications [58].

There are many other toolkits available for developers for visualizing data, developing educational applications and training exercises [59]. With time, better and powerful tools and technologies will be available for the developers to create highly immersive VR/AR/MR experiences.

IV. Survey Analysis

To identify the awareness of the field of virtual tourism and digital heritage among the users of the Internet, we opted to conduct a survey analysis. For better response, we limited our survey to less than ten (10) questions. The questions asked in the survey were all close-ended questions with mandatory responses. Table V shows the questions asked in the survey. We also identified the region from where the response was collected using the IP-based location services. We divided the responses according to the following regions: (1) Far east and south-east Asia (including Australia), (2) Central & south Asia, (3) Middle east & northern Africa, (4) Europe, (5) North America, and (6) Latin & south America. The survey was distributed through academic links; hence, most of the responses are from people who are associated with the education sector. We receive almost 550 responses, out of which 534 are valid responses.

TABLE V. SURVEY QUESTIONS AND THEIR POSSIBLE RESPONSES

Q. No.	Questions	Possible Responses
1	Gender	Female, Male, Not Specify
2	Age Group	Baby Boomers, Gen X, Millennial, Gen Z
3	Are you aware of Vitual Tourism?	Yes/No
4	Are you aware of Digital Heritage?	Yes/No
5	Have you ever experienced Vitual Tourism?	Yes/No
6	Have you ever experienced Digital Heritage?	Yes/No
7	Are you willing to experience Vitual Tourism?	Yes/No/May be
8	Are you willing to experience Digital Heritage?	Yes/No/May be

A. Demographics of the Responses

Demographics of the collected data is shown in Fig. 3. Out of the 534 responses, 21% identified themselves as male, 10% as female, while 69% preferred not to disclose their gender (shown in Fig. 3(a)).

For the age groups, 2% only identified themselves as Baby Boomers (above 56 years old), 17% as Generation X (43-55 years old), 44% as millennials (aged 30-42 years), and 37% as Generation Z (20-29 years old).

Region-wise, we got 16% responses from Far East and south-east Asia, 27% from central & south Asia, 21% from middle east & northern Africa, 16% from Europe, 13% from north America, and 7% from Latin & south America, as depicted in Fig. 3(b). The demographic results show that although the responses are not a lot, but the sample covers a major portion of the world population with people from all age groups.

B. Awareness of VR and DH

The awareness of existing applications for virtual tourism and digital heritage is shown in Fig. 4(a) and 4(b) respectively. In the overall scenario, more people are aware of virtual tourism than digital heritage. But comparatively, Millennials and Generation Z have more awareness than the older age groups. It happens because of the technological savvy nature of the younger generations.

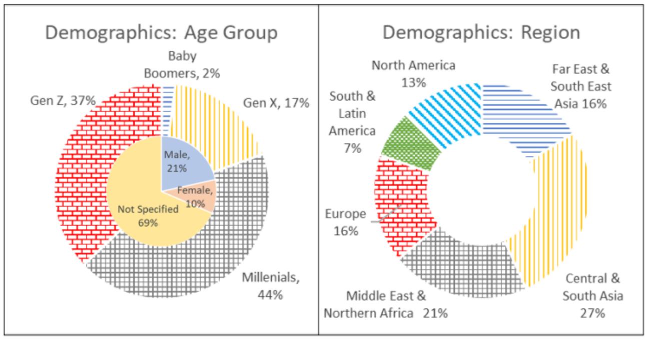

Fig. 3. Demographics of the Responses for the Survey. (a) Age Groups and Gender (b) Regions.

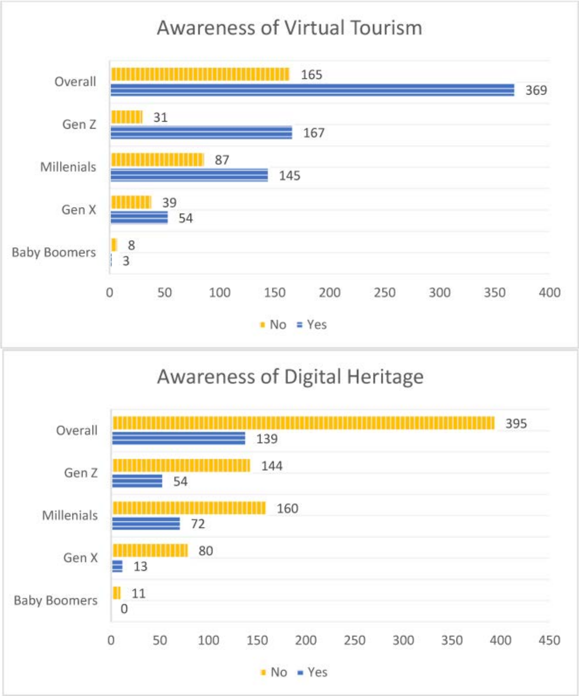

Fig. 4. Response Statistics about the Awareness of (a) Virtual Tourism and (b) Digital Heritage.

C. Experience with VR and DH

Fig. 5(a) and 5(b) show the results of the people who have actually experienced the virtual tourism and digital heritage applications, respectively. We see similar trends, as in Fig. 4. But if we compare the results of Fig. 4 and Fig. 5, we see that although many people are aware of the virtual tourism; however, fewer have experienced it.

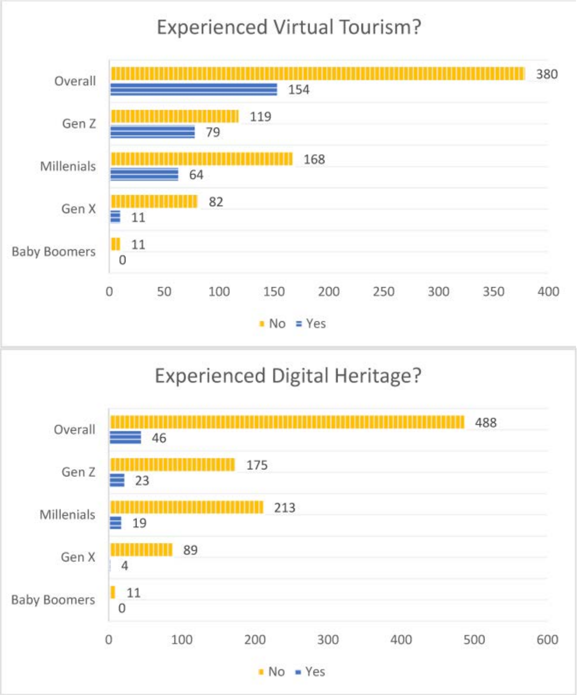

Fig. 5. Response Statistics about the How many People have Experienced of (a) Virtual Tourism and (b) Digital Heritage.

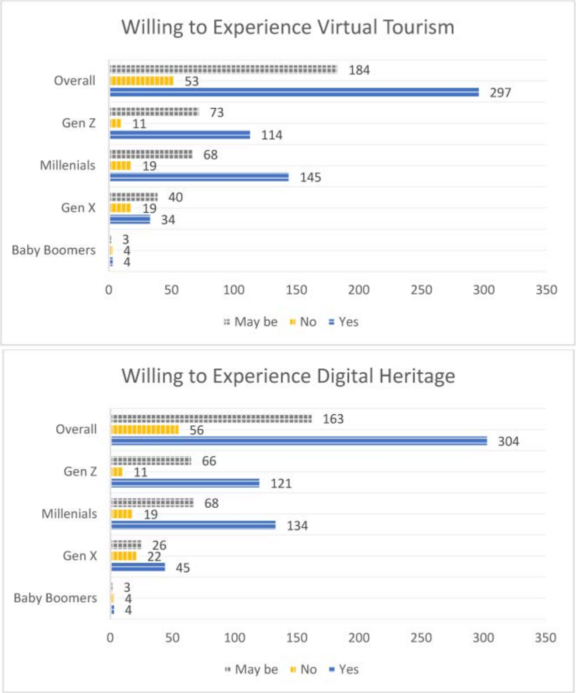

Fig. 6. Response Statistics about the How Many People have shown Willingness to Experience (a) Virtual Tourism and (b) Digital Heritage.

In case of digital heritage, the values are even lower. Again, the younger age group is more interested in the concept of virtual tourism as compared to the older age groups.

D. *Willingness to Experience VR and DH*

Finally, Fig. 6 shows the willingness of people to experience the applications of virtual tourism and digital heritage. It can be observed that most people have shown interest in the field, and they plan to visit the website and use applications that provide them with a virtual experience. However, many people still prefer the real traditional experience. The reasons that motivate people to experience the virtual environment or even the real environment with a remote axis are discussed in the next section. We also discuss the demerits of virtual tourism and digital heritage.

V. Pros and Cons of VR & DH

Although, there are many advantages of virtual tourism and digital heritage; however, the experience lacks certain supplementary aspects that have real importance and impact on the tourists. Some of these issues are discussed in the following subsections as advantages and disadvantages.

A. *Advantages*

1) Safety and security: One of the biggest advantages for the person who chooses virtual tourism over physical one is the safety and security of the individuals. Many tourist destinations are filled with cheaters and scammers and even kidnappers. There have been many incidents where people were abused mentally and physically [60]. VT provides a safe and secure experience from the protected home environment.

2) Control on view: In a VT, the users may have control over what they want to view and what they want to avoid. For example, some people are introverted and lack skills in interacting with other people and consider them as aliens, which helps them to avoid self-embarrassing behavior. VT allows the users to eliminate these experiences and focus on what they want to view and how they want to view the remote environment.

3) Cost effectiveness: Although tourism is one of the financially stable industries; however, not everyone is blessed with enough fortune to visit faraway places due to the cost of traveling, accommodation, and fares. VT and DH provide a feasible opportunity to the less privileged people as the virtual tourism cost considerably less than the traditional tourism. Though, the experience is not similar, but the users can save on cost by opting for VT. Some of the VTs are available free of cost for promotional purposes, while digital heritage sites are supported by governmental funding to make them accessible for free of cost.

4) Less impact on vulnerable destinations: Natures beauty is significantly destroyed whenever a location becomes a tourist spot. Tourism industry requires accessibility, accommodation, and utilities for the visitors. Hence, roads are made, hotels are erected and the people who visit later may damage the environment. In contrast, virtual tour can be recorded without endangering the environment and natural beauty can be preserved.

5) Preserve environment: The direct benefit of DH is the preservation of the cultural, historical, scientific, educational, and linguistic resources. For example, many artifacts lose their originality when tourists visit the historical sites. Likewise, access to ancient sculpture, sites, and books can destroy important parts and evidence of the history. Therefore, access to these resources is enabled via virtual, augmented and/or mixed reality.

6) Try before buy: VT provides the opportunity for tourists to first try the cheaper virtual experience before deciding to travel to the actual destination. This avoids or at least limits bad experiences for the travelers. They can try the virtual tour by experiencing it and make an educated decision to save time and money.

7) Permanent memory in high resolution: Everyone likes to take pictures and make videos of the place they visit. It helps them to recall their memorable moments and to capture the beauty and details of the visited places. VT and DH allow them to have high-quality pictures and videos of their experience. Furthermore, they can experience the environment again, anytime they want.

8) Visit the past, the present and even the future: With the Advent of virtual tours and digital heritage, a person is able to walk among dinosaurs, witness the landing on the moon and even walk on water. A user can experience the historical achievements of mankind and places which have been destroyed by time and urbanization. Similarly, a person can revisit his experience of the past, which s/he enjoyed with the loved one. Envisaging the human imagination, we can even visit the future world, which we want to create for our next generations.

B. Disadvantages

1) Lack of physical interaction: In real tourism, people share cultural knowledge and experience with other people through physical interaction by participating in the activities. When tourists visit any place, they take part in the cultural events, chat with the local people and gain valuable insights from their daily life. Such experience becomes long lasting, and they can share with other people effectively. Visiting and experiencing various diverse cultures improves humans' inter-personal skills. However, in a virtual experience, a user is not able to experience the diverse culture of the world and remain unknown of the fellow human beings.

2) Artificially enhanced scenery: Some of the virtual tourism application provide CGI (Computer-generated imagery) enhanced scenery, which is quite different from the actual environment or destination. Mostly, this is done to motivate the user for marketing purposes; however, this may come as fraud or intentionally mislead the users from reality. Therefore, some of the users may not opt for virtual tourism and prefer to physically visit the destination. In case, if a user witnesses such a difference experience, then user will be reluctant to experience virtual tours in the future.

3) Lack of relaxation: Some people travel for sight-seeing, as well as relaxation; however, the virtual tourism may not provide relaxation. On the other hand, some people feel tired after using the AR/VR systems due to the artificial visual movements. People who are claustrophobic or suffer from vertigo and epilepsy, would not be able to have a decent experience from the virtual tours.

4) Anti-globle village concept: The world is fast becoming a global village with technological advances, such as, fast travelling, Internet, social media, etc. People are becoming close to each other as they interact through these platforms. However, travelling is still the most significant way that makes people be a part of that global village. In virtual tourism, physical contact is missing, which enable the sense of being together. Younger generations are already distancing themselves from actual physical contacts and rely on online communication and the concept of VT will only augment this problem.

5) Change of environment: One of the most common reasons for travelling is a change in environment. Mostly, people have a busy schedule with consistent daily timetable, which they follow for months and years. They start feeling bored and wearied by this perpetual routine. Hence, they look for vacation with a change in scenery and itinerary in mind. Virtual tourism may create a change of experience for a few hours, but the minute change does not impact the person psychologically and they do not feel thrilled and animated.

6) Lack of availability to everyone: The technologies which are used to enable VT and DH are still expensive and their application is still not available for everyone to explore. Although most of the applications are free, but the cost of Internet and display devices/mobile phones (with high-end computer graphics) affects the availability of virtual tours.

7) Lack of financial gains: A tourist destination can earn a lot due to the visiting travelers through tickets, most of which is used for the management of the destination. At the same time, there are some supplementary industries that observe an increase in business due to the increase in travelling such as hotels, restaurants, travelling agencies, airlines and bus service, guides, etc. The concept of VT can reduce the numbers of tourists, which could have a severe impact on the earning of the tourist destination, as well as the supplementary industries.

VI. Related Work

In this section, we present similar works done by various researchers in the context of virtual tourism and digital heritage. In literature, we found different surveys and review papers [9-10] [27] [32-33] [61] [64-72] [74] discussing the feasibility, business value, social impact, marketing trends, technological evaluation, challenges, and issues. Other research articles [62] [63] [34] [73] [75-76] proposed diverse solutions pertaining to virtual, augmented, and mixed realities, while targeting virtual tourism and/or digital heritage. A brief statistical overview of existing studies in terms of citations and year of publication is provided in Table VI, which explore the surveys and reviews published in the field of virtual tourism and digital heritage. It is evident that most of the related works targeting virtual tourism as compared to digital heritage. Moreover, many people are citing the work done in VT, which shows lack of efforts in DH domain.

Verma et al. [10] has provided a comprehensive review of the literature related to virtual tourism with focus on the technologies, methodologies, and impact of VR/AR on tourism industry. They have also identified potential stakeholders and presented a quantitative and qualitative analysis of published research in tourism domain. Fan et al. [32] has analyzed the impact of immersive technologies on the virtual tourism by examining the social interactions and experience feedbacks from the users. Liang et al. in [61] reviewed augmented reality for tourism using cluster-based analysis with four empirical studies. They have based their recommendations on identified future directions to propose further investigation in the emerging area of gamification and explored the potential negative consequences of augmented reality. In [62], authors have explored the alternative ways of travelling during the pandemic and identified virtual tourism as a solution. The author of [9] has reviewed around 32 journal papers, published during the years 2000-2018, to not only identify the impact of VR and AR on virtual tourism but also suggested future directions. Similarly, Loureiro et al. [63] have used citation network analysis and text-mining to study 56 journal and 325 conference papers for identifying the requirements, challenges, solutions, and future trends in the field of virtual tourism using AR/VR technologies. Egger et al. in [64] have provided a literature review on AR/VR technologies and identified the strengths and weaknesses in the context of accessibility and marketing towards tourism.

TABLE VI. LITERATURE REVIEW OF THE VIRTUAL TOURISM AND DIGITAL HERITAGE REVIEW AND SURVEY PAPERS

Loannides et al. [76]	39	2014	DH

Beck et al. [65] have performed a comprehensive review on VR for tourism and discovered that the VR is complementing tourism as a marketing tool rather replacing it. However, this paper was published before the COVID pandemic and since then the trends have changed as suggested in [10]. Yung and Khoo-Lattimore, in their review paper [66], have identified various factors, methodologies, and class of virtual technologies that can benefit VT. They have also identified research gaps and potential tourism sectors in this field. A critical review is presented in [67] to understand the research progress on VR/AR in tourism and hospitality from 2000 to 2018. Based on the review of 60 journal articles, they have recommended research directions in VR/AR with their management. Authors of [68] have reviewed the existing and potential exploitation of Virtual Learning Environments (VLEs) within hospitality, leisure, sport, and tourism. Other research studies in [69], [70], and [71] provided short reviews on identifying enabling technologies of VR and AR in transition from tourism to e-tourism.

Bekele et al. in [33] have reviewed the trends in VR/AR/MR that can benefit the cultural heritage paradigm. They also identified application areas in digital cultural heritage and identified appropriate technologies for various digitizing cases in preserving heritage and culture. Batchelor et al. in [72] have presented a literature review on digital and smart heritage by identifying the requirements, challenges, and analyzing the complementary technologies. Champion and Rahaman in [27] provided a collection of websites and repositories on 3D model of heritage sites. They also reviewed various platforms that support the digital heritage and provided guidelines for future proofing and preserving the heritage using digitization. Authors in [73] have discussed digital freehand sketching, digital measurements, photographic techniques for creating panoramas, 3D models and interactive tours, interactive virtual tours, VR techniques and 2D and 3D model creation for legacy digitization and other trends. Similarly, researchers have provided various literature reviews that discuss the topics and research domains [74] and identified challenges and solutions for preserving digital heritage [34], [75], [76].

Review papers to analyze the AR/VR technologies in the field of virtual tourism are many; however, the technologies are changing with the advancements in sensing, tracking, and computing capabilities. We noticed a lack of interest and limited research work in digital heritage domain compared with virtual tourism. As digital heritage and environment for virtual tourism have similarity in media creation, interaction, and immersive experience; hence, a survey to review the AR/VR technologies and application for both VT and DH was missing. This paper has fulfilled this gap and provided a single knowledge source for people working in the blended domain.

VII. CONCLUSION

In this paper, we have reviewed and analyzed the concepts of virtual and augmented realities, which have a significant role in the field of virtual tourism and digital heritage. We have presented an in-depth analysis about the commercial technologies and web/mobile application, which can benefit the research community, especially, novice researchers in comprehending the current spectrum in the field of virtual tourism and digital heritage. We have presented the survey analysis of the awareness, experience, and willingness of using virtual tourism and digital heritage by the users of various age groups. The results have shown that the young generations are excited to experience these technologies. In the end, we also provide the advantages and disadvantages associated with virtual and remote tourism.

ACKNOWLEDGMENT

The work presented in this paper is funded by the Deputyship for Research and Innovation, Ministry of Education, Kingdom of Saudi Arabia, under the project No (20/16), titled: “Virtual journey into the history of the Kingdom of Saudi Arabia”. We would also like to extend special thanks to all the people who participated in the conducted survey.

Using a Fuzzy-Bayesian Approach for Predictive Analysis of Delivery Delay Risk

Ouafae EL Bouhadi[1], Monir Azmani[2], Abdellah Azmani[3], Mouna Atik el ftouh[4]
Intelligent Automation Laboratory, FST of Tangier

Tetouan, Morocco

***Abstract*—Although one of the major roles of delivery logistics activities is to ensure a good quality of customer service, certain risks such as damage, delay, return of transported goods occur quite often. This makes risk control and prevention one of the requirements of transport supply chain quality. The article focuses on the analysis of the risk of delay, which is often considered fundamental for the quality of service and as a center of additional costs related to the violation of time windows. Such a risk can harm the image of a supplier, which can even lead to the loss of customers in case of recurrence. The aim of the following case study is the development of a fuzzy-bayesian approach that anticipates, by predictive analysis combining Bayesian networks (BNs) and Fuzzy logic, the possible delays affecting the smooth running of a delivery operation. The results of the implementation of the late delivery risk prediction model are validated by verifying three axioms. In addition, a sensitivity and scenario analysis is performed to validate the model and identify the parameters that have the most adverse impact on the occurrence of such a risk. These results can help carriers/transport providers to minimize potential late deliveries. In addition, the developed model can be used as a basis for different types of predictions in the field of freight transport as well as in other research areas.**

Keywords—Delivery logistics; risk management; predictive analysis; bayesian network; fuzzy logic

I. Introduction

On-time delivery is often considered as a performance indicator in the field of freight transportation [1]. However, any delay in goods delivery to their destination can harm the activities of the actors involved (shipper, carrier, warehouseman, and final customer) and affect their profitability. Therefore, measuring the risk of delay in advance enables reliable decisions to be made when planning deliveries. Consequently, the effect of such a risk can be reduced or even eliminated. This study focuses on the analysis of delivery delay to assist transportation companies in making decisions and optimizing their planning. Despite, the development of a delay risk prediction model is hampered by the unavailability of data. With this in mind, this paper contributes by implementing a fuzzy-bayesian approach to overcome the problem of missing or unavailable data.

The occurrence of delay in freight transport operations is influenced on the one hand by external factors such as road events (accidents, congestion, and weather conditions). On the other hand, by internal factors related to carriers' decisions in terms of resource selection and delivery planning [2]. This paper has studied all of these elements, and it has designed a predictive model integrating the different cause-effect relationships between several factors (internal and external) impacting on-time delivery. For this, it opted for BNs [3] thanks to its advantage of modeling, probabilistic reasoning of uncertain systems [4], and causal analysis.

The article is structured as follows: an overview of the literature related to delivery delay and the application of BNs in the transportation domain is given in Section II. The construction of the fuzzy-Bayesian model and its validation are presented in Section III. Section IV provides a discussion of the results obtained. Finally, the conclusion and further research are covered in Section V.

II. Related Work

In this section, we provide a brief overview of literature regarding our context of study, namely delayed deliveries, and for Bayesian network applications in transportation field.

A. *Delayed Deliveries*

Delayed deliveries mean goods arriving at their destination out of schedule. According to ATRI (American Transportation Research Institute), in 2016, trucking operations in the U.S. experienced about 1.2 billion hours of delays alone due to traffic congestion. This number of delays generates $74.5 billion in additional operational costs [5]. Because there are other causes of delay besides congestion, these additional costs continue to rise.

According to [6] various factors can disrupt delivery reliability, among them personnel issues, vehicle breakdowns, and poor planning. This means that resource selection by checking vehicle conditions and driver performance in addition to the adequacy of planning have a significant effect on speed of service. Furthermore, other external factors such as accessibility to delivery points, accidents, unforeseen events (public works), and methodological conditions [6]–[8] can cause further delays.

The occurrence of delay largely influences [9]–[12]:

- Additional costs: these costs are typically related to a delay penalty, and vehicle operating costs such as maintenance and vehicle rental in the case of private fleet use. As well as driver-related costs, that include salary and benefits. In addition, delay can lengthen the storage period, resulting in inventory holding costs.

- Warehouse productivity: arriving late at the warehouse may result in overlapping deliveries. This will influence the availability of unloading bays and labor as well as overloading the workforce to wait for late deliveries.
- Customer satisfaction: late deliveries can affect the operations of the consignees. This will have a significant impact on the customer relationship. As a result, customers find themselves in a situation of frustration. In case of recurrence, this situation exposes suppliers to the loss of customers.
- Loss of opportunity to consolidate shipments: the occurrence of delays contributes to the lack of opportunity to consolidate shipments due to the uncertainty of meeting delivery deadlines.
- Carrier profitability: this is generally affected by the additional costs incurred, the damage to the carrier's image due to the loss of customers and the extra time generated which reduces the opportunity to make more deliveries.

The concept of predicting the risk of late delivery is generally studied in the context of improving service quality. In the literature, the prediction of such risk is performed using several techniques from artificial intelligence.

Keung et al. [13] have opted for machine learning methods such as KNN, and ANN to predict shipment delays. The authors [14] used Random Forest and SVM for on-time delivery prediction. Berrones-Sanz [15] also proposed a model for on-time delivery prediction using logistic regression. In order to predict on-time delivery violation, [16] relied on ANN machine learning technique. As for [17], they proposed a neural network-based model to anticipate delivery time.

In addition, BNs are among the most popular prediction methods in various research areas [18]. This paper exploits the potential of BNs in risk prediction to anticipate the occurrence of delay in a delivery operation.

B. *Applications of BNs in the Transportation Field*

BNs are applied in several domains: diagnosis (medical and industrial), risk management, spam detection, fraud detection, data mining, and text mining, etc.[19]. In the transportation domain, BNs are used for different types of prevention. Gregoriades and Mouskos [20] used BNs to quantify the risk of accidents in order to locate black areas. The authors [21] developed a bayesian model for the identification of features affecting the safety of motor carriers. Zhu et al. [22] presented a bayesian approach for contextual (e.g., dynamic traffic information) or non-contextual (e.g., instantaneous driving speed) evaluation of driving behavior. As for [23], they modeled drivers' vehicle use behavior according to time of day. The use of BNs also extends to other transportation axes, namely traffic congestion prediction [24], [25] as well as freight demand prediction [26].

III. Modeling the Risk of Late Delivery using a Fuzzy-bayesian Approach

A BN is "a graphical probabilistic model consisting of a set of nodes (variables of interest in the domain) and arcs (causal phenomena). In addition to a set of local probability distributions (network parameters)" [3], [27], [28]. A BN allows modeling the effect of a fact or an uncertain event on another via the representation of the causal relationship between those events [29]. In this case, an arc from X to Y can be interpreted as 'X causes Y'. Fig. 1 shows that the knowledge gained about the overlay of fragile products determines the knowledge about the damage of goods.

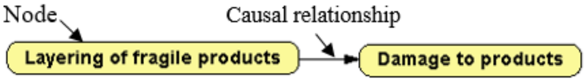

Fig. 1. Example of a Causality Representation.

The study is based on exhaustive bibliographical research, in addition to a survey of experts, in order to identify all the parameters (factors) which can hinder the delivery of a good to its destination in time. As well as the schematization of the dependency relations between these parameters, in order to build the structure of the Bayesian network. The approach followed introduces a methodology for modeling and evaluating the risk of late delivery using BNs by following these steps:

Definition of the BN structure: Determining the relationships between nodes allowed us to design a causal graph based on a three-level architecture.

- The first level represents the input or feeder nodes that have an indirect effect on the risk of delay; they fall into five categories detailed in Table I;
- The second level consists of the intermediate nodes that represent the various intermediate cause factors (direct causes, or cause-effects) that lead to the impact factors encapsulated in the third level (final impacts);
- The third level contains the final impacts that define the factors that directly and negatively influence the arrival of goods at their destination on time.

Generate conditional probabilities of intermediate effects and final impacts: The generation of conditional probability tables will be made using Sugeno's fuzzy inference implementation.

Model validation: This step consists of relying on Bayes theory and posterior probabilities relating to intermediate effects and final impacts, in order to study the effect of a state linked to an input parameter on the envisaged risk. In addition, sensitivity analysis and partial validation are performed to validate the model.

A. *Definition of the BN Structure*

The construction of the Bayesian network architecture can be done in two different ways:

- Objective methods: by using a database to apply the structure's learning methods.

- Subjective methods: by gathering knowledge from experts in the field, through written questionnaires, individual interviews or brainstorming sessions.

The first approach necessitates a large quantity of data. and it may establish dependencies or independencies between some variables that are inconsistent with the experts' opinions [30]. For this reason, researchers prefer the use of the second approach where experts are involved to verify the causal links between the network variables. [31]. In the literature, several researchers have relied on expert knowledge among them [31]–[35].With this in mind, the article used the subjective method.

Based on a survey of experts in the freight transportation field and a literature review of the various factors that drive the occurrence of delay risk, a set of network input parameters are identified and presented in detail in Table I. In addition to the intermediate effects and final impacts presented in Table II. The survey consisted of two questionnaires, the first was conducted to verify and validate the identified variables and the second to establish the causal relationships between the variables.

After identifying the variables (Tables I and II) that will constitute the nodes of the graph and studying the causal relationships between them, the structure of the Bayesian network is developed and illustrated in Fig. 2.

B. *Generation of Conditional Probabilities of Intermediate Effects and Final Impacts*

After building the Bayesian network structure, the next step is to compute the conditional probability tables (CPT) for each variable. These CPTs can be computed based on the knowledge of the experts or using learning algorithms from a database. Although there is no more database in the literature adapted to the parameters identified to build the graph structure, the article is oriented towards the use of subjective methods.

Since the number of conditional probabilities in the developed network is 1032, it is difficult to rely on expert knowledge to evaluate such a large number of probabilities[36]. In fact, in the literature, many researchers have developed models to lower the number of CPTs of a BN. As an example, causal interaction models that have attracted the interest of several researchers such as [37]–[41]. One of the most widely used models is the Noisy-OR model introduced by [39] which allows for the specification of non-deterministic interactions between the parents associated with an effect [42].

In addition, other methods such as fuzzy logic [43] allowing the reduction of numbers of questions asked to experts and the generation of probability tables [2], [44], [45] .With this in mind, the paper relied on this method to first express the experts judgments by fuzzy rules, and then generate the conditional probability tables by a fuzzy inference mechanism. These fuzzy rules are of the type 'If the driver's performance is bad then the occurrence of the accident is high. Here the value of "high" for the accident occurrence is qualitatively represented by a linguistic variable expressed in natural language. For the different rules, the accident occurrence node can be translated into one of the following values: low, medium, high. In addition, for the different nodes of the graph, their influences are revealed by three linguistic values (states) represented in Table III. Since the quantification of these linguistic variables oscillates in interval 0.1, the article opted for the expression of these values in fuzzy form to ascertain the degree of each node's membership in all its fuzzy subsets. As an example, the accident occurrence node is high with 90%, medium with 8% and low with 2%.

The implementation of the approach adopted for generating conditional probability tables is done in three steps:

- Definition of fuzzy variables, their associated linguistic values(variable whose values are qualitative and represent natural language expressions [62] and their membership functions;
- Determination of fuzzy rule bases: a base of "if-then" rules, is used by the "fuzzy inference system" in order to translate the input variables into output [62];
- Development of inference mechanism that forms conclusions based on the fuzzy rules and the input data [63].

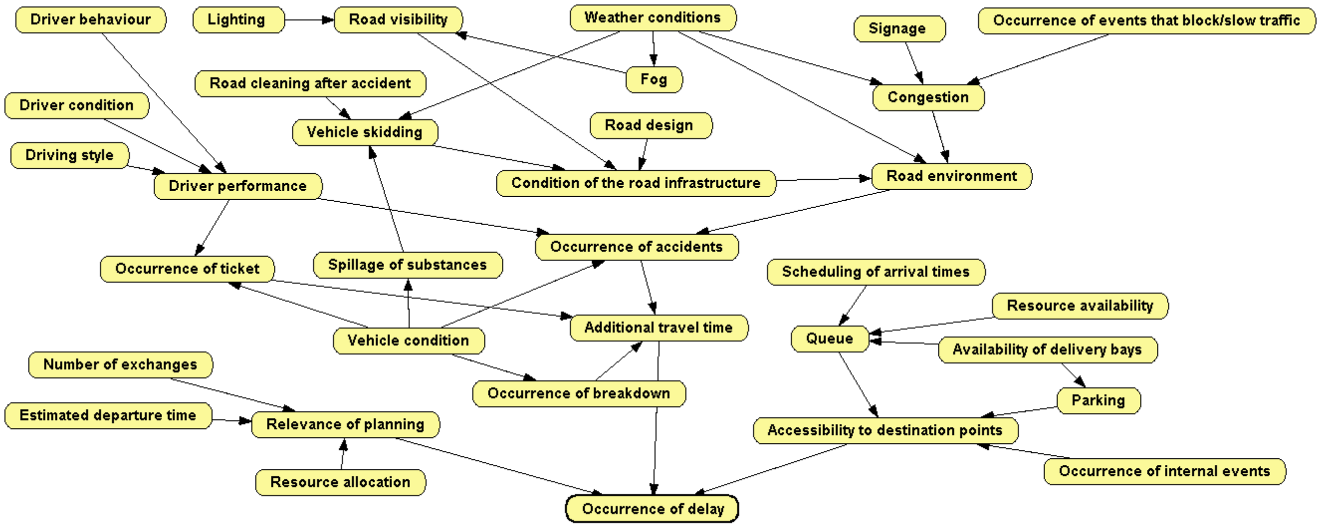

Fig. 2. The Structure of the Bayesian Network Modeling the Risk of Delay of a Delivery.

TABLE I. DESCRIPTION OF THE INPUT PARAMETERS OF THE CAUSAL GRAPH

Variable class	**Variable name**	**Description**
Parameters related to the road	Road design	It refers to the geometric nature of the road, such as the number of lanes and direction of traffic. [46].
	Lighting	Lighting conditions (artificial light, daylight, darkness, twilight) have a considerable effect on the occurrence of road accidents, due to the adaptation of speed with visibility conditions [47].
	Road cleaning after accident	Improper cleaning of accident sites can result in the vehicle skidding due to the presence of body fluids, fuel and other debris.
Traffic parameters	Signage	Traffic signal control considers the control of traffic signals and the existence of stop sign and yield sign [48] .
	Weather conditions	Weather conditions can disrupt driver capabilities, pavement friction, road infrastructure conditions, and vehicle stability and maneuverability, due to reduced visibility, extreme temperatures, precipitation, high winds, and lightning [49]. As a result, they affect traffic demand (carriers postpone or cancel planned delivery operations), traffic safety (accident rates), and traffic flow relationships (changes in the fundamental traffic flow variables, volume, speed, and density influence the capacity of a road system) [50].
	Occurrence of events that block/slow traffic	Traffic can be disrupted by the occurrence of a variety of events, including: Unexpected events such as road accidents, vehicle breakdown in the middle of the road, land subsidence and public works [51]; Irregular social events such as political demonstrations, diplomatic visits [51], sporting events; Regular events such as festive events (religious, national or international holidays) and vacation departure; In addition, the delivery period also influences traffic. Delivery during peak hours can slow down traffic.
Parameters related to personnel (drivers, planners, ...) or planning systems	Driver behavior	Driver behavior is considered one of the major sources of traffic accidents [52]. These behaviors include failure to observe speed limits, safety distance, and poor vehicle handling that manifests itself in hard braking, and hard acceleration, especially when visibility is reduced, and when climbing hills [53].
	Driving style	A driver's habitual driving style that includes calmness behind the wheel, level of attention contribute to traffic accidents [54], [55].
	Driver condition	The poor condition of drivers is often due to fatigue, alcohol consumption, negative emotions (worries and fear of arriving late), drowsiness, headaches, respiratory illnesses, and fever [56].
	Number of exchanges	The increase in the number of exchanges resulting from indirect deliveries leads to more loading/unloading operations [57], and therefore an increase in the risk of delay due to uncontrolled/estimated time at the exchange points.
	Departure time	A travel time estimate is said to be accurate if it could help improve the quality of service by delivering the goods on time [58]. For this, the departure time must be sufficient to cover the planned route within the required time window.
	Resource allocation	Personnel, vehicle condition (breakdown), and delivery points are among the factors that cause delay to occur [6]. Therefore, optimal allocation of resources (vehicles, warehouses, personnel, etc.) to routes helps to reduce the risk of delay.
Vehicle-related parameters	Vehicle condition	Vehicle condition is one of the causes of accidents [59]. Poor physical condition of the vehicle can cause vehicle breakdown and hence the occurrence of delays. In addition, negligence in checking the administrative condition of vehicle can be the cause of vehicle ticketing.
Parameters related to delivery areas (warehouses)	Availability of delivery bays	The lack of adequate delivery bays for different vehicle sizes leads to long queue [60]. In this case, drivers try to park their vehicles far away or illegally near the delivery site. This leads to long queue.
	Resource availability	The lack of human resources in the delivery areas is one of the factors that lead to long queue[60]. Similarly, the lack of material resources (handling equipment, forklifts, etc.) can aggravate this problem.
	Internal events	Internal events such as strikes over working conditions can slow down or block access to delivery areas.
	Scheduling of arrival times	Synchronizing inbound and outbound delivery operations within a warehouse requires reliable arrival times [61]. Lack of scheduling of arrival times (delivery deadlines) with carriers can cause overlapping operations of multiple deliveries, subsequently resulting in long queues.

TABLE II. PRESENTATION OF INTERMEDIATE EFFECTS AND IMPACTS ON DELAY

Intermediate effects		**Final Impacts**
• Road visibility • Vehicle skidding • Condition of the road infrastructure • Spillage of substances • Congestion • Occurrence of ticket	• Road environment condition • Driver performance • Queue • Parking • Occurrence of accidents • Occurrence of breakdown	• Additional travel time • Accessibility to destination points • Relevance of planning • Occurrence of delay

TABLE III. STATES OF THE BAYESIAN NETWORK NODES

Nodes	Linguistic values
Road design	Good, medium, bad
Lighting	Good, medium, bad
Fog	Low, medium, heavy
Road visibility	Good, medium, bad
Condition of the road infrastructure	Good, medium, bad
Road cleaning after accident	Appropriate, medium, inappropriate
Spillage of substances	Low, medium, strong
Vehicle skidding	Low, medium, significant
Weather conditions	Normal, medium, extreme
Occurrence of events that block/slow traffic	Low, medium, high
Signage	Good, medium, bad
Congestion	Low, medium, high
Road environment	Good, medium, bad
Vehicle condition	Good, medium, bad
Driver performance	Good, medium, bad
Driver behavior	Good, medium, bad
Driving style	Good, medium, bad
Driver condition	Good, medium, bad
Occurrence of accidents	Low, medium, high
Occurrence of breakdown	Low, medium, high
Occurrence of ticket	Low, medium, high
Additional travel time	Low, medium, high
Number of exchanges	Low, medium, high
Resource allocation	Good, medium, bad
Relevance of planning	Good, medium, bad
Estimated departure time	Good, medium, bad
Scheduling of arrival times	Good, medium, bad
Occurrence of internal events	Low, medium, high
Resource availability	High, medium, low
Availability of delivery bays	High, medium, low
Queue	Fast, medium, slow
Parking	Very close, close, far
Accessibility to destination points	High, medium, low
Occurrence of delay	Low, medium, high

To better assimilate our proposed approach, we explain CPTs generation for ‘Congestion’ node. In this case, the inference mechanism aims at determining the probabilities of the occurrence of congestion with respect to the states of the nodes: Signage, weather conditions, occurrence of events blocking/disrupting the traffic.

The membership function used for the different nodes of the graph is Gaussian, as it provides less error compared to other triangular and trapezoidal functions [64]. An example of the description of the membership function for the weather variable is provided in Fig. 3.

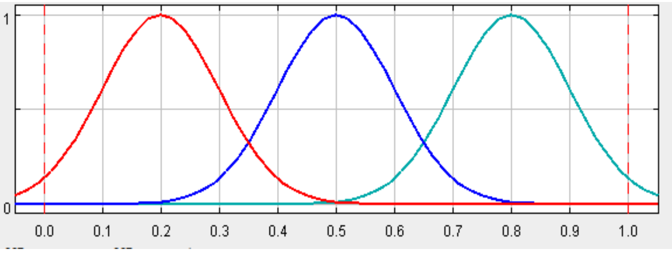

Fig. 3. Membership Functions for the Weather Variable.

After defining the membership functions for the congestion nodes and its antecedents, subsequently, a fuzzy rule base is determined to evaluate the variation of the congestion node with respect to the states of its parent nodes or its causes. This fuzzy rule base is detailed in Table IV.

TABLE IV. FUZZY RULES OF THE 'CONGESTION' NODE WITH ITS PARENT NODES

Rule number	Signage	Weather conditions	Occurrence of events	Congestion
1	Bad	extremes	High	high
2	Bad	extremes	Medium	high
3	Bad	extremes	Low	medium
4	Bad	medium	High	high
5	Bad	medium	Medium	medium
6	Bad	medium	Low	medium
7	Bad	normal	High	medium
8	Bad	normal	Medium	medium
9	Bad	normal	Low	low
10	Medium	extremes	High	high
11	Medium	extremes	Medium	medium
12	Medium	extremes	Low	medium
13	Medium	medium	High	medium
14	Medium	medium	Medium	medium
15	Medium	medium	Low	medium
16	Medium	normal	High	medium
17	Medium	normal	Medium	medium
18	Medium	normal	Low	low
19	Good	extremes	High	high
20	Good	extremes	Medium	medium
21	Good	extremes	Low	medium
22	Good	medium	High	medium
23	Good	medium	Medium	medium
24	Good	medium	Low	low
25	Good	normal	Low	medium
26	Good	normal	Medium	low
27	Good	normal	Low	low

The inference mechanism is triggered by initializing the input variables with precise values representing the peak of the Gaussian distribution and activating a set of fuzzy rules. This mechanism uses the Sugeno inference system. The aim is to identify degrees of membership to each fuzzy subset. The calibration of these degrees provides the CPTs of the BN.

Consider the example of inferring the congestion node knowing that the signage is average, the methodological conditions are normal, and the occurrence of traffic blocking/interfering events is low. The initial values of the input variables represented in rule 18 of Table VI will feed the fuzzy inference system. The latter is implemented with the Fispro software.

The results of the fuzzy inference are illustrated in Fig. 4, thereafter; the different results are aggregated, in order to combine them into a single value for each state. This value is the result of the union of the different conclusions of the rules activated with the max method.

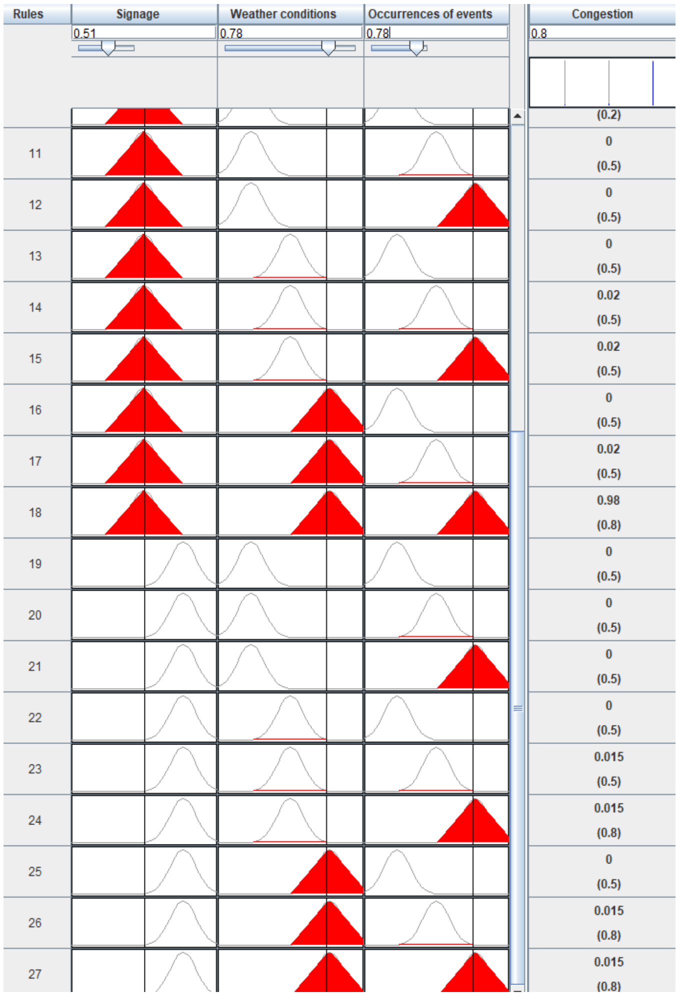

Fig. 4. Fuzzy Inference of the Variable 'Congestion.

The conclusions of the activated rules of rule 18 are summarized in Table V. Thus, the low value of congestion is 0.98, and the average value is 0.020. Now, since each possibility of a fuzzy subset must be greater than zero, a value of 0.001 is given to the null probability, in this case the high value is 0.001.

Congestion (low) = max (0.98, 0.015, 0.008) = 0.98.

Congestion (medium) = max (0.015, 0.008, 0.020) = 0.020.

Congestion (high) = 0.001.

The conditional probabilities for the different states of the variable 'congestion' of the rule 18 is calculated in the following way:

P (Congestion = low | Occurrence events = low, Weather = normal and Signage = medium) = 0.98/(0.98+0.020+0.001)=0.979.

P (Congestion = medium | Occurrence of events = low, Weather = normal and Signage = medium) = 0.020/(0.98+0.020+0.001)=0.019.

P (Congestion = high | Occurrence of events = low, Weather = normal and Signage = medium) = 0.001/(0.98+0.020+0.001)=0.001.

TABLE V. DEGREE OF MEMBERSHIP FOR EACH FUZZY SUBSET OF THE VARIABLE 'CONGESTION

Rule activated	**Language value of the output variable**	**Degree of membership**
R27	Low	0.015
R26	Low	0.015
R24	Low	0.015
R23	Medium	0.015
R18	Low	0.98
R17	Medium	0.020
R15	Medium	0.020
R14	medium	0.020
R9	Low	0.008
R8	medium	0.008
R6	medium	0.008

C. *Anticipation of Scenarios and Interpretation of Results*

After constructing the Bayesian network using Open Markov tool, it is used to deduce the probabilities of certain events by setting evidences (states) for certain nodes and study their effects through the propagation of their probabilities on the child nodes. At this level, the input parameters' impact on the occurrence of delay is studied through four scenarios listed as follows:

- Scenario 1: favorable road environment and delivery areas input parameters, unfavorable transport company input parameters.
- Scenario 2: unfavorable road environment and delivery areas input parameters, favorable transport company input parameters.

- Scenario 3: favorable road environment and delivery areas input parameters, favorable transport company input parameters.
- Scenario 4: unfavorable road environment and delivery areas input parameters, unfavorable transport company input parameters.

The input parameters related to the transport company correspond to those related to the vehicles, the staff (drivers, planners ...) and the planning systems.

The input parameters related to the road environment and delivery areas correspond to those related to the road, traffic and warehouses.

The four scenarios corresponding to different configurations of the input node states are detailed in Table VII.

After feeding the BN with the states of each scenario, the inference mechanism provides probability propagation over intermediate effects and final impacts to quantify delay occurrence. Table VIII, shows the probability distribution for some nodes in the network.

TABLE VI. CONDITIONAL PROBABILITY TABLE OF THE 'CONGESTION' NODE

					Conditional probability		
Rule number	**Signage**	**Weather conditions**	**Occurrences of events**	**Congestion**	**Low**	**medium**	**high**
1	bad 0.22	extremes 0.18	high 0.21	high	0.001	0.015	0.984
2	bad 0.22	extremes 0.18	medium 0.52	high	0.001	0.020	0.979
3	bad 0.22	extremes 0.18	low 0.78	medium	0.001	0.979	0.020
4	bad 0.22	medium 0.5	high 0.21	high	0.001	0.020	0.979
5	bad 0.22	medium 0.5	medium 0.52	medium	0.001	0.988	0.011
…	…	…	…	…	…	…	…
18	medium 0.51	normal 0.78	low 0.78	low	0.979	0.020	0.001
19	good 0.81	extremes 0.18	high 0.21	high	0.001	0.015	0.984
20	good 0.81	extremes 0.18	medium 0.52	medium	0.006	0.988	0.006
…	…	…	…	…	…	…	…
25	good 0.81	normal 0.78	high 0.21	medium	0.015	0.984	0.001
26	good 0.81	normal 0.78	medium 0.52	low	0.979	0.020	0.001
27	good 0.81	normal 0.78	low 0.78	low	0.979	0.020	0.001

TABLE VII. DESCRIPTION OF THE SCENARIOS ACCORDING TO THE VALUES OF THE INPUT PARAMETERS

Input parameter	**Value**			
	Scenario 1	***Scenario 2***	***Scenario 3***	***Scenario 4***
Road environment and delivery areas parameters				
Road design	good	bad	good	bad
Lighting	good	bad	good	bad
Post-accident road cleaning	appropriate	inappropriate	appropriate	inappropriate
Signage	good	bad	good	bad
Weather conditions	normal	extremes	normal	extreme
Occurrence of events that block/impede traffic	low	high	low	high
Availability of delivery bays	high	low	high	low
Resources Availability	high	low	high	low
Occurrence of internal events	low	high	low	high
Scheduling of arrival times	good	bad	good	bad
Transport company parameters				
Driving style	bad	good	good	bad
Driver condition	bad	good	good	bad
Driver behavior	bad	good	good	bad
Vehicle condition	bad	good	good	bad
Resource allocation	bad	good	good	bad
Estimated departure time	bad	good	good	bad
Number of exchanges	high	Low	low	high

TABLE VIII. PROBABILITY DISTRIBUTION FOR BAYESIAN NETWORK NODES

Node	State	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Congestion	Low	0.9790	0.0010	0.9790	0.0010
	Medium	0.0020	0.0150	0.0020	0.0150
	High	0.0010	0.9840	0.0010	0.9840
Occurrence of a breakdown	high	0.9790	0.0010	0.0010	0.9790
	Medium	0.0200	0.0020	0.0020	0.0174
	Low	0.0027	0.9790	0.9790	0.0010
Occurrence of an accident	Low	0.0022	0.0012	0.9574	0.0010
	Medium	0.0418	0.9574	0.0416	0.0173
	high	0.9559	0.0214	0.0010	0.9817
	Low	0.0209	0.9166	0.9166	0.0052
Occurrence of ticket	Medium	0.0052	0.0592	0,0592	0.0209
	high	0.9738	0.0242	0.0242	0.9738
Accessibility to destination points	High	0.9635	0.0010	0.9635	0.0010
	Medium	0.0355	0.0155	0.0355	0.0155
	Low	0.0010	0.9835	0.0010	0.9835
Delay	Low	0.0017	0.0050	0.9718	0.0010
	Medium	0.0861	0.9624	0.0272	0.0160
	High	0.9121	0.0327	0.0010	0.9830

In the case of the first scenario, the occurrence of congestion is low with a probability of 97.9%. Concerning the occurrence of a breakdown and ticket, and accident are important with respectively 97.9% and 97.3% and 95.5%. As for the accessibility to the destination, point tends to be high with 96.3%. Therefore, the probability of the occurrence of delay is important with a value of 91.1%.

For the second scenario, the probability of congestion occurrence is high with a probability of 98.4%. Regarding the occurrence of accident is more likely to be 'medium' with a probability of 95.7%, as for the occurrence of breakdown and ticket are low with respectively 97.9% and 91.6%, In addition, the accessibility to the destination point tends to be low with 98.3% which leads to an average risk of occurrence of delay of 96.2%

For the third scenario, the inference model predicts a low probability of congestion occurrence with a rate of 97.9%. Also, the risks related to the occurrence of an accident, breakdown and a ticket are low with respectively 95.7%, 97.9% and 91.6%. In addition, the accessibility to the destination point tends to be high with 96.3%. Therefore, the probability of delay occurrence is very low with 97.1%.

For the fourth scenario, congestion tends to be high with a rate of 98.4%. Also, the risks of the occurrence of an accident, a breakdown or a ticket are high with respectively 98.1%, 97.9% and 97.3%. As for the accessibility to the destination, point is low with a percentage of 98.3%. Hence the highest probability of the occurrence of delay with 98.3%.

Based on the results of the inference of the first two scenarios, we can conclude that the parameters related to the transport company have more impact on the occurrence of delivery delay than those related to road and delivery environment.

D. Sensitivity Analysis

The sensitivity analysis identifies the factors ranked according to those that have more impact on the probability of a node [65]. The Fig. 5 shows the tornado diagram [66] of the "delay occurrence" sensitivity analysis. According to the figure, variables such as vehicle condition, resources availability, estimated departure time, number of exchanges, and resource allocation contribute more to the occurrence of late deliveries. Poor vehicle condition is the main parameter influencing the risk of delay. This can be justified by its resulting events such as the occurrence of breakdowns and accidents, as these have a significant impact on the occurrence of such risk.

E. Partial Validation

In order to validate the proposed model, the paper uses partial validation allowing the verification of three axioms presented by [67] and opted by various researchers such as [68], [69]: (1) The occurrence of change (increase/decrease) in the probability of the parent node thus changes the probability of the child node; (2) The values of the child nodes must be consistently affected by the changes made to the probability distributions relative to the parent node; In the case of a node with more than one parent (e.g., x and y), the overall effect of x and y must be greater than the individual effects of parent x or parent y.

For example, when the probability of "road design = good" increases from 70% to 75%, the probability of "road infrastructure condition = good" and "road environment = good" increases from 77% to 80% and 84% to 86% respectively. In light of this variation, when the probability of "Occurrence of events that block/slow traffic=low" increases from 74% to 78%, the probability of "congestion=low" and "road environment=good" increases from 78% to 82% and 87% to 90% respectively, which is consistent with the axiom. Similarly for the other nodes of the graph.

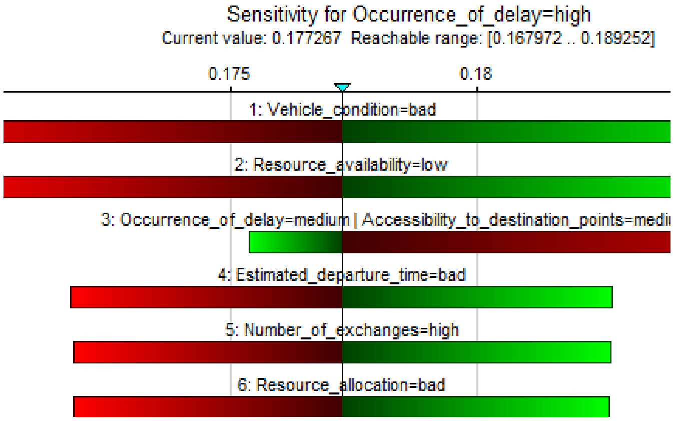

Fig. 5. Sensitivity Analysis for Occurnce of Delay.

IV. Discussion

In this paper, an analysis of potential delivery delays is developed using a Bayesian fuzzy model. BNs have been used in various existing studies to analyze the risk of delay in different areas such as maritime transport[45], [70], rail transport [71] and air transport [72]. Compared to the existing works, the developed model focuses on the occurrence of delay in the road freight transport domain. This model consists of many internal and external factors that cause delay to occur. Sensitivity analysis and interpretation of the results of four scenarios show that the internal factors related to the transport companies have a stronger effect on the occurrence of late deliveries than the external factors. This means that the transport company decisions in terms of resource selection, in addition to planning relevance, have a considerable effect on delivery reliability than road and delivery events such as congestion, weather conditions and availability of delivery bays. Therefore, optimized resource (physical and material) allocation to the right routes and a smart routing planning design plays an important role in ensuring on-time deliveries. In order to validate the results of this model, an example test of three axioms is performed.

V. Conclusion

The respect of delivery deadlines is crucial to ensure the quality of logistics services. Unfortunately, it often happens that this deadline is not respected, leading to a series of more or less unfortunate consequences. This article focuses on predicting the risks of delays in deliveries with the aim of anticipating them in order to either avoid them or be better prepared to deal with them and reduce the impact of poor quality of service. To do this, the article proposes a fuzzy Bayesian model combining the Bayesian approach and fuzzy logic in order to monitor the occurrence of delivery delays. This model is based on a set of factors causing the delay of deliveries and their causal relationships represented by a causal graph. Fuzzy logic intervenes by the generation of fuzzy rules based on conditional probability tables. Such a model is particularly effective, especially for the type of problem dealt with through this article. It is positioned as an excellent alternative to deep learning for making predictions in the absence of massive data.

One of the limitations of the proposed model is the identification of all the factors that cause delivery delays, the lack of integration of all these factors can affect the effectiveness of this model in correctly predicting possible delays.

The generalization of the model to all risks that can degrade the quality of delivery services such as damage, theft and loss, is a potential perspective to the work presented here. Similarly, a comparative study between a Bayesian-fuzzy model and a model derived from deep-learning around the prediction of delivery risks and the management of the crises that follow are very promising avenues of research.

***Abstract*—Student scores in TOEFL IBT reading, listening, and writing may reveal weaknesses and deficiencies in educational institutions. Traditional approaches and evaluations are unable to disclose the significant information hidden inside the student's TOEFL score. As a result, data mining approaches are widely used in a wide range of fields, particularly education, where it is recognized as Educational Data Mining (EDM). Educational data mining is a prototype for handling research issues in student data which can be used to investigate previously undetected relationships in a huge database of students. This study used the EDM to define the numerous factors that influence students' achievement and to create observations using advanced algorithms. The present study explored the relationship among university students' previous academic experience, gender, student place and their current course attendance within a sample of 473 (225 male and 248 female). Educational specialists must find out the causes of student dropout in TOEFL scores. The results of the study showed that the model could be suitable for investigation of important aspects of student outcomes, the present research was supposed to use the statistical package for social sciences (SPSS V26) for both descriptive and inferential statistics and multiple linear regressions to improve their scores.**

Keywords*—Educational data mining; students score; linear regression; TOEFL; Statistics

I. Introduction

Over the last decade, test developers and experts have fixated much of their time and focus on developing a theoretical view of language ability in order to understand better the nature of language proficiency, as well as developing and applying more sophisticated statistical tools to analyze language tests and test takers' performance in order to best tap these issues[1]. However, language testing research shows that language aptitude is not the only factor influencing test takers' performance. Almost all screening processes in academic environments, from seeking college admission to applying for an exchange student programmer, require the applicant to present TOEFL iBT or other Standard English language test scores.

The TOEFL iBT (Test of English as a Foreign Language) Language testing is largely concerned with whether the results clearly effectively reflect test takers' underlying ability in a certain area in a given testing setting [2]. After graduation, English proficiency is necessary for developing career options and attaining aspirational goals in the workplace [3]. The Educational Testing Service (ETS) commissioned a recent survey study and found a high link between high English proficiency and the income of young professionals (full-time workers in their 20s or 30s) across all major industries. This higher income allows them to put more money into improving their English abilities, which are "a vital instrument for success in today's world". Test-takers personality factors to the testing scenario, such as education level, Gender, and place, can all affect their performance [4]. But these construct-irrelevant elements are regarded as potential causes of test bias, which might cause the acquired results to be unrepresentative of the underlying skill that a language test is attempting to assess. As a result, a thorough assessment of the likely effects of such factors is worthwhile.

Taking these factors into account and the popularity of the TOEFL iBT as a proficiency exam worldwide, this study aims to determine the future effects of test education level, Gender, and place on TOEFL iBT listening reading and writing results.

II. Literature Survey

Test fairness is a challenging topic in the literature when it comes to language testing. Debates about test fairness aim to create tests free of discrimination and contribute to testing equity [5, 6]. When students with the same language ability perform differently on a test, it may be called discriminatory. When the substance of the test is discriminatory to test takers from certain groups, other criteria such as education level, Gender, and test place play a factor. The test's requirements may have different impacts on test takers from different groups; test taker factors such as education level, Gender and place can all contribute to test bias.

These factors can impact a test's validity and lead to measurement mistakes. As a consequence, in the design and development of language exams decreasing the impact of these factors that are not part of the language competence is a top objective [7].

The association between TOEFL score and GPA was shown to be positive and statistically significant; however, it was less for engineering students than for students in other professions and for engineering courses than for non-engineering courses. In logistic regressions of CAE pass rate and graduation rate, the TOEFL score was also statistically significant, showing an increased probability of success with a higher TOEFL score. However, model goodness-of-fit values were low, showing that many students defied overall trends in their performance [8].

Accord to the previous survey, a mixed ANOVA was used to answer the following study question: Is there a significant difference between pre and post TOEFL test scores for male and female students? Is there an interaction between male and female students' pre and post TOEFL test scores? According to those findings, there was a substantial change between pre and post TOEFL exam scores, but no significant variation between genders. Furthermore, no correlation was found between male and female students' pre and post TOEFL test scores [9].

In agreement with the past research, there was a relationship between overseas students' academic performance and their language skills, academic self-concept and other factors that influence academic achievement. The research looked at first-year international students enrolled in undergraduate business programs at a Canadian English-medium institution. The following data was gathered on the students: grades in degree program courses, annual GPA, and EPT scores (including sub scores).

Students also filled out an academic self-concept measure. In addition, instructors in two obligatory first-year business courses were interviewed regarding the academic and linguistic requirements in their courses and the profile of successful students to acquire additional information about success in first-year business courses [10].

In the other side the purpose of this study was to determine whether there was a significant difference in the capacity of male and female students to respond to factual and vocabulary-in-context questions on the TOEFL-like reading comprehension test. The results of reading comprehension tests taken from twenty-one male and twenty-one female students in the English Education Program were used for secondary data analysis. Through the use of random sampling, samples were chosen. Utilizing an independent sample t-test, data were evaluated [11].

On the other hand in this study, the self-efficacy of university students in responding to TOEFL questions is examined in relation to gender and participation in TOEFL courses. This study uses a descriptive design with a total sample of 200 university students from two large institutions who are majoring in both English and non-English [12].

III. Proposed Methodology

After reviewing data and determining the research aim and objectives, this paper examines the effects of characteristics such as education level, attendance, and student gender to examine students' scores in TOEFL iBT reading, listening, and writing using data mining approaches. For this study's techniques and data preparation procedures, methodologies are discussed below.

A. Dataset

The data for this study came from 473 students. Arabic is one of their first languages. 473 students in total took the TOEFL. The study enlisted the participation of 225 male and 248 female students (Table I).

TABLE I. Attributes of the Dataset

Attributes	**Details**
Gender	Male, Female
Education level	Faculty
Place	Cairo, Sheikh Zayed
Attendance	Number of Course Attendance

B. Data Preparation

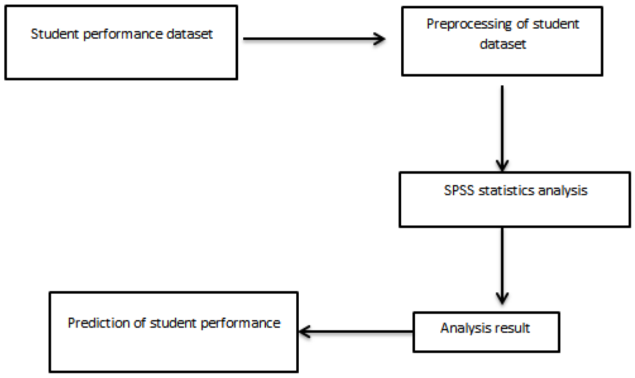
All activities were taken from the raw data to create the final dataset (data that was entered into the design tool). The dataset's variables were prepared to generate the models needed in the next phase.

The students received a variety of English language skills, including a TOEFL preparation session, during the rigorous English language program. The TOEFL scores of the students were used as the research tool. At the end of the course, students take the TOEFL (paper-based test). Students were in class for five hours a day and were given TOEFL-related assignments. Listening, grammar/structure, and reading are the three skills that make up the TOEFL score. The TOEFL score ranges between 310 and 677. This study aims to determine the future effects of test education level, gender, place, and attendees on TOEFL iBT listening, reading, and writing results.

IV. Model and Algorithm

Fig. 1 depicts a framework for predicting student success. First, the data on student performance is fed into this system. This student data set has been preprocessed to eliminate noise and make the data set more consistent. The input data set is then subjected to various SPSS statistics analyses. Next, data analysis is carried out. Finally, different algorithms' categorization results are compared.

Likewise, gender is another factor that is usually studied, but there is a lack of good research to identify whether male and female language learners have significantly different TOEFL results. From a psychological standpoint, there are numerous variables related to gender [13].



Student performance dataset
Preprocessing of student dataset
SPSS statistics analysis
Analysis result
Prediction of student performance

Fig. 1. A Framework for Student Performance Prediction.

In general, females are believed to be more successful in language learning than males. Therefore, many scholars in language acquisition studied how gender disparities can affect students' language learning proficiency. In other words, ten studies found that female students were superior to male students in reading comprehension. In contrast, five studies found that male students were superior [14,15] also undertook a quantitative study to see if there are any gender differences in TOEFL scores and found no significant differences. The Educational Testing Service (ETS), on the other hand, came to a different result.

According to the survey, female pupils are more advanced than male students [16]. Females, for example, outperformed males in writing and reading, though the difference was minor. On the other hand, Male students performed higher in terms of listening and comprehension, as well as vocabulary proficiency [17].

Additionally, a standardized English language assessment examination, such as the Test of English as a Foreign Language, is required at most English language colleges and universities (TOEFL). However, because there are few standardized evaluation measures for all candidates, English proficiency ratings are occasionally utilized for purposes other than evaluating the "abilities of non-native English speakers to use and understand English."

However, in the lack of standard ranking techniques for all candidates, the TOEFL score may be used as a stand-in for those criteria; the TOEFL score is occasionally employed as a predictor of how well a potential student will perform at a university. Even when the TOEFL is not used as the main measure of academic success, minimum TOEFL score requirements are frequently enforced.

Despite the fact that the underlying English-language communication abilities that TOEFL scores represent may be significantly more important to academic performance in specific areas, TOEFL score minimums for admission frequently do not vary among academic majors or fields of study. Requiring the same minimum TOEFL score whatever of a student's selected major may lead to the exclusion of otherwise talented students from academic programmers where academic achievement is not contingent on language competence [18]. For example, an increased TOEFL score is less correlated with academic success in college students than in other college students (possibly because English communication skills largely determine academic success in these areas). It may be reasonable to adopt the TOEFL score entry requirements. More lenient for engineering applicants, especially those who can show enough preparation through means other than a TOEFL score.

Despite the fact that course enrollment has tripled in the past 10 years, little is known about the impact of environment tests and attendance on learning. According to a recent study of college students, course attendance and the student place have an impact on the examination scores. Therefore, differences in student accomplishment between groups should be viewed with caution. This study adds to the body of knowledge by addressing a recurring problem of earlier research: determining the impact of various classroom test conditions on exam scores. The features of test environments are rarely described in previous research. This study compares test scores from students who took examinations off-campus with test scores from students who were called back to school for probationary exams within a semester [8].

V. Experiments and Results

The analysis of this paper was done using the statistical package for social sciences (SPSS V26) for both descriptive and inferential statistics. In this work, ANOVA was used as a statistical analysis method. Because this study examines the significance of group differences, it uses an ANOVA statistical model with a continuous dependent variable (TOEFL scores) and categorical independent factors.

Because this study tries to observe the interaction between gender differences, ANOVA is the most appropriate statistical procedure among the numerous varieties of ANOVA [19]. Pre and post TOEFL scores are within-subject factors, while male and female are between-subject variables. To address the first study question, a statistically significant mean difference between before and post TOEFL scores will be studied. After that, we'll look at the statistically significant mean difference between male and female TOEFL scores. The impacts will next be compared between the TOEFL scores of males and females.

Table II provides descriptive statistics for the selected variables, including the minimum (Min), maximum (Max), mean (M), standard deviation (SD), and coefficient of variation (CV) (M=48.36,SD=7.519,CV=1 5.55%),(M=47.24,SD= 7.972,CV=16.88%),(M=47.07,SD=8.354,CV=17.75%), (M=475.38,SD=70.869,CV=14.91 %) respectively.

Table II shows some descriptive statistics and bivariate correlations among the selected variables provided in this section.

TABLE II. Descriptive Statistics

	N	**Min**	**Max**	**Mean**	**SD**
Listening	473	24	68	48.36	7.519
Grammar	473	27	68	47.24	7.972
Reading	473	27	67	47.07	8.354
Total	473	300	653	475.38	70.869

TABLE III. MULTIPLE CORRELATIONS

		Listening	Grammar	Reading	Total
Listening	***Pearson Correlation***	1			
	P-value				
	N	473			
Grammar	***Pearson Correlation***	.647***	1		
	P-value	.000			
	N	473	473		
Reading	***Pearson Correlation***	.642***	.781***	1	
	P-value	.000	.000		
	N	473	473	473	
Total	***Pearson Correlation***	.847***	.911***	.909***	1
	P-value	.000	.000	.000	
	N	473	473	473	473

Table III displays the bivariate correlations between the study's primary variables; all of the correlations were statistically significant at 0.001. These correlations vary between.642 and.642, indicating that all variables in the study have substantial moderate to strong multiple correlations.

Furthermore, the results of the multiple regression were reported, and it can be noticed that all variables have significant positive effect on the total score since (P<0.001), as a result, the null hypothesis is rejected, and the alternative hypothesis is accepted in Table IV.

TABLE IV. REGRESSION COEFFICIENT

Model		**Unstandardized Coefficients**		**Standardized Coefficients**	**t**	**Sig.**
		B	***Std. Error***	***Beta***		
1	***(Constant)***	.334	1.234		.270	.787
	Listening	3.336	.032	.354	102.996	.000***
	Grammar	3.396	.038	.382	90.461	.000***
	Reading	3.257	.036	.384	91.499	.000***

*** P < 0.001

Table IV, the assumptions of this study were examined using multiple regression analysis in this part.

Table V, the F-test in ANOVA table confirms the significance of the model since (F=546827.6, P<0.001).

TABLE V. ANOVA TABLE

Model		**Sum of Squares**	**Df**	**Mean Square**	**F**	**Sig.**
1	***Regression***	2363572.748	3	787857.583	52762.172	.000^{b}
	Residual	7003.222	469	14.932		
	Total	2370575.970	472			

On the other side, the impact of demographic variables on the students' overall scores will be studied in this section. Finally, the normal distribution test was done utilizing Skewness and kurtosis tests to choose between parametric and nonparametric testing Table VI [20].

TABLE VI. TEST OF NORMALITY

	N	**Skewness**		**Kurtosis**	
		Statistic	***Std. Error***	***Statistic***	***Std. Error***
Total	473	.066	.112	-.756	.224

Table VI, the values of Skewness and kurtosis for the score were within the range of ±2, indicating that the total score was normally distributed, according to the normality statistics.

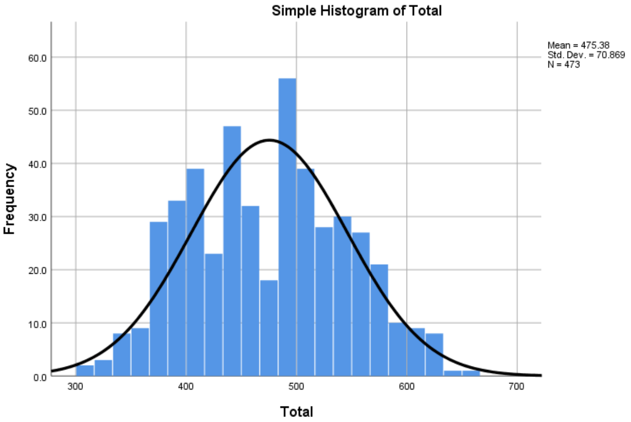


Fig. 2. Histogram and the Normal Curve of the Total Score.

Fig. 2 displys a normal distribution of data.

First hypothesis: there is a significant difference in total scores regarding the Gender of the students. The independent-samples t-test is the appropriate parametric test because Gender is a categorical variable with two independent categories.

Table VII, some descriptive statistics of the total score according to each category were given.

Fig. 3 can be concluded from that the average degree of females (487.49) was greater than that of males (462.04).

In addition, Levene's test for equality of variances was done and found that the variances were equal since $(F = .449, P > 0.05)$. The results of the independent-sample t-test show that there is a significant difference in total scores between males and females since P-value is less than 0.05 as $(t = -3.961, P < 0.001)$ Table VIII.

TABLE VII. DESCRIPTIVE STATISTICS OF THE TOTAL SCORES REGARDING THE GENDER

Gender	**N**	**Min**	**Max**	**Mean**	**Std. Deviation**
female	248	300	653	487.49	70.863
male	225	313	623	462.04	68.590
Total	473	300	653	475.38	70.869

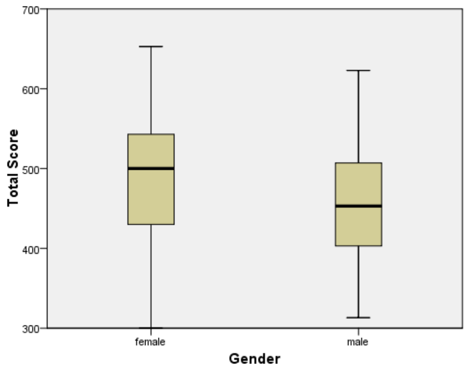

Fig. 3. Boxplot for the Total Scores of Students Regarding the Gender.

TABLE VIII. INDEPENDENT SAMPLES T-TEST

Levene's Test for Equality of Variances			t-test for Equality of Means					
	F	*P-value*	*t*	*df*	*Mean*	*Std. Error*	*95% CI of the Difference*	
							Lower	*Upper*
Equal variances assumed	.449	.503	-3.961	471	-25.452	6.426	-38.078	-12.826
Equal variances not assumed			-3.967	469	-25.452	6.415	-38.058	-12.845

***P < 0.001

In Table VIII, the results of the independent-sample t-test show that there is a significant difference in total scores between males and females since P-value is less than 0.05 as$(t = -3.961, P < 0.001)$.

Moreover, in the second hypothesis: there is a significant difference in total scores regarding the attendees of the students. Since the student's attendance is a categorical variable with more than two independent categories, the suitable parametric test is the analysis of variance (ANOVA) test.

In Table IX, some descriptive statistics of the total score according to each category were given.

Fig. 4 presented that the average scores of students attending for the first time (477.19) was greater than that of the second time (474.39), and the third time (473.07).

In Table X, the results of the ANOVA test show that there is no significant difference in total scores between the number of attendees since the P-value is greater than 0.05 as$(F = .151, P > 0.05)$.

TABLE IX. DESCRIPTIVE STATISTICS OF THE TOTAL SCORES REGARDING THE ATTENDANCE

Attendees	N	Minimum	Maximum	Mean	Std. Deviation
1	226	323	640	477.19	71.650
2	124	313	623	474.39	65.787
3	123	300	653	473.07	74.747
Total	473	300	653	475.38	70.869

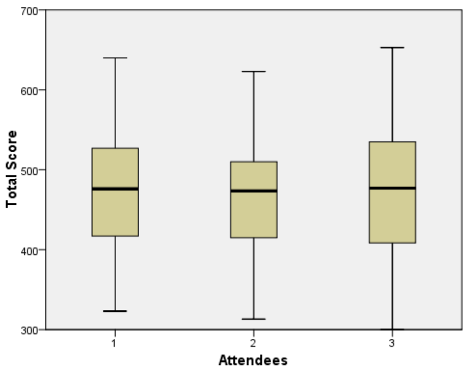

Fig. 4. Boxplot for the Total Scores of Students Regarding the Attendees.

TABLE X. ANOVA TABLE

	Sum of Squares	Df	Mean Square	F	P-value
Between Groups	1525.638	2	762.819	.151	.860
Within Groups	2369050.333	470	5040.533		
Total	2370575.970	472			

As well the third hypothesis: there is a significant difference in total score regarding the place of the test. Since the place of the test is categorical variable with two independent categories, so the suitable parametric test is the independent-samples t-test.

Table XI shows some descriptive statistics of the total score according to each category were given.

Fig. 5 displayed that the average scores of students attend in Sheikh Zayed (484.81) were greater than those attending Cairo (466.38).

TABLE XI. DESCRIPTIVE STATISTICS OF THE TOTAL SCORES REGARDING PLACE OF THE TEST

place	N	Min	Max	Mean	Std. Deviation
Cairo	242	300	640	466.38	71.684
Sheikh Zayed	231	350	653	484.81	68.905
Total	473	300	653	475.38	70.869

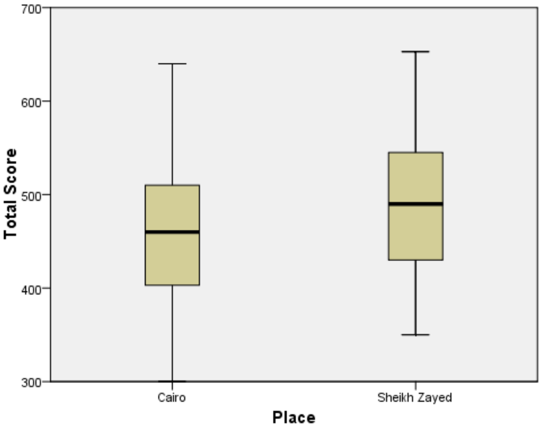

Fig. 5. Boxplot for the Total Scores of Students Regarding the Place of the Test.

TABLE XII. INDEPENDENT SAMPLES T-TEST

t-test for Equality of Means						
	t	df	Mean	Std. Error	95% CI of the Difference	
					Lower	*Upper*
Equal variances assumed	-2.848	471	-18.430	6.470	-31.144	-5.715
Equal variances not assumed	-2.851	471	-18.430	6.464	-31.132	-5.727

In Table XII, Levene's test for equality of variances reveals that the variances were equal since$(F = .475, P > 0.05)$. The results of the independent-sample t-test show that there is a significant difference in total scores between Cairo and Sheikh Zayed since P-value is less than 0.05 as$(t = -2.848, P < 0.01)$.

Subsequently, the fourth hypothesis shows a significant difference in total scores regarding the level of education**.** Since the level of education is a categorical variable with more than two independent categories, the suitable parametric test is the analysis of variance (ANOVA) test.

TABLE XIII. DESCRIPTIVE STATISTICS OF THE TOTAL SCORES REGARDING THE LEVEL OF EDUCATION

Table XIII shows some descriptive statistics of the total score according to each category were given.

Fig. 6 concluded that students' average scores were different across the level of education.

Table XIV shows the results of the ANOVA test show that there is a significant difference in total scores across the level of education since the P-value is less than 0.05 as$(F = 8.407, P < 0.001)$.

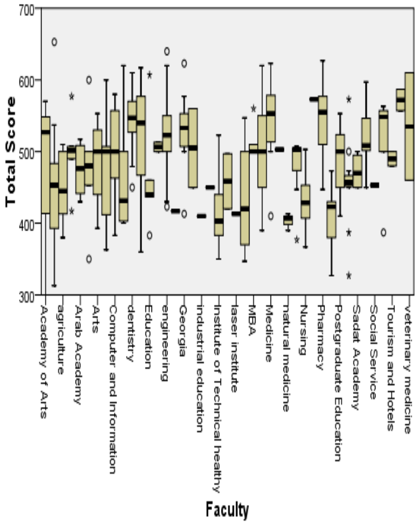

Fig. 6. Boxplot for Students' Total Scores Regarding the Level of Education.

TABLE XIV. ANOVA TABLE

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	1068908.842	42	25450.211	8.407	.000
Within Groups	1301667.129	430	3027.133		
Total	2370575.970	472			

Finally, the fifth hypothesis: there is a significant difference in TOEFL parts (Listening, Grammar, and Reading) regarding the Gender.

Table XV shows some descriptive statistics of the TOFEL parts according to each category were given.

TABLE XV. DESCRIPTIVE STATISTICS OF THE TOEFL PARTS REGARDING THE GENDER

Gender		Listening	Grammar	Reading
female	***N***	248	248	248
	Minimum	24	27	28
	Maximum	68	68	67
	Mean	49.36	48.58	48.41
	Std. Deviation	8.060	7.869	7.932
male	***N***	225	225	225
	Minimum	32	27	27
	Maximum	68	67	67
	Mean	47.26	45.76	45.59
	Std. Deviation	6.720	7.838	8.572
Total	***N***	473	473	473
	Minimum	24	27	27
	Maximum	68	68	67
	Mean	48.36	47.24	47.07
	Std. Deviation	7.519	7.972	8.354

Fig. 7, can be concluded that for Listening, the average degree of females (49.36) was greater than that of males (47.26), for Grammar, the average degree of females (48.58) was greater than that of males (45.76), and for Reading the average degree of females (48.41) was greater than that of males (45.59).

Then, Levene's test for equality of variances was conducted. It can be noticed that for listening, we have unequal variances since ($F = 7.566, P < 0.01$) but for Grammar, we have equal variances since($F = .007, P > 0.05$)and the same for Grammar. We have equal variances since($F = 1.870, P > 0.05$). The results of the independent-sample t-test show that there is a significant difference in listening scores between males and females since P-value is less than 0.05 as($t = -3.082, P < 0.01$). Moreover, there is a significant difference in grammar scores between males and females since P-value is less than 0.05 as($t = -3.900, P < 0.001$). Finally, there is a significant difference in reading scores between males and females since P-value is less than 0.05 as($t = -3.716, P < 0.001$) Tables XVI and XVII.

In Tables XVI and XVII, since the Gender of the students is categorical variable with two independent categories; the suitable parametric test is the independent-samples t-test.

VI. Conclusion

This study looked at the TOEFL results of 473 students based on how much time they spend studying, their educational level, gender, course attendance, and place. AS EXPECTED, the TOEFL scores improved from pre- to post-test, and the change was statistically significant. In this survey, there was significant difference by educational level, gender, attendance, and place difference. Furthermore, there was a relationship between male and female students' before and post TOEFL scores. As a result, the study's findings offer students with useful information. Furthermore, TOEFL educators can propose that the more time a student devotes to learning, the higher their TOEFL score will be. This also aids programmer makers in class design by giving them a sense of what students (who are prepared for the TOEFL) could expect. Because many students are applying to universities each year, generalizing TOEFL scores to the general population is insufficient.

***Abstract*—The Internet of Health Things (IoHT) is receiving more attention from researchers because of its wide use in the healthcare field. IoHT refers to medical devices whose main purpose is to transmit health data in a secure and lossless manner between them and healthcare personnel. However, in a medical emergency, sensors transmit vital patient data simultaneously and frequently, increasing the risk of congestion and packet loss. This problem is highly undesirable in an IoHT system, leading to undesirable results. To address this issue, a new approach based on Named Data Networking (NDN) (which is considered as the most appropriate internet architecture for IoT systems) is proposed to control congestion in IoHT systems. The proposed approach, Average delay-based early congestion Detection (ADCD), detects and controls congestion at consumer nodes by calculating the average queuing delay based on the one-way delay similar to that proposed in Sync-TCP. Then according to the calculated value, ADCD divides the network into three states: no-congested state, less congested state, and heavily congested state. The adjustment of the congestion window size is done according to the state of the network. ADCD was implemented in ndnSIM and compared to the Interest Control Protocol ICP. The results show that ADCD maximizes bandwidth utilization compared to ICP and maintains a reasonable delay.**

Keywords*—Named data networking; internet of health things; congestion control; congestion detection

I. Introduction

The Internet of Things (IoT) is a collection of intelligent devices that can communicate, interact and exchange information with each other [1]. It interconnects billions of small devices to deliver information at any time and across the world [2]. IoT has been primarily applied in several domains like healthcare, smart home, smart cities, industries, transportation and logistics, etc. In healthcare, IoHT has been proposed as an extended version of IoT to connect people and smart objects in the medical field [3]. It refers to medical devices, healthcare sensors and intelligent biomedical applications that enable the exchange and treatment of various types of healthcare data with each other and with healthcare people [3], whose main objective is to transmit health data securely and without loss. This data can be patient monitoring data, patient analyses, consultations or even sensitive data such as heart rate and breathing.

In the case of a medical emergency or patient vital signs monitoring, sensors implanted on patients detect and transmit vital patient data simultaneously and frequently, which increases the risk of congestion and consequently packet loss. In IoHT, congestion is highly undesirable and can lead to undesirable outcomes such as patient death. However, ensuring that packets arrive at their destination in time guarantees patients' safety and survival [4]. Due to the importance and sensitivity of the transmitted data, congestion should be avoided as much as possible and controlled if this is not possible.

However, the IP protocol stack on which the IoT is based was designed for a different purpose and cannot handle the important challenges caused by the heterogeneity of the devices and the importance of the traffic generated, highlighting the limitations of IP. However, the current IP solutions are working hard to support IoT systems, but the gaps in IP are still hard to hide. Along with efforts to adapt IP to the IoT and other content-based architectures, Information Centric Networking (ICN) [5] promises to support IoT systems and emerging internet applications natively. It is a switch from a host-centric communication model to a content-centric system, caching at intermediate nodes, and the use of multiple paths and sources. With its features, ICN has the potential to be a reliable framework for IoT by connecting billions of heterogeneous constrained objects. Indeed, ICN provides easy access to data and reduces data recovery time and the load on data producers. NDN [6] is considered as the appropriate ICN architecture for IoT systems among several ICN architectures.

NDN is a new internet architecture based on the content of data rather than its IP address. NDN defines three roles: Consumer, Router and Producer and offers two types of packets; the interest packet, containing the required content name and the data packet, containing the required content. There are three elements to every NDN node as shown in Fig. 1; Content Store (CS), Pending Interest Table (PIT) and Forwarding Interest Base (FIB). The CS stores copies of the content that passes through it so that future demands for the same content can be satisfied. The PIT is a table that preserves the records of incoming and outgoing interest and data packets. The FIB transfers interest and data packets between nodes through routing protocols [7]. The data transfer process between NDN nodes is as follows, the consumer asks for content by sending an interest packet.

FIB
Router 1

Fig. 1. NDN Information Distribution in Case of IoHT Environment.

The routers use FIBs to forward this packet to the content producer and create a PIT entry list on each router to define the reverse path. Then, the producer transfers the related content via the reverse path to the consumer, and the CS saves the content that traverses it for future utilization [8].

An example of the data transfer process between NDN nodes is shown in Fig. 1. Suppose that consumer one starts this process and sends an interest packet containing the requested name. This interest packet is transferred to the producer using the FIB services. The requested content is put into a data packet and is stored in the CS of router three and router two for future utilization. Subsequently, if consumer two requires the same content, its interest packet is locally satisfied from the CS of router two without the need to forward this packet to the original content producer. In the case of IoHT, the consumer can be a doctor, a patient, a nurse, a medical application, a hospital or any medical or IoT device that desires to obtain data/information concerning the health field. The producer can also be a doctor, a patient, a nurse, a medical application, a hospital or any medical or IoT device that has data/information concerning the health field. The router's mission is to route the data/information concerning the health field between the consumer and the producer.

To address the problem of congestion in healthcare field, and as NDN congestion control mechanisms that are based on the estimation of RTTs as the main indication of congestion are not reliable in NDN-IoHT because the RTT value changes frequently due to caching or multipath. This paper proposes a new approach based on Sync-TCP [9] (which has been proposed to control congestion based on measurements of the One-way Transit Time (OTT) between senders and receivers of packets) to control congestion in NDN-IoHT. OTTs are more accurate in reflecting queue delay resulting from network congestion than RTTs.

In our approach, congestion is detected by calculating the average queuing delay based on the one-way delay similar to that proposed in Sync-TCP [9]. Then according to the calculated value, the network is divided into three states; no-congested state, less-congested state and heavily congested state. The adjustment of the congestion window size is made according to the state of the network. Increased in case of a no-congested network and decreased in a less-congested and heavily congested network. The choice of congestion control at the consumer nodes comes from the fact that the method used for congestion detection is based on variations of OTTs which is more reliable at the consumer node than at the router node because consumers are able to estimate the one-way delay of the data packet using the transmission time available in its header and the reception time of this packet. The rest of the paper is organized as follows: Section II presents background and related work, Section III describes the proposed method, Section IV presents results and discussion and Section V concludes the article.

II. Background and Related Work

A. NDN for IoT

ICN has been proposed as a promising future internet architecture to fill the gaps in the CoAP/RPL/6LowPan/802.15.4 protocol stack on which the IoT system is based and improve its deployment and data distribution [10]. Among the ICN architectures proposed in the literature, NDN is considered as the most appropriate ICN architecture for IoT systems. In effect, the characteristics of NDN, namely hierarchical naming of unique content that is independent of its location, caching in intermediate routers, multipath, multisource, name-based routing, support for user mobility, the use of encryption for better access control, make it a very suitable platform for IoT system traffic and applications.

Several works have been done on this topic to show that NDN is the most suitable and promising architecture for IoT. In [11], the authors suggested that NDN can meet IoT requirements and is the most suitable architecture for IoT scenarios. In [12], the authors showed that the semantics of NDN meets the requirements of IoT applications and its main challenges. They also showed that the communication model used by NDN "based on the content name" allows IoT networks an easy deployment and configuration. In [13], the authors proposed a comparative study of ICN architectures in an IoT context and concluded that NDN is an architecture most suitable for IoT systems. In [2], the authors proposed an NDN integration in IoT devices and then evaluated this proposal in a Smart Farming application scenario to prove that NDN is an architecture most suitable for IoT systems. In [14], the authors described the advantages of the NDN architecture compared to the current IP internet architecture for IoT systems and then explained how NDN can be included in an IoT architecture. In [15], the authors discussed the main characteristics of NDN in IoT, then they proposed an IoT architecture via NDN named IoT-NDN for various IoT domains. Some studies have discussed the requirements of IoT and how ICN architectures support them without examining which of these architectures is most appropriate for IoT.

B. *Related Work*

In NDN architecture, the problem of network congestion is the subject of much active research focused on minimizing transit delays and reducing packet loss caused by the transfer capability of routers. In NDN architecture, data packets are the leading cause of congestion because they are much larger than interest packets. Therefore, to control congestion, many research works propose controlling the sending rate of interest packets to limit the returning rate of data packets. Several congestion control mechanisms have been proposed in the literature, classified as receiver-based control, Hop-by-hop control, and Hybrid control [16]. In this paper, we present some NDN congestion control works. Among the first interest control protocols proposed for NDN is the Interest Control Protocol (ICP) [17], which detects congestion at the consumer node by measuring delay and timer expirations. The window size adjustment is made at the receiver level using the AIMD (Additive-Increase Multiplicative-Decrease) mechanism. If RTO (Retransmission Time-Outs) is triggered, the consumer decreases its congestion window by MD (Multiplicative Decrease). Otherwise, it increases its congestion window by AI (Additive Increase). The authors of [18] proposed DCP "Delay-based Congestion Control Protocol" based on the window and the receiver. DCP detects congestion based on the value of the queue delay. If this delay is below a given threshold, DCP considers that the link is not congested. Otherwise, DCP considers the link is congested. The calculation of queuing delay is done by measuring the delay returned by the producer or intermediate nodes along the path of the transmitted data packets. DCP uses a linear controller to adjust the congestion window. In [19], the authors proposed a hop-by-hop congestion control mechanism (HCCM) based on explicit notification of interest packet rates. This mechanism detects congestion by calculating the queue length of the interest packets of the output interface. According to the value found, each router between the congested node and the consumer can adjust the sending rate of interest packets. The authors used two levels in the queue, qmax and qmin, representing the maximum and minimum queue occupancy thresholds respectively. Once the queue reaches one of the levels (qmax or qmin), the router sends a notification to the downstream node to inform it of the congestion state and the regulation of the sending rate of interest packets. In [7], the authors proposed EC-Elastic, an Explicit Congestion Control Mechanism that detects congestion at the routers by measuring the sojourn time of packets in the queue using CoDel-AQM algorithm and then, according to this value, the router marks the concerned data packets to inform the consumer nodes to reduce their sending rate of interest packets. At the consumer node, if the phase is a slow start, the congestion window is increased by one and decreased by $\beta_{1,}$ and if the phase is the congestion avoidance, the congestion window is increased by $\frac{WWF}{cwnd}$ using the Window-correlated Weighting Function WWF of Elastic-TCP [20] and decreased by β2. In [21], the authors proposed the MPCC Multipath Congestion Control mechanism, which is based on two principles: Multipath discovery that tags each sub-path with a path tag in the forwarding process and then based on these tags, a tag-aware forwarding strategy has been proposed to discover and manage sub-paths. For multipath congestion control, the authors proposed a Multipath Window Adaptation Control (MWAC) scheme to control the congestion window. In [22], the authors proposed DPCCP Delay-based Path-specified Congestion Control Protocol based on three modules, namely: The congestion estimation module, which aims to measure the number of backlogged packets for every sub-flow using RTT and baseRTT, where the number of backlogged packets measured for a sub-flow is the product of the sub-flow queuing delay and the sub-flow rate. The fairness control module which is used to calculate the target number of backlogged packets for each sub-flow to equalize the aggregate queuing delay [23] and the flow control module, which aims to adjust the rate based on the queuing delay and the target number of packets in the queue using the Adaptive Additive Increase Additive Decrease (A-AIAD) algorithm.

Different from prior works, this paper proposes a new approach that controls congestion by calculating the average queuing delay based on the one way delay similar to that proposed in Sync-TCP [9]. Then according to the calculated value, the network is divided into three states; no-congested state, less-congested state and heavily congested state for efficient and lossless deployment in an IoHT environment. The adjustment of the congestion window size is made according to the state of the network. Increased in case of a no-congested network and decreased in a less-congested and heavily congested network.

III. The Proposed Method

A. *Motivation*

The NDN paradigm has several features, such as caching in intermediate routers that serve future requests for the same content without going through the content producer. This feature reduces the content retrieval time and the charge on the content producer. The use of multiple paths and multisource to avoid congestion of one path over another and to divert requests in the event of a congested path. However, the use of RTT (Round-Trip Time) estimates as a primary indication of congestion are unreliable in NDN-IoHT because the value of RTT frequently changes due to caching and multipath causing problems for congestion control mechanisms that are affected by RTT variation particularly in the event of large RTTs which are treated as losses despite having no packet losses, thus halving the rate of sending packets of interest and consequently more time to fully utilize the bandwidth.

An explicative example of the inefficiency of this congestion detection method was discussed in [18]. In this article, the authors shows that the increase in RTT along the path can be caused by the PIT congestion of one of the routers and not by the data path congestion. In addition, when using caching, the content retrieved from the cache has a shorter RTT. This situation can lead to an erroneous increase in the congestion window size because a short RTT value is perceived as a sign of bandwidth availability, which can cause packet loss [18].

Our approach is motivated by these problems of considering RTT as an indication of congestion, which is not tolerated in an IoHT environment because the transmitted data are important and critical and the recovery time plays a crucial role in this domain. In an NDN-IoHT environment, a congestion control mechanism should achieve the following goals: Avoid congestion if possible and, in cases where congestion cannot be avoided, control it; Ensure delivery of healthy data transmitted in the network and minimize packet loss; Utilize available bandwidth and maintain low packet delivery delay.

B. *Congestion Detection*

The congestion detection method of ADCD is inspired by the Sync-TCP algorithm proposed in [9]. It detects congestion based on One-way Transit Time (OTT) measurements. OTTs are more accurate in reflecting queue delay resulting from network congestion than RTTs. In NDN, each node (router or producer) adds the time of its transmission in the header of each data packet so that the consumer can estimate the one-way delays. When the consumer receives this packet, it can estimate the one-way delay of the data packet using the transmission time available in its header and the reception time of this packet by subtracting the reception time of the packet from the sending time of that packet as follows:

$$OTT = A_T - T_T \tag{1}$$

where, A_T refers to the data packet arrival time and T_T refers to the transmission time of this data packet. Similar to DCP [18], we are focused only on the measurement of the relative delay between data packets to know whether the content is served from a new data producer or not. ADCD uses changes in queuing delay of a path to detect congestion. For each data packet received, the consumer ADCD obtains a new estimate of the queuing delay and then calculates it average. The average queuing delay is based on the changes in the current queuing delay measure as follows:

$$AvgQDelay = 0.875 * AvgQDelay + 0.125 * CurrQDelay \tag{2}$$

Where CurrQDelay is the current queuing delay, it is estimated by taking the minimum observed OTT and subtracting it from the current delay as follows:

$$CurrQDelay = \text{Current\_delay} - OTT_{min} \tag{3}$$

Where Current_delay is the one-way delay incurred by data packets and OTT_{min} is the minimum one-way delay. The current queuing delay CurrQDelay is calculated for each received data packet once the minimum OTT and current_delay are updated, as shown in Algorithm 1. Once AvgQDelay is calculated, ADCD situates it in one of the network states.

Algorithm 1 AvgQDelay Estimation Algorithm

```
Function ONDATA(DataPacket)
    Current_delay ← CurrentTime
    $OTT_{min}$ ← min ($OTT_{min}$, Current_delay)
    $OTT_{max}$ ← max ($OTT_{max}$, Current_delay)
    $OTT_{mid}$ ← ($OTT_{min}$ + $OTT_{max}$) /2
    CurrQDelay ← Current_delay - $OTT_{min}$
    AvgQDelay ← 0.875 *AvgQDelay + 0.125 * CurrQDelay
end function
```

ADCD considers three network congestion states; no-congested state, less-congested state and heavily congested state. ADCD determines these three states based on the changes in the received OTTs and adjusts the congestion window size cwnd according to the degree of congestion in the network. The role is as follows:

$AvgQDelay \le OTT_{mid}$ no-congested state

$OTT_{mid} < AvgQDelay < OTT_{max}$ less-congested state

$AvgQDelay \le OTT_{max}$ heavily congested state

If $AvgQDelay \le OTT_{mid}$, ADCD considers the network non-congested. In this status, ADCD has a low queuing delay, a sign of bandwidth availability. In this case, the ADCD consumer increases its congestion window according to the network phase (Slow Start or Congestion Avoidance) to utilize the available bandwidth.

If $OTT_{mid} < AvgQDelay < OTT_{max}$, ADCD considers the network low congested. As the risk of packet loss is low, the congestion window is decreased by the factor $\beta_{1.}$

If $AvgQDelay > OTT_{max}$, ADCD considers the network heavily congested and decreases its congestion window by the factor β2.

Where, OTT_{max} is the maximum one-way delay and OTT_{mid} is the mid-point between OTT_{max} and OTT_{min}. The values of OTT_{max}, OTT_{min} and OTT_{mid} are updated whenever a data packet is received by the consumer according to the following formulas:

$$OTT_{min} = \min(\text{Current\_delay}, OTT_{min}) \tag{4}$$

$$OTT_{max} = \max(\text{Current\_delay}, OTT_{max}) \tag{5}$$

$$OTT_{mid} == (OTT_{min} + OTT_{max})/2 \tag{6}$$

C. Adjustment of the Congestion Window

When the consumer calculates AvgQDelay and locates the status of the network, it proceeds to the adjustment of the congestion window size. ADCD controls the congestion window size in two phases Slow Start and Congestion Avoidance. ADCD adopts the Additive Increase mechanism in Slow Start phase and increases its congestion window by one while cwnd <= ssthresh, where ssthresh is a predefined threshold. In the congestion avoidance phase, which corresponds to cwnd > ssthresh, ADCD adopts the Window-correlated Weighting Function WWF of [20] and increases its congestion window by $\frac{WWF}{cwnd}$. The objective of using this function is to improve bandwidth utilization. Its formula is as follows:

$$WWF = \sqrt{\frac{\text{RTTmax}}{\text{RTT current}} * \text{cwnd}} \qquad (7)$$

where $\text{RTT}_{\text{current}}$ is the current RTT, RTT_{max} is the maximum RTT and cwnd is the last congestion window size.

ADCD starts the communication with the Slow Start phase and increases its congestion window by one by sending an interest packet to the network. Once the corresponding data packet is received, the consumer extracts the sending time and calculates AvgQDelay according to equation 2. If AvgQDelay is less than or equal to OTT_{mid}, the network is considered not congested. In this case, the consumer continues to increase the congestion window exponentially to use the available bandwidth fully. Otherwise, the network is considered less congested if AvgQDelay is between OTTmid and OTTmax. In this case, the consumer decreases its congestion window by the factor β_1= 0.8. Otherwise, if AvgQDelay exceeds OTT_{max}, the network is considered heavily congested, and the consumer decreases its congestion window by the factor β_2 = 0.5 and enters into the congestion avoidance phase to slowly increase its congestion window. In this phase, the congestion window increases by using the WFF function. If the consumer receives a NACK packet or TimeOut, The congestion window is divided by two using a multiplicative decrease. Algorithm 2 summarizes the congestion window adjustment steps at the consumer node.

Algorithm 2 CWND Adjustment Algorithm

```
On data reception do
    if slow start then
        cwnd ← cwnd + 1
    else
        cwnd ← cwnd + $\frac{WWF}{cwnd}$
    end if
    if NACK or TimeOut received then
        cwnd ← cwnd / 2
    end if
```

IV. Results and Discussion

In this section, we present the experiment's parameters and then evaluate the performance of the proposed mechanism ADCD in different scenarios using ndnSIM [24], an NS3-based simulator that has been proposed for NDN networks. We compare the performance of ADCD to that of ICP [17] in terms of throughput, delay, and packet loss rate.

A. Simulation Parameters

The first scenario is shown in Fig. 2. It represents the ideal case of a non-congested network for evaluating the performance of ADCD to demonstrate the high bandwidth utilization that can be achieved under the optimal conditions. It contains a consumer, a router, and a content producer. The bandwidth of the consumer-router path is 60 Mbps with a delay of 10ms, and the bandwidth of the router-producer path is 100 Mbps with a delay of 10ms. The second scenario is illustrated in Fig. 3. This scenario contains three consumers who request the same content, two routers, and two content producers. The three consumers have an equal bandwidth of 50Mbps with different delays, 10ms for consumer1, 5ms for consumer2, and 10ms for consumer3. The size of the transmitted data packet is 1024 bytes, and the simulation time was in the 30s.

B. Throughput

Throughput refers to the total number of packets successfully transmitted between the source and the destination every second. Fig. 4 compares the throughput between ADCD and ICP in the first scenario, while Fig. 5 compares ADCD and ICP in the second scenario. In both figures, time in seconds is defined on the x-axis, and throughput in Mbps is defined on the y-axis.

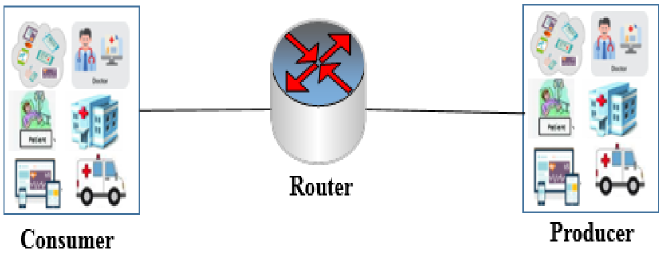

Fig. 2. Topology of the 1st Scenario.

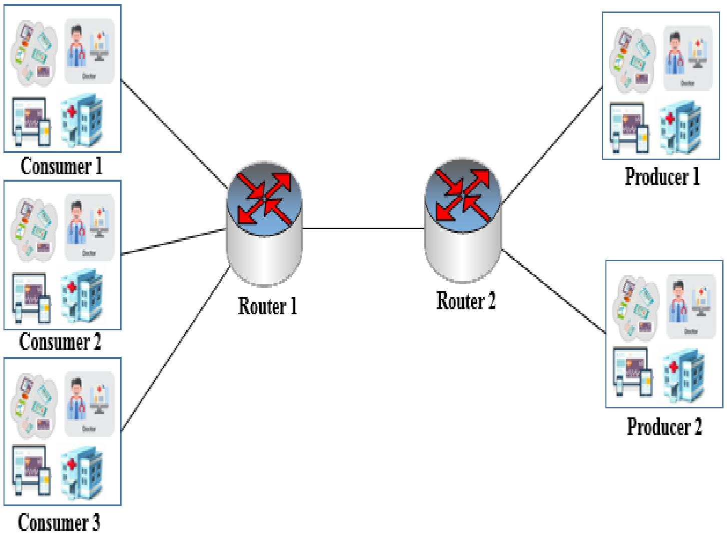

Fig. 3. Topology of 2nd Scenario.

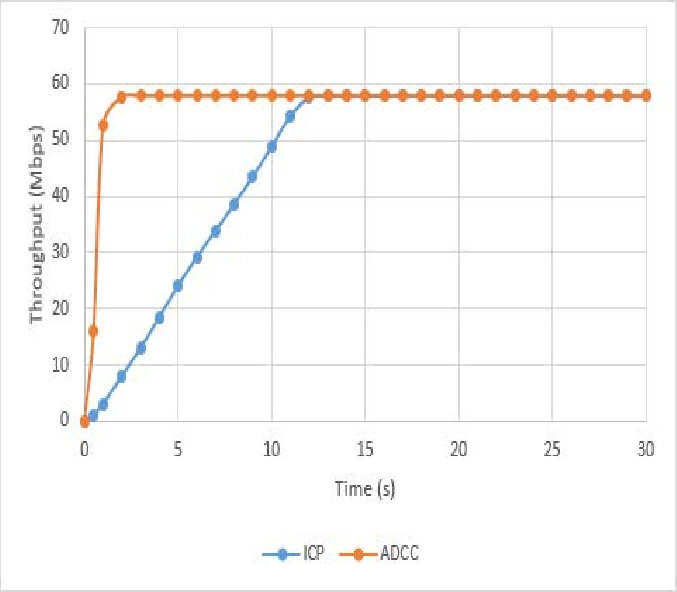

Fig. 4. Throughput of the 1st Scenario.

Fig. 4 shows the ability of the proposed mechanism to use the available bandwidth fully in the case of a non-congested network. This figure clearly shows that ADCD outperforms ICP in terms of throughput. The ADCD consumer could use an average throughput of 56.33 Mbps of the link capacity, while ICP used 45.63 Mbps. The increase in throughput with ADCD compared to ICP is due to the algorithm used by ADCD for congestion window adjustment, which rapidly increases its congestion window in the slow start phase, and then in the congestion avoidance phase, uses a window correlated weighting function (WWF) which aims to increase the use of the available bandwidth. However, ICP uses the AIMD algorithm to increase its congestion window, which rapidly increases the congestion window in the slow start phase, but in the congestion avoidance phase, it increases the congestion window by 1/cwnd, which increases the window slowly and consequently, a lower throughput than ADCD.

Similarly, in Fig. 5, which represents the throughput of the second scenario, we observe that the ADCD mechanism achieves better throughput than ICP. This is explained by the fact that ADCD divides the network into three states; no-congested state, less congested state, and heavily congested state. When it sees an increase in average queuing delay, it situates this value in one of the three states and reacts quickly by adjusting the size of the congestion window by β_1 or β_2. However, in ICP when a timeout is detected, it divides the congestion window by two, dividing the amount of data to be transmitted in the network by two, consequently decreasing the throughput.

These results demonstrate the capability of ADCD to manage the NDN network by transferring packets over the network bandwidth without causing network congestion or queue overflow. In the case of a congested network, ADCD responds quickly to the congestion problem while maintaining an optimal throughput.

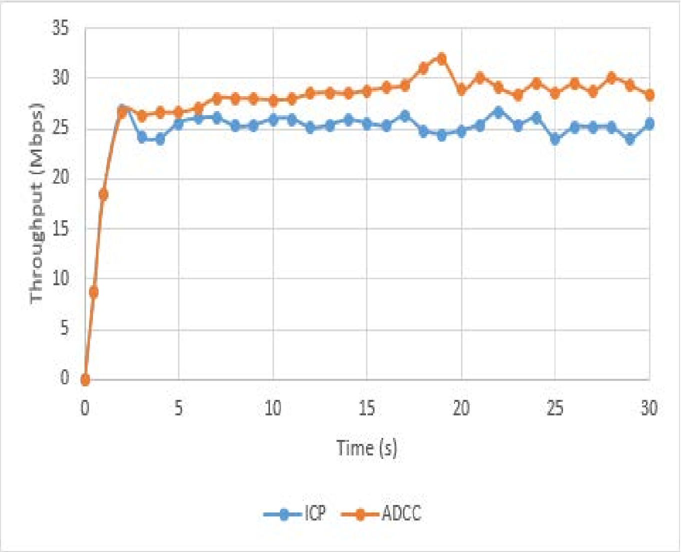

Fig. 5. Throughput of 2nd Scenario.

C. Delay Measurement

Delay is an essential factor for healthcare applications. It is the time taken for a packet to reach its destination from the source. Fig. 6 presents the delay measurements of the first scenario, Fig. 7 presents the delay measurements of the second scenario, and the average delay of scenarios 1 and 2 is presented in Table I.

In Fig. 6, we observe that ICP has a lower delay than ADCD, the consumer ICP has an average delay of 0.054s while the consumer ADCD has an average delay of 0.072s. In Fig. 7, we observe that ADCD has a lower delay than ICP. The consumer ADCD has an average delay of 0.26s while ICP is 0.42s. This is explained because ICP slowly increases its congestion window to transmit packets with lower throughput, fewer packets circulate in the network, and a lower transmission delay. However, the method used by ADCD to adjust the congestion window aims to increase the use of available bandwidth, thus allowing medical data to be transmitted with higher throughput and a reasonable transmission delay.

In the second scenario, the number of consumers has increased, so more requests for content are circulating in the network. ADCD handled this situation by calculating the average queuing delay for early congestion detection and reacting before overflowing the queue, consequently an optimal data transmission delay.

TABLE I. AVERAGE DELAY OF BOTH SCENARIOS

Mechanisms	**ADCD**	**ICP**
Scenario 1	0,072	0,054
Scenario 2	0,26	0,42

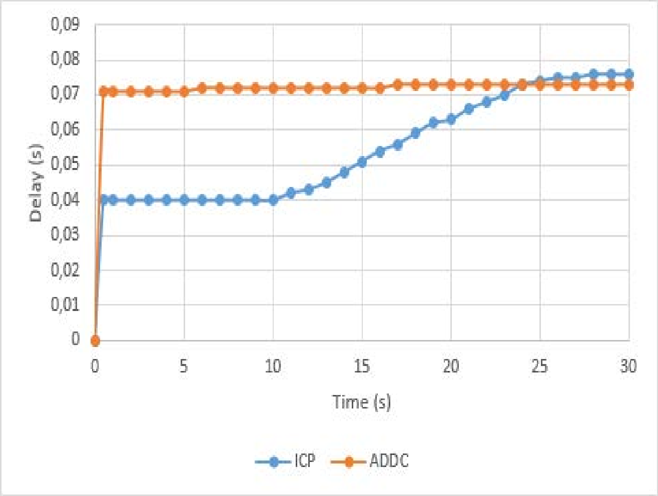

Fig. 6. Delay of the 1st Scenario.

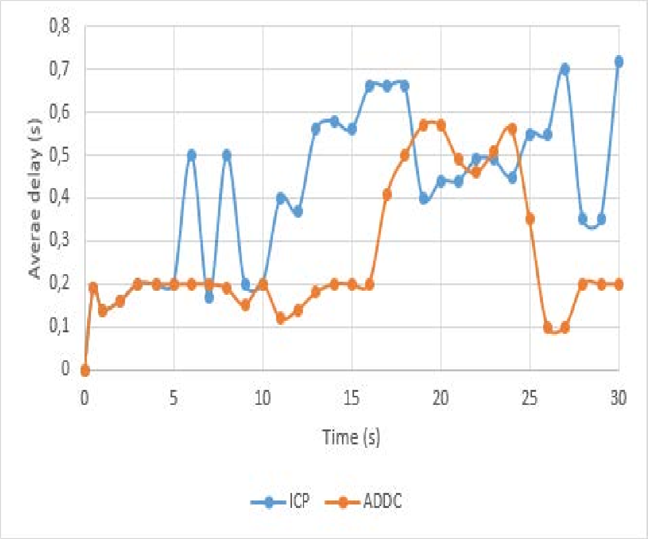

Fig. 7. Delay of 2nd Scenario.

D. Packet Loss Rate

The packet loss measurement is the difference between the number of packets transmitted and the number of packets received by the same node. It represents the number of packets abandoned per second. Congestion control mechanisms aim to reduce packet loss rate while increasing throughput and the use of available bandwidth. The simulation results of packet loss rate of the two scenarios are presented in Table II, where it is observed that the performance of ADCD and ICP are practically similar with a negligible packet loss rate.

TABLE II. PACKET LOSS RATE OF BOTH SCENARIOS

Mechanisms	ADCD	ICP
Scenario 1	0	0
Scenario 2	0,042	0,087

V. CONCLUSION

This paper proposes a new NDN-based approach, an Average delay-based early congestion Detection (ADCD), to control congestion in IoHT systems in which congestion is highly undesirable and can lead to undesirable results. In this approach, congestion is detected and controlled at consumer nodes by calculating the average queuing delay based on the one-way delay similar to that proposed in Sync-TCP, and then according to the calculated value, ADCD divides the network into three states: no-congested state, less congested state and highly congested state. The adjustment of the congestion window size is made according to the network state. The different simulations performed show the effectiveness of ADCD for early detection and control of congestion while improving network bandwidth utilization, maintaining optimal delay, and low packet loss rate.

In future work, we envisage extending the multipath analysis to independently managed paths to exploit the capability of NDN "multipath" to manage complex communication scenarios in IoHT systems.

***Abstract*—Massive volumes of multidimensional array-based spatiotemporal data are generated by climate observations and model simulations. The growth in climate data leads to new opportunities for climate studies at multiple spatial and temporal scales. Managing, analyzing and processing of big climate data is considered to be challenging because of huge data volume. In this work multidimensional climate data such as precipitation and temperature are processed and analyzed in the Spark MapReduce Platform, since Spark platform is computationally more efficient than Hadoop-MapReduce Platform of same configuration. In temporal scale monthly and seasonal analysis of climate data has been carried out to understand the regional climate. The prediction of Rainfall on monthly and seasonal time scales is very much important for planning and devising agricultural strategies and disaster management, etc. As the prediction of climate state is very challenging, in this study an attempt is being made for the prediction of the rainfall using the time series analysis in the same framework. As a test case the time series approach such as Auto Regression Integrated Moving Average (ARIMA) has been used for the prediction of rainfall. The proposed approach is evaluated and found to be accurate in the analysis and prediction of climate data and this will surely guide for the researcher for better understanding of the climate and its application to multiple sectors.**

Keywords—Spatiotemporal; big climate data; spark; ARIMA

I. Introduction

Big climate data are preferably provided to scientists for on-demand processing and for analyzing critical problems which may help them to relieve from time consuming computational tasks. Since processing of big climate data requires efficient data management approaches, scalable computing resources and complex parallel computing algorithms, so dealing with this problem is considered to be more challenging task. To address these kinds of challenges, high performance computing technologies have been applied to climate data analysis, modeling and prediction [3]. Many exhaustive big data analytics applications have evolved based on big climate data, also the emergence of various technologies such as Internet of Things (IoT), cloud computing and many advanced Big Data analytics tools have begun to investigate on climate, as well as established various intelligent analytic platforms and new technological advancements have further emphasized its importance and potential impacts on climate science and Big data science development [14][15].

Traditional Big Data techniques are usually incapable of handling large amounts of spatiotemporal data. For example, research has added spatial indexing, spatiotemporal indexing [1] and trajectory analytics features to Hadoop. One of the basic idea of using spatiotemporal data, with respect to large spatial database systems, is the emergence of moving objects [4]. A moving object is a spatial object that varies in geographical position or dimensions over a time period [6]. For Example, Rainfall in one region differs from others; also a river that switches its path over a geologic time scale may be represented as a moving line. Moving region can also be indicated by a hurricane which switches its dimension and geographic position as it evolves [16]. Thus there is a need for High Performance Computing (HPC) environment to process big spatiotemporal data.

The number of cores in HPC environment is persistently getting increased depending on the application’s requirement. Since these applications generate large volumes of spatiotemporal data, that will ultimately be stored and accessed in parallel [15]. The Scientific applications like weather prediction models use standard high-level libraries and data formats such as Network Common Data Format-4 (NetCDF- 4) and Hierarchical Data Format 5 (HDF 5), which will helps to store and operate on the dataset that is situated inside a parallel file system interface. There are various file formats and software libraries in order to reduce the restrictions imposed by plain binary files. Because of which NetCDF file format has been introduced for systematic reading and writing of various kinds of scientific data, mainly for array data. NetCDF file is composed of various kinds of data, which includes BYTE, CHAR, SHORT, LONG, FLOAT, and DOUBLE. The main intention of NetCDF file is to store rectangular arrays of data such as Interactive Data Language (IDL) arrays [12]. NetCDF files are self-descriptive; that is, every file consists of the basic information required to read.

Big spatiotemporal data have gained huge attention in recent years. Analyzing such massive amount of multidimensional data is one of the most common requirements today and processing of this data is considered to be most challenging task. The ability to assess global concerns such as climate change and natural disasters, as well as their influence on different sectors such as agriculture and disease, requires efficient data processing. This is challenging not only because of the large data volume, but also because of the intrinsic high-dimensional nature of the climate data. The emergence of Apache sparks provides quicker solution for big spatiotemporal data analysis and processing speed has reduced drastically compared to the traditional way of processing multidimensional data with multi core processors.

In the proposed work we have used Spark MapReduce Framework for processing of big spatiotemporal data at multiple spatial and temporal scales. In the proposed work we have also considered time series rainfall data, we have read rainfall data (precipitation) of past 11 years (2010-2020) and identified the Box-Jenkins time series seasonal ARIMA approach for prediction of rainfall for Bengaluru region on monthly scales. Seasonal ARIMA model(2, 0, 2) (0, 0, 0) for rainfall was identified the best model to forecast rainfall for next 5 years with confidence level of 76 percent by analysing last 11 year’s data (2010-2020).

Apache Spark is an integrated platform for cluster computing to facilitate efficient big data management and analytics [13]. It is a non-proprietary, distributed computing scheme which enhances the MapReduce framework. Spark system is made of various main modules including Spark core and various high level libraries such as Spark’s MLlib for machine learning, GraphX for graph analysis, Spark Streaming for stream processing and Spark SQL for structured data processing [17]. It functions as a consolidated tool for Machine learning, SQL, Streaming and Graph processing and it supports batch, interactive and stream processing.

Spark is considered to be one of the excellent platform for Data Scientists as it has number of data-centric tools which may assist the data scientists to move forward ahead of the problems that is pertinent in a single machine and also it assist data engineers since it has an integrated method that takes out the need to utilize various special-purpose tools for streaming, machine learning, and graph analytics [13]. More importantly Spark is very essential for researchers, as the platform fosters new opportunities and ideas to design and develop distributed algorithms and also to test their performance in various clusters [9].

The rest of this paper is organized as follows: Section 2 provides overview of various research on Hadoop based approaches to process array-based multidimensional spatiotemporal data; Section 3 presents our proposed Spark-based approach to process multidimensional spatiotemporal data and provides highlights on prediction of rainfall using ARIMA model; Section 4 describes evaluation results of our proposed work by performing sequence of experiments; finally, Section 6 gives summary of the proposed research and envisage on future enhancement.

II. Background Study

Big Data analytics has evolved with advanced opportunities for research, development, business and innovation. It has been identified by four Vs: volume, velocity, veracity and variety and may deliver value via processing of Big Data [2]. The conversion of these four Vs into the 5th (value) is one of the magnificent challenges for processing capacity. The emergence of Cloud Computing as a new standard is to provide computing as a utility service is to deal with various processing needs such as on demand services, pooled resources, elasticity, broad band access and measured services. The capability of delivering computing capacity promotes a possible solution for the conversion of Big Data's 4 Vs into the 5th (value). The continuously increasing volume of big data has accelerated technological developments and practical applications.

Earth is composed of complex dynamic system; as big data analytics works with vast amounts of climate data, it poses greater challenges in climate research than in any other field [3]. Climate change is the present concern throughout globe and also a data-intensive subject, making it one of the main research area for big data experts in recent decades [4][5]. The anomalous growth of climate data makes climate data to be a candidate in the Big Data research. The climate scientists have been exploring on historic data to understand the physics and dynamics, merge millions & billions of daily global observational records and undertake simulations of various climate-change scenarios, all of which leads to huge volumes of data [8].

Extremities in climate such as floods, droughts, and cold and heat-waves may lead to considerable impact on society, ecology and also on the economy globally [7]. Thus spatiotemporal data acquisition, analysis, management and processing are considered to be more important, which will be helpful for various sectoral applications. Spatiotemporal data refers to the data which is connected to both space and time and is considered to be at least 2-dimensional and often 3-dimensional, such that the volume of data gets increased at tremendous speed [8]. Since the general database cannot manage such large volumes of data, there is a need of large database software to play a significant role in the management of spatiotemporal data. Big data is collected from a range of sources, archived, and processed in a variety of computing modes, including cloud computing, mobile computing, edge computing, and wearable computing.

Spatiotemporal data mining is the process of identifying interesting patterns and critical information from spatiotemporal data. Discovering weather patterns, anticipating earthquakes and storms, exposing the progressive history of towns and regions, and identifying global warming trends are the examples of such processes. The unusual rise in spatiotemporal data, combined with the introduction of new technologies, has increased the demand for automatic spatiotemporal knowledge realization. Spatiotemporal data mining techniques are very much essential for many organizations which take decisions based on huge spatiotemporal datasets. As these data are multidimensional in nature, the complexities of such data and their interrelationships create computational and statistical challenges [11].

Researchers of climate science have been exposed to ample of recognized resources of Big climate data for analysis and prediction ,for instance, the NASA Global Climate Change (climate.nasa.gov), the Climate Observing System (GCOS), NASA Center for Climate Simulation (nccs.nasa.gov), Global Earth System Grid Federation (esgf.llnl.gov), the National Center for Atmospheric Research (ncar.ucar.edu), United Nations Global Pulse (unglobalpulse.org), the Climate Data Guide (climatedataguide.ucar.edu), and many other international and national climate analysis and monitoring centers over the world.

Multi-dimensional, array-based data model are mainly used to represent Climate data .The GRIB, HDF and NetCDF are the three most commonly used data formats to store climate data. HDF5/NetCDF4 was mainly developed to enable support for nested structures, ragged arrays, unsigned data types, chunking data structure, and caching techniques which ultimately helps to systematically organize climate science data and to have control over the changing computer models [10]. Meanwhile in order to flexibly use data as multi-dimensional arrays, many software and libraries such as Panoply, h5py, and NetCDF-Java were introduced.

These real time standard software and data formats have added major benefits to store, acquire, examine and exchange climate data. Also there are number of tools available for performing climate data analytics and visualization, one of such tool is Apache Open Climate Workbench, a Python-based tool to carry out interpretations on climate science employing remote sensing rainfall data taken away from various sources and also using climate model outputs.

Since the above mentioned tools and libraries deal with only discrete machines and have restrictions on cloud computing systems, compatibility with HPC and scalability. The absence of proper libraries leads to difficulty in dealing with variety, veracity, format and resolution of Big Climate Data that give rise to a challenge in the emergence of advanced computing technologies.

1) Big climate data management and analytics: In [19] authors have presented a case study supervised by Deutscher Wetterdienst (DWD) which includes storage of array based multidimensional raster data with hands-on exposure on extraction and processing of gridded meteorological data sets. As the big data acquire various challenges such as repositioning, managing and processing with high computational requirements [18]. One of the key resolutions to this is achieved through the database system having the capability of parallel processing and distributed storage. In [19] authors have conducted a study on processing of the multi-temporal satellite image data using SciDB, which is an array-based database mainly used to accumulate, manage and perform computations on such data. The main goal of the proposed work is to provide elastic solution using SciDB to accumulate and execute time series analysis on multi-temporal satellite imagery.

In [21] authors have illustrated the working of SpatialHadoop, It is regarded as one of the first capable open-source MapReduce frameworks to support spatiotemporal data. The working of ST-Hadoop have been illustrated in [20],which has given a support for spatio-temporal data and considered to be one of the first proficient open-source MapReduce framework. In [22] authors have introduced SciHadoopa, a Hadoop plugin that aids scientists in identifying logical queries in data models based on arrays. SciHadoop was used to run queries as map/reduce programs over the logical data model. Authors have shown implementation of a SciHadoop paradigm for NetCDF data and evaluate the performance of five separate optimizations that address the following goals representing an integrated aggregate function query.

2) Time series analysis for rainfall prediction: Time series analysis is a statistical technique that deals with time series data, or trend analysis. Time series data means that data is in a series of particular time periods or intervals. The data is considered to be in three types, such time series data which includes set of observations on the values that a variable takes at different times, Cross-sectional data which is the data made of one or more variables, collected at the same point in time, Pooled data which is a combination of time series data and cross-sectional data. Various research groups attempted to predict rainfall on a seasonal time scales using different techniques. Below we have discussed existing work done related to rainfall prediction using ARIMA.

Climate and rainfall are highly non-linear and complicated phenomena, which require classical, modern and detailed models to obtain accurate prediction. Authors in [23] have considered various statistical models for prediction of rainfall time series data for designing a model, models such as the statistical method based on autoregressive integrated moving average (ARIMA), the emerging fuzzy time series(FST) model and the non-parametric method(Theil’s regression) were used. To evaluate the prediction efficiency, they have used 31 years of annual rainfall data from year 1982 to 2012 of Ibadan South West, Nigeria. ARIMA (1, 2, 1) was used to derive the weights and the regression coefficients, while the theil’s regression was used to fit a linear model. The performance of the model was evaluated using Mean Squared Forecast Error (MAE), Root Mean Square Forecast Error (RMSE) and Coefficient of determination.

To forecast future climatic data, the ARIMA model was utilized. The authors in [24] have proposed ARIMA based daily weather forecasting tool which they have considered as case study for predicting weather of Varanasi. The authors have implemented the ARIMA algorithm in R to create an ARIMA-based weather forecasting tool. The Indian Meteorological Department provided 65 years of daily meteorological data (1951-2015) for this study. The accuracy of the model was calculated according to the root mean square error (RMSE) estimated for each forecasting. They approximated future values for the following fifteen years using ARIMA (2, 0, 2) for rainfall data and ARIMA (2, 1, 3) for temperature data. The root means square error values for rainfall and temperature data were 0.0948 and 0.085, respectively, indicating that the technique functioned correctly. The outcome of this can be further used for the management of solar cell station, agriculture, natural resources and tourism. The error is regarded to be minimal by observing at the values of RMSE, indicating that the ARIMA model has forecasted the data properly.

III. Research Methodology

In the proposed work we have considered Spark MapReduce framework which is considered to be one of the excellent platform for Data Scientists as it has number of data-centric tools which may assist the data scientists to move forward ahead of the problems that is pertinent in a single machine.

1) Data analysis and processing using spark map reduce: As weather data is considered to be multidimensional array based, so in the proposed work, we have considered precipitation and temperature data of Bengaluru region for rainfall prediction and also seasonal weather analysis has been carried out on other states of India. Various experimentation are carried out by reading, analyzing and processing the data. NetCDF data are procured from National Center for Environmental Prediction (NCEP) & India Meteorological Department (IMD) has been used. Following are the work carried out.

- Initially Raw station-level NetCDF based temperature and precipitation data of Bangalore district which is located between 12^o latitude and 77^o longitude has been read in the Google Colab Environment. The data considered for analysis is from Jan 2010-Dec 2020 (11 years data). Data from each year are displayed as a single plot and also 11 years data is also plotted as single graph to analyze past 11 years data and use it for processing to assist in future prediction.
- Mean value has been computed for every year (Jan-Dec) using past 11 years data and plotted as a single point in a graph for analysis.
- Mean value has been computed for all 11 years using Spark MapReduce Platform and plotted as a single graph. This step is considered to be more important as data is effectively processed using spark MapReduce platform for analysis and future weather prediction. The detailed diagram illustrating how the data is processed using spark platform can be seen in (Fig. 1). Following are the steps
  - First step is to import and execute main library files for setting up Spark MapReduce functions in google colab environment.
  - Raw station level precipitation data (pr_wtr) of banglore (from Jan 2010-Dec 2020) is read individually and data frame for each year are created.
  - New data frame is created by adding years as columns (total No. is 12) ie from 2010-2020 and values of corresponding year are placed in the appropriate place and convert the datframe to .csv file.
  - Split Data: As spark MapReduce works by splitting the data and assigning key-value pairs (key is day and value is pr_wtr). In this step, we split the data row wise, and perform read operation using spark.read.option() function. Each row refers to daily data of every year i.e. row 1 is Day 1 data from 2010 to 2020, similarly next row is day 2 data from 2010 to 2020. Same applies till last row which is day 365 from the year 2010-2020. Temporary last column is created in data frame to hold the final row-wise mean value.
  - Map phase: This step computes sum of all the values in each row and calculate 'n' value, where 'n' is No. of columns(2010-2020).we use the formula, n=lit(len(df.column)-1.0) and use the value of it in the next step.
  - Reduce Phase: Row mean is calculated using reduce function of spark ie using reduce ((add,(col(x) for x in df.column[1:]))/n).alias("11 years mean") and the same is displayed.
  - Aggregate Phase: This step Aggregates all mean values, place that in last column created in step 4.
  - Finally display the aggregated precipitation value as a single plot.

2) Seasonal analysis: In the proposed work, we have considered seasonal analysis of temperature and precipitation data of Bangalore to analyze the state of weather during various seasons such as pre-monsoon (March 1-May 31), monsoon (June 1 to September 30), post-monsoon (October 1 to December 31). Various graphs were shown to illustrate season-wise analysis of the weather of particular region such as Bangalore. Comparison of weather status of different cities is undertaken. The results of the same are discussed in Section IV.

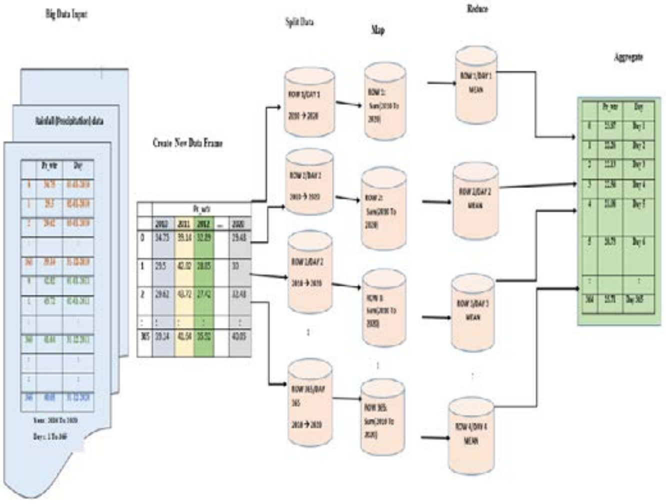

Fig. 1. Spark MapReduce Model to Compute Aggregated Climate Parameters, namely, Precipitation and Temperature.

3) Time series forecasting using ARIMA model: In this study, we have considered past 11 years data and trained them using ARIMA (autoregressive integrated moving average) model. The trained model is used for future forecasting.ARIMA is a class of models that predicts a given time series based on its own past values. An ARIMA model is one where the time series was differenced at least once to make it stationary.

The working principle behind autoregressive (AR) model is that there is a relationship between the present value and the past values. It means that the present value is equal to past values adding with some random value. Moving average (MA) model says that present value is related to the residuals of the past. AR is not capable of forecasting nonlinear data; it can be utilized for data which are linearly related. Using AR and MA together will give best results. But it can be used for stationary weather data and forecasting short term weather. So the proposed work considers ARIMA model which works good for long-term rainfall prediction. We worked on ARIMA (2,0,2) for rainfall data**.**Following steps are used for time series forecasting of rainfall using ARIMA

1) Plot the data.

2) Make the data stationary.

3) Identify the model technique best suited for rainfall forecasting. In the proposed work we have used ARIMA model.

4) Build the model.

5) Compute the mean and Root Mean Squared error (RMSE) value. Use the same for finding accuracy of model.

6) Do the future forecasting based on accuracy of ARIMA model.

Generalized equation used in ARIMA model is as as shown below (1).

$$Y_t = \alpha + \beta_1 Y_{t-1} + \beta_2 Y_{t-2} + \cdots + \beta_p Y_{t-p}\, \varepsilon_t + \phi_1 \varepsilon_{t-1} + \phi_2 \varepsilon_{t-2} + \cdots + \phi_q \varepsilon_{t-q} \qquad (1)$$

Where α is intercept term, β_1 is is the coefficient of lag1 that the model estimates, Y_{t-1} is the coefficient of lag1 that the model estimates.

IV. Results and Discussion

The proposed work is executed in Google Colab environment. Python code is used for implementation and necessary libraries were imported. Following are the results. In Fig. 2(a-c) precipitation rainfall data is read individually and plotted as separate graph. Whereas Fig. 2(d-e) shows 5 years and 11 years plot as single graph.

Next we have computed Mean value for every year (Jan-Dec) using 11 years data (2010-2020) and plotted as a single point in a graph for analysis. The same is plotted in line and bar graph as shown in the Fig. 3(a-b).

Mean value has been computed for 11 years (Jan 2010-Dec 2020) using Spark MapReduce Platform and plotted as a single graph. Fig. 4 shows how aggregated mean value is placed in new data frame and shows the final plot after applying to Spark MapReduce.

The Table I shows overview of daily dataset of perceptible water (in mm) for rainfall prediction from the years 2010 to 2020. These daily data of past 11 years has been processed using Spark MapReduce Platform which gives aggregated result as shown in Table II. The same result is used in the analysis and prediction of future rainfall.

The seasonal analysis of Bangalore weather using temperature data of 2012 has been shown below in Fig. 5. The bar plots shows pre-monsoon, monsoon and post monsoon temperature.

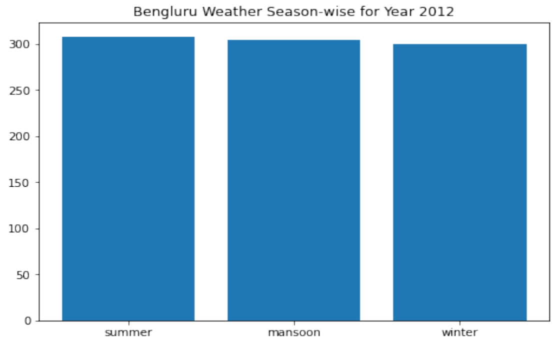

Fig. 5. Seasonal Temperature Analysis of Bangalore for the Year 2012.

The sample first five rows of precipitation dataset (pr_wtr) for the year 2010 is shown in Fig. 6. Time series forecasting is done using ARIMA model. We have worked on ARIMA (2, 0, 2) for rainfall data. Past 11 years rainfall data is trained using the model and the same is used for future prediction. Fig. 7(a-b) shows ARIMA forecasting results. Metrics used for evaluation are Mean error (ME) and Root Mean Squared Error (RMSE). Average error is calculated as shown below in equation (2).

$$\text{Average error} = \text{ME}/\text{RMSE} * 100 \qquad (2)$$

The accuracy for rainfall data considered in our work using ARIMA (2, 0, 2) model is found to be 76.8.

V. Conclusion

Vast amounts of climate data are being generated rapidly by satellite observations and numerical climate models. Agriculture, tourism, water, electricity, wildfire management, and other sectors are all require climate data. The utility of climatic data depends on timely analysis. Existing technologies, such as Apache Hadoop, which are based on the idea of breaking problems down into smaller chunks and solving them on a cluster of commodity servers, have emerged as a possible solution for analysing huge climate datasets. Apache Spark has recently emerged as a viable alternative to Hadoop's disk-based architecture. The proposed work considers analysis and processing of big spatiotemporal data using Spark MapReduce platform. Multidimensional NetCDF based precipitation and temperature data from NCEP and CSIR-4PI are considered for analysis. Analysis shows that Spark platform is computationally more efficient (double the No. of times) than Hadoop - MapReduce Platform of same configuration. Monthly and seasonal analysis of climate data has been carried out. Time Series prediction approach such as ARIMA (2,0,2) model was used for forecasting future rainfall of Bangalore region, results shows that ARIMA performs well for long term weather prediction. Performance analysis of the model has been carried out using NetCDF data of NCEP and CSIR-4PI Bangalore.

***Abstract*—The Widespread use of the Internet of Things (IoT) has influenced many domains including smart cities, cameras, wearables, smart industrial equipment, and other aspects of our daily lives. On the other hand, the IoT environment deals with a massive volume of data that needs to be kept secure from tampering or theft. Detection of security attacks against IoT context requires intelligent techniques rather than relying on signature matching. Machine learning (ML) and Deep Learning (DL) approaches are efficient to detect these attacks and predicting intrusion behavior based on unknown patterns. This study proposes the application of five deep and ML techniques for identifying malware in network traffic based on the IoT-23 dataset. Random Forest, Catboost, XGBoost, Convolutional Neural Network, and Long Short-Term Memory (LSTM) models are among the classifiers utilized. These algorithms have been selected to provide lightweight security systems to be deployed in the IoT devices rather than a centralized approach. The dataset was preprocessed to remove unnecessary or missing data, and then the most significant features were extracted using a feature engineering technique. The highest overall accuracy achieved was 96% by applying all classifiers except LSTM which recorded a lower accuracy.**

Keywords*—*Internet of Things (IoT); malware deletion; random forest; Catboost; convolutional neural network; long short-term memory (LSTM); XGBoost

I. Introduction

The Internet of Things (IoT) refers to the billions of connected physical devices through the Internet, for global storage and data exchange [1]. Recently, the IoT has been involved in a variety of fields in our daily life, including smart cities, cameras, wearables, smart industrial equipment, household appliances, medical devices, and even nuclear reactors [2]. The infrastructure of the IoT devices has limited storage, hardware, and battery life, making the sophisticated or standard security algorithms difficult to be applied in such a domain with limited resources it has. Furthermore, the IoT environment deals with a large amount of data, making it subject to botnets, firmware hijacking, distributed denial of service attacks, eavesdropping, the man in the middle, and other attacks. The network security of IoT devices is considered more critical compared to network security due to the large number of attacks, its small size, and multiple vulnerabilities of IoT tools [3]. By 2025, it is expected that 41,600 million IoT devices will have been shipped around the world. According to the 2022 SonicWall Cyber Threat Report [4], malware decreased somewhat in 2021, indicating a third consecutive year of decline and a seven-year low. An increase in attacks during the second half of 2021 nearly wiped out the 22 percent decline in malware that researchers observed at the midpoint of the year, reducing the total decrease for 2021 to just 4 percent, where 2022 Global Cyberattack was registered approximately 60,1 million IoT Malware attacks, whose volume increased by 6 percent in 2021. This growth indicates a plateau compared to the previous two years, during which these attacks increased by 218 percent and 66 percent, respectively.

The research question behind this work is “Is it possible to enhance the accuracy of malware and benign detection in the IoT environment based on deep and ML techniques using a standard dataset that holds network traffic information? And what is the potential of deploying these techniques in end-systems?” Hence, to solve this question, five different deep and machine learning approaches are suggested to be applied to the IoT-23 dataset. The IoT-23 dataset has 14 labels for 20 malicious and 3 benign captures and many features; therefore, to reduce the computational cost of using the IoT-23 dataset, only the malware captures were explored, and only ten labels were analyzed.

The main purpose of this study is to analyze traffic traces and network behavior of IoT devices by using the 23-IoT dataset, which consists of attributes from network traffic based on different protocols to identify malware. After that, using preprocessing stage and feature engineering to extract the most significant features and thereby reduce the dataset's dimensionality. Then applies classification techniques that include Random Forest, Catboost, CNN, LSTM, and XGBoost algorithms, to detect malware and benign traffic, which helps in developing a robust intrusion system capable of detecting different types of attacks. Finally, to accomplish the evaluation and better prediction, the classifier models are subjected to cross-validation, optimization, and comparison.

The following is the structure of this research study: Section 2 depicts the related works by applying deep and machine learning techniques to detect malware activities based on the IoT-23 dataset. Section 3 outlines the suggested methodology in this research, while Section 4 discusses the various machine learning and deep learning models implemented. Moreover, Section 5 discusses the results of each model. Finally, the conclusion and future work.

II. Related Work

The evolution of the sophisticated IoT environment has necessitated the development of malware and benign system detection based on the recent deep and ML techniques, as detailed in the previous section. Many researchers have used various deep and ML models to achieve network traffic analysis to address this issue. For example, in [5], the authors implemented deep and ML algorithms, namely, RF, Naive Bayes (NB), Multi-Layer Perceptron (MLP), Support Vector Machine (SVM), and AdaBoost (ADA). The dataset used in this work was the IoT-23 dataset and the best accuracy of detection was achieved by using the RF model with a value of 99.5%.

In [6], the researchers applied four algorithms to the IoT-32 dataset, including CNN, Decision Trees, Naive Bayes, and SVM. All IoT-23 dataset's labels were analyzed in this work the highest accuracy achieved was 73% by using the decision tree model, CNN achieved 69.35%, and SVM attained 69% of accuracy. Based on the same dataset, another author was analyzing all labels of the dataset by using Decision Trees, RF, Naive Bayes, SVM, AdaBoost, XGBoost, CNN, and Multi-Layer Perceptron models [7]. The highest accuracy achieved was 74% by-using Decision Trees, RF, and MLP models.

On the other hand, the authors in [8] achieved a better detection rate near 100% of the f1-score metric; however, only four malware types (Hide and Seek, Torii, Mirai, and Trojan) were involved and Okiru malware was not analyzed. Support Vector Machine (SVM), Extreme Gradient Boosting (XGBoost), Light Gradient Boosting Machine (LightGBM), Isolation Forest (iForest), Local Outlier Factor (LOF), and Deep Reinforcement Learning (DRL) classifiers were used to do binary classification and multiclassification.

On another trend, a DL ensemble for network malware detection was proposed based on IoT-23, LITNET-2020, and NetML-2020 datasets [9]. Deep Neural Network (DNN) and Long Short-Term Memory (LSTM), and a meta-classifier (i.e., logistic regression) were applied. The method employed a two-step process for the detection of network anomalies to improve the capabilities of the suggested methodology. For the feature engineering challenge in the first stage, data pre-processing, a Deep Sparse AutoEncoder (DSAE) was used. For classification in the second phase, a stacking ensemble learning strategy was applied. The proposed method was evaluated on IoT-23, LITNET-2020, and NetML-2020 datasets, and only Benign, Mirai, Attack, PartOfAHorizontalPortScan, and C&C malware types are classified in this work. The classification type that was applied by the authors is binary classification to recognize normal from abnormal attacks and the accuracy achieved is around 100%.

In [3], the authors have built and performed IoT anomaly detection systems based on actual IoT-23 large data for identifying attacks based on artificial NN like Convolutional NN (CNN), Recurrent Neural Networks (RNN), and Multilayer Perceptron (MLP). As a consequence, Convolutional Neural Networks outperform Multilayer Perceptron and Recurrent Neural Networks in IoT anomaly detection, with a metric accuracy score of 0.998234 and a minimal loss function of 0.008842. The Mirai, DoS, NScan, Normal, and MITM_ARP attacks are classified in this work.

An anomaly-based intrusion detection model to detect malware in IoT network traffic was created and implemented on IoT-23, IoT Network Intrusion, BoT-IoT, and MQTT-IoT-IDS2020 datasets [10]. A multiclass classification model was created using CNN (Convolutional Neural Network) models and then uses to accomplish binary and multiclass classification via the transfer learning principle. Three model architectures were suggested by the authors, namely, 1D, 2D, and 3D CNN models. The utilized multiclass classifier not only can classify 15 different types of attacks but also efficiently differentiate them from normal network data [11]. The authors included seven attacks and one normal from the IoT-32 dataset: Normal, Attack, C&C, FileDownload, HeartBeat, Okiru, Port Scan, and Torii attacks. The proposed models achieved high values in the used performance metrics, where all models reached more than 99.89% for accuracy, precision, recall, and f1-score metrics.

The authors in [12] used Bidirectional Generative Adversarial Networks (BiGAN) and Adversarial Autoencoders (AAE) to detect malware in network traffic based on the full IoT-23 dataset version. The proposed models outperformed traditional ML such as RF, by getting an f1-score of 99. However, not all labels were analyzed in this work, only nine malware types were classified. Sahu, Amiya Kumar, et al. [13] proposed a DL-based classifier for detecting IoT attacks. The CNN model is used to learn the IoT features, and then an LSTM-based classifier is used to classify them. The model was applied to eight labels on the IoT-23 dataset, which included Command and Control (C&C), Distributed Denial of Server (DDoS), File Download, Heart Beat, Part of A Horizontal Port Scan, Mirai, Torii, and Okiru. A 96% accuracy rate in detecting malicious devices was achieved but the Benign label was ignored. Dartel, Bram. The author in [14] suggested a ML technique comprising Decision Tree, RF, Support Vector, and an ESP32. The sub-labels of the IoT-23 dataset are judged irrelevant because their methodology is focused on malware detection rather than malware classification. The result was running on an IoT device that really works as an IoT device, so it was easy to run the device next to the malware detection algorithm.

Using a similar size dataset, they divided it into two separate datasets. In addition, the data were randomly dispersed throughout them in order to limit the number of multiclass labels, hence the metrics showed a significant disparity in class size. Following this, they used the following ML techniques: RF, Naive Bayes, Support Vector Machine, and Decision Tree. 99.5 percent of the accuracy of the RF algorithm produced the best results [15]. They suggested using ML techniques like Support Vector Machine, Decision Tree, and RF to classify malware attacks like DDoS attacks, and also, a Principal.

Component Analysis (PCA) was used to reduce the number of dimensions. The results of PCA were measured against what would have happened if PCA hadn't been used. When PCA was used, the algorithm ran much faster with fewer features than it did when PCA wasn't used. When it comes to classifying attacks, Decision Tree and RF are better than SVM [16].

Authors in [17] proposed a method for Malware Detection in Fog Layer. This method has three important phases for pre-processing: feature extraction, feature selection to reduce the number of features, and classification. Convert the binary files to hexadecimal using HexDump, segmentation into 4-gram, features selection and reduction using Gain Ratio; decision tree and Component Analysis (PCA). Finally, apply decision tree classifier. The accuracy was Acc. 96.7. The authors [18] have presented a new method based on ML for detecting Mirai malware "NBaIoT" dataset, which data consist of features infected by the Mirai Malware, is used in that study. The Cross-Validation technique has been used for data splitting to overcome overfitting, and the experiment was conducted using ANN. The achieved accuracy is 92.8%. The Opcode dataset has been used in this research; it consists of 70,140 normal and 69,860 malicious malware. The IoT Device dataset's benign or malignant input is classified using a deep neural network (DNN). The obtained accuracy reached 99.7 % [19]. Table I summarize the related works and provide a comparison between different approaches.

III. METHODOLOGY

Generally, the research methodology has been designed for detecting about 10 IoT malware types which will be explained in detail in this section. To detect IoT malware attacks, five ML and DL algorithms are implemented based on the IoT-23 dataset, namely, RF, Catboost, Convolutional Neural Network, Long Short-Term Memory (LSTM), and XGBoost. The proposed methodology has five stages to be accomplished to evaluate the algorithms: data collection, pre-processing, feature selection, training and testing, and classification stages as shown in Fig. 1.

A. Data Collection

To use machine learning techniques, a dataset with a large number of samples that have been contextualized and labeled correctly is necessary. This section gives a quick overview of the chosen dataset in this work. The IoT-23 dataset is chosen since it provides a large dataset with twenty-three captures of various IoT network traffic that include three benign and twenty malware traffic captures [20]. It is a modern dataset that consists of more than one million network traffic of IoT devices and was first published by the Stratosphere Laboratory in January 2020, with captures spanning the years 2018 to 2019. The main goal of creating this dataset is to create a large dataset under real circumstances for researchers that h valid malware and benign traffic labels in order to apply machine learning algorithms to enhance intrusion detection in IoT environments.

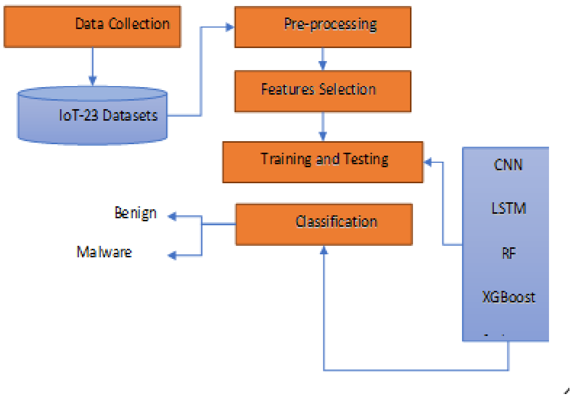

Fig. 1. The Proposed Methodology in this Work.

This dataset has 14 labels for 20 malicious and 3 benign captures that include Part-Of-A-Horizontal-PortScan, DDoS, Attack, FileDownload, Okiru, Benign, C&C-HeartBeat-FileDownload, C&C, C&C-FileDownload, C&C-HeartBeat, C&C-Mirai, C&C-FileDownload, Okiru-Attack, and C&C-Torii. Despite this, the dataset contains 21 feature properties that determine the feature of the connections, one of which is the class label, as shown in Table II. Some of the features are nominal, and some features have time-stamp values, while others are quantitative. In this work, only the malware captures were investigated to reduce the computational cost of using the full version of the IoT-23 dataset, as well as only ten labels were analyzed: Part-Of-A-Horizontal-PortScan (753565 rows), DDoS (138777), C&C-Mirai (1), C&C-HeartBeat (341), C&C (15100), Attack (3915), Benign (195270), FileDownload (13), C&C-FileDownload (43), C&C-Torii (30), and C&C-HeartBeat-FileDownload (8) labels.

TABLE II. THE DESCRIPTION OF THE IMPORTANT FEATURES OF IOT-23 DATASET [9]

Feature No.	Feature Name	Data Type	Feature Description
1	Ts	int	Timestamp of the capture.
2	Uid	str	The capture's Unique ID.
3	id.orig_h	str	Originating IP where the attack happened.
4	id.orig_p	int	Source port used by the responder.
5	id.resp_h	str	The destination IP address of the device on which the capture happened.
6	id.resp_p	int	Destination port used from the response from the device on which the capture happened
7	Proto	str	Transaction or Network protocol
8	Service	str	Application protocols such as DNS, FTP, HTTP, SMTP, SSH, etc.
9	Duration	float	The overall duration of the transmission between device and attacker
10	orig_bytes	int	The transaction bytes from source to destination.
11	resp_bytes	int	The transaction bytes from destination to source.
12	conn_state	str	Represents the current connection state
13	local_orig	bool	The connection is locally initiated.
14	local_resp	bool	The response is locally initiated.
15	missed_bytes	int	The number of missing bytes of a transaction
16	History	str	The connection state's history.
17	orig_pkts	int	The total packets being sent to a device.
18	orig_ip_bytes	int	The total bytes being sent to a device.
19	resp_pkts	int	The total packets being sent from a device.
20	resp_ip_bytes	int	The total bytes being sent from a device.
21	Label	str	Type of capture: Benign or malicious, alongside with Type of the malicious capture

B. Pre-processing Stage

Data pre-processing is the process that transforms raw data into a form that can be read, accessed, and analyzed. The pre-processing stage is of major importance, to ensure or enhance the total performance or accuracy of any system before applying the machine learning algorithms. In this work, the full IoT-23 dataset is used that has around 20GB in size. When we extract this file into the local hard disk, in windows 11, 23 folders are created; however, only 20 folders are utilized that are relevant to malware captures. To read the data from each folder, a 'read_table' function from Pandas is imported to extract all data from 'conn.log.labeled' file, this function is applied in the Jupyter platform that supports python programming language. Therefore, 20 variables are created to read all data from each folder, and then the 'concat' function from Pandas is applied to combine all these variables for creating a Dataframe that can save data to a CSV file using 'to_csv'. But before saving such data to the CSV file, we need to change the labels for some rows of the extracted data. For example, some rows have a '-Malicious PartOfAHorizontalPortSca' label, while others have '(empty) Malicious PartOfAHorizontalPortScan', so all these labels denote one attack and will be changed to the 'PartOfAHorizontalPortScan' label; therefore, we did the same step for all other labels for creating unique labels.

C. Features Selection

The process of selecting the features that have the greatest impact on the prediction outcomes is of major importance to increase the overall accuracy. Therefore, in this section, effective steps will be explained in detail. After the pre-processing stage, all data is stored in a CSV file named 'iot23_combined.csv', and this file is loaded to a Dataframe by using the 'read_csv' Panda's function. After that, the first feature is removed since it represents the number of rows in the IoT-23 datasets. On the other hand, all labels will be analyzed in this work except the 'Okiru' label, because of the computational cost of the large size of the IoT-23 dataset, as well as we found that some researchers have done malware detection by using only a few labels not all of them [8], [9].

Furthermore, in order to delete data that is not related to the 'label' column in this dataset, a correlation matrix is applied to all features, as shown in Fig. 2. The correlation matrices show the strength of correlation by using a scale from dark blue to yellow. The negative correlation is represented by dark-blue, while yellow represents the positive correlation, and green denotes to the weak correlation. From the figure, the yellow color indicates that the features are strongly correlated while the dark blue indicates that the features are weakly correlated. Furthermore, the repeated features should be removed when any exist by applying the 'get_duplicate_features' function from the 'fast_ml' library, and now the data is ready for the training and testing stage.

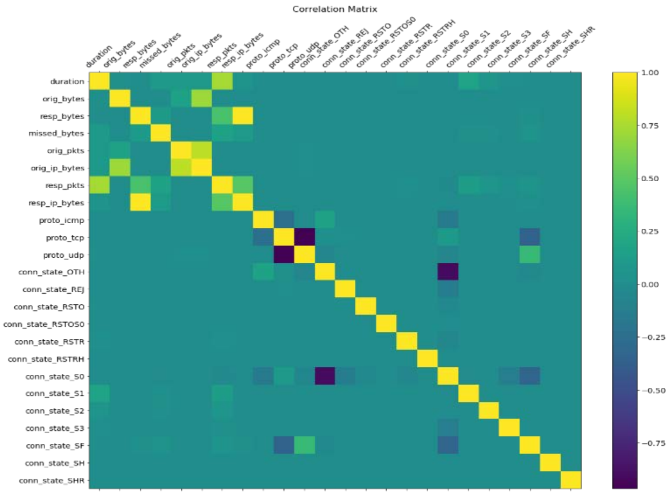

Fig. 2. The Correlation Matrix for All IoT-23 Dataset's Features.

D. Training and Testing

The process of training and testing the proposed machine learning models will be explained in this stage. This process depends on the prepared dataset in the previous stage to train and test five machine learning algorithms (CNN, LSTM, RF, XGBoost, and Catboost) until these models can distinguish the malware from the benign captures. However, there are a few steps that should be taken into consideration such as splitting the data into test and train data by applying the 'train_test_split' function from the Sklearn library, which is a function to split the matrices into random train and test subsets. Sklearn is a free python library, and being created to perform some techniques in the machine learning field such as classification, regression, and grouping. Applying the 'train_test_split' function is very important for an unbiased evaluation of all suggested machine learning models and checking the final accuracy not only in the training data but also in the test data that have not been seen or trained before in such models. In this work, the size of training data is 80%, while the test data is 20% of all the prepared data. After all these steps, all the models are ready to be trained and tested with different parameters depending on the requirements of the model being run at the time of execution.

E. Classification

Classification is a supervised learning perception that is responsible forsplittings data into separate classes, and can be applied in various classification issues such as facial detection, speech recognition, handwriting recognition, and document categorization. In this work, after the proposed models are trained on the IoT-23 dataset, and then a set of data isolated from these models are used to check the accuracy of the trained models to correctly separate all data according to their labels. Accuracy, Precision, F1-Score, and Recall are the measures used to evaluate the algorithms' efficiency, and their definitions are as follows:

- Accuracy: is the percentage of correctly labeled classes in relation to the total number of classes and is given by the next equation:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

Precision: how many of the positive class classifications made by the model are correct? and is given by the next equation:

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

- Recall or Sensitivity: how many of the positive class scenarios with expected values are correct? and is given by the following equation:

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

- F1-score: is a harmonic average that combines precision and sensitivity into one measure, and the following equation shows how to calculate this measure:

$$F1-score = \frac{2*Precision*Recall}{Precision+Recall} \tag{4}$$

Where TP (True-Positive) means the model classifies malware cases as positive (malware cases classified as malware correctly). Whereas FN (False-Negative) represents mistakenly classified malware as negative (malware classified as normal or benign but the truth is that malware has existed). Moreover, TN (True-Negative) denotes correctly current cases classified as negative or no malware that has existed in the current cases. Finally, FP (False-Positive) means mistakenly classified malware as positive (malware classified as malware but the truth is that no malware exists).

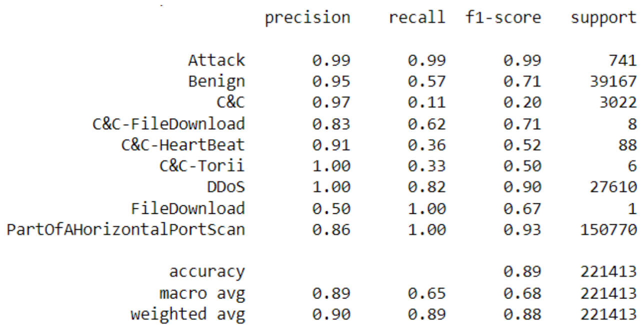
IV. Experimental Results

In this section, various experiments were carried out intending to check the accuracy of detection of the proposed models in this work. To effectively identify the IoT malware and benign captures, Random Forest (RF), CatBoost, XGBoost, LSTM, and CNN were implemented. The measure performances used in this work include confusion matrix, classification report (precision, recall, f1-score, accuracy), and ROC curves, for comparing the different performance of the proposed models.

A. Random Forest Classifier's Experiments

As mentioned in the implementation section, a random forest classifier is used because of its accuracy is higher, due to this classifier takes the final prediction based on the forecast from each tree, not from a single decision tree. The random forest achieved the highest detection accuracy for differentiating malware and benign captures with a value of 89% as portrayed in Fig. 3. Besides, in this figure, three measure metrics ((precision, recall, f1-score) are appeared for each label, while the overall accuracy is presented to show the total detection accuracy for all labels included in this work. The highest precision attained is for C&C-Torii and DDoS with a value of 100% for both of them, the highest recall was 100% for FileDownload and PartOfAHorizontalPortScan, and the highest f1-score was 99% and 93% for Attack and PartOfAHorizontalPortScan, respectively. The f1-score is more important than precision and recall because it can assist balancing the metric between positive and negative samples. Additionally, two malwares (C&C-HeartBeat-FileDownload, C&C-Mirai) have not appeared in the classification report because the small number of samples they have: 1 for C&C-

Mirai and 8 samples for C&C-HeartBeat-FileDownload. Furthermore, this the figure has micro-averaging and macro-averaging curves, where the micro-averaging is used to score each prediction equally and the macro- averaging is used to examine the overall performance of the classifier based on the most common class labels.



```
                          precision    recall  f1-score   support

                  Attack       0.99      0.99      0.99       741
                  Benign       0.95      0.57      0.71     39167
                     C&C       0.97      0.11      0.20      3022
         C&C-FileDownload      0.83      0.62      0.71         8
            C&C-HeartBeat      0.91      0.36      0.52        88
               C&C-Torii       1.00      0.33      0.50         6
                    DDoS       1.00      0.82      0.90     27610

PartOfAHorizontalPortScan      0.86      1.00      0.93    150770

                accuracy                           0.89    221413
               macro avg       0.89      0.65      0.68    221413
            weighted avg       0.90      0.89      0.88    221413
```

Fig. 3. The Classification Report of Random Forest Model.

To draw a ROC (receiver operating characteristic curve) curve for these labels, we need to encoded them to integers ranging from 0 to 8: Attack=0, Benign=1, C&C=2, C&C-FileDownload=3, C&C-HeartBeat=4, C&C-Torii=5, DDoS=6, FileDownload=7, and labels PartOfAHorizontalPortScan=8. These labels were numbers according to their appearance in the classification report in Fig. 3. The ROC curve shows the performance of the classification of the model, as shown in Fig. 4. Additionally, as we see this graph has classes that range from 0 to 8, where class 0 = Attack, class 1= Benign, and so on. The best ROC curves area values were 100% for the Attack and FileDownload.

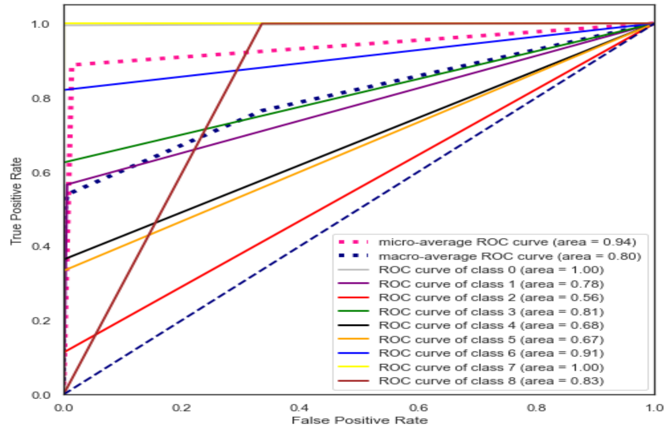

Fig. 4. The ROC Curve of Random Forest Model.

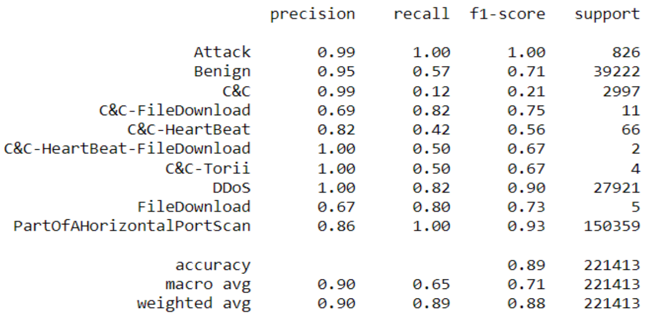
B. *XGBoost Classifier's Experiments*

The XGBoost classifier achieved the same total accuracy as the random forest with a value of 89% as shown in figure 5. The highest precision attained is for C&C-Torii, C&C-HeartBeat-FileDownload, and DDoS with a value of 100% for all of them, the highest recall was 100% for Attack and PartOfAHorizontalPortScan, and the highest f1-score was 100% and 93%, for Attack and The ROC curve of Random Forest model, PartOfAHorizontalPortScan, respectively.

We notice also that 'C&C-HeartBeat-FileDownload' is presented in this model, so the encoding process is changed starting from 0 to 9 according to the order that these labels appear in the classification report as shown in Fig. 5, Attack=0, C&C-HeartBeat-FileDownload=5, so on.



```
                            precision    recall  f1-score   support

                    Attack       0.99      1.00      1.00       826
                    Benign       0.95      0.57      0.71     39222
                       C&C       0.99      0.12      0.21      2997

                  accuracy                           0.89    221413
                 macro avg       0.90      0.65      0.71    221413
              weighted avg       0.90      0.89      0.88    221413
```

Fig. 5. The Classification Report of XGBoost Model.

The highest ROC curves area values were 100% for the Attack and 91% for both C&C-FileDownload and DDos labels as shown in Fig. 6.

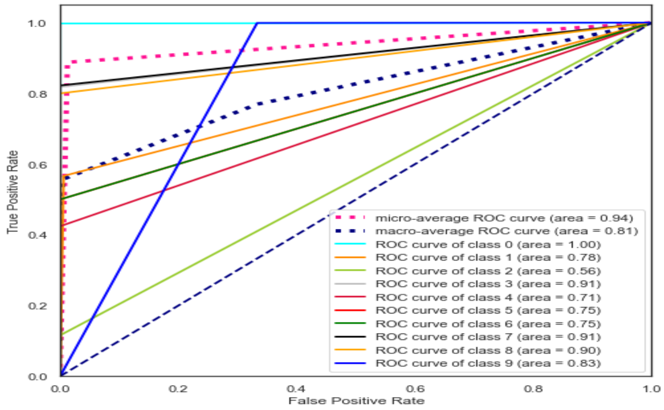

Fig. 6. The ROC Curve of XGBoost Model.

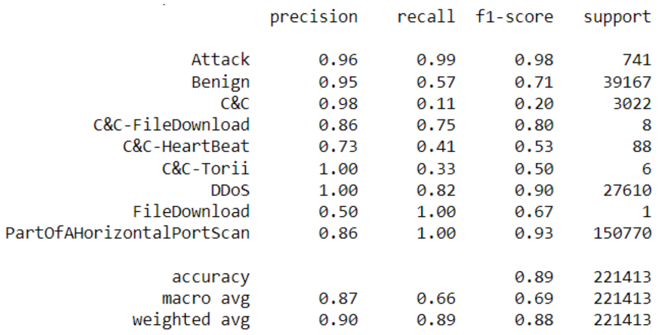
C. *CatBoost Classifier's Experiments*

CatBoost classifier reached the same overall accuracy as the Random Forest and XGBoost with a value of 89% as depicted in Fig. 7, but it takes more time than both of them. The 'C&C-HeartBeat-FileDownload' label does not appear in the classification report of this model since the very small number it has. The highest precision got is 100% for both C&C-Torii and DDoS, and also 96% for the Attack label. Furthermore, the highest recall was 100% for FileDownload and PartOfAHorizontalPortScan, 99% for the Attack, while the highest f1-score was 98%, 93%, 90%, for Attack, PartOfAHorizontalPortScan, and DDos labels, respectively.

On the other hand, the ROC curve was drawn for this model, where the highest area values were 100% for both Attack and FileDownload and 91% for the DDos label as shown in Fig. 8.



```
                           precision    recall  f1-score   support

                  Attack       0.96      0.99      0.98       741
                  Benign       0.95      0.57      0.71     39167
                     C&C       0.98      0.11      0.20      3022
         C&C-FileDownload       0.86      0.75      0.80         8
           C&C-HeartBeat       0.73      0.41      0.53        88
               C&C-Torii       1.00      0.33      0.50         6
                    DDoS       1.00      0.82      0.90     27610
            FileDownload       0.50      1.00      0.67         1
PartOfAHorizontalPortScan       0.86      1.00      0.93    150770

                accuracy                           0.89    221413
               macro avg       0.87      0.66      0.69    221413
            weighted avg       0.90      0.89      0.88    221413
```

Fig. 7. The Classification Report of CatBoost Model.

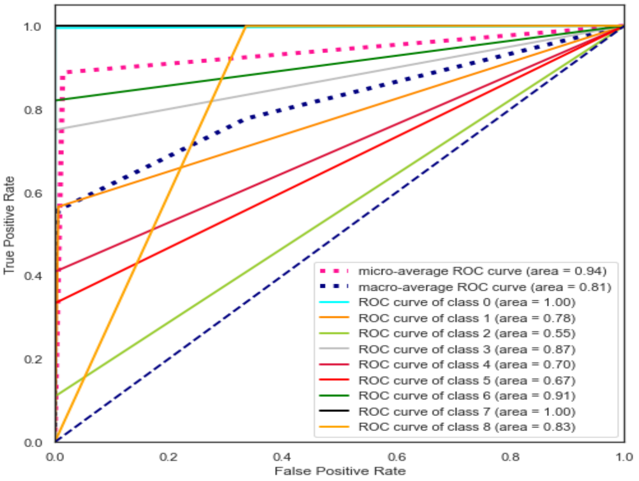


Fig. 8. The ROC Curve of CatBoost Model.

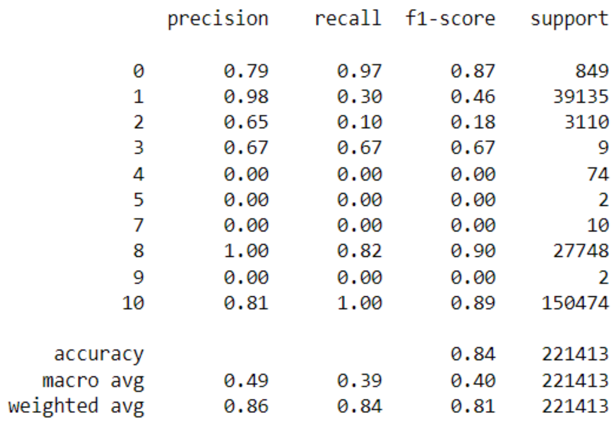
D. *CNN Classifier's Experiments*

CNN classifier is a deep learning algorithm is built based on many dense layers, as we explained in the methodology section. The proposed CNN model has ten layers and before train this model, the data is transferred into integers by applying 'MinMaxScaler' from the Sklearn library, and also the 'get_dummies' function from the Panda's library is applied to all used labels in this model, to change categorical variable into dummy/indicator variables. Unlike XGBoost, Random Forest, and CatBoost models, the classification report of the CNN model shows all used labels even if some labels have 0% for precision, recall, and f1-score metrics. However, the overall accuracy got by this model is lower than these models with a value of 84%, as shown in Fig. 9. The encoding numbers for this model is as follow: Attack=0, Benign=1, C&C=2, C&C-FileDownload=3, C&C-HeartBeat=4, C&C-HeartBeat-FileDownload=5, C&C-Mirai=6, C&C-Torii=7, DDoS=8, FileDownload=9, and PartOfAHorizontalPortScan=10. The C&C-Mirai label has not appeared in the classification report since it has only one case, while C&C-Torii, C&C-HeartBeat, C&C-HeartBeat-FileDownload, and FileDownload labels have appeared, but the measure matrices have 0%. The highest precision achieved is 100% for DDoS and 98% for Benign. Furthermore, the highest recall was 100% for PartOfAHorizontalPortScan, 97% for the Attack, while the highest f1-score was 90%, 89%, 87%, for DDos, PartOfAHorizontalPortScan, Attack labels, respectively.



```
              precision    recall  f1-score   support

           0       0.79      0.97      0.87       849
           1       0.98      0.30      0.46     39135

Fig. 9. The Classification Report of CNN Model.

On the other hand, the ROC curve was drawn for this model, where the highest area values were 100% for FileDownload, C&C-FileDownload, Attack, and C&C-HeartBeat-FileDownload classes, 93% for DDos class as shown in Fig. 10. Moreover, the micro-average ROC curve achieved the highest area value with 98% as compared to the previous models, they only attained 94%. Furthermore, the macro-average ROC curve has a 'nan' value because of including the C&C-Mirai label data, when we remove this label from being trained, this value change to 82%, which is the highest value compared to the mentioned models.

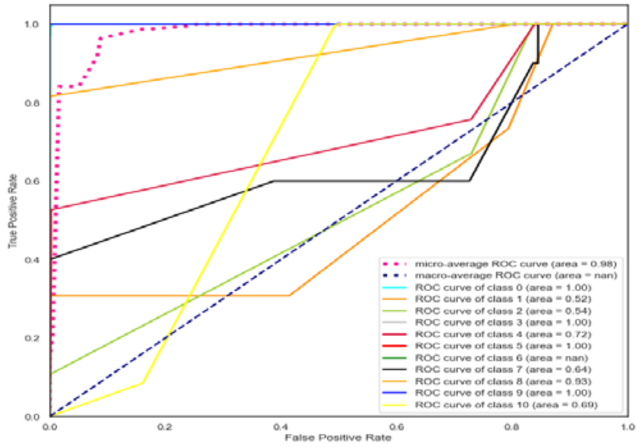

Fig. 10. The ROC Curve of CNN Model.

E. *LSTM Classifier's Experiments*

LSTM model is applied using various LSTM cells starting from 50 to 2000 cells, but the results were not good as the previous models. The highest overall accuracy is 78%; however, only DDoS and PartOfAHorizontalPortScan showed better results in the classification report of this model, while the rest had 0% for the used measure matrices, as depicted in Fig. 11. The encoding numbers for this model is exactly as in the CNN model.

On the other hand, the ROC curve was drawn for this model, where the highest area values were 99% for C&C-HeartBeat-FileDownload and C&C-FileDownload, 89% for C&C-Torii, 82% for DDoS, and 88% for PartOfAHorizontalPortScan label, as depicted in Fig. 12.

These values are the lowest among all other used models. Furthermore, the micro-average ROC curve achieved an area value of 88% and the macro-average ROC area reached 57% when we removed class number 6 from being calculated.

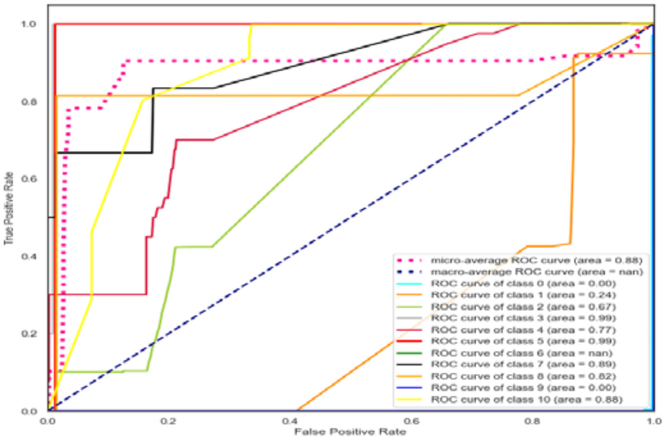

Fig. 12. The ROC Curve of LSTM Model.

However, an experiment was conducted for all the classifiers used in this paper. First, by using the CNN model, the accuracy of this model reached 96% when the Okiru and benign labels were excluded from being trained and tested, as shown in Fig. 13.

Furthermore, the RF model when Okiru and benign labels were removed and achieved the same accuracy results as CNN, as depicted in Fig. 14.

Fig. 17. The Classification Report of the LSTM Model without Okiru and benign Labels.

V. Discussion

First, only 100000 rows from the twenty-malware traffic captures were loaded, in which 11 malware labels and one benign label have existed. We have done this way to use a balanced dataset that includes all labels. However, some steps must be carried out before using the classifiers, a preprocessing step was applied to remove irrelevant or missing data from the dataset, and then a feature engineering technique was performed to extract the most significant features and thus reduce the dataset's dimensionality. Three experiments have been done to investigate the best accuracy of detection based on multi-class classifications. The first one was to include all existed labels but the best accuracy achieved is not exceeded 74%. In the second and third experiments, one or more labels are removed from being classified. According to the experiments' outcomes done in the second one, RF, Catboost, and XGBoost models achieved the highest accuracy with 89% for all malware labels except the Okiru label. The CNN results were lower than RF, Catboost, and XGBoost algorithms, with a value of 84%. The worst accuracy was attained by using LSTM with a value of 78%, and we have to improve the parameters of cells size up to 4000 but not enhance. Furthermore, to enhance the accuracy more than the ones recorded in the first and second experiments, a third one was conducted. Furthermore, when we remove the benign and Okiru labels from being trained, the accuracy of RF, Catboost, and XGBoost algorithms raised to 96%. Besides, the CNN results recorded lower accuracy than RF, Catboost, and XGBoost algorithms, for all labels except Okiru; however, when we excluded the benign label data from being trained, the overall accuracy increased to 96% based on the classification report outcomes.

When comparing our methodology outcomes, almost the same accuracy of detection has been achieved as the authors had in [6] and [7], where the best-recorded accuracy was 74% for the best model by including all labels of the IoT-23 dataset. However, the model achieved a higher accuracy of detection reached 89% for the best model by including all labels except Okiru malware.

Moreover, some studies achieved a higher accuracy more than 96% which was attained by the best models of this work. However, these studies are not analyzed all existed labels of the IoT-23 dataset. For example, the authors in [8] involved detection for four malware types, while in [9] and [10] papers only five malware types were classified, and eight and nine malware types were analyzed in [11] and [12], respectively. Finally, in ML context RF and boosting algorithms are the best candidates for the proposed security system. Based on the performance of the RF in this paper it performs the training in less time. The authors [22] recommend Catboost for better prediction in their model. They have less consumed of time cost and high performance to embed in IoT devices to detect in real-time. Table III shows the comparison our models with other work.

TABLE III. Comparison our Models with other Work

Dataset	Number of labels	Technique	Accuracy
A. K. Sahu [13]	8	CNN	96 %
Dr. R. Thamaraiselvi [15]	binary	RF, Naive Bayes, Support Vector Machine, and Decision Tree	99 %
B. Roy et al. [23]	5	LSTM and BRNN	72 %
H. HaddadPajouh et al. [24]	CC	LSTM and BNN	84 %
Amiya Kumar Sahu[25]	9 without benign	CNN and LSTM	96 %
Our models all labels	12	RF, CatBoost, Xgboost, CNN, and LSTM	74 %
Our models without okiru	11	RF, CatBoost, Xgboost, CNN, and LSTM	89 % except CNN 84% and LSTM 78%
Our models without benign	10	RF, CatBoost, Xgboost, CNN, and LSTM	96 % except LSTM 95%

VI. Conclusion

The IoT environment deals with massive data that must be protected from being modified or stolen by attackers. This research paper proposed the application of five deep and ML algorithms to detect malware in network traffic based on the IoT-23 dataset. RF, Catboost, Convolutional Neural Network, Long Short-Term Memory (LSTM), and XGBoost classifiers are implemented and evaluated. Three experiments have been conducted for each classifier, to evaluate the best performance matrices that can be recorded among all classifiers. In the first evaluation task, the best accuracy achieved is 74% by using RF, Catboost, and XGBoost models for classifying all labels of the IoT-23 dataset. While the second experiment was to detect all labels except Okiru malware, the same models achieve the highest accuracy with a value of 89%. Finally, the last one was done without Okiru and benign labels, all models except LSTM get an accuracy of 96%.

In conclusion, machine and DL models can perform detection tasks with a high degree of accuracy and reliability. Analysis of a huge amount of traffic data can be accomplished to detect various types of intrusion. The paradigm of distributed detection can provide a deep analysis functionality particularly if the device operating pattern is involved. However, the available datasets in the literature are intended for central traffic characterization.

VII. Further Work

The work applied in this paper is limited to using malware traffic captures and only reading the first 100000 rows from each capture, which leads to unbalance data, especially for C&C-Mirai (1 one row), C&C-HeartBeat (341 rows), FileDownload (13), C&C-FileDownload (43), C&C-Torii (30), and C&C-HeartBeat-FileDownload (8). Therefore, to enhance the overall accuracy, we can remove the small size malware types from being classified. Besides, extra datasets can be used such as IoT Network Intrusion, BoT-IoT, and MQTT-IoT-IDS2020, to collect more balanced data for creating a big dataset to improve the detection accuracy, especially in DL techniques. Moreover, using more advanced CNN models such as vgg16 or vgg19 can be an avenue for further evaluation. Finally, the available datasets for evaluation consider centralized methodologies; the research community demands other datasets involving end-system operating patterns which may detect novel attack.

Power Grid Resource Integration of Enterprise Middle Station based on Analytic Hierarchy Process

Shaobo Liu, Li Chen, Wenyuan Bai, Zhen Zhang, Fupeng Li*
State Grid Gansu Electric Power Company
Lanzhou Gansu730030, China

***Abstract*—With the transformation from smart grid to power Internet of Things, new power businesses such as power grid automation and power quality monitoring are constantly emerging. The load environment of power grid is changeable. In order to meet the needs of multi-service, the integrated access scheme for power grid resources in power enterprises is gradually diversified, which brings challenges to the unified management and control of power grid communication network. In this paper, SDN technology is used to improve the operation and maintenance management and control of power communication network, which aims at the integration scheme of power grid resources in power enterprises. Based on the controller cluster technology, combined with the new power business requirements, this paper designs a software-defined network centralized control architecture of the new business of power communication network. The architecture realizes the operation and maintenance management of network resources under the centralized control architecture of typical enterprise scenarios, such as power grid enterprises. The convergence speed is improved by 27%. The minimum value of iterative convergence is 31% better than that of other methods. The system requirement is reduced by 13.5%, which is helpful to improve the efficiency of node dynamic allocation and ensure the need of large-capacity data transmission of smart grid. The research in this paper can realize the two-way interaction, real-time expansion and unified deployment of power business in the future, and promote the intensive and lean development of power communication network.**

Keywords—Power grid enterprises; SDN; power grid resources; centralized control architecture; power communication network

I. Introduction

Under the environment of orderly release of new policies, such as power generation, consumption plan and incremental business of power grid, all kinds of users will actively participate in the related industries of power distribution and consumption side. At the same time, with the development of sensing, edge computing, big data processing and other technologies, the transformation from smart grid to power Internet of Things is accelerating. The information exchanges with things and things, people and things is more frequent [1]. The power grid resource business center cooperates with the customer service center. The data center and the IOT management center to jointly support the power grid business applications, such as power outage analysis, accurate fault research and judgment, and line loss analysis in the same period [2]. It can arrange enterprise-level business services to solve the problems of non-standard business services, difficult precipitation and insufficient sharing.

Resource aggregation in China and abroad has also been widely concerned and discussed by experts and scholars. The author in [3] uses the panoramic theory to integrate a variety of micro grid resources, which takes into account the complementarity of various distributed generations. micro grid aggregation not only minimizes the damage to the power grid caused by the output fluctuation of the micro grid, but also improves the security of the system and ensures the optimization of its own economic benefits. The author in [4] considers the uncertainty of EV behavior characteristics of Load Aggregator (LA), and uses this method to integrate discrete EV energy storage. The author in [5] puts forward the resource evaluation system and resource quality distinction criteria for demand response, and builds a demand response resource integration model for multiple user load groups. In [6], Virtual Power Plant (VPP) is introduced into the wind power and EV, with power balance as the constraint. Taking the highest comprehensive economic benefit of its discharge as the goal, the mathematical model of the power generation plan is constructed.

The research proposes a scheme for fast recovery of the power communication network after a fault occurs. To make the time delay of the power business meet the provisions of the standard IEC 61850, a new network calculus method is proposed. Author proposes an SDN platform, which is suitable for the large-scale intelligent meter reading system, and can balance the load of power communication network through flow monitoring, load assessment, active control and path selection. However, with the gradual expansion of the distribution communication network, there are some problems such as low efficiency of network management and control, lack of rationality of the architecture, and lack of reliability. The research proposes an algorithm, which can realize the load scheduling of the QoS. Meanwhile, in order to reduce the delay of service transmission, the algorithm adopts the scheme that the multiple SDN controllers cooperate to manage the traffic of power communication network, but there is still the problem of complex protocol conversion between different communication media. The research innovatively introduces the SDN centralized control architecture into the power wide area communication network, and proposes a new fair resource allocation algorithm for power services, which is used to ensure that high-priority services are allocated to the shortest path for transmission and maximize throughput. Considering the burden of communication network, it affects the operation and maintenance management and control of power communication network.

The main innovations of this paper are:

1) This paper proposes to use the NFV technology to complete the software of various terminal hardware functions of general hardware.

2) Improve all kinds of power distribution and consumption monitoring and control equipment, centralize the proprietary hardware into a general hardware, and use software to realize its functions.

3) Based on the analytic hierarchy process (AHP), a multi-objective decision-making algorithm is proposed to the multi-domain communication network of power business, which takes the performance of the enterprise middle station network as the judgment index.

II. Related Work

A. The Overall Structure of the Enterprise

In the environment of power Internet of Things, the information transmission between power users and power grid becomes more frequent. The demand for power consumption quality, real-time and reliability of information is higher and higher. The safe and efficient power communication network is the key link to cope with this demand. The comprehensive control function of the power communication network is the most important one [7]. This paper is based on the architecture of the resource control system of enterprise middle station as shown in Fig. 1.

The architecture covers three parts: power business data forwarding layer, SDN cluster control system and software-based power business layer. The first layer mainly includes passive optical network, wireless private network, industrial Ethernet and other hardware devices. The NFV technology is used to transform the switches and other equipment of the multi-domain accesses network. The OpenFlow general protocol is used to realize the integrated management and control of the cluster control system over the underlying equipment routing, bandwidth allocation, inter-domain switching and other functions. The underlying switch only needs to complete simple information forwarding and flow table matching tasks [8]. The southbound interface, which is responsible for the communication with the terminal, is responsible for providing a channel for information interaction with the control system. At the same time, distribution transformer videos surveillance, power consumption information acquisition and other services are connected to the data forwarding layer through the underlying hardware devices so that the control system can flexibly monitor and control them.

B. Power Communication Network SDN Operation and Maintenance Control

Realize the centralized operation, maintenance, management and control of power communication network, optimize the allocation of resources, and increase the flexibility and compatibility of the network. The idea of applying the SDN to the current power communication networks operation and maintenance management is shown in Fig. 2.

This paper uses the method of operation and maintenance management and control for reference to improve various power distribution monitoring and management and control devices. It concentrates the proprietary hardware on a general hardware, uses software to realize its function, and makes it support programmable network interface.

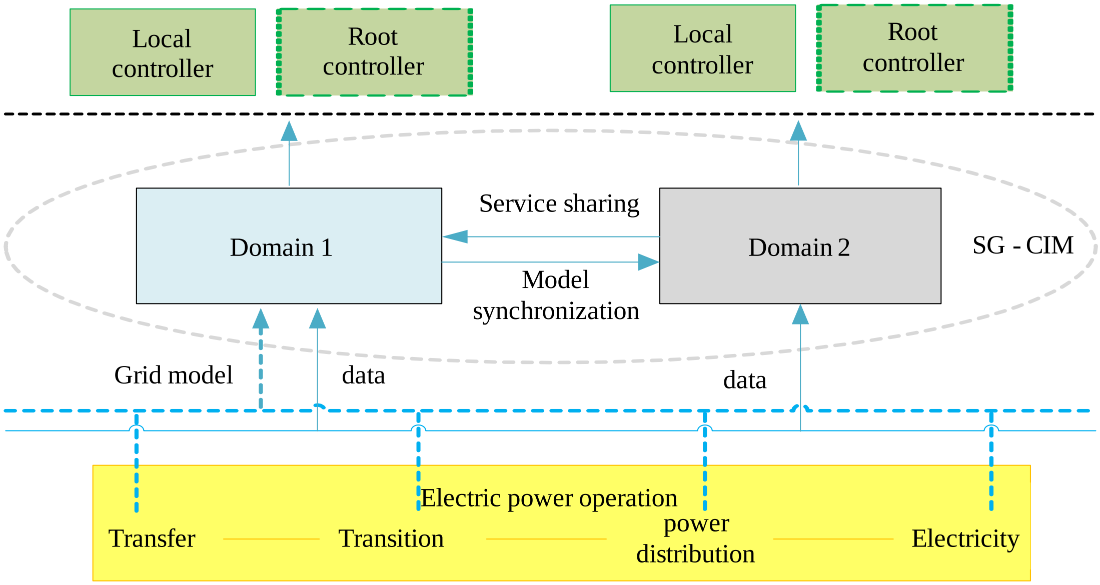

Fig. 1. Enterprise Mid-stage Control Architecture.

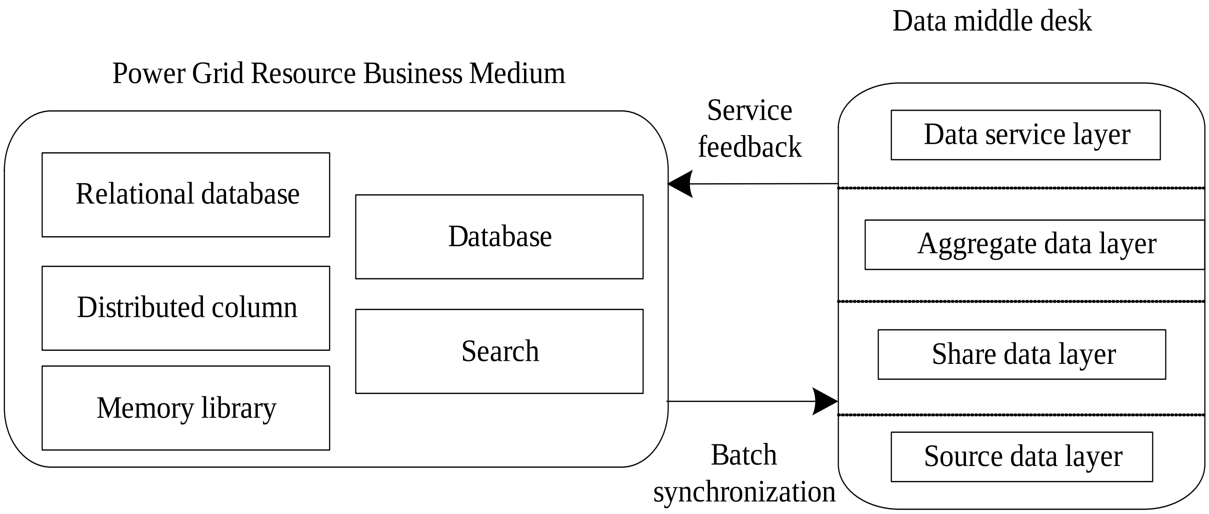

Fig. 2. Network Operation and Maintenance Control based on SDN Technology.

III. SDN High Reliability Control Scheme based on Cluster Technology

In the SDN control architecture, the controller is in the core position and is the basis of realizing the control function. How to deploy the controller and how to achieve the function is the key to realize the centralized management and control of the power communication network. This paper chooses the relatively mature and perfect controller cluster technology in the industry to complete the flexible deployment of various controllers in the architecture control layer, and realizes the operation and maintenance management and control functions of the power communication network through software [9]. The network realizes the data interaction between different functional controllers through a unique cluster communication process. The SDN control architecture based on the controller cluster is shown in Fig. 3.

The architecture is divided into three layers from top to bottom. The first layer is the cluster management layer, which mainly completes the functional task allocation of the root controller and the information synchronization between them. The root controller layer is responsible for ensuring the consistency of the overall state of the network and processing the corresponding business in time. The third layer is the local controller layer, which is responsible for handling complex and diverse local services. At the bottom are some switches, which are used to forward and process the underlying information [10].

The application of cluster technology to the control system can make the centralized control architecture reduce the risk of single point failure of control equipment under the original control mode, which increases the good scalability. It also copes with tens of thousands of switch traffic, significantly shorten the transmission delay of southbound interface protocol packets, and optimize the network transmission quality [11]. For any network G, there are three parts, namely network node devices, communication links, and topology [12]. The reliability R of the network G mainly depends on the reliability L_n of the node equipment. The reliability of the link L_1 and the topology N.’ s Functional relationship is as follows:

$$R \in \left(L_n, L_1, N\right) \tag{1}$$

Formula 1 shows that the network reliability is directly proportional to the reliability quality of the three network factors.

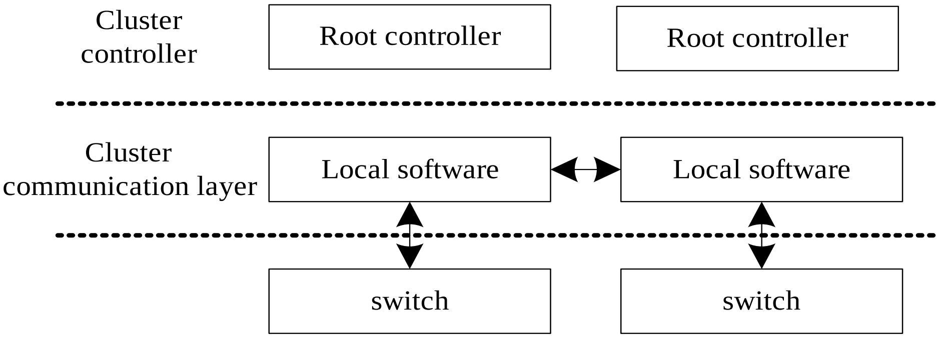

Fig. 3. SDN Control Scheme based on Cluster Technology.

IV. Interdomain Switching Algorithm based on the Analytic Hierarchy Process

When choosing the algorithm, we need to use the appropriate algorithm according to the actual needs. In the evaluation of multi-type resource characteristics of the multiple users participating in the aggregation by the analytic hierarchy process (AHP), the dimension of the clustering vector is low, so this paper analyzes the inter-domain hierarchical switching.

The analytic hierarchy process (AHP) analyzes various influencing factors of things from different perspectives. Its main steps are shown in Fig. 4.

1) Construct multi-index decision matrix: Firstly, on the basis of analyzing the target of the problem, the scheme set *X* to be selected and the index matrix *S* to make judgment are obtained.

Where $X=\{x_1,x_2,\cdots,x_m\}$ represents that there are *m* alternatives. $S=\{s_1,s_2,\cdots,s_n\}$ indicates that there are *n* evaluation indicators. Then, a multi-index evaluation matrix is constructed:

$$A=(\alpha_{ij})_{mn}=\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \cdots & \vdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \tag{2}$$

Where a_{ij} represents the result of alternative plan x_i relative to the judgment index s_i.

2) Vector normalization method

The matrix A is normalized.

$$b_n=\frac{a_n}{\sqrt{a^2 a_{ij}^2}} \ ,i=1,2,\cdots,m \tag{3}$$

Where, matrix b is the benefit matrix, matrix a is the allocation matrix, i is the set of nodes accessible to ants other than the elements in the tabu list, and a_n represents whether to allocate a frequency band to n users.

3) The characteristics of different parameters are analyzed and compared to establish the corresponding comparison matrix.

Compare each parameter of the candidate scheme. Take the relative importance of the impact factors as the standard. Conduct pairwise comparison. Finally, evaluate different levels according to Table I [13].

4) Perform pairwise comparison on the parameters of different levels, wherein the comparison result forms a judgment matrix $C=\left(c_{ij}\right)$ As shown in the formula (4), the parameter *i* in the matrix $c_{ij}>0$ is more important than the parameter *j*.

$$C=(c_{ij})_{n\times n}=\begin{bmatrix} c_{11} & \cdots & c_{1n} \\ \vdots & \cdots & \vdots \\ c_{n1} & \cdots & c_{nn} \end{bmatrix} \tag{4}$$

For the comparative decision matrix C:

$$CI=\frac{\lambda_{max}(C)-N}{RI} \tag{5}$$

Where CI represents the consistency index, RI represents the average random consistency index, and CR represents the random consistency ratio, and $\lambda_{\max}$ is the increment of the solution converted into pheromone.

$$CR=\frac{CI}{RI} \tag{6}$$

Where *n* denotes the order of the comparison matrix. $\lambda_{\max}\left(c\right)$ represents the largest eigenvalue of the comparison matrix C[14].

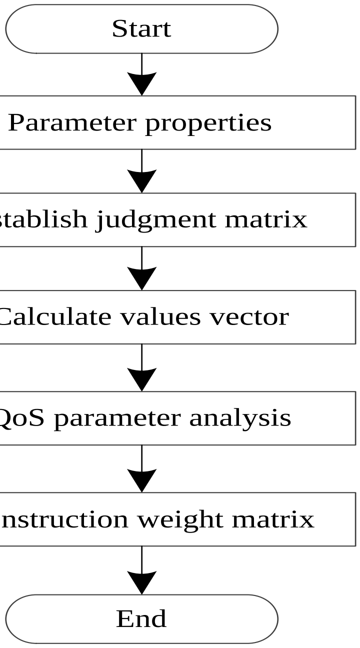

Fig. 4. Power Resource Hierarchical Analysis Process.

TABLE I. A Comparison Table of the Importance of Different Parameters

Comparison of the importance of *i* and *j*	The value of a_{ij}
Equal	1
A little important	3
Important	5
Very important	7
Very strong importance	9

When CR < 0.1, it indicates that the consistency check of the comparison matrix C constructed by AHP is qualified. When CR > 1, it indicates that the consistency check of the comparison matrix C constructed by AHP is unqualified. At this time, the judgment matrix A needs to be reconstructed until the consistency check is qualified [15].

5) The calculation judgment index is the weight of each factor: Assume that the characteristic vector corresponding to the maximum eigenvalue $\lambda_{\max}(C)$ of the comparison matrix C of the decision index is shown in Table II.

According to the comparison matrix of different candidate schemes under each index, the respective weight matrix is calculated as follows:

$$W'' = \{w_1', w_2'' \cdots w_n'\} \tag{7}$$

$$W^P = \{w_1^p, w_2^p \cdots w_n^p\} \tag{8}$$

Finally, the distribution coefficients of the different alternatives can be obtained by multiplying W^P and W'. For weight sorting, the scheme corresponding to the maximum weight is the best scheme at the total level. The decision function is expressed as:

$$f_{AHP} = \max\left(W^p \times W'\right) \tag{9}$$

The flow chart of the decision algorithm is shown in Fig. 5.

TABLE II. THE RI VALUE OF THE ORDER COMPARISON MATRIX

10	1.49

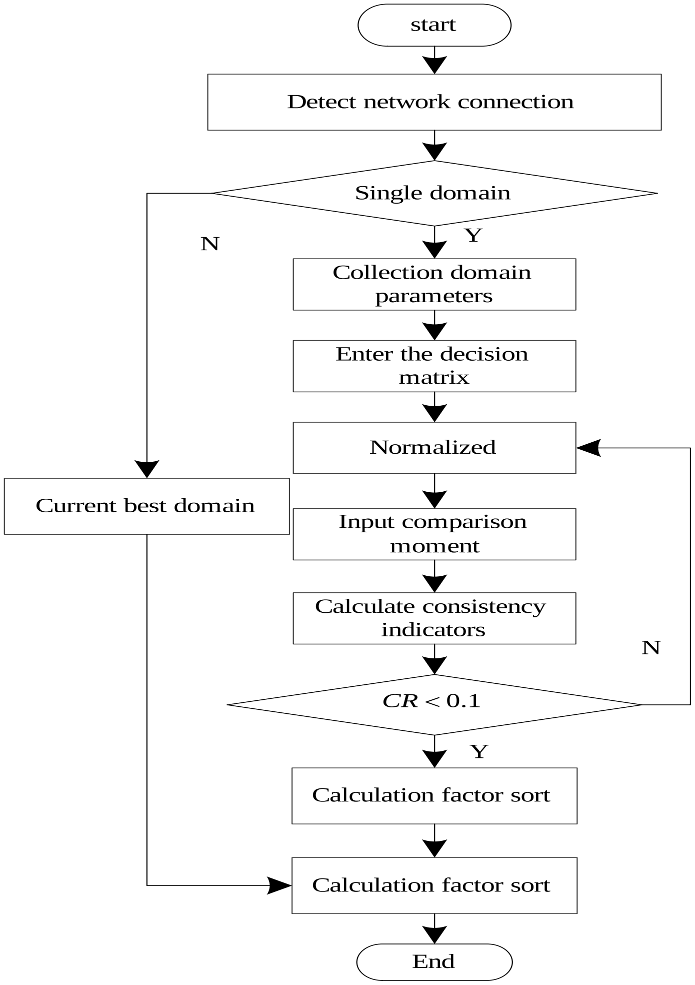

Fig. 5. AHP Algorithm Flow Chart.

V. Simulation Experiment Analysis

A. Contrast Solution

In order to verify the performance of the algorithm in this paper, the following algorithm is used as a comparison scheme.

1) RAR _ RS _ BiG: according to the algorithm idea, first perform augmentation operation on each SFC (Service Function Chain), that is, add backup VNF (Virtualised Network Function） in each SFC chain to meet the availability of the whole chain. Where: RAR is the file attribute.

2) JDBS _ s: all VNF instances in the JDBS _ s algorithm are implemented based on the single-tenancy technology.

3) GREP: The core idea of GREP to improve the availability of AHP is to provide backup for the VNF with the lowest availability in its corresponding SFC. Then, gradually provide backup for the less reliable VNF until the availability requirements of SFC are met.

B. Parameter Settings

For AHP, the number of VNFRs contained in each AHP is an integer randomly selected from the list [3, 4, 5, 6]. The CPUDRC, memory DRC and bandwidth resource requirements of each VNFR follow the uniform distribution of (10, 50) units. There are 10 kinds of VNFs in the simulation. The initial availability of each original VNF and the availability of each backup VNF are subject to the uniform distribution of (0.99, 0.999). The number of AHP to be mapped, the availability requirements of AHP, and the CPU BRC and memory BRC required to instantiate a VNF will be used as variables in different simulation scenarios

C. Simulation Results and Performance Analysis

1) Comparative analysis of processing ability: In order to reduce the impact on errors, each set of results is based on the statistical values obtained from 10 experiments. The error bar to the figure represents the 95% confidence interval. In the simulation, enough resources are set for the data center so that all AHPs can be mapped to the network. Therefore, in each set of experimental results, the final number of servers started, the amount of CPU and memory backup resources consumed and the BRC can be used as indicators to measure the performance of each algorithm. The final performance comparison between the changed AHP availability Fig. 6 shows the resource consumption comparison and the final BRC comparison of each algorithm under the changed AHP availability.

In the experiment of this scenario, the number of AHP to be mapped is 1000. The CPU BRC and memory BRC required for instantiating a VNF are both set to 20 units.

As shown in Fig. 4.2(a), it is a comparison of the final number of servers used by each algorithm. From the results, it can be seen that the number of servers used by the algorithm in this paper is the least. Compared with RAR _ RS _ BiG, JDBS _ s and GREP, they can use up to 29%, 29% and 42% of the servers respectively. JDBS _ s is the single-tenancy version of the roBS algorithm, that is, except for the difference in the implementation of VNF and IJ, other algorithms, such as AHP mapping algorithm, resource reservation algorithm, and VNFR merging algorithm of the same type, are the same as the method in this paper. By comparing the algorithms, it can be seen that when the availability requirement of AHP is lower than the initial availability of VNF, that is, the experimental scenarios with availability requirements of 0.90 and 0.99, the two algorithms have similar performance. This is because in this case, the availability of the current VNF can meet the needs of AHP. There is no need to reserve a backup for each original VNF.

2) Comparative analysis of algorithm performance: In this paper, based on the AHP algorithm, Matlab2014b is used as the simulation software to select the multi-domain network for the integrated automatic business of power grid resources in the enterprise middle station. The selection results are recorded for comparative analysis.

The electric power communication system requires high network security. There are many video surveillance services, which are interactive. The bandwidth is the key to ensure high-quality video streaming, so it requires a large communication bandwidth and a relatively high transmission delay. The demand for packet loss rate is weaker than the former two. The comparison matrix is shown in Table III.

The maximum eigenvalue $\lambda_{\max}\left(C\right)$ and eigenvector γ of the matrix C are obtained by using the eig function in MATLAB. It can be concluded that the CR value is less than 0.1 through formulas (10) and (11). The decision matrix meets the consistency requirements and can be used to calculate the weight vector. The weight vector is normalized to obtain the single factor and weight coefficient combination of service 1:

$$W^{'} = \{w_1, w_2, w_3, w_4\} = \{0.0469, 0.0926, 0.3641, 0.4964\} \tag{10}$$

$$W^{P} = \begin{pmatrix} w_1, w_2, w_3, w_4 \\ w_1', w_2', w_3', w_4' \end{pmatrix} \tag{11}$$

According to the decision function, the distribution coefficient of the total hierarchy is calculated. The simulation results are shown in Fig. 7.

The results are:

$$ts = \left(0.2715, 0.7285\right) \; f_1 = \max\left(ts\right) = 0.7345$$

Where 0.7285 represents the utility value f_1 of the best access domain 2 of the service, i.e., the distribution transformer video surveillance service in the current environment. Similarly, 0.2715 represents the utility value f_1 of the best access domain 1 of the service in the current environment. For the service f_1, domain 2 shall be selected as the best handover target network.

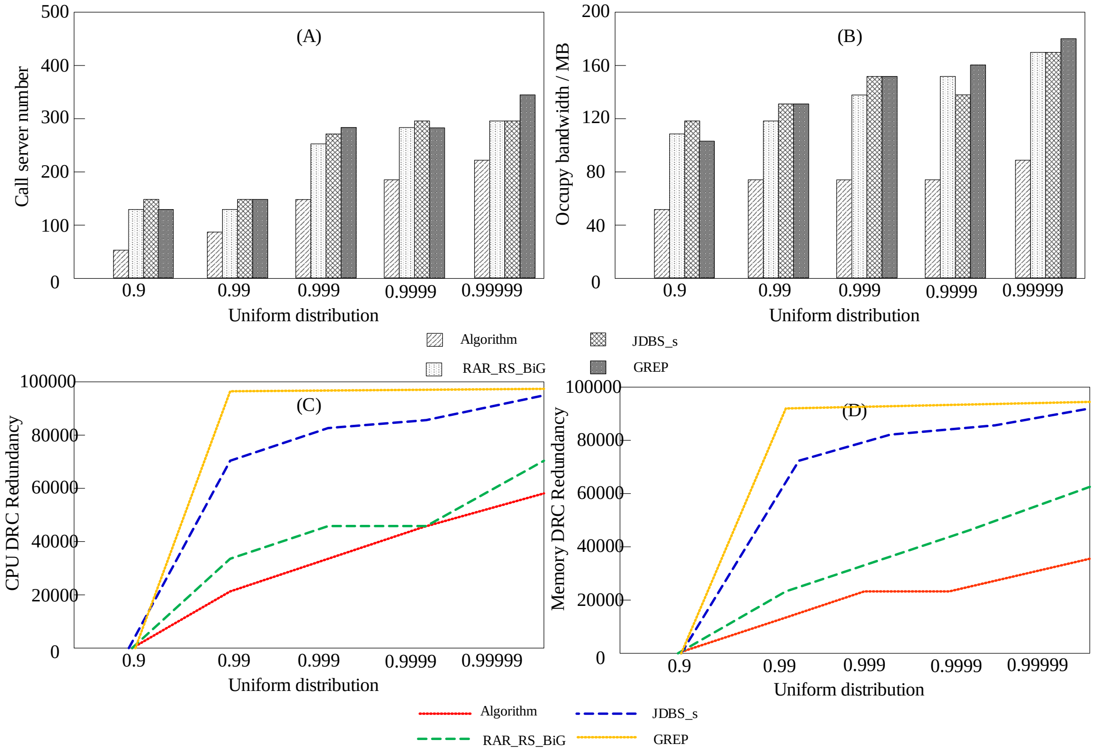

Fig. 6. Resource Consumption Comparison of each Algorithm and the Final BRC Comparison.

TABLE III. DISTRIBUTION VIDEO SURVEILLANCE SERVICE COMPARISON MATRIX

Comparative indicators	Time delay	Bandwidth	Packet loss rate	Hop count
Time delay	1	1/3	5	5
Bandwidth	3	1	8	9
Packet loss rate	1/5	1/8	1	2
Hop count	1/5	1/9	1/2	1

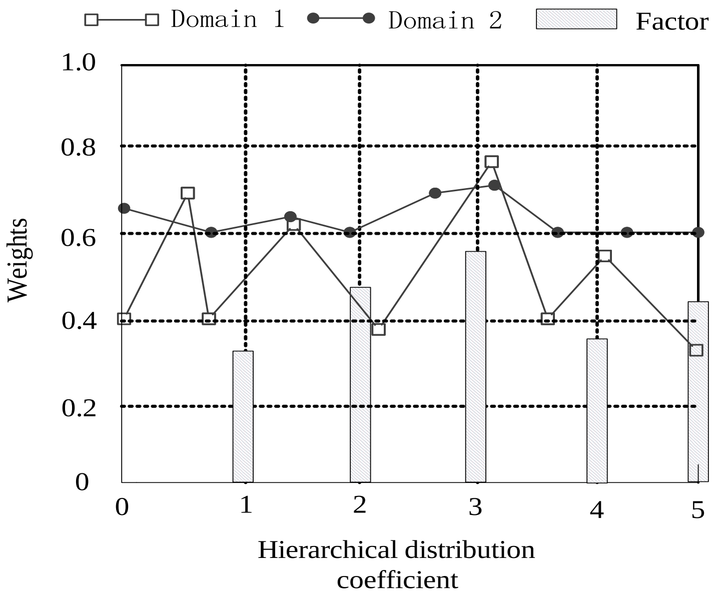

Fig. 7. Simulation Results.

In the aspect of electric power business, this paper selects typical business to study. In view of the intelligent electric power business, the analysis of its demand for the electric power communication network is more conducive to practical application. In addition to the control system, the intelligent electric power equipment is also an important component of the electric power communication network. Based on the analysis of the overall control system, this paper carries out a more in-depth and comprehensive study of the control system of the electric communication network.

VI. Conclusion

In this paper, the key technologies of the future electric power data Wan communication are studied. Through the research of network intelligent operation and maintenance and business scheduling strategy in enterprise platform environment, the research of resource elastic configuration and integration technology for IP network and optical transmission network, the efficient use of the IP layer and the optical layer network resources is realized, and the reliable operation of business is ensured, which is beneficial to that access of new equipment of a subsequent network and the rapid open of new services. Main work is as follows:

1) Design the overall framework of software defined network centralized control for the new business of electric power communication network.

2) The realization of network resource operation, maintenance management and control under centralized control architecture combined with typical application scenarios such as virtual power plant is done.

3) The simulation software is used to verify the realization of typical functions of SDN centralized control system.

The intelligent power equipment is also an important component of the electric power communication network. This paper is only based on the overall control system, and does not conduct in-depth research and design of intelligent power equipment. In the future, the optimization objectives and constraints in the construction of resource aggregates can be further improved, for example, the aggregation degree of resources can be optimized when considering spatial differences to achieve the simultaneous optimization of the characteristics and regions of resource aggregates.

***Abstract*—COVID-19 disease can be classified into various stages depending on the severity of the patient. Patients in severe stages of COVID-19 need immediate treatment and should be placed in a medical-ready environment because they are at high risk of death. Thus, hospitals need a fast and efficient method to screen large numbers of patients. The enormous amount of medical data in public repositories allows researchers to gain information and predict possible outcomes. In this study, we use a publicly available dataset from Springer Nature repository to discuss the performance of three machine learning techniques for prediction of severity of COVID-19: Random Forest (RF), Naïve Bayes (NB) and Gradient Boosting (GB). These techniques were selected for their good performance in medical predictive analytics. We measured the performance of the machine learning techniques using six measurements (accuracy, precision, recall, F1-score, sensitivity and specificity) in predicting COVID-19 severity. We found that RF generates the highest performance score, which is 78.4, compared with NB and GB. We also conducted experiments with RF to establish the critical symptoms in predicting COVID-19 severity, and the findings suggested that seven symptoms are substantial. Overall, the performance of various machine learning techniques to predict severity of COVID-19 using electronic health records indicates that machine learning can be successfully applied to determine specific treatment and effective triage.**

Keywords—Severity prediction; COVID-19; random forest; Naïve Bayes; gradient boosting

I. Introduction

Research has shown that electronic health records (EHR) are becoming increasingly valuable to predict health outcomes or disease diagnoses [1]. For many years, researchers have been analysing EHR with statistical and machine learning techniques for prognostic evaluations. Statistical techniques are designed to determine relationships between variables, and machine learning techniques are designed to make the most accurate predictions based on EHR. Although both techniques play an important role in research, previous analysis has shown that machine learning outperforms statistical techniques because of the recent advancement of tools for data analytics and large quantity of data humanity has access to since the information explosion [2]–[4].

A significant number of prediction models utilising EHR have been proposed in the literature over past years, including in the recent COVID-19 pandemic [1]. The COVID-19 pandemic presented massive data for examining social, behavioural, public health, and economic impacts [5]. Many recent studies have conducted data mining analysis using various available datasets that focus on the occurrence of confirmed, fatal and recovered COVID-19 cases globally to understand the threats and predict the subsequent planning of containment activities [6]–[9].

The severity of COVID-19 disease varies from mild to critical stages. Screening of positive COVID-19 patients at primary care clinics is used as the initial triage to determine the severity stage and admission to hospital [10]. With use of the conventional methods, the process to manage COVID-19 patients in the initial triage is not efficient because of long waiting times for screening [11]. It has previously been observed that limited hospital resources and staff during the COVID-19 pandemic makes it important to decide which patients require more urgent treatment and which patients that can wait [12]. Therefore, a timely clinical decision is important to help in early detection of serious disease and provide effective treatment for the individual patient, which is important for reasonable allocation of medical resources.

In recent years, machine learning techniques have attained popularity in the health area because of their capability to deal with enormous, complex and unbalanced data, and yield outcomes such as prediction [6]. Many machine learning techniques have been employed in forecasting the potential spread of COVID-19 [5], [11], [13], [14]; however, few studies have reported on the severity prediction of COVID-19 patients [15], [16].

This study discusses the initial prediction of the severity of the COVID-19 stage by clinical information in EHR using machine learning techniques. Early prediction of severity of the COVID-19 stage allows the healthcare organization to develop an effective disease management approach, which may help prevent the progression of the disease. It also helps overcome the limited number of staff in the hospitals by enabling frontliners to help the screening process. By classifying COVID-19 patients into the stage of severity, it helps doctors to prioritized critical patients thus making the screening process more efficient. Further, it may improve the quality of life of the patient. This study also examines the significance of the 21 variables of COVID-19 in the study population. The scope of this study covers the design of the screening system application and the development of machine learning model for the system.

II. METHODOLOGY

A. Project Methodology

We used a hybrid methodology (Fig. 1) which combine waterfall and agile methods. The hybrid methodology model consists of five phases: Requirement, Design, Develop, Test and Evaluation. The requirements and evaluation phases are from the waterfall methodology and the design, test and develop phases are from the agile methodology.

In the requirement phase, we collected the project resources such as dataset, tools and machine learning techniques. We designed the high-level system designs, flowchart and graphical user interfaces in the design phase. In the develop phase, we developed the predictive models using machine learning techniques and we test the predictive models until the best results were achieved. We evaluated the models in the evaluation phase using performance metrics such as accuracy, precision and sensitivity.

B. Model Training Flow

Fig. 2 shows the model training flow that we implemented in the development phase to train and test the machine learning techniques. We used the raw data for data preprocessing, feature selection, train model with training and testing data, and evaluate the model. The data preprocessing involves removing some irrelevant features that does not relevant, removing missing values, removing outliers, data transformation and data balancing. After obtaining the cleaned data, it will be split into two parts which is training data and testing data. The model will learn from the training data while testing data will be used to evaluate the model performance.

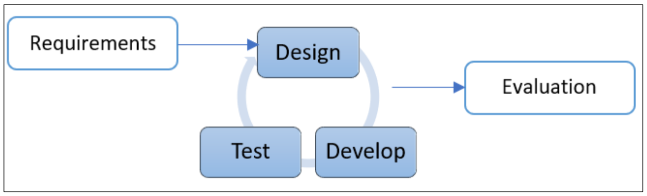

Fig. 1. Hybrid Methodology Model.

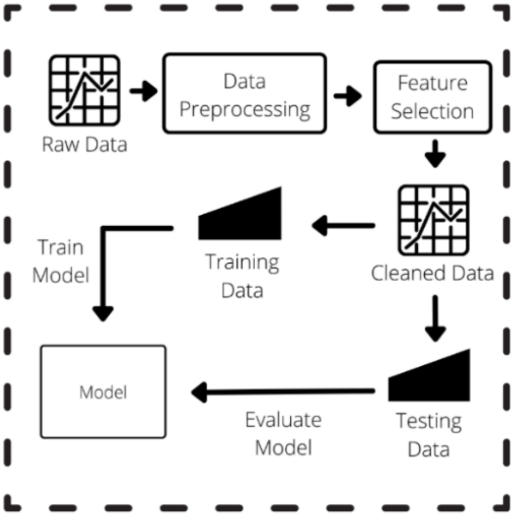

Fig. 2. Model Training Flow.

C. High-Level Screening System Design

The screening system (Fig. 3) consists of two main components: a) system and b) model. The system component requires an input from user to make a screening prediction using the predictive model derived from the model component. The system will response with output (prediction results) and store the results in the database.

D. System Flowchart

The flowchart of the screening system describes the way how the proposed system should work. As shown in Fig. 4, the flow begins with user login. Users need to register their username and password to use the system. When they enter their credentials, the system will verify the user and only allows authenticated users to login into the system. If they fail to verify themselves, the user must input the username and password again. There are two types of users for this system which is the doctor and the nurse. When nurse login, they can enter patient's information and predict the severity of the COVID-19 patient. The system will display the predicted outcome and the score of the severity prediction. The input entered by the nurse will be stored in the database so that doctors can view the data. When the doctor login, the system will show the record of patients and their status. Doctors can keep track of patients' status so that they know which patients are still waiting to be examined and which have been examined.

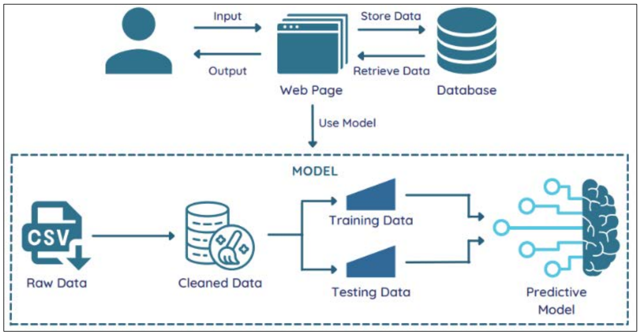

Fig. 3. High-Level Screening System Design.

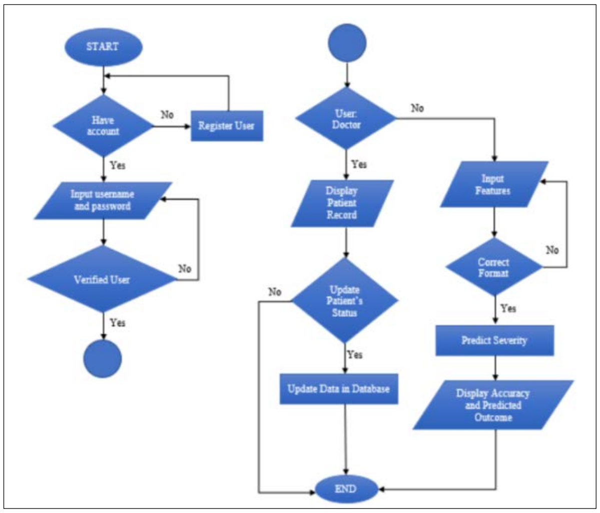

Fig. 4. System Flowchart.

E. Graphical user Interface Design

Fig. 5 shows graphical user interface (GUI) for the screening system that will serve as a way for medical practitioners to interact with the system. The GUI consists of seven web pages with forms for inputs and tables and graph for outputs.

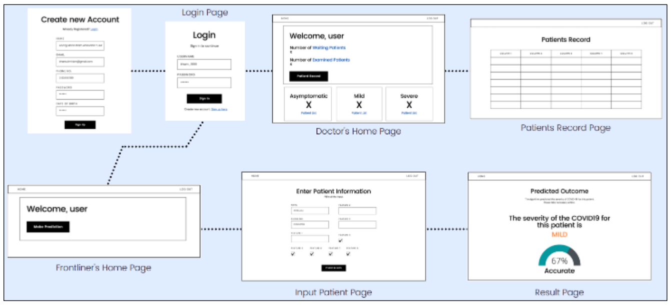

Fig. 5. Proposed Graphical user Interface.

III. Development of Machine Learning Model

A. Dataset

The dataset was obtained from the Springer Nature data repository and consists of 478 patients (https://springernature.figshare.com/articles/dataset/Data_associated_with_the_article_Epidemiological_and_clinical_characteristics_of_imported_cases_with_COVID-19_infection_a_multicentre_study/12159918). The dataset contains the epidemiological and clinical characteristics of COVID-19 cases in China, and consists of 21 variables, including the patient's demographic profile, epidemiological characteristics, clinical data, contact history, case cluster, outcome and type of case. The performance of machine learning models depends upon the quality of the data. Thus, pre-processing was conducted on the dataset to handle missing values, outliers and data generalisation.

After the pre-processing, only eight independent variables that is relevant to COVID-19 symptoms that will be used to predict the dependent variable (type) with three class labels. Table I illustrates the description for each variable.

The original dataset distributions of each class in the target variable are disproportionate which may result in a poor predictive accuracy over the minority class [17] and bias towards the majority class. Thus, to rebalance the data, this study used the synthetic minority oversampling technique (SMOTE) which will increase the minority class to match with majority class. This data balancing technique aims to avoid imbalanced classification in developing predictive models on the dataset. The results before resample and after resample using the SMOTE technique are shown in Fig. 6.

B. Tools

We developed the predictive models using python programming language that provide useful libraries such as Scikit-learn for feature extraction and model training and testing. We designed the GUI forms with text fields and buttons using HTML and CSS. We stored the data in a MySQL database.

C. Pre-processing and Feature Extraction

We analysed and compared the accuracy of three feature selection methods to identify the features or variables that most likely contribute to the severity of illness. The feature selection methods are Pearson Correlation, Random Forest Importance and Recursive Feature Elimination (RFE). Fig. 7 shows the accuracy comparison of feature selection methods applied with the Random Forest model.

TABLE I. VARIABLE DESCRIPTION

Variable	Description
Gender	The gender of the patient.
Age	The patient's age in years.
Fever	Whether the patient have fever.
Cough	Whether the patient have cough.
Fatigue	Whether the patient have fatigue.
Dyspnea	Whether the patient have dyspnea.
Headache	Whether the patient have headache.
H-Temperature	The patient's highest temperature.
Type	The type of cases or the level of severity for the COVID-19 case. (1=Asymptomatic, 2=Mild, 3=Severe)

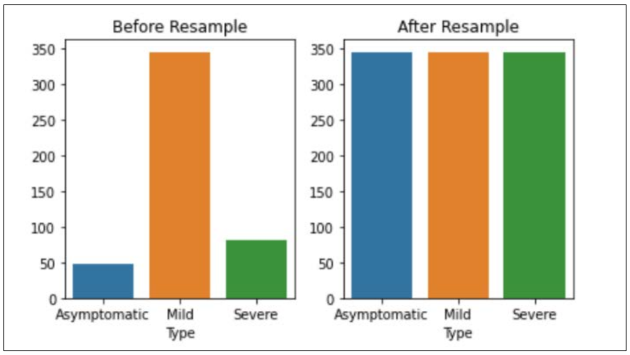

Fig. 6. Original Dataset vs Synthetic Minority Oversampling Technique Dataset.

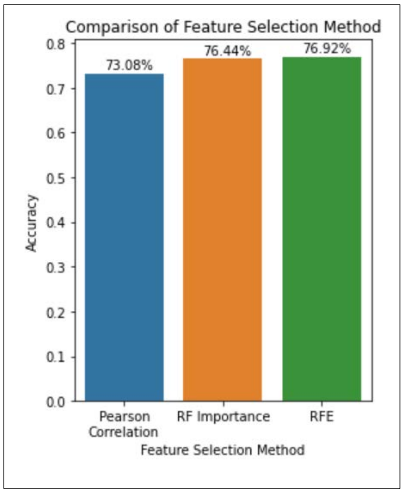

Fig. 7. Comparison of Feature Selection Methods.

The results show that the Random Forest model produces the highest accuracy of 76.92% when using RFE, compared with 76.44% for Random Forest Importance and 73.08% for Pearson Correlation. Thus, RFE was used to determine the importance of the eight features or variables according to the contribution in COVID-19 illness. We used RFE with cross-validation to remove features or variables iteratively and find the most relevant features or variables that contribute to the severity of illness and have strong correlations between the selected features or variables. Fig. 8 shows the accuracy of the model obtained with cross-validation using different numbers of features.

Based on the line chart in Fig. 8, the accuracy of the model is at the highest (78.0%) when the number of features selected is seven. Thus, we used those seven features in this study, which are Gender, Age, Fever, Cough, Fatigue, Dyspnoea and H-Temperature.

D. Model Training

We applied three machine learning techniques: Random Forest (RF), Naïve Bayes (NB) and Gradient Boosting (GB). The brief methodology, working procedure and differences are provided below.

1) Random forest: RF is an ensemble method that combines multiple decision trees (DTs) together in a single forest. It is a powerful supervised machine learning algorithm that is capable of performing both classification and regression tasks with high accuracy [18]–[20]. Various studies in the medical area have used RF algorithms to, for example, diagnose diabetes mellitus [21], [22], identify cervical cancer [23]–[25], or predict the risk of severity for COVID-19 patients at hospital admission [26].

In predicting COVID-19 severity, the RF technique will choose random samples from a given dataset and build an individual decision tree for each sample. One single RF model will have many DTs. Each DT will generate a prediction based on RF technique. As can be seen in Fig. 9, each prediction result contains a vote and the majority votes will be chosen as the final result.

2) Naïve bayes: The NB algorithm works on the Bayesian theorem whereby the probability of a class depends on the probabilities of its variables [27]. The NB classifier is used to maximise the probability of the target class given the features. Previous studies reported that NB can be used to solve the classification problems with multiple classes [28], [29]. In this study, NB can be utilised in the type of COVID-19 severity. Fig. 10 shows the equation used in NB.

3) Gradient boosting: GB is a method to develop classification models by optimising known techniques, such as DT, by adding new learners in a gradual sequential manner [30], [31]. This algorithm is also helpful as a prediction model as it has been used in past research [32], [33] to predict COVID-19. Individually, DT might give a weak prediction ability. However, when combined in an ensemble method, it can improve the accuracy by sequentially upgrading its performance. Fig. 11 shows how boosting in an ensemble method works.

$P(X) = P(c) \times P((c) \times \dots \dots \times P((c) \times P(c)$

Fig. 10. Equation in NB Classifier [27].

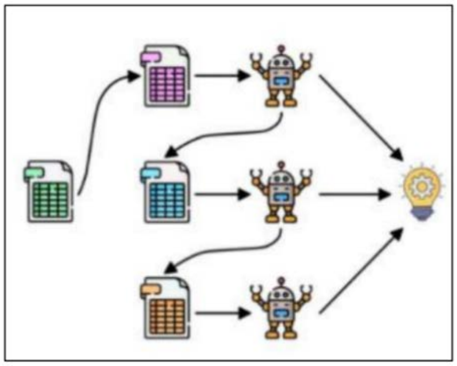

Fig. 11. Boosting Method.

As shown in Fig. 11, although the GB classifier is part of an ensemble method, this method is different from RF in that it does not take the majority vote from each tree. In contrast, it generates the results at a single tree and improves them sequentially until it obtains a good result. The RF, NB, and GB models were run using python software with the abovementioned independent variables or features (Gender, Age, Fever, Cough, Fatigue, Dyspnoea and H-Temperature) and dependent variable (Type), with three class labels.

E. Evaluation Method

We evaluated the performance of machine learning techniques according to evaluation metrics: accuracy, precision, F1-score, recall, sensitivity and specificity. These evaluation metrics used four basic attributes based on confusion matrix which are: True Positive (TP), True Negative (TN), False Positive (FP) and False Negative (FN). We calculated the accuracy values using Eq. (1).

$$\text{Accuracy} = TP + TN/(TP + FP + TN + FN) \tag{1}$$

We used precision, recall, F1-score, sensitivity and specificity to support the accuracy values. The method for these metrics is described in Eq. (2), Eq. (3) , Eq. (4) , Eq. (5) and Eq. (6), respectively.

$$\text{Precision} = TP/(TP + FP) \tag{2}$$

$$\text{Recall} = TP/(TP + FN) \tag{3}$$

$$\text{F1-score} = 2 \times (\text{Recall} \times \text{Precision})/(\text{Recall} + \text{Precision}) \tag{4}$$

$$\text{Sensitivity} = TP/(TP + FN) \tag{5}$$

$$\text{Specificity} = TN/(TN + FP) \tag{6}$$

IV. Results

Our main objective is to compare the three machine learning models based on the accuracy performance in this section. In order to analyze the differences, we compare the performance accuracy using the five-fold cross-validation with stratification as a testing method to derive the best predictive model for optimal results. We measure the performance using various metrics including classification accuracy, precision, F1-score, recall, specificity and sensitivity to ensure the predictive model was fit to produce accurate results. Table II shows the performance of the three machine learning models that have been investigated in this study.

Overall, results show that all the machine learning models can be used for predicting the severity of COVID-19 patients. However, the RF model produced the highest accuracy value of 78.4. This may be because of advantages of the RF model, such as building each tree independently and averaging the votes. The averaging method may be advantageous when dealing with multiclassification that aggregates individual predictions into a collective prediction.

The RF and GB models recorded the same values for precision, specificity and sensitivity, which are 91.0, 94.7 and 98.6, respectively. The NB model obtained perfect recall and sensitivity values of 100.

TABLE II. RESULTS OF RF, NB AND GB FOR COVID-19 SEVERITY PREDICTION

Performance measures	**Machine learning model**		
	Random Forest	**Gradient Boosting**	**Naïve Bayes**
Accuracy	**78.4**	**77.5**	**76.1**
Precision	91.0	91.0	89.0
F1-score	95.0	95.0	94.0
Recall	99.0	99.0	100
Specificity	94.7	94.7	93.3
Sensitivity	98.6	98.6	100

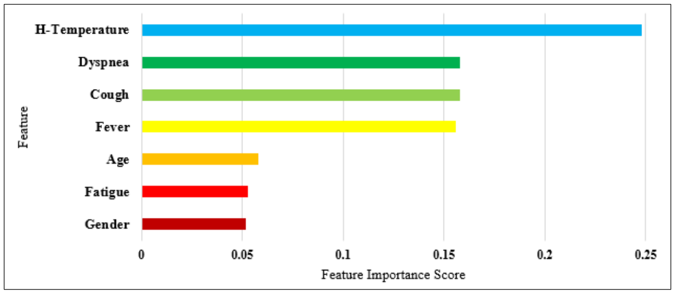

Fig. 12. Visualising Significant Features for COVID-19 Severity Stage Prediction Produced by RF Model.

We conducted another experiment using the RF model to determine the significant features or symptoms in predicting the severity stage of COVID-19 patients. The result is illustrated in Fig. 12, in which the most significant feature is H-Temperature.

V. Discussion

This study set out to report on the performance of machine learning techniques in predicting the severity of COVID-19 patients by using a publicly available dataset from the Springer Nature repository that contains clinical information of COVID-19 patients. Machine learning techniques provide an additional effective way of early screening of patients and do not replace the clinical evaluation.

In our study, results showed that the three machine learning techniques had similar average predictive accuracy in classifying severity of COVID-19 patients (accuracy >0.75). This is consistent with prior findings using an RF model in clinical data [15] and other prior findings using RF, GB, and ensemble learning algorithms in primary care [34]. The RF model outperformed the other machine learning models with the highest accuracy to predict the severity stage of COVID-19.

Despite the similar accuracy, this study found minimum variations for other performance values between the machine learning models. The specificity values were regularly high for RF and GB models, which indicate that the proportion of patients without severe COVID-19 symptoms was correctly classified. The sensitivity and precision values were also consistently high for RF and GB models, indicating that the models identified most of the COVID-19 patients with mild, severe and critical disease severity stages.

The findings of this study have important implications for developing a COVID-19 severity screening system to assist doctors to manage COVID-19 patients before they are examined. Since the outbreak of COVID-19, hospitals have been struggling to keep up with the number of patients because of limited staff. Patients need to be screened so that doctors can prioritise the severe patients as they are at high risk of death. Therefore, more efficient ways to screen the patients are needed because manual screening can be time consuming. By using a COVID-19 severity screening system powered by machine learning models, hospitals can deploy frontliners who are not medical experts to help screen the patients before they undergo actual examination by the doctors. Thus, the time to screen the patients can be shortened.

VI. Conclusion

Machine learning techniques help to reduce the effort and time for medical practitioners to conduct early predictions for healthcare management purposes. As the number of deaths due to COVID-19 increases, a COVID-19 severity screening system is essential to reduce the progression of the disease. In this study, a comparison of three machine learning techniques, RF, NB, and GB were performed, and RF was found to achieve the best performance score. The results of our study show the potential of applying machine learning techniques in the early predictions of a COVID-19 severity screening. Using RF algorithm, body temperature (H temperature) has been found to be important criteria for diagnosing COVID-19 severity level. This may call further investigation to explore temperature data visualization for temperature monitoring of COVID-19 patients. Other than that, a hybrid of machine learning techniques with optimisation algorithms with more data will be examined to further improve accuracy.

Acknowledgment

The authors would like to thank the Ministry of Education Malaysia and Universiti Teknologi MARA (UiTM) for their financial support to this project under UiTM Internal REI Grant 600-IRMI/REI 5/3 (001/2019). We would also like to thank the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Selangor, Malaysia for all the supports.

Electronic Personal Health Record Assessment Methodology: A Review

Dirayana Kamarudin, Nurhizam Safie, Hasimi Sallehudin
Faculty of Information Science and Technology
Universiti Kebangsaan Malaysia
Selangor, Malaysia

***Abstract*—ePHR (Electronic Personal Health Record) is not a new concept in the era of electronic health information. The advantages of ePHR in improving health outcomes through patient empowerment have been recognized globally and almost all countries that implement electronic health records (EHR) have created ePHR. This study identifies the components of the ePHR implementation study methodology that has been conducted throughout the country. The types of ePHR studies selected were adoption studies, acceptance studies, readiness studies, and evaluation studies. This study's systematic literature review process is identification, screening, eligibility, data abstraction, and analysis. A total of 16 final journals were analyzed from 173 journals identified from 5 databases (Science Direct, WoS, Scopus, JMIR, and PubMed) regardless of the year of publication until April 1st, 2021. Among the findings based on the four objectives of the study, there are two findings that are considered important and interesting by the author; first, the existence of 22 additional variables to the evaluation model by almost all studies in this study which shows a clear need to improve the evaluation model which is the TAM Model. Second, although the proposal of conducting a scientific study to evaluate the perspective of ePHR stakeholders before ePHR is developed only appeared once, based on this study and the knowledge of the authors, it is a starting point for the successful implementation of ePHR. These two findings contribute to the recommendations for the best design of the ePHR implementation study described in this paper.**

Keywords—Personal health record; ePHR; ePHR evaluation variable

I. Introduction

A. PHR (Personal Health Record)

PHR is part of health information. Health Information can provide five supporting powers to individuals, namely prevention, treatment, protection, health service and resource planning [1]. A physician knows the more knowledge about a patient, the higher the patient's chances of receiving the best possible health care. Patients also need adequate health resources to recover more quickly while receiving fewer complications from the optimal treatment [2]. The increasing population equipped with new and complex health treatments has increased the demand for better and more efficient health services around the world. Complicated health problems have created more complex health care processes. The need for complete health information for better treatment is also increasing. Now, it can be seen that the increase in Electronic Health Record (EHR) initiatives is one of the methods of winning this issue [3], [4]. PHR emerges from an EHR and is defined as a health record related to a patient-administered treatment [5]. PHR is a general data set of individual lifelong health information that the public understands that can be securely [6] accessed at any time for the purpose of treatment (illness) and wellness. PHR is owned and managed entirely by the individual or a party appointed by that individual. PHR can exist in the form of electronic health records that comply with recognized interoperability standards and can be sourced from a various sources while accessed, shared, and operated by individuals [7]. EHRs are generated throughout the patient's engagement with healthcare-related parties. This information consists of patient demographic data, patient progress records, patient problems, patient medications, patient health reading level information, patient medical history, patient immunizations, laboratory test result data and patient x-ray report. EHRs automate the workflow of physicians. EHR has some limitations because its records are based entirely on data reported by healthcare providers [8], [9] resulting in the existence of a trend that allows patients to gain access to their health data and makes them the owners of such data called PHR [10]. Based on the literacy study [10], PHR and EHR have different purposes, namely PHR is for the personal domain and EHR is for the organizational domain. The PHR is used for self-health management and monitoring that can be collaborated with the patient's digital device. At the same time PHR can integrate with EHR, EMR and other systems such as health insurance systems. PHR and EHR also can be integrated to exchange relevant patient health information [10]. Electronic Medical Record (EMR) is an application that consists of a repository of clinical data, clinical decision support, medical terminology, order requests by staff and medical practitioners and clinical documentation applications [7]. This environment supports patients' EMR in inpatient and outpatient environments and is used by healthcare practitioners to document, monitor, and manage health delivery services. Individual health information can be created, collected, managed and consulted by physicians and staff of healthcare organizations [7].

B. PHR Implementation

Based on this studies, it was found that PHR has existed since 1973 [11] and ePHR has existed since 2001 [12]. PHR is classified based the on health service provider, user type and system channel [5]. PHR user profiles are patients/individuals, health professionals and authorized third parties (patient/ individual families and government parties) who perform the process of consultation, monitoring and maintenance of individual health [10]. PHR exists in the form of paper, and computer systems integrated between several health facilities and hybrids (computer systems that can be accessed anywhere) [10]. There are 20 types of data (Allergies, Demographic, Documents, Evolution, Family History, General, Genetic, Home Monitor, Immunizations, Insurance, Laboratory Results, Major Illness, Medications, Prescriptions, Prevention, Providers, Scheduling, Social History, Summaries and Vital Signs) that exist in the PHR and half of them (Documents, Evolution, Immunizations, Insurance, Laboratory Results, Medications, Prescriptions, Scheduling, Summaries and Vital Signs) exist in the EHR [10].

C. Implementation of ePHR in Malaysia

Until April 1st, 2021, its shows that Malaysia has not yet conducted any ePHR acceptance study. Referring to the Information Technology Strategic Plan of the Ministry of Health Malaysia 2016-2020 [13], ePHR is not listed as one of the initiatives to be implemented. However, there is a journal [14] that shows the production of variable models (UTAUT2 and PMT) to study of ePHR acceptance in Malaysia. Still, the authors found no references to show the results of studies using such models. Next, there is a study [15] prepared for the Ministry of Health Malaysia (MoHM) to develop a Lifetime Health Record (LHR) system [13]. The study yielded the structure of the LHR dataset. This dataset is prepared for the MoHM based on the clinical consultation process and the use of patient demographic records in the clinic. This LHR dataset is provided according to the needs of healthcare professionals. The proposed LHR has three components namely Patient Master Information, Health Condition Summary and Episode Summary. This research concludes that ePHR needs to be developed by taking into account the structure and components of LHR records according to the needs and perspectives of Malaysians. Also, there was last finding a study [16] about LHR in hospital and clinic of Ministry of Defense Malaysia.

D. Need for the Review

According to Alsahafi [5] the implementation of the health record computer system is moving from a service provider control information system to a patient/individual control information system, namely, ePHR (electronic PHR). He also noted that several countries such as the United States, England and Australia have chosen to implement globally integrated ePHR to improve the quality of health service delivery. The results of his study concluded that, although the advantages of ePHR are agreed almost worldwide, the acceptance rate of the implementation of ePHR is still at a low level. The authors have agreed with HS Park's suggestion that research is needed before ePHR is developed to identify the real needs and concerns of those interested in ePHR [17] and thus be one of the ways to solve the problem of low ePHR acceptance rate. Based on the reading of the journal until April 1st, 2021, the authors have agreed that a systematic review of the literature on the methodology of existing ePHR implementation studies (readiness, adoption, adaptation and evaluation) is needed to determine the best study design for ePHR studies.

II. Objective of Study

The objectives of the study to be archived sequentially are as follows:

1) To identify the scope of the ePHR implementation study: The authors define the meaning of the scope of ePHR implementation as a study of two research boundaries, namely studies before or after the implementation of ePHR and the categories of ePHR study respondents such as patients, public, health professionals and others.

2) To identify ePHR implementation research methodology: The methodological component chosen in this study is the method of collecting and analyzing research data which is qualitative, quantitative or mixed methods. Next, the authors want to see, the method is categorized according to the scope of the study that has been identified when achieving the first objective.

3) To identify ePHR implementation acceptance models and the results: The authors want to identify the models that exist in ePHR implementation studies including the variables that exist in those studies. Next, the authors wanted to obtain all results from all selected studies.

4) To identify ePHR implementation study recommendations: The authors want to get specific improvement suggestions for the implementation of ePHR that exist and are not bound to the scope of the study that has been identified in the achievement of the first objective.

III. Methodology

Referring to systematic literature review study by Mohamed Shaffril [18], the systematic literature review process used for this study follow the same process which are identification, screening, eligibility, data abstraction and analysis.

A. Identification

To identify the journal topic for this study, the search was made based on the review searching topic map as in Fig. 1.

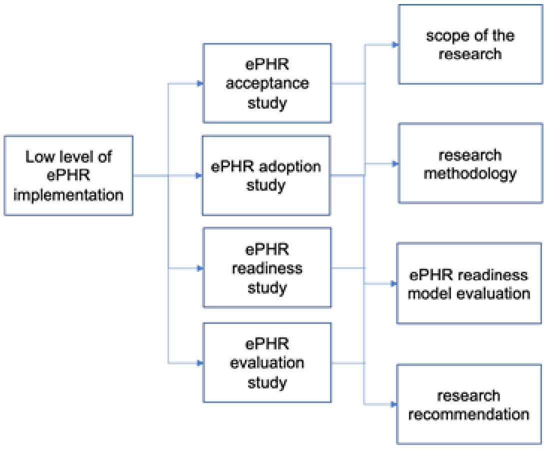

Fig. 1. Review Searching Topic.

Journal searches based on the topics in Fig. 1 were made in the databases of Science Direct (SD), World of Science (WoS), Scopus, Journal of Medical Internet Research (JMIR) and PubMed. As of April 1, 2021, the number of journals obtained based on the selected keywords and databases are as shown in Table I. The total number of a document identified was 173. The keywords used throughout this study are as follows:

1) Keyword A = "Personal Health Record" AND "Acceptance"

2) Keyword B = "Personal Health Record" AND "Adoption"

3) Keyword C = "Personal Health Record" AND "Readiness"

4) Keyword D = "Personal Health Record" AND "Evaluation"

TABLE I. NUMBER OF JOURNAL BY KEYWORD AND DATABASE

	SD	**WoS**	**Scopus**	**JMIR**	**PubMed**	Total
Keyword A	0	12	11	1	3	27
Keyword B	3	30	41	3	9	86
Keyword C	0	1	1	0	0	2
Keyword D	2	23	21	1	11	58
Total	5	66	74	5	23	173

B. Screening

The first screening is a review of the title and author of the document. Duplicate documents will be removed from the list. Next, a second screening was made by selecting published documents as journals and published in English. The journal is also a journal that is in the final stages. The screening results are as in Table II. Since the document identification results show that studies on the implementation of PHR are still lacking, this study does not specify the year of publication of the journal. The final number of journals after the second screening was 53.

TABLE II. NUMBER OF JOURNAL BY KEYWORD AFTER SCREENING

Keyword	**Journal**	**Total**
Keyword A	[19], [17], [20], [21], [14], [22], [23], [24],	**8**
Keyword B	[25], [26], [27], [28], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [39], [40], [41], [42], [43], [44], [45], [46], [47], [48], [49], [50]	**26**
Keyword C	[51]	**1**
Keyword D	[52], [53], [54], [55], [56], [57], [58], [59], [60], [61], [59], [62], [63], [64], [65], [66], [67], [68]	**18**
Total Journal		**N=53**

C. Eligibility

At this stage, the journal abstract is read carefully to identify the scope, methodology, evaluation model, results and recommendations of the study. If such information is not available in the abstract, a reading will be performed on the main document of the journal. Journals containing incomplete information are removed for further processing. Finally, a total of 16 articles as in Appendix I were selected for analysis. The percentage of the selected journal that provides sufficient information for the study is described in Table III. It shows only 9% of the journals found could be analyzed.

TABLE III. NUMBER AND PERCENTAGE OF SELECTED JOURNAL FOR THE STUDY

Identification			**Screening**			**Eligibility**
Keyword A						
27	Y	8	8	Y	6	6
	N	19		N	2	
Keyword B						
86	Y	26	26	Y	8	8
	N	60		N	18	
Keyword C						
2	Y	1	1	Y	0	0
	N	1		N	1	
Keyword D						
58	Y	18	18	Y	2	2
	N	40		N	16	
173	Y	53 (31%)	53	Y	16 (30%)	16 (9% of journal found)
	N	120 (69%)		N	37 (70%)	

Notes:
Y = Selected journal after certain review process
N = Rejected journal after certain review process

D. Data Abstraction and Analysis

The methods of analysis used in this study are as follows:

1) Data extraction: Data related to the five major themes were extracted from the journal's primary documents. The themes are the scope, methodology, evaluation model, results and recommendations of the study.

2) Data grouping: Data for the scope, methodology and evaluation model were consolidated and grouped according to sub-themes as in Appendix I. The original data for the results and recommendations were summarized and grouped according to the themes of the data as in Appendix II.

IV. FINDINGS

The findings of the study were compiled based on the objectives of the study.

A. Study about the Scope of the ePHR Implementation

Based on the analysis, it was found that 9 (56%) studies were implemented before ePHR was implemented. 8 (50%) studies were conducted before ePHR was implemented. 10 (62%) studies made patients as respondents, 5 (31%) studies used health professionals, 3 (19%) studies used the general public and 1 (6%) studies used health organization management staff. Only 1 of the 16 studies incorporated 3 groups of respondents: patients, health professionals and management staff of health organizations and the study was conducted before the implementation of ePHR. All studies (3 studies) involving the general public were evaluated before ePHR was implemented. Meanwhile, 6 out of 10 studies involving patients were evaluated after the implementation of ePHR.

B. Study about the Research Methodology for ePHR Implementation

It was found that 11 (69%) studies were conducted with a quantitative method, 3 (19%) studies with mixed-method and 2 (12%) studies with qualitative method. For the studies conducted before implementation of ePHR, only 7 (78%) studies were conducted quantitatively and the remaining 2 (22%) studies were conducted qualitatively. Furthermore, for the studies conducted after the implementation of ePHR, 4 (50%) studies were conducted quantitatively, 3 (38%) studies with mixed methods and 1 (12%) studies were conducted qualitatively. It is found that all studies that make the public as respondents use a similar method that is quantitative methods. Meanwhile, 6 (60%) studies on patients were conducted quantitatively, the remaining 3 (30%) studies were conducted qualitatively and 1 (10%) studies were mixed method.

C. Study about the Acceptance Models and Results for ePHR

It was found that eight (50%) studies adapted the TAM (Technology Acceptance Model) model as the evaluation model, two (12%) studies used the UTAUT (Unified Theory and Use of Technology) model and 6 (38%) studies used the SDT (Self-Determination Theory) model. Of the 16 studies, only 1 study used the TAM model completely without additional variables. The remaining 15 (94%) studies selected additional variables based on researcher's knowledge named SDT. Of the 15 studies, 7 (47%) studies were combined with the TAM model, 2 (13%) studies were combined with the UTAUT model and the remaining 6 (40%) studies used the SDT model entirely. TAM combined variable model developed by Fred Davis in 1989 based on TRA (Theory of Reasoned Action) by Ajzen and Fishbein [24]. TAM contains two main factors of acceptance of a technology: Perceived Usefull (PU) and Perceived Ease-of-Use (PEOU). Venkatesh developed UTAUT in 2003 due to the integration of 8 models [69]. UTAUT has three factors that influence Behavioral Intention (BI) Factors: Performance Expectancy, Effort Expectancy, and Social Influence. Two factors that influence Use Behavior Factors are BI and Facilitating Conditions. There are four types of moderators, namely, Gender, Age, Experience and Voluntariness of Use. The SDT variables that has identified by this study are as shown in Table IV.

Referring to Appendix II, the results of the study are summarized into thhree themes, namely, all IVs have an effect on DV, some IVs do not have an effect on DV and the number of themes produced. It was found that almost all studies gave the same results, that is, all the variables (IVs and themes) studied have been scientifically proven to affect the implementation of ePHR.

D. Study about Recommendations for ePHR Implementation

Appendix II contains recommendations from 16 studies summarized into 8 themes and taken the total frequency of the recommendations were raised. Table V shows the list of suggestions arranged according to most frequently mentioned.

A summary of all the findings categorized according to the first three objectives of the study is as in Appendix III.

TABLE IV. SDT VARIABLE BY QUALITATIVE STUDY

SDT Variable (Quantitative Study)	Journal
1. Confidentiality 2. Privacy	[27]
3. e-Health Literacy	[19]
4. Physician Autonomy Support 5. Autonomous Causality Orientation 6. Basic Needs Satisfaction	[32]
7. Health-care technology self-efficacy	[31]
8. Perceived data privacy 9. Security protection 10. Perceived health-promoting role model	[22]
11. Subjective Norm, 12. Security & Privacy 13. Computer self-efficacy	[43]
14. Task Technology Fit 15. Patient Activation Measure	[33]
16. Physician-patient Relationship	[23]
17. Technology Barriers	[24]
18. Perceived Risk 19. Facilitating Conditions	[17]
20. Compatibility 21. Communicative	[70]
22. Impact on current workflow	[38]

TABLE V. LIST OF RECOMMENDATION

Percentage of frequency	Recommendation
62%	1) Increase ePHR awareness or education among stakeholder
50%	2) The health proffesional should play a central role to improve utility and consequently the adoption of the ePHR
31%	3) Design ePHR application acording to stakeholder need and concern
19%	4) Policymakers, and health-care providers must pay additional attention to increasing individuals conviction and confidence in using the ePHR
6%	5) Conduct sufficient study to identify stakeholders' perspective and need before ePHR development/ implementation.
6%	6) Healthcare policy-makers, physicians, and developers must consider actions to improve the usability of ePHR in the future
6%	7) Some legal and ethical issues also need to be considered for ePHR adoption
6%	8) Improve the quality of the physician-patient relationship

V. Discussion of Result

Based on the findings of the study, the matters to be discussed of result are divided into three, namely the improvement of the evaluation model, the selection of key recommendations and the best design for ePHR implementation study.

A. Improvement of ePHR Evaluation Model with SDT

Referring to Appendix I, 69% (11 out of 16) of the studies were carried out quantitatively using the popular model that is TAM or UTAUT and 91% (10 out of 11) of the studies created an additional variable (SDT) that was combined with the existing model. These additional variables are scientifically proven to impact ePHR implementation. This shows that there is a need for improvement of either TAM or UTAUT models to evaluate health digital initiatives and researchers cannot wait for these improvements and are forced to develop their own SDT. The scientific selection of SDT was not addressed clearly in most of the research paper. It was found that the additional variables used by the researchers were based on the knowledge of the researchers [27], [31].

Based on the findings of this study, it can be concluded that there is a significant scenario of adding variables to the TAM and UTAUT models. Therefore, researchers who want to study the implementation of ePHR and want to identify the appropriate evaluation model, the authors suggest that they refer to the list of SDT variables in Table IV to get broad ideas for determining additional variables that want to be combined with the TAM or UTAUT model. All SDT variables listed have been scientifically proven by researchers and almost all of these variables have been evaluated from the patient's point of view. Researchers who want to improve the TAM or UTAUT Model or want to create a new model, researchers can also refer to Table IV to develop the most suitable model to evaluate the implementation of digital health initiatives so that the initiative is finally accepted and used fully.

B. Selection of Key Recommendation of ePHR Implementation

Although the awareness program is the most frequently mentioned recommendation, but the authors strongly agreed that the fifth recommendation in Table VI is the main and best recommendation that should be considered by all parties involved in the implementation of ePHR. Directly, the fifth recommendation is the first step to the success of the third recommendation expressed by 31% of the study. The fifth recommendation can indirectly help implementation the remaining recommendations.

C. The Best Design for ePHR Implementation Study

From these two findings, 9/16 studies (56%) were conducted before the ePHR was implemented and 6% conducted sufficient studies to identify the perspectives and needs of stakeholders before the development/implementation of the ePHR, the authors argue that although the studies before and after did not show significant differences in the pattern of results and percentage of the population, there are research recommendations before the development/implementation of ePHR that are selected as key recommendations as described in previous sub topic that can be taken seriously by ePHR implementation researchers.

It was found that seven out of nine (78%) studies conducted before the implementation of ePHR, were carried out qualitatively, since the majority of studies carried out before the implementation of ePHR were carried out qualitatively, this study uses the same approach. It is in line with the concept of research design [71] which is exploratory towards the perspective of the general public, patients and health professionals towards the development/implementation of ePHR which is more suitable to be carried out qualitatively.

As explained in sub-topic V(A), the ePHR implementation study is thought to be most suitable to be carried out by using the TAM model which is improved with SDT variables as in Table IV which can be studied on patients, the public and health professionals together or separately.

VI. Limitation and Recommendations

From the point of view of digital initiative evaluation theory, this study only focuses on the evaluation of ePHR implementation. The authors chose to identify the components of the research methodology specific to ePHR before answering the question of whether the components of the ePHR evaluation model are similar to the digital initiative evaluation model in other areas such as finance, transportation and so on. Before comparisons can be made, a review of digital initiative evaluation studies in other fields must be conducted. The next question that may be studied is the model of evaluating health digital initiatives from the point of view of the public, patients, health professionals and health service providers as health digital initiatives have now changed from professional-centric to patient-centric.

VII. Conclusion

It is hoped that the results of this study can help those who want to develop, implement and evaluate ePHR. The authors believe that the new variables listed are realistic and up-to-date variables as well as recommendations that have been identified as relevant to be implemented for the successful implementation of ePHR.

Acknowledgment

We gratefully acknowledge that this work supported by the Ministry of Higher Education of Malaysia under the FRGS/1/2020/TK0/UKM/02/9 and Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia. We would also like to acknowledge the editors and anonymous reviewers for their valuable guidance.

Appendix. III. SUMMARY OF FINDINGS

No.	Objective of Study	Category	Findings
1.	Scope of ePHR Implementation Study	• Study Time Category ◦ Before the implementation of ePHR ◦ After ePHR Implementation • Respondent Category ◦ Patients ◦ Public ◦ Organization ◦ Health Professionals	• 9/16 studies (56%) were conducted before ePHR was implemented • 8/16 studies (50%) were conducted after ePHR was implemented. • 10/16 studies (62%) were conducted on patients • 5/16 studies (31%) were conducted on health professionals • 3/16 studies (19%) were conducted on the general public • 1/16 studies (6%) were conducted on management staff. • 1/16 studies combined 3 groups of respondents (patients, health professionals and management staff) conducted prior to ePHR implementation. • 3 studies involving the public were evaluated before the ePHR was implemented • 6 of the 10 studies involving patients were evaluated after ePHR implementation
2.	Metodology of ePHR Implementation Study	• Methodology Category ◦ Quantitative ◦ Qualitative ◦ Mixed Methods	• 11 studies (69%) were conducted using quantitative methods • 3 studies (19%) were conducted with mixed methods • 2 studies (12%) were conducted with qualitative methods • 7 out of 9 studies (78%) conducted before the implementation of ePHR, were carried out quantitatively. • 7 out of 9 (78%) studies conducted before the implementation of ePHR, were carried out qualitatively. • 4 out of 8 studies (50%) conducted after the implementation of ePHR, were carried out quantitatively. • While 3 studies are mixed methods and the remaining 1 study is carried out qualitatively.
3.	Assessment Model of ePHR Implementation Study	• Assessment Model Category ◦ Technology Acceptance Model (TAM) ◦ Unified Theory of Acceptance and Use of Technology (UTAUT) ◦ Self Determination Theory (SDT)	• 8 studies (50%) used TAM • 2 studies (12%) used UTAUT • 15 studies (94%) established additional variables (SDT) ◦ 7 out of 15 studies (47%) combined SDT with TAM ◦ 2 out of 15 studies (13%) combined SDT with UTAUT ◦ 6 out of 15 studies (40%) used SDT without TAM / UTAUT combination.

Contribution of Experience in the Acquisition of Physical Sciences Case of High School Students Qualifying

***Abstract*—This work deals with the importance of experimental practice in the teaching of physical sciences. By practice, we rarely mean practical work carried out in the laboratory. We examined the relationship between students' knowledge of physical science and how practice may or may not help them understand chemical and/or physical concepts. What emerges from a survey distributed to our students is that they are very favorable of the use of the practice. The problem posed in this work consists in identifying the impact of experiments on the acquisition of knowledge and in responding to the problems of learning through experience in the short and medium term. The analysis of the answers allowed us to conclude that the experiment in class, by the teacher, helps to understand the physical and chemical phenomena and can be done before or after the study of the theory. The length and difficulty of practical work sometimes worry students, trying to follow the protocol step by step. This fact underscores the importance of clarity of purpose, through which students can be guided toward questioning what is expected of them, such as knowing how their knowledge has increased.**

Keywords—Experimental practice; physical sciences; students; practical Work PW

I. Introduction

A. Contexte and Problematic

Support for the conduct of experiments and the manipulation of devices by high school students qualifying during practical work has been a long-standing need for teaching the physical sciences: “Physics and chemistry are experimental sciences must be taught as such” [1], could be read in recent official instructions.

From an educational point of view, the goal of the plan is for students to question themselves, act logically and communicate, and build their learning by being representative of scientific activities [2]. Numerous dissertations highlight the advantages of experience in terms of developing transversal skills and increasing the attractiveness of students for the physical sciences, but few are interested in its role in the acquisition of short or medium scientific knowledge term in students. For this reason, it seems interesting to us to study the impact on the students of the manipulation during the experimental phases on the acquisition of scientific knowledge: the realization of experiments allows the students to acquire better knowledge in the short and medium-term?

School instructions regularly evoke the links between theory and experimental practice which plays various roles [3], for example when they recall that experimental activities "constitute the very foundation of physics and chemistry" [4].

There is a large debate around experimental practice to which several researchers have tried to answer. Should theory be taught before practice, or should theory be based on practice?

For Duhem (2016) [5], to say that the theory is built by relying directly on the facts is a mistake, since the theory is not based on experience; it is rather controlled by experience. In other words [6], the physical theory does not start from the experimental facts; it seeks what are the fundamental properties that must be attributed to things and the relations that must be established between the changes of these properties in order to be able to deduce relations from them equivalent to those given by observation.

If we say that theory precedes experience, the best example to cite is that of general relativity proposed by Einstein in 1915. A beautiful, revolutionary theory that nothing could prove at the time. The first experimental verification did not come until 1919 with the Eddington experiment. On the other hand, if we say that experience precedes theory, we have the example of King Frederick II of Denmark who had funded an astronomical research center in the 16th century, which enabled unpublished and precise observations made by Tycho Brahe.

And it is thanks to these observations that Kepler was able to propose his laws on the movement of stars [7].

Constantly concerned about "how" to improve our classroom practice, we have researched, at various levels of our professional curriculum, the difficulties experienced by students in learning physical sciences. We sought, among other things, to know the conceptions of Moroccan high school students qualifying on the role of experience in teaching/learning in physical sciences.

To answer this problem, we will first look at the place of experience in the teaching of physical sciences and then, secondly, we will discuss the methodology used. We will present and analyze the results collected, in order to answer the questions of the problem.

B. Place of Experience in Teaching Physical Sciences

Experimental activities allow the learner to practice the experimental process, criticize, formulate hypotheses, design experiments, to interpret results. We consider that the experimentation helps in a good understanding of the concepts in physical sciences or initiates the construction of knowledge and know-how among the students.

The practical experience can thus be used to consolidate the acquired knowledge and to fill the various gaps of the theoretical course, in order to avoid any type of failure.

Different approaches combine to identify the real factors of failure, by pointing out the gap between saying and doing, between concepts and their uses [8].

Other factors can thus directly influence the decision to act towards such an educational system or a style of learning, in particular in practical work: (a) self-confidence, (b) the need to refer to others, (c) the need to use one's experience, and finally, (d) instilling the training model [9].

The learner profile defined by the program requires that the learner be able to carry out simple scientific experiments capable of highlighting certain facts and detecting the causes. The learner must therefore handle, observe [10].

Experimental activities are carried out in three forms [11]: The first form called "Practical Work" (PW) is a session devoted to manipulations made by students outside the class and guided by the teacher: verification of law, determination of a physical quantity, preparation of solutions, etc.

The other two consist of integrated activities during the course:

- In "course experiments", manipulations are usually done by the teacher, but the teacher sometimes allows the students to manipulate.
- In PW - courses, the manipulations are done primarily by the students.

Putting students in different learning situations allows them to diversify their approaches to a concept. In [12], the more they are confronted with different situations, the more they can discuss this concept and the easier it will be for them to memorize a given concept.

Other experimental learning situations exist, namely the integration of virtual environments for the simulation of various practical works, such as in physics-chemistry [13, 14, 15].

The development of the scientific spirit among learners has thus become more than ever a major objective of science education [16].

The steps to carry out practical work are specified by Joris Deguet and Guillaume Piolle, research professors in their research who specified that the method for doing a practical work takes place schematically in four phases represented in Table I.

TABLE I. PHASES FOR CARRYING OUT PRACTICAL WORK

Phases for carrying out practical work			
Preparation of the experimental protocol	**Carrying out the experiment**	**Collection of results**	**Interpretation and conclusion**
It is provided in the subject of the practical work, and it can be recalled in the report to make it easier to read, or to specify the stage that the student is describing.	The actual manipulations. They follow in practical sessions in the laboratory.	Detail all the experimental results collected during the lab, as well as their precise context. The results are linked to the protocol, to the experiment, and await interpretation, and they do not in themselves constitute a concluding element in a practical report.	This is the key phase of the experimental method, the most important of the report. At this stage, conclusions are drawn, and above all variations in results when the experimental protocol is modified. It is at this stage, by the quality of the writing, that the understanding of the problem is assessed.

C. Obstacles to the Physical Science Experiment

On the practical level, obstacles sometimes stand in the way of the experience, in the case of the educational actors questioned, the lack of equipment and chemicals (silver nitrate for example), the lack of a preparer in the laboratory, and the time allotted for finding equipment and preparing (rehearsing) pose a problem for subject teachers. In [17], the creation of virtual modeling environments can be a good alternative to solve these obstacles.

II. MATERIALS AND METHODS

A. Research Approach

We opted for a quantitative study based on the exploration and description of the data collected, as well as the comparison with related studies for discussion. The objective of our chosen approach is to get a set of concrete ideas of our research problem and objective.

We chose to use a quantitative method instead of a qualitative one, because:

- it reassured the interviewee and increased the response rate;
- it clarifies ambiguous answers;
- it allows us to transmit the questionnaire to the person;
- it allows the questionnaire to be passed on to the person who is competent to answer it; and
- suitable for questionnaires with "drawers".

B. Sample

The surveys are conducted, during the 2018-2019 school year, in two provincial directorates of the Ministry of Education and National Training; Sidi Bernoussi and Moulay Rachid belonging to the Casablanca-Settat regional. The choice of these directorates is related to reasons of facilitation of the research process.

Our sample consists of n = 300 qualifying secondary school students (common core and first year of the baccalaureate), 94% of the students responded because the questionnaire was given to them in class and they had time to answer it. Indeed, simple random sampling (SRS) was used in our study.

C. Method of Data Collection

We opted for the anonymous questionnaire as our data collection instrument. The questionnaire items were divided into four parts:

- Organization of the practical sessions: determine if the organization of the practical sessions and the objectives are clear enough.
- Theory and experience: determine if one is separable from the other.
- Role of experience: determine how the student perceives learning through experience.
- Progress of the practical work sessions: determine how the pupils perceive the availability of the teacher.

And finally, a section where students could freely answer three open questions:

- In your opinion the practical sessions allow us to acquire new knowledge and skills?
- In your opinion, what are the strengths and weaknesses of TPs?
- Did the practical sessions help you understand the course in physical sciences?

III. Results and Discussion

After the collection of data by the questionnaire, we proceeded to a statistical treatment using Excel software. The results were shown in the various figures below.

A. Organization of Practical Work Sessions

Fig. 1 gives the results of the two questions relating to the teacher's explanation and the clarity of the objectives of the practical sessions as answered by the respondents:

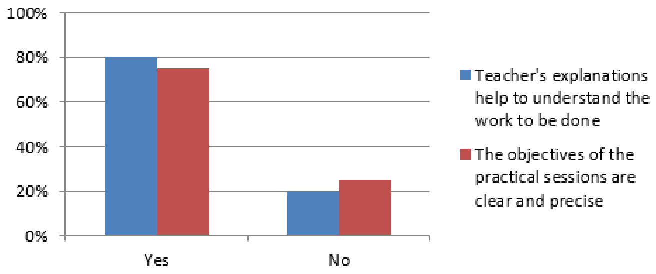

Fig. 1. Organization of Practical Work Sessions.

It turns out that: For 80% of the students questioned, the teacher's explanations help to better understand what is expected of them, and 75% declare the clarity of the objectives of the practical sessions.

Work on effective teaching practices [18-29], show that the teaching activities of efficient and equitable teachers are characterized by the principle of clarity, clarity in the presentation of tasks and instructions to be performed by students, clarity in the general organization of activities teaching. The explanation of concepts and concepts is done simply and logically.

What we noticed during the exercise of this profession of professor of physical sciences, is that, even if it is certain that the pupils should not be left in ignorance of the objective of practical work, they have a relative lack of autonomy. Indeed, as soon as part of the work is left to their judgment, we can say that they do not feel comfortable and ask a lot of questions.

Among the stated goals of good practical work in numerous publications are the familiarization of students with the scientific process [30]; [31], cognitive and psychomotor skills (Galloway et al., 2016) [32] and a better understanding of how science works [30, 31], without forgetting that there is a strong link between a learner's motivation and his results (Deci, Vallerand, Pelletier, Ryan, 1991) [33].

B. Theory and Experience

In Fig. 2, we have presented the results of the student survey concerning their opinion on the theory of experience.

87% of students believe that theory must precede experience, which again shows a relative fear of the student facing the unknown, a lack of self-confidence and autonomy.

In conclusion, for the pupils, it is useless to see the experiments before the theory; consequently, they prefer to already know the subject on which they must concentrate.

According to the literature many experiments were carried out without being guided by a well-established theory but were instead undertaken to explore new areas. Let's look at some illuminating examples: The development of electromagnetism is a good example: many electrical phenomena were discovered by physicists such as Charles Dufay, André-Marie Ampère, and Michael Faraday in the 18th and 19th centuries through experiments that did not have been guided by no developed theory of electricity.

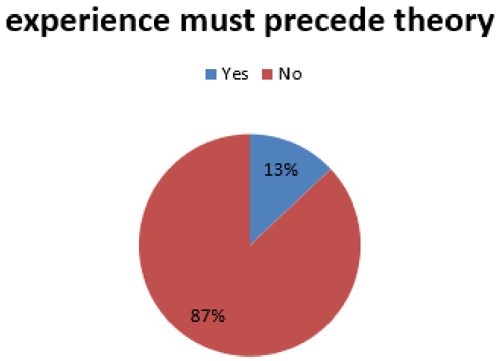

Fig. 2. Theory Vice Versa Experience.

Another example to cite: is the constant and laborious experimental effort that characterized the field of particle physics, especially the fundamental constituents of the proton and neutron, which were discovered through several exploratory experiments at the end of the 1960s to the Stanford Linear Accelerator.

For the second question of this item, we find in Fig. 3 that Almost 89% of students think that experience helps them understand the theory. When we analyzed the results, we could read that assisting or experimenting helps them build an image of the theory and keep it in mind.

The practical work during which the student is supposed to think, act and manipulate is always preceded by theory, where the knowledge at stake in these labs is already in place, which leads to reinforcing the lack of autonomy among the students of the second qualifying.

These results do not mean that experience should not have a close relationship with theory; in the end, there is only one physics, and it must ensure unity [7]. So, we can deduce that it is up to the teachers to clarify to the students the importance and the complementarity between the theory and the experiment whatever the first one.

For the last question in this section, we find in Fig. 4 that 70% of students think that the physical sciences cannot be taught without carrying out the experiments and also that the description of the experiment alone is not enough to understand the theory (76%). On the other hand, they need theory and practice to understand physical and chemical concepts.

The teachers want the PW to develop scientific attitudes as well as a creative and critical dimension in the pupils, the latter for their part, are much more reserved about the achievement of the objectives characterizing scientific attitudes.

They perceive the practical work under an aspect linked to the manipulative techniques and the illustration of the course [34]. On the other hand, we can find a part of the teachers who declare that the physical sciences can be taught without experimenting, in particular, at the forefront of national concerns and priorities in the discourse of the main political actors in Morocco [35].

C. *Role of Experience*

76% of the pupils think that the pupil learns more from the experience than he did than that of the teacher, 77% prefer the experiences which were made in the group. All this is linked to the previous question, which asks them if practical work helps them to better understand the physical sciences (Fig. 5).

The learning of manipulation techniques is facilitated, according to the literature and the teachers, by precise descriptive protocols, supplemented by illustrations and diagrams of the technique to be understood for the labs carried out by students in groups [36].

The teachers, for their part, emphasize their role to play in this learning as a student guide, in particular by validating or correcting the student's actions during the practical work [37].

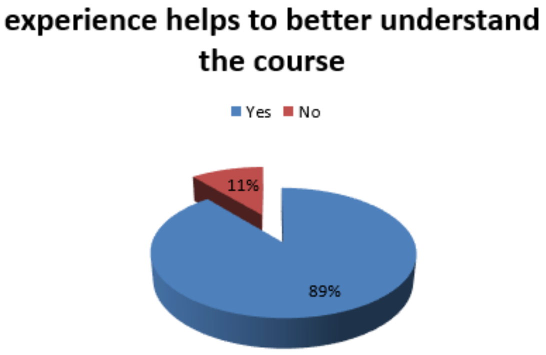

Fig. 3. Theory and Experience.

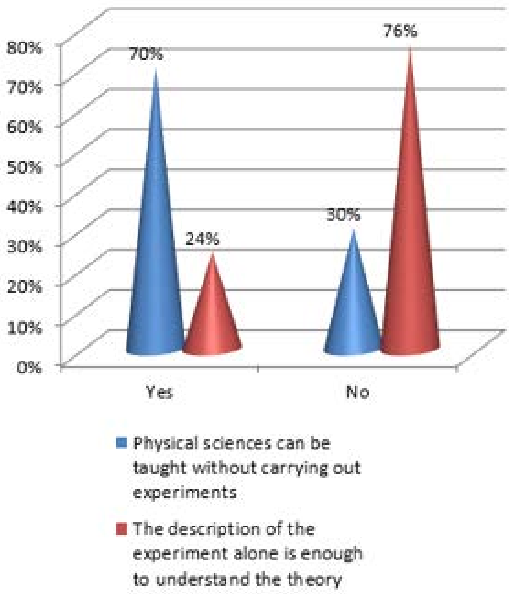

Fig. 4. Physical Sciences can be Taught without Experience.

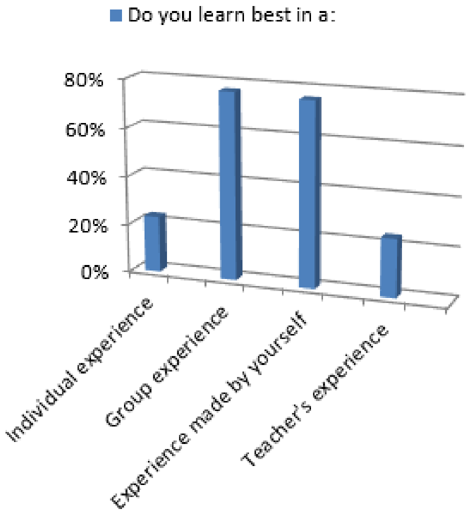

Fig. 5. Types of Experience that Students Learn Best.

D. Progress of the Practical Work Sessions

For students, the lesson must be flexible enough to integrate the discussion on a topical subject if the opportunity arises; for this, we asked the student's opinions on the course of the practical sessions (Fig. 6).

It appears that:

- The majority of the students questioned affirm that the teacher helps to build knowledge and overcome the difficulties encountered in understanding physical and chemical concepts.
- Most students are very interested in experimental activities; with the majority finding that the teacher helps them better understand the course.
- The results of this document have shown that the use of experience (under the guidance of the teacher), as an educational means in the teaching of the physical sciences and plays an important role among learners in the plan of acquisition of correct knowledge and concepts related to the program.

The teachers, for their part, emphasize their role to play in this learning as a student guide, in particular by validating or correcting the student's actions during the session.

For the last part concerning the three open questions, is not discussed in this report. The reason is that the majority of students surveyed did not answer these questions.

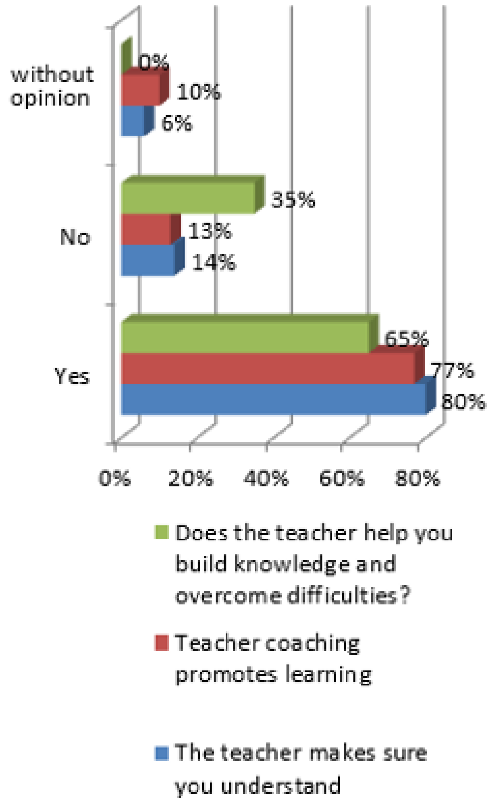

Fig. 6. Role of the Teacher in the Practical Work Sessions.

IV. Conclusion

Our work aimed to explore the role played by experience from the students' point of view. The results obtained according to the statistics were favorable and benevolent and go to achieve the objective of the research and respond to the problem raised. The results that we can draw from our brief experience allowed us to raise many points of interest in our opinion:

- The importance of the physical sciences comes through experimentation, whether it is a demonstration in the classroom or the form of practical work, carried out in groups by the students themselves.
- The classroom teacher's experiment helps to understand physical and chemical phenomena and can be done before or after studying the theory.
- Try to vary as much as possible in the practical work sessions, showing the theory before the experiment or letting them discover the theory. We could see that they preferred to know the theory before applying it to the labs.
- Practical work PW helps students to visualize the concepts taught, explore and develop their critical thinking skills.

We can recommend to information and communication technologies, in particular carrying out practical experiments using digital tools in environments which depend on certain factors which seem to influence these practices.

Indeed, the reflection on the modalities of digital use by students gives rise to several debates [38].

In addition, and a context of virtual experiential learning, several pedagogical approaches can reinforce the playful learning approach, particularly at a distance, which thus represents a powerful vector for promoting socio-professional skills [39].

To this is added the importance of the educational act and the effective role played by the school in the construction of society based on solidarity and equal opportunities in different social and environmental environments [40].

V. Recommendations

For research in didactics, this study can serve as a support for various didactic reflections on experimental practice and in particular, the development of practical work in physical sciences taking into account the opinions of learners. It can allow a reflection on an interaction between pupil and teacher and, between groups of pupils to promote their autonomy and participation in the construction of their knowledge.

An interesting avenue for future research would be to seek to confirm these results by using a larger sample by conducting more similar experiments in other scientific disciplines to be able to draw a more general conclusion.

In addition, we can identify in future research the constraints and obstacles hindering the integration of information and communication technologies for practical laboratory work (lack of training, software, appropriate materials, assistance administrative, etc.).

We can thus take advantage of the learning difficulties often detected when learners do not reach the level required for their age groups. They can take the form of poor motivation, limited memorization or concentration, inability to solve problems, maladaptive social behaviors, etc. [41].

The concepts of evaluation and oral communication are also important, making it possible to gradually improve learners' communication techniques and skills, while maintaining minimum stress and keeping the oral communication project in its persuasive dimension [42].

We can refer to the various works of educational researchers, such as those of Fallon in 2019 who explained that the first research focused on understanding scientific concepts using physical equipment, but technological advances mean now that there are new options for introducing this learning, through the use of technology and simulation.

Indeed, the results indicate that the students developed a solid foundation of procedural knowledge about building different circuits and functional knowledge about circuit components which they applied to different circuit designs.

Adding that teachers need to be very vigilant and work closely with learners, to ensure that accurate understanding is developed [43].

We can thus appeal to the research of Yardley's 2012 [44], research aim to introduce readers to the theories underlying experiential learning, which considers the theoretical basis of experiential learning from a learning perspective social and constructionist and applies it to three stages of medical education: the first experience in the workplace, internships, and residency.

Another study investigated the level of usefulness of e-module based on experiential learning in the physical sciences. The authors worked on Research and Development (R&D). The method used is a descriptive method with data collection instruments, namely the usefulness questionnaire of the electronic module evaluated by the teacher.

The results showed that e-modules based on experiential learning were very useful in learning physics [45].

The results obtained can be exploited in future attempts to ensure better integration of the experience in the Moroccan education system, the main actors must collaborate to overcome the obstacles that prevent this integration, namely: the Ministry of Education and of training, and the teacher.

VI. Limitations

Although this study yielded important results in the quantitative database dealing with the importance of experimental practice in the teaching of the physical sciences, it has certain limitations.

Indeed, the research is limited to a small sample belonging to two provincial directorates of the Ministry of Education and National Training; Sidi Bernoussi and My Rchid belonging to the Casablanca-Settat regional academy in Morocco.

We did not consider the rural environment. This was due to the lack of equipment and resources available to the research team, which forced us to work only in the Casablanca-Settat region.

Another limitation is that we have relied solely on the physical sciences, rather than other important scientific disciplines that are meant to be incorporated and generalized in this study.

Acknowledgment

We warmly thank all the teachers and all the administrative staff of the chemistry department affiliated with the Ben M'Sick Faculty of Sciences of the Hassan II University of Casablanca for their support and help in carrying out this work.

Fit-Gap Analysis: Pre-Fit-Gap Analysis Recommendations and Decision Support Model

LAHLOU Imane, MOTAKI Nourredine, SARSRI Driss, L'YARFI Hanane
Nationale School of Applied Sciences of Tangier
Tangier, Morocco

***Abstract*—Enterprise Resource Planning (ERP) system has been defined as a configurable Commercial Off-The-Shelf (COTS) system integrated into multiple business functions. For most companies, adopting ERP has become necessary to maintain market competitiveness. However, ERP implementation is still critical because project success depends on multiple parameters and involves several stakeholders. This article deals with the Fit-Gap analysis stage, which is an essential step in ERP implementation. This study was carried out through a literature review and interviews with experts to gather information and support stakeholders toward a successful Fit-Gap phase. It presents a set of recommendations for clients and consultants to consider before starting the Fit-Gap Analysis phase, and it presents an approach, with a decision support model represented as Business Process Modelling Notation (BPMN) based on several parameters to be used during the Fit-Gap Analysis stage to bridge gaps. The results obtained are intended for clients and consultants to make the most rational decision to bridge gaps based on the recommendations found, the approach and the decision support models presented.**

***Keywords*—ERP systems; misfit; customisation; fit-gap analysis**

I. Introduction

Information systems are at the company's core [1]. Indeed, an information system is composed of workers, processes, systems, applications, databases, and rules. It is accountable for storage and information processing. It provides information to the employees [1]. Successful company management is attainable by providing the right information to the right person. However, an efficient information system helps to have a productive and competitive company. Many enterprises have and use an Enterprise Resource Planning (ERP) system for its managerial characteristics.

ERP is a software package that automates and integrates a company's business processes [2]. Nowadays, Small and Medium-sized (SMEs) and Large Enterprises are adopting these systems for their many organisational advantages.

Scientific research has focused on ERP implementation since it is a significant phase in its life cycle. Researchers have also emphasised some key success factors, given the high degree of failure rate cited in previous research and observed in the field [3] [4] [5] [6].

Several success factors for the implementation project have been mentioned in the literature, among which we found that the ERP was not adapted to the company's business processes. Indeed, the ERP does not always meet the customer's needs. Here, we notice a gap, or what is also known as a misfit, between the system and the company's business process. Therefore, this gap can be bridged in several decision-making [7]:

- Entirely adopt the ERP standards and completely abandon its processes (we called this the vanilla method) through the Business Process of Re-engineering (BPR).
- Waive some of its established requirements.
- Find workarounds to bridge this gap (this may be achieved by introducing other applications or manual work).
- Customise the ERP system to fit the company's processes.

The company should decide the strategy to align the ERP systems with the customer needs and business processes, which will inevitably be a project success factor. Leading and evaluating this decision-making is an interesting aspect to consider. Therefore, it is going to guarantee the project's success. Making the right decision is a key factor to avoid falling into a standard problem of ERP systems implementation i.e., over-customisation.

ERP over-customisation is a classical issue. Several research pathways have approached the issue from different angles to address it, in a theoretical or empirical way. However, the tools and methods that have been developed only propose a partial solution to the problem. Hence, the need to develop a new study includes a solution to solve the entire issue. Even though scientific research has a keen interest in this problem, it is still topical to find companies that do not handle having a system set up correctly to meet their needs. The cause is often because of unsuccessful management of gaps.

This article deals with the Fit-Gap Analysis phase by presenting first, the literature review concerning this phase; Second, recommendations to be taken into consideration before starting the Fit-Gap Analysis stage. And finally, an approach and decision support model to address gaps.

II. Literature Review

To define this study and understand the proposed problem, the following section discusses some points that are directly related to the subject through a literature review i.e., ERP misfit, misfit types, Fit-Gap Analysis, ERP customisation, and synthesis.

A. ERP Misfit

ERP misfit is a derivation of a broader concept called Task Technology Misfit (TTF) to explain the gap between ERP systems in terms of technology and the organisation's requirements [2]. Fig. 1 explains it in an illustration form [8]. Indeed, several studies have used this concept to have improved clarification regarding ERP misfit [9] [3] [10]. Therefore, it would be wise to learn more about the TTF and investigate the topic to have a better understanding of ERP misfit.

The TTF theory shows the degree of Information Technology (IT) capability to support user requirements. It is important to state that information systems can only have positive effects on the system or the user performance if they align with the user requirements in terms of tasks [11]. It is, therefore, clear that TTF is an excellent system performance indicator and even better than user satisfaction or technology use [12].

The projection of the TTF theory on ERP systems is, therefore, being the ERP misfit. To have an efficient ERP and better use of it, it is important to have a high degree of fits and consequently a very low degree of misfits. The primary cause of failure in implementation projects reports this ERP misfit with the customer's requirements [13]. This is a real problem to be taken seriously when implementing an ERP in a company. This is because it could cause much more damage than poor performance or reduced flexibility and agility [14]. It could also lead to large financial losses on the scale of hundreds of millions of dollars, or even near-bankruptcy [15].

B. Misfit Types

Many studies have classified misfits according to several categories and different angles, ranging from broad categories to subcategories. There are perceived misfits and real misfits [16]. It remains significant to distinguish the two misfits to know how to solve them [17].

Perceived misfits are misfits that do not cause any difficulty in the business or taxes. They are usually caused by ERP systems functioning ignorance, unrealistic customer expectations, and resistance to change. No matter how well the ERP technically works, it can still face opposition. So having motivated users and cooperation from the business team is crucial [18].

Real misfits are the true inadequacy of the ERP systems with the customer needs, including imposed misfits and voluntary misfits [15]. The imposed misfits are therefore due to either an obligation set by the authorities or by industrial standards [19], contrary to the voluntary misfits, which are company choices to distinguish itself in the market [7].

There are two other misfit types that can be considered subcategories of the previous types, "deep structures" and "surface structure" [20]. The deep structure type is at the core of misfits. They occur when things, properties, states, or transformations are erroneous or represent deficiencies in the system [21]. In addition, surface misfits can cause mismatches if the software does not offer the proper format for reports, provide the appropriate roles to access information, or have a suitable user interface [7].

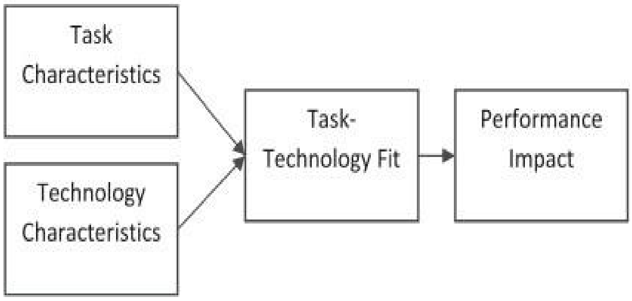

Fig. 1. Task Technology Misfit Diagram.

There is another misfits classification made by Soh et al. by grouping the most common mismatches into three categories: input, processes, and output misfits [21].

Input misfit is the inability of the ERP systems to capture different objects, attributes, or documents in the ERP database [22]. It is a misfit concerning the data entries and the diverse relationships between the entities in the data model [21]. It is natural that the absence of certain elements, in terms of data, will lead to severe software deficiency and will affect its performance [2]. Therefore, input misfits can be included in the deep misfit category [16].

Process misfit refers to, the incompatibility between the business requirements and the ERP systems in terms of required processes and procedures [21]. ERP is supposed to represent the workflow activities of the enterprise as they are in the real world. This inability to model them in the ERP system is a process misfit. Typically, that will affect information quality, presenting the user with poor quality or illogical information [2]. This misfit category is also included in the deep misfit [16].

Output misfit is the incompatibility between the ERP systems and the business requirements, in terms of information format presentation, interface content, or reports. The information which is poorly presented to the user will take an extended amount of time to be understood and could eventually be misinterpreted [23]. Therefore, output misfits can be included in the surface misfits [16].

Another category can be added to the three other types. Established by Soh et al, it is the latent structure [20] containing three additional categories proposed by D.M. Strong and O. Volkoff, i.e., role misfit , control misfit, and organisational culture misfit. In this article, only input, process, and output misfits are treated. Fig. 2 represents misfit types according to Eli et al., Joost A. A. van Beijsterveld and Willem J. H. van Groenendaal and Tan Shiang-Yen et al. [7] [16] [2].

C. Fit-Gap Analysis

Fit-Gap Analysis is a critical phase in the ERP life cycle. It is used for ERP systems selection and to generate inputs for the design phase [24]. Therefore, we note high-level Fit-Gap analysis in ERP pre-implementation and detailed Fit-Gap Analysis during implementation projects [25]. Fit-Gap Analysis is conducted by several stakeholders: ERP vendors, consultants in charge of the implementation project, and customers who will implement the ERP systems [26].

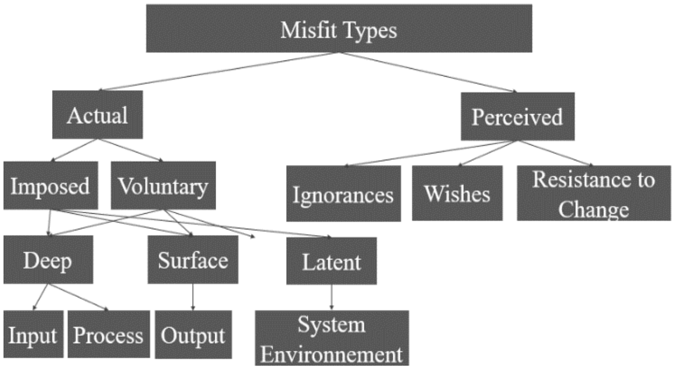

Fig. 2. Misfits Type.

In high-Level Fit-Gap Analysis, the aim is to select the most suitable ERP systems for the company [8]. It is based on a fit between the customer requirements and the ERP systems capability. It is, therefore, a matter of minimising the gap between the ERP systems and the customer needs by selecting the ERP that best meets these criteria. The right choice will increase the chances of successful project implementation.

The high-Level Fit-Gap Analysis can be done by following these steps [11]:

- a review of customers' business needs and ERP systems capabilities.
- the selection of a comparison approach.
- a comparison of business needs with ERP systems capabilities and the documentation of fits and gaps.

Once the most suitable ERP is selected, the company can move on to the next phase, which is the detailed Fit-Gap Analysis. Indeed, this phase is critical. It is about collecting all the misfits and fits between the ERP and the customer requirements. As soon as the set of gaps is determined, it should be resolved by a successful implementation of the project [24]. The gap resolution can be done either by customising the ERP system or by adjusting to business processes. The detailed Fit-Gap Analysis is therefore used to determine the degree of change that needs to be made to both the softwares and the company [27].

D. ERP Customisation

Customisation is a term used to refer to ERP modification to align with customer needs [28] [29] [30]. The customer specifies his business requirements. If the ERP meets them, there will be no need to customise the system. Otherwise, the client is left with several alternatives, among them, ERP customisation [31]. To make such a decision, several parameters come into play. We often find the cost-benefit aspect as key [32]. However, some important parameters are not always taken into consideration by stakeholders. For instance, S. Koch and K. Mitteregger insist on the study maintenance and its costs to decide whether to customise ERP systems or not [33].

Despite the many benefits that ERP customisation can bring, such as increasing the local efficiency of the company [34], and user satisfaction [35], most scientific research remains categorical about minimising customisation to achieve a successful implementation project [36] [37]. Indeed, customisation increases the duration of the implementation project. It can generate bugs and update issues. One can even say that it can jeopardise the many benefits that ERP can bring [2] [38]. However, it is still usually necessary. The question one might ask is, what limit must never be exceeded to not sway towards over-customisation?

E. Synthesis

In the literature there are various studies proposing several techniques and methods to provide a solution to ERP misfit, several evaluation methods have been proposed to treat the issue partially.

Numerous studies proposed to study the relationship between ERP customisation and system maintenance. S. Koch and K. Mitteregger conducted a study to evaluate the relationship between customisation degree and support effort [33]. While B. Light presented, two cases, describing customisation performed and the maintenance implications [28].

S. Parthasarathy and S. Sharma realised the research on the customised ERP efficiency. They adopted a quantitative method using Data Envelopment Analysis model [37]. The purpose is to examine customised ERP efficiency and the relationship between customisation degree and ERP package efficiency [37].

Customisation can also impact ERP quality. S. Parthasarathy realised an empirical study based on framework and advanced a set of hypotheses to establish the relationship between the customisation carried out by ERP vendors and ERP resulting quality [31].

Customisation has also to take into account different types of ERP systems. Elin Uppström et al. proposed different options for Cloud ERP and One-premise ERP and discuss the difference between there [39].

C. S.-P. Ng treated the relationship between ERP alignment types, operational characteristics, degree of system use, user satisfaction, and system benefits [35].

Hustad et al. have described the different types of misfits and types of tailoring [7].

Table I (Appendix) is a synthesis of these studies carried out in the previous research about the Fit-Gap Analysis phase, ERP misfit, and ERP customisation.

Based on the research related to ERP misfit, Fit-Gap Analysis, and ERP customisation, it is clear that there is a need for a study that takes into account all of this research to support consultants and clients during the pre-Fit-Gap Analysis phase and the Fit-Gap Analysis.

III. Research Methodology

This study aims to avoid redundant errors in previous projects in the Fit-Gap Analysis phase. A set of recommendations are presented concerning Fit-Gap Analysis. This recommendation should be reviewed before starting this stage. Later in this paper, an approach and a support model are presented as Business Process Modelling Notation (BPMN) to support stakeholders in this phase. These two main objectives can be formulated as three questions:

RQ1: What are the recommendations that should be reviewed before starting the Fit-Gap Analysis phase?

RQ2: What are the parameters to consider during the Fit-Gap Analysis phase?

RQ3: Which decision support model should be used to address the gap?

Furthermore, this study was conducted based on a literature review. It uses Kitchenham et al. methodological guidelines [40] [41]. The relevant literature on the Fit-Gap Analysis stage, ERP customisation, and ERP misfit were reviewed, summarized and supplemented with information available from case studies and surveys. We also identified the recommendations to be considered before the Fit-Gap Analysis stage and the most important parameters to bridge gaps through the literature. We could establish this study by following three main steps: planning, conducting, and reporting.

Moreover, theoretical findings related to Fit-Gap Analysis were combined with ERP practical recommendations to derive insights.

Subsquently, we conducted interviews with experts in ERP systems: consultant in the digital transformation of financial services, legal services, and HR management, SAP BO Project Manager, and Associate Manager SAP – S/4HANA certified. The interviews were based on a questionnaire (Appendix).

Fig. 3 explains the methodology followed in diagram form.

Obtaining Results
Elaboration Pre-Fit-Gap Analysis recommendations and Support Model Fit-Gap Analysis
Interview with experts
Data Triangulation

Fig. 3. Illustration of the Methodology Followed.

To establish a model for companies and consultants, some key indicators need to be defined:

- accessible and understandable,
- easy to understand and implement, and
- representative of reality and adaptable to implementation projects.

IV. Result and Discussion

After the literature and experts recommendations, Pre-Fit-Gap Analysis recommendations are established to consult and consider before initiating the Fit-Gap Analysis. An approach and a decision support model to support stakeholders during the Fit-Gap Analysis are conceptualised using BPMN. Fig. 4 presents the study results.

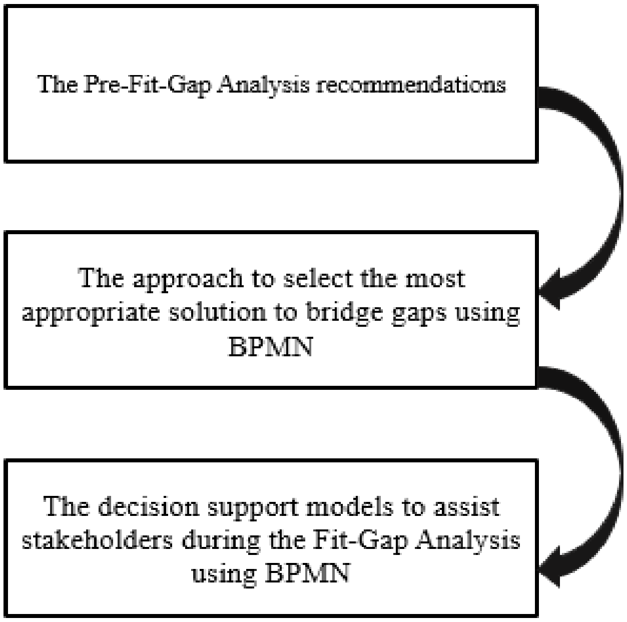
This study will support the consultants and the customers throughout the Fit-Gap Analysis phase consequently the failure rate of the implementation project will be reduced. The first step is to give them recommendations to consider before starting the Fit-Gap Analysis stage to avoid redundant mistakes in previous implementation projects. The second step is to present an approach and a decision support model to prepare them for the Fit-Gap Analysis phase to bridge gaps.

A. *Pre-Fit-Gap Analysis Recommendations*

Pre-Fit-Gap Analysis recommendations are intended for both the customer and the consultants. They will be handy to prepare the stakeholders for the Fit-Gap Analysis phase and support them in making the most rational decisions, thus, avoiding mistakes that could lead to failure. Pre-Fit-Gap Analysis recommendations are presented and discussed in the eleven recommendations below.

1) Minimise customisation while trying to realise that there is a trade-off between effort and value: As mentioned, several times in the literature, customisation generates an additional cost and increases the implementation project duration. Studies have converged on a single result: customisation should be minimised to succeed [42] [43] [3]. T. Sommers and K. Nelson analysed the responses of 86 organisations, confirming this result [3].

S. Parthasarathy and S. Sharma have shown through their studies that low customisation would increase ERP efficiency. According to this study, the best situation for better system efficiency in terms of productivity is adopting the ERP standards, with minimal customisation [37].



The Pre-Fit-Gap Analysis recommendations
The approach to select the most appropriate solution to bridge gaps using BPMN
The decision support models to assist stakeholders during the Fit-Gap Analysis using BPMN

Fig. 4. Illustration of the Study Results.

Customisation risks are that it introduces errors into the system, making updates more difficult and increasing maintenance costs [2] [33]. A study result made by S. Koch and K. Mitteregger shows that there is a correlation between customisation and ERP support effort. Therefore, increasing the customisation degree will increase the support effort specifically for the help desk [33].

It is clear from the previous studies regarding ERP customisation and the success factors of the implementation project that minimal customisation would be the most appropriate for ERP implementation success. Therefore, before starting the Fit-Gap Analysis phase, both the business team and the consultants should be aware that customisation should be minimised. It should be used only in case of extreme necessity and in exceptional circumstances, such as losing competitiveness in the market [37].

It is, therefore, making a compromise between effort and benefit by trying to minimise the ratio between effort and benefit. However, the effort has been defined in several ways and estimated with different methods. S. Koch and J. Mitlöhner proposed a study reviewing the literature on effort estimation methods for ERP projects, their validations, and limitations [32].

2) Train the internal team on the operation and ERP systems functionalities: Several studies have investigated the Critical Success Factors (CSF) of the ERP implementation project [3] [4] [5] [6]. Given the number of failures that have occurred over the years, Muscatello et al. reported that 40% of the implementation projects are partially successful while 20% fail [44].

Among the CFSs found in the literature that leads implementation projects to success, there is training [45]. This is a vital component of the project. However, there are two stages of training. A training session for the business team before starting the Fit-Gap Analysis phase, and another training session for end-users. Both steps are crucial for the implementation project to be successful. However, this article is more concerned with the first one.

Training can also increase user satisfaction. It is an investment that brings individual benefits and advantages to the entire company [5]. Indeed, this concerns SMEs and large organisations. Laukkanen et al. reported in their study that SMEs have poor knowledge of the ERP systems and that this should change [46].

The Business team should be trained on the ERP systems and their functionalities before starting the Fit-Gap Analysis phase to have a positive attitude towards its implementation. This would increase its acceptance by project stakeholders and end-users [47]. And therefore, training is an excellent approach to reducing resistance to change [46], thus avoiding over-customisation. It is also a way of involving the users and the business team in the implementation project, especially the Fit-Gap Analysis phase, that leads to better system optimisation and consequently a better use of the system [48].

3) Ensure operational departments' involvement: Department managers should be involved in the implementation project and especially Fit-Gap Analysis. It is not the consultants who have to decide on ERP customisation. The internal experts of the company should also be involved in this decision. The idea is not to rely heavily on the consultants, but to lead the project together by engaging the internal team more [43].

The operational department's involvement would conduct to a better ERP acceptance. This would lead to project ownership and participation in the organisation's improvement and subsequently reduce resistance to change. The company will ensure that the project is both technical and managerial success.

4) Work in harmony between internal and external teams: A Fit-Gap Analysis is carried out in teams by several stakeholders. To succeed in the Fit-Gap Analysis and achieve the fixed goals, it is essential to have cohesion within the team.

It is challenging to build the client's trust in external experts especially when client believes that they will maximise customisation to increase implementation cost since it is billed by the hour [43]. However, trusting the consultants is essential because they know the ERP systems better and can suggest improvements to the business.

Trust can only be established between internal and external teams by following certain aspects:

- having greater transparency of both parties, and
- making sure that the consultants have enough experience and knowledge of the business.by putting in place business team training.

Conflict management is also an important factor in Fit-Gap Analysis success. It allows for better group cohesion and better trust between stakeholders which opens the possibility for several solutions to the problems [49].

G. Chen et al. considered three approaches to conflict management: cooperative, competitive, and avoiding [50]. The cooperative approach allows better teamwork based on mutual help and spontaneous communication between team members. This approach also permits an exchange of ideas that stimulates creativity and innovative solutions [49].

The competitive approach is another alternative used when leaders expect very high performance. They prefer to use conflict to choose the best-performing ideas. This approach creates a competition between the stakeholders which limits the Fit-Gap Analysis phase's success [49].

The avoiding approach is based on solving problems early before they become serious issues. Leaders who use this approach tend to pay special attention to the professional needs of their subordinates. This is a conflict prevention approach. However, this method does not resolve the conflict but dissipates it [49].

It is better to adopt the cooperative approach that will push for better cohesion and communication and stay away from the avoiding approach that limits stakeholder's productivity. This way, leaders will have high expectations; hence they will employ the competitive approach which can be beneficial if used moderately [49].

5) Know the technical implementation type desired by the client: After selecting the solution that will best fit the customer's needs, a selection of deployment options is then made. The company faces several deployment options that highly depend on the system's location and other criteria chosen by the client. These criteria can be IT footprint reduction, customisation degree estimated, or update frequency (SAP Consultant). It is, therefore, crucial to be aware of deployment options chosen by the company before starting the Fit-Gap Analysis phase, as it has a direct relationship with it. But before explaining this point further, we need to get acquainted with the existing deployment options by taking the example of a leader in the ERP market, which is SAP.

There are three types of deployment options that SAP offers to its customers, on-premise, hosted private cloud, and public cloud. With an on-premise deployment, the customer deploys the licensed SAP software in its on-premise data center, i.e. the ERP is loaded and runs on the company's infrastructure, such as servers, networks, computers, etc. [46]. The customer opts for perpetual user rights for the software. He also becomes responsible for the associated hardware, implementation, and ongoing operations. Besides, on-premise ERP offers freedom of customisation [46] [51].

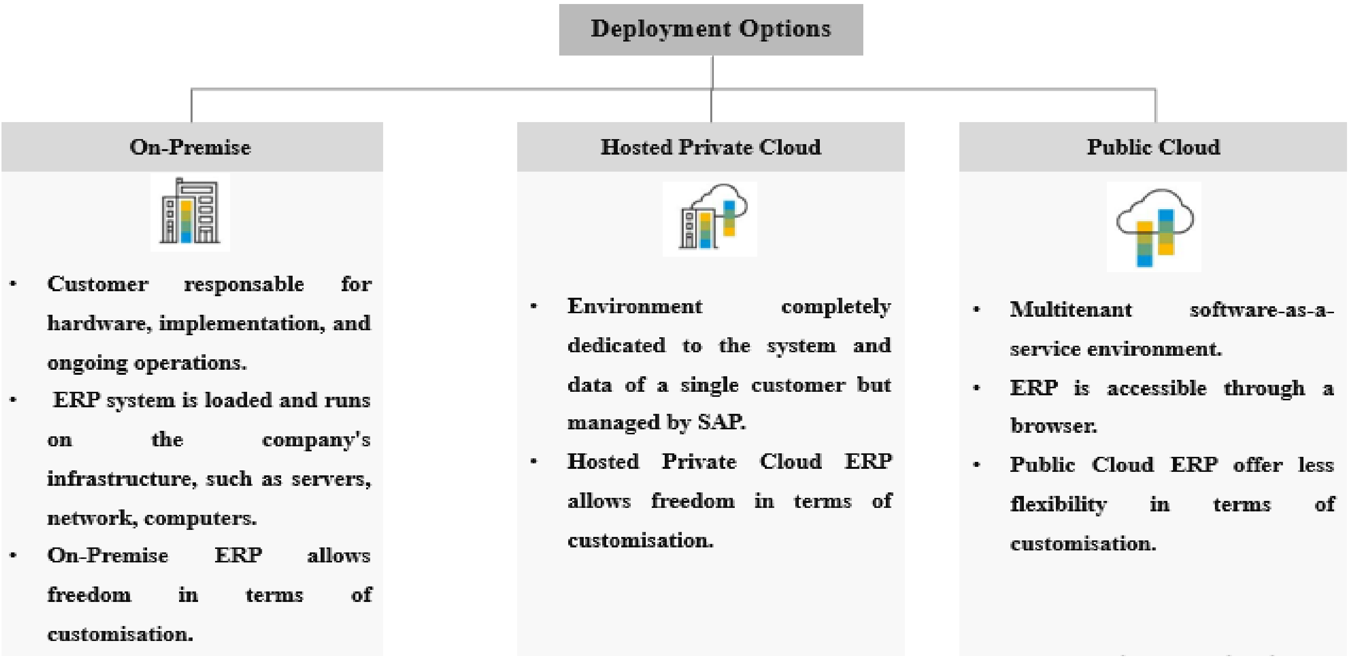
The second option is hosted private cloud, which is an environment entirely dedicated to the system and data of a single customer but managed by SAP. It is a deployment either through a perpetual license or a subscription commitment. That means the company can have its license or buy it from SAP and host it at SAP. SAP, in this case, also offers management and application service. Alternatively, the company may opt for a subscription but still decide to have its dedicated environment. In this deployment option, the company also has freedom of customisation (SAP Consultant).

The third option is the public cloud. This is a shared environment between several customers, and the software is present as Software As A Service (SAAS). SAAS is accessible through a browser [5]. Here, the company opts for a subscription-based commitment while SAP manages the software. In this deployment, the customer does not have much freedom of customisation because the source code is shared between several customers (SAP Consultant).

We have seen that some deployment options present more freedom of customisation, namely on-premise and hosted private cloud deployment, while SAAS offers less flexibility in terms of customisation. That's why it is important to know what deployment type the company has opted for before starting the Fit-Gap Analysis phase. There is no point in considering source code customisation if it is not possible with a SAAS deployment. Fig. 5 explains the different deployment options offered by SAP.

6) Evaluate the time and budget required for the implementation project: A project is a set of actions to be carried out in a predetermined time, putting in place human and material resources, that are budgeted for, and resulting in a pack of deliverables [2].

In any project, it is a question of time and budget. Before starting the Fit-Gap Analysis phase, it is essential to know the pre-defined time and budget to not exceed them. It is a question of ensuring that the solutions were chosen in the Fit-Gap Analysis phase regarding these two criteria.



- Customer responsable for hardware, implementation, and ongoing operations.
- ERP system is loaded and runs on the company's infrastructure, such as servers, network, computers.
- On-Premise ERP allows freedom in terms of customisation.

- Environment completely dedicated to the system and data of a single customer but managed by SAP.
- Hosted Private Cloud ERP allows freedom in terms of customisation.

- Multitenant software-as-a-service environment.
- ERP is accessible through a browser.
- Public Cloud ERP offer less flexibility in terms of customisation.

Fig. 5. Deployment Options.

Customisation may be seen by some as a solution that does not require an enormous cost in the short term. But it is a tremendous investment in the long- term compared to a BPR. If the company cannot implement BPR, it commits to allocating resources in the long term after the ERP is implemented [52]. To control the Total Cost of Ownership (TCO), the company should follow a structured framework to justify the radical changes that the ERP imposes [52].

Before considering any solution to bridge the gap, it is required to evaluate its cost and duration. It is, therefore, necessary to know the time and cost in the short and long term that each solution will generate to respect and best utilise the client's resources.

7) Learn about the standards proposed by the vendor: ERP systems are integrated software composed of business processes that are recognised as best practices in the industry [44]. It is critical to be aware of these standards that the ERP offers to aim at improving the company's business.

Indeed, these standards can improve business processes because they are the best practices identified across many industries. It is not only a matter of avoiding costly and risky customisation, but about improving the company's performance by adopting these practices. For this reason, it is decisive to choose the ERP that contains the standards that best fit the company's business. This is done by implementing an ERP systems selection strategy. For instance, ERP selection criteria using critical decisions analysis [53].

Before starting the Fit-Gap Analysis phase, it is essential to determine all possibilities offered by the chosen system, especially if it improves the company's performance.

8) Know flexibility degree of the system: Flexibility has been a multidimensional construct, representing the ability of a system to make the necessary readjustments to respond to environmental changes without making significant sacrifices to the company's performance [54]. Then, it is simply up to the adaptability of the system to change.

M. W. Mudie and D. J. Schafer studied ERP flexibility as an information system and not just its technical aspect [55]. They, therefore, cited two of its major components, the technical infrastructure, and the human infrastructure. The technical infrastructure is composed of applications, data, and technological configuration, while the human infrastructure is composed of knowledge, and skills required for the effective management of information technology resources in the organisation [56].

This article focuses on the technical aspect of flexibility as an element to be considered before the Fit-Gap Analysis phase. According to Byrd and Turner, the technical infrastructure flexibility includes integration and modularity [56].

Thus, before starting the Fit-Gap Analysis phase, it is crucial to evaluate the modularity aspect of the system. Duncan defined modularity as the ability to add, change and remove any software, hardware, or infrastructure data component with ease and without overall damage [57]. The idea is to evaluate what options the system offers in terms of configuration in case of a gap before considering source code modification. Once again, it is about studying all the possibilities available to resolve the gap before considering source code customisation.

9) Know the company's information technology infrastructure (IT infrastructure): IT infrastructure is the portfolio of resources that are used and shared by the company, whether at a technical or organisational level [58], allowing data to be exchanged within and with other companies. The company's IT infrastructure enables data development and use and the anticipation of future business requirements [55].

It is, therefore, significant to determine the IT infrastructure that the firm has to recognise the company's resources in human and technical capital before starting the Fit-Gap Analysis phase. This would affect solution selection to bridge the gap. Sometimes, the company cannot consider a BPR solution if it does not have certain human resources. This is also the case for the ERP customisation that requires some IT knowledge that the company should have or seek to have.

10)Know the Fit-Gap Analysis phase impact on the system maintenance: Before discussing the relationship between system maintenance and the Fit-Gap Analysis phase, it is important to define what system maintenance is. After the ERP systems implementation, it then moves to the next phase, the operation, and maintenance phase. According to Stefan Koch and Kurt Mitteregger, system maintenance begins with the vendor and first version delivery and ends with the entire product retirement. It comprises all changes to the system after it is operational. However, a distinction should be made between corrective, adaptive, and product care maintenance [33].

There is an unavoidable link between maintenance and ERP implementation projects. Hence there is a relationship between the Fit-Gap Analysis phase and maintenance [52]. The annual maintenance cost can reach up to 25% of the implementation project. This is partly because of customisation, which causes additional long-term maintenance costs. ERP vendors neither encourage this practice nor support any customisation requested by the customer [29]. The maintenance is costly because of customisation and is entirely borne by the customer [52].

It is essential to know that with each update or improvement applied to the ERP systems, all customisation should be reviewed, reapplied, and retested [59]. This becomes more complex when the person who built the customisation is not available to review, reapply or retest it. If the customer decides not to apply these updates, he may be held responsible for all the bugs in the system [52].

The literature has also emphasised the importance of communicating and collaborating with external stakeholders, especially the ERP system's vendor, to maintain the system successfully [33].

The customer should not forget that even with successful implementation, improper management of its maintenance can be costly, and can even prevent the customer from realising

ERP systems benefits. It can also cause daily transactions to fail [60].

Before starting the Fit-Gap Analysis phase, it is important to know the maintenance cost, the strategy to deal with it, and to consider it when choosing a solution during the Fit-Gap Analysis phase to estimate long-term TCO.

11)Know the company's operational characteristics complexity: The company's operational characteristics have been defined as the quantity and/or data complexity to be processed, the reports produced, the databases, and the operational processes interacting with other operational processes of different departments. For a multinational company, operational characteristics complexity increases. This is normal given data size and the frequent interaction with other business units, customers and supplier numbers [35].

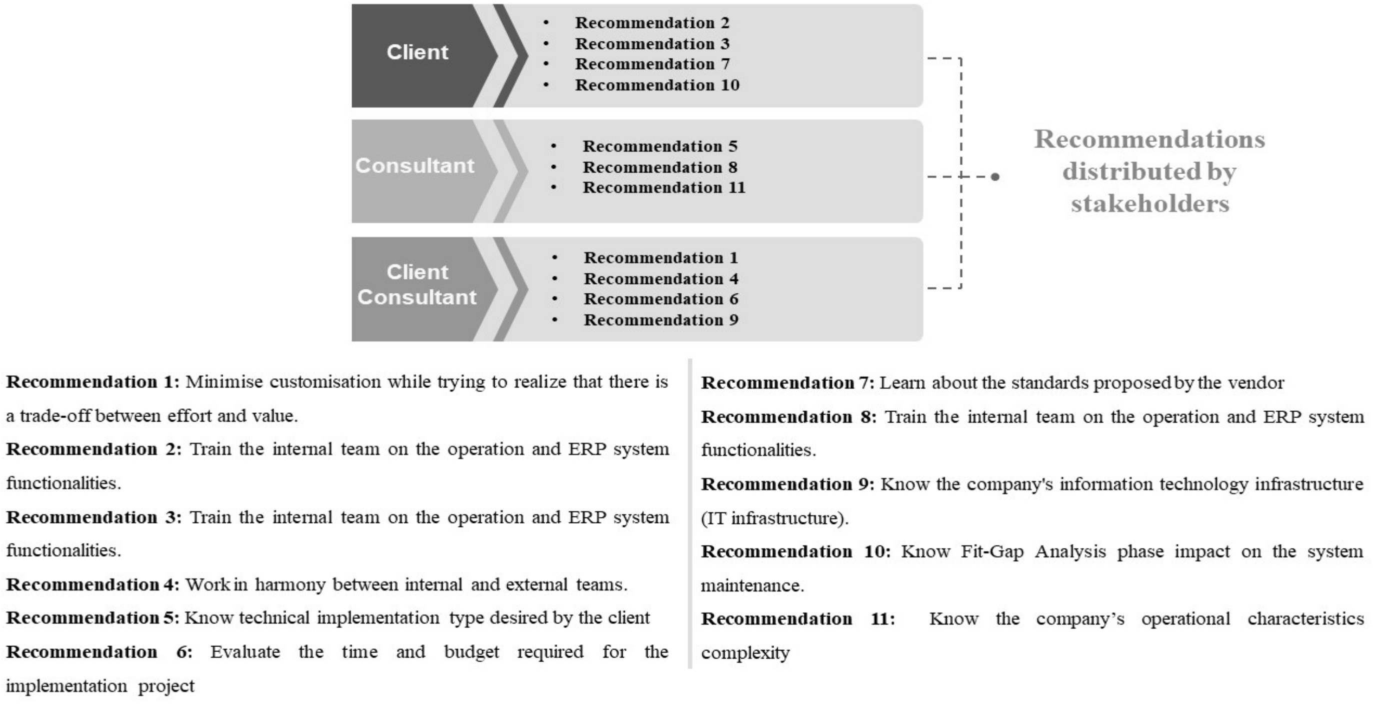
Ragwusky and Gefen have shown that ERP systems for large structures are better suited and adjusted for multinationals, hence companies with high operational characteristics' complexity [61]. This was confirmed by the study conducted by Celeste See-Pui Ng. It showed that when operational characteristics complexity increases, this is associated with a better fit with the ERP systems, whether it is in terms of processes, interfaces, or data [35]. This result should be taken into consideration by the stakeholders. Before starting the Fit-Gap Analysis phase, it would be interesting to know the company's operational characteristics complexity to estimate the fit between the ERP systems and the customer's needs.

Fig. 6 lists all the pre-Fit-Gap analysis recommendations according to the different stakeholders.

B. *Approach to be followed during the Fit-Gap Analysis Phase*

To assist stakeholders to manage the Fit-Gap Analysis phase, we designed an approach based on the findings of D. Pajk and A. Kovačič [8] and Gattiker & Goodhue [17] (Fig. 7 and Fig. 8).

First, a comparison between the customer business need and ERP systems capability to identify a set of misfits and the fits should be done. We are not going to treat the fit case because it does not pose a problem. We are going to deal with the misfit case. It is a question of categorising it into perceived misfit or actual misfit. In case it is a perceived misfit, i.e., either resistance to change, wishful thinking, or ignorance of how the ERP works, it should be solved through training and human resource management. If it is a real misfit, the proposed model should be as follows.



Recommendation 1: Minimise customisation while trying to realize that there is a trade-off between effort and value.

Recommendation 2: Train the internal team on the operation and ERP system functionalities.

Recommendation 3: Train the internal team on the operation and ERP system functionalities.

Recommendation 4: Work in harmony between internal and external teams.

Recommendation 5: Know technical implementation type desired by the client

Recommendation 6: Evaluate the time and budget required for the implementation project

Recommendation 7: Learn about the standards proposed by the vendor

Recommendation 8: Train the internal team on the operation and ERP system functionalities.

Recommendation 9: Know the company's information technology infrastructure (IT infrastructure).

Recommendation 10: Know Fit-Gap Analysis phase impact on the system maintenance.

Recommendation 11: Know the company's operational characteristics complexity

Workaround Solution

Fig. 8. The Proposed Approach to Selecting the Appropriate Method to resolve the Gap.

Fig. 8 shows the approach to be followed in the Fit-Gap Analysis phase according to D. Pajk and A. Kovačič [8] and Gattiker & Goodhue [17] and subsequently proposed model application to bridge the gap.

C. Decision Support Model

We conceptualised a decision support model to support the stakeholders to manage gaps (Fig. 9, Fig. 10, Fig. 11 and, Fig. 12 in Appendix). It is based on the misfit type, the development cost, the implementation project time, the vendor’s roadmap, the uniqueness of the business processes, the criticality, frequency of the tasks, human infrastructure, and finally the data compatibility with the partners.

To apply the model, we require categorising the identified misfit. First, we need to know whether the misfit is perceived or real. Once in front of an actual misfit, it needs to be sub-categorised as either imposed misfit or voluntary misfit.

1) Imposed misfit: We are going to initially deal with the first case, which is the imposed misfit (Fig. 9 in Appendix). This misfit is what the authorities or industry standards impose. The company should comply with its requirements. However, customisation should be minimised. Therefore, before considering it, they should to look for other alternatives like consulting the vendor's roadmap, which may contain the imposed requirements.

If customisation is required, it should be analysed in terms of cost and time. It can be kept if it fits with the project duration and project budget. If not, a workaround can be proposed. It could be a third application or manual work. Fig. 9 (Appendix) explains the process to follow in the case of a realmisfit imposed.

2) Voluntary misfit: When it is a voluntary misfit, i.e., a misfit chosen by the company not imposed, the stakeholders should move on to another sub-categorisation and see if it is a surface misfit or a deep misfit (Fig. 10, Fig. 11, and Fig.12 in Appendix). If it is a deep misfit, it is then a misfit input or a misfit process.

In case it is an input misfit (Fig. 10 in Appendix), the vendor's roadmap should be consulted to see if it contains the requirements desired by the company. In case it does not, the task frequency and criticality concerned should be assessed. Assuming that the tasks are critical and frequent, customisation should be considered. Supposing not, the organisation should adapt to the system. Fig. 10 (Appendix) explains the model to be followed in the case of an input misfit.

Assuming that it is a misfit process (Fig. 11 in Appendix), then the vendor's roadmap should be consulted. If it does not contain the customer's requirements, the uniqueness of the business process in the market should be assessed. Supposing that it is a unique business process, customisation should be considered. If it is not, the company can start BPR while ensuring there is an adequate human infrastructure and no resistance to change. Fig. 11 (Appendix) explains the model to be taken in the process misfit case.

In the surface misfit case, it is, then, a question of misfit output (Fig. 12 in Appendix). The importance and coordination of the data format concerning the partners should be assessed.

In case the company's data format is already coordinated with the partners, customisation should be considered. Where the data format is not coordinated with the partners, the cost and time needed for the customisation should be discussed. And it may be possible to change the system and adapt it to the client's current format if this does not need an enormous investment. In case the company's data format is already coordinated with the partners, customisation should be considered. Fig. 12 (Appendix) explains the process to solve the gap in the misfit output case.

V. Conclusion and Future Work

The Fit-Gap Analysis is a crucial phase in the ERP implementation project. Identifying all the points leading to the success of the Fit-Gap Analysis is essential to technical and managerial success. Through the literature and business expert recommendations, we were able to collect a set of recommendations to be considered before the Fit-Gap Analysis phase. These recommendations should be consulted by both the consultants and the internal team.

These recommendations address the key points to consider before starting the Fit-Gap Analysis phase. They cover technical aspects, such as knowledge of the software's flexibility, technical implementation, system maintenance, minimisation of customisation, and the company's IT structure. Furthermore, a managerial aspect such as training, involvement of internal stakeholders, trust between consultants and internal team through improving communication, a better understanding of the standards proposed by the ERP, and a deeper insight of the company's functioning.

To assist the stakeholders in the implementation project to make the most rational decision in solving the gap based on the misfit type, we proposed a decision support model considering several parameters to bridge the gap: the development cost, the time of the implementation project, the vendor's roadmap, the business processes uniqueness, the adequate human infrastructure, the criticality and tasks frequency, and lastly data compatibility with the partners.

This model minimised customisation while respecting the company's resources. Therefore, before considering the system customisation, it is necessary to search for other ways to bridge the gap, such as consulting the vendor's roadmap, as it may contain the requirements requested by the customer. If customisation is considered, it is necessary to study its cost and time aspect before applying it. It is therefore improving the company's performance while bridging the gap.

This study can be improved by conducting a case study in the field to merge it. We can also address another aspect of the Fit-Gap Analysis phase. This is the evaluation of the chosen solution to bridge the gap through performance indicators and a post-Fit- Gap Analysis risk management study.

This study can also be refined by discussing the introduction of other technologies that can complement the ERP system and then solve ERP system issues, especially gaps. One such technology can be the blockchain. However, it is necessary to do an in-depth study of the blockchain technology since this technology is still in its early stages and requires seeing how it can complement the ERP system.

APPENDIX

TABLE I. CENSUS OF ARTICLES

Articles	Research Questions addressed by the articles
[35]	Does ERP system alignment influence system usage, user satisfaction, and system benefits?
	Do operational characteristics types influence the alignment of the ERP system, the degree of customisation, and system use?
	How does ERP system quality and/or service quality affect the relationship between ERP alignment types, operational characteristics, and degree of customisation in terms of system use, user satisfaction, and system benefits?
[33]	Does the degree of customisation have an influence on the maintenance and the degree of support? If so, is the influence positive or negative?
[8]	How do the reference models contribute to the Fit-Gap Analysis?
[16]	How do recognize the real misfit from those that are perceived?
	How to manage and understand the implementation of an ERP?
[31]	What impact does customisation have on ERP quality?
[37]	What is the relationship between ERP customisation and efficiency?
	How we can measure ERP system efficiency?
[62]	How can we know the degree of customization required for an early ERP implementatio
[7]	What are the different types of misfits? What are the types of tailoring?
	Is there a relationship between tailoring types and misfit types?
	What are the internal factors influencing making decisions process?
[39]	What changes need to be made to existing customisation options?
	What new ERP customisation options are available?
	Are the existing ERP customisation options viable for Cloud ERP?
[24]	What is the company's customisation impact preferences on the gap resolution strategy?
[63]	How we can establish customisation choices using nominal group technique and analytical hierarchy process?
[43]	Why do some companies adopt a very high level of customisation?
	What are the factors that drive ERP customisation?
	How do these factors lead to customisation?
[17]	What are the needs of consultants and software engineers in terms of requirements elicitation in the ERP domain?
	Can we provide a tool-based approach to requirements elicitation in the ERP domain?

	Can the tool-based approach support the daily work of consultants?
[28]	What customisation types are carried out to ERP software?
	Why do organisations undertake ERP software customisation?
	How might customisation impact future maintenance of the ERP software?
[33]	What is the relationship between the amount of customisation and the resulting support effort?
[15]	What are package-organisation misalignments?
	Why do package-organisation misalignments arise?
	When do organisations customise packages and when do they adapt to the package instead?
[43]	What are the factors that push ERP system customisation?
	How do these factors lead to ERP system customisation?
[49]	How do different transformational leadership behaviors influence the adoption of different conflict management methods and, consequently, influence the performance of ERP customisation projects?

An Improved Deep Learning Model of Chili Disease Recognition with Small Dataset

Nuramin Fitri Aminuddin, Zarina Tukiran, Ariffuddin Joret, Razali Tomari, Marlia Morsin
Department of Electrical and Electronic Engineering
Universiti Tun Hussein Onn Malaysia, Batu Pahat, 86400, Johor, Malaysia

***Abstract*—Due to its tasty and spicy fruit with nutritional qualities, chili is a demanding crop widely farmed around the world. Hence, it is essential to accurately determine the health status of chili for agricultural productivity. Recent years have seen impressive results in recognition fields due to deep learning approaches. However, deep learning models' networks need an abundant data to perform well and collecting enormous data for the networks is time-consuming and resource-intensive. A data augmentation method is proposed to overcome this problem. It was applied to a small dataset of healthy and diseased chili leaf by utilizing geometric transformation method. Eventually, two deep learning models of CNN and ResNet-18 were evaluated using augmented and original datasets. From a series of experiment, it can be concluded that the trained deep learning models using original and augmented datasets perform better with an average accuracy performance of 97%.**

Keywords—Chili leaf; deep learning; data augmentation; geometric transformation

I. Introduction

Chili (Capsicum sp.) is an important spice from the family Solanaceae that originates from South and Central America [1]. It is a demanding crop and extensively cultivated in tropical Asia and equatorial America with a high genetic diversity due to its edible and pungent fruit with nutritional values [2]. Vitamin C, potassium, phosphorus fibre, antioxidants like vitamin A, and flavonoids like β-carotene, α-carotene, lutein, zeaxanthin, and cryptoxanthin are among the nutritional values contained in a chili fruit which have the ability to suppress several human cancers [3]. However, owing to the impact of fungus, bacteria, viruses, pests, and climate on the chili cultivation process, the chili itself is susceptible to a variety of diseases. These diseases make it difficult for chili to thrive, reducing the production and quality of the fruit. It is estimated that 60-70 percent of diseases and early disease symptoms are detected just on leaves [4]. Hence, it is necessary to identify chili diseases precisely and implement early preventive and treatment measures.

Since the advent of deep learning, deep learning models have made significant advances in disease recognition [5]. Good performance from deep learning models normally needs a large number of parameters and enormous data to make these parameters operate properly. In order to do so, manual data collection and labelling [6] are required to get enormous data, which is resource-intensive and time-consuming. As a result, it can be hard to gather enough data to train the deep learning models, which significantly limits the accuracy of chili disease recognition.

With small collection of datasets, several research [7-10] in the chili agricultural field has used the data augmentation method to increase the volume of datasets. The method generates data artificially via adding augmented images to the existing dataset through either oversampling or warping [11]. By using oversampling augmentation such as generative adversarial networks (GANs), augmented images with a low likelihood of occurring label (abnormal) are added to the original datasets, preventing a deep learning model from being biassed toward the majority label of images during the recognition process. Even though GANs have intriguing promise, they need a substantial number of initial original images in order to train and create an augmented image [12]. As a result, depending on the initial size of the original dataset, GANs may not be a viable option.

In contrast, warping augmentations such as geometric transformation alter original images in such a way that their labels are maintained [13] , and this is accomplished without requiring a minimum amount of the original image to be present. Most of research [10, 13-15] that employed geometric transformation to augment original images concentrated on single transformation operation such as rotation, flipping, and scaling. To the best of the author knowledge, there has been very limited research on numerous fusions of geometric transformation operations in order to produce augmented images throughout the years. Hence, this research examines the data augmentation method known as a geometric transformation and its several transformation fusions on a small chili dataset. The augmented and original images are then fed into two deep learning models, Convolutional Neural Network (CNN) and Residual Network (ResNet-18), developed from scratch for chili disease recognition.

The contributions of this research findings can be summarized as follows. According to the findings of this research, the optimal level of accuracy for recognising chilli diseases depends on the category of datasets used and the size of the deep learning model. The finding implies that the best optimal recognition accuracy came from small datasets with both original and augmented images that were fed to a larger-sized model. This is in contrast to datasets with only original data (original datasets) and datasets with only augmented data (augmented datasets). All of the research experiments reveal that the deep learning models created from scratch are accurate to a maximum reported accuracy of 99.7%.

The remainder of this paper is organised as follows. The original dataset of healthy and diseased chili leaf produced for this research is explained in Section II. Meanwhile, Section III delves into the data augmentation method's transformation process, focusing on geometric transformation and its several transformation fusions. The architectures of deep learning models for feature extraction and recognition purposes are then discussed in Section IV. In Section V, the experimental procedures and testings used in this research to acquire the accuracy performance findings are described and the conclusion of this research is presented in Section VI.

II. Chili Leaf Image Dataset

In this research, the camera of an Oppo Reno 2 smartphone was used to capture images of chili leaf in the Batu Pahat state of Johor, Malaysia. Both types of leaf showed healthy and indications of bacterial spot disease. Only 1200 original chili leaf images were able to be acquired due to the low quantity of chilli crops in the research site. Of those 1200 images, 600 showed healthy chili leaf, while the remaining 600 showed diseased chili leaf. The images are captured in auto-focus mode at a resolution of 3000 x 4000 pixels before being resized down to 224 x 224 pixels.

III. Geometric Transformation

Data augmentation can be described as the mapping of any method that artificially increases the original dataset using the preservation label of transformations [13]:

$$\varphi = Y \rightarrow Z \qquad (1)$$

where Y is the original dataset and Z is the augmented dataset of Y. The original dataset that has been artificially increased is therefore expressed as:

$$Y' = Y \cup Z \qquad (2)$$

where Y' stores the original dataset as well as the transformations described by φ. It is worth noting that the preservation label of transformations reflects that if an image d is an element of class f, then $\varphi(d)$ is likewise an element of class f. Given that there is an infinite number of mappings $\varphi(d)$ that fulfil the criterion of preservation label of transformations, this research assesses an augmentation method, namely the geometric transformation.

Geometric transformation is a data augmentation method that alters the image's geometry by relocating the locations of each pixel's value [16]. The image's fundamental pattern of a class is preserved, but it has been shifted to a new place and alignment. This research explores the types of geometric transformation such as reflection, translation, rotation, shearing, scaling, and several fusions between them.

Reflection [17] mirrored an image around the horizontal (x-axis) or vertical (y-axis). It assists users in increasing the amount of images of an original dataset by requiring the original image matrices' rows to be inverted. In a horizontal reflection, the left and right sides of the image are turned horizontally. As shown below, the f_x and f_y components indicate the pixel's present location after reflection across the x-axis, while the coordinates of the object's original position in the image are denoted by x and y:

$$A = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (3)$$

where A is the process equation of reflection on the x-axis. In a vertical flipping, the image is turned upside down such that the y-axis is on top and the x-axis is on the bottom. The f_x and f_y components indicate the pixel's present location after reflection across the y-axis, while the coordinates of the object's original position in the image are denoted by x and y, where B is the process equation of reflection on the y-axis:

$$B = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (4)$$

Then there is translation [17], which is the process of shifting an object in an image from one location to another. The translation can be performed in four directions: down, up, right and left, which helps prevent positional bias in a set of translated images. The f_x and f_y components indicate the pixel's present location after translation, while the coordinates of the object's original position in the image are denoted by x and y, where C is the process equation of translation:

$$C = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} T_x \\ T_y \end{bmatrix} \qquad (5)$$

Next, rotation [18] entails spinning the original image, either in the left or right direction, with angles ranging from 1^o to 359^o. The f_x and f_y components indicate the pixel's present location after rotation while the coordinates of the object's original position in the image are denoted by x and y, where D is the process equation of rotation:

$$D = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} cos\varphi & -sin\varphi \\ sin\varphi & cos\varphi \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (6)$$

Additionally, shearing [17] is the process of altering the shape of the original image in a single direction. Shearing can be done in either the x-axis or the y-axis direction. The f_x and f_y components indicate the pixel's present location after shearing while the coordinates of the object's original position in the image are denoted by x and y.

Consequently, (7) shows the shearing in the x-axis direction, whereas (8) shows the shearing in the y-axis direction. The E and F are the process equations of images sheared on the x-axis and the y-axis directions, respectively.

$$E = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} 1 & shX \\ 0 & 1 \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (7)$$

$$F = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ shY & 1 \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (8)$$

In contrast, scaling [18], often known as zooming or cropping, is the process of enlarging and shrinking the original image in order to view more information. The operation of the process is to enlarge or shrink the image from a starting X, Y position to a destination X, Y. The f_x and f_y components indicate the pixel's present location after scaling, while the coordinates of the object's original position in the image are denoted by x and y,where G is the process equation of scaling.

$$G = \begin{bmatrix} f_x \\ f_y \end{bmatrix} = \begin{bmatrix} Xscale & 0 \\ 0 & Yscale \end{bmatrix} . \begin{bmatrix} x \\ y \end{bmatrix} \qquad (9)$$

An object in an original image that has been reflected, whether on the x-axis or the y-axis, can be translated by shifting the reflected image into a new location, resulting in a fusion of reflection and translation transformations. Given that H and I are the process equations of images reflected on the x-axis and the y-axis, respectively, and then translated, the equations are as follows:

$$H = A \cup C \tag{10}$$

$$\mathrm{I} = B \cup C \tag{11}$$

This research also includes the fusion of reflection and scaling transformations. Given that J and K are the process equations of images scaled, and then reflected on the x-axis and the y-axis, respectively, the equations are as follows:

$$J = G \cup A \tag{12}$$

$$K = G \cup B \tag{13}$$

Additionally, this research also has a fusion of scaling and shearing transformations. Given that L and M are the process equations of images scaled, and then sheared on the direction of the x-axis and the y-axis, respectively, the equations are as follow:

$$L = G \cup E \tag{14}$$

$$M = G \cup F \tag{15}$$

Finally, there can be more than two fusions of geometric transformations. Given that N and O are the process equations of images scaled, then reflected on the x-axis and the y-axis, respectively, and lastly followed by translation, the equations are as follows:

$$N = G \cup A \cup C \tag{16}$$

$$O = G \cup B \cup C \tag{17}$$

IV. Developments of Deep Learning Model

In the leaf disease recognition domain, researchers have employed enhanced deep learning network architecture through various models [9-10] and applied them to chili disease recognition. This research employs two types of deep learning models: CNN and ResNet-18, which are developed from scratch using the Deep Network Designer [19]. An accuracy measure in [20] is used as a metric to evaluate the performance of these models. The architecture of each model is described in further detail in the following section.

A. CNN Architecture

Output, input, and hidden layers are the three primary layers of a CNN model [21]. It is common for the hidden layers to have convolutional with rectified linear unit (ReLU) function, pooling, and fully connected layers. The convolutional layer comprises a collection of filters that are used to identify features of varying sizes. Each filter convolves throughout an input image by moving horizontally for a certain amount of time, then moves vertically for another amount of time until the whole image has been convolved. A nonlinear activation function, which is the ReLU, is then applied to the convolution process' outputs. The layer which pools the neuron cluster outputs from the convolution layer into a single neuron is called the pooling layer. The pooled output is then given to a fully connected layer, which adds a bias vector and multiplies it by a weight matrix before feeding it to a softmax layer, which executes the classification operation (output). The architecture of a CNN model is shown in Fig. 1.

B. ResNet-18 Architecture

ResNet is suggested in [22] as a solution to the issues of performance deterioration and gradient vanishing caused by the depth expansion of an CNN model. Convolution layers, pooling layers, fully linked layers, softmax layers, and shortcut connections make up the architecture of a ResNet-18 model shown in Fig. 2. The shortcut connections represent the connections that travel between two layers. There are two main kinds of pooling layers in the ResNet-18 model architecture in this research. The first of these layers is the max-pooling layer, which chooses the maximum element from the area of the feature map covered by the convolution filter. For the second layer which is the average pooling layer, instead of picking the maximum element, it works by calculating the average value of the element from the region of the feature map.

The building layer of ResNet-18 is seen in Fig. 3 with an input x parameter and the desired output $H(x)$. The block makes use of a shortcut connection that enables it to immediately learn the residual $F(x) = H(x) - x$ in order to generate the desired output $[F(x) + x]$, hence avoiding performance deterioration and gradient vanishing due to an excessive number of convolutional layers.

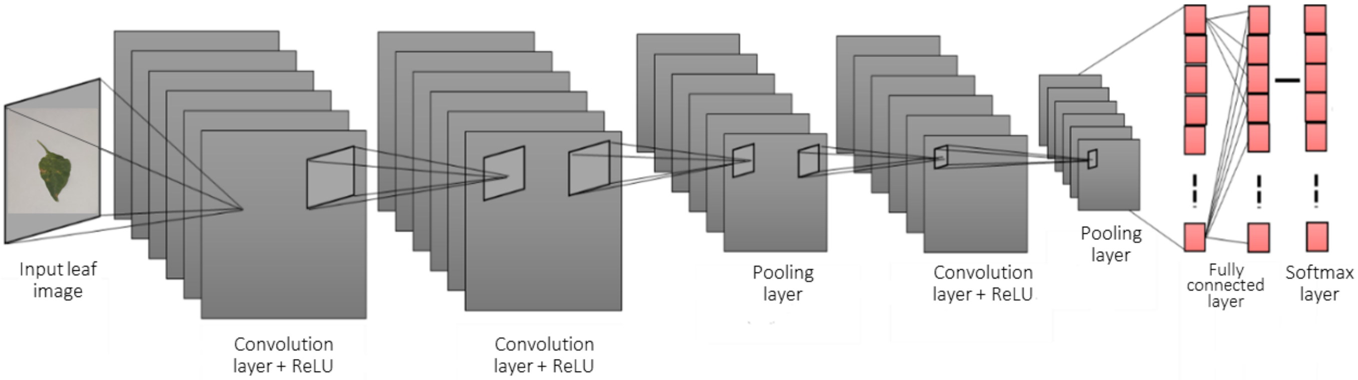

Fig. 1. CNN Model Architecture.

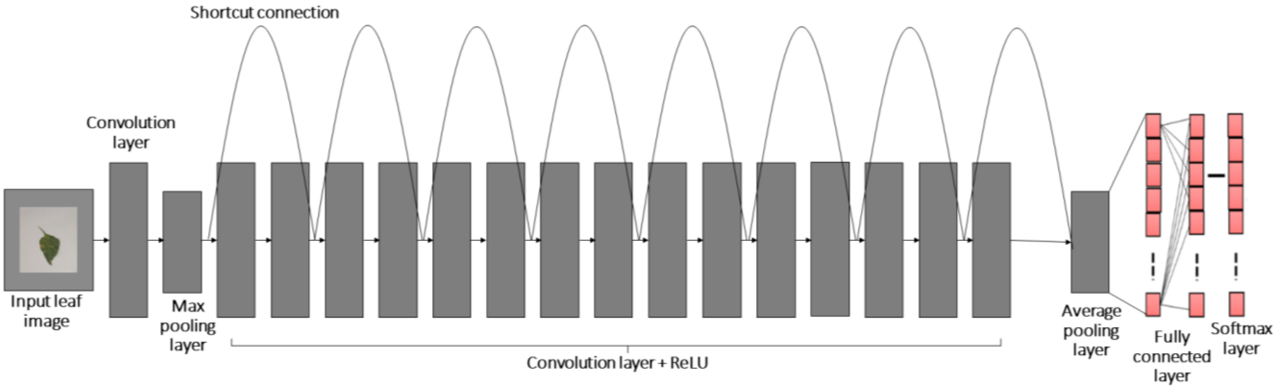

Fig. 2. ResNet-18 Model Architecture.

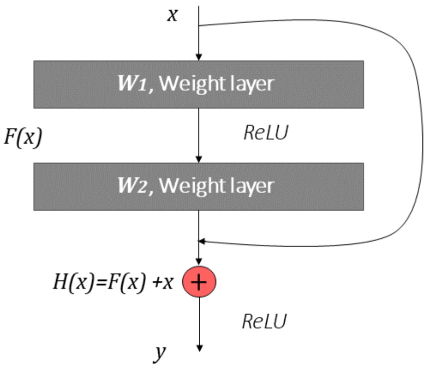

Fig. 3. The Building Layer of ResNet-18.

The ResNet building layer in Fig. 3 employs the residual mapping function [23] described below , where σ:

$$P = W_2\sigma(W_1x) \quad (18)$$

denotes the activation function of ReLU. Through a second activation function of ReLU, the output y can be obtained:

$$y = F(x, \{W_i\}) + x \quad (19)$$

A linear transformation of output y can also be obtained by multiplying W_s to x in (19) as shown below.

$$y = F(x, \{W_i\}) + W_sx \quad (20)$$

V. Results and Discussion

The accuracy performance results for both the CNN and ResNet-18 models on original and augmented datasets of healthy and diseased chili leaf are acquired via the use of experimental setup and testing, which are detailed in the following section.

A. Experimental Setup

All of the models in the experiments run on MATLAB® with an Intel® CoreTM i3 processor operating at 3.4 GHz. The models' networks are fed data from three different categories of datasets: datasets with only original data (original datasets), datasets with only augmented data (augmented datasets), and datasets with both original and augmented data (original + augmented datasets). Only 1200 images from each category datasets are fed into the models in order to preserve the data balance. Therefore, 40 images from the original datasets are chosen to be augmented, consisting of 20 random images of healthy chili leaf and 20 random images of diseased chili leaf. During the augmentation process, which comprises of 15 geometric transformations, 600 augmented images are produced and preserved in the augmented datasets, while the original images are discarded. For original + augmented datasets, 300 images of original and augmented healthy chili leaf, as well as 300 images of original and augmented diseased chili leaf, are used. Table I shows the specific information for all the datasets in this research.

TABLE I. DATASETS INFORMATION

Type of datasets	*Ori_HC	*Ori_DC	*Aug_HC	*Aug_DC	Total images
Original	600	600	0	0	1200
Augmented	0	0	600	600	1200
Original + Augmented	300	300	300	300	1200

*Ori_HC = Original images of healthy chili leaf
*Ori_DC = Original images of diseased chili leaf
*Aug_HC = Augmented images of healthy chili leaf
*Aug_DC = Augmented images of diseased chili leaf

When the CNN and ResNet-18 models are fed with a dataset, 70% of the data in the dataset is utilised to train the models, while the remaining 30% is used to test the models. During training, the hyperparameter settings [24] of both models, such as batch size, learning rate, maximum epoch, testing frequency and optimizer, are fixed such that the optimum performance of both models is equal. Table II summarises the fixed hyperparameter settings for both models.

TABLE II. FIXED HYPERPARAMETER SETTINGS

Hyperparameter setting	Value
Batch size	32
Learning rate	0.0001
Maximum epoch	30
Testing frequency	50
Optimizer	Stochastic gradient descent with momentum (sgdm)

In each experiment, the accuracy performance of a developed model given an input dataset is determined using the following formula:

$$Accuracy_{Od} = \frac{Testing\ accuracy_{Ori\_HC} + Testing\ accuracy_{Ori\_DC}}{2} \quad (21)$$

$$Accuracy_{Ad} = \frac{Testing\ accuracy_{Aug\_HC} + Testing\ accuracy_{Aug\_DC}}{2} \quad (22)$$

$$Accuracy_{OAd} = \frac{Testing\ accuracy_{Oad\_HC} + Testing\ accuracy_{Oad\_DC}}{2} \quad (23)$$

*Od = Original datasets

*Ad = Augmented datasets

*OAd = Original + augmented datasets

*Oad_HC= Ori_HC + Aug_HC

*Oad_DC = Ori_DC + Aug_DC

B. *Experimental Testing*

Fig. 4 displays the geometric transformations that were performed on images of healthy and diseased chili leaf in order to create augmented images. The performed geometric transformations are based on the process equations in section III.

The accuracy results obtained by developed models when applied to the three categories of datasets, which are referred to as original datasets, augmented datasets and original + augmented datasets are shown in Table III.

Table III shows that after applying both models to the three categories of datasets, the accuracy performance achieved for each dataset varies. The CNN model produced accuracies of 92.3%, 82.5%, and 94.2% for the original datasets, augmented datasets, and original + augmented datasets, respectively. Conversely, the ResNet-18 model achieved accuracies of 99.2%, 91.8 %, and 99.7% for the original datasets, augmented datasets, and original + augmented datasets, respectively. In every experiment undertaken, it can be concluded that the ResNet-18 model outperforms the CNN model in terms of accuracy.

Despite the fact that both models were trained on 600 images per class, the average accuracy attained from the original datasets was only 95.8%. The geometric transformation method improved performance and yielded the best accuracy result of the two models, with an average recognition accuracy of 97% from both models that can be seen from original + augmented datasets. These findings indicate that the geometric transformation method improves the abilities of the models to generalise [25] by modifying the orientation of original image while retaining its original information.

On the other hand, the accuracy results from the augmented datasets showed that if the models were only trained with augmented images, the accuracy dropped by 8.6% and 9.8% on average compared to the accuracy of the original datasets and the original + augmented datasets. This is due to the black pixel areas (background areas) in the augmented images created by geometric transformation and the absence of the attention mechanism [26] that is found in the original images. The deep learning models use more background areas of the augmented images as distinct regions in the training process, leading to lower accuracy performance.

F) Shearing on the y-axis. G) Scaling. H) Reflection on tℎe x-axis and Translated. I) Reflection on tℎe y-axis and Translated. J) Scaling and Reflected on the x-axis. K) Scaling and Reflected on the y-axis. L) Scaling and Sheared on the x-axis. M) Scaling and Sheared on the y-axis. N) Scaling, Reflected on the x-axis and then Translated. O) Scaling, Reflected on the y-axis and then Translated.

TABLE III. ACCURACY RESULTS OF DATASETS

Type of datasets	Accuracy given by CNN	Accuracy given by ResNet-18
Original datasets	92.3%	99.2%
Augmented datasets	82.5%	91.8%
Original+augmented datasets	94.2%	99.7%

VI. Conclusion

This research proposed the data augmentation method known as a geometric transformation and its several transformation fusions on a small chili dataset and tested on two deep learning models, CNN and ResNet-18. A clear improvement in accuracy performance results were seen for both models after adding augmented images into the original datasets. The accuracy of both models went up by 94.2% for the CNN model and 99.7% for the ResNet-18 model.This suggests that a combination of the original and augmented images can improve the accuracy performance of the models substantially. Further research also revealed that ResNet-18 had the highest accuracy performance among both models when no data augmentation was used.

Acknowledgment

This research was supported by Universiti Tun Hussein Onn Malaysia (UTHM) through Tier 1 (vot H916). Special appreciation to the IoT Laboratory, UTHM, for providing related facilities.

Arabic Image Captioning: The Effect of Text Pre-processing on the Attention Weights and the BLEU-N Scores

Moaz T. Lasheen, Nahla H. Barakat
Faculty of Informatics and Computer Science, The British University in Egypt, Cairo, Egypt

Abstract—**Image captioning using deep neural networks has recently gained increasing attention, mostly for English langue, with only few studies in other languages. Good image captioning model is required to automatically generate sensible, syntactically and semantically correct captions, which in turn requires good models for both computer vision and natural language processing. The process is more challenging in case of data scarcity, and languages with complex morphological structures like the Arabic language. This was the reason why only limited number of studies have been published for Arabic image captioning, compared to those of English language. In this paper, an efficient deep learning model for Arabic image captioning has been proposed. In addition, the effect of using different text pre-processing methods on the obtained BLEU-N scores and the quality of generated images, as well as the attention mechanism behavior were investigated. Furthermore, the "THUMB" framework to assess the quality of the generated captions is used -for the first time- for Arabic captions' evaluation. As shown in the results, a BLEU-4 score of 27.12, has been achieved, which is the highest obtained results so far, for Arabic image captioning. In addition, the best THUMB scores were obtained, compared to previously published results on common images.**

Keywords—Arabic image captioning; computer vision; deep learning; image captioning; natural language processing

I. Introduction

A. Overview

Recently, automatic image captioning became a hot topic, building on the success of deep neural networks in the areas of computer vision and Natural Language Processing (NLP) tasks. Image captioning models require two main components; the first is to extract the image's features, detect its objects, and describe their relationships; while the second is the language model that converts those features to a meaningful word sequence [1, 2]. These models are initially trained on a data set of images, along with their corresponding captions [3].

Studies for caption generation is largely in English due to the availability of data sets and other pre-trained image and language models. The most commonly used architectures are Encoder-Decoder, with or without additional, optional layers, like different attention mechanisms and different embedding models [3-5]. The Encoder–Decoder architecture mainly uses several variations of a Convolutional Neural Network (CNN) as encoders, where high-level feature are extracted from the input images, which are then passed to the decoder (language) model; where Recurrent Neural Networks (RNN) have been widely used. Recently, transformers, as well as Generative Adversarial Neural Networks (GANS) models have been used. Encoder architectures included AlexNet, VGG-16 Net, RESNet, GoogleNet and DenseNet [6]. However, RESNet showed better performance, and had fewer training parameters compared to other common encoders like VGG variants [3]. For language models (the decoders), Long Short-Term Memory (LSTM), RNN, Gated Recurrent Units (GRU) have been adopted [6]. However, the LSTM is the most widely used decoder, for its ability to remember long term dependencies in the generated word sequence [6]. Several attention models have also been proposed; including hard or soft, top-down, bottom-up, semantic, and other attention methods [6, 7]. Attention methods are also used with GANs and Reinforcement Learning, which have shown excellent performance [8]. For more details on English image captioning, please refer to the reviews in [3-9]. The situation is different for Arabic image captioning, as only few models have been proposed with less satisfying results. This can be attributed to the complex morphological structure of the Arabic language, and the scarcity of data sets of images with Arabic captions. Image captioning has many valuable applications; like image indexing and retrieval, assisting visually impaired people, robot vision systems, medical image description, analysis of traffic data, and other industrial applications [10, 11].

In this paper, an efficient model for Arabic image captioning is proposed, utilizing an encoder-decoder architecture, with soft attention mechanism, and beam search to generate best captions. The paper attempts to answer the following research questions: 1) what is the effect of different Arabic text pre-processing methods on the BLEU-N scores, the behavior of the attention mechanism, and quality of the generated captions? 2) Dose beam search improve BLEU-N scores?

As the result section shows, the proposed model achieved the highest BLEU-4 score so far; for Arabic image captioning. In addition, the quality of the generated captions compares favorably to the related work, as measured by THUMB score, which is used for the first time for Arabic captions evaluations, as well as ratings of four Arabic native speakers.

The rest of the paper is organized as follows: Section B summarizes this study's contributions, followed by a review and analysis of the related work in Sections II. The experimental methodology, results and discussion, are presented in Sections III and IV respectively. Section V discusses the effect of text pre-processing methods on the attention visualization, and the paper conclusion is presented in Section VI.

B. *The Paper's Contributions*

- The proposed model in this paper for Arabic image captioning achieved the highest BLEU-4 Score so far,
- For the first time, the paper investigates the effect of Arabic text pre-processing on the attention mechanism, as well as the BLEU-N scores,
- For the first time, images' captions are qualitatively evaluated using THUMB scores,
- The paper presents the most comprehensive literature review for Arabic image captioning.

II. Related Work

The first published study on Arabic image captioning was in 2018 by [12]. Since then, the majority of the published studies used Encoder-Decoder architectures, with or without attention mechanisms; and recently, transformers have been used. The following Sections summarize the work in this area.

A. *Encoder – Decoder based Models*

The model which obtained the best results as measured by the BLEU-4 score is [12]. This model is different from all other published ones, as it uses Region Convolutional Neural Network (RCNN) to map the image objects to Arabic root words, where a transducer based algorithm has been used for this purpose. The output root words are then passed to an LSTM to generate the standard Arabic caption, and a dependency tree constraints algorithm has been used to ensure that the generated caption is grammatically correct. The authors reported the BLEU-N scores on Middle Eastern newspapers & Flickr8 data sets [12]. In [13] , a CNN was used as the encoder, and LSTM as decoder, on a part of Flickr8 data set, and used BLEU-N for evaluation, with two additional measures. A different study by [14] also used the VGG OxfordNet as encoder and RNN-LSTM as decoder. Arabic Flickr8 plus sample of MS COCO data set with Arabized captions have been used. The authors in [2], translated the captions of Arabic Flickr8 data and made it available online. The authors [2] also proposed a model using VGG16 CNN and LSTM as encoder and decoder respectively. They also proposed a base model, which generate English captions, which are then translated to Arabic.

B. *Encoder – Decoder Models with Attention Mechanism*

In [15], the authors proposed three different encoders, utilizing CNNs for feature extraction and single, and/or multiple objects detection. A final hybrid model was proposed with attention mechanism, which is used for detected objects prioritization. They used LSTM with soft attention and beam search were used for the decoder. The data set used was MS COCO, and Flicker30. Unlike other studies, the authors assessed the quality of the generated captions by measuring the semantic similarity between the generated captions and ground truth captions. Another method that used attention is [16], as shown in the next section.

C. *Encoder – Decoder Architectures with Transformers*

Two studies reported their results [16] and [17]. In [16] three models were proposed. The first uses MobileNetV2 network as encoder, LSTM with attention as the decoder. The second was MobileNet V2 (GRU) as encoder, and GRU with attention as decoder. Finally, a transformer-based model was also proposed, where EffeceintNet is used as the encoder, and a transformer based architecture as the decoder. FARASA segmenter has been used for text pre-processing, and BLEU-N scores were reported. Different transformer based models were proposed in [17] which were initialized with AraBERT and GigaBERT pre-trained transformers, then fine-tuned by detecting object tags in images using OSCAR method. Flickr8 and part of MS COCO data sets have been used, and BLEU-N scores are reported.

D. *Analysis of the Related Work*

A comparison of the BLEU-N scores for the studies reviewed in this section can be found in Section IV, Table IV. From that table, it can be seen that the best reported BLEU-N scores are by [12], who used root words to generate captions, followed by [14], then the transformers based models in [16]. It was also noted that transformers achieved minor improvements on the BLEU-N scores. However, the comparison of BLEU-N scores does not provide a concrete conclusion which model is better; as most of the studies did not use a common train/ validation/ test splits. For example, [16] used 90%, 10 % for training, and testing respectively. Also, in [17], the MS COCO images used only for training, Flickr8 test set have been used for testing. Similarly, in [13], 1500, 250, and 250 images have been used for training, validation and testing respectively. Excluding the results by [12], the BLEU-4 results are close, which does not pinpoint the value of a specific architecture over the others. Furthermore, none of the studies reviewed here investigated the effect of pre-processing methods on the BLEU-N scores or the quality of the generated captions.

III. Experimental Methodology

A. *The Dataset*

The data set used in this paper is the Arabic-Flickr8 [2], which is a translated version from the original English Flickr8, using Google Translate. The best 3 translated captions are kept and further edited by native Arabic speakers. For the purpose of training, validation, and testing, Karpathy's data splits [18]; 6000, 1000, 1000 images for training, validation, testing respectively are used. Unlike its English version which has 5 captions for each image, the Arabic Flickr 8 has only 3 captions.

B. *The Model Architecture*

The model used in this paper follows the Encoder- Decoder architecture, with attention mechanism, teacher forcing, and beam search. The selection of the Encoder and Decoder networks is based on their prior excellent performance in computer vision and NLP problems, details as follows:

1) The Encoder: The RESNet-101 [19], is a CNN that has 101 layers, and was chosen -for the first time in Arabic image captioning**-** as the encoder; due to its proven ability to extracts very rich feature set from an image. RESNet stands for Residual Neural Network architecture [19], which is able to overcome the vanishing gradients problem using skip connections. The output of the encoder is passed to the next part of the architecture with its same dimensions.

2) The attention mechanism: The objective of using attention mechanisms [7] in image captioning is to allow focusing on a specific part of the image, while generating the captions. It calculates the weights of different pixels of the encoded images, which are then used by the Decoder. In this paper, soft attention has been used, which is trained in an End-to-End manner using Back-propagation. The soft attention weights are determined by image features and the LSTM previous output.

3) The decoder: An LSTM network is used as the decoder. The LSTM is a variation of the RNNs with additional gates, and is able to overcome the vanishing gradients problem encountered when processing long sequences. Those gates make the RNN decide which tokens should be retained in the memory and which to forget [3]. In the context of image captioning, the decoder looks at different parts of the image; while producing different parts of the output sequence, by weighting different pixels of the output of the encoder. The LSTM cell and hidden states are initialized using the encoded image at the first step; and the encoded image attention weights alongside the decoder weights at each step are computed. The attention weights with the embedding of the token from the previous step, are then concatenated and the LSTM produces the new states.

C. Pre-processing

In this section, the pre-processing steps used are described:

1) Captions' Pre-processing and Tokenization: In this study, Pyarabic [20], which splits image captions into tokens using spaces, and The FARASA segmenter [21] have been used. FARASA [21] is an Arabic word segmenter, which breaks Arabic words into their constituent clitics. For example, the word "wkatabna" (و كتبنا) meaning: "and we wrote" is composed of three clitics "w+katab+na", namely the conjunction article "w" meaning "and" as prefix, the stem "katab" (كتب), possessive pronoun "na" (نا) as suffix. Another example which is very common is the "AL - ال", which corresponds to "the" in English. In the context of image captioning, using FARASA segmenter results in a smaller unique vocabulary size because all different forms of a word are treated as one, but the number of total number of tokens increases, as different suffixes are separated and counted.

2) Image pre-processing: The image pre-processing is kept to the minimum; where all images are resized to 256 (smaller edge) pixels. The center 224x244 pixels was cropped, before transforming them to Pytorch tensors; and normalize using the mean and standard deviation of the IMAGENET dataset.

D. Pre-trained Word Embedding

The Aravec; a pre-trained word embedding have been used to provide richer representations for the image captions. In this study, the skip gram model trained with Wikipedia data have been used [22].

E. The Beam Search

For training and validation, teacher forcing has been used [3], as it makes the model learn the context in more efficient way. At the testing stage, beam search has been used to generate the best captions. Beam search [3] works by finding the top-k words with the highest decoder scores at each step, calculate the additive scores for each of the pairs from current and previous steps and get the best combinations, in each decoding step. In this way, beam search outputs the completed sequences with highest scores. The beam size that resulted in captions with best BLEU-4 score is chosen.

F. Modeling

Two models have been designed to generate image captions; and investigate the effect of the following settings on the quality of the generated captions:

- The use of different text pre-processing in particular, FARASA word segmenter and PyArabic tokenization,
- The use of different Beam Sizes.

1) Model 1: It was decided to start with a base model, as a reference for comparison. So, PyArabic tokenizer, with AraVec pre-trained embedding was used, to compensate for the smaller number of captions for the Arabic Flicr8 data set, compared to its English version.

2) Model 2: In this model, FARASA Segmenter has been used to pre-process the captions, and similar to model 1, AraVec embedding model has been utilized.

For both models, beam search has been used to generate best captions, and they were evaluated on Flickr8 test set, as well as 200 images randomly selected from MS COCO data set, to further test the robustness of our models.

G. Evaluation Methods

1) The BLEU–N Score: The BLEU [23] stands for Bilingual Evaluation Understudy, which is a metric originally proposed to evaluate the quality of machine translation models. As image captioning can be thought of as translation from image features to text describing that image, it has been widely used to evaluate image captioning models. BLEU-1, 2, 3, 4, measures the fraction of n-grams that appear in both the generated and ground truth captions, where n takes the values, 1, 2, 3 and 4.

2) The THUMB 1.0: As human evaluation of the generated captions is still considered the gold standard, the THUMB framework for caption's evaluation is used. THUMB stands for "Transparent Human Benchmark" [24]. THUMB is based on two major scores; namely, precision and recall, which are measured on a scale from 1 to 5. This in addition to penalty scores which are deducted from the average of precision and recall scores, to penalize any problems in the fluency and /or conciseness of the generated captions, as well as any issues concerning the use of inclusive language. The following sections briefly introduce the THUMB 1.0 [24] framework.

a) Precision: As the measure entails, the Precision (P) assess how precise the image is described by the generated caption, which is mainly intended to detect the common failures of the language model part. Precision is measured on a scale from 1 to 5, where 0.1 point is deducted in situations like, minor difference in colors, counts, the caption is not accurate, but do not mainly contradict with image's contents, in addition to other attributes like occasions, locations, etc. [24].

b) Recall: Recall (R) evaluates how good (complete) does the caption describe the image contents; including main objects, their relationships and colors. Therefore, it penalizes the generic, short captions that are usually generated by the majority of image captioning methods. If the image description (caption) is too generic, where different diverse images can be imagined based on that caption, then the recall score tends to be low [24].

c) Penalties: Penalties are given to penalize fluency problems; which assesses the text structure, regardless of the image contents. As most of automatically generated captions do not suffer fluency problems, points are deducted from the average of the precision and recall scores. A penalty of 0.1 is given for grammatical or spellings mistakes, as they are easily corrected. For other more serious problems like duplication, broken sentences, a minimum of 0.5 points are deducted. The Conciseness is also evaluated in this framework, where penalties are given for unnecessarily long, detailed captions, where 0.5 points are deducted. However, as the majority of automatically generated captions tend to be short, this penalty is not very common [24]. The final type of penalties is given on describing humans with terms that deviate from inclusive language**,** which ranges from 0.5 for subjective comments, to 2.0 for more severe problems. A final rule in this framework, is that double penalties should be avoided. If a problem is penalized using precision, it should not be penalized again by recall [24].

IV. Results and Discussion

A. Model 1 Results

Results of model 1 are shown in Table I. From this table, it can be seen that the model achieved BLEU-4 score of 8.29, which is superior to 9 of previously published BLEU-4 scores. This can be attributed to the strong encoder architecture used as well as the use of the attention mechanisms and beam search.

B. Model 2 Results

Results of model 2 are shown in Table II. From this table, it can be seen that the BLEU-N scores have significantly increased for all beam sizes. The best BLEU-4 results were obtained with beam size of 5. The results show that the use of FARASA segmenter significantly improved all the scores. These results are consistent with [12], where root words have been used, which is a similar approach to FARASA pre-processing. This model achieved *the highest BLEU-4 scores* obtained on the Arabic Flickr8 data set so far. Fig. 1 shows the BLEU-4 scores obtained at different beam sizes, for PyArabic, compared to FARASA pre-processing. From this figure, it can be seen that the best results were obtained with beam size 5. This can be attributed to the improvements of the completed sequence of words with beam size of 5, compared to the ground truth captions for the test set.

C. Results on 200 Images from MS COCO

As an additional test of the models quality 200 randomly selected images from MS COCO data set with Arabized captions were used. The results are shown in Fig. 2. From this figure, it can be seen that better results were obtained; again by the model with FARASA segmenter, and beam size of 3, which is the same situation as Flickr8 test set. Fig. 3 compares the performance of the two models on MS COCO data set.

TABLE I. Scores of Model 1 on Arabic Flickr8 with Beam Search

Model	**BLEU-1**	**BLEU-2**	**BLEU-3**	**BLEU- 4**
Model 1 + Beam size 1	39.01	24.45	13.01	7.27
Model 1 + Beam size 3	40.10	25.58	14.28	7.89
Model 1 + Beam size 5	39.10	25.13	13.96	**8.29**

TABLE II. Comparison of BLEU-4 Score for FARASA pre-processing, and Beam Sizes

Model	**BLEU 1**	**BLEU 2**	**BLEU 3**	**BLEU 4**
FARASA + Beam size 1	57.45	43.79	31.86	22.81
FARASA + Beam size 3	59.90	47.40	36.13	26.89
FARASA + Beam size 5	58.71	46.52	35.71	**27.12**

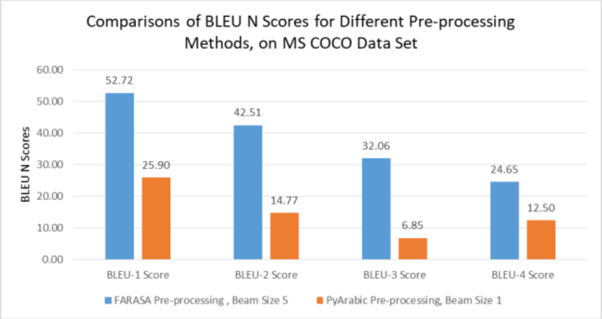

Fig. 3. Comparison of BLEU-N Scores, for Models 1 and 2, on 200 Images from MS COCO.

D. *Results' Comparison with Related Work*

Fig. 4 shows our BLEU-4 results, compared to previously published work, and Table III shows our BLEU-N scores as compared to previously published results on Arabic Flickr8. From this table, it can be seen that the highest BLEU-4 score are achieved by the model trained with FARASA segmenter and beam size of 5. Furthermore the PyArabic model also achieved high BLEU- N scores, which are superior to 9 of related work results. As noted in the related work Section II, most of those studies did not report the data splits they used, others used different splits like [14] and [17], who used parts of both Flickr8 and MS COCO data sets, and [16], who used 90/10 for training and testing, while [17] used combined data set for training, but the testing was only done on part of Flickr8 data.

E. *Qualitative Evaluation of our Results*

As a complementary measure to the obtained BLEU–N scores, it was important to seek qualitative evaluations, to validate the BLEU-N scores results, and show that our models predict accurate and meaningful description for the images. Table IV shows a sample of the captions generated by our models, compared to others previously published captions for same images. As human evaluations are still considered the gold standards to evaluate the quality of machine generated captions, four native Arabic speakers were asked to rank ours, and others captions for each image. Based on the average ranking for the evaluators, they reported that our model's captions have better quality in 16 out the 29 (55%) captions listed in Table IV. In particular, those which are generated with models used PyArabic pre-processing. Other related work methods are better in 8 out of 29 (28%), and both have the same quality in 5 out of the 29 (17%) images.

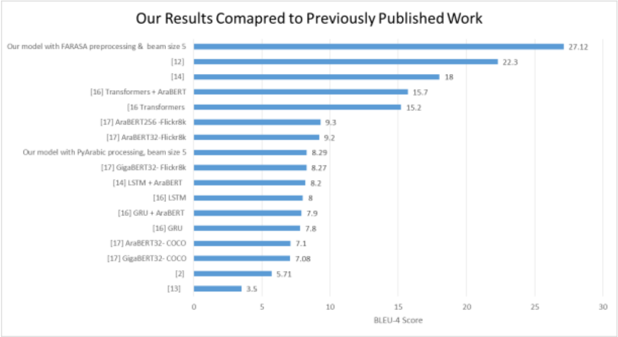

Fig. 4. Our Results Compared to those of Previously Published Methods.

TABLE III. OUR RESULTS AS COMPARED TO PREVIOUSLY PUBLISHED METHODS

Model	**BLEU 1**	**BLEU 2**	**BLEU 3**	**BLEU 4**
[2]	33.18	19.26	10.49	5.71
[16] Transformers + ARABERT	44.30	N/A	N/A	15.70
[16] Transformers	42.70	N/A	N/A	15.20
[16] LSTM + ARABERT	38.30	N/A	N/A	8.20
[16] LSTM	35.10	N/A	N/A	8.0
[16] GRU + ARABERT	37.6	N/A	N/A	7.9
[16] GRU	35.3	N/A	N/A	7.8
[14]	52.00	46.00	34.00	18.0
[12]	65.8	55.9	40.4	22.30
[13]	34.40	15.40	7.60	3.50
[17] AraBERT32-Flickr8k	39.10	24.6	15.0	9.2
[17] AraBERT32- COCO	36.5	22.1	12.9	7.1
[17] AraBERT256 -Flickr8k	38.7	24.4	15.1	9.3
[17] GigaBERT32- Flickr8k	38.6	24.1	14.4	8.27
[17] GigaBERT32- COCO	36.0	21.5	12.4	7.08
Our model with PyArabic & beam size of 3	39.108	25.131	13.962	8.29
Our model with FARASA & beam size 5	58.708	46.523	35.712	**27.12**

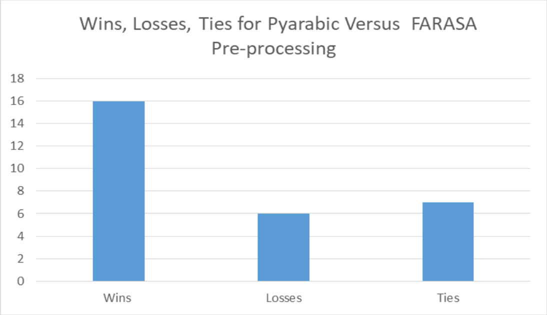

Fig. 5. Summary of THUMB Score Comparison between PyArabic, and FARASA based Models.

To further evaluate and quantify the differences in the captions' quality, THUMB 1.0 [24] was employed, which is utilized for Arabic image captioning for the first time in this paper**.** Therefore, three different native Arabic speakers were asked to use the THUMB framework, and evaluate the captions in Table IV. Based on the average of ratings by the three evaluators; Fig. 5 compares the THUMB scores of our two models. From this figure, it can be seen that PyArabic model has better quality captions, where it obtained 16 wins, 6 losses and 7 ties; compared to FARASA based model. Similarly, Fig. 6 summarizes the comparison results between our models and the related work, showing our models' wins, losses and ties. Again, and similar to the first four evaluators, our models obtained higher THUMB scores, where 15 and 17 wins; 5 and 7 losses; and 9 and 5 ties were obtained by our PyArabic and FARASA based models respectively. Fig. 7 shows detailed comparison between our model's Precision, Recall, and Penalties, compared to those of related work. From this table that our models obtained better scores, but had more penalties, in particular for FARASA based model. Even though

FARASA based model compares favorably to the related work models; however, it has more penalties, due to token repetitions, like example 2, location issues, like example 6, where the caption “little girl in people” should have been “little girl with people” , in Arabic “فتاة صغيرة في الناس” should have been “فتاة صغيرة مع الناس”. Again, in spite of the fact that BLEU-N scores for FARASA based model are much higher than PyArabic based model, it tends to output short, more generic descriptions, compared to PyArabic based models, where the structure and/or the semantics of the captions are better for the latter. The improved results for FARASA based models could be partially attributed to the increase of the number of tokens, like the suffix “AL” "ال", possessive pronoun “na” (نا), “TAA Marboota” “ة”, while number of unique stem words decreases. Another reason is that; due to the tendency of producing short, more generic captions, then the overlap of the N-grams with the ground truth captions in the test set increases, hence the higher BLEU-N scores. The important question here is: should FARASA based models be used as they have higher BLEU-N scores? The answer depends mainly on the nature of the image to be captioned. For example, the captions for images 1, 5, 7, 13 are of same quality for both models. However, if the image scene is busier, then PyArabic based models would be better, like the case of images 2, 3, 6, 18, etc. As Fig. 5 shows, PyArabic based model produces better, stronger sentences semantically; however, the difference of the models scores are minor in most of the cases, which favors the use of FARASA based models. It should be noted here that it is hard to conclude that PyArabic based models are qualitatively better than FARASA based models; as only a sample of 29 images were shown here, which are common between all published work, and obtaining the THUMB scores for more images could reverse the situation, which is likely, as the BLEU-4 score for FARASA based model is much higher. One more thing that could give us a hint, and may help in answering the question; is to be able to understand the internal logic of the model during the caption generation process. This can be achieved by visualizing the attention mechanism weights during caption generation, which is explored in Section V.
