V. Attention Mechanism and Pre-processing Methods

Motivated by the results obtained in Section IV, where the use of PyArabic and FARASA segmenter lead to different BLEU-N; as well as THUMB scores, we thought it would be interesting to visualize the sequence of the tokens generated with images' attended parts by each model. Therefore, attention scores visualization is used to investigating the effect of different text pre-processing methods on the generated captions. Put it another way; it is required to investigate whether the attention mechanism attends the image salient features the same way during word sequence generation; for different pre-processing methods.

Fig. 8 to 15 show the attention visualization for four different images and their captions, while the alignment of tokens is shown with the images' attended parts during sequence generation. Interestingly, it is noticed from those figures, that the attention mechanism behavior is somehow different in FARAS based model compared to PyArabic based model. Take for example Fig. 8 and 9, which visualize the attention by FARASA and PyArabic models respectively. Even though the length of the sequence is shorter in Fig. 8 (FARASA based model), it can be noticed that the model perfectly attends the token "فتاة"," Girl" , which spans images 2,3,4, then "in" "فى"in 5 , then " the water" "ماء+ ال"6,7,8, which made the attended image features very prominent. This is not the case in Fig. 9, where an additional word "water""ماء" is not clearly visualized like Fig. 8. Looking at Fig. 10 and 11, it can be seen that the attention mechanism better attends the image's salient features in case of FARASA based model, where the attention shows the dogs and the snow clearly, which is not the case in Fig. 11 for PyArabic. One explanation is that FARASA pre-processing outputs larger number of tokens for the same image region, therefore, higher attention scores.

In addition to the above, attention visualization is also useful in detecting a model's failure, even if it is not very clear in the caption. Consider for example Fig. 12 and 13, where the generated caption is " child in the air", while the attention is attending the cat face, which is the same for PyArabic based model, "Man is sitting on a chair", still the attention is on the cat's face. This is a clear failure of both models, which may not be noticed in case of PyArabic model, as there is a man sitting there in the image. From those examples, it can be concluded that FARASA based model better attends the image's salient features during caption generation, compared to PyArabic model. A third, and more interesting example is shown in Fig. 14 and 15, where an images composed of two individual images, for two different scenes are stacked together. For Fig. 14, the generated caption is "three people in the water", and the attention shows that the dog is counted as one of the three persons in the image, and the water is clearly attended as well. This is not the case for Fig. 15, with the caption "Man Surfing", where one person is attended, while the surfing token is aligned with the dog, which is a clear failure of the model.

From those examples, it can be concluded that FARASA segmenter improves the attention mechanism behavior, which explains the high BLEU-N scores of its model. However, more examples needs to be looked at, to confirm such conclusion.

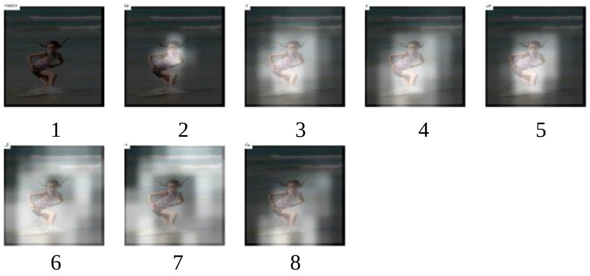

Fig. 8. Attention Weights Visualization for FARASA based Model: The Caption is "Girl in the Water".

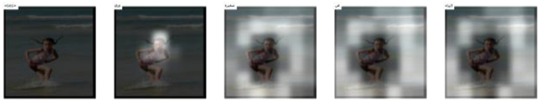

Fig. 9. Attention Weights Visualization for PyArabic based Model. The Caption is "Little Girl in the Water."

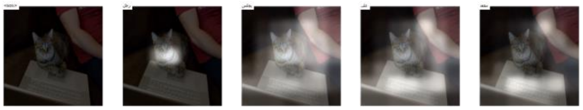

Fig. 13. Attention Visualization for PyArabic based Model. The Caption is: "Man Sitting on Chair".

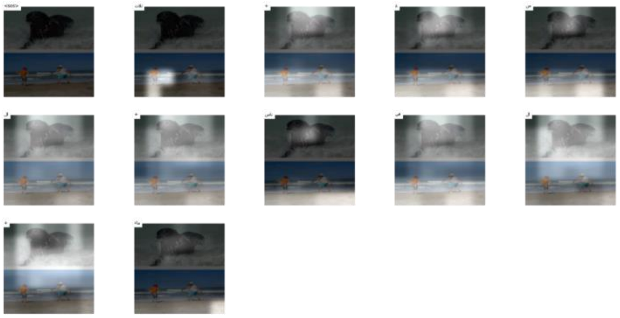

Fig. 14. Attention Visualization with FARASA based Model. The Caption is: "Three People in Water".

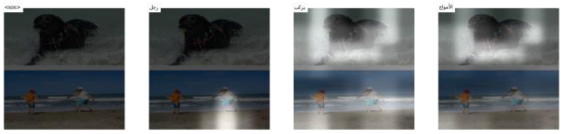

Fig. 15. Attention Visualization for PyArabic based Model. The Caption is: "Man Surfing".

VI. Conclusion and Future Work

In this paper, an efficient model for Arabic image captioning is proposed, and the effect using beam search, as well as the pre-processing on the testing BLEU-4 score is investigated. The model with FARASA segmenter achieved the state of the art BLEU-4 score. The results are also consistent with the results of the model which used root words to generate Arabic captions. In addition to the BLEU-N scores, the generated captions were also qualitatively evaluated by two teams of Arabic native speakers, the first team the captions, while the other used the "THUMB" framework for evaluation. The generated captions using two different text pre-processing models achieved the best THUMB scores, where the model with PyArabic pre-processing showed better results on the sample used. Another interesting finding in this paper is that the different text pre-processing methods influence the attention mechanism, where FARASA based model showed better attention visualization for the used samples. The generated captions also compares favorably to all previous related work, quantitatively, and qualitatively. The paper also show that the choice of the right architecture, with the right pre-processing of Arabic text and the use of beam search can significantly improve the quality of the generated captions.

From the work done in the area of Arabic image captioning including this study, it can be concluded that the use of transformers did neither significantly improve the BLEU-N results, nor the use of larger data sets in training.

As a direction of future research, more efficient models can be investigated to improve the obtained results in this area, utilizing Generative Adversarial Networks. Another direction is to propose new text pre-processing methods and additional evaluation methods to cope with morphologically rich languages like the Arabic language.

***Abstract*—Infertility is a crucial reproductive problem experienced by both men and women. Infertility is the inability to get pregnant within one year of sexual intercourse. This study focuses on infertility in men. Many causes that can cause infertility in men including sperm quality. Currently, identification of human sperm is still done manually by observing the sperm with the help of humans through a microscope, so it requires time and high costs. Therefore, high technology is needed to determine sperm quality in the form of deep learning technology based on video. Deep learning algorithms support this research in identifying human sperm cells. So deep learning can help detect sperm video automatically in the process of evaluating sperm cells to determine infertility. We use deep learning technology to identify sperm using the You Only Look Once version 4 (YOLOv4) algorithm. Purpose of this study was to analyze the level of accuracy of the YOLOv4 algorithm. The dataset used is sourced from a VISEM dataset of 85 videos. The results obtained are 90.31% AP (Average Precision) for sperm objects and 68.19% AP (Average Precision) for non-sperm objects, then for the results of the training obtained by the model 79.58% mAP (Mean Average Precision). Our research show result about identification of human sperm using YOLOv4. The results obtained by the YOLOv4 model can identify sperm and non-sperm objects. The output on the YOLOv4 model is able to identify objects in the test data in the form of video and image.**

Keywords—Classification; deep learning; identification; sperm; sperm head; you only look once version 4

I. Introduction

In the last two decades, the reproductive problem in men that has received much attention is infertility. Infertility is caused by many things, one of which is abnormalities in sperm morphology. Morphological abnormalities experienced by sperm include thin heads, amorphous heads, or bent or asymmetrical neck is of little clinical use [1]. Many studies have reported some analytical disturbances of sperm morphology tests in the details of the sperm sections that were carried out manually. Several studies related to technology to support the diagnosis of infertility in sperm include Computer Assisted Sperm Analysis (CASA), Automatic Assessment of Biochemical Markers of Seminal Plasma, Histopathology Assessment [2]. The technology development that has been carried out still requires further development to get better results, in order to be able to get accurately analyze and identify infertility problems. Currently, there are many studies that predict the cases of infertility. The method that is commonly implemented is the observation method from patient medical record data at a hospital [3]. A number of studies have shown that the factors that cause infertility include age, smoking habits, marijuana use, heroin, hormone disorders, and immunological disorders [4]. These factors can increase the risk of having abnormal sperm so that it becomes infertility.

Identification of sperm is still mostly done manually by humans by observing directly with the aid of a microscope. This requires a high time and cost. To overcome these problems needed a high technology, it is using deep learning. Research on deep learning has been widely carried out [5, 6, 7, 8, 9].

Convolutional Neural Network (CNN) is a development of deep learning that has been developing since 2012. This method can identify sperm morphology accurately based on images [5]. Accurate identification results are influenced by the quality of full image data or with large pixel sizes, so that accuracy and detection performance can be more optimal [6]. In addition to analyzing the morphology of the sperm, CNN can identify sperm based on motility. The dataset used is video [7]. The best results were obtained at the Mean Average Error (MAE) which was 8.786. This shows that the prediction of sperm motility is a fast and consistent process [8]. In the study [9] used Region Based Convolutional Neural Network (R-CNN) to evaluate sperm head motility in video data [7]. The results obtained in this study were 91% and MAE was 2.92.

Research [8, 9] has not been able to identify sperm and non-sperm objects through video. Therefore, our research carried out the latest and most updated breakthrough in the form of YOLO (You Only Look Once). The YOLO algorithm is a floating of CNN which functions as object detection in multiple images [10]. The YOLO algorithm is a more efficient method than object detection algorithms in other machine learning, because it makes everyone can use a 1080 Ti or 2080 Ti GPU to train a super-fast and accurate object detector [11]. Therefore, it is necessary to build a model using the YOLO method to identify sperm and non-sperm based on video.

*Corresponding Author.

II. Materials and Methods

The process conducted in this study is illustrated in Fig. 1.

Fig. 1 shows an illustration of the workflow this research with many steps. The first step is to collect images for the dataset, then resize the image and annotate it based on the object class. The second step is split data to generate train, validation, and test data. The next step is training data based on predetermined hyperparameters. The last step is to evaluate the model from the results of training data and data testing.

A. Dataset

The data used is from Simula Open Dataset with the address https://datasets.simula.no/visem/. This VISEM dataset is a multi-modal dataset that contains data sources such as videos, biological analysis data, and participant data, however in its use for this study only data in the form of videos are used as research datasets. The VISEM dataset contains 85 video recordings of anonymous data from 85 different donor participants with the AVI (Audio Video Interleave) extension and the resolution of each video is 640 x 480 pixels with 50 fps frame rate. Based on the video, 1330 images are produced which will be processed. Fig. 2 shows a piece frame of microscopic video the VISEM dataset.

B. Annotation Data

In this step, two object annotation classes are given for the image to be trained. The classes created in this annotation are sperm and non-sperm. Each frame is annotated in the form of bounding boxes on the morphology of the sperm head and an object that is not sperm. The results of annotations have been made for sperm class is 105.465 bounding boxes. While for the non-sperm class, 22.425 bounding boxes have been annotated. For this annotation use Yolo_mark which is sourced from GitHub https://github.com/AlexeyAB/Yolo_mark.git. The following display of the data annotation can be seen in Fig. 3.

C. Deep Learning

Deep Learning is a branch of machine learning that is inspired by the human cortex by applying an artificial neural network with many hidden layers [12]. There are many types of Deep Learning, such as Deep Auto Encoder, Deep Belief Nets, Convolutional Neural Network, and others. Deep Learning can solve computer difficulties in understanding the meaning of raw input data that is by breaking the desired complex mapping into a series of nested simple mappings.

D. Convolutional Neural Network (CNN)

Convolutional Neural Network is a subdivision of a Deep Learning algorithm used in computer vision to solve certain cases or problems, such as classifying and detecting objects in images, photos, or videos [13]. The characteristics of CNN have a 3D arrangement of neurons (height, width, and depth). The illustration of CNN architecture can be seen in Fig. 4.

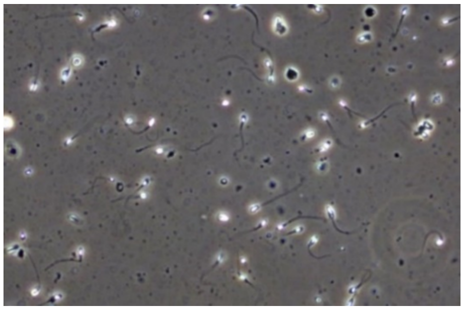

Fig. 2. Frame from Microscopic Video of VISEM Dataset.

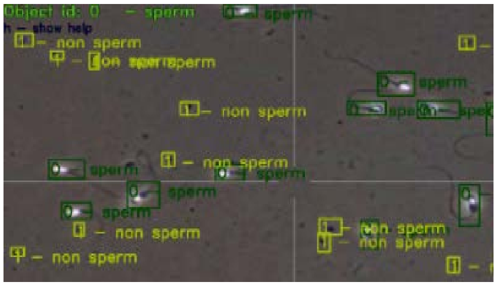

Fig. 3. Display Data Annotation of Image Extraction VISEM Dataset.

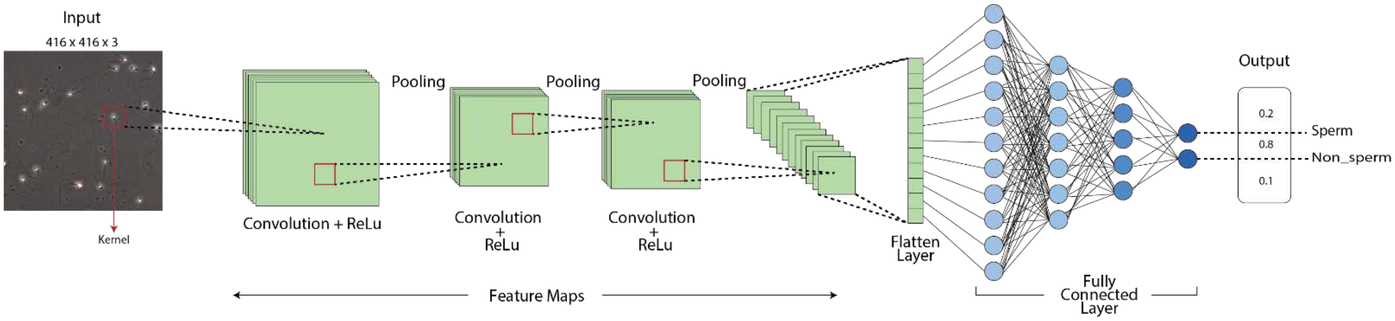

Fig. 4. The Architecture of Convolutional Neural network (CNN) [13].

Fig. 4 shows processes to receive image prediction from CNN. Here we can see the CNN processes are input image, convolution, ReLu, pooling, and fully connected layer.

1) Convolution: The mathematical definition of convolution is the total number of multiplications between the corresponding elements (having the same coordinates) in two matrices or two vectors [14]. Convolution can also be defined as the process of multiplying an image using an external mask or sub-windows to create a new image.

2) Pooling: The pooling layer is a layer that has the function to reduce the spatial size of the convolution process. So as to reduce the computational resources required to process data by reducing the dimensions of the feature map. This pooling layer can make the model training process more effective because the pooling layer is the dominant feature extraction [15].

3) Rectified Linear Units (ReLU): ReLU is the part of the linear function code that removes the negative part to zero and keeps the positive part of the convolution result. Many studies have shown that ReLU outperforms the sigmoid activation function and empirical ground [16]. ReLu activation function is defined as:

$$a_{i,j,k} = max(z_{i,j,k}, 0) \tag{1}$$

Input of the activation function is $z_{i,j,k}$ at location (i,j) on the k-th channel. Simply put, ReLU outputs 0 when $a_{i,j,k} < 0$, and otherwise, it outputs a linier functions when $a_{i,j,k} \geq 0$. Fig. 5 is visual representation of ReLU activation function.

4) Fully connected layer: Fully Connected Layer is a layer that is fully connected; this layer of neurons is connected directly to other neurons by two adjacent layers without being connected to any layer [17]. The Fully Connected Layer processes the output of the final pooling or convolutional layer, which has been flattened. The results of this process will then be continued using the softmax function to get the probability of the input being in a certain class [18].

E. *You Only Look Once (YOLO)*

You Only Look Once or YOLO is a new approach to object detection and development of CNN. YOLO differs from previous research in that detecting an object reuses its classifier; instead YOLO frames object detection as a regression problem with spatially separated bounding boxes and associated class probabilities [10].

Fig. 6 illustrates the YOLO process in making the input image into an image that has been given a bounding box. The first step is the input image will be resized, and then the second step runs a convolutional neural network, after that it does non-max suppression and produces an image that has been identified with a bounding box.

YOLO is implemented as a convolutional neural network. This architecture is inspired by the GoogleNet model for image classification. The YOLO network has 24 convolution layers followed by 2 fully connected layers. Simply uses 1×1 reduction layer followed by 3×3 convolutional layers. The prediction of the final output of this YOLO network is a tensor of 7×7×30. Fig. 7 shows the YOLO architecture in processing image predictions.

There are several versions YOLO of the development of research that has been carried out, in this study using YOLOv4. YOLOv4 overcomes this problem by creating a CNN that operates in real-time on a conventional GPU, and requires only one conventional GPU for training. The purpose of YOLOv4 is to design the speed of operation of the object detector in producing systems and optimization for parallel computing. YOLOv4 hopes that the designed object can be easily trained and used.

Modern detectors usually consist of two parts consisting of a backbone and a head, for a backbone that has been trained previously with ImageNet. Head used to predict the class and bounding boxes of the object. For detectors running on the GPU platform, the backbone used can be VGG, ResNet, ResNetXt, or DenseNet. For detectors running on the CPU platform, the backbone used is SqueezeNet, MobileNet, or ShuffleNet. The development of object detectors in recent years often inserts several layers between the backbone and the head, these layers are usually used to collect feature maps from different stages. We can call this layer the neck object detector. In general, the neck consists of several bottom-up paths and topdown paths. Networks equipped with this mechanism include the Feature Pyramid Network (FPN), Path Aggregation Network (PAN), BiFPN, and NAS-FPN [11].

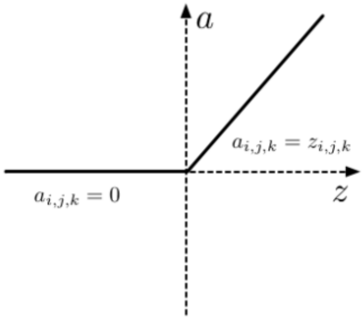

Fig. 5. Display Representation of ReLU Activation Function [16].

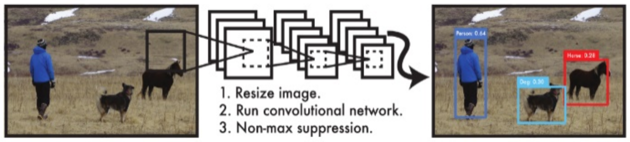

Fig. 6. Processing Images with YOLO Detection System [10].

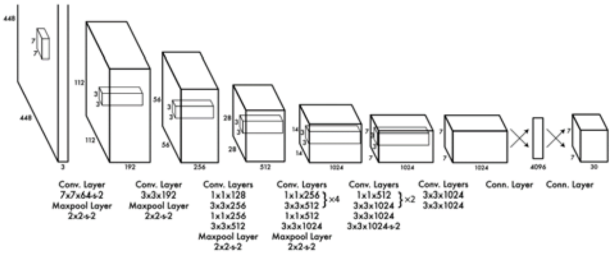

Fig. 7. Display YOLO Architecture [9].

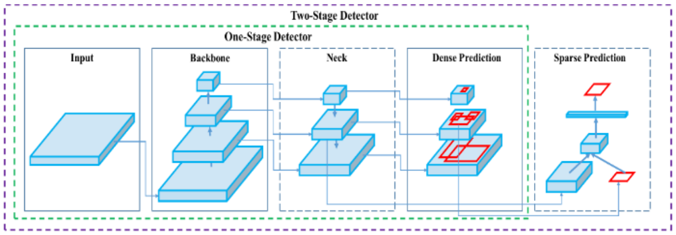

Fig. 8. Structure Modern Detector of YOLOv4 [10].

Based on Fig. 8, YOLO research uses modern detectors, so the researchers make several terms; there are Bag of Freebies (BoF) and Bag of Specials (BoS). The definition of the Bag of Freebies (BoF) is that researchers can perform an optimization to produce better accuracy and not increase inference costs by using training methods. The BoF used for the backbone are DropBlockRegularization, Class Label Smoothing, and CutMix and Mosaic Data Augmentation. BoF for this backbone is useful for increasing the variability in the input image so that the model built has a higher quality for images obtained from different environments. The definition for Bag of Special (BoS) is a set of plugin modules and post-processing methods that only increase inference costs by a small amount, however can significantly improve accuracy in object detection. The BaS used in the backbone include Mish Activation, Cross-Stage Partial Connections (CSP), Multi-Input Weight Residual Connection (MiWRC) [12].

F. *Confusion Matrix*

Confusion Matrix is a performance measurement or performance in solving machine learning classification problems, where the output results can be in the form of two or more classes. Confusion matrix is a predictive analysis tool that displays and compares the actual value with the predicted model value. Prediction models that can be used to get the results of the evaluation matrix are Accuracy, Precision, Recall and F1 Score [19]. This confusion matrix is shown in Fig. 9.

		Actual Values	
		1 (*Positive*)	0 (*Negative*)
Predicted Values	1 (*Positive*)	TP (*True Positive*)	FP (*False Negative*)
	0 (*Negative*)	FN (*False Negative*)	TN (*True Negative*)

Fig. 9. Display Component of Confusion Matrix.

TP (True Positive): The amount of data that is positive and is predicted to be true as positive.

FP (False Positive): The amount of data that is negative however is predicted to be positive.

FN (False Negative): The amount of data that is positive however is predicted to be negative.

TN (True Negative): The amount of data that has a negative value with a correct prediction as negative.

1) Accuracy: Accuracy is a ratio of selected relevant objects to all selected objects. Accuracy can also be defined as a comparison of an object that is correctly identified with the total number of existing objects and the error rate is an object that is identified incorrectly with the total number of existing objects [20].

$$Accuracy = \frac{TP+TN}{TP+TN+FF+FN} \times 100\% \qquad (2)$$

2) Precision: Precision is a level of accuracy of information desired by the user with the prediction results given by the model or system [21].

$$Precision = \frac{TP}{TP+FP} \times 100\% \qquad (3)$$

3) Recall: Recall is the ratio of the number of objects that are detected correctly or True Positive compared to all positive data, recall that has a high value means that the system or model created can classify object classes correctly [22].

$$Recall = \frac{TP}{TP+FN} \times 100\% \qquad (4)$$

4) F1 Score: F1 Score or called the harmonic mean, is a picture of the relative influence between precision and recall [23].

$$F1\ Score = 2 \times \frac{Recall \times Presisi}{Recall + Presisi} \qquad (5)$$

G. *mAP (Mean Average Precision)*

Mean Average Precision or mAP is used as the work evaluation value of the object detection model. Mean Average Precision measures the performance level of the file weights resulting from training mode [24]. The solid mAP equation can be seen in the following equation.

$$mAP = \frac{1}{c}\sum_{t=1}^{c} AP_i \qquad (6)$$

III. Result and Discussion

A. *Train Model Results*

This study uses 3 types of dataset distribution in terms of finding the best level of accuracy. The first division structure is 80% train data, 10% validation data, and 10% test data. The next data division is 70% train data, 25% validation data, and 5% test data. The final data distribution is 60% train data, 20% validation data, and 20% test data. Based on the 3 types of split data, it produces different accuracy values, however the difference in the accuracy values obtained is not too significant. The number of iterations carried out during the training of this model is 6000 iterations. The learning rate was chosen for hyperparameter in model YOLOv4 sperm detection: 0.002, 0.0002, and 0.00002 [9]. The following is a table of accuracy results obtained from training data.

In Table I, testing of all scenarios uses a hyperparameter learning rate of 0.002. We can see that the AP results of each object being trained have the greatest results in two different scenarios. The biggest AP result for sperm objects is in the second scenario with a value of 90.31%. As for the non-sperm object, the biggest result is in the first scenario with a value of

68.35%. The biggest mAP result is in the first scenario of 78.81%.

Table II is a test using a learning rate of 0.0002 from three scenarios. The results obtained from this test are for the biggest AP of the two objects in the second scenario. The AP obtained for sperm objects is 90.37%, while the AP for non-sperm objects is 68.78%. The biggest mAP result is in the second scenario of 79.58%.

Table III uses a learning rate of 0.00002 to get AP results in each scenario. In this training, the biggest AP value for sperm objects is found in the third scenario, with an AP value of 88.42%. As for the AP value of non-sperm objects, the biggest AP result is in the second scenario of 64.40%. The biggest mAP result is in the second scenario of 76.11%.

TABLE I. ACCURACY RESULTS OBTAINED FROM DATA TRAINING WITH A LEARNING RATE OF 0.002

No	**Data Composition**	**AP**		**mAP**
		Sperm	***Non Sperm***	
1	Train 80%, Validation 10%, Test 10%	89.51%	68.13%	78.81%
2	Train 70%, Validation 25%, Test 5%	90.31%	65.35%	77.83%
3	Train 60%, Validation 20%, Test 20%	88.52%	65.24%	76.88%

TABLE II. ACCURACY RESULTS OBTAINED FROM DATA TRAINING WITH A LEARNING RATE OF 0.0002

No	**Data Composition**	**AP**		**mAP**
		Sperm	***Non Sperm***	
1	Train 80%, Validation 10%, Test 10%	89.66%	67.99%	78.83%
2	Train 70%, Validation 25%, Test 5%	90.37%	68.78%	79.58%
3	Train 60%, Validation 20%, Test 20%	89.86%	67.42%	78.64%

TABLE III. ACCURACY RESULTS OBTAINED FROM DATA TRAINING WITH A LEARNING RATE OF 0.00002

No	**Data Composition**	**AP**		**mAP**
		Sperm	***Non Sperm***	
1	Train 80%, Validation 10%, Test 10%	86.94%	62.54%	74.74%
2	Train 70%, Validation 25%, Test 5%	87.82%	64.41%	76.11%
3	Train 60%, Validation 20%, Test 20%	88.42%	63.10%	75.76%

Table I, Table II, and Table III shows that the mAP generated based on several data sharing results in an accuracy range of 74% - 79%. The result of the highest training data accuracy is 79.58% which is found in the distribution of 70% test data, 25% validation data, 5% test data, with a learning rate of 0.0002. The results of the lowest training accuracy are 74.74% which are found in the distribution of 80% test data, 10% validation data, 10% test data, with a learning rate of 0.00002. AP results from Sperm and Non Sperm objects differ greatly. This is due to the fact that the number of datasets used for training is imbalanced data. The best AP result in identifying sperm objects is 90.31% and for non-sperm objects it is 68.13%. The biggest results are obtained from the sharing of data and different learning rates.

B. *Graphical Results of Precision, Recall, F1-Score and on Train Model*

The results of the tests carried out in this study obtained the values of precision, recall and F1-score of several types of learning rates. The results obtained in the model training are good, because the results of each precision, recall and F1-score do not experience very large differences in values. Based on each learning rate that produces the highest value, there is a learning rate of 0.0002 with an average value of 0.8 of the precision, recall and F1-score values. The results of precision, recall, and F1-score illustrate that the model that has been made can predict and retrieve information well. The graph can be seen in the Fig. 10, Fig. 11, and Fig. 12.

Fig. 10 shows a graph of the values of precision, recall, and F1-score of three scenarios based on a learning rate of 0.002. It can be seen that the values of precision, recall, and F1-score in the second and third scenarios have a slight difference. However, the second scenario has a value that is superior to precision and F1 scores with values of 0.75 and 0.81. While the third scenario outperformed the recall value of 0.88, only 0.01 difference from the recall in the second scenario.

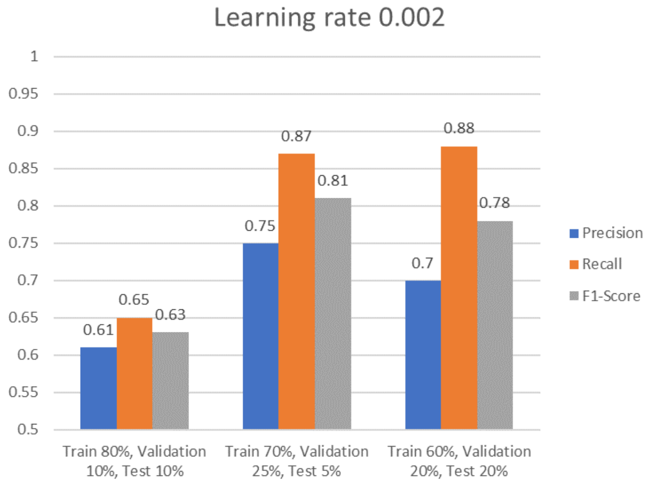

Fig. 10. Graph of Precision, Recall and F1-Score Values at a Learning Rate of 0.002.

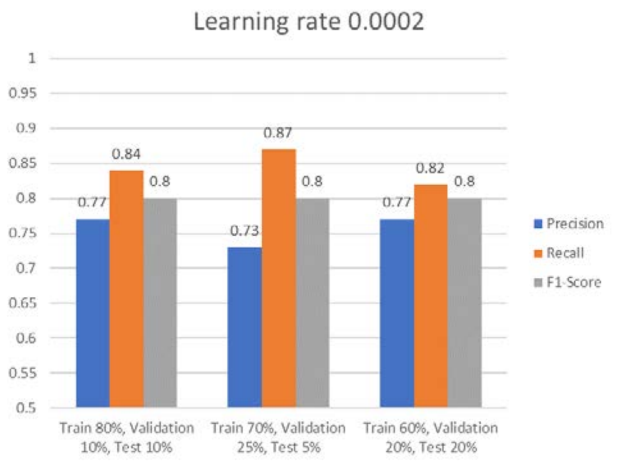

Fig. 11. Graph of Precision, Recall and F1-Score Values at a Learning Rate of 0.0002.

Fig. 11 shows a graph of the values of precision, recall, and F1-score of three scenarios based on a learning rate of 0.0002. It can be seen that the values of precision, recall, and F1-score get a slight difference in the values of the three scenarios. The highest precision value is found in the first and third scenarios with a value of 0.77. then the largest recall value is in the second scenario with a value of 0.87. While the relative F1-Score has the same value in the three scenarios with a value of 0.8.

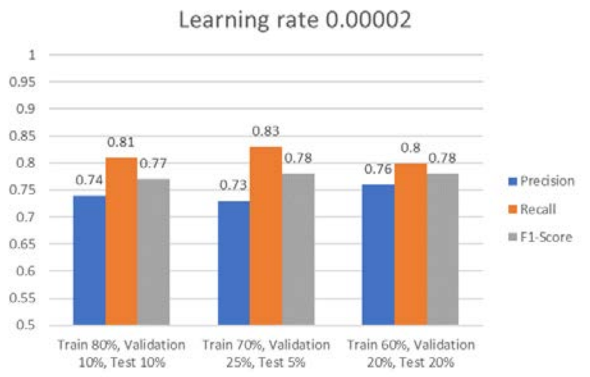

Fig. 12. Graph of Precision, Recall and F1-Score Values at a Learning Rate of 0.00002.

Fig. 12 shows a graph of the values of precision, recall, and F1-scores from three scenarios based on a learning rate of 0.00002. It can be seen that the value of precision, recall, and F1-score in the second scenario has a superior recall value with a value of 0.83. Meanwhile, the highest precision value is found in the third scenario with a value of 0.76. Then for the largest F1-Score value in the second and third scenarios with a value of 0.78.

C. *Overfitting Handling on YOLOv4 Model*

Overfitting occurs when the amount of training data used a slight variation. Based on the training data in this study using training data that has many variations. Training data is taken from several pieces of video frames on the VISEM dataset. YOLOv4 model in doing overfitting analysis according to Alexey the creator of the YOLOv4 model, validation loss in YOLOv4 should not be too much attention because it will tend to decrease continuously, so only mAP accuracy must be considered. If there is a stagnation in the data training process, it is likely that overfitting has occurred. Fig. 13 shows the results of the data training in this research.

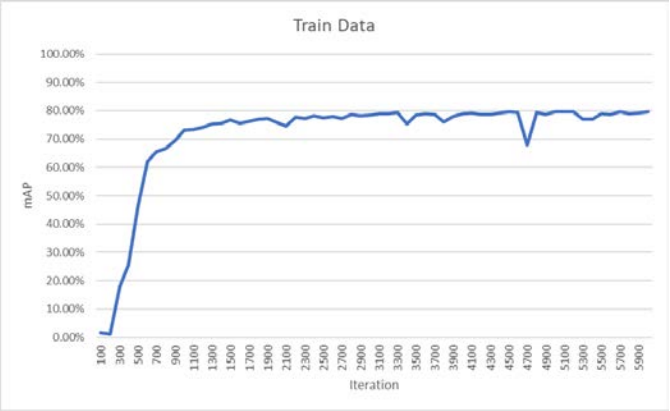

Fig. 13. Graph of Train Data Result from Split Data 70% Train, 25% Validation, and 5% Test with 0.0002 Learning Rate.

Fig. 13 is the result of data training from split data 70% train, 25% validation, and 5% test using a learning rate of 0.0002 which gets the highest mAP results in this research. The graph obtained does not stagnant so that the accuracy of mAP continues to run until the 6000 iteration. The mAP value obtained is 79.58% based on the results of the training data that has been done.

D. *Test Results on the YOLOv4 Model*

The test on this model is done by using a clip from one of the videos from the VISEM dataset. This is because at certain seconds the appearance of the VISEM video dataset will change. This model detects Sperm and Non-Sperm objects in the form of video so that the results of object checking by the model will be displayed based on the frame detected from the video being tested. The following detection results can be seen in Table IV and Table V.

TABLE IV. THE RESULTS OF THE EVALUATION TEST OBJECT ON THE YOLO MODEL

No	Frame Id	Model Prediction		TP	FP	FN
		Sperm	Non Sperm			
1	1	25	8	31	2	0
2	14	25	9	31	3	0
3	26	18	14	30	1	1
4	38	21	13	33	1	0
5	43	23	12	34	1	0
6	55	17	10	26	1	1
7	67	18	9	26	1	0
8	79	19	9	28	0	0
9	86	19	9	27	1	0
10	97	20	9	28	1	0

Table IV shows the result of an evaluation using confusion matrix to get the number of objects that have been detected or not. Detection is collected by object, the results obtained that almost all objects can be detected accurately. The layer capture taken from the YOLO model experiment in the form of video is taken as much as 10 frames, because there are so many frames generated from 1 video.

Table V describes the results of data processing obtained in the process in Table IV. These values are used to obtain precision, recall, AP, and mAP values. The results obtained will be a benchmark for the accuracy of the model in detecting objects. We can see the results of the experiment stated that the model can detect more than 80% of the number of objects in a video frame.

Based on the description in Table IV and Table V, it can be stated that the model can detect sperm and non-sperm objects with good results. In the sperm and non-sperm sections, a bounding box has been successfully created with a video quality of 50 fps, however there are one or two objects that are not legible, this is due to the object being cut off by the video frame. Fig. 14 is a display of the detection results from the model that has been created.

TABLE V. CALCULATION RESULTS OF PRECISION, RECALL, AP, AND MAP

No	Precision	Recall	AP		mAP
			Sperm	Non Sperm	
1	0.94	1.00	0.94	0.73	0.83
2	0.91	1.00	0.99	0.82	0.90
3	0.97	0.97	0.99	0.96	0.98
4	0.97	1.00	0.98	1.00	0.99
5	0.97	1.00	0.99	1.00	0.99
6	0.96	0.96	0.99	1.00	0.99
7	0.96	1.00	0.99	1.00	0.99
8	1.00	1.00	1.00	1.00	1.00
9	0.96	1.00	0.99	1.00	0.99
10	0.97	1.00	0.99	1.00	0.99

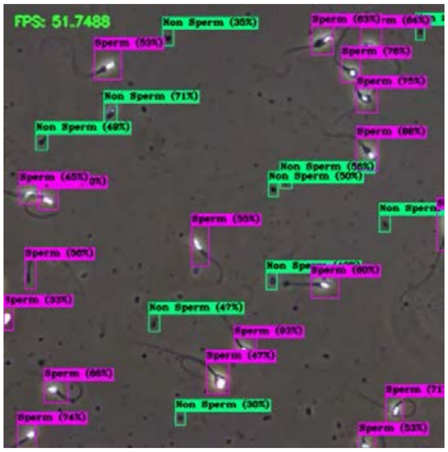

Fig. 14. Display Testing.

IV. CONCLUSION

This research develops an object detection development using the YOLOv4 algorithm to detect sperm and non-sperm objects. Using a dataset derived from the open source Simula Open Dataset, then the data in the form of videos is extracted into 1330 images. In this study, the training process was carried out with 3 different learning rate experiments, namely 0.002, 0.0002, 0.00002. In each of these experiments, 3 data divisions were made for each of the reading rates being tested. The best accuracy results are found in experiments with a learning rate of 0.0002 which has an accuracy value of 79.58% mAP on 70% train data distribution, 25% validation and 5% test. Each trial process for training uses 6000 iterations to create the training data. The test in this study uses video, the results of which are that all objects can be detected properly and have been labeled with a bounding box. In this study there were cases where the model was not able to detect optimally because the video data used contained blurred objects and sperm objects that were cut off by the frame.

ACKNOWLEDGMENT

The experiment in this research used NVIDIA Tesla K80 and Tesla K20 provided by Department of Computer Science, University of Lampung.

***Abstract*—Image segmentation is an essential technique of brain tumor MRI image processing for automated diagnosis of an image by partitioning it into distinct regions referred to as a set of pixels. The classification of the tumor affected and non-tumor becomes an arduous task for radiologists. This paper presents a novel image enhancement based on the SCA (Sine Cosine Algorithm) optimization technique for the improvement of image quality. The improved FLICM (Fuzzy Local Information C Means) segmentation technique is proposed to detect the affected regions of brain tumor from the MRI brain tumor images and reduction of noise from the MRI images by introducing a fuzzy factor to the objective function. The SCA weight-optimized Wavelet-Extreme Learning Machine (SCA-WELM) model is also proposed for the classification of benign tumors and malignant tumors from MRI brain images. In the first instance, the enhanced images are undergone improved FLICM Segmentation. In the second phase, the segmented images are utilized for feature extraction. The GLCM feature extraction technique is considered for feature extraction. The extracted features are aligned as input to the SCA-WELM model for the classification of benign and malignant tumors. The following dataset (Dataset-255) is considered for evaluating the proposed classification approach. An accuracy of 99.12% is achieved by the improved FLICM segmentation technique. The classification performance of the SCA-WELM is measured by sensitivity, specificity, accuracy, and computational time and achieved 0.98, 0.99, 99.21%, and 97.2576 seconds respectively. The comparison results of SVM (Support Vector Machine), ELM, SCA-ELM, and proposed SCA-WELM models are presented to show the robustness of the proposed SCA-WELM classification model.**

Keywords*—*Sine cosine algorithm; extreme learning machine; fuzzy c means; GLCM feature; support vector machine

I. Introduction

Brain tumor-related deaths are increasing worldwide according to the reports of the WHO (World Health Organization). The people affected by brain tumors are suffered from the symptoms of headache, vomiting, mildness of eye vision, and many more as per the medical study. The early treatment of tumor-related disease is essential to avoid recurrent deaths. To make treatment faster, automated segmentation and classification techniques are the requirements for medical diagnosis. The pre-processing step is simple and essential in brain-image analysis. Pre-processing is generally used to reduce the noise and enhance the image resolution and contrast. Many pre-processing approaches are used, like un-sharp masking, veneer filters as well as median-filters. Median filters are usually utilized during the pre-processing phase to protect the boundaries of an image [1]. The image segmentation of brain tumors from "magnetic resonance imaging (MRI)" is a significant assignment for the medical diagnosis of brain tumors. The conventional fuzzy c-means clustering (FCM) algorithm is sensitive to noise. This paper proposes an improved fuzzy local information-based FCM image segmentation to address the difficulties of segmentation. Sehgal et al. [2] proposed a segmentation strategy based on neural network optimization that uses neighborhood attraction using MRI. By taking into account the local attractiveness, the strategy changed the classic FCM method. The enhanced FCM clustering (IFCM), takes into account local attractions, based on two components: characteristics as well as a span of attraction. To partition brain tumor MRIs, researchers used the method published by Nabizadeh et al. [3] for calculating characteristics from the association between the tumors and with brain's LaVs. The method is divided into 4 steps: pre-processing, segmentation, and feature extraction with classification. Li et al. [4] suggested a brain tumor partition technique that incorporated anisotropic diffusion filtering as a pretreatment step, followed by partition as well as tumor extraction utilizing region with circularity using the FCM technique.

Machine learning has ignited considerable interest in modern computers in the field of medicine. In the area of brain-tumor recognition, a variety of advanced machine learning approaches are applied. Advanced methods are employed to identify the use of brain pictures and improve the quality of the information collected, such as image labeling, image reconstruction, skull removal, and registration [13]. As a result, machine learning has enabled clinics, engineers, and computer scientists to collaborate to develop semi-automated and eventually completely automated tumor diagnostic systems with improved accuracy and processing speed. Motivated by

the advancements of machine learning, we have proposed the following contributions.

A. Contribution of the Research Work

Three contributions are proposed based on image enhancement, image segmentation, and classification. The contributions are summarized as follows:

- In the first aspect, the position and velocity parameters of the SCA algorithm are modified to enhance the quality of the images.
- In the second aspect, the fuzzy factor in FLICM segmentation is replaced with a new fuzzy factor to improve the tumor detection and noise reduction capability from the brain MRI images. The mathematical analysis for the improved fast and robust FLICM segmentation algorithm is presented to authenticate the proposed segmentation.
- In the third aspect, the weights of the Mexican Hat Wavelet -ELM model optimization by the SCA optimization technique are proposed to enhance the classification performance.

The paper is organized as follows. Section 2 presents the research implementation diagram, Section 3 presents the Sine cosine algorithm for image enhancement, the proposed fast and robust FLICM segmentation technique and proposed SCA-WELM model explanation, and Section 4 presents results and discussion of the proposed image enhancement, segmentation, and classification, Section 5 presents the conclusion and followed by the references.

II. Related Work

Several segmentation techniques are presented by the researchers, and some of the latest research is included in the related work. Pinheiro et al. [5] devised a novel MRI technique for detecting brain tumors. Global threshold partitioning has been applied after pre-processing of input MRIs. Before watershed partition, Morphological approaches have been used to improve its results. Elazab et al. [6] proposed an "adaptively regularized kernel-based fuzzy C-means (ARKFCM)" segmentation to reduce computational time than the KFCM segmentation. FCM clustering algorithms with spatial constraints are proposed to remove the noise proposed in [7,8]. Chao et al. [9] proposed a GM-ARKFCM algorithm to show better segmentation than ARKFCM. Cherfa et al. [10] proposed AKFRFCM using Particle swarm optimization to improve segmentation capability. Tao Lei et al [11] presented a "fast and robust FCM (FRFCM)", which uses more parameters, and fails drastically to reduce Gaussian noise, beyond 30%. Satyasis et al. [12] proposed an improved fast and robust FCM algorithm (IFRFCM) to improve the noise reduction capability. Belean et al. [14] proposed a density-based spatial clustering procedure driven by a level-set approach for microarray spot segmentation and quality measures were obtained. Wenxiu et al. [15] proposed a two-phase selective segmentation method, in which the first phase reduces noise on segmentation and the second phase shows the selective segmentation on the preprocessed image.

There are several machine learning methodologies and methods to detect brain tumors by utilizing MRIs. An approach has been described by El-Dahshan et al. [16], during the discovery phase, an artificial feedback neural network and KNN are used. Saritha et al. [17] explained a new method for identifying usual and unusual brain MRI images pathologically. Three features are extracted using wavelet entropy-based spider-web plots. Yang et al. [18] suggested a recent method for MRI-based early recognition of brain tumors. With the RBF function, a kernel-type SVM is used as a classifier. In [19], Kalbkhani et al. employed 2D DWT and generalized autoregressive conditional heteroskedasticity (GARCH). The features are extracted using linear discriminate analysis (LDA), and the feature vectors are reduced using PCA. For the detection process, KNN, as well as SVM identifiers, are used. A method for tumor detection was proposed by Xiao [20] and Abd-Ellah et al. [21]. The input image is used to extract three kinds of characteristics: intensity-based, texture-based, and symmetry-based features. Mohsen et al. [22] employed a recent MRI method for recognizing brain tumors. For dimensionality reduction, PCA is utilized to reduce picture features. A BPNN determines if a subject's pictures are normal or irregular. Soltaninejad et al. [23] suggested a mixed method for MRI recognition of brain tumors. A feedback pulse-coupled neural network is used to preprocess the image (FPCNN). For feature extraction and reduction, PCA and the discrete wavelets transform (DWT) are employed. Using two-level DWT decomposition, the LL sub-band data is delivered to the PCA. For the detection stage, PCA has been utilized to choose a vector of seven features. The FFBPNN is then used to identify whether or not the MRI image is usual or unusual. Abdel-Maksoud et al. gave a new approach for detecting brain tumors using MRIs in [24]. A median filter is used to preprocess MRI images before DWT extracts features. PCA has been used to reduce the number of features, whereas RBF and kernel type SVM has been used to recognize them. Tustison et al. [25] extracted features using Daubechies wavelets, which were subsequently processed using PCA to decrease feature vectors.

The usual and unusual MRIs haave then detected utilizing an SVM as well as RBF. Nabizadeh et al. [26] described a hybrid method to recognize brain tumors utilizing MRIs. The suggested approach involves LS-SVM, GLCM, and noise filtering in three levels: preprocessing, and feature extraction with detection. The four features collected are energy, correlation, homogeneity, and contrast. Huang et al. [27] discovered that the brain MRI dataset is studied using MLP, LVQ, RBF, and SOM classifiers in the recognition step. Median, as well as Gaussian filters are utilized during preprocessing state. Boarder could be extracted by utilizing Gaussian thresholding. GLCM has been utilized to extract features, which results in 21 features that are then reduced to 8 by PCA. Mahima et al. [28] proposed a fractional order contour detection PDE (partial differential equation) model with a regularization term for noise reduction and maintaining the regularity of level set function (LSF). A cellular neural network (CNN) model is used to solve the proposed contour detection PDE. Bogdan et al. [29] proposed an edge-based active contour model (ACM) driven by cellular neural networks (CNNs) for the segmentation procedure. Javeria et al.

[30] proposed the inceptionv3model for deep feature extraction, and quantum variational classifier (QVR) with the 2020-BRATS dataset and achieved more than 90% detection accuracy. Muhammad et al. [31] proposed Berkeley's wavelet transformation (BWT) and deep learning classifier and achieved an accuracy of 98.5%. Ramin et al. [32] Proposed Cascade Convolutional Neural Network (C-ConvNet/C-CNN) classifier with the BRAT-2018 dataset and achieved a dice score of 0.9113 for enhancing tumor. Isselmou et al. [33] deep wavelet autoencoder model with 2500 MR brain images of brat dataset and achieved an accuracy of 99.3% and 0.1 loss validation.

III. Methodology

A. Research Flow Diagram

The research work follows the following steps: (i) The Dataset-255 brain tumor images are collected and the SCA technique is applied for image enhancement and segmented by the novel Improved FLICM segmentation techniques. Further (ii) the segmented images undergo GLCM feature extraction; (iii) in the third stage, the extracted features are fed as input to the proposed SCA weight optimized WELM model for the classification of the benign and malignant tumors; (iv) in the fourth stage classification comparison results of the models are presented. The research implementation phase is shown in Fig. 1.

B. The Sine Cosine Algorithm (SCA)

Swagat et al. [34] proposed PSO and APSO algorithms for enhancement of the gray images, but not applied to brain tumor images. The "sine cosine algorithm" (SCA) [35] is an optimization algorithm based on the sine and cosine functions search also not utilized for brain MRI image enhancement.

According to sine cosine algorithm [35] the position equation is updated as

$$X_i^{n+1} = \begin{cases} X_i^n + \alpha_1 \times sin(\alpha_2) \times |\alpha_3 p^{gbest} - X_i^n|, \alpha_4 < 0.5 \\ X_i^n + \alpha_1 \times cos(\alpha_2) \times |\alpha_3 p^{gbest} - X_i^n|, \alpha_4 \geq 0.5 \end{cases} \quad (1)$$

Where $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ are the random variables and α_1 is given by.

$$\alpha_1 = a\left(1 - \frac{n}{K}\right) \quad (2)$$

Where “ is the current iteration, K is the maximum number of iterations”. p^{gbest} is the global best position of the pixels in the image.

The X_i^n signifies the “current position” and X_i^{n+1} signifies the “new position”. The α_1 is the next position in the search, α_2 determines direction of movement, α_3 controls the current movement, and the parameter α_4 uniformly switches among the sine and cosine functions. The parameter and α_1 is given by.

$$\alpha_1 = a\left(1 - \frac{n}{K}\right)$$

Where the current iteration is given by n, maximum numbers of iterations are denoted by K and a is a constant. Now considering the population images Xi as corresponded image position ξ_l in the image and applies the SCA algorithm for image enhancement.

$$\xi_i^{n+1} = \begin{cases} \xi_i^n + \alpha_1 \times sin(\alpha_2) \times |\alpha_3 p^{gbest} - \xi_i^n|, \alpha_4 < 0.5 \\ \xi_i^n + \alpha_1 \times cos(\alpha_2) \times |\alpha_3 p^{gbest} - \xi_i^n|, \alpha_4 \geq 0.5 \end{cases} \quad (3)$$

With the equation operation on the image, the new position of the pixel values of the images is calculated for image enhancement. The pseudo code for the algorithm implementation is presented in Table I.

C. Improved Fast and Robust Fuzzy Local Information C Means (FRFLICM) Algorithm

According to enhanced fuzzy c means EnFCM [36] algorithm the image ξ is considered from the original image and is given by.

$$\xi_k = \frac{1}{\alpha}\left(x_k + \frac{\alpha}{N_k}\sum_{j\in N_k} x_j\right) \tag{5}$$

Where the gray value of k^{th}pixel of image ξ is given by ξ_k, x_j is neighbors of x_k, N_k is set of neighbors around x_k. Now the new objective function is given by.

$$J_s = \sum_{l=1}^{N}\sum_{k=1}^{c}\gamma_l\, u_{kv}^{m}\|\xi_l - v_k\|^2 \tag{6}$$

Where " u_{il} represents the fuzzy membership of gray value l." γ_l is the number of the pixels having the gray value equal to$l$, and $l = 1,2,\ldots.N$.

According to the FLICM segmentation [37], the fuzzy factor is given by.

$$G_{kv} = \sum_{\substack{k\in N_v \\ v\neq k}} \frac{1}{d_{vk}+1}(1-u_{kv})^m\|x_v - v_k\|^2 \tag{7}$$

To improve the noise reduction capability the fuzzy factor is modified, and the new cost function is given by with improved fuzzy factor as.

$$J_s = \sum_{l=1}^{N}\sum_{k=1}^{c}\gamma_l\, u_{kv}^{m}\|\xi_l - v_k\|^2 + \sum_{v=1}^{N}\sum_{k=1}^{c} {G_{kv}}^2 \tag{8}$$

$$J_s = \sum_{l=1}^{N}\sum_{k=1}^{c}\gamma_l\, u_{kv}^{m}\|\xi_l - v_k\|^2 + \sum_{v=1}^{N}\sum_{k=1}^{c} \left(\sum_{\substack{k\in N_v \\ v\neq k}} \frac{1}{d_{vk}+1}(1-u_{kv})^m\|x_v - v_k\|^2\right)^2 \tag{9}$$

With the new objective function, the segmentation accuracy has been improved and segmentation results are presented in the result section.

D. Wavelet ELM Model with SCA Optimization

In this research work, we propose an SCA optimization for wavelet ELM weight optimization (SCA-WELM) that learns the output weights of the ELM classifier. The pseudo-code for SCA weight optimization of the WELM model is presented in Table II. The SCA-WELM model with hidden and output layers is shown in Fig. 2.

The output function of ELM [38] with L hidden neurons is represented by.

$$y = \sum_{k=0}^{L}\beta_k h_k(w_k; x) \tag{10}$$

where $h(w;x) = [1, h_1(w_1;x), \ldots\ldots., h_L(w_L;x)]$ is the hidden feature mapping and β is the weight vector of all hidden neurons to an output neuron, $h_k(\cdot)$is the activation function of hidden layer. Equation (10) can be written as.

$$H\beta = y \tag{11}$$

Where H is the $N \times (L+1)$hidden layer feature-mapping matrix, whose elements are as follows:

$$H = \begin{bmatrix} 1 & h_1(w_1;x_1) & \cdots & h_L(w_N;x_1) \\ \vdots & \vdots & \vdots & \vdots \\ 1 & h_1(w_1;x_N) & \cdots & h_L(w_N;x_N) \end{bmatrix} \tag{12}$$

And $h_L(w_N;x_N) = [w_1x_1 + w_1x_1 \ldots\ldots\ldots w_Nx_N].\varphi(t)$

Where $\varphi(t) = c(1-x^2)exp\left(-\frac{x^2}{2}\right)$ and $c = \left(\frac{2}{\sqrt{3}}\pi^{-1/4}\right)$

Equation (10) is a linear system, which is solved by

$$\beta = H^{\dagger}\, d, \qquad H^{\dagger} = (H^TH)^{-1}H^T \tag{13}$$

Where $H^{\dagger}$ is the "Moore–Penrose generalized inverse of matrix H " and $d = [d_1, \ldots\ldots, d_N]^T$.

And $d = \begin{bmatrix} d_1 \\ d_2 \\ \vdots \\ d_n \end{bmatrix}$, $\beta = \begin{bmatrix} \beta_1 \\ \beta_1 \\ \vdots \\ \beta_n \end{bmatrix}$

IV. Results and Discussion

A. Database Description

The Dataset-255 is collected from "Harvard medical school of architecture (URL: http://med.harvard.edu/ AANLIB/)"[12, 39] which consists of "255 (35 normal and 220 abnormal) 256x256 axial plane brain images" are shown in Table III. "Abnormal brain MR images of Dataset-255 are from 11 types of diseases including Alzheimer’s disease. The Dataset-255 consists of abnormal images of 4 new types of diseases such as chronic subdural hematoma, cerebral toxoplasmosis, herpes encephalitis, and multiple sclerosis".

TABLE III. Details of Dataset-255 [12]

Dataset	Total number of images		Training Images		Testing Images	
	Normal	Abnormal	Normal	Abnormal	Normal	Abnormal
Dataset-255	35	220	28	176	7	44

B. Feature Extraction

The "gray-level co-occurrence matrix (GLCM)" [40] statistical features such as "standard deviation, DM (Directional Moment), entropy, coarseness, energy, kurtosis, homogeneity, and energy" features are considered for this research work and presented in Table IV.

TABLE IV. Normalized Feature for Dataset-255

Sl.No.	Features	Values
1	Standard Deviation	0.4587
2	DM	0.8751
3	Entropy	0.9953
4	Coarseness	0.6895
5	Energy	0.7854
6	Kurtosis	0.4122
7	Homogeneity	0.2527

C. Enhancement Results

For the enhancement of the images, the sine cosine algorithm (SCA) has been proposed and compared with the PSO and APSO techniques [34, 41].

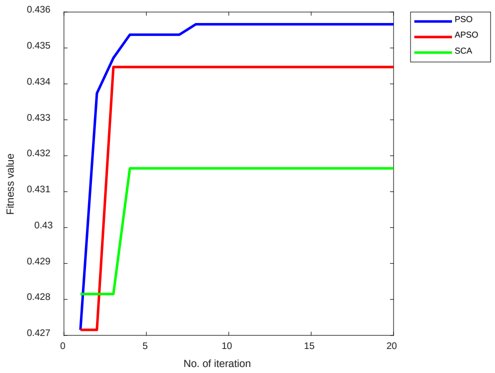

Fig. 3. Image Enhancement of the Benign Tumor Image-1 using PSO, APSO and SCA.

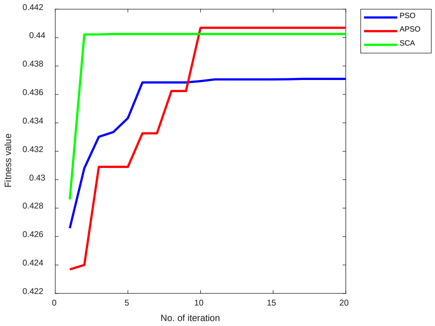

Fig. 4. Image Enhancement of the Benign Tumor Image-2 using PSO, APSO and SCA.

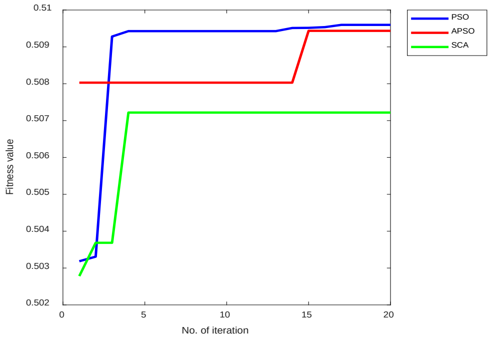

Fig. 5. Image Enhancement of the Malignant-tumor Image-1 using PSO, APSO and SCA.

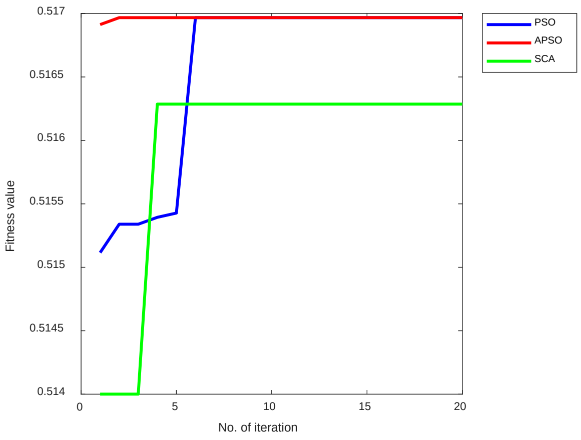

Fig. 6. Image Enhancement of the Malignant Tumor Image-2 using PSO, APSO and SCA.

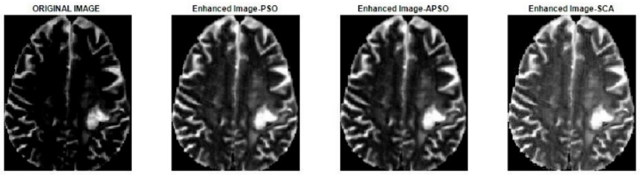

Fig. 7. Benign Tumor Image-1 Image Enhancement using PSO, APSO and SCA.

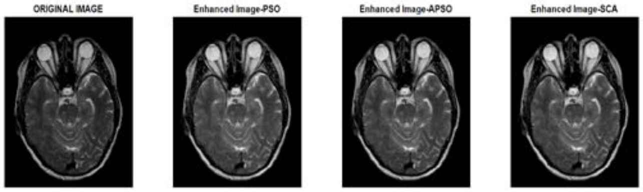

Fig. 8. Benign Tumor Image-2 Image Enhancement using PSO, APSO and SCA.

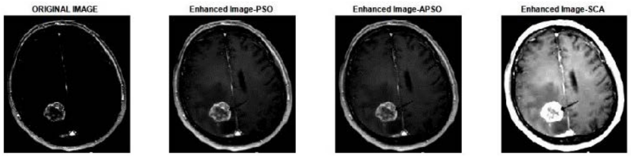

Fig. 9. Malignant Tumor Image-1 Image Enhancement using PSO, APSO and SCA.

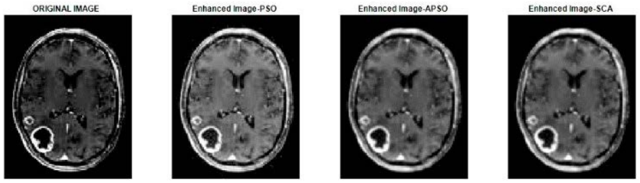

Fig. 10. Malignant Tumor Image-2 image Enhancement using PSO, APSO and SCA.

From Fig. 3 and Fig. 4, it is observed that the fitness value for SCA is 0.4318 and 0.4412 for Benign tumor image1 and image-2, which indicates better image enhancement than the other PSO and APSO methods. Moreover, from Fig. 5 and Fig. 6, it is found that the fitness value is 0.5072 and 0.5162 for malignant tumor image1 and image-2. The higher fitness values for malignant tumor images and lower values for benign tumors indicate better image enhancement of the image. Fig. 7 and Fig. 8 show the benign tumor image-1 and image -2 image enhancement using PSO, APSO, and SCA having fitness values of 0.4318 and 0.4417, and Fig. 9 and Fig. 10 show the malignant tumor image-1 and image -2 image enhancement using PSO, APSO, and SCA having fitness values 0.5072 and 0.5162. Table V presents the fitness values of Benign and Malignant tumor image enhancement.

TABLE V. FITNESS VALUES OF BENIGN AND MALIGNANT TUMOR IMAGE ENHANCEMENT

	Fitness Value	
Algorithm	Benign	Malignant
PSO	0.4367	0.5095
APSO	0.4412	0.5085
SCA	0.4417	0.5162

D. Segmentation Results

The segmentation results are presented in Fig. 11 to Fig. 14. Fig. 11 shows the segmentation of the brain tumor using the FLICM Algorithm. It is visually observed that the noise is not reduced up to the requirement as compared to the other segmentation methods due to the fuzzy factor involvement. Fig. 12 presents the segmentation using the KWFLICM segmentation technique and the segmentation accuracy is 98.48% due to the spatial factor. Fig. 13 shows the segmentation by using the FRFCM Algorithm, which shows a better improvement in terms of accuracy to 98.84% due to the medial filtering in the fuzzy partition matrix and Fig. 14 shows the segmentation by utilizing the proposed improved FLICM technique which has higher accuracy of 99.12% due to improvement in the fuzzy factor. It is visually observed clearly that the proposed Improved FLICM technique has more noise reduction capability than the other segmentation algorithms. The segmentation accuracies are presented in Table VI.

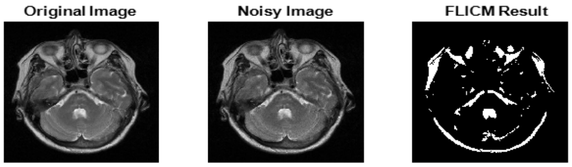

Fig. 11. Segmentation using FLICM Algorithm.

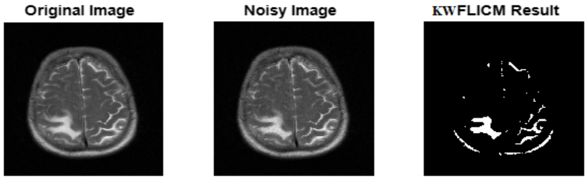

Fig. 12. Segmentation using KWFLICM Algorithm.

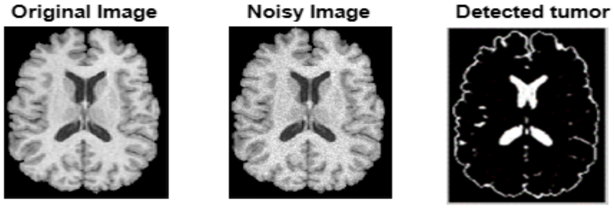

Fig. 13. Segmentation using FRFCM Algorithm.

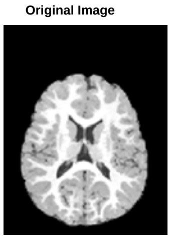

Fig. 14. Segmentation using Proposed Improved FLICM Algorithm.

TABLE VI. IMAGE SEGMENTATION ACCURACY

	Noise level
Algorithm	Speckle Noise
En FCM	97.72
FLICM	98.11
KWFLICM	98.48
NDFCM	98.78
FRFCM	**98.84**
Improved FLICM	**99.12**

E. Quality Measures

To achieve the performance comparison of segmentation, two quality measures are considered "Structural Similarity (SSIM) index and the Quality Index based on Local Variance (QILV) [12]. SSIM is sensitive to the noise and the QILV" is related to the blurring of the edges of the images. On the above, the PSNR (Peak Signal to noise ratio) is also an important parameter related to noise reduction capability. It is observed that the PSNR is 35.39 dB for the proposed FRFLICM segmentation technique which is higher in comparison to the other FCM-based segmentation techniques, which are shown in Table VII. The higher value of PSNR shows a better noise reduction capability. Moreover, the higher value of SSIM and the lower value of QILV shoe the better the segmentation performance.

TABLE VII. QUALITY MEASURES FOR THE MR IMAGE WITH SPECKLE NOISE

	Speckle Noise		
Algorithm	**SSIM**	**QILV**	**PSNR(dB)**
En FCM	0.7748	0.7458	18.14
FLIFCM	0.7894	0.8248	22.14
KWFLICM	0.8287	0.8589	24.52
NDFCM	0.8578	0.8785	26.35
FRFCM	**0.9101**	0.9428	**31.33**
FRFLICM	**0.9758**	0.9541	**35.69**

F. Classifier Performance Measure

Dataset-255 containing T2-weighted magnetic resonance brain images is considered for this research work. To avoid overfitting we have employed a 5×5 cross-validation procedure. "Sensitivity, specificity, accuracy" are the measure of system performance [12].

$$Sensitivity = \frac{TP}{TP + FN} \quad , \quad Specificity = \frac{TN}{TN + FP} \quad ,$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

The "5×5-fold cross-validation for each run of Dataset -255" is presented in Table VIII. Table IX shows the "5×5-fold cross validation" procedure for run-1 of Dataset-255. The calculations are considered for the modified SCA-WELM classifier.

TABLE VIII. 5×5 CROSS VALIDATION FOR EACH FOLD DATASET-255 DURING EACH RUN (SCA-WELM CLASSIFIER)

	Fold-1	Fold-2	Fold-3	Fold-4	Fold-5	Total	Accuracy (%)
Run-1	51	51	50	51	50	253	**99.2156**
Run-2	51	51	50	50	51	253	99.2156
Run-3	51	50	50	51	50	252	98.82
Run-4	50	50	51	51	50	252	98.82
Run-5	51	51	51	51	51	255	100
Average Accuracy result							**99.21**

TABLE IX. 5×5 CROSS VALIDATION OF RUN-1 FOR DATASET-255 (SCA-WELM CLASSIFIER

Fold	Test instances	TP	FN	TN	FP	Accuracy (%)
Fold -1	51	43	1	7	0	98.039
Fold -2	51	44	0	7	0	100
Fold -3	51	43	1	7	0	98.039
Fold -4	51	44	0	7	0	100
Fold -5	51	43	1	7	0	98.039
	Average Accuracy result					**99.21**

TABLE X. PERFORMANCE MEASURE OF DIFFERENT CLASSIFIERS

	Dataset -255			
Classifier	Sensitivity	Specificity	Accuracy in (%)	Computational Time in Seconds
SVM	0.96	0.93	96.85	256.2356
ELM	0.97	0.99	97.86	221.3657
SCA-ELM	0.98	0.93	98.97	167.1478
SCA-WELM	**0.98**	**0.99**	**99.21**	**97.2576**

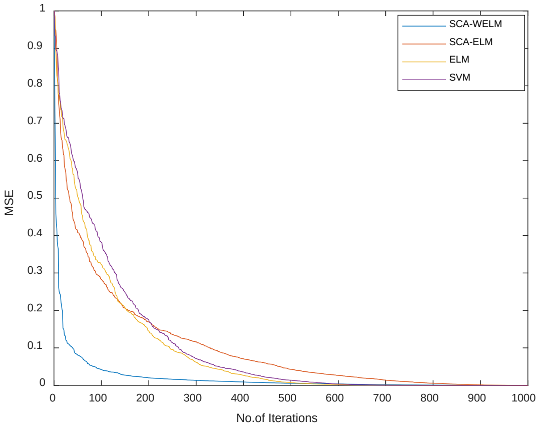

Fig. 15. Mean Square Error Results Comparison.

The proposed SCA-WELM outperforms than other mentioned classifiers in terms of "sensitivity, specificity, and accuracy". The accuracy obtained by SVM, ELM, SCA-ELM, and SCA-WELM is 0.98, 0.99, and 99.21, respectively. Computation time for the proposed SCA-WELM is achieved as 97.2576 seconds (see, Table X). For Dataset-255, it is observed from Fig. 15 that the proposed SCA-WELM model took nearly 360 iterations to converge whereas the SVM, ELM, and SCA-ELM took 530iterations, 580iterations, 430 iterations, and 330 iterations respectively. From the results of mean square error, it is confirmed that the proposed SCA-WELM model provides better performances in terms of accuracy and computational time.

V. Conclusion

In this paper, we have proposed a sine cosine algorithm for image enhancement techniques to improve image quality. The image enhancement technique increases the contrast and smoothens the image by automatic pixel adjustment. A fast and robust FLICM-based segmentation technique has been employed to remove the speckle noise and detect the regions of the brain tumor. The comparison results are presented with other conventional EnFCM, FLICM, KWFLICM, NDFCM, and FRFCM segmentation techniques. The accuracy achieved by the proposed improved FLICM technique shows the robustness of the segmentation technique. Moreover, the higher values of SSIM and PSNR in the case of proposed improved KLICM segmentation confirm the increase in noise reduction capability. The segmented images undergo the GLCM feature extraction technique and the normalized features are presented for classification. The SCA optimization technique has been employed for the optimization of the weights of the wavelet extreme learning machine. The Mexican hat wavelet function is considered in the hidden neurons to increase the capability of classification. Dataset-255 has been considered for this research. The proposed SCA-WELM classifier model has outperformed in classifying the tumors into Benign and Malignant categories. The proposed SCA-WELM model can be applied for breast cancer, and liver tumor medical imaging classification. The proposed model will work for only features as input from the feature extraction methods, but not with images as input to the model like CNN models, which may be a drawback of the research, but this novel method can be applied for different medical images datasets. The novel level set method for 3D brain tumor segmentation [42] and active contour approaches [43] will be the future work of this research to have better visibility and comparison results.

A Machine Learning and Multi-Agent Model to Automate Big Data Analytics in Smart Cities

Fouad SASSITE, Malika ADDOU, Fatimazahra BARRAMOU
Team (ASYR) - Laboratory of Systems Engineering
Hassania School of Public Works (EHTP)
Casablanca, Morocco

***Abstract*—The objective of this paper is to present an architecture to improve the process of automating big data analytics using a multi-agent system and machine learning techniques, to support the processing of real time big data streams and to enhance the process of decision-making for urban planning and management. With the rapidly evolving information technologies, and their utilization in many areas such as smart cities, social networks, urban management and planning, massive data streams are generated and need an efficient approach to deal with. The proposition in this paper adopts the concept of smart data which focuses on the value aspect from big data. The proposed architecture is composed of three layers: data acquisition and storage, data management and processing and the service layer, based on a multi-agent system to automate the big data analytics; the proposed model describe the functionalities of the system and the collaboration between agents, these autonomous entities receive data streams in real time, they perform operations of preprocessing, big data analytics and storage into a Hadoop cluster. The techniques of machine learning are also used to enhance the process of decision making, such the use of classification algorithms to predict habitat type based on the characteristics of a population to help making efficient urban planning decisions. The proposed system can serve as a platform to support data management and to conduct effective decision-making in smart cities.**

Keywords—Big data analytics; machine learning; smart data; multi-agent system; automation; decision-making; urban planning

I. Introduction

With the increasingly rapid evolution of information technologies, and its use in many areas such as smart cities, social networks, online business applications, transportation data, urban management, and planning. These massive data are generated with high velocity and require real-time processing, the emergence of the concept of Big Data in many areas has become a reality that imposes itself on systems based on traditional data management and processing technologies such as relational databases. The amounts of generated data are increasingly unstructured due to the diversity and the heterogeneity of the data sources, some studies [1] are claiming that the use of connected object can reach more than 25 billion in 2020. This rapid growth of generated big data imposes new challenges in terms of storage, data analytics and processing, it requires new approaches to provide more reliable solution to deal with the big data.

Useful information, actionable knowledge and valuable data is normally incorporated into these voluminous raw data, Smart Data is the approach that focuses on the value aspect of the big data and try to exploit these huge masses and discover knowledge from these data [2].

Smart data with a focus on veracity and value has been introduced, The goal is to effectively clean or rectify imperfections in the raw data and put the action on the valuable data, which can be effectively used by businesses and governments for planning, evaluation, control and intelligent decision making [3], [4], in order to turn big data into smart data, some researches [5] focuses on the importance of the preprocessing steps and others [6] proposes to highlight the importance of improving four fields of interest:

- Reliable infrastructures,
- Data Organization and management,
- analyze and prediction,
- Decision support and automatization.

This research is in line with this theme of research, and it tries to give a contribution in this area by proposing a multi-agent system in order to automate the processing and analysis of Big Data and to improve the decision-making process, to better use the collected Big Data and to give a sense of these data.

The use of this paradigm in smart cities constitutes an added value in the process of data management and the exploitation of the most of these data to refine the decision making in real time, for problems that require actions in real time and in an automatic way without human intervention based on autonomous agents dotted with artificial intelligence to solve problems related to smart cities such as the congestion of traffic flows, or for the decision making in the long and medium term such as to predict and anticipate the equipment and the necessary infrastructures for the urban planning.

The applications of this proposition can be in several domains notably in the field of urban management and planning, the use of this system can improve the handling of big data issued from the management of smart cities and help to exploit the amount of data generated and analyze it in an intelligent way to create machine learning models that can guide efficient decision making in these cities.

This paper is structured as follows: Section II will discuss some paradigms related to this research topic. Section III will highlight and discuss some related works. Section IV describes the proposed approach. Section V will study the conducted experimentations in this work and the final section will conclude and gives some perspectives.

II. Background of the Study

This section will highlight some of the main concepts related to this research work, First, we will highlight the complexity and diversity of the nature of big data from smart cities, and then show the value of smart data which focuses on the value aspect of the big data and on intelligent processing. Next, we will expose the importance of multi-agent systems in the process of big data processing automation in order to automate the process of real time decision making. Finally, we will explain the importance of machine learning techniques and algorithms, to strengthen the cognitive part of the proposed system.

A. *Big Data to Smart Data*

Big data usually refers to data with large volume of datasets characterized by the complexity and challenges to handle it due the nature of those data and the actual technologies to store and process this type of data [7], [8] the main characteristics in the literature to classify the data as big data:

- Volume, Variety velocity shows the manner in which the data has been generated and the process of storing and processing it.
- Value and Veracity focuses on value aspect, the usefulness, and the quality of data.

In order to automate the process of big data analytics a study of the nature of this data should be done to understand it, basically the big data sources generates three main formats [9] as described in the Fig. 1.

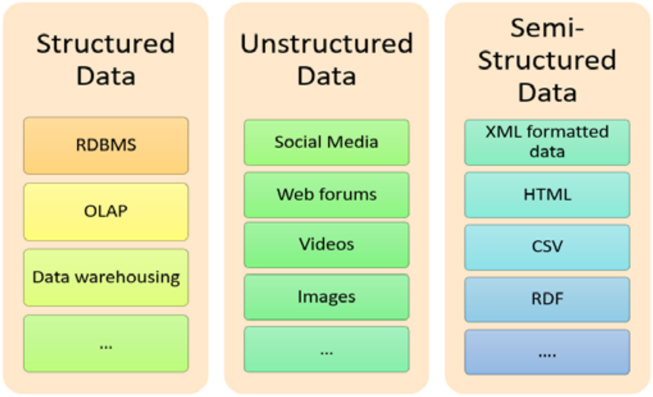

Fig. 1. Taxonomy of Big Data Types.

Smart data (value-based) has been introduced, to highlight valuable data, which can be effectively used by companies and governments for effective planning, monitoring, evaluation, reporting and intelligent decision-making. Three core attributes are necessary for data to be intelligent: it has to be accurate, actionable and agile [10], [11].

A. *Multi-agent System*

Multi-agent System can be defined as a collection of autonomous entities know as agents [12]. The agents can in a collaborative way solve complex problems [13], [14] they can interact with the environment and the other agents to achieve goals or the complete tasks the agents are characterized with:

- Sociability: To reach their goals they can share their knowledge or request useful information other agents.
- Autonomy: The agents can perform some appropriate actions and executing the process of decision-making.
- Proactivity: The agents can perform effective actions by using their historical data, the data from the sensors or from other agents or their environment.

The real value added of agents can be reached through the use of the collaborative work of each agent to solve complex problems.

In this work the framework JADE is used, [15] which is a multi-agent system platform that provides the infrastructure to deploy agents, this platform assures this functionality with the help of other components like:

- Directory Facilitator: DF is the component responsible for providing yellow pages services in the platform, it allows agents to publish their services by sending requests of registration, and this operation allows other agents to collaborate through the published services.
- Agent Management System: AMS is a necessary component in an agent platform; this module is responsible for managing the agents, and assuring the operations of creation, destruction, migration, etc. of the agents in the platform.
- Message Transport Service: this service is responsible of transporting messages between agents in the platform; these messages meet the standards described in the FIPA-ACL.

B. *Machine Learning*

Machine learning is field of Artificial intelligence that relates to a wide range of algorithms for making intelligent predictions based on a data set. These data sets are often characterized with large volume [16], Recent advances in machine learning field have achieved what seems like a human standard of semantic understanding and information extraction and some ability to sense abstract patterns with higher accuracy than human experts [17], [18].

The machine learning techniques are nowadays widely used in different domains like the computer vision, prediction, classification, recommendation, semantic analysis, natural language processing and information retrieval [19] [16], [20].

III. Related Work

This section will highlight some research works with relation of this research question.

In the literature, several researches are done to study the processing and management of big data.

With the technological advancements we are experiencing today, the large amounts of data generated are multiplying rapidly, and the process of manipulating these data is complicated, hence the need to automate the process is justified in several areas like the in industry [21], [22] or in the urban planning and management domain [23].

The use of big data analytics[24] is widely demanded in multiple areas such as security and intrusion detection [25], healthcare [26], The proposition of [27] aims to provide a process composed of the two sub-processes the first for big data management and the second for the big data analytics each sub-process is composed of set of operations described as bellow:

- Big Data Management:
    - Acquisition and recording,
    - Extraction, cleaning, and annotation,
    - Integration, Aggregation and Representation.
- Big data analytics:
    - Modeling and Analysis,
    - Interpretation.

The authors [28], [29] proposed a method based on the generation of workflows of data processing based on a service oriented approach[30], the idea is to divide the totality of the functionalities of the system into a set of services, these services are organized according to four main phases:

- Planning stage,
- Discovery stage,
- Selection stage,
- Execution stage.

The system selects according to the request received a set of services in each phase and then generates a workflow based on the selected services

Other authors [31] proposed a the main steps for extracting value form big data through the definition of four steps:

- Gather data,
- Load data,
- Transform data
- Extract data.

Several works presented in the literature try to give the necessary steps for the system to realize the tasks of analysis and big data processing, but they don't put the action on giving the possibility to the system to have an adaptive behavior according to the nature of the processing and the requests received by the system in an autonomous way, and they need a human intervention to program and manage tasks. The use of the multi-agent paradigm in this sense can enhance the cognitive capabilities of the system of learning efficient ways to process and analyze data and to help in improving the processes of decision-making based on a knowledge base.

IV. Proposed Approach

In order to increase the efficiency of the big data management and analytics process and to implement a new strategy to improve the analysis and processing operations through automation, a model based on three layers architecture and a multi-agent system is proposed.

A. *The Proposed Model*

The proposed model is mainly based on a multi-agent system and adopts the Smart Data approach that focuses on the value aspect of data in order to optimize the exploitation of the large masses of data stored on big data storage clusters. This model has the objective of automating the processing of big data and improving the efficiency of decision making in this context using machine learning models.

As presented in the Fig. 2, this architecture is based on a collection of autonomous entities to constitute a multi-agent system. The multi-agents are organized according to three-layer architecture:

- The data acquisition and storage layer: This layer is responsible for interacting with the heterogeneous data sources that usually a system handling big data can interact with, for example in the field of smart cities management often the system interacts with data coming from different sources whether it is from sensors or external data sources, these data being of various types and generated at different rates, in batches or in real time streams.

This layer also allows to manage the storage of the generated or collected data platform through the use of an HDFS storage cluster which is distributed over several nodes in order to guarantee high availability and also to distribute the data processing operations.

There is also a knowledge base that can help the agents in making decisions and choosing the necessary processing step for each request received by the system.

- The data management and processing layer: In this layer, there are principally the modules dedicated to data processing and analysis, such as components for pre-processing operations like cleaning, filtering, normalization, transformation, and data reduction, as well as the components for data processing like the entities for data processing and analysis in batches specially for historical data and stream processing in the case when the system deals with real time streams of data.
- The data services layer: The main role of this layer is to communicate the results of the processing performed by the system as a result of a query to the applications and services, the monitoring of dashboards and the production of reports, as well as to provide interfaces that facilitate the interaction of the applications with the proposed system.

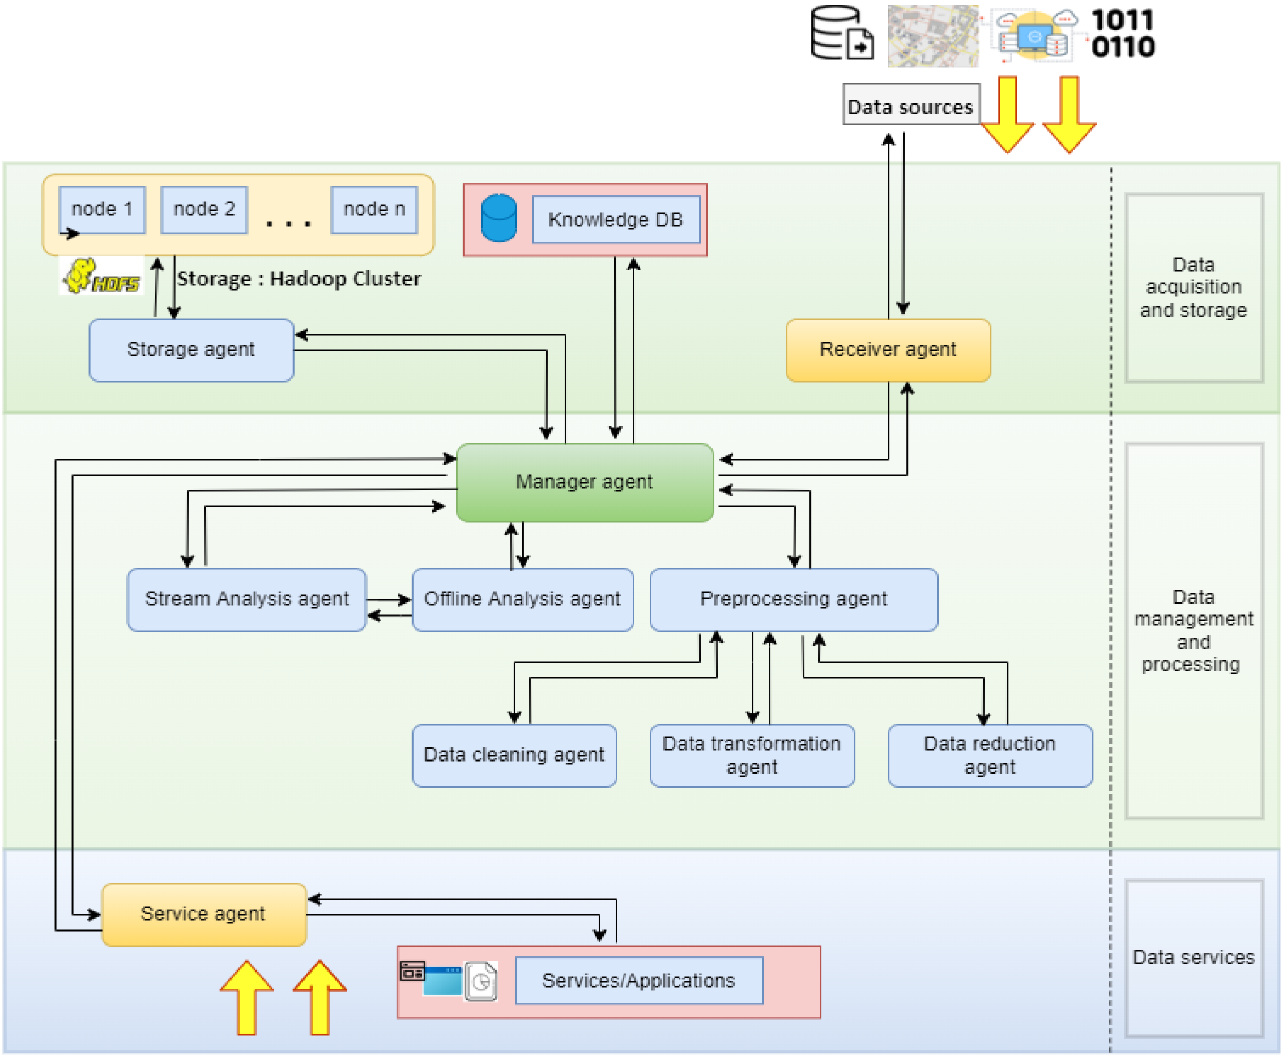

Fig. 2. The Proposed Multi-layer Architecture for the MAS.

Such functionality can help improve and automate the decision-making process, as well as the management and processing of real-time data. The proposed system can serve as a platform to support data management and to conduct effective decision-making in smart cities.

B. Components of the Proposed Multi-agent System

The proposed multi-agent system, through the cooperation of the agents, can automate the processing and the management of the data, in accordance with the three layers of the system: data acquisition, data management and processing, and the services and communication layer.

The system is composed of multiple agents:

- Receiver agent: This agent represents the system's interface with the data sources. The receiving agent handles data of multiple types and from different sources, such as sensors, external databases, web services, etc. and at different rates, streaming or batch.
- Storage Agent: this agent is in charge of all operations related to storage management and data reading from the Hadoop cluster.
- Service Agent: This agent is designed to interact with applications and services and to communicate the processing results through user friendly interfaces and applications. With this agent, the end-users can also schedule or send requests or execute certain tasks.
- Offline Analysis Agent: This agent allows the system to perform operations and tasks related to data batch processing, it can handle the requests of data analysis using voluminous historical data, and usually those data are collected and stored into the cluster storage. Those tasks of processing can help to automate the process of scheduled or per period data analysis tasks.
- Stream Analysis Agent: the main function of this agent is to process data streams that are usually in real time. The use of technologies that are generating data in real time such as sensors and devices that are transmitting requests and data streams in real time. These queries expect responses from the system in real time.

The collaboration between the two agents responsible of processing: the stream Analysis Agent and the Offline Analysis

Agent can resolve complex problems of data processing for example the requests they require to handle data streams in real time and needs to perform operations on the historical data already stored on the system, this collaboration is carried by the Manager Agent.

- Knowledge Base Component: is a database used by the multi-agent system to store rules to facilitate the selection process of the adaptive behavior of the agents based on the type of the request and the data to process.
- HDFS storage Cluster: is the component of the system that supports distributed data storage through the use of many data blocks or partitions. This distributed file system stores the data using several nodes, called data nodes, and managed by the name node which try to balance the load between theses nodes.

The HDFS also assure the replication of the data to guarantee high availability. adopting this type of storage is more appropriate due to requirement of data processing and to the nature of the big data constraints [32], especially when the system deals with fast processing queries with low latency.

- Preprocessing Agent: The preprocessing stage is considered as a primordial phase that help extract to value aspect from the raw big data. The smart Data approach focuses and consider it like a key to prepare the data, since the data generated from real world applications are imperfect and may contains some redundancies, inconsistencies, and noisy values.
- Data Cleaning Agent: This is an agent that checks the received data and imposes a strategy to clean the received dataset. The Smart data aspect focuses on the preprocessing steps and the cleaning phase is an important one with the aim to remove noisy and redundant instances [33] to allow the system to operate automatic learning algorithms on reliable datasets.
- Data Transformation Agent: This agent is designed to change the data format according to the processing needs, to smooth out the training phase by applying data normalization, aggregation, and filtering operations.
- Data Reduction Agent: This agent has an essential contribution in the work of the system by reducing the time of data processing which will impact the positively the process by reducing the time latency, deleting the faulty data and reducing the volume, in this phase there are several techniques in the literature [34] that can be applied with the aim to simplify the datasets dimensionality reduction, discretization and instance reduction.
- Manager Agent: The manager agent has in important role in the proposed system it represents the main component responsible of coordination of the tasks sharing between the other agents.

This entity can take an adoptive behavior based on the nature of the requests received and a knowledge base.

C. Operating Principle

The proposed multi-agent system described previously shows the necessary steps to assure the functioning of the system in different situations.

The system can interact with external applications and data sources and subsequently initiate or execute data analysis operations mainly by triggering two agents, the one responsible for data acquisition or services:

- Receiving a request from a sensor generating a data flow or from an external api or service applies the collaboration of the agents of the system.

Once the request is received by the receiving agent and sends it to the Manager, the latter distributes the tasks to store and process this request. The tasks of pre-processing, online analysis and offline analysis are performed to respond to this request in real time, after that the service agent can transfer the result.

- Receiving a request from the application layer as in the case of scheduling a task or generating a report or a specific request to execute.

The Service agent sends the request to The Manager agent which decides to collect the necessary data from the data cluster or to retrieve it from the data sources; and according to the type of this request, it makes the decision to send this data to one of the data processing agents, either in stream or in offline analysis and returns the result through the service agents.

V. Experimentation and Tests

The proposed approach consists in developing a multi-agent model for the automation of big data processing and analysis by applying the smart data approach.

This section attempts to highlight the adaptive behavior of the proposed system by the study of three cases of use of the system.

The system is composed a set of agents linked to stored algorithms that are defined by the organization's business rules. These agents will be distributed across multiple nodes in order to promote task distribution and load balancing across nodes.

For the implementation of this approach the JADE [15] Framework was adopted.

The communication and the interactions between agents is principally done through the exchange of messages [35] each message is labeled with an act of communication such as: request, inform, notify, propose, etc.

The Fig. 3 represents a snapshot of the behavior of the multi-agent agent system at a time t, where the different communications between the agents of the proposed system can be observed, this communication can be done by sending ACL messages or by sharing information in the environment of the agents, this communication can be in the context of a collaboration, coordination, or negotiation, the agents adopt an adaptive behavior according to the nature of the data and the requests received by the system.

Fig. 3. The Communication between the Agents of the Proposed System.

This part will study the adaptive behavior of the proposed multi-agent system by illustrating three case studies where an explanation of the operating principle of the system and the flow of processing that changes depending on the nature of the request received by the system will be presented, the three scenarios are related to the field of management and planning of smart cities.

The first is to study the behavior of the system using a large dataset that contains data from the last census in Morocco for the city of Casablanca. The used data contain information and characteristics about the habitat and individuals in order to build a machine-learning model to predict the type of habitat according to the evolution of individuals. Thus, predict the equipment and infrastructure necessary for the urban planning of this city.

The second scenario is to show the behavior of the system and its use for listening to changes and storing data from different data sources.

And the third scenario is to use the system for real-time prediction tasks using the machine learning model already created in the first scenario.

A. Case 1: Training a Machine Learning Model from a DataSet Stored in HDFS

In this case the request issuing from the services and applications layer which consists in asking the system to launch a learning operation from a dataset stored in the Hadoop storage cluster, the Fig. 4 explain the explains the information exchange between the different components of the system in this case.

An explanation of the steps will be attempted using a sequence diagram illustrated in Fig. 5.

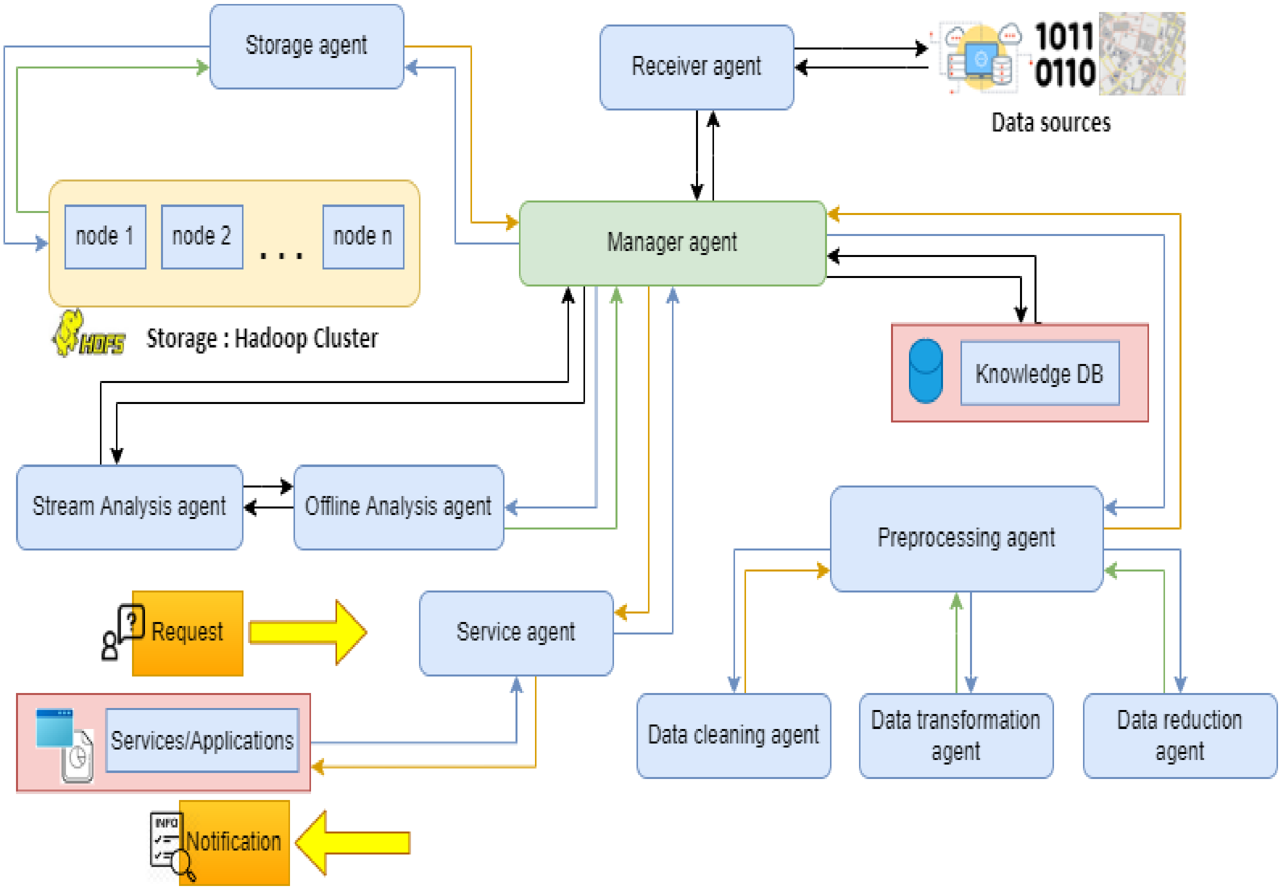

Fig. 4. The Flowchart of Training a ML Model using the Proposed MAS.

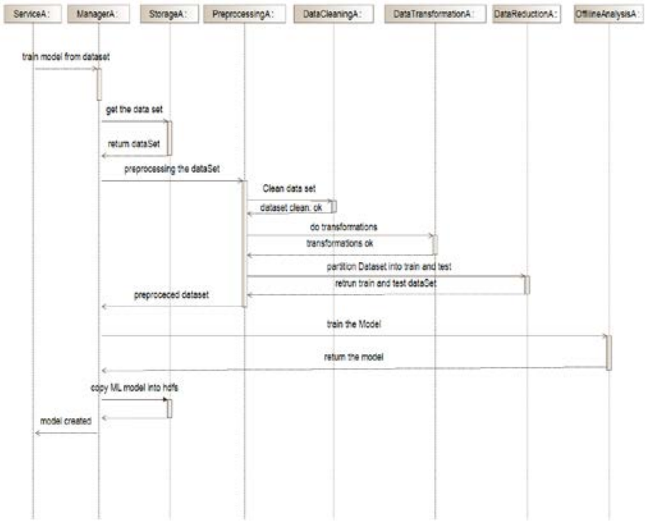

Fig. 5. Sequence Diagram of Training a ML Model using the Proposed MAS.

The service agent receives the request and sends it to the agent manager who is in charge of distributing the operations between agents, it sends the request to retrieve the Dataset to the storage agent, then it sends the Dataset for preprocessing operations by the Preprocessing Agent, which delegates tasks as necessary to the transformation, reduction and data cleaning agents.

Then the partitioned datasets are ready for the phases of training and testing by the Offline Analysis agent, once the model is valid the Manager agent sends the request to the storage agent to copy it on the storage cluster and notifies the service agent of the creation of the requested model.

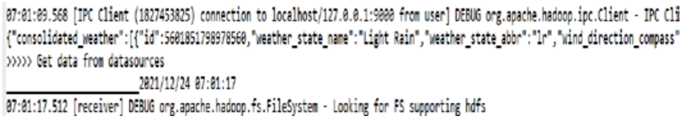
This generated model will be used to serve prediction requests that the system can receive and respond to in real time.

B. Case 2: Collecting Data from a Data Source and Storing it in HDFS

The proposed system can interact with several data sources such as databases, sensors, connected objects-IOT and external applications.

In this case the system is used to receive data from an external source which is an API[36] that provides weather data, the system opted to collect and store its data for the city of Casablanca in the HDFS file system.

In this example the agent will send request to the API in every specified lapse of time to get and store the last data of the weather about the city of Casablanca, the Fig. 6 represents a snapshot of a request of an example of a request sent by the system to get weather data.



```

Fig. 7. The Response of the API formatted as Json Object.

The Receiver agent can listen to changes in a data source or collect values from a data source according to the desired behavior e.g. in this case the Receiver agent adopts a TickBihaviour for each time lapse it retrieves the data and sends the request to the Manager agent to initiate the request for preprocessing to the Preprocessing agent, once the data is cleaned up and ready to be stored the Manager agent asks the Storage agent to copy it to the storage cluster. Fig. 7 shows an example of stored data: Name of the location, time of the location, name of the time zone in which the location is located, internal identifier of the forecast, date to which the forecast or observation refers, compass point of the wind direction, one or two letter abbreviation of the weather condition.

Fig. 8 tries to illustrate the functioning of the system using a diagram sequence.

C. Case 3: The use of a Machine Learning Model for Real-Time Prediction

In this case of study, the behavior of the system will be analyzed in the case where it must process prediction requests in real time.

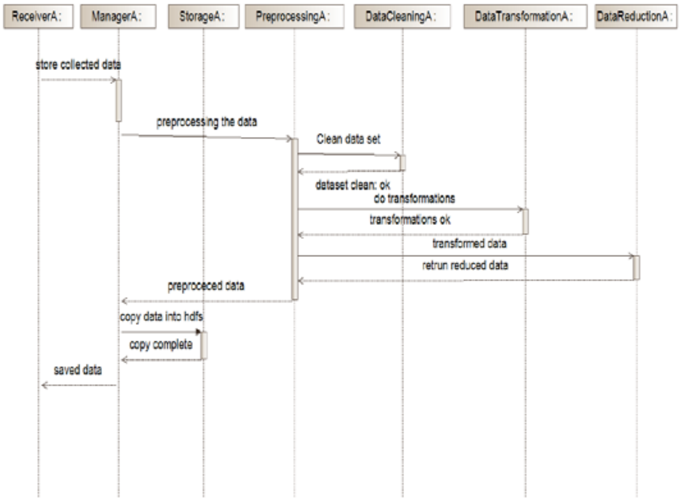

Fig. 8. Sequence Diagram of Collecting Data from a Data Source and Storing it in HDFS.

The first step is to build the model machine learning that will be used for future predictions, and to store it in the cluster, in this step a dataset will be used which contains data about households and individuals in Casablanca from the last general census of population and housing from HCP[37] this data set is made public in 2019, we conducted based on the analyze of this data a previous work to help in enhancing urban planning in the region of Casablanca by predicting the type of habitat and estimate the necessary equipment [23].

1) Training and test machine learning model: In the beginning of this learning phase the dataset used is already prepared cleaned and preprocessed, the start will be splitting the main dataset into two datasets usually in the literature the split is made into two part a larger one with 80% used to train the model and the part with 20% used to test the model, the Fig. 9 illustrate the steps of training the machine learning model used in this study.

The step of choosing the adequate algorithm is data-centric step based on the type of the data and the nature of the problem, in this study this dataset will be used to predict the type of habitat based on the characteristics of the studied population, it's a classification problem, in the next part a test of the main machine learning algorithms for supervised learning on the dataset will be performed.

We will present in this part the metrics and the obtained results for each used machine learning algorithm on the same dataset:

To evaluate the relative performance of different classification models, it is necessary to specify the appropriate quantitative criteria for the evaluation. The performance metrics are specified for the classifier:

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (1)$$

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Nagative} \quad (2)$$

$$F1Score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (3)$$

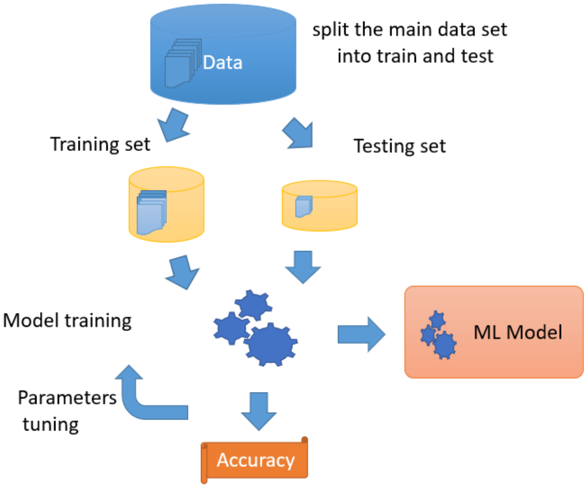

Fig. 9. Steps of Training ML Model using Classification Algorithms.

This section highlights the evaluation of the proposed model on the dataset for each classification algorithm.

a) Naïve bayes: A Naive Bayes classifier is a probabilistic machine learning model used in classification cases to discriminate different objects and labels based on a set of features, this classifier is based on the bayes theorem [38], with the naïve hypothesis of a conditional independence of each combination of features given the value of the class variable, the Table I presents the evaluation metric for the naïve bayes algorithm:

$$P(y|x_1, \dots, x_n) = \frac{P(y)P(x_1,\dots,x_n|y)}{P(y|x_1,\dots,x_n)} \quad (4)$$

TABLE I. CLASSIFICATION REPORT FOR THE ML ALGORITHM: NAÏVE BAYES

METRIC	SCORE (%)
precision	64
recall	61
f1-score	61

b) Multilayer perceptron: The MLP [39] multilayer perceptron is a type of artificial neural network organized as a set of multilayers, the process of information flowing from the input layer to the output layer only. It is therefore a feedforward network, each layer consists of a variable number of neurons, the neurons of the last layer being the outputs of the global system, The MLP are widely used in classification, prediction and recognition use cases, the Table II presents the metrics for the use of the multilayer perceptron classifier:

TABLE II. CLASSIFICATION REPORT FOR THE ML ALGORITHM MULTI LAYER PERCEPTRON

METRIC	SCORE (%)
precision	73
recall	73
f1-score	71

c) Random Forest: Random forest is a classifier that can be defined as a meta estimator which corresponds to a number of decision tree classifiers, this algorithm performs a splitting of the training data into a specific number of data subsets used to perform training on multiple decision trees, the subsets used for training the model are slightly different, and then a voting method is used to select the best model [40], the Table III shows the metrics for the use of the Random forest algorithm:

TABLE III. CLASSIFICATION REPORT FOR THE ML ALGORITHM RANDOM FOREST

METRIC	SCORE (%)
precision	85
recall	85
f1-score	84

d) Summary: The Table IV summarizes the evaluation metrics and give a comparison for the used classification algorithms.

TABLE IV. SUMMARY OF THE METRICS USING SUPERVISED LEARNING

METRIC	Precision	Recall	F1-Score	Accuracy
Naïve Bayes	0.64	0.61	0.61	0.61
MLP	0.73	0.73	0.71	0.73
Random Forest	0.85	0.85	0.84	0.85

To select the model to be deployed and used for future prediction requests some metrics are used like precision, recall, f1-score, and the accuracy.

Based on the results obtained, the most accurate model can be choose, in this case the model trained with Random Forest Algorithm, the next step will be to the step of serializing this model into the storage of the proposed system.

Serialization of the trained ML Model: In order to use the trained ML models in the different applications, the step of serialization still necessary, especially when the trained model is a result of huge dataset and machine learning algorithm that consumed a lot of resources to get to the validation phase of the model.

The reuse of the stored model still a good strategy that allows the system to use immediately the model, as explained in the Fig. 10.

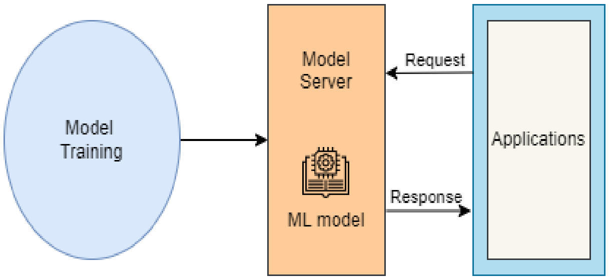

Fig. 10. Serialization and use of the Machine Learning Model.

The use of the trained model by the MAS system:

The proposed system can handle real-time prediction requests using the principle of collaboration between different agents, as shown in the Fig. 11 first the system get the request of prediction from the application and service layer this request is received with the service agent which will transmit it to the agent manager, the latter will call the storage agent to retrieve the serialized model in order to use it for this request and send the request for preprocessing to format it and to get the parameters or the datasets in this request, once done the operation of prediction by the stream analysis agent, this result will be sent to the service agent to bring up the response to the demanding application.

The system can handle the communication with different applications by defining an interface for communication with the proposed system,

And defining multiple functionalities to download, upload, store or analyze data by defining several functions.

For example, the receiver agent can receive requests of type:

$\text{Function}_i(\text{Arg}_1, \text{Arg}_2, \ldots, \text{Arg}_n) \Rightarrow D_i$

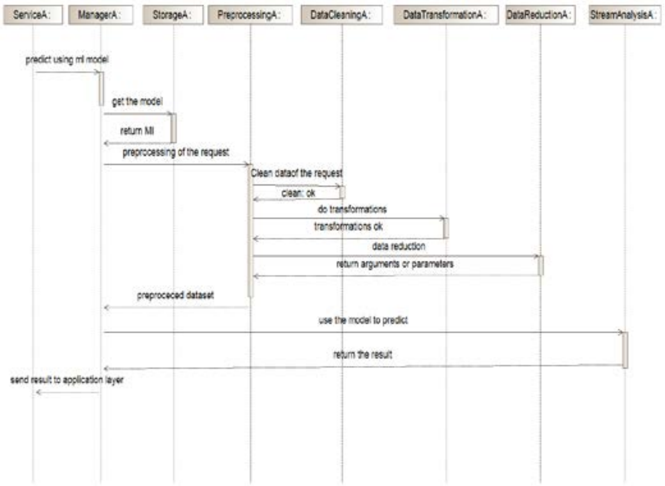

Fig. 11. Sequence Diagram of using a Machine Learning Model for Real-time Prediction.

These functions and services could be used in other applications like the one in the Fig. 12, which will interface with the proposed system and use these features.

VI. CONCLUSION AND PERSPECTIVES

In this paper, a multi-agent system to automate big data analytics in real time based on the smart data approach was proposed, a model with a multilayer architecture was presented, and the adaptive behavior of this system was illustrated through some case studies, especially in the case of training and the using machine learning models.

The use of intelligent processing, automating big data analytics through the use of the multi-agent system and machine learning techniques can help to solve complex problems such in the field of Urban planning and management in smart cities, by providing actionable data and efficient decisions.

To summarize, the paper tries to highlight the challenges following the processing of big data specifically issued from smart cities, these data are in different formats (structured, semi-structured, unstructured). In addition, they are generated at different rates by batch or in real time in streams. These voluminous amounts of data present many challenges including the management of these data, the latency of processing time and mainly the effective exploitation of these data to extract useful information.

To overcome these problematic, the paper proposes a model based on a multi-agent system that adopts the smart data approach which focuses on the value aspect of data and the application of intelligent processing in order to extract useful information from these voluminous masses of big data and to drive an efficient decision making, the proposed system automates its data processing processes, and thanks to the autonomous and cognitive capabilities of the agents they can manage and make decisions in real time, And to illustrate the adaptive behavior of the system through the autonomous behavior of the agents, we proposed 3 scenarios:

- The system builds a machine learning model of the classification from a large dataset that contains the demographic data of the city of Casablanca from the last census in Morocco in 2019, to predict the type of housing adequate to a profile of household or citizen for this several tasks were performed by the agents including the preprocessing phase and the choice of appropriate classification algorithm according to the study of metrics and then the serialization of the model, in order to use it for future requests for prediction in real time.
- The system listens to the various data sources and stores the data in the Hadoop storage cluster in real time.
- The system responds to real-time prediction demands by using machine learning models already built and stored in the system to improve the real-time decision-making process.

Such a proposition can find applications in several areas including the management and planning of smart cities known with the generation of huge amounts of data, this proposition can contribute in the effective use of these data and the extraction of valuable information that can guide effective decision-making to improve for example the management of traffic flows and road traffic, the anticipation of needs in terms of equipment in smart cities, reduce energy consumption, the monitoring of KPIs, the reporting and monitoring of smart cities.

In perspective, we will work on enhancing the system with other functionalities, focusing on the improvement of agent behaviors and the machine learning models. To test this approach, solve several problems in urban planning and management in smart cities.

The proposed approach in this paper represents a real opportunity to enhance the process of big data analytics by the exploit of the cognitive functionalities of the agents and to empower their capabilities using a knowledge base which will facilitates the process of decision- making made by agents to take actions in a autonomous way, such adaptive behavior can solve serious problems in smart cities like energy consumption and traffic congestion.

***Abstract*—A brain tumor is the cause of abnormal growth of cells in the brain. Magnetic resonance imaging (MRI) is the most practical method for detecting brain tumors. Through these MRIs, doctors analyze and identify abnormal tissue growth and can confirm whether the brain is affected by a tumor or not. Today, with the emergence of artificial intelligence techniques, the detection of brain tumors is done by applying the techniques and algorithms of machine learning and deep learning. The advantages of the application of these algorithms are the quick prediction of brain tumors, fewer errors, and greater precision, which help in decision-making and in choosing the most appropriate treatment for patients. In the proposed work, a convolution neural network (CNN) is applied with the aim of detecting the presence of a brain tumor and its performance is analyzed. The main purpose of this article is to adopt the approach of convolutional neural networks as a machine learning technique to perform brain tumor detection and classification. Based on training and testing results, the pre-trained architecture model reaches 96% in precision and classification accuracy rates. For the given dataset, CNN proves to be the better technique for predicting the presence of brain tumors.**

Keywords—Brain tumor; machine learning; convolutional neural network; MRI images

I. Introduction

A brain tumor is one of the major health problems related to human brain abnormalities [1]–[3]. It is a collection or a combination of unnatural tissue in the brain [4]. It usually occurs due to the fast growth of abnormal or damaged cells and created lamps of tissue in the brain. To find out whether the brain contains a tumor or not, MRI images are the first step in medical diagnosis [5], followed by manual analysis by an expert who looks for lesions in the brain. MRI is the most common and widely used technique for brain tumor detection and brain imaging as it proves better results especially when it It's about detecting differences between body tissues [6]. Compared to the computerized tomography (CT) scan and other techniques, MRI images are safer and can produce higher contrast images of brains [4]. Likewise, due to the high resolution of the images provided by MRI scans, a lot of information about the brain structure and the brain tissues are easily provided, this has considerable advantages in the field of image analysis [7], [8]. There are four standard sequences used in MRI scans modalities: The T1-weighted MRI (T1), T2-weighted MRI (T2), T1-weighted contrast-enhanced MRI (T1-CE), and FLAIR [9], [10]. In general, the T1W contrast-enhanced is the most commonly used modality, because it allows an easy annotation of the healthy tissues [11], [12].

Deep learning is a type of artificial intelligence derived from machine learning. Unlike programming where the content to execute the predetermined rules, here the machine can learn by itself, relying on a network of artificial neurons inspired by the human brain. Due to its higher performance in several fields as screening medical face mask [13], image description and a lot of challenges, the exploitation of DL technique in the medical image for classification, detection, and segmentation is highly encouraged [14]. In fact, various human diseases could be detected using such techniques, including COVID-19 [15]–[19], Parkinson's disease [20], breast cancer [21], diabetes diseases [22], medical image segmentation [23], and heart disease prediction [24]–[26]. A vast range of different scientific topics has developed because of advances in AI [27]–[35].

Convolutional neural networks (CNNs) are deep neural networks that have the capability to classify and segment images [36], [37]. CNN architectures for classification and segmentation include a variety of different layers with specific purposes, such as a convolutional layer, pooling layer, fully connected layers, dropout layers, etc. Recent studies on deep learning with convolutional neural networks have achieved excellent performance that is almost at the same level of performance of practicing radiologists [38], [39].

In recent years, CNN has been used in medical image segmentation. It has achieved great success in the field and auxiliary diagnosis. Compared to the traditional methods, network architecture gives to CNN algorithms the ability to learn complicated features from images [40], also CNNs are the top ranked and most popular algorithms used in computer vision, and actively contribute in this specific area of imaging due to their capability of detecting significant features, more particularly when it comes to medical imaging in which to processing difficult images with several details is needed, indeed CNN-based approaches are placed in the well-used leader board of the many image understanding challenges, especially Brain Tumor segmentation (BRATS), the biomedical challenge of Image Computing and Computer Assisted Intervention (MICCAI), ISBI (International Symposium on Biomedical Imaging), and IPMI (Information Processing in Medical Imaging) [41]. In this context, an application of a machine learning algorithm based on convolutional neural networks for the detection and classification of brain tumors is proposed.

The remainder of this paper is organized as follows: Section II presents a brief review of related works. Section III explains our proposed methodology and the machine learning algorithms implementation. Some performance evaluation techniques are presented in Section IV. Results and discussion are given in Section V. Section VI presents a conclusion with a discussion regarding the future works.

II. Related Work

In the research published in recent years relating to the segmentation of brain tumors, there is two branches of machine learning methods: Supervised learning and unsupervised learning .The difference between these models is simple, in supervised learning human intervention is needed at least to label the data appropriately, the machine learning model learns through iterating the operations of prediction of the labeled data communicated as input and improves the results by adjusting the response each time [42].

In unsupervised method-based segmentation, the human touch always needed for validating output variables [43], among its techniques there is the support vector machine (SVM) method and the fuzzy clustering approach are used. These methods have achieved the best performance when it comes to predicting or detecting a tumor, on the other hand the performance obtained is a little weak when the border between the normal tissue and the tumor area is blurred. Also, the extraction process usually takes time because the extraction algorithms have to extract a lot of information and details related to these edges and a lot of essential features.

Segmentation is the process of separating the image into distinct regions and is one of the most vital and demanding aspects of computer-aided clinical diagnostic tools. Although brain tumor segmentation is primarily done manually, it is very time consuming and the segmentation is subject to variations both between observers [44]. Therefore, an automatic and robust brain tumor segmentation will have a significant impact on brain tumor diagnosis and treatment.

Convolutional neural networks (CNN) differ from other machine learning techniques in the fact that the segmentation is done automatically and does not require the intervention of an expert as well as the feature extraction which is done with precision, on the other hand there are several parameters to be learned by a neural network (CNN) which results in expensive computation time and requires process graphics units (GPU) to train the model [45]. The role of a CNN network consists of two main tasks: feature extraction and data classification, the convolution and pooling layer are responsible for feature extraction, fully connected layers help to achieve the classification task [46]. In [47], the authors presented a convolutional neural network for brain tumor detection, 2 CNNs models were made as a comparison to find the best model for classification. The first model includes one convolution layer, the second includes two layers. This study showed that increasing convolutional layers improves the model performances and resulted in accuracy of 93% and a loss value of 0,23.

Among the techniques for using artificial neural networks, there is also transfer learning, the principle is simple, instead of designing a new CNN model and training it from scratch, existing architectures which are well trained on large dataset and which have demonstrated their performance are used, this makes it possible to use each transfer learning model and adapt it to the desired stain according to the nature of the task and the characteristic to be detected or classified [48].

Due to their ability to self-learn without the intervention of an expert, CNN models based on Transfer learning techniques have achieved excellent performance, the use of the weight sharing technique provides an adequate network and allows to automatically detect the tumor through the MRI images [49].

A research published in [50], Aimed boosting accuracy by the use of transfer learning strategy they implemented three transfer learning approaches using pre-trained CNN models, namely: VGG19 ,Inception V3 and MobileNet V2, They obtained respectively an accuracy rate of 88,22%, 91% and 92%. The authors concluded that the MobilnetV2 is the most efficient Model compared to the other models.

Using the ANN approach, Authors in [51],worked on two classes named benign tumors and malignant tumors, they started by preprocessing the images with the filters, then applied the average color moment technique on the images to extract the characteristics. After the transmission of these characteristic maps to the ANN, the classification was made with an accuracy rate of 91.8%.

A study published in [52], the model uses the histogram statistical equalization technique which consists in applying a transformation to each pixel of the image by calculating several statistical characteristics such as the average sum, the variance, the entropy, the dissimilarity, this model is therefore used for low-grade and high-grade class images of cervical glioma. The results obtained from the proposed method of accuracy, sensitivity and specificity reached 83.6% accuracy, 80.88% sensitivity and 86.84% specificity.

One of the techniques used in the detection of characteristics and classification of images consists in combining the concept of deep learning, CNNs, with other methods of preprocessing, these techniques include data augmentation, edge detection, genetic algorithm (GA), discrete wavelet transform (DWT) and principal component analysis (PCA). Authors in [53] have combined the two techniques of data augmentation and edge detection, data augmentation makes it possible to increase the amount of data artificially, other images are generated from the first images provided. The edge detection will allow finding the region of interest (ROI), the extraction of the characteristics is done thanks to a simple CNN model. They obtained 89% classification accuracy.

The results of these searches are classified in Table I, highlighting the classification model with a description of the chosen preprocessing technique, as well as the scores obtained based on the metrics used in each work.

III. MATERIALS AND METHODOLOGY

A. Global Overview on Proposed Detection Model

To complete the image classification task using machine leaning techniques such as conventional neural networks, these steps must be followed in sequential order: data extraction, data preprocessing, Feature selection, learning and classification Considering the common standard process of machine learning, our first step concerned the collection of data, the data is retrieved from Kaggle datasets of Brain MRI Images [54] The data folder concerns a set of 3000 MRI data images classified according to the presence or not of the tumor and labelled (Yes tumor and No tumor). In the development of our CNN architecture, we took into consideration several criteria to avoid limitations that are not suitable for our case study. One of the major limitations is the limited data, medical images are difficult to retrieve for privacy reasons and other several reasons, to have a robust model a large number of medical images is needed; there is currently some techniques which can limit this problem like Data augmentation. Several technical considerations are also considered. For example, the use of complicated transforms which can disturb the learning process is avoided, according to some research results, it was found that complicated transforms are not always better than simple ones because they can introduce some noise in the features and disturbs the learning process.

For the data pre-processing step, image partitioning techniques as well as the normalization of their size are involved. After this stage, the CNN is defined and implemented model as an algorithm for brain tumor detection. Then the input data is divided into training, validation, and test data. Having defined and compiled the model, evaluation metrics algorithm is defined in order to evaluate the model performance, then some predictions are made by executing the model on some MRI images. Fig. 1, describes the CNN architecture model implemented in our work, Layers definitions and roles are described in Subsection D.

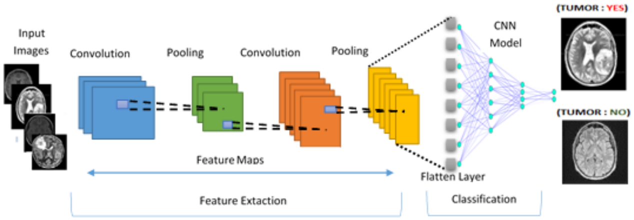

Fig. 1. Architecture of the Proposed Model.

B. Dataset Collection and Preprocessing

This section present some information about the database used, in fact a publicly accessible Kaggle database [54] is used . This database is composed of three folders, the first folder contains 1500 MRI scans presenting a brain tumor, the second folder contains 1500 MRI of healthy brains, in addition there is a folder containing some unlabeled MRI scans for testing purpose, the latter is not used, because another approach for the test data is planned. Thus, the final database obtained is built on the first 2 files and consists of 3000 images as input data distributed as follows: 1500 images with tumor and 1500 images without tumor. Fig. 2 illustrates the sample images of the dataset.

MRI images are not necessarily clear, sometimes visualization defects the quality of the image, these defects result from poor quality of image distortion and resolution, and could lead to a false analysis, and affect patient treatment options. Therefore, several preprocessing techniques can be introduced to make the images more robust and more usable by the neural network, the most common techniques concern the aspect ratio: uniform image size, dimensionality reduction, and data augmentation. The images have been resized to (224, 224, 3) = (image width, image height, number of channels) to facilitate the learning process.

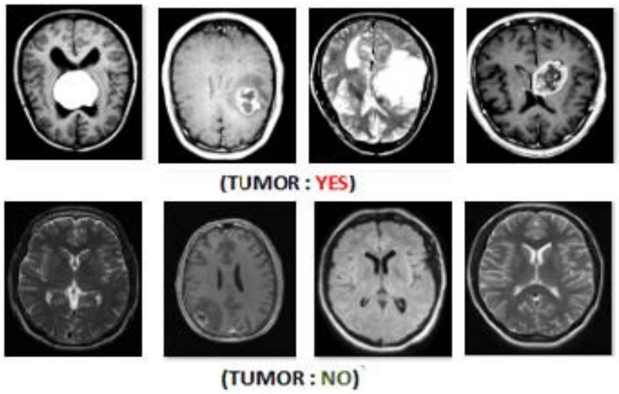

Fig. 2. Samples Images for Brain Tumor Dataset.

Input image will be processed into the first pre-process which is the process of wrapping and cropping, it consists of the removal of unwanted outer areas and some of the peripheral areas from a photographic or illustrated image, after that the database is divided into training, testing, and validation sets with an 80:10:10 ratio. The 3000 images dataset is split into training, testing, and validation sets of 2398, 300, and 300 images respectively, and then all the images are processed in the collection into an array. The last step is the coding when the tagged data are transformed into a numerical label so that they may be interpreted and analyzed. Fig. 3 describes the flowchart followed by the model from input images and preprocessing to the CNN model algorithm and the prediction of healthy and unhealthy brains.

C. Machine Learning Algorithm for Classification

Classification algorithms classify brain tumors into respective categories. It has an essential task in interpreting, extracting features, analyzing, and interpreting images in many applications. The CNN model must first extract features from each image before learning how to distinguish between the images provided to it. In this research, a CNN model with several layers is proposed; four convolution layers, three Maxpooling layers, one flatten layer, and six dense layers. In general, the core building blocks of convolutional neural networks are convolutional layers, activation functions, pooling, and fully connected layers. To improve the results in the output of the CNN network, the input data must go through several stages. The main objective is to correct the adjustments, allowing the CNN to recognize the inaccurate features in the images. The over-fitting correction is done through four techniques: data augmentation, dropout, batch normalization, and pooling. These process steps represent the hidden layers of the neural network and are used to perform the CNN model. Some definitions and roles of these layers are described below.

To build our proposed model, the first required Conv2D parameter is the number of filters that the convolutional layer will learn. In the proposed architecture, the input is an image of (224*224*3) size, 20 filters are implemented with a kernel size of (4*4). The same parameters are kept for the other two convolution layers with a reduction in kernel size to (2*2). After each convolution operation, the Maxpooling layers with successive calls to the dense layers and the RELU activation function are introduced. In the dense layers, the unit's values are respectively (1024, 512, 256, 128, 64). Finally, the Softmax function is used as the activation function in the output layer. There are 14 547 134 parameters in total. All these details are described in Fig. 4, which illustrates the architecture of our proposed model.

- Convolutional layer Is the main layer of a convolutional neural network, and composed of a filter for the input data, a feature map and a feature detector known as the CNN core whose role is the detection and the extracting of the features in the image, such as edges and colors [55].
- The Pooling layer Thanks to the spatial variance property, Maxpooling teaches the neural network that it is the same characteristic to be detected despite the differences that may exist between the images of the same object, namely the way in which the images are presented, dimensions, textures. This can only be done after having a ready features map.
- Flatten Layer represents the input layer for the artificial neural network, this phase consists of grouping an entity map in a column, and hence the name "Flattening", this allows to have a large data vector compatible with the neural network input.
- Max-Pooling Layer: Maxpooling is used to extract the most relevant features in the images, in the original entity map, the end is always the maximum value, and unnecessary details in each image have are removed to allow network of neurons to do the job efficiently.

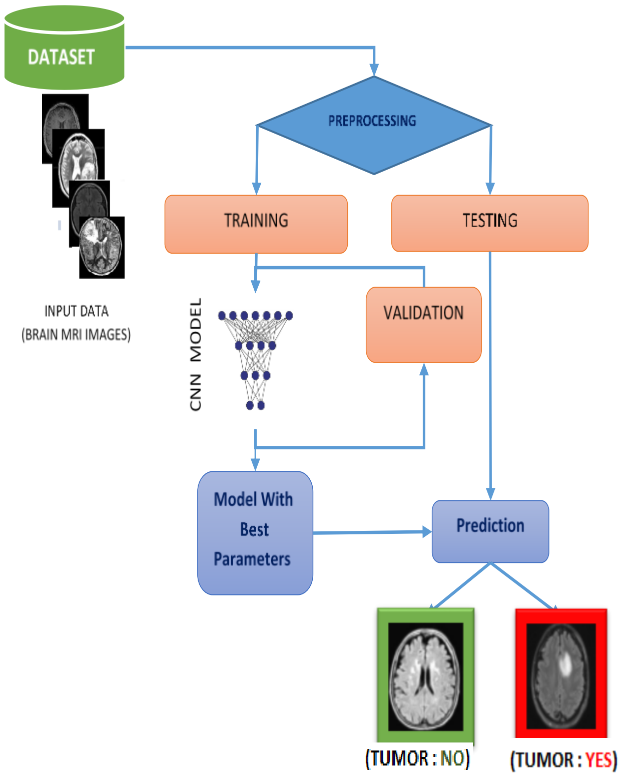

Fig. 3. The Flowchart to Implementation of the CNN Model.

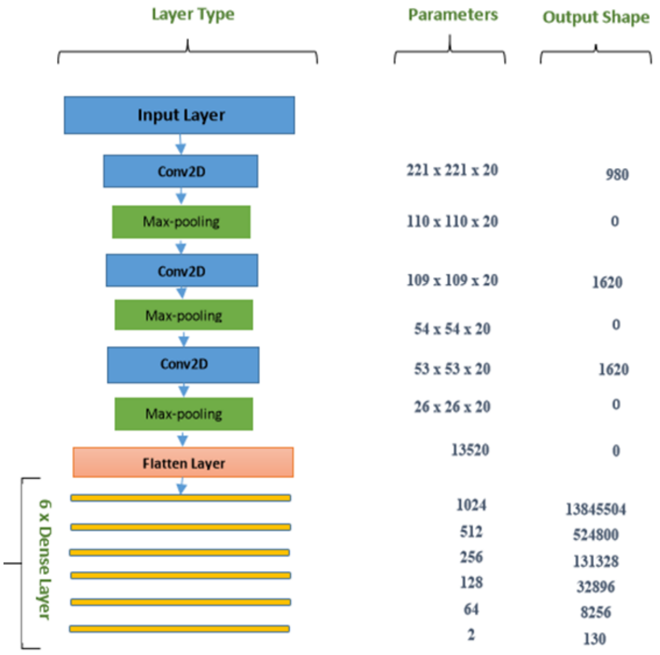

Fig. 4. The Proposed Architecture for CNN Model.

IV. Performance Evaluation Metrics

Several standard evaluation metrics are generally introduced to evaluate the performance of the system, among these metrics there is Accuracy, Precision, Recall, AUC, F1_score, confusion matrix and Receiver Operating Characteristic curve (ROC). The principle of metrics and their mathematical calculation formula is detailed below.

- Confusion Matrix

A confusion matrix is represented by a two-dimensional table which summarizes the results of the predictions of the classification carried out and allows to compare between the correct and false results of the prediction, which allows to see at what point a model can be confused in its predictions and to measure these performances. In a confounding matrix the results are classified into four main categories: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). The four elements of the confusion matrix are shown in Table II.

TABLE II. Elements of the Confusion Matrix

Element	Description
TP	Images containing the tumor and correctly classified.
NP	Images not containing the tumor and correctly classified.
FP	CNN classifies images as containing tumors but that does not contain any tumor.
FN	CNN classifies images as not containing any tumor but are containing a tumor.

- Loss Function

Loss function is a function that evaluates the difference between the predictions made by the neural network and the actual values of the observations used during learning. The more the result of this function is minimized, the more the neural network performs. Its minimization, reducing to a minimum the difference between the predicted value and the actual value for a given observation, is done by adjusting the different weights of the neural network.

V. Results and Discussion

Several standard evaluation metrics are generally introduced to evaluate the performance of the system, among these metrics there is Accuracy, Precision, Recall, AUC, F1_score, confusion matrix and Receiver Operating Characteristic curve (ROC).

A. Training Results

The CNN model is trained using a notebook from the open Google Colab platform which allows to take full advantage of popular Python libraries like TensorFlow and Keras. Colab notebooks run this code on Google's cloud servers and put in our service the power of Tesla K80 GPU with 12 GB of GDDR5 VRAM, increasing performance and reducing training time considering the large number of parameters to train with the proposed CNN model .in addition this platform had an Intel Xeon Processor with two cores running at 2.20 GHz, and 13 GB of RAM. Fig. 5 and Fig. 6 show the evolution of the accuracy and loss curve during the two training and validation periods.

From the plot of Accuracy curves in Fig. 5 which represents the graph evolution during the training period and the validation period, it is clearly seen that the training accuracy is higher than the validation accuracy; the same for the loss curve in Fig. 6, the training curve is above the validation curve which leads to the conclusion that the proposed CNN model has no overfitting issue.

B. Testing Results

The performance of the proposed methodology was evaluated by the measures of precision, specificity, accuracy and, above all, the ROC curve for two classes (normal and abnormal brains) and compared to the performance of other classifiers, the metrics mathematical equations are detailed below.

$$Specificity = \frac{TN}{TN+FP} \tag{1}$$

$$Sensivity = \frac{TP}{FN+TP} \tag{2}$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{3}$$

$$Precision = \frac{TP}{TP+FP} \tag{4}$$

$$F1 - Score = 2 * \frac{Precision * Sensivity}{Precision+Sensivity} \tag{5}$$

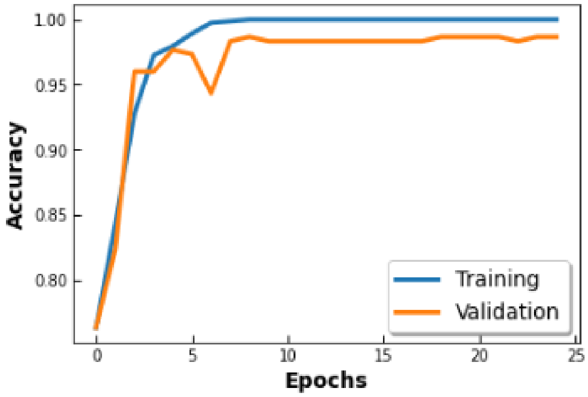

Fig. 5. Accuracy Curve of the Proposed Model.

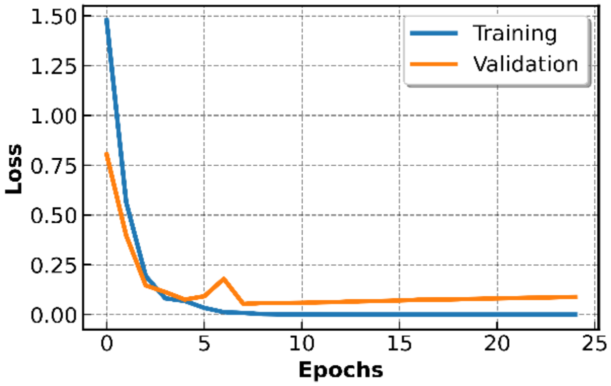

Fig. 6. Loss Curve of the Proposed Model.

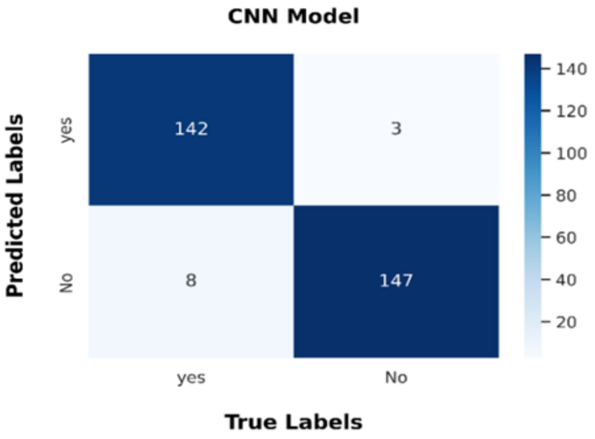

Fig. 7. Confusion Matrix of the Proposed Model.

According to the results of the values obtained by the confusion matrix in Fig. 7, it’s shown that 142 positive cases of brain tumors from 300 were correctly classified by the model and 147 Non-tumorous brain images were correctly classified as belonging to the negative class by the model. The TP, TN, FP and FN values emerged by the confusion matrix are then used by the code for the calculations of the Loss Metrics accuracy, as well as the precision values and sensitivity. The results of the evaluation metrics are provided in Table II.

Another way to visualize the sensitivity and specificity of the model is by creating a ROC curve, which is a plot that displays the sensitivity and specificity of a logistic regression model. The AUC ROC equals the probability of having a randomly chosen “true” rating greater than a randomly chosen “false” rating. In the case of an ideal classification, the AUC ROC value is equal to 1, for a value of 0.5 (case of the diagonal line on the curve) this explains that the classifier only guesses [56].The plot of the ROC curve in Fig. 8 indicates that the highest area is under the curve with a percentage of 96%, which means that the CNN model correctly classifies the images into their categories. Table III report all the performance evaluation metrics of the proposed model.

C. Discussion

Our experimental results demonstrate that the proposed CNN model converges better than the ANN approach, the Random Forest classifier, Transfer learning algorithms, and other CNN models. As shown in Table IV, the proposed model achieved the best accuracy rate of 96% and the best F1-Score of 96.5% with a precision of 98%. These values are high and well ranked compared to the results obtained by the other models already mentioned. Table IV compares the different models and allows us to conclude that our model is the best ranked in terms of accuracy.

Through the analysis of the accuracy and loss curves during the two periods of training and validation, the graph proves that the model has no overfitting issues and returns an average loss value of 0.28, which means that the model is doing well in predicting tumor health and unhealthy brains. The ROC curves show that our proposed CNN model is a reliable system for the detection and classification of brain tumors.

TABLE III. PERFORMANCE EVALUATION OF THE PROPOSED MODEL BASED ON SCORING METRICS

Evaluating Metrics	**Performance Score**
Loss	0,2896
Accuracy	96.33%
Precision	97.93%
Sensitivity	95%
F1–Score	96.44%
Specificity	75.72%

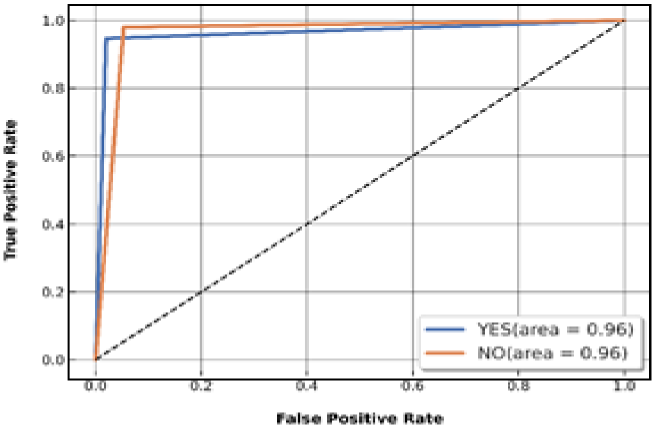

Fig. 8. ROC Curve of the Proposed Model.

In addition to the research work, the performance of the proposed model has been compared with the results obtained by other studies focused on the same case study of brain tumors. For example, the authors in [57] proposed a 7-layered 2 CNN; they obtained an accuracy of 95%. Another technique proposed in [58] using cascaded CNN for segmentation, Vgg19 and data augmentation approach, obtained an accuracy value of 86.7%, 78.9%, and 95.6% for AD, lesion, and normal class. Authors in [59] used the support vector machine and 82% accuracy was obtained. Compared to these models, our proposed CNN model remains the best ranked in terms of accuracy, whether for those adopting the same convolutional neural network architectures or those using other segmentation techniques.

TABLE IV. COMPARATIVE SUMMURY OF DIFFFERENT CLASSIFIERS FOR SEGMENTATION ACCURACY

Study	**Method/Classifier**	**Accuracy Rate**
[47]	CNN	93%
[50]	MobileNet V2	92%
	Inception V3	91%
	VGG19	88%
[51]	ANN	91,8%
[52]	Radom forest with ROI process	83,6%
	Radom forest without ROI process	87,6%
Proposed Study	**CNN Model**	**96%**

VI. Conclusion and Persepectives

In this paper, a CNN model for the segmentation of MRI images of brain tumors into two classes with tumors and without tumors is proposed. The proposed method for detection and classification of MRI images provided the best accuracy achieved by other neural network models. These medical images have undergone preprocessing and resizing before being processed by the convolutional neural network. Training and validation were performed on 3,000 high-resolution MRI images. The performance of the CNN model is evaluated using several evaluation metrics. Through this experiment, the proposed model is found to outperform other CNN models in several performance aspects, including 96% overall accuracy and 98% accuracy. Finally, for the given dataset, CNN proves to be the best technique to predict the presence of brain tumors. Based on performance evaluation metrics and curve analysis, this work demonstrates the ability of a CNN network to detect and classify tumors in the brain with a higher accuracy rate. This work has presented the architecture of convolutional neural networks and has demonstrated their performance when applied to an adjusted database of brain images. In future work, the architecture of the proposed model could be perfected, and its reliability and performance will be evaluated with a large database.

***Abstract*—Clustering analysis is the process of identifying similar patterns in various types of data. Heterogeneous categorical data consists of data on ordinal, nominal, binary, and Likert scales. The clustering solution for heterogeneous data clustering remains difficult due to partitioning complex and dissimilarity features. It is necessary to find a solution to high-quality clustering techniques to efficiently determine the significant features of the data. This paper emphasizes using the firefly algorithm to reduce the distance gap between features and improve clustering performance. To obtain an optimal global solution for clustering, we proposed a hybrid of mini-batch k-means (MBK) clustering-based entropy distance measures (EM) with a firefly optimization algorithm (FA). This study compares the performance of hybrid K-Means, Agglomerative, DBSCAN, and Affinity clustering models with EM and FA. The evaluation uses a variety of data from the timber perception survey dataset. In terms of performance, the proposed MBK+EM+FA has superior and most effective clustering. It achieves a higher accuracy of 96.3 percent, a 97 percent F-measure, a 98 percent precision, and a 97 percent recall. Other external assessments revealed that the Homogeneity (HOMO) is 79.14 percent, the Fowlkes-Mallows Index (FMI) is 93.07 percent, the Completeness (COMP) is 78.04 percent, and the V-Measure (VM) is 78.58 percent. Both proposed MBK+EM+FA and MBK+EM took about 0.45s and 0.35s to compute, respectively. The excellent quality of the clustering results does not justify such time constraints. Surprisingly, the proposed model reduced the distance measure of all heterogeneous features. The future model could put heterogeneous categorical data from a different domain to the test.**

Keywords—Clustering; mini batch k-means; entropy; heterogeneous categorical; firefly optimization algorithm

I. Introduction

Categorical data or known as qualitative data is a type of data that can be stored and identified using the names or labels that have been assigned to it. Most statistical analysis approaches are incompatible with it, and only bar graphs and pie charts can visualize the data. Due to the rapid emergence and growth of information, it has become increasingly important to discover the group structure of objects within them. It also has difficulty extracting helpful information. One of the most effective methods that can extract such information is clustering. This technique allows organizing the data to access the information. Using clustering techniques, data analysts can easily extract valuable information from large datasets without supervision. The categorical clustering techniques were widely used in many real-world applications such as security analytics [1][2] and solving cold-start recommendation problems [3].

The traditional methods commonly used for data clustering problems are hierarchical and partitional. In some cases, the clustering process relies on distance or similarity measures. In a clustering algorithm, the data objects are typically represented in Euclidean distance in *k*-means. The clustering process's objective is to minimize the square distance from the cluster center to the cluster domain. *k*-means is widely used as a clustering algorithm and is effective when dealing with enormous volumes of data. However, *k*-means cannot be directly applied to data sets with categorical features. The transformation and parameter adjustment into numerical form is required since machines cannot interpret the categorical features directly. Label encoding, one hot encoding, and dummy variable encoding are methods for converting categorical data into numerical data.

Meanwhile, *k*-modes using simple matching dissimilarity measures can directly be applied for purely categorical data clustering. As categorical data cannot be estimated using mean or medians, the Euclidean distance metric was replaced with a simple matching dissimilarity measure, and the mean calculation for representing centroids was substituted with modes. However, these methods have some disadvantages, such as empty groups may appear in the first step of the solution and the final division of data is not optimal due to the appearance of extreme points. It is also trapped in local optima and local maxima and is sensitive to initial cluster centers.

Nature-inspired algorithms have gained much attention as global optimization tools to assist in solving various real-life complex optimization problems such as profit production [4], scheduling [5], queuing system [6], market segmentation, and opinion mining [7]. Nature-inspired algorithms have received a lot of attention as global optimization tools to help with real-life complex optimization problems like profit production [4], scheduling [5], queuing systems [6], market segmentation, and opinion mining [7].

Stochastic methods can be used to overcome clustering problems. Optimization methods refer to finding feasible solutions for problems to give an efficient, robust solution. Recent research has used Artificial Bee Colony (ABC) [8] and Cuckoo Search [9] to improve categorical data clustering quality. Optimizing a complex clustering problem is difficult due to the lack of a single measure that works best for heterogeneous categorical data.

This paper proposes the hybrid firefly algorithm and MBK to improve clustering performance using entropy distance metrics as similarity measures. The experimental results were also compared using the entropy distance method with Mini Batch *k*-Means (MBK), *k*-Means, Agglomerative Hierarchical, Density-based spatial clustering of applications with noise (DBSCAN), and Affinity Propagation clustering methods on a public survey data.

The rest of the paper follows the organization of the section as follows. Section II describes the related works. Section III explains the firefly algorithm. The mini-batch k-means algorithm is in Section IV. The proposed algorithm is introduced in Section V. The experimental results are discussed in Section VI. Section VII and Section VIII are the discussion and conclusion of the paper.

II. Related Work

The related work on categorical clustering, FA, and clustering models that use metaheuristic methods are reviewed in this section. Nominal, binary, ordinal, and Likert data types are categorical [10]. The combination of these data types is simultaneously considered to have heterogeneous information or data. The main goal of data clustering is to predict and find the groups for each data object from unlabeled data. On the other hand, selecting appropriate representations for data is one of the central problems in machine learning and data mining.

Clustering categorical data is very challenging. The challenge includes processing non-categorical variables and a required procedure for applying the similarity measures for the matching process. Regarding the grouping data from previous studies, the set-valued *k*-modes algorithm outperforms three existing categorical clustering techniques and is scalable to big datasets [11]. Algorithm new *k*-means like a method for categorical clustering data has shown that the proposed clustering method outperformed the k-means [12]. A Unified Entropy-Based Distance Metric for ordinal-and-nominal attributes on both real and benchmark data sets shows that the proposed metric surpasses the existing alternatives. A Unified Entropy-Based Distance Metric for ordinal-and-nominal attributes on both real and benchmark data sets shows that the proposed metric surpasses the existing alternatives [13]. A holo-entropy-based hierarchical clustering technique for categorical data outperforms other known algorithms in terms of efficiency, accuracy, and reproducibility [14].

The linear programming model outperformed the traditional and other enhanced *k*-modes algorithms on categorical datasets [8]. Learning-Based dissimilarity for categorical data clustering outperforms in terms of several performance indicators [16]. Compared to *k*-modes, the *k*-Approximate Modal Haplotype achieves an average performance increase of 0.51 percent in Precision and 0.40 percent in Normalized Discounted Cumulative Gain. However, because of their scalability, *k*-modes are more flexible to utilize [3]. The conventional categorical clustering performed well but provided local optimum solutions that affect data division.

The firefly optimization algorithm is one of the techniques that has been effectively used to solve issues in several areas due to its global optimum solution, resilience, efficiency, and capacity to handle problems in various sectors, including NP-hard, versatility, and other outstanding benefits. A comprehensive overview of FA that covers the various domains where the method is applied to a wide range of real-world applications with satisfying clustering results. Regarding clustering validity metrics, the FA shows that the new clustering methods outperform existing clustering and other hybrid metaheuristic methodologies [17]. In both distance and performance measurements for clustering tasks, the inward intensified exploration fa and compound intensified exploration fa models show statistically significant superiority [18]. Both algorithms are proposed to overcome the limitation of the FA model and *k*-means clustering. Compared to other algorithms, the firefly algorithm with *k*-means clustering produces better results, demonstrating the usefulness of the firefly algorithm with *k*-means clustering in offering a competitive solution to the traveling salesman problem [19]. *k*-means clustering with modifying the firefly algorithm is significantly more efficient than other algorithms [20]. From this, it can be seen that the combination of FA and conventional clustering algorithms outperform them in many real-world data sets, including numerical data.

Furthermore, in the previous literature, some clustering techniques for categorical datasets combined with other hybridization of optimization have been investigated and outperform the traditional *k*-modes algorithm in several aspects [21], as well as Fuzzy *k*-partition based on the ABC, outperforms the baseline algorithm in terms of its validity clustering for categorical data clustering [8]. The ABC algorithm was inspired by the foraging habits of bees and is one of the swarm-based metaheuristic optimization algorithms. Several studies in categorical clustering for hybridization of global optimization using a conventional clustering algorithm. However, few studies on hybridizing global optimization algorithms and conventional clustering algorithms use entropy as a distance measure.

Therefore, in this research, MBK+EM+FA has proposed to find the optimum global result for heterogeneous categorical data clustering using entropy distance as a similarity measure.

Because of its automatic subdivision and capacity to deal with multimodality, FA is preferred above other algorithms [22].

III. Firefly Algorithm (FA)

Recently flashing behavior of fireflies has been identified as unique to the species. FA is established by Xin She Yang [15], and it was based on the idealized behavior of the flashing characteristics of fireflies. From the literature, it is found that the FA algorithm can outperform when compared to many other algorithms. FA algorithm expands, and new variants emerge to solve all optimization problems. FA is chosen instead of other algorithms due to its simple, flexible, fast convergence, which efficiently solves many real-world problems.

FA is a swarm-intelligence-based algorithm, so it has similar advantages to the other swarm intelligence-based algorithms. FA has two significant advantages over other algorithms: automatic subdivision and the ability to deal with multimodality. FA offers simplicity, flexibility, and ease of implementation. Recently, FA is one of the bio-inspired algorithms used to solve clustering problems inspired by biochemical and social aspects of real fireflies [19]. Fireflies' behaviors, such as short and rhythmic flashes, can be considered operators of computational intelligence methods. The basic assumptions formulation of the FA algorithm is as follows.

- The intensity of a firefly decreases with the increase in distance. The firefly attracts the firefly that is closer to it. The light intensity I decrease as the distance r^2 increases, $I \propto \frac{1}{r^2}$.
- All fireflies are unisex and attracted to other fireflies regardless of their sex.
- The objective function defines the brightness of a firefly.

The FA algorithm has two critical features: variation in the light intensity and formulation of attractiveness (Yang 2010). The flashes are used as a communication tool by fireflies. Light is absorbed in the media, so the attractiveness of two fireflies will vary with the degree of absorption. The light intensity, $I\ (r)$ varies to the inverse square law as stated in equation 1.

$$I\ (r) = \frac{I_s}{r^2} \tag{1}$$

The light intensity, I, and the absorption coefficient, γ, varies with the distance, r for a given as in equation 2.

$$I\ = I_0 e^{-\gamma r} \tag{2}$$

Where I_0 is the original of the light intensity. The combined effect of inverse square law and absorption can be assumed as Gaussian form and represented in equation 3.

$$I\ = I_0 e^{-\gamma r^2} \tag{3}$$

The attractiveness of fireflies is proportional to the light intensity of the adjacent fireflies. The attractiveness, β of firefly is in equation 4.

$$\beta(r) = \beta_0 e^{-\gamma r^2} \tag{4}$$

Where β_0 is attractiveness at $r = 0$, the Euclidean distance between the firefly, i at x_i, and firefly, j at x_j, is given by equation 5.

$$r_{ij} = \sqrt{\sum_{k=1}^{d}(x_{ik} - x_{jk})^{\ 2}} \tag{5}$$

The computation movement of firefly i is attracted to another more attractive, brighter firefly j, and the formula is in equation 6.

$$x_i = x_i + \beta_0 e^{-\gamma r_{ij}^2}(x_i - x_j) + \alpha\left(rand - \frac{1}{2}\right) \tag{6}$$

Where α is the randomization parameter and $rand$ is a random number generator uniformly distributed between 0 and 1. The second represents the attraction, and the third term is randomization.

Algorithm 1: The Pseudocode of FA

```
Start
Initialize algorithm parameters:
Define the objective function $f(x)$, where $x = (x_1, \ldots\ldots, x_d)$
Generate the initial population of fireflies $x_i$ $(i = 1, 2, \ldots\ldots, n)$
Determine the light intensity of the firefly at $x_i$ by using objective function $f(x_i)$
**While** ($K$<Maximum_Generation) // Where $k = 1$ to maximum
    **for** $p = 1 : n$ // all $n$ fireflies
        **for** $q = 1$ to $n$ //$n$ fireflies
            if ($I_p$< $I_q$)
                Move firefly $p$ towards $q$ by using
                $x_i = x_i + \beta_0 e^{-\gamma r_{ij}^2}(x_i - x_j) + \alpha\left(rand - \frac{1}{2}\right)$
            **end** if
            Calculate new solutions and update light intensity for the next iteration
        **end** for $q$
    **end** for $p$
    Sort the fireflies based on the intensity value and find the current best solution.
end while
```

IV. Mini Batch K-Means (MBK) Clustering

A distributed random batching strategy known as Mini Batch K-means was used to store and update the data incrementally. Data and prototype values from each batch were used to update the cluster—the learning rate increases with the number of iterations in a batch. Before reaching a consensus, clusters must go through several iterations. There are several benefits to using MBK, such as its shorter computation time, the most simple unsupervised learning that solves clustering methodologies, and higher accuracy when dealing with mixed and huge datasets [23].

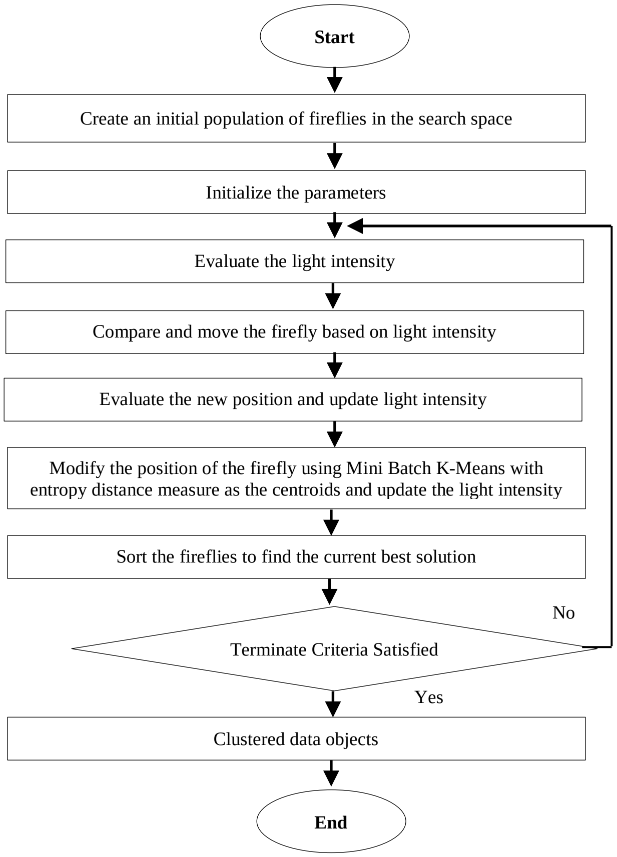
MBK+EM (Mini Batch K-Means with Entropy Measure) is an embedded entropy distance measure with Mini Batch K-Means that aims to determine the quality of the performance of clustering in heterogeneous categorical data. The previous experiment demonstrates that the Mini Batch K-mean with Entropy Measure at k =2 outperformed other clustering algorithms in clustering accuracy at 88%, V-Measure at 0.82, Adjusted Rand Index at 0.87, and Fowlkes-Mallow's Index at 0.94. The experiment was fixed seven times the average minimum elapsed time-varying for cluster generation, k at 0.26s.

V. Proposed Algorithm

The MBK algorithm has an advantage in reducing the amount of computation to converge to a local solution [24]. However, it has a drawback to finding the local optimum clustering results and the existing FA, which has a problem remembering the best solution for each firefly in the past. When there are no brighter-colored fireflies around, it also moves at random. The FA in this research performs the clustering procedure with the optimal centroid point. Therefore, the MBK is combined with the firefly optimization algorithm to obtain the global optimum solution and gives the firefly method a substantial improvement in clustering performance.

FA was chosen over other optimization algorithms because previous research shows that hybridizing FA with conventional clustering algorithms improves result quality [19]. The MBK+EM+FA algorithm combines the advantages of its distance measure, which would be possible to improve the clustering performance. One step of the MBK algorithm is utilized at the end of all the iterations of FA.

Fig. 1 depicts the process flow of the proposed hybridization FA with MBK+EM. The MBK+EM operator is incorporated into the FA to locate the centroid. The fireflies distribute randomly in the search space based on the objective function from the population at random from the given data objects. The distance between the firefly's position and the actual data in the dataset determines the intensity of each firefly. After analyzing the distance, all data shows the minimum distance value among the fireflies. The movement of the fireflies in the search space indicates the firefly's brightness. The iterative process of the swarm involves a comparison of the intensity of one firefly to another firefly, and the firefly's brightness defines its firefly movement. The attractiveness varies according to the distance between the two fireflies. Then, calculate the intensity for new fireflies based on firefly movement. To determine the new position, apply the MBK+EM operator to the entire population of fireflies. For each firefly, the MBK+EM operator is used to compute the mean value of all associated objects. Then, update the intensity values and evaluate the new firefly position for the entire firefly. Before proceeding to the next iteration, the fireflies' selection depends on their intensity value. The result is continuously updated during iterative processes until the stopping criteria are met. A post-process to select the final centroids for determining the best solution while ranking the position of the fireflies.



Start
Create an initial population of fireflies in the search space
Initialize the parameters
Evaluate the light intensity
Compare and move the firefly based on light intensity
Evaluate the new position and update light intensity
Modify the position of the firefly using Mini Batch K-Means with entropy distance measure as the centroids and update the light intensity
Sort the fireflies to find the current best solution
No
Terminate Criteria Satisfied
Yes
Clustered data objects
End

Fig. 1. Flowchart of Proposed MBK+EM+FA Algorithm.

The proposed Hybrid FA+MBK algorithm with EM phase is indicated in Algorithm 2. The following is a brief overview of all aspects of the Hybrid FA algorithm. The proposed algorithm starts by initializing the algorithm parameter in Step 2. The declaration of objective function performs in Step 3. The next step is randomly initiating fireflies' initialization. The position of the firefly represents the centroid of the clustering problem. Step 5 aims to determine the light intensity of the firefly to calculate the distance between the position of the fireflies. It is the initialization phase to estimate the light intensity of each firefly. Step 6-Step 10 demonstrates the movement of the fireflies in the search space, indicating the firefly's brightness. The intensity of one firefly compared with other fireflies during the iterative process in the swarm and the firefly's brightness defines its firefly movement.

The intensity value estimates the new position and place of the firefly obtained after the completion of movement calculation in steps 11 and 12. Global optima were used in the proposed firefly algorithm to control the movement of the firefly. This research will update a maximum global optimum in any iteration of the algorithm. Based on fireflies' brightness, fewer fireflies will move towards the brightest firefly. Then, the light intensity will be updated, and the current feasible or optimal solution will be found.

In steps 13 and 14, the MBK with EM is applied to the entire population of the fireflies to find a new position by updating light intensity. In the proposed FA, entropy distance was used to compute the distance of fireflies to global optima.

Step 15 focuses on the optimal values in each cluster that could discover after all the data are clustered by sorting the light intensity. Finally, the iteration executes until the maximum number of iterations.

Algorithm 2: The Pseudocode of MBK+EM+FA

```
1.  Input
2.  Initialize algorithm parameters
3.  Define the objective function $f(x)$ , where $x = (x_1, \ldots\ldots, x_d)$
4.  Generate the initial population of fireflies $x_i$ $(i = 1, 2, \ldots\ldots, n)$
5.  Determine the light intensity of the firefly at $x_i$ by using objective function $f(x_i)$
6.  While ( $K$ <Maximum_Generation) // Where $k = 1$ to maximum
7.      for $p = 1 : n$ // all $n$ fireflies
8.          for $q = 1$ to $n$ //$n$ fireflies
9.              if ($I_p$< $I_q$)
                Move firefly $p$ towards $q$ by using
                $x_i' = x_i + \beta_0 e^{-\gamma r_{ij}^2} + \propto \left(rand - \frac{1}{2}\right)$
10.             end if
11.             Calculate new solutions and update light intensity
12.         end for $q$
13.         Apply MBK with entropy distance measure, then find new solutions and update light intensity
14.     end for $p$
15.     Sort the fireflies based on the intensity value and find the current best solution;
16. end while
17. Output: Clustered data objects
```

VI. Experimental Results

A. Dataset

The experiment was performed using the secondary data of a survey on public timber utilization. The data pre-processing and cleaning procedures included removing unwanted observations, fixing the data structure, and imputing the missing data. The number of instances is 2407 was obtained from the Malaysian Timber Industry Board (MTIB), Malaysia. The dataset consists of 111 categorical features such as race, type of housing, level of knowledge, etc. This type of data is considered heterogeneous categorical data [25].

B. Parameter Settings

This subsection explains the parameter, notation, and value associated with FA evaluation. We adapt the same parameter values as suggested by the originator of FA in the late year between 2007 and 2008 [26]. The population size is 2407, the total number of respondents involved. As a stopping criterion, we also set the maximum number of iterations equal to 25. Rosenbrock is used as a benchmark objective function since previous research has shown that Rosenbrock is one of the objective functions that has shown successful performance [27]. This research implemented a static parameter for the generation and number of fireflies. The maximum value for Beta (β), Alpha (α), and Gamma (γ) is 1, 0.2, and, respectively. The algorithm parameters are summarized in Table I.

TABLE I. PARAMETER SETTING

Parameter	Notation of Parameter	Parameter Value
Brightness	Objective Function	Rosenbrock
Beta (β)	Attractiveness	1
Alpha (α)	Randomization of Parameter	0.2
Gamma (γ)	Light Absorption Coefficient	1
Number of Fireflies (n)	Population	2407
Number of Generations (g)	Iteration	25

C. Performance Measures

An external validation measure and a confusion matrix and used for the performance measure. The external validation measure is Homogeneity (HOMO), Fowlkes-Mallows Index (FMI), Completeness (COMP), and V-Measure (VM). The validation assures how good the clustering solutions are by their different ways of computations. This measure aims to measure and validate the clustering quality [28].

In the confusion matrix [16], there were four performance metrics such as true positive (TP), false positive (FP), true negative (TN), and false-negative (FN). TP is the metric that could accurately predict the optimized feature from the features in feature space collection. In contrast, the TN metric predicts the weaker feature or incorrect feature relevant to the diabetes classification process in feature space, and the FP measure can predict the incorrect diabetes feature in feature space. FN rate is an outcome of the model incorrectly predicting the negative feature effectively.

F-measure (F) is a combination of precision and recall that measures the cluster that contains only objects of a particular class and is used to balance false negatives by weighting recall parameter $\eta \geq 0$. The formula of the F-measure is in Equation 7.

$$F = \frac{(\eta^2 + 1)\ P \times R}{\eta^2 \times P + R} \tag{7}$$

Precision (P) estimates the ratio of the true positives among the cluster. The formula of Precision is in Equation 8.

$$P = \frac{TP}{TP + FP} \tag{8}$$

Recall (R) is a combination of all objects grouped into a specific class. The formula of recall is in Equation 9.

$$R = \frac{TP}{TP + FN} \tag{9}$$

Fowlkes-Mallows Index (FMI) quantifies the performance of a clustering technique by comparing it to other clusters. A score close to zero indicates largely independent labeling, whereas a value close to one reflects clustering agreement. The formula for FMI is in Equation 10.

$$FMI = \frac{TP}{\sqrt{(TP + FP)(TP + FN)}} \tag{10}$$

Accuracy (ACC) is defined only as the proportion of the actual results. The accuracy measure can be referred to in Equation 11.

$$ACC = \frac{1}{n}\sum_{i=1}^{k} a_i \qquad (11)$$

Where a_i is the number of data objects in both clusters, i and k are the numbers of clusters, and n is the total number of objects in the dataset. HOMO covers all clusters that contain only data points members of a single class. A score between 0.0 and 1.0 is obtained. A score of 1.0 stands for perfectly homogeneous labeling.

$$HOMO = -\sum_{c,k}^{1} \frac{n_{ck}}{N} \, log \, log \, (\frac{n_{ck}}{n_k}) \qquad (12)$$

Completeness (COMP) is considered comprehensive if it incorporates all data points that belong to a given class. A score between 0.0 and 1.0 is obtained. A labeling score of 1.0 indicates perfect labeling. V-measure can be used to ascertain the degree of agreement between two clustered datasets that have been clustered independently. The formula of completeness defined in Equation 13.

$$COMP = 1 - \sum_{c,k}^{1} \frac{n_{ck}}{N} \, log \, log \, (\frac{n_{ck}}{n_k}) \qquad (13)$$

V-Measure (VM) is the harmonic average between homogeneity and completeness. It can be used to determine the degree of agreement between two clustered datasets that have been clustered independently. Furthermore, if any of the two VM failed to meet the criteria, the clustering number remains zero.

$$V - Measure\ (VM) = 2 \times \frac{(HOMO \times COMP)}{(HOMO + COMP)} \qquad (14)$$

D. Experimental Results

It has been explained earlier than due to local optimum issue which aimed to improve performance of clustering external validity using heterogeneous categorical data. Several clustering algorithms were accelerated and tested with the coincident clustering problem to produce good clustering results. Moreover, the categorical nature of data creates additional complexity in clustering. MBK + EM + FA has been proposed to address such limitations of existing clustering algorithms. The technique's efficiency can be evaluated by measuring the quality of clustering results of various parameters. In order to judge the performance of the proposed technique over state-of-the-art algorithms of the other four hybrid clustering algorithms, such as a hybrid of *k*-means, Agglomerative, DBSCAN, and Affinity with EM distance metric, we conduct several experiments. Thus, this section highlights the experimental results for all five clustering algorithms: MBK, *k*-means, Agglomerative, DBSCAN, and Affinity embedded with FA and without FA using the performance measures and the computational time.

Table II demonstrates the performance of the algorithms mainly on f-measure, Precision, and recall. To add, it is interesting to note that the proposed MBK+EM+FA outperforms other algorithms with the highest in terms of F-measure, Precision, and recall, with 97%, 98%, 97%, and 96.30%, respectively. It has increased more than 0.15 of F-measure, 12% of Precision, and 16% of recall compared to MBK+EM, which is no FA is embedded as an optimization strategy. The performance of the proposed clustering algorithm was also compared with other clustering algorithms.

TABLE II. CLUSTERING PERFORMANCE FOR F-MEASURE, PRECISION AND RECALL

Clustering Algorithms	**F**	**P**	**R**
MBK+EM+FA	0.97	0.98	0.97
MBK+EM	0.82	0.86	0.81
K-Means+EM+FA	0.44	0.36	0.60
K-Means+EM	0.16	0.19	0.14
Agglomerative+EM+FA	0.44	0.36	0.60
Agglomerative+EM	0.16	0.19	0.14
DBSCAN+EM +FA	0.45	0.36	0.59
DBSCAN+EM	0.17	0.12	0.32
Affinity+EM+ FA	0.02	1.00	0.01
Affinity+EM	0.01	0.38	0.00

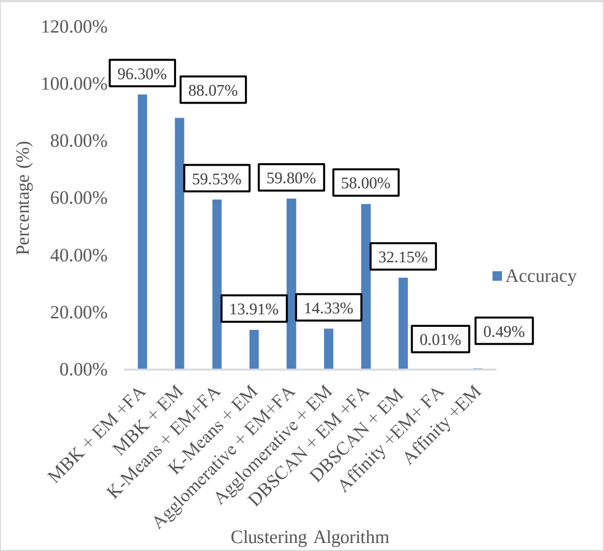


Fig. 2. Comparison of Accuracy Performance.

Fig. 2 shows the accuracy score of all algorithms. Overall, most algorithms have shown an increase in accuracy when a hybrid with FA. Only Affinity+EM is excluded. The proposed MBK+EM+FA has increased by 2.9%. It is revealed that the proposed algorithm is more accurate and capable of converging compared to other algorithms. It is observed that the f-measure, Precision, recall, and accuracy of the proposed clustering algorithm are the highest values. These values indicate that the performance of the proposed clustering algorithm was satisfactory based on high-performance parameters achieved.

Table III shows the comparative performance of the proposed clustering algorithm compared with other hybrid clustering algorithms based on external validation in terms of homogeneity, FMI, completeness, and V-Measure. Interestingly, all five clustering algorithms mostly performed better with the hybrid FA. All measurements have demonstrated much increment. It shows that clustering validation on homogeneity agreement, the perfectness of labeling, and independent ability in clustering and clustering agreement is acceptable. However, the most efficient clustering algorithm is the proposed MBK+EM +FA. As seen in the table, it is evident that the increase of about 0.3 compared with MBK+EM for all external validation measurements. Most of the values are between 0.78 and 0.94. The highest FMI value is 0.9307. The obtained FMI indicates a good clustering agreement offered by the proposed MB+EM+FA due to the value being almost zero.

The time consumption of the algorithm is defined as the time required to assess all the data to generate clusters. The elapsed time of the algorithms is calculated and expressed in seconds, as shown in Table IV. Table IV indicates that the proposed MBK+EM+FA that uses entropy measure and FA consumes less time than K-Means+EM+FA, Agglomerative+ EM+FA, DBSCAN+EM+FA, and Affinity+EM+FA. It reveals that the hybrid proposed algorithm is much more effective than others. However, the use of MBK+EM+FA is a bit higher in computational time compared to MBK+EM. However, as mentioned in the previous section, it offers a good accuracy performance. A slight increase in execution time does not cause an issue in the practical use of the algorithm because a better performance is obtained. Overall, the computational time is less than a minute. Thus, it can be said to be sufficient time for the execution of cluster data since the proposed algorithm involves a searching mechanism compared to the others [29][30].

TABLE III. CLUSTERING PERFORMANCE COMPARISON FOR HOMO, FMI, COMP AND VM

Clustering Algorithms	**HOMO**	**FMI**	**COMP**	**VM**
MBK+EM+FA	0.7914	0.9307	0.7804	0.7858
MBK+EM	0.4777	0.804	0.4576	0.4673
K-Means+ EM+FA	0.0006	0.7192	0.0639	0.0013
K-Means+EM	0.4479	0.7742	0.4218	0.4343
Agglomerative+EM+FA	0.0006	0.7192	0.0639	0.0013
Agglomerative+EM	0.4496	0.7679	0.4214	0.4349
DBSCAN+EM+FA	0.0090	0.6938	0.0324	0.0141
DBSCAN+EM	0.0005	0.7033	0.0392	0.0002
Affinity+EM+FA	0.8493	0.1285	0.1232	0.2152
Affinity+EM	0.729	0.1178	0.101	0.1699

TABLE IV. EXECUTION TIME (PER SECONDS)

Clustering Algorithms	**Time (s)**
MBK+EM+FA	0.4589
MBK+EM	0.3550
K-Means+ EM+FA	0.5839
K-Means+EM	0.7850
Agglomerative+EM+FA	14.1792
Agglomerative+EM	13.9627
DBSCAN+EM +FA	87.7652
DBSCAN+EM	8.3744
Affinity+EM+FA	23.03922
Affinity+EM	11.7965

VII. DISCUSSION

The capability and effectiveness of a clustering approach to reduce the clustering error and improve the accuracy are the most crucial qualities in clustering. There is no inherent distance between the feature of categorical data analysis remains challenging. This research aims to evaluate the clustering efficiency of heterogeneous categorical data. Entropy is a measure of information. The entropy distance generates within the clustering algorithm approach allows us to measure the distance of features systematically quantified. The entropy aided the clustering algorithms in selecting the center of the centroid. Due to the nature of the entropy, it can investigate the compatibility of data to produce weighted values that can represent each class in the dataset. The initial weight value of entropy can study the data well and produces a higher accuracy.

Introducing the FA approach in the proposed clustering algorithms establishes a new search strategy for finding a globally optimal solution. The aim is to find the nearest features based on the entropy distance measure. In this case, the total number of categorical features is 111 features. Overall, achieving a clustering algorithm embedded with FA provides a good performance. It supports the previous work FA can contribute to an efficient solution due to its flexibility, simplicity, and fast convergence [31]. FA also offers a global search strategy [17] that can explore more search spaces for all features in finding the nearest neighbor. The generated value for the entropy measure seems to improve when using the FA. It could reflect in the clustering similarity measure based on a data point in both the intra-distance and inter-distance among the features. As illustrated in the above results, the best performance is by the proposed MBK+EM+FA. However, the high quality of the clustering results in more than constitutes for such restrictions of elapsed time. In addition, more work can be done such as embedding the *k*-interpolation model based on Kriging Method [25] and other computational optimization methods.

VIII. CONCLUSION

This research compares clustering algorithms that utilize the fundamental behavior of the firefly algorithm in order to improve clustering problem-solving. The proposed firefly algorithm can locate the cluster centers by comparing several clustering techniques to refine the centers as input. The experimental results have proved the effectiveness, capability, and efficiency of the FA and MBK with EM in improving the clustering performance in heterogeneous categorical data of public perception of timber utilization as compared to MBK+EM, K-Means+EM+FA, K-Means+EM, Agglome rative+EM+FA, Agglomerative+EM, DBSCAN+EM +FA, DBSCAN+EM, Affinity+EM+ FA, and Affinity+EM. In improving the solution, other objective functions considering inter and intra-cluster measurements could be used in future research to improve the proposed models. Another aspect is the evaluation of heterogeneous categorical data from a different domain.

***Abstract*—The imbalanced dataset is a prominent concern for automotive deep learning researchers. The proposed work provides a new mixed pooling strategy with enhanced performance for imbalanced vehicle dataset based on Convolution Neural Network (CNN). Pooling is crucial for improving spatial invariance, processing time, and overfitting in CNN architecture. Max and average pooling are often utilized in contemporary research articles. Both techniques of pooling have their own advantages and disadvantages. In this study, the advantages of both pooling algorithms are evaluated for the classification of three vehicles: car, bus, and truck for imbalanced datasets. For each epoch, the performance of max pooling, average pooling, and the new mixed pooling method was assessed using ROC, F1-score, and error rate. Comparing the performance of the max-pooling method to that of the average pooling method, it has been found that the max-pooling method is superior. The performance of the proposed mixed pooling approach is superior to that of the maximum pooling and average pooling methods. In terms of Receiver Operating Characteristics (ROC), the proposed mixed pooling technique is approximately 2 per cent better than the maximum pooling method and 8 per cent better than the mixed pooling method. Using a new pooling technique, the classification performance with an imbalanced dataset is improved, and also a novel mixed pooling method is proposed for the classification of vehicles.**

Keywords*—*Average pooling; convolution neural network; imbalance dataset; max pooling; mixed pooling

I. Introduction

Automotive companies are conducting cutting-edge research on vehicle platoon management to improve 'vehicle-to-vehicle' communication for enhanced performance. Vehicle platoon management increases customer and societal benefits by attaining greater fuel efficiency, less pollution, less road congestion, and fewer road accidents [1] to [2]. To improve performance, a key feature of vehicle platoon management is categorizing vehicles based on their size and grouping them suitably to achieve reduced aerodynamic drag when driving in the longitudinal direction, as illustrated in Fig. 1. To achieve the requirement, vehicles having Advanced Driving Assistance System (ADAS) features such as lane-keeping, automated cruise control, pedestrian safety, platoon management, and others must have at least two cameras installed. Vehicle platoon management is also categorized as ADAS [3], which falls within the L2 and L3 levels of vehicle automation. As vehicle automation level increases from L1 to L5 then vehicle intelligence should also increase to improve safety. Considering the features given by automotive manufacturers for modern vehicles, it is clear that camera utilization is expanding day by day, necessitating further study into image processing algorithms. Strict safety requirement calls for the need for more cameras in vehicles along with other sensors. As the number of cameras on a vehicle increases, image processing output will become more vital for controlling the vehicle according to safety requirements.

CNN has been widely used in vehicle image processing applications like pedestrian safety [4], vehicle classification [5,6,7], and many more applications. The focus of current research is on categorizing vehicles by type, which is the initial stage in vehicle platoon management before combining them for greater efficiency. To begin with car, bus, and truck are three classes of vehicles that are regularly seen on highways, and these three have been taken into consideration for experimental work using CNN. To train the CNN algorithms, high-quality and sufficient volumes of images are required. Unlike other applications where image datasets are publicly available, such as medical imaging, sign language identification, pattern recognition, and so on, the availability of vehicle image datasets is limited. Open repository datasets may not contain all of the images needed to do experimental work on the specified topic. In another instance, researchers have created datasets for vehicle rear parts in [8], and a few vehicle datasets are published in open source PKU-VD [9], VeRi-776 [10], VehicleID [11], as well as different vehicle datasets are available for smart city study [12]. But, to get dataset access from open source, researchers need to get approval from the owners. However, researchers must obtain permission from the owners of open-source datasets to access them. Still, sometimes delays or no response can be expected when seeking approval from the owners. There are few open access datasets for automotive applications [14,15,16]. While developing required image dataset, all this leads to an imbalanced image dataset collection, which is a prevalent problem in the automotive arena. In multiclass analysis, imbalance datasets indicate that the dataset's distribution includes unequal amounts of images for each class. Uneven quantities of images will impact the accuracy of the learning algorithms. In comparison to the amount of car images, the availability of images in open source for bus and truck images are minimal. As a result, various image augmentation techniques such as flipping, rotation, cropping, and so on are used to increase the quantity of bus and truck images. Therefore, to increase the classification performance even with an imbalanced dataset a mixed pooling approach has been proposed in this research. In the further sections deal with the works carried out related to vehicle classification using CNN and the motivation behind the mixed pooling implementation to improve the performance of the CNN learning algorithm for the imbalance vehicle datasets has been explained.

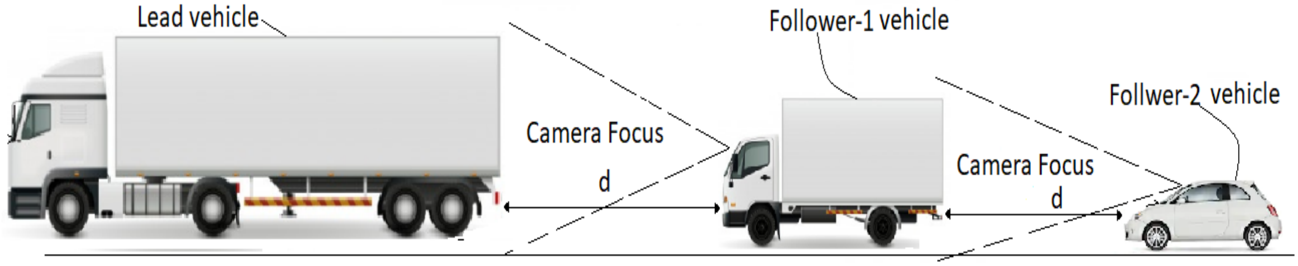

Fig. 1. Example for Three Vehicles in Platoon Management, Where the First Vehicle is called as Lead Vehicle and subsequent Two Vehicles are called as Follower-1 and Follower-2. Vehicles Separated from each with Distance - d.

II. Related Work

Deep Learning methods for image processing currently dominate computer vision, particularly for image recognition related applications. Several works utilising Deep Learning for vehicle detection are documented in the literature.

Using the CNN deep learning technique, [23] proposed a daytime vehicle detection system. Using appearance-based feature extraction techniques, the experiment yielded improved results. Fast R–CNN-based vehicle classification algorithm for real-time traffic surveillance was developed by Wang et al. [24]. A dataset of 60,000 images depicting traffic junction was compiled and divided into training and tested data, on which the suggested approach achieved an accuracy of 80.051%. Chauhan et al. [25] have developed a CNN-based framework for the classification and counting of vehicles on highways. On the collected dataset of 5,562 CCTV camera videos of highway traffic, the suggested framework achieved 75 percent MAP. Jo et al. [13] have suggested a GoogLeNet framework for vehicle categorization based on transfer learning. The authors demonstrated that the provided classifier achieved a 0.983% accuracy rate on the ILSVRC-2012 data set. Chia-Chi Tsai et al., 2018 [17], developed an improved Convolutional Neural Network architecture based on deep learning methods for intelligent transportation applications. Improved Spatio-Temporal Sample Consensus is the name of a method developed by Yu Wang et al. [26] for detecting and classifying moving vehicles. First, the moving vehicles are detected using the Spatio Temporal Sample Consensus technique, based on the brightness variation and shadow of the vehicles. In addition, using feature fusion algorithms, the objects are categorised based on area, face, licence plate, and vehicle symmetry characteristics. In the study proposed by Kaiming He [18], the deep networks are equipped with the pooling approach called spatial pyramid pooling. This eliminates the requirement of fixed size image being given as input to the network. The novel network structure, termed SPP-net, may provide a fixed-length representation independent of image size/scale. Pyramid pooling is also robust to object deformations. With these features, SPP-net improves all CNN-based image classification algorithms.

Deep feature-based techniques can effectively improve the accuracy of vehicle classification, but they require an enormous quantity of data to attain considerable accuracy. Hence, in this current work an attempt has been made to achieve good accuracy with moderate dataset size.

III. Motivation

CNN's components include a convolution layer, a pooling layer, and a flattening layer that performs feature extraction and uses the output of the flattening vector for classification. The convolution layer performs a linear operation that extracts a feature map from an image. For the given image, the ith convolution layer generates ith output feature map and it can be represented as mentioned in (1) where ‘w_i’ is kernel or filter and ‘x’ is the input image with 2D convolution operator and y is an output.

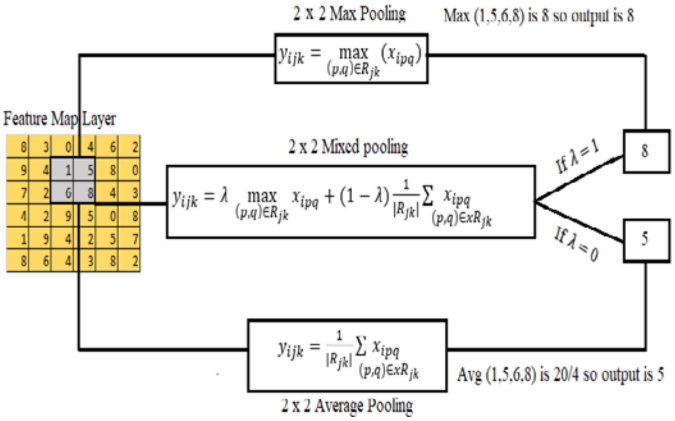
$$y_i = f(w_i * x) \tag{1}$$

The kernel used in convolution will travel across the image left to right and top to bottom, the amount of movement for the given input image depends on the input image size and kernel size. The activation function in the convolution layer produces a feature map, which is fed into the pooling layer. Pooling is a nonlinear function that generates output by summing the net of certain pixel positions. The pooling layer has numerous advantages in CNN architecture, including improved processing time, noise invariance, and overfitting. In the following sections below some of the most commonly utilized pooling strategies are discussed.

A. Max Pooling

Max Pooling selects the maximum value in the feature map for the selected filter dimension. Here computation has made faster [19, 20] because of the elimination of non- max values and the output of the max pool will reduce from X to Y as mentioned in Fig. 2. By selecting the max value in the feature map, max-pooling picks the brightest pixel from the given image. Max pooling can be represented mathematically as given in (2). Where for given ith feature map x is the input element at (p,q) within pooling region R_{jk} which represents local neighbourhood position (j,k)with output y.

$$y_{ijk} = \max_{(p,q)\in R_{jk}} (x_{ipq}) \tag{2}$$



2 x 2 Max Pooling
Max (1,5,6,8) is 8 so output is 8
$y_{ijk} = \max_{(p,q)\in R_{jk}} (x_{ipq})$
Feature Map Layer
8 3 0 4 6 2
9 4 1 5 8 0
7 2 6 8 4 3
4 2 9 5 0 8
1 9 4 2 5 7
8 6 4 3 8 2
2 x 2 Mixed pooling
$y_{ijk} = \lambda \max_{(p,q)\in R_{jk}} x_{ipq} + (1-\lambda)\frac{1}{|R_{jk}|}\sum_{(p,q)\in xR_{jk}} x_{ipq}$
If λ=1
8
If λ=0
5
$y_{ijk} = \frac{1}{|R_{jk}|}\sum_{(p,q)\in xR_{jk}} x_{ipq}$
Avg (1,5,6,8) is 20/4 so output is 5
2 x 2 Average Pooling

Fig. 2. Toy Example to Illustrate 2x2 Max, Average and Mixed Pooling Principle.

B. *Average Pooling*

Average pooling selects the average value in the feature map for the selected filter dimension. The computation is faster [21] since it selects the average value of each region and the output value is lowered from X to Y, as illustrated in Fig. 2. By selecting the average value in the feature map, average pooling picks the average pixel from the given image. Average pooling is represented mathematically as given in (3). Where for given ith feature map x is the input element at (p,q) within pooling region R_{jk} which represents local neighbourhood position (j,k)with output y.

$$y_{ijk} = \frac{1}{|R_{jk}|}\sum\nolimits_{(p,q)\in xR_{jk}} x_{ipq} \quad (3)$$

C. *Mixed Pooling*

Max pooling performance will degrade when the feature map has a low pixel value and average pooling performance will degrade when the feature map has high pixel values. To overcome this problem, mixed pooling approach has been implemented [22]. As illustrated in Fig. 2, the mixed pooling approach combines both max and average pooling by picking any one method during execution. Mixed pooling can be represented as in (4). Where λ can be 1 or 0 and is chosen at random; pooling strategy is average if λ is 0 and pooling strategy is to max if λ is 1.

$$y_{ijk} = \lambda \ \max\nolimits_{(p,q)\in R_{jk}} x_{ipq} + (1-\lambda)\frac{1}{|R_{jk}|}\sum\nolimits_{(p,q)\in xR_{jk}} x_{ipq} \quad (4)$$

D. *Proposed Novel Method*

In the current work, novel pooling method has been proposed to get the benefits of mixed and max pooling. Because mixed pooling has the advantage of taking into account both the max and average value of the pixels, it has been implemented after the first layer of convolution, and max pooling has been implemented in the second and third layer pooling, as shown in Fig. 3 for a three-layer CNN. The proposed method has the advantage that once the first convolution layer captures the maximum needed feature using mixed pooling; the subsequent layer using max pooling will reinforce the features.

IV. Methodology

The present work begins with gathering bus, car, and truck images and creating the requirement dataset for the vehicle platoon environment. With the developed dataset training, testing and validation has been performed for three different pooling scenarios as presented in Fig. 3. Performance evaluation for all three pooling scenarios has been visualized using ROC Curve.

A. *Dataset Creation*

To undertake experimental work in deep learning, the first step is to develop a suitable image dataset to train the deep learning algorithm. The car images were acquired from an open-source repository [14], the bus images were acquired from an open-source repository [15], and truck images were acquired from the open-source repository [16]. There were approximately 3000 images available for truck and bus, and nearly 8000 images were acquired for the car vehicle class. The image data size for bus and truck has been increased from 3000 images to 5000 images using image augmentation techniques. Different image augmentation techniques like padding, flip, rotate, tilt, blur, crop, adding noise, etc. have been incorporated based on the available images. Therefore, the total number of images used to conduct the experiment is 5000 for the bus and truck classes and 8000 for the vehicle class.

B. *Training, Testing and Validation Dataset*

As demonstrated in Fig. 4 by utilizing open source and different augmentation techniques final dataset has been created. The training and testing ratio are set at 80% and 20%, respectively. To optimize the CNN algorithm's learning performance, 20% validation datasets were used.

C. *CNN Architecture*

As mentioned earlier, a three-layer Convolution Neural Network has been implemented as shown in Fig. 5. The experiment has been carried out using Python 3.7.9, with IDE PyCharm and OpenCV Library. The CNN architecture has taken care of feature extraction, including filtering, image segmentation, and image enhancement for images that are 64 by 64 in size.

CNN model consists of convolution layer, pooling layer, fully connected layer, and output layer. The first convolution layer consists of 32 filters, followed by 64 filters in the second and third layers. Padding has been considered to maintain input and output image size. Three alternative pooling strategies have been studied in terms of pooling techniques. In Scenario-1, all three pooling configurations are max pooling. In Scenario-2, all three pooling configurations are mixed pooling and in Scenario-3 the first pooling configuration is mixed pooling and the second two pooling configurations are max pooling. The output of pooling with window size 2 and stride size 2 is fed to the size 2 of the fully connected layer. The fully connected layer is the deep layer which is used for classification. Finally, the fully connected layer passes its input to softmax with 2 layers for the final classified image output. Each scenario's output is executed in three distinct steps, and the outcomes are summarized and discussed in the following section.

2. All 3 layers are mixed pooling	5000	8000	5000
3. Proposed method where first layer is mixed and second and third layer is Max	5000	8000	5000

Fig. 5. Implementation Methodology.

D. Performance Evaluation

Standard formulae of accuracy, precision, recall, and F1 score, as indicated (5) through (8), were used to evaluate the performance of three distinct pooling procedures. Here, True Positive (TP) is a correctly predicted class, False Positive (FP) is a label that does not belong to class but is predicted as positive, True Negative (TN) is the correctly predicted for class that does not belong to the class, False Negative (FN) is wrongly predicted for class that does not belong to the class.

$$\text{Accuracy} = \frac{(\text{TP + TN})}{(\text{TP + TN+ FP+ FN})} \quad (5)$$

$$\text{Precision} = \frac{\text{TP}}{(\text{TP+ FP })} \quad (6)$$

$$\text{Recall} = \frac{\text{TP}}{(\text{TP + FN })} \quad (7)$$

$$\text{F1 Score} = \frac{2 \text{ x TP}}{((2 \text{ x TP}) + \text{FP+ FN })} \quad (8)$$

V. Results and Discussion

As depicted in Fig. 5. imbalance image datasets were fed into the CNN model and run individually for each of the three cases and the results obtained are as shown in Fig. 6. In Fig. 6, label 0 denotes the bus class, label 1denotes the car class, and label 2 denoted the truck class. ROC graphs are also being used to visualize the results of Scenario-1, Scenario-2, and Scenario-3 as illustrated in Fig. 7, Fig. 8, and Fig. 9, respectively.

A. Scenario-1(All Three Max Pooling)

Fig. 7 illustrates the accuracy attained for all three classes using the ROC curve for Scenario-1. The acquired findings show that the achieved average accuracy is 98 % with 100 % accuracy for vehicle classification and 95 % and 97 %accuracy for bus and truck classification. After execution, false-positives for bus and truck are 150 and 250 images, respectively, and false-negatives are 250 and 150 images for the 20% overall dataset during testing.

B. Scenario -2 (All Three Mixed Pooling)

The ROC curve for Scenario-2 is shown in Fig. 8. The average accuracy achieved is 98%, with 100% classification for car class and 94 % and 97 % for bus and truck class, respectively. The false-positive rate for bus and truck is 150 and 300 images, respectively, whereas the false-negative rate for the 20% overall dataset during testing is 300 and 150 images.

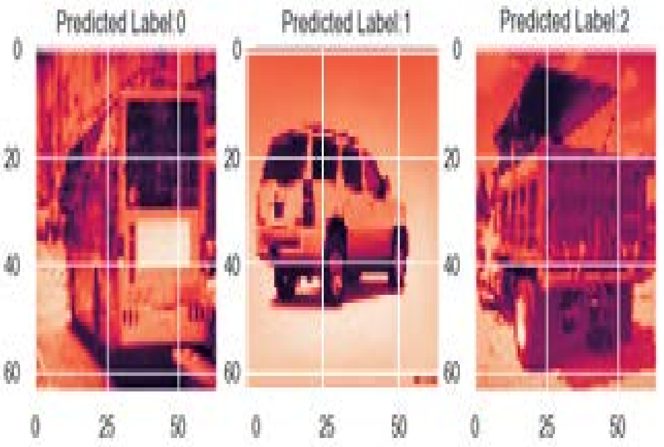

Fig. 6. Predicted Output (Label Convention: Label 0 -Bus, Label 1- Car, Label 2-truck).

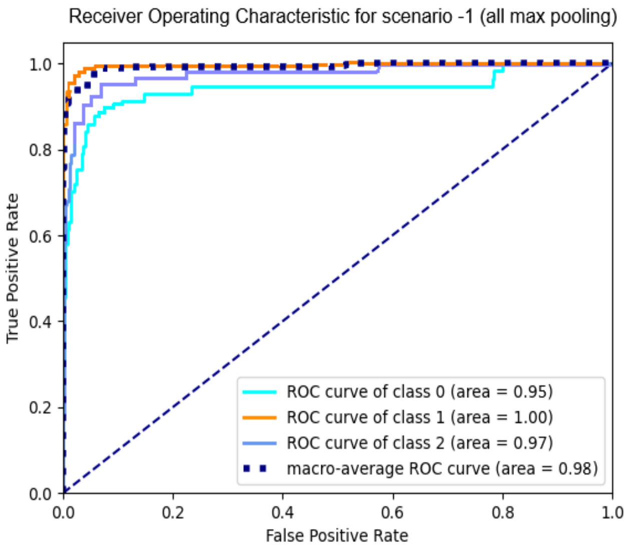

Fig. 7. ROC for Scenario-1, Where Class 0 is for Bus, Class 1 is for Car and Class 2 is for Truck.

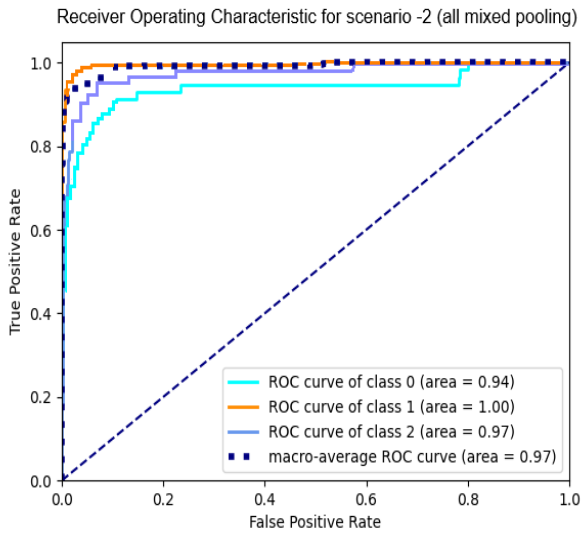

Fig. 8. ROC for Scenario-2, where Class 0 is for Bus, Class 1 is for Car and Class 2 is for Truck.

C. Scenario-3 (New Mixed Pooling)

Fig. 9 depicts the ROC curve for Scenario-3. While 100% of cars are correctly classified, 94% and 97% of buses and trucks are correctly classified. The number of false-positive images for the bus and truck is 150 and 50 respectively and the number of false-negative images is 50 and 150, respectively for the 20% overall dataset during testing.

D. Epoch Error Rate

From Fig. 10, it can be observed that the learning cycle has been completed nearly at 50 epochs for all three scenarios. However, in the proposed methodology, the pooling error rate is decreased to 0.7 percent, whereas the error rate in max-pooling is 1% and 1.4 per cent in mixed pooling.

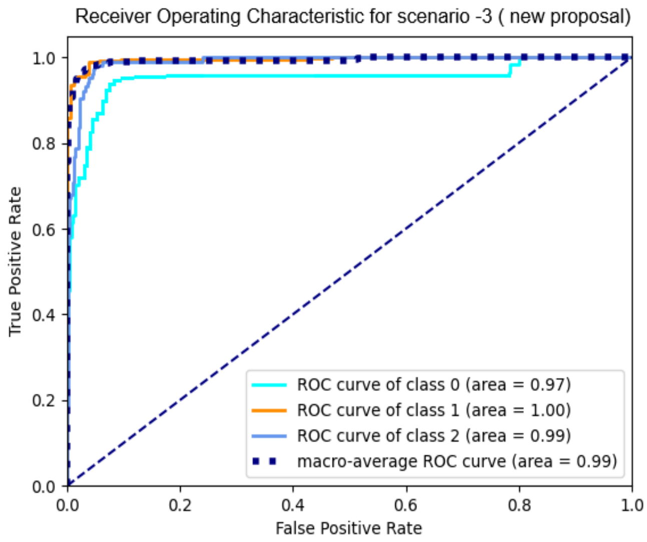

Fig. 9. ROC for Scenario-3, Where Class 0 is for Bus, Class 1 is for Car and Class 2 is for Truck.

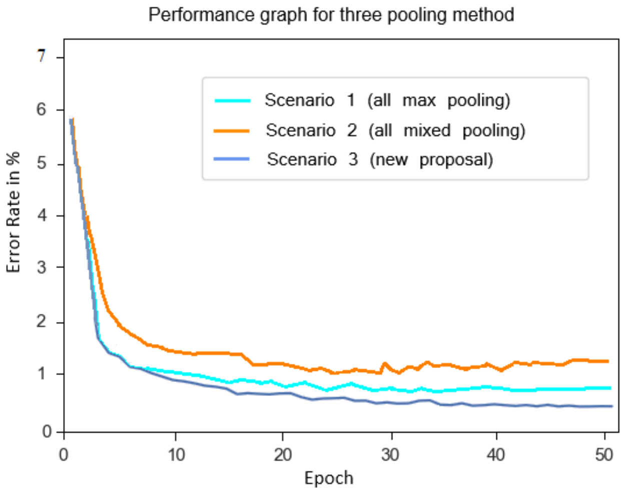

Fig. 10. Performance at different Epochs of for Three different Pooling Scenarios.

E. Overall Performance Evaluation

As the literature review reveals no evidence of deep learning based vehicle grouping to aid in vehicle platoon management, an attempt has been made where the proposed methodology enhances the performance of vehicle classification using an imbalanced image dataset. For the three different situations that were taken into consideration for the experimentation, Table I list the performance metric values for accuracy, precision, recall, and f1-score for multiclass vehicle classification. From the experimental outcomes, it can be inferred that the suggested strategy outperformed other methods while using its own dataset for the platoon management system.

To demonstrate the improved performance of the proposed method, the results obtained from the proposed method is compared with the other methods as shown in Table II. The proposed method also shows a consistent classification performance for all the vehicle classes.

TABLE I. SUMMARY OF THE PERFORMANCE EVALUATION FOR ALL THREE SCENARIOS

Class	**Performance Metric**	**Scenari-1 output in %**	**Scenari-2 output in %**	**Scenari-3 output in %**
BUS	Accuracy	95	94	97
	Precision	97	97	99
	Recall	95	95	97
	F1 Score	96	95	98
Car	Accuracy	100	100	100
	Precision	100	100	100
	Recall	100	100	100
	F1 Score	100	100	100
Truck	Accuracy	97	97	99
	Precision	95	94	97
	Recall	97	97	97
	F1 Score	96	96	98
Bus, Car & Truck	Average Accuracy in % for all 3 class	98	97	99
Bus, Car & Truck	Average error rate in % at epoch 50	1.4	1	0.7

TABLE II. PERFORMANCE COMPARISON WITH PROPOSED METHOD TO OTHER METHODS

Method	**Vehicle class considere d**	**Accuracy**	**Precision**	**Recall**	**F1 Score**
F-RCNN (8)	Bike , Bus and Truck	94.4	88.6	93.5	88
YOLO (7)	Bus, Car, and Truck	99	Not applicable	Not applicable	Not applicable
CNN-Super learner (6)	Bus, Car, Truck, Pedestrian, and Bike	99	98	98	99
Propose d method	Bus, Car, Truck	99	99	99	99

VI. CONCLUSION

A frequent challenge in deep learning-based vehicle classification task is obtaining sufficient visual data for the experimentation. In this regard, a customized dataset for vehicle platoon management has been created combining open source repositories and employing image augmentation techniques. The customized dataset has resulted in an imbalanced dataset consisting of 8000 car images, 5000 bus images, and 5000 truck images. The analyses carried out showed that, the performance of classification algorithm with existing methods considering the imbalance dataset is inconsistent across all vehicle classes, lowering the overall performance of the classification task. Whereas, the proposed novel mixed pooling method with three-layer CNN architecture performs significantly well even for the imbalanced dataset. This also highlights the importance of pooling in CNN. Additionally, the selection of the optimal pooling mechanism plays crucial role in optimising the efficiency of the learning algorithm in a CNN architecture. Employing the proposed method, experimental results show that the suggested strategy outperforms the traditional max and mixed pooling approaches by 2% and 8%, respectively for the imbalanced bus and truck datasets. From the accuracy gained using the proposed method, it is evident that selecting the optimal pooling mechanism is crucial for boosting the performance of CNN architecture. Thus, proposed mixed pooling method outperformed other methods on the imbalance dataset. Further research will focus on the performance of the proposed mixed pooling technique with additional CNN layers and a larger number of epochs.

Framework to Develop a Resilient and Sustainable Integrated Information System for Health Care Applications: A Review

Ayogeboh Epizitone
ICT and Society Research Group,
Information and Corporate Management, Durban University of Technology, Durban, South Africa

***Abstract*—The reconstruction of the health sector amidst the forth industrial revolution has been confronted with many challenges. Many benefits have been attributed to the vital role played by technology in realizing and constructing a robust health information system. However, amidst the digitalization in the healthcare system, several challenges such as integration and fragmentation have been affecting the structure of the Health Information Systems (HIS) which subsequently influences decision making and resource allocation. Therefore, this paper through a comprehensive systematic review afford a proposition for a develop a resilient and sustainable information system for Health Care applications. The study reveals the parallel impact of health information technology application in the healthcare arena and highlight the need for more in-depth research on HIS that incorporate novel scientific methods. Additional this study also presents a body of evident that reveal the inadequacies of the HIS to tackle the constant transformative changes presently confronting the global healthcare systems.**

***Keywords*—Health information system; integrated information system; e-health; bioinformatics**

I. Introduction

Over the last decades there have been remarkable advancements in medical informatics with the development of the health information systems (HIS) championing this course [1, 2]. This has benefited the continuous changing societies in the attainment of sustainable health care as well as efficient and effective information management. An increase in life expectancy and resource allocation are among some of the known attributes foster by this progress. The current HIS developmental path has been gearing toward a global information system to cater for a universal health coverage and civil registration and vital statistics [3]. However, despite the unique contribution of the HIS in shaping health care systems and applications, there are still many current challenges associated with the implementation of the HIS.

Theoretically, the HIS is commended as a system that plays an important role in the integration of different departments as well as support information flow [4]. Practically these systems are considered to be asymmetrical, resulting to distorted functions within the health care environment [3]. Highlighting the need for efficient development and strategic management of HIS. However, despite the strong influence exerted by Information and Communication Technology (ICT) in the realizations of the diverse health care goals [5]. Previous research on information systems has been reported to be short of due diligence in tackling the global healthcare systems transformation [6]. Hence, the need for study that employ novel scientific approaches such as an integrated data science approach and machine learning techniques is indispensable and essential for development of a framework that enhance the current HIS, as well as providing practical findings to realigns the healthcare global transformation.

Over that last decades, information technology (IT) has presented several opportunities as well as equal challenges to many disciplines. In fact, within the healthcare arena, IT through the HISs has facilitated many benefits and transformations such as eHealth [6] and apt decision making that has attracted many nations to invest and assimilate these systems [2, 6, 7]. However, amidst this digitalization in the healthcare arena, there have been several challenges presented such as integration, data quality and the structure of the HIS [3, 6, 8, 9]. Authors also highlight the lack of concerns on the transformative changes in the Healthcare industries and the need for a strengthened HIS [3, 5-7]. Therefore, studies that tackles these problems are vital and necessary for the strengthening of a nations' HIS. This paper seeks to explore extant literature base on HIS to ascertain the knowledge, constraints and perceptions on Health Information Systems deliverables, and afford a proposition for resilient and sustainable HIS.

II. Literature Review

The contributions of an integrated information system in the healthcare arena have been alluded in literature with several authors attesting to the value creation it brings to the field [6, 8, 10-12]. According to English, Masilela, Barron and Schonfeldt [4] a robust integrated information system is pivotal to an efficacious healthcare delivery. Many attributes have been accorded to the successful deployment of HIS especially in the current times [5, 6, 8, 13]. However, there are many persistent challenges revolving around the technological and institutional scopes [2, 4-7, 13, 14].

Research on HIS is considered to be of great importance due to the role it plays in realizing the two urgent priorities of globally health; universal health coverage, and civil registration and vital statistics systems [3, 15, 16]. Similarly, HIS's research is also asserted to be pivotal in supporting the attainment of sustainable development goals by 2030 [1, 3, 5, 17]. However, despite this disposition, a large amount of research done on HIS recurrently highlight major shortcomings in prior studies, in meeting the developmental and anticipated transformation confronting the complex healthcare system [3, 6, 7]. Ostern, Perscheid, Reelitz and Moormann [6],criticize HIS research for focusing on trifling agenda such as, investment and failing to assimilate healthcare industries transformative concerns. Literature further reveal the unsatisfactory trepidations from scholars on addressing potential long lasting changes in the healthcare industries [6, 7].

Critical review of literature highlights the need for well-prepared HIS research to exploit it potentially to tackle healthcare systematic problems thoroughly. In order to afford diverse solutions apt for the healthcare industries and its many actors such as the healthcare providers, government and technology companies [6]. Lluch [11], alluded the need for further research for HIS optimal development and cost effective applications. Scholars, further indicated the deficiency of adequate HIS [5, 8]. Najimudeen, Aldheleai and Ubaidullah [8] identified the impeded widespread use of HIS to be attributed to implementation challenges such as lack of; basic facilities, experts, medical personals e-readiness and technical complexities. Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12], categories these challenges as operational basing them on the experiences of the actors in the healthcare. These authors call for more research to strengthen the HIS [4, 5, 12].

Literature also revealed many HIS research to be qualitative lacking empirical finding and scientific rigour [3, 5, 6]. Despite the growing data and advancement of ICTs in the health sector, Authors purported that there is a distinct dearth of macro analysis that elucidate impact [18]. Suresh and Singh [18], argued that impact data for ICTs in health development remain a grand challenge.

Many studies also reveal the challenges faced by developing countries implementing HIS [8, 18]. While many advances have been attained by developed nation, Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12] reveal the tussle in developing countries where several barriers hinder the development of HIS which resultantly influences decision making due to the chaotic and fragmented state of HIS [18, 19]. These authors allude the need for developing countries to pay attention to the local needs, priority, environment, infrastructure and capacity to harness technological solutions.

Additional, many studies have been conducted in developed countries like Australia, USA and Europe and practical solutions and framework for HIS have developed, implemented and adopted [18]. Whereas in developing countries there is a deficit in studies and solutions on HIS phenomena [12, 18]. Some studies have suggested that developing countries harbor many barriers to HIS development such as inadequate resources, lack of data ownership and feedback [12, 18, 19].

III. Methodology

The important of HIS has been herald in literature with the challenges hindering it implementation and optimization. The demand for a better understanding of the phenomena confronting HIS development, utilization and optimization is paramount to the effectiveness of these systems in the places where they are deployed. Couple with the necessities of the global priorities and sustainable goals for a global healthcare system. The need to comprehensive review extensive literature is paramount and a needed step in the attainment of a sustainable and resilient HIS. This study being qualitative in nature and aiming to uncover insight on HIS utilizes a comprehensive systematic review [14, 20]; adopting an abductive approach that ensue a systematic content analysis procedure on extant literature and studies of HIS research [20-23].

Preceding the review, search engines are utilized to perform search on online databases and websites using the keywords to retrieve the needed data for this study. For the purpose of adequately responding to the study objective to uncover insight that aid HIS sustainability and resilient, articles containing keywords and references to “Health Information System” AND “HIS” are analysis painstaking. Identification of these articles was done through an exhaustive literature search on prominent journals and database feature studies on HIS. Table I outlines some of the journals, databases and Keywords used.

IV. Discussion and Result

Literature reveal the urgent parallel need for global health information systems that afford valuable aid to effective decision making which is paramount in rendering effective healthcare applications [18, 24]. The review on health information system was conducted in line with prior methodology that explores extant literature extensively to ascertain current insight and knowledge of these systems.

A. ICT and HIS

Many facets of the HealthCare segment have been significantly impacted by ICT [18]. Making the value of an effective information system indispensable in today era. Literature attribute the difference between good and bad decision to be associated with the difference between life and death [18]. Authors posit the optimization of ICT capabilities in the healthcare arena can be realize via the fusion of primeval and novel technologies [18]. According to Suresh and Singh

[18], ICT serve as an irreplaceable mediator for community access to Healthcare and information. Highlighting the detrimental role of information in effective decision-making. Similarly, Najimudeen, Aldheleai and Ubaidullah [8], revere ICT mediation in facilitating access to medical care and information, branding its support within the healthcare sector as "healing at a distance". However, despite the involvement of ICT in improving healthcare, several authors have advocated for the redesigning of ICT within the healthcare arena [14, 25].

B. Benefits of ICT in HealthCare Delivery

The appraisal of integrated information systems like HIS has always been center on the growing numbers of implementation. However, many studies have recounted that increase implementations and adoptions does not equate success. Literature, places emphases on improvement, efficiencies and effectives of outcomes and methods directly concerns with healthcare as a true definition of success [18]. Suresh and Singh [18] reports the important of health information that serve as vehicle to track health needs, guide health programs design and implementation and quality assessment. A similar study by Najimudeen, Aldheleai and Ubaidullah [8] enumerate on the value of HIS in health care delivery. According to Najimudeen, Aldheleai and Ubaidullah [8], HIS has afforded tremendous opportunities that includes the plunging of medical errors, advancing of healthcare admin efficiency and medical information management.

C. Challenges in Health Information Systems

Despite the advancement and development of the ICT applications in the health sectors there exist several challenges. Some authors have attributed these challenges to be foster by issues such as connectivity, ICT literacy and lack of technological convergence [14, 18, 24]. According to Fusheini and Eyles [24] the effectiveness and efficiency of healthcare delivery is significantly affected by these challenges. Contemporary studies highlight the lack of incorporation of stakeholder and technological design flaw to be contributing to these challenges[14, 25]. A study by Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12], categorizes these challenges in themes that included human resources, data issues and infrastructure among many others. The Table II summarizes these challenges identified in the diverse studies.

Funding has been identified in several studies to be a critical challenge influencing the implementation and strengthening of HIS. Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12], contend that the effectiveness and optimization of HIS is hinder and influence by financial deficiencies. Fusheini and Eyles [24] added to this claim revealing the lack of ample resources to afford funding. Many authors highlighted the need for the inclusion of financial needs associated with HIS in the annual plans [12, 26].A similarly study by Bergum, Kusumasindra, Øren, Falch and Sahraoui [27] and Al-Nashy [28] support this assertion and emphasis on the need for a sustainable finance for HIS implementation. These authors indicate the vitality of stable and sufficient financial sources for HIS enactment. Implying the lack of acknowledgement and incorporation of funding for HIS, results to shortage of finances needed to address financial related needs associated with HIS function and implementation as they arise.

TABLE II. EXTANT HIS CHALLENGES

Challenges	**Cited Sources**
Finance (Funding Sources)	Manoj et al. 2013; Al-Nashy 2015; Bergum et al. 2015; Fusheini and Eyles 2016; Dehnavieh et al. 2019.
Communication Infrastructure	Dehnavieh et al. 2019; Najimudeen, Aldheleai and Ubaidullah 2021.
Data (completeness, ownership and security)	Kiberu et al. 2014; Karuri et al. 2014; Suresh and Singh 2014; Dehnavieh et al. 2019; Farnham et al. 2020.

Communication Infrastructure which comprises of ICTs' infrastructure for Internet, Mobile and Electricity's infrastructure has been in the center of Healthcare sector. These infrastructures are vital to the efficient and effective functioning of operations in the healthcare arena. However, several studies have reported communication infrastructure to be inapt [8, 12]. Authors argue that the inadequacies of supporting infrastructure are among the challenges disclosed by stakeholders [8]. Several studies highlight the internet connection restriction in many countries to be problematic to the utilization of HIS in many areas [12].

Data management has influence several aspects in the health sector and many decision-making has been reliance on quality and analysis of data [29]. However, there is an information usage deprivation for decision making in the healthcare arena [12, 30]. Even though information and data usage has been encouraged and developed in many countries, it still remains an enormous problem. According to Karuri, Waiganjo, Daniel and Manya [19], data management has significantly influence health decision-making and funding allocation [12, 18, 19]; indicating data management to be a significant determinant in the optimization and implementation for HIS. Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12] argue that all countries encounter data related problems with some experiencing data concerns more than the others.

Infrastructures are a formidable foundation in many HIS deployment. Literature reveals the challenges presented by infrastructures like political, cultural, social and structural to the implementation of HIS to be daunting. These infrastructures are considered to serve as a major challenge to HIS with many citations in literature [12, 24]. Hence, some authors recon they be ascertained forthright in relation to the HIS efficacy [12, 18]. Suresh and Singh [18] indicate their availability and adequacy to be paramount to HIS. Whilst, Dehnavieh, Haghdoost, Khosravi, Hoseinabadi, Rahimi, Poursheikhali, Khajehpour, Khajeh, Mirshekari and Hasani [12], further reveal several challenges such as political instability, linguistic, regional cooperation and technical-economic associated with these infrastructures that indirectly or directly influence HIS operation. Additionally, Fusheini and Eyles [24] reveal the adverse outcome of this constraint on healthcare delivery.

Workforce capacity are also among the principal challenges face by the HIS implementation and optimization. Many study reveal the efficacy of HIS to be reliance on the human competency and capacity of staff [19, 31]. However, many studies allude workforce shortage, incompetency, accuracy and motivation as dares confronting HIS efficacy [12, 19, 26].

Top Management and leadership has been herald in many information systems to be a dare that hinder the effectiveness and efficacies of these systems. Likewise, in the HIS, several top management and leadership functions have been reported to be vital in the operation of HIS. Among which are planning, participation, perception and support that are alleged to be inadequate [12, 26]. Authors highlight the need to win top management from all level that includes, national and provincial levels for HIS implementation [19, 26]. Similarly, Adaletey, Poppe and Braa [32] and Manya, Braa, Øverland, Titlestad, Mumo and Nzioka [33] cheer the attainment of these key stakeholders involvement in HIS deployment. Many other studies call for the restructuring of management role and early formation of team [12, 19, 34, 35].

Deficiency of Training has been professed in literature to significantly reduce the HIS optimization [12, 19, 26, 34, 35]. Many studies call for the need to provide training to stakeholders, highlighting their lack of skills and competencies to be attributed to the absence of adequate trainings [10, 12, 19, 26, 28, 31, 32]. Study done by Manya and Nielsen [34] and [26], accentuate the need for training methods that include workshops and formal educational courses that incorporate biomedical informatics course.

Other challenges found in literature include project management, application selection criteria, stakeholder communication and coordination and pre-deployment (Pilot System) [12, 26, 35]. Their inadequacy serves as a major barrier to HIS implementation and efficacy.

V. Conclusion and Future Research

The importance of HIS and it capabilities in the delivery and deployment of quality healthcare application cannot be understated. As the call for an improve and universal healthcare advances, it is pertinent to explore and develop effective models to attain these objectives. Although many developing countries have already enacted technological solutions to enhance their healthcare section. The findings of this study show that there exists a strong body of evidence in literature that highlight the unfitness of the HIS for the transformative changes confronting the globe today. Correspondingly, several studies reveal the need for a strong and hybrid HIS to eliminate some of the present challenges confronting the deployment of an integrated information system like the District HIS (DHIS).

Notwithstanding the commendable benefits of the HIS, the findings reveal there is a need and call for active engagements of countries to strengthening these systems in alignment with the global priorities. While many studies have been undertaken in regards to HIS, the plethora of challenges confronting its implementations and utilization seem to remain a grand huddle in the advancement of healthcare applications. Eleven of these challenges was reported in this study with seven most prominent discussed. The challenges reveal the inadequacies of the HIS to tackle the constant transformative changes presently confronting the global healthcare systems.

Additionally, the findings of this study highlights the necessity for further research on HIS deployment optimization that take into consideration their challenges and concerns. And also, provide valuable insight into HIS offerings and dares for decision maker and HIS stakeholders.

Acknowledgment

The author would like to thank the Durban University of Technology writing retreat committee for their support and assistance.

TEC Forecasting using Optimized Variational Mode Decomposition and Elman Neural Networks

Maladh Mahmood Shakir, Zalinda Othman, Azuraliza Abu Bakar
Faculty of Information Science and Technology
University Kebangsaan Malaysia
Bangi, Selangor, Malaysia

***Abstract*—Forecasting the ionosphere layer's total electronic content (TEC) is crucial for its impact on satellite signals and global positioning systems (GPS) and the ability to predict earthquakes. The existing statistical-based forecasting models such as ARMA, ARIMA, and HW suffered from the TEC non-stationarity nature, which requires algorithmic handling of the forecasting and the mathematical part. This study proposes a hybrid method that incorporates several components and is designated as Optimized Variational Mode Decomposition with Recursive Neural Network Forecasting (OVMD-RNN) to forecast TEC. Before using the Elman Network to train each component, Variational Mode Decomposition (VMD) was used to decompose the signal into its essential stationary components. In addition, the proposed method includes an optimization algorithm for determining the best VMD decomposer parameters. The GPS Ionospheric Scintillation and TEC Monitor (GISTM) at Universiti Kebangsaan Malaysia station have been used to evaluate the method based on collected datasets for three years, 2011, 2012, and 2013. The experiment findings show that the model has successfully tracked all the up and down patterns in the time series. The results also reveal that VMD-based training might not always provide good results due to the residual signal. Finally, the evaluation focused on generating loss value and comparing it to the ARIMA benchmark. It showed that OVMD-RNN had accomplished a maximum improvement percentage of ARIMA with a value of (99%).**

***Keywords*—Elman neural networks; forecast; hybrid model; optimized Variational Mode Decomposition; total electronic content**

I. Introduction

The global navigation satellite system (GNSS) has become a critical system for providing a wide range of services and applications in the modern world. As a result, its dependability and performance are critical for various systems. The state of the ionosphere and its amount of influence by solar radiation and the geomagnetic field is one of the factors that affect GNSS radio communication transmissions [1].

Researchers utilise a quantitative metric to explain the effect of solar radiation on the total electron content (TEC) of the ionosphere layer. This variable represents the variability of solar radiation's impacts on the ionosphere layer, as well as it's geographically and temporally represented global positioning system (GPS) coordinates and time information. A dependable and accurate TEC forecasting can provide useful feedback to GPS receivers and improve numerous GPS-dependent services. Scientists created the International Reference Ionosphere (IRI) project to anticipate electron density, ion composition, electron and ion temperature, and vertical electron column density due to the relevance of ionosphere prediction. As a result, IRI is a collaborative international initiative of the Committee on Space Research (COSPAR) and the International Union of Radio-science (URSI) to build and refine a reference model for the Earth ionosphere's most critical plasma properties [2].

The main goal of majoring in TEC is to foresee any delays in GPS or communication signals in general, which could impair the operation of numerous devices. Earthquake forecasting is another application of measuring and evaluating TEC. Studies have shown that the ionosphere is influenced by the Sun's position and radiation and geomagnetic activity, and seismic activity in the Earth's crust and surface. These impacts can aid in predicting an earthquake several days ahead of time [3].

The challenging aspect of TEC prediction is its non-stationarity nature. This has brought a limitation to the existing studies that uses statistical-based forecasting models such as ARMA, ARIMA, and HW [4]. Hence, researchers have tested the capability of neural networks in the general and recursive types of neural networks [5]. The latter is more preferred because of its feedback or memory aspect, which enables more flexibility in modelling the dynamics of the time series. However, RNN is not sufficient because of embedded non-stationarity in the time series, which requires algorithmic handling of the forecasting in addition to the mathematical part. VMD decomposition is a possible candidate for decomposing the original time series into various stationary components [6], However, it is still encountering an issue in deciding the optimal number of intrinsic mode components for better forecasting performance and obtaining optimal VMD components before forecasting is needed. Hybrid architecture is a good candidate approach through combining RNN with optimal VMD settings. With such a hybrid combination, the VMD will decompose the original time series into stationary components that are easier to be learned by the following RNN layer.

The current forecasting models suffered from the TEC non-stationarity nature. This study describes a new method for forecasting the TEC time series that combines three components: decomposing the original signal to its stationary components using Variational Mode Decomposition (VMD), parameter optimization using Genetic Algorithm (GA), and forecasting using the Elman Neural Network, a well-known Recurrent Neural Network (Elman NN).

In the next Section II, related works on TEC forecasting and current approaches have been presented. In Section III, the proposed method has been described, i.e., OVMD-RNN and the methodology flow. The experimental works have been presented in Section IV as well as the results, whereas Section V gives conclusions.

II. Related Work

TEC forecasting increases the knowledge of ionosphere space weather to give accurate warning and mitigation of TEC impacts. Due to the time-series nature of TEC forecasting, researchers prefer traditional time series forecasting models such as Auto Regression Moving Average (ARMA) and its derivatives [7]. The VMD-ARMA (VARMA) model is described in [8] as a non-stationary signal decomposition technique based on Variational Mode Decomposition (VMD) paired with Auto Regressive Moving Average (ARMA) to estimate ionosphere delay values 1-hour ahead.

However, despite their large training requirements, some researchers have favoured non-linear models with a high approximation, such as Artificial Neural Networks (ANN) [9]. The TEC signal’s non-linear nature is one of the factors driving the researchers' interest in employing ANN models for TEC forecasting. [10] is one of the first researchers to use ANN for TEC forecasting, further aided by [11]. According to them, the capacity to use ANN to predict TEC in places where appropriate training data was absent has been demonstrated empirically. [11] used ANN with a single hidden layer in addition to input and output layers, as described by the 6:9:1 configuration.

According to the newest research, a single hidden layer is sufficient, and adding more layers necessitates more training without increasing accuracy. However, studies have shown that ANN does not outperform basic linear models like ARMA and Auto Regressive Integrated Moving Average (ARIMA) [1], which is essentially ARMA plus an integration component. Both ARMA and ARIMA have outperformed the IRI global reference model. ARMA's and ARIMA's superiority Holt-Winter models, which add a component for seasonable effect, were also seen compared to the global IRI model [12, 13]. Several scholars have made a comparison of ARIMA with ANN. Based on mean absolute error (MAE) and root mean square error (RMSE) values, the performance of the ARMA and ANN models are validated on both geomagnetic quiet and disturbed days [14]. For the ARMA and ANN models, forecasting errors are higher on geomagnetically disturbed days; when tested using MAE and RMSE, ANN outperformed ARMA. Hybrid models of ARMA and ARIMA were used in other investigations. For 1-hour ahead forecast of ionosphere TEC, [12] used hybrid ARIMA models based on Wavelet Transform (WT) and Empirical Mode Decomposition (EMD).

A hybrid GA and ANN model was suggested by [15] to forecast 1-hour vertical TEC for one station in China. The Backpropagation Neural Network (BP) and the GA approach train parameters in a two-step process. GA tunes the weights and biases of the original neural network in the first stage. Model's weights and biases are recorded as a lengthy chromosome. The fitness function expressed as a prediction error is used to evaluate each chromosome's performance in the population. A Wavelet Neural Network (WNN) is utilised to model the ionosphere time series in Iran by [16]. WNN is a hybrid of wavelet theory and neural network theory. One of the advantages of TEC modelling with WNN is its ease of use and speed of computation.

More recent studies have used machine learning algorithms for GPS TEC forecasting. The performance of a Gaussian kernel-based machine learning algorithm was compared to that of ANN and ARMA in [1]. The outcomes of their work have demonstrated dominance over them.

the authors in [17] employed a hybrid model in which the TEC time series was divided into its stationary components using VMD. Then a kernel extreme learning machine was used to anticipate the data. Kernel extreme learning machines were compared to ANN in this study, and the results show that the former is superior in forecasting accuracy. The idea of combining VMD with neural networks can be found in older time series forecasting research. Integration of VMD and generic regression neural networks is the focus of [17].

Another example is [18], who used VMD in conjunction with an extreme learning machine to model the Monthly Precipitation Time Series. Overall, researchers have attempted to forecast TEC time series in various locations for accomplishing needed actions such as handling delays of satellite signals GPS and forecasting earthquakes.

III. Proposed method

This study proposes a time series forecasting model using a VMD, and ENN hybrid architecture called an Optimized Variational Mode Decomposition with Elman Recursive Neural Network Forecasting (OVMD-RNN). It contains the following contributions.

- It develops a framework for TEC forecasting based on decomposition, optimization and ENN.
- It provides GA for finding the optimal IMF components K and the correlation coefficients α for VMD.
- It integrates the developed OVMD by GA with ENN for forecasting the TEC.
- It evaluates the hybrid framework based on our data and compares it with recent models in the literature.

A. Preliminary

1) Variational mode decomposition: The application of VMD is the initial step in the approach. The purpose of VMD is to decompose the TEC signal into bandwidth-limited components of varying frequencies. The decomposition helps eliminate the signal's random behavior and makes it more forecastable. Before VMD, researchers discovered various decomposition techniques, including Fourier transforms, wavelet transforms, and EMD [19]. However, research has shown that VMD outperforms EMD.

In the VMD algorithm [20], the real-valued input signal is viewed as an ensemble of sub-signals (modes) with a narrow band of frequencies around a few light frequencies. The VMD algorithm is represented as a variational problem with constraints:

$$\min_{\{u_k\},\{w_k\}} \left\{\sum_k \left\|\partial t\left[\left(\delta(t)+\frac{j}{\pi t}\right)*u_k(t)\right]e^{-jw_kt}\right\|_2^2\right\} \quad (1)$$

$$\text{s.t } \sum_k u_k = f$$

where, u_k denotes variational model components, and w_k are the corresponding centres of each variation model component.

The optimization is solved using Lagrangian multiplier λ and quadratic penalty α as follows;

$$L(u_k,\omega_k,\lambda) =$$

$$\alpha\sum_k \left\|\partial_t\left[\left(\left(\delta(t)+\frac{j}{\pi t}\right)*u_k(t)\right)*e^{-j\omega t}\right]\right\|_2^2 \quad (2)$$

$$+\|f-\sum_k u_k\|_2^2+\langle\lambda, f-\sum_k u_k\rangle$$

The augmented Lagrangian equation is then solved using the algorithm of alternate direction multipliers [20].

The values of the number of components K and penalty α play a significant role in VMD decomposition performance [21]. Specifically, a large value of K indicates interferential decomposition, whereas a small value indicates incomplete decomposition. As a result, the best values for K and α must be determined. Therefore. The problem formulation is being reformulated as follows.

Assume y(t) represents a TEC time series. The goal of this study is to predict its value for the future time horizon, Tf. Because of its non-stationary aspect, first, it must be decomposed using the type VMD procedure before forecasting. The result of the decomposition is K modes that are expressed as follows:

$$\sum_{k=1}^{K} u_k(t) = \hat{y} \quad (3)$$

The decomposition's objective function is formulated to maximizes the correlation between intrinsic components Corr such as.

$$Corr = \frac{Cov(y(t),\hat{y}\,(\mathrm{t}))}{\sigma(y(t))\sigma(\hat{y}(t))} \quad (4)$$

$$\begin{cases} [K,\alpha]^* = \\ argmin(1-Corr) = argmin(1-\frac{Cov(y(t),\hat{y}\,(\mathrm{t}))}{\sigma(y(t))\sigma(\hat{y}(t))}) \end{cases} \quad (5)$$

2) Genetic algorithm: A genetic algorithm (GA) is a stochastic searching algorithm with heuristic knowledge. It provides a way to find the optimal value of an objective function based on random generating of candidate solutions, heuristic interaction between them, and selecting elites from one generation to provide the offspring representing the next generation until convergence or meeting the stopping criterion [22]. GA is inspired by the theory of survival of the fittest that was proposed by Darwin [23]. The GA pseudocode is given in Algorithm 1.

Algorithm 1 GA Optimization

```
Input
    S //number of solutions in generation
    N//number of generations
    Objective function
Output
    Best solution
Start
1-  Initiate first population
2-  Current generation =first population
3-  Evaluate current generation
4-  Select elites (using roulette wheel)
1-  Perform crossover ((using uniform crossover) and mutation
    (using probability)
2-  Combine solutions
3-  if not meeting stopping criterion go to 3
4-  best solution =solution of best fitness value of the last
    generation
End
```

GA was employed to optimize the objective function of the decomposition Equation 5, and the two variables K and α represent the chromosome. Algorithm 1 shows the steps of GA to obtain the best K and α values. The first step consists of randomly generating the initial population in this work. The population is evaluated based on the objective function stated in Equation 5. Then, a roulette wheel selection mechanism is applied to select the parent that will undergo the crossover operation, used within a specific probability.

Similarly, the mutation operator is performed on the new solution within a pre-defined probability to maintain the diversity of the population. After that, the produced population will replace the worst solutions of the previous generation. These steps are repeated till meeting the stopping criterion. Finally, GA will return the best solution (i.e., best K and α values).

3) The Elman neural network: An Artificial Neural Network, or ANN, is a massively parallel distributed processing system made up of densely interconnected neural computing parts that can learn, gain knowledge and make it available for use. ANN architecture is defined by the network of neuron connections, the training or learning mechanism for calculating the connection weights, and the activation function.

Even though the Multilayer Perceptron neural network (MLP) can solve a wide range of complex issues, it can only map the input space to the output space in a static way. Elman Neural Network (ENN) [24] is a simple recurrent neural network with dynamic characteristics. The structure of Elman RNN is identical to a three-layered MLP, except for an additional layer called a context layer, which is engaged in the former. In Elman RNN, the hidden neurons are activated by both the input and context neurons. The hidden neurons feed forward to activate the output neurons while also feeding back to activate the context neurons. As a result, the context layer allows ENN to respond to dynamism.

The ENN is trained using the BP algorithm, as shown in Equation 6 [25].

$$W(t+1) = W(t) - \mu\frac{\partial E(t)}{\partial W(t)} \quad (6)$$

where, μ denotes the learning rate.

A conceptual diagram of Elman RNN is presented in Fig. 1.

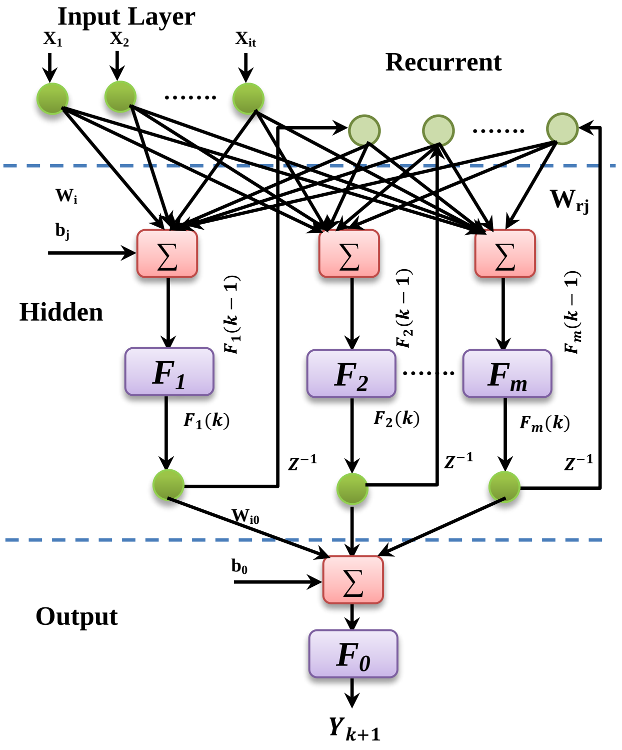

Fig. 1. The Structure of ENN [26].

B. Methodology Flow

As shown in Fig. 2, the developed methodology of the forecasting method consists of three phases after pre-processing: 1- Optimized VMD Decomposition, 2 - Elman RNN training, and 3 - forecasting. The phases are conceptual, but practically they have an interconnected nature. The optimization requires calculating the loss function to rank candidate solutions. On the other hand, the optimal evaluation setting is used for the VMD decomposition. Next, the result is used for ENN training and the trained ENN is used for forecasting.

1) Phase 1: Optimized VMD Decomposition: As is presented in Fig. 2, in the first phase, the data is entered into the optimized VMD decomposer, which is responsible for dividing the time series into various IMF components with the assistance of a genetic algorithm that optimizes K and α values.

2) Phase 2: ENN Training: After decomposing the TEC time series into its IMF components in the first phase, the IMF passed to the recursive neural networks (ENN) to train the ENN model. The training phase comprises of two parts: the first part is the backward path that takes an existing neural network topology and calculates weight changes based on the gradient of the error. The second part is the forward path that uses current weights to propagate.

3) Phase 3 Forecasting: Once the ENN is trained, the testing phase (forecasting) is used. It uses the optimized VMD and trained ENN for forecasting the IMFs and after that a summation of the forecasted time series is used to forecast the overall time series. Such an evaluation includes providing the discrepancies between the predicted values and the actual values.

C. Training and Testing Flow

The interaction between the training phase and the testing phase is given in Fig. 3. As it is shown in the figure, the data comes as s stream, and it is partitioned into two parts: the historical part w_h and the future part w_f. The data in w_h was used for training, while the data in w_f was for performance evaluation. For the testing, the predicted value was compared with the original value stored in w_f and used to calculate testing errors.

D. Data pre-processing and partitioning

Pre-processing comprises data visualization and determining whether missing records exist. In the case of missing records, an average window over multiple days is used to replace the missing value in one day. After that, the data were partitioned. The purpose is to divide the data into training and testing data. The training data will come from the past, whereas the testing will occur in the future, forecasting time intervals. The signal and the duration of the time window are inputs. The output is a matrix consisting of training and testing data. The data will be passed through the time window, and samples will be added. The final sample is a prediction based on these samples. Following data collection, the data is divided into two categories: training and testing.

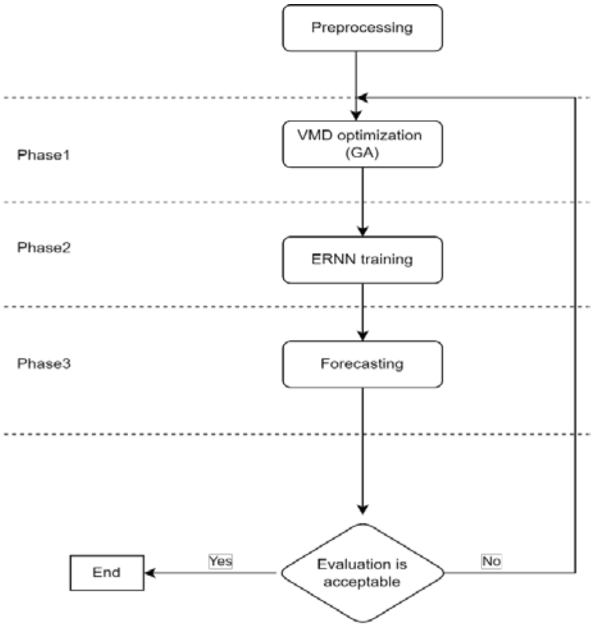

Fig. 2. A General Methodology Flowchart in TEC Forecasting.

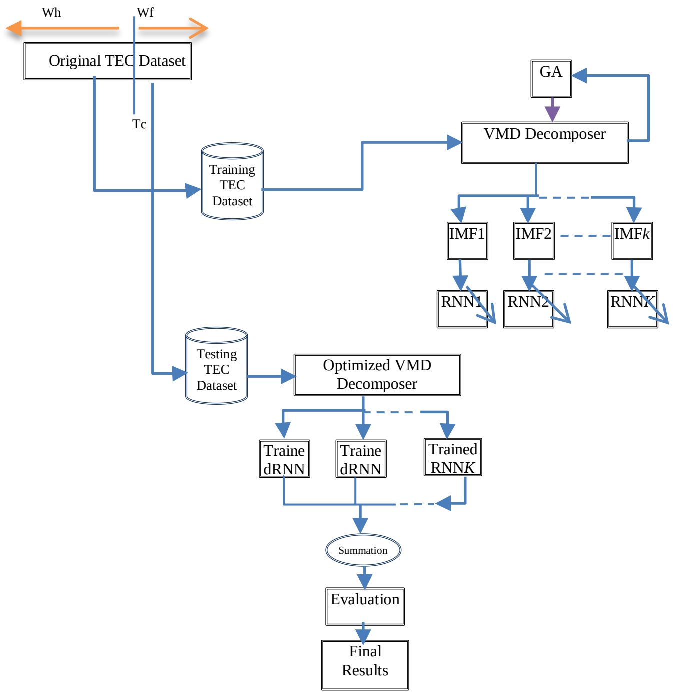

Fig. 3. Training and Testing Phases of TEC Forecasting.

E. Data Description

Data are recorded by the GPS Ionosphere Scintillation and TEC Monitor (GISTM) with a dual-frequency receiver GSV4004B at UKM station, geographic coordinate: 2.55 °N, 101.46 °E. At the L1 (1575.42 MHz) and L2 (1227.6 MHz) frequency bands, the GSV4004B receiver can track up to 11 GPS satellites. Amplitude and phase are monitored at 50 Hz, while code/carrier divergence (C/No) is sampled at 1 Hz for each satellite. The GPS Ionospheric Scintillation and TEC Monitor (GISTM) shows ionospheric delay over Universiti Kebangsaan Malaysia (UKM) station from 2011 to 2013.

F. Parameter Setting

GA optimization has been employed to find the best values of K and α. Considering that the optimization process consumes considerable computational time, only a few numbers of individuals were permitted to participate. For GA, the number of iterations is set to 6, the number of individuals to 5, the searching range for K between 2 and 16, and the searching range for α between 1,000 and 10,000 for GA optimization. The parameters are shown in Table I.

The proposed method has also been compared to ARIMA using the parameters mentioned in Table II. The observation's lag time is set to 30, the degree of difference is set to 2, and the moving window size is set to 15.

TABLE I. PARAMETER SETTING FOR GA

Dataset	No. of iterations	Crossover prob.	Mutation prob.	***K***	***α***
2011-2012	6	0.5	0.3	[2,16]	[1000,10000]
2013	10	0.5	0.3	[2,16]	[1000,10000]

TABLE II. ARIMA PARAMETER SETTINGS

Parameter name	**Value**
Number of lag observations (p)	30
Degree of differencing (d)	2
Moving average window size	15

For ENN, the number of epochs was set to 6 and 10 for 2011 & 2012 and 2013, respectively. The number of neurons in the first layer was set to 60; the second layer was set to 30. The time window lag was set to 30. The parameter settings are shown in Table III.

TABLE III. ELMAN RNN PARAMETER SETTINGS

Parameter name	**2011 &2012**	**2013**
Number of epochs	6	10
Neurons present in the First layer	50	50
Neurons in the hidden layer	30	25
Time-window (time lag)	30	30

G. Performance Metrics

The evaluation is based on two measures:

The first one is the mean squared error (MSE) which is given to evaluate the prediction of one time series, and is given by Equation 7.

$$MSE = \frac{1}{n}\sum_{t=1}^{n}(Y_t - F_t)^2 \qquad (7)$$

where, Y_t denotes the ground truth value of the time series at moment t, and F_t denotes the predicted value of the time series.

The second metric is the improvement percentage from one model to another, and it is used to evaluate the relative improvement of proposed model over the benchmark as shown in Equation 8.

$$Percentage = \left|\frac{MSE_{Our} - MSE_{RMSE}}{MSE_{RMSE}}\right| \qquad (8)$$

IV. EXPERIMENTAL RESULTS AND ANALYSIS

This section presents the obtained results from the experiments conducted in this study and analysis the results of the developed OVMD-RNN and its comparison with the benchmark ARIMA.

For the 2011 and 2012 datasets, 21 months were used for training and the remaining three months for testing. Fig. 4 depicts the original TEC time series for 2011 and 2012 before applying the proposed model, and the non-stationarity (the frequency varies over time) can be seen. Fig. 5 shows the testing data's TEC time series for three consecutive months.

For further evaluation, the proposed model has been tested on another dataset for the year 2013. Fig. 6 depicts the original TEC time series for 2013 before applying the proposed model. Fig. 7 is the TEC time series for two consecutive months for the testing data.

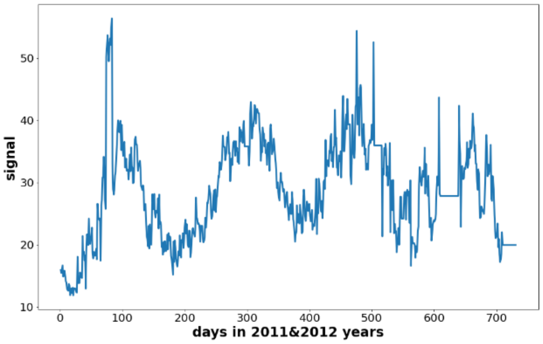

Fig. 4. TEC for 2011 and 2012 Dataset.

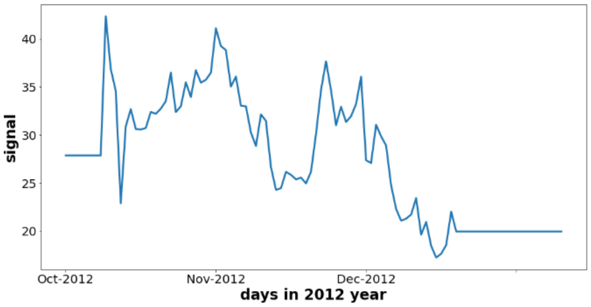

Fig. 5. TEC Time Series for Three Consecutive Months for Testing Data.

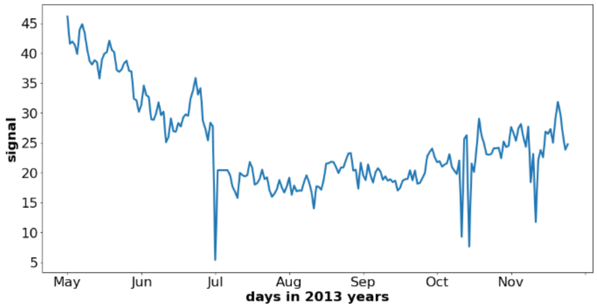

Fig. 6. TEC for 2013 Dataset.

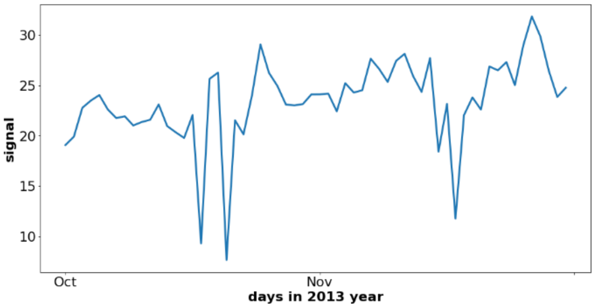

Fig. 7. TEC Time Series for Two Consecutive Months for Testing Data.

A. VMD Decomposition

1) K=5: Firstly, the TEC time series for 2011-2012 has been decomposed into its components using VMD and analyzed into five IMFs, which representing the optimal number of K components obtained through GA optimization, as shown in Table IV. Fig. 8 shows K=5 components for the test TEC time series data part.

2) K=7: As shown in Fig. 9, the testing TEC time series for 2013 was decomposed into its components and analysed into seven IMFs representing the optimal number of K components obtained through GA optimization.

B. Forecasting

Fig. 10, for example, displayed the visualisation of mode 2 forecasting and their comparison to real values. The visualization of mode 4 forecasting and its comparison to real values are depicted in Fig. 11. The visualisation shows that the proposed model OVMD-RNN can follow all the up and down peaks in the original data.

TABLE IV. THE BEST K AND α VALUE BY THE GA

Best *K*	**Best α**	**Algorithm**
5	9948	GA

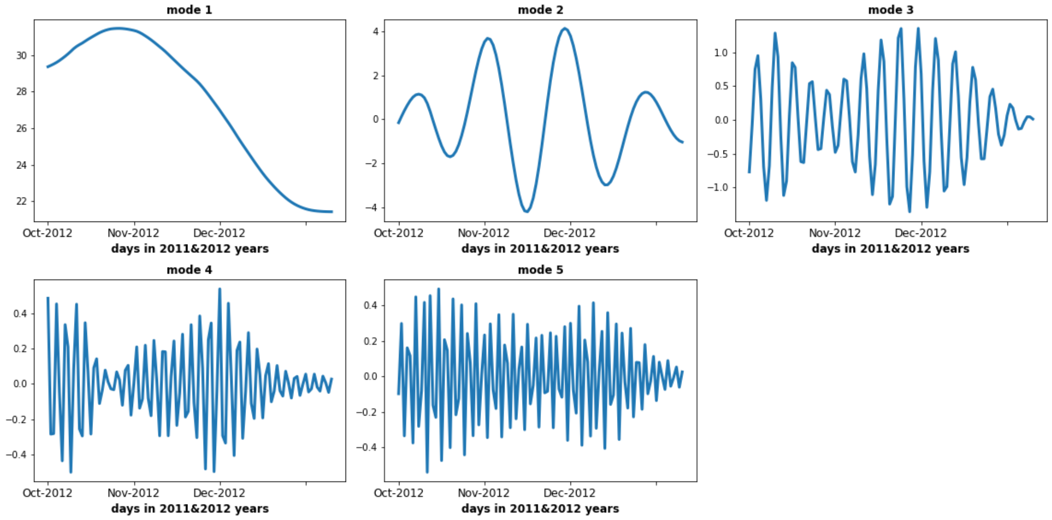

Fig. 8. VMD Decomposition for K=5 for Testing Data.

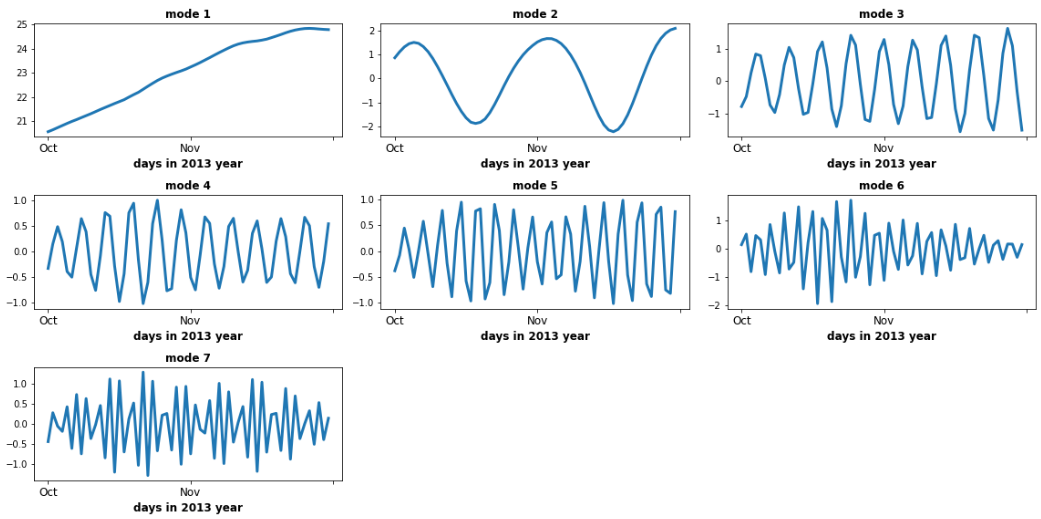

Fig. 9. VMD Decomposition for K=7 for Testing Data.

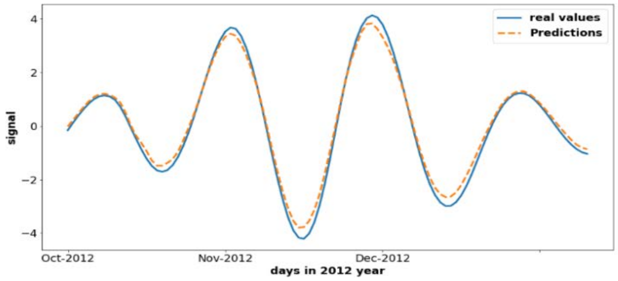

Fig. 10. Real Values Vs Prediction of VMD Mode 2.

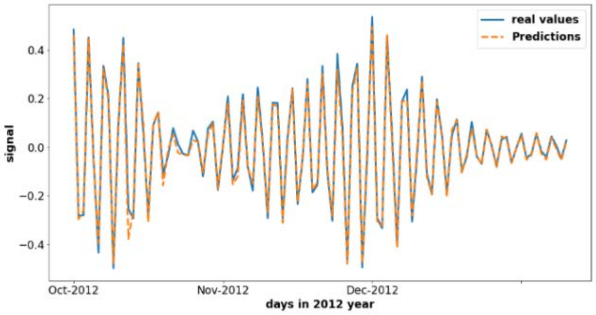

Fig. 11. Real Values Vs Prediction of VMD Mode 4.

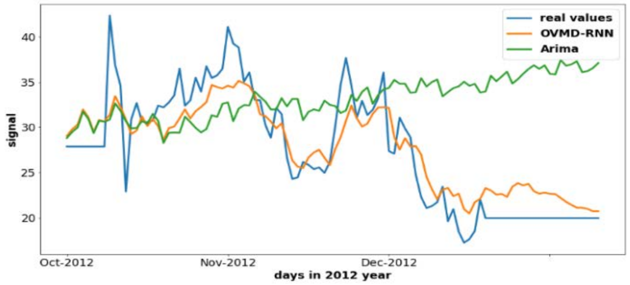

Fig. 12. A Comparison between Real Values, OVMD_RNN and ARIMA for K = 5.

The forecasting results have been presented in Fig. 12. It is observed from the figure that in the three models, the proposed model has provided better forecasting compared with ARIMA, which has shown a lack of capturing the trend and the pattern in the original time series. Furthermore, it has been discovered that the proposed model correctly predicted the four peaks in the original data, which show a level of 40 in October and November and a little lower level in late November and early December.

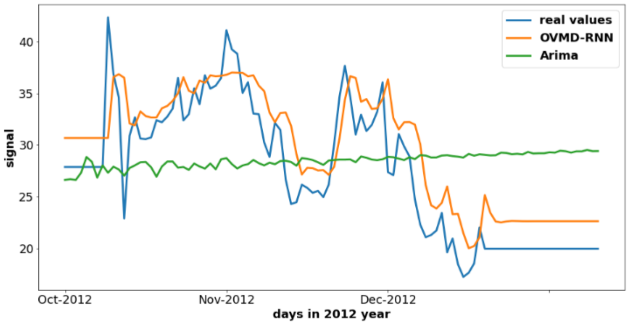

Fig. 13. A Comparison between Real Values, OVMD_RNN and ARIMA for K = 1 (without VMD).

Fig. 13 presented the forecasting results for the years 2011&2012 in the last three months. Without applying VMD (K=1), observing Fig. 12, 13, it is noticed that K=1 has better tracking than a higher loss at the training. VMD interprets it has caused the removal of an essential part of the signal, which has led to missing by the neural network while training for K= 5, when K=1, this has not been observed because this part was preserved when training by ENN. This provides that VMD based training might not always provide good results due to the residual signal that is deleted by this process.

For further evaluation, the forecasting behavior in the year 2013 is presented for the proposed model and its comparison with ARIMA.

As is shown in Fig. 14 and 15 increasing the value of K has enabled better prediction. Furthermore, the model has successfully tracked all the up and down patterns in the time series, ranging between 15 and 30.

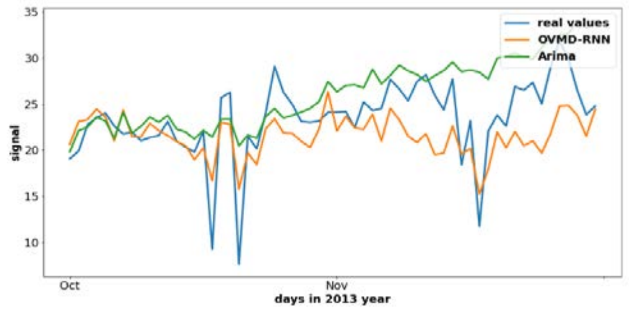

Fig. 14. A Comparison between Real Values, OVMD_RNN and ARIMA for K = 7.

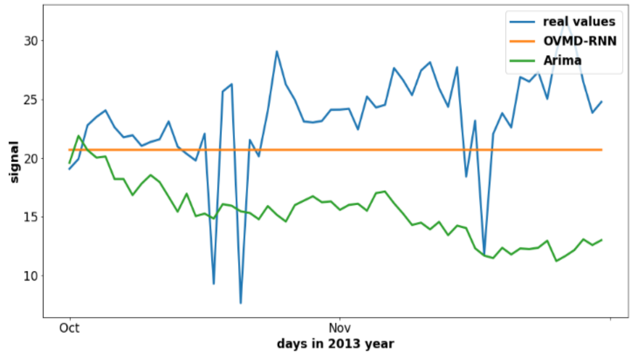

Fig. 15. A Comparison between 2013 Real Values, OVMD_RNN and ARIMA for K = 1 (without VMD) and K = 7.

Fig. 14 presented the forecasting results for the year 2013 in the last two months because the first months have been used for training. It is observed from the figure that the proposed model has provided better forecasting compared with ARMIA, which has shown a lack of capturing the trend and the pattern in the original time series. In addition, it is noticed that the proposed model has successfully forecasted all the up and down peaks in the original data, which appears with the level of 10 for October and at the end of November with the level of 35.

Fig. 15 presented the forecasting results for the year 2013 in the last two months. Without applying VMD (K=1), the model can't track the trend of the time series.

C. Evaluation

The evaluation was focused on creating the loss value and comparing it to the ARIMA benchmark.

1) Loss value: The loss value in the training phase is presented in Fig. 16, which shows that K=1 has the highest loss value than K=5, which is the value resulting from GA. In addition, for leading the optimality of GA.

Observing Fig. 13, it is noticed that K=1 has better tracking than a higher loss at the training. In K=5, the VMD process removed some important parts and caused some missing during Elman training. The result shows VMD-based training might not always provide good results due to the residual signal deleted by the process.

The loss value in the training phase is presented in Fig. 17 for the dataset 2011-2012, which proves the superiority of the proposed forecasting model when the value of K is selected optimally.

Regarding the loss value K=5, the proposed model has been compared to ARIMA, as shown in Fig. 17. The proposed approach has a smaller error or loss value than ARIMA. The results demonstrate that it is superior.

To summarize the performance, the overall loss value K =1 has been presented, which indicates VMD decomposition and K= 7, which suggests the result of GA.

In Fig. 14 and 15, it is observed that increasing the value of K from 1 to 7 has enabled a lower value of loss than ARIMA, which proves the superiority of the proposed forecasting model when the value of K is selected optimally.

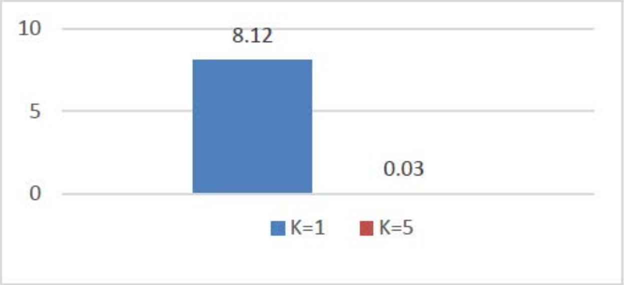

Fig. 16. The Loss Value of OVMD-RNN for When K =1, K=5.

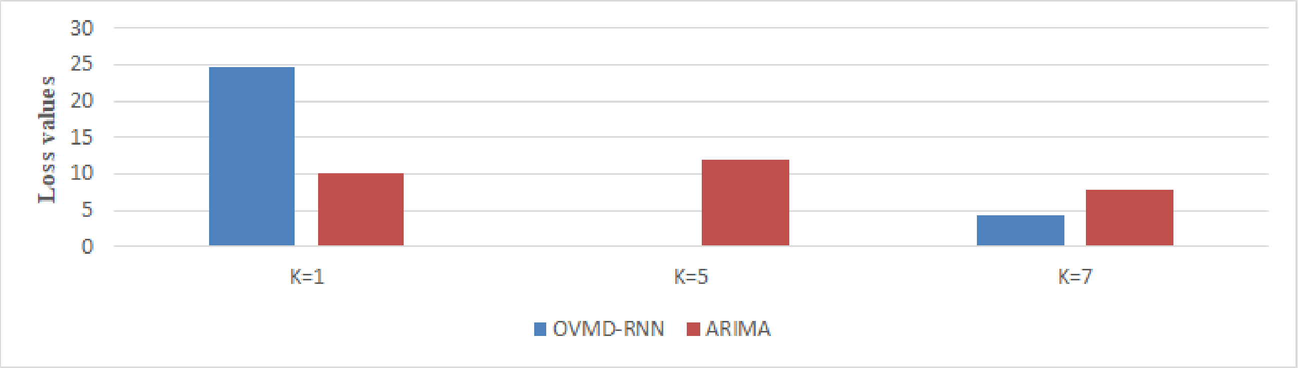

Fig. 17. The Loss Value of OVMD-RNN Vs ARIMA.

2) Accuracy: In terms of the loss value K = 5, OVMD-RNN has been compared to ARIMA, as shown in Fig. 12, Because proposed approach has a smaller error or loss value than ARIMA, the results demonstrate that it is superior. The improvement percentage is 99% as calculated based on Equation 9.

$$Percentage = \left|\frac{RNN-ARIMA}{ARIMA}\right| = \left|\frac{0.05-12.47}{12.47}\right| = 0.99 \qquad (1)$$

TABLE V. OVERALL PREDICTION COST FOR ARIMA AND OVMD-RNN BASED ON DIFFERENT YEARS AND VALUES OF K

	2011&2012		2013	
K	1	5	1	7
ARIMA	6.92	12.04	10.14	7.79
OVMD-RNN	8.12	0.03	24.72	4.29
Improvement percentage	0.17	99%	%143	%44

From Table V, K = 1 indicates that VMD has not been applied. So, the non-stationary time series were not divided into stationary components but were predicted directly using ENN and ARIMA. For K = 5 and K = 7, these values were obtained by implementing GA on both times series 2011-2012 and 2013, respectively, to find the best K value. These K values provide the lowest loss value.

D. Observations

From the results obtained, it has been observed that TEC is a non-stationary time series making it challenging to forecast. Moreover, VMD is a good candidate for decomposing TEC time series into stationary components. Still, sometimes VMD-based training might not always provide good results due to the residual signal.

The proposed model (OVMD-RNN) does not implement multi-time series collected from different areas to be generalized. Therefore, extending the model to accept multi-time series at one time will enable more accurate forecasting; this can be applied for future work.

V. SUMMARY AND CONCLUSION

This paper has created a novel forecasting approach for the TEC time series. VMD is used to split the original TEC time series into necessary stationary components, considering the non-stationarity of the data and the need to include non-linear knowledge for forecasting. Each essential TEC component was trained and forecasted using an Elman RNN. In addition, the method consists of an optimization algorithm for determining the best VMD decomposer parameters. The VMD parameters, K and α selection, utilized the GA optimization method. The GPS Ionospheric Scintillation and TEC Monitor (GISTM) with a dual-frequency receiver GSV4004B at the UKM station evaluated our obtained dataset for three years, 2011, 2012 and 2013. The evaluation was focused on creating the loss value and comparing it to the ARIMA benchmark. It showed that the proposed progressive technique with two decomposition values for K = 4 and 5 and a significant reduction of the loss value was superior. Future research will develop multi-dimensional TEC forecasting from multiple places within the same geographic region.

ACKNOWLEDGMENT

We like to thank the Data Mining and Optimization (DMO) Lab of Faculty of Information Science and Technology, Universiti Kebangsaan Malaysia (UKM), College of Science for Women, University of Babylon, Iraq for the expert's knowledge sharing, and the Space Science Centre (ANGKASA) UKM, for providing the data. Massive appreciation to UKM for providing grant GGP-2020-032 for funding this research and the Iraq Government for sponsoring the postgraduate study.

Assaying the Statistics of Crime Against Women in India using Provenance and Machine Learning Models

Geetika Bhardwaj, Dr. R. K. Bawa
Department of Computer Applications, Punjabi University, Patiala, India

Abstract—**Now-a-days, the surging of crime against women is occurring at a startling rate in India. According to the National Commission for Women, there was a 46% increase in reports of crimes against women in the initial months of the year 2021 in comparison with the same period in 2020. However, to handle this problem, the need of the hour is to fetch relevant and timely information about the various types of crime taking place and make specific predictions based on the existing information to safeguard women from future predictable contingencies. AI and Machine learning mechanisms have become a powerful tool in predicting the crime rate in India under various crime categories by analyzing the crime patterns, crime–centric areas, and the comparative study of various crime categories. Hence, from 2001 to 2019, a women's crime-based dataset from NCRB has been used in this paper, which included various crime sub-categories, for instance; molestation, sexual harassment, rape, kidnapping, dowry deaths, cruelty to family, importation of girls, immortal traffic, sati prevention act, and others. To acquire a better understanding of the data, a framework has been created which makes use of provenance and machine learning algorithms on the dataset, which has been grouped based on several factors such as distribution of cases convicted or reported every year, safest and un-safest states for women in India, etc. Different machine learning algorithms, such as gradient boosting and its many versions, Random forest, and many more, have been used on the dataset. Their performances are evaluated using various metrics such as accuracy, recall, precision, F1 score, and root mean error square.**

Keywords—Crime against women; provenance; scalar techniques; machine learning techniques; decision tree; random forest; gradient boosting; XgBoost; CatBoost; LightGBM

I. Introduction

The overall crime rate in India is increasing at a steady pace. Crime cannot be predicted as it is either efficient, coincidental, or goes unreported. Various modern advancements and hi-tech procedures enable criminals to carry out their crimes when it comes to cybercrime. As far as women's crimes are concerned, it has been seen that a girl can be a victim or target of a crime from the moment she is born or even before. According to crime statistics, authority violations against women, for example, chain grabbing, sex abuse, child abuse, assault, and murder, are rapidly increasing [1]. Hence, keeping that in view, the establishment of the gender equality principle was done in the Constitution of India, and to uphold and implement the Constitutional mandate, the state has created several laws as well as has taken various actions to guarantee equal rights, eradicate social injustice, and prohibit multiple forms of violence and massacres [2].

India's National Crime Records Bureau records various incidents showing that crime against women increased by 6.4%, and it occurs every three minutes [3]. The reports also revealed that in 2011 the number of reported crimes against females was more than 228,650. In the year 2015, reported incidents were more than 300,000. It can be deduced that there was a rise of 44% in felonies against the members of fair sex.7.5% of females residing in the state of West Bengal in India account for 12.7% of reported crimes against women [4]. The female population of Andhra Pradesh accounts for 7.3% of total India's women population, and 11.5% of all reported crimes against women were from this state. Hence to compile all the information, a graphical analysis has been shown in Fig. 1 to define the rate of women crimes in India in different states for 2018. It is also important to note that exact figures on the breadth of case occurrences are difficult to obtain because many cases go unreported. This is mainly due to the potential reporter's fear of scorn or embarrassment and tremendous pressure not to jeopardize the family's honor [5].

A crime investigation system should be able to rapidly and efficiently identify crime patterns to detect and act on future crime trends to work on such crimes. Various law enforcement agencies and state governments should take significant steps to reduce such crimes and promote a secure environment for women [6]. Multiple scholars have been working on detecting women-related crime worldwide in the field of research. Data Analytics and machine learning have contributed notably to detecting and preventing crime, providing a basis for crime analysis. They are also acknowledged as a relatively new and highly sought-after area of research. In reality, law enforcement agencies are seeking the support of data mining and AI techniques to help deter crime and ensure law enforcement. In a nutshell, data mining is a branch of the multidisciplinary subject of database knowledge discovery. The input in the process of Data mining is the unprocessed data, which is transformed into information that is used to produce precise projections and applied to real-life circumstances (through inference and analysis). Multiple techniques, such as scientific and statistical machine learning algorithms, have recently been used in the recognition of images and speech, detection of medical ailments, and classification [7] and are additionally designed to estimate crime rates for a particular year formed on statistical information of crime against females.

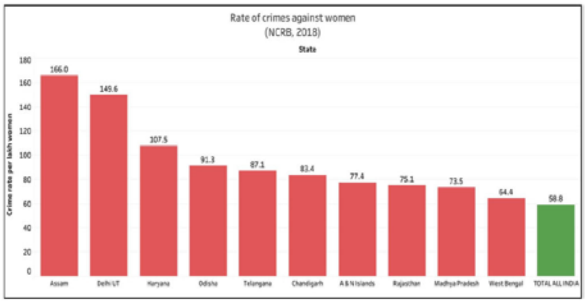

Fig. 1. Rate of Crimes against Women in the Year 2018.

In a nutshell, it can be said that studying the crime data helps us to solve criminal cases and is taken as a first step to prevent the1 crime via which we can reduce or deter criminals and their activities. But depending on raw data is utterly erroneous as it contains plenty of noise, incomplete or missing values, etc. to confuse the investigation team so that they cannot afford either forecast its future features or catch the culprit. Hence, to work on such destructed data, we want to create a decision-making system that can analyze the crime data, find the data uncertainty, and remove the errors.

The essential part and main motive behind this research work is data provenance which is a novelty and is used to train the system so that we can work on the uncertainty of the crime data against women. Provenance aids in getting into the origin of data and various transformations made on the data over time. Suppose the analysis is done based on data obtained from a particular source that no longer exists or is unavailable to us; in that case, the data provenance generated might be the guiding light to establish the uncertainty in the data.

Hence, the contribution of the research for analyzing the statistics of women-based crimes in India using crime data provenance is as follows:

1) The information is gathered from NCRB and Kaggle between 2001 to 2019, which is further pre-processed to remove NAN or missing values.

2) Later feature scaling techniques such as Min-Max, Standard scalar, and PCA is being applied to scale or generalize the values.

3) At the end, the scaled data is further evaluated using various evaluation parameters such as accuracy, rmse, R2, mse, precision, recall, etc to find the best technique for predicting the crime.

The study has been divided into several sections where Section I has been already defined as an Introduction; Section II defines the related work. The proposed model is demonstrated in Section III, which includes information about datasets, libraries, data collection, data provenance, data pre-processing, feature scaling, algorithms, and evaluative parameters. Section IV mentions the results, whereas Section V concludes the study.

II. Related Work

Many scholars have investigated crime control concerns and proposed various crime prediction algorithms. The qualities of the techniques and the dataset, along with the challenges, have been used as a benchmark (Table I) to determine the accuracy of the prediction and generate the research gap. In [7], the authors examined and found the key factors influencing crime in certain parts of the country. They employed clustering, a graphical representation based on determining which areas have the greatest and minor crimes. In addition, the authors have implemented the Community Detection Algorithm. The authors presented a method for predicting crime without human involvement [8] using computer vision and machine learning technologies. The paper employed rectified linear units (ReLU) and convolutional neural networks (CNN) to identify weapons in images, such as knives or guns. This aided in confirming the occurrence of a crime and identifying the event's site. The results looked highly accurate, with roughly 92% accuracy for a test set. In [9], the authors developed a provenance capturing mechanism that aims to trace digital evidence's transformation to bolster the trustworthiness of digital evidence when the incident response takes place on the affected system. In their work, the data provenance was recorded simultaneously in both the systems, i.e., the incident response system and the affected system.

Likewise, in [10], the authors employed a variety of machine learning algorithms on data of criminal cases in India to find patterns in criminal activities in a particular geographical location. The aim was to reduce the number of pending criminal cases by classifying them based on their crime patterns to solve them faster. Different machine learning algorithms were applied, and a comparison was made based on several parameters to find the best algorithm to solve this problem efficiently. It had been concluded that the Random Forest Classification method was best suited to predict the desired results after classification. In [11], the authors created a prediction model that can be used for the prognosis of crime rates accurately, and they tested the accuracy of six different types of Machine learning algorithms on crime data, which included Linear Regression, SVM, KNN, decision trees, Nave Bayes and CART (Classification and Regression Tree). The authors of [12] described how the frequency of crimes and crime features in India, such as rape, sexual assault, and kidnapping, may be examined using machine learning models in the investigation process.

Similarly, in [13], the authors worked on several machine learning algorithms predicting crimes. They devised a new framework to combine two machine learning algorithms, i.e., XGBoost and TF-IDF, to improve the results of various algorithms used in text mining to predict crimes. The improvement of data accuracy to strengthen the accuracy of crime prediction overweighs the optimization process of algorithms. The inaccuracy of crime data might result in an inaccurate prediction of a specific category of crime that has its basis in the historical data. Training a good classification model is imperative in improving the accuracy of data, which in turn forms the basis for analyzing and accurately predicting crime. The text-based classification of theft crime data based on the two algorithms, i.e., XgBoost and TF-IDF, were also used to get a logical and error-free classification effect of data. This was a constructive trial at a machine learning algorithm for data mining of police-related data and quintessential for predicting crime.

TABLE I. ANALYSIS OF THE PREVIOUS WORK

Ref	Dataset	Techniques	Outcomes	Limitation
[8]	Dataset containing criminal tools	CNN, ReLu	Accuracy = 90.02%	High computational cost
[11]	Real world data	KNN	Mean = 0.33	Accuracy needed to be improved
[34]	Crime reports	Visionary system, natural language processing	The system detected the crime based on analysing analytic provenance trails.	Multiple techniques needed to be incorporate for achieving the better results
[30]	NCRB data	Linear Regression	Acc = 83%	Limited dataset

[13]	data collected from 2009 to 2019	Tf-IDF, XGBoost model	Prec = 92.3%
			Rec = 91.6%
			F1 score = 91.9%
				Values of performance metrics needs to be enhanced

[31]	Data collected from past 10 years	Logistic Regression	Acc = 80.769%	Less scalability
		Random forest	Acc= 76.923%	
		Naïve Bayes	Acc = 80.769%	
		Decision tree	Acc= 76.923%	
[33]	Crime dataset	Huber Regression	Results obtained in the form of predictions and score of each state where women crime has taken place	Design complexity

No research on data provenance classification in criminal data has been conducted. Scientific data is kept in databases. Therefore, provenance management solutions were created with that in mind. No system has taken the provenance of crime data and its implementation concerns and challenges into account. Various women-based crimes have been targeted using multiple machines and deep learning techniques. Still, it has been discovered that researchers have encountered specific issues, either in terms of detection or system performance. A few models, such as logistic regression, KNN, Relu, and SVM, had a complex design, used a limited dataset, or needed improvement in their performance. As a result, the research's primary motivation is to fill the gaps to forecast a better system for detecting crime utilizing data provenance.

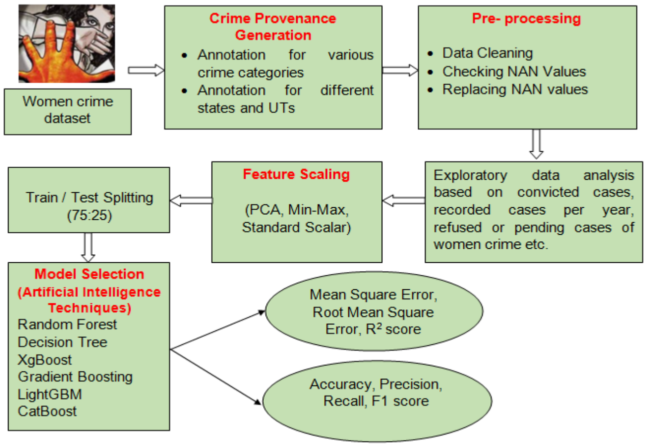
III. PROPOSED SYSTEM

A framework has been designed to analyze the statistics of women-based crimes in India, named the Crime Data Provenance Framework, as shown in Fig. 2. This framework aims to design a methodology to use the provenance of the given crime data in the form of annotations (a subtext or metadata which provides additional information about the actual data) to create crime classes that are used further for the classification and prediction of crime data. There are a variety of crime sub-categories in this framework which has become the basic building block, and prediction models have been applied. The results have been compared and analyzed. The framework has only been implemented for a single category of crime, i.e., crime against women. The various steps in the framework are categorized into several sub-sections wherein each sub-section elucidates the purpose and tasks performed in each step.

A. Data Collection

The data has been accumulated from the government website named National Crime Record Bureau (NCRB) [35] and Kaggle [36]. The website was established on 11th March 1986. The general aim was to empower Indian Police with Information Technology and Criminal Intelligence to make law enforcement more productive. The data from 2001 to 2015 was in .xls format, and the rest from 2015 to 2019 was in pdf format. Some books helped to understand how crime provenance trends can be represented in a textual form that could later become part of Provenance. The first book, named 'Violence Against Women in India' prepared by International Center for Research on Women, aimed at elaborating on the trends and patterns in crime against women, and the second book was 'Tackling Violence Against Women: A Study of State Intervention Measures' which was a report prepared by Bhartiya StreeShakti, a voluntary, autonomous, apolitical organization committed to empowering women, families and the society at large. The report aimed to study different aspects of crime against women by taking perspectives from other professionals like Lawyers, Police Personnel, Public Prosecutors, and Medical Officials [12].

At a fleeting glance, the data seemed to have a lot of dimensions as there were a lot of crime subcategories. There were several crime categories as shown in Fig. 3 and each category had further subcategories. Each crime subcategory had different crime status categories. For instance, our crime category was CRIME AGAINST WOMEN. Further, it had subcategories such as cruelty by husband and relatives, kidnapping of women and girls, Indecent Representation of Women (Prohibition) Act, 1986, and many more.



Women crime dataset
Crime Provenance Generation
• Annotation for various crime categories
• Annotation for different states and UTs
Pre- processing
• Data Cleaning
• Checking NAN Values
• Replacing NAN values
Exploratory data analysis based on convicted cases, recorded cases per year, refused or pending cases of women crime etc.
Feature Scaling
(PCA, Min-Max, Standard Scalar)
Train / Test Splitting (75:25)
Model Selection (Artificial Intelligence Techniques)
Random Forest
Decision Tree
XgBoost
Gradient Boosting
LightGBM
CatBoost
Mean Square Error, Root Mean Square Error, R² score
Accuracy, Precision, Recall, F1 score

Fig. 2. Crime Data Provenance Framework.

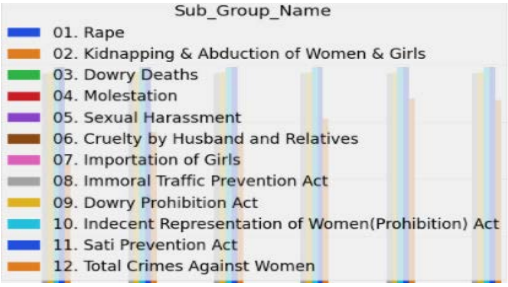


Fig. 3. Various Crime Categories under Crime against Women.

B. Provenance Generation

The crime against women has been subcategorized based on physical or mental abuse, or both caused to women under various circumstances with varying intentions. Different laws are formulated to deal with cases for each crime category, and they have been listed along with their annotations as a small sample data in Table II.

In addition to this, the number of cases for different categories of crime reported at various places has also been organized and segregated according to various States and Union territories. As we know, India has 28 States and 8 Union Territories, and the data has been compiled by the number of cases of different crime categories reported in these places. The states and union territories have been annotated to be used as Provenance for crime prediction purposes. Table III consists of the name of a state and a Union Territory and their annotations as a sample.

TABLE II. SAMPLE OF ANNOTATIONS FOR DIFFERENT CRIME CATEGORIES

Case Sub-categories	Crime Act/Section	Case Code (Annotations)
Rape	Section 376 IPC	CSR-376
Kidnapping & Abduction of Women & Girls	Sec. 363-373 IPC	CSK-363-373
Commission of Sati Prevention Act 1987	NA	CSSP-1987
Protection of Women from Domestic Violence Act 2005	NA	CSDV-2005

TABLE III. SAMPLE OF ANNOTATIONS FOR DIFFERENT STATES AND UNION TERRITORIES

Name of the State/Union Territory	State/UT Code(Annotations)
Arunachal Pradesh	SCAR
Puducherry	UTPU
Himachal Pradesh	SCHP
Jharkhand	SCJH
Karnataka	SCKA
Kerala	SCKE
Madhya Pradesh	SCMP
Maharashtra	SCMH
Manipur	SCMA
Meghalaya	SCME
Mizoram	SCMI

C. Crime Data Pre-processing Phase

The Preprocessing of data is necessary to clean it and make it suitable for a machine learning model, which improves the effectiveness and precision of the machine learning model. Loading libraries and setting up the platform is the prerequisite to initializing the process of Data pre-Processing Fig. 4. Several Python libraries, such as Matplotlib, Numpy, Sklearn, Itertools, SimpleImputer, Seaborn, Maths, and Pandas, have been loaded to perform specific functions [14-16].

	A	B	C	D	E	F	G	H	I	J	K

Fig. 4. Preprocessing of Dataset.

D. Exploratory Data Analysis

The pre-processed data has been categorized into various categories, including the most unsafe and safe states for women in India from 2001 to 2013, as displayed in Fig. 5. The classification of different categories of women-based crimes, distribution of cases convicted per year, and distribution of cases reported per year (i.e., from 2001 to 2010) has been displayed in Fig. 6 and Fig. 7, which show that the convicted cases in terms of the total number of crimes against women range from 25000 to 35000 while as in the year 2010.

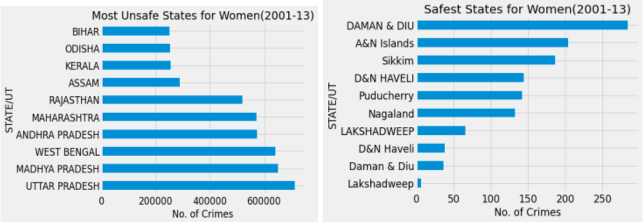

Fig. 5. Most Unsafe and Safe States for Women in India.

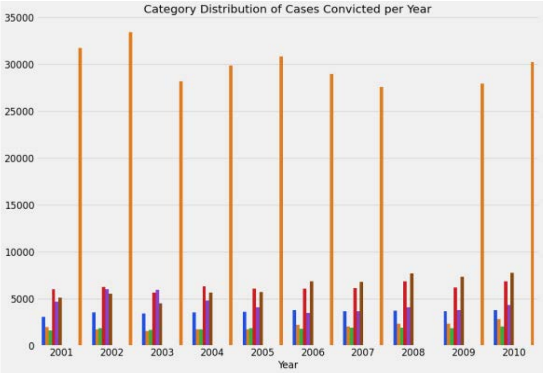

Fig. 6. Convicted Cases of Crime against Women in India.

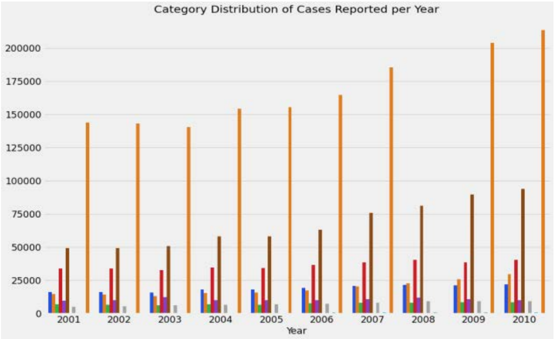

Fig. 7. Reported Cases of Crime against Women in India.

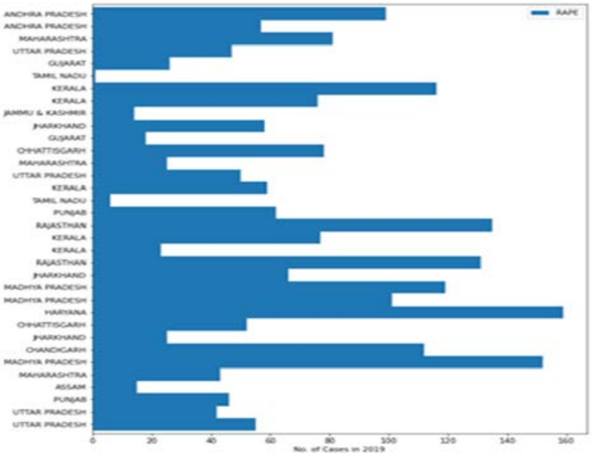

Fig. 8. Statewise Records of Rape Cases in 2019.

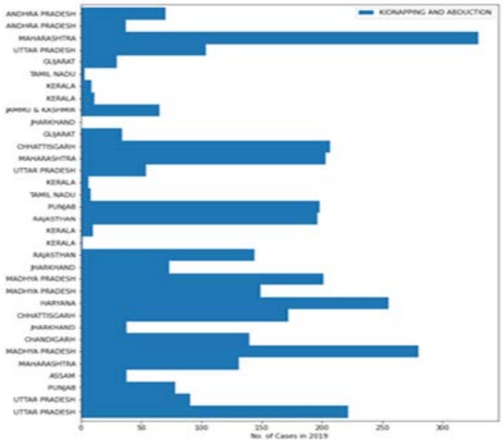

Fig. 9. Statewise Records of Kidnapping and Abduction in 2019.

In addition, Fig. 8 and Fig. 9 explore the data for the most recent year, 2019, the statistics displaying states that fell most heavily in crimes such as rape, the modesty of women, cruelty by husbands, kidnapping, and so on. The state of Haryana had the most rape cases, followed by Madhya Pradesh, while Tamil Nadu had the least. Similarly, Maharashtra ranked first in kidnapping and abduction, while Tamil Nadu and Kerala tied for last place. Dowry deaths have decreased dramatically across the country, with at least five states reporting the lowest number of women affected by dowries. Women's molestation has also reduced in several states, including Gujarat, Jammu & Kashmir, and many other conditions. Uttar Pradesh, Andhra Pradesh, and other states have many offenses involving spouse or relatives' maltreatment.

On the other hand, Andhra Pradesh ranks first among all states regarding girl importation as we know that the input to all these attributes is in numerical data. Hence, standardizing it using various scaling techniques mentioned in the next section is essential.

E. Feature Scaling

Feature scaling is the final stage in machine learning data processing. It is a method for standardizing the independent variables in a dataset within a given range. Multiple scaling techniques can be used here, but the one given priority is the one that offers more optimized results after normalizing the data [17-21]. Hence in this section, the scaling techniques such as Min-Max Scalar, Principal component analysis, and Standard Scalar have been used to showcase the performance of machine learning models such as decision tree, gradient boosting, and its many versions and random forest. These models have been applied to the dataset taken from various women-based crimes like cruelty by husbands, rape cases, an insult to modesty, kidnapping and abduction cases, dowry deaths, and importation of girls and are shown graphically in Fig. 10 to 12.

1) Min Max: The entire data is scaled between 0 and 1. To calculate min-max, the formula is shown in Eq. (1):

$$x_{scaled} = \frac{(x-x_{min})}{(x-x_{max})} \tag{1}$$

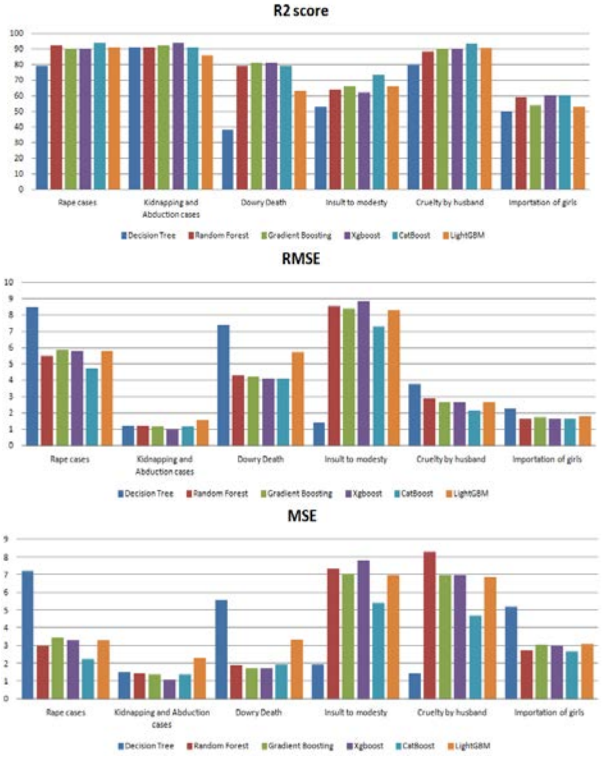

Fig. 10. Analysis of Algorithms using Min-Max Scalar.

On assaying Fig. 10, it can be said CatBoost worked well for importaton of girls, cruelty by husband, insult to modesty, and rape cases by 60, 93.4, 73.4, and 94 R^2 score, respectively while as XgBoost obtained great score in dowry death cases and kidnapping by 81 and 94 R^2 score respectively. On the other hand, for both mean square error and root mean square error best values have been obtained by CatBoost and XgBoost as compared to the other algorithms.

1) Standard scalar: It scales the values in such a way where the standard deviation or variance is 1 and mean is 0. The formula is shown in Eq. (2):

$$x_{scaled} = \frac{(x - mean)}{std\_dev} \qquad (2)$$

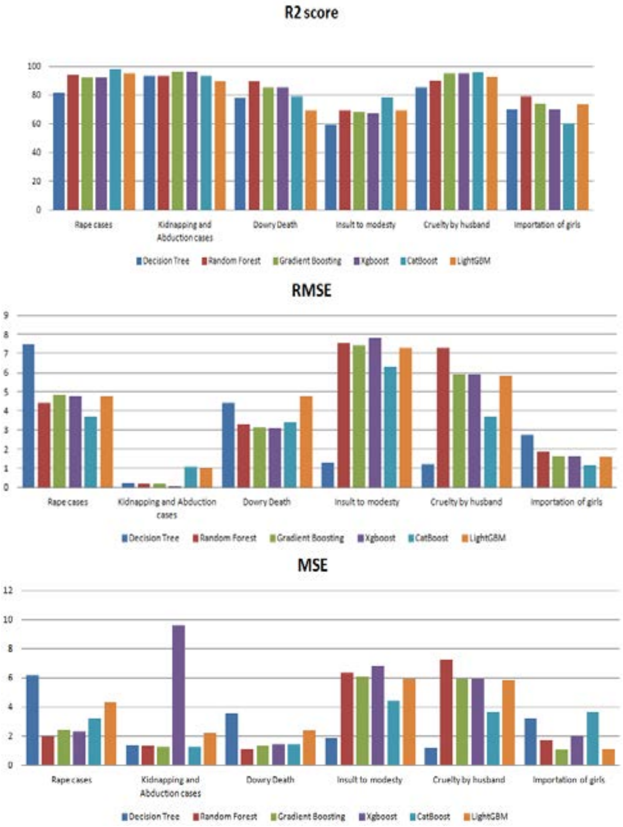

Fig. 11. Analysis of Algorithms using Standard Scalar.

The analysis in Fig. 11 determines that CatBoost worked well for the importation of girls, cruelty by husbands, an insult to modesty, and rape cases with 79, 93.4, 78.4, and 98 R2 scores, respectively. At the same time, XgBoost obtained a great score in dowry death cases and kidnapping with 89 and 96 R2 scores, respectively. On the other hand, for root mean square error and mean square error, the best values have been obtained by CatBoost and XgBoost as compared to the other algorithms.

2) Principal component analysis: A statistical technique in determining interrelations among a set of variables. The conversion of correlated variables to a set of uncorrelated variables takes place.

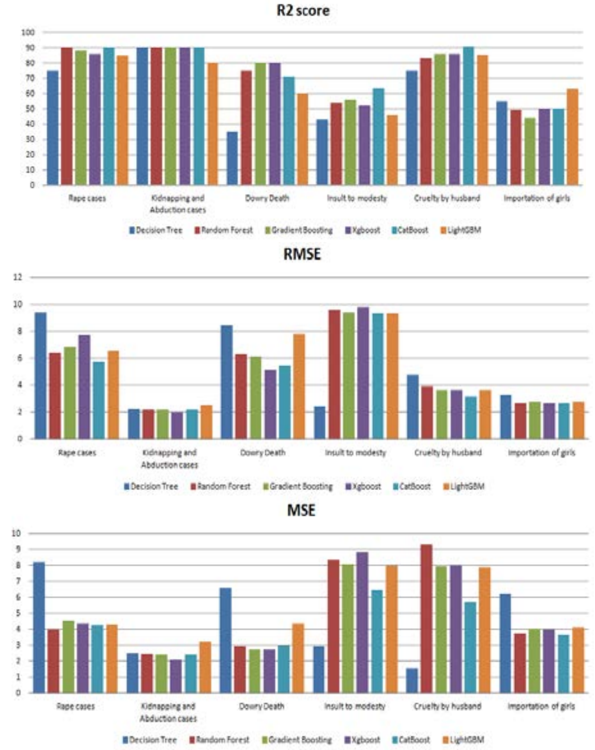

Fig. 12. Analysis of Algorithms using Principal Component Analysis.

On assaying Fig. 13, it can be said that LightGBM, CatBoost, XgBoost, and Random Forest gave better results for the women crime dataset by 63, 90.4, 80, 90 R2 scores, 2.76, 31.6,20.3,64.6 root mean square error value for data such as importation of girls, cruelty by husband, dowry, and rape, respectively.

The Scaling technique that gave the best results after normalizing the data was Standard Scalar. After feature scaling, the dataset has been divided into two halves. The first half consists of 75% of the training dataset, and the remaining half has a 25% testing dataset on which application of machine learning algorithms has been made.

F. *Model Selection*

Various machine learning models have been applied on the women crime dataset. A variety of models have been used on the dataset as one particular model cannot give accurate results as each model has its own characteristics and working technique. The output produced by each one of them is compared to get the best results. Features of each one of them have been discussed subsequently.

1) Decision tree: It is a representation of every all probable solutions to a problem/decision which is based on particular specifications [20]. It is organized in a tree-like form with two nodes: the Leaf Node and the Decision Node and Leaf nodes keep track of the outcomes of those decisions and have no other branches, on the other hand Decision nodes can have multiple branches depending upon the number of decisions made [21]. The features of the given dataset are used to make judgments or run tests. The values of decision tree can be calculated by computing the impurity of a node and its entropy which are shown in Eq. (3) and Eq. (4):

$$I_G(\mathrm{n}) = 1 - \sum_{i-1}^{J} (pi)^2 \qquad (3)$$

where J is the count of classes present in the node and p is the distribution of the class in the node.

$$Entropy = \sum_{i=1}^{c} -(pi)^* log_2(pi) \qquad (4)$$

where C is the number of classes present in the node and p is the distribution of the class in the node.

2) XgBoost: It is based on the concept of gradient boosting. It also makes use of decision trees. It is a custom, parallelized tree building algorithm which contains several decision trees. It provides features like efficient handling of missing data, and automatic feature selection [18].

3) Gradient boosting: Gradient Boosting is one of the most powerful techniques to construct predictive models. It trains many models in parallel. Every new model minimizes the loss function using the Gradient Descent Method. It is a greedy algorithm, and overfitting of the training dataset can happen quickly. It benefits from regularization methods by penalizing various parts of the algorithm and improving the algorithm's performance by reducing overfitting [22].

4) Random forest: It uses the concept of many decision trees to solve a compounded problem and helps improve the model's performance [23]. A random forest has the following characteristics. It combines several decision trees from distinct subsets of the provided dataset and averages them to increase the dataset's predicting accuracy. The number of trees and precision has a linear relationship, which helps to avoid over-fitting. It is divided into two phases: In the first phase, a random forest is created by mixing N decision trees, and in the second phase, predictions are made for every tree formed in the former step. The Random Forest algorithm is solved by Eq. (5) to Eq. (8):

$$RFfi_{\mathrm{i}} = \frac{\sum_{\mathrm{j}eall\,treas} normfi_{ij}}{T} \qquad (5)$$

$$normfi_{\mathrm{i}} = \frac{fi_i}{\sum_{jeall\,features} fi_j} \qquad (6)$$

$$fi_{\mathrm{i}} = \frac{\sum_{\mathrm{jinode\ j\ splits\ on\ feature\ i}} ni_j}{\sum_{keallnodes} ni_k} \qquad (7)$$

$$Ni_j = W_j C_j - W_{left(j)} C_{left(j) - W_{right(j)} C_{right(j)}} \qquad (8)$$

Here ni_{i} means importance of node j, $\mathrm{W_i}$ = weighted number of samples reaching node j, $\mathrm{C_i}$ = the impurity value of node j, left(j)= child node from left split on node j, right(j) = child node from right split on node j, fi_{i} = the importance of feature i, $RFfi_{\mathrm{i}}$ = the importance of feature i calculated from all trees in the Random Forest model, *normfi* = the normalized feature importance for i in tree j, T = total number of trees [19].

5) CatBoost: CatBoost is an open-source algorithm which uses gradient boosting on decision trees. It allows the use of non-numerical. It uses a combination of one-hot encoding and an advanced mean encoding [24].

6) LightGBM: Microsoft created LightGBM, a free and open-source distributed gradient boosting platform for machine learning. It's a decision tree-based gradient boosting framework that improves a model's efficiency while minimizing the utilization of memory. It uses a split strategy which is leaf-wise rather than level-wise, and consequently produces complex trees, which is the primary factor in attaining higher levels of accuracy [25].

G. Evaluation Metrics

Various evaluation metrics have been used such as accuracy; F1 score, precision, recall, root mean square error, and R score to test the performance of the applied machine learning models. Each one of them has been discussed briefly below:

Accuracy: The percentage of predicted values that match actual values is calculated by accuracy [25] and is shown in Eq. (9).

$$Acc = \frac{True\ Positive + True\ Negative}{True\ Positive + True\ negative + False\ Positive + False\ Negative} \qquad (9)$$

F1 Score: It is used to assess the authenticity of a test. The Harmonic Mean of precision and recall is the F1 Score which has ranges between 0 and 1. It tells you how accurate and how robust our classifier is [26]. It is calculated by Eq. (10).

$$F1\ Score = 2\frac{Precision * Recall}{Recall + Precision} \qquad (10)$$

Precision: It is the number of positive classifiers divided by the total number of positives both true as well as false number of correct positive outcomes. [25]. It is calculated by Eq. (11).

$$Precision = \frac{True\ Positive + True\ Negative}{True\ Positive + False\ Positive} \qquad (11)$$

Recall: The number of rational positive results divided by total relevant samples [25]. It is calculated by Eq. (12).

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \qquad (12)$$

Root mean square error: Euclidean distance uses to indicate how far predictions differ from true measured values [27]. It is one of the most widely used criteria for assessing the accuracy of predictions [28]. The root mean square error is calculated by Eq. (13).

$$RMSE = \sqrt{\sum_{i=1}^{j} \frac{II_{x(j)-x(j)} II^2}{n}} \qquad (13)$$

where n denotes the number of data points, x(j) refers to the j-th measurement, and x(j) belongs to the prediction which corresponds to the measurement.

R^2 score: It is known as coefficient of determination. It is the proportion of the variance in the dependent variable that is forecasted from the independent variable(s) [13] and is calculate by Eq. (14).

$$R^2 = 1 - \frac{SS_{RES}}{SS_{err}} \qquad (15)$$

where $\underline{SS_{RES}}$ is the residual sum of squared errors and SS_{err} is the total sum of squared errors.

IV. Results

The performance of the algorithms based on the various parameters such as accuracy, recall, root mean square error, precision, and F1 score has been computed during testing phase as shown in Table IV along with the discussion.

TABLE IV. Computation of Various Metrics for Machine Learning Models

Algorithms	**Metrics**				
	Accuracy	***Recall***	***RMSE***	***Precision***	***F1 Score***
Decision Tree	72	71	2.31	77	71
Random Forest	**92**	**85**	**0.91**	**86**	**85**
Gradient Boosting	74	80	2.25	79	80
Xgboost	88	78	1.35	78	78
CatBoost	79	84	2.11	84	85
LightGM	80	84	1.98	85	85

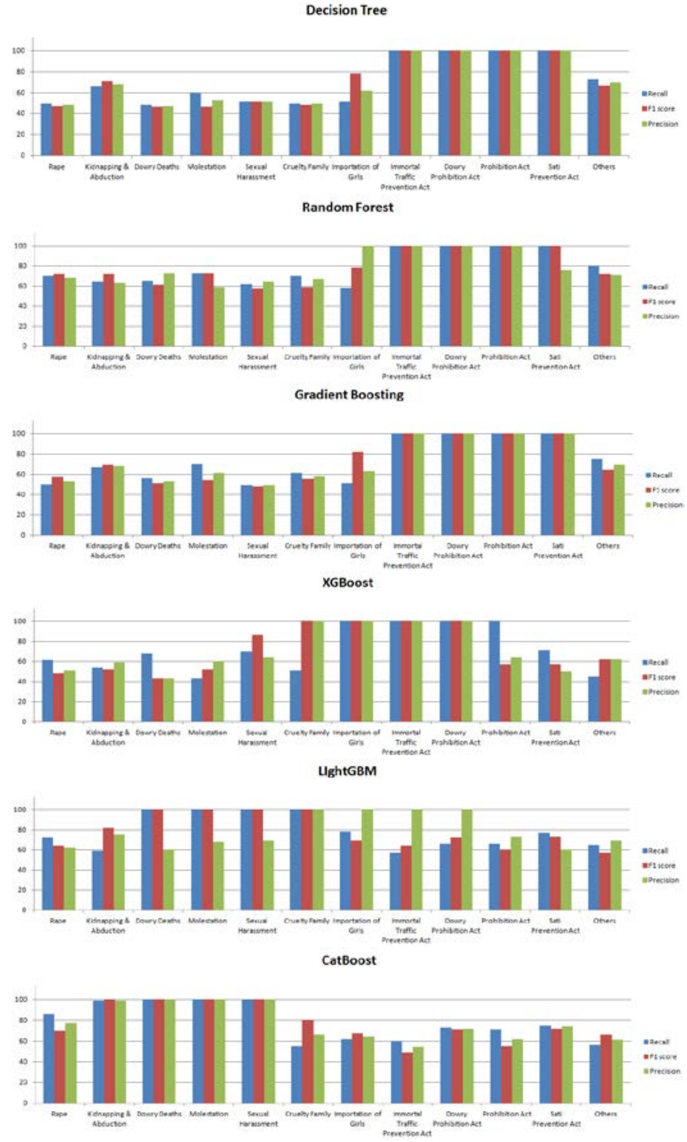

Fig. 13. Evaluation of Various Machine Learning Models using Three Different Metrics

On analyzing it can be said that random forest obtained the highest accuracy by 92%, recall by 85% and precision by 86%, F1 score by 85% on comparison with other algorithms. Besides this, each woman's recall, precision, and F1 score based on criminal activities such as dowry deaths, sexual harassment, importation of girls, prohibition act, sati prevention act, etc., have also been computed shown in Fig. 13. These parameters have been calculated to analyze the work of each learning model, as mentioned.

V. Discussion

In this research paper, the proposed system checks the credibility of the women based crime data by applying various machine learning models. Their performances have been evaluated using various evaluation metrics such as accuracy, recall, precision, F1 score, and root mean error square, with random forest achieving the highest accuracy of 92%, recall of 85%, the precision of 86%, F1 score of 85%, and the root mean square error value of 0.91 is obtained which is highest when compared to other algorithms. In addition to this, the work of various researchers in analyzing women's crime using different datasets has been also considered and compared with our study to understand our research work in a more efficient manner as shown in Table V.

TABLE V. Comparative Analysis of Previous Work with our Work

Ref	**Techniques**	**Dataset**	**Accuracy (%)**
[29]	Random forest	Crime in India dataset	86
[30]	Linear regression	National Crime Records Bureau (NCRB) crime data	83
[31]	Naïve Bayes	Collection of data from 2001 to 2012	81
[32]	KNN	Primary data	77
Our study	**Random forest**	**National Crime Record Bureau from year 2001 to 2019**	**92**

After comparing, it has been concluded that our study has achieved a great result in terms of accuracy for the National crime record bureau (2001-2019) with 92%, while linear regression has obtained less accuracy by 83% on applying the data that has been collected from the same repository. Overall, KNN has obtained the lowest accuracy value by 77% while working on the primary data.

VI. Challenges Faced during Research Work

During this research, we faced specific challenges while collecting the data, which is the most important step for crime-based research. Like this, the three main problems that we came across were:

1) No uniformity in Data: The data collected initially from 2001 to 2015 had a different data format and many parameters related to the case status. Still, the data from 2015 onwards was more compressed and less comprehensive. In addition, many crimes go unreported, and no one has a record of them.

2) Varying data formats: The data from 2001 to 2016 was in excel format and had a different format and parameters, and data from 2016 onwards was in pdf format and had a different set of parameters. A lot of time was taken to pre-process data into a desired, standardized format.

3) Size of the crime data: The data was huge as there are 11 sub-categories of crime against women, and each crime sub-category case status is stored. There are 13 types of case status. All this information is stored for 27 states and 8 Union Territories. The records taken were for 15 years. As the data size was huge, rectifying the problems with the data was an uphill task. Along with it, the data taken from books was compatible for analysis.

4) Missing values in crime data: There were a lot of missing values in the data, so the data cleaning was time-consuming. Hence, the SimpleImputer technique was used to handle missing data.

VII. Conclusion

The study focuses on the investigation of women's crime statistics such as rape, abduction, dowry deaths, molestation, sexual harassment, cruelty to family, importation of girls, immortal traffic, dowry prohibition act, prohibition act, sati prevention act, and others from 2001 to 2019 in various Indian states using data provenance and machine learning models. It has been discovered that Random Forest proved to be the best approach when compared to the others. Moreover, the proposed system demonstrates that the algorithms used for machine learning perform effectively in analyzing various crimes against women across states and union territories. Hence, the same technique can also be applied to search for information about other crimes in states with a higher crime rate. In addition, deep learning algorithms might be utilized to improve prediction accuracy while dealing with complex criminal cases in India.

XBLQPS: An Extended Bengali Language Query Processing System for e-Healthcare Domain

Kailash Pati Mandal[1], Prasenjit Mukherjee[2], Atanu Chattopadhyay[3], Baisakhi Chakraborty[4]
Computer Science and Engineering, National Institute of Technology, Durgapur, India[1, 2, 4]
BBA (H) and BCA (H) Department, Deshabandhu Mahavidyalaya, Chittaranjan, India[3]

***Abstract*—The digital India program encourages Indian citizens to become conversant with e-services which are primarily English language-based services. However, the vast majority of the Indian population is comfortable with vernacular languages like Bengali, Assamese, Hindi, etc. The rural villagers are not able to interact with the Relational Database Management system in their native language. Therefore, create a system that produces SQL queries from natural language queries in Bengali, containing ambiguous words. This paper proposes a Bengali Query Processor named Extended Bengali language Query Processing System (XBLQPS) to handle queries containing ambiguous words posted to a Healthcare Information database in the electronic domain. The Healthcare Information database contains doctor, hospital and department details in the Bengali language. The proposed system provides support for the Bengali-speaking Indian rural population to efficiently fetch required information from the database. The proposed system extracts the Bengali root word by removing the inflectional part and categorizing them to a specific part of speech (POS) using modified Bengali WordNet. The proposed system uses manually annotated parts of speech detection of a word based on Bengali WordNet. Patterns of noun phrases are generated to detect the correct noun phrase as well as entity and attribute(s). Entity and attributes are used to prepare the semantic table which is utilized to create the Structured Query Language (SQL). The simplified LESK method is utilized to resolve ambiguous Bengali phrases in this query processing system. The accuracy, precision, recall and F1 score of the system is measured as 70%, 74%, 73%, and 73% respectively.**

Keywords*—Relational database management system (RDBMS); modified bengali WordNet; LESK algorithm; structured query language (SQL); natural language query

I. Introduction

Indian citizens have become more familiar and conversant with online or electronic systems like e-banking, e-governance, e-health, e-tourism, and e-education due to the empowerment through the digital India program. Nowadays most government facilities are electronic based. However, the vast majority of the Indian population is village based. There are 0.7 million villages in India. Most villagers are not accustomed to the English-based systems. They are comfortable with their own vernacular language(s) and Bengali is one of them. Bengali is widely used in West Bengal, Andaman and Nicobar Islands, Tripura, Assam, and other states. The Bengali language is the official language of Bangladesh, West Bengal and Tripura. One of the major e-service requirements in the rural interiors is related to healthcare systems. Health care domain-based e-services in vernacular languages are a really challenging task. Today, the query-response model in vernacular language is an open research problem in the research community. This is because the resources of vernacular languages are very low and difficult to implement. A good query response model in the Bengali language can be helpful for naive users to extract information without any technical knowledge. WordNet plays a vital role to develop the query-response model. The Query expansion (QE) is a well-known technique used to enhance the effectiveness of information retrieval. A new approach for QE using Wikipedia and WordNet as data sources is described in [1]. The IndoWordNet is an important lexicographic resource for different Indian languages. The lexical matrix has been used to construct the relational semantics as discussed in [2]. In the article [3], The BWN is a WordNet database for the Bengali language. It consists of lexical source files, a grinder, a WordNet database, and an interface. Using the WNDB interface, users can interact with the BWN documents in various ways as explained in [3]. The African Wordnet Project aims to develop aligned wordnets for African languages spoken in South Africa. The focus of this article will be on isiZulu as one of the selected languages used in [4]. The meaning of an ambiguous word has been determined according to its context. The proposed method generates context by comparing a doubtful word with words in the input document for similarity. The similarity computation is based on BabelNet's semantic framework. [5].

The naive users who access the online Healthcare Information Management System in the Bengali language is a challenging task. Therefore, this paper proposes a modified Bengali WordNet and a natural language query-response system, namely Extended Bengali language Query Processing System (XBLQPS) that can handle natural language queries in Bengali. This automated system generates responses from the knowledge database. A relational Database Management System (RDBMS) is used to implement the knowledge database. This work is an enhancement of the work of [6], where a Query Processing System for the Bengali language has been proposed and discussed.

This research article consists of various sections. Section II narrates related works. Section III describes the objective of the proposed system where Section IV explains the proposed system and Section V describes analysis and discussion of the proposed system. Section VI is about the modified Bengali WordNet and health information database. Section VII illustrates the used tool and IPA notation. Section VIII derives the time complexity of the proposed system. Section IX is related to analyze the precision, recall, and accuracy of the

XBLQPS, Section X presents the limitations and future works. The proposed system is concluded in Section XI.

II. Related Work

Bengali WordNet databases are useful and a few good implementations have been done by Pushpak Bhattacharyya [2] and Farhana Farque [3]. The proposed work is influenced from Pushpak Bhattacharyya [2], Farhana Farque [3] and A. Haque [22].

The article [7] stated a question-answering model using natural language query where interactions between table and question are complex type. The sketch-based approach has been applied to solve the complexity as in [7]. Word sense disambiguation (WSD) is to find the proper meaning of a word in any context. It involves incorporating word knowledge from external knowledge resources to remove equivocalness. A WSD tool has been implemented using Hindi WordNet where it is a knowledge-based approach as in [8]. In the paper [9], the sense Induction approach has been used in the algorithm for word sense disambiguation (WSD) in Bengali. Ten frequently used Bengali ambiguous terms and 200 phrases of each term are utilized to test the WSD model. The radix tree-based structure is used to keep context information as well as faster searching of a word in the paragraph. The WordNet is used as a knowledge base to disambiguate the word as discussed in [10]. The Case-Based Reasoning interpretation technique was used to decipher the confusing word Gurmukhi, also known as Punjabi, in Indian Regional Language. The solution to the new problem was inferred from the previously solved problems as described in [11]. Machine translation at the human level can be helpful greatly using WSD. Through the FP-Growth method, Authors [12] provide a system for WSD in their study as in [12]. The fuzziness of semantic relation has been applied in Fuzzy Hindi WordNet (FHWN). Various membership values of semantic relations of the FHWN were considered to extract the correct sense as in [13]. In the article [14], the authors described the root word extraction technique from the Bengali inflected nouns by applying well-defined grammatical mapping rules (GMRs) between nominal bases and inflections. The proposed methodology can be applied to the Bengali grammar and inflected words that were described in [14]. To decipher the confusing term, the LESK algorithm has been utilized. The result set of the proposed system is in line with the result set of KBBI as well as provides an accuracy of 78.6% for one of the ambiguous words while 62.5 % for two ambiguous words as explained in [15]. The effort of identifying the meaning of a word in a certain situation is known as word sense disambiguation (WSD). The novel WSD [16] model has been introduced where the proposed model calculates each word's meaning uniquely. The creation of Arabic WordNet (AWN) has made lexical resources available to the Arabic NLP community. The usage of this resource cannot be considered because there are fewer AWN Synsets than other WordNets that has been elaborated in [17]. In the article [18], Vietnamese and Korean both are morphologically rich languages. The high homograph rate in the Korean language is word ambiguities that affect neural MT (NMT). There isn't a sufficient, publicly accessible parallel Korean and Vietnamese that can be utilized to train translation models as implemented in [18]. A hybrid approach is used for Urdu word stemming that is helpful for information extraction, textual categorization, data analysis and related applications. This proposed approach [19] works on unigram, bigram, and trigram features that were discussed in [19]. The word was disambiguated by combining the sense relativeness algorithms with a neural model in the paper [20]. The proposed model works on POS-labeled text corpus and the length of the context may be varied as discussed in [20]. The raw collection of Bangla text has been used to generate meaning-tagged data. The Bangla meaning tagged data contains root word form and their POS type of an ambiguous word with 86.95% performance as implemented in [21]. The Bangla Word Sense Disambiguation System can be distinguished by some confusing Bangla phrases. Parsing and detection are two main working phases of the proposed system [22]. An Algorithm has been developed that clears the confusing word according to the categories of ambiguous words that are nouns, adjectives, and verbs as in [22]. Authors were focused on how to differentiate the important records and generate a summary from them. In the proposed system, the authors applied natural language processing, WordNet and lexical chains for the summary generation of a text as explained in [25]. An Arabic WordNet (AWN) has been used to overcome the WSD problem where word semantic similarity has been checked by multiple Arabic stemming algorithms. This work is related to reducing the gap in Arabic NLP compared to English as in [26]. Table I shows the results of a comparative investigation of existing systems with the proposed system.

TABLE I. A Comparison of Identical Systems using the XBLQPS

SL NO.	AUTHOR(S) & SYSTEM	METHODOLOGY USED IN SAME TYPE SYSTEM	METHODOLOGY APPLIED IN THE PROPOSED SYSTEM (XBLQPS)
1	S. Basuki et al. & LESK Algorithm Utilization for Word Sense Disambiguation (WSD) for Indonesian Homograph Word Meaning Determination [15]	1) The LESK procedure has been used to disambiguate Indonesian Homograph Word referred in [15]. 2) This system provides 78.6% accuracy if one ambiguous word present, and 62.5% accuracy if two ambiguous words present. 3) The time complexity has not been discussed for this system	1) The proposed system uses the LESK algorithm, modified Bengali WordNet and formation of patterns to disambiguate the Bengali word. 2) The overall accuracy of XBLQPS is 70%. 3) The time complexity has been calculated for the proposed system.
2	M. S. Kaysar et al.& Applying FP-Growth Algorithm to Disambiguate Bengali Words [12]	1) The FP-Growth Algorithm has been used to disambiguate the Bengali ambiguous word. 2) This system provides 80% accuracy. 3) The time complexity has not been specified here.	1) The LESK has been used to disambiguate the Bengali ambiguous word. 2) The XBLQPS provides 70% accuracy. 3) The complexity has been computed here.

3	D. O et al. & Word Sense Disambiguation Utilizing Word Vector Representation from a Knowledge-based Graph Based on Word Similarity Calculation [5]	1) The system referred in [5] has been used to disambiguate the ambiguous word using similarity calculation with help of semantic network structure of BabelNet. 2) This system does not generate pattern(s). 3) The precision, recall and F1 score on semEval-2013 dataset are 75%, 75%, and 75% respectively whereas on semEval-2015 are 69.2%, 62.6% and 65.8%.	1) The XBLQPS uses LESK algorithm and modified Bengali WordNet to disambiguate the ambiguous word. 2) The XBLQPS generates pattern(s). 3) The precision, recall and F1 score for the proposed system are 74%, 73% and 73% respectively.
4	M. Biswas et al. & Construction of a Bangla Sense Annotated Corpus for Disambiguation of Word Sense [21]	1) The system referred in [21] creates sense annotated corpus containing ambiguous word. 2) The accuracy of sense annotated corpus is 86.95%. 3) The time complexity has not been discussed for this system.	1) The XBLQPS creates SQL from the Bengali language query containing ambiguous word. 2) The proposed system provides 70% accuracy. 3) The time complexity of XBLQPS has been computed.
5	K. P. Mandal et al. & An unique Bengali Language Query Execution System in the field of health [6]	1) The system referred in [6] does not able to handle the query containing ambiguous word. 2) This system does not use LESK algorithm. 3) The time complexity of this system is $O(n^4)$.	1) The XBLQPS can process the query containing ambiguous word. 2) This system uses LESK algorithm. 3) The time complexity of the proposed system is $O(n^3)$.
6	C. Lachichi et al. & Machine translation and external linguistic elements have been used to enrich Arabic WordNet[17]	1) The system referred in [17] uses Machine Translation and External Linguistic Resources to enhance the Arabic WordNet. 2) It is an Arabic WordNet enhancement system. 3) The average accuracy of this system is 0.48.	1) The XBLQPS uses Bengali WordNet to disambiguate the Bengali ambiguous word. 2) It is a Bengali language query processing system. 3) The accuracy of the XBLQPS is 0.70.
7	A. Haque et al. & Utilizing dictionary-based approach, a Bangla word sense disambiguation model has been proposed [22]	1) The system referred in [22] is a dictionary based Bengali word sense disambiguation system. 2) The accuracy of this system is 82.40%. 3) This system does not convert Bengali natural query to SQL.	1) The XBLQPS is a query processing system containing Bengali ambiguous word. 2) The accuracy of the XBLQPS is 70%. 3) The XBLQPS converts Bengali natural language query to SQL.

III. Objective of the Proposed System

- The main objective of this research is to create a system that can handle natural language queries in Bengali in the healthcare domain. A naïve user will be able to extract healthcare information without any technical knowledge.
- The proposed system will be able to handle natural language queries that are containing ambiguous words in Bengali.
- The proposed system will be able to generate a response from the Bengali Query that contains ambiguous words.
- The proposed system will generate SQL from natural language queries in Bengali without any manual intervention.

IV. Proposed XBLQPS

Following are the steps of the proposed system:

Step 1: The user logs into the proposed system and submits the Bengali language query.

Step 2: The system slices the query into token(s).

Step 3: The root word extraction and POS tagging are done with the help of modified Bengali WordNet.

Step 4: Once the POS tagging is over, the proposed system generates pattern(s) with the help of noun and noun phrases.

Step 5: The ambiguous term is disambiguated using the simplified LESK method. The proper sense of an ambiguous Bengali word was discovered by examining the most significant number(s) of common words existent between the word's current context and gloss.

Step 6: After identification of the correct sense of every pattern, entity and attribute are also determined from the table named “table_entity_attribute_sensing” for semantic analysis.

Step 7: Once entity and attribute are detected, a set of predefined rules are used to generate an SQL query.

Step 8: After generating the SQL query, the proposed system executes and retrieves desired information from the health information database.

There are three tables in the health information database. "table_hospital" contains the hospital's name and address. The "table_doctor" includes the doctor's name, qualification, specialization, fee, and a particular doctor connected with the department and hospital. The “table_department” contains the department’s name and which department exists in which hospital.

Finally, the desired result sends to the user. The workflow diagram of the XBLQPS is depicted in Fig. 1. The workflow diagram (Fig. 1) shows the functionality of each component of the proposed system.

V. Analysis and Discussion of the Proposed System

The detailed analysis and description of each component of the proposed system are as follows.

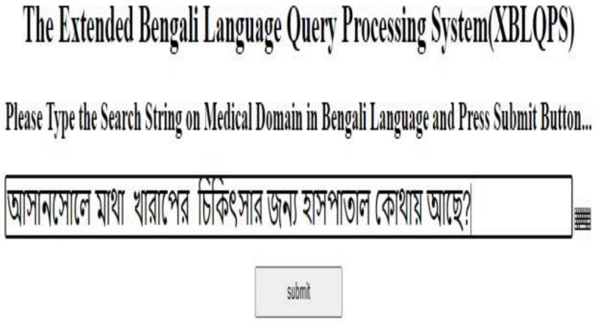
Component 1: Login into the system and submit the query in the Bengali language.

The user logs in to the proposed system and submits the query string in the Bengali language. For instance, a query has been provided. The example of query 1 is given in Fig. 2.

আসানসোলে মাথা খারাপের চিকিৎসার জন্য হাসপাতাল কোথায় আছে?

(asansole matʰa kʰaraper tʃikitsar dʒno ɦaspatal kotʰae̯ atʃʰe?)

(Where is a hospital for treatment of mental diseases in Asansol?)



The Extended Bengali Language Query Processing System(XBLQPS)

Please Type the Search String on Medical Domain in Bengali Language and Press Submit Button...

আসানসোলে মাথা খারাপের চিকিৎসার জন্য হাসপাতাল কোথায় আছে?

Fig. 2. Example Query 1 in Bengali.

Component 2: Tokenization

The query string will be sliced into small linguistic units called tokens after removing punctuation mark(s). These token(s) are stored in a string array. Table II shows the array indexing in the string array of the user-submitted query after tokenization.

Component 3: Root word extraction

The nominal word is the main backbone of SQL formation. Often the noun exists in the inflected form in the Bengali sentences as Bengali is a highly inflected language. Before POS tagging and extraction of correct sense, each token is compared with the inflectional part table i.e. “table_inflectional_part” which is shown in Table XV in the modified Bengali WordNet DB. The proposed system compares each token with the inflectional part table, that is, Table XV. If any of the inflectional parts in the inflectional part table matches with the trailing part of the token, then the XBLQPS removes the matched part from the token. In this way, the proposed system extracts the root word by removing the matched part from the token. If the trailing part of the token does not match with the inflectional part table in the Modified Bengali WordNet DB, then the XBLQPS will consider that the token itself will be a root word. After removing the inflectional part, all token(s) will be stored again in another string array. After extraction of the root word, the string array has been given in Table III.

TABLE II. Tokenization

array index	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
String array of user query	আসানসোলে (asansole)	মাথা (matʰa)	খারাপের (kʰaraper)	চিকিৎসার (tʃikitsar)	জন্য (dʒno)	হাসপাতাল (ɦaspatal)	কোথায় (kotʰae̯)	আছে (atʃʰe)

TABLE III. Root Word Extraction

array index	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
String array of root word	আসানসোল (asansol)	মাথা (matʰa)	খারাপ (kʰarap)	চিকিৎসা (tʃikitsa)	জন্য (dʒno)	হাসপাতাল (ɦaspatal)	কোথায় (kotʰae̯)	আছে (atʃʰe)

Component 4: POS tagging

The proposed system utilizes a POS string array (Table IV) with the same length as the string array of the root words (Table III) for keeping track of parts of speech of every token. The POS string array (Table IV) is helpful for pattern generation of noun phrases. The proposed system selects each token and compares it with the table named “table_word” (Table IX) in the modified Bengali WordNet DB. If the token matches with the table named “table_word” in the modified Bengali WordNet DB, then the corresponding “word_id” field value will be retrieved. The retrieved “word_id” will be compared with the “word_id” field of the table named “table_sense” is shown in Table XI, from where the proposed system will map the “synset_id”. Using “synset_id”, the XBLQPS will retrieve the “parts_of_speech” field value from the table “table_synset”is given in Table X and that will be inserted into the POS string array (Table IV). If the token does not match with the modified Bengali WordNet DB, then the token will be treated as noun (বিশেষ্য) and that will be inserted into the POS string array (Table IV) as a noun (বিশেষ্য). The selected token's array index value is same in POS string array (Table IV) and string array of root word (Table III). Each token of the query will be compared in the modified Bengali WordNet DB and on finding a match with a word, it will be stored in POS string array (Table IV) in the form of its parts of speech derived from the parts of speech definition given alongside the word in the modified Bengali WordNet proposed in the paper, except the token আসানসোল (Asansol) which is a proper noun; the name of a place. That why the POS string array (Table IV) value of আসানসোল is treated as a noun (বিশেষ্য), which means all unknown tokens which do not match with the modified Bengali WordNet DB will be treated as a noun (বিশেষ্য). The string array after pos tagging has been given in Table IV.

Component 5: Pattern generation of noun phrases

The noun and noun phrases are very much important for entity and attribute(s) identification which are main components of SQL formation. The correct noun or noun phrases have been identified by pattern generation because often the Bengali noun phrase is consisting of more than one consecutive noun (বিশেষ্য) or noun with an adjective (বিশেষণ). The proposed system will generate pattern(s) for the consecutive noun (বিশেষ্য) or consecutive any combination of a noun (বিশেষ্য) and adjective (বিশেষণ). More than one consecutive noun (বিশেষ্য) or combination of noun (বিশেষ্য) and adjective (বিশেষণ) will generate more than one pattern whereas nonconsecutive noun (বিশেষ্য) will generate single pattern. The token which is not belong the noun (বিশেষ্য) or adjective (বিশেষণ) is simply ignores by the proposed system. The system will generate more than one pattern for array index 0, 1, 2 and 3 of the POS string array (Table IV) because this array index contains combination of noun (বিশেষ্য) and adjective (বিশেষণ). The single pattern will generate for array index 5 because this is a non-consecutive noun (বিশেষ্য). During pattern generation, the token order occurrence will be maintained by the proposed system and that will be stored in a string array. The string array of pattern has been given in Table V. The generated patterns for the user given query are as follows.

1) আসানসোল (asansol)
2) মাথা (mat^{h}a)
3) খারাপ (k^{h}arap)
4) চিকিৎসা (tʃikitsa)
5) আসানসোল মাথা (asansol mat^{h}a)
6) মাথা খারাপ (mat^{h}a k^{h}arap)
7) খারাপ চিকিৎসা (k^{h}arap tʃikitsa)
8) আসানসোল মাথা খারাপ (asansol mat^{h}a k^{h}arap)
9) মাথা খারাপ চিকিৎসা (mat^{h}a k^{h}arap tʃikitsa)
*10)*আসানসোল মাথা খারাপ চিকিৎসা (asansol mat^{h}a k^{h}arap tʃikitsa)
*11)*হাসপাতাল (ɦaspatal)

Component 6: Sense extraction of pattern(s) using LESK algorithm and semantic analysis

After generation of pattern(s), every pattern will be compared with the value of “word_name” field of the table named “table_word” (Table IX) in the modified Bengali WordNet DB. If the pattern matches with the value of “word_name” field of the table named “table_word”, then corresponding “word_id” will be fetched. The fetched “word_id” will be compared with the value of “word_id” field of the table named “table_sense” is shown in Table XI. If the match is found then corresponding synset_id will be retrieved. Finally, the retrieved “synset_id” will be compared with the value of “synset_id” of the table named “table_synset” is indicated in Table X. If the match is found then the corresponding “parts_of_speech”, “gloss_concept_defination”, “example_sentence”, “meaning” and “possible_attribute” field’s values will be retrieved from the table named “table_synset”. The retrieved “possible_attribute” value will be compared with the value of “attribute_name” field of the table named “table_entity_attribute_sensing” is specified in Table XIV. If the“possible_attribute” field’s value of the table named “table_synset” matches with any value of “attribute_name” field of table named “table_entity_attribute_sensing”, then corresponding row value will be fetched from “table_entity_attribute_sensing”.

TABLE IV. POS TAGGING

Array Index	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
POS string array	বিশেষ্য (biʃeʃɔ)	বিশেষ্য (biʃeʃɔ)	বিশেষণ (biʃeʃn)	বিশেষ্য (biʃeʃɔ)	অব্যয় (oboe̯)	বিশেষ্য (biʃeʃɔ)	সর্বনাম (sr[2]bonam)	ক্রিয়া (kir[2]ia)

TABLE V. PATTERN GENERATION OF NOUN PHRASES

Array Index	**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
String array of patter	আসানসোল (asansol)	মাথা (matʰa)	খারাপ (kʰarap)	চিকিৎসা (tʃikitsa)	আসানসোল মাথা (asansol matʰa)	মাথা খারাপ (matʰa kʰarap)	খারাপচিকিৎসা (kʰarap tʃikitsa)	আসানসোলমাথা খারাপ (asansol matʰakʰarap)	মাথা খারাপচিকিৎসা (matʰa kʰarap tʃikitsa)	আসানসোলমাথা খারাপ চিকিৎসা (asansol matʰa kʰarap tʃikitsa)	হাসপাতাল (ɦaspatal)

The row which will be fetched from "table_entity_attribute_sensing" that will be inserted into "table_semantic"is given in Table XVI for semantic analysis where the value of "meaning" field of the tablenamed "table_synset" will be inserted into the "value" field of the table named "table_semantic", If anytime exists NULL value in the "meaning" field then the "value" field of the table named "table_semantic" will also be NULL. Sometimes the pattern may contain more than one value at the "possible_attribue" field. The proposed system fetches all values of "possible_attribute" field and compared with value of "attribute_name" field of the table named "table_entity_attribute_sensing". The matched row values are fetched from "table_entity_attribute_sensing", inserted into "table_semantic" for semantic analysis. If the pattern contains NULL value at their "possible_attribue" field then the pattern simply ignores by the proposed system. If a "word_id" contains only one "synset_id" in the table named "table_sense", that means the pattern is unambiguous .If a"word_id" contains more than one "synset_id" in the table named "table_sense", that means the pattern is ambiguous. To identify the correct sense of the ambiguous pattern, the XBLQPS considers user given query as well as value of the "gloss_concept_defination" and "example_sentence" fields of the table named "table_synset". Next step, the system applies LESK algorithm referred in [27] to find out correct sense of ambiguous pattern(s). The XBLQPS counts the number of common word(s) by comparing between current user given query with the value of "gloss_concept_defination" field of the table named "table_synset" as well as the value of "example_sentence field". The proposed system adds up those above-mentioned count values and selects the row value from the table named "table_synset" which gives maximum count value. The pseudo code of the simplified LESK algorithm is shown in Table VI.

TABLE VI. THE PSEUDO CODE OF THE SIMPLIFIED LESK ALGORITHM

```
Function LESK_simple(word, sentence)
Ideal sense=widely used sense of a word
Maximum common word=0
Context=number of word present in the sentence
Do select every meaning from a set of meaning of every word
Favourite=a set of words present in the gloss example
Collision=compute_collision(favourite, context)
If collision > maximum common word then
Maximum common word=collision
Ideal=meaning
End [27].
```

Eleven patterns have been generated from the user given query; among them five patterns i.eমাথা (matʰa), খারাপ (kʰarap), চিকিৎসা (tʃikitsa), মাথা খারাপ (matʰa kʰarap) and হাসপাতাল (ɦaspatal) match with table named "table_word". The remaining six patterns i.e. আসানসোল (asansol), আসানসোল মাথা (asansol matʰa), খারাপ চিকিৎসা(kʰarap tʃikitsa), আসানসোল মাথা খারাপ (asansol matʰa kʰarap), মাথা খারাপ চিকিৎসা (matʰa kʰarap tʃikitsa) and আসানসোল মাথা খারাপ চিকিৎসা (asansol matʰa kʰarap tʃikitsa) do not match with table named "table_word" and the proposed system treats these mismatched pattern(s) as a value. These values will be compared with the three tables named "table_hospital", " table_department" and "table_doctor" are shown in Table XVII, Table XVIII and Table XIX respectively. These values will be compared with the values present in these three tables and on finding a match with any value of among these above mention three tables, the corresponding attribute name will be retrieved. The retrieved attribute name will be again compared with value of "attribute_name" field of the table named "table_entity_attribute_sensing". If the retrieved attribute name matches with any value of "attribute_name" field of table named "table_entity_attribute_sensing", that corresponding row value will be fetched from "table_entity_attribute_sensing" and inserted into "table_semantic" for semantic analysis. If these values do not match with above mentioned three tables, they are simply ignored by the proposed system.

Among these six patterns, only the pattern আসানসোল (asansol) matches with the value of "hos_add" field of the table named "table_hospital", the attribute name i.e. "hos_add" will be retrieved. The retrieved "hos_add" attribute again will be compared with the value of "attribute_name" field of the table named "table_entity_attribute_sensing". If the "hos_add" matches with "attribute_name" field of the table named "table_entity_attribute_sensing", then the row value will be fetched and will be inserted into "table_semantic" for semantic analysis. Those patterns which match with table named "table_word", some of them are ambiguous and some are unambiguous.

Patterns খারাপ (kʰarap), চিকিৎসা (tʃikitsa) and হাসপাতাল (ɦaspatal) have single "synset_id" means these patterns are unambiguous and their corresponding "possible_attribute" field's value will be retrieved. These retrieved "possible_attribute" will be compared with value of "attribute_name" field of the table named "table_entity_attribute_sensing". If the retrieved attribute name matches with any value of "attribute_name" field of table named "table_entity_attribute_sensing", then corresponding row value will be fetched from "table_entity_attribute_sensing". The row which is fetched from "table_entity_attribute_sensing", will be inserted into "table_semantic" for semantic analysis. Patterns খারাপ (kʰarap) and চিকিৎসা (tʃikitsa) contain NULL value at their "possible_attribute" field that why these patterns will be ignored by the proposed system. Pattern হাসপাতাল (ɦaspatal) contains "hos_name" at their "possible_attribute" field. The value "hos_name" is compared with "attribute_nane" field value of the table named "table_entity_attribute_sensing", then the row value is fetched and inserted into the "table_semantic" for semantic analysis. But patterns মাথা (mat^{h}a) and মাথা খারাপ (mat^{h}a k^{h}arap) contains more than one synset_ids means these patterns are ambiguous. Now the proposed system applies the LESK algorithm on patterns মাথা (mat^{h}a) and মাথা খারাপ (mat^{h}a k^{h}arap) to extract the correct sense.

The pattern মাথা(mat^{h}a) contains more than one sense in the modified Bengali WordNet DB. Here the proposed system uses retrieved "gloss_concept_defination" and "example_sentence" field value from the table named "table_synset" that has been given below.

Sense 1: gloss_concept_defination –কোন পশুর শরীরের উপরের অংশ যেখানে চোখ,নাক, কানযুক্ত থাকে (the upper part of body which contains eyes, nose, ears etc.)

example_sentence –মাথার চিকিৎসা মনোরোগবিদ্যা বিভাগ আছে সেই হাসপাতালে করানো ভালো (It is better to treat mental diseases in a hospital which has psychiatric department.)

Sense 2: gloss_concept_defination –কোন পশু যে দল, সংস্থা অথবা দেশ নিন্ত্রয়ণ করে

matha – head (head of family, head of a state, leader of a nation, head of a group of humans or animals who controls others.).

example_sentence –গ্রামের মাথাদের কথাই শেষ কথা (The words of the head of a village is final). Here head of a village is human being.

The user given query will be compared with the "gloss_concept_defination" as well as "example_sentence" field value of the pattern মাথা. The sense 1 contains maximum number of overlapping word(s). These overlapping words are মাথা, চিকিৎসা and হাসপাতাল. But the sense 2 does contain only one overlapping word i.e. মাথা. So the sense 1 will be closest sense of the pattern মাথা and the value of "possible_attribute" field of that row of the "table_synset" is to be selected. The retrieved possible attribute name is again compared with value of "attribute_name" field of the table named "table_entity_attribute_sensing". If the retrieved attribute name matches with any value of "attribute_name" field of the table named "table_entity_attribute_sensing", then corresponding row value will be fetched from the "table_entity_attribute_sensing". The row which will be fetched from "table_entity_attribute_sensing", and that will be inserted into "table_semantic" for semantic analysis.

The pattern মাথা খারাপ (mentally challenged) contains more than one sense in the modified Bengali WordNet DB. Similarly, the proposed system will retrieve "gloss_concept_defination" and "example_sentence" field value from the table named "table_synset" that has been given below.

Sense 1: gloss_concept_defination –কোন জীব যে উন্মাদ বা মানসিক অসুস্থ (a mentally challenged living being.)

example_sentence –মাথা খারাপের রোগীকে মানসিকরোগের হাসপাতালের ডাক্তার দ্বারা চিকিৎসা করানো দরকার (mentally challenged people should be treated by psychiatric doctor)

Sense 2: gloss_concept_defination –কোন অনিশ্চতার সমন্ধে উদ্বেগ (to be unusually anxious over a trivial matter.)

example_sentence –তুচ্ছ ব্যপার নিয়ে তুমি মাথা খারাপ করোনা (Do not be anxious over such a small matter.)

The user given query will be compared with "gloss_concept_defination" as well as "example_sentence" field value of the pattern মাথা খারাপ. The sense 1 contains maximum number of overlapping word(s). The overlapping word is চিকিৎসা. But the sense 2 does not contain any overlapping word(s). So the sense 1 will be closest sense of the pattern মাথা খারাপ and the value of "possible_attribute" field of that row of the "table_synset" is to be selected. The retrieved possible attribute name will be compared again with value of "attribute_name" field of the table named "table_entity_attribute_sensing". If the retrieved attribute name matches with any value of "attribute_name" field of table named "table_entity_attribute_sensing", then corresponding row value will be fetched from "table_entity_attribute_sensing". The row which will be fetched from "table_entity_attribute_sensing", and that will be inserted into "table_semantic" for semantic analysis. Our proposed system has disambiguated two Bengali ambiguous words মাথা and মাথাখারাপ asমনোরোগ (mental disease) for current context. Therefore two same entries occur for id 4 and 6 in Table VII. The instance of "table_semantic" for above mention user query has been given in Table VII.

TABLE VII. SENSE EXTRACTION OF PATTERN (S) USING LESK ALGORITHM AND SEMANTIC ANALYSIS

id	entity	attribute_name	primary_key	foreign_key	candidate_key	value
1	table_hospital	hos_add	hos_id			আসানসোল(asansol)(propoer Noun)
2	table_hospital	hos_name	hos_id			
3	table_department	dept_name	dept_id	hos_id		মনোরোগ(mnor[2]og)(mental disease)
4	table_doctor	doc_specialist	doc_id	hos_id	dept_id	মনোরোগ(mnor[2]og)(mental disease)
5	table_department	dept_name	dept_id	hos_id		মনোরোগ(mnor[2]og)(mental disease)
6	table_doctor	doc_specialist	doc_id	hos_id	dept_id	মনোরোগ(mnor[2]og)(mental disease)

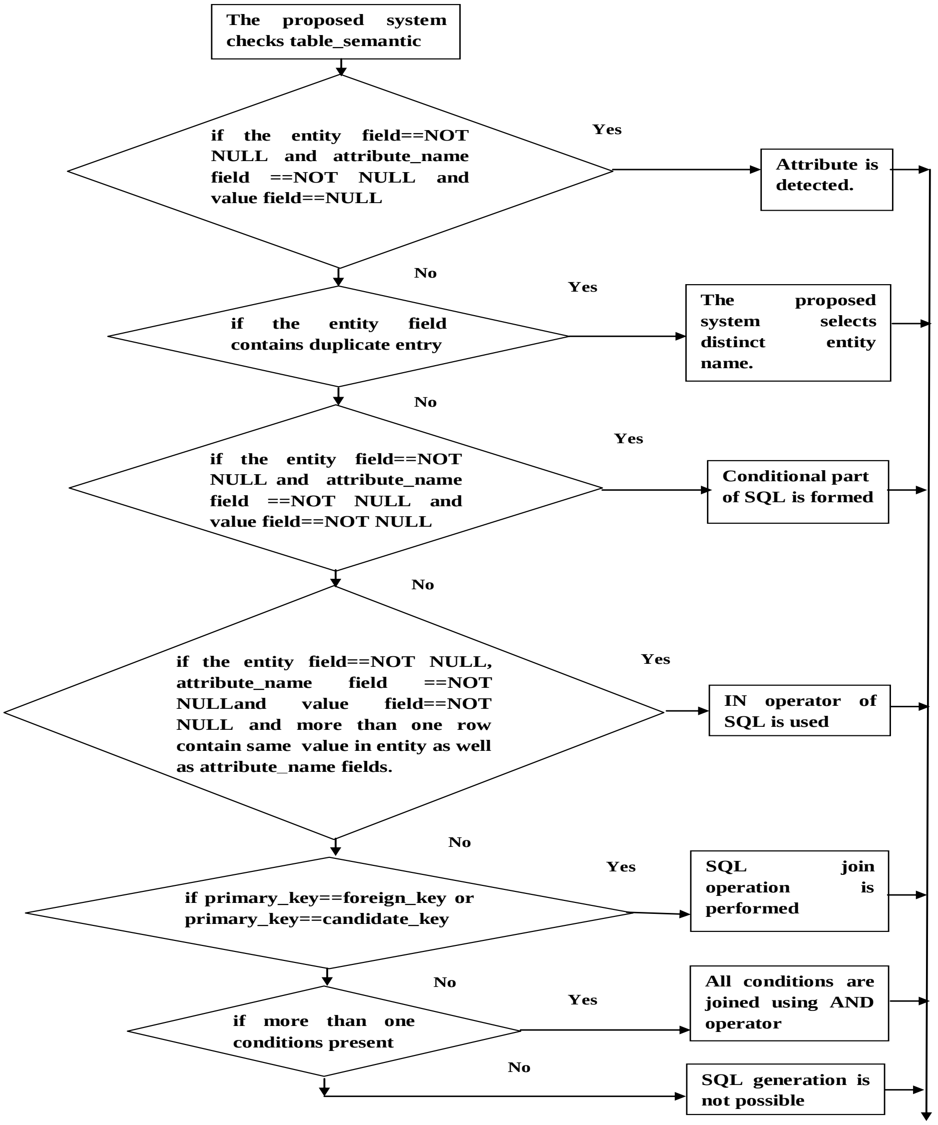
Component 7: SQL formation

The proposed system will generate SQL from “table_semantic”. The proposed system will consider only one entry if more than one rows have the same value in entity, “attribute_name”, “primary_key”, “foreign_key”, “candidate_key” and “value” fields. Id 4 and 6 contains same values in“entity”, “attribute_name”, “primary_key”, “foreign_key”, “candidate_key” and “value fields”. One entry will be deleted between id 4 and 6 from the “table_semantic”. Hence the refinement instance of the table named “table_semantic” has been given in Table VIII.

Some predefine postulates have been taken for SQL formation from one of our research article has been described in [6]. The desired result retrieving query in SQL can be given by SELECT attribute 1, attribute 2, attribute 3… attribute n FROM entity 1 (table 1), entity 2 (table 2), entity 3 (table 3)… entity n (table n) WHERE condition 1 and condition 2 and condition 3… and condition n. There are few clauses are fixed any retrieving query. These are SELECT, FROM and WHERE. The proposed system has to determine the correct possible attribute(s), entities and condition(s). Predefine postulates have been described below as well as conditional flowchart has been given in Fig. 3.

TABLE VIII. REFINEMENT TABLE OF SEMANTIC TABLE

id	entity	attribute_name	primary_key	foreign_key	candidate_key	value
1	table_hospital	hos_add	hos_id			আসানসোল(asansol)(propoer Noun)
2	table_hospital	hos_name	hos_id			
3	table_department	dept_name	dept_id	hos_id		মনোরোগ(mnor[2]og)(mental disease)
4	table_doctor	doc_specialist	doc_id	hos_id	dept_id	মনোরোগ(mnor[2]og)(mental disease)



The proposed system checks table_semantic
if the entity field==NOT NULL and attribute_name field ==NOT NULL and value field==NULL
Yes
Attribute is detected.
No
if the entity field contains duplicate entry
Yes
The proposed system selects distinct entity name.
No
if the entity field==NOT NULL and attribute_name field ==NOT NULL and value field==NOT NULL
Yes
Conditional part of SQL is formed
No
if the entity field==NOT NULL, attribute_name field ==NOT NULLand value field==NOT NULL and more than one row contain same value in entity as well as attribute_name fields.
Yes
IN operator of SQL is used
No
if primary_key==foreign_key or primary_key==candidate_key
Yes
SQL join operation is performed
No
if more than one conditions present
Yes
All conditions are joined using AND operator
No
SQL generation is not possible

Fig. 3. Conditional Flowchart for SQL Rules Generation.

Postulate i: The proposed system predicts attribute if the “entity” field, “attribute_name” field and “value” field of the table named “table_semantic” contain NOT NULL, NOT NULL, NULL value respectively, then whatever attribute present in the “attribute_name” field is treated as attribute. In case such type of condition does not occur, then the proposed system considers all attributes i.e. denoted by “*”. Finally this attribute is appended by “.” operator with their corresponding entity field value of that row.

Postulate ii: The system predicts entity name from entity field value(s) of the table named “table_semantic”. For duplicate entry the system selects distinct entity field value.

Postulate iii: The proposed system predicts condition if the “entity” field, “attribute_name” field and “value” field of the table named “table_semantic” does not contain NULL, NULL, NULL value respectively, then whatever attribute present in the “attribute_name” field will be treated as condition. This attribute will be appended by “.” operator with their corresponding entity field value followed by “=” symbol and value of the field value of that row in the semantic table.

Postulate iv: The proposed system determines IN clause in condition if the “entity” field, “attribute_name” field and value field of the table named “table_semantic” does not contain NULL, NULL, NULL value respectively. More than one row in the table named “table_semantic”, the “entity” field as well as corresponding “attribute_name” field contains same value means that particular attribute of that entity has a list of values. Then the attribute will be appended by “.” operator with their corresponding “entity” field value followed by IN clause and a list of values will be placed within opening and closing parenthesis separated by “,”.

Postulate v: The “primary_key” field value of one entity matches with “foreign_key” or “candidate_key” of other entity that means joining occurs.It is a property of relational database. The proposed system appends matched “primary_key” field value by “.” with corresponding “entity” field value followed by “=” symbol and matched “foreign_key” or “candidate_key” value append by “.” with corresponding “entity” field value.

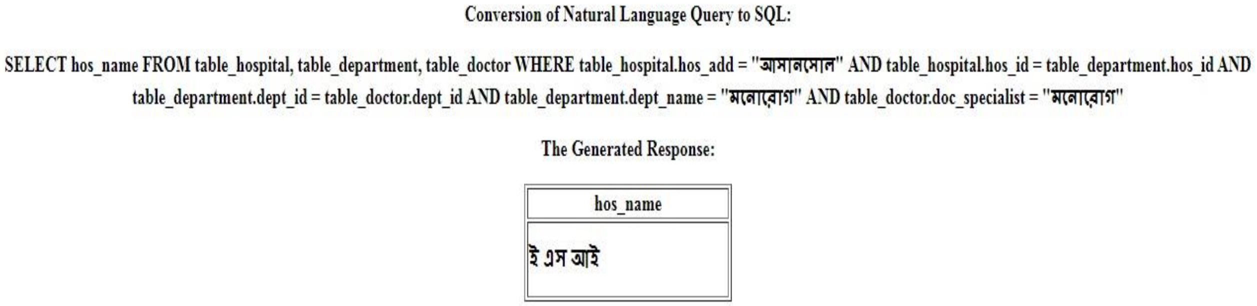
Postulate vi: The proposed system combines all conditions using AND operator if more than one conditions are present.

The proposed system converts the user given Bengali query i.e. আসানসোলে মাথা খারাপের চিকিৎসার জন্য হাসপাতাল কোথায় আছে? into SQL has been given below.

SELECT hos_name FROM table_hospital, table_department, table_doctor WHERE table_hospital.hos_add= 'আসানসোল' AND table_hospital.hos_id = table_department.hos_id AND table_department.dept_id = table_doctor.dept_id AND table_department.dept_name = 'মনোরোগ' AND table_doctor.doc_specialist = 'মনোরোগ'.

Component 8: SQL executed by the proposed system.

The proposed system will execute the SQL that will be generated from user given query i.e. given in Bengali language. After execution of the SQL, the expected result will be generated. The response of the user query1 has been given in Fig. 4.



Conversion of Natural Language Query to SQL:

```
SELECT hos_name FROM table_hospital, table_department, table_doctor WHERE table_hospital.hos_add = "আসানসোল" AND table_hospital.hos_id = table_department.hos_id AND
table_department.dept_id = table_doctor.dept_id AND table_department.dept_name = "মনোরোগ" AND table_doctor.doc_specialist = "মনোরোগ"
```

The Generated Response:

hos_name
ই এস আই

Fig. 4. Response of the Query 1 in Bengali.

VI. Modified Bengali WordNet and Health Information Databases

The data repository of XBLQPS is made up of a modified Bengali WordNet database and a health information database. The modified Bengali WordNet database has been developed with help of Bengali WordNet database as referred in [3]. Table IX, Table XI, Table XII and Table XIII has been kept same as the Bengali WordNet whereas, Table X has been modified by introducing two fields named meaning and “possible_attribute” by the authors. The Health information database contains other tables named “table_inflectional_part”,“table_entity_attribute_sensing”,“table_semantic”,“table_hospital”,“table_department” and “table_doctor” which have been introduced and developed by the authors. The table named “table_semantic”, “table_hospital”, “table_department” and “table_doctor” have been taken from our research article referred in [6]. The proposed system thus has modified the original WordNet database of [3] and shall now be termed as “Modified Bengali WordNet DB”. Each word in the Modified Bengali WordNet DB contains its parts of speech definition introduced manually as according to the largest probability of its use. We have not referred to any standard Bengali POS Tagger but to our own prepared POS definitions in Modified Bengali WordNet DB. The Modified Bengali WordNet DB and Health information database consist of a set of tables as follows:

Structure of table “table_word”

The table named “table_word” consists of two fields’ “word_id” and “word_name”. The field “word_id” is primary key field whereas “word_name” field contains Bengali word.Data types and sizes of these two fields are int(10) and varchar(100) respectively. The instance of the table “table_word” has been given in Table IX.

TABLE IX. STRUCTURE OF TABLE “TABLE_WORD”

word_id	**word_name**
7	বিভাগ(bib^{ɦ}aɡ) (department)
16	অপথ্যালমোলজি （ɔpt^{h}ɛlmolodʒi）(ophthalmology)
23	মাথাখারাপ(mat^{h}ak^{h}arap) (mental disease)

Structure of table “table_synset”

The table named “table_synset” consists of “synset_id”, “parts_of_speech”, “gloss_concept_defination”, “example_sentence”, “meaning” and “possible_attribute”. The “synset_id” is the primary key field of this table. The “parts_of_speech” field contains possible parts of speech value of the Bengali word which is stored in table “table_word”. The “gloss_concept_defination”, “example_sentence” and “meaning” field contain definition, example of sentence and meaning of above mention Bengali word respectively. The “possible_attribute” field contains likelihood relationship of a particular Bengali word with medical domain. If a “possible_attribute” field does not contain any value that means it has NULL value.Data types and sizes of these six fields are int(10), varchar(50), varchar(150), varchar(200), varchar(300) and varchar(150) respectively. The instance of the table “table_ synset” has been given in Table X.

TABLE X. STRUCTURE OF TABLE “TABLE_SYNSET”

synset_id	**parts _of_ speech**	**gloss _concept_ definition**	**example_sentence**	**meaning**	**possible_attribute**
2	বিশেষ্য(biʃeʃo)(noun)	একটি প্রতিষ্ঠানের বিশেষ অংশ	রবি রয় অস্থিচিকিৎসা বিভাগে রডাক্তার		dept_name
5	বিশেষ্য(biʃeʃo)(noun)	চক্ষুরোগ সমন্ধীয় চিকিৎসা	চক্ষুরোগে আক্রান্ত ব্যক্তি রাত্রে চশমা ব্যবহার করেন	চক্ষুবিজ্ঞান	dept_name,doc_specialist
10	ক্রিয়া(kir[2]ia) (verb)	কোন অনিশ্চতার সমন্ধে উদ্বেগ	তুচ্ছ ব্যপার নিয়ে তুমি মাথা খারাপ করোনা	বিরক্ত করা	

Structure of table “table_sense”

The table named “table_sense” has two fields. These two fields are “word_id” and “synset_id”. The primary key field consists of both fields. This table is used to map a “word_id” to its corresponding “synset_id”. Data types and sizes of these two fields are int(10) and int(10) respectively. The instance of the table “table_ sense” has been given in Table XI.

TABLE XI. STRUCTURE OF TABLE “TABLE_SENSE”

word_id	**synset_id**
7	2
16	5
23	10

Structure of table “table_hypernym”

The table named “table_hypernym” consists of two fields. These two fields are “synset_id” and “hypernym_id". The “synset_id” field stores the synsetid value of a Bengali word which is stores in the table “table_word” whereas “hypernym_id” field value is nothing but a “synset_id” of a another word. These two words have hypernym and hyponym relationship.Data types and sizes of these two fields are int(10) and int(10) respectively. The instance of the table “table_hypernym” has been given in Table XII.

TABLE XII. STRUCTURE OF TABLE “TABLE_HYPERNYM”

synset_id	**hypernym_id**
7	3
8	3

Structure of table “table_tree”

The table named “table_tree” consists of two fields. These two fields are “hypernym_id” and “parent_id”. The “hypernym_id” is “synset_id” of a Bengali word. The “parent_id” is parent word id of a hypernym word. This table maintains the hierarchical relationship between hypernym and hyponym word. The parent_id field value contains zero that represents root word of the tree. Data types and sizes of these two fields are int(10) and int(10) respectively. The instance of the table “table_tree” has been given in Table XIII.

TABLE XIII. STRUCTURE OF TABLE “TABLE_TREE”

hypernym_id	**parent_id**
3	0

Structure of table “table_entity_attribute_sensing”

The table named “table_entity_attribute_sensing” consists of “id”, “entity”, “attribute_name”, “primary_key”, “foreign_key” and “candidate_key”. The “id” field is the primary key field of this table. The “entity” field contains name of participating entities in medical domain. The “attribute_name” field stores attribute name, “primary_key” field contains primary key, “foreign_key” contains foreign key and “candidate_key” stores candidate key value of corresponding entity. The sometimes foreign key and candidate key may not exist, that time these key fields contain NULL value.The “table_entity_attribute_sensing” is an independent table. This tablehas been used to map entity from attribute, or primary key, foreign key, candidate key from entity.Data types and sizes of these six fields are int(10), varchar(50), varchar(50), varchar(50), varchar(50) and varchar(50) respectively. The instance of the table “table_entity_attribute_sensing” has been given in Table XIV.

TABLE XIV. STRUCTURE OF "TABLE_ENTITY_ATTRIBUTE_SENSING"

id	entity	attribute_name	primary_key	foreign_key	candidate_key
1	table_hospital	hos_name	hos_id		
2	table_hospital	hos_add	hos_id		
3	table_hospital	hos_district	hos_id		

Structure of table "table_inflectional_part"

The table named "table_inflectional_part" consists of "id" and "inflectional_part". The id field is primary key field of this table. The "inflectional_part" field stores inflectional part of the Bengali word. Data types and sizes of these two fields are int(10) and varchar(50) respectively. The instance of the table "table_inflectional_part" has been given in Table XV.

TABLE XV. STRUCTURE OF "TABLE_INFLECTIONAL_PART"

id	inflectional_part
1	টি(t̪i)
2	ে(e)
3	ের(er[2])

Structure of table "table_semantic"

The table named "table_semantic" includes id, entity, "attribute_name", "primary_key", "foreign_key", "candidate_key" and "value" fields. The "id" field is the primary key of this table. The entity name, corresponding attribute name, primary key, foreign key, candidate key and value are held by fields named"entity", "attribute_name", "primary_key", "foreign_key", "candidate_key" and "value" respectively. The "table_semantic" is an independent table. This table has been used to construct the SQL.Data types and sizes of these seven fields are int(10), varchar(50), varchar(50), varchar(50), varchar(50), varchar(50) and varchar(100) respectively. The instance of the table "table_semantic" has been given in Table XVI.

TABLE XVI. STRUCTURE OF "TABLE_SEMANTIC"

id	entity	attribute_name	primary_key	foreign_key	candidate_key	value
1	table_hospital	hos_add	hos_id			আসানসোল(asansol) (propoer Noun)
2	table_hospital	hos_name	hos_id			
3	table_department	dept_name	dept_id	hos_id		মনোরোগ(mnor[2]og)(mental disease)

Structure of table "table_hospital"

The table named "table_hospital" includes "hos_id", "hos_name", "hos_add", "hos_district", and "hos_state" fields. The "hos_id" field is the primary key of this table. This "hos_id" field used to identify uniquely each entity instance of the table. The hospital name, hospital address, district name and state name where hospital is situated, are held by fields named "hos_name", "hos_add", "hos_distrct", and "hos_state" respectively.Data types and sizes of these five fields are int(10), varchar(100), varchar(100), varchar(100) and varchar(100) respectively. The instance of the table named "table_hospital" has been given in Table XVII.

TABLE XVII. STRUCTURE OF "TABLE_HOSPITAL"

hos_id	hos_name	hos_add	hos_district	hos_state
1	মুর্শিদাবাদজেলাহাসপাতাল (mur[2]ʃidabaddʒelaɦaspatal) (Murshidabad District Hospital)	লালগোলা(lalgola) (Lalgola) (proper noun)	মুর্শিদাবাদ (mur[2]ʃidabad) (Murshidabad) (proper noun)	পশ্চিমবঙ্গ(pʃt̪ʃimbɔŋg) (West Bengal) (proper noun)
8	হাওড়াজেলাহাসপাতাল (ɦaoɽadʒelaɦaspatal) (Howrah District Hospital)	আমতা(amta) (Amta) (proper noun)	হাওড়া (ɦaoɽa) (Howrah)(proper noun)	পশ্চিমবঙ্গ(pʃt̪ʃimbɔŋg) (West Bengal) (proper noun)

Structure of table "table_department"

The table named "table_department" includes "dept_id", "dept_name", and "hos_id"fields.Data types and sizes of these three fields are int(10), varchar(100) and int(10) respectively. The instance of the table "table_department" has been given in Table XVIII.

TABLE XVIII.STRUCTURE OF "TABLE_DEPARTMENT"

dept_id	dept_name	hos_id
70	নবজাতক(nbdʒatk) (neonate)	7
170	মনোরোগ(mnor[2]og) (psychiatry)	12

Structure of table "table_doctor"

The table named "table_doctor" includes "doc_id", "doc_name", "doc_qualification", "doc_ specialist", "hos_id" and "dept_id" fields. Data types and sizes of these six fields are int(10), varchar(100), varchar(100), varchar(100), int(10) and int(10) respectively. The instance of the table "table_doctor" has been given in Table XIX.

TABLE XIX. STRUCTURE OF "TABLE_DOCTOR"

doc_id	doc_name	doc_qualification	doc_specialist	hos_id	dept_id
1000	কেয়া গরাই(kea gr[2]ai̯) (Keya Gorai)	এম.বি.বি.এস. (M.B.B.S.)	অপথ্যালমোলজি(ɔptʰɛlmolodʒi) (Ophthalmologist)	1	10
1010	শমীতা দাশগুপ্ত(ʃmita daʃgupta) (Shamita Dasgupta)	এম.ডি. (M.D.)	অস্থি(ɔstʰi) (Orthopaedist)	2	20

VII. TOOLS AND INTERNATIONAL PHONETIC ALPHABET (IPA) NOTATION USED

Software tools like HTML, PHP, MySQL and Avro Bengali keyboard has been used to developed the XBLQPS. The HTML has been used to develop the web pages structure. A sever side scripting language i.e. PHP has been used to provide customize interface as well as process the user request. MySQL is used as back end database to store the data. The IPA notation for Bengali language has been taken from the website https://en.wikipedia.org/wiki/Help:IPA/Bengali.

VIII. TIME COMPLEXITY

The time complexity has been calculated for algorithmic steps of the proposed system.

Step 1: Login into the system and submit the query in Bengali language.

Let, as an example query আসানসোলে মাথা খারাপের চিকিৎসার জন্য হাসপাতাল কোথায় আছে?. The time complexity has been calculated on the proposed algorithm using the above example query. The time has been calculated in each algorithmic step that is given below.

Step 2: Tokenization

Let, there be n number of token(s) in user given query has been given in Fig. 5.

Time taken for tokenization of n token(s) = n unit time.

The number of tokens will be generated from above example query has been given in Table XX.

Here for this query time taken for tokenization=8 unit time because number of token(s) i.e. n=8.

Step 3: Root word extraction

Let, there be p numbers(s) of inflection part in the table “table_inflectional_part”, and also assume that q number(s) of token(s) which are matched with value of “inflectional_part” field.

∴ Time taken= p×q unit time.

Here p=3, q=3.

Therefore, time taken=3×3=9-unit time.

Step 4: POS tagging

Let, there be r number(s) of “word_name” in the “table_word”.

Let, there be r number of “word_id” and “synset_id” in the table “table_sense”.

Let, there be r number(s) of parts of speech in the table “table_synset”.

∴Time taken = (p×r+r×r+r×r) unit time.

Here r=3 for “table_word”.

r=3 for “table_sense”.

r=3 for “table_sysnset”.

∴Time taken= (3×3+3×3+3×3) unit time=27-unit time.

Step 5: Pattern generation of noun phrases

Let, n number(s) of token(s) are participating for pattern generation where the token occurrence orders are to be maintained.

∴Time taken=n+(n-1) +(n-2)+⋯+1-unit time.

=n/2 (n+1)

There are 11 numbers of patterns which are already generated in Table V.

Therefore, time taken = 11 unit time.

Step 6: Sense extraction of pattern(s) using LESK algorithm and semantic analysis.

Time taken for unambiguous pattern={n+(n-1)+(n-2)+⋯+1}(r+r+r) unit time.

=n/2 (n+1)(r+r+r)

Let, there be u number(s) of similar “word_id” in the “table_sense”.

Let, v number(s) of “synset_id” contains “possible_attribute” field value among u number(s) of similar “synset_id”.

Let, x number(s) of values exists “attribute_name” in the table “table_entity_attribute_sesing”.

Let, y number(s) of instance(s) have been inserted in the table “table_semantic”.

Time taken for ambiguous pattern={ n+(n-1)+(n-2)+⋯+1}(r+r×u+u×r+v×x+v×y) unit time.

Time taken for unambiguous patterns =8(3+3+3)=72 unit time.

u=number of similar “word_id” in the “table_sense” =3.

v=3, x=3, y=6.

∴Time taken for ambiguous patterns= 8(3+3×3+3×3+3×3+3×6) unit time=384 unit time.

1	2	3	…	n - 2	n - 1	n

Fig. 5. Token(s) of user given Query.

TABLE XX. TOKEN OF USER GIVEN QUERY.

Number of tokens	1	2	3	4	5	6	7	8
Token of example query	আসানসোলে (asansole)	মাথা (matʰa)	খারাপের (kʰaraper)	চিকিৎসার (tʃikitsar)	জন্য (dʒno)	হাসপাতাল (ɦaspatal)	কোথায় (kotʰae̯)	আছে (atʃʰe)

Step 7: SQL formation

Let, time taken for SQL formation=z unit time.

6 postulates have been applied on 4 rows of “table_semantic” to form SQL.

∴Time taken =(4×6) unit time =24 unit time.

Step 8: SQL executed by the proposed system

Let, time taken for SQL execution=t unit time.

∴Time complexity =f(n,p,q,r,t,u,v,x,y,z)

=n+p×q+(p×r+r×r+r×r)+n+(n-1)+(n-2)+⋯+1+{n+(n-1)+(n-2)+⋯+1}(r+r+r)+{n+(n-1)+(n-2)+⋯+1}(r×u)+r×u+u×r+v×x+v×y+z+t

∴f(n)≅n+n×n+(n×n+n×n+n×n)+n+(n-1)+(n-2)+⋯+1+{n+(n-1)+(n-2)+⋯+1}(n+n+n)+{n+(n-1)+(n-2)+⋯1}n+n×n+n×n+n×n+n×n+n+n

$$= n + n^2 \; + 3n^2 + \frac{n}{2}(n+1) + \left\{\frac{n}{2}(n+1)\right\}(3n) + \left\{\frac{n}{2}(n+1)\right\} n + n^2 + n^2 + n^2 + n^2 + n + n = n + 4n^2 + \frac{n^2}{2} + \frac{n}{2} + \frac{3n^2}{2}(n+1) + \frac{n^2}{2}(n+1) + 4n^2 + n + n$$

$$= n + 8n^2 + \frac{n^2}{2} + \frac{n}{2} + \frac{3n^3}{2} + \frac{3n^2}{2} + \frac{n^3}{2} + \frac{n^2}{2} + n + n$$

$$= O(n^3)$$

Time taken for SQL execution t=11 unit time.

∴Time complexity algorithm.

= (8+9+27+11+72+384+24+11) unit time.

=546 unit time.

IX. Precision, Recall and Accuracy Analysis of the XBLQPS

Example of Precision, recall and accuracy analysis of the proposed XBLQPS.

111 numbers of queries have been submitted into the proposed system by the user. Four different types of queries based on their output have been given as examples. The output has been classified into “expected output” and “select output”. “expected output” and “select output” have been further categorized into positive and negative. The Confusion Matrix [23], [24] for the proposed system has been given in Table XXI.

TABLE XXI. Confusion Matrix

Expected output Vs. Select output	**Select output-Positive**	**Select output-Negative**
Expected output-Positive	True positives (TP)-46	False positives (FP)-16
Expected output-Negative	False negatives (FN)-17	True negatives (TN)-32

Some categorized sample queries has been given below as an example.

TP- আসানসোলে মাথা খারাপের চিকিৎসার জন্য হাসপাতাল কোথায় আছে?

TN- বাকুড়া জেলাহাসপাতালে অ্যাম্বুলেন্সের ব্যবস্থা আছে?

FP- সুমিত রায়ের শিক্ষাগত যোগ্যতা কি?

FN-বাকুড়া হাসপাতাল

Precision = TP/(TP+FP)=46/(46+16)=46/62=0.74

Our system has a precision of 0.74 - in other words, when it predicts a query is fetched, it is correct 74% of the time.

Recall = TP/(TP+FN)=46/(46+17)=46/63=0.73

Our system has a recall of 0.73 - in other words, it correctly identifies 73% of all fetched queries.

Accuracy=(TP+TN)/(TP+FP+FN+TN)=(46+32)/(46+16+17+32)=78/111=0.70

Our system has an accuracy of 0.70 - in other words, it gives 70% correct predictions of fetched queries.

F1 Score = 2*(Recall * Precision) / (Recall + Precision)=(2*0.73*0.74)/(0.73+0.74)=1.08/1.47=0.73

Our system has F1 score is 0.73 – in other words, overall measure of our system’s accuracy is 73%.

X. Future Work

The XBLQPS uses a simplified version of the LESK algorithm. It depends on the maximum number of the common word(s) between word gloss and the current context of the word. As the gloss may be limited for a domain in the proposed Bengali WordNet, it may happen that the proposed system sometimes fails to disambiguate an ambiguous word. Our proposed system uses a manually annotated parts of speech method for the detection of parts of speech of a word which is based on the largest probability of its use. The proposed system needs to be improved by using a modified version of the LESK algorithm and automated POS tagging method for better handling natural language queries with ambiguous words and this can be marked as a future work of this proposed system.

XI. Conclusion

The XBLQPS uses a simplified version of the LESK algorithm. It depends on the maximum number of the common word(s) between word gloss and the current context of the word. As the gloss may be limited for a domain in the proposed Bengali WordNet, it may happen that the proposed system sometimes fails to disambiguate an ambiguous word. Our proposed system uses a manually annotated parts of speech method for the detection of parts of speech of a word based on the largest probability of its use. In the future, the proposed system needs to be improved by using a modified version of the LESK algorithm and automatic POS tagging method for better efficiency wherein the gloss shall be enhanced to accommodate several synonymous applications of a word in that particular domain. Moreover, we may enhance the proposed system to work with unstructured databases. Retrieving data from a relational database management system from a Bengali language query containing the ambiguous word is a challenging task. The proposed XBLQPS will be able to handle a domain-specific Bengali language query containing an ambiguous word which will be helpful even for a naive user. The naïve user can access the database without knowledge of for-mal language i.e. SQL (Structured Query Language). The XBLQPS is an enhancement and advanced form of BLQPS of the work discussed in [6]. The XBLQPS incorporates the handling of ambiguous Bengali words using the LESK algorithm and a modified WordNet in Bengali. The time complexity, precision, recall, accuracy and F1 score have been analyzed for our proposed system. The time complexity of XBLQPS is $O(n^3)$ as compared to the time complexity of BLQPS of [6] which is $O(n^4)$ which shows that the time efficiency of XBLQPS is better than BLQPS.

ACKNOWLEDGMENT

This study was conducted at the National Institute of Technology (NIT), Durgapur, Research Project Lab, which is part of the Department of Computer Science and Engineering. The authors express their gratitude to the Department of Computer Science and Engineering, NIT, Durgapur, India, for providing educational resources for this research.

Kailash Pati Mandal his obtained Bachelor of Technology in Computer Science and Engineering from Bengal College of Engineering and Technology, Durgapur, India in 2006. In 2011, he received Master's degree in Computer Science and Engineering from the Jadavpur University, Kolkata, India. He is currently a part-time Researcher in Computer Science and Engineering in the field of Natural Language Processing at the National Institute of Technology (NIT), Durgapur, India.

Prasenjit Mukherjee obtained his PhD in Computer Science and Engineering from National Institute of Technology (NIT), Durgapur, India under Visvesvaraya PhD scheme Program, Ministry of Electronics and Information Technology (MeitY), Govt. of India. His research interests include machine learning, deep learning, natural language processing, knowledge engineering, and database management systems. He has more than 15 international publications.

Atanu Chattopadhyay received the M.Sc degree in Applied Mathematics and Computing from Indian Institute of Technology (Indian School of Mines), Dhanbad, India. He is presently a fulltime Lecturer in the Department of BBA(H) & BCA (H), Deshabandhu Mahavidyalaya, Chittaranjan, West Bengal, India. His research interest includes Mathematical Analysis and Natural Language Processing.

Baisakhi Chakraborty obtained her PhD in Computer Science and Engineering from National Institute of Technology, Durgapur, India in 2011. Her research interests include knowledge systems, knowledge engineering and management, database systems, data mining, natural language processing, and software engineering. She has several researchers under her direction. She has more than 30 international publications. She has a decade of industry experience and 17 years of academic experience.

MSDAR: Multi-Stage Dynamic Architecture Intrusion Detection System

Ahmed M. ElShafee[1]
Ahram Canadian University
Cairo, Egypt

Marianne A. Azer[2]
National Telecommunication Institute
Nile University, Cairo, Egypt

***Abstract*—Ad hoc networks have been through extensive research in the last decade. Even with their desirable characteristics, major issues related to their security need to be considered. Various security solutions have been proposed to reduce the risks of malicious actions. They mainly focus on key management, authentication, secure localization, and aggregation techniques. These techniques have been proposed to secure wireless communications but they can only deal with external threats. Therefore, they are considered the first line of defense. Intrusion detection systems are always required to safeguard ad hoc networks as such threats cannot be completely avoided. In this paper, we present a comprehensive survey on intrusion detection systems in ad hoc networks. The intrusion detection systems and components and taxonomy as well as different implementations and types of IDSs are studied and categorized. In addition, we provide a comparison between different Intrusion Detection Systems' architectures. We also propose a Multi Stage Dynamic Architecture intrusion detection system (MSDAR), designed with a multi-stage detection approach making use of both signature-based and anomaly detection benefits. Our proposed intrusion detection system MSDAR is featured by its dynamic architecture as it can be deployed in the network using the Distributed Hierarchical Architecture. The viability and performance of the proposed system MSDAR are tested against the Distributed Denial of Service Attacks through simulations. Advanced performance parameters were used to evaluate the proposed scheme MSDAR. Experimental results have shown that the performance of MSDAR improves by using multiple stages of different detection mechanisms. In addition, based on simulations, the Detection Rate increases when the sensitivity level increases.**

Keywords—Ad hoc networks; attacks; DDoS; intrusion detection; security

I. Introduction

Emerging technologies have contributed in revolutionizing our daily life. To mention a few, Artificial Intelligence (AI) [1], Blockchain, cryptocurrencies [2], Internet of Things (IoT) [3], cloud computing, and wireless technology. Wireless technology is critical to today's communications [4], and essential to developing technologies within the next years. Wireless communications are almost based on ad hoc or special purpose connections. Mobile Ad hoc Networks (MANETs) are key players in the future of wireless communication [5]. They consist of distributed nodes without any predetermined infrastructure [6]. The lightweight mobile devices have the capabilities of sensing and processing received information [7]. The devices have a limited transmission range that needs intermediate nodes to reach other far nodes. Due to their special features, ad hoc networks are susceptible to a wide range of attacks [8], exterior and interior threats and misbehaving modes [9]. Some of these attacks are initiated to deprive legitimate users of network services. Other attacks have the objective of gaining unauthorized access to network resources [10].

MANETs have many different challenges regarding designing security solutions due to their vulnerability to eavesdropping, lack of trusted management, limited computation capabilities, and power sources which increase their vulnerability to Denial of Service (DoS) attacks and also can become incapable of running heavy security algorithms. Due to the open, self-organized, infrastructure-less environment of MANETs, there is a chance that trusted nodes to be hijacked. Therefore, any security solution should be designed to defend the network against both insider and outsider attacks. In MANETs, insider attacks are more problematic and difficult to overcome. Security solutions for ad hoc networks are considered to be one of the most active and attractive research areas. Researchers mainly focus on key management [11], authentication, secure localization, and aggregation techniques to secure wireless communications [12]. The current security solutions can only deal with external threats, and therefore they can be considered the first line of defense. However, insider attackers that already exist within the first perimeter of defense can penetrate the whole network and cause severe damage. Therefore, Intrusion Detection Systems are considered the second line of defense as they come into action after the intrusion has already occurred [13]. There are two types of Intrusion Detection Systems (IDSs), signature based detection IDS, and anomaly-based detection IDS [14]. Signature-based IDSs (misuse detection) require a knowledge base containing the behavioral patterns of different attacks. When the IDS detects a certain pattern that refers to an attack, it alerts the network's users against this specific attack. The main disadvantage in such implementation is that only known attacks are caught and reported. This may surge the percentage of false negatives. On the other hand, anomaly detection, IDSs (behavior-based detection) are not designed to catch threats using their signature or pattern. They are developed to learn the normal behavior patterns of both users and network applications to discover and report any altered patterns. In anomaly-based IDSs, new and unknown attacks can be detected and reported whenever they occur. However, any abnormal benign behaviors will be caught and reported as new threats. This may increase the percentage of false positives.

This research introduces a newly developed trust-based IDS for wireless ad hoc networks. The proposed Multi Stage Dynamic Architecture Intrusion Detection System (MSDAR) takes into consideration multistage detection mechanisms to increase its capability to detect different types of intrusions. The first and third stages are based on anomaly detection, while the second is signature-based detection. In the third stage, an additional parameter is used, it is called the sensitivity level.

The contributions of this paper are as follows.

1) The Intrusion Detection Systems components and taxonomy as well as different implementations and types of IDSs are studied and categorized. The study's objective is to understand the algorithms and design parameters and their impact on performance and functionality.

2) A comparison between different Intrusion Detection Systems' architectures from the points of view of complication, precision, scalability, and possibility of failure is provided.

3) The taxonomy of IDSs' architectures, detection algorithm, and additional design parameters is presented.

4) Our proposed intrusion detection system architecture and the operational algorithm are explained in detail. The proposed MSDAR is designed with a multi-stage detection approach making use of both signature-based and anomaly detection benefits. Simulation analysis methodology, simulation parameters, simulation metrics used for performance evaluation, and simulation results are also presented and discussed in detail.

The remainder of this paper is organized as follows: In Section II, we give an overview of the related work done for securing ad hoc networks using Intrusion Detection Systems. Section III gives an insight into our implementation. Section IV presents the simulation results and evaluation of our proposed scheme MSDAR. Section V is focused on discussing the results and mentioning the limitations Of MSDAR. Finally, Section VI concludes the paper and presents future directions are presented.

II. Related Work

Intrusions are any kind of unauthorized or unapproved activities within the network. Intrusion Detection Systems are schemes and tools, used to discover, assess and report intrusions that may compromise the network. IDSs should continuously adapt and improve, to be able to discover new attacks and attack strategies. Many factors have motivated the development of IDSs. First, the presence of security flaws and vulnerabilities in a complex system makes it susceptible to malicious intrusions. Second, is the inefficiency of most of the prevention techniques that were designed and implemented to prevent possible attacks. Third, the exposure to insider attacks is expressed to be much more harmful than outsider attacks, even in most secure systems. Finally, newly emerged attacks need considerably advanced security solutions. This makes IDSs an attractive and important research area. For this research, different implementations and types of IDSs are studied and categorized in this section. The study's objective is to understand the algorithms and design parameters and their impact on performance and functionality, to overcome any unexpected flaws in our new proposed technique MSDAR. This section is organized as follows. Structural components and building blocks are introduced in Section A. Section B gives an insight into IDSs' architecture taxonomy. Supplementary design parameters and their taxonomy are introduced in section C.

A. Intrusion Detection Systems' Components

Because of their common goals, most of IDSs share the same structural patterns [15]. Data collecting and formatting, analysis and detection, and reaction mechanism units are the three primary parts of any IDS. The main components of the intrusion detection systems are depicted in Fig. 1. Various data types from different sources are collected, formatted and sorted at the data collection and formatting unit and then delivered to the analysis and detection unit. Collected data is analyzed and processed and then compared to the normal system behavior in anomaly-based IDS, or the signature of known attacks in signature-based IDS, or finally the well-defined specifications of a program or protocol in specification-based IDS [16]. After an action is detected as malicious, it is reported to the response mechanism. The response mechanism is defined according to the designed response policy. Different responses can only be categorized into two groups; passive responses and active responses. The passive response is done by simply notifying the authorized entity of the identified malicious action or intrusions detected. On the other hand, an active response is any form of action aiming to mitigate the threat or expected damage resulting from an intrusion or attack. This can be done by terminating network connections for certain periods or blocking IP addresses/Physical addresses linked to the attack. The response policy should also illustrate the response period as it can be either permanent or temporary. IDSs with active response mechanisms can also be aliased as Intrusion Prevention Systems (IPSs).

B. Intrusion Detection Systems Architectures Taxonomy

Intrusion detection systems can be deployed in the network using different architectures [17]. These architectures can be classified into two broad categories; Standalone, and collaborative, as shown in Fig. 2. Early IDSs were implemented as stand-alone systems having only local monitors and analysis units at each node. Local monitors and analysis units serve only their host nodes by detecting abnormal events according to the predefined detection policy. The response against any action is addressed and limited to the node's level with no extra extension. Stand-alone IDSs are not immune against distributed attacks and they can't be reliable for detecting malicious events occurring simultaneously at different locations inside the network. Therefore, there is a need for Collaborative IDSs. In collaborative architectures, an IDS enforces cooperation between monitors to provide a considerably more scalable and accurate model than stand-alone IDS. Collaborative IDS are also classified according to the communication model between both monitor units and analysis units as depicted in Fig. 2. Collaborative IDSs classification includes four subcategories, centralized, decentralized, distributed, and finally, our newly proposed architecture that is illustrated in this paper; hierarchically-distributed. Centralized IDSs, depend on one single centralized analysis unit in addition to several distributed monitoring units at each node or entity in the network. Two main disadvantages of such IDSs are the scalability limitations and the Single Point of Failure (SPoF). This is because the single analysis unit can handle only a limited number of monitoring units and it can be an easy target for direct attacks to disable the entire functionality of the intrusion detection system. Decentralized IDSs make use of multiple analysis units distributed in different locations within the network. Each analysis unit is responsible for accumulating, aggregating, and analyzing data from different monitoring units. Finally, a head analysis unit on top of all other analysis units receives this information, to make nondiscriminatory decisions regarding network entities and events. Such architecture supports scalability and overcomes the bottleneck congestion presented in centralized IDSs. In Distributed IDSs, each entity in the network is equipped with a monitor unit and an analysis unit. Each node shares its information with its peers in a completely distributed model. Collected data are organized and analyzed among all nodes. In Distributed IDS architecture, both congestion and SPoF disadvantages are avoided. However, an extra processing requirement is added to each node within the network. This additional requirement may consume extra processing and power capabilities during intrusion detection activities which in turn minimize the nodes' capabilities required to process normal flow. Therefore, a new architecture is proposed to overcome the disadvantages mentioned above. It is based on both Distributed and Hierarchical Architecture (DHA-IDS) as shown in Fig. 3.

Fig. 2. Extended Intrusion Detection Systems Architectures Taxonomy.

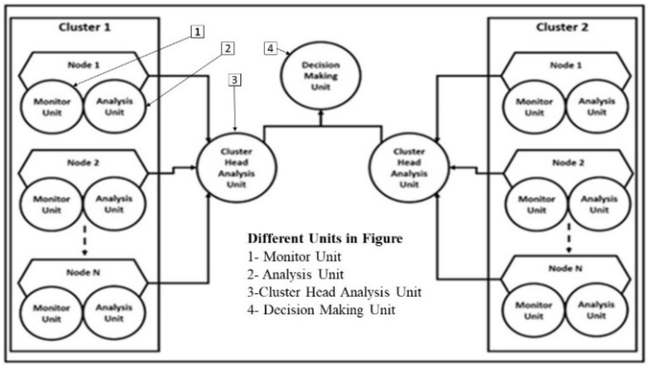

Fig. 3. Proposed Distributed Hierarchical Intrusion Detection System (DHA-IDS) Model.

In DHA-IDS, each node has its own monitor and analysis units. Each node is responsible for monitoring and analyzing only data collected by itself, then it forwards the analyzed data about different network activities to the cluster head analysis unit directly above it. Each cluster head analysis unit is responsible for collecting data from the nodes within its cluster. It then runs the second phase of processing and analyzing to correlate all collected information. At the end, each cluster head analysis unit forwards the correlated information to the response unit which is responsible of deciding a proper action related to detected intrusions. If an attack is directed to the response mechanism unit, one of the cluster head analysis units will become responsible of replacing the response mechanism unit. Similarly, in case the attack is extended to the cluster heads, each node will depend on its information and make its own decision regarding any suspected action. Therefore, this proposed DHA-IDS can perform in the worst attack conditions and it can degrade its architectural level from Distributed Hierarchical to Standalone, in order to retain the system's self-robustness. Furthermore, the new proposed architecture overcomes many disadvantages of different architectures mentioned above like; bottleneck congestion, SPoF, processing and power overheads. Table I compares between the different architectures presented in this section and the proposed DHA-IDS. They are compared based on complexity, accuracy, scalability, and risk of failure.

C. Intrusion Detection Systems Design Parameters Taxonomy

Different parameters are taken into consideration when a new IDS is designed. These parameters influence the IDS performance. Some of these parameters are presented in the following sections.

1) Source of data: According to the source of data, IDSs can be classified as Host-based, Network-based, and Hybrid. In stand-alone architectures, data is collected and analyzed locally from each node independently. Another approach is collaborative security, which is accomplished by multiple correlated sources. Data can be collected either locally and independently, or globally from each node (host-based) in the network then the collected data can be correlated and analyzed in a holistic form [18]. In such IDSs, monitoring units are deployed locally in the host to detect host-targeted attacks. Examples of such attacks are the ones aiming to exhaust the hosts' resources or gain unauthorized access to systems' components and data. Data can also be collected from network traffic (network-based) instead of nodes' local data [19]. Monitoring units are deployed in firewalls, or routers to capture all network packets. This information can help to detect different threats and possible attacks and spot abnormal activities in the network. Finally, some IDSs depend on their design and implementation on both sources of data, host-based, and network-based. This type of IDS is described as (hybrid-sourced). Hybrid-sourced IDSs can detect various types of attacks targeting any of the host or network components.

2) Scheduling of analysis: The intrusion detection process can trail different schedules (real-time, offline). In real-time analysis [20], data is collected, then immediately correlated and analyzed. Instantly, an appropriate decision is taken regarding the detected behavior. On the other hand, offline analysis [21] is performed after all nodes forward their collected data to the analysis unit. While the data is being analyzed, the nodes pursue their normal operation. Whenever they receive a decision concerning the network activities, they act accordingly.

3) Initiation: Nodes in IDSs can voluntarily participate in the intrusion detection process like in proactive systems. Monitoring units collect data that is automatically forwarded to analysis units. On the contrary, in driven systems, nodes wait for a direct request to send their own data regarding any activity in the network. Also, the passive nodes don't request neighboring nodes' data. They only receive data passing by their perimeter passively.

4) Types of shared data: Collaborative IDSs depend on sharing data among the network elements. There are three types of data: Raw, partially processed, and fully processed. Raw data is collected by nodes that are not equipped with any analysis units. Data is then forwarded to other nodes with higher processing capabilities for analysis. Environmental data and behavior logs are examples of raw data. In case of partially processed data, nodes are more powerful, so they can be used to minimize the traffic overhead due to forwarding every single piece of raw data at each node in the network. Also, IDSs make use of partially processed data to minimize the processing capabilities required by each node in the IDS's higher levels. Finally, the existence of malicious or abnormal activity in the network is determined by the fully processed data. Therefore, confirmed intrusions, attacks, decisions, and alerts regarding a node can be considered fully processed data. Fig. 4 depicts the taxonomy of IDSs' Architectures, detection algorithms, and additional design parameters. Table II summarizes the classification and the comparison between some IDSs that have been proposed in the literature with respect to different parameters such as Communication architecture, and detection algorithms. This is in addition to other design parameters such as data source, shared data type, scheduling of analysis, and response mechanism point of view.

III. Proposed System Architecture

This section presents our proposed system architecture and operational algorithm. The proposed MSDAR is designed with a multi-stage detection approach. The first stage is implemented using anomaly detection with a classifier mechanism. The system in this stage has a statistical prediction of most successive events in the network. The analysis unit compares the current event to the pre-predicted event, if they match; then the system is considered to be operating in its normal state. If the current event doesn't match any of the pre-predicted events, then it will be considered an anomaly. The second stage is implemented using a signature-based detection mechanism. At this phase, the analysis unit compares the current event - detected as an anomaly in the first stage - to the predefined attacks behaviors' and signatures' profiles. Therefore, an anomaly detected in the first stage is considered as the audit data for the second stage. The third stage and the following ones are implemented using anomaly detection with a classifier mechanism that has an additional parameter taken into consideration. This parameter is the Sensitivity level of upcoming comparisons. Sensitivity Level SL is incremented each time the system needs to make further investigations regarding the group of events suspected to be an intrusion and correspondingly to minimize the false positive intrusion percentage. The state diagram of the proposed system MSDAR is depicted in Fig. 5. MSDAR follows the standardized structure of known collaborative IDSs. Data collection and formatting units are the first components of its structure. It is designed to have various data sources distributed through the network, and at each host within the network perimeter. Monitor unit and mini-analysis unit are implemented at different data sources. Collected and formatted data are forwarded to the main analysis and detection unit where the analysis processes follow the scheme shown in the flow chart depicted in Fig. 6. Finally, the response unit has the role of propagating a proper response related to any detected intrusion. The response is decided according to the designed response policy. The active response is considered against any intrusive action.

IV. MSDAR Simulation Results

This section describes the technique used to evaluate MSDAR performance, using the OMNET++ Simulator. The simulated network consists of 80 nodes acting as routers, two workstations acting as data sources, and one application server acting as the victim. All nodes are assigned static IP addresses to enable the possibility of tracking routing tables at each node.

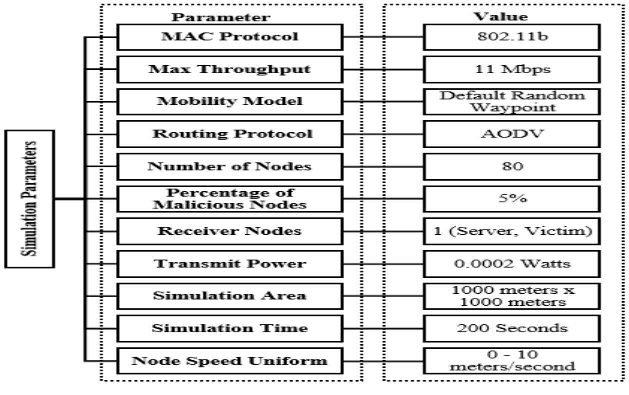
For the simulation, AODV is used as the routing protocol. Fig. 7 summarizes the simulation parameters. For the attack scenario, a certain percentage of nodes are manipulated to act as malicious attackers. The monitored systems' behavioral statistics are then gathered. The following statistics are included: total packets transferred, total packets received, total packets deleted, total packets changed, latency, total connections to the victim node, and average throughput… etc).

A. Simulation and Analysis Methodology

Each event that scores greater than the predefined threshold is marked as an intrusion. Subsequently, a proper action using the MSDAR response mechanism is initiated. In the final stage of the simulation process, overall network performance evaluation is presented in graphs to validate MSDAR's ability to detect the existence of intrusive actions. The following tables present the parameters used for the simulation, testing scenario, and collect statistical data respectively. To assess the efficacy of our suggested system, it is important to measure its ability to distinguish between intrusive and non-intrusive activities, with a minimum number of false alarms. In our evaluation, we adopted the approach in [36]. The metrics used are defined in Table III [36]. The previously mentioned singular metrics were used to form new performance measures. These performance measures are introduced in Table IV [37]. Some researchers consider DR and TPR as the same measure: the proportion of intrusive events that were identified as attacks to all other normal events [37].

To have a fair comparison between IDSs performance, the authors in [36] proposed a metric called Capability of Intrusion Detection (CID) based on some of the metrics mentioned in Table IV, according to (1).

$$CID = -B(1-\beta)\log(PPV) - B(\beta)\log(1-NPV) - (1-B)(1-\alpha)\log(NPV) - (1-B)(\alpha)\log(1-PPV) \quad (1)$$



Parameter	Value
MAC Protocol	802.11b
Max Throughput	11 Mbps
Mobility Model	Default Random Waypoint
Routing Protocol	AODV
Number of Nodes	80
Percentage of Malicious Nodes	5%
Receiver Nodes	1 (Server, Victim)
Transmit Power	0.0002 Watts
Simulation Area	1000 meters x 1000 meters
Simulation Time	200 Seconds
Node Speed Uniform	0 - 10 meters/second

Simulation Parameters

Fig. 7. Simulation Parameters.

TABLE III. Metrics Defined for IDS's Performance Evaluation [36]

Met ric	Meaning	Explanation
FP	False Positive.	The probability of having an alert while no intrusion occurs.
TP	True Positive.	The likelihood of receiving an alarm during an incursion.
FN	False Negative.	The likelihood of not receiving an alarm when an incursion occurs.
TN	True Negative.	The likelihood of not receiving an alert if no incursion happens.
PPV	Positive Predictive value.	The likelihood that an intrusion results in an alert.
NPV	Negative Predictive Value.	The likelihood of no inclusion results in no alert.
B	Base Rate.	The likelihood of an intrusion in the audit data gathered.

TABLE IV. Advanced Performance Measures for IDS's Evaluation [37]

Performance Parameter	Definition	Equation	Value Range
Classification Rate (CR)	The ratio between accurately classified events and the total number of events.	$\frac{TP+TN}{TP+TN+FP+FN}$	CR > 0 CR < 1
Detection Rate (DR)	The proportion of properly identified attacks to the total number of intrusive occurrences.	$\frac{TP}{TP+FN}$	DR > 0 DR < 1
False Positive Rate (FPR) (α)	The proportion of non-intrusive events detected as attacks to the total number of non-intrusive occurrences.	$\frac{FP}{FP+TN}$	FPR > 0 FPR < 1
True Positive Rate (TPR) (1-FNR) (1-β)	The proportion of intrusive events detected as attacks to the total number of regular occurrences.	$\frac{TP}{FP+TN}$	TPR > 0 TPR < 1

B. Simulation Results

One of the most difficult tasks is data gathering [38]. In our simulations, we used the dataset DARPA 2000 Lincoln Laboratory Scenario (LLDDoS) 2.0 which is provided by MIT [39]. It consists of a DDoS attack run by five attackers. A number of simulation sessions are used to carry out this assault scenario. Over time, these sessions were organized into 5 attack stages. MSDAR has been simulated and tested against LLDDOS 2.0.2. The following graphs have been deduced from the simulations. Fig. 8 illustrates the point-to-point throughput during the five time phases of the attack. It shows five peaks at each attack incidence. Fig. 9 illustrates the number of connections directed at the victim node. It can be noticed that the number of connections is exponentially increasing with time. Fig. 10 and Fig. 11 demonstrate the average throughput of the network and received throughput at the victim node respectively. The Receiver Operating Characteristic (ROC)

Curve [40] is the detection rate as a function of the false positive rate and the corresponding calculated CID curve as a function of false positive rate for the different stages (sensitivity levels) of MSDAR respectively. Fig. 12 depicts the ROC of our scheme. From Fig. 12, it can be concluded that the Detection Rate increases when the sensitivity level increases. For αavg = 0.5 we achieved average DR = 0.48, 0.68 and 0.9 at SL = 1, 3 and 5 respectively. The ROC curve is not useful in determining the optimal operation point of MSDAR. On the contrary, the optimal operation point for each stage is declared by the CID curve shown in Fig. 12. Table V shows the maximum CID Levels corresponding to different parameters. It can be deduced that the performance of MSDAR improves by using multiple stages of different detection mechanisms.

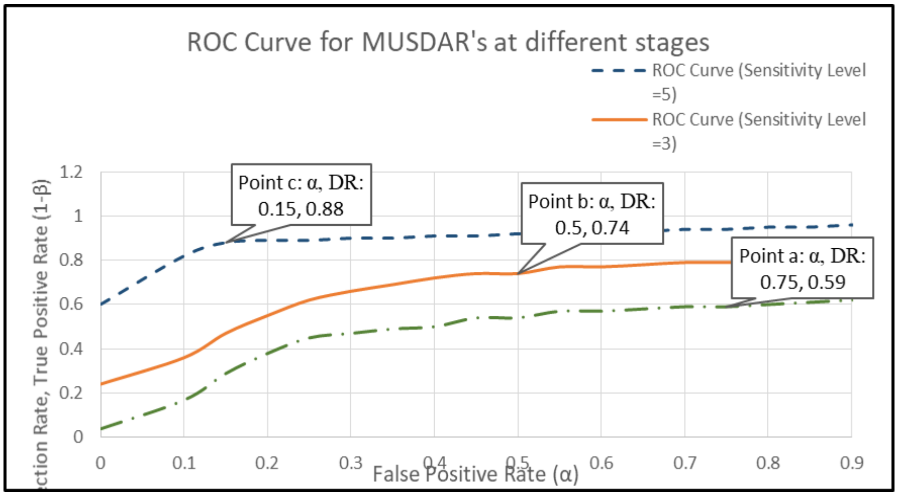
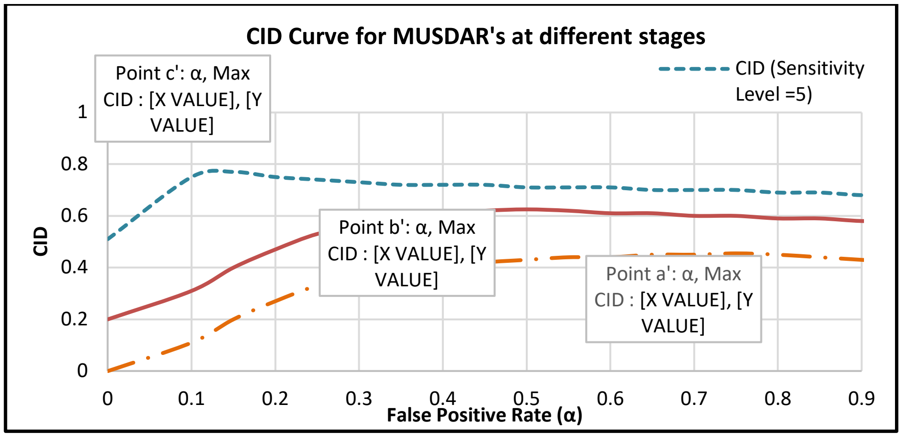
TABLE V. MAXIMUM CID LEVELS CORRESPONDING TO DIFFERENT PARAMETERS

Point	α	SL	Maximum CID Level
a'	0.75	1	0.455
b'	0.5	3	0.625
c'	0.15	5	0.77



(a)



(b)

Fig. 12. MSDAR ROC Curve and its Corresponding Capability of Intrusion Detection (CID).

V. Discussion and Limitations

Our newly developed Multi Stage Dynamic Architecture (MSDAR) was explained in detail from the points of view architecture, sequence diagram, and flow chart. It was tested against DDoS attacks through simulations. Each event that scores greater than the predefined threshold is marked as an intrusion. Subsequently, a proper action using the MSDAR response mechanism is initiated. An important factor in evaluating the effectiveness of our proposed system was its ability to distinguish between intrusive and non-intrusive activities, with minimum false alarms. Results have shown that by increasing the IDS sensitivity level, the detection rate increases. The optimal operation point for each stage is declared by the CID curve. This research can be extended by using the statistical test (t-test/p-test/ANOVA to compare and benchmark our method with others. Machine learning models have been used for intrusion detection for over a decade [40]. We plan to use machine learning in one of the stages of our multistage Intrusion detection system MSDAR [41]. We will also use the model from [42] to assess the effectiveness of our suggested approach using machine learning.

VI. Conclusion and Future Work

Despite the various applications of Mobile Ad Hoc Networks, security challenges need to be addressed for both internal and external attacks. Intrusion detection systems are regarded as the second line of security against many types of attacks. Due to MANETs' special characteristics, traditional Intrusion detection systems cannot be used. In this paper, we distinguished between the different approaches used for intrusion detection mechanisms in a structured way. We classified intrusion detection systems with respect to different categories, such as architectures and design parameters. We introduced a standardized building block for intrusion detection systems for MANETs that summarizes different classifications of IDS techniques. In addition, a survey that shows the most popular design parameters used in different IDSs was presented. We proposed a multi-stage intrusion detection system (MSDAR) which is featured by its dynamic architecture as it can be deployed in the network using the Distributed Hierarchical Architecture (DHA-IDS), as it can dynamically change its deployment architecture. Simulations have shown that in case of an attack directed to the response mechanism unit, one of the cluster head analysis units is responsible for replacing the response mechanism unit. Similarly, in case the attack is extended to the cluster heads, each node depends on its data and makes its own decision regarding any suspected action.

Therefore, the proposed MSDAR can perform in the worst attack conditions and it can modify its architectural level from Distributed Hierarchical to Standalone, in order to retain the system's self-robustness. Furthermore, the new proposed architecture is capable of incapacitating many disadvantages of different architectures like; bottleneck congestion, single point of failure, processing, and power overhead. The suggested system's MSDAR effectively lowers false positives, increasing the intrusion detection system's capability and detection rate (CID) are increased by using the multi-stage feature. By measuring the CID level and comparing it to the detection rate, we were able to determine the optimal operation point for each stage in the proposed system. As a result, the total detection rate rises, increasing the network's functional efficiency to a tolerable level. In future work, MSDAR can be tested for different types of attack scenarios.

***Abstract*—The distributed integrated energy station includes an electric energy storage device, heat storage device, cold storage device and other devices. Aiming at the problem of low data acquisition accuracy of energy storage device caused by using a single sensor or acquisition scheme in the existing methods, a new data acquisition method of energy storage device of distributed integrated energy station is designed based on double decision tree algorithm. The data acquisition process of double decision tree algorithm is constructed. On the basis of the process, the mathematical models of electric energy storage device, heat storage device, cold storage device and hybrid energy storage device are established. Then the double decision tree algorithm is used to solve the constructed model, and the acquisition pseudo code is given. So far, the data acquisition of distributed integrated energy station energy storage device based on double decision tree has been completed. The results of case analysis show that the accuracy of this method is higher than 98%, and the collection time is less than 30 ms.**

***Keywords*—Double decision tree; distributed; integrated; energy station; energy storage device; data collection**

I. Introduction

The energy storage devices of integrated energy stations such as photovoltaic, electric energy storage, cold and heat energy storage, and natural gas combined cooling, heating and power supply can improve the reliability and energy utilization efficiency of the power supply system [1-2], and reduce system line losses. However, each energy system usually operates independently, resulting in the inability of many energy systems to coordinate effectively, which is prone to safety hazards and low energy utilization problems [3-4]. Therefore, the efficient collection of energy storage device data in distributed integrated energy stations is of great significance to its rapid development [5].

A decision tree algorithm is a method of constructing a decision tree for preliminary screening data based on data attribute information. The algorithm has higher learning performance, higher computing precision and higher computing efficiency. This algorithm has been widely used in many fields [6]. However, the decision tree operation is more complex and the parallel computing capability is low. Based on this, the dual decision tree algorithm came into being. It has the advantage of enhancing the parallel computing capability of the decision tree, and can be applied to collect the data from the energy storage device of the distributed energy station. Among them, the C4.5 algorithm is an efficient algorithm in the decision tree algorithm. Using the C4.5 algorithm to generate a decision tree helps to accurately select data collection points from the data source and facilitate subsequent data processing [7]. The dual decision tree algorithm can use decision trees to filter the data required by the user from the data set. After it establishes the data set, it is processed again through another decision tree to achieve high-quality and high-efficiency data collection.

Li Junnan et al. studied the collection and application of power energy big data based on the big data cloud platform [8]. This method utilizes the big data cloud platform to realize the collection of power and energy big data. Du Peng et al. studied a wide-area data acquisition scheme based on the power dispatching data network [9]. Certain results have been obtained using the wide area method of data collection in the power dispatching data network. However, the above two methods are applied to the data collection of energy storage devices in distributed integrated energy stations. Because the device needs to collect data on four aspects of electricity storage, cold storage, heat storage and hybrid energy storage during the data collection process. As a result, the acquisition accuracy is low and the time is long.

In order to solve the above problems, this paper studies the data acquisition method of the energy storage device of the distributed integrated energy station based on the double decision tree. It establishes the mathematical model of each energy storage device in the distributed integrated energy station. The dual decision tree algorithm is applied to the data collection of the energy storage device of the distributed comprehensive energy station, which improves the data collection effect of the energy storage device of the distributed comprehensive energy station.

II. Data Collection of Energy Storage Devices in Distributed Integrated Energy Stations

In this paper, in the process of researching the data acquisition method of the energy storage device of the distributed integrated energy station, the data sampling idea based on the double decision tree is first designed. Then, on this basis, the mathematical model of each energy storage device in the distributed integrated energy station is established. Finally, the dual decision tree algorithm is applied to the data collection of the energy storage device of the distributed integrated energy station, and the pseudo code is generated.

*Corresponding Author.

A. Data Collection Idea of Double Decision Tree Algorithm

The process of the data collection method of the energy storage device of the distributed integrated energy station based on the double decision tree is as follows:

In the sample, a decision tree for initially collecting the original data of the energy storage device is established through the C4.5 algorithm. It uses the established decision tree to filter and sort out the original data, realize the preliminary screening of the data, and make the re-collected data samples show a balanced distribution state [10]. The established decision tree can be reused, reducing data training and collection time. A second tree is established based on the data contained in the first established tree, and the collected data is further analyzed. The specific process is shown in Fig. 1.

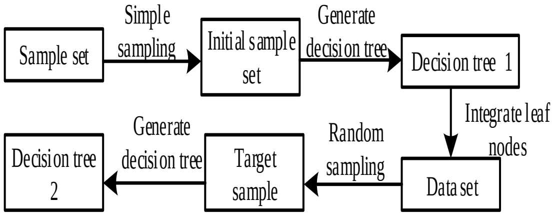

Fig. 1. Double Decision Tree Collection Process.

In Fig. 1, the sample set is the energy storage device data of the target distributed integrated energy station. It includes historical operation data of the energy storage device and corresponding file information.

On the basis of the acquisition process of the double decision tree in Fig. 1, a mathematical model of the energy storage device of the distributed integrated energy station is established.

B. Constructing Mathematical Model of Energy Storage Device in Distributed Integrated Energy Station

Distributed integrated energy stations usually include three loads of heat, cooling and electricity. Therefore, before collecting the data of the energy storage device of the distributed integrated energy station, the mathematical model of the energy storage device of the distributed integrated energy station is established from the aspects of electricity storage, heat storage, cold storage and hybrid energy storage.

1) Electric energy storage device model: The establishment of the model of the electric energy storage device in the distributed integrated energy station should focus on considering the electric energy capacity constraints, the maximum power, the complementary constraints and the charging and discharging efficiency [11]. In the process of model establishment, the energy consumption of the electric energy storage device caused by the change in time during the operation of the electric energy storage device is not considered.

When the time is set as t, the charging power and discharging power of the electric energy storage device are represented by $P_{char}(t)$ and $P_{dis}(t)$ respectively, and $W_E(t)$ is the remaining power of the energy storage device. In this paper, the mathematical model of the electric energy storage device of the distributed integrated energy station is established as follows:

$$\begin{cases} 0 \le P_{dis}(t) \le P_{\max}, 0 \le P_{char}(t) \le P_{\max} \\ W_E(t) = W_E(0) + \int_0^t \left[\eta_c P_{char}(t) - P_{dis}(t) / \eta_d \right] dt \\ W_{E_{\min}} \le W_E(t) \le W_{E_{\max}} \\ P_{dis}(t) P_{char}(t) = 0 \end{cases} \tag{1}$$

In formula (1), η_c represents the charging efficiency of the electric energy storage device. η_d represents the discharge efficiency of the electric energy storage device. $W_E(0)$ and $P_{\max}$ represent the initial remaining power and the maximum charging and discharging power of the electric energy storage device, respectively. $W_{E_{\min}}$, $W_{E_{\max}}$ and $P_{dis}(t)P_{char}(t) = 0$ respectively represent the remaining power operation area of the electric energy storage device and the complementary constraint, and the complementary constraint is used to limit the state unity of the electric energy storage device.

2) Case analysis Model of heat and cold storage device: The distributed integrated energy station adopts cold storage and thermal storage to realize sensible heat energy storage and phase change energy storage. Sensible heat energy storage is a low-cost energy storage method. Phase change energy storage realizes energy storage by storing and releasing heat in the process of changing the physical state of materials. It has a higher cost [12], but the temperature fluctuation is small. The phase change energy storage method is selected as the energy storage method of the heat storage and cold storage devices of the distributed integrated energy station. This method has a high energy storage density, and when the heat storage and temperature difference are the same, it can ensure that the heat storage of the phase change material is only one-quarter to one-fifth of the sensible heat material. The temperature during energy storage and release can be controlled and kept constant.

Both cold storage and heat storage devices have energy consumption characteristics when storing and releasing energy. And the energy has a certain dissipation with time.

The model formula of the heat storage (cold storage) device of the distributed integrated energy station is as follows:

$$\begin{cases} 0 \le P_{TI}(t) \le P_{\max}, 0 \le P_{TO}(t) \le P_{\max} \\ W_P(t) = \eta_T W_P(t-1) + \eta_{TI} P_{TI}(t) - P_{TO}(t) / \eta_{TO} \\ 0 \le W_P(t) \le R_{HS} \\ P_{TI}(t) P_{TO}(t) = 0 \end{cases} \tag{2}$$

In formula (2), $W_P(t)$ and $1-\eta_T$ respectively represent the residual heat of the heat storage (cold storage) device at time t and the loss rate of the heat storage (cold storage) device per unit time. η_{TI} represents the heat storage (cold storage) efficiency of the heat storage (cold storage) device. η_{TO} represents the heat (cold) efficiency of the heat storage (cold storage) device.

R_{HS} and $P_{\max}$ represent the maximum capacity and maximum heat release (cold) power of the heat storage (cold storage) device, respectively, $P_{TI}(t)$ represents the heat storage (cold storage) power of the heat storage (cold storage) device when the time t is time; $P_{TO}(t)$ represents the heat storage (cold storage) power when the time t is Cold storage) device to release heat (cold) power.

The calculation formulas of the two heat storage and cooling efficiencies are as follows:

$$\eta_I = \frac{1.16G(\mathrm{T}\,2-\mathrm{T}1)\times 100\%}{Pt_1/60} \tag{3}$$

$$\eta_O = \frac{1.16G(\mathrm{T}1-\mathrm{T}\,2)\times 100\%}{Pt_2/60} \tag{4}$$

In the formula, the total amount of hot water collected after 90s of water supply to the end of heat storage or cold storage is described by G. The power is denoted by P, and the collected hot water and cold water time are denoted by t_1 and t_2, respectively. The mean value of outlet water temperature and the value of cold water temperature are described by $\mathrm{T}1$ and $\mathrm{T}\,2$, respectively.

1) Hybrid energy storage system model: The internal energy of the energy storage system of the distributed integrated energy station is in a complementary state [13]. Compressed air energy storage and molten salt heat storage are used in molten salt heat storage non-supplementary combustion compressed air energy storage systems. Combining multiple energy stores can improve the economics of energy storage systems.

The turbine inlet is heated by the heat of the molten salt heat storage system of the hybrid energy storage device. Convert thermal energy into electrical energy, and set an electrothermal device to convert electrical energy into thermal energy [14]. It realizes the four-quadrant operation of the hybrid energy storage device of the distributed integrated energy station for two types of energy flows, electric energy and thermal energy.

According to the four-quadrant operation principle of the hybrid energy storage device, P_{in} is represented by P_o and the electric energy input power and output power of the hybrid energy storage device, respectively. H_{in} and H_o represent the electric energy input power and output power of the hybrid energy storage device, respectively. τ_1 represents the energy input time interval. τ_2 represents the energy output time interval, and the model of the hybrid energy storage device can be obtained as follows:

$$\begin{bmatrix} P_o(t) \\ H_o(t) \end{bmatrix} = \begin{bmatrix} \eta_{Com}\eta_{Tur} & \eta_{Tur}\eta_{Hs}\eta_{H-E} \\ \eta_{Heat}(1-\eta_T\tau_1) & \eta_{Hs}(1-\eta_T\tau_2) \end{bmatrix} \begin{bmatrix} P_{in}(t-\tau_1) \\ H_{in}(t-\tau_2) \end{bmatrix} \tag{5}$$

In the formula, η_{Com} represents the compressor efficiency. η_{Tur} stands for turbine efficiency. η_{Hs} and η_{H-E} represent heat storage efficiency and turbine inlet air heating efficiency, respectively. η_{Heat} represents the heater efficiency.

C. Data Acquisition for Energy Storage Equipment of Distributed Comprehensive Energy Station

The dual decision tree algorithm is applied to the established model of each energy storage device of the distributed integrated energy station. The data collection of the energy storage device is realized by using the double decision tree algorithm.

The decision tree algorithm is a typical inductive reasoning algorithm. The decision tree algorithm needs to clarify the attributes of each node of the tree and obtain the required attribute data. In order to improve the operation performance of the decision tree algorithm, the concept of information gain is introduced into the decision tree algorithm. We use the amount of information gained in the operation process to clarify the test attributes required for each node of the decision tree [15], and the decision tree algorithm is usually used to select attributes with a larger number in the operation process.

The C4.5 algorithm is a decision tree method that replaces the information gain of the attribute classification level evaluation index with the information gain rate. This method can effectively improve the defect that the traditional decision tree algorithm is limited to local optimization. The C4.5 algorithm uses the automatic discretization method to process the attributes with continuous values, and avoids the over-learning of the decision tree by pruning the decision tree. Algorithm C4.5 builds a decision tree using information that is relevant to the collection and classification. Let L represent the case set, C_i represent the case sample class label, and $i=1,2,\cdots,n$, and the information entropy formula for data collection can be obtained as follows:

$$I(L) = -\sum_{i=1}^{n} \frac{F(C_i,L)}{|L|}\log_2\frac{F(C_i,L)}{|L|} \tag{6}$$

In the formula, $|L|$ and $F(C_i,L)$ represent the number of samples in the case set L and the number of cases belonging to the C category in the case set A, respectively.

In the case where the number of values k exists in the selected attribute X . According to the probability of each information obtained from the training set, the formula for the conditional entropy of the decision tree is formed as follows:

$$E_x = \sum_{i=1}^{k} \frac{|L_i|}{|L|} I(L_i) \tag{7}$$

In the formula, $|L_i|$ is the number of cases of various subtrees in the attribute X , and the formula for obtaining mutual information is as follows:

$$G(X) = I(L) - E_x \tag{8}$$

Algorithm C4.5 selects the heuristic search extended attribute score, and the extended attribute selects the attribute with the largest information gain. The heuristic method can be effectively applied to the normalization process and in the presence of different attribute values, the attributes that reflect high-quality information gain can be selected. It obtains the attribute information gain rate formula as follows:

$$g_\tau(X) = \frac{G(X)}{Z(X)} \tag{9}$$

Branch the energy storage device data by the value of attribute X to obtain the $Z(X)$ value of the dataset, $Z(X) = -\sum_{i=1}^{k} \frac{|L_i|}{|L|} \log_2 \left(\frac{|L_i|}{|L|} \right)$. After completing the above calculations, based on the flow of the dual decision tree data collection method in Fig. 1, simple random sampling is performed on the original data set to obtain an initialization sample B . It applies the C4.5 algorithm to build the first decision tree within the initialization sample. After traversing all the leaf nodes of the first decision tree, the corresponding samples are stored in the sample data set, and the data is sent to the next data set $B_i\{i = 1, 2, \mathrm{L}\ \ , m\}$ until the set requirements are met. Sampling stops after all data traversal is completed. Randomly draw samples from the data set obtained by the first decision tree, and use $Z * \frac{|B_i|}{\sum_i^m B_i}$ to represent the number of samples from the data set i , where Z and $|B_i|$ represent the number of target samples and the number of samples in the dataset i , respectively; The target sample Z_t is all the samples extracted, and the second decision tree is generated by using the target sample Z_t that has been extracted. Through the second decision tree, the final collection of the data of the energy storage device of the distributed integrated energy station is realized.

The pseudo code for generating the data collection method of the energy storage device of the distributed integrated energy station with the dual decision tree is shown in Fig. 2.

```
Input: dataset Z
Output: selected data
Initialize Tree←NULL;
If Z is empty or meet other end conditions, then terminate;
End if
For all attributes in the dataset $a$ do
    Calculate the information gain rate;
End For
$a_{best}$← the attribute with the largest information gain rate;
Tree←$a_{best}$ is the root decision node;
$Zv$←Sub-dataset based on $a_{best}$ division;
For all $Zv$ do
    $Treev$←C4.5($Zv$)
    Add $Treev$ to the corresponding branch of $Tree$;
End for
Return $Tree$
Find Last Child Node(Tree Node $node$ , ArrayList $Zi$($i$=1,2,…,$m$));
If no child node then
    do $Zi$.Add($node$);
    If the number of $Zi$ samples < initial limit value then
        do $i$ ++;
    End if
Else
    For Tree Node $n$ in $node$. Child Nodes do
        this  Find Last Child Node ($n$,$Zi$)
    End for
For all $Zi$ do
    Random sampling, the number of samples is $Z * \frac{|B_i|}{\sum_i^m B_i}$ ;
    Integrate into the target sample set $Zt$
End for
Input dataset $Zt$;
Initialize $Tree$←NULL
Terminate if $Zt$ is empty or encounter other end conditions
End if
For all attributes in the dataset $a$ do
    Calculate the information gain rate;
End for
$a_{best}$← The attribute with the largest information gain rate;
$Tree$←$a_{best}$ is the root decision node;
$Zv$←Sub-dataset based on $a_{best}$ division;
For all $Zv$ do
    Add the $Tree$ to the corresponding branch of the $Tree$
    $Treev$ ← C4.5 ($Zv$)
End for
Return $Tree$
```

Fig. 2. Data Acquisition Pseudocode.

So far, the design of the data acquisition method for the energy storage device of the distributed integrated energy station based on the double decision tree is completed. The next step will verify the effectiveness of the proposed method through case analysis.

III. Case Analysis

In order to validate the data acquisition method of distributed comprehensive energy storage device based on double decision tree is effective. A distributed integrated energy station in a certain industrial park is selected as the experimental object. The distributed comprehensive energy station includes three electric energy storage devices, two heat storage devices, two cold storage devices, and one compressed air hybrid energy storage device. The method of this paper is used to collect the data of each energy storage device of the distributed integrated energy station, and the validity of the data collection method of this paper is verified.

A. Energy Storage Device Data Acquisition Test

We set the sampling time to 20s, and the actual sampling interval is 2s. The LMG671 conventional broadband power detection instrument and the designed data acquisition method of the energy storage device of the distributed integrated energy station based on the double decision tree are used to collect the power of each energy storage device. The results within the statistical sampling time are shown in Tables I to III.

10	1652	2234	2361	3117	2834	2567	2635	2378
12	1634	2218	2347	3152	2864	2534	2654	2364
14	1685	2296	2359	3194	2837	2517	2685	2391
16	1625	2247	2347	3158	2861	2564	2675	2354
18	1685	2234	2315	3175	2816	2574	2634	2361
20	1647	2264	2374	3149	2837	2598	2684	2341

Comparing and analyzing the three tables above, it can be seen that the power value of the energy storage device collected by the method in this paper is basically the same as the actual value. However, the difference between the power value detected by the conventional detection device and the actual value is higher than the difference between the method in this paper and the actual value. It shows that compared with the conventional detection device, the power value of the energy storage device collected by the method in this paper is more accurate.

On the basis of the above collection results, in order to further verify the data collection performance of the method in this paper, accuracy is selected as the evaluation index to evaluate the data collection performance. The accuracy of the power data collected by the method of this paper, the big data cloud platform method [8] and the wide-area method [9] is collected for the 8 energy storage devices of the distributed integrated energy station. In order to visually demonstrate the data acquisition performance of the method in this paper, the MATLAB tool is used to generate the comparison results of the power acquisition accuracy of the energy storage device shown in Fig. 3.

From the experimental results in Fig. 3, it can be seen that the power collection accuracy of the distributed integrated energy station energy storage device power using the method in this paper is higher than that of the big data cloud platform method and the wide area method. The accuracy of the method in this paper to collect the data of the energy storage device of the distributed integrated energy station is higher than 98%. The experimental results effectively verify that the method in this paper has high data acquisition performance. The main reason is that the method in this paper uses the double decision tree algorithm to effectively improve the data collection performance through two decision tree processing. It has high data acquisition accuracy and high practicability of data acquisition of energy storage equipment in distributed integrated energy stations.

B. *Real-time Test of Data Acquisition of Energy Storage Device*

The real-time data collection of each energy storage device in a distributed integrated energy station affects the normal operation of the energy storage device. Set the attribute data to be collected to 2500. The method of this paper is used to collect the average collection time of each sample of the power, DC current and DC voltage of the energy storage equipment of the distributed integrated energy station. The statistical results are shown in Tables IV to VI.

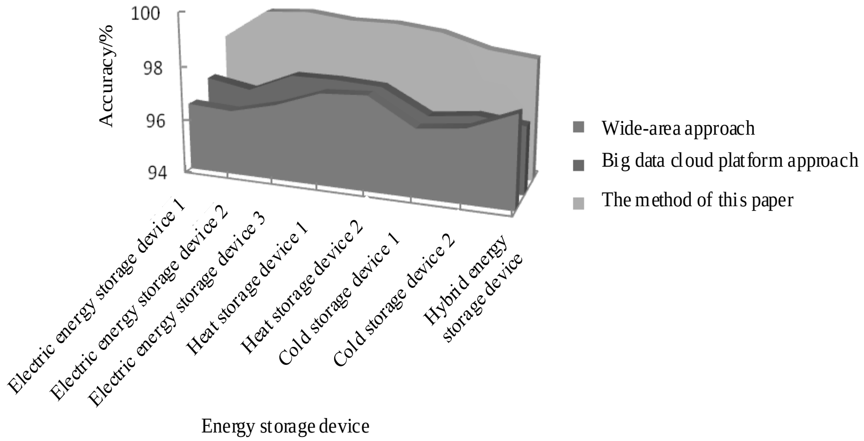

Fig. 3. Accuracy of Power Collection of Energy Storage Devices.

TABLE IV. ENERGY STORAGE DEVICE POWER COLLECTION RESULTS

Attribute data/pcs	Electric energy storage device 1/kW	Electric energy storage device 2/kW	Electric energy storage device 3/kW	Heat storage device1/kW	Heat storage device2/kW	Cold storage device1/kW	Cold storage device2/kW	Hybrid energy storage device/kW
500	1625	2215	2364	3125	2854	2534	2685	2352
1000	1652	2234	2385	3152	2843	2516	2675	2341
1500	1623	2285	2349	3147	2861	2537	2647	2364

TABLE V. DC VOLTAGE ACQUISITION RESULTS OF ENERGY STORAGE DEVICE

Sampling time/s	Electric energy storage device 1/V	Electric energy storage device 2/V	Electric energy storage device 3/V	Heat storage device1/V	Heat storage device2/V	Cold storage device1/V	Cold storage device2/V	Hybrid energy storage device/V
500	125.4	135.6	151.2	141.5	131.2	128.5	171.5	161.9
1000	124.2	134.5	150.4	141.6	131.5	128.6	170.8	160.24
1500	125.2	135.2	151.2	142.2	131.6	128.9	171.2	161.3
2000	125.4	134.4	151.3	141.6	131.8	128.7	171.4	161.8
2500	125.5	135.5	151.4	142.5	131.7	128.3	171.2	161.5

TABLE VI. DC CURRENT ACQUISITION RESULTS OF ENERGY STORAGE DEVICE

Sampling time/s	Electric energy storage device 1/A	Electric energy storage device 2/A	Electric energy storage device 3/A	Heat storage device1/A	Heat storage device2/A	Cold storage device1/A	Cold storage device2/A	Hybrid energy storage device/A
500	5.75	6.35	6.25	5.64	6.35	9.52	7.52	8.25
1000	5.35	6.52	6.34	5.28	6.85	9.45	7.46	8.64
1500	5.46	6.45	6.15	5.46	6.28	9.25	7.18	8.15
2000	5.27	6.85	6.28	5.31	6.45	9.34	7.64	8.34
2500	5.81	6.34	6.54	5.28	6.75	9.52	7.58	8.62

From the analysis of Tables IV to VI, it can be seen that the method in this paper can complete the target collection attribute data volume. And it counts the time required to collect different data volumes during the collection process, and draws its statistical results as Fig. 4.

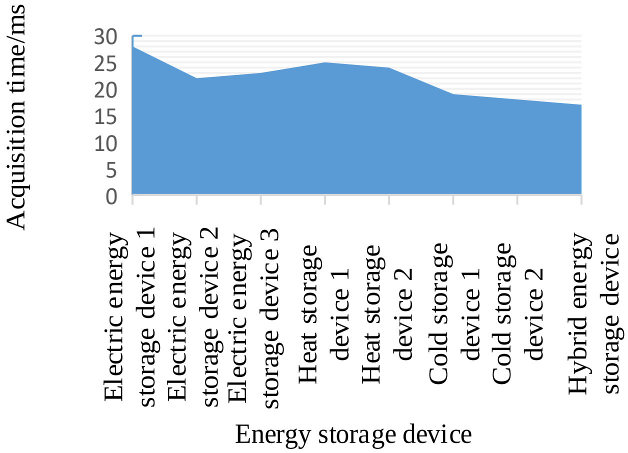

Fig. 4. Real-time Data Collection

The experimental results in Fig. 4 show that the power, DC current and DC voltage data collected by the method in this paper are all less than 30 ms. The reason for the short acquisition time of the method in this paper is that the decision tree for preliminary acquisition of the original data of the energy storage device is established by the C4.5 algorithm. It uses the established decision tree to filter and sort out the raw data. It realizes the preliminary screening of data and improves the collection efficiency. Using the method in this paper to collect various data from energy storage equipment in distributed integrated energy stations not only has high acquisition accuracy. This method has a high real-time acquisition, which again verifies the high data acquisition performance of the method in this paper. It can be applied to the practical application of data acquisition of energy storage devices in distributed integrated energy stations.

IV. CONCLUSION

Distributed comprehensive energy stations are an important direction for integrating and optimizing the energy Internet. In this paper, a mathematical model of each energy storage device in a distributed integrated energy station is established. It collects energy storage device data through a dual decision tree method and draws the following conclusions:

1) The accuracy of the proposed method is higher than 98%, and the collection time is less than 30ms, which can improve the data collection efficiency and collection accuracy. The method in this paper can obtain ideal data collection results in a short time, and the tree-like decision tree structure can intuitively reflect the status of the data to be collected and improve the accuracy of data collection. The method is applied to the data collection of energy storage devices in distributed integrated energy stations, and has high engineering practice value.

2) The proposed method improves the defect of inaccurate collection caused by too much useless information in massive data. It avoids unbalanced sampling space caused by differences in data distribution between different samples, and provides greater convenience for subsequent data analysis.

3) In this study, it is not considered that the electric energy storage device can provide heat and cooling data through the heat pump in the process of outputting electricity. The accuracy of power collection of energy storage devices needs to be further improved and studied.

Reduced False Alarm for Forest Fires Detection and Monitoring using Fuzzy Logic Algorithm

Maria Susan Anggreainy, Bimo Kurniawan, Felix Indra Kurniadi
Computer Science Department, School of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480

***Abstract*—The purpose of this research was to detect forest fires in efforts to minimize the incidence of false alarms. The research method used is divided into several stages, namely planning, analysis, design, implementation, testing, and maintenance. Arduino acts as a data collector on the field, which will later be used to detect forest fires and false alarms. Fuzzy logic is used as the essence of the algorithm and will provide a higher level of accuracy for forest fire detection and false alarms. In testing the fuzzy program, the fuzzy output between Arduino and the fuzzy on the monitoring dashboard has a small difference of 0.99%. It can be concluded; the application can minimize the occurrence of false alarms to reduce the user's workload.**

***Keywords*—False alarm; fuzzy logic; forest fires detection; sensor; microcontroller**

I. Introduction

Forests are the lungs of the world because forests will absorb carbon dioxide (CO2) in the air and release oxygen (O2) which is very useful and creates a balance of ecosystems for living things. Therefore, forest fires are something that must be prevented and minimized their impact. The primary sources for ecological degradation currently are the Forest Fires [1]. Huge losses and serious threats to ecosystems are a common consequence of forest fires [2]. Indonesia is one of the countries with the largest forest area in the world. With forested land area throughout Indonesia's mainland is 94.1 million hectares or 50.1% of the total land area. However, although the forest area owned by Indonesia is quite high, the number of forest and land fires (Karhutla) in Indonesia is also quite high. Based on data quoted from the Directorate of Land and Forest Fire Control, Ministry of Environment and Forestry of the Republic of Indonesia, forest, and land fires in Indonesia in 2019 alone reached 1,649,258 hectares [3]. Forest fires are one of the big problems in Indonesia because forest fires are very dangerous impact on the environment and people due to smoke and carbon emissions from fires [4]. The most technology to detect fire Hotspots have been using satellite imagery and then processed to determine the number of hotspots and their locations. Some drawbacks in this technology that in bad weather or cloudy then the satellite system cannot penetrate [5][6]. In this research, it is proposed sensor system that uses multiple sensors related to fire parameters, especially fires on peatlands with special specifications fire case. Common fire parameters such as temperature, smoke, fog and carbon dioxide are applied in this system then measure the indicator using a special sensor [7]. This high number of forest and land fires is the source of several problems. Among them are disturbing human health as well as flora and fauna, hindering community activities such as flights and school activities, destroying the earth with CO2 content released during forest and land fires, and the clean water crisis caused by water that should be filtered by rocks in the ground, instead being mixed with post-fire soil [8]. The number of forests and lands that burn every year in Indonesia is one of the reasons why early detection of forest and land fires can help humans in handling forest and land fires. Therefore, the proposed solution to this problem is by utilizing the technology that is currently popular, namely Arduino which is one of the Internet of Things (IoT) [9]. Currently IoT Devices and sensors enable monitoring various environmental variables, such as temperature, humidity, etc. [10]. Arduino based platform IoT enabled fire detector and monitoring system is the solution to this problem [11] [12]. To implement this research, we will use GSM which is used to deliver WhatsApp to the user via the number given in the simulation program. Based on data from the Indonesia IoT Forum, there are 400 million sensor devices installed. However, use in the agricultural sector is only 4 percent. This low number can be interpreted by the wide space for IoT innovation in the agricultural sector. This monitoring dashboard is used to improve response to forest fires. So that the impact of forest and land fires can be minimized as much as possible. previous research there are several research on algorithms to calculate the probability of fire occurrence [13], forest fire models and warnings based on GIS grid platform [14] studying fire alarms and based on methods based on infrared technology [15]. However, the shortcomings of this study have not been able to reduce false alarms.

II. Methodology

The method used in this research is an experimental method. The system is built through the design stage hardware, software, implementation, and testing.

A. Hardware Design

Hardware design carried out based on the block diagram in Fig. 1. System. It consists of input, process, and output. Block diagram of a forest fire detector prototype using a power bank as a resource for the microcontroller and sensors. Starting from the input or input, the input block diagram is in the form of smoke sensors, fire sensors and temperature sensors which are used as input from the tool to start the fire detection process or not. For the microcontroller used is Arduino Uno Rev3 which functions as the main processing component and components that can connect input with output. In the output section there is no component to print the output, but it can be seen from the website and WhatsApp notifications using the mobile phone of forest guards.

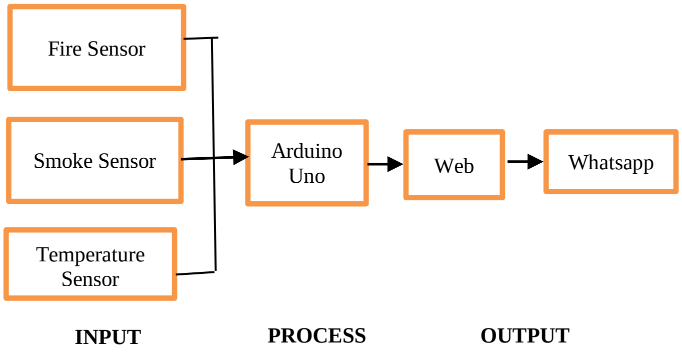

Fig. 1. Block Diagram.

There are three sensors used in this research, namely:

1) Smoke detection sensor: The smoke detection sensor used is the Gravity Analog Infrared CO2 Sensor. This sensor works by sucking air around the sensor, then the sensor will determine the gas concentration of the inhaled air [16]. The sensor will get the gas concentration result in Parts-per-million (ppm). For example, if the result is 1,000ppm CO2. So that means there are 1,000 CO molecules and 999,000 other gas molecules. Fig. 2 shows the physical form of the smoke detection sensor used.

Fig. 2. Gravity Analog Infrared CO2 Sensor.

2) Fire detection sensor: The fire detection sensor used is a 5 Channel Flame Sensor. This sensor uses infrared rays in 5 directions with a range of 120 degrees and in the wave range of 700 nm – 1100 nm, with a detection distance of less than 1 meter and a response time of about 15 microseconds. The fire detection sensor works by detecting infrared radiation generated by the fire, then the sensor converts the detection into analog and digital signals for further processing. Fig. 3 shows the physical form of the fire detection sensor used.

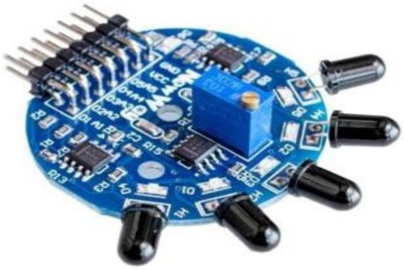

Fig. 3. Sensor Flame.

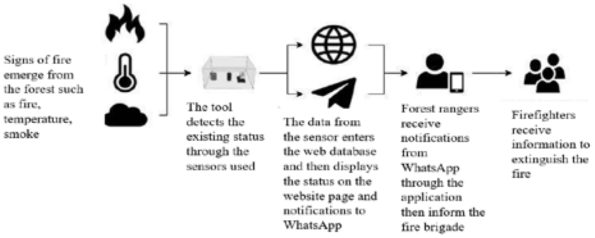
3) Temperature detection sensor: The temperature detection sensor used is the DS18B20 Temperature Sensor, this sensor has a sensor that is quite precise and does not require external components to work. This sensor can measure temperatures from -55°C to +125°C with an accuracy of ±0.5°C. Fig. 4 shows the physical form of the temperature detection sensor used.

Fig. 4. DS18B20 Temperature Sensor.

B. Software Design

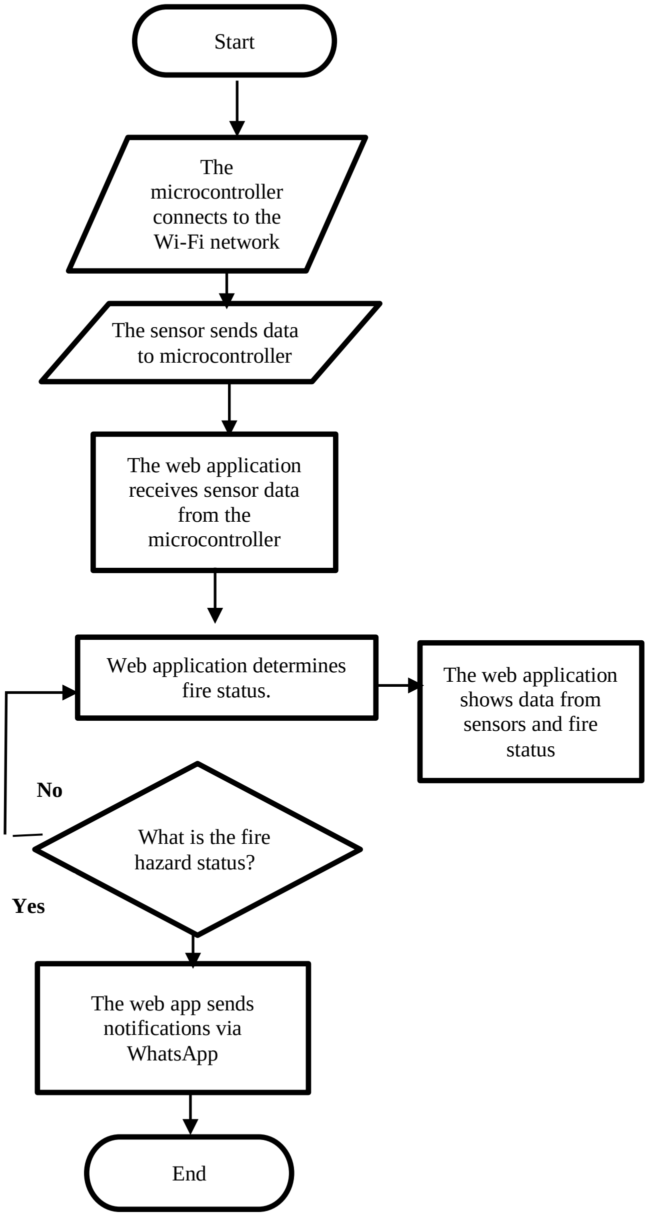
The analysis is carried out in the form of observations of the surrounding environment. When a forest fire occurs it cannot be detected by forest rangers, forest guards only know that if a forest fire occurs, smoke will raise in the sky and the fire conditions are largely handled by the firefighters because the fire was too big. The detection process is carried out manually which makes fires difficult to control because the fires are getting bigger, burning forest areas, and the process of forest fires is relatively long. Therefore, an application is needed to monitor and detect forest fires that are useful for minimizing the incidence of false alarms and responding to forest fires handling. The business process of this application is that this application receives sensor data from the microcontroller, then the application will determine the fire status based on the sensor data received by utilizing fuzzy logic, and then the application will send a notification to the forest ranger via WhatsApp, if the fire status is a hazard, then this information also sent to firefighters. Application design business processes to monitor and detect forest fires can be seen in Fig. 5.



Signs of fire emerge from the forest such as fire, temperature, smoke
The tool detects the existing status through the sensors used
The data from the sensor enters the web database and then displays the status on the website page and notifications to WhatsApp
Forest rangers receive notifications from WhatsApp through the application then inform the fire brigade
Firefighters receive information to extinguish the fire

Fig. 5. Design Business Processes.

The flowchart of the system created is described by the sequence of processes in detail from one process to the next so that the system flows easy to understand. Fig. 6 shows the flowchart of the system that has been made the classification procedure begins with the receipt of sensor data sent by the microcontroller via the API. After that the application will process the data using fuzzy logic to determine the fire status. Fuzzy logic works by receiving data received from the sensor, then classify each data based on the membership function and generate the degree of membership of each sensor data. After that the value of the membership degree will be processed using the rule and will produce the fire status membership degree, which is then entered into the membership degree graph to determine the fire status. If the fire status is declared dangerous, then the application will send a notification message to all contacts WhatsApp stored in the database and displays the status of the fire as a hazard on the monitoring dashboard. Meanwhile, if the fire status is safe or alert, the application only displays the status of a safe or alert fire on the monitoring dashboard.



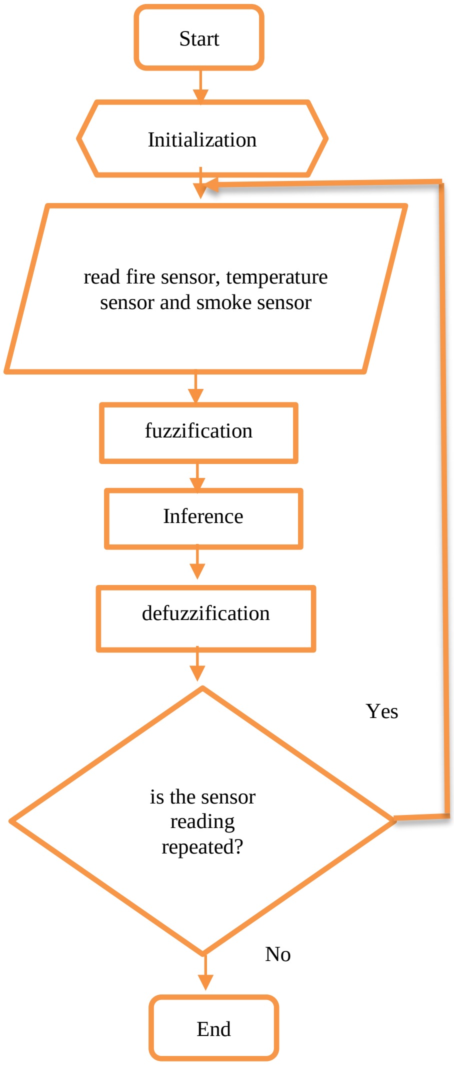
Start
The microcontroller connects to the Wi-Fi network
The sensor sends data to microcontroller
The web application receives sensor data from the microcontroller
Web application determines fire status.
The web application shows data from sensors and fire status
No
What is the fire hazard status?
Yes
The web app sends notifications via WhatsApp
End

Fig. 6. Flowchart System.

In Fig. 7, the fuzzification sub-system will process input data when doing data reading [17]. The data is in the form of firm values or crispy. In this research using Sugeno Fuzzy for inferencing [18]. The following are the stages of the process of Sugeno Fuzzy Inference:

1) Fuzzification: The fuzzification sub process will change the firm value that exists in the membership function or degree of membership. Based on the analysis carried out, the fire status is divided into three, namely, safe, caution, and danger. Where the three statuses are determined based on the variables of Temperature, Smoke, and Fire. Each of these variables has its own status classification. Temperatures are classified into three states, namely, Normal with temperatures less than or equal to 30°C, Warm with temperatures between 30°C and 60°C, and Hot with temperatures greater than or equal to 60°C.

The temperature membership set can be seen in Fig. 8, the membership set function is divided into three ranges, namely, normal [15, 30, 45], warm [30, 45, 60], and hot [45, 60, 75].



Start
Initialization
read fire sensor, temperature sensor and smoke sensor
fuzzification
Inference
defuzzification
Yes
is the sensor reading repeated?
No
End

Fig. 7. Fuzzy Design.

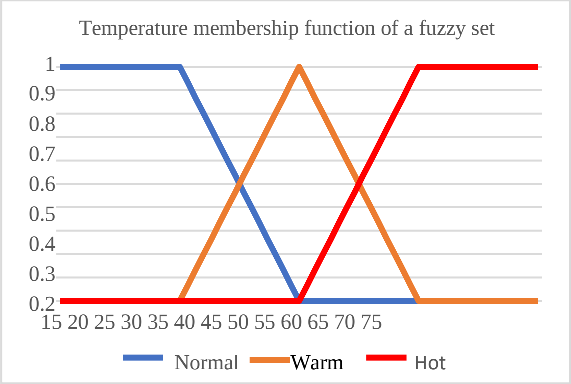


Fig. 8. Temperature Membership.

The smoke membership set can be seen in Fig. 9, in the membership set function is divided into three ranges, namely, thin [200, 600, 1000], medium [600, 1000, 1400], and dense [1000, 1400, 1800].

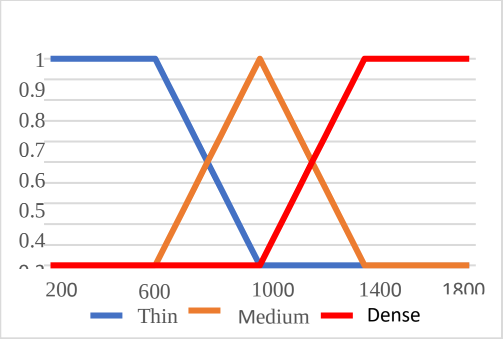

Fig. 9. Smoke Membership.

Fire membership set can be seen in Fig. 10, fire membership set is divided into two ranges, namely, true and false.

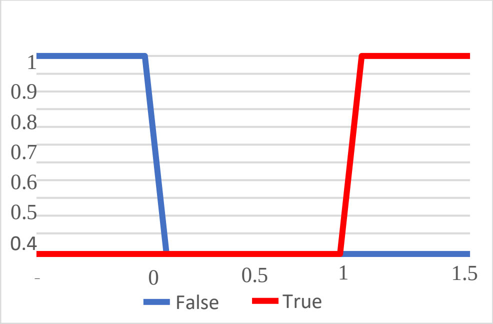

Fig. 10. Fire Membership.

The membership sets above will be used to get the output value by going through the implication stage.

2) Inference: At this stage each rule or rule in the fuzzy knowledge base will be associated with a fuzzy relation. The general form of this function is If x is A then y is B. Based on the results of the linguistic variables determining the fuzzy set, the following rules or rule implications can be seen in Table I and set of fire status can be seen in Fig. 11.

TABLE I. FIRE STATUS RULES

Number rule	Temperature	Smoke	Fire	State
1	Normal	Thin	True	Caution
2	Normal	Thin	False	Safe
3	Normal	Medium	True	Danger
4	Normal	Medium	False	Safe
5	Normal	Dense	True	Danger
6	Normal	Dense	False	Danger
7	Warm	Thin	True	Danger
8	Warm	Thin	False	Safe
9	Warm	Medium	True	Danger
10	Warm	Medium	False	Safe
11	Warm	Dense	True	Danger
12	Warm	Dense	False	Danger
13	Hot	Thin	True	Danger
14	Hot	Thin	False	Safe
15	Hot	Medium	True	Danger
16	Hot	Medium	False	Caution
17	Hot	Dense	True	Danger
18	Hot	Dense	False	Danger

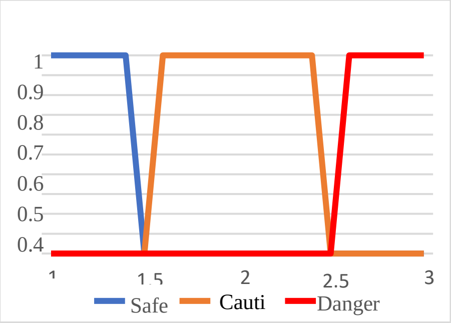

Fig. 11. Set of Fire Status.

At this stage the function used is the minimum calculation, namely by taking the lowest value from the fuzzy set of temperature, smoke, and fire based on the rules that have been made.

$$\alpha i = \mu\ A1\ (X) \cap \mu\ B1\ (X) = \text{MIN}\ \{\mu\ A1\ (X), \mu\ B1\ (X)\} \quad (1)$$

The fire status variable is used to determine the status of the fire status with the Implication function, which consists of safe, alert, and danger with a range as depicted in Fig. 11. That is, safe defuzzification value is 1 – 1.5, Alert 1.5-2.5, and danger 2.5 – 3. Defuzzification

This stage is done by taking the maximum value obtained from taking the minimum value from each rule that has the same rule output.

$$\text{Usf [Xi]} = \text{MAX (Usf [Xi], Ukf [Xi])} \quad (2)$$

- Usf [Xi]*:* value of the i-th order fuzzy solution.
- Ukf [Xi]: value of the i-th order fuzzy solution.

After that, the composition of the maximum value is obtained as follows:

Safe = MAX (rule 2, rule 4, rule 8, rule 10, rule 14)

Caution = MAX (rule 1, rule 3, rule 6, rule 7, rule 16)

Danger = MAX (rule 5, rule 9, rule 11, rule 12, rule 13, rule 15, rule 17, rule 18)

Then Defuzzification is done by entering the maximum value of each output rule into the weighted average formula:

III. Result and Discussion

In Table III, the temperature is stable below 30°C, Smoke is stable in the range of 428ppm to 456ppm and Fire is not detected at all. So based on the rules in Table II, the fire status is Safe.

TABLE II. Test Results with no Fire Conditions

Minute	Temperature (°C)	Smoke (ppm)	Fire	Fire Status
1	28.31	440.63	False	Safe
2	28.19	428.13	False	Safe
3	28.19	428.13	False	Safe
4	28.13	428.13	False	Safe
5	28.13	428.13	False	Safe
6	28.25	428.13	False	Safe
7	28.25	440.63	False	Safe
8	28.19	428.13	False	Safe
9	28.19	456.25	False	Safe
10	28.06	428.13	False	Safe
11	28.13	440.63	False	Safe
12	27.94	428.13	False	Safe
13	27.94	428.13	False	Safe
14	28	440.63	False	Safe
15	28	428.13	False	Safe

In Table III there are three types of fire status that appear. In minutes 1 – 4 there is a fire alert status caused by temperatures exceeding 30°C, smoke in the range of 440ppm to 471ppm, and detected fire. Meanwhile, at minute 5, the status of the fire that occurred was Safe, which was caused by not detecting the fire. This is evidenced by the data at 6 minutes when the fire was detected again, and the fire status returned to Alert. At 9, 13, and 15 minutes there was a Danger fire status, this was caused by a temperature exceeding 45°C, Smoke exceeding 440ppm and a detected fire.

TABLE III. Test Results with 50cm from the Fire

Minute	Temperature (°C)	Smoke (ppm)	Fire	Fire Status
1	32.06	471.88	True	Caution
2	32.13	440.63	True	Caution
3	31.63	471.88	True	Caution
4	35.31	440.63	True	Caution
5	36.56	471.88	True	Safe
6	35.19	440.63	True	Caution
7	37.19	456.25	True	Caution
8	49.25	440.63	True	Caution
9	53.25	609.38	True	Danger
10	48.5	471.88	True	Caution
11	44.63	440.63	True	Caution
12	51.56	440.63	True	Caution
13	47.75	1159.38	True	Danger
14	50.94	428.13	True	Caution
15	53.56	440.63	True	Danger

In Table IV, it can be seen that the farther the distance from the fire source causes the slightly lower temperature detected.

TABLE IV. Test Results with 100cm from the Fire

Minute	Temperature (°C)	Smoke (ppm)	Fire	Fire Status
1	31.63	428.13	False	Safe
2	31.69	428.13	False	Safe
3	31.94	440.63	False	Safe
4	32.13	440.63	False	Safe
5	32.25	440.63	False	Safe
6	32.44	1128.13	False	Safe
7	32.56	440.63	False	Safe
8	32.75	440.63	False	Safe
9	32.88	440.63	False	Safe
10	33.06	440.63	False	Safe
11	33.06	1190.63	False	Caution
12	33.19	471.88	False	Safe
13	33.13	487.5	True	Caution
14	33.25	471.88	False	Safe
15	33.31	487.5	False	Safe

The test results with burning mosquito drugs are shown in Table V.

TABLE V. Test Results with Burning Mosquito Drugs

Minute	Temperature (°C)	Smoke (ppm)	Fire	Fire Status
1	31.63	428.13	False	Safe
2	31.69	428.13	False	Safe
3	31.94	440.63	False	Safe
4	32.13	440.63	False	Safe
5	32.25	440.63	False	Safe
6	32.44	1128.13	False	Safe
7	32.56	440.63	False	Safe
8	32.75	440.63	False	Safe
9	32.88	440.63	False	Safe
10	33.06	440.63	False	Safe
11	33.06	1190.63	False	Caution
12	33.19	471.88	False	Safe
13	33.13	487.5	True	Caution
14	33.25	471.88	False	Safe
15	33.31	487.5	False	Safe

TABLE VI. TEST RESULTS WITH 15 PORTABLE STOVES

Minute	Temperature (°C)	Smoke (ppm)	Fire	Fire Status
1	30.38	428.13	FALSE	Safe
2	30.38	440.63	FALSE	Safe
3	30.31	456.25	FALSE	Safe
4	30.25	440.63	FALSE	Safe
5	30.44	440.63	FALSE	Safe
6	30.38	440.63	FALSE	Safe
7	30.38	1159.38	FALSE	Safe
8	30.44	440.63	FALSE	Safe
9	30.44	440.63	FALSE	Safe
10	30.44	440.63	FALSE	Safe
11	30.44	440.63	FALSE	Safe
12	30.5	428.13	FALSE	Safe
13	30.5	428.13	FALSE	Safe
14	30.63	428.13	FALSE	Safe
15	30.5	428.13	FALSE	Safe

The test results are shown in Table VI, it can be concluded that the false alarm detection accuracy is 100%.

Fuzzy logic testing is done by comparing the fuzzy output value on a series of systems with fuzzy output values found in web. Test performed 10 times is shown in Table VII.

TABLE VII. TEST RESULTS WITH 10 PORTABLE STOVES

Input			Output		Difference	Error
Temperature (°C)	Fire	Smoke (ppm)	Arduino	Web		
23.4	48.8	26.5	2	1.28	0.72	5.62%
29.25	774	1.31	2	2	0	0%
24	50	20	2	1.4	0.6	4.28%
25	25	280	4	4	0	0%
35	25	300	5	5	0	0%
15	500	25	1	1	0	0%
25	200	100	2.73	2.73	0	0%
25	350	200	3	3	0	0%
10	800	20	1	1	0	0%
15	200	500	4	4	0	0%
Average					0.13	0.99%

IV. CONCLUSION

Based on the web-based and WhatsApp-based Forest fire monitoring dashboard detection application that has been done, it can be concluded that: applications can be used by forest halls and forest rangers, the application is implemented by utilizing Arduino along with Arduino sensors to get real time data, the application implements Sugeno Fuzzy Inference for classify fire status and detect false alarm based on data received from Arduino.

Based on the results of tool design and testing, it can be concluded that the performance of the tool as an early fire detector, also functions as a monitoring system for room conditions against potential fires, is able to represent the results of reading all multisensory data and can classify the condition of the room being monitored properly. According to the input data received by the hardware and software. In testing the fuzzy program, the fuzzy output between Arduino and the fuzzy on the monitoring dashboard has a small difference of 0.99%. This shows that fuzzy logic control on multisensory data reading has a high level of accuracy.

Universitas Komputer Indonesia
Bandung, Indonesia

***Abstract*—Mathematics is one of the main subjects in school. In some schools, the learning methods used are still using conventional methods, namely lectures and exercises. The main difficulty in learning mathematics is how to make the material presented more interesting so that it does not make students bored and easy to understand the material. The use of an attitude of interest in games that knows no age and the various advantages of games gives rise to a combination of learning mechanisms called gamification. Gamification is the process of applying game mechanics to non-game activities to increase user interactivity. Gamification in the m-learning mathematics application was developed using the Attention, Relevance, Confidence, and Satisfaction (ARCS) learning model and the octalysis framework gamification method. Gamification in this mathematics m-learning application applies a game strategy using a system of levels, missions, challenges, points, progress bars, leader boards, and badges. The results of this study indicate that this application can be used as an alternative medium for learning mathematics and student engagement with the result that gamification applied to the m-learning mathematics application can increase student interest by 35%, increase student motivation by 33%, and improve understanding 42% of students towards learning mathematics.**

Keywords*—*Gamification; m-learning; mathematics; attention; relevance; confidence; and satisfaction (ARCS) model; octalysis framework; student engagement

I. Introduction

Mathematics is one of the disciplines that is studied at all school levels, given from elementary students to higher levels [1]. Mathematics is considered a difficult subject because the characteristics of mathematics are abstract, logical, systematic, and full of confusing symbols and formulas [2]. This is because mathematics learning is still conventional, which causes teachers to have difficulty developing the material contained in the book because of the large number of materials to be taught, while from the student aspect, students' lack of interest in learning mathematics, understanding of concepts that are not mature, enthusiasm for learning is high. less and students are not motivated when learning mathematics, and many students view mathematics as a difficult and boring subject[3].

The development of ICT has helped a lot in the field of mathematics education [4]. Computer-assisted mathematics learning applications have been widely developed as alternative learning media [5][6]. Mobile application development (m-learning) is one of the media that is currently widely used in the development of learning applications other than e-learning [7]. This is supported by easy access [8], a more flexible learning process [9], as well as its ability to provide interactive and communicative mechanisms [10] to be one of the causes of the development of e-learning learning models toward m-learning [11].

Gamification is the process of using in-game mechanisms or rules for non-game activities to increase user interactivity [12]. Gamification offers application design that embeds game elements so that it has more appeal to application content because game concepts are known to be fun and easy to understand. [13]. This is because the gamification application model must have the characteristics of attracting the attention of students to use it, able to build student motivation and competence, build student confidence and be interactive to build reasoning and mindset when completing tasks and satisfaction, namely students feel happy when they complete their assignments. [14][15]. To develop a gamification mechanism in a learning application, a reference model is needed [16]. The ARCS learning model unites several forms of student attitudes, namely attention, relevance, confidence, and satisfaction [17], where this model is designed to encourage student learning motivation by prioritizing attention to students [18], as well as applications that adapt the subject matter to the student's learning experience, which can create student confidence and create a sense of satisfaction for the student to study harder [19]. In order to develop the ARCS model, an octalysis gamification framework is needed where the gamification concept is designed by analyzing eight aspects of game psychology [20], which is a gamification concept with an emphasis on human-focused design [21], to optimize human motivation in a system, as opposed to function-focused design [22].

From the previous literature, the implementation of mobile applications, gamification techniques, and the ARCS learning model is still being developed partially, there has been no research that has tried to combine these three elements in a unified system. Therefore, the objective of this research is to develop a model and application of gamification-based mathematics m-learning by integrating the ARSC model and octalysis framework. The implementation of the application is carried out to test and prove whether the concepts and applications that have been developed previously can increase student involvement in mathematics.

II. Literature Review

A. Gamification

Gamification is a product, a way of thinking, a process, an experience, a way of design, and a system that is involved, which uses game elements to solve non-game problems. [23][24]. In the world of education, it can also be said that gamification is a process of changing existing activities or studying activities and making learning content like a game [25]. Gamification is using game mechanics to provide practical solutions by building specific group engagement [26]. In more detail [27], defines gamification as a concept that uses game-based mechanics, aesthetics, and game thinking to engage people, motivate action, promote learning and solve problems. In addition, gamification also provides additional motivation to ensure that students participate in complete learning activities [28]. The concept of gamification in an educational environment has the aim of maximizing students' learning comfort, thereby inspiring and motivating them to continue their learning process [29]. The Gamification Model proposed in 2015 (Fig. 1), consists of elements Mechanics which refers to the elements that comprise gamification, Measurement which refers to how progress in gamification is evaluated. Behavior - refers to the desired actions that players will cultivate as a result of playing the game, and Rewards - refers to the types of incentives given to players for fulfilling a requirement or task in the game [30].

B. ARCS Learning Model

Attention, Relevance, Confidence, and Satisfaction (ARCS) is a learning model developed as an alternative that can be used by teachers to motivate student learning by carrying out learning activities well [31]. This learning model contains four components that are an integral part of learning activities, namely (1) generating and maintaining student attention during the learning process (Attention), (2) providing subject matter relevant to students (Relevance), and (3) providing truest self to students (Confidence), and (4) foster student satisfaction with the learning process (Satisfaction) [32]. Within the teaching framework, the motivational analysis must be an ongoing process, to ensure that gamification matches the motivational factors as learning takes place [33]. The ARCS model has provided several specific steps to examine the relevant motivational features in the use of various media in the learning process [34][35]. Fig. 2 shows the ARCS Model applied to an educational game-based learning application.

C. Octalysis Gamification Framework

Octalysis is a gamification framework developed by Yu-kai Chou in 2015. The Octalysis method has two levels, where the first level is an analysis of game elements from the Octalysis framework, while the second level is the application of game elements in four phases that have been provided. Octalysis is based on a gamified framework designed using eight core drives [36]. Fig. 3 shows the gamification framework using the octalysis method at the first level, which consists of eight core drives in the octalysis framework, namely: (1) Epic Meaning and Calling: in this drive, someone is convinced that they are doing something great or feel that they are the chosen ones for doing something, (2) Development and Accomplishment: internal drive to make progress, develop skills and overcome challenges, (3) Empowerment of Creativity and Feedback: users engage in creative processes such as trying different combinations, (4) Ownership and Possession: these drives make users motivated because they feel like they have something, (5) Social Influence and Relatedness: drives that come from the environment, (6) Scarcity and Impatience: the drive to get something for not having it, (7) Unpredictability and Curiosity: the drive to know what will happen next, and (8) Loss and Avoidance: this drive is based on avoiding something negative happening [37].

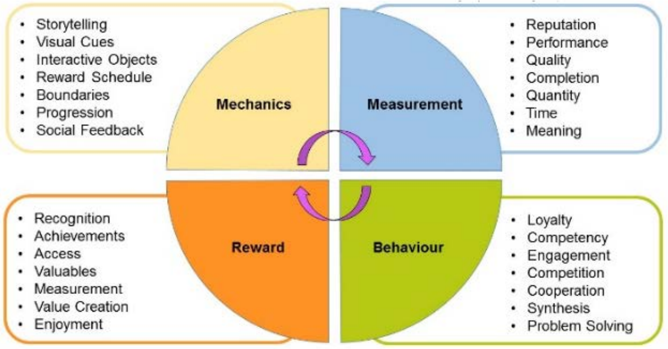

Fig. 1. Gamification Model of Learning. Available from: http://ivantehrunningman.blogspot.com/2015/04/gamification-oflearning.html.

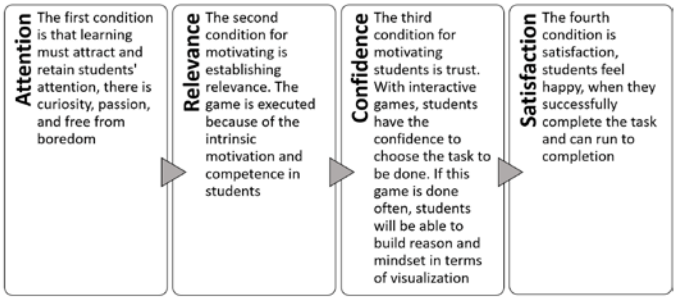

Attention
The first condition is that learning must attract and retain students' attention, there is curiosity, passion, and free from boredom

Relevance
The second condition for motivating is establishing relevance. The game is executed because of the intrinsic motivation and competence in students

Confidence
The third condition for motivating students is trust. With interactive games, students have the confidence to choose the task to be done. If this game is done often, students will be able to build reason and mindset in terms of visualization

Satisfaction
The fourth condition is satisfaction, students feel happy, when they successfully complete the task and can run to completion

Fig. 2. ARCS Model in Educational Game Learning Media.

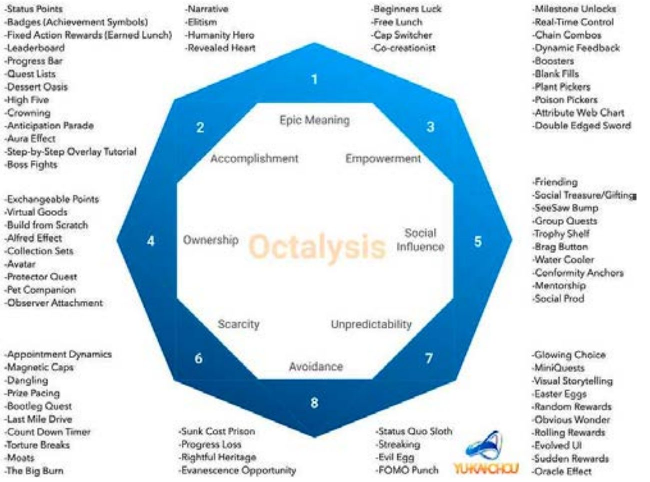

Fig. 3. Level I Octalysis Gamification Framework.

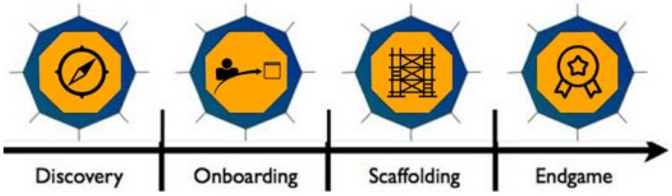

Fig. 4. Level II: Octalysis Level II Gamification Framework.

After applying the game elements that will be used, the elements are arranged into four phases which are part of the octalysis framework, level II. Fig. 4 The following shows the four phases of the second level octalysis framework [38]: (1) Discovery phase which is the initial stage where new users enter the application system and introduction of the application, (2) The onboarding phase is the phase where users begin to get to know the flow and application rules, (3) The scaffolding phase is the phase where users start using the application after getting to know the flow and the main mission of the application, and (4) The endgame phase aims to keep players using the application after the goal of the application has been achieved.

D. Multimedia Development Life Cycle (MDLC)

In the field of learning, the use of multimedia has been widely used, starting from the use of text, images, animation, video, and audio, to motivate students to like teaching materials. Fig. 5 shows the software development method used, namely the Multimedia Development Life Cycle (MDLC) introduced by Luther [39] and developed by Sutopo [40].

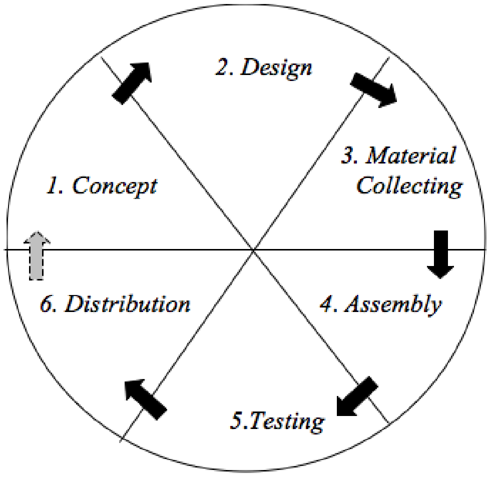

Fig. 5. Multimedia Development Life Cycle.

The concept is the activity to determine the purpose and who are the users of the program [41], Design is the stage of making specifications regarding the program architecture, style, appearance, and material/material requirements for the program [42], Material collecting is the activity of collecting materials following the needs being worked on [43], Assembly is the activity of making all multimedia objects or materials. Application development is based on the design stage, such as storyboards, flowcharts, and/or navigation structures [44], Testing is carried out after completing the assembly activity by running the application program and seeing whether there are errors or not [45], and distribution where the application will be stored in a storage medium. This activity can also be called the evaluation part to develop a finished product to make it better. The results of this evaluation can be used as input for the concept stage of the next product [46].

III. Research Method

This research was conducted using a quantitative descriptive research method [47] namely a research method that provides an objective description of an existing problem analytically and measurably [48].

Fig. 6 shows the five stages of research design carried out in this study, namely problem formulation, data collection, software development using MDLC, and conveying the results.

Creating Application, Implementation and Testing
User Acceptance, Post Test Evaluation
Result and Conclusion

Fig. 6. Research Design.

The first stage is problem formulation which is an attempt to uncover various things related to the problem to be answered or solved. In this study, the formulation of the problem was carried out by identifying the existing mathematics learning problems, what are their shortcomings, and the solutions offered for their completion. This is the aim of the research conducted.

The second stage is the collection of research data utilizing literature studies, discussions, and questionnaires. The literature study was carried out by collecting previous studies related to the ARCS learning model, the theory and implementation of gamification, and the mechanism of MDLC software development. In addition, discussions with the school, namely teachers and students in mathematics, were carried out to collect data on learning materials, get input and describe the desired solution. Meanwhile, the use of questionnaires was carried out for scientific measurement of the results obtained from this research.

The fourth stage is the development of m-learning mathematics software. In this research, software development is carried out using the MDLC method, which starts from the conceptual section which contains the system model to be developed, the users, and its functions in it. Followed by the design and development section, where the system design is carried out, making the assets in the system developed, coding the system, and conducting initial testing. The last part at this stage is an evaluation by testing the system both functionally and in terms of acceptance of its users.

The fifth stage is to summarize the results that have been obtained, provide conclusions, state the limitations in the system built, and direct the development of further research.

IV. Result and Discussion

A. Analysis of Current Learning Conditions

Based on the discussion conducted by the researcher using interviews and field observations (Fig. 7), there are two things found in the learning process of mathematics subjects, namely that the learning process is still done conventionally. The teacher provides learning materials through books, blackboards, and written exams. Meanwhile, students receive learning by listening and doing the tests given by the teacher. On the other hand, there are no alternative tools that can be used by students in the learning process, limiting students to be able to learn and understand mathematics subject matter.

Based on these problems, a solution was developed to build m-learning applications for mathematics subjects that can be used by students to learn from anywhere, with more interactive and interesting content in the form of gamification in mathematics subjects.

B. Conceptualizing Mathematics M-Learning Gamification

Fig. 8 shows the conceptualization of the application carried out to describe what things will be done by the system along with its methods and work functions. Application development starts from user needs, implementation of the ARCS model, and gamification in the application, followed by application development to achieve the expected goals.

2. Student grades increase

Fig. 8. Conceptual Development of Mathematics Gamification Applications.

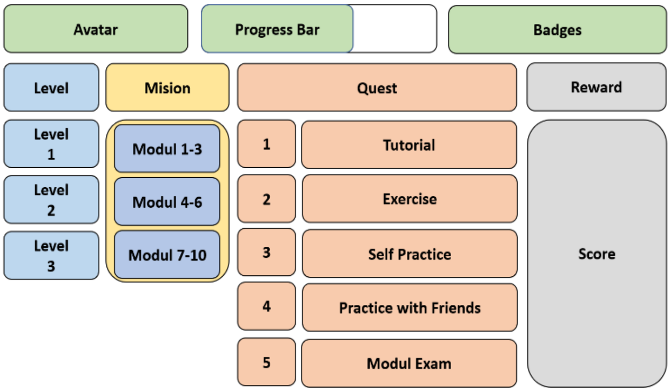

Fig. 9. Mathematics m-learning Gamification Model.

Gamification modeling in the m-learning mathematics application (Fig. 9) was developed by providing educational game effects in the form of game levels related to the learning module for mathematics materials, quests which are challenges that must be completed by students, rewards in the form of points and badges, and avatar that can be customized by students.

C. Octalysis Gamification Analysis

The octalysis method has eight core elements, each of which has a game technique that can be chosen to be implemented. Mathematics learning applications are built using the concept of gamification with the octalysis framework method. This method begins with the level 1 stage by analyzing the elements that will be applied, and then enters the second stage, namely, level 2 making gameplay.

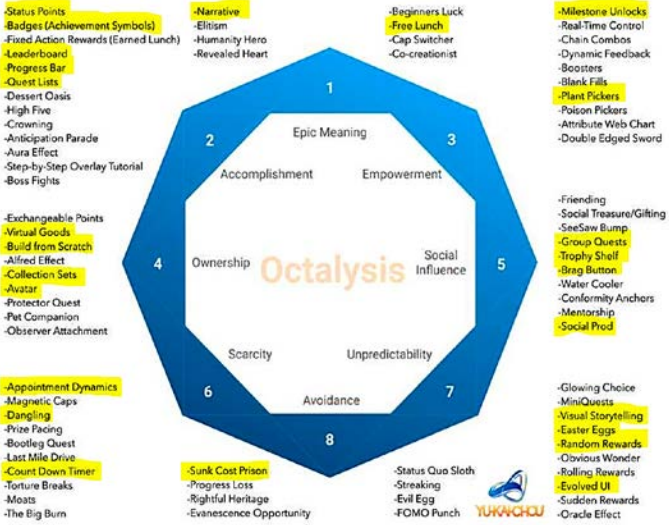

Fig. 10. Octalysis Gamification Elements are used.

Fig. 10 shows that there are 25 elements of the octalysis framework used in the development of this gamification application.

1) Elements of Epic Meaning and Calling, the application convinces the user that he is doing something bigger than himself or that he is "chosen" to do something. Game techniques used in the application to be built include:

a) Narrative, the application will start with a narrative or story that gives an idea of why the user should play the game or use this application.

b) Free Lunch, to attract users there is a limited item for 20 users at the start of the game.

2) Development and Accomplishment elements are used to encourage users to make progress, develop and overcome existing challenges or tasks. Game techniques used in the application to be built include:

a) Progress Bars, there are 2 types of progress bars in the application. The first progress bar is useful for showing the progress of the usage adventure, this progress bar illustrates how far the user has completed the existing material, for example, the user has completed 5 of the 6 chapters that are displayed using the bar. The second progress bar is used to show the user's ability or results in completing each material.

b) Achievement Symbols are used in the form of badges or badges. Every completed action or task will get feedback in the form of a badge. Status Points: each user has status points as a measuring tool or assessment in carrying out existing tasks.

c) The leaderboard is used as a facility to compare the achievements of one player with other players. The use of the leaderboard also aims to motivate players to always feel challenged to be the best.

d) Quest List, is used to displaying what tasks or challenges the user has to do in the application.

3) Empowerment is an element that is made so that users can be as creative as possible in solving problems. The following are the game techniques used in the application to be built:

a) Milestone Unlock: Correlating with the quest list, the existing materials, exercises, and exams cannot be accessed directly by the user. Availability depends on the related task, if the related task has been completed; it means that the user has met the requirements to access the material in question.

b) Plant Picker: Each user has different abilities; they can freely determine the reward they choose.

4) Ownership and Possession are elements where users are motivated because they feel like they own something. When a player feels ownership, he innately wants to make what he has better and have more of it. The following are the game techniques used in the application to be built:

a) Avatar: Each user has their avatar.

b) Virtual Goods: Correlating with the avatar game element, where the existing avatar is created based on the user's wishes, the user can choose the hair, clothes, and eyes for his avatar.

c) Build-From-Scratch: User avatars can be changed by purchasing items in the shop and using limited items from quest/task rewards.

d) Collection Sets: Users can provide feedback in the form of likes to their friends for group activities or assignments.

5) Elements of Social Influence and Relatedness are used to encourage users about guidance, competition, jealousy, group seeking, social possessions, and friendship so that users continue to use existing applications. The following are the game techniques used in the application to be built:

a) Trophy Shelves: Trophy Shelves are implemented in the leaderboard and profile where each user can see other users' searches.

b) Group Quest: There are several materials where training sessions must be carried out together, with this game technique users can interact with each other.

c) Social Prods: Implemented in the form of “likes” after doing Group Quests as a form of appreciation for fellow users.

6) The element of Scarcity and Impatience is the drive that motivates us simply because we cannot have something immediately, or because there is great difficulty in getting it. The following are the game techniques used in the application to be built:

a) Dangling and Anchored Juxtaposition: Energy usage limits the number of tasks taken per day.

b) Appointment Dynamics: This game technique is implemented using push notifications, where users will be given a message every week to use this application.

7) Unpredictability and Curiosity elements are user urges to find out what will happen next. The following is the game technique used in the application to be built:

a) Mystery Boxes/Random Rewards: There are mystery box items as rewards in several missions.

b) Easter Eggs/Sudden Rewards: There are limited rewards on some missions if the user reaches certain conditions.

c) Visual Storytelling: Dealing with Narrative elements where these elements are used as a visualization of the existing narrative.

d) Evolved UI: The existing UI will evolve according to the user level.

8) The Loss and Avoidance element motivates the user through the fear of losing something. For example, if our mission gets a low star rating, the user's points are reduced. The following are the game techniques used in the application to be built:

a) The Sunk Cost Prison: Due to dangling and anchored juxtaposition, the user's energy will be reduced if he exits the application while carrying out certain processes, for example in the training process.

b) Countdown Timers: related to the sunk cost prison and Dangling and Anchored Juxtaposition after the energy runs out the user cannot perform activities for a certain time.

The game elements that have been obtained at the level I are applied to four stages of gamification level II Octalysis namely discovery, onboarding, scaffolding, and endgame which can be seen in Table I.

TABLE I. ELEMENT GAMIFIKASI OCTALYSIS LEVEL II

Phase	Description
discovery	The discovery phase is the initial stage where a new user enters the application system and introduces the application. In this phase, the application uses several technical games, namely Narrative, Visual Storytelling, Free Lunch, and Avatar. Users are first presented with a story that describes why they should use this application and complete the missions according to the Narrative and Visual Storytelling game techniques. After that, the user creates his avatar as a character who will carry out the existing mission. The introduction ends with the award of points and gold as a form of Free Lunch.
onboarding	The Onboarding phase is the phase where the user gets to know the flow and rules of the application. The implementations in it are Progress Bars, Badges, Status Points, and Evolved UI. Students enter the main page in the form of a UI that displays the selected character. Then, students can see Status Points in the form of Points and Energy which are the value handles while using the application. Students can also see various assignments and their rewards on the Quest List page.
scaffolding	This phase is the phase where users start using the application after getting to know the flow and main mission of the application. Users perform activities according to the Quest List to achieve the goals of the application. Users can see the ranking of learning achievements through the leaderboard of accumulated points from completed tasks, besides that users can see the badges earned on the profile page (Trophy Shelves). At this stage, the user is presented with a challenge in which the user evaluates in the form of doing exercises and exams using the Fisher-Yates Shuffle algorithm to reduce the level of cheating. There are joint exercises as the implementation of the Group Quest and each user can give appreciation to his opponent in the form of likes as the implementation of the Social Prod. The results of practice and exams are visualized grades with stars. Each completed Quest earns rewards. Users then have activities to get Badges, according to existing conditions. Here implements Social Treasures and Collection Sets, and there is also a Milestone Unlock where this will unlock badges, as well as Easter Eggs. With the Easter Eggs mechanism, learning can be determined based on the user's decision, this is in line with the plant picker component game. The use of the application is limited according to the amount of energy remaining (The Sunk Cost Prison and Dangling and Anchored Juxtaposition), if the energy runs out the user must wait for a certain time (Countdown timer). Previously created avatars can be changed and customized via items purchased on the implementation avatar pages of Virtual Goods and Build-From-Scratch.
endgame	The last phase is the Endgame phase. This phase aims to keep players using the application after the goals of the application have been achieved. The implementation of this phase uses Appointment Dynamics where users will get notifications periodically.

D. ARCS Model and Octalysis Gamification Mapping

This stage is carried out by mapping the ARCS learning model based on the Attention, Relevance, Confidence, and Satisfaction categories, as well as the octalysis method in application development.

Table II shows the mapping mechanism of the ARCS learning model in the Attention category and the octalysis method.

TABLE II. MAPPING MODEL ARCS (ATTENTION) AND OCTALYSIS METHOD

ARCS Model - Attention			
Sub Category	***Description Category***	***Element Octalysis***	***Description***
Perceptual arousal	Media must have things that can attract users	*Narrative, Visual Storytelling*	The use of narration and visual storytelling to explain why they should use the app and learn the lessons.
		Avatar	Users have their avatar where the appearance of the avatar can change according to student achievements.
	Perception of stimulation through surprise	*Free lunch*	Students who access the app first get special rewards
		Easter Eggs (Sudden Reward)	There is a limited reward if the user reaches certain conditions
		Appointment Dynamic	Students are always reminded every week to study through notifications
	Perception of design through uncertainty	*Mystery Boxes (Random Rewards)*	Students can get random items from the mystery box
Variability	Interesting presentation of material	*Narrative, Tutorial*	Video media is used so that students do not get bored easily.
Inquiry arousal	Students can study the material independently	*Narrative, Tutorial*	With the narration in the learning video, students can learn independently
	Students can determine the learning process	*Plant picker*	The learning flow of each student is different, students can determine their process

Table III shows the mapping mechanism of the ARCS learning model in the Relevance category and the octalysis method.

Table IV shows the mapping mechanism of the ARCS learning model in the Confidence category and the octalysis method.

TABLE III. MAPPING MODEL ARCS (RELEVANCE) AND OCTALYSIS METHOD

ARCS Model - Relevance			
Sub Category	***Description Category***	***Element Octalysis***	***Description***
Goal Orientation	Explanation of learning objectives	*Narrative*	Before students can see the learning video, the learning syllabus is presented first.
Motive Matching	Explanation of the benefits of learning	*Narrative*	Before students can see the learning video, the learning syllabus is presented first.
Familiarity	Learning adaptation to students	*Narrative*	Examples of problems in learning adapted to the lives of students today

TABLE IV. MAPPING MODEL ARCS (CONFIDENCE) AND OCTALYSIS METHOD

ARCS Model - Confidence			
Sub Category	***Description Category***	***Element Octalysis***	***Description***
Learning Requirements	Learning requirements	*Milestone Unlock*	Students must meet certain requirements to carry out a lesson
		Quest List	Students can see the criteria for taking existing subjects
Success Opportunities	Provides many, varied, and challenging experiences that enhance learning success	*Group Quest*	The available exercises are divided into 2 types, namely individual training and group training (multiplayer)
Personal Control	There is feedback on student learning outcomes	*Status, Progress Bar*	Learning results can be seen through the number of stars and progress bar
		Rewards/ Achievement Reward	Every time you complete a quest, students get rewards
	Student responsibility for learning	*Dangling and Anchored Juxtaposition*	Students cannot arbitrarily carry out continuous learning, learning activities are limited by energy so students must be able to take advantage of their time
		The Sunk Cost Prison	Related to Dangling and Anchored Juxtaposition, students must be responsible if they cannot complete the learning process or leave in the middle of the process.
		Countdown Timers	Students cannot carry out the learning process, there is a time back, the rewards of the student's irresponsibility during the learning process

Table V shows the mapping mechanism of the ARCS learning model in the Satisfaction category and the octalysis method.

E. Analysis System Architecture

M-learning application development has three subsystem architectures in it. The first sub-system is the frontend application which functions as a gamification application used by students, a backend application used by teachers to manage the system and monitor student learning outcomes, and the internet which is used for the exchange and storage of application data. The architecture of the mathematical m-learning application can be seen in Fig. 11.

Functionally, the frontend application is an application that has gamification features. This application is used by students to learn math subjects.

TABLE V. MAPPING MODEL ARCS (SATISFACTION) AND OCTALYSIS METHOD

ARCS Model - Satisfaction			
Sub Category	***Description Category***	***Element Octalysis***	***Description***
Intrinsic reinforcement	Internal satisfaction that can motivate students	*Badges (Achievement Symbol)*	Students get rewards in the form of badges as a visualization of their achievements
		Trophy Shelves	All learning achievements can be seen through the profile page
		Virtual Goods, Build From Scratch	*Existing avatars can be changed and created according to the user's wishes*
		Evolved UI	The existing UI changes according to user achievements
Extrinsic Rewards	External achievements that can motivate students	*Status, Leaderboard*	There is a student leaderboard to motivate which is obtained from accumulated points (status) obtained from rewards
Equity	Students can get learning feedback from other students	*Social Prod, Collection Sets*	Students can give feedback "like" after doing the exercise together

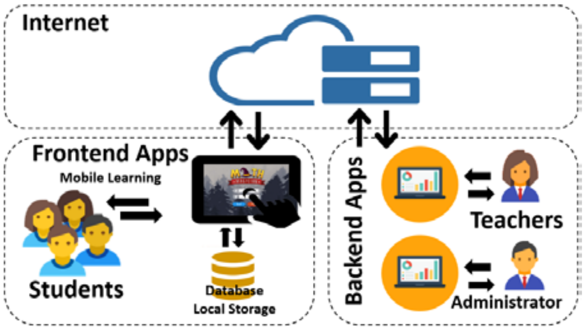

Fig. 11. Mathematics m-learning Application Architecture.

Fig. 12 shows the functionalities developed in the mathematics m-learning application, where there are login functions, viewing materials, doing exercises, taking exams, viewing quests, viewing profiles, viewing the leaderboard, and creating avatars.

F. Gamification Logic Design

To develop the functionalities described in the use case diagram, a logical design is made for each function that shows the learning flow that can be carried out in the application of m-learning mathematics. The flow can be seen in Fig. 13 which starts from accessing the module to its completion, calculating scores and badges as an award for student achievement of the material that has been completed.

1) Tutorial design process: Learning materials (tutorials) are studied using a linear tutorial model and branched tutorials depending on the actions taken by students according to the application of game elements in the previous analysis. The linear tutorial causes students can't able to choose freely to access the material they want to learn, and must follow the sequence according to the order of the existing material. Meanwhile, in the branching tutorial, students can take other materials if they have special items through random rewards. The tutorial flow can be seen in Fig. 14.

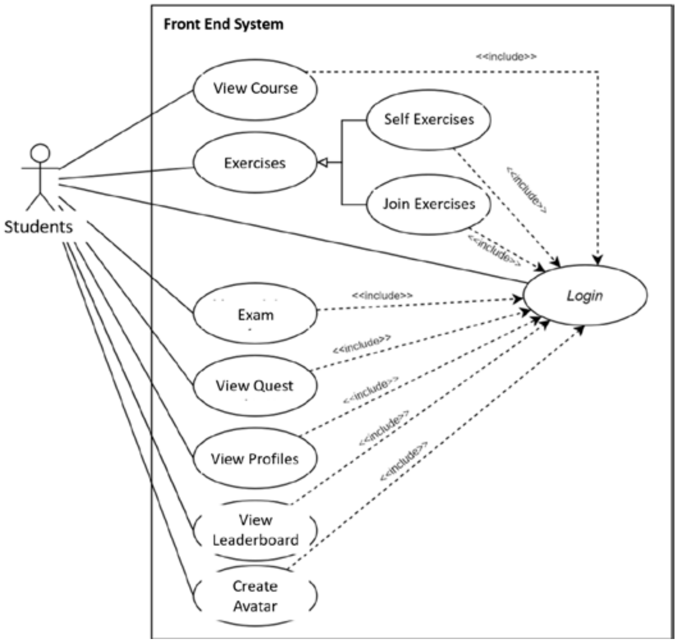

Fig. 12. M-learning Application Frontend use-case Diagram.

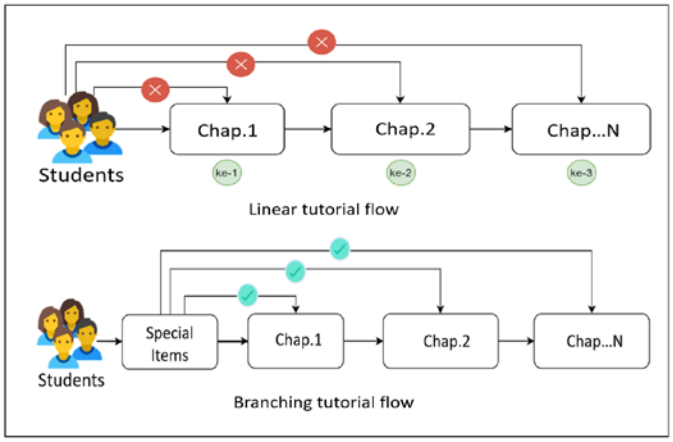

Fig. 14. Tutorial Flow.

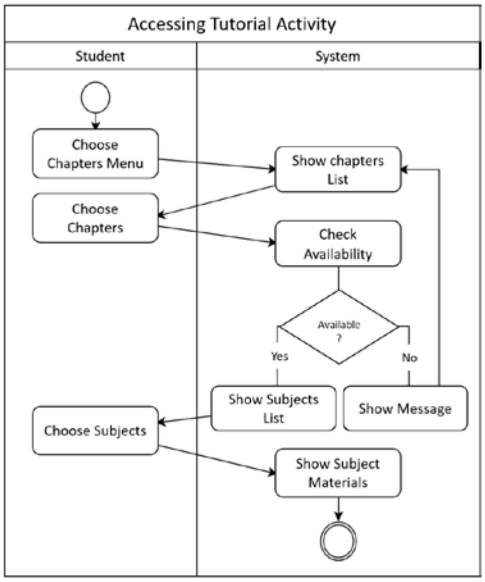

Fig. 15. Accessing Tutorial Activity Diagram.

Fig. 15 is an activity diagram that shows how students access the tutorial functions in the system. The tutorial consists of chapters and subjects of mathematics lessons that students can choose from.

2) Exercise and exam design process: The evaluation process is carried out using two methods, namely practice questions and exams. Students can do 2 practice modes, namely self-practice (Fig. 16), joint practice or multiplayer (Fig. 17), and independent exam (Fig. 18). At the time of practice, the number of questions that came out was 10 questions and 5 questions for joint practice. Meanwhile, at the time of the exam, the questions that came out were 15 questions, in which the questions were in the form of multiple choices.

Fig. 18. Self-examination Evaluation Flow.

There is a special feedback feature after doing joint exercises, where students can give likes to other students after the exercise is finished. This is to give appreciation and socialization between students. The feedback flow can be seen in Fig. 19.

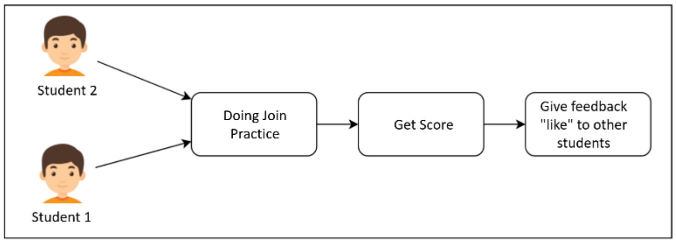

Fig. 19. Joint Practice Feedback Flow.

Fig. 20 shows an activity diagram of the exercise and exam functions that can be performed by students. The function of exercise and exam is an evaluation carried out by the system when a student has completed a chapter of learning in the system.

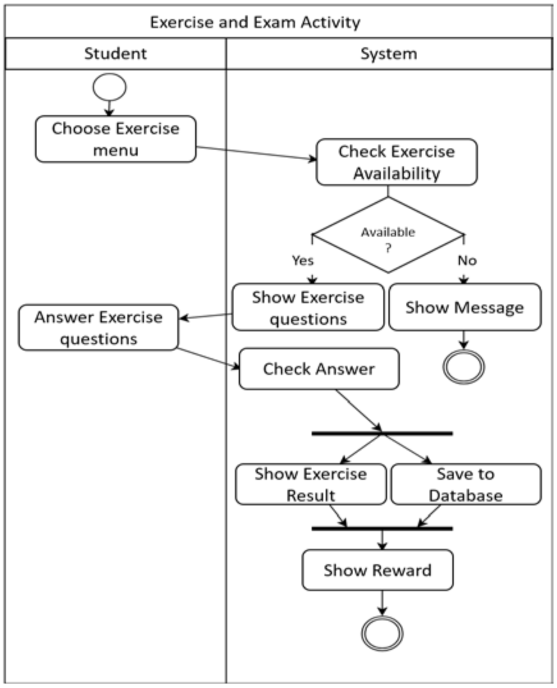

Fig. 20. Exercise and Exam Activity Diagram.

3) Quest flow design: Not all existing processes can be accessed freely by users; certain requirements must be completed first. The following is an analysis of the quest flow in the application that was built, which can be seen in Fig. 21.

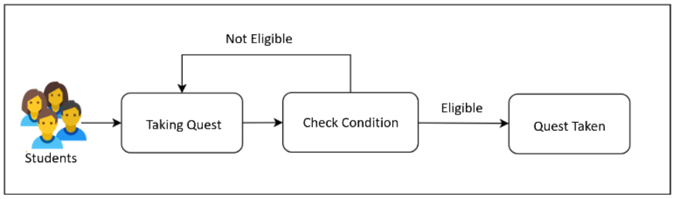

Fig. 21. Quest Selection Flow.

4) Rewards flow design: The form of rewards is adjusted to the status used in existing applications; rewards can be in the form of points or badges for students who have completed an activity. The flow of rewards can be seen in Fig. 22.

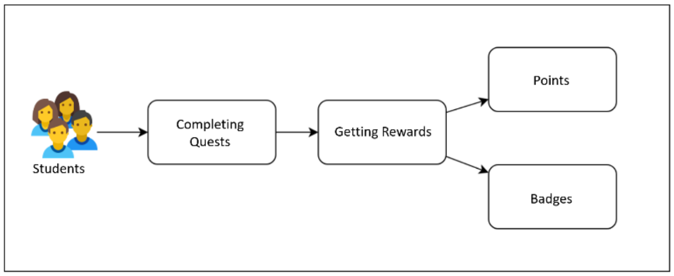

Fig. 22. The Flow of Rewards.

5) Leaderboard flow design: The leaderboard is obtained from the accumulation of student learning outcomes, obtained from the completion of tutorials, completion of exercises and exams as well as other activities. Fig. 23 shows the workflow of the leaderboard creation activity as well as an activity diagram to access the leaderboard contained in the system.

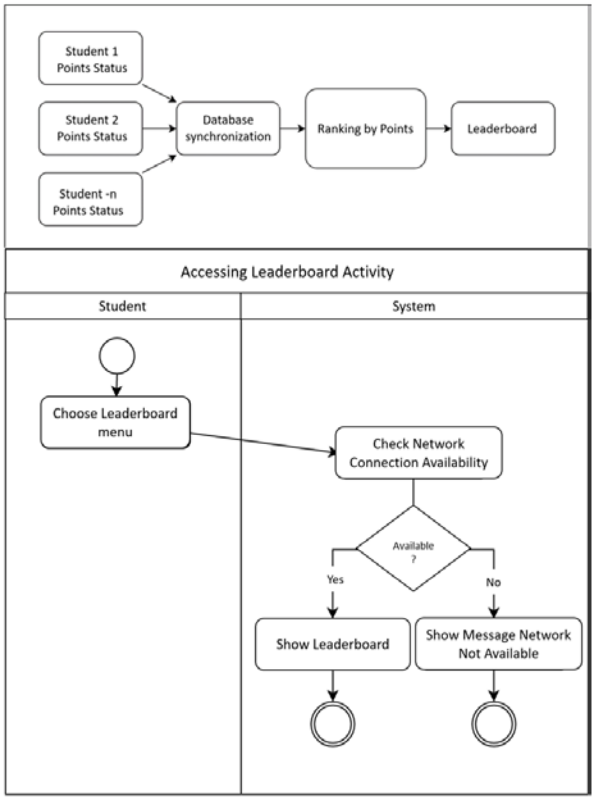

Fig. 23. Leaderboard Flow and Activity Diagram.

6) Avatar flow design: The avatar in the application can change according to the student's level status. Changes in avatars depend on student learning achievements, namely tutorials, evaluations, and points obtained. The following is the avatar flow for the application to be built, which can be seen in Fig. 24.

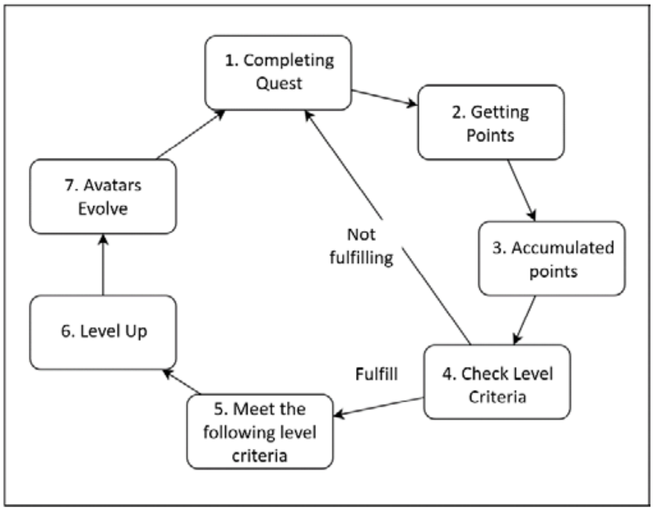

Fig. 24. Avatar Evolution Flow.

Fig. 25 shows student activities to customize their avatar. Avatars can be changed visually according to the level, badges, and rewards that students have.

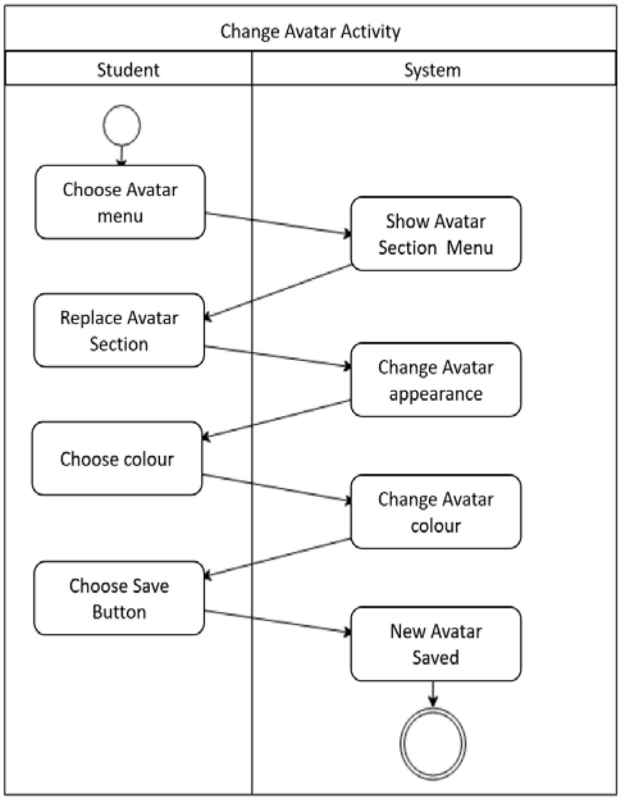

Fig. 25. Avatar Change Activity Diagram.

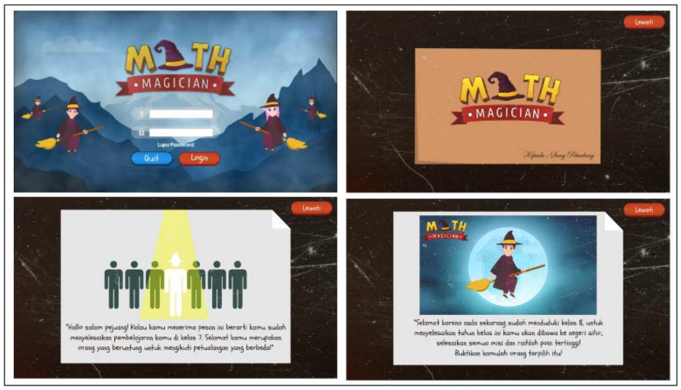
G. Gamification Asset Design

Assets in the application are symbols that are used to show the concept of gamification in the application that is made. Fig. 26 shows the assets used to deliver students understand the application that will be used.



"Hallo salam pejuang! Kalau kamu menerima pesan ini berarti kamu sudah menyelesaikan pembelajaran kamu di kelas 7. Selamat kamu merupakan orang yang beruntung untuk mengikuti petualangan yang berbeda!"

"Selamat karena anda sekarang sudah menduduki kelas 8, untuk menyelesaikan tahun kelas ini kamu akan dibawa ke negeri sihir, selesaikan semua misi dan raihlah poin tertinggi!
Buktikan kamulah orang terpilih itu!

Fig. 26. Introduction Gamification Asset.

Meanwhile, Fig. 27 is the badge assets that are used to show the form of rewards for student achievement in this gamification application.

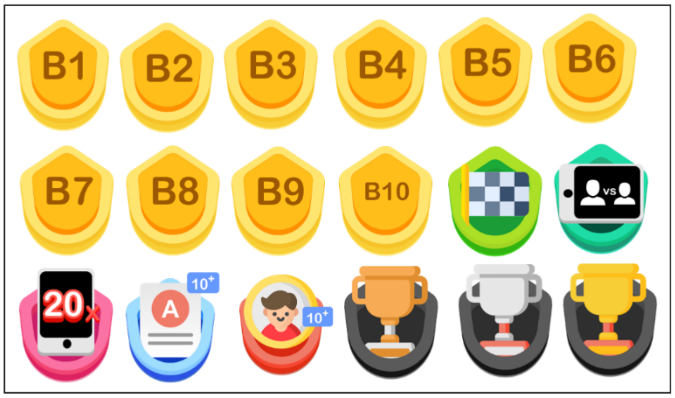


Fig. 27. Badges Gamification Asset.

Fig. 28 shows the assets associated with the Level which is divided into three where each level has a sub-level. The level is adjusted to the achievement of the learning modules that have been completed by students.

Fig. 29 shows the avatar assets that can be used by students after completing the learning stages in the application. The avatar designed in the application consists of shapes that represent the level of the game and can evolve when students advance to the next level.

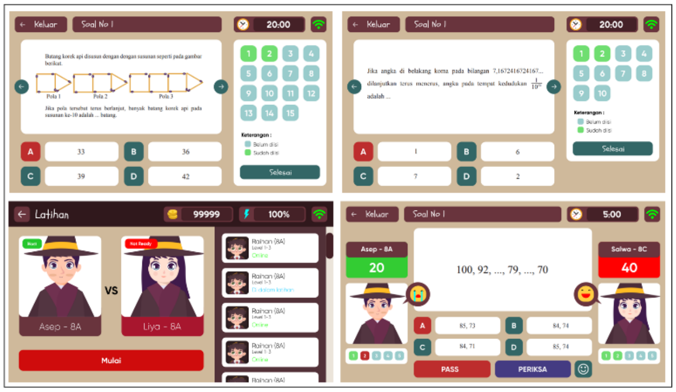

Fig. 32. Practice and Exam Gamification Asset.

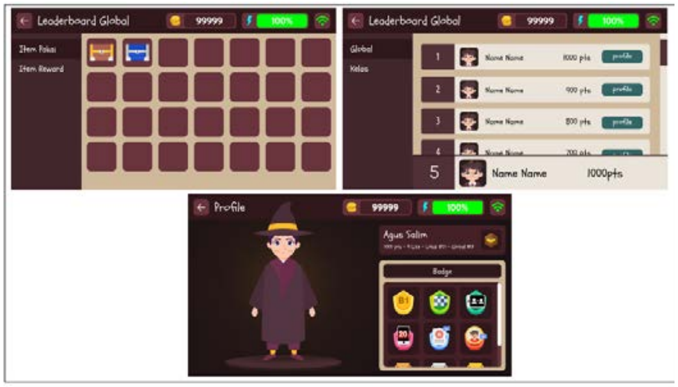

Fig. 33. Profile and Leaderboard Gamification Asset.

Fig. 33 shows the profile assets and leaderboard in the application, this feature is used to see what items have been collected as a form of reward for completing the material and to see the student leaderboard and the points they have.

H. Application Testing

The tests carried out on the application consist of functional (alpha), beta and quasi-experimental testing. The method used in alpha testing is black box testing which focuses on the functional requirements of the system being built and in the beta stage, user assessments of the software are carried out through interviews and questionnaires. Meanwhile, quasi-experimental testing was used to measure the effect of using the application on students' understanding, interest, and motivation.

Alpha testing is a functional test that is used to test the new system. Alpha testing focuses on the functional requirements of the software. Alpha test results can be seen in Table VI.

Beta testing is a test that is carried out objectively, where testing is carried out directly on students. The method used is a questionnaire that is used to conclude the quality assessment of the application being built [49]. The following is the sampling formulation for the questionnaire:

$$n = \frac{N}{1 + Ne^2}$$

n: number of samples

N: Population (421)

e: threshold (10%)

$$n = \frac{421}{1 + 421 * (10\%)^2} = 80,81 \approx 81$$

Based on existing calculations, the number of samples obtained is 81 or equivalent to 2 Grade VIII classes, with an average number of students per class of 42 students. Two test classes were selected, namely grade VIII-A (40 students) and grade VIII-C (41 students) which had 81 students according to the calculation of the number of samples.

The questionnaire was given consists of nine questions related to the quality of the application which can be seen in Table VII, meanwhile for the measurement of results using a Linkert scale with weighted answers which can be seen in Table VIII.

TABLE VII. QUESTIONNAIRE QUESTIONS

No	Questions
1	Is the application easy to use?
2	Is the use of colors, buttons, and letters for the appearance (interface) of the application attractive?
3	Does the app encourage me to study math?
4	Can the application help me in understanding math lessons?
5	Is the material presented following the lesson given?
6	Is the material presented interesting and easy to understand?
7	Does using a ranking system motivate me to study?
8	Does the group practice system make learning interesting?
9	Does the use of avatars make the learning system interesting?

TABLE VIII. QUESTIONNAIRE ANSWER SCORE

Answer Category	Score
Strongly agree	5
Agree	4
Neutral	3
Disagree	2
Strongly disagree	1

The results of the final application assessment are the overall calculation of the questionnaire results obtained from student answers, which can be seen in Table IX, with the application quality assessment criteria shown in Table X.

TABLE IX. OVERALL QUESTIONNAIRE RESULTS

Category Answers	Score	Frequency of Answers	Total Score
Strongly agree	5	302	1510
Agree	4	246	984
Neutral	3	181	543
Disagree	2	0	0
Strongly disagree	1	0	0
Total		729	3037

P = (3037/3645) x 100% = 83%

TABLE X. APPLICATION QUALITY ASSESSMENT

No	Percentage Value	Criteria
1	0% - 19%	Very bad
2	20% - 39%	Bad
3	40% - 59%	Neutral
4	60% - 79%	Good
5	80% - 100%	Very good

Based on the results of the overall questionnaire, the application criteria showed 83%, which means that the application was in very good criteria.

Meanwhile, to determine the effect of using the application on students (student engagement), quasi-experimental testing was carried out by conducting pre-test and post-test activities through three activities, namely, understanding the material, filling out motivational questionnaires, and filling out interest questionnaires. The results of the pre-test and post-test will be compared using normalized gain score analysis which is calculated using the following formulation:

Normalized gain(g) = (post-test score– pre-test score) / (maximum score - pre-test score)

The results of the quasi-experimental testing activities obtained the results shown in Table XI and Fig. 34.

Based on the results of the tests carried out, it was concluded that there was an increase in student engagement in learning mathematics after using the gamification mechanism in the m-learning application. The increase was found in student understanding by 42%, student interest in applications by 35%, and student motivation by 33%.

TABLE XI. ASSESSMENT OF STUDENT ENGAGEMENT

Student Engagement	**Score**	***Pre-Test***	***Post-Test***	***Gain***
Student Understanding	Average	58,64	72,47	0,42
Student Interest	Average	58,30	73,07	0,35
Student Motivation	Average	58,84	72,57	0,33

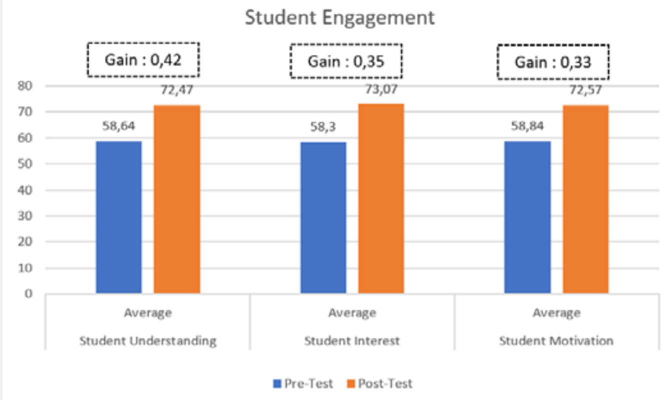

Fig. 34. Results of the Student Engagement Test on the Application.

This study is in line with research [50] where gamification can create student engagement in the learning process, as well as research [51] where there is an increase in better understanding by using gamification-based applications. Gamification-based mobile applications are also an effective and efficient alternative learning media in addition to classroom learning, because the game model can be used anywhere [52], besides that students have a competitive sense in learning because this gamification model shows rankings between participants [53].

The limitations of this research are the absence of features that facilitate schools to update the content in the application if there is a curriculum change, the ability of the application to be able to monitor and provide intelligent direction to students and teachers, and the data storage mechanism is still simple.

Therefore, the development of this research in the future will be involving elements such as artificial intelligence [54][55] to improve students' predictive abilities, in addition to applying augmented reality technology for application interaction [56] as well as having the ability to store and track data and student progress securely using blockchain technology [57][58].

V. CONCLUSION

In this study, we developed a mathematical mobile learning application that combined elements of gamification with the octalysis method and the ARCS learning model.

The purpose of this research is to see how far the role of the application can provide students' engagement in mathematics. The results obtained indicate that there is an increase in understanding by 42%, student interest by 35%, and student motivation by 33% after using the application. This is measured by a pre and post-test mechanism that is carried out on several students who use the application.

As future work, we plan to develop this application by adding interactive modules to adjust the curriculum changes that occur. Addition of intelligent monitoring and evaluation modules can monitor and provide referrals for students and teachers effectively and efficiently. Develop module content with technologies such as augmented reality, as well as secure data storage mechanisms that are easy to trace and transparent using blockchain technology.

ACKNOWLEDGMENT

We would like to thank SMP Negeri 1 Cangkuang, Bandung Regency - West Java, as a place for testing and implementing mathematical gamification applications, as well as the Universitas Komputer Indonesia (UNIKOM) for providing funding for the development of this research.

Energy-based Collaborative Filtering Recommendation

Tu Cam Thi Tran[1, [0000-0001-5811-6952]], Lan Phuong Phan[2], Hiep Xuan Huynh[3*, [0000-0002-9213-131X]]

Faculty of Information Technology, Vinh Long University of Technology Education (VLUTE), Vinh Long province, Vietnam[1]
College of Information and Communication Technology, Can Tho University (CTU), Can Tho city, Vietnam[2, 3]

***Abstract*—The core value of the recommendation model is the using of the measures to measure the difference between the jumps (e.g. pearson), some other studies based on the magnitude of the angle in space (e.g. cosine), or some other studies study the level of confusion (e.g. entropy) between users and users, between items and items. Recommendation model provides an important feature of suggesting the suitable items to user in common operations. However, the classical recommendation models are only concerned with linear problems, currently there is no research about nonlinear problems on the basis of potential/energy approach to apply for the recommendation model. In this work, we mainly focus on applying the energy distance measure according to the potential difference with the recommendation model to create a separate path for the recommendation problem. The theoretical properties of the energy distance and the incompatibility matrix are presented in this article. Two experiment scenarios are conducted on Jester5k, and Movielens datasets. The experiment result shows the feasibility of the energy distance measures/ the potential in the recommendation systems.**

Keywords—Energy distance; energy model; collaborative filtering; recommendation system; distance correlation; incompatibility

I. Introduction

Recommendation systems suggest the suitable items to a user based on his/her purchased items or his/her rated items [9]. There are many implementations of a recommendation system based on different factors and applied to different contexts, such as the recommendation systems determining the user's rating values according to the magnitude of the angle (e.g. cosine) [22], or the recommendation systems based on the difference of the users (e.g. pearson) [19][2], or the recommendation systems based on the confuse of one user with another (e.g. entropy) [4], some other recommendation systems based on the statistical implication [12][18].

Collaborative filtering recommendation model [6] mainly based on users, items. In particular, the Singular Value Decomposition algorithm - a classical method from linear algebra used as a technique to reduce size in machine learning - is combined with recommendation model, or Alternating Least Squares (ALS) - a matrix factorization algorithm – is used for the larger-scale collaborative filtering problems, or some techniques for selecting random or popular items are also integrated to recommendation systems. However, most of the recommendation models revolve around the problems of linear relations, not the problems of nonlinear relations.

In this article, we propose a new collaborative filtering recommendation model to consider nonlinear relations instead of focusing only on linear relations between users. This approach is performed on the basis of determining the relationship/distance between users in pairs, especially Newton's gravitational potential energy (known as potential energy, shortly energy) between two users. In this collaborative filtering recommendation model, the relationship between two users is determined through calculating the maximum mean discrepancy (MMD), or a lack of compatibility or similarity between two or more users.

The article is structured as follows. In Section II, we present collaborative filtering based on energy. Section III presents the learning model, data division methods and evaluation methods. In Section IV, we propose the new recommendation model based on energy. In Section V, we show the experiment on the Jester5k, and MovieLense datasets. Section VI is the conclusion of the article.

II. Collaborative Filtering

Collaborative filtering [3][15][22] is the process of filtering or evaluating items using the opinions of others. Collaborative filtering technology gathers the opinions of large interconnected communities on the webs, and supports filtering of substantial quantities of data. The recommendation system [1] uses a lot of information such as: the items, the users and the rating values to suggest the suitable items to user. However, the unwanted information has been removed by using the computerized methods before presenting the recommendation result to the user.

In collaborative filtering [1], the recommendation system searches for similar users to make predictions. The user's rating model is a useful feature for determining similarity. Normally, the collaborative filtering recommendation methods use ratings without additional information about the user or the item to recommend the suitable items.

The recommendation system [9][10][11] is an information system [17], includes a set of four:

$$S = < U, I, R, f > \tag{1}$$

Where

U - is the set of users (the closed universe), $U = \{u_1, u_2, \ldots, u_n\}$ with $u_k \in U, k = 1..n$. U is a finite set of n objects (a nonempty set)

*Corresponding Author.

I - is the set of items $I = \{i_1, i_2, \ldots, i_m\}$ with $i_j \in I, j = 1..m$. I is a finite set of m attributes (a nonempty set).

$R = \{r_{ij}\}$, with $i = 1..n$, $j = 1..m$. R is a rating matrix, where r_{ij} is rating value of the user u_i to item i_j.

$$R = \begin{bmatrix} r_{11} & r_{12} & r_{13} & .. & r_{1m} \\ r_{21} & r_{22} & r_{23} & .. & r_{2m} \\ r_{31} & r_{32} & r_{33} & .. & r_{3m} \\ .. & .. & .. & .. & .. \\ r_{n1} & r_{n2} & r_{n3} & .. & r_{nm} \end{bmatrix}$$

For example, Table I is a rating matrix where the rating value ranges from 1 to 5 or not available.

$f : U \, x \, I \rightarrow$ R - is the total decision function called the information function such that $f(u, i) \in R_i$ for every $i \in I$, $u \in U$. Function $f(u_k, i_j)$ is used to measure the relevance (the rating value) of item i_j with user u_k. The rating value $f : U \, x \, I \rightarrow R$.

A. Energy Distance

The energy distance [7][8][13] is the distance between the probability distributions. Energy is defined as the similarity in the form of potential energy between objects in gravitational space. The potential energy is zero if and only if the positions (centers of gravity) of the two objects coincide, and the potential energy increases as the difference between the objects in space increases. The concept of potential energy can be applied to collaborative filtering. Let U_1 and U_2 be independent random vectors in U , where F and G are cumulative distribution functions, and they correspond to each other. Accordingly, $\|.\|$ represents the Euclidean normal of its argument, E represents the expected value, and a random variable U_1' represents a copy (iid), which is independent and distributed like U_1; that mean, U_1 and U_1' are iid. Similarly, U_2 and U_2' are iid. The squared energy distance [16][20][24] can be determined according to the expected distance between random vectors.

$$D^2(F, G) := 2E\|U_1 - U_2\| - E\|U_1 - U_1'\| - E\,\|U_2 - U_2'\| \geq 0 \qquad (2)$$

Consider the null hypothesis that two random variables, U_1 and U_2, have the same cumulative distribution functions: F = G. For samples $u_{11}, \ldots, u_{1n}$ from U_1 and $u_{21}, \ldots, u_{2m}$ from U_2, respectively, the E-statistic for testing this null hypothesis is:

$$\varepsilon_{n,m}(U_1, U_2) := 2A - B - C \qquad (3)$$

where A, B, and C are simply averages of pairwise distances:

$$A = \frac{1}{nm} \sum_{i=1}^{n} \sum_{j=1}^{m} \|u_{1i} - u_{2j}\|, \qquad (4)$$

$$B = \frac{1}{n^2} \sum_{i=1}^{n} \sum_{j=1}^{n} \|u_{1i} - u_{1j}\|, \qquad (5)$$

$$C = \frac{1}{m^2} \sum_{i=1}^{m} \sum_{j=1}^{m} \|u_{2i} - u_{2j}\|: \qquad (6)$$

One can prove (3) that $\varepsilon(U_1, U_2) := D^2(F, G)$ is zero if and only if U_1 and U_2 have the same distribution $(F = G)$. It is also true that the statistic $\varepsilon_{n,m}$ is always non-negative. When the null hypothesis of equal distributions is true, the test statistic.

$$T = \frac{nm}{n+m} \varepsilon_{n,m}(U_1, U_2) \qquad (7)$$

B. Incompatibility Matrix

The incompatibility matrix E represents the energy distance between users. The incompatibility matrix $E = \{e_{ij}\}$, with $i = 1..n$, $j = 1..n$, e_{ij} is calculated by formula (2).

$$E = \begin{bmatrix} e_{11} & e_{12} & e_{13} & .. & e_{1n} \\ e_{21} & e_{22} & e_{23} & .. & e_{2n} \\ e_{31} & e_{32} & e_{33} & .. & e_{3n} \\ .. & .. & .. & .. & .. \\ e_{n1} & e_{n2} & e_{n3} & .. & e_{nn} \end{bmatrix}$$

For example, Table II shows the matrix representing the energy distance between users by using information of Table I.

C. Incompatibility Neighborhood

The neighborhood of the user u_a is defined by the energy distance between the users and u_a . The neighborhood is filtered with a certain number of the users, who has the lowest potential energy (i.e. k nearest neighbors - knn).

TABLE I. AN EXAMPLE OF THE RATING MATRIX R

u_9	4.472	6.480	6.708	7.549	4.000	3.316	2.645	7.000	0

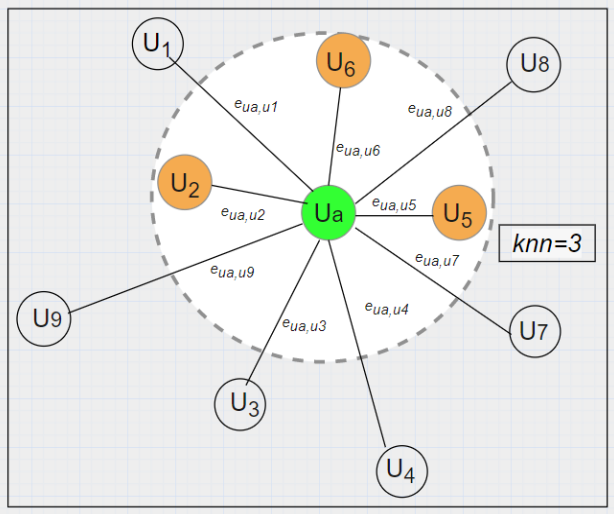

Fig. 1. The Neighborhood of u_a with knn = 3.

To find the k-nearest neighbors (knn) for u_a, the energy distance is used. Fig. 1 shows the 2D space of the incompatibility points with the active user u_a - the users with low energy will be displayed closer together. If knn equals to 3, u_2, u_5 and u_6 are selected to be three nearest neighbors of u_a.

D. Rating prediction

The predicted rating $\hat{r}_{aj}$ of user $u_a$for item i_j is calculated by (8),

$$\hat{r}_{aj} = \frac{1}{\sum_{i \in N(a)} e_{ai}} \sum_{i \in N(a)} e_{ai}\, r_{ij} \tag{8}$$

where: e_{ai} is the incompatibility between u_a and the user u_i in the neighborhood. $N(a)$ is knn of the user u_a. r_{ij} is the rating value of the user u_i to item i_j.

E. Top N Items Recommendation

To recommend the suitable items to the active user u, N items with the highest ranking are selected. The ranking of each item i is calculated by the ranking function. This function is reversible to map the predicted rating on the normalized scale back to the original rating scale. Normalization is used to remove individual rating bias by users who use lower or higher ratings than other users. A popular method is to center the rows of the rating matrix by formula:

$$h(r_{ui}) = \hat{r}_{ui} - \bar{r}_u \tag{9}$$

Where $\bar{r}_u$ is the average of all available ratings in row u (i.e. the available ratings of user u) of the rating matrix R; $\hat{r}_{ui}$ is the predicted rating of user u to item i.

III. Recommendation Evaluation

A. K-folds Cross Evaluation

In order to evaluate the effectiveness of recommender models [5][25], k-folds cross evaluation method is performed. In this article, the dataset is divided into a training set and a testing set with k-folds = 5. The dataset is splitted into 5 subsets, all subsets of equal size, 80% (4 subsets) of the dataset is used for training and 20% (1 subset) of the dataset is used for testing. The model is evaluated recursively 5 times, each time using a different train/test split, which ensures that all users and items are considered for both training and testing. The results are then averaged to produce the final result.

B. Evaluation

To evaluate the recommendation model, three measures of error: 1. Mean Absolute Error (MAE); 2. Mean Squared Error (MSE); and 3. Root Mean Square Error (RMSE) is used. The evaluation of the error of the recommendation model is an important step in the design of the recommendation system. This helps the designer to select the model and they can check the error of the model before the designer applies this model in practice.

- Root Mean Square Error (RMSE) [14][23]. Root mean square error between real rating value r_{ij} and the predicted rating value $\hat{r}_{ij}$ is calculated by fomular (10).

$$RMSE = \sqrt{\frac{\sum_{(i,j) \in n} (r_{ij} - \hat{r}_{ij})^2}{|n|}} \tag{10}$$

- Mean Squared Error (MSE) [14][23]. The mean square error between real rating value r_{ij} and the predicted rating value $\hat{r}_{ij}$ is calculated by fomular (11).

$$MSE = \frac{\sum_{(i,j) \in n} (r_{ij} - \hat{r}_{ij})^2}{|n|} \tag{11}$$

- Mean Absolute Error (MAE) [14][23]. The mean absolute error between real rating value r_{ij} and the predicted rating value $\hat{r}_{ij}$ is calculated by fomular (12).

$$MAE = \frac{1}{|n|} \sum_{(i,j) \in n} \left| r_{ij} - \hat{r}_{ij} \right| \tag{12}$$

IV. Energy based Recommendation Model

A. Model

Fig. 2 presents the general overview of energy-based recommendation model including four components: the dataset (U x I x R), energy including incompatibility matrix which is calculated by the energy distance measure, predicted ratings performing the prediction, and the table of predicted rating to be used for recommending top n items to active user u_a.

The dataset consists of a set of m items (items), where $I = \{i_1, i_2, \dots, i_j, i_{j+1}, \dots, i_m\}$ and the set n users (users), where $U = \{u_1, u_2, u_k, u_{k+1} \dots, u_n\}$, the rating values $R = \{r_{11}, r_{12}, \dots, r_{1n};\ r_{21}, r_{22}, \dots, r_{2n}; \dots; r_{m1}, r_{m2}, \dots, r_{mn}\}$, u_a is the active user to be recommended.

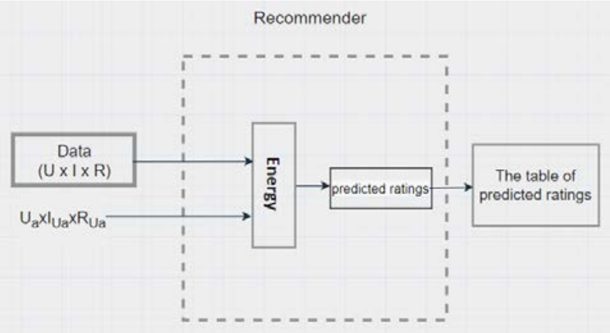

Fig. 2. Energy-based Recommendation Model.

B. Algorithm

The recommendation algorithm of the energy based model includes six steps as the folow:

```
Algorithm. Energy-based recommendation

    Input: The data matrix (U x I x R); and the active user needs to be suggested $u_a$
    Output: The rating prediction table to be used for recommendation to the active users $u_a$;
Begin
Step 1: Calculating the incompatibility matrix E by using the energy distance of $u_a$ with all users
Step 2: Finding k nearest neighbors (int u, int i, int [][]R, int [][]E)
    // u is the users, i is the items, rating is the rating matrix, E is the incompatibility matrix.
    if (R[u][i] != 0 && E [$u_a$][ u] != 0)
Step 3: Predicting the rating value of $u_a$ for items based on k nearest neighbors.
        <$R^{'}$[a][j] = (1/E($u_a$, u))(E($u_a$, u) $R^{'}$[i][j])>
Step 4: Calculating the ranking of each item <List_N[i]>;
Step 5: Sorting the list of predicted ratings in descending order < Sort (List_N)>;
Step 6: Recommeding the top $N$ item with the highest ranking to the active $u_a$ < Print (Top-N>);
End.
```

V. Experiment

A. Datasets

Experiment is performed on the Jester5k and MovieLense datasets. These two datasets are summarized in the Table III, and the distribution of ratings of them is displayed Fig. 3.

Jester5k[1] contains the ratings of 5000 anonymous users collected from the Jester Online Joke Recommendation System between April 1999 and May 2003. This data set contains 5000 users and 100 jokes with ratings ranging from -10.00 to +10.00. All selected users have rated 36 or more jokes.

MovieLense [2] (100k) were published in 1998 by GroupLense (https://grouplens.org). This dataset includes 100,000 (100k) ratings from 943 users for 1682 movies with ratings ranging from 1 to 5. Each user has rated at least 20 movies.

B. Tool

The "recommenderlab" package [21] is used in experiment of this article; specifically, user based collaborative filtering model using cosine measure (named UBCFCosine RS).

TABLE III. THE TABLE TO DESCRIBE DATASETS: JESTER 5K AND MOVIELENSE

Names	Number of rows (users)	Number of col.s (items)	Number of ratings	Value domain of ratings
Jester5k	5000	100	362106	-10 - +10
MovieLense	943	1682	99392	1 - 5

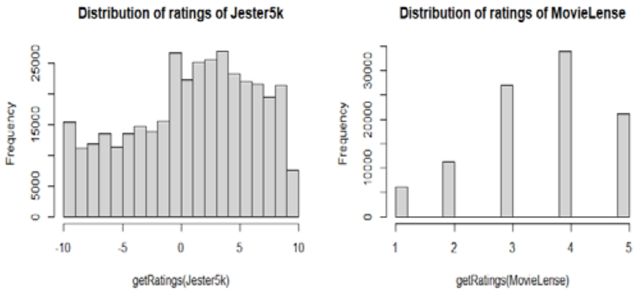

Fig. 3. Distribution of Ratings of Jester5k vad Movielense Datasets.

We have implemented the proposed energy based recommendation model (named UBCFEnergy RS) in R language. This model is integrated into the recommenderlab package. We have also written a function to compare the results of the proposed model UBCFEnergy RS and the selected model of recommenderlab package UBCFCosine RS.

C. Scenario 1: Recommendation on Jesterk5k

This scenario evaluates the errors (MAE, RMSE, MSE) of two recommendation models UBCFEnergy RS and UBCFCosine RS.

The comparison results of errors (MAE, MSE, RMSE) of the two models are shown in Fig. 4 for each known ratings (given = 2, 16, 36) on all k nearest neighbors knn = 10, 20, 30, 40. The results show that the error of the UBCFEnergy RS model is always smaller than that of UBCFCosine RS model.

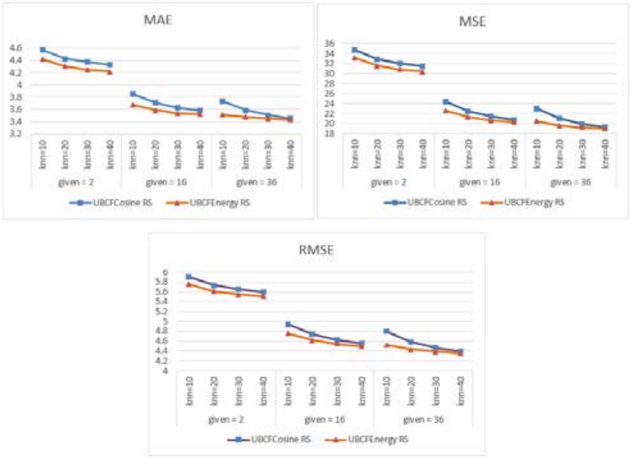

Fig. 4. Errors for each given (2, 16, 36) on all knn = 10, 20, 30, 40.

[1] https://rdrr.io/cran/recommenderlab/man/Jester5k.html, accessed on February 01, 2021.

[2] https://rdrr.io/cran/recommenderlab/man/MovieLense.html

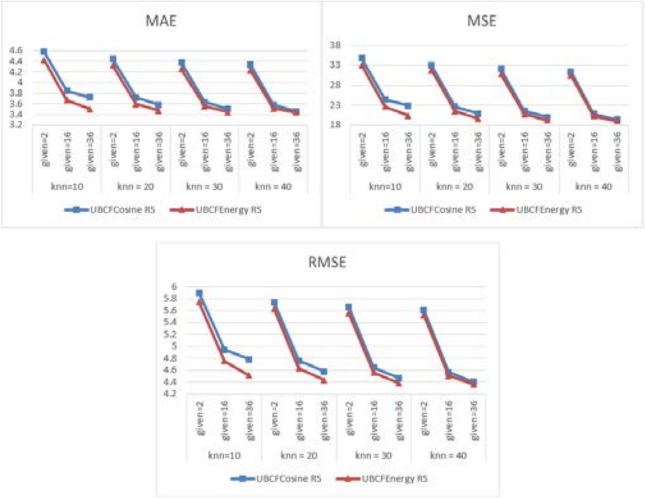

Fig. 5. Errors with each knn (10, 20, 30, 40) for all given = 2, 16, 36.

Fig. 5 presents the errors of UBCFEnergy RS and UBCFCosine RS for each k nearest neighbors knn = 10, 20, 30, 40 on all known ratings (given = 2, 16, 36). The experiment result also show that the proposed model is better than UBCFCosine RS model.

D. Scenario 2: Recommendation on MovieLense

This scenario presents the experement result of two models UBCFEnergy RS and UBCFCosine RS on MovieLense dataset.

Fig. 6 shows the comparison results of errors (MAE, MSE, RMSE) of the two models for each known ratings (given = 4, 10, 20) on all k nearest neighbors knn = 10, 20, 30, 40. Fig. 7 presents the errors of two models for each k nearest neighbors knn = 10, 20, 30, 40 on all known ratings (given = 4, 10, 20). Both results indicates that the errors of UBCFEnergy RS model are smaller than those of UBCFCosine RS model.

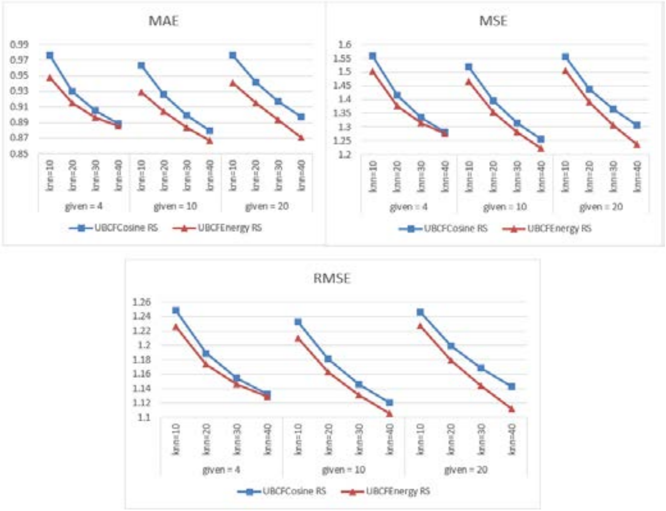

Fig. 6. Errors for each given (4, 10, 20) on all knn = 10, 20, 30, 40.

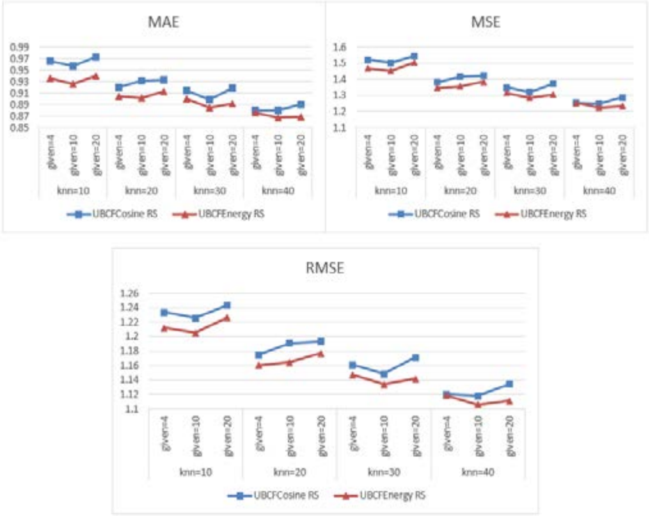

Fig. 7. Errors with each knn (10, 20, 30, 40) for all given = 4, 10, 20.

VI. Conclusion

We have built a new recommendation model based on energy UBCFEnergy RS. The errors (MAE, MSE, RMSE) of this model are compared with the error of user based collaborative filtering model using cosine measure of recommenderlab" package UBCFCosine RS on Jester5k and MovieLense datasets, two datasets commonly used in evaluating the effectiveness of recommendation models. The experimental results of the proposed recommendation model have the lower errors than the compared model on both Jester5k and Movielense. Therefore, the energy-based recommendation model shows the feasibility of applying the energy distance to build the recommendation systems.

***Abstract*—Agriculture remains an important sector of the economy. Plant diseases and pests have a big impact on plant yield and quality. So, prevention and early detection of crop disease are some of the measures that must be implemented in farming to save the plants at an early stage and thereby reduce the overall food loss. Grapes are the most profitable fruit, but they are also vulnerable to a variety of diseases. Black Measles, Black Rot, and Leaf Blight are diseases that affect grape plants. Manual disease diagnosis can result in improper identification and use of pesticides, and it takes a long time. A variety of deep learning approaches have been used to address this issue of the identification and classification of grape leaf diseases. However, there are also limits to such approaches. Therefore, this paper uses deep learning with the concept of ensemble learning based on three famous Convolutional Neural Network (CNN) architectures (Visual Geometry Group (VGG16), VGG19, and Extreme Inception (Xception)). These three models are pre-trained with ImageNet. The performance of the proposed approach is analyzed using the Plant Village (PV) dataset of common grape leaf diseases. The Proposed model gives higher performance than the results achieved by using each Deep Learning architecture separately and compared with the recent approaches in this study. The proposed system outperformed the others with 99.82% accuracy.**

***Keywords*—Ensemble learning; grape leaf diseases; convolutional neural network (CNN); transfer learning**

I. Introduction

Agriculture is one of the most important sectors in the world, providing humans with food, raw materials, and other essentials. According to the United Nations (FAO) Food and Agriculture Organization, the world's population will reach 9.1 billion by 2050. As a result, to meet the nutrient needs of such a large population, the food growth rate needs to be boosted to 70% by 2050 [1]. Plant disease is one of the leading causes of crop loss. A plant disease is an abnormal condition that modifies the appearance or function of a plant. The visible effects of the disease on plants are described as symptoms. A symptom is any detectable change in the plant's color, form, and/or functions in response to a pathogen or disease-causing agent. The leaf is the most essential portion of the plant to inspect for illness. Plant leaf diseases are divided into three categories: fungal, viral, and bacterial [12, 13].

A. Fungal Diseases

Parasitic organisms have a system of branching threads that make up their bodies. Fungi can enter the host via stomata, but many can pierce a solid surface. Once within, they can either expand through the live cells or stay primarily in the gaps between them. Black Rot, Black Measles, Leaf Blight, and Leaf Rust are signs of these diseases.

B. Viral Diseases

Viruses are not dispersed by water or wind, unlike bacteria and fungi. But insects and worms are the primary vectors of viral pathogens to plants.

C. Bacterial Diseases

Bacteria are small. There are two hundred kinds of bacteria that cause diseases in plants. Their form determines their classification. Spherical, rod-shaped microorganisms and twisted rods are the three primary kinds that may be known. There are many symptoms of a bacterial infection. Leaf Spot is considered the most prevalent of them.

Plant diseases, and how to quickly diagnose and address them to improve the health of crops, are among the most important problems that face agriculture and have an impact on its trade. Identifying the disease before it spreads over the farm to other plants and treating it is a massive challenge in and of itself. It takes a lot of time and effort to determine what kind of disease it has. Furthermore, not all disease types can be accurately identified by the farmer's naked eye.

Initially, plant infections can be detected with the help of an agricultural professional who is familiar with plant diseases. However, manual plant disease identification and determination is a strenuous task and takes a long time. A person's knowledge and experience determine the accuracy of a manual prediction [2].

To overcome the above problems, many studies on machine learning (ML)-based technologies, such as support vector machines (SVM) [3], K-nearest neighbors (KNN) [4], have recently been applied to improve decision-making to classify plant diseases [5]. However, all these proposed approaches face several challenges, including identifying regions of concern for processing and analysis (feature representation). Now, Deep Learning (DL) is considered the next evolution of machine learning, such as convolutional neural networks (CNN) [6]. This work proposes an approach for classifying grape plant diseases based on Ensemble Learning that aggregates three customized CNN architectures with trained weights (VGG16, VGG19, and Xception). The following are the study's major contributions:

- Enhance classification performance.
- Reduce overfitting.

The rest of this paper is structured as follows: In Section II, related works present the most common plant disease terminologies and techniques. The proposed model and materials are illustrated in Section III. Section IV discusses the results of the proposed model and compares them with other related models. Section V, the conclusion. Section VI, the future work.

II. Related Work

Many methods for disease classification from the planet leaf have been presented, especially on the Plant village dataset. The Plant village Dataset [7] is a well-known, publicly available crop leaf collection that contains thousands of images. It has been used in various research and achieved good results. Some of these are as follows:

Akshai KP et al. [8] proposed a method to classify images of grape plant diseases from the Plantvillage dataset using the trained model. The CNN, VGG19, ResNet-152v2, and DenseNet models are all trained. The DenseNet model was the most accurate, with a score of 98.27%. For the convolution layer, a rectified linear activation function, or ReLU activation function, is utilized, and for the output layer, a Softmax activation function is used. The images were reduced to 224x224 pixels using Kera's image data generator, then augmentations like rotation, zoom, and shift were added. At a ratio of 80:20, the dataset is split into training and validation sets. This work had the problem of splitting the dataset into training and validation only and testing the model with the same data, which led to overfitting.

Y. Nagaraju et al. [9] proposed a fine-tuned VGG-16 network to categorize eight different apple and grape leaf types together. The Kera’s library is used to load the pre-trained VGG-16 network. In a typical model, the SoftMax (classifier) layer is removed, and a new output layer (classifier) with a SoftMax activation function is added. The disease dataset for apples and grape leaves is split 80:20 with an accuracy of 97.87%. This work had the problem that although using 30 epochs, the accuracy was 97.87%.

E. Hirani et al. [10] proposed deep learning methods for identifying plant diseases. A Plantvillage dataset is used at a ratio of 80:20, with 70295 images for training and 17572 images for validation. This work used three methods: a customized convolutional neural network, INCEPTIONv3, Small Transformer Network (STN), and Large Transformer Network (LTN), with an accuracy of 95.566%, 97.14%, 97.66%, and 97.98%. This work had a problem with the resolution of images at 256*256 that needed more computation and time in the training and testing phases.

K. Z. Thet et al. [11] proposed a fine-tuning VGG16 with the GAP layer instead of VGG16’s two fully connected layers before the SoftMax layer to classify the diseases on grape leaves. This work has achieved 98.4% more accuracy than others. It mostly focused on five diseases that are prevalent in Myanmar Grapevine Yard. This work had a problem with the overall performance where the number of epochs and batch size were not determined.

III. Proposed Methodology

A. Dataset Description

The Plant Village dataset [7] is used to examine the proposed model performance in the classification of grape leaves diseases. It is a large and freely accessible database. It contains over 55,000 RGB images divided into 38 classes representing 14 different plant species. There are 12 healthy leaf classes as in Fig. 3 and 26 unhealthy leaf classes as in Fig. 1, 2, 4 out of 38 total. The grape leaves images are used in this study, which includes 4,062 images divided into four classes shown in Table I. The following is a summary of each selected disease [13, 14]:

1) Grape: black rot: Black rot fungus attacks on leaves grown in warm, wet seasons, the black rot fungus attacks the upper surface of the leaves, turning them reddish-brown and causing round to angular dots to emerge. As the spots merge, irregular reddish-brown blotches appear as shown in Fig.1.

2) Grape: leaf blight: It is also a fungal disease on leaves grown in high humidity conditions, caused by Exserohilumturcicum. At first, small yellow dots emerge along the leaf margins, then grow to become brown patches as shown in Fig. 4.

3) Grape: esca (black measles): The esca fungus can affect leaves at any time during the growing season, but it is most common in July and August. The symptom is an interveinal "striping". In red varieties, the "stripes" are dark red, while in white cultivars, they are yellow. Fig. 2.

B. Proposed System

In this work, a powerful approach for classification grape leaves diseases based on Ensemble Learning has been presented as shown in Fig. 5.

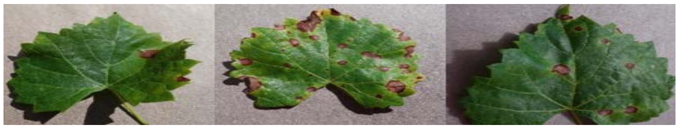

Fig. 1. Grape_Black_Rot.

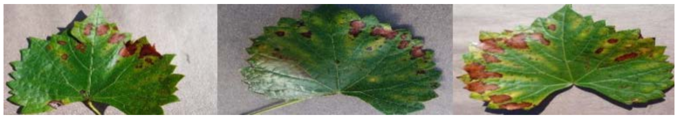

Fig. 2. Grape_ Esca (Black Measles).

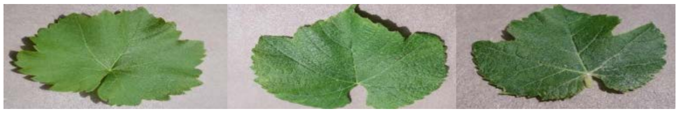

Fig. 3. Grape_Healthy.

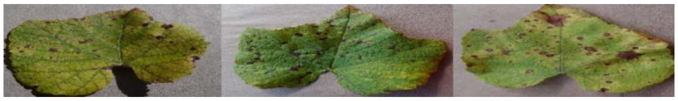

Fig. 4. Grape_ Leaf Blight.

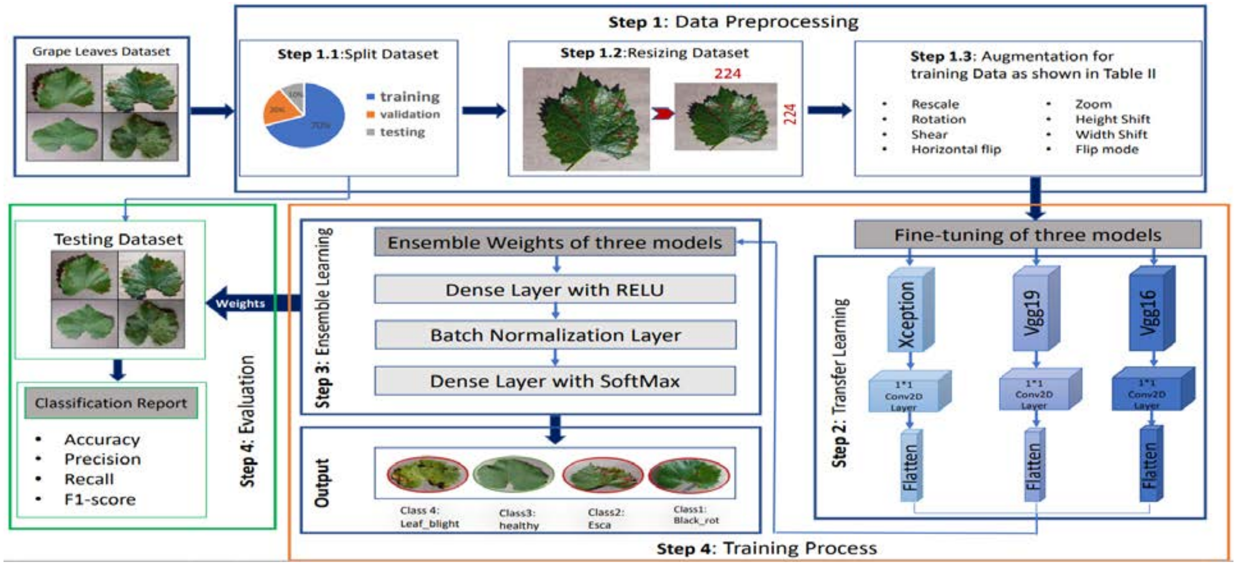

Fig. 5. The Framework of the Proposed Model.

1) Data preprocessing: Preprocessing of the dataset is one of the major roles in training a model. First, divided dataset into three categories: training 70%, validation 20%, and 10% for testing, as shown in Table I. Second, grape images are resized to 224*244*3 pixels. Third, applied data augmentation techniques to generate more training data and avoid overfitting. These techniques include rescale, rotation, shear, horizontal flip, zoom, height shift, width shift, and flip mode on the training set. The data augmentation is applied only to the training data shown in Table II.

TABLE I. DESCRIPTION OF PLANT VILLAGE DATASET

Grape Dataset						
Fig	**Class Name**	**Cause of disease**	**Total samples**	**Training Samples (70%)**	**Validation Samples (20%)**	**Test Samples (10%)**
1	Black Rot	Fungus	1180	826	236	118
2	Esca		1383	969	276	138
3	Leaf blight		1076	754	215	107
4	Healthy	--------	423	296	85	42

TABLE II. AUGMENTATION TECHNIQUES SUMMARY

Techniques	**Values**
Rescale	1./255
Rotation	30
Shear	0.1
Horizontal flip	True
Zoom	0.3
Height shift	0.2
Width shift	0.2
Flip mode	Nearest

2) Model building: Transfer learning is a great approach because it allows to use a pre-trained CNN model with multiple datasets to train a specific dataset.

VGG-16 and VGG-19 [15] refer to the "Visual Geometry Group". They're two different versions of the same structure. The differences between them are as follows, respectively: The VGG-16 consists of 16 layers of the deep neural network, whereas the VGG-19 consists of 19 layers. Both networks contain blocks, where each block is composed of 2D convolution and pooling layers. The Conv2D layer [16] extracts a feature of the image using filters or kernels. The filter is passed throughout the width and height of the input and the dot products function between the input and filter is calculated at every position. Convolution Layer Formula (1).

$$n_{out}= [\frac{n_{in}+2p-k}{s}]+1 \tag{1}$$

It also contains ReLU (Rectified Linear Activation Function) [17, 18] that returns all negative values set to zero (2). The function and gradient in ReLU (2) and (3).

$$\text{ReLU}(x) = \max(0, x) \tag{2}$$

$$\frac{d}{dx}\ ReLU(x)\text{=1 if x > 0; otherwise} \tag{3}$$

The Conv2D layer is followed by a pooling layer to reduce the computation and the number of parameters. Max pooling (4) is one of the most used pooling operations. Then the matrix is flattened into a vector. The flattened vector is passed into the FC (Fully Connected) layer. FC is used to connect each node in one layer to each node in another layer. The last layer is SoftMax. It is located at the end of the FC layer, which predicts a multi-class.

$$\text{S}(x) = \underset{i\,=\,1}{\overset{N}{max}}\ x_i \tag{4}$$

Xception [19] refers to Extreme Inception. First, the data passes through the entering flow, then eight times through the middle flow, and finally through the exit flow. Batch normalization is applied to all convolution and separable convolution layers. Separable convolutions are time-saving and more efficient than classical convolutions.

The proposed model depends on a customized CNN with trained weights from the VGG16, VGG19, and Xception models. The learning scenario starts with receiving grape leaves images from the input layer. The input layer is shared with three pre-trained networks. Three models are reshaped by freezing all their layers. But we removed the top layer (output layer) from each model to add the proposed output layers.

Added two layers, a Conv 1x1 layer with 1024 filters with padding-zero and stride-one, to collect the most important features and allow for reduced dimensionality followed by a flattening layer to convert the matrix to the tensor of one dimension (vector). As illustrated in Fig. 6-8.

3) Ensemble learning: After applying the flattening layer to each model, added the merged layer to aggregate the flattening layer from each network and use it as an input (new input) for the ensemble learning model. Then, added a dense layer that allowed every neuron in this layer to connect to the next layer by weight followed by a batch normalization layer, which allows each layer to make learning more independent. Finally, added the output layer with the SoftMax activation function to predict the final output.

4) Training phase: The proposed model compiled with the Adam optimizer [20] is a stochastic gradient descent method with a learning rate equal 2e-5. The loss function is a categorical cross-entropy [21] that is used in the multi-class classification task equation (5) to calculate the loss. The proposed model is fitted at epochs where value equals 10, train batch size equals 16, and validate batch size equals 8.

$$\text{Loss}=-\sum_{i=1}^{output\ size} y_i . \log \hat{y}_i \tag{5}$$

5) Testing phase: The best-saved weights were loaded after those testing images were loaded. Finally, images were resized to 224*224 and fed the testing images to the model to classify four classes of the grape leaves' diseases.

IV. Experimental Work & Results

A. Experimental Settings

This work demonstrates that the highest accuracy is achieved with a relatively small dataset of grape leaves in the plant village dataset using ensemble learning (e.g., VGG16 Model, VGG19, and Xception). The dataset is divided into a ratio of 7:2:1 as shown in Table I. All experiments are implemented using Colab [22] provided by Google, the Keras framework [23] that can run on top of TensorFlow, and the Python programming language. All experiments were conducted on a 12 GB NVIDIA Tesla K80 GPU (Graphical Processing Unit) and 12 GB of RAM.

B. Experimental Evaluation

The performance of the proposed model is evaluated using accuracy (9), precision (6), recall (7), F1-score (8), and confusion matrix in the testing phase equations shown in Table III. Moreover, loss, accuracy, validation loss, and validation accuracy are calculated during different epochs in the training phase, as shown in Fig. 10-17. Also, we compared our proposed model performance as shown in Table V with other models (e.g. [8]) that work on the same dataset as shown in Table IV and with each architecture used in the proposed model separately. Summary of the training model in the Fig. 9 to understand the underlying parameters.

TABLE III. Performance Equations Summary

Assessments	Equation	Equ.No
Precision (P)	$\frac{TP}{TP+FP}$	(6)
Recall (R)	$\frac{TP}{TP+FN}$	(7)
F1-Score (F)	$2 * \frac{P*R}{P+R}$	(8)
Accuracy (Acc)	$\frac{TP+TN}{TP+TN+FP+FN}$	(9)

Where:

True Positive (TP) the model predicts the positive class correctly. True Negative (TN) model correctly classifies the negative class. In a false positive (FP), the model predicts the positive class incorrectly. In false negative (FN), the model predicts the negative class incorrectly.

The total training time for the proposed model is about 24 min 28 sec ± 2 min with 10 epochs, and the test time is about 5 seconds. Other models in [8] use 20 epochs in training. However, our proposed method achieved the highest accuracy, showing the feasibility of our proposed method. Compared with existing methodologies, we can see that our proposed model has some degree of competition in terms of accuracy and precision, as shown in Tables IV and V. The robustness of our suggested approach is confirmed by these results.

TABLE IV. Result of Existing Models

Model	Precision	Recall	F1-score	Accuracy	epochs
CNN [8]	94.60	94.58	94.56	94.58	20
VGG [8]	95.54	95.32	95.32	95.32	20
RESNET [8]	97.11	97.04	97.05	97.04	20
DENSENET [8]	98.31	28.27	98.28	98.27	20

TABLE V. CLASSIFICATION REPORT FOR PROPOSED MODELS

Model	Classes	Precision	Recall	F1-score	Support	Accuracy

V. Conclusion

Visual observation for classifying grape leaf diseases can be misleading because of a lack of prior knowledge and similarities among diseases. This paper introduces an automated mechanism for classifying grape leaves as healthy or diseased (e.g., black measles, black rot, and leaf blight) using transfer learning (e.g., VGG16, VGG19, and Xception). This classification has been done by extracting the features from the grape images using different pre-trained networks and then using the ensemble learning method for these networks to enhance the diagnosis accuracy. The novelty of the work lies in the fact that, instead of training each network alone and then concatenating the final results to get better results, all the networks are trained together, allowing the fully connected layer to discover the best ensemble method to concatenate the results of previous networks. The proposed model achieved an accuracy of 99.82% compared to recent models that used grape leaf disease in the training process across the existing online Plant Village dataset. This work demonstrated the value and benefits of using ensemble learning and transfer learning. This study has achieved its objectives to improve the performance of classifying plant diseases and reducing overfitting.

VI. Future Work

Looking ahead, we hope to test the power of our model on more complex datasets and increase the number of categories of agricultural diseases.

An Extractive Text Summarization based on Candidate Summary Sentences using Fuzzy-Decision Tree

Adhika Pramita Widyassari[1], Edy Noersasongko[2], Abdul Syukur[3], Affandy[4]
Faculty of Computer Science, Universitas Dian Nuswantoro, Semarang, Indonesia[1, 2, 3, 4]
Department of Informatic, STT Ronggolawe Cepu, Blora, Indonesia[1]

***Abstract*—This study aims to predict candidate summary sentences in extractive summary using the Fuzzy-Decision Tree method. The fuzzy method is quite superior and the most widely used in extractive summaries, because Fuzzy has advantages in calculations that are not cryptic, so it is able to calculate uncertain possibilities. However, in its implementation, the fuzzy rule generation process is often carried out randomly or based on expert understanding so that it does not represent the distribution of the data. Therefore, in this study, a Decision Tree (DT) technique was added to generate fuzzy rules. From the fuzzy final result, important sentences are obtained that are candidates for summary sentences. The performance of our proposed method was tested on the 2002 DUC dataset in the ROUGE-1 evaluation. The results showed that our method outperformed other methods (baseline and sentence ranking) with an average precision of 0.882498, Recall 0.820443 and F Measure 0.882498 with CI for F1 0.821-0.879 at the 95% confidence level.**

***Keywords*—Text summarization; extractive; fuzzy; decision tree**

I. Introduction

The development of information and communication technology, especially the internet, has an impact on increasing the number of publications of articles on websites or online media which are very useful for decision-making processes and movements regarding everyday life for humans. However, reading the entire text or obtaining relevant information on a particular topic becomes a tedious and time-consuming task. Automated text summarization is recognized as a solution to this problem, because automatic text summaries generate summaries that include all key relevant information quickly without losing the original intent of the text.

There have been many different methods and approaches in the field of text summarization. One approach is abstractive and extractive text summarization. In an abstract summary, sentences generated by summaries are called new sentences, or paraphrases, that use words that are not in the text to generate summaries. Abstract summarization is much more complex and relatively more difficult than extractive summarization. In contrast to abstractive text summarization, the results of the extractive summary consists of fully extracted content, just as the summary result is a sentence or word extracted from the original text [1].

Based on the latest three-year literature, the extractive approach is quite widely used [2] [3]. Several different approaches handled the process of extracting text summarization, one of which is the Frequency-based term weighting approach [4]. The rule-based approach is a study by Naik & Gaonkar [5], which provides the rule-based summarizer with the highest average accuracy, f Measure, and recall values, but has never been tested with broader data contradictions.

In making a summary, the concept of classification can be used by classifying sentences into two groups, namely sentences that are included in the summary (which are important sentences) and sentences that are not included in the summary (sentences that are not important). The fuzzy method has often been used in classification cases and gives good results in both classification and prediction. Fuzzy has the advantage in that its calculations are not rigid (fuzzy), so that it is able to take into account uncertain possibilities [6] [7]. The fuzzy approach is quite widely used in extractive summaries [8]. The fuzzy logic approach is a commonly used method because it can prevent data inconsistencies involving the human role of reviewing sentences and agreeing to select specific sentences to create a summary sentence [9]. The fuzzy system works with different features or multiple inputs from the index. The score for each feature is then passed to the fuzzy inference system as input for later use of IF THEN rules in human knowledge.

Although the fuzzy method is quite superior in extractive summary, in this case, fuzzy has a complexity in terms of determining the rules or basic rules used during inference. Some fuzzy cases use rules obtained by experts, namely humans, while humans can be subjective and can make mistakes. It is feared that this does not reflect the actual data representation. From these problems, a special method is needed for determining the rules of the fuzzy inference system (FIS). Therefore, in this study, the rule to determine candidate summary sentences from FIS will be generated using a Decision Tree. Thus the rules used in the inference engine will represent the actual situation.

In this paper, we propose a text summarizing method that begins by predicting the candidate summary sentences and then compares them with the reference summary results provided by the expert (dataset used is DUC 2002). The proposed summary method is a fuzzy rule-based system for identifying and selecting sentences. To create a fuzzy rule, we use a Decission Tree. Auto-generated text summaries can reduce reading-related cognitive efforts, especially with large amounts of textual information [10]. Contribution to this work is to propose an automatic text summarizing method by predicting candidate summary sentences using fuzzy and decission tree (fuzzy-decission tree) methods in extractive summarizing areas, comparing the proposed method with other methods. The remainder of this paper is organized as follows. Section II describes related work. Section III details this method. Section IV reports experiments for performance evaluation and discussion. Section V discusses conclusions and future work.

II. Related Work

This section analyzes the state of research on automatic text summarization from the last few years using a fuzzy logic approach. The things analyzed include algorithms, datasets, text features, performance, and comparison measures used. Fuzzy logic and NLP are interconnected [11] to solve tasks such as text addition, sentiment analysis, and knowledge representation. This is because fuzzy logic overcomes the problem of inaccuracy and ambiguity of human language by providing a description of the dataset with a linguistic concept defined as a fuzzy set [12]. The following are some of the works that use fuzzy logic in text summarization.

Research conducted by Megala et al., 2014 compares the performance of the fuzzy logic method with the artificial neural network method in summarizing the text. The method is tested by non-automatic evaluation using legal documents. As a result, fuzzy logic is superior in measuring f-measures compared to artificial neural networks, namely 0.46 for fuzzy logic and 0.42 for artificial neural networks [13]. Researchers Megala et al., 2015 again summarized text with fuzzy logic to extract the size, produce a summary and classify segments using Conditional Random Fields (CRF). The evaluation was carried out with legal decision documents, showing that it yielded 0.26 for the f-measure and the method was able to classify all segments in the case [14].

The next research is multi-document summarization using cross-document relationships using fuzzy on news. There are three jobs being carried out, among others: extracting sentence components, performing semantic relationships between text units using Cross-document Structure Theory (CST), and scoring sentences using fuzzy logic. The summary results are obtained from the sentences with the highest ranking. Evaluation reached 0.33 for ROUGE-1 with a 2002 DUC [15]. Summarizing text research with a new model by combining three methods. CLA is used to overcome redundancy, this model uses CLA to reduce redundancy problems, PSO is used to assign feature weights, fuzzy logic is used for sentence assessment. The features used to select important sentences include keywords, sentence length, nouns, thematics, and sentence positions. Method performance excels at f-measure 0.48 when tested on the 2002 DUC dataset [9]. Research on an automatic summary system with a fuzzy approach to extract some features to get important information on student assignment texts. This summary system was tested on a collection of text responses from students to assignments given in a Virtual Learning Environment (VLE). The proposed model is then compared with the method of score, Baseline, sentence and model with ROUGE [16].

Text summary for single document using fuzzy logic approach by extracting sentence features and calculating word scores [17]. Choose a summary sentence by calculating the weight of the sentence and compiling it into a summary. Sentence weights are obtained from calculating word scores and extracting sentence features with fuzzy inference. So that the sentences that stand out are based on fuzzy inference measurements which will later be included in the summary. The method was evaluated using ROUGE-N on the DUC 2002 dataset and then compared with other methods, and the results were superior to the comparison method. The next research is to develop a text summary using fuzzy models in many documents [18]. The fuzzy method is used to handle the uncertainty of feature weights. In this model, the cosine similarity is added to solve the redundancy problem. The evaluation was carried out using ROUGE at DUC 2004. As a result, the proposed method performed higher than the comparison method (Yago Summarizer, TexLexAn, PatSum, ItemSum, and MSSF). In recall measurement, the result is superior, namely 0.1555 on Rouge-2, but lacking in precision when compared to the Patsum method [19].

Extractive summary research that produces an abstract summary. Abstractive summary is obtained by combining the extractive sentence selection process (which uses fuzzy logic) and the long-term two-way short-term memory (Bi-LSTM) method to update the network weights, so it is called the Fuzzy long short-term memory (FLSTM) method. The fuzzy approach is used to get the most important and relevant sentences by extracting information from the document. Important and relevant sentences obtained from the fuzzy extraction method are then used as input for the Bi-LSTM method to produce an abstract summary. The model was then evaluated using ROUGE on the DUC and CNN datasets. The proposed model shows better performance empirically than other comparison methods [20].

Subsequent text summarizing research proposes the integration of two methods, namely the Restricted Boltzmann Machine and Fuzzy logic, hence the name FRBM (Fuzzy Restricted Boltzmann Machine). These two methods have different ways of producing precise summary sentences, but these two methods have something in common, namely, they are unsupervised methods used to summarize text. The summary generated by fuzzy logic is then integrated with the summary generated by the Restricted Boltzmann Machine. The advantage of the FRBM model is that in dealing with noise during training, it is more resistant than RBM [21].

Automatic text summarization uses three different algorithms. It is a two-tailed score for local contextual information (LCIS), key term weighting by sentence, and a fuzzy graph sentence score (FGSS). The LCIS score was used to identify the LCIS, the weighting was used to increase the weight of the important terms, and the fuzzy graph sentence score was used to document the centroid by calculating the appropriate fuzzy graph sentence score. It exhibits superior averages compared to previous studies and requires no training or testing [22].

The next research, summarize unsupervised extractives with fuzzy logic method. Fuzzy logic is used because it is based on natural language that is easy to understand. This summary is built using the Python language. The features used include position, bitcoin, tritoken, cosine similarity, thematic sentence length, numerical data and TF-ISF. The method was tested on the UCI, BBC and DUC 2004 datasets using the ROUGE-1 evaluation. The results conclude that fuzzy logic makes feature extraction sharper and more precise [23]. The next extractive summary research is to summarize the text documents of students' essay assignments using the fuzzy C-Means method. The feature used in this research is the sentence weighting feature. The summary obtained is the sentence with the highest weight in the cluster [24].

In the next research, extractive summaries combine three approaches, namely fuzzy, evolutionary and clustering. The workings of this model begins with clustering, namely grouping sentences according to their similarities. Then extract the significant sentences of each cluster. An evolutionary optimization approach is used to find the optimal weights for text features. Fuzzy inference is used to determine the final score of the sentence. The proposed model was tested on three datasets namely CNN, DUC 2021 and DUC 2022. The results show that the hybrid method produces a good summary [3].

III. Porposed Method

In this section, the proposed method of summarizing extractive techniques using fuzzy and decision tree methods is proposed. Fuzzy method is used to extract features, while decision is used to help fuzzy in making rules (rule based). The proposed model is described in Fig. 1 and is broken down into five main steps, as follows:

A. Preprocessing

Preprocessing is the initial stage for text summarization. Some of the pre-processing steps needed in this research are as follows: Removing punctuation and special words that are not used. Segmentation, the process of separating text into sentence units. Tokenization is the process of separating words from each sentence. Stop word removal, removing a collection of unused words. And steamming is the process of converting each word to its basic form by removing prefixes, affixes and suffixes.

B. Features used

At this stage, describe the extracted features. Feature extraction is used to get important sentences from text sources that have been preprocessed before. This feature ensures the importance of each sentence that goes into the summary. So that the summary contains sentences with high scores. Therefore, selecting the right features can have a big impact on the quality of the summary. In this study, used seven extracted features for each sentence in the input data. The seven features are:

1) Sentence position: The key concept here is that sentences that appear at the beginning or end of the input text are considered more important than other sentences. So for the initial and final sentences, initialize 1 and those that are not the initial and final sentences are initialized 0 [25].

Score (S_i) *= 1 for First and Last sentence,*

0 for other sentences (1)

2) Sentence lenght (in document): The sentence length feature in the document is used to filter out short sentences such as the author's name, address and date that might be found in news documents. Sentences that are too short are not expected to be part of the summary [5]. So that in this feature normalization of sentence length is carried out, namely the ratio of the number of words that appear in the sentence to the number of words that appear in the longest sentence of the document [25].

$$Score\ (Si) = \frac{No.of\ a\ word\ occurring\ in\ S_i}{No.Word\ Occurring\ in\ longest\ Sentence\ from\ document} \tag{2}$$

3) Sentence length (in paragraph): In this feature, short sentences may not represent the topic of the document because the words contained in it are few. Thus, long and short sentences are given low scores. The value of sentence length in paragraphs is calculated based on the equation: [26]

$$Score\ (Si) = \frac{No.of\ a\ word\ occurring\ in\ S_i}{No.Word\ Occurring\ in\ longest\ Sentence\ from\ paragraph} \tag{3}$$

4) Thematic word: This feature is quite important in text summarization because terms that appear frequently in a document may be related to the topic. The thematic word count indicates the words with the maximum relativity possible [25]. After getting the thematic words in the text, then look for the ratio of the number of words in the sentence that appears in the thematic word to the length of the sentence (the number of words in the sentence).

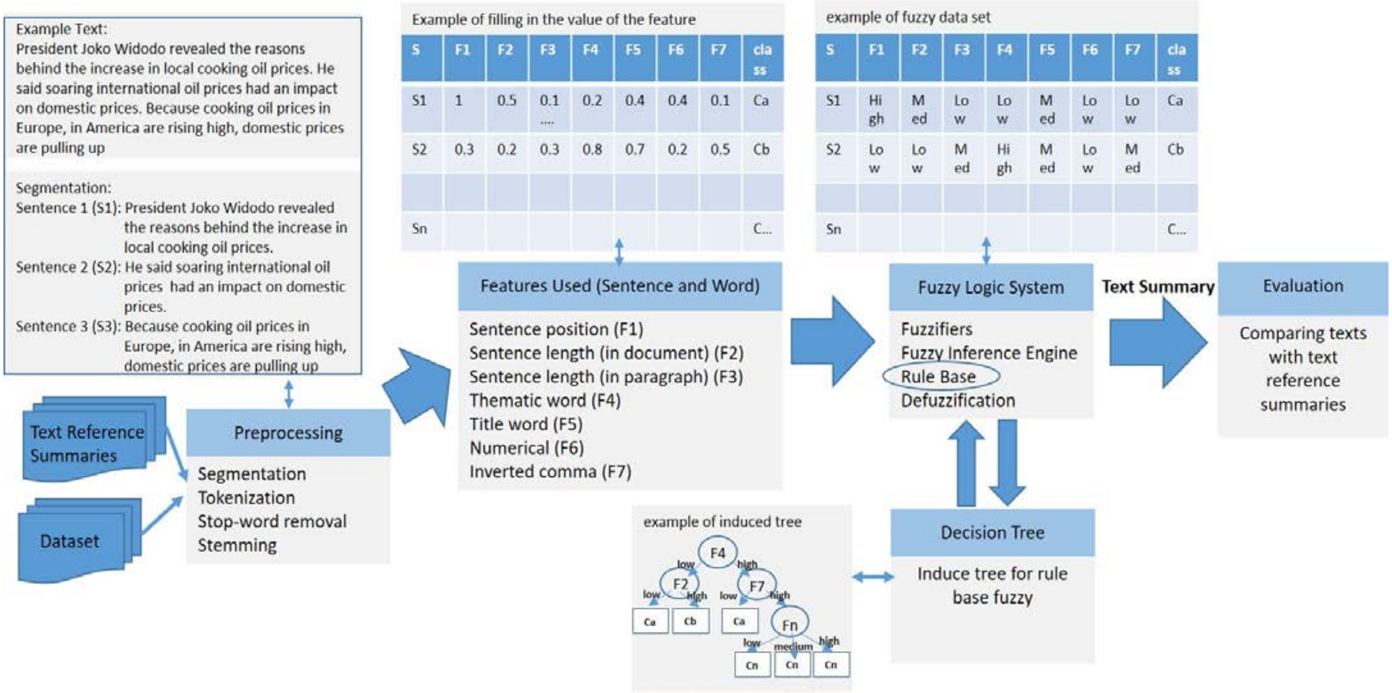
$$Score\ (S_i) = \frac{No.Thematic\ word\ in\ S_i}{Length\ (Si)} \tag{4}$$

5) Title word: This feature is used to find the number of words in the title that appear in the sentence. Words in sentences that also appear in the title is given a high score [6]. Calculate score for this feature which is the ratio of the number of words in a sentence that appears in the title to the length in that sentence (the number of words in that sentence).

$$Score\ (S_i) = \frac{No.Title\ word\ in\ S_i}{No.word\ occuring\ in\ S_i} \tag{5}$$

6) Numerical: In the summary, text or sentences containing numbers are considered informative. So in this feature, sentences with a lot of numerical data need to be considered to be included in the summary. The way to calculate it is to calculate the ratio of the number of numeric data in a sentence divided by the length of the sentence [21].

$$Score\ (S_i) = \frac{No.Numerical\ data\ in\ S_i}{\text{No.word occuring in } S_i} \tag{6}$$



Example Text:
President Joko Widodo revealed the reasons behind the increase in local cooking oil prices. He said soaring international oil prices had an impact on domestic prices. Because cooking oil prices in Europe, in America are rising high, domestic prices are pulling up

Segmentation:
Sentence 1 (S1): President Joko Widodo revealed the reasons behind the increase in local cooking oil prices.
Sentence 2 (S2): He said soaring international oil prices had an impact on domestic prices.
Sentence 3 (S3): Because cooking oil prices in Europe, in America are rising high, domestic prices are pulling up

Example of filling in the value of the feature

S	F1	F2	F3	F4	F5	F6	F7	class
S1	1	0.5	0.1	0.2	0.4	0.4	0.1	Ca
S2	0.3	0.2	0.3	0.8	0.7	0.2	0.5	Cb
Sn								C...

example of fuzzy data set

S	F1	F2	F3	F4	F5	F6	F7	class
S1	High	Med	Low	Low	Med	Low	Low	Ca
S2	Low	Low	Med	High	Med	Low	Med	Cb
Sn								C...

Features Used (Sentence and Word)
Sentence position (F1)
Sentence length (in document) (F2)
Sentence length (in paragraph) (F3)
Thematic word (F4)
Title word (F5)
Numerical (F6)
Inverted comma (F7)

Fig. 1. The Proposed Method of Summarizing Extractive Techniques using Fuzzy and Decision Tree.

7) Inverted comma: Inverted commas usually indicate direct conversation, title or name, and also contain important information [26]. The inverted comma is calculated using the following equation.

$$Score\ (S_i) = \frac{No.Inverted\ comma\ in\ S_i}{No.word\ occuring\ in\ S_i} \quad (7)$$

C. Fuzzy Logic System

Fuzzy logic has often been used for various applications because fuzzy logic is easy to understand, flexible and tolerant of inaccurate data. One of the characteristics of fuzzy logic is the use of verbal instructions described in fuzzy sets and rules. The way the fuzzy logic system works there are four parts as follows:

1) Fuzzifiers: The first process in the Fuzzy system is to transform raw crisp values into membership values through membership functions. This means that the membership function for each fuzzy set must be determined first. In this section, the input is the value of text summarizing features (in the form of numbers), which by using the membership function will be converted into lingiustic. The membership function used for this summary model is the Triangular Membership Function (TMF). Where each feature has three fuzzy sets, namely: high, medium and low.

2) Fuzzy inference engine: This section is the main part of fuzzy logic. Here will be calculated formulas so as to produce output. There are two things that serve as a reference for this calculation, namely the membership function in the previous section and also the fuzzy rule. So that fuzzy input is needed from the fuzzifier in making decisions based on rules. For our proposed summary model, the inference used is Mamdani fuzzy inference (FIS). Due to its simple and most common min-max operating structure it is used in many applications. In addition, Mamdani is more suitable for text summarization systems because it can capture expert knowledge which allows us to describe abilities in a more insightful and more human-like way. To process it using the help of MATLAB.

3) Rule base: The rule design process is an important part in the fuzzy classification algorithm. In this study, to help activate the rule, the decision tree method was used in designing the if-then rules. From the results of making the decision tree, 33 if-then rules are obtained. To see a more detailed explanation of the decision tree method, see section 3, part d.

4) Defuzzification: converting linguistic inference results back into sharp outputs. In this study, the centroid defuzzification method was chosen for us to use. This method is the default method where it works by returning the center of the area under the curve.

D. Decision Tree (for Rule Fuzzy)

Decision tree is one of the most famous studies to describe the decision-making process based on existing knowledge. Each branch of the decision tree can be converted into a decision rule, and all these decision rules can generate a decision rule base (Mu et al., 2019). Therefore, in this research, each feature value that is input in fuzzy where the linguistic fuzzifier process has been made instead of the membership function of each feature, will be used as training data for the decision tree algorithm to produce a decision model. To produce a decision tree, the C4.5 algorithm is used to process the training data. This stage begins with calculating the entropy value that will be used to calculate the gain value for each feature. The feature with the highest gain value will then be set as root. The formulas for calculating entropy and gain are shown in Equation (8) and Equation (9). The step of calculating entropy and gain for each feature is repeated continuously until all features are partitioned.

$$Entropy(S) = \sum_{n=1}^{c} - {p_i}^2 \, log \, p_i \qquad (8)$$

$$Gain(S, A) = Entropy(S) - \sum\nolimits_{v \in Values(A)} \frac{|S_v|}{S} Entropy(S_v) \quad (9)$$

From the decision tree that has been made, 33 if-then rules are obtained which will be used in the fuzzy process. Fig. 2 below shows one of the rules formed from the results of the decision tree.

IF (Thematic is medium) and (Sentence length in a paragraph is high) and (Sentence length in a document is medium) and (Sentence position is high) and (Numerical is low) and (Inverted Comma is low) and (Tittle word is medium) THEN (sentence is Yes)

Fig. 2. Sample IF THEN RULE Results from Decision Tree.

E. *Evaluation*

In the evaluation of this research, the results of the text summary from the system will be compared with the reference summary from the expert (human). In the evaluation used the Recall-Oriented Understudy for Gisting Evaluation (ROUGE) which was used to measure the similarity between system generated summaries and human reference summaries (Lin & Hovy, 2003). The ROUGE evaluation produces three measures, namely: recall, precision and f-measure. The measure is calculated by counting the words that overlap between the computer-generated summary and the human-generated ideal summary. Precision is the number of n-grams that appear together in the system summary and reference summary divided by the total number of n-gram reference summaries. Whereas Recall is the number of n-grams that appear together in the system summary and the reference summary divided by the total number of n-grams in the system summary. Precision and recall ranged from 0 to 1. When the precision score was 1, all n-grams in the text summary were in the reference summary. F-Measure is a combination of precision and recall, which is a weighted harmonic average of precision and recall. The study of Steinberger & Jezek, 2009 showed that automated evaluation using the unigram version of ROUGE-N, namely ROUGE-1 correlated well with human evaluations based on various statistics. Therefore, this study uses the evaluation of the system summary results with ROUGE-1.

IV. Experiment and Result

This section describes the evaluation of the performance results of the Fuzzy Decision Tree method. Shows a comparison of our proposed Method with other methods. The Baseline method and the Sentence method are also implemented to be used in the evaluation process as a comparison to the Fuzzy-Decision Tree method.

A. *Compared Methods*

1) Fuzzy-decision tree: In our Fuzzy-Decision Tree method, the first start by setting the fuzzy set in three input variables: high, medium, low (for each feature). The selected sentences must represent an informativeness or indicate the level of importance of a sentence classified in the output variable as YES/NO. To assist our work in designing fuzzy models, used the Fuzzy Logic Toolbox in MATLAB. The type of inference, used is Mamdani. To help create an IF THEN rule, used the Decision Tree method.

2) Baseline: The baseline system is the basic information collected before a program starts. For comparison if using DUC 2002, use Baseline-1 DUC 2002. Baseline-1 is the first 100 words from the beginning of the document as determined by DUC 2002 https://www-nlpir.nist.gov/projects/duc/duc2002/baselines.html [25].

3) Sentence ranking: Sentence method selects sentences based on word frequency. First of all choose fetch keywords. After that it calculates the frequency of each keyword such as how often it appears from the maximum frequency this keyword is taken and calculates the number of frequency weights. And the last one is extracting high-frequency sentences [27].

B. *Dataset*

In this experiment, 10 data were taken in the form of text documents from the DUC 2002 dataset. So that the total words in this experiment were 3803, the total sentences were 242 sentences. Each text document contains an average of 380 words and an average of 24 sentences. Data for evaluation, 10 reference summary documents have been provided by language course experts based on the desired key concepts. The total data consists of 2122 words and 98 sentences. Each reference text document contains an average of 212 words and eight sentences. As an evaluation of the comparison between the summary data generated by the system and the reference summary data, used n-gram statistics. Measurement with n-gram ROUGE has a 95% confidence level so that it is highly correlated with human judgment.

C. *Result and Discussion*

For evaluation of summary texts, this study uses a set of ROUGE metrics that have become the standard for automatic summary evaluation. Evaluation is done by comparing the results of the summary of the system with the results of the summary of human references. To compare summaries, n-grams are used. ROUGE-I is consistently highly correlated with human judgment and has high recall and significance test precision with manual evaluation results. So in the experiment of summarizing the text, the ROUGE-1 measurement was used. Table I shows the comparison of the summary results of the proposed method, namely the Fuzzy-Decision Tree with the summary results of the baseline and summary results of the sentence method from the 2002 DUC collection.

TABLE I.

R = Recall, P = Precision, F1= F Measure

The application of the ROUGE-1 metric resulted in the performance of the tested method on 10 data taken from the DUC 2002 dataset which is presented in Table I. From the table it is shown that the Fuzzy-Decision Tree method has superior performance in all documents tested except for the AP880228-0013 document, where the sentence method outperforms the Fuzzy-Decision Tree in the evaluation of recall 0.87313 and F1 0.86029.

Table II highlights the average performance results of F-Measure, Recall and Precision produced by the Fuzzy-Decision Tree method, the Baseline method and the sentence ranking method. From the table, it shows that the Fuzzy-Decision method has the best average, namely the average F Measure is 0.882498, the average precision is 0.882498 and the average recall of 0.820443 with CI for F1 0.821-0.879. Followed by the performance of the sentence ranking method which is close to the Fuzzy-Decision Tree method, namely the average F-Measure is 0.732114, the average precision is 0.741642 the recall average is 0.726289 with a CI for F1 of 0.678-0.786. Considering the dataset used is DUC 2002, which is news text, the results are reasonable, because the performance for Recall and precision will be higher if the text used is short text.

The results show that the Fuzzy-Decision Tree performance is significantly better than baseline summary and Sentence ranking. Then compared the performance of the Fuzzy-Decision Tree summary and other summarizers by checking for precision and recall. In this case, the best precision and recall of Fig. 3 and Fig. 4, provide strong evidence of its feasibility in text summarization applications.

Fig. 5 describes the results of the method based on the performance confidence interval (CI). The CI and f measures of the method indicate that the systems cannot be considered equal. The performance of the Sentence ranking method is almost close to the Fuzzy-Decision Tree method, while the Baseline method remains the farthest. This is because the Baseline method only selects the first sentence of the original text. Poor performance of Baseline method due to its simplicity compared to other methods. The sentence ranking method is close to the fuzzy decision tree because the sentence ranking method is based on word frequency, where word frequency represents most of the summary content. And this shows that there is a correlation between one of the features in the Fuzzy-Decision Tree method, namely the thematic word feature because it counts themes that often appear in a document that may be related to the topic.

TABLE II. SUMMARY OF PERFORMANCE COMPARISON

Method	R	P	F1	C1 for F1
Fuzzy-Decision Tree	**0.820443**	**0.882498**	**0.849603**	**0.821-0.879**
Baseline	0.396211	0.546239	0.457002	0.408-0.506
Sentence	0.726289	0.741642	0.732114	0.678-0.786

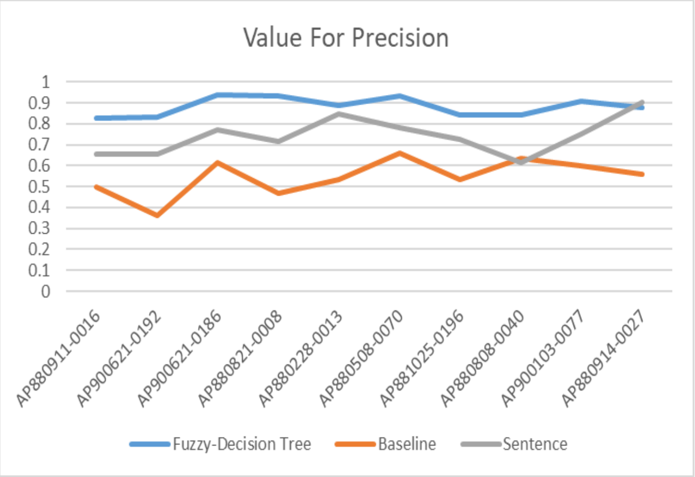

Fig. 3. Precision Result Comparison.

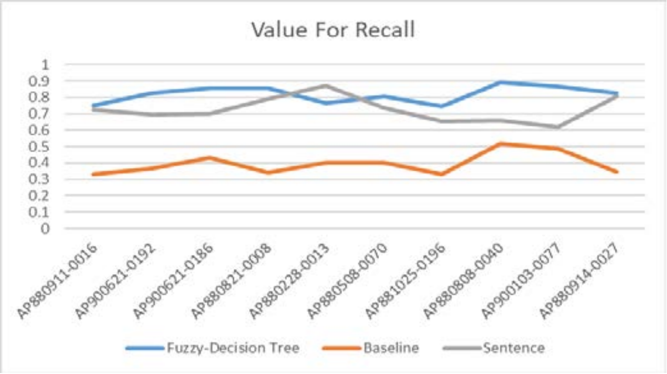

Fig. 4. Recall Result Comparison.

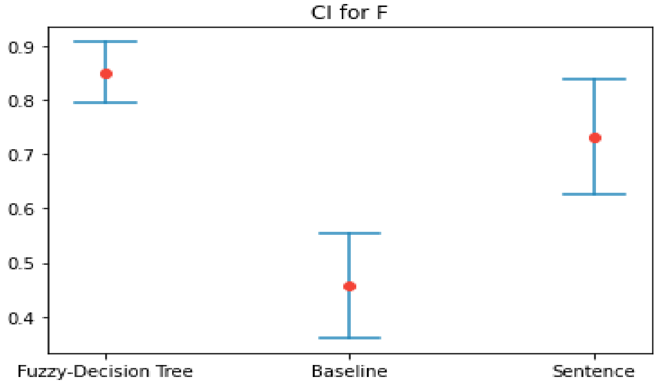

Fig. 5. Confidence Interval (CI) for F1.

V. Conclusion and Future Work

In this study a text summarization is proposed that starts by predicting candidate summary sentences and then compares it with the results of a human-given reference summary. The summary method proposed is a system with a fuzzy approach that identifies and selects important sentences based on important features. Important features in this study include: sentence position, sentence length in the document, sentence length in paragraphs, thematic words, title words, numeric data and inverted commas. Fuzzy logic is used because it is believed to be able to handle uncertain information such as language ambiguity. To optimize the creation of a fuzzy rule base, a decision tree method is added so that the built rules reflect the actual data representation. Contributions in this paper include: 1. Combination method between fuzzy logic and decision tree (fuzzy-decision tree) which has never been applied to extractive summary research before; 2. Comparison of the proposed method (fuzzy-decision tree) with other methods (baseline and sentence ranking).

Evaluation of the proposed method shows that our method outperforms other methods included in the comparison method, namely baseline and sentence ranking. By evaluating ROUGE-1, our method excels with mean precision 0.882498, mean drawdown 0.820443 and F Measure 0.882498 with CI for F1 0.821-0.879 at 95% confidence level tested in single-document test data. However, the performance of the method has not been tested on multi-documents.

For our next work that is part of this research is to add other important features that have not been used in our proposed summary, such as the similarity feature between sentences thereby reducing sentence redundancy in the summary, and the word frequency feature for making summaries. The results are more informative comparing with other more diverse summary methods and adding focus to summary results not only on quality but also on more diverse summary quantity such as 20%, 30% or 40% summary.

***Abstract*—Parkinson’s disease (PD) is the world’s second most neurodegenerative disorder that results in a steady loss of movement. The symptoms in patients occur slowly with the passage of time are and very hard to identify in its initial stage. So, early diagnosis of PD is the foremost need for timely treatment to people. The introduction of smart technologies like the Internet of Things (IoT) and wearable sensors in the healthcare domain offers a smart way of identifying the symptoms of PD patients. In which smart sensors are worn on the patient’s body which continuously monitor the symptoms in patients and track their possible health status. The major objective of this work is to propose a machine learning-based healthcare model that best classifies the subjects into healthy and Parkinson's patients by extracting the most important features. A step regression-based feature selection method is followed to improve the classification of PD. A Shapiro Wilk test is adopted to check the normality of the gait dataset. This model is implemented on three publicly available Parkinson’s datasets collected from three different studies available on Psyionet. All these data sets contain VGRF recordings obtained from eight different sensors placed under each foot. Experimentation is done on the Jupyter notebook by utilizing Python as a programming language. Experimental results revealed that our proposed model with effective pre-processing, feature extraction, and feature selection method achieved the highest accuracy result of 95.54%, 98.80%, and 94.52% respectively when applied to three datasets. Our research inducts knowledge about significant characteristics of a patient suffering from PD and may help to diagnose and cure at an early stage.**

Keywords*—*Internet of things (IoT); sensors; parkinson's disease (PD); machine learning (ML); vertical ground reaction force (VGRF)

I. Introduction

The old age people of today's society suffer from a large number of neurodegenerative disorder diseases like Alzheimer’s disease, dementia and Parkinson's Disease (PD), etc. PD is the second most affecting neurodegenerative disease after Alzheimer's disease affecting people worldwide. A report generated by the Parkinson's Foundation states that 10 million people live with Parkinson's disease (PD) worldwide and among these, approximately one million people are from the United States (US). This report also states that men are 1.5 times more affected by PD as compared to women [1]. 1.04 million people were diagnosed with PD in the US in 2017 and it is estimated to be 1.6 million by 2037 [2]. The progression of PD differs from one person to another person and there does not exist any standard test for the diagnosis of PD and detection is done only based on observations of its symptoms. The clinical demonstrations of PD mainly include tremors in hands, slowing movement, limb rigidity, altered taste in smell, posture instability, etc. [3]. The symptoms in patients occur slowly with time so it's very hard to detect or diagnose this. PD mainly arises due to the degradation of dopamine cells in the brain which control the movement of limbs in the body. By the time symptom appears 50 to 80% of dopamine neurons have already died [4].

Recent discoveries reveal that analysis of gait patterns can be considered a better approach for the detection of neurodegenerative diseases like PD [5] [6]. In the past few years, the invention of smart motion analysis systems and sensors-based motion-capturing devices offers an opportunity for researchers to work on more advanced gait analysis techniques. Smart wireless sensor devices like smart watches, smart bracelets, stand-alone video cameras, smartphones, insole sensors, and other portable devices provide the easiest way of capturing the motion and movement disorders among patients with PD [7]. Major approaches utilized for analysis of gait dataset include smart motion capturing cameras, inertial measurement unit (IMU) based sensors to discover sharp motion and body force in a particular direction [8], plantar pressure determined by utilizing planter sensors, some force subtle platforms for measuring VGRF, High-resolution Electromyography (EMG) devices to capture muscles actions [9]. The neuroimaging approach involves expensive optical cameras and force platforms, while foot-worn sensors offer a reliable, fast, simple, and reasonable gait analysis approach. However, gait analysis faces lots of challenges like high data dimensionality, nonlinear data dependency, and complex correlation.

In recent years, ML techniques have revealed the impressive capability to support clinicians not in identifying the existence of PD but also supports in categorizing the states of PD on the basis of the motor indicators of the subjects [10] [11].

For the detection of PD, ML techniques have been applied to different kinds of measured data like handwritten patterns

[12-14], speech data, neuroimaging data [15], smell identification data [16], spontaneous cardiovascular oscillations [17], and gait data [18]. Many researchers are now working on the early, precise, and timely detection of PD, particularly when ML techniques are applied to learn major strategies. UPDRS and H&Y are two important rating scales utilized for monitoring the progression of PD [19] [20]. H&Y scale is the most commonly utilized rating scale for effective validation of severity level according to functional disability. Therefore, the major objective of the current study was to develop an ML model that could help physicians to diagnose PD by utilizing gait data generated from IoT-based wearable sensors. After that performance of that model is analyzed by using different performance evaluation measures. The major contribution of this work is as follows:

1) This work provides a significant way of detecting/ dosing the PD in patients using an IoT environment.

2) This work proposed a PD diagnosis model by utilizing effective feature extraction and selection method.

3) This work also adopts various performance evaluation metrics to predict healthy and PD patients with the help of collected data patterns.

4) The work also focuses on the comparison of the proposed model on the basis of selected and unselected features set in classifying healthy and PD patients in an IoT environment.

This paper is organized as follows: Section II describes the major causes, symptoms, and measurable indicators of PD. Section III introduces materials and methods utilized for our experimental purpose. Section IV presents different performance metrics utilized for evaluating the performance of the proposed model. Section V describes the result obtained through the implementation of our model. Conclusions are drawn in Section VI. In last, limitations and future directions are described in Section VII.

II. Outline About Major Causes, Symptoms and Measurable Indicators of PD

Parkinson’s disease occurs due to brain disorder and is a progressive neurodegenerative disease that results in inadvertent or non-controllable movements, such as shaking, toughness, and difficulty with steadiness and coordination as shown in Fig. 1.

Categorization of major symptoms of PD is described Major symptoms of PD are described below:

1) Motor symptoms (movement-based symptoms)

- slowed movement (bradykinesia) means muscles weakness,
- tremor means muscles are at rest
- rigidity or stiffness
- Unbalanced postures etc.

2) Non-Motor symptoms (non-movement-based symptoms)

- depression
- loss of smell sense
- sleep disorder
- Inconvenience in thinking and focusing etc.

Even though, PD is incurable because the symptoms of PD usually start steadily and become worse over time. So, early detection of PD can assist to follow proper medication/surgical treatment so that the symptoms can be alleviated. H & Y and UPDRS are two generally utilized clinical ranking scales for monitoring the progression of PD [22] [23]. The former rating scale considers only motor symptoms while the latter assesses both motor and non-motor symptoms.

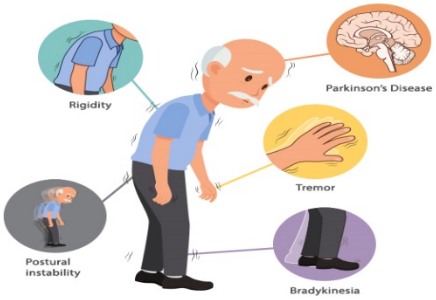

Fig. 1. Parkinson ’s Disease Symptoms Appearance [21].

III. IoT Approach Toward PD Diagnosis

In the traditional medical scenario, diagnosis of PD is a very hard task because it involves proper tracking of the patient's tasks throughout the day. Because there can be a gradual variation in symptoms throughout the day. But patients have no proper sources to track their activities and may lose the most important observations. Another way that the patient moves to the clinician for proper assessment of their postural steadiness and rigidity level which requires transportation cost and time.

The advancement of various smart sensor-based technologies and their integration into the healthcare system reduces the pressure of treatment of various neurological diseases like Parkinson’s disease. “Kevin Ashton” 1999 introduced the concept of the Internet of Things (IoT) which offers connectivity among various wearable sensors and internet platforms that result in amazing remote monitoring services for patients [24]. So, with the introduction of IoT tracking the major symptoms of PD becomes easy [25]. Symptoms collection is possible by just simply placing a few small wireless sensors on the patient body and remotely monitoring the symptoms and details of the patient. So, quality of life can be improved by importing new smart technologies.

Fig. 2 illustrates how a PD patient is treated in an IoT environment while performing any activity. Smart sensors were worn on patients' bodies while they performed their activities. The recording of smart sensors was continuously transferred to the system-based storage or cloud using various transmitting technologies like Bluetooth, Wi-Fi, etc., and after that data is analyzed by utilizing various machine intelligence techniques.

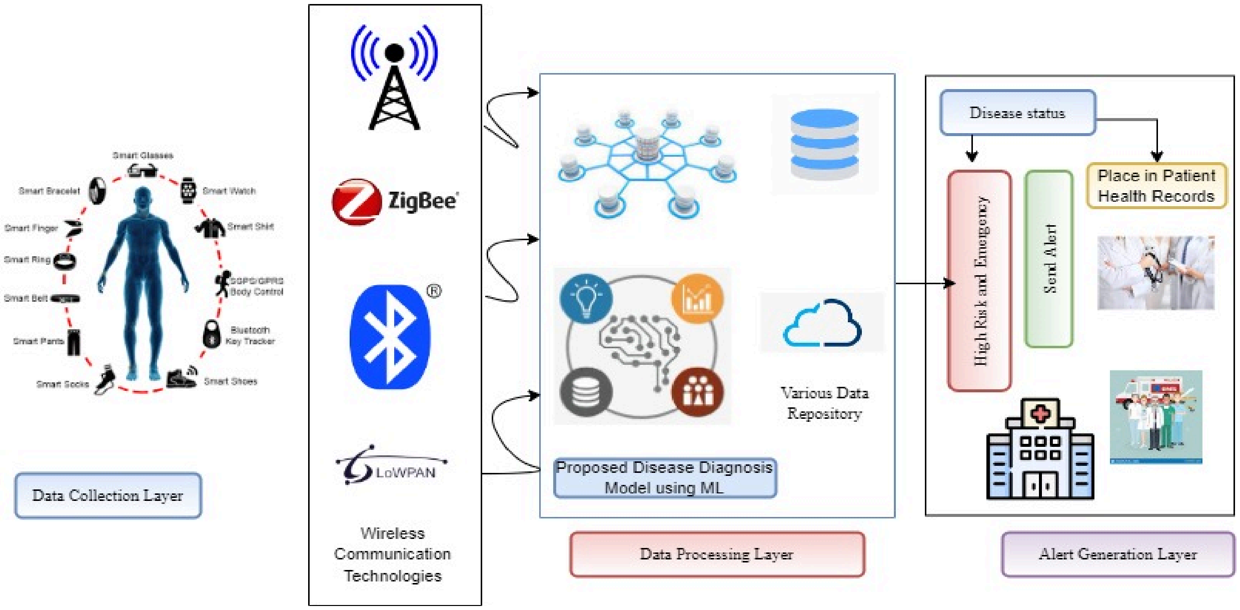

Fig. 2. PD Patients Monitoring and Classification using Wearable Sensors in IoT Environment.

IV. Materials and Methods

This section will describe the data set and techniques utilized for the implementation of our work.

A. PD Dataset Description

Parkinson’s dataset utilized in this study is publicly available at Psyionet [23]. This dataset was collected via a team of three scientists at the “Movement disorder unit of the Tel-Aviv Sourasky Medical Center, Israel” and named after that Yogev et al. [24] consist of the dataset recordings when subjects walking on level ground, Frenkel-Toledo et al. [25] contains dataset recordings when the patient walking on a treadmill and Hausdorff et al. [26] contains recordings when subjects moving at a comfortable place with RAS. This dataset recording was taken from 73 healthy subjects and 93 subjects affected by Parkinson’s disease. In this work, three datasets are separately considered for the identification of healthy and Parkinson's patients.

Table I details the total number of PD and healthy patients from three datasets with their associated physical and clinical characteristics. For small and simple depiction these datasets are denoted as Ga [24], Si [25], and Ju [26]. Each shoe had pressure sensors shown in Fig. 3. Table II depicts the absolute position of sensors in the X-Y coordinate framework. The VGRF signal representation of PD and the non-PD patients is shown in Fig. 4.

The mean and Standard Deviation of each physical feature's age, height, and, weight are taken out to know the average of each characteristic and dispersion of the dataset relative to its mean value.

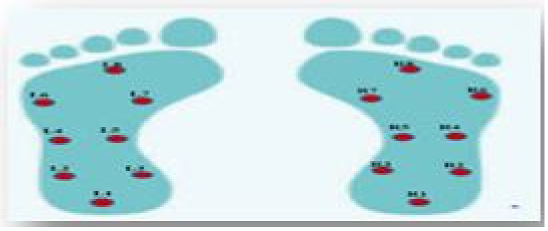

Fig. 3. Pressure Sensors Positioned under each Foot to get the Best Collection.

B. Proposed ML-based Parkinson's Disease Diagnosis Model

Fig. 5 shows the proposed graphical representation for the diagnosis of PD. First of all, data is collected from wearable eight-foot sensors worn on both left and right feet. After that data may pass through the data pre-processing phase, feature extraction/ selection phase, and final classification phase in which different ML models are applied [31] [32] [33] [34].

- Data Preprocessing

The dataset was collected from different walking tests to avoid the gait starting and ending effect the initial twenty and last twenty data from each gait cycle were removed [35]. The progression of PD among a person can be retrieved through the variations of gait because the walking patterns of individuals changed over time. Therefore, a better study regarding the disease's significant features can provide the best way to understand gait disorders and can be considered significant biomarkers.

Fig. 5. Proposed ML-based Parkinson's Disease Diagnosis Model.

- Feature Extraction

The most important features extracted from raw sensors are depicted in Table III. A Shapiro-Wilk test is utilized to test the normal distribution of features with a confidence bound of 6% for the hypothesis test.

- Data Normalization

The data set was collected from different sensors. Multiple regression techniques are followed to reduce the distribution in the gait data set. That is represented by the equation:

$$Xi = \beta_0 + \sum_{i=1}^{n} \beta_j \, Y_{i,j} + \in i \qquad (1)$$

Where X_i denotes the dependent spatiotemporal features of the ith observation, $X_{i,j}$ denotes the jth physical features like age, weight, height, and walking speed, β specifies the unknown regression coefficient, and $\in i$ denotes the residual error observed for ith iteration. Further feature extraction is performed after normalizing the data.

TABLE III. EXTRACTED SET OF FEATURES WITH THEIR CATEGORY AND NAME

Category	**Feature Name**	**Description**
Time	Stance-duration	The period for which one foot is in direct contact with the floor
	Swing- duration	The period for which the body is completely on the support of one leg
	Stride- duration	The time b/w two continuous events of a similar foot
	Step-time	the time gap b/w starting interaction of one foot to starting contact of contralateral foot
Length	Stride-length	Distance b/w two consecutive ground contacts of the same foot
	Step-length	The gap b/w starting contact of one foot to starting contact of the other foot
Frequency	Cadence	No. of steps occupied per unit of time
Temporal	Swing stance ratio	The proportion of swing to stance interval
	Standardized stance duration (std stn-dur)	The ratio of stance duration to the stride time i.e., (stn-dur/str-dur)
	Standardized swing duration (std-sw-dur)	The ratio b/w swing duration to stride duration, i.e., (sw-dur/str-dur)
	Standardized double limb support (std-DLS-dur)	The ratio among DLS to the stride duration stride time, i.e., (DLS-dur/str-dur)
Force	Heel-strike force	Sensor values mean underneath the heel for initial 5% sample points instance interval of the total gait cycle
	Toe-of force (To-force)	Mean of sensor values underneath the toe for the last 5% sample points instance interval of the total gait cycle
	Centre of pressure (x,y) (COP_x, COP_y)	The total amount of pressure field acting on a body causing a force to act on the ground

- Optimal Feature Selection

Feature selection is a significant step that must be followed before the classification process because it improves overall classification performance and results in less computational time and complexity [30]. A stepwise regression method is applied to select the optimal feature set for classifying the patients into healthy and PD classes. First of all, correlation among various autonomous variables (like gender(G), weight (w), height (h), and walking speed (s)) are calculated by utilizing the Spearman correlation coefficient. Reduction in data dispersion is calculated by utilizing the coefficient of variation with a 95% confidence level (CDL) and a standard error (SE) [31]. The statistical measurable significance of the outcome is evaluated by the value of p as ($p<0.001$). Table IV: describes all selected sets of features.

- Random Forest Tree (RFT)

RFT is introduced by Bierman [31]. RFT is used as a classification technique for this model because analysis of different data mining reveals the RFT as the best one when computed on different datasets in paper [33]. This model works well for both classification and regression-based problems. This method also comes under the ensemble approach as it combines multiple Decision trees. This method was mainly introduced to resolve the pruning problem that occurred in the decision tree approach. Besides searching for the most significant feature while distributing a node, this algorithm looks for the best feature amongst a random set of attributes. RFT method follows the bootstrap aggregating or bagging approach for training the learners. The working procedure of RFT is described in Fig. 6.

TABLE IV. SELECTED SET OF FEATURES WITH NORMALIZED VALUES

Coefficient of Variation (%)	**Raw /Un-normalized Data**			**Standardized Data**		
	ME	***90% CL***	***SE***	***ME***	***90% CL***	***SE***
Cadence	9.28	[8.45:15.47]	1.32	4.98	[4.41:6.55]	0.68
Stride interval	10.45	[8.62:12.26]	0.91	5.41	[5.09:7.71]	0.67

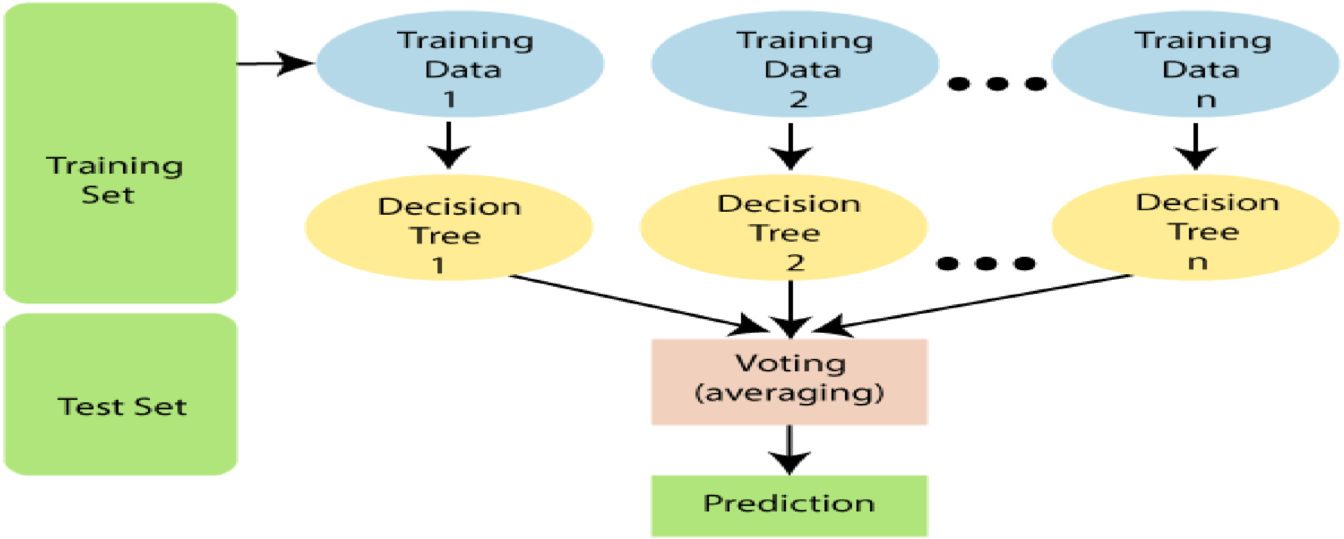

Fig. 6. Working Procedure followed by RFT.

RFT method follow the following steps:

1) For a given training set S=s_1, s_2,……, s_n with classes $Z_{=}z_1,z_{2…,}z_{n,}$ bagging method repetitively (B times) selects a random sample with replacement and applied these samples to fit the tree. For b=1,... B: Selects n training samples from S and Z; and call them S_b, $Z_{b.}$

2) Train the classification tree R_b on S_b, $Z_{b.}$

3) After training phase, predictions for unknown sample S' can be done by taking the majority votes from each classification tree.

4) For a given training set S=s_1, s_2,. ….., s_n with classes $Z_{=}z_1,z_{2…,}z_{n,}$ bagging method repetitively (B times) selects a random sample with replacement and applied these samples to fit the tree. For b=1, ..,B: Selects n training samples from S and Z; and call them S_b, $Z_{b.}$

5) Train the classification tree R_b on S_b, Z_b

6) After training phase, predictions for unknown sample S' can be done by taking the majority votes from each classification tree.

C. Implementation Details

Implementation of the proposed model is done on Jupyter IDE an open-source software developed to support highly interactive data science and scientific computing using Python as a programming language. Most important data computing, visualization, and performance measures and machine learning-based libraries including such as (pandas, NumPy, Matplotlib, sns, metrics, and sklearn) are utilized to support various built-in functionality for computation purposes. Random forest tree (RFT) is utilized as classification techniques to classify subjects into healthy and PD classes and tuned with specific hyperparameters (Max_depth=20, n-estimators=550, criteria=entropy) using Grid search cross validation method [34].

V. Performance Evaluation Metrics

The performances of different ML models can be evaluated by using Accuracy, Recall, Precision, and F1_Score.

- Accuracy

Accuracy mainly refers to the fraction of truly classified samples to the total no. of samples.

$$\text{Accuracy} = \frac{\text{Tn+Tp}}{\text{Tn+Tp+Fn+Fp}} \tag{2}$$

- Recall/Sensitivity

Recall mainly refers to the correctly classified samples by the ML model.

$$\text{Recall} = \frac{Tp}{Tp+Fn} \tag{3}$$

- Precision or Positive Predicted value (PPR)

Precision mainly refers to the proportion of truly classified samples among all positive samples.

$$\text{Precsion} = \frac{Tp}{Tp+Fp} \tag{4}$$

- F1_Score

F1_score ranges between the value 0(refers to worst) and 1(refers to best) and it specifies the balance between recall and precision. It is also called a "weighted harmonic means of precision and recall" and results in an accurate mean of performance of the test.

$$\text{F1\_}Score = 2 \times \frac{\text{Precision}\times\text{Sensitivity}}{\text{Precision+Sensitivity}} \times 100\% \tag{5}$$

VI. Result and Discussion

To avoid the statistically unbiased and overfitting problem, a five-fold CV (Cross-Validation) method is applied. After that, it was arbitrarily divided into five equivalent parts and among five, four subsets are utilized to train the model and the remaining subsets are utilized to test the model. This study addressed a classification problem on three different datasets by utilizing two different feature sets. Table V, VI will show the performance results from three different datasets. The graphical visualization of the performance results is shown in Fig. 7-10. It also shows that there is a great improvement in model performance when is trained with an extracted set of features. For the Ga sub dataset, there is an improvement of approximately 2% can be identified when utilizing feature selection. In the same manner, for the Ju sub dataset, there is an improvement of 4% can be identified when utilizing feature selection technique. Almost the same improvement can be found, for the Si sub dataset, there is an improvement of approximately 2% can be identified when utilizing feature selection. The result revealed that the best combination of related features obtained through feature selection improve the overall performance of proposed ML model. Along with that, it will also reduce execution time both in the training and testing phases.

TABLE V. PERFORMANCE RESULTS BEFORE THE APPLICATION OF THE FS METHOD FOR INDIVIDUAL SUB-DATASET UTILIZING 5-FOLD CV METHOD

Data Sets	**Accuracy**	**Precision**	**Recall**	**F1_Score**
Ga [27]	93.5	88.12	87.4	89.42
Ju [28]	94.42	92.50	90.21	95.60
Si [29]	92.52	90.20	91.21	89.1

TABLE VI. PERFORMANCE AFTER THE APPLICATION OF FS METHOD FOR INDIVIDUAL SUB-DATASET UTILIZING 5-FOLD CV METHOD

Data Sets	**Accuracy**	**Precision**	**Recall**	**F1_Score**
Ga [27]	95.54	91.12	89.4	91.42
Ju [28]	98.80	96.50	95.12	95.24
Si [29]	94.52	91.20	92.12	89.97

It is observed that when proposed model applied on three datasets provide the best accuracy result in the classification of patient into healthy and PD class. Along with that, by evaluating the differences in results between three datasets, it can be notified that proposed ML models show their best results in the case of the Ju dataset. It is also notified that results obtained on Ga are much better as compared to Si. Result can also present the fact that the smaller number of patients with little severity and high severity is more important. It is highly notifying that the patients with little severity may be considered healthy by ML models in some cases and may be considered patients in some cases. High severity patients can be easily separated from healthy subjects.

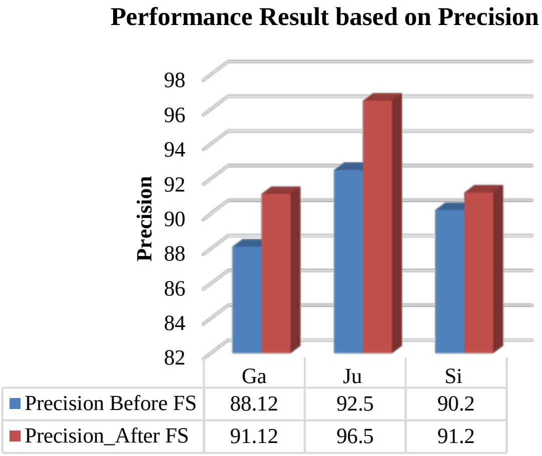

Fig. 8. Precision Score with and without Feature Selection.

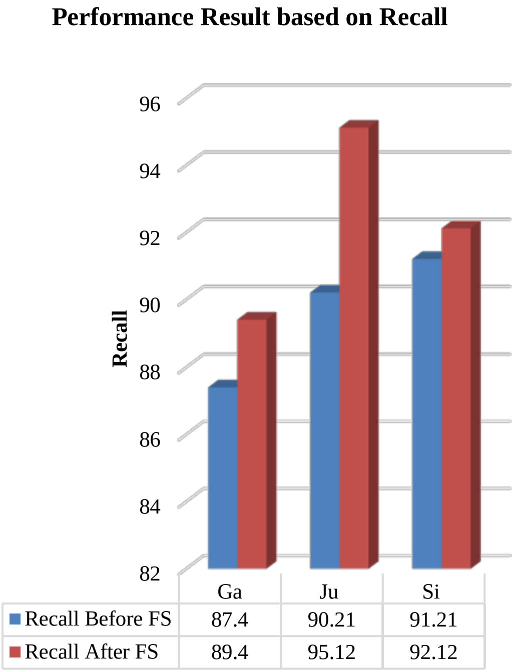

Fig. 9. Recall Score with and without Feature Selection.

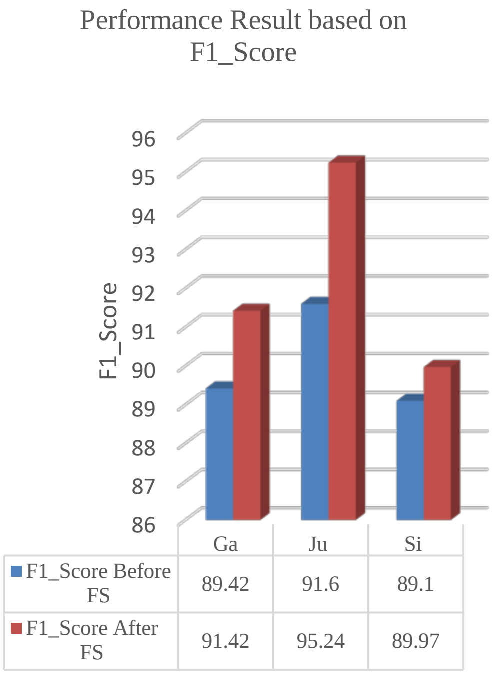

Fig. 10. F1_Score with and without Feature Selection.

Table 7 shows the comparison between the proposed work and the existing work. Results revealed that our proposed work is more precious than the existing work and will support maximum accuracy of 98.80%.

TABLE VII. ACCURACY COMPARISON BETWEEN PROPOSED WORK AND PREVIOUS WORK

Reference	**Features Type**	**No. of Features**	**ML Technique**	**Accuracy Score (%)**
Wu and Krishnan [35]	Time	3	SVM	90.32
Perumal and Sankar [36]	Frequency	10	SVM, NN, LDA	87.52-92.5
Abdul hay et al. [37]	Frequency and Time	3	MEDIUM Gaussian SVM	94.8
Khoury et al. [38]	Spatiotemporal	19	K-NN, DT, RF	83.3-92.86
Alam et al. [39]	Time	33	SVM, K-NN	93.6
Khera et al. [40]	Time Features	10	KNN, SVM, DT, RF	85-98.50
Proposed Work	Spatial, Time and Force	8	RFT	98.80 (Ju), 95.54 (Ga), 94.52 (Si)

VII. CONCLUSION

Wearable sensors offer a smart way of assessing the movement disorders among patients suffering from PD and provide a potentially vast quantity of informative data in order to quantify and monitor the progression of PD among patients. The current work, proposed a ML based PD diagnosis model and evaluated on VGRF dataset (Ga, Si, Ja) composed of different gait cycles that is publicly available on Psyionet. The performance of proposed model assessed by utilizing accuracy, precision, recall and F1_score as performance evaluation measures. The current work, presented that the proposed model outperformed other existing model to classify the patient into healthy and PD classes when subjected to preprocessed gait dataset with selected set of features. A five-fold cross validation method is implemented to achieve the accuracy result of 98.80 on Ju dataset, 95.54 on Ga dataset and 94.52 on Si dataset.

VIII. FUTURE DIRECTION

The conclusion reveals that the proposed model provides best results in the classification of PD but still faces some challenges. Future work concerns the introduction of more relevant features in order to enhance the diagnosis of PD and investigation of the cost-effective hybrid ML/Ensembles ML models and also handling the issue of imbalanced data.

ACKNOWLEDGMENT

I am highly thankful to Dr. Pooja Mittal for her comments and support in the preparation of this manuscript.

A Novel Methodology for Disease Identification using Metaheuristic Algorithm and Aura Image

Manjula Poojary, Yarramalle Srinivas
Department of Computer Science, GITAM Deemed to be University
Visakhapatnam, India

***Abstract*—Every human has a specific Aura. Every organism in the human body emits energy comprising of Ultra Violet radiation, thermal radiation, and electromagnetic radiation. These energy levels help to underline the physical health inside the human body. In general, these energy levels are called Aura. In order to capture the energy levels, specific cameras like Kirlian are used. These cameras try to capture the energy distribution and map them to the individual organs of the human body. In this article, we present a methodology using Image processing techniques, where Bivariate Gaussian Mixture Model (BGMM) is considered as a classifier to identify the diseases in humans based on the energy distribution. In this article, we have considered five different categories of diseased organs that are identified based on the energy distribution. The preprocessing is subjected to the morphological technique and Particle Swarm Optimization (PSO) algorithm is considered for feature extraction. The segmentation process is carried out using the feature extracted and training is carried out using the BGMM classifier. The result obtained is summarized using various other methods like Support Vector Machine (SVM), Artificial Neural Network (ANN), and Multiclass SVM (MSVM). The results showcase that the proposed methodology exhibits recognition accuracy at 90%.**

Keywords—Aura images; BGMM; image classification; multiclass SVM; artificial neural network

I. Introduction

Image processing is the primary step in image analysis. It helps to both process the image, and enhance the image and also helps in the effective recognition of deformities inside the image regions based on the feature extraction techniques [1]. In image processing the primary objective is to process the input image so that effective recognition can be achieved [2]. Among the various application of image processing recently much emphasis is subjected to the area of medical imaging. In medical imaging the acquired medical images are processed, enhanced and the features are extracted for the effective identification of the disease [3, 4]. Of late, many article have been proposed for effective identification of image deformities based on the medical images as inputs. Some of the techniques in this area of research include; methodologies based on non-parametric technique such as pixel-based techniques, region-based techniques, shape based, texture-based techniques etc. [5, 6, 7, 8]. The research is also extended further by developing parametric models for better classification and identification of medical diseases using methodologies like GMM, Hidden Markovian Models, Markovian Random fields etc. [9, 10, 11, 12]. It is also presented in the literature that parametric model-based approach is more adaptive compared to the non-parametric model [13, 14, 15, 16]. The latest advancement in the area of computer communication technologies led towards the development of machine learning technique and thereby literature has been driven in this direction of research, using machine learning technique such as Convolution Neural Network (CNN), Artificial Neural Network (ANN), Bayesian belief network etc. [17, 18, 19, 20]. However, in spite of the numerous works presented by the authors, effective identification and diagnosis is only subjected after the acquisition of medical scans and by then the disease might have entered the human anatomy. However very little work is reported in the literature to estimate the deformities inside the human body well before the disease is noticed.

This article attempts in this area of research where the Aura images are considered and using the Aura images as the input, prior detection of the disease can be identified even before the development of the disease. For this purpose, we have considered the database of Aura images, namely; Bio-Well data set consisting of Aura images. In this article we have tried to highlight the diseases like nervous system, thorax, thyroid, abdomen disease and throat diseases. The article is further presented in the following sections, where Section II deals with the brief introduction to Aura images, Section III deals with dataset considered. Feature extraction based on the PSO is highlighted in Section IV of the article. Section V deals with classification technique based on BGMM and methodology is highlighted in the corresponding Section VI. The results derived are compared with the existing algorithm and are presented in corresponding results Section VII of the article. Section VIII of the article summarizes with conclusion.

II. Aura Images

The Aura images are nothing but the energy field surrounding the human. Every individual is attributed with a specific Aura. The Aura images exhibit different colors in tandem with the colors of VIBGYOR, where each color is related to the chakras of the human body. The violet color in the colors of VIBGYOR indicates crown chakra, indigo specifies the third eye chakra, blue indicates throat chakra, green indicates the heart chakra, yellow color indicates the solar plexus, orange color indicates the sacral chakra and red indicates the base chakra. Each of the colors corresponding to the chakras are linked with an organ in the human body and they exhibit the behavior of the individual. The red color indicates the anxiety levels and the orange color represents the structure of the kidney or reproductive organ, yellow is subjected to the spleen, the working condition of lungs can be identified by the green color, throat and thyroid are reflected by the blue color, the nervous system problem can be identified by the violet and indigo color is subjected to the problem related to lungs. The main advantage of the Aura images is that, if the intensity around each chakra is identified, the specific disease which is likely to appear can be known in prior by the higher intensity depicted in these colors [20, 21].

III. Bio-Well Dataset

Bio-Well dataset records a large number of human aura images that are captured using a device called Gas Discharge Visualization (GDV), which is based entirely on Electro photonic imaging (EPI). These images are used for imaging analysis to identify many of the physical problems associated with the person. The GDV device captures the electronic cloud on the finger, those electronic images or finger images are transmitted to the GDV device for image processing. The images obtained from GDV are processed. The Bio-Well database includes aura images associated with the fingers, full aura images of the body plus aura images associated with the chakras of the human body. Bio-Well image provides a person with a wide range of seals and observations about strength and endurance for the whole body, energy centers, organs and systems. Bio-Well is used by hundreds of physicians, clinicians and researchers around the world.

IV. Particle Swarm Optimization Algorithm (PSO)

PSO is metaheuristic, populace is primarily based totally on stochastic seek set of rules stimulated with the aid of using social conduct of birds flocking at the same time while trying to find the food. Here every particle represents bird and they are able to fly in unique route and every particle has speed and position and swarm represents group of birds or populace. The idea of food searching behavior of birds is used to mathematically model the algorithm. This algorithm is used to solve the optimization problem and PSO seeks for maximum cost with the aid of using the iterations.

Suppose group of birds are randomly flying and attempting to find the food in a place (search area), social behavior of the birds is moving in the direction of a crowd. Assume that there is only one piece of food in a place being searched and all of the birds do not know the position of the food however they know how far they're in each iteration.

The search procedure used are

- Follow the bird that's nearest to the food.
- Birds do not know the best position.
- If any member can locate the appropriate path, rest of the members will comply with quickly. Starting with the randomly initialized populace and moving in randomly initialized directions, every particle is going through the search area and remembers the best preceding positions of itself and its neighbors. That is every particle seeks for maximum value through updating the iterations. In every iteration each particle is updated following the two best values, .i.e. pbest (best particle position) and gbest (group best particle position).

A. Mathematical Model

In PSO every particle is taken into consideration to be solution and every particle has its speed, position and fitness values. In swarm every particle remembers its position called particle_bestFitness_value(pbest), particle_bestFitness_position. A record of global_bestFitness_position(gbest) and global _bestFitness_value is maintained. Position and velocity is calculated using (1) and (2)

$$\mathrm{x}_\mathrm{i}^{\mathrm{t+1}} = \mathrm{x}_\mathrm{i}^\mathrm{t} + \mathrm{v}_\mathrm{i}^\mathrm{t} \tag{1}$$

in which x_i^t is the previous position of the particle, v_i^t *is* particle velocity and x_i^{t+1} is current position.

$$\mathrm{v}_{\mathrm{k=1}}^\mathrm{t} = \mathrm{wv}_\mathrm{k}^\mathrm{i} + \mathrm{c}_1\mathrm{r}_1(\mathrm{xBest}_\mathrm{i}^\mathrm{t} - \mathrm{x}_\mathrm{i}^\mathrm{t}) + \mathrm{c}_2\mathrm{r}_2(\mathrm{gBest}_\mathrm{i}^\mathrm{t} - \mathrm{x}_\mathrm{i}^\mathrm{t}) \tag{2}$$

here w is inertia weight, c1, c2 is positive constants, r1,r2 is random values within the range[0,1].

$xBest_i^t$ is best particle position and $gBest_i^t$ is global best.

Calculate the fitness value of every particle using the objective function and pick out the best fitness value as gbest.

Algorithm

1. Initialize parameter and population
2. Calculate fitness value (optimum) for every particle. If the fitness value is the higher than best fitness value (pbest) then set new value as global best (gbest). Choose the particle with high-quality fitness value as gbest.
3. For every particle calculate speed and position. Calculate fitness value and locate gbest.
4. Repeat this method till circumstance met.
5. Replace counter t=t+1
6. Output is gbest(global best) and x_i(position)

V. Bivariate Gaussian Mixture Model (BGMM)

The image segmentation is the primary factor for image analysis and retrieval. Various colors are proposed for different image processing scenario. For various image processing scenarios, different colour models are suggested. Through the use of hue and saturation in a bivariate Gaussian mixture model (BGMM), human perception of a picture can be described in HIS (hue saturation intensity) colour space. The image is regarded as a finite mixture of BGMM for the purpose of image segmentation, with the feature vector of each image region having a bivariate Gaussian distribution. Through the use of a bivariate frequency surface and the K-means algorithm, the number of components in the mixture are determined. The model parameters are calculated by deriving the revised equations of the model parameters for the EM-algorithm. The segmentation is carried through maximizing the component likelihood. It is common to assume that the feature vector of the image follows a bivariate Normal (Gaussian) distribution when modelling the bivariate features of the image. The Probability density function of the BGMM is given by.

$$\mathrm{f}(\mathrm{x}_1,\mathrm{x}_2) = \frac{1}{2\pi\sigma_1\sigma_2(\sqrt{1-\mathrm{p}^2})} e^{-\left[\frac{1}{2(1-\rho^2)}\left[\left(\frac{\mathrm{x}_1-\mu_1}{\sigma_1}\right)^2 - 2\rho\left(\frac{\mathrm{x}_1-\mu_1}{\sigma_1}\right)\left(\frac{\mathrm{x}_2-\mu_2}{\sigma_2}\right) + \left(\frac{\mathrm{x}_2-\mu_2}{\sigma_2}\right)^2\right]\right]} \tag{3}$$

where μ_1, μ_2 are any real numbers.

$\sigma 1 > 0$, $\sigma 2 > 0$; $-1 <= \rho <= 1$

in which μ1, σ1 are the mean and variance of the image with 1st features and μ2, σ2 are the mean and variance of the image with the 2d features, ρ is referred to as the shape parameter.

If $\rho = 0$ this implies correlation (x, y) = 0. i.e.

$$\mathrm{f(x1, x2)} = \frac{1}{2\pi\sigma 1\sigma 2(\sqrt{1-p2})} \mathrm{e}^{-\left[\frac{\left[\left(\frac{x_1-\mu_1}{\sigma_1}\right)^2+\left(\frac{x_2-\mu_2}{\sigma_2}\right)^2\right]}{2}\right]} \tag{4}$$

$$= \mathrm{f}(x_1)(x_2) \tag{5}$$

x and y are normal variables.

Equations for first feature is

$$\sigma_1 = \frac{K_1 \pm \sqrt{{K_1}^2 - 4K_2}}{2} \tag{6}$$

$$where\ K_1 = \left(\frac{2e(x_1-\mu_1)(x_2-\mu_2)}{\sigma_2}\right)\left(\frac{-1}{2(1-\rho^2)}\right) \tag{7}$$

$$and\ K_{2=} \frac{2\,(x_1-\mu_1)^2}{(1-\rho^2)} \tag{8}$$

Equation for second feature is

$$\sigma_2 = \frac{-K_3 \pm \sqrt{{K_3}^2 - 4K_4}}{2} \tag{9}$$

$$\text{where } K_3 = \frac{1}{2(1-\rho^2)} \frac{2e\,(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1} \tag{10}$$

$$and\ K_4 = \frac{-\,(x_2-\mu_2)^2}{(1-\rho^2)}$$

VI. Methodology

The analysis of the disease based on the Aura images is done using the BGMM classifier by adopting the following steps.

Step 1: Morphological processing

The first step in the identification of the disease is to acquire the image and process the image. In order to have a precise enhancement it is customary to process the image by the integration of morphological technique together with segmentation so as to acquire the inherent outer Auras effectively [22]. The input image is converted to binary image and using the technique of morphology such as erosion and dilation the input image is processed. This process enhances the quality of the image and in order to further enhance the quality of the image technique like closing, Hit and Miss are used for effective smoothing and filling the holes inside the images. These processed images are considered for segmentation.

Step 2: Segmentation

In this process the images are clustered into groups such that the homogeneous pixels are together in a specific group based on a criterion obtained using the color intensity. These intensities of pixels are given as input to the BGMM so that high intensity regions can be identified. These regions with high intensity attribute to the deformity.

Step 3: Feature extraction

The methodology carried out in two phases training and testing which is shown in Fig. 1. Each aura image of individual extracted and the high intensity levels identified from the BGMM are used to recognize the disease.

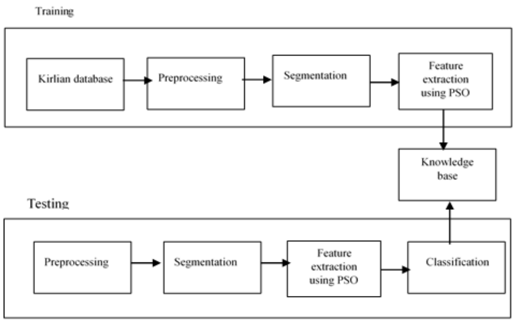

Fig. 1. Model of the Proposed Methodology.

VII. Result and Discussion

In order to present the results, the Aura images are classified based on the intensity levels. Different techniques such as ANN, MSVM and PSO with BGMM are considered for undergoing the comparative study and the various images considered are presented in Fig. 2-11. Fig. 2 shows the depleted energy distribution around neck, abdomen, leg and back. Fig. 3 indicates the energy holes in various regions due to pressure. Fig. 4 shows health issues in head, heart and abdomen region. Disease regions are indicated with breakage in the images region indicates the health problems in throat, heart, stomach and leg area due to hyper tension is shown in the Fig. 5. The aura image which was taken before meditation is given in Fig. 6. The different aura images based on the chakras is given in Fig. 7 to 11. The Fig. 7 shows the high energy levels in the heart and head regions. The problem in digestive system is observed in the Fig. 8. Health issues in the various organs shown in the Fig. 9. The Fig. 10 shows imbalanced energy level in root, solar plexus and throat chakras. Fig. 11 shows the high energy level in the root, sacral and throat chakras indicates health issues in related organs.

All the aura images are obtained from biowell data set. These images are captured using Kirlian based device called Gas discharge visualization (GDV).

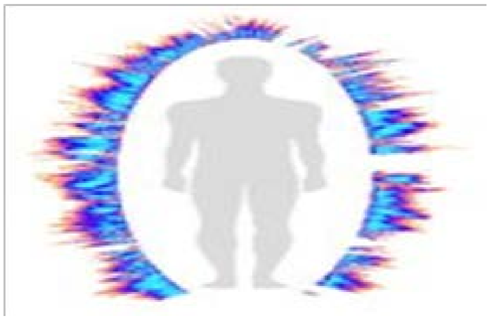

Fig. 2. Energy Depletion in Leg, Abdomen, Back and Head.

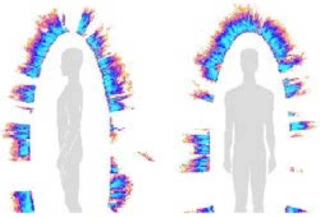

Fig. 3. Energy Holes in Various Organs.

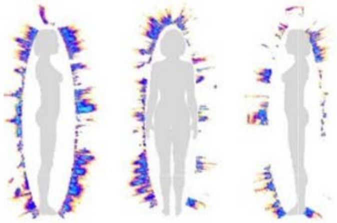

Fig. 4. Energy Depletion in the Region of Head, Heart and Abdomen.

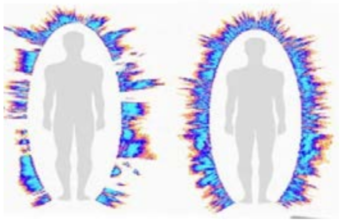

Fig. 5. Energy Holes in the Region of Throat, Heart, Stomach and Leg Area.

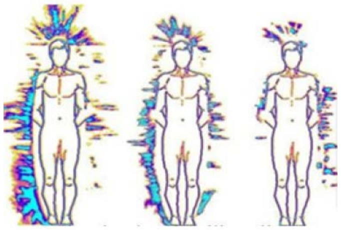

Fig. 6. Diseased Aura Image in Various Organs.

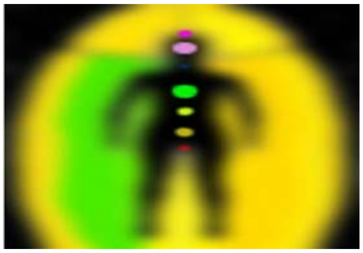

Fig. 7. Health Issues in Heart and Head (Migraine).

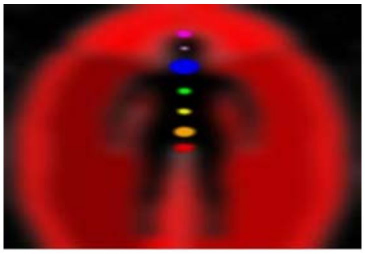

Fig. 8. Health Issues in Throat and Digestive System.

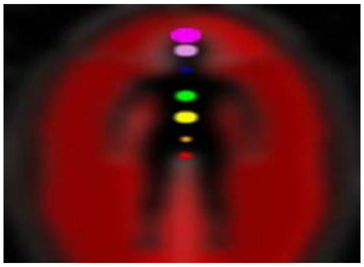

Fig. 9. Health Issues in Pineal Gland, Nervous System, Heart and Kidney.

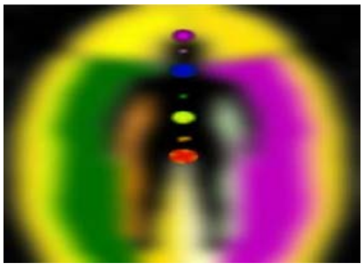

Fig. 10. Health Issues in Addrenal Gland, Solar Plexus , Throat and Brain.

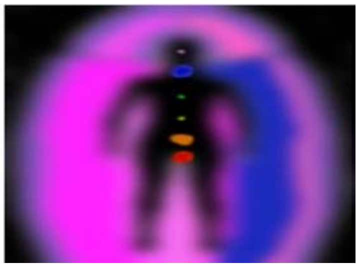

Fig. 11. Problems in Throat, Urogenital System and Spinal Cord.

The comparative analysis is carried out using technique based on ANN, MSVM technique and the proposed model based on PSO. The organs considered for the identification of the disease are nervous system, thorax, thyroid, abdomen and throat. The results obtained are depicted in the Table I. The result shows that proposed method has greater accuracy when compared to the existing model.

TABLE I. COMPARATIVE STUDY OF PROPOSED METHOD WITH OTHER METHODS

Organs having Problem	**No. of samples Trained**	**No. of samples tested**	**No. of samples recognized with ANN**	**No. of samples recognized with MSVM**	**No. of samples recognized with Proposed model**	**Accuracy (%)**
Nervous system	5	43	24	29	39	90%
Thorax	6	55	30	39	47	86%
Thyroid	7	34	12	19	29	87%
Abdomen	5	65	34	39	59	91%
Throat	7	39	21	29	32	83%

From the table it is observed that the proper methodology based on PSO helps to identify the diseases in advance compared to the other methods.

VIII. Conclusion

Aura images have a capability of disease identification. These images can be considered for the identification of the disease with respect to a specific organ. Both testing and training phases are carried out where the test image is identified based on the intensity whether it is prone to disease or not. A new methodology is considered for feature extraction based on BGMM together with PSO. The Bivariate feature H and S are given as input to the model, derived primarily based on Bivariate Gaussian distribution. It helps to identify the color intensities and thereby helps in identifying the high intensity levels resembling the disease. The comparative analysis carried out shows the proposed method helps in effective recognition of the diseases well in advance when compared to other state-of-art methods.

***Abstract*—Automatic detection of epilepsy based on EEG signals is one of the interesting fields to be developed in medicine to provide an alternative method for detecting epilepsy. High accuracy values are very important for accurate diagnosis in detecting epilepsy and avoid errors in diagnosing patients. Therefore, this study proposes the Enhanced Gradient Boosting Machines Fusion (Enhanced GBM Fusion) for automatically detecting epilepsy based on electroencephalographic (EEG) signals. Enhanced part of GBM Fusion is the pattern of majority voting evaluation based on the fusion of five-class and two-class GBM, called Enhanced GBM Fusion. The raw signal is extracted using Discrete Fourier Transform (DFT) and Discrete Wavelet Transform (DWT), then feature is selected by using Genetic Algorithm (GA) before classification. This proposed method was evaluated using five classes (normal in open eyes, normal in close eyes, interictal with hippocampal, interictal, and ictal) from the University of Bonn. The experimental results show that the proposed Enhanced GBM Fusion can increase the accuracy of GBM Fusion of 99.8% to classify five classes of epilepsy based on EEG signal. However, the performance of Enhanced GBM Fusion cannot be generalized to other datasets.**

Keywords—Epilepsy; enhanced gradient boosting machine fusion; electroencephalographic (EEG) signal; discrete wavelet transform (DWT); discrete fourier tansform (DFT); genetic algorithm (GA)

I. INTRODUCTION

Globally, WHO estimates that about five million people are diagnosed with epilepsy yearly. Low and middle-income countries are nearly three times more than high-income countries to be diagnosed with epilepsy [1]. This is feasible due to the increased risk of endemic conditions, variations in medical infrastructure, the availability of preventive public health programs, and accessible healthcare services.

Epilepsy is a chronic medical disorder with clinical symptoms and signs due to intermittent brain function disorders. It occurs due to abnormal or excessive electrical discharge from neuron paroxysms of various etiologies. Generally, epilepsy is attended in unpredictable, unprovoked recurrent seizures that affect a variety of mental and physical functions. Seizure is a spontaneous electrical hyperactivity activity of a group of nerve cells in the brain and is not caused by an acute brain disease. “Seizure” in epilepsy is an incurable disease. However, about 70% of people with epilepsy can be free from seizures with proper treatment. Neuroscientists generally predict seizures based on an abnormal electroencephalographic (EEG) pattern in the brain. An EEG is a device that records activity in the brain, including seizures.

A method with high accuracy is needed to detect whether the ongoing seizure is an epileptic seizure or a fake seizure. Visual examination of the EEG signal is necessary to determine the occurrence of epilepsy. Unfortunately, checking the EEG signal manually takes a long time, and sometimes the results are missed or false-alarm detections [2]. Automatic epilepsy detection has been studied since the 1970s in the form of literature in the hope of helping the medical world in detecting automatic epilepsy based on EEG data [3]. In general, automatic epilepsy detection can be categorized into two groups which are conventional approaches and Deep learning approaches.

Misdiagnosis of epilepsy is a fatal error because it can lead to inappropriate treatment and death. Therefore, a high accuracy value is essential in the automatic detection of epilepsy. The automatic detection of epilepsy from five classes of EEG data has been tried using various approaches, but not many of them achieve accuracy above 98%. This study presented a method for automatic epilepsy detection based on the motivation that the method can classify five classes of EEG signals with greater than 98 percent accuracy. This study utilized a combination of Discrete Fourier Transform (DFT) and Discrete Wavelet Transform (DWT) for feature extraction in the frequency and time-frequency domains. The output from the feature extraction by DFT and DWT is extracted again using a statistical feature and crossing frequency features. To obtain the best features that would be used for classification, feature selection based on a Genetic Algorithm (GA) is used in this study. This study proposes a method to enhance GBM Fusion that was previously used by Sunaryono et al. [4].

The distinguish of this study from the study conducted by Sunaryono et al. [4] is that this study proposes the Enhanced Gradient Boosting Machine Fusion, where the method will focus more on errors that occur in the classification results. Errors in this classification will be evaluated to see if there is a

*Corresponding Author

pattern in the errors. The pattern will be applied to the Enhanced Gradient Boosting Machine Fusion classification for higher accuracy. The workflow for the proposed method can be seen in Fig. 1. By using the proposed method, this study hopes to have good accuracy results (above 98%) and the study also hopes to contribute to helping the medical world to detect epilepsy automatically so that people with epilepsy can be diagnosed accurately and quickly.

Fig. 1. Flowchart of the Proposed Method.

The remaining sections are organized as follows. Section II provides related works. The Section III outlines the materials and methods utilized in this study. In Section IV, the experimental result and discussion are presented. In Section V, the conclusion is reached.

II. Related Work

This section provides literature study based on the University of Bonn dataset: Wu et al. [5] carried out their research using the Complete Ensemble Empirical Method (CEEMD) to decompose signal data into 12 IMFs and one residue. XGBoost was used as a classification method where the results detected an accuracy higher or equivalent to 99% in 12 cases of two and three classes. Ullah et al. [6] use a Pyramidal One-Dimensional Deep Convolutional Neural Network (P-1D-CNN) as an architecture to perform feature extraction to classify three classes. To improve accuracy, the author added majority voting on the architecture, which has significantly increased the accuracy of P-1D-CNN. This architecture yields an accuracy of 99.1 ± 0.9% in the two and three-class cases.

Türk and Özerdem [7] performed Continuous Wavelet Transform (CWT) as a feature extraction method on EEG signals to get a time-frequency 2-D scalogram image. The scalogram images were used as input for CNN classification. The classification result with the highest accuracy was 99% for three classes and 93.6% for five classes. Wang et al. [8] propose the Discrete Wavelet Transform (DWT) method as a feature extraction method and uses the Gradient Boosting Machine and Grid Search Optimization to optimize the hyperparameters. The study resulted in an accuracy of 96.5% for classifying three classes using a dataset from the University of Bonn.

Sunaryono et al. [4] also suggested using Discrete Wavelet Transform (DWT) in automatic epilepsy detection. Gradient Boosting Machine fusion (GBM Fusion) method is proposed to increase the accuracy of classifying three classes to 99.45%. The proposed fusion combines the results of the classification of 2 classes and three classes using majority voting.

Singh and Dehuri [9] produced 100% accuracy in two and three classes case. Also, they produced 93.33% in five classes case with a hybrid technique using DWT-based Singular Value Decomposition fuzzy *k*-nearest neighbor (SVD-F*k*NN) classifier. On a substantial scale, DWT-based SVD decomposes the input EEG signals into sub-bands. The extracted feature is classified using several '*k*' values for the F*k*NN classifier.

Zhao et al. [10] implemented a 1-D DNN based on CNN for robust automatic epilepsy detection that consisted of three convolutional blocks and three fully connected layers. In addition, each convolutional block consists of five distinct layer types. The proposed method achieved an accuracy of 93.55% in the five classes problem. Zhao et al. [11] continue the research with proposed a method called SeizureNet based on CNN that utilizes two convolutional neural networks to extract features and a fully connected layer to learn high-level features. This method has achieved 95.84% accuracy in five classes case.

Sukriti et al. [12] used two entropy features, called refined composite multi-scale dispersion entropy (RCMDE) and multi-scale dispersion entropy (MDE) to detect seizure from EEG data with one way analysis of variance (ANOVA) as a feature selection method before being classified by Support Vector Machine (SVM). The best accuracy achieved is 96.67% in three classes case using RCMDE.

Zhang et al. [13] modeled a multi-scale non-local (MNL) network, 1 D CNN, to identify epilepsy automatically. Signal pooling and multi-scale non-local layers were added to boost CNN performance. The MNL network achieved 98.64% accuracy in classifying three classes case. Fast Fourier Transform (FFT) and PCA neural network (PCANet) are utilized by Li and Chen [14] as feature extraction method. From EEG signal, a frequency matrix was created using FFT, and the feature was extracted using PCANet. The extracted feature is classified using SVM. The proposed method achieves its best accuracy in classifying three classes case with a 99.6% accuracy score.

III. Material and Method

A. EEG Dataset

The data used is data that has been collected by the Department of Epileptology University of Bonn (UoB), Germany, which was obtained by Andrzejak et al. [15]. This data consists of an analog signal which is converted to 12-bit digital and then filtered by a bandpass filter in the range of 0.53 to 40 Hz. The datasets are grouped into five sets denoted by A, B, C, D, and E, where each class has different characteristics, as detailed in Table I. Each dataset has 100 single-channel EEG data segments, and each data has a duration of 23, 6 seconds for a total of 4097 samples. Sample signal for five datasets as shown in Fig. 2. This study evaluated the proposed automatic epilepsy detection using EEG waves from all sets.

B. Discrete Wavelet Transform

Discrete Wavelet Transform (DWT) is a technique for performing signal analysis that provides a representation of a signal in time and a signal that can be computed efficiently. In DWT, the signal to be analyzed will pass through the filter process with different frequencies and scales. DWT will divide the signal into two: high frequency using a highpass filter and low frequency using a lowpass filter. DWT has a more flexible frequency window function than CWT, where the DWT frequency window narrows when observing high-frequency information and widens when analyzing low-frequency resolution. As defined in equation 1, for example, the parameter m is an integer that controls the dilation of the wavelet, the parameter m, k are an integer that controls the translation of the wavelet, s_0 is a preset scaling parameter, and its value is greater than 1. 0 is a translation parameter that has a value greater than zero and is the parent of the wavelet.

$$\Psi_{m.k}(t) = \frac{1}{\sqrt{s_0^m}} \Psi\left(\frac{t-kt_0 s_0^m}{s_0^m}\right) \tag{1}$$

In this study, DWT is used to decompose the EEG data obtained through the discrete Fourier transform process. Various wavelet families and wavelet levels are used in DWT to provide a scaling function. The wavelet decomposition L-level determines the signal's frequency band according to its level. The output of DWT were the coefficient vectors.

C. Discrete Fourier Transform

DFT is a technique to perform feature extraction using the frequency domain. DFT is beneficial because DFT makes it possible to find the spectrum of a signal with a finite duration. Since DFT treats the data periodically, it will express the input data's periodicity along with each periodic component's relative strength. The method proposed in this study uses the implementation of Fast Fourier Transform (FFT) since FFT is an efficient algorithm to compute DFT. The use of FFT is to divide the original EEG data into five frequency sub-sections, namely gamma (>30 Hz), beta (between 12 and 30Hz), alpha (between 8 and 12 Hz), theta (between 4 and 8 Hz), and delta (< 4Hz) using DFT as described in equation 2.

TABLE I. Dataset Overview

Dataset	Patient Status	Setup	Phase
A	Healthy	Surface EEG	Open Eyes
B	Healthy	Surface EEG	Close Eyes
C	Epilepsy	Intracranial EEG	Interictal Hippocampal Position
D	Epilepsy	Intracranial EEG	Interictal Epileptogenic Zone
E	Epilepsy	Intracranial EEG	Ictal

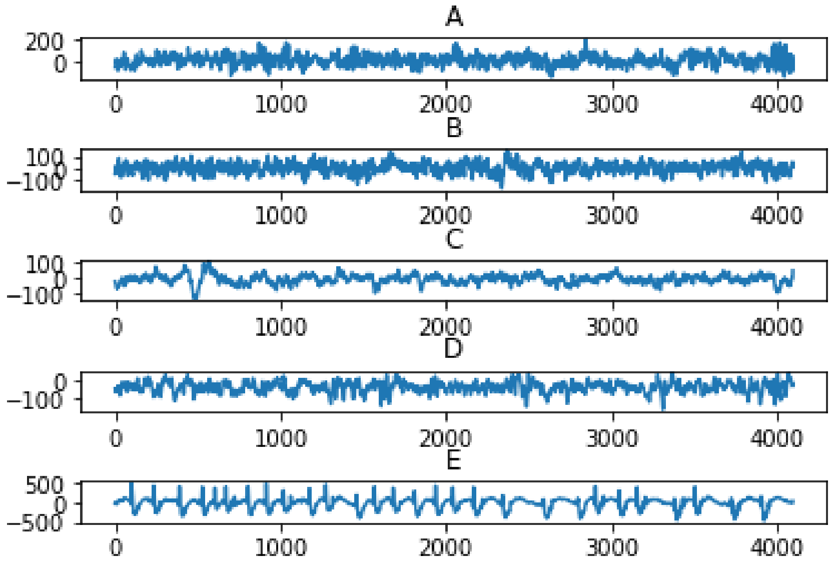

Fig. 2. Dataset EEG Samples.

$$F_n = \sum_{k=0}^{N-1} f_k \, e^{-\frac{2\pi ink}{n}}, \; n \in [0, N-1] \quad (2)$$

The transformed data is filtered using a band-pass filter to produce $F_\gamma(n), F_\beta(n), F_\alpha(n), F_\theta(n)$, and $F_\delta(n)$ signals at the respective sub-band frequencies. The EEG signal that has been in the form of frequency will be transformed again into the time domain using Inverse DFT to get an EEG signal that has been decomposed in the time domain as described in equation 3.

$$f_s(k) = \frac{1}{N}\sum_{n=0}^{N-1} F_s(n) e^{\frac{2\pi ink}{n}}, n \in [0, N-1], s = \gamma, \beta, \alpha, \theta, \delta \quad (3)$$

D. Statistical Feature

Information on data distribution can be obtained from percentiles by dividing the data into 100 equal parts. To get the percentile of p^{th}, the elements of the coefficient vector are ordered from smallest to largest. Eq (4) is used to get the n^th index of the p^{th} percentile, and N represents the length of the vector coefficient.

$$n = \frac{p}{100}(N+1) \quad (4)$$

The result was five statistical signal features retrieved from the results of each DWT coefficient vector, namely, the 95th percentile, 75th percentile, 50th percentile, 25th percentile, and 5th percentile. Thus, 5(L+1) statistical features were retrieved from all coefficient vectors of the DWT L-level decomposition result.

E. Crossing Frequency Features

Zero-Crossing Frequency (ZCF) is a condition where the two elements of the vector coefficient have a frequency that crosses zero or changes signs from positive to negative and vice versa. ZCF was chosen to replace Zero Crossing Rate (ZCR) because ZCF has a more straightforward calculation and the exact duration data. This work extracted ZCF from the coefficient vector of DWT results to capture the signal's frequency information. Suppose N is the span of the coefficient vector, $v(k)$ is the k^{th} component of the coefficient vector, and sgn is the sign function, then ZCF can be obtained by equation 5.

$$ZCF = \frac{1}{2}\sum_{k-1}^{N-1}\left|sgn\big(v(k+1)\big) - sgn\big(v(k)\big)\right| \quad (5)$$

This study also uses the Mean Crossing Frequency (MCF) to complete the signal frequency information that ZCF has obtained. MCF is described as the frequency of two subsequent components of the vector cross m; if m is the average value of the coefficient vector, MCF can be calculated by using equation 6.

$$MCF = \frac{1}{2}\sum_{k-1}^{N-1}|sgn(v(k+1) - m) - sgn(v(k) - m)| \quad (6)$$

With the L-level of decomposition, a total of 2(L+1) crossing frequency features were obtained from the coefficient vector of the DWT result.

F. Feature Selection using Genetic Algorithm

Genetic Algorithm (GA) is an optimization algorithm that is a population-based search algorithm that uses the concept of survival of the fittest. GA is inspired by natural selection[16]. A new population is generated by repeated iterations of the genetic operator on the individuals present in the population. The critical elements of GA are chromosome representation, selection, crossover, mutation, and computation of fitness functions. The Fitness function determines the ability to compete of an individual. The fitness value determines the probability of selecting an individual for reproduction. The selection phase is to choose parents based on their fitness values to carry their genes to the next generation. Crossover is the phase where the parents reproduce, and the crossover point is chosen randomly from the parents' genes. Offspring is made by exchanging genes between parents. Of the many offspring made, several offspring can experience mutations with a low random probability. This happens to maintain diversity in the population and prevent premature convergence.

GA dynamically changes the search process through crossover and mutation probabilities to achieve the optimal solution. GA has better global search capabilities because GA can modify the encoded gene. Besides that, GA can also evaluate many individuals and generate several optimal solutions. As stated by Katoch et al. [17], offspring derived from crosses of parental chromosomes have a high probability of deleting the genetic scheme of parental chromosomes. The cross formula is defined as equation (7).

$$R = \frac{G + 2\sqrt{g}}{3G} \quad (7)$$

G is the fixed number of generations determined by the population and g is the number of generations.

A classification with many features will increase the complexity of the training process. Many features also do not always result in good classification [18]. In this study, GA is used as a feature selection method to eliminate features that will not be used in the classification. Firstly, feature selection technique using GA was began by randomly creating the initial population of chromosomes, which are binary mask vectors of length comparable to the number of features. The genes on the chromosomes could take on the value 0 or 1. If the value of the i^th gene was 0, then the i^th feature was disregarded for classification; else, the feature was chosen. Feature selection using A fitness function was used to determine the quality of each chromosome. The fitness function for feature selection using GA makes use of the accuracy rate of a classifier that has been trained with chromosome-specific features. Until the final requirements are reached, the population is iteratively modified through crossover, mutation, and selection.

G. Gradient Boosting Machine Fusion

To construct new base-learners to be maximally correlated with the negative gradient of the loss function, which is related to the entire ensemble, is the principle of the Gradient Boosting Machine (GBM) [19]. Unlike the Decision Tree and Random Forest algorithms, the random forest combines several decision tree outputs to generate predictions. In GBM, each decision tree predicts from the previous error decision tree [20]. Therefore, GBM is a classification method that always tries to reduce errors. If $y = z(s(t))$ is an estimate of functional dependence, then for the loss function model, $\Psi(y, z)$, is formulated in eqution (8).

$$\hat{z}\big(s(t)\big) = \hat{y} = \arg min \Psi(y, z) \quad (8)$$

To optimize the function, $\hat{y}$ is used as a parameter in the function as $in\, \hat{y} = \sum_{i=1}^{M} \hat{y}_i$. This is what distinguishes GBM from other machine learning. In GBM, a "greedy stagewise" approach is derived from the weak-learners increment function. The function is formulated in equation (9).

$$(p_t, \theta_t) = \arg \overset{min}{p, \theta} \sum_{i=1}^{N} \Psi\big(y_i\, , \widehat{f_{t-1}}\big) + ph(x_i, \theta) \quad (9)$$

In this study, GBM Fusion is used to classify multi-class models. To improve the classification results where several classifiers would be trained as basic classifiers to classify EEG signals into five and two classes. After classifying five classes and two classes, the best results will be taken through majority voting using equation (10), suppose C is a class.

$$C(x_o) = \underset{k \in \{0,1,2,3,4\}}{\arg max} \left(\sum_{i=1}^{4} I_k \begin{matrix} s \in \{0, 1\} \\ or\ s \in \{0, 2\} \\ or\ s \in \{1, 2\} \\ or\ s \in \{1, 3\} \\ \cdots \\ or\ s \in \{3, 4\} \end{matrix} \right) \sum_{i=1}^{4} I_k\big(y_s^i\big) \quad (10)$$

H. Enhanced GBM Fusion

This study enhances the research of Sunaryono et al. [4] by evaluating the pattern of errors in the majority voting to improve the classification performance of automatic epilepsy detection in five classes case. The steps below were utilized to train Enhanced GBMs fusion and predict the class label for unknown data using Enhanced GBMs fusion.

- Obtain the decomposed signals $f_\gamma, f_\beta, f_\alpha, f_\theta$, and f_δ by decomposing the original EEG signal using DFT.
- Perform DWT with L-level decomposition to the initial EEG data to produce the coefficient vectors C1.
- Perform DWT with L-Level of decomposition to the decomposed EEG data for frequency sub-band $\alpha, \beta, \gamma, \delta$ and θ to obtain the coefficient vectors as C_2.
- Obtain feature sets F_1 by extracting 2(L+1) crossing frequency features and 5(L+1) statistical features from the coefficient vectors C_1.
- Obtain feature sets F_2 by extracting 10(L+1) crossing frequency features and 2 5(L+1) statistical features from the coefficient vectors C_2.
- Perform feature selection using GA to F_1 and F_2 to determine which are the most important features.
- Train two 5-class GBMs, X1 and X2, utilizing the selected features from F_1 and F_2 as input features, respectively.
- Train twenty 2-class GBMs with the selected features from F_1 and F_2 to classify the EEG signal as either class 0 and class 1 (named F_1^{01} and F_2^{01}), class 0 and class 2 (named F_1^{02} and F_2^{02}), class 0 and class 3 (named F_1^{03} and F_2^{03}), class 0 and class 4 (named F_1^{04} and F_2^{04}), class 1 and class 2 (named F_1^{12} and F_2^{12}), class 1 and class 3 (named F_1^{13} and F_2^{13}), class 1 and class 4 (named F_1^{14} and F_2^{14}), class 2 and class 3 (named F_1^{23} and F_2^{23}), class 2 and class 4 (named F_1^{24} and F_2^{24}), class 3 and class 4 (named F_1^{34} and F_2^{34}).
- Suppose x_0 is an EEG signal without labels. Using F_1 and F_2, predict the class label of x_0 to obtain y_1 and y_2, respectively.

a) If y_i = 0, then predict the class label of x_0 using models F_i^{01}, F_i^{02}, F_i^{03}, and F_i^{04} to obtain $y_i\, y_i^{01}, y_i^{02}, y_i^{03}$, and y_i^{04} from each model, for i = 1, 2.

b) If y_i = 1, then predict the class label of x_0 using models F_i^{01}, F_i^{12}, F_i^{13}, and F_i^{14} to obtain $y_i\, y_i^{01}, y_i^{12}, y_i^{13}$, and y_i^{14} from each model, for i = 1, 2.

c) If y_i = 2, then predict the class label of x_0 using models F_i^{02}, F_i^{12}, F_i^{23}, and F_i^{24} to obtain $y_i\, y_i^{02}, y_i^{12}, y_i^{23}$, and y_i^{24} from each model, for i = 1, 2.

d) If y_i = 3, then predict the class label of x_0 using models F_i^{03}, F_i^{13}, F_i^{23}, and F_i^{34} to obtain $y_i\, y_i^{03}, y_i^{13}, y_i^{23}$, and y_i^{34} from each model, for i = 1, 2.

e) If y_i = 4, then predict the class label of x_0 using model F_i^{04}, F_i^{14}, F_i^{24}, and F to obtain $y_i\, y_i^{04}, y_i^{14}, y_i^{24}$, and y_i^{34} from each model, for i = 1, 2.

- Class x_0 was predicted by majority vote based on the result of 5-class and 2-class GBMs.
- Evaluate the pattern of errors from GBMs Fusion majority voting to disregard the pattern of errors.
- Class x_0 predicted using majority voting on the result of 5-class and 2-class GBMs but while disregarding the error pattern.

Suppose x_0 is some EEG signals that must be classified after the feature extraction and selection stage. x_0 is classified using two 5-class GBMs, and suppose the result is class 4 from F_1 and class 4 from F_2. Further classification with twenty 2-class GBM, because both results from F_1 and F_2 is class 4 then the model that will give output only the model F_1^{04}, F_1^{14}, F_1^{24}, F_1^{34}, F_2^{04}, F_2^{14}, F_2^{24}, and F_2^{34}, the given output is class 4, class 4, class 2, class 4, class 4, class 4, class 2, and class 4, respectively. The final prediction of class x_0 after majority voting is class 4. However, because x_0 has the original class 2, the prediction result of x_0 is wrong. Therefore, the 8 GBMs models that give results of class 4 are ignored so that the majority voting results become class 2.

I. Experimental Setup

Experiments for this study have been conducted to validate the proposed method for detecting epilepsy using EEG signals in three cases. In the first case, two 5-class GBMs were trained with F_1 and F_2 to classify EEG signals. In the second case, twenty 2-class GBMs were trained with F_1 and F_2 to classify EEG into two classes, namely class 0-1, class 0-2, class 1-2, class 1-3, class 2-4, class 0-3, class 0-4, class 1-4, class 2-3, and class 3-4. In the third case, Enhanced GBM Fusion was utilized to classify EEG signals into five classes, and the results will be compared to those of previous studies.

This experiment was run on a mid-spec computer with a specification of 2.2GHz Intel(R) Core(TM) i7-8750H, 16GB RAM, NVIDIA GeForce GTX 1050 Ti GPU, and Windows 10 Home Single operating system to ensure that the proposed method is implemented on everyday life. The proposed method uses the python programming language with several libraries, namely NumPy [21], DEAP [22], scikit-learn [23], and PyWavelets [24]. This experiment uses fold-cross validation in which the EEG data is randomly divided into ten sections with equal proportions for each section.

IV. Result and Discussion

A. Classification of Five Class GBM

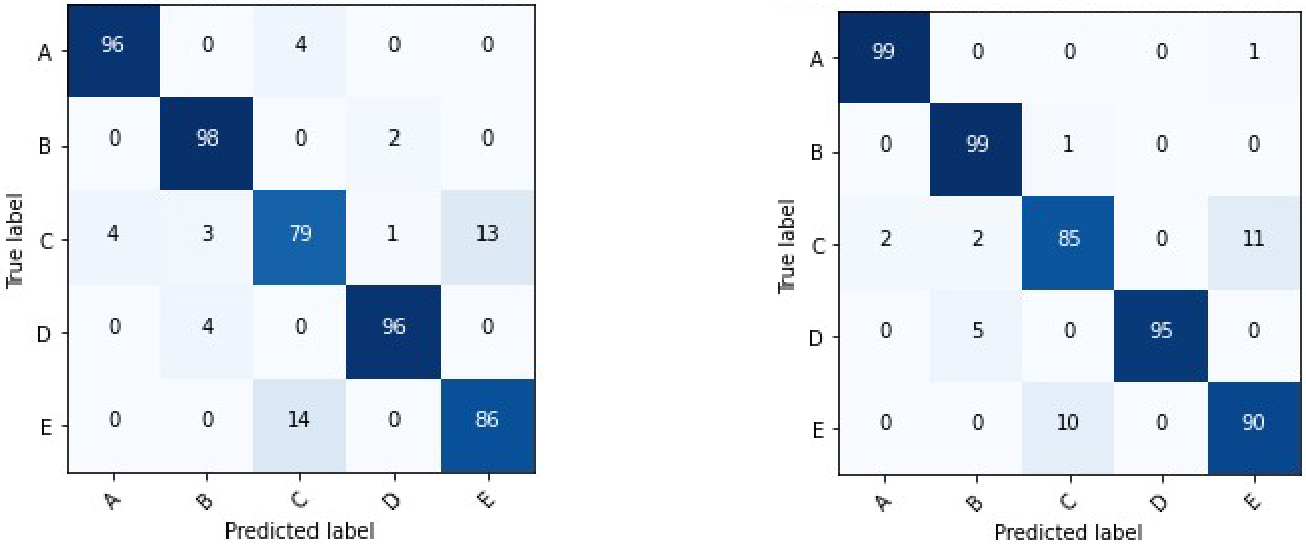
The accuracy of the 5-class classification using GBM with F_1 and F_2 has been summarized in TABLE II. The classification results using F_1 have a higher average of 91.13%, compared to F_2 with an average of 88.08%. The best result using F_1 feature is using Daubechies 6 (Db6) family wavelet with a decomposition level of 8 with the accuracy score of 91.99%. However, Db6 with a decomposition level of 8 needs more selected features to achieve the best accuracy than Symlet 16 (Sym16) and Symlet 20 (Sym20). For F_2 feature, the best result achieved is 93.6% by applying Biorthogonal 5.5 (Bior5.5) with the decomposition level of 3 while having the least original feature and having the lowest decomposition level compared to the rest as in Table II. The F_2 data has the same number of features after feature selection, while in F_1 data, more selected features are needed to get the highest accuracy results.

As shown in Fig. 3, confusion matrix was utilized to evaluate EEG signals that were incorrectly classified by F_1 using Db6 wavelet with decomposition level 8 and F_2 using bior5.5 wavelet with decomposition level 3. 5 classes model A-B-C-D-E FFT-Sub-band-Wavelet had a better classification result in class A, B, C, and E, while from 5 classes model A-B-C-D-E Wavelet had a better classification in class D.

The experimental results showed that raising the decomposition level of DWT does not necessarily increase the classification accuracy of 5-class GBM. These results also demonstrated that conducting DFT as added feature extraction method prior to DWT to generate features set F_2 does not always increase the accuracy of classification for 5-class GBM.

TABLE II. Summary of Five Class GBM Classification

Classifier	***Wavelet***		***Original Feature***	***Selected Feature***	***Accuracy with selected Feature***
	Family	***Level***			
F_1 Classifier	Db6	8	63	29	91.99
	Sym16	5	42	21	90.39
	Sym20	5	42	24	91.00
F_2 Classifier	Bior5.5	3	140	65	93.60
	Symll	5	210	65	89.20
	Db15	7	280	65	87.80



(a) Five Classes Model a-b-c-d-e.

(b) Five Classes Model -a-b-c-d-e Fft-Subband-Wavelet.

Fig. 3. Confusion Matrices of 5-Class GBM using each Features.

B. Classification of Two Class GBM

The result of the classification of 2-class GBM using F_1 and F_2 features have been summarized in Table III and Table IV, respectively. The wavelet family and decomposition level used in F_1 and F_2 are the same for each class classifier. In the experiment before using the feature selection, the accuracy results using F_2 data have higher accuracy results with an accuracy of 95.08% compared to F_1 data with an average of 93.99%, as in TABLE III and TABLE IV. The only F_1 feature before feature selection with higher accuracy against F_2 is using F_1^{14} classifier using rbio2.4 wavelet family and decomposition level of 6 with an accuracy score of 90.73% against F_2^{14} with an accuracy of 90.04% by applying the same wavelet family and decomposition level. In the experiment using feature subset, the average accuracy of the F_1 and F_2 features increased with an average accuracy of 99.19% in both data, with the highest accuracy being 100% and the lowest being 94%, as shown in TABLE III and TABLE IV, respectively. These results demonstrated that using feature selection most of the time can improve classification accuracy. The experimental results also showed that conducting frequency sub-band decomposition prior to DWT to generate features set F_2 can improve the classification accuracy of 2-class GBM.

C. Enhanced GBM Fusion Classification

Previously, the results of the 2-class model accuracy were obtained using F_1 and F_2, where the results from these models were combined and used in GBM Fusion and Enhanced GBM Fusion using majority voting. The classification results using GBMs Fusion resulted in an accuracy of 97.2% in the classification of 5 classes, with 14 misclassifications listed in Table V. Table V shows that the misclassification results mainly occur in the data with the highest majority voting value of 3, 5, or 8. This value will be used as a value of 0 during the enhanced GBM Fusion classification. The accuracy of 99.8% in the 5-class classification was also successfully achieved using Enhanced GBM Fusion by leaving one misclassification result at index 440 with confusion matrix as in Fig.4. This happened because the majority voting result in Enhanced GBM fusion at index 440 was 3 in the 5th row, which means the prediction result in the index 440 is class 4, which should be class 0. As shown in Fig. 4, all the EEG signals from class B, class C, class D, and class E were correctly predicted by Enhanced GBMs Fusion. Only one signal from class A was misclassified as a class E.

TABLE III. SUMMARY OF TWO CLASS GBM CLASSIFICATION USING F_1

Classifier	Family	Level	Original Feature	Selected Feature	Accuracy with Original Feature (%)	Accuracy with Selected Feature (%)
F_1^{01}	Db24	2	21	4	95,12	100

Table VI is comparison proposed method with the results of previous studies, the highest accuracy of five classes classification by the previous studies is 97.39% by Sunaryono et al. [4], which means that this study has an increase in the five-class classification by 2.41% from the best results in previous studies. The proposed method has the potential to classify five classes for the detection of epilepsy. However, this method is limited with the dataset that is used. The effect of this limitation that is this method still lack validation from other datasets.

V. Conclusion

In this study, Enhanced GBM Fusion is proposed to be an automatic epilepsy detection method from EEG signal data. The proposed method obtains an accuracy value of 99.8% in classifying five classes A-B-C-D-E on a dataset from the University of Bonn. EEG signal data were decomposed using DWT and DFT as feature extraction methods. The decomposed signal is used to extract the crossing frequency feature and statistical feature. Genetic Algorithm is used as a feature selection method to get discriminatory features to improve the classification performance. For the whole experiment, the proposed method can improve the accuracy compared to normal GBM in classifying EEG signals. With the results that have been obtained, this study can be a reference for the medical world to detect epilepsy automatically so that people with epilepsy can be diagnosed accurately and quickly.

The drawback of the proposed method is that the determination of patterns on Enhanced GBM Fusion to improve performance must be done by hard coding. The performance of the proposed method may not be comparable to that of other datasets.

Acknowledgment

This study is a follow up research from Sunaryono et al. [4] with the title of “Gradient boosting machines fusion for automatic epilepsy detection from EEG signals based on wavelet features”.

This research was funded by the Ministry of Research, Technology and Higher Education of the Republic of Indonesia under Penelitian Disertasi Doktor (PDD) Program, and under scholarship scheme No. T/927/IT2/HK.00.01/2021 managed by Institut Teknologi Sepuluh Nopember (ITS) Surabaya.

***Abstract*—In education sector, personalization is an evolutionary term that gained a high attention due to its effectiveness in raising the enterprise competence level. This research aims at proposing a novel model for effective smart testing, which considers the student's Facebook activities in determining the students' personality and constructing his suitable exam. The aim of this examination perspectives to ensure the reliable student evaluation according to his gained knowledge to ensure that no other factor interferes which may negatively affect the reliable evaluation. The research also applies text analytics techniques to ensure the exam balance. The proposed model has been applied and evaluated with professors' percentage equal to 96.5 % and successfully reach students satisfaction percentage with average equal to 96.63%.**

Keywords—Personalization; data mining; sentiment analysis; social networks; e-learning

I. Introduction

Online education is no longer considered as an additional tool, but a vital solution that strongly supported the whole educational operation against crashing. Although this situation was not planned, however, results revealed that online education is the main factor for increasing information retention, reducing learning time, and raising the stakeholders' satisfaction level which confirmed that this adaption in the learning strategies is here to stay. The transformation of the education system towards online education has been already introduced with limits, however, this situation has moved to a significant surge forward. This shift away from classrooms does not only include the teaching classes, but it also requires other learning activities adaptation such as projects' work, practical sessions, as well as the immense need to adapt the student's assessment perspective [1]. Consequently, bolstering the online learning systems' capabilities can be currently considered a strategic objective for the educational field.

Moreover, online education has raised the alarm to focus on personalized learning as the pieces of evidence have confirmed its effectiveness of tuning the evaluation process to rely on students' personalization rather than memorization [2]. As highlighted in [3], personalized learning supports students to perceive learning with enthusiasm as it becomes more relevant and compatible with the student's characteristics [4]. Accordingly, focusing on exams personalization has become one of the goals that gained a high priority and importance as it could lead to a strong positive impact. Such an opportunistic assessment perspective in conducting the students' exams in an adequate environment based on their own pace ensures equal opportunity for all students [5]. This increasing goal for performance evaluation based on individual characteristics has been globally monitored. This recent evaluation vision has gone far beyond the traditional approach with changing the whole evaluation scheme. This research targets to intelligently transform the evaluation process from stressing, unaccommodating, and monotonic process to an effective, knowledgeable, and reliable perspective, which could be tagged as "smart testing".

Data as well as information analytics techniques play a vital role in smart testing that could successfully incorporate the personalization process into smart testing by the intervention of the behavioral students' data for tracing the suitable exam and facilitating the questions' characteristics selection [6]. On the other hand, data resources such as social networks, forums, and corporates' databases are the foundations for the personalization process for monitoring the personal behavior and characterize the student personality which consequently supports the smart testing process [7]. These resources are the pillar for revealing the student's primitive actions, his interaction preferences, as well as his trends. This revealed information feeds the testing process with the required measuring criteria for generating a suitable exam for the student [8].

This research proposes a smart model for generating a suitable exam for the student based on his personality. The student's personality has been determined based on his social network activities and educational data. The proposed model depends on the corporate database and the Facebook data as the main data resources for the personalized smart testing process.

II. Related Work

Enhancing the online education towards a more reliable process has been proposed in several researches [9] [10]. One of these researches have been presented by [11] who developed interactive learning resources with proposing to considers the learner activities during the learning process, however, the proposed enhancement focused on the closed activities cycle which was later considered by [12] could mislead the explored actions by not considering the traditional student behavior. Additionally, the research by [13] focused on tracking the student skills targeting the learning path recommendation based on a set of conducted exams. however, this approach lacked considering many exam criteria during the evaluation process such as the difficulty level.

Engaging intelligent systems in the e-learning process has been introduced from many perspectives. Different researches proposed intelligent methods for learning objectives recommendations with respect to the student progress [14]. Another research by [15] adopted the recommendation perspective to recommend the suitable department for the Fayoum university students. Other researchers have applied a variety of intelligent techniques such as the Bayes model [16], evolutionary algorithms [17], and association network [18]. In [19], Item Response Theory has been applied targeting to update the education path for the student according to his ability. Additionally, a recent research by [20] proposed a recommender system for lessons' study plan to maintain the student learning time. The proposed researches focused on the learner path; however, it is vital for an intelligent assessment method which opens the adaptation perspective using reliable criteria.

Focusing on the contribution of text analytics in the e-learning process. Text analytics has contributed to many researches in different tasks. A research in [21] proposed investigating the capability of the student in managing the exam time during the exam using text analytics, however, no consideration of other exam characteristics such as the exam level or specialty. Another research in [22] introduced text analytics in assignments' assessment for detecting plagiarism level.

Although as mentioned by [23], focusing on the student's social networking activities for discovering his behavior patterns is still considered an unexplored field, however, some researchers proposed some directions. While different empirical researches have investigated the impact of social networking and the education sector stakeholders' performance [24] [25], others have focused on the reasons that raise the power of social networking on the students in the learning process [26] [27]. It is a fact that social network influence on the educational process can take either direction, positive or negative [28], however, the success lies in lighting the shed towards the correct path [29]. Although some of the studies have tried to highlight the negative impact of the time spent in using social networking and the student's performance [30] [31], however, most of these studies revealed that there is no significant relationship between the two activities [32] [33]. Moreover, social networking extended its intervention on the learning process by offering academic resources and encourage the direct interaction among the education sector stakeholders [34]. On the other hand, researchers have highlighted that social networking users who are underage, therefore most probably students, have limited their social networking relations to their friends, not their family. Focusing on the interaction methods, some researchers argued that girls are most probably using images and share more videos on their posts more than boys [35]. More recently, the researches in [36] [37] [38] have proposed the approach of considering the Facebook activities to support the learning process by active discussion, sharing material, and continuous communication. Other researches such as in [39] [40] focused on the relation between students' engagement in Facebook activities and their willingness for class engagement. The presented researches and others have shyly considered social networking in the learning process with a limited role for continuous communication, while in the current research, social networking has a vital role and proved its effectiveness in enhancing the learning process reliability.

III. The Proposed Model for Smart Testing

The proposed smart testing model includes three main stages, "social-based exploration for the student preference", "semantic-based question bank construction", and "setting the student preference-based exam". The following sections will discuss each stage in detail.

A. *Stage One: Social-based Exploration for the Student Preference*

This stage aims at identifying the suitable type of questions for each student. Three types are available, they are illustration, long text, and short text questions. In this stage, the students' main data is collected from the faculty database including name, id, gender, email, education history (place, courses, and degrees), and Facebook account. The student's current educational status is already monitored including the registered courses, the number of credit hours gained, and remaining credit hours.

Social networks are considered the main data source in this stage. Using the Facebook account, the student's public posts are extracted and categorized to be either text or other media. This research only focuses on these two categories as the aim of this classification is to identify the suitable questions' type for the student. Moreover, the text category is also classified as short or long text. The short text category leads to the closed test questions including MCQ and T/F, while the long text leads to the open text questions including the discussion and state questions. It is vital to mention that the research depends on the student's social public data in order to avoid violating the student data privacy as social network users.

The student social activities data source is represented as follows:

The set of student's posts is represented by a set of vectors, each vector includes the post identified and its content.

$\text{ST\_Posts (STID)} = \{<\text{Post\_ID, PContent}>_j \mid j \in N\}$

All the students' posts are represented in the parent set as follows:

$\text{ALL\_ST\_Posts} = \bigcup \text{ST\_Posts (STID)} = \{<\text{STID, ST\_Posts (STID)}>\}$

Each post belongs to one of the five types, they are: short text, long text, illustration, long text &illustration, and short text & illustration. Detecting the post type is performed and the tagging is applied which can be represented as follows:

$\text{ST\_TagPosts (STID)} = \{<\text{Post\_ID, PContent, PType}>_j \mid j \in N\}$

The posts' types are then weighted to determine the student preferences, the performed steps are as follows:

The percentage of the posts with type "short text" referring to all number of posts

$$\text{PText}\ (STID)\ = \frac{\sum_{n=1}^{k} \text{PText(STID)}}{|\text{ST\_TagPosts (STID)}|} * 100$$

PText(STID) ⊆ ST_TagPosts (STID) where PType = Short Text

The percentage of the posts with type "long text" referring to all number of posts

$$\text{PText}\ (STID)\ = \frac{\sum_{n=1}^{k} \text{PText(STID)}}{|\text{ST\_TagPosts (STID)}|} * 100$$

PText(STID) ⊆ ST_TagPosts (STID) where PType = Long Text

The percentage of the posts with type "fig" referring to all number of posts

$$\text{PFig (STID)}\ = \frac{\sum_{n=1}^{k} \text{PFig(STID)}}{|\text{ST\_TagPosts (STID)}|} * 100$$

PFig(STID) ⊆ ST_TagPosts (STID) where PType = Illustration

Then the student preferences are then arranged in descending order according to the revealed percentage. The student preference set has three ordered members, each member is a vector that includes the preference order, preference type, and percentage.

Skill (STID) = {<order, preference, Percentage> | order ∈ {1,2,3}, preference ∈ {short text, long text, illustration}}. In the case of equal percentages, then the student will be considered according to the equal percentages by stating the included types in the hybrid set. Although the proposed model considers the highest student's preference, however, ordering the student's skill is vital in case that the first preference does not match with the suitable type with the course questions' type. In this case, the following student preference is considered.

B. Stage Two: Semantic-based Question Bank Construction

This stage focuses on building the test bank for the subject under examination. The main source of this stage is the course curriculum. The following steps describe the construction process in detail. In this stage, a semantic-based mesh tree is built relating the questions' tags with the subject key terms according to the subject nature. Each key subject can be related to one or more question tags. Both keys; key terms and key question tags; are tagged with one of the three types; text, illustration, and hybrid; which highlight the possible type of questions for these keys. The generated tree is used for the examination of the test bank questions' suitability which is an additional step to ensure test bank stability. Additionally, the test bank questions are tagged with the suitable keywords targeting to build an ILOs based balanced exam.

1) Step 1: Key questions tags determination: The outcome of this step is determining the question tags that are included in the exams. the questions' tags set is built based on Bloom's Taxonomy Verb Chart [41]. Bloom Taxonomy has 271 verbs which are listed as Key question terms. These terms are tagged with the suitable category and skill which highlight that this term examines a certain skill and suitable for a certain category. Bloom's Taxonomy can be represented as a set of vectors, each vector includes the verb and the corresponding skill.

Bloom's Taxonomy = {<V_j, S_j >}

Where j ∊ N

V_j is one of the Bloom verbs

S_j is the corresponding key skill, S_j ∊ Skill, Skill = {knowledge and understanding, intellectual, practical}

The key questions' tags set is represented as follows:

KQues = {<T_i, S_i, C_i>}

Where i ∊ N

T_i is a verb in the Bloom set which represents the question key

S_i is the corresponding key skill, S_i ∊ Skill

C_i is the corresponding category, C_i ∊ Category, Category = {short text, long text, figure}

2) Step 2: Key terms extraction: The main source to extract the questions' key terms is the course curriculum. The course curriculum which includes the Intended learning objects (ILOs) which describe the required topics for the course. For example, "Identify the principles of economics and management" is one of the ILOs of the database systems course. Analyzing this sentence to identify the main keywords leads to extracting a set of four keywords "identify, principles, economics, management". ILOs are analyzed to extract the main keywords of the course subject. Additionally, the course recommended textbook is also considered to expand the keywords' set. The recommended textbook is considered to match the extracted keywords with the book subjects' headings with also considering the subheadings as part of the main heading. The relation between the course ILOs and the textbook headings is the pillar of building a semantic network that fully considers the related course keywords.

Formally describing the tagged sentences is as follows:

$$\text{ILOTag}\ (S_i) = \{< K_1, Tag_1 >, < K_2, Tag_2 >, \ldots < K_n, Tag_n >\}$$

Where K_n is the token and tag_n is its attached tag

Extracting the subject key terms with the construction of the semantic network is presented by the following algorithmic steps.

// ILOs key terms semantic relations

```
For each ILO in the course description
        Extract main terms
        Apply terms' tagging
        Identify verbs as the key question tags
Identify nouns as the key terms
Build key terms semantic relations (In-relation) where In-relation identify the terms in the same ILO
// Textbook key terms semantic relations
Extract headings' tree
For each heading level
   For each heading
        Extract main terms
        Apply terms' tagging
        Identify verbs as the key question tags
Identify nouns as the key terms
Build Level 1_Heading semantic relations (In-relation) where In-relation identify the terms in the same heading
Build Level 2_Heading semantic relations (parent-relation) where parent-relation identify the relation between headings' terms
// integrate Textbook-ILO network
For each key term in the ILO, identify synonym and antonym
Extract matched heading key term with ILO key term, synonym, and antonym
Integrate the two networks' branches
// Build Key terms/Key question tags semantic relation
For each key term in the key terms set
Identify synonym and antonym
Apply KeyTerm relation set
For each key question tag in the question tags set
Identify synonym and antonym
Apply QuesTag relation set
For each ILO
Identify ILO key term as $K_i$
Extract KeyTerm $K_i$ relation set
Identify ILO verb as $QT_i$
Identify question tag $QT_i$ relation set
Append Key terms/Key question tags semantic relation ( $K_i$ – $QT_i$ )
```

3) Step 3: Building semantic based test bank: The test bank is a group of question sets. each set includes the questions that examine one of the course ILOs. In this step, building the test bank question sets is achieved. Each question in the test bank is tagged with an attribute vector. The vector includes time, mark, difficulty level, associated key terms set, associated key question tags set. The time, mark, difficulty level attributes are identified by the professor, while the associated key terms and questions tags are explored by applying the following algorithmic steps.

```
For each question in the question bank
        Identify question key tags
        Identify question key terms
        Match question key terms with network members
        If success
Tag the question with network members id
                Identify the question ILO id
                add question to ILO questions' set
        Else
                Raise an alarm
```

At the end of this step, each ILO id questions' set should have a group of members which are the questions that examine the ILO. If the ILO set is empty, then acquiring questions from the professor is applied.

C. Stage Three: Setting the Student Preference-based Exam

At this stage, the student exam is built according to his revealed skill. The questions are selected randomly from the corresponding categories based on the required number of questions and the determined exam time. The following algorithm steps are performed to build the required exam.

```
Given   Student_Pref (STID)
        Test_Bank = {<Pref, Skill, Difficulty, {< QID, QText, QDuration, QMark >}}
Set Exam_time
Set Exam_Grade
If Student_Pref (STID) ∊ {ShortText, LongText, illustration}
Questions_Set = select questions from Test_Bank where Category = Student_Pref (STID)
Else
Questions_Set = select questions from Test_Bank
Initiate Exam_test bank
Set courseSkillsSet
SkillTime = ExamTime / |courseSkillsSet|
SkillGrade = ExamGrade / |courseSkillsSet|
Set CourseDiffSet
While ALLQues_time < Exam_Time  && ALLQues_Grade < Exam_Grade {
For each skill j in course_skills
    Set ILO set
    ILOTime = Skilltime / | ILO set |
    ILOGrade = SkillGrade / |ILO set|
    DiffTime = ILOTime / | CourseDiffSet|
    DiffGrade = ILOGrade / | CourseDiffSet|
    For Each ilo in ILO set
      For each Difficulty i in course_Difficulty
While DiffQues_time < DiffTime &&  DiffQues_grade < DiffGrade {
Question = Random Choice (Questions_test bank) where Skill = j and Difficulty = I and   ILO = ilo
 If DiffQues_Time + Question.Question_Duration <= Diff_Time
&& DiffQues_Grade+ Question.Question_Grade <= DiffGrade
 {
   DiffQues_Time = DiffQues_Time + Question.Question_Duration
   DiffQues_Grade = DiffQues_Grade + Question.Question_Grade
   Append (Exam_Content, Question_Text)
   AllQuesTime = AllQuesTime + DiffQues_Time
   AllQuesGrade = AllQuesGrade + DiffQues_Grade }}}
```

IV. Experimental Case Study

The research has two validation milestones. First, validating the model success in exploring the suitable student's skill based on his social activities are performed while validating the constructed exam is also considered as the second milestone. The following sections discuss the case study setup, the performed steps, and the validation results.

A. Stage One: Exploration for the Student Preference

In this research, the dataset included the skills classification for 473 students. The dataset is based on the data which was provided in the research of [1]. The research of [1] included research that adapts the online system to satisfy the student. The original dataset included 752 students while the response was 631 students, and a satisfaction level with an average of 75 % of them have been satisfied with the proposed enhanced system with a total of 473 students in the online exam based on a series of conducted exams. The current research acquired the students' data who had been satisfied with a total of 473 students. The acquired data included all the personal and academic students' data. Extracting the required social data is performed through implementing a simple program and the data is stored as four attributes, student id, corresponding social user id, post content, post type. As a result of this process, the final experiment dataset included 380 students after removing the incomplete students' records.

A five-month range of public Facebook posts; starting from January 2018 to May 2018; have been gathered from the students' accounts. This short time range has been considered to avoid the large number of posts that may require extensive tools and software for big data which was not the scope of this paper. The posts' contents have been processed to detect the post type. The post type classification is illustrated in Table I.

The results have been compared with the results in [1]. This comparison has revealed 93% success for correct exploration to the student's most suitable skill. By analyzing the presented results, a focus has been performed on the incorrect classified students and the time period for their posts has been enlarged. A sample of these students' posts with a range of eight months starting from November 2017 to May 2018 has been extracted and the model has been applied for the student re-exploration. 40 % of these students have been re-classified to the correct skill. Therefore, this minor experiment revealed that the 7% failure in the correct classification was according to the short time range for the extracted social data due to the minor activity of the student in the three months on focus.

B. Stage Two: Semantic-based Question Bank Construction

This stage focuses on constructing the courses' questions' bank in a semantic-based format. This research argues that this proposed construction supports the applicability to generate a suitable balanced preference-based exam. The following subsections discuss the conducted steps in detail with demonstrating the required validation.

1) Step 1: Key questions tags determination: As previously discussed, the Bloom verbs are considered the question tags. 271 verbs are included in the key questions' tags set. For example, the key question term "Define" is suitable for the understanding skill and the text category. A sample of the taxonomy is illustrated in Table IV.

2) Step 2: Key terms extraction: The experiment focused on "systems analysis and design" course which are obligatory to the students in the information systems department. Table V illustrates the ILOs statistics for the courses on focus with examples for each course.

TABLE I. Post Types

Post Content	**Type**
Single Video or image	Illustration
Single text sentence where words' count is less than 10 words	Short text
Single text sentence where words' count is more than 10 words	Long text

According to this classification, the students' posts have been tagged with the appropriate class, a statistical illustration of the students' posts is presented in Table II, while another perspective of this classification was illustrated in Table III presenting the statistics of classified students based on their social activity.

TABLE II. Statistics of Posts

Type	**Statistics**
multimedia	445,584
Short text	420,254
Long text	239,901
Illustration & Short text	558,069
Illustration & Long text	168,704
Total	1,832,512

TABLE III. Statistics of Students

Type	**Number of Students (%)**
multimedia	70 (12.96 %)
Short text	62 (11.48 %)
Long text	40 (7.4 %)
Illustration & Short text	238 (44.07 %)
Illustration & Long text	130 (24.07%)
Total	540

TABLE IV. SAMPLE OF WORDNET VERBS CATEGORIES

Key Question Term	**Skill**	**Category**
write	Knowledge and Understanding	Long Text & Short Text
state	Knowledge and Understanding	Long Text & Short Text
outline	Knowledge and Understanding	Long Text & Short Text
classify	Knowledge and Understanding & intellectual	Long Text & Short Text
define	Knowledge and Understanding	Long Text
discuss	Knowledge and Understanding	Long Text

TABLE V. SAMPLE OF COURSES' ILOS

Course	**Skill**	**ID**	**ILOs**
Systems Analysis and Design	Knowledge and Understanding	1	Discuss specifications and strategic planning for a given project.
		2	Recognize different methods for data analysis and design.
		3	Illustrate management process for software projects and productions.
	Intellectual Skills	4	Analyze information systems problems, setting goals and requirements.
		5	Identify main ideas, patterns, components, attributes and detect relationships between these components in software analysis with different designs.
		6	Select appropriate methodologies and techniques for a given problem solution and setting out their limitations and errors
	Practical	7	Describe different analysis and design methodologies.
		8	Analyze system process and data requirements
		9	Apply different IS methodologies for analysis and design.

Text processing tasks have been applied to the courses' ILOs [42]. According to [43] the most suitable processing tasks for correctly extracting keywords that ensure avoiding conflict or missing the word's meaning are lemmatization and part of speech tagging.

Consequently, lemmatization and Part of Speech tagging (POS) are applied for the ILOs, nouns are extracted as keywords and indexed. As a result, each ILO is tagged with two references, the skill Id, and the set of corresponding keywords' Ids. For Example, ILO text "Discuss specifications and strategic planning for a given project" has the following two steps:

Lemmatization: "Discuss specification and strategic planning for a give project"

POS tagging: $\text{ILOTag}\ (ILO_i) = \{<\text{Discuss}, \text{V}><\text{specification}, \text{NNS}><\text{and}, \text{CC}>,<\text{strategic}, \text{JJ}><\text{planning}, \text{NN}><\text{for}, \text{IN}>,<\text{a}, \text{DT}><\text{give}, \text{VBN}><\text{project}, \text{NN}>\}$

The ILO is then tagged with the set of keywords' Ids which are: "specification", "planning", "project" in addition to the skill id. Moreover, synonyms and antonyms of the specified terms are identified and included in the set members. Statistically speaking, the experiment included a total of 9 ILOs, a total of the extracted keywords equal to 26. Each ILO was tagged with a range of 2 to 7 keywords. At the end of this stage, the relation between the ILOs and the corresponding keywords is revealed for each course.

3) Step 3: Building semantic based test bank: In this stage, the relation between the test bank questions and the ILOs are explored based on the extracted keywords. It is recommended that the test bank for each course included 300 questions. Each question is tagged with one of the three types (short text, long text, multimedia) according to its key question tag. Tagging each question with its corresponding keywords is then applied.

According to [44], bi-gram keywords provide the highest accurate accuracy. Therefore, uni-gram keywords and bi-gram keywords are constructed, then, the matching process is applied. Each question is tagged with two keywords subsets, the first subset includes the matched uni-gram keywords while the second includes the matched bi-gram keywords. the following example is a sample of the performed process while Table VI presents a statistical presentation with the step results.

Question: A system request will generally have these items: project sponsor; business need; business requirements; business value; special issues or constraints

Keyword (s): system, request, project, sponsor, business, need, requirement, value, issue, constraint

Matched bi-gram Keyword (s): (system, problem), (system, requirement), (requirement, problem), (problem, limitation), (problem, error), (limitation, error).

Matched ILOs ID: 4, 6, 8

Validating the tagging process has been performed by the course professors. The validation process has confirmed the higher accuracy in tagging the questions with bi-gram keywords, therefore, following the bi-gram keywords' tagging was the main path to the next phase for constructing the student's exam.

Table VII demonstrates the evaluation criteria and the evaluation percentage according to the professors' perspective. It is shown that the proposed model has succeeded in classifying the test bank questions with an average success percentage equal to 96.6 %.

C. Stage Three: Setting the Student Preference-based Exam

As mentioned in [45], the stakeholders' satisfaction is one of the main objectives for organizations in any field. Therefore, this research targets not only moving in the right track for the smart testing paradigm but the students' satisfaction, as well as the professors' satisfaction, are also essential objectives for this research. Therefore, generating the preference-based exams for the students has been applied and validated by both the professors and the students as follows:

A focus on the successfully classified students is performed, fifty successfully classified students have been randomly selected for testing the stage of generating a suitable exam. The selection process ensured the variety of the students' preferences. As previously illustrated, five categories are considered, therefore, twenty of the students/preference/course have been targeted. Generating the exams followed the proposed algorithmic steps and the constructed tests have been reviewed by the course professors. Table VIII demonstrates the statistical measures of the conducted exams. It is shown that the proposed model has succeeded in generating a suitable exam for the students with an average success percentage equal to 96.5 %. The 3.5 % failure goes to the lack of questions that could be required to complete the exam time or the exam grade, therefore, the experiment has been revised after feeding the test bank with an additional 50 questions for each course that has a variety in the marks distribution and required time. This adaptation has filled the required gab and the exams were successfully generated based on the professors' evaluation.

On the other hand, the students' satisfaction has been measured and the results are demonstrated in this section. Conducting two generated exams have been developed, first a randomly generated exam without considering their preferences and a randomly generated exam after applying the proposed model. The results are presented in Table IX while illustrated in Fig. 1- 3.

TABLE VIII. EXAM VALIDATION

Total No. of generated exams	50
No. of exams that are correctly generated	48
Average No of questions / Student	25
Minimum No of questions / Student	19
Maximum No of questions / Student	40

TABLE IX. COMPARISON FOR THE AVERAGE STUDENTS' RESULTS

	Excellent		**Very Good**		**Good**		**Fair**		**Fail**	
	No	%	No	%	No	%	No	%	No	%
Random Exam	6	12	8	16	16	32	9	18	11	22
Model-Based Exam	16	32	10	20	14	28	5	10	5	10

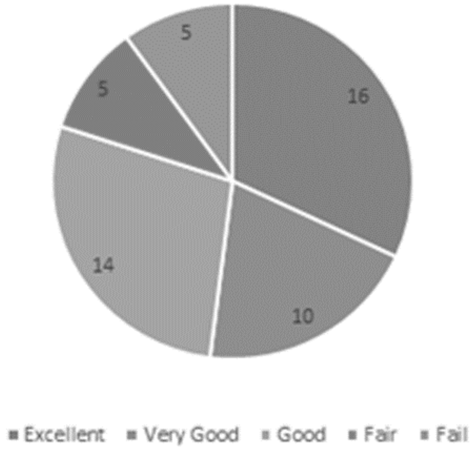

Fig. 2. Model-based Exam Distribution.

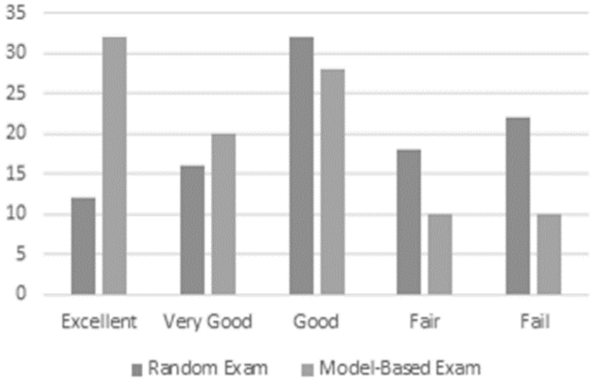

Fig. 3. Comparison between the Two Exams' Results (Random Exam and Model-based Exam).

V. Conclusion

This study proposed a student personalized exam model which is based on two main approaches. The first approach focuses on exploring the student's personalization characteristics targeting to detect his questions' preferences. This target has been on focus to ensure the questions' types suitability for the student which leads to a higher evaluation accuracy to the student learning level. The second approach utilizes text analytics techniques in different goals. It contributes to revealing the student preferences in addition to its contribution in constructing the exam contents. The proposed model considers the balance while generating the student exam according to different criteria including the difficulty level, the intended learning outcomes coverage, the required time, and the degrees' distribution in addition to the student's preferences. According to the experiment evaluation results, the proposed model succeeds in reaching 96.5% of the professor satisfaction in the constructed exams.

The proposed model confirmed its effectiveness in approaching smart testing, however, enhancement directions can further contribute effectively to the same direction. One of the proposed enhancements is considering the students' emotions which provide more accuracy to his on-time preferences. Another direction is the automated generation to the questions' banks to ensure the full course coverage. Finally, the current research relied on the highest student preference, considering the preferences according to its adequacy level could be an effective enhancement to ensure the full smart testing perspective coverage.

AUTHORS’ PROFILE

Ayman E. Khedr, Professor. I am currently a professor in the university of Jeddah, College of Computing and Information Technology at Khulais. I have been the vice dean of post-graduation and research and the head of Information Systems Department in the Faculty of Computers and Information Technology, Future University in Egypt. I am a professor in the Faculty of Computers and Information, Helwan University in Egypt. I have previously worked as the general manager of Helwan E-Learning Center. My research is focused around the themes (scientific) data and model management, Data Science, Big Data, IoT, E-learning, Data Mining, Bioinformatics and Cloud Computing.

Abdulwahab Ali Almazroi, Associate Professor, received his M.Sc. and Ph.D. in Computer Science from the University of Science, Malaysia, and Flinders University, Australia, respectively. He is currently serving as an Associate Professor in the Department of Information Technology, College of Computing and Information Technology at Khulais, University of Jeddah, Saudi Arabia. His research interests include parallel computing, cloud computing, wireless communication, and data mining.

Amira M. Idrees, Professor. I'm a professor in Data Science, the head of information systems department, faculty of computers and information technology, Future University in Egypt. I have been the head of scientific departments and the vice dean of the community services and environmental development, Faculty of Computers and Information, Fayoum University. I'm currently an associate professor in the Faculty of Computers and Information Technology in Future University and the head of University Requirements Unit. My research interests include Knowledge Discovery, Text Mining, Opinion Mining, Cloud Computing, E-Learning, Software Engineering, Data Science, and Data warehousing.

Churn Prediction Analysis by Combining Machine Learning Algorithms and Best Features Exploration

Yasyn ELYUSUFI, M'hamed AIT KBIR
LIST Laboratory
STI Doctoral Studies Center
Abdelmalek Essaadi University, Morocco

***Abstract*—The market competition and the high cost of acquiring new customers have led financial organizations to focus more and more on effective customer retention strategies. Although the banking and financial sectors have low churn rates compared to other sectors, the impact on profitability related to losing a customer is comparatively high. Thereby, customer turnover management and analysis play an essential part for financial organizations in order to improve their long-term profitability. Recently, it appears that using machine learning to predict churning improves customer retention strategies. In this work, we discuss some specific machine learning models proposed in the literature that deal with this problem and compare them with some emerging models, based on Ensemble learning algorithms. As a result, we build a predictive churn approaches that look at the customer history data, check to see who is active after a certain time and then create models that identify stages where a customer can leave the concerned company service. Ensemble learning algorithms are also used to find relevant features in order to reduce their number which is of great importance when performing the training step with some classical models such us Multi-Layer Perception Neural networks. The proposed approaches can achieve up to 89% in accuracy when other research works, dealing with the same dataset, can achieve less than 86%.**

Keywords—Customer churn; prediction; machine learning

I. Introduction

Customer churn analysis deals with customer attrition rate in companies that offer some services. According to Forrester research statistics related to churn impact [1], it costs five times more to catch new customers compared to keeping the existing ones. As well, the Harvard Business School report states that on average, 5% increase in customer retention results in increase from 25% to 95% in profits. There are so many classic ways to keep customers from leaving [2]; by finding answers to the following issues:

- What are we, as a company, doing to cause customer turnover?
- What are our customers doing that is contributing to their leaving?
- How can we better manage our customer relationships to make sure it does not happen?

On the other hand, predictive analytics uses prediction models that approximate the risk of customer attrition and the degree of their dissatisfaction with regard to services offered by the organization. In addition, new technologies have increased bank access to customer data, which has made customer attrition analysis increasingly easy and accessible. In fact, predicting customer attrition can help banks to plan suitable marketing campaigns to convince clients who are potentially candidates for leaving [3].

Overall, actually demand for customer attrition analysis is increasing, the study of the characteristics related to the customers profile and behavior, by consulting their transactions history, remains the most widely used approach in research works related to this domain, most of these are statistical learning methods. This takes up the following question, which learning model can best predict customer churn? By taking a look at methods used in the literature, we can find that popular methods to predict churn likelihood are logistic regression (LR) [4], K-Nearest Neighbor (KNN) [5], decision trees (DT) [4] and SVM [6].

In this work, we seek to use and evaluate performances of new methods that can reach best results, compared to those cited above, at predicting customer churn which can give suitable responses to the following questions:

- How successful are the cited Machine learning methods in predicting customer churn?, answering this question will allow us to know which methods give the most reliable predictions based on many metrics;
- How are the relevant features according to some machine learning algorithms ?, answering this question allows us to pick up the most relevant features so as to use the training samples with reduced size vectors, which allows time saving in both training and generalization steps. Relevant features can be combined later with high accuracy machine learning algorithms to enhance performances.

However, methods cited above have reached their limits and have practical difficulties resulting in the emergence of a new generation of algorithms called Ensemble learning algorithms: Random Forest (RF), eXtreme Gradient Boosting (XGBoot) and Light Gradient Boosted Machine (LightGBM) models [7]. Light GBM model has many of XGBoost's assets, such as sparse optimization, parallel processing, regularization and bagging [8]. These algorithms belong to two families of ensemble decision tree models, Bagging and Boosting. We are also interested in this study by artificial neural networks

(ANN) based models, especially Multi-Layers neural network [22].

In this study, we are also interested by improving performances of machine learning models, related to predicting customer churn, by exploring ensemble learning algorithms capabilities to find relevant features. Indeed, the use of relevant features with some classical machine learning models is important when carrying out the training step.

This paper is a part of a series of research carried out by a team of our laboratory, interested in users profiling and related predictive analyzes [9] [10] [11]. The work is presented as follows; in the first section we present literature review of churn prediction works using machine learning models. In the second section we present data pre-processing, modeling, and comparison with some cited works. In the third section, we present our approach of best feature exploration in order to improve the quality of prediction using Multi-Layer Perceptron model. The results interpretation and conclusion comes in the last section.

II. Related Work

Today the industry is in competition with a limited number of potential customers because of the increasing saturation of the market [12]. Customers seek value-added relationships with their suppliers in order to stay loyal [13]. Companies are therefore looking for strategies to engage customers in their process in order to have a tangible idea of the required benefit. In order to improve this process, these companies are seeking to recognize customer behaviors that indicate a decline in his relationship with the company; this is established as customer relationship management (CRM). It's used by companies to efficiently assign their resources in order to maintain and improve customer relations [14], it's also used to lock onto customers churn rate. Churning specify the decrease in the consumption of a service provided by the company or the termination of that service, it can also be defined as an un-subscription. Several models have been proposed for customer behavior prediction in order to choose the auspicious time when the human resources department must give them more attention, after which incentive strategies should be followed in order to preserve this relationship and make it as profitable as possible. Many methods have been presented in the literature to determine the churn rate, they differ depending on the contractual and non-contractual nature of the work, the corresponding data structure availability and the amount of accessible transaction history. The following paragraph will be devoted to the presentation of research works related to our problematic and the promising machine learning models they use.

The results of some churn prediction models can vary on a wide spectrum; in this specific context a study of measuring the predictive accuracy of customer churn models was presented in [15]. In the same way, Breiman made the foundation for churn analysis based on classification and regression trees [16]. Upon this work, the cited author has also built additional methods by using bootstrap aggregators or bagging methods [8]. The bagging used proceeds by bootstrapping replicates of the training set, followed by creating the aggregation of predictors. In this use case Random forests introduced in [17] builds upon the previous model by introducing a new layer obtained by randomizing the bagging. In fact, a random subset of descriptors is used to expand trees, each one use a sample of the training set. It must be mentioned that RF method is known by its sensibility to data with unbalanced number of samples, which is typical to customer churn data sets, as the percentage of customers who churn is small or relatively unknown. In the same context, Xie proposes a new learning approach, called improved balanced random forests to produce better prediction results. In the present work we will assess the impact of using data re-sampling and scaling (robust-scaling method) before applying machine learning models. The following sections will be devoted to the preprocessing, modeling, evaluation, and comparison of machine learning model performances. These methods are used to help financial organizations to make decisions about the suitable strategy to prevent the customer from leaving the financial organization.

III. Our Work

A. Goal of the Work

The goal of this work is to explore whether bank's customers are about to leave the organization or not. In order to make an efficient model to predict customer churn we will use machine learning models. The event that defines the customer abandonment is the closing of the customer's bank account Fig.1

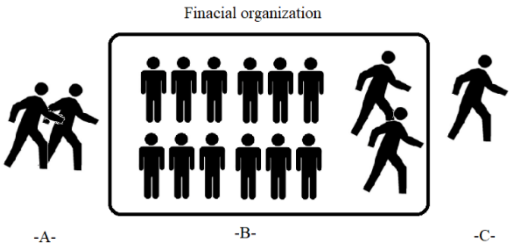

Fig. 1. Customer Churn Issue.

A-segment customers can need marketing campaigns to let them join the financial organization, when the B-segment customers can need to use machine learning models in order to predict who is about to leave and finally we can analyze C-segment customers so that more importance can be given to the suspicious profile thereby gaining more knowledge about how to make them more loyal.

B. Dataset

The dataset under study is called "Bank Customer" [18], the data was collected from an anonymous organization with customers in France, Spain and Germany. This public dataset consists of 10000 observations and 12 features, containing customer's information, where the “Exited” feature refers to customer abandonment status (target class). In order to find the churning client and to help making decision about the precaution that the financial organization should undertake we decided to study several machine-learning models, evaluate their performances and combine their decisions. The following table shows the used features, see Table I.

TABLE I. USED FEATURES

Feature	Signification
Surname	The surname of the customer
CreditScore	The credit score of the customer
Geography	The country of the customer(Germany/France/Spain)
Age	The age of the customer
Tenure	The customer's number of years in the bank
Balance	The customer's account balance
NumOfProducts	The number of bank products that the customer uses
HasCrCard	Does the customer has a card? (0=No,1=Yes)
IsActiveMember	Does the customer has an active mebership (0=No,1=Yes)
EstimatedSalary	The estimated salary of the customer
Exited	Churned or not? (0=No,1=Yes)

IV. DATA PRE-PROCESSING

Before the pre-processing, re-sampling and data scaling, we can analyze data relevance according to each feature and each machine learning algorithm. In fact, we decided to reveal the relevant feature by analyzing the columns one by one, looking for their dependency towards the churn. The following features are removed, because they do not have impact in the final decision:

- Row Number: It corresponds to the record row number
- Customer Id: It contains random values
- Surname: It represents the surname of a customer

Concerning the other features, we discuss their impact on customer churn by briefly analyzing the data.

- Credit Score: People with a credit score between 680 and 689, about 342 customers, are more loyal than others and less likely to leave the organization.
- Age: As shown in Fig. 2; it's certainly clear that the age feature is relevant, since customers with age between 35 and 55 are more likely to leave their organization than customers with other ages.

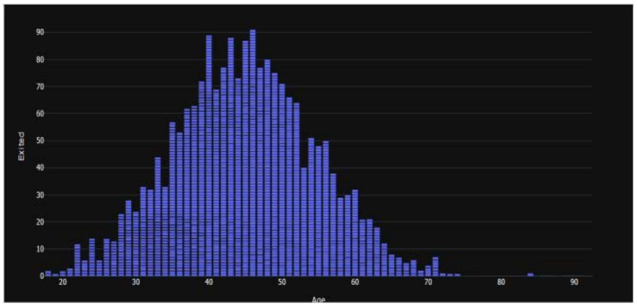

Fig. 2. Age Distribution.

- Tenure: It mentions the number of years spent by the customer with the organization. Normally, people with Tenure=7 are more loyal, about 851 customers.
- Balance: It's an important indicator, as people with a balance between 122k and 127k are more loyal to the organization.
- Number of Products: it indicates the number of products that a customer has purchased through the organization, people with Number of Products >=2 are more loyal to the organization, about 4242 customer.
- Has Credit Card: It indicates the fact that a customer has a credit card or not. People possessing a credit card are less predisposed to leave the organization, 30.09% of customers that churned have not a card, about 613 customer.
- Is Active Member: It indicates the presence of transactions over the customer account, active customers are more predisposed to stay with bank and 63.9% of customers that churned are not active.
- Estimated Salary: It indicates the estimated salary of the customer. The costumers with salary between 175k and 185k are more likely to leave the organization, about 122 costumers, while the more loyal costumer with salary between 77.5k and 82.5k, about 222 costumers.
- Gender: As shown in Fig. 3, we can infer that gender feature plays an essential role in churn prediction.
- Geography: It indicates customer's location. Being close to the bank can affect customer decision, especially with home changing.

In order to prepare data, we will apply the one hot encoding process for Geography feature to allow a more expressive categorical data, as shown in Table II.

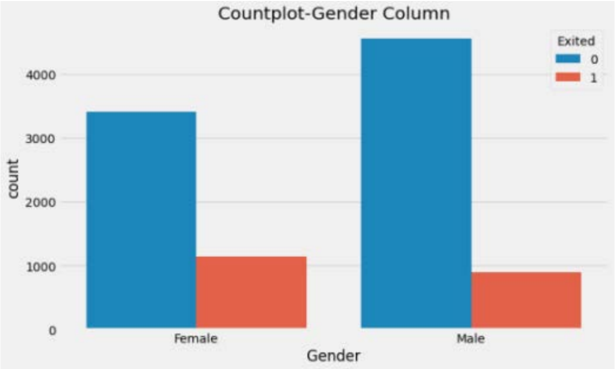

Fig. 3. Gender Distribution.

TABLE II. GEOGRAPHY FEATURE ONE HOTE ENCODING

Geography_France	Geography_Germany	Geography_Spain
1	0	0
0	0	1
1	0	0
1	0	0
0	0	1

According to Geography feature analysis, the histogram shown in Fig. 4 can infer that the total number of customers who exited is highest from Germany, which means that the bank needs to focus more on those customers followed by France customers and finally Spain customers.

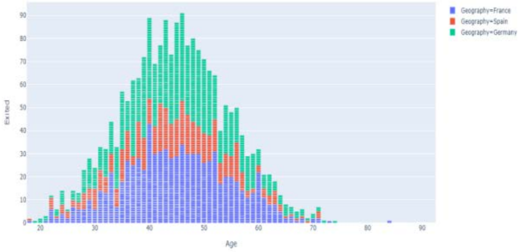

Fig. 4. Age Histogram Depending on Customer Location.

The Age feature is a numerical continuous number. According to Fig. 4, the age range between 35 and 55 are likely to leave. Furthermore, according to correlation study Fig. 5, the Age feature is correlated with 0.29 with the target and certainly will be a relevant variable for prediction.

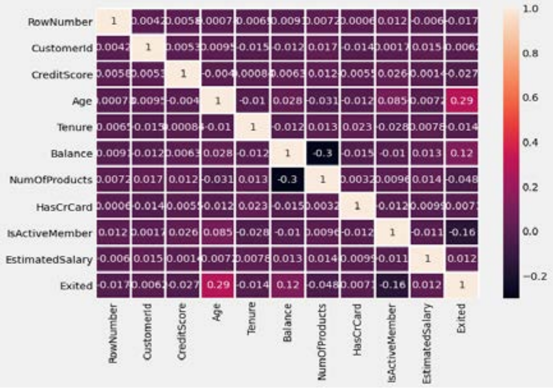

Fig. 5. Heatmap (Correlation with Target).

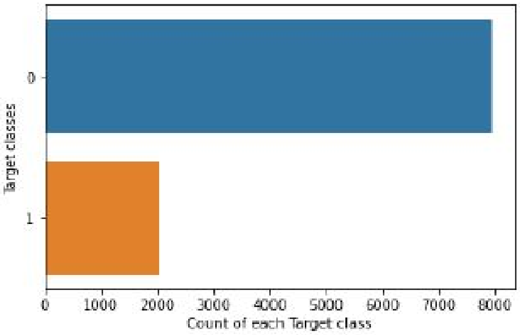
V. Re-Sampling And Modelling

A. Re-Sampling

In many works, the re-sampling technique is used to deal with unbalanced datasets [19] [20]. It is based on removing under-sampling respectively adding over-sampling samples from the majority in respective of the minority class. As shown in Fig. 6, we can check easily that the distribution of the target feature is unbalanced.



.

Fig. 6. Count Plots of Target Feature "Exited".

We decide to apply the over-sampling for increasing the number of samples as illustrated in Fig.7.

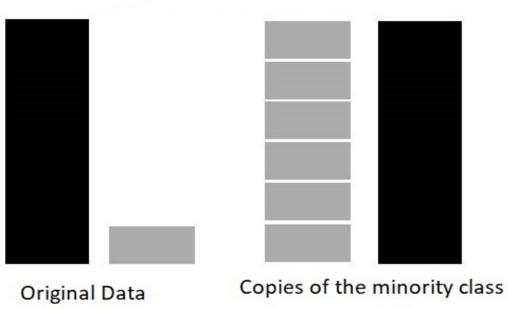


Fig. 7. Re-Sampling Method (Over-Sampling).

B. Evaluation Metrics

In order to assess machine-learning capabilities, the evaluation is based on many metrics. The most used ones are: accuracy, sensitivity, specificity, Matthew's Correlation Coefficient (MCC), that are based on confusion matrix information, presented by the following Table III, and Cohen's kappa and Matthew's correlation coefficient based on agreement and disagreement probabilities.

TABLE III. Confusion Matrix

		Actual Values	
		Success(1)	***Failure (0)***
Predicted Values	Success(1)	Truepositive	False negative
	Failure(0)	False positive	Truenegative

1) Accuracy: The accuracy calculates how many correct results your model managed to identify.

$$\text{Accuracy} = \frac{True\ positive+True\ negative}{Total\ number\ of\ samples} \quad (1)$$

2) Sensitivity: The sensitivity represents the fraction of relevant results that were retrieved; it uses also the information provided by the confusion matrix.

$$\text{Sensitivity} = \frac{number\ of\ true\ positives}{number\ of\ true\ positives+number\ of\ false\ negatives} (2)$$

3) Specifity: The specificity also called true negative rate, measures how well a model can identify true negatives.

$$\text{Specificity} = \frac{number\ of\ true\ negatives}{number\ of\ true\ negatives + number\ of\ false\ positives} (3)$$

4) Cohen's kappa: The Cohen's Kappa is a statistic measure, commonly referred to as inter-rater reliability. This metric reflects the reliability of two raters, who are rating the target result and the real one, and identifies how frequently the raters agree. Cohen's kappa, symbolized by letter $\boldsymbol{\kappa}$, this later range between -1 to 1, and it depends on the probability of agreement minus the probability of disagreement. When $\boldsymbol{\kappa}$=0 the amount of agreement has a random value, and κ=1 represents perfect agreement.

$$\%\ of\ agreement = 100 \times \kappa^2 \quad (4)$$

5) Matthew's correlation coefficient (MCC): Matthew's correlation coefficient (MCC), is a metric that aims to evaluate the quality of binary classification. MCC is often used when dataset are unbalanced, and it's unimpressed by disproportions related to dependent variables. MCC metric takes values between -1 and 1. When MCC score is equal to -1, this reflects an unexceptionable misclassification, however when it's equal to 1, a perfect classification is detected, while zero value indicates that the model is no better than random values.

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP+FP)\times(TP+FN)\times(TN+FP)\times(TN+FN)}} \quad (5)$$

C. Modeling

After the application of the process of over sampling using SMOTE library of python, we count 15926 samples while the original dataset count only 10000 observations. After, we need to standardize the data using a scaling stage. We used Robust-Scaling method [21], computed by subtracting the median from the feature value and dividing by the inter-quartile range (75% value - 25% value). This step is followed by dataset splitting, into testing and training sub-sets, the training subset count 90% of dataset. In our work, we will assess the impact of seven supervised machine-learning algorithms: Logistic Regression (LR) [4], K-nearest neighbors(KNN) [5], Random Forest (RF) [22], Decision Tree [4], Support Vector Machine (SVM) [6], XGB and Light GBM [7].

In order to choose the best model, for XGB and LightGBM, the following empirical hyper-parameter setting has been adopted see Table IV:

TABLE IV. HYPER PARAMETER USED FOR XGB AND LIGHTGBM MODELS

Learning Rate	0.05
Max Dept	5
Estimators	500

The Multi-Layer Perceptron (MLP) was configured so that the input layer has a number of neurons identical to the number of features. We proceed with two hidden layers; 15 neurons are used in the first hidden layer, 10 neurons in the second hidden layer. The stochastic gradient descent (SGD) was used as the solver function, with learning rate fixed to 0.05. Finally, the model will be trained for 500 epochs.

Parameters discussed in the precedent two paragraphs are used in all our experiments.

The evaluation process of each model, before and after over-sampling process, gives metric scores indicated respectively in Table IV and Table V.

After re-sampling and scaling, the accuracy score has been enhanced for all the models except for LR, this can be justified by the fact that this technique is susceptible to over-fitting and assumes linear relationship between independent attributes.

TABLE V. EVALUATION METRIC WITH ROBUST SCALING NORMALIZATION

Name	Accuracy	Sensitivity	Specificity	Cohen's Kappa	MCC
LR	0.803	0.213270	0.960710	0.227233	0.267877
KNN	0.830	0.402844	0.944233	0.404683	0.422475
CART	0.793	0.492891	0.873257	0.370652	0.370736
RF	0.849	0.436019	0.959442	0.465812	0.489577
SVM	0.847	0.345972	0.980989	0.415727	0.470908
XGB	0.851	0.478673	0.950570	0.489586	0.504743
LightGBM	0.857	0.507109	0.950570	0.515891	0.528854
MLP	0.847	0.454976	0.951838	0.469582	0.487264

TABLE VI. EVALUATION METRIC WITH ROBUST SCALING NORMALIZATION AND (OVER-SAMPLING)

Name	Accuracy	Sensitivity	Specificity	Cohen's Kappa	MCC
LR	0.824231	0.794155	0.853598	0.227233	0.649173
KNN	0.844319	0.841169	0.847395	0.404683	0.688586
CART	0.827997	0.858958	0.797767	0.370652	0.657615
RF	0.890772	0.885642	0.895782	0.465812	0.781516
SVM	0.861896	0.822109	0.900744	0.415727	0.725570
XGB	0.888889	0.872935	0.904467	0.489586	0.777994
LightGBM	0.889517	0.874206	0.904467	0.515891	0.779227
MLP	0.863779	0.834816	0.892060	0.469582	0.728408

These results show that ensemble decision tree models and Multi-Layer neural network produce higher accuracy when dealing with the "Bank Customer" dataset. However, finding best parameters for these methods is not a small task. In fact, it is time consuming with a high number of features. Consequently, using just relevant features to present dataset samples can be helpful when setting the appropriate model parameters and can affect the classification results.

The results in table VII were obtained by research works operating on the dataset described in this paper.

TABLE VII. RESULTS OF EVALUATION METRIC USING LR, RF, AND KNN MODELS PUBLISHED IN [5]

Name	Accuracy	Sensitivity	Specificity	Cohen's Kappa	MCC
LR	0.811	0.964	0.211	0.231	0.273
RF	0.866	0.969	0.465	0.513	0.539
KNN	0.836	0.962	0.342	0.376	0.409

Results presented in this table compared to those obtained in table VI show that the accuracy was improved for LR, RF and KNN models respectively by 1.3%, 2.4% and 1.4%. On the other hand, the accuracy given by the XGB and Light GMB models was respectively increased by 2.2%, 2.3% with respect to the highest accuracy result obtained in able VII. In the following section, we will proceed to feature importance analysis, using Scikit-Learn library [23], according to RF, XGB and Light GBM, models with the best obtained accuracy score. This analysis aims to enhance the quality of prediction and to make the training phase easier for some machine learning models such as Multi-Layer neural network.

VI. FEATURE RELEVANCE EXPLORATION

Feature relevance represents the reduction in node impurity weighted by the probability of reaching that node. The number of observations cumulated by the node divided by the total number of observations corresponds to the node probability. Higher values correspond to features that are more relevant. For each decision tree, nodes relevance is calculated, by taking only two child nodes (binary tree):

$$ni_j = w_j C_j - w_{left(j)} C_{left(j)} - w_{right(j)} c_{right(j)} \qquad (6)$$

ni_j: Importance of the node j

w_j: Proportion of observations that get at the node j

C_j: Impurity of node j

left (j) and right(j): Child node resulting from splitting the node j.

The relevance of each feature is then calculated by:

$$fi_i = \frac{\sum_{j: node\ j\ splits\ on\ feature\ i} ni_j}{\sum_{k \epsilon\ all\ nodes} ni_k} \qquad (7)$$

fi_i: The relevance of feature i

This term can be normalized by dividing by the sum of all feature relevance values:

$$\mathrm{normfi_j} = \frac{\mathrm{fi_j}}{\sum \mathrm{j \in all\ features\ fi_j}} \qquad (8)$$

The final feature relevance, at the Random Forest grade, is defined by the mean of all the trees. The sum of the feature's relevance value on each tree is calculated and divided by the total number of trees:

$$\mathrm{RFfi_i} = \frac{\sum \mathrm{j \in all\ trees\ norm\ fi_{ij}}}{\mathrm{T}} \qquad (9)$$

$\mathrm{RFfi_i}$: The relevance of feature is calculated from all trees in the RF model.

Norm ($\mathrm{RFfi_i}$): The normalized feature relevance for feature in the tree j.

T: Total number of trees.

The application of feature relevance calculation according to the three models with the best accuracy score > 88.8 % (RF, XGB and Light GBM) are shown in Fig. 8, Fig. 9, and Fig. 10.

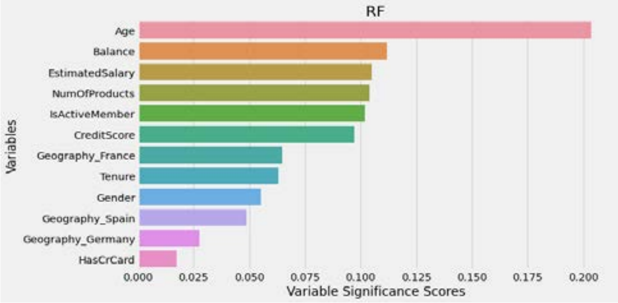

Fig. 8. RF Feature Relevance.

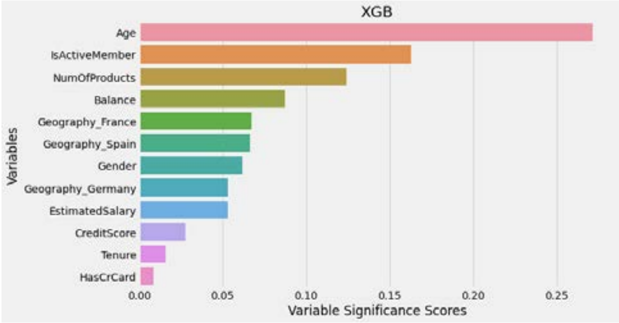

Fig. 9. XGB Feature Relevance.

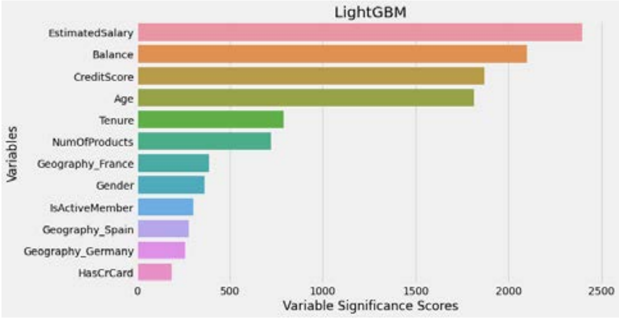

Fig. 10. Light-GBM Feature Relevance.

The feature selection process was performed using the empirical hyper-parameters setting cited below.

A. Feature Selection usingXGB and LightGBM

After the calculation of feature relevance for each machine learning algorithm, the above results show that the most eight relevant features according to RF are:

- Age,
- Balance,
- Estimated Salary,
- Number Of Products,

- Is Active Member,
- Credit Score,
- Geography_France,
- Tenure.

The most eight relevant features according to XGB are:

- Age,
- Is Active Member,
- Number Of Products,
- Balance,
- Geography_France,
- Geography_Spain,
- Gender,
- Geography_Germany.

While the most eight relevant features according to Light-GBM model are:

- Estimated Salary,
- Balance,
- Credit Score,
- Age,
- Tenure,
- Number Of Products,
- Geography_France,
- Gender.

The goal of this part of study is to find relevant features according to each machine-learning algorithm and to try after to use just those features with other algorithms such as MLP neural network. This can make the training process easier and leads to time saving in both training and generalization steps.

According to the chosen hyper-parameters, the accuracy reaches 88.88% for the XGB model and 88.95% for Light GBM model.

B. *Using MLP Model with Relevant Features*

After implementing feature scaling for all inputs variables in order to have values with comparable ranges, we will study the effect of using relevant features with MLP model. The most relevant features are those that appear at least twice in the union of relevant features sets elaborated by RF, XGB and Light-GBM models. These features are:

- Age,
- Balance,
- Estimated Salary,
- Number Of Products,
- Is Active Member,
- Credit Score,
- Geography_France,
- Tenure,
- Gender.

We did the simulation with nine relevant features with MLP model.

After applying the feature selection with ensemble decision tree models and using these features to train MLP model, only the Cohen's Kappa metric has been improved, which reflect the perfect agreement between the observed and predicted outcomes, it has been improved by 19.40%. According to the results shown in Table VIII, we can deduce that even after removing three features, the MLP performances are not drastically affected.

TABLE VIII. OBTAINED METRICS 9 MOST RELEVANT FEATURES WITH MLP MODEL

Name	**Accuracy**	**Sensitivity**	**Specificity**	**Cohen's Kappa**	**MCC**
MLP	0.831764	0.844981	0.818859	0.663601	0.663902

VII. RESULTS INTERPRETATIONS

In this research, we have compared the results of applying eight machine-learning algorithms, LR, KNN, CART, RF, SVM, XGB, Light GBM and MLP with other studies using "Churn Customer" dataset [5]. Our study aims to predict accurately customers predisposed to stay with bank and to honor their commitments. For a given model, a high accuracy would indicate that the model is able to predict the decision that a customer can make (exit the bank/ stay with the bank). After the evaluation of the eight models, we notice that RF model got the best accuracy score with 89.07%. It must be mentioned that we have adopted three pre-processing steps, which consists of data re-sampling, scaling and hyper parameter setting. Light GBM model was the second more accurate model, with an accuracy of 88.95%. The third more accurate model was the XGB model with an accuracy score of 88.88%. While Artificial Neural Network (MLP) classifier accuracy score got 86.37%.

Concerning feature number reduction, the use of relevant features as input of the MLP neural network shows that the predicting capabilities of this model were not seriously affected. In fact, the accuracy is still around 83.17%, even if three features were not used. This result is important because the training phase is easier to engage when using a reduced number of features.

VIII. CONCLUSION AND FUTURE WORK

In this paper, we proposed an approach for churn customer prediction, using a dataset with 10000 observations. After the comparison of our results to those obtained by other existing approaches [5], with respect to the used dataset, ensemble decision tree and Multi-layer neural network models have demonstrated good performances. In this work, we were also interested in improving the obtained results by exploring ensemble learning algorithms capabilities to find relevant features that can be fed to some classic machine learning models, as an example MLP neural network. The MLP model performances were not seriously affected by the reduction of features number, from 12 to 9, even some metrics were improved.

We can notice that this approach can be a motivation to make better decisions when dealing with personalized data and can also be generalized to deal with sophisticated concepts such as NLP (Natural language processing), in order to semantically analyze customer posts. We are also interested, as a perspective, in assisting MLP implementation by using Big Data tools to enhance its performances. In fact, it is possible to involve Spark libraries to enable running various machine-learning algorithms on distributed systems. Integrating these tools to this work will give the speed and the capacity to perform better results with a large amount of data.

Vellore, India

Abstract—**Opinion mining is a natural language processing based on sentiment classification technique to determine the sentiment of the reviews. The major existing text Convolutional Neural Network (CNN) algorithms are derived based on 3×3 size kernels which extract ineffective review text-features and lead to less classification accuracy. Moreover, most of the traditional CNN versions output three classes such as positive, negative, and neutral as their classification results. Hence, a novel algorithm namely 'RAVO driven *Multi-Size Kernel structured Text CNN for classifying ecommerce reviews (MSK-TCNN-RAVO)*' is proposed in this work. This proposed approach utilizes five multi-size kernels ($3 \times 7, 5 \times 7, 1 \times 3, 1 \times 5, 1 \times 7$), multi-dimensional kernels (1D & 2D), and integrates varying size kernels to extract text-features effectively. In addition, the performance of multi-kernel CNN is highly enhanced by RAVO algorithm based on rider optimization. Moreover, the proposed approach is highly effective to process '*review-stop-words removal*' that decrease the complexity and time consumption of the opinion mining process. Most existing systems use single pooling operations which reduce feature map processing performance, hence, dual pooling operations (both Max and Average pooling) are employed in this research. Furthermore, it is configured to generate five classification outputs such as bad, fair, neutral, good, and excellent to support better decision-making with 95.5% accuracy. This method is evaluated using different quality metrics and five review-databases to measure the performance, and the results reveal that the proposed method outperforms the other existing review classification algorithms.**

Keywords—Natural language processing; opinion mining; convolutional neural network; text sentiment classification; ecommerce review

I. INTRODUCTION

Social media plays a very important role in almost everybody's day to day life. It allows the people to convey what they think and feel about the products in the e-commerce website. This is called an opinion or review. Online shopping is a form of e-commerce which allows consumers to directly buy goods or services from a seller over the internet [1]. Most of the e-commerce websites incorporate provisions which enable the consumer to post their opinions about the product, companies, or their experiences etc.

Online shopping is being performed by millions of users every day, as a result of this, a huge amount of reviews are being generated constantly. Handling these reviews manually to extract knowledge is a tedious task and hence, companies use classification tools to categorize the customer reviews to understand the customer's mindset. Opinion Mining is also known as Sentiment Analysis (SA) is the automated process of identifying opinions in text, and labeling them as positive, negative or neutral, based on the emotions expressed by the customer. It includes text analysis, computational linguistics to identify and extract subjective information in source materials [2].

The rest of the article is structured as follows: A summary of traditional methodologies for review classification is provided in Section II. Section III covers the proposed approach in detail with diagrammatic representations. Results and discussions are included in Section IV. The work has been concluded in Section V.

II. RELATED WORK

The existing review classification algorithms discussed in various works of literature are summarized in this section. Anam et al. [3] proposed a voting classifier (LR-SGD) model for textual-tweets classification as happy or unhappy for emotion recognition. The dataset contains a lot of contrary tweets which are used for evaluation. The weakness of this work is that, the combination of different models should be employed to increase the performance. Ren and Wu [4] proposed a sentence-based analysis model to identify investor herd behaviour. The data is taken from blue-chip stocks in Chinese stock market. The work's limitation is that it uses only a small amount of data for experimentation, arising doubt on the algorithm's efficacy.

Sasikala and Sheela [5] expressed a sentiment analysis technique called Deep learning modified neural network to process the online product reviews. The food review dataset has been taken as input for the proposed technique. The drawback is that, the keyword processing only detects the sentiment expressed in a single word, and frequently fails to provide all information needed to interpret the context. Zeeshan et al. [6] proposed an opinion mining methodology using lexicon and neural networks for classifying online movie reviews. The reviews are collected from the IMDB database. The disadvantage is that, the resultant vectors will be in larger dimension and contain a large number of null

*Corresponding Author.

values, resulting in sparse vectors. Jia et al. [7] proposed a hierarchical gated deep memory network with position-aware for aspect-based sentiment analysis. The algorithm is evaluated on laptop and restaurant datasets. The limitation of the work is that the accuracy is very low while predicting the neutral polarity.

Cheng et al. [8] proposed a multi-channel model that combines the CNN and the bidirectional gated recurrent unit network with attention mechanism for text sentiment orientation analysis. Two public datasets such as IMDB and Yelp 2015 review dataset is used to evaluate the algorithm. It does not include any syntactic structure features, hence, this model cannot be used for sentiment classification task. Dong et al. [9] proposed a CNN based on multiple convolutions and pooling for text sentiment classification. The reviews from English and Chinese datasets are used as input for evaluation. The four convlotuion operations proposed in this work perform low on English emotions.

Gupta et al. [10] proposed a feature-based supervised model to identify the extremist reviewers who target whole brand. The datasets are created by crawling reviews from Amazon website. The weakness of the work is that it requires larger training time for even smaller datasets. Madbouly et al. [11] proposed a hybrid classification approach of tweets based on user ranking for online social networks. The dataset consists of tweets with their feature used as input. Tweets were filtered manually to exclude non-English tweets which will increase the execution time of the algorithm. Bhalla and Bagga [12] proposed an RB-Bayes method based on Naive Baye's theorem for prediction to remove problem of zero likelihood. The algorithm is evaluated on a small dataset which contains text data. The efficiency of the model is not proved in large-scale databases. Zhang and Zhong et al. [13] proposed an e-commerce reviews mining method called sentiment similarity analysis to explore user's similarity and trust. The experimental dataset is collected from Amazon.com. The essential parameters involved in calculating the trust between users is not considered in this work which leads to less accuracy.

Aziz et al. [14] proposed the Contextual analysis mechanism to find the relationship between words and sources to predict Supervised machine learning model performance. The experiment is conducted on four different domain datasets collected from Amazon. The result of the prediction algorithm is less while performing real time analysis for individual changes of dataset. Iqbal et al. [15] proposed a hybrid framework for sentiment analysis which bridges the gap between lexicon-based and machine learning approaches. The reviews dataset is collected from UCI ML repository. The proposed framework works only for specific domain and does not support other domains like cyber-intelligence, law-enforcement sector, etc.

Liu et al. [16] proposed a modified fuzzy approach for cyber hate classification. This model uses four datasets collected from Twitter regarding four types of hate speech. Because the intersectionality of different types of hate speech is not addressed, more diversified features are extracted for hate speech detection. Fang et al. [17] proposed a multi-strategy sentiment analysis method with semantic fuzziness to extract the customer’s opinions expressed in sentiment Chinese phrases. The input reviews are taken from search forum website. Since the emotional phrases are not included in this work, calculation errors arise which results in lower accuracy.

A. Problem Statement

In the field of SA, machine learning methods such as Decision Tree [18], Logistic Regression [19], Support Vector Machine [20], Naive Bayes [21] and others have shown promising results, but most of them overly rely on hand-crafted features and necessitate a lot of manual design and adjustment, which is time-consuming and costly. Deep learning methods have achieved excellent performance with the help of large-scale corpus in many research fields, and become a research hotspot in SA [22]. However, in the majority of traditional text sentiment classification algorithms, the sentence-level sentiment classification remains difficult for various reasons, including a lack of semantic understanding and low classification accuracy. Moreover, the major existing methodology uses only 3 × 3 and 2D kernels which cannot be able to extract the review-text features effectively. Most of the current classification method commonly preprocesses only the basic stop-words, numbers, & symbols, and maintains the words which does not reveal any sentiment information (Ex: around, surround, door etc.). Keeping those words in the classification phase increases the complexity and time consumption of the method. In some existing literatures, when the length of a word in an input review is less than the length of the sentence matrix, the padding operation is used to pad with sufficient amount of NULL data in order to meet the original length of the sentence matrix. This padded NULL data reduces the impact of real data and dominates over it which results in less effective feature representation and negatively impacts the classification accuracy. Substantially, many classification methods classifies the reviews into two (happy, unhappy) or three classes (positive, negative, neutral) which results in an ineffective decision making process.

The main contribution of this paper is to propose a novel e-commerce review classification method namely RAVO based Multi-Size Kernel structured Text CNN based Review Classification (MSK-TCNN-RAVO) based on a new variant of CNN. This method utilizes a convolutional operation that employs multi-size, multi-dimensional kernels to generate enriched features which yields high review classification accuracy. This research demonstrates the concept of varying kernels applied on 1D kernels in order to extract features exclusively from accurate data rather than padded data, which is one of the key processes of this work. This work introduces a new concept called review-stop-words removal, in which, the words that do not convey any sentiment information are eliminated. Keeping these review-stop-words in classification increase the complexity and the time-consumption of both training and testing process. To our knowledge, there are no studies in the available literatures that address the removal of non-sentimental words during the classification stage. Subesquently, it is configured to generate five classification outcomes which will help companies make better business decisions. Finally, to improve the performance of the classifier, the proposed work is driven by a Rider driven African vulture optimization algorithm based on the overtaker's strategy of the Rider optimization algorithm.

III. Methodology

The proposed review-classifier network is designed based on Convolutional Neural Network (CNN). The design of this new MSK-TCNN-RAVO method is one-of-a-kind, allowing for correct classification of review data. The following are the unique aspects of the proposed work:

- Input processing for 7 × 7 size sentence matrix rather than a traditional 5 × 5 size.
- Design of multi-size Convolutional kernels.
- Integration of both 1D and 2D kernels during convolution process.
- Introducing the concept of varying kernel based convolution process to extract features exclusively from accurate data rather than padded data.
- Pooling layer constructed by dual pooling operations
- Configured to generate five classification results viz. Bad, Fair, Neutral, Good, and Excellent.

The aforementioned modifications make this MSK-TCNN-RAVO method as a novel work and more effective than existing Text-based CNN classifiers to classify the review-data. The proposed work is mainly divided into three sections such as: MSK-TCNN-RAVO review training process, MSK-TCNN-RAVO review testing process, and Optimization using Modified African Vulture Algorithm.

The workflow of the proposed work is shown in Fig. 1. The input reviews from three domains such as Laptop, Camera, Mobile is taken from Amazon website. The dataset as a whole has a lot of long sentences, with an average of 11.44 sentences per review. The proposed method has both training and testing sections. The basic stopwords, numbers, and symbols are removed from the input reviews in the preprocessing section and words which do not reveal any sentiment information is removed in review-stop-words removal section. The sentence matrix (SM) is generated by extracting each word from the enhanced reviews and placing it in matrix form. The above mentioned process is common for both training and testing section. Each review from the SM is fed as input to the proposed algorithm's training process and trained network is created. Similarly, in the testing section, each review from SM is fed as input to the proposed algorithm's testing process and it continues until all the reviews are processed. Finally, the review classification report is produced from the testing section.

A. MSK-TCNN-RAVO Review Training Process

1) Pre-processing: Reviews are usually composed of incomplete expression, a variety of noise and poorly structured sentences. Noise and unstructured Twitter data will affect the performance of tweet sentiment classification [23], [24]. Prior to feature selection, a series of preprocessing steps are performed on reviews to reduce the meaningless data in the review sentences.

Stop-words are words which have no value (positive or negative) in a sentiment analysis system that are meaningless in information retrieval, hence, they must be eliminated from the data set. For example stop words include "the", "as", "of", "and", "or", "to", etc. Stop word removing is substantial in the preprocessing, it has some advantages like reducing the size of stored data set and it improves the overall efficiency and effectiveness of the analysis system [25]. The proposed system uses a list of stop words obtained from Onix Text Retrieval Toolkit website [26].

In this proposed research work, three crucial pre-processing steps are carried out using text processing functions of MATLAB research tool to remove the (i) basic stop-words (ii) numbers, and (iii) symbols. The resultant pre-processed review is stored in the review-arrayR_{pp}.

2) Review-stop-words removal: The input of this section is the pre-processed review data. In the actual pre-processing section, the basic stop-words, numbers, and symbols are removed. But the remaining enhanced review contains the word which does not reveal any sentiment information, and those words are called as “Review-Stop-words”. Keeping those words will increase time consumption and the complexity of the classification process. A tool is developed to assist for the generation of review-stop-words. Any sample review dataset can be fed as input to this generalized tool which comprises two steps, viz. basic stop-words removal and unique words extraction. Afterwards, the review-stop-words are extracted manually and the review-stop-word list can be generated.

Fig. 2. Sample List of Review-Stop-Words.

The sample review-stop-words are shown in Fig. 2.The survey-stop-words are loaded in the survey-stop-words-arrayL_{ssw}. In the pre-processed review, the survey-stop-words are removed based on the L_{ssw} list. The resultant survey after this removal process is stored in the review-array R_{ssw}.

3) Sentence matrix generation: The Sentence Matrix SM represents a sentence in the matrix form. The dimension of SM is fixed as 7×7. It is fixed by maintaining a trade-off between complexity and accuracy. A sentence of the enhanced review (after removing basic stop-words, numbers, symbols, and review-stop-words) R_{ssw} is extracted and each word of it is placed in the matrix form.

In this research work, the convolution process is carried out by taking SM as input using the combination of both 2D kernels such as 3×7 , 5×7 and 1D kernel such as 1×3, 1×5, and 1×7 in order to extract the review text feature representation effectively.

4) Training of MSK-TCNN-RAVO Algorithm: This algorithm is comprised of multi-size, multi-dimensional kernels. The varying kernel adopted in this technique retrieves features only from the exact data and not from the padded data. The dual pooling operations applied in this algorithm increase the efficiency of the feature map processing. The training process is carried out in order to produce five classification results. The architecture of the algorithm is depicted in Fig. 3.

a) 3×7 *Size Kernel based Convolution*: This convolution process is performed using six 3×7 size kernels such as k_0,k_1,k_2,k_3,k_4, and $\mathrm{k}_5$which is represented in Fig. 4. The column width of these kernels is fixed as seven, because the length of Sentence Matrix SM is seven. First the kernel k_0 is used to convolute the sentence matrix SM to produce convoluted matrix $\mathrm{CM}_{\mathrm{k0}}$. This process is performed using (1) to (5).

$$k_0 = \begin{bmatrix} 1 & 1 & 1 & 0 & 1 & 1 & 1 \\ -1 & 1 & 1 & 0 & 1 & 1 & -1 \\ -1 & -1 & -1 & 0 & -1 & -1 & -1 \end{bmatrix} \quad (1)$$

$$A = \sum_{m=0}^{3-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_0(m,n), i = 0, j = 0 \quad (2)$$

$$B = \sum_{m=0}^{3-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_0(m,n), i = 2, j = 0 \quad (3)$$

$$C = \sum_{m=0}^{3-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_0(m,n), i = 4, j = 0 \quad (4)$$

$$CM_{k0} = \begin{bmatrix} A \\ B \\ C \end{bmatrix} \quad (5)$$

Herein, A, B, C represents the convoluted result by applying convolution on row of 0, 2, and 4 respectively inSM, and CM_{k0} indicates convoluted matrix by k_0 kernel.

Equation (1) defines the kernel k_0. Equation (2) computes the convoluted value by projecting the k_0 over the element of $SM(0,0)$. It means the convolution process performed on 0th row and 0th column in SM, and stored in A. Likewise the Equation (3) computes the convoluted result by considering the position $SM(2,0)$ and the output is assigned in B. The Equation (4) computes the convoluted result by considering the position $SM(4,0)$. Finally, the convoluted matrix CM_{k0} with size 3×1 is constructed by placing the A, B, and C values in the order using (5). Similarly the other 3×7 size kernels such as k_1, k_2, k_3, k_4, and k_5 is convoluted to find the convoluted matrix CM_{k1} , CM_{k2} , CM_{k3} , CM_{k4} , and CM_{k5} respectively.

b) 5×7 *Size Kernel based Convolution*: Here, the convolution process is performed using four 5×7 size kernels such as k_6 , k_7 , k_8 , and k_9 to generate four convoluted matrices such as CM_{k6}, CM_{k7}, CM_{k8}, and CM_{k9}. The four 5×7 size kernels are depicted in Fig. 5.

The kernel k_6 is used to compute the convoluted matrix CM_{k6} with size 6×1 using (6) and (7).

$$k_6 = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & -1 & -1 & -1 & -1 & 1 \\ 1 & -1 & 0 & 0 & 0 & -1 & 1 \\ 1 & -1 & -1 & -1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \quad (6)$$

$$\mathrm{CM}_{\mathrm{k6}} = \begin{bmatrix} \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 0, j = 0 \\ \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 1, j = 0 \\ \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 2, j = 0 \\ \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 3, j = 0 \\ \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 4, j = 0 \\ \sum_{m=0}^{5-1} \sum_{n=0}^{7-1} SM(i+m, j+n) * k_6(m,n), i = 5, j = 0 \end{bmatrix} \quad (7)$$

k_9

Fig. 5. Representation of 5 × 7 Size Kernelsk_6, k_7,k_8, and k_9.

In Equation (7), the kernel k_6 is projected over the rows of padded-SM from row = 0 to row = 5, and the convolution process is performed. Similarly the other convoluted matrix such as CM_{k7}, CM_{k8}, and CM_{k9} is convoluted.

c) One Dimensional Varying Kernel based Convolution: In Sentence matrix SM, the length of a word may be less than the matrix length 7. In this case, padding operation pads the necessary quantity of NULL data to meet the length of the SM. However, the padded data diminishes the effect of real data in feature representation, lowering review classification accuracy. Hence, this research employs the concept of 1D varying kernels such as $1 \times 3, 1 \times 5$, 1×7 which have the length bounded in the range of 1×7 as shown in Fig. 6. The words which have length less than 7 in SM undergone the convolution operation with the aid of either the varying kernel 1×3 or 1×5. The words which have length equal to 7 in SM undergone the convolution process by using the kernel of 1×7 size. This concept extracts the features from the exact data and not from the padded data, which is one of the key processes of this research.

Fig. 6. Illustration of Varying Kernels.

The convoluted matrix computation for the kernel k_{10} is performed using (8) to (14).

$$k_{10}^{1\times3} = \begin{bmatrix}1 & 1 & 1\end{bmatrix} \tag{8}$$

$$k_{10}^{1\times5} = \begin{bmatrix}1 & 1 & 1 & 1 & 1\end{bmatrix} \tag{9}$$

$$k_{10}^{1\times7} = \begin{bmatrix}1 & 1 & 1 & 1 & 1 & 1 & 1\end{bmatrix} \tag{10}$$

$$H_{SM} = \text{HeightOfSentenceMatrix(SM)} \tag{11}$$

$$L_i = \text{Word Length } (SM_i)$$

$$i \in [0, H_{SM} - 1] \tag{12}$$

$$C_i = \begin{cases} \sum_{n=0}^{3-1} SM(i,n) * k_{10}^{1\times3}(0,n), if\ L_i <= 3 \\ \sum_{n=0}^{5-1} SM(i,n) * k_{10}^{1\times5}(0,n), else\ if\ L_i <= 5 \\ \sum_{n=0}^{7-1} SM(i,n) * k_{10}^{1\times7}(0,n), else\ if\ L_i <= 7 \end{cases}$$

$$i \in [0, H_{SM} - 1] \tag{13}$$

$$\mathrm{CM}_{\mathrm{k10}} = \begin{bmatrix} \mathrm{C}_0 \\ \mathrm{C}_1 \\ \mathrm{C}_2 \\ \mathrm{C}_3 \\ \mathrm{C}_4 \\ \mathrm{C}_5 \\ \mathrm{C}_6 \end{bmatrix} \tag{14}$$

where

H_{SM} - Height of the Sentence Matrix SM

Height Of Sentence Matrix – Function to find the height of sentence matrix SM

L_i - Length of ith word in SM

Word Length – Function to compute length of the specific word in SM

C_i - Convoluted value of 10th varying kernel corresponding to ith row of Sentence Matrix SM

n – Column movement index

$\mathrm{CM}_{\mathrm{k10}}$ - Convoluted matrix related to k_{10} kernel.

Equation (8) to Equation (10) defines the 10th varying kernel's variation such as $k_{10}^{1\times3}$, $k_{10}^{1\times5}$ and $k_{10}^{1\times7}$. Equation (11) computes the height of the Sentence Matrix SM and stores in the term H_{SM}. Equation (12) computes the length of each word of SM. Equation (13) computes the convoluted value of each word of SM using 10th varying kernel, by using the kernels $k_{10}^{1\times3}$ or $k_{10}^{1\times5}$ or $k_{10}^{1\times7}$ depending on the length of word L_i. The Equation (14) shows the convoluted matrix by merging the seven values of C_i. Similarly, the convoluted matrix such asCM_{k11}, CM_{k12}, and CM_{k13}will be computed.

d) ReLU Operation and Feature Matrix Generation: In this research, the ReLU function is used as activation function after convolution process. The function returns 0 if it receives any negative input, but for any positive value x, it returns the same value [27]. The ReLU activation function is designed for the convolution matrixCM_{k10} is based on Equation (15).

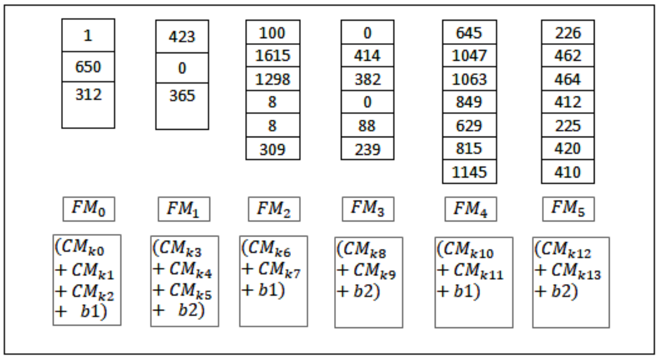
$$CM_{k0}^{i} = \left[\begin{array}{l} CM_{k0}^{i}, if CM_{k0}^{i} >= 0 \\ \quad 0, \qquad else \end{array}\right. \tag{15}$$

where $i \in [0, n-1]$

n – Height of the convoluted matrix CM_{k0} (Let it be 3 for 3×7 size kernels). Similarly the other convolution matrixes ranging CM_{k1} to $CM_{k13}$are computed based on (15).

The feature matrix is generated in order to reduce the quantity of convoluted matrix from 14 to 6. This helps to improve the speed of the review-analysis. Herein, the bias value participates its part similar with the traditional neural network. The bias value $b1$ is set as 1 and bias value $b2$ is set as 0. The illustration of feature matrix generation on the Sentence Matrix is shown in Fig. 7.

e) Pooling Operations: The pooling operation reduces the size of the feature map by keeping the key information. This research applies two types of pooling operations such as maximum pooling and Average pooling which essentially extracts the essence of the feature map. The feature matrix FM_0, FM_1 with 3×1 dimension is undergone the Max pooling and Avg. pooling operation which results a individual single value by computing the maximum value and average value respectively. The feature matrix FM_2, FM_3 with 6×1 dimension is undergone both the pooling operation based on Fig. 8.



FM_0	FM_1	FM_2	FM_3	FM_4	FM_5
1	423	100	0	645	226
650	0	1615	414	1047	462
312	365	1298	382	1063	464
		8	0	849	412
		8	88	629	225
		309	239	815	420
				1145	410
$(CM_{k0} + CM_{k1} + CM_{k2} + b1)$	$(CM_{k3} + CM_{k4} + CM_{k5} + b2)$	$(CM_{k6} + CM_{k7} + b1)$	$(CM_{k8} + CM_{k9} + b2)$	$(CM_{k10} + CM_{k11} + b1)$	$(CM_{k12} + CM_{k13} + b2)$

Fig. 7. Illustration of Feature Matrix Generation on the Example Sentence Matrix.

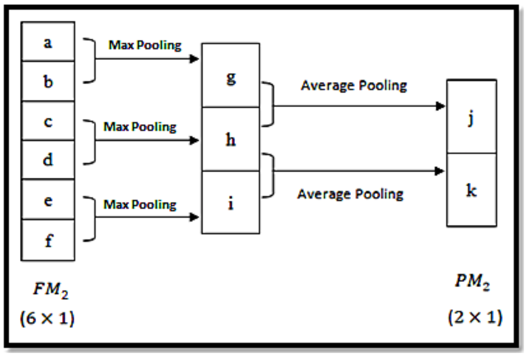


Fig. 8. Pooling Operation Performed in the Feature Map FM_2.

Similarly the feature matrix FM_4, FM_5 is undergone both the pooling operations as shown in Fig. 9. The illustration of pooling layer computation is depicted in Fig. 10. The 2×1 dimension is the resultant matrix after the pooling operations.

f) Feature Map Vector Generation: The feature map vector generation is performed to collect the same features of same size kernels into small groups. The size reduced 3×7 kernels are grouped in order to generate feature map vector FV_0 using (16).

$$FV_0 = \{ PM_{0,}^{0} PM_{0,}^{1} PM_{1,}^{0} PM_{1}^{1} \} \tag{16}$$

Similarly, the size reduced 5×7, and one dimensional kernel oriented pooled feature maps are grouped to generate the feature map vector FV_1, FV_2 respectively using (17) and (18).

$$FV_1 = \{ PM_{2,}^{0} PM_{2,}^{1} PM_{3,}^{0} PM_{3}^{1} \} \tag{17}$$

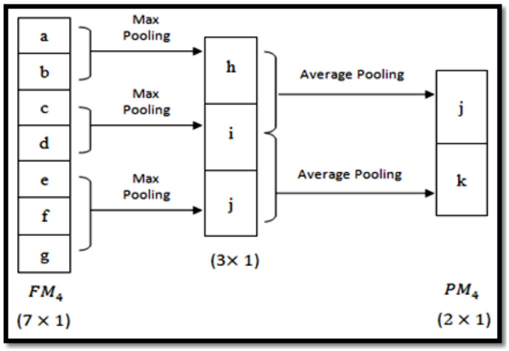

Fig. 9. Pooling Operation Performed in the Feature Map FM_4.

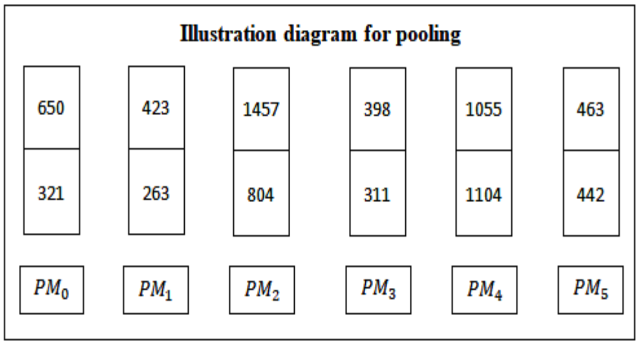

PM_0	PM_1	PM_2	PM_3	PM_4	PM_5
650	423	1457	398	1055	463
321	263	804	311	1104	442

Fig. 10. Illustration of Pooling Layer Computation.

Likewise, the feature map vector FV_2 is originated using the one dimensional kernels oriented pooled feature maps such as PM_4 and PM_5 based on (18).

$$FV_2 = \{ PM^0_{4,} PM^1_{4,} PM^0_{5,} PM^1_5 \} \tag{18}$$

g) Softmax Function: The resultant feature map vectors FV_0 , FV_1 , and FV_2 holds four elements each. The output of the convolution layer is flattened into a 1D array called as F, which is given as input to the fully connected layer. The output layer in an artificial neural network produces the given outputs for the program. In the training section of the proposed RAVO-MSKTCNN algorithm, the manually marked category information such as BD, FR, NL, GD, EX with target values 1, 2, 3, 4 and 5 respectively are fed to support the learning process. The extracted flattened features of the given training review sample is converted into probabilistic distributions form by softmax function. This data is compiled by the target values of training categories until it converges by the back propagation concept. Thus the training of a review data is progressed. Multi reviews are trained using the MSK-TCNN-RAVO algorithm, and the trained network of the same is generated.

B. MSK-TCNN-RAVO Review Testing Process

The testing process of proposed algorithm is used to classify the review data with the aid of the trained network. The Fig. 11 depicts the architecture of the testing process of the proposed MSK-TCNN-RAVO network. The basic stop words, numbers, and symbols are removed from the test reviews in the preprocessing section and words which do not reveal any sentiment information are removed in review-stop-words removal section.

The enhanced reviews SM is fed as input to the testing section of the MSK-TCNN-RAVO algorithm and the convolution operations such as 3×7 , 5×7 , and one dimensional varying kernel based convolution are performed on SM to generate the corresponding convoluted matrices. The ReLU function is used as an activation function after convolution process, and feature matrix is generated in order to reduce the quantity of convolution matrices from 14 to 6 as shown in Fig. 7. The dual pooling operation such as Max and Average pooling is applied and finally the feature map vector is generated. The extracted feature map is given to the MSK-TCNN-RAVO network as a feature which is then classified into five classes as shown in Fig. 11. This process is repeated until all the test reviews are processed. The classification report generated by the proposed algorithm can be used for better decision making process.

Algorithm -1 of review testing process

```
Step 1: The test review is given as input
Step 2: Remove basic stop words from the given test review
Step 3: Remove the survey-stop-words from the pre-processed test reviews
Step 4: Convert the processed test review into a Sentence Matrix (SM) of size $7 \times 7$
Step 5: Design six $3 \times 7$ size kernels such as $k_0$, $k_1$,$k_2$,$k_3$,$k_4$, and $k_5$.
Step 6: Convolute the Sentence Matrix (SM) by $k_0$ kernel and find the Convolution Matrix $CM_{k0}$
Step 7: Repeat Step 6 with the other kernels such as $k_1$,$k_2$,$k_3$,$k_4$, and $k_5$ to obtain the Convolution Matrix $CM_{k1}$, $CM_{k2}$, $CM_{k3}$, $CM_{k4}$, and $CM_{k5}$ respectively.
Step 8: Design four $5 \times 7$ size kernels such as $k_6$, $k_7$,$k_8$,and $k_9$.
Step 9: Convolute the Sentence Matrix (SM) by $k_6$ kernel and find the Convolution Matrix $CM_{k6}$.
Step 10: Repeat Step 9 with the other kernels such as $k_7$,$k_8$, and $k_9$ to obtain the Convolution Matrix $CM_{k7}$ , $CM_{k8}$ , and $CM_{k9}$ respectively.
Step 11: Construct four one dimensional varying kernels of size $1 \times 3$ , $1 \times 5$ , $1 \times 7$ . Name the four kernels as $k_{10}$ , $k_{11}$,$k_{12}$,and $k_{13}$.
Step 12: Compute Convolution matrix $CM_{k10}$ via one dimensional varying kernels $k_{10}^{1\times3}$, $k_{10}^{1\times5}$, and $k_{10}^{1\times7}$.
Step 13: Compute convoluted matrix $CM_{k11}$ using kernels $k_{11}^{1\times3}$, $k_{11}^{1\times5}$, and $k_{11}^{1\times7}$
Step 14: Compute Convolutional matrix $CM_{k12}$ using kernels like $k_{12}^{1\times3}$, $k_{12}^{1\times5}$ and $k_{12}^{1\times7}$
Step 15: Compute convoluted matrix $CM_{k13}$ using kernels such as $k_{13}^{1\times3}$, $k_{13}^{1\times5}$, and $k_{13}^{1\times7}$.
Step 16: Activate the convoluted matrices such as $\mathrm{CM}_{\mathrm{k0}}$ to $\mathrm{CM}_{\mathrm{k13}}$using the ReLU activation function.
Step 17: Construct the feature matrix $FM_0$ to $FM_5$ using the convoluted matrices $CM_{k0}$to $CM_{k13}$.
Step 18: Apply the max pooling and average pooling operations on the feature matrix $FM_0$ to $FM_5$ and compute the corresponding pooled matrix $PM_0$to $PM_5$ of $2 \times 1$ size.
Step 19: Construct $3 \times 7$ kernel based feature map vector $FV_0$ to $FV_2$.
Step 20: Feed the output of fully connected layer to Softmax activation function.
Step 21: Output classification results for test reviews based on RAVO driven MK-TCNN network.
```

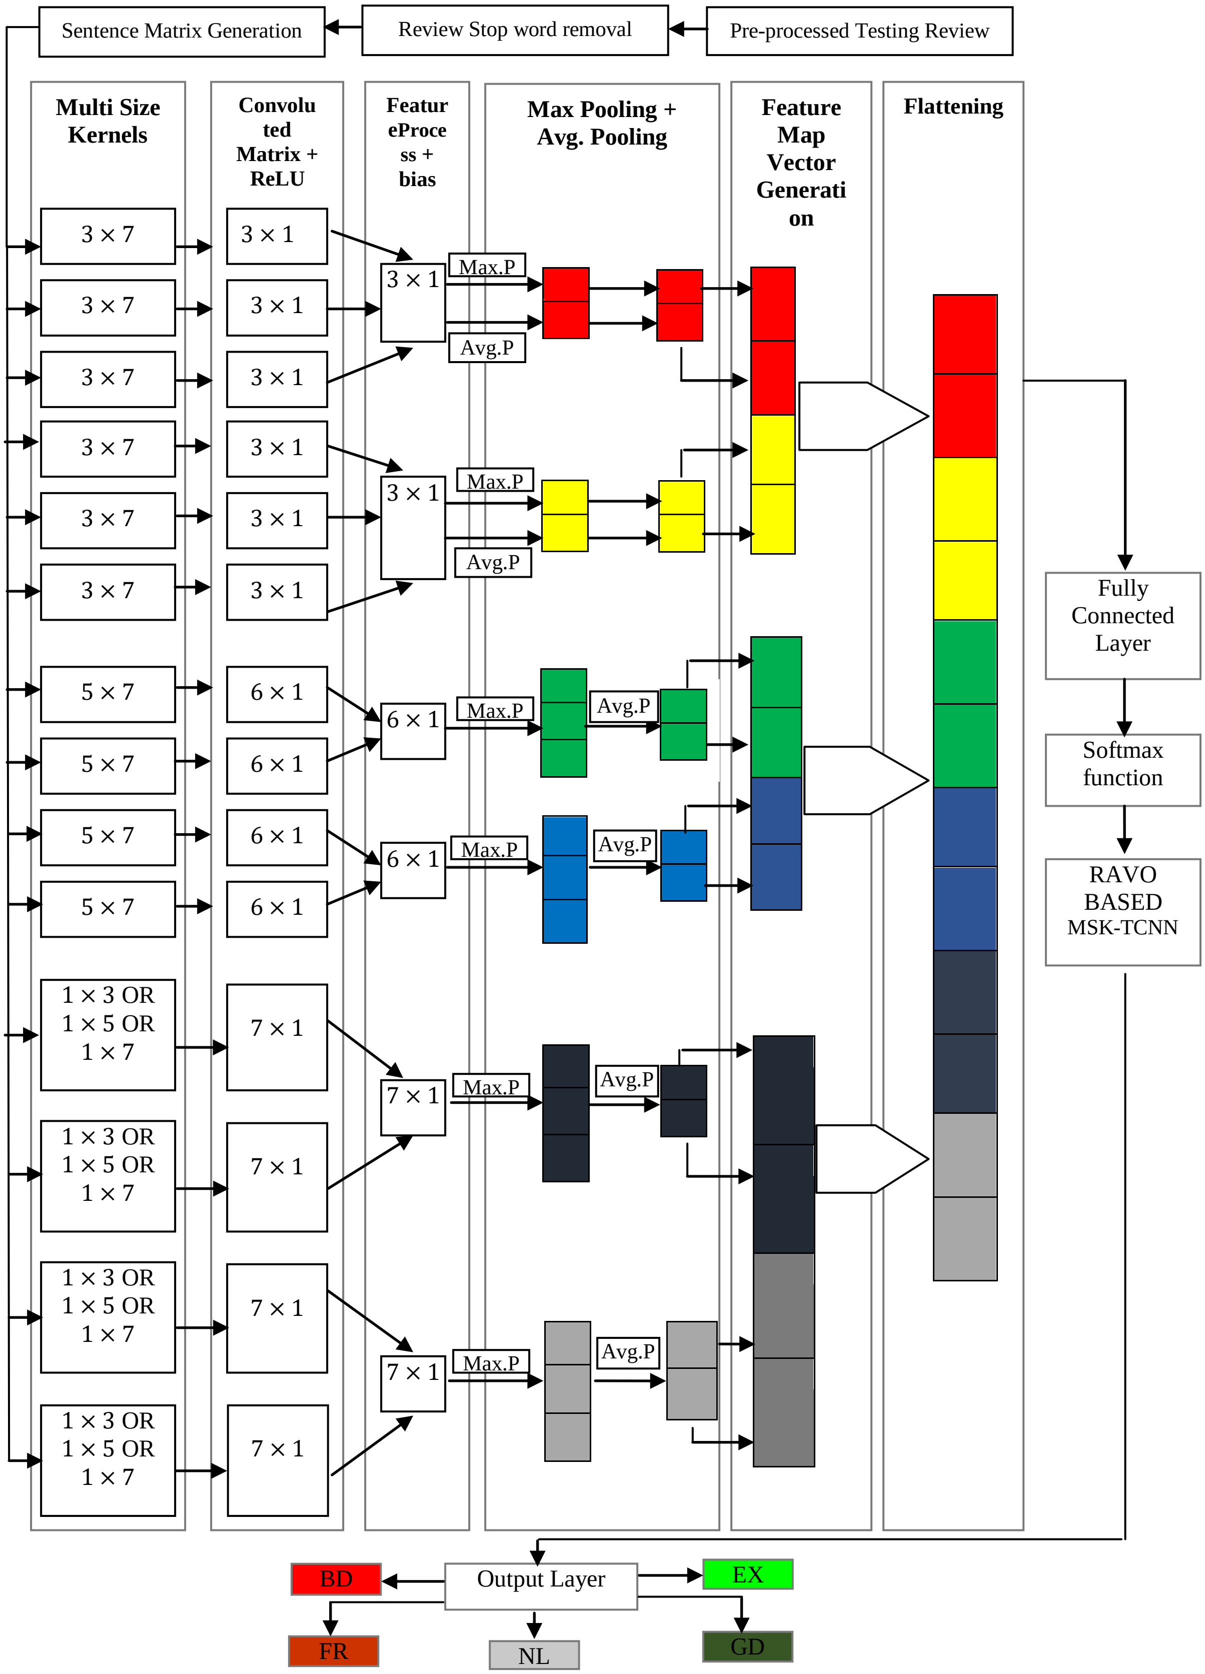

Fig. 11. Architecture Diagram of the Testing Section of the Proposed MSK-TCNN-RAVO Method.

C. RAVO Driven MSK-TCNN

The proposed MSK-TCNN-RAVO network is driven by Rider driven African vulture optimization algorithm based on over taker's strategy of rider optimization algorithm. The parameters of the MSK-TCNN-RAVO is tuned by considering the significant parameters of RAVO such as multi kernel size (M_{ks}), Pooling type (P_o), and Feature map Vector (F_{mv}). These parameters are analyzed using (19).

$$T_p = \{M_{ks=1\ to\ t} \,||F_{mv=1\ to\ t} \,||P_{o=1\ to\ t}\} \tag{19}$$

Where, T_p denotes the hidden layers to be optimized in which t represents the initialization parameters of RAVO from MSK-TCNN-RAVO. In addition to the hidden layers, number of epoch, learning rate, batch size are considered as the hyper parameters for obtaining maximum efficiency in terms of performance matrices such as accuracy, precision, recall, F-Score, Time taken, MSE, Misclassification ratio, ranking index, etc. Moreover, these parameters are taken from MSK-TCNN to evaluate the performance based on Mean Square Error (MSE) and Logarithmic Loss. The MSE is considered as a fitness value of MSK-TCNN-RAVO that is processed until it reaches the minimal MSE. Equation (20) is considered as fitness evaluation.

$$F_{(T_p)} = \min(MSE\ , lss) \tag{20}$$

After the initialization of the fitness value the following equation is utilized for determining the best solution.

$$R_i = \begin{cases} Best_{sol1} & if\ p_i = L_1 \\ Best_{sol2} & if\ p_i = L_2 \end{cases} \tag{21}$$

The selection of best solution is obtained by Roulette wheel selection strategy as shown in Equation (22).

$$p_i = \frac{F_{(T_p)}}{\sum_{iter=1}^{n} F_{(T_p)}} \tag{22}$$

Where, R_i and $F_{(T_p)}$ are, respectively, the probability solution and the fitness solutions of each individual as i. This process is repeated until reaches the n number of iterations. This strategy enhances the diversity in AVOA. Then the second strategy of AVOA is rate of starvation which is determined using (23) and (24).

$$s = t \times \left(sin^w\left(\frac{\pi}{2} \times \frac{iter}{maxiters}\right) + \cos\left(\frac{iter}{maxiter}\right) - 1\right) \tag{23}$$

$$V_s = (2 \times rand_1 + 1) \times z \times \left(1 - \frac{iter}{maxiter}\right) + s \tag{24}$$

Where, V_s denotes the satiated vultures, i denotes the iteration, $maxiter$ denotes the maximum iteration, z denotes the random number in range (-1 and 1), t represents the random value in range (0 and 1). Here, the starvation of vulture is determined by $z < 0$ and $z > 0$ conditions, that show vulture is starved and not starved, respectively. According to this RAVO is executed exploration strategy.

$$\text{P (i+1)} = \begin{cases} \mathrm{R(i) - D(i)} \times V_s \text{ if } \mathrm{P_1} \geq \mathrm{rand_{P_1}} \\ \mathrm{X \times R(i) - P(i)} \text{ if } \mathrm{P_1} < \mathrm{rand_{P_2}} \end{cases} \tag{25}$$

Where, $P(i+1)$ is new position vector, V_s denotes the number of vulture gratified using (24) in the current iteration. Moreover, the variables in the following denotes

X➔ Coefficient vector to maximize the random motion that is measured using $\mathrm{X} = 2 \times \mathrm{rand}$ in which rand is random number in range of 0 and 1.

P (i)➔ The position vectors of the current iteration.

$$\mathrm{P(i+1) = R(i)} - V_s + \mathrm{rand_2} \times ((\mathrm{up_b} - \mathrm{lw_b}) \times \mathrm{rand_3} + \mathrm{lw_b}) \tag{26}$$

In aforementioned Equation (26), $\mathrm{rand_2}$ is the random value in range of 0 and 1. $\mathrm{lw_b}$, and $\mathrm{up_b}$ are the variable that lower bound and upper bound, respectively. The Equation (26) is utilized to generate random solution based on the range of $\mathrm{lw_b}$, and $\mathrm{up_b}$. The "$\mathrm{rand_3}$", increases the coefficient of random. Here, $\mathrm{rand_3}$ reaches nearly 1, it disseminates the solution with similar order that increases random motion based $\mathrm{lw_b}$. Therefore, the diversity can be increased and explored maximum search space solution. Then, the model is moving on exploitation strategy if the $|F_{(T_p)}|$ has obtained below 1.

D. Exploitation

The exploitation has incorporated with two strategies where $\mathrm{P_2}$ and $\mathrm{P_3}$ are the parameters to determine the strategy to be executed. The ranges of these parameters are initialized at 0 and 1 before executing the searching process.

(i) Phase 1

In the first phase, the exploitation is obtained only when the value of $\left|F_{(T_p)}\right|$ reaches between the range of 1 and 0.5. Here, determining the $\mathrm{P_2}$ value is highly significant before the execution of searching process with the range between 0 and 1. Here, the "$\mathrm{rand_{P2}}$", generates random number between 0 and 1. If $\mathrm{rand_{p2}} \geq \mathrm{P_2}$, the Siege-fight strategy is executed. Conversely, if $\mathrm{rand_{p2}} < \mathrm{P_2}$, rotation flight is processed. The mathematical formula of this is shown in (27).

$$\mathrm{P(i+1)} = \begin{cases} \mathrm{D(i)} \times \left(F_{(T_p)} + \mathrm{rand_4}\right) - \mathrm{d(t)}\text{if } \mathrm{P_2} \geq \mathrm{rand_{p2}} \\ \quad \mathrm{d(t) = R(i) - P(i)} \qquad \text{if } \mathrm{P_2} \geq \mathrm{rand_{p2}} \end{cases} \tag{27}$$

1) Competition for food: If the condition has obtained $\left|F_{(T_p)}\right| \geq 0.5$, means that the vultures in the environment are highly satiated and they have considerable energy for surviving. This can be determined by Equation (28).

$$D(i) \times (V_s + rand) - d(t)$$

$$d(t) = R(i) - P(i) \tag{28}$$

Where, $D(i)$ is evaluated using (27), V_s denotes the rate of vulture satiated, $rand_4$ denotes the random number ($0\ and\ 1$) helps for generating random coefficient.

Then the vulture nest strategy is rotating flight that is based on spiraling between whole vulture and one of the two best vultures. The mathematically formulation of these strategy is shown in (29) and (30).

$$S_1 = R(i) \times \left(\frac{rand_5 \times p(i)}{2\pi}\right) \times \cos(p(i)) \tag{29}$$

$$S_2 = R(i) \times \left(\frac{rand_6 \times p(i)}{2\pi}\right) \times \sin(p(i)) \tag{30}$$

$$P(i+1) = R(i) - (S_1 + S_2) \tag{31}$$

Where,

$R(i)$ is executed based on same strategy as earlier mentioned. Cos and Sin are utilized in this work based on sine and cosine function. $rand_5$ and $rand_6$ are random number generated in the range of 0 and 1. S_1, and S_2 are generated using (29) and (30). Equation (31) to update the newly generated solution.

(ii) Phase 2:

In the second phase of exploitation, the two vultures' movements accumulate several types of vultures over the food source, and the siege and aggressive strive to find food are carried out. If $\left|F_{(T_p)}\right| \leq 0.5$, this phase is relying on $rand_{p3}$ in the range (0 and 1). If $rand_{p3} \geq p_3$, various vultures are accumulating over the food. Otherwise, if $rand_{p3} < p_3$, the aggressive siege flight strategy is executed. The mathematical formulation of this is shown in equation (32).

$$P(i+1) = \begin{cases} equ\ (31) if\ rand_{p3} \geq P_3 \\ equ\ (32) if\ rand_{p3} < P_3 \end{cases}$$

$$A_1 = Best_{Vult_1}(i) - \frac{Best_{Vult_1}(i) \times p(i)}{Best_{Vult_1}(i) \times p(i)^2} \times F$$

$$A_2 = Best_{Vult_2}(i) - \frac{Best_{Vult_2}(i) \times p(i)}{Best_{Vult_2}(i) \times p(i)^2} \times F$$

$$(i+1) = \frac{A_1 + A_2}{2} \tag{32}$$

a) Aggressive Competition for Food

If $|F_{(T_p)}|$ < 0.5 occurs, repositioning the vultures using equation (33)

$$P(i+1) = R(i) - |d(t)| \times over_t\ (d) \tag{33}$$

Here, the updating strategy of Rider Optimization is executed especially based on over taker's strategy. This strategy helps to enhance the performance of AVOA. Therefore, Rider based enhanced AVOA can make highly effective performance.

$$over_{t+1}^{0}(\text{iter, k}) = over_t(i,k) + [d^Z(t)] * X^{hv}(hv,k)$$

Where, $over_t(i,k)$, represents the iter_{th} vulture in the k_{th} coordinates, $d^Z(t)$, represents the direction of i_{th} rider at the time t, and in the range (-1 and 1) $X^{hv}(hv,k)$, represents the head vulture in the k_{th} coordinates. Moreover, the computation of $d^Z(t)$ is achieved by using (34) to (36).

$$d^Z(t) = \left[\frac{2}{1-\log(S_t^R(iter))}\right] - 1 \tag{34}$$

$$S_t^R(i) = \frac{r_t(i)}{max_{i=2}^{R} r_t(i)} \tag{35}$$

$$r_t\ (i) = \frac{1}{||X_i - L_T||} \tag{36}$$

$S_t^R(i)$ represents the relative success rate of the i_{th} vulture at the time t and it will be in the interval of 0 and 1. Finally, determine the coordinate selection based on normalized distance vector that obtained by gauging the difference of i_{th} vulture and head vulture using equation (37).

$$l(i,j) = |X_t(i,j) - X^h(h,j)| \tag{37}$$

The value of j is selected for $l(i,j)th$ values are less than its fitness value. Therefore, the Rider's over taking strategy improves the performance by replacing Levy fight strategy. The RAVO can provide high performance than traditional African Vulture Optimization algorithm.

IV. Analysis and Discussion

This section is very important in any research paper which portrays the efficiency of the proposed or the other existing methods. The proposed MSK-TCNN-RAVO classification task is compared with three existing methods mentioned below:

1) Weakly supervised deep embedding for review Sentence sentiment classification (WS_RSSC) [28].

2) Sentiment similarity analysis based mining of user's trust from e-commerce reviews (SSA_TER) [29].

3) CNN based multiple convolution and pooling for text sentiment classification (CNN_MCP_TSC) [30].

In order to test the proposed MSK-TCNN-RAVO classifier, the training and testing reviews are taken from five benchmark databases. The product reviews from different categories such as Mobile, Laptop, and Camera are taken from Amazon website. The names of the different datasets are given below:

1) Dataset of Laptop Product Review (DS1_LPR) [28].

2) Dataset of Camera Product Review (DS2_ CPR) [28].

3) Dataset of Mobile Product Review for NOKIA 3310 (DS3_MPR3310) [28].

4) Dataset of Mobile Product Review for SAMSUNG EPIC 4G (DS4_MPRSE4G) [31].

5) Dataset of Mobile Product Review for NOKIA 105 (DS5_MPR105) [32].

From each dataset, 7000 reviews are extracted, out of that, 4000 reviews are utilized for training and the remaining 3000 reviews which are completely new to the MSK-TCNN-RAVO classifier is used for testing purpose to ensure the classifier's efficiency. Following that, 2000 more reviews are extracted from the training samples to act as test reviews, totaling 5000 test reviews for each dataset.

A. *Classification Accuracy*

The Accuracy of the classifier is computed using (38) and its values are represented in Table I.

$$Accuracy = \frac{TP+TN}{(TP+FP+FN+TN)} \tag{38}$$

A true positive (TP) is an outcome where the model correctly predicts the positive class. Similarly, a true negative (TN) is an outcome where the model correctly predicts the negative class. A false positive (FP) is an outcome where the model incorrectly predicts the positive class. And a false negative (FN) is an outcome where the model incorrectly predicts the negative class.

TABLE I. CLASSIFICATION ACCURACY ANALYSIS FOR FIVE DATABASES AND FOUR METHODS

Database Name	**Classification Accuracy (%)**				
	WS_RSSC Method	**SSA_TER Method**	**CNN_MCP_TSC Method**	**Proposed MSK-TCNN-RAVO Method (Before RAVO)**	**Proposed MSK-TCNN-RAVO Method (After RAVO)**
DS1_ LPR	78.2	79	80.5	**86.7**	**90.6%**
DS2_ CPR	77.6	77.3	78.9	**84**	**89.6%**
DS3_ MPR3310	80.1	81.5	82.4	**89.6**	**93.2%**
DS4_ MPRSE4G	81.8	82.6	84	**90.5**	**95.5%**
DS5_ MPR105	79.3	80.4	81.4	**88.9**	**92.4%**

The accuracy of the proposed model is high in all datasets when compared to other models. The highest accuracy is produced for the DS4_MPRSE4G dataset which is 95.5% after performing optimization via RAVO. The result shows that the proportion of classified true results produced by the proposed work is high when compared to other models.

B. *Precision*

Precision measures the exactness of a classifier. It can be calculated using (39).

$$Precision = \frac{TP}{TP+FP} \tag{39}$$

The average precision values are represented in Table II. The precision is computed for each method for all the five datasets. Average precision of a specific method is computed by averaging the precision value of five datasets. The precision value for a specific dataset is computed by testing 5000 test review samples. The proposed methodology has a higher precision value, indicating that the proposed model produces less false positives, implying that the proposed model's prediction is more reliable. The average value of the proposed method is 0.89

TABLE II. AVERAGE PRECISION ANALYSIS FOR FOUR METHODS

Method	**Average Precision**
WS_RSSC Method	0.74
SSA_TER Method	0.80
CNN_MCP_TSC Method	0.79
Proposed MSK-TCNN-RAVO Method	**0.89**

C. *Recall*

Recall measures the completeness, or sensitivity, of a classifier. Higher recall means less false negatives, while lower recall means more false negatives. The Recall can be calculated using (40).

$$Recall = \frac{TP}{(TP+FN)} \tag{40}$$

The average recall values are depicted in Fig. 12. The MSK-TCNN-RAVO method achieves the higher recall value of 0.895 which indicates that the percentage of true positives correctly classified by the proposed model is high compared to other existing models.

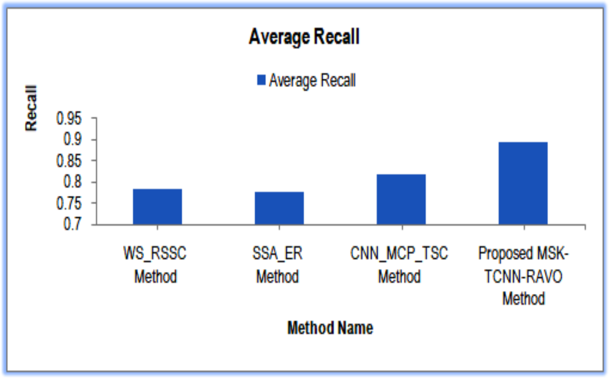

Fig. 12. Average Recall Analysis for Four Methods.

D. F-Score

In F-Score, precision and recall can be combined to produce a single metric known as F-measure, which is the weighted harmonic mean of precision and recall. The F-score can be calculated using (41).

$$Fscore = \frac{2*(precision*Recall)}{(Precision+Recall)} \tag{41}$$

The F-Score analysis is represented in Fig. 13. The F-Score value corresponding to a specific method and particular database is computed by processing the 5000 test review samples. Highest F-score value 0.947 is achieved by the MSK-TCNN-RAVO method for the DS4_MPRSE4G dataset.

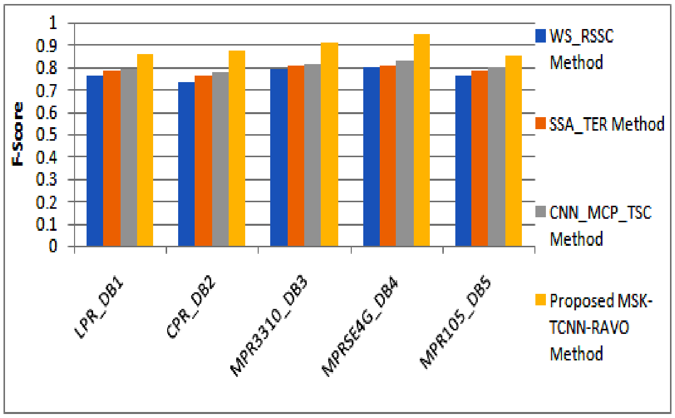

Fig. 13. F-Score Analysis for Five Database and Four Methods.

E. Mean Square Error

In Machine Learning, main goal is to minimize the error which is defined by the Loss Function. It can be computed using (42). The MSE analysis values are listed in Table III.

$$MSE = \frac{1}{N}\sum_{i=1}^{N}(PR_i - GT_i)^{\,2} \tag{42}$$

Here, N denotes the No. of samples tested, PR_iindicates the predicted class for ith sample, and GT_i denotes the ground truth class for ith sample.

It can be observed from the Table III that the MSE value for the proposed method is drastically minimized after the RAVO optimization. The least error value after optimization is 426, which indicates that the proposed method's prediction error rate is very low when compared to the other three current models. The WS_RSSC method produces the highest error value of 1090 in this analysis for the DS1_LPR dataset.

F. Cross Entropy

This metric is used in neural networks when a classifier's output is multiclass prediction probabilities. In general, minimizing categorical cross-entropy gives greater accuracy for the classifier [33]. It can be computed using (43), and it's computed values are depicted in Fig. 14.

$$LogarithmicLoss\ (lls) = -\frac{1}{N}\sum_{i=1}^{N}\sum_{j=1}^{M} y_{ij}\ * \log(p_{ij}) \tag{43}$$

TABLE III. MSE ANALYSIS FOR FIVE DATABASES AND FOUR METHODS

Database Name	MSE				
	WS_RSSC Method	**SSA_TER Method**	**CNN_MCP_TSC Method**	**Proposed MSK-TCNN-RAVO Method (Before RAVO)**	**Proposed MSK-TCNN-RAVO Method (After RAVO)**
DS1_ LPR	**1090**	1050	975	**665**	**615**
DS2_ CPR	1120	1135	1055	**800**	**745**
DS3_ MPR3310	995	925	880	**520**	**473**
DS4_ MPRSE4G	910	870	800	**475**	**426**
DS5_ MPR105	1035	980	930	**555**	**503**

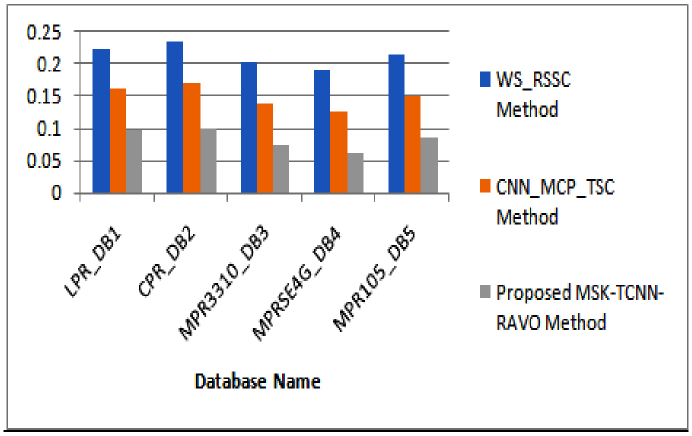

Fig. 14. Cross Entropy Analysis for Five Databases and Three Methods.

Here,$y_{ij} = 1$, if the sample i belongs to class j else 0. p_{ij} is the probability of the classifier that predicts of sample i belonging to class j. Since, the SSA_TER method is not coded based on neural network, this analysis is performed for the other three methods and all datasets. The proposed method gives a least value of **0.**0619 after RAVO optimization on DS4_MPRSE4G dataset which means it gives high probability for classified data with more stabilized value.

G. Time Taken

In time taken analysis, the time consumed by the methods to produce the classification results is evaluated. The time taken by all methods is listed in Table IV.

In this analysis, WS_RSSC method takes the least execution time for all datasets. But, when considering the classification accuracy of the proposed method, the excess time taken by the proposed model is acceptable. The time consumption difference between WS_RSSC and the MSK-TCNN-RAVO classifier is very less i.e., 1.26 seconds. Similarly, the time consumption difference between CNN_MCP_TSC and the proposed classifier is only 0.76 seconds.

TABLE IV. TIME TAKEN ANALYSIS FOR FIVE DATABASES AND FOUR METHODS

Database Name	Time Taken (in seconds)			
	WS_RSSC Method	SSA_TER Method	CNN_MCP_TSC Method	Proposed MSK-TCNN-RAVO Method
DS1_ LPR	5.472	5.892	7.513	**6.726**
DS2_ CPR	5.593	5.986	7.742	**6.995**
DS3_ MPR3310	5.401	5.802	7.298	**6.497**
DS4_ MPRSE4G	5.512	5.923	7.632	**6.883**
DS5_ MPR105	5.456	5.841	7.396	**6.654**

H. *Misclassification Ratio*

This analysis is carried out to determine the ratio of incorrect classification results generated by the classifier. It can be computed using (44). The ratios of misclassified results generated by all the methods are depicted in Fig. 15.

$$Misclassification = \frac{FP+FN}{Total\ Data} \qquad (44)$$

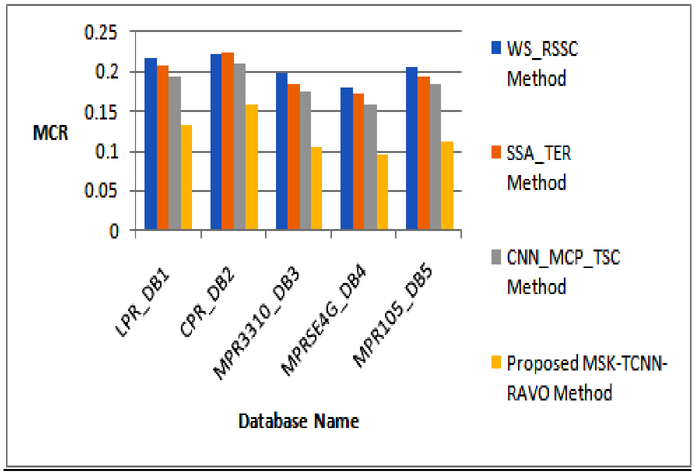

Fig. 15. Misclassification Ratio Analysis for Five Databases and Four Methods.

From the analysis, the misclassification ratio produced by the proposed method is very low for DS4_MPRSE4G dataset which is 0.095. It shows that the proposed classifier produces very low incorrect classification results. The second best method which has less misclassification ratio is CNN_MCP_TSC which has 0.160 for the same dataset.

I. *Performance based Ranking İndex*

This analysis ranks the review classification methods based on the ranking index. The ranked values are depicted in Fig. 16.

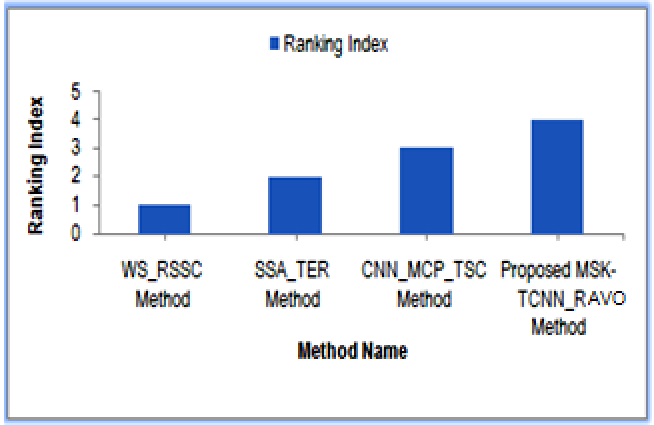

Fig. 16. Ranking İndex Analysis for the Four Methods.

According to classification accuracy, precision, f-score, recall, mean square error, cross entropy, misclassification results, and the ranking index of each method is decided. The best method among the four methods is set with rank 4, i.e., the highest rank. The second best method is ranked by 3 and so on. Hence, from the above Fig. 16, the proposed method achieves the highest fourth rank which shows it is the best method for review classification than the other existing methods.

V. CONCLUSION

In this work, a classification method namely MSK-TCNN-RAVO is proposed for e-commerce reviews. The proposed algorithm is executed on five different datasets from three different domains utilized for experimentation and efficient analysis, with 7000 review samples per database being used for training and testing the proposed classifier. The MSK-TCNN-RAVO classifier achieves the highest classification accuracy of 95.5% when compared to other three existing algorithms such as WS_SSC, SSA_TER, and CNN_MCP_TSC which achieves the accuracy of 81.8%, 82.6%, and 84% respectively. The highest F-Score value of 0.947 is achieved by the proposed method when compared to other three methods. The proposed MSK-TCNN-RAVO classifier outperforms the other three approaches in all metrics, and it consistently performs well on the DS4_MPRSEG4 dataset. When compared to the WS_RSSC technique, the proposed classifier improves classification accuracy by 8.54% before RAVO and 12.86% after RAVO optimization. Furthermore, the MSK-TCNN-RAVO classifier achieves the highest values on all evaluation metrics such as Classification accuracy, Precision, Recall, F-Score, MSE, Cross entropy, and Misclassification ratio, which proves that the proposed method is well suited for opinion mining. When processing the emoticons in the input reviews, the computing complexity of the proposed work grows. Additionally, a slight tweak to the method will be planned to address the increased CPU utilization observed when the emojis are being trained into the classifier. In future work, it is intended to modify the coding to extend the MSK-TCNN-RAVO classifier to produce hepta classifier which classifies the reviews into seven mode classification results. Furthermore, in order to further enhance the classification accuracy and reduce processing time, an extended stop words list will be employed as a future improvement to eliminate basic stop words and survey stop words in the preprocessing phase.

***Abstract*—Computer vision has its numerous real-world applications on Visual Object Tracking which includes human-computer interaction, autonomous vehicles, robotics, motion-based recognition, video indexing, surveillance and security, human-computer interaction, autonomous vehicles, robotics, motion-based recognition, video indexing, surveillance and security. The factors affecting the tracking process is due to low illumination, haze and cloudy environment and noisy environment. In this paper, we aim to extensively review the latest trends and advances in adaptive enhancement algorithm and evaluate the performance using Full reference like, SSIM (Structure Similarity Index Measure), MS-SSIM (Multi-scale Structure Similarity Index Measure), ESSIM (Edge Strength Structural Similarity Index), FSIM (Feature Similarity Index Measure), VIF (Visual Information Fidelity), CW-SSIM (complex wavelet structural similarity), UQI (Universal Quality Index), IEF (Image Enhancement Factor), IQI (Image Quality Index), EME (Enhancement Measurement Error), CVSI (Contrast and Visual Salient Information), MCSD (Multiscale contrast similarity deviation), NQM (Noise Quality Measure), Gradient Magnitude Similarity Mean (GMSM), Gradient Magnitude Similarity Deviation (GMSM) and no-reference image quality measures Perception based Image Quality Evaluator (PIQE), Blind/Reference less Image Spatial Quality Evaluator (BRISQUE), Naturalness Image Quality Evaluator (NIQE), Average Gradient (AG), Contrast, Information Entropy (IE), Lightness order Error (LOE). The main purpose of adaptive image enhancement is to smooth the uniform area and sharpen the border of an image to improve its visual quality. In this paper, fourteen image enhancement algorithms were tested on LoL dataset to benchmark the time taken to process them and their output quality was evaluated. Results from this study will give insights to image analysts for selecting image enhancement algorithms which acts as a pre- processing stage for Visual object Tracking.**

***Keywords*—Tracking; robotics; surveillance; enhancement**

I. Introduction

In weakly illuminated environments, the images and video quality are often degraded. This leads to reduction in the performance of particular systems, such as those used in consumer electronics, visual surveillance and intelligent traffic analysis. For example, the low lighting conditions in nighttime environments can produce images and video with low contrast, which reduces the visibility [1]. Digital images used with contemporary imaging- and vision-related applications [2] and capturing the image in inappropriate lighting environment have a low-light effect, deficient contrast, and improper colors [3]. Therefore, it is very difficult to capture images with high-quality in that the low-light effect environment which may reduce the performance related to image processing and computer vision applications [4, 5], and such images usually comprise of vast dark regions with reduced visibility [6]. Samples of such images are shown in Fig. 1. There exist various image enhancement algorithms for improving the quality of images acquired under cloudy or other conditions.

Fig. 1. Various Types of Low-light Images. (a) Night Time Image; (b) Unevenly illuminated Image; c) Shadowed Environment Image; d) Image with a Dark Appearance.

Lowlight images are images that have a dark appearance, have uneven illumination, and they are captured in a shadowed environment [7]. The input parameters for these algorithms can vary from very minimal to relatively extensive. Depending on the algorithm the time taken to process an image can also vary. Based on the type of algorithm used and the input parameters specified the output quality of the resultant image will be different. Given with numerously available image enhancement algorithms, it is not feasible to evaluate all of them to determine their suitability. The primary objective of this study is to evaluate a suite of commonly used

*Corresponding Author.

image enhancement algorithms on low-illumination images. In the first phase of this study, fourteen image enhancement algorithms like Improved Type-II Fuzzy Set-based Algorithm, Retinex-based Multiphase Algorithm, Fusion-based enhancing method, Adaptive Image Enhancement Method for Correcting Low-Illumination Images, Fast efficient algorithm for enhancement of low lighting, A Multiscale Retinex, Bio-inspired multiexposure fusion frame work, Deep low light image enhancement, Adaptively Increasing Value Histogram Equalization (AIVHE)) were tested on LOL dataset to benchmark the quality of the output image and the time taken to process them.

Due to the rapid development of image enhancement technology, various enhancement algorithms such as retinex model [9–11], fuzzy theory [12, 13], Fusion based approach [14, 15], Deep learning Approach [16,17], Histogram Equalization based approach [18,19] etc. were developed. For example, as shown in Fig. 2, around 250 literatures on image enhancement algorithms were studied. The methods involved mainly include histogram equalization, Retinex model, Fusion based Approach, Fuzzy based approach and deep learning methods. Each of the image enhancement methods has their own advantages as well as disadvantages. The eye of a human has the ability of filtering the influence of light and obtains the reflectivity of the surface of the object to determine colour. Therefore, the formation of a low-light image can be described as follows:

$$L(x,y)=R(x,y)\cdot B(x,y) \tag{1}$$

where L(x, y) is the original image, R(x, y) is the reflection image, B(x, y) is the illuminance image and (x, y) is the pixel coordinates.

In this paper, we provide the progress of image enhancement algorithms during the past two decades. We mainly introduce the image enhancement methods separately in three aspects based on supervised methods, unsupervised methods and quality evaluation. The block diagram of the whole framework is shown in Fig. 3 in this paper.

The rest of paper is organized as follows. Section III introduces the image enhancement techniques based on Fuzzy based, Retinex based and Fusion based, Histogram based and Deep learning-based approach. Section IV elaborates in detail the image quality assessment using Full-reference, No-reference and Image Error Measurement. Section V deal with the results and discussions. Sections VI elaborates about results and discussions.

II. Datasets Used

The LOL dataset comprise of 500 low-light and normal-light image pairs and divided into 485 training pairs and 15 testing pairs. Most of the images are indoor scenes. The resolution of all images is 400×600.

III. T2FS, RB and HE based Image Enhancement

A. T2FS[20]

A Type-II fuzzy set (T2FS) based algorithm [20] was introduced for enhancing the contrast of grayscale medical images. This algorithm improves the contrast by Fuzzifying the image. Then, apply the Type-II fuzzy membership function are determined with the lower and upper ranges of the Hamacher t-conorm, where, α is a parameter that controls the amount of contrast enhancement, in that it should satisfy $0 < \alpha \leq 1$, when $\alpha > 0.6$, better contrast enhancement is obtained [20]. An improved type-II fuzzy set (IT2FS) algorithm [21], using Fuzzified image followed by Hamacher t-conorm method and then finally applying Gamma Correction The enhanced output of Improved Type-II fuzzy set-based algorithm with different α values is as shown in the Fig. 4(a) When α is between 0.3.5 and 0.55, the results will be obtained with satisfactory visual quality. When increasing α, the brightness is reduced while the contrast is enhanced selecting the proper value of α leads to desired results. To produce satisfactory results the proper gamma value can be around 0.50.

B. Retinex based Algorithm

Zou, Y et al. [22] and Kallel, F et al. [23] introduced various image enhancement algorithms for contrast enhancement in CT images. There exists different low-intricacy concept which improves the image illumination. Among such concepts, the single-scale retinex (SSR) model proposed by Jobson et al. [24] was examined because it involves simple calculations and improves the illumination of images. In brief, the SSR model works by estimating an illumination image from its degraded counterpart by performing a discrete convolution (*) between a degraded image and a discrete 2D Gaussian surround function (DGSF) [25].

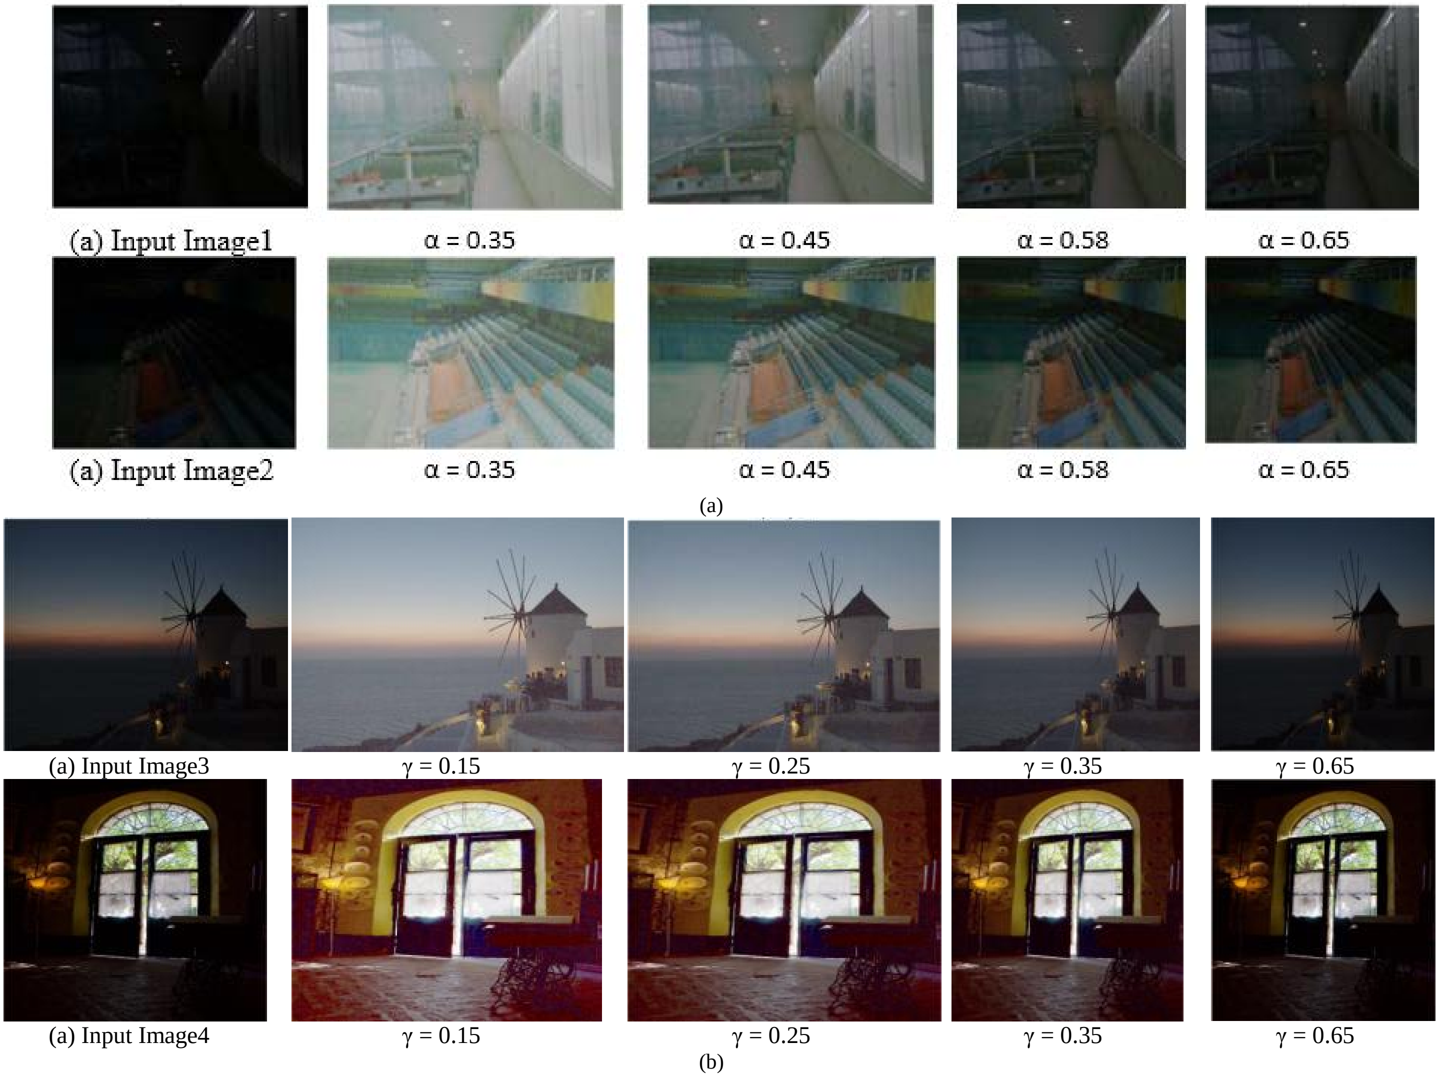

Fig. 4. (a) Type-II Fuzzy Set-based Algorithm with different α Values, (b) Retinex-based Multiphase Algorithm with different γ Values.

1) RBMA [26]: Mohammad Abid et al. [26] proposed RBMA which involves in determining the log of the illumination and the original images followed by computation of GCS (Gama Corrected Sigmoid function) .The enhanced output of Retinex-based Multiphase Algorithm with different values of γ is as shown in the Fig. 4(b).

Intensive experiments reveal that acceptable quality results are obtained when the γ value is between 0.1 and 0.35.

2) FBEM [27]: Xueyang Fu et al. [27] employed an illumination estimating algorithm based on morphological closing image and an illumination image. The two inputs - improved and contrast-enhanced versions of the first decomposed illumination were derived using the sigmoid function and adaptive histogram equalization. Designing two weights based on these inputs, an adjusted illumination is produced by fusing the derived inputs with the corresponding weights in a multi-scale fashion. Through a proper weighting and fusion strategy, the advantages of different techniques are blended to produce the adjusted illumination. The final enhanced image is obtained by compensating the adjusted illumination back to the reflectance.

In this fusion-based framework, images under different weak illumination conditions such as non-uniform illumination, backlighting, and nighttime can be enhanced.

3) AIEM [28]: Wencheng Wang et al. [28] proposed Adaptive Image Enhancement Method for Correcting Low-Illumination Images. The original RGB image is converted to HSV color space, and the V component is used to extract the illumination component of the scene using the multiscale Gaussian function. Then based on the Weber-Fechner law, a correction function is constructed, and two images are obtained through adaptive adjustments to the image enhancement function parameters based on the distribution profiles of the illumination components. Finally, an image fusion strategy is formulated and used to extract the details from the two images. Compared with the classic algorithm, the AIEM algorithm can improve the overall brightness and contrast of an image and the enhanced images appear clear, bright, and natural.

4) FEAE [29]: Xuan Dong et al. [29] proposed a Low lighting video enhancement algorithm by applying the invert operation on low lighting video frames, and then performing haze removal on the inverted video frames, before performing the invert operation again to obtain the output video frames.

5) LIME [30]: Xiaojie Guo et al. [30] proposed an effective low-light image enhancement (LIME) method. More concretely, the illumination of each pixel is first estimated individually by finding the maximum value in R, G and B channels. Further, we refine the initial illumination map by imposing a structure prior on it, as the final illumination map. Having the well-constructed illumination map, the enhancement can be achieved accordingly.

6) BIMEF [31]: Zhenqiang Ying et al. [31] proposed a framework mainly consists of four main components:

The first component, named Multi-Exposure Sampler, determines how many images are required and the exposure ratio of each image to be fused; the second component, named Multi-Exposure Generator, use a camera response model and the Specified exposure ratio to synthetic multi-exposure images; the third component, named Multi-Exposure Evaluator, determines the weight map of each image when fusing; the last component, named Multi-Exposure Combiner, is to fuse the generated images to the final enhanced result based on the weight maps.

7) SRIE [32]: In this paper, a weighted variational model for simultaneously estimating reflectance and illumination is presented. First, by analyzing the characteristic of the logarithmic transformation, we show that the logarithmic transformation is not proper to be directly used as regularization terms. Then, based on the previous analysis, a weighted variational model is introduced for better prior representation and an alternating minimization scheme is adopted to solve the proposed model.

8) NPEA [33]: Shuhang Wang et al. [33] proposed an enhancement algorithm for non-uniform illumination images. In general, this paper makes the following three major contributions. First, a lightness-order error measure is proposed to access naturalness preservation objectively. Second, a bright-pass filter is proposed to decompose an image into reflectance and illumination, which, respectively, determine the details and the naturalness of the image. Third, a bi-log transformation is applied, which is utilized to map the illumination to make a balance between details and naturalness.

9) BPHE [34]: In Brightness Preserving Bi-Histogram Equalization (BBHE) [34], the Input image is splitted into two sub images based on the mean of the input image. Samples of the input image which are less than or equal to mean forms one sub image, the other sub image consists of samples which are greater than the mean. Each of these sub images are independently equalized based on their respective histograms. The first sub image, containing samples less than or equal to mean, are mapped into the range from the minimum gray level to the input mean. The second sub image, containing samples greater than the mean are mapped into the range from the mean to the maximum gray level.

10)MSRA [36]: Daniel J. Jobson et al. [36] extend the designed single-scale center/surround retinex to a multiscale version that achieves simultaneous dynamic range compression/color consistency/ lightness rendition. This extension fails to produce good color rendition for a class of images that contain violations of the gray-world assumption implicit to the theoretical foundation of the retinex. Therefore, we define a method of color restoration that corrects for this deficiency at the cost of a modest dilution in color consistency.

11)LightenNet [38]: The purpose of LightenNet [38] is to learn a mapping, which takes a weakly illuminated image as input and outputs its illumination map that is subsequently used to obtain the enhanced image based on Retinex model. The architecture is LightenNet. LightenNet consists of four convolution layers, *i.e.*, patch extraction and representation, feature enhancement, nonlinear mapping, and reconstruction.

IV. Image Quality Assessment

Image Quality Assessment (IQA) is considered as a characteristic property of an image. Degradation of perceived images is measured by image quality assessment. Usually, degradation is calculated compared to an ideal image. Quality of image can be described technically as well as objectively to indicate the deviation from the ideal or reference model. It also relates to the subjective perception or prediction of an image [8], such as an image of a human look. Image Quality Assessment is grouped into two categories based on the availability of a reference image. The categories of Image Quality assessment methods are as shown in Fig. 5.

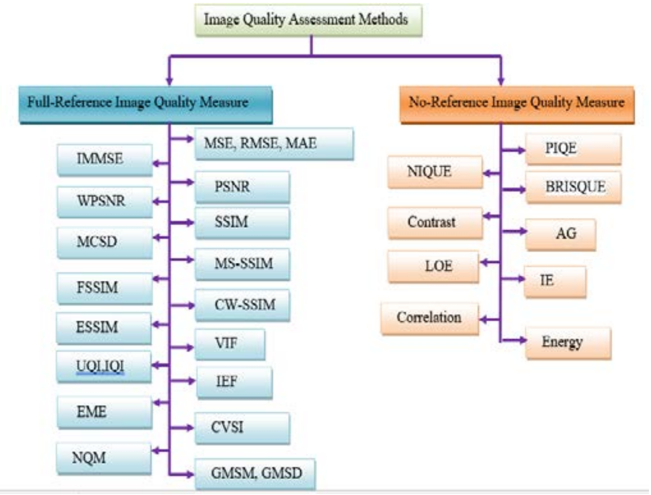

Fig. 5. Categories of Image Quality Assessment Methods.

V. Results and Discussion

A comparison is made with fourteen methods that are, T2FS [20], RBMA [26], FBEM [27], AIEM [28], FEAE [29], LIME [30], BIMEF [31], SRIE [32], NPEA [33], BPHE [34], CAVIEHE [35], MSRA [36], MSRCR [37], LightenNet [38] and the outcomes of such comparisons are evaluated by 30 metrics. Fig. 6 to 9 demonstrates the comparison results. Table I to Table XXIX exhibit the recorded metrics scores and processing times of the conducted comparison. Fig. 6 demonstrates the comparison results. Fig. 10 shows the GMS map for the entire different algorithm (Table I to Table XXIX) exhibit the recorded metrics scores and processing times of the conducted comparison.

VI. Conclusion and Future Work

Low Light image enhancement formulas are more helpful for various vision applications. It can be found that many of the existing scientific study have neglected a lot of issues; i.e. no technique is precise for different circumstances. The review has demonstrated the undeniable fact that shown methods have neglected the methods to reduce the noise concern which can be shown within the output images of the image enhancement algorithms. The issue of uneven and also over illumination may also be an issue for enhancement methods. So it will be expected to change the prevailing methods in this manner that altered strategy may continue steadily to function better. In near future, to eliminate the issues of present research a different integrated algorithm is going to be proposed.

Table XXX shows the performance evaluation of all Algorithms. In this paper fourteen Image enhancement algorithms were compared and finally LNET gives the best output quality image and LIME method gives the least run time.

***Abstract*—Vegetation density is one type of information collected from vegetation cover. Vegetation density influences evapotranspiration in terrain, which is essential in assessing how vulnerable peatlands are to fire. The Keetch and Byram Drought Index model, which evaluates peatland fire vulnerability, divides vegetation density into heavily grazed, softly grazed, and un-grazed. Manual approaches for analyzing vegetation density in the field, on the other hand, need a significant amount of resources. Image data acquisition, pre-processing, feature extraction, classification, feature selection, classification, and validation are all computer vision approaches used to solve these problems. Artificial intelligence algorithms and machine learning approaches promise outstanding accuracy in modern computer vision research. However, in the classification process, the impact of feature extraction is critical. Pattern identification at Back Propagation Neural Network (BPNN) is problematic because the feature extraction dimension is excessively complicated. The solution to this problem is using the feature engineering technique to choose the characteristics. This research aims to explore how feature engineering influences the accuracy of results. According to the statistics, implementing the recommended strategy can increase accuracy by 1% and increase kappa by 1.5%. This increase in vegetation density classification accuracy might help detect peatland vulnerability sooner. The novel aspect of this paper is that, after feature extraction, a feature engineering strategy is used in the machine learning classification stage to reduce the number of complex dimensions.**

***Keywords*—Vegetation cover; vegetation density; feature extraction; feature engineering; accuracy**

I. Introduction

The Keetch and Byram Drought Index (KBDI) model uses vegetation cover conditions as one of the parameters to generate the land drought index [1]–[5]. The density of vegetation cover in KBDI peat is classified into three groups: extensively grazed, gently grazed, and un-grazed. To quantify peatland fire vulnerability used the KBDI peat drought index[3]. Peatland fires have occurred in South Kalimantan in recent years. The fires have become a more common occurrence. Whether intended or not, human activities are responsible for 99.9% of land fires. The existence of human intervention is referred to as anthropogenic [6]. Automation can predict land fire susceptibility to anthropogenic influences. Land cover analysis can be automated utilising machine-learning artificial intelligence approaches combined with computer vision techniques.

Various researches have attempted to classify vegetation cover using computer vision and artificial intelligence techniques. The precision and accuracy of vegetation cover identification have greatly improved because of advancements in remote sensing data (Dronova et al., 2012; Mihail et al., 2018; Rios et al., 2021). Land classification analysis using remote sensing, on the other hand, necessitates a significant investment of time and money on the part of researchers.

Previous research indicated that using ordinary cameras for automated land cover categorisation could not discern between trees, weeds, and grass. They have not accomplished these difficulties [7]–[9]. Artificial intelligence-based machine learning classification is necessary to distinguish between trees, weeds, and grasses. The classification method consists of a support vector machine (SVM), naive Bayes, and an artificial neural network (ANN) [10]–[13]. According to some of that research, image classification requires feature extraction or the conversion of an image into numerical to be classified using artificial intelligence methods. Features are crucial in the field of image classification and recognition.

On the other hand, previous researchers looked at converting natural colour information (RGB) to more suited colour space and used that to discern between vegetation and non-vegetation. Philipp and Rath [14] distinguish between vegetation and non-vegetation using the Lab, Luv, and HSV colour spaces. However, because the dimensions of feature extraction are too broad and complicated, machine learning techniques perform poorly. By lowering the dimensions of feature extraction, feature engineering can minimise the number of input features [15], [16].

To deal with the challenge of distinguishing between heavily grazed, lightly grazed, and un-grazed. A novel

*Corresponding Author.

technique was developed that combined pre-processing, feature extraction and selection, as well as classification. Segmentation based on distance threshold is employed as pre-processing. We employed grey level concurrent matrix (GLCM) and Backward Elimination to extract and choose the feature. A backpropagation neural network is utilised in the classification approach or analytical methods to distinguish between heavily grazed, lightly grazed, and ungrazed. Based on the approach, a technique for acquiring wetland image data will be developed and tested on pure vegetation stands with a height > 20 m above the canopy [12].

The contribution of this study was validated by comparing the results of feature selection based on the classification method to (1) show the effect of feature selection on classification performance; (2) analyze the relationship between feature selection and image classification performance; (3) determine the parameters needed to achieve the best performance results on the classification model, and (4) present the results of the best classification model for determining vegetation density.

This paper's contents are categorized as follows: Previous works on this research are highlighted in Section II. Section III outlines our research strategy. Section IV explains the materials and methods used in our experiment. The experiment design is described in Section V. Following that Section V summarizes the experiment's results and discussion. Finally, in Section VI, we reach a conclusion.

II. Related Work Use

There have been previous land categorisation studies in general land regions [17]–[19], wetlands [20]–[24], and peatland research [25], [26]. The study by Herdiyeni et al. [8] looked at how to identify plant health by utilising characteristics based on the local binary pattern variant (LBPV) approach, morphological features, and colour features and employed a probabilistic neural network (PNN) with a performance of 72.15%.

The bulk of this research employed artificial intelligence to evaluate land cover using remote sensing data, while field validation was rarely performed. For land cover analysis, the most often used artificial intelligence approaches include supervised machine learning, Back-propagation neural network (BPNN) with an accuracy of 97.65%, support vector machine (SVM) with an accuracy of 97.45%, and neural networks (ANN) with an accuracy of 96.95% [17]. The study of Tan et al. [18] compares the performance of the random forest (RF), decision tree (DT), SVM, and ANN techniques to map three typical landscapes. The results show that ANN performs relatively poorly compared to the performance of other methods. Based on this research, further research is needed to improve the ANN method, which is done in this research. In addition, based on Zaldo-Aubanell et al. [19] stated that this research is important and highly preferred, especially when applying data nationally, and has been carried out by many world researchers to solve their domestic problems. This is the reason for the importance of using data that follows the problems faced nationally.

III. Material and Proposed Method

A. Tools and Location Research

The study took place in Block I of the Liang Anggang protected forest in Banjarbaru, South Kalimantan. Kayu Tangi Production Forest Management Unit [27] is in charge of this area. Fig. 2 depicts the research site. Fig. 2(a) research site in data collecting and Fig. 2(b) location distance between Syamsuddin Noor airstrips illustrate the research location. The nearby population has primarily utilised the existing peatland for agricultural land and plants. Peatlands ranging from shallow (100 — 200 cm) to extremely deep (> 300 cm) encompass 749.87 hectares (78.43 %). According to Zaldo-Aubanell et al. [19] this data based on a national scale and more important also widely used because it adapts more uses to the regional national scale.

B. Proposed Framework

Land cover picture data from the research location was utilised to create the dataset for this investigation. The data used was 450 images taken from drones 20 meters above the item. At this point, the proposed technique processes variables extracted from feature extraction using the Backward Elimination algorithm. Feature selection picks features that influence the BPNN classification process accuracy. The hidden layer, neuron size, momentum, learning rate, and training cycle are BPNN indicators. Measurements are used to determine whether or not the categorization findings are accurate and optimum (Fig. 1).

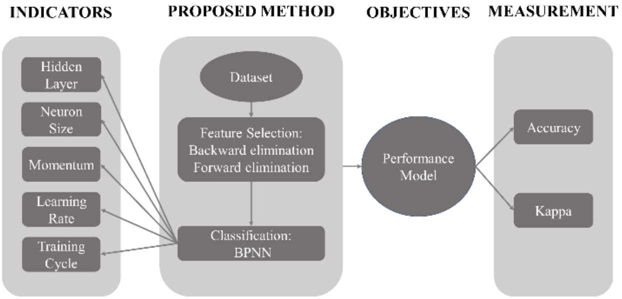

Fig. 1. Research Framework.

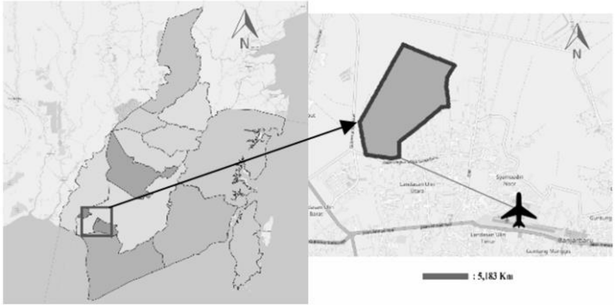

Fig. 2. The Research Location (a) The Location on the Map of South Kalimantan in the Red Box and (b) The Distance from the Syamsuddin Noor Airstrip.

C. Research Design

This research used artificial intelligence based on BPNN as a computer vision methodology to categorise vegetation density. The procedure consists of data capture, pre-processing, segmentation, feature extraction, feature selection, classification, and validation are the steps of classification design. Fig. 3 illustrates the steps.

1) Data acquisition: With a 900-degree gimbal angle, data was collected using a Mavic Pro drone. The drone is positioned at a distance of 20 meters from the object. The information is separated into three categories: heavily grazed, moderately grazed, and ungraded. The three groups will be separated based on the plant growth at the location of the study. Herbs and shrubs that are lightly grazed make up tree vegetation in heavily grazed areas. On the other hand, un-grazed consists of dry (dead) vegetation, rivers (water), land, and towns. Up to 300 images are collected for use as training data.

2) Pre-processing image: This research focuses on vegetation density, and initial image processing is done using a static threshold value. Then segmentation is done using the green colour of the tree as a threshold. This study used the Euclidean distance (equation 1) approach to colour distance-based segmentation.

$$d(x,y) = \sqrt{(x-y)^2} \tag{1}$$

3) Feature extraction: The chosen image is converted into a set of numerical parameters. This numerical parameter is critical for differentiating an item. Using a Grey-Level Co-occurrence Matrix (GLCM), the feature extraction approach is employed to get quantitative values. The likelihood of two grey levels co-occurring is stored in GLCM [28].

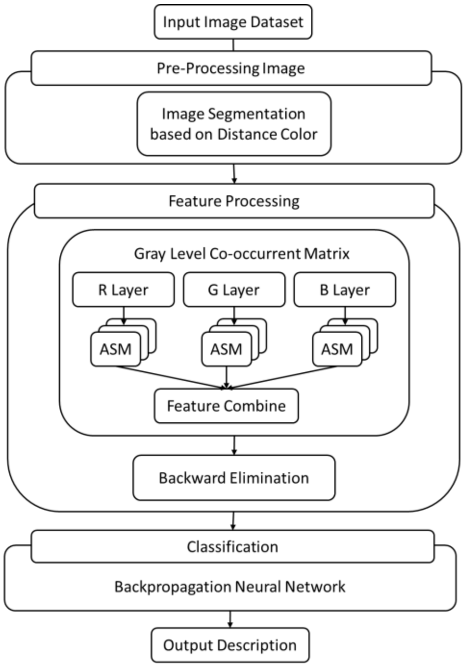

Fig. 3. Research Design.

The second-order moment or energy (ene), entropy (ent), contrast (con), homogeneity (hom), and correlation are retrieved from the vegetation picture to represent the data co-occurrence matrices indicated in equations (2) to (6) (cor). The distribution of co-occurrence values is designated by k and l with different angles, 0^0, 45^0, 90^0, and 135^0, at the offset provided (1,1) by p(k,l). Rotation invariant, mean, and variance of orientation-dependent characteristics are computed individually for different angles using different angles.

$$ene = \sum_{k=0}^{L-1}\sum_{l=0}^{L-1}\{P(k,l)\}^2 \tag{2}$$

$$ent = -\sum_{k=0}^{G-1}\sum_{l=0}^{G-1}P(k,l)\times Log\big(P(k,l)\big) \tag{3}$$

$$con = \sum_{n=0}^{G-1}n^2\{\sum_{k=0}^{G}\sum_{l=0}^{G}P(k,l)\}\{n = |k-l| \tag{4}$$

$$hom = \sum_{k=0}^{G-1}\sum_{l=0}^{G-1}\frac{1}{1+(k-l)^2}P(k,l) \tag{5}$$

$$cor = \frac{\sum_{k=0}^{G-1}\sum_{l=0}^{G-1}(k,l)(P(k,l) - \mu_k{'}\mu_l{'}}{\sigma_k{'}\sigma_l{'}} \tag{6}$$

The equation is used to solve the correlation equation (7).

$$\begin{aligned}
P_x(k) &= \sum_{l=0}^{G-1}P(k,l)\\
P_y(l) &= \sum_{k=0}^{G-1}P(k,l)\\
\mu'_k &= \sum_{k=0}^{G-1}\sum_{l=0}^{G-1}k * P(k,l)\\
\mu'_l &= \sum_{k=0}^{G-1}\sum_{l=0}^{G-1}l * P(k,l)\\
\sigma'_k &= \sum_{k=0}^{G-1}\sum_{l=0}^{G-1}P(k,l)(k-\mu'_l)^2\\
\sigma'_l &= \sum_{k=0}^{G-1}\sum_{l=0}^{G-1}P(k,l)(l-\mu'_l)^2
\end{aligned} \tag{1}$$

4) Feature selection: Feature Selection is a machine learning method in which a collection of data features is utilised to train algorithms. Feature selection has become a hot topic in pattern recognition, statistics, and data mining, according to Oded Maimon [29].

One of the essential aspects that might affect classification accuracy is feature selection since if the dataset contains multiple features, the dataset's dimensions will be significant, lowering classification accuracy. The issue with feature selection is dimensionality reduction, as all elements are required initially to achieve maximum accuracy.

According to Maimon [29], there are four fundamental causes for dimension reduction:

- Decreasing the learning cost.
- Increasing the learning performance.
- Reducing outside dimensions.
- Reducing redundant dimensions.

Because not all features/attributes are relevant to the problem, the fundamental notion of Feature Selection is to choose a subset of existing characteristics without transforming them. Some of these qualities or attributes are even bothersome and diminish accuracy. To increase accuracy, noisy or useless features must be deleted. Furthermore, having many characteristics or qualities will slow down the computation process. Backward elimination starts with the entire collection of characteristics and removes any leftover features from the specified ExampleSet in each round. Performance is calculated for each element published using the inner operator, such as cross-validation. Only the attributes that cause a modest performance decrease are finally eliminated from consideration. Then a new round with a different selection begins. This method removes the usage of additional memory, the memory used to hold the data, and any memory necessary to perform the inner operator. After the termination requirements are fulfilled, the speculative spin parameter defines how many spins will be made in a row. Elimination will continue if performance improves during the theoretical round. Any extra missing characteristics would be restored if no speculative spin were performed. This process might help avoid the model being stuck on a local optimum.

The difference with forwarding selection is that it starts with an empty attribute and adds any new characteristics from the specified set in each round. The inner operator, such as cross-validation, is used to assess performance for each feature added. Only the most significant performance boost attribute is included in the selection. Then a new round with a different selection begins.

5) Classification: According to Witten [30], data mining is a series of processes to obtain knowledge or patterns from data sets. Data mining solves the problem by analysing the data already in the database. The method of finding a model or function that explains or distinguishes a concept or data class intends to estimate the course of an object whose label is unknown [31].

The classification stage uses the BPNN artificial intelligence method. An artificial neural network (ANN) is a learning algorithm that implements a simple network connected to neurons and units. The performance of ANN is similar to the version of the human brain in recognising a specific pattern. ANN can provide effective classification results even though the input data contains noise and is incomplete [32], [33]. One type of ANN that is often used is Backpropagation. Backpropagation architecture comprises three layers, including the input layer, hidden layer and output layer [32], [33]. Fig. 4 shows a simple visualisation of the Backpropagation structure. Backpropagation formulation can be formulated in equation 8.

$$y = f(\sum_{i=1}^{L} w_i x + b) \qquad (2)$$

By displaying the weight vector, x as the input vector, and b as the bias value, f is the activation function. One hidden layer (10 neurons), one output layer, purely log sig activation function, and 1000 epochs were utilised.

6) Validation: Validation measures are utilised to assess the classification performance of the model. This study uses two types of validation measures: accuracy and kappa. The percentage of cells categorised exactly in class I to the total number of cells is called accuracy. The following is an example of accuracy:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} x\ 100\% \qquad (9)$$

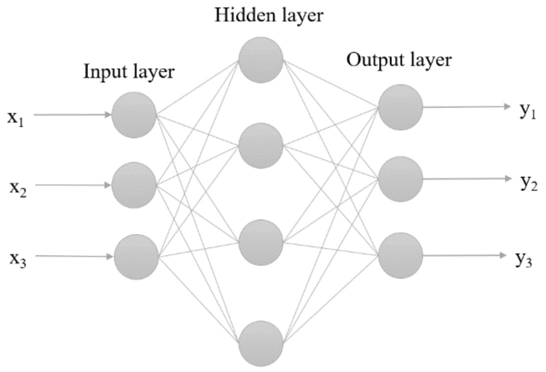

Fig. 4. Backpropagation Architecture.

True Negative (TN), False Positive (FP), False Negative (FN), and True Positive (TP) values will be calculated to obtain accuracy, precision and recall values. The accuracy value describes how accurately the system can classify the data correctly. In other words, the accuracy value compares the data that is classified correctly and the whole data. The precision value describes the number of positive data categories classified correctly divided by the total data classified as positive.

Another indicator of accuracy is the kappa coefficient. Kappa is a measure of how the result of a classification compares to a given value by chance. It can take a deal from 0 to 1. If the kappa coefficient equals 0, there is no similarity between the classified image and the reference image. If the kappa coefficient equals 1, the image is classified, and the ground truth image is identical. Thus, the higher the kappa coefficient, the more accurate is the classification.

IV. Experimental Design

This study demonstrates how data influences the best characteristics. The approach used on this dataset is tested during the classification process, ensuring that the classification results are accurate and based on the best features. The accuracy gained in this study is compared to other experiments to determine the optimum accuracy.

The original image is used to extract features using the feature extraction approach, eq. (2) to (6) using the GLCM feature extraction method. For each image, a total of 60 features are created. These attributes are taken from each colour layer, which includes red, green, and blue. According to equations (1) to (3), GLCM creates 20 texture-based features for each colour received from four distinct angles, with each corner yielding five particular features.

Consequently, the final data consists of 300 photos multiplied by 60 characteristics. The BPNN classification algorithm was used to analyse the feature findings. In this study, each parameter in the BPNN classification technique was evaluated, and an assessment was based on the usage of the backward elimination-based feature selection approach. Backward elimination findings are compared to past investigations, specifically forward selection.

In performance evaluation, sampling and validation processes are employed with multiple tens. The dataset is divided into ten values for cross-validation, with each component evenly distributed. The experiment was repeated ten times according to the number of cross-validations and the average training and performance classification testing outcomes. The classification model's performance is assessed when a confusion matrix is created. This investigation obtained the most notable performance findings using MATLAB (www.mathworks.com).

V. Result and Discussion

The discussion is broken down into three stages: data preparation, feature extraction, and classification (Fig. 2). At each stage of the research, the results are revealed.

A. Segmentation

The segmentation results show segmentation that only takes the green colour from the image. To obtain the image's unique characteristics according to the agreed class will then use the segmented image. Table I is an image of the segmentation results of the three types of labels that have been agreed upon.

B. Feature Extraction

The GLCM technique is used to turn the selected pictures into functional characteristics. A new matrix with 300 images and 60 features is created by combining feature approaches. From Table II each row of the matrix represents data, while the columns reflect the characteristics of each piece of information.

The column comprises the variables F1, F2, F3, F4 to F120, as given in Table I. Columns are variables that hold the values for each GLCM texture feature. The GLCM method's second-moment angle features, contrast, and correlation with 0 degrees orientation direction on the red layer are F1, F2, F3, and F4. In the GLCM approach, the other Fn characteristics include orientation and colour layers. The kurtosis value on the blue layer is the next F60 feature. The data numbers received from the dataset are represented by the matrices in rows 1 to 300. All characteristics were employed in the classification process in this study. Therefore it's safe to infer that they all help get the best classification results.

C. Evaluation of BPNN Classification based on Parameters

The supporting parameters are used to evaluate the BPNN classification. The test results are shown in Fig. 5, utilising a training cycle value of 10 to 100 cycles.

As shown in the Fig 5, the results indicate that the optimal training cycle was used for 100 cycles with an accuracy of 84.67% and a kappa of 77%. These findings suggest that increasing the number of training cycles increases accuracy and kappa performance. This result is consistent with numerous other studies that employed neural network training cycle settings and showed excellent performance on long training cycles.

The learning rate experiment on the BPNN technique is also applied from 0.1 to 1, utilising the highest performance results from the training cycle, which is 100 cycles (Fig. 6). The results reveal that a learning rate of 0.1 produces the most significant outcomes compared to other learning rates. When applying a high learning rate, the pattern created from the results of the accuracy performance based on the learning rate reveals that performance steadily falls. The solution is not ideal because the high learning rate and performance are reduced [34].

TABLE I. Segmentation Result

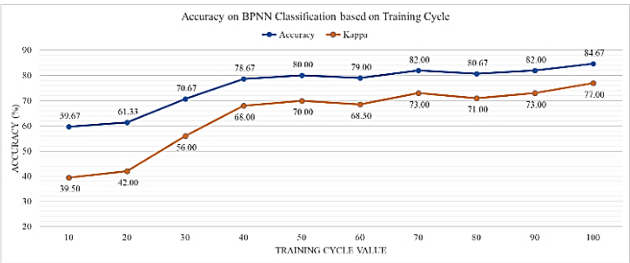

Fig. 5. Evaluation of BPNN based on Training Cycle.

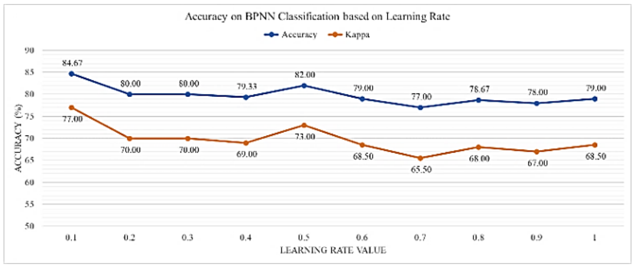

Fig. 6. Evaluation of BPNN based on Learning Rate.

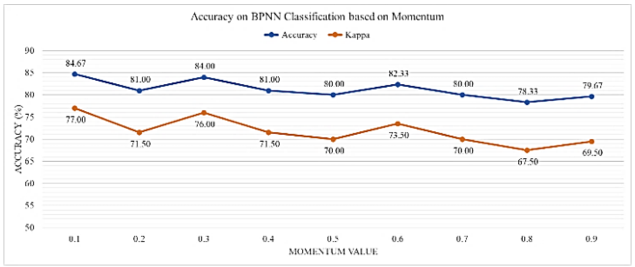

Fig. 7. Evaluation of BPNN based on Momentum.

The momentum parameter is used to evaluate BPNN in Fig. 7. The accuracy performance based on momentum follows the same pattern as the learning rate results, with ups and downs, and the most significant results when given a momentum value of 0.1. These findings align with earlier research that claims that a small momentum value brings features closer together without boosting convergence [34].

D. BPNN Classification Testing based on Feature Selection

To choose features in this experiment used the backward elimination feature. The maximum number of eliminations parameters is somewhere between 10 and 60 (shown in Fig. 8). These parameters are applied to the BPNN classification algorithm, utilising the optimal training cycle, learning rate, and momentum parameters from the previous experiment, 100, 0.1, and 0.1, respectively.

The accuracy is 85.67 % when using a maximum total elimination of 10, and backward elimination training delivers significant results. These data show a 1% improvement over the BPNN classification algorithm without feature selection. With a 1.5 % increase, measurements with kappa have the same performance pattern as measurements with accuracy.

E. Evaluation Comparison between Feature Selection

We used the forward selection to acquire the best performance and compare assessments for feature selection (shown in Fig. 9). Forward selection is based on the selection of empty attributes, and each iteration adds unneeded attributes from the quantity of data for each additional attribute, according to the working idea. Only the traits that increase performance the most are added to the selection in the forward selection, which begins with the alteration of the selection. Backward elimination allows for the most significant results since it starts with a complete data set and deletes each characteristic for each repetition. Backward elimination, like the forward selection, uses cross-validation to predict performance and deletes attributes that cause a drop in performance.

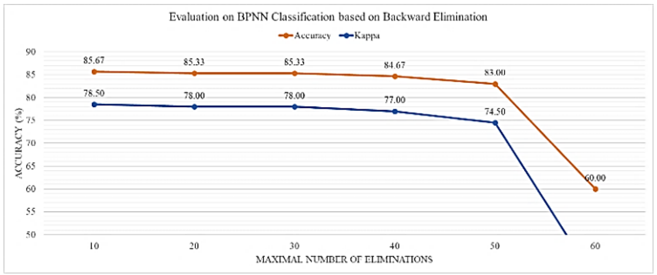

Fig. 8. Evaluation of BPNN based on Backward Elimination.

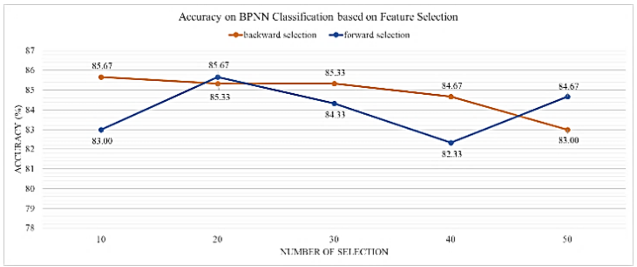

Fig. 9. Comparison BPNN Classification based on Features Selection.

The findings demonstrate that when ten features are applied, and the selected features are eliminated via backward selection, the most outstanding performance obtained from both feature selection approaches offers the same accuracy of 85.67%. Using forward selection produced an 85.67% performance with 20 and 60 chosen features, respectively. The backward selection highlights the behaviour of the accuracy findings as much as possible by picking features from a large number of characteristics in the data. It is conceivable that using the feature impacts the findings' correctness. While the forward selection is based on the calculation of the correlation matrix by taking the relationship between features that produce the highest correlation coefficient and only considering the relationship between features, the backward selection is based on the calculation of the correlation matrix by taking the relationship between features that produce the lowest.

VI. Conclusion

This study aims to determine the state of plant cover to quantify peatland fire vulnerability. As a result, this research may help some fire-prone countries overcome their problems. This research provides an automated identification approach based on the original image and ambient circumstances. The improved performance is due to the revised flow for determining cover situations. When the feature selection approach is coupled, the findings demonstrate an increase in performance—the proposed strategy results in a 1% improvement in accuracy and a 1.5 % increase in kappa. The rise happened when the feature selection utilised forward and backward elimination features. As a result, many features have suboptimal capabilities, and the feature selection approach can provide native features that are suitable for determining vegetation cover situations. Feature engineering can minimise the number of input dimensions in visual feature extraction while increasing the accuracy of vegetation density categorisation. As a result, it can improve machine learning. Using the Keetch and Byram Drought Index model, it will be more effective to use engineering characteristics in the vegetation density workflow classification system to evaluate peatland fire. The scope of this study is confined to making suggestions about the impact of feature engineering. At the classification step, to enhance accuracy may make further efforts by comparing machine learning classification approaches.

Acknowledgment

This study was completed with partial funding from Riset Keilmuan with the Riset Mandiri Dosen scheme from LPDP through the Directorate of Resources, the Directorate General of Higher Education, Research, and Technology. Ministry of Education, Culture, Research and Technology (contract: 010/E4.1/Ak.04.RA/2021). The authors thank to LPPM Universitas Lambung Mangkurat.

***Abstract*—E-learning is the most promising and fastest growing activity since the advent of the COVID-19 pandemic. Although the pandemic seems to have been eradicated in several countries of the world, it is worth mentioning that some positive cases of the covid-19 variant have been detected. This could accelerate the rate of infection again. Hence the interest generate in reinforcing the quality of distance learning platforms. Technical and vocational training (TVT) in Mauritania is based on science, technology, engineering, and mathematics (STEM) disciplines. Unfortunately, the expansion of the COVID-19 pandemic has negatively impacted the quality of education with a halt in teaching affecting 8000 students. Yet, the quality of education in these disciplines is a key factor in meeting the demands of emergence and economic growth. This paper advocates the mixed pedagogical model by proposing a techno-pedagogical solution to improve the quality of teaching and learning processes. The proposed solution combines the use of technologies such as Modular Object-Oriented Dynamic Learning Environment (Moodle) and Web Real Time Communication (WebRTC) to provide pedagogical services in a context with a limited Internet connection. In addition, we set up a signaling system to maintain direct communication between the pairs, Application Programming Interface (API) of Multipoint Control Unit (MCU) to ensure simultaneous collaboration in a peer-to-peer context, used implementations of security protocols such as Datagram Transport Layer Security (DTLS) and Secure Real-time Transport Protocol (SRTP) to secure data transport.**

Keywords—TVT; STEM; Mixed education; Moodle; WebRTC; signaling system; MCU; DTLS; SRTP

I. INTRODUCTION

Education is a key instrument for promoting growth and economic development. In view of this, the Mauritanian government, with the support of its partners, has launched a project under the leadership of DCS-SARL for the development of the technical and vocational training sector (TVT).

The training centers in Mauritania welcome around of 8,000 students each year in Science, Technology, Engineering and Mathematics (STEM) disciplines. These disciplines require the implementation of strategies to ensure the quality of the teaching system in order to meet the requirements of economic development requiring the performance of the educational process.

In addition, the pandemic of the COVID-19 impacted the living and working conditions and has in turn forced the States to take measures concerning social distancing in order to prevent its propagation in the society. To this effect, these professional technical training (FTP) centers have been victims of a blockage in their teaching-learning processes, drastically reducing the number of class sessions. This has had serious consequences on both the pedagogical continuity and the quality of teaching.

In spite of these shortcomings, these training centers must work to improve their teaching in accordance with quality assurance standards to enable students to be competitive and effective in the labor market, but also to increase the ratio of the population of age to attend these professional training courses.

The lack of a suitable pedagogical model for these training centers and the lack of a better techno-pedagogical infrastructure have favored the migration to ICT-based solutions in order to improve the quality of teaching, while ensuring pedagogical continuity online.

The need for a pedagogical model adapted to these training centers and the poor quality of the techno-pedagogical infrastructure led us to encourage these training centers to migrate to ICT-based solutions in order to improve the quality of teaching, while ensuring pedagogical continuity online in case face-to-face courses are not possible.

In the literature, authors [1] [2] have shown the usefulness of adopting the blended learning model for traditional training. The latter consists in combining traditional teaching methods with e learning in order to increase the efficiency of the teaching systems.

Other authors [3] have proposed mechanisms to improve the effectiveness of blended learning by adopting the model of teaching based on the integration of online and offline activities (O2O). This strategy aims to increase the utilization of the teaching system by providing access to learning content in an environment with limited internet connection.

In the works [4] [5] [6], the authors have advocated the so-called social-constructivist pedagogical model to improve the quality of teaching, according to which the teacher creates learning situations that invite learners to collaborate and cooperate via innovative techno-pedagogical services in order to develop concrete professional skills.

Teaching must rest on professional practice to meet the needs of the labor market. The authors [7] have proposed strategies to involve synchronous education development in the learning process.

This form of education, involving instantaneous, face-to-face interaction, allows schools to train students in correct concepts and awareness of work and mastery of professional skills through specialized synchronous courses.

These research discussions led us to propose a quality hybrid solution using innovative and flexible technologies to the profile of TVT centers. The proposed solution offers synchronous and asynchronous pedagogical services appropriate and adapted to the context of the TVT centers.

The rest of this paper is organized as follow: Section II describes technical and vocational training and discusses of Technological background in e-learning; Section III presents software architecture of system proposed; Section IV describes hybrid learning architecture; Section V is dedicated to discussion and result and finally in Section VI provides the conclusion and perspectives of ours works.

II. Related Work

In [8], the authors propose a survey. This survey reveals the fear, the anxiety of learners for the handling of distance learning platforms.

The authors' contribution [9] presents the collaborative platforms Google Classroom, Zoom and Microsoft Team and compares them. They show the negative impact of using distance learning platforms on the mental health of learners.

These limitations have led us to propose a technological solution appropriate and suitable to the context of technical and vocational training.

A. Technical and Vocational Training

The technical and vocational training (TVT) in Mauritania is provided by the National Institute of Promotion [10]. Its purpose is to provide individuals with the knowledge and skills necessary to practice a trade or profession in order to integrate into the labor market as a worker's helper, specialized worker, skilled worker, technician or senior technician.

The mission of the TVT articulated around the following axes:

1) Satisfaction the needs of the labor market in qualified personnel.

2) Improving the professional skills of workers.

3) The development of the individual's potentialities in the perspective of the accomplishment of his professional project.

4) The promotion of the entrepreneurial spirit, with a view to self-employment.

5) Educational and professional orientation, information and advice on skills.

The Technical and Vocational Training system under the MENFTR composed of: (1) 16 technical education and vocational training schools (EETFP); (2) Higher Center for Technical Education (CSET) and (3) Six private training establishments that train mainly in the tertiary and service sectors.

Concerning the training curriculum, the TVT offers initial training courses organized as follows:

- Certificate of Competence (CC); 6 to 9 months duration.
- Certificate of Professional Aptitude (CAP), lasting 2 years.
- Technician's Certificate (BT), lasting 2 years.
- Higher Technician Certificate (BTS), lasting 2 years.
- Technical Education Certificate (BET), lasting 4 years.
- Technical baccalaureate, lasting 3 years.

The number of TVT students for the 2020-2021 training year is 7,885, including:

- 238 at CSET.
- 7,125 students in EETFPs.
- 190 students at the Ighraa Institute.
- 332 Pupils in Private Establishments.

These students divided according to educational level as follows:

- BTS : 722.
- BT : 2726.
- CAP : 2895.
- Technical baccalaureate and BET: 1542.

B. Technological Background in e-learning

Today, ICT have become an integral part of the culture of society. Their places are increasingly important in all areas of life. This presence of ICT is all the more felt at the level of education systems.

Several studies such as [11] [12] show that the appropriate use of technological innovations in teaching can contribute to improving the quality of teaching and learning.

Nevertheless, technical and professional training resting essentially on STEM disciplines requires the adoption of learning practices that promote interactivity and collaboration to develop practical and professional skills in students that will enable them to compete on the market of work.

In addition, the low level of TVT students in the field of ICT encourages the adoption of flexible technological solutions to use in order to eliminate any obstacle to the use of ICT to the detriment of the deep exploitation of educational services.

Indeed, the authors [13] have shown the relevance of using Moodle technology to facilitate interaction and create a dynamic learning environment for mixed-mode courses. According to the authors [14], Moodle is a practical tool containing versatile and rich enough functionalities for teaching.

Moodle remains an asset for learners because it offers the possibility of working at their own pace by alternating course sessions and face-to-face and distance learning activities. In this context, we use this technology to provide, through our techno-pedagogical solution, an adaptation and organization of lessons with the aim of developing a certain autonomy in the learner: we are talking about asynchronous learning.

In addition, asynchronous teaching via Moodle illustrates some insufficient of teaching when one is looking for real-time exchange. For the authors [15], face-to-face interaction between teaching actors is a key factor in improving the quality of online teaching.

This synchronous teaching modality reflects traditional classroom teaching where students become actively involved in their learning by interacting with each other, but also with their teacher to produce their educational activities.

Several technologies have materialized the synchronous mode in the online teaching process by promoting collaboration between actors.

However, online collaborative solutions applying in an organizational network and including interactive spaces in STEM fields require a certain type of access to resources. The generalization of broadband access is one of the fundamental conditions for quality online education.

Unfortunately, the context of technical and vocational training centers often has a limited internet connection. This can pose a problem of efficiency of the distance education system. Research work [16] on technologies that can operate in a local IP environment and offer innovative collaborative services via the web, led us to take an interest in WebRTC technology.

According to the analysis study in the works [17], WebRTC technology is better compare to other real-time interaction tools for several reasons: (1) WebRTC allows interaction in peer-to-peer mode without the using an intermediate server. This remarkably reduces latency; (2) WebRTC integrated into the bandboxes of recent browsers without any intermediate configuration or installation.

In view of these discussions, we combine these two technologies, namely Moodle and WebRTC, to provide a quality e-learning solution offering educational services in synchronous and asynchronous mode, with the possibility of operating in an intranet network. In addition, these services are accessible via a simple browser requiring neither download nor installation of plugins on client workstations. This could have a positive impact on the implementation of services adapted to the needs of TVT centers

III. Software Architecture of the Proposed Solution

This paper aims to improve the quality of hybrid training, both theoretically and in terms of the development of tools that promote interaction and collaboration between the various actors in teaching and learning activities.

The architecture proposed (Figure 1) below consists of several software components interacting with each other via the network.

It aims to improve the quality of education in TVT centers through the following inputs.

A. Simultaneous Multi-communication Model

In our system, several services are outcome from WebRTC technology using VoIP to foster collaboration between educational participants. Gold, This technology is based on a "peer-to-peer" exchange mode allowing reduces the need for network infrastructure and minimizes latency without needing additional facilities.

These services hold into account socio-constructivist aspects that require the integration of several simultaneous connections.

Indeed, several researchers [18] advocate a mesh model based on a multipoint control unit (Figure 2) to centralize the processing of all audio and video streams. The MCU, also called a conference bridge, is a central gateway in a multipoint video conferencing system.

For this purpose, we used a software implementation of MCU based on a pairwise architecture named P2P-MCU to allow teachers to initiate simultaneous communications with their students via WebRTC.

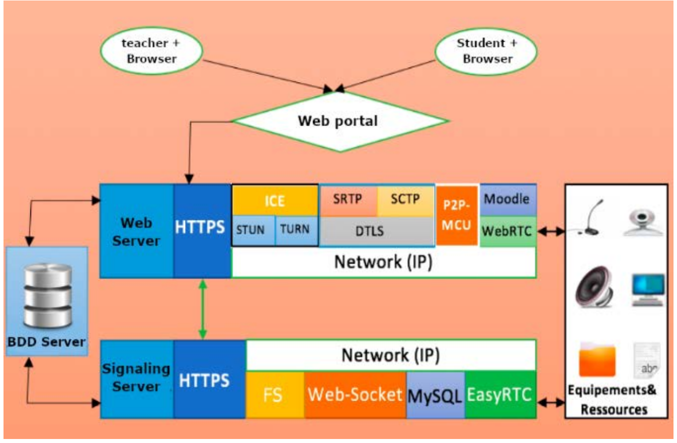

Fig. 1. Architecture Logicielle du Système D'enseignement.

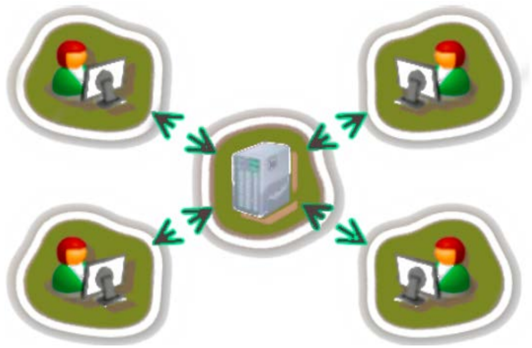

Fig. 2. "Mesh" Topology based on a Multipoint Control Unit.

B. Data Transit System

Most WebRTC capable devices sit behind one or more layers of NAT and may have security layers that block certain ports and protocols (sometimes with Deep Packet Inspection or DPI).

In addition, many of them placed behind corporate proxies and firewalls, not to mention firewalls and NAT on home Wi-Fi routers. In intranets, NAT gateways pose techniques that prevent direct communication between peers. Indeed, the main reason for this problem is because NAT corrects IP addresses and port numbers in order to hide private hosts.

As a result of the puncture technique limitation, it is necessary to use the services of an intermediate host that serves as a relay for the packets. This relay is usually located in the public Internet and relays packets in a direct communication between two hosts that are behind NAT.

For this specification, we use the relay tools STUN, TURN and ICE [19] to bypass NAT or firewall restrictions.

C. Media / Data Security Mechanism

Our scope of work requires real-time multimedia applications that require the use of SRTP as a transport protocol for the following reasons: fast delivery is preferred over reliable delivery and packet loss is acceptable to avoid delays resulting from rescheduling or retransmission of packets.

TLS (Transport Layer Security) cannot be used because it requires a reliable and slower protocol than a datagram-based protocol. In this perspective, DTLS (Datagram Transport Layer Security) brought adaptations to the TLS protocol to work in datagram communications by introducing counters and explicit messages [20].

Due to the unreliability of datagram-based protocols, DTLS incorporates mechanisms to retransmit the packet. This involves sending verification messages back to the server within a timeout period of 500-1000ms to ensure proper receipt of the messages. These verification messages also provide a means of avoiding denial of service (DoS) attacks, which in UDP, are very easy to carry out thanks to the exchange of a cookie.

In regard to these discussions, we have used in our scope the DTLS protocol as a basic security protocol for data and SRTP to ensure end-to-end confidentiality, message authentication and replay protection (Figure 3).

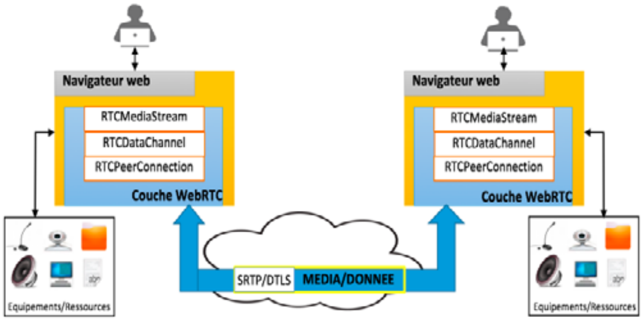

Fig. 3. Secure peer-to-peer Communication using DTLS/SRTP.

D. Signaling System

Signaling (Figure 4) is the mechanism for coordinating communication by exchanging identification and control messages between WebRTC pairs. In effect, it allows two or more WebRTC-capable web browsers to join, exchange contact information, negotiate a session that defines how they will communicate, and then finally establish the media channels between pairs for the transport of media streams exchanged directly between them [21].

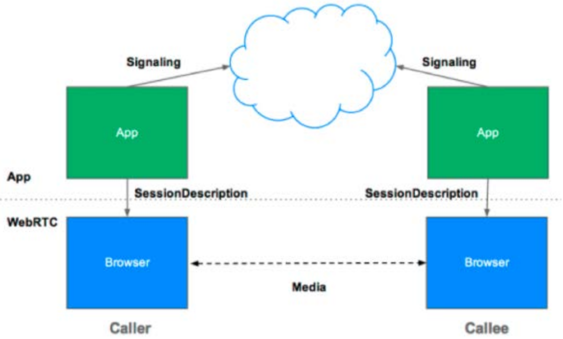

Fig. 4. Signaling Architecture.

The W3C and IETF standardization bodies have not imposed a particular signaling protocol in WebRTC in order to leave developers free to choose one of the existing protocols (SIP or Jingle) or to customize their own signaling protocol using web sockets. This signaling protocol choice strategy avoids redundancy and maximizes compatibility with already established technologies.

In this context, we used the EasyRTC implementation based on the Web-Socket protocol to create our own signaling system.

IV. Hybrid Learning Architecture

The proposed architecture (Figure 5) aims at proposing a device offering not only collaborative services while respecting the social-constructivist aspects but also the adaptation of the course flow to the learners' needs in order to ensure the same or better levels of interaction than those of traditional class's level.

Fig. 5. Hybrid Learning Architecture.

Our approach allows TVT centers to improve the quality of their teaching system by integrating a hybrid system using both the capabilities of the Moodle platform and WebRTC technology. This architecture is structured in four layers:

1) Synchronous Learning Layer (SLL).
2) Asynchronous Learning Layer (ALL).
3) Infrastructures Layer (IL).
4) Signaling Layer (SL).

A. Synchronous Learning Layer (SLL)

This layer provides synchronous and real-time socio-constructivist learning activities based on WebRTC technology. Such a technology containing the MediaStream, PeerConnection and DataChannel APIs enables VoIP to operate in web browsers. Indeed, this layer essentially allows teachers and their students, through a simple browser:

1) To make projections and follow courses at a distance via video conferencing.

2) To transmit files (courses, exercises) to students in real time.

3) Share the teacher's office environment with students Interfaced with practical equipment.

4) To ensure the exchange system between the teacher and the students via instant messaging.

5) Disable the user's webcam.

6) Reactivate the previously deactivated webcam in the middle of a conversation.

7) Allow a teacher to eject a student from the system.

B. Asynchronous Learning Layer (ALL)

This layer, which ensures asynchronous learning, allows learners to follow the educational activities at their own pace. This flexibility of time for course delivery is a relevant solution to maximize access to higher education because it offers flexibility to the constraints that usually prevent professionals from participating in the classical course in universities.

To do so, we adopted the Moodle platform, which offers powerful and learner-centered tools. It also offers a collaborative environment that enhances both teaching and learning.

This layer also has a simple to use and easy to learn interface thanks to Moodle's constant usability improvements. It essentially offers the following tasks:

1) User, class and course management.

2) Scheduling of courses at a given date and time.

3) Course content management via a rich and versatile activity system.

4) Document management.

5) Reports and statistics management.

6) Learner evaluation management.

C. Signaling Layer (CL)

The signaling layer enables the creation of a real-time communication channel by defining a coordination mechanism between e-learning users.

Several developers have relied on the WebRTC API to provide libraries that hide the complexity associated with signaling and thus facilitate the development of WebRTC signaling servers. Figure 6 shows the software components of the signaling server. The operation of our system depends essentially on the signaling server implemented from the following modules:

1) Web-socket: allows creating bidirectional flows allowing the exchange in real time in both directions of communication.

2) EasyRTC: provides a library to simplify the development of WebRTC applications.

3) MySQL: allows connecting and making queries on the database.

4) FS: allowing the import of HTTPS server configuration files with SSL keys.

D. Infrastructures Layer (CS)

This layer hosts the physical servers allowing implement the physical infrastructure management applications. These are servers for traversing NAT/Firewall and the database server:

1) Servers to traverse NAT/Firewall: An ICE framework offered at this level, to overcome the difficulties of networking in the real world. ICE uses the highly reliable Xirsys STUN and TURN servers to try to find the best path to connect pairs. It tries all the possibilities in parallel and chooses the most efficient option that works. It tries to establish a connection using the host address from the operating system and a network card of a device.

2) Database servers: This layer contains a database server in order to keep or find all the data or information related to the educational activities of the system. The database is at the center of our computerized system allowing the collection, formatting, storage and use of data

V. Discussion and Result

A. Discussion

The proposed solution was used for one year by two technical and vocational training centers. These centers have experienced and appreciated the structural management of the trainings such as classes, pedagogical levels, teachers, students and annual enrollment in classes.

More than 40% of the students in these centers have benefited from online courses. They have been able to follow course sessions, practical work and even exams at a distance.

These students have shown remarkable progress in understanding and absorbing the courses, which is reflected in their exam scores. According to the observation, the online courses attract the intention of the students to cooperate and collaborate more with the teachers and each other to better understand the course concepts.

B. Results

We designed the system following an architecture composed of two main parts such as the back-end and the front-end.

The back-end is the processing center that is at the heart of our distance learning system. It is a set of functionalities to be implemented in the INAP-FTP system in order to ensure the integration of the online course management in the core of this system.

The front-end is used to propose a space dedicated to the actual management of the course as described in our architecture. It is a system based on Moodle that allows us to propose practical mechanisms and standards for the management of quality pedagogical activities. Indeed, we take advantage of the set of relevant tools as proposed by Moodle without any intervention to modify the basic technical settings of Moodle components.

We then illustrate some system interfaces.

1) Login area: This space (Figure 6) allows users to authenticate via the above interface in order to be able to use the various distance-learning services.

VI. Conclusion

This paper deals with improving the quality of the TVT teaching system using innovative technologies adapted to the context of TVT centers in Mauritania.

Such a solution aims to offer relevant educational services both in synchronous and asynchronous mode between teachers and students.

However, innovation in distance education systems illustrates a concern for adaptation for those involved in education. It is more precisely about the integration of ICTs requiring configurations and adaptations for its members who often do not have sufficient experience in ICTs. This is why we have taken care in our work to choose flexible ICTs to use in order to concentrate as much as possible on the educational process.

The conclusive results of this work will enable education stakeholders to initiate and develop quality educational services through collaborative and innovative exchange systems. Our work provides evidence to dispel doubts about the quality of distance learning.

In terms of perspectives, our next steps will be to study the issues of availability and scalability in a context of optical fiber recently implemented in Mauritania.

***Abstract*—This study describes preliminary results of a research related to Intelligent Programming Tutor (IPT) which is derived from Intelligent Tutoring System (ITS). The system architecture consists of four models. However, in this study student model mainly student characteristic was focused. From literature, 44 research articles were identified from a number of digital databases published between 1997 to 2022 base on systematic literature review (SLR) method. The findings show that the majority 48% of IPT implementation focuses on knowledge and skills. While 52% articles focused on a combination of two to three student characteristics where one of the combinations is knowledge and skill. When narrow down, 25% focused on knowledge and skills with errors or misconceptions; 4% focused on knowledge and skill with cognitive features; 5% focused focus on knowledge and skill with affective features; 2% focused on knowledge and skill with motivation; and 9% based on knowledge and skill with learning style and learning preferences as students' characteristics to build their student model. Whereas 5% focused on a combination of three student characters which are knowledge and skill with cognitive and affective features and 2% focused on knowledge and skill with learning styles and learning preferences and motivation as students' characteristics to construct the tutoring system student model. To provide an appropriate tutoring system for the students, students' characteristic needs to decide for the student model before developing the tutoring system. From the findings, it can say that knowledge and skills is an essential students' characteristic used to construct the tutoring system student model. Unfortunately, other students' characteristic is less considered especially students' motivation.**

***Keywords*—Intelligent tutoring system; intelligent programming tutor; student characteristics; student model**

I. Introduction

Intelligent Tutoring System (ITS) is a computer software system that can mimic the methods and dialog of natural human tutors, generate real time and on-demand instructional interactions as and when required by individual students. The implementation of ITSs also incorporate computational mechanisms and knowledge representations in the fields of Artificial Intelligence (AI) which addresses how to reason about intelligence together with multimedia and internet; Psychology on the other hand, consists of Cognitive Science which addresses how people think and learn, while the Education field focuses on how to provide the best support for teaching and learning [1] as illustrated in Fig. 1.

Fig. 2 depicts the evolution of ITS from the 1960s to the year 2000. The introduction of AI techniques and Expert Systems technology to CBI (Computer-Based Instruction) gave rise to ITS [2]. Early 2000, internet has become a central core to the educative environment, thus ITS incorporated with web platform so that the ITS can be accessed anytime and anywhere and known as Adaptive Web-Based Educational System (AWBES) [1].

An ITS architecture basically consists of four models [3] as illustrated in Fig. 3 which are 1) Domain Model - known as the expert or cognitive model. This model contains procedures, theories and problem-solving tactics of the domain to be learned; 2) Student Model - known as user or learner model. Considered as the main component of an ITS. The component gives special responsiveness to the students' cognitive and affective states and their progress in their learning process; 3) Tutoring Model - known as Pedagogical Model or Instructional Model. The model accepts information from the Domain Model and uses Student Model for making decisions on tutoring plans and actions; 4) Interface Model - provides the interface with which the students interact with the ITS.

The main aim of ITS is to improve students' learning process [4]. An ideal condition of the learning process is where students can receive lessons, resolve exercises and obtain immediate feedback. The feedbacks and hints are provided based on the analysis of the responses to each problem-solving step given by students.

In recent years, the development and improvement of ITS has been growing rapidly. Among some of the improvements include improvements on the problem-solving system that can support and help to give feedbacks and hints to students; improvements on model tracing that assesses students' current knowledge that facilitates the next step in order to support problem solving. In addition, improvements on knowledge tracing were also carried out that allows assessment of students' skills and knowledge level in order to release a new tutorial to facilitate learning and finally improvements on tutorial dialogues to support problem solving [5].

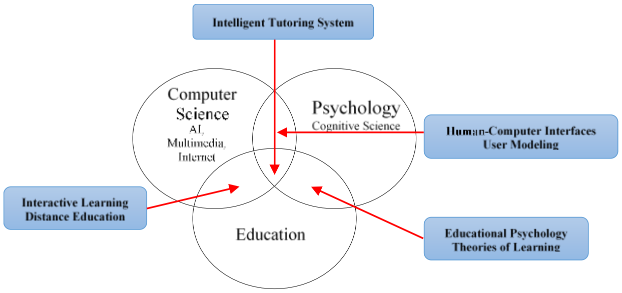

Fig. 1. The Development of ITS.

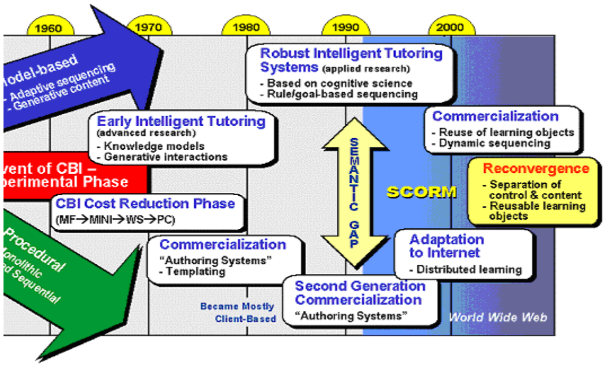

Fig. 2. The Evolution of ITS [2].

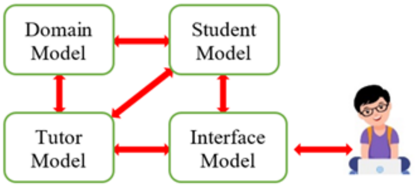

Fig. 3. ITS Architecture.

Educators agree that the most effective form of teaching is through one-to-one interaction with students [6]. In this context, ITS has an upper advantage as it provides personalized tutoring that is tailored to students' needs [5], [7], [8]. According to the findings from previous studies conducted by Kulik and Fletcher [9] and Colchester et al. [10], ITSs have successfully raised students' performance compared to those who were taught in conventional classes.

Chrysafiadi and Virvou [7] claim that, ITS to be become more adaptive and personalize, students' characteristic as student model need to be considered. The students' characteristic comprises of knowledge and skill; errors or misconceptions; learning styles and learning preferences; cognitive features; motivation; and affective features.

Knowledge refers to familiarity with theoretical concepts and factual information and skills refer to the proficiencies developed through practice [7]. During the learning process, errors or misconceptions can be identified. The concept of error or misconceptions can be defined as a process or fact that does not match a given norm [11]. Learning Styles and Learning Preferences - refer to how a student identifies, gathers and processes their learning materials [12]. While Cognitive features refer to students' aspects such as attention, knowledge, ability to learn and recall memory, opinion, attention, collaborative skills, capabilities to solve problems and make conclusions, analyzing abilities and critical thinking [7]. Literally motivation is the desire to do things. Motivation plays a significant role in students' learning process [13]. Emotional factors are known as affective features such as sadness, happiness, frustrations, anger, interest, boredom, distractions, aims and confusion [14]. Subsequently, affective features can be based on students' motivations [7].

Among the stated students' characteristics, motivation is considered as the main factor for engaging students in their learning [15], [16] and in academic performance [17]. Meanwhile, Abuhmaid [18], Hamzah et al., [19] and Sundar and Kumar [20] argue that students' motivation is an important factor in ensuring the success of ITS implementation. Abuhmaid [18] also pointed that motivation factors need to be considered when designing any ITS materials. Studies on the relationship between motivating factors and learning have been a prominent research topic in the field of education as well as studies focusing on eLearning [15].

McGill [21], for example, studies the use of robots to influence students' motivation when learning introductory programming. In order to ensure students feel motivated to use eLearning, Hamzah et al., [19] applied the ARCS+G (Attention, Relevance, Confidence, Satisfaction + Gamification) as motivational design model in the development process in their study. Another study conducted by Nikou and Economides [22] examined the impact of using mobile devices during the learning activity on students' learning motivation. Results obtained by Abuhmaid [18] reveal that utilizing the flipped learning strategy in an eLearning environment has a significant improvement on students' motivation to learn. Tambunan, Rusdi and Miarsyah [23] suggest that a combined usage of eLearning with a Problem Based Learning (PBL) model and motivation is an effective way to improve students' learning outcomes. Even though some may argue that a game environment can be used to ensure a good transfer of knowledge in a fun way, Yedri et al., [24] claim that a balance between learning transfer and motivation is the major key to success.

A. Intelligent Tutoring System for Learning Programming

Programming tools have been actively researched in their effectiveness to support teaching and learning. Pears and his colleagues [25] have summarized these programming tools into five categories one of which is ITSs. As highlighted in the previous section, ITSs provide many benefits in students' learning process.

An IPT (Intelligent Programming Tutor) is a specific implementation of an ITS for learning programming. The ideas behind the use of IPT are to create a learning process where students can receive tutelage, resolve exercises and receive instant feedbacks imitating one-to-one human tutoring.

As explained above, IPTs is derived from ITS' ideas in which students' characteristics also need to be considered in creating a conducive and effective learning process. In the following section, an exhaustive systematic literature review (SLR) was carried out to identify what types of student characteristics were used to design the IPT.

II. Method

In this section, a SLR (Systematic Literature Review) was carried out to obtain answers to the following question: What types of student characteristics were used to design the IPT? SLR was conducted in this study as it is a process that can be used for recognizing, evaluating and interpreting research materials to answer several research questions [26].

To answer the question stated above, PICOC as proposed by Petticrew and Robert [27] was used in the study. PICOC comprise of five elements which are Population, Intervention, Comparison, Outcomes and Context. Table I shows a summary of PICOC for this study.

TABLE I. Summary of PICOC

Population	Student
Intervention & Comparison	Intelligent Programming Tutor or Intelligent Tutoring System
Outcomes	Student characteristics in Intelligent Programming Tutor or Intelligent Tutoring System
Context	Reviews of all studies of Intelligent Programming Tutor or Intelligent Tutoring System within the domain of Programming subject

The identification of primary sources from journals, conferences and online databases is important to ensure a wide coverage of potential sources. A survey of literature included all research works published from online database such as ACM Digital Library, Google Scholar, IEEE Explore, ISI Web of Knowledge, Science Direct and Springer. These online databases were selected to be used in this study as they are the most popular and frequent databases used by previous researchers in investigating the use of eLearning. In addition, references retrieved from SLR articles were analyzed to identify any literature that may have been ignored or overlooked during the search.

Using Booleans of AND, OR in the keyword combinations conducted include keywords such as intelligent programming tutor; intelligent tutoring system AND programming; and programming AND intelligent tutoring system. The use of the Boolean OR is to incorporate alternative synonyms and spellings while the usage of the Boolean AND is to link the major terms.

A search of these databases and journals allow the data collection to be inclusive and comprehensive. A total of 73 papers were selected which the searching technique described above. These articles were reviewed while papers that were not categorized under any refereed journal articles such as proceedings or editor-reviewed papers were excluded from the final analysis. The focus of this review was on refereed articles which assist in ensuring the quality and relative rigor of data sources. Therefore, research papers that did not conduct an in-depth discussion of their ITS in programming particularly those that did not investigate student characteristic(s) were omitted. Papers that were not published in English language and gray papers such as those without any bibliographic information (publication date/type, volume and issue numbers) were also excluded. Duplicated papers were also excluded (only the most recent, complete and improved one is included) from the SLR in this study. In total, 44 relevant papers which were published between 1997 and 2022 were gathered and thoroughly examined in this study.

III. Result and Discussion

A. Data Analysis

In Table II, the 44 articles were organized based on what type of student characteristics was used to construct the user model; what modelling technique was applied to construct the user model for the intended IPT system; the subject domain and learning environment.

B. Synthesis of SLR on Student Characteristics for Student Model in IPTs

Fig. 4 illustrates how students' characteristics were considered in constructing user model mainly in IPTs base on 44 articles which was revealed in Table II.

From Fig. 4, 48% or 21 articles were found mainly focused on knowledge and skills as student characteristic for their user model. The objective of this characteristic is to improvised students' theoretical concepts knowledge and programming proficiencies skills in particular topic of programming subject. To develop the user model base on knowledge and skills as student characteristic, different researchers use different modelling technique such as Bayesian network, Markov Decision Process, Regression model, Rule Base and K* classifier. However, the common modelling technique is Rule Base because it is easier to build due to improved authoring tools and remain a popular option.

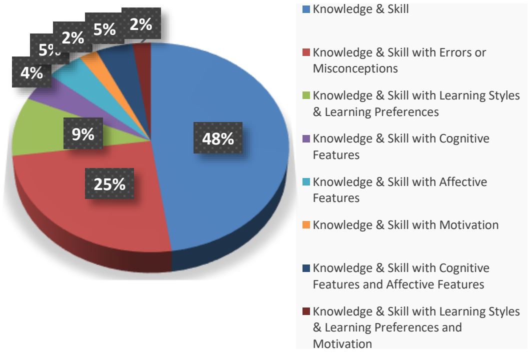

Fig. 4. Students' Characteristics for user Model in IPTs.

TABLE II. SUMMARY OF IPT REVIEW

Student Characteristic	IPT	Modelling Technique	Subject Domain and Learning Environment
Knowledge & Skill	ALLIGATOR [28]	-	To teach data flow diagram using visual programming environment with multiple informative and tutoring feedback components.
	AOMS [29]	-	To teach graph using C Programming
	BITS [30]	Bayesian network	To teach programming concept using C++.
	BOTS [31]	Markov Decision Process	To teach pseudocode in using game environment.
	ChiQat – Tutor [32]	Regression model	Using visualization to teach link list.
	COLLEGE [33]	-	Editing, compiling the source code, and executing the object code with aid of animation and visualization.
	CIMEL ITS [34]	Rule Base	To teach OOP concepts and observe students' progress and offer assistance based on pedagogical strategies adapted to the individual student.
	CPP-Tutor [35]	-	To teach programming concept using C++ and provide hints and feedback during problem-solving in tutorials.
	CS-I [36]	Rule Base	To teach programming concept using C++ and detect each students' level of understanding.
	DrJava [37]	-	To write, test and debug Java programs.
	EduJudge [38]	-	Submission, management and automatic evaluation of programming exercises.
	KSC-PaL [39]	K^* classifier	Collaborate with students to solve problems on data structures mainly on linked lists, stacks, and binary search tree.
	Marmoset [40]	-	To write and test Java code and helps the instructor to monitor student progress.
	OmniCode [41]	-	To teach novice students basic programming concept using Python.
	ProgTool [42]	-	Using visualization to teach OOP concepts.
	PASS [43]	-	Assisting beginners in learning programming.
	PLTutor [44]	Rule Base	To teach syntax and semantic of JavaScript using visualization.
	PLWeb [45]	-	Assist instructors to design computer programming exercises and to help students to study and practice programming exercises.
	SCALE [46]	-	Teach multiple topics consisting of pseudocode, sequential search, binary search subprograms and recursive.
	ViLLe [47]	-	Developed to visualize programming syntax written by students in Java or C++.
	WebTask [48]	-	To write Java code in a method body, testing, and received feedback in animation and visualization environment.
Knowledge & Skill with Errors or Misconceptions	ADIS [49]	Constraint Based Modelling	To teach basic algorithms of linked-lists, stacks, queues, trees and graph by visually.
	ADIL [50]	-	To teach C language and explain logical errors.
	AutoLEP [51]	-	Helps students to find and work through bugs in C language and also provides immediate detailed feedback.
	Collab ChiQat [52]	-	Developed to teach linked lists, stacks, and binary search trees in collaboration environment.
	iList [53]	-	Helps students to learn linked lists in visualization form.
	iSnap [54]	Contextual Tree Decomposition algorithm	To teach programming control structure using block-based programming.
	INCOM [55]	Constraint Based Modelling	Help students on programming logic using Prolog.
	J-LATTE [56]	Constraint Based Modelling	To teach Java in terms of design and syntax.
	OOPs [57]	Constraint Based Modelling	Help students to understand and overcome their misconceptions in OOP and reinforce the correct learning methods.
	ProBot [58]	Rule Base	Use game concept to improve students' abilities in programming control structures.

	@KU-UZEM [59]	Constraint Based Modelling	To teach C language and to overcome misconceptions in terms of concept and syntax.
Knowledge & Skill with Learning Styles & Learning Preferences	ABITS [60]	Association Rule Mining And Fuzzy C-Means Clustering	Introduction to Java Programming.
	EDUCA [61]	Neural Networks	Introduction to Maya Programming Language.
	ELM-ART [62]	-	Introduction to LISP Programing. Sample based problem solving support, detailed analysis of student answers, solving support, reminder option.
	Protus [63]	-	Help students during programming learning process by advising students to take an appropriate action when needed, monitoring their progress and tracking student learning styles.
Knowledge & Skill with Cognitive Features	APT [64]	ACT-R theory	To write short programs in Lisp, Pascal or Prolog
	WPAS [65]	-	Supporting programming learning activities with various difficulty levels.
Knowledge & Skill with Affective Features	E-Learning 3.0 [66]	Fuzzy-Logic and Nayve Bayes classifier algorithm	To teach Java according student emotions.
	PIT [67]	-	Teach programming skill and provide feedback based on students' emotion.
Knowledge & Skill with Motivation	FITS [68]	Bayesian networks	To teach flowchart using game environment.
Knowledge & Skill with Cognitive Features and Affective Features	Java Sensei [69]	Neural Networks, Fuzzy Logic	To teach Java and analyze student cognitive and emotion level during using the system.
	JavaTutor [70]	ACT-R theory & machine learning techniques	Teach Java by interacting human-to-computer and body expressions.
Knowledge & Skill with Learning Styles & Learning Preferences and Motivation	LOs [71]	Rule Base	Used simulation-based to teach array sorting.

Whereas another 52% or 23 articles focused on a combination of two to three student characteristics where one of the combinations is knowledge and skill. From the study, it was identified that 25% or 11 articles focused on knowledge and skills with errors or misconceptions as students' characteristics to build the student model. The researchers aim is to improvise the students' knowledge by learning from mistakes. From the educational point of view, learning from mistake or error can be powerful learning process, especially for learning programming. Students learn much faster when they made mistake first, especially in programming. In other words, getting the incorrect answer helps them to remember the correct one. To develop the student model base on these two students' characteristics, the researchers has considered three different modelling techniques which are Constraint Based Modelling, Contextual Tree Decomposition algorithm and Rule Base. Among these three techniques, Constraint Based Modelling is most preferred by the researcher because the algorithm was originally developed as a hypothesis about how student learn from their mistakes.

Two articles or 4% focused on knowledge and skill with cognitive features as students' characteristics for their student model. The cognitive features are students' ability to learn and recall memory and also capabilities to solve problems and make conclusion were used to construct the user model. ACT-R (Adaptive Control of Thought—Rational) theory was used to develop the tutoring system student model. The theory using a cognitive architecture that uses production rules to model student problem solving processes.

Another two articles or 5% focused focus on knowledge and skill with affective features as students' characteristics for their student model. This model was able to recognize and analyze student emotion such as frustration, boredom, engagement, confusion and excitement through students' facial expressions. The system was developed base on Fuzzy-Logic and Naive Bayes classifier algorithm.

One article or 2% focused on knowledge and skill with motivation as students' characteristics to construct the user model. The model was developed using Bayesian networks in game environment call tic-tac-toe. While another four article or 9% construct the student model based on knowledge and skill with learning style and learning preferences. The model able to track students' learning styles during their learning process by advising students to take an appropriate action when needed. Association Rule Mining and Fuzzy C-Means Clustering and Neural Networks were considered as modelling technique to construct the student model base on students' characteristics.

There are two articles or 5% focused on a combination of three student characters which are knowledge and skill with cognitive and affective features. The user model was developed to analyze students' cognitive and emotional conditions during the learning process. The model use ACT-R theory for knowledge representation while affective features were obtained through body expressions using sensor detection. The detection performed using machine learning techniques.

Lastly, one article (2%) focused on knowledge and skill with learning styles and learning preferences and motivation as students' characteristics to construct the tutoring system student model. The model able to detect students' learning styles and preferences using some predefine rules during the learning process and to motivate the students, simulation and visualization was used in the system user interface design.

From Jamal and Naemah [72] point of view, the effective teaching of programming subjects can be achieved by providing an appropriate tutoring system for the students. To achieve this, what type of students' characteristic need to be decided for the student model before developing the tutoring system [7]. From Fig. 4, it can say that knowledge and skills is an essential students' characteristic used to construct the tutoring system student model. Unfortunately, other students' characteristic is less considered especially students' motivation.

From the findings presented in Table II and Fig. 4, it can be seen that only 4.0% or 2 articles [68], [71 considered motivation as a student characteristic for the student model in IPT. On the other hand, Hooshyar et al. [68] used the game approach to motivate students to learn programming algorithm while Tuparov, Tuparov and Jordanov [71] used simulation-based ITP to help motivate students to understand array sorting. These motivations only encourage students as per view only.

Based on the results obtained from the existing literature thoroughly discussed above, it can be concluded that there is a lack of focus on motivation as a students' characteristic for student model mainly in IPT and generally in ITSs. Since student motivation is an important factor [15], [73] in learning programming [74], therefore the same consideration needs to be considered at the IPTs level and also ITSs.

IV. Conclusion

IPT is derived from ITSs. To develop an IPT system, students' characteristics need to be considered first before construct the student model which is one of important model in ITS architecture. From this study, it was identified that motivation was less considered as students' characteristics in constructing student model for IPT and generally in ITSs. Motivation and learning are highly complex aspects of human behaviour. Motivation has been agreed as a crucial aspect affecting learning behaviour, learning process and learning achievement. So, the same concern need to be consider in tutoring system implementation where can bring numerous benefits.

News Analytics for Business Sentiment Suggestion

Sirinda Palahan
School of Science and Technology
University of the Thai Chamber of Commerce
Bangkok, Thailand

***Abstract*—Business and economics news has become one of the factors businesses consider when making decisions. However, the exponential increase in the availability of business information sources on the internet makes it more difficult for entrepreneurs to keep up with and extract useful insights from many news articles. Although many preceding works focused on the sentiment extracted in the news, the results were intended for everyone. The sentiments based on a user's queries are needed to provide customized service. Hence, this paper proposed a system integrated into a chatbot to automatically understand users' queries and recommend sentiments based on news articles. The main objective is to provide entrepreneurs, especially those considering international trade and investment, with the sentiments embodied in the latest news articles to help them keep up with the business and economic trends relevant to them. The methodology is based on deep learning and transfer learning. A pre-trained deep learning model was fine-tuned for natural language processing tasks to perform sentiment analysis in news articles. A survey questionnaire was used to measure the effectiveness of the system. The survey result showed that most users agreed with the predicted sentiments from the system.**

***Keywords*—Sentiment analysis; deep learning; pre-trained model; natural language processing**

I. Introduction

One of the important sources of business information for entrepreneurs is news articles. News, especially business and economics news, has become one of the factors that entrepreneurs consider when deciding to trade or expand the business to other countries. The news could be more than just a medium to report on what has happened or carry information about the topics or entities discussed in the articles. They could also carry sentiments or trends toward the main content, such as products or companies mentioned in the articles. In other words, news conveys how the authors and people feel about the entity. This public sentiment is crucial to business because it tells how the public feels about the product or service. It also significantly influences the future of the product or service industries. But with the advancement in internet technology, the amount of news articles is increasing rapidly. Therefore, it has become a challenge for entrepreneurs to keep up with the rapidly increasing number of news sources, filter out unreliable sources, find all relevant information they need, and extract sentiments manually.

Sentiment analysis is a natural language processing (NLP) technique used to determine and extract subjective information in a text. The information could be people's opinions, sentiments, or attitudes towards entities. Due to the rapid growth of data on social media, sentiment analysis has become one of the most active research topics in NLP. Moreover, due to its superior performance in many application domains, deep learning has gained popularity, thanks to advanced cloud-based technology and increasing computing power. Among the success of deep learning in various application domains, deep learning has been used in sentiment analysis [1-3]. Many deep learning models can be applied or adapted to NLP datasets to attain high accuracy [4]. Therefore, this paper focuses on applying deep learning to automatically analyze many news articles and recommend sentiments based on news articles. The suggested sentiment can be considered an indicator that reflects consumers' attitudes and economic outlook toward the specific product in the country. Therefore, it can help a user make proper business decisions.

There are two main contributions to this paper. First, a deep-learning-based model is proposed to automatically understand users' queries and analyze and recommend sentiments based on current news articles. Second, the proposed model was integrated into a chatbot to provide an end-to-end solution in a business and economic domain so that the model could be tested in practice. As a result of this system, users can stay up to date on business and economic trends relevant to their specific fields.

The rest of the paper is organized as follows. First, an overview of the related works is presented in Section II. Next, the methodology of the proposed system is discussed in Section III. Then Section IV shows the results and findings. Finally, Section V gives conclusions regarding this work.

II. Related Work

Sentiment analysis has begun to be used in economics and finance recently. Many studies are concentrating on using sentiment analysis for stock prediction. Several works [5-7] analyzed tweets' moods or opinions and used machine learning methods for prediction. [5] studied whether the collective mood states extracted from the Twitter feed can be used to predict the value of the Dow Jones Industrial Average (DJIA). They used a Self-Organizing Fuzzy Neural Network to predict the changes in DJIA closing values. The results showed that the prediction accuracy was significantly improved when including a calm sentiment. [6] calculated a sentiment score of each tweet using a dictionary-based method and created feature vectors of sentiment scores to train a support vector machine (SVM) to classify the stock trend. The best accuracy was 90.34%. [7] also used a dictionary-based method with eight sentiments to analyze Twitter data. However, the results showed that adding sentiment data did not significantly improve accuracy.

Recent works [8-10] have developed a prediction model based on a deep learning approach. [8] used deep learning models to extract features from news headlines and predict stock prices. A Convolutional Neural Network (CNN) model was used to transform the sequence of words in the news title to the level of sentiment. The sentiment and other technical indicators were inputs to the Long Short-term Memory (LSTM) model to predict the price movement. The model achieved a 97.66% accuracy rate. [9] employed a similar approach where they extracted sentiments in the news content on Sina Weibo, China's largest online social network. They then input the sentiment features and technical indicators into an RNN-boost model to predict the stock volatility in the Chinese stock market. [10] enhanced LSTM by utilizing an attention mechanism to make predictions on the final output and informative outputs from hidden states. The results show that the attention-based LSTM improved prediction accuracy and reduced computational time.

Several other papers have focused on the economic sentiment embodied in the news and social media, especially Twitter. The author in [11] proposed a new technique to measure economic sentiment embodied in the news. Unlike survey-based economic sentiment measures, their index relies on extracting sentiment from news articles. The technique was applied to two applications. In the first application, they use their news sentiment index to predict consumer sentiment based on surveys. They found that the news sentiment is strongly predictive of Michigan Consumer Sentiment Index and the Conference Board's Consumer Confidence Index. Second, they investigated how the macro-economic response to sentiment shocks. They found that positive sentiment shocks increase consumption, output, and interest rates and temporarily reduce inflation. The author in [12] build a model to predict the sentiment index of a company based on news about that company. The authors evaluated their model by measuring the model's accuracy to predict the company's stock price movement. The result showed that the model has an average accuracy score of around 70.1%. The author in [13] proposed an automatic news chatbot that provides a variety of news articles organized into chatrooms based on news topics. When a user enters a chatroom, the chatbot provides the latest news articles on a given topic. A user can also ask specific questions regarding the topic, which a chatbot will answer with short sentences and provide a link to an article containing the answer. The drawback is a user cannot start a conversation by asking a specific question. Instead, a user must pick one of the topics to have conversations about that topic.

While most of the preceding work focused on the sentiment extracted in the news content where the results were intended for everyone, such as the consumer sentiment or sentiments for stock predictions, the sentiments based on a user's queries are needed to provide a customized service to the users. As a result, this work proposed a system that automatically understands users' queries and recommends sentiments based on current news articles. The system was integrated into a chatbot to provide easy access to the system for users. The system would help users to keep up with the latest business and economic trends in their fields of interest.

III. Methodology

This section describes the system architecture and how it processes users' queries to suggest product sentiments to users. The system consists of four components: a conversational interface, a keyword extraction module, a news search module, and a sentiment analysis module, as shown in Fig. 1. First, a user sends a query through a conversational interface. Next, the query is sent through the system. After receiving the query, the system extracts a keyword from the query and gathers news articles from trusted sources related to the keywords. It then analyzes the articles and suggests the sentiment. The news articles' list and their sentiment are then sent back to a user. The details of each component are explained in the following subsections.

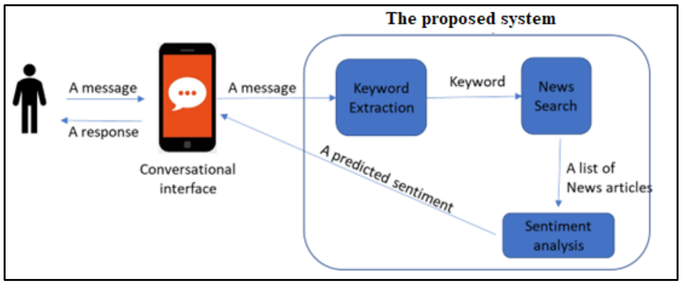

Fig. 1. The Architecture of the Proposed System.

A. The Conversational Interface

The first component is a conversational interface acted as a chatbot to interact with users. The LINE messenger app was used as the conversational interface for this work because it is Thailand's most used messaging app [14]. Thus, the system can easily be accessible to Thai users.

(b)

Fig. 2. The Conversational Interface. (a): Regular Response (b): Response with Empty List of Local News.

The conversational interfaces are shown in Fig. 2(a) and 2(b). Fig. 2(a) shows a response to the LINE messenger app when a user sends a message, "What is the direction of shoes in Thailand?". The first line in the response message is the sentiment of the keywords "shoes" and "Thailand." After the first line, it shows a list of local and global news articles related to the keywords. The local news is the news from local news providers such as bangkokpost.com or vietnamnews.vn. The global news is the news from global news providers such as channelnewsasia.com or asia.nikkei.com. If there is no related news, the list will be empty, as shown in Fig. 2(b) where the list of local news is empty.

The system suggests three types of sentiment: positive, neutral, and negative. The interpretation of the sentiments of keywords is as follows. The positive and negative sentiments mean the keywords have a positive or negative economic outlook. While the neutral sentiment means the keywords have neither a positive nor negative economic outlook.

B. The Keyword Extraction Module

The main objective of this module is to extract keywords in a user's query and pass the keywords to the news search module for searching relevant news articles. The keywords can be a single word or a combination of words in a query. Fig. 3 displays an overview of the input and output of the keyword extraction module. First, a user sends a message, "What is the trend of tourism in Myanmar?" via a conversational interface. Next, the message is sent to the keyword extraction module. The module then extracts keywords; in this example, the extracted keywords are "tourism" and "Myanmar." The News search module then uses this keyword to search for relevant news articles. If the module cannot identify any keywords, the system will tell a user that no keywords can be identified and ask a user to try a different query.

The module first tokenizes the sentences and identifies parts of speech (POS) tags to extract keywords. The keyword in the message is a combination of words tagged as nouns and proper nouns, both singular and plural. The result of tokenizing and POS tagging the sentence “What is the trend of tourism in Myanmar?' looks like this:

('What', 'WP')

('is', 'VBZ')

('the', 'DT')

('trend', 'NN')

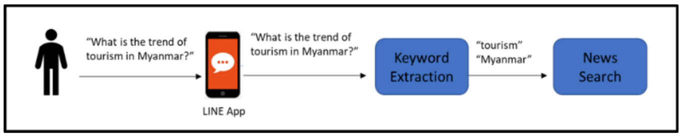
('of', 'IN')

('tourism', 'NN')

('in', 'IN')

('Myanmar', 'NNP')

('?', '.')



"What is the trend of tourism in Myanmar?"
LINE App
"What is the trend of tourism in Myanmar?"
Keyword Extraction
"tourism" "Myanmar"
News Search

Fig. 3. An Overview of the Input and Output of the Keyword Extraction Module.

The tagging result has three nouns: 'trend,' 'tourism,' and 'Myanmar' in the sentence. After filtering out the word 'trend,' the keyword is "tourism Myanmar."

This work used the NLTK toolkit [15] for tokenizations and POS tagging. NLTK is a leading tool for working with NLP in Python. It provides various libraries for text processing, including tokenizations and POS tagging. Tokenization is how a sentence is broken into words and punctuations. For example, "What is the trend of tourism in Myanmar?" is tokenized as ['What', 'is', 'the', 'trend', 'of', 'tourism', 'in', 'Myanmar', '?']. After that, the module classifies words into parts of speech and labels them accordingly using a POS tagger. The POS tagger uses a UPenn Tagset, as shown in Table I.

TABLE I. A LIST OF PART-OF-SPEECH TAGS

Tag	**Description**
CC	Coordinating conjunction
CD	Cardinal number
DT	Determiner
EX	Existential *there*
FW	Foreign word
IN	Preposition or subordinating conjunction
JJ	Adjective
JJR	Adjective, comparative
JJS	Adjective, superlative
LS	List item marker
M.D.	Modal
N.N.	Noun, singular, or mass
NNS	Noun, plural
NNP	Proper noun, singular
NNPS	Proper noun, plural
PDT	Predeterminer
POS	Possessive ending
PRP	Personal pronoun
PRP$	Possessive pronoun
R.B.	Adverb
RBR	Adverb, comparative
RBS	Adverb, superlative
RP	Particle
SYM	Symbol
TO	*to*
UH	Interjection
VB	Verb, base form
VBD	Verb, past tense
VBG	Verb, gerund, or present participle
VBN	Verb, past participle
VBP	Verb, non-3rd person singular present
VBZ	Verb, 3rd person singular present
WDT	Wh-determiner
WP	Wh-pronoun
WP$	Possessive wh-pronoun
WRB	Wh-adverb

C. *News Search Module*

This module searches for relevant articles across trusted news sources using the extracted keyword from the keyword extraction module. Two lists of trustworthy news sources were curated: a local and global list. The local list contains high-reputable local news sources from each country, while the global list contains high-reputable news sources covering news mainly from Asia and worldwide. The local news sources are as follows:

- https://en.vietnamplus.vn
- https://english.vov.vn
- https://aecnewstoday.com
- www.irrawaddy.com
- https://elevenmyanmar.com
- https://english.cambodiadaily.com
- www.phnompenhpost.com
- https://laotiantimes.com
- https://www.bangkokpost.com/

The global news sources are as follows:

- asiatimes.com
- www3.nhk.or.jp
- https://asia.nikkei.com
- https://www.asiaone.com
- https://www.businessnewsasia.com
- https://www.channelnewsasia.com
- http://annx.asianews.network
- www.businesstimes.com.sg

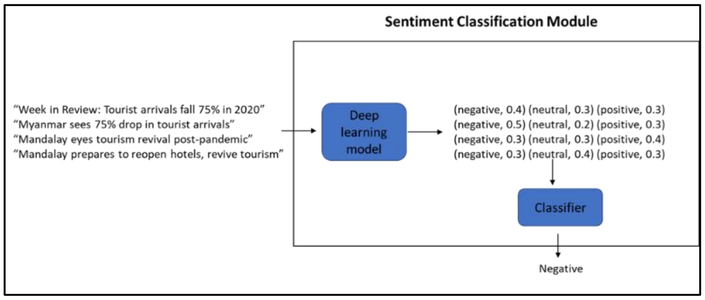
Google Programmable Search Engine (formerly known as Google Custom Search) was used to search across a collection of local and global news sources. A custom search JSON API was created with the Google Programmable Search Engine to retrieve search results automatically in JSON format via RESTful requests. In addition, this module was set to return news articles published within 12 months.

D. *Sentiment Classification Module*

This module classifies a sentiment related to the user's keyword. The sentiment of the keyword is based on sentiments of its related news articles. The keyword's sentiment depends on how the news providers and people feel about the content the keyword was discussed. This module consists of two models: a deep learning model and a classifier, as shown in Fig. 4.

Fig. 4 shows how the Sentiment Classification Module works. This example uses a user query "What is the trend of tourism in Myanmar?" where the news search module returns a list of news articles as follows:

- Article 1: Week in Review: Tourist arrivals fall 75% in 2020.
- Article 2: Myanmar sees 75% drop in tourist arrivals.
- Article 3: Mandalay eyes tourism revival post-pandemic.
- Article 4: Mandalay prepares to reopen hotels, revive tourism.



Sentiment Classification Module
"Week in Review: Tourist arrivals fall 75% in 2020"
"Myanmar sees 75% drop in tourist arrivals"
"Mandalay eyes tourism revival post-pandemic"
"Mandalay prepares to reopen hotels, revive tourism"
Deep learning model
(negative, 0.4) (neutral, 0.3) (positive, 0.3)
(negative, 0.5) (neutral, 0.2) (positive, 0.3)
(negative, 0.3) (neutral, 0.3) (positive, 0.4)
(negative, 0.3) (neutral, 0.4) (positive, 0.3)
Classifier
Negative

Fig. 4. An Example of How the Sentiment Classification Module Works.

After receiving a list of news articles, the sentiment classification module performs two steps. First, it calls a deep learning model to calculate sentiment scores for each article. There are three sentiments: negative, neutral, and positive. Hence each article is assigned three scores for the three sentiments. The result from the first step would look like this:

- Article 1: (negative, 0.4) (neutral, 0.3) (positive, 0.3).
- Article 2: (negative, 0.5) (neutral, 0.2) (positive, 0.3).
- Article 3: (negative, 0.3) (neutral, 0.3) (positive, 0.4).
- Article 4: (negative, 0.3) (neutral, 0.4) (positive, 0.3).

Second, it classifies a sentiment for the keywords by choosing the sentiment with the highest average scores from all news articles. From the example, the averages of the three sentiments from four articles are below:

- (negative, 0.375) (neutral, 0.3) (positive, 0.325)

The averages show that the negative sentiment has the highest score, so it classifies the sentiment's keywords as "Negative". The system then sends the result back to the user, saying, " The tourism trend in Myanmar is Negative.".

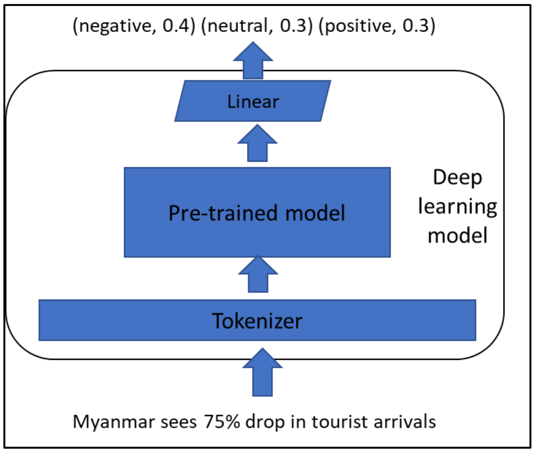
1) Sentiment classification module: Many works provide methods and tools for sentiment analysis. Recently, most meth-ods have been based on deep learning with transfer learning. Deep learning is a sub-field of machine learning methods based on neural networks. The networks typically have three or more layers, performing feature extraction and transformation via a cascade of multiple layers of linear and nonlinear processing nodes. The lower hidden layers near the input layer learn simple features, while the higher layers learn complex features derived from lower layers.

A transfer learning is a machine learning technique where a model is trained for one task and applied to a different but related task. The common approach to using transfer learning for deep learning is to use a pre-trained model. A pre-trained model is chosen from available models typically released by research institutes for this approach. The pre-trained model is then trained and fine-tuned on a new dataset for the task of interest.

Many pre-trained deep learning models can be employed for the task. Hence, four models were tested in the experiments, Bert, RoBERTa, XLM-R, and XLNet. The best model would be selected for the system. Google's Bert [16] is a bi-directional model pre-trained on an unlabeled text that can be used to create a wide range of tasks by fine-tuning with just one additional output layer. RoBERTa [17] extends the original BERT model where the researchers fine-tune the original BERT model with a huge dataset and improved input representation. XLM-R [18] is a cross-lingual language model trained with MLM (Masked Language Modeling) on one hundred languages and terabytes of texts. Finally, XLNet [19] is an auto-regressive language model which uses the context word to predict the next word. The model has also addressed some drawbacks of BERT and outperformed BERT in many tasks.

A linear layer was added on top of the pooled output to calculate sentiment scores, as shown in Fig. 5. Next, all models were trained and fine-tuned for a classification task where the outputs are probabilities of three classes: positive, negative, and neutral.

2) The dataset: The dataset used to train and fine-tune models was curated by [20]. The dataset contains about 5000 news titles from financial news resources, where each title was labeled as positive, negative, or neutral by annotators with good backgrounds in business and investment. The classes reflect an investor's perception of business and market conditions on the news. The positive class means the news title appears to positively influence the market and vice versa for the negative class. If the news title reflects neither positive nor negative influence, the news title is considered neutral. Each news title was trimmed to have the maximum sequence length of 256 for fast processing in a real-time environment. Examples of news titles and their sentiments are shown in Table II.



(negative, 0.4) (neutral, 0.3) (positive, 0.3)

Myanmar sees 75% drop in tourist arrivals

Fig. 5. The Architecture of the Proposed Deep Learning Model.

TABLE II. EXAMPLES OF NEWS TITLES AND THEIR SENTIMENTS

News Title	Sentiment
According to Gran, the company has no plans to move all production to Russia, although that is where the company is growing.	neutral
Technopolis plans to develop in stages an area of no less than 100,000 square meters to host companies working in computer technologies and telecommunications, the statement said.	neutral
With the new production plant, the company would increase its capacity to meet the expected increase in demand and would improve the use of raw materials, and therefore increase the production profitability.	positive
According to the company's updated strategy for the years 2009-2012, Basware targets a long-term net sales growth in the range of 20 % -40 % with an operating profit margin of 10 % -20 % of net sales.	positive
The international electronics industry company Elcoteq has laid off tens of employees from its Tallinn facility; contrary to earlier layoffs the company contracted the ranks of its office workers, the daily Postimees reported	negative
A TinyURL link takes users to a scamming site promising that users can earn thousands of dollars by becoming a Google (NASDAQ: GOOG) Cash advertiser.	negative

IV. RESULTS AND DISCUSSION

This section shows the performance of different pre-trained deep learning models for model selection and the system's performance based on a user survey. Error analysis and some discussions are also provided.

A. Model Selection

Four deep learning models were tested for model selection. The models were Bert, RoBERTa, XLM-R, and XLNet. The Transformers and FastAI libraries [21, 22] with the default architecture were used to implement the deep learning models where weights were initiated randomly. First, the dataset was divided into a train and test set with a split ratio of 60:40. The training set was used to fine-tune the pre-trained models, and the test set was used to select the best model. Next, the models were trained with the Adam optimization algorithm with an accuracy rate as a metric. Adam optimization algorithm is an algorithm to update the weights in neural networks during training. The Adam optimization algorithm was chosen because it works well in many empirical results and is recommended as the default algorithm [23, 24]. The key metrics to evaluate the performance of the models are accuracy rate and computation time on the test set.

From Table III, the accuracy rates of Bert, RoBERTa, XLM-R, and XLNet are 0.8500, 0.8633, 0.7367, and 0.8667, respectively. From the results, RoBERTa is tied with XLNet regarding the accuracy rate, but it took the least computational time, so RoBERTa was chosen for the system.

TABLE III. EXPERIMENTAL RESULTS ON A MODEL SELECTION

Model	Accuracy Rate	Computational Time (Seconds)
Bert	0.8500	0.0428
RoBERTa	0.8633	0.0378
XLM-R	0.7367	0.3742
XLNet	0.8667	0.0399

B. Performance Evaluation

There is no public ground truth for evaluating the accuracy of the predicted sentiments of keywords because a sentiment of a keyword depends on the current economics, and it can change as time goes by. For this reason, a user survey was employed to measure the system's effectiveness from users' perspectives. First, the participants were asked to make a few queries using keywords of their choices and give feedback on the results. After that, users were asked two questions:

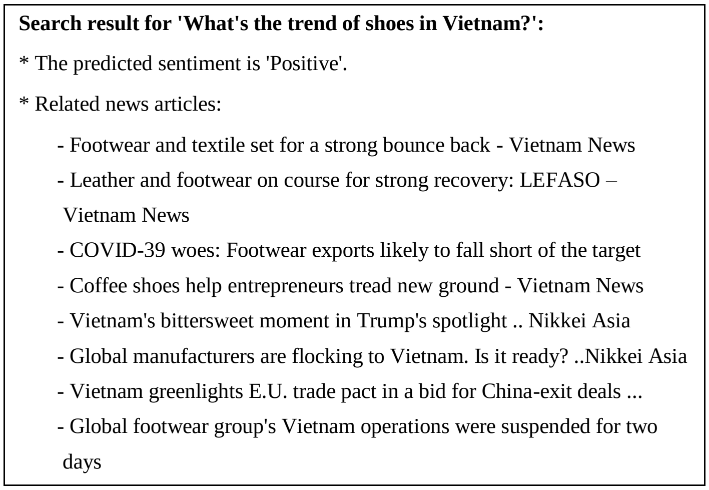
1) On a scale of 1 – 5, with 1 being highly irrelevant and 5 being highly relevant, how relevant each news article is to your keyword?

2) What sentiment would you assign to your keyword from your perspective?

The first question is to measure the relevancy of the news articles to the keyword. Participants were asked to rate an individual news article. A relevance rating for the keyword was calculated by averaging the ratings of all of its news articles. The second question measures the accuracy of the keyword sentiment from the users' perspective. It is used as a keyword accuracy rate, the fraction of predictions the system got right according to users' perspectives.

For example, a user searching for a 'What's the trend of shoes in Vietnam?' result is shown in Fig. 6. In the figure, the predicted sentiment for the keyword is "Positive," where the extracted keyword for the user's query is 'shoes Vietnam'. The system also returned related recent news articles to the user. Each title contains a link to its original news source.

Next, the participants were asked to rate each article in terms of relevancy to the keywords. The rating scale is 1 to 5. Table IV shows a news relevance rating for each news article and the news relevance score, which is an average of all ratings. For this example, the news relevance score is 3.88, indicating that the news articles are somewhat relevant to the keyword. The participants were also asked what sentiment they would assign to the keyword based on the news and their perspective. For example, for the keyword 'shoes in Vietnam', the user assigned a 'Positive' sentiment the same as the sentiment predicted by the system.



Search result for 'What's the trend of shoes in Vietnam?':

* The predicted sentiment is 'Positive'.

Fig. 6. Search Result for a user's Keyword.

TABLE IV. RELEVANCE RATINGS

Keyword	News Title	News Relevance Rating
shoes in Vietnam	Footwear and textile set for a strong bounce back - Vietnam News	5
	Leather and footwear on course for strong recovery: LEFASO - Vietnam News	5
	COVID-39 woes: Footwear exports likely to fall short of the target	3
	Coffee shoes help entrepreneurs tread new ground - Vietnam News	5
	Vietnam's bittersweet moment in Trump's spotlight - Nikkei Asia	3
	Global manufacturers are flocking to Vietnam. Is it ready? - Nikkei Asia	3
	Vietnam greenlights E.U. trade pact in bid for China-exit deals ...	2
	Global footwear group's Vietnam operations were suspended for two days	5
	Relevance rating	**3.88**

Fifteen users participated in the survey. Seven of the users were entrepreneurs, and the remaining users were senior students with a major in international business management. Each user made 3 to 4 queries. The total number of queries was 40. The survey results show that the average relevance rating is 2.66 out of 5, and the accuracy rate of the keyword sentiment is 0.35. The average relevance rating and accuracy rate for each sentiment category were also computed, as shown in Table V. The results look promising, with a 62.50% accuracy rate for the positive articles and a 2.93 relevance rating for the negative articles.

TABLE V. THE RELEVANCE RATING AND THE ACCURACY RATE BY CATEGORY

Sentiment	Relevance Rating	Accuracy Rate
Negative	2.9342	0.3636
Neutral	2.5133	0.2380
Positive	2.7142	0.6250

C. Error Analysis

After the evaluation process, classification errors were examined to identify how to improve the system. First, a confusion matrix was constructed to see what categories the system misclassified and what categories had been predicted correctly. From the confusion matrix in Table VI, the system predicted Neural sentiments the most (21/40), whereas users assigned Positive sentiments the most (24/40). So the results of 14 keywords that the system predicted Neutral sentiments, but users assigned Positive sentiments were examined. The examination result shows that a few articles sound positive but were assigned Neutral sentiment by the system. The Neutral sentiment also received the lowest relevance rating and accuracy rate, as shown in Table V. These results may be due to the class imbalance in the dataset used to train the model, where 59% of articles were Neutral. In comparison, only 12% and 28% of articles were Negative and Positive, respectively. Based on this finding, the system's performance in the Neutral category could be improved by employing a resampling technique to deal with an unbalanced dataset.

TABLE VI. CONFUSION MATRIX

		User Sentiment			**Total**
		Negative	**Neutral**	**Positive**	
Predicted Sentiment	**Negative**	4	2	5	11
	Neutral	2	5	14	21
	Positive	2	1	5	8
Total		8	8	24	40

Second, the queries that received the correct sentiments were analyzed. The result shows that they also received a higher news relevance rating. The finding may indicate that higher relevant news articles will likely improve the sentiment accuracy. To test if higher relevant news articles would help boost the accuracy rate, queries whose average relevance rating is less than 3 were removed and re-calculated the accuracy rate. There are 22 queries whose average relevance rating is less than 2. After removing those queries, the accuracy rate went up to 0.5. From the analysis, the search engine should be improved to return more relevant news articles so that the algorithm has better information to calculate a sentiment.

Third, since the accuracy of keyword sentiments depends on the accuracy of predicted sentiments of news articles related to the keyword, the senior students who participated in the survey were asked to rate sentiments of the news articles in the search results from the survey. There were 268 news articles from 40 queries. Next, the accuracy rate and a macro-F1 score of the news sentiment were computed by comparing the predicted sentiment classifications from the model to the sentiments rated by the users. The accuracy rate and a macro-F1 score are 0.6679 and 0.4343, respectively. These results show that the system could accurately classify news sentiments, but those articles were irrelevant to their keywords. These results also emphasize the need to improve the system's search engine.

D. Discussion

The accuracy rate and a macro-F1 score of the news sentiment from the system are 0.6679 and 0.4343, respectively. These results are similar to the result in [11], where the authors proposed a new technique to measure economic sentiment embodied in the news. In [11], the macro-F1 score was calculated using the 100-article test set for which they compared predicted sentiments from various models to human-provided sentiments. The lowest macro-F1 score was 0.406 from using Lexicon only, and the highest macro-F1 score was 0.525 from their proposed method. According to these macro-F1 scores, sentiment analysis is still very challenging. The majority of the current sentiment analysis techniques are data-driven machine learning techniques. Hence they have limitations in terms of data size and inconsistency of ground truth [25]. Furthermore, labeling needs to be done by humans, and human ability to label large volumes of data is limited. Moreover, there is a great deal of subjective opinions when it comes to business news. A bad situation for one business might be good for another business. As a result, it is essential to provide clear and concise instructions to produce high-quality annotations. In this study, the participants were asked to make queries related to their businesses or expertise to evaluate results from those businesses' perspectives.

V. CONCLUSION

This paper presents a methodology to automatically understand a user's query about a product and provide its sentiment embodied in news articles. The system is based on deep learning and transfer learning to build a model using a pre-trained deep learning model fine-tuned for sentiment analysis in news articles. The news articles are automatically searched and collected by the news search module from the lists of trustworthy news sources both locally and globally to ensure the quality of news articles. Finally, the model was integrated into a chatbot and tested in practice. The satisfaction survey shows participants agreed with the results, with a relevance rating of 2.66 and an accuracy rate of 35%. The evaluation by category shows that the positive articles received the highest accuracy rate of 62.50%, while the negative articles received the highest relevance rating of 2.93. In the future, the news search module could be improved to return relevant search results with higher precision by adding more capabilities such as semantic understanding to understand user intention better. Moreover, the sentiment classification module could be improved by re-training the deep learning model with different parameters.

Sentiment Analysis using Term based Method for Customers' Reviews in Amazon Product

Thilageswari a/p Sinnasamy, Nilam Nur Amir Sjaif
Razak Faculty of Technology and Informatics
Universiti Teknologi Malaysia
Kuala Lumpur, Malaysia

***Abstract*—Customers' review in Amazon platform plays an important role for making online purchase decision making, however the reviews are snowballing in E-commerce day by day. The active sharing of customers' experience and feedback helps to predict the products and retailers' quality by using natural language processing. This paper will focus on experimental discussion on Amazon products reviews analysis coupled with sentiment analysis using term-based method and N-gram to achieve best findings. The investigation of sentiment analysis on amazon product gain more valuable information on related text to solve problem related services, products information and quality. The analysis begins with data pre-processing of Amazon products reviews then feature extraction with POS tagging and term-based concept. e-Commerce customer's reviews normally classify different experience into positive, negative and neutral to judge human behavior and emotion towards the purchase products. The major findings discussed in this journal will be using four different classifier and N-grams methods by computing accuracy, precision, recall and F1-Score. TF-IDF method with N-gram shows unigram with Support Vector Machine learning with highest accuracy results for Amazon product customers' reviews. The score reveals that Support Vector Machine for unigram achieved 82.27% for accuracy, 82% precision, 80% Re-call and 72% F1-Score.**

Keywords*—*Sentiment analysis; e-commerce; term based; n-gram

I. Introduction

The huge growth of opinion sharing platform in E-commerce such as Amazon, E-bay, Shopee, Zalora and Lazada could facilitates the customers to understand better about products that been available in online platform [1] [2]. Sharing customer's experience and feedback help to predict the products and retailer quality by using natural language processing. Furthermore, customer's experience rating (1 to 5 stars) and reviews also play important role to express customers satisfaction namely 4 and 5 score represent positive attitude, score 3 represent neutral and score 1 and 2 represent negative attitude [3] [4]. Product star ratings in E-commerce used to evaluate product quality information and online customer behavior from various dimensions whether it could be positive or negative.

Amazon is one popular online platform for buying and selling online products purchase by customers [2] [5]. Customers' review and rating in Amazon platform plays important role to make a purchase decision however the reviews have grown remarkably in e-Commerce. Naturally, it consumes plenty of time to digest and explore huge amount of reviews to make a right decision [2] [3] [6] [7]. Other than that, customer may also get indecisive to make right purchase decision especially the 3-stars in Amazon represent neutral. In addition, there are also inadequate summary of dominant reviews from E-commerce platforms for satisfied customers [8]. The semantic words in reviews also create noise to the result and low frequency problem.

The aim of this paper is to explore on quality of text representation and categorization with better classifiers as to measure and judge the important raw information. Therefore, sentiment analysis help predicts the polarity sentiments in reviews which could be positive, neutral or negative. Sentiment analysis explores expression and emotion of customers which feeds extract important information from customers' reviews [6]. Sentiment classification strategy evaluate and described the text in reviews with aspect level by identifying interest words from reviews using text mining method [6] [9], whereby sentiment analysis approach machine learning and dictionary based method [10]. Machine learning method classifies the text and dictionary method identifies polarity of words. In this case, text mining would drive the information to organize text as positive, negative and neutral. Text mining retrieves the relevant information to segregate between structured and unstructured data [11] [12]. This paper will present experimental result and analysis using term based method using data from Amazon products. The objective of this paper is to reveal the insightful meaning and identify the polarity pattern from unstructured data using sentiment analysis. It includes method as data pre-processing, feature extraction, sentiment polarity prediction and classification.

This paper would be sorted out such a manner that after this introduction, Section II comprises of related works it covers some of previous studies on sentiment analysis. Later in Section III, it elaborates text mining methods. The following Section IV will explain in detail of the approach on data and method as solution to this paper summary. The methodology used in this experiment as describe deeply in this section. Next, Section V present summary of result on discussion obtained from experiment. Section VI discuss on contribution of this paper to customers using e-Commerce. Finally, the last section concludes the findings of paper and acknowledgment.

II. Related Work

This section presents several studies with different approaches to analyze sentiments in review. Many researchers have experience to work with customers' reviewers in using sentiment analysis. Naturally Customers' reviews are very important to identify product satisfaction, product features and services for convenient customers [3] [4] [13]. The sentiment analysis result from various method helps provide effective purchase decision and reducing search cost in E-Commerce. Sentiment analysis polarize the review into positive, neutral and negative with natural language processing for judging human behavior and attitude [6]. Authors in [14] have worked with sentiment analysis using Support Vector Machine (SVM) to analyze reviews in tweets. The survey results present several techniques and methods of sentiment analysis which provides different results but if combine both methods then it produces better result. The main factors of best result are selection of methodology for data preprocessing, feature extraction phase and ratio between training and testing. Hence, author Minu with other researchers [15] has conduct experiments on mobile products reviews using machine learning algorithms and exploring the result with different datasets. POS tagging used to recognize the reviews noun, adjective, verb and adverb. The aspects are than polarize into positive and negative using TextBlob and machine learning approaches such as K-Nearest Neighbour, Support Vector Machine, Multinomial Naïve Bayesian and Bernoulli Naïve Bayesian used for predict the result. The best accuracy of mobile reviews is given by K-Nearest Neighbour and Bernoulli Naïve Bayesian. Furthermore, the sentiment analysis also implemented on different language for analyze various machine learning algorithm with N-gram as feature extraction [16]. Arabic opinion from twitter collected and associate data pre-processing with the phrases for noise reduction. N-gram which is number of terms used to search word such unigram (1), bigram (2) and trigram (3) used as feature extraction to generate frequent appealing words. By applying machine learning approaches the result present that PA and RR using unigram, bigram and trigram present best result as 99.96%. On other hand, online customer reviews from Tokopedia been analyze for understanding service quality level using sentiment analysis [17]. Whereby the unstructured data performed starting with data pre-processing, TF-IDF implemented for identifying frequent itemset and reduce noisy from dataset. Finally, Naïve Bayes classifiers used for measure accuracy, recall and precision. The result shows Naïve Bayes present very good result for classifying sentiment and the overall methods used are more effective to perform better. More details on text mining methods been discussed in Section III.

III. Text Mining Methods

Some prominent researchers have used text mining methods in E-commerce such as the Amazon reviews from large textual database in the form of structured and unstructured data [12] [18]. Text mining includes process such as data collection, data pre-processing, feature extraction, classification and measurement. Even Machine learning tools been utilized to explore text mining method to organize and categorize data in further details. The process data used for predictive analysis, business application, business intelligence, decision support system and data warehouse where there is a need to refer customers' requirement [19]. There are four method of text mining are discussed in this section such as Term based, Phrase based, Concept based and Pattern based.

A. Term Based

The dataset filtered and stemmed to obtain frequency of term used to represent as document is presented with term-by-frequency matrix [18]. While Term base method contributes terms into documents as to discover weights for each describe terms. Term frequency and inverse document frequency (TF-IDF) model generally been used to calculate frequent word in a document with inverse proportion of word whereby the model converts textual data to Vector Space Model (VSM) [20].

TF : Term Frequency refer to number of term in a documents [18] [21]. TF calculated as [22] :

$$\mathrm{TF}(t,d) = \frac{n_t}{N_{(T,d)}} \qquad (1)$$

Nt represent number of frequency of term t in a document d, *N(T,d)* shows sum of total terms *T* in document.

IDF : Inverse Document Frequency refer to calculated (log(N/DF)) number of documents containing term as shown below [18] [21].

$$\mathrm{IDF} = \log \frac{D}{n_d} \qquad (2)$$

D represent sum of documents in the corpus, *nd* number of document. Hence, TF-IDF calculated as:

$$\text{TF-IDF} = \text{TF} * \text{IDF} \qquad (3)$$

Yusheng Zhou with other researchers, has implemented TF-IDF algorithm to investigate helpfulness of online reviews and which later explores correlation between review title and content on review helpfulness [21]. Other than that, in social media such as Twitter and Facebook also utilize TF-IDF method to extract and categorize sentiment in reviews from unstructured data [20] [23]. Those studies indeed help decision making by identify polarity (positive, neutral, negative) of reviews using sentiment analysis method. The researcher also capitalizes TF-IDF extraction method with Amazon dataset to analysis customers' reviews on products in making decisions and improving performance of retailers [24]. Other than English language reviews, Bahasa reviews from Tokopedia website been collected to analysis and identify hidden pattern which supports companies using TF-IDF method using sentiment analysis process [17].

B. Phrase Based

Phrases based filtration rarely been implemented by researcher due low frequency, noisy appearance with synonym words and second class statistical properties [12] [25]. The advantage of phrase-based method would be less doubtful and more presentable and represents accurate result on phrase basis.

C. Concept Based

This method concerns more on relevant and extract valuable meaning of sentences using natural language processing [18] [12] [18] [25]. Concept based model consist of three components. The first component is to analyze synonym structure of sentences by extracting verbs and arguments from text and then, to present Conceptual Ontological Graph (COG) model as one to one relationship among constituents [12] [26]. The third is to extract information using vector space model whereby it helps screening importance term in every sentences. Concept based mining measure closeness between the documents to evaluate usefulness of concept sentence level (Conceptual term frequency, ctf), document level (term frequency, tf) and corpus level (Document frequency, df).

D. Pattern Based

In text document reviews, pattern based method uses pattern deploying and pattern evolving for discover hidden pattern and trend [27]. Analysis on pattern based is discovered with method such as association rule, frequent item set mining, sequential and closed pattern mining [12]. This helps to reduces low frequency and misinterpretation by leading performance and support of related patterns. Pattern based techniques include algorithms such as Generalized Sequential Patterns (GSP), Prefix-Projected Sequential Pattern Mining (PrefixSpan), Suffix Arrays, Sequence Joining and nGram Linking [27]. Based on investigation, evaluation of those algorithms to Sequence Joining give preferably best result compared to others algorithm. The researcher works with pattern based method using association rules to determined hidden trend and sentiment in online text from social network [28].

IV. Data and Methods (Methodology)

This research propose sentiment analysis techniques and term based method to identity polarity of reviews from E-commerce site whereby the customer reviews has two components, namely, ratings and reviews [5] [7] [9]. These two columns have been incorporated in this study for assessment. Fig. 1 shows methodology of sentiment analysis to be develop using Amazons' electronic customer reviews whereby the analysis process begin with data pre-processing (refer section B), than feature extraction (refer section C), sentiment classification (refer section D) and finally Evaluation score (refer section E). The method develops using python Jupiter notebook, Anaconda.Navigator 1.10.0 whereby it is free open-source distribution can be supported in windows, macOS and Linux. SciKit-Learn and Natural Language Tool Kit (NLTK) libraries used for develop this model.

A. Data Collection

The compiled data for this paper are extracted from Amazon electronic category; it is downloaded from Kaggle in English language [29]. The file was in Comma Separated Values (CSV) whereby it's convenient to consume in python. The sample data provide customers' rating of score 1 to 5 stars and reviews which was written in English language and covers electronic products which been purchased online using Amazon.com. In total, 34,633 customers' reviews were collected from the website. For each review, rating and product details are provided. The variable and description of dataset are shown in Tables I and II. Table II provides number reviews by classes from 1 to 5. The dataset has been chosen to identify polarity of reviews.

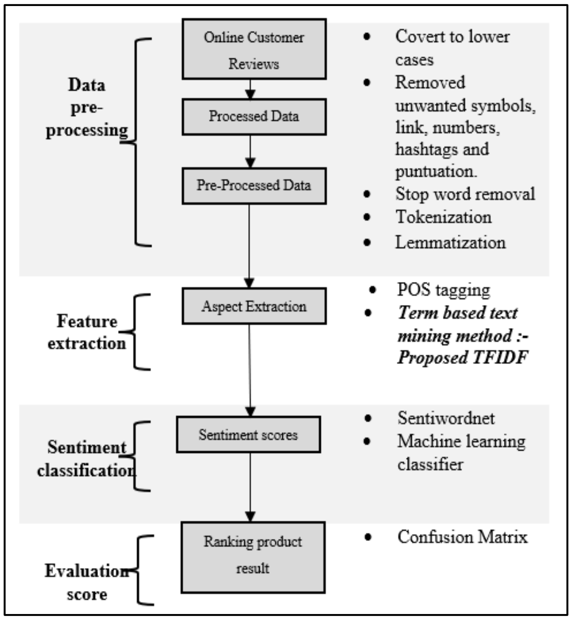

Fig. 1. Sentiment Analysis Process Flow.

TABLE I. Description of Dataset

No	Variables	Description of variables	Variables choose for this study (Yes/No)	Description
1	Id	Products' ID	No	N/A
2	Name	Products' Name	No	N/A
3	Asins	Amazon standard identification numbers	No	N/A
4	Brand	Products' brand	No	N/A
5	Categories	Products' categories	No	N/A
6	Manufacturer	Amazon or Amazon Digital Services	No	N/A
7	Review Date	Date of review data	No	N/A
8	Review ID	Unique ID for review	No	N/A
9	Review Rating	Customers' rating	Yes	Dependent Variable :- The rating is given by customer to the purchase product in the form of score ranging from 1 to 5.
10	Reviewer Name	Name of the reviewer	No	N/A
11	Review Title	Title of the review	No	N/A
12	Review Text	Text of the review	Yes	Independent Variable:- The reviews is unstructured text where expressed sentiments on purchase product positive or negative.

TABLE II. CONTENT OF DATASET

Number of Reviews	34660
Number of Columns	21
Number of reviews with rating 5	23774 (68.66%)
Number of reviews with rating 4	8541 (24.67%)
Number of reviews with rating 3	1499 (4.33%)
Number of reviews with rating 2	410 (1.16%)
Number of reviews with rating 1	402 (1.18%)

B. *Data Preprocessing*

Pre-processing phase is very important method in sentiment analysis for present quality result and enhance accuracy of the classifier to customers, it applies to Amazon dataset as shown in Table I. It also converts unstructured data to structured data which is suitable format for feature extraction. The first step of data preprocessing is converting selected alphabets into lower cases and omit all unwanted symbols, links, numbers, hashtags and punctuation. Followed by, step as below:

Convert to lowercase: The model will consider upper case as different words, hence converting to lowercase will remove noise in dataset.

Removal of unwanted symbols, links, numbers, hashtags and punctuation: By removing those details can reduce the feature space and which does not help in performance of result.

Stop word removal: Stop words will ~~is~~ not required for analysis, hence, it been removed from reviews for simplify of the text and improve performance of result. Example of stop words are ‘a’, ‘is’, ‘are’ and ‘that’.

Tokenization: The process of breaking the sentences into phrases and words.

Lemmatization: Method for switching the words into root meaning. For example, ‘used’ to ‘use’.

POS tagging: Part-of-speech tagging where it will identify each words of reviews from noun, adjective, verb and adverb.

After preprocessing, feature extraction is takes place for sentiment analyses.

C. *Aspect Extraction*

Part-of-Tagging (POS) is preferred method to identify each words of review noun, adjective, verb and adverb [15] [30]. Table III and Table IV show sample of POS tagging results after preprocessing.

Based on word segmentation, the keywords from text been identified for further process. Then, term-based text mining method was performed to generate most frequent itemset with TF-IDF model. In between, N-gram play important role to represents number of texts as unigram (1), bigram (2) and trigram (3) [16] [20]. When applying N-gram it can represent numbers of word needed in frequent itemset. Fig. 2, 3 and 4 show comparative evaluation and analysis on most frequent words based on N-gram features. The summary result present that ‘great’ is most frequent unigram words used in Amazon product dataset after removing all noisy or unwanted words whereas based on Fig. 3 ‘easy use’ is most frequent bigram words and Fig. 4 ‘amazon fire tv’ show most frequent trigram words in selected dataset.

TABLE III. SAMPLE RESULT -1 FROM DATA PRE-PROCESSING

Original Review	great for beginner or experienced person. Bought as a gift and she loves it
After convert to lower cases remove unwanted symbols	great for beginner or experienced person bought as a gift and she loves it
After removal of stop words	great beginner experienced person bought gift loves
After Lemmatization	['great', 'beginner', 'experienced', 'person', 'bought', 'gift', 'loves']

TABLE IV. SAMPLE RESULT-2 FROM DATA PRE-PROCESSING

Original Review	great for beginner or experienced person. Bought as a gift and she loves it
Star Rating	5
After POS tagging	[('great', 'JJ'), ('beginner', 'NN'), ('experienced', 'VBD'), ('person', 'NN'), ('bought', 'VBD'), ('gift', 'NN'), ('loves', 'NNS')]

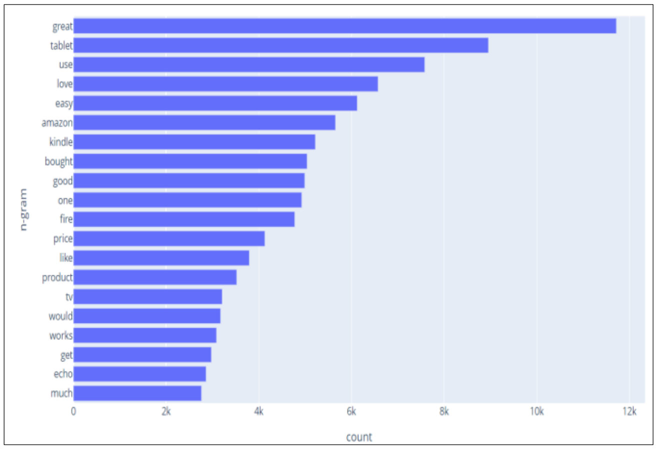

Fig. 2. Most Frequent Unigram Words.

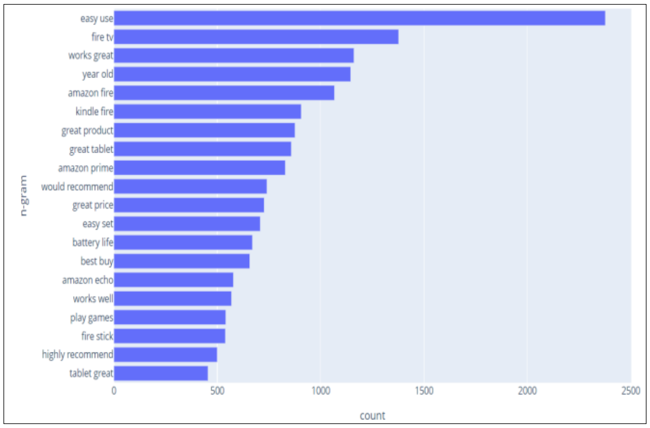

Fig. 3. Most Frequent Bigram Words.

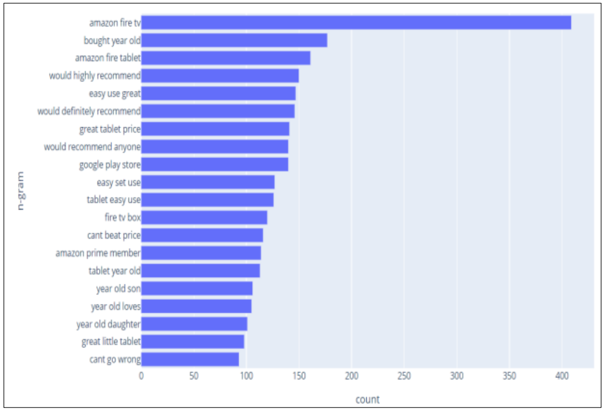

Fig. 4. Most Frequent Trigram Words.

D. Sentiment Classification

Lexicon based method SentiWordNet is used for expressed sentiment in words by scoring each words [31] [32] [33] [34]. SentiWordNet is like dictionary assign to each synset of WordNet with English language with positive and negative scores. Over 100,000 English words are in SentiWordNet for sentiment approaches with positive and negative scores. Based on POS tagging, for each synset are assign to scores from 0 to 1. The final positive and negative score of each sentence calculated with below equation:

$$\text{pos\_score} = \sum_{i=i}^{n} pos\_score\_senti(i) \tag{4}$$

$$\text{neg\_score} = \sum_{i=i}^{n} neg\_score\_senti(i) \tag{5}$$

$$\text{senti\_score} = \begin{cases} \frac{pos\_score}{tota\_score} if\ pos > neg \\ \frac{neg\_score}{total\_score} if\ neg > pos \end{cases} \tag{6}$$

Total senti score below and equal to 0 is consider negative reviews and above 0 is consider as positive reviews. Based on Table IV total score of review is 0.875 which consider as positive review. In line with this finding, diverse machine learning classification methods been used to evaluate sentiment on reviews. First of all, training and testing samples are divided as trained sample 70% and test sample 30%. While four classifier Naïve Bayes, Support Vector Machine, Decision Tree and K-Nearest Neighbour are applied for find accuracy, precision, F1-score and recall. Machine learning (ML) approach is focus on future decision making to manage textual data with intelligence whereby different ML algorithms provide different result for comparison [9] [16] [35].

$$\text{Precision} = \frac{(True\ Positive)}{True\ Positive\ + False\ Positive} \tag{7}$$

$$\text{Recall} = \frac{True\ Positive}{True\ Positive\ + False\ Negative} \tag{8}$$

$$F_{Score} = \frac{2 * Precision * Recall}{Precision + Recall} \tag{9}$$

E. Evaluation Score

After comparing four machine learning approaches in Amazon reviews the result is evaluated with confusion matrix hence it present true positive (TP), false positive (FP), true negative (TN) and false negative (FN).

TP : The output where it correctly predicts the positive class.

FN : The output where incorrectly predicts the negative class and mislabeled as negative.

FP : The output incorrectly predicts the positive class whereby mislabeled as positive.

TN : The output where correctly predicts the negative class.

V. Result and Discussion

As discussed in Section III, the paper develop model on term-based sentiment analysis process with Amazon products. The textual data analyzed using python programming language and the result obtained from experiments shown in Table V. After data pre-processing, feature extraction demonstrates frequent itemset for polarize the reviews into sentiments [6] [9]. Data pre-processing first that required conducted data analysis for reduction of noise and for perform best result [5] [20]. In order detected overall sentiment of dataset 4 different type classification methods like Naïve Bayes, Support Vector Machine, Decision Tree, K-Nearest Neighbour approach with trained and tested using Amazon products dataset. Based on 4 machine learning classifier and by N-gram applied Decision tree show highest accuracy and Support Vector Machine show highest precision, recall and F1-Score. The result indicates Support Vector Machine model performs well with proposed method with Amazon product dataset. In between, unigram show us better performance whereas trigram shows us poor performance. The N-gram weight was most traditional features applied compared the best accuracy as the result present unigram perform well compared to other N-gram [16]. Hence, TF-IDF features with N-gram show different results as different machine leaning models. The approach is efficient and more robust for process and evaluates unstructured Amazon product reviews [17]. The similarity performance is only seen in Naïve Bayes model for precision, recall and F1-score. Table V shows average summary result for positive, negative and neutral classes for different machine leaning models with TF-IDF and N-gram.

TABLE V. Summary of Performance with TF-IDF and N-gram

	Accuracy (%)			Precision (%)			Recall (%)			F1-Score (%)		
N-Grams	1	2	3	1	2	3	1	2	3	1	2	3
Naïve Bayes	78.869	79.01	79.23	63	63	63	79	79	79	70	70	70
Support Vector Machine	82.27	79.22	79.04	82	79	67	80	79	79	72	70	70
Decision Tree	99.98	99.91	99.59	78	73	74	77	64	39	78	67	45
K-Nearest Neighbour	63.33	33.83	58.75	75	66	70	50	19	29	56	19	33

VI. Contribution

Online ratings and reviews evaluate customer view and influence sales performance. Another important contribution is had been information show attitude and behavior of customers toward purchase products to make decision which led to customers' satisfaction. Sentiment detection from online reviews also influences prospective customers on online decision purchasing and a better understanding on products. The classification of reviews positive, negative and neutral evaluate subjective information and describe nature of opinion in better way. Other than that the manipulation of unstructured data being processed with intelligent technology is for present quality text information for judging human behavior. Hence, based on analyze result retailers can improve their products' price, quality and services.

VII. Conclusion

There are two main dimensions for identifying sentiments in Amazon online products with reviews and star ratings. The proposed text preprocessing and machine learning model with TF-IDF and N-gram method have been used for investigate performance of Amazon products dataset as the result as discuses in section 5. The most important insight from this study would be classification of reviews in positive, negative and neutral for present overall performance result. For future work, different text mining method might improve accuracy result for Amazon product dataset. Furthermore, different sentiment analysis techniques such as hybrid deep learning models can be proposed together with N-gram features to perform better result and comparison. In overall, we believe all features applied in this study would improve the performance of E-commerce sites.

Acknowledgment

An Iootfuzzer Method for Vulnerability Mining of Internet of Things Devices based on Binary Source Code and Feedback Fuzzing

Guangxin Guo, Chao Wang*, Jiahan Dong, Bowen Li, Xiaohu Wang
State Grid Beijing Electric Power Research Institute, Beijing, China

***Abstract*—With the technological progress of the Internet and 5G communication network, more and more Internet of Things devices are used in it. Limited by the cost, power consumption and other factors of Internet of Things devices, the systems carried by the Internet of Things devices often lack the security protection provided by larger equipment systems such as desktop computers. Because the current personal computers and servers mostly use the x86 architecture, and the previous research on security tools or hardware-based security analysis feature support is mostly based on the x86 architecture, the traditional security analysis techniques cannot be applied to the current large-scale ARM-based and MIPS-based Internet of Things devices. Based on this, this paper studies the firmware binary program of common Linux-based Internet of Things devices. A binary static instrumentation technology based on taint information analysis is proposed. The paper also analyzes how to use the binary static instrumentation technology combined with static analysis results to rewrite binary programs and obtain taint path information when binary programs are executed. Firmware binary fuzzing technology based on model constraints and path feedback is studied to cover more dangerous execution paths in the target program. Finally, iootfuzzer, a prototype vulnerability mining system for firmware binaries of Internet of Things devices, is used to test and analyze the two technologies. The results show that its fuzzing efficiency for Internet of Things devices is better than other fuzzing technologies such as boofuzz and Peach 3. It can fill in some gaps in the current security analysis tools for the Internet of Things devices and improve the efficiency of security analysis for Internet of Things devices, which contributes to the field through automated security vulnerability detection systems.**

Keywords*—Internet of things; system vulnerabilities; source code; fuzz testing; instrumentation technology

I. Introduction

At present, the interaction between IoT devices and the outside world is mostly carried out through the network. Usually, the software monitors the input data of external users, and the user's operation on the device is received and processed through several specific softwares [1]. Therefore, to analyze the vulnerability of this software, it is necessary to start from the code path through which external user data flows and find the problem code that external users, or attackers, can reach [2].

At the same time, in the past commonly used fuzzy testing based on path feedback, almost all of them adopt the way of the full instrumentation, such as path record instrumentation for all jump instructions at the end of the code block [3]. This instrumentation method will lead to a lot of programs internal processing codes unrelated to user input being instrumented, and then will make the code unrelated to external input data generate a new execution path so that the fuzz test tool will mistakenly think that the new execution path is caused by the fuzz test sample, and use the fuzzing test sample to further mutate and test in the follow-up. This will reduce the efficiency of fuzz testing.

At present, the work of source code vulnerability mining mostly depends on manually defined rules, but this method has some drawbacks: on the one hand, manually defined vulnerability mining rules often need to rely on the expertise and work experience of experts [4]. It is difficult to ensure full coverage of the possible causes of vulnerabilities, and it is easy to have the possibility of false positives and underreporting. On the other hand, it takes a lot of manpower to mine loopholes according to the rules. Due to manual judgment, the phenomenon of false underreporting will still occur [5]. With the development of technology, researchers began to use machine learning methods for vulnerability mining. This method does not need to define vulnerability rules, but still needs to define vulnerability features. Although it has reduced the manual workload, there are still drawbacks to feature coverage. In recent years, with the increasing popularity of deep learning, many scholars have begun to try to apply deep learning methods to vulnerability mining, and have made good progress [6]. In the process of data preprocessing, only whether the source code contains vulnerabilities is divided, and the types of vulnerabilities are not classified, so the existing work can only detect whether a piece of code contains vulnerabilities, and cannot accurately detect the types of vulnerabilities.

Scandariato et al. [7] tested the bag-of-words technique with a hybrid approach combining N-gram parsing and statistical feature selection to predict vulnerable software components. Yamaguchi [8] proposed a new graphical representation, called the code property graph, by traversing the graph to discover vulnerabilities. However, designing effective traversals to detect complex vulnerabilities can be very difficult. Thus, the authors propose an automatic method for traversing code attribute graphs to effectively locate taint-style vulnerabilities generated by uncleaned data streams, and use it to experiment with five popular open-source projects. The number of source codes without vulnerabilities in the data set is much larger than the number of source codes with vulnerabilities. It is difficult to learn the characteristics of a

*Corresponding Author.

small number of samples, while a large number of samples are prone to over-fitting during training.

To solve the problem that it is difficult to apply the fuzzing technology based on path feedback to the firmware binary program of ARM and MIPS Internet of Things devices and the efficiency of fuzzing test is low, this paper proposes a binary static instrumentation technology based on the taint information analysis. Firmware binary fuzzing testing technology based on model constraints and path feedback is studied in depth. The binary static instrumentation technology based on taint information analysis is studied, which can solve the problem that the current ARM and MIPS architectures lack taint information analysis tools. It analyzes and instruments the conditional branch jump of the target program in firmware affected by external input data to provide information feedback to the fuzz testing tool. The firmware binary fuzzing testing technology based on model constraints and path feedback is studied, which can improve the efficiency of fuzzing testing technology such as model constraints and path feedback combined with the above technology applied to the vulnerability mining of the target device, and focus the fuzzing test on the dangerous path to achieve the effect of improving the efficiency of fuzzing testing. The abstract syntax tree of function is used to represent the function, and multiple functions are annotated in open source datasets to capture the intrinsic representation of vulnerabilities, which proves that the model is effective for cross-project vulnerability detection at the functional level. Finally, the effectiveness of the above technology is proved by comparative experiments.

The main innovations of this paper are:

1) Adopt a feedback type fuzz test technology to carry out vulnerability mine on that firmware of the Internet of things equipment, and select the conditional branch jump points influenced by external user input data, namely taint information, as path feedback data of the fuzz test.

2) Design and implement a firmware vulnerability mining prototype system based on binary static instrumentation and feedback fuzzing for ARM and MIPS architectures.

3) Based on the results of taint information analysis, the target binary program is instrumented to improve the execution efficiency of the fuzz testing process.

Through the binary static technology based on the Internet of Things device vulnerability analysis, the fuzzing testing tool can obtain the feedback information of the relevant test samples in the process of fuzzing testing, and guide the generation of the fuzzing test samples. At the same time, the relevant algorithm is designed to select more valuable samples, and the model constraints are used to make the fuzzy test towards a higher coverage.

II. Related Work

A. Binary Static Instrumentation Technique

Static Binary Instrumentation (SBI) modifies the binary program file stored in the storage medium to generate an instrumented binary file and save it to the storage medium. When the program is executed, the instrumented binary file is run [9]. The idea of binary static instrumentation technology is very simple, which is to modify the binary file through the target file format to achieve the purpose of adding specific new code, but it needs to statically analyze the instrumented program in advance or describe it through the configuration file [10]. One of the core parts of binary static instrumentation technology is the selection of instrumentation positions. An example of an instrumentation error is shown in Fig. 1.

Static instrumentation technology modifies and hijacks the original code execution flow of the program so that the program jumps to the instrumentation code to execute when it runs to a specific location and completes the specific functions inserted by developers [11]. The selection of the insertion point will not only affect the efficiency of the program execution but also affect whether the program can be executed normally. In instrumentation tools that use binary static instrumentation techniques, directly editing the target binary file format and modifying and inserting code is the most common implementation.

B. Feedback Fuzzy Test Technique

Under the condition that the source code can be instrumented, AFL, honggfuzz, and other fuzzing tools all adopt the feedback fuzzing technology. These fuzz testing tools use the execution path information of fuzz test samples as feedback information to guide the sample generation tool to generate samples that can improve the coverage of fuzz test code (path) [12]. AFL uses customized GCC to insert the functional code of path recording and path feedback into the compiled binary program through source code instrumentation so that the program can record and feedback the execution information of fuzzy test samples during running [13]. In the absence of source code, binary instrumentation is generally used to obtain the key information in the running process of the target program, which requires researchers to develop and customize it for specific situations. Under the condition of no source code, AFL can still fuzz binary programs with the QEMU tool, but the efficiency of fuzz testing is low [14]. InsFuzz uses binary static instrumentation to interpolate non-source binary programs, inserting path records and feedback code into binary programs to achieve the same effect as source instrumentation [15]. Through the feedback fuzzing testing technology, the efficiency of fuzzing testing can be effectively improved. Inefficient fuzzing test samples can be discarded in time, and only the fuzzing test samples which may generate new execution paths can be mutated so that the whole fuzz testing work can be carried out in the direction of improving the code test coverage.

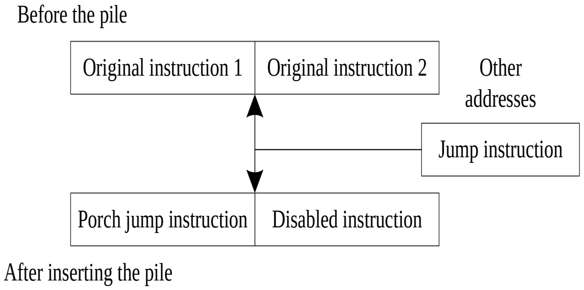

Fig. 1. Example of CISC Instrumentation Causing Program Runtime Errors.

III. Research on Binary Static Instrumentation Technology based on Stain Information Analysis

C. Analysis Flow and Algorithm of Taint Information

To improve the effective code coverage rate of the subsequent fuzz testing tool, the technology performs simulation execution on the target binary program, and therefore, more functional codes need to be analyzed as much as possible in the taint information analysis process. Because the target binary program in this paper is the network program in the firmware of the Internet of Things device, which uses socket, bind, accept, fgets, send, and other functions to build the data receiving and sending part of the network application program. These programs all have a clear function to receive external input data. The Internet of Things device firmware program uses the fgets function to receive external data packets transmitted through the network through the file descriptor of the socket.

Since program codes are executed in a simulation execution mode when taint information analysis is carried out [16], even if the analysis is not purely static, partial run-time information is missing. The coding fragments are shown in Table I.

TABLE I. Code Fragment

Code fragment:
<META HTTP-EQUIV="0,0x271t" CONTENT="no-cache"> If iggate,10000,(ffile * dword_654BC V0=400; V1=”Bad Request”; V2=”No request found” Return sub_D343（V0, V1, V2）; <META HTTP-EQUIV="Cache-Control" CONTENT="no-cache, must-revalidate">

As shown in the variable s in Table I, during simulation execution and taint analysis, it is impossible to accurately assign the external input variable or simulate the external input that can explore all execution paths [17]. Therefore, it is necessary to apply some methods to analyze the code that operates on the external input data as much as possible during simulation execution and taint analysis.

D. Research on Firmware Binary Fuzz Testing Technology for Internet of Things Devices based on Model Constraints and Path Feedback

- Fuzz testing coverage and sample selection algorithm

When the feedback information received by the sample variation module finds that an execution path is generated, it indicates that the current fuzzy test sample triggers a new execution path [18], which means that the change of some fields in the sample triggers the change of the flow direction of the program control stream, and by performing sample variation on the sample again and generating a new sample. There is a greater probability that the code coverage of the fuzz test can be improved, so it is placed in the queue of samples to be mutated.

In the whole process of fuzzing testing, this paper defines an index of dangerous branch jump coverage, which is used to record and judge the index data in the process of fuzzing testing:

$$C_{danger} = \frac{DB_{executed}}{DB_{all}} \times 100\% \tag{1}$$

In Formula 1, DB_{all} represents the number of branch jumps influenced by the external user input data in the target binary program, and $DB_{executed}$ represents the number of branch jumps influenced by the external user input data that have been executed in the current fuzz test.

A queue $Q = \{S_0, S_1, \cdots, S_n\}$ and a queue $M = \{m_0, m_1, \cdots, m_n\}$ of fuzzing test samples to be tested are defined for the fuzzing test samples transmitted to the fuzzing testing module. During the fuze testing process, the fuze test samples in the queue Q are transmitted to the fuzz testing module in a first-in first-out order [19]. If a new execution path is generated after the fuzz test samples are executed, then pass it to the use case generation function and add the newly generated fuzzing test sample to the fuzzing test sample queue M.

- Target feedback data processing

An array $DB = \{DB_0, DB_1, \cdots, DB_n\}$ is used to record the execution of the current fuzz test sample in the target binary program. This data is fed back after the target binary program executes the external input data processing function. At the same time, the array $AC = \{AC_0, AC_1, \cdots, AC_n\}$ is defined to record the total number of times that the branch jump of each taint condition is executed in the fuzz test so far.

As shown in Equation 2, a weight must be defined for each fuzzy test sample to represent the "value" of the fuzzy test sample:

$$\begin{cases} P_{ij} = 1 \quad (DB_{ij} \neq 0) \\ P_{ij} = 0 \quad (DB_{ij} = 0) \\ W_i = \sum_{j=0}^{n} \left(\frac{P_{ij}}{AC_j} \times 1000 \right) \end{cases} \tag{2}$$

The weight of each branch is $1000 / AC_i$. When a taint condition branch jumps in the fuzz test and the total number of times it has been executed so far is AC_i, its reciprocal is multiplied by 1000 to get its weight. The factor of 1000 is used to prevent too many executions from causing the reciprocal to be too small, and the value becomes 0 after the decimal place is normalized. The factor can increase with the number of fuzz tests without affecting the weight ordering.

IV. Experimental Analysis

E. *Function Comparison of Stain Analysis Tool*

At present, there is no mainstream tool of the same type supporting ARM and MIPS that is open source or available for download for comparison, as shown in Table II.

TABLE II. Comparison Results of Stain Analysis Tools

Tool name	x86	arm	mips	Required documents
Pin	Y	N	N	Source Code
Taintgrind	Y	Y	N	Source Code
TaintEraser	Y	N	N	Source Code
TEMU	Y	N	N	Source Code
PyDaint	Reserved interface	Y	Y	Binary

Most mainstream tools rely on the source code to recompile the analysis target before running the analysis. PyDaint not only supports the ARM and MIPS architectures studied in this paper, but also can be extended to further support x86 architectures [20].

The test framework is shown in Fig. 2.

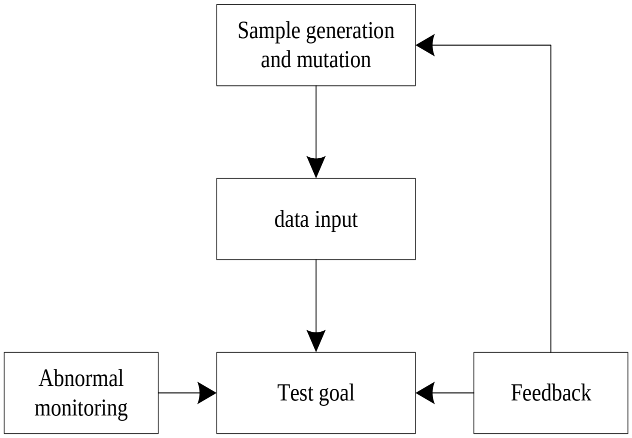

Fig. 2. Basic Framework of Paste Test.

F. *Instrumentation Performance Test of Tainted Information Flow*

Because this project uses QEMU user mode to run simulation on x86 _ 64 computers for ARM and MIPS architectures, it is difficult to carry out relevant timing statistics. Therefore, to test the effect of binary static instrumentation based on taint information analysis on the execution efficiency of the original binary program, the Web service programs of ASUS AC88U router based on ARM architecture and D-LinkDIR882 router based on MIPS architecture are instrumented respectively. It takes for normal user interaction (simulated access and packet reception through a Python program) before and after instrumentation in a test environment. The experimental results are shown in Table III and Table IV.

TABLE III. Comparison of Execution Efficiency before and after HTTPD Instrumentation in ARM Architecture

Test object Sample number	Before insertion	After insertion
100	432.58ms	846.39ms
1000	4545.74ms	8682.94ms

The average time for httpd to send and receive data is about 4.3ms before instrumentation, and 8.7ms after instrumentation. In the experimental environment, the instrumentation loses about 1.02 times of performance.

TABLE IV. Comparison of Execution Efficiency of Lighttpd before and after Instrumentation of MIPS Architecture

Test object Sample number	Before insertion	After insertion
100	32.59ms	96.34ms
1000	228.39ms	972.21ms

The average time for lighttpd to send and receive data is about 0.28ms before instrumentation, and 0.99ms after instrumentation. In the experimental environment, the instrumentation loses about 2.5 times of performance.

G. *Fuzzy Test Function Comparison*

Before analyzing the experimental results of fuzz testing efficiency, as shown in Table V, we first compare the functions of several common fuzz testing tools with the fuzz testing tool iboofuzzer implemented in this paper.

TABLE V. Comparison Results of Fuzz Test Tools

Tool names	Network Program Fuzziness Test	Path feedback	Path feedback without source code	Model constraints
AFL	N	Y	Partially supported	N
AFL-net	Y	Y	Partially supported	N
Peach 3	Y	N	N	Y
boofuzz	Y	N	N	Y
iboofuzzer	Y	Y	Y	Y

Iboofuzzer is a fuzzy testing subsystem developed for the network binary program in the Internet of Things device firmware in this paper, which supports model constraints and path feedback, and can obtain the feedback information of the target binary program by using instrumentation tools in common use scenarios without source code.

H. *Fuzzy Test Efficiency Test*

When using the original boofuzz for fuzz testing, the sample random mutation function is added to avoid the premature end of the fuzz test due to sample exhaustion. At the same time, the iboofuzzer framework is used to count the coverage information of boofuzz and Peach 3 tests, but it is not fed back to the sample generation module for analysis and comparison. In the testing process, the original boofuzz is tested based on model constraints and random data. For Peach

3, its listening mode is used, and the fuzzy test samples are actively obtained from Peach through the framework of iboofuzzer and then sent to the target binary program. The test parameters are shown in Table VI.

TABLE VI. FUZZY TEST TOOL EXPERIMENTAL VARIABLES

Tool names	Sample generation method	Information feedback
boofuzz	Random data	No
boofuzz	Model constraints	No
Peach 3	Model constraints	No
iboofuzzer	Model constraints	Path feedback

For each of the four test conditions in Table VI, a blur test was performed for about 8 hours.

- Comparison of coverage rate of insertion point in fuzzy test

The coverage rate of instrumentation points in the fuzzing test process represents the proportion of different branches of instrumented points executed in the whole fuzzing test process, as shown in Fig. 3.

In this comparative experiment, the coverage of boofuzz, which uses random data generation for fuzz testing, is the lowest in the whole 8-hour test. The second-lowest is boofuzz, which uses model constraints to generate samples. It is lower than Peach 3 in the first few hours, and then gradually approaches. Peach 3 has the second-highest coverage and iboofuzzer has the highest coverage. That is to say, the quality of samples generated by iboofuzzer is higher, and the test coverage of dangerous paths is larger. In the experimental environment, the coverage rate of the algorithm in this paper is the highest, and the target binary program after interpolation can still process a single fuzzy test sample in milliseconds.

- Comparison of the number of new execution paths for fuzz testing

The number of new execution paths generated during fuzz testing represents the ability of the fuzz testing tool to find new code test paths throughout the fuzz testing process, which is shown in Fig. 4.

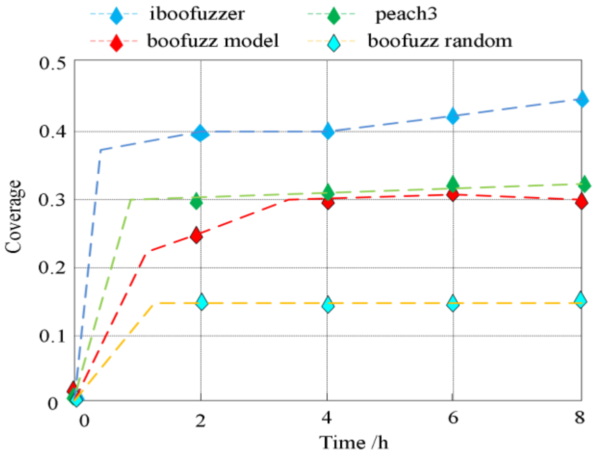

Fig. 3. Comparison of Fuzz Test Instrumentation Point Coverage.

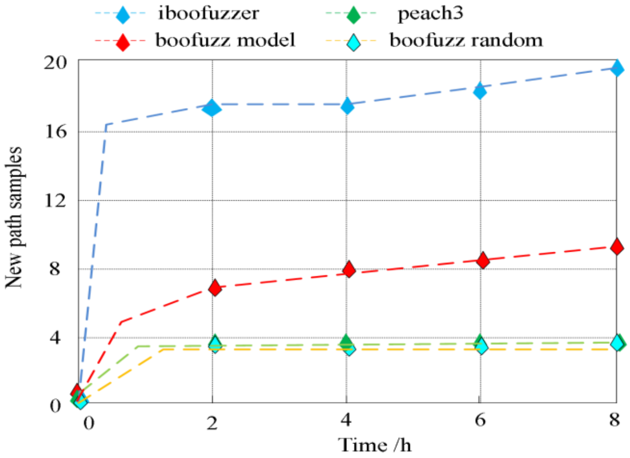

Fig. 4. Comparison Chart of the Number of New Execution Paths for Fuzz Testing.

Peach 3 and boofuzz with random data both generate fewer new path samples, while iboofuzzer generates the newest path samples, that is, the samples generated by iboofuzzer are more effective in discovering new paths. The distortion efficiency is improved by increasing the proportion of the effective distortion in the total distortion. Samples with effective distortion can reach the target basic block faster, while samples with invalid distortion will make the program fall into the situation of path explosion.

The object of vulnerability mining in this paper is the network binary program in the Internet of Things devices, which has certain format requirements for the input data, so the generation of samples based on model constraints can not only solve the problem of lack of original data samples in fuzzy testing, but also improve the code penetration of samples, and avoid the samples being abandoned in the format check function of the target program. At the same time, the fuzzy test focuses on the dangerous path affected by the external input data, and mutates new fuzzy test samples to improve the coverage of the dangerous path. To improve the efficiency of fuzzy testing, the path feedback information and the calculated sample weight are used to guide the mutation generation of fuzzy testing samples.

V. CONCLUSION

In this paper, we study the static instrumentation of the firmware binary program of the Internet of Things device based on ARM and MIPS architecture, and innovatively combine the taint information analysis with the binary instrumentation and apply it to the firmware program of the Internet of Things device to improve the efficiency of fuzzing the dangerous path in the tested program of the firmware program of Internet of Things devices. The main work includes:

1) Analyze the taint information with the firmware binary program of the Internet of Things device based on ARM and MIPS architecture.

2) The feedback fuzzing technology is applied to the firmware binaries of the IoT devices based on ARM and MIPS architectures, and the target binaries are moved from the IoT devices to desktop computers for fuzzing by using QEMU open source tools and binary static instrumentation technology.

3) Select some of the common security tools to compare with the subsystems of the prototype system iootfuzzer in different types, and use the tools that can fuzze the research goal of this paper to carry out the comparison experiment of fuzzing efficiency.

The fuzz testing subsystem in this paper is implemented based on boofbzz, and it needs to write samples to generate template files for different test objectives, which is a heavy workload. In the future, we can consider implementing the technology of automatically generating the corresponding template through the captured network communication packets to reduce the cost of preparation work in the early stage of fuzz testing. Complex vulnerabilities usually have a long ROC chain. These vulnerabilities may not only be related to one file, but also to multiple files, which will greatly affect the effect of vulnerability mining. Dynamic analysis is to detect vulnerabilities in the process of program running, which makes dynamic analysis more complex. In the future, the above two directions will be studied in depth.

Mobile Learning in Science Education to Improve Higher-Order Thinking Skills (HOTS) and Communication Skills: A Systematic Review

Adilah Afikah[1], Sri Rejeki Dwi Astuti[2], Suyanta Suyanta[3], Jumadi Jumadi[4], Eli Rohaeti[5]
Department of Science Education, Universitas Negeri Yogyakarta, Yogyakarta, Indonesia[1, 4]
Department of Chemistry Education, Universitas Negeri Yogyakarta, Yogyakarta, Indonesia[2, 3, 5]

***Abstract*—Today, the increasing use of technology and mobile applications in education was interesting. This research was a systematic review study with limited 30 articles from 2012 to 2021. It aims to answer research questions about what mobile devices used in learning and what learning approaches are used in science learning to improve higher-order thinking skill and communication skills. The findings of this study were in line with the research objectives: First, the most appropriate mobile devices used to achieve learning objectives are mobile phones, followed by PDAs, tablets, iPad, laptops, e-books, and iPods. Second, the learning approach used in science learning to improve higher-order thinking skills and communication skills are a collaborative learning approach, inquiry learning, project-based learning, problem-based learning, game-based learning, and flipped classroom learning. It was hoped that this research can be an illustration for other researchers to create innovative learning approaches. Some research that can be done next based on this research is how mobile learning in social learning or comparing the two, further research on the most appropriate learning media for mobile learning, and research on the effectiveness of implementing approach strategies in mobile learning.**

Keywords—Communication skills; higher-order thinking skills; mobile learning; science education

I. Introduction

Mobile technology provides many advantages for users, such as ease of carrying, sensitivity in operating systems and applications, connecting between different spaces and times, and facilitating social interaction. The improvement of technology and mobile applications in education is a common phenomenon observed worldwide [1]. Mobile technology has great appeal for researchers, including researchers from education field [2]. Technology in education makes students enter into social learning contexts and appropriate situations with circumstances to encourage students to learn together or collaboratively.

Mobile learning is electronic learning through mobile technologies such as computers, laptops, cell phones, audio players, and electronic books [3]. Mobile learning allows students to learn in collaborative learning with other students to share ideas with the help of the Internet and technological developments that can be done without the boundaries of space and time [4]. Always-connected mobile device allow students to access course information and provide students with opportunities to interact with content and to explore it.

Mobile learning can help remove the barriers between learning and real life. Mobile learning is powerful in its appeal of bringing new space, time, and geography into the classroom. According to some researchers, mobile learning can be a bridge between formal and informal learning to judge the difference between the two based on the context and its features [5]. Most of the literature discusses the affordability of mobile learning to implement its methods, strategies, and applications, which are mostly teacher-centered.

However, the realization of its practical implementation has not been much because its implementation has various obstacles and challenges. There are limited financial resources, inadequate educational policies for mobile learning that have not developed rapidly, human resources that do not have a good understanding, and there is still a lack of skilled personnel for effective implementation of pedagogy. Another challenge is changing the pedagogical understanding that teachers have to understand mobile learning, the lack of resources for complex tools such as infrastructure and bandwidth, parental trust because there are perceptions of health and psychological problems that follow and are associated with prolonged use of mobile devices by students. And then the lack of educators trained with mobile learning [6]–[12].

In addition to the actual implementation problems that arise in learning practices, there are fundamental problems regarding the theoretical and pedagogical foundations in mobile learning applications in the world of education, which are still lacking and not yet on target. Many authors have discussed and have investigated this with a socio-constructivist approach and found that communication features on mobile devices can encourage collaboration and become the basis of mobile learning. However, students can participate and can collaborate in learning with themselves and others, not with the devices or media used [13]. Therefore, every element of education, government, teachers, students, and society, must adapt to mobile learning so that its effectiveness can be felt.

In the 21st century, one of the biggest challenges faced is maintaining students' interest and involvement to keep interacted and connected through mobile devices in effective learning [14]. The importance of developing students' higher-order thinking competencies, such as problem-solving and critical thinking skills [15]. Mobile learning can be an innovative option for education [5]. Mobile learning not only helps students and teachers understand the content of the material in learning, but also facilitate communication, problem-solving, creativity, and students' higher-order thinking skills.

Based on this, appropriate pedagogical and theoretical methods are needed to assist teachers in designing mobile learning [16]. This method has a strategy to integrate mobile learning into the classroom to achieve learning objectives with mobile devices. In addition, existing strategies must instill critical inquiry skills in learning while still presenting problems for students to provide solutions [17].

This review, derived from a systematic content analysis science education empirical research articles, sought to address the following questions:

- What mobile devices use in learning?
- What learning approaches are used in science learning to improve higher-order thinking and communication skills?

II. Literature Review

A tool containing several solutions to educational problems often describes technology [17]. Education aims to make people knowledgeable, creative, informative, digitally capable, and adaptable [5]. Furthermore, information technology such as the internet and multimedia systems that have been utilized and applied in learning aims to improve the quality of learning by facilitating students' access to adequate resources and services [18].

One of the benefits of a mobile learning system is that students can participate in different learning situations, such as school learning and online distance learning [2]. However, distance learning is not in a room like schools in general, but in a scope that is not traced by using cellular technology beyond the existing distance [19].

Mobile learning aims to provide a different and meaningful student learning experience, but it is not the primary learning method because it must have the right learning approach. Mobile devices can influence and improve student learning outcomes and motivation in learning. However, there are limitations in its application; although teachers and students will become more familiar than usual because of the efficiency and effectiveness of this method in learning, teachers and students must maintain educational ethics [3]. Research also shows that with awareness and adequate support from all aspects of education, mobile learning will answer the 21st-century challenges of learning anywhere and anytime, a centered and innovative learning method.

Higher-order thinking skills are the ability of students to think at a higher level. Students who have these abilities will analyze, evaluate, and create innovations in solving problems. These mobile and science learning skills are necessary because many problems can be solved using higher-order thinking skills [20]. Higher-order thinking skills can improve with various learning approach strategies, learning media, and teaching materials.

Cognitive taxonomy bridges understanding higher-order thinking skills' concepts and characteristics. The most popular cognitive taxonomy is Bloom's taxonomy, revised by [21], consisting of two dimensions: the dimensions of knowledge and cognitive processes. The Knowledge Dimension classifies the types of knowledge students acquire into four types: factual, conceptual, procedural, and metacognitive. While the cognitive process dimension consists of six levels: remembering (C1), understanding (C2), applying (C3), analyzing (C4), evaluating (C5), and creating (C6) [22].

The three categories of HOTS assessment abilities are as follows: first, the ability to transfer concepts to other concepts, higher-order thinking skills as a form of knowledge possessed, the ability to relate to other people in unfamiliar situations. Second, critical thinking skills are the ability to understand logical problems, reflective thinking skills, and the ability to argue that can focus on making decisions or doing something. Third, problem-solving skills (problem-solving), namely the ability to find new ways, unconventional and creative solutions [23].

Communication refers to a person's ability to express ideas using words and language that can be accepted both in written and spoken form, such as articulating, explaining, describing, clarifying, listening, questioning, sharing, which are from a learning process [2]. Communication skills are the main factor to be able to understand learning. Teachers, students, and everyone in the educational environment can support each other's learning goals by communicating. In addition, communication has a significant contribution to student success in school aligns with millennial habits and lifestyles that are identical to communication technology if used wisely by students [24].

One of the learning objectives is to master the concept; students must also have good communication skills to convey their knowledge and find. However, based on the research results, many students still do not have good communication skills [5]. Therefore, a method is needed in the form of an appropriate learning approach to develop students' communication skills, and their understanding of concepts can be appropriately conveyed.

III. Material and Method

A. Research Design

This research is systematic literature review. The systematic review is a critical and transparent method for finding, determining, selecting, and synthesizing sources of information from published empirical evidence so that it can answer research questions to be carried out. The systematic review is a research method that based on evidence that has had high credibility in many research disciplines in recent years, including education.

B. Sample and Data Collection

The data used in this research is secondary data. Secondary data applies the documentation method from existing data, not data obtained from direct observation. This research's secondary sources are books, proceedings, and scientific articles in reputable journals accessed on databases in Table I. The keywords used in the search for articles in the SCOPUS database were mobile learning, higher-order thinking skills, and communication skills. The article search was limited from 2012 to 2021, with 30 articles.

TABLE I. THE NUMBER OF PAPERS FROM EACH JOURNAL ANALYZED

Publisher	Frequency	Percentage (%)
https://scholar.google.co.id	3	10

C. Analyzing of Data

The main focus of the study in this research is learning science with mobile applications/technology to improve higher-order thinking and communication skills. Therefore, a systematic review requires an appropriate search for the most relevant primary empirical studies. In addition, it is essential to provide details on how the review process was carried out so that the review is transparent and adequate. Therefore, in the following sections, the process of searching, selecting, extracting, and analyzing data is briefly discussed.

- Define research questions to extract the main search.
- Identify relevant keywords in the primary literature search that will use.
- Select various online databases, journals, and conference proceedings to search.
- Conduct a review by reading the article's abstract about the research topic. The author takes descriptive information such as author, year of publication, topic, type of research, and findings.
- Manage results (citations and abstracts) according to the purpose and formulation of the research problem
- Write the results of the review according to the research topic.

Based on our primary research question, we have four main search terms: Mobile Learning, Science, Higher-order thinking skills, and communication skills. Based on the results obtained in an online database search, 30 articles were synthesized and analyzed to answer research questions.

IV. RESULT

A. Mobile Device use in Learning

Mobile devices that should be used in learning are mobile devices that are easy to carry and have easily accessible on and off buttons. Portable devices, such as cell phones and tablets meet this requirement, with the exception of laptops due to their lack of speed in their ease of use. The results of the study report that in learning mobile phones are the most frequently used mobile devices according to the Table II. However, some studies did not identify the device used [25].

TABLE II. MOBILE DEVICES USED IN LEARNING

Mobile Device	Percentage (%)
Phone	34
PDAs	22
Tablets	16
iPads	11
e-books	2
iPods	1

B. Learning Approach in Science to Improve Higher-Order Thinking Skills and Communication Skills

There are 83% of studies that aim to measure student learning improvements who report achieving their stated goals [1]. Exploratory science learning can be carried out outside formal classroom settings, such as in a natural environment [26]. In the previous research review, of all subjects, natural science was the subject whose mobile learning applications were most frequently used in research [27]. Environmental science is the subject matter in science learning that focuses most of the research, followed by geography and physics [1].

Mobile learning positively impacts students' understanding of learning materials and inferring them. Mobile learning should reflect on every learning encounter with communication and collaboration [28]. Furthermore, mobile devices in learning can expand teacher pedagogy and develop students' critical thinking skills and 21st-century skills [29].

However, cultivating communication and high-level skills takes longer, and measuring these abilities requires the right tools and approaches. Below Table III are the learning approach strategies used in mobile learning to improve higher-order thinking skills and communication skills of students in science.

TABLE III. LEARNING APPROACH STRATEGIES USED IN MOBILE LEARNING

Learning Approach	Percentage (%)
Collaborative Learning	25
Inquiry Learning	25
Project-Based Learning	19
Problem-Based Learning	14
Game-Based Learning	10
Flipped Classroom Learning	7

V. DISCUSSION

A. Mobile Device use in Learning

Using mobile devices in learning can help students gradually develop their statistical thinking in everyday life. Students have the concept of independent learning with their character so that interaction occurs continuously [30]. Currently, mobile devices in the classroom as mobile learning has a more significant effect than learning that does not use mobile devices [5].

The affordability of mobile devices that can cross space and time in learning can be utilized to build appropriate learning methods and scenarios. Furthermore, the availability of talented resources and interactive comfort between the natural world and the virtual world can answer the problems of mobile devices in learning [30]. From the development of mobile devices in the last ten years, smartphones, tablets, and computers are the most popular new technology devices in learning.

The existence of various kinds of mobile devices in the world of education that continues to develop, such as cellphones, laptops, students can use them positively to create an interactive knowledge space that focuses on students. Teachers have an important role in supervising the use of mobile devices in learning. Teachers must make students learn with the maximum use of mobile devices [31]. The use of mobile devices in learning helps students to access information, find communication styles, and hone higher-order thinking skills. Therefore, the existence of mobile devices in learning is an essential part of learning innovation.

Previous research by [32] also found that mobile phones were the most frequently used learning devices. In many countries, mobile phone ownership data is more than 100%, with almost everyone owning more than one mobile device; this shows that mobile devices in this study are very affordable [11]. This data also reveals that many devices are used in mobile learning, not depending on what type of device is used but on the access to have the mobile device.

A study conducted by [3] also got the same result: cell phones are the most popular mobile devices for learning. This is because mobile phones have the advantage of multi-tasking; they have various exciting features to help learn, such as photography and video recording. In addition, other features such as GPS, Bluetooth, SMS, Multimedia Messaging Service (MMS), and all kinds of educational software, including the internet and e-books, can be easily accessed by students.

B. *Learning Approach in Science to Improve Higher-Order Thinking Skills and Communication Skills*

1) Collaborative learning

One excellent science learning approach to achieve specific mobile learning targets is collaboration. This is because collaborative learning has the right strategies and methods. Students follow the learning process constantly and continuously to understand the material in each learning process [5], [17]. Collaborative learning is a teaching method where students learn together in a group, and students can help each other for learning purposes. This makes collaborative learning that can provide social experiences and self-development [5].

Collaborative learning is a learning approach to encourage and facilitate students, teachers, classmates, and the community, to be able to interact both inside and outside the classroom. Collaborative learning that occurs outside the classroom can be the primary learning approach. The provision of unstructured learning assignments, learner-centered teaching methods, and mobile learning tools help increase social interaction among peers [30]. In addition, the mobile collaborative learning approach pays excellent attention to student communication in every class activity.

Collaborative learning with mobile technology was the most relevant learning to promote, facilitate, and enhance interaction and collaboration between learners [2]. The collaborative learning approach improves the ability of students to work together in groups, share goals, understand, and discuss to achieve agreed goals [33].

The collaborative learning approach in mobile learning is based on students' ability to engage in productive learning from the information held in study groups that enable students to become researchers and discoverers of knowledge [5]. In many studies, students usually participate in more than one learning activity. For example, a student uses a mobile device to search for new information from his knowledge and share that knowledge with other students. In that case, this builds the learner's constructivist abilities in collaborative learning [3], [25]. This approach will make students ready for digital era learning and generation.

When students study in a collaborative learning environment, students can discuss and exchange information to find answers to problems in their daily lives. Learners will learn from real-life facts and understand current issues regarding the subject matter in learning. Thus students can be involved in various social interactions such as interpersonal, intra-group, intergroup interactions, between humans and the actual and historical environment, and self-reflection [2].

In collaborative learning, students in groups achieve learning goals and learn according to the division of tasks given with full responsibility. The teacher motivates students to be more active in learning activities [1]. When the collaborative learning approach is applied correctly, discussions between students in groups will be smoother and wiser so that students can understand various aspects of specific knowledge and theories in depth. Therefore, students' higher-order thinking skills and communication skills can develop.

Developing knowledge, higher-order thinking, and communication skills should engage students in an open learning environment. Students can learn flexibly and interactively with various alternatives for building knowledge socially in shared learning and investigation groups [30].

2) Inquiry learning

One of the excellent science learning approaches in mobile learning is the inquiry learning approach [5]. Inquiry learning facilitates students to ask questions, conduct investigations or searches, and do experiments to research independently to get the knowledge they need, supported by the theories above [34].

Mobile learning with an inquiry approach is reported to have a diverse focus of study, produces contrasting results, and places greater emphasis on progressive, trustworthy, genuine, and social characteristics [1]. Inquiry learning generally has stages, namely, questioning, inquiry, critical thinking, and problem-solving in which evidence is gathered, findings are reported, explanations are obtained, and conclusions are agreed [35].

Each stage of the inquiry learning approach requires students to think critically and analytically in solving problems. Inquiry-based learning is associated with phenomena by the knowledge that students have previously to help students build new knowledge [36]. It follows the characteristics of students, namely learning through direct experience, primarily through their activities [37]. Therefore, the teacher plays an essential role as a facilitator who provides material and problems to be investigated and guides students in solving problems to understand the existing concepts.

The use of mobile devices in inquiry learning is more effective than learning with lecture methods, independent learning, and cooperative learning [5]. Moreover, integrating mobile devices with inquiry learning can expand students' learning opportunities, the depth of the material understanding and improve students' higher-order thinking skills in completing investigations on scientific problems by synchronizing the results obtained with the explanations given by the teacher [17].

3) Project-based learning

The following science learning approach applied in mobile learning is project-based learning [5]. Project-based learning makes students investigate complex problems and solve them [38].

Project-based learning requires good cooperation and coordination between appropriate group members and appropriate interactions to improve student learning outcomes [39]. Project-based learning is a learning strategy that allows students to benefit from completing learning investigations in the form of thoroughness and accuracy, students have the opportunity to create from their understanding, students can learn and assess learning.

Students are expected to learn and have the ability to design projects in order to solve real-life problems. In addition, project-based learning can improve students' higher-order thinking and communication skills because learning consists of comprehensive, follow-up, and communicative activities to find and combine concepts [5].

4) Problem-based learning

The following science learning approach applied in mobile learning is problem-based learning [5]. Problem-based learning is a learning model that uses a phenomenon or a problem as the primary focus to develop problem-solving and self-organization skills. Problems often used in this learning model are problems in everyday life connected to the subject matter. Problem-based learning requires students to explore knowledge, create ideas, gather information, and solve and answer problems with appropriate solutions [40]. In problem-solving, there is an exchange of knowledge possessed and information collected between each student to solve the problem. The teacher acts as a facilitator to direct the problem so that student discussions focus on solutions.

In the process, the problem-based learning model has beneficial aspects regarding improving students' communication skills. First, students are involved in solving problems. Students' verbal communication skills will develop when they investigate problems, debate theories related to problems, identify problems, propose solutions to problems, analyze and evaluate the problem-solving process, and share experiences related to the process. Second, at each stage of problem-based learning, students' motivation and confidence in communicating can increase. Third, the knowledge obtained by students at the end of the learning process is their original, from the knowledge construction and exploration process they do in problem-based learning. [2].

Problem-based learning encourages students to make meaning from real-life problems that involve higher-order thinking and communication skills. In addition, it involves problem-solving skills, interdisciplinary learning processes, independent learning, and cooperative learning so that all skills involved can be increased [41].

5) Game-based learning

A game-based learning approach can be applied in mobile learning [1]. Games today are developed as entertainment, but some are also developed for learning purposes. Games that are specially designed with technology in education will stimulate the curiosity level of students to learn the existing material [42]. This game-based learning approach can be a choice for teachers to develop interactive learning media. The games aim to support the learning process and increase knowledge in carrying out the learning process compared to the general concept of learning, namely reading.

Game-based learning is a form of learning packaged with games based on specific plans, programs, tools, and equipment prepared by the teacher, and then students are trained in playing the game to achieve the learning objectives set. The game-based learning process is the right tool to represent, visualize, manipulate, and interact with learning content through technology integration [43]. Game-based learning that is packaged excitingly, according to learning objectives, explores and builds concepts, makes students motivated to develop higher-order thinking skills, especially in analysis. In addition, students' communication and collaboration skills are needed in-game activities, especially in groups.

6) Flipped classroom learning

The following science learning approach applied in mobile learning is the flipped classroom [44]. The reverse class is mixed learning, namely learning in two ways; through face-to-face and through virtual or online interactions that combine synchronous learning and asynchronous self-learning. Synchronous learning occurs directly in the classroom, while asynchronous learning is independent learning. The teaching and learning process in the flipped classroom is different; namely, students learn the subject matter that has been given by the teacher via mobile devices at home before the face-to-face class starts.

In learning activities in class, students are asked to do assignments according to the subject matter that has been given by the teacher before, and students discuss subject matter that is not understood with friends and the teacher. By doing assignments at school, when students experience difficulties, they can be directly consulted with their friends or the teacher to solve the problem immediately. A flipped classroom is a learning approach strategy that can minimize the amount of direct instruction in teaching practice but still maximize the interaction process both inside and outside the classroom. This approach strategy makes maximum use of cellular technology [44].

As long as students learn outside the classroom in independent learning, students use mobile devices, such as cellphones, laptops, and computers. This mobile device is beneficial for students in following the learning and is very dependent on it. The flipped classroom approach in its application sharpens students' communication skills [5]. Every teacher and student meets online with the intermediary of a mobile device so that learning runs optimally, two-way communication continues.

The highest percentage of learning approach that used to improve students' higher-order thinking skills and communication skills in science learning are collaborative learning and inquiry learning.

This study has several limitations that reduce the generalizability of the findings: First, this study examines what mobile learning devices are most often used in science learning regardless of the students' economic background. Second, and most importantly, various factors other than mobile devices and learning approaches can improve students' higher-order thinking and communication skills

VI. Conclusion

This research can add to the basis of scientific research and be useful for future researchers because it provides an up-to-date review of mobile learning in science. The most appropriate mobile device used to achieve the learning objectives is a mobile phone, followed by PDAs, tablets, iPad, laptops, e-books, and iPod. Furthermore, it is hoped that this research can be an illustration for other researchers to create innovative learning approaches. The innovative learning approach used in science learning to improve higher-order thinking skills and communication skills is collaborative, inquiry, project-based, problem-based, game-based, and flipped classroom learning. In addition, mobile learning has provided a context in which there are many ways to achieve educational goals, such as independent learning, learning anywhere and anytime, learning to interests, and learning to recognize the characteristics of the student.

VII. Recommendation

Based on the learning approach and theory, the problem faced as a teacher and developer of a learning environment is to ensure that learning will occur adequately and comfortably so that students feel interested in learning. Therefore, one of the essential requirements to fulfill such mobile learning is the learning approach and theory.

Some research that can be done next: First, research on how mobile learning in social learning or comparing the two. Secondly, further research on the most appropriate learning media for mobile learning. And thirdly, research on the effectiveness of implementing approach strategies in mobile learning.

***Abstract*—Interactive Image Segmentation is a type of semi-automated segmentation that uses user input to extract the object of interest. It is possible to speed up and improve the end result of segmentation by using pre-processing steps. The use of superpixels is an example of a pre-processing step. A superpixel is a collection of pixels with similar properties such as texture and colour. Previous research was conducted to assess the impact of the number of superpixels (based on SEEDS superpixel aglorithms) required to achieve the best segmentation results. The study, however, only examined one type of input (strokes) and a small number of images. As a result, the goal of this study is to extend previous work by performing interactive segmentation with input strokes and a combination of bounding box and strokes on images from Grabcut image data sets generated by Topology preserved regular superpixel (TPRS). Based on our findings, an image with 1000 to 2500 superpixels and a combination of bounding box and strokes will help the interactive segmentation algorithm produce a good segmentation result. Finally, the size of the superpixels would influence the final segmentation results as well as the input type.**

Keywords—Image segmentation; superpixel; input type; interactive segmentation

I. Introduction

Computer vision is an artificial intelligence subfield that teaches computers to understand and interpret their visual environment. Image processing is a subset of computer vision that entails enhancing or extracting useful information from images. Image segmentation, a subprocess of image processing, on the other hand, is a technique that allows humans to extract objects of interest from images. Image segmentation can be done manually, semi-automatically, or fully automatically.

In automated segmentation, there is no user involvement. Semi-automated segmentation, also known as interactive segmentation, requires little to no user intervention during the segmentation process. The ultimate goal of image segmentation is to fully automate the process. However, because of the image complexity, automated segmentation continues to face significant challenges in producing satisfactory results. As a result, for better image segmentation results, semi-automated or interactive image segmentation methods are preferred.

Traditionally, image segmentation is performed using information from each individual pixel in the image. This process, however, consumes a significant amount of processing power. Ren and Malik [1] proposed superpixel as a solution to this issue. A superpixel is a group of pixels with similar properties, such as texture or colour. The introduction of the superpixel altered the segmentation processing steps.

Since the introduction of superpixels, many interaction segmentation methods have used them as part of the pre-processing phase [2-5]. However, different interactive segmentation algorithms employ different superpixel algorithms of varying sizes. For instance, [6] and [7] used the SLIC superpixel algorithm [8] with 1000 and 2000 superpixels superpixel per image, respectively. In addition, [9] used a meant-shift superpixel algorithm with 100 superpixels per image. As can be seen, no standard method exists in interactive segmentation for determining the size of a superpixel. As a result, a study [10] was conducted using MSRM interactive segmentation [11] and the SEEDS superpixel algorithm[12] to assess the effect of the number of superpixels required to achieve the best segmentation results. According to the study, 500 superpixels per image were the optimal size for achieving a good segmentation result. The study, however, only looked at one type of input (strokes) and a small number of images. Therefore, the purpose of this paper is to expand on the previous study on the following:

- Using all images from the Grabcut dataset [13] (50 images).
- Using different superpixel algorithm e.g., Topology preserved regular superpixel (TPRS) [14].
- Using various input types, such as bounding box and strokes.

The study's findings will be compared to state-of-the-art interactive algorithms on a variety of metrics.

The study's findings will provide information on the optimal size of the superpixel for TPRS based on the input types utilised by the MSRM interactive segmentation algorithms. In addition, it will serve as an extra guideline when TPRS superpixels are used with other segmentation algorithms.

In the following section, interactive segmentation will be discussed, followed by an overview of the various user input types used in interactive segmentation, maximal similarity-based region merging, and topology preserved regular superpixel algorithms.

II. Literature Review

Interactive image segmentation has been used in a variety of applications. For example, a tool for medical volume images has been created (SmartPaint [15] and MRI for orthopaedic surgery[16]. In the field of remote sensing, a segmentation tool for lithological boundary detection has also been developed [17]. It has also proven to be very useful in agriculture, assisting farmers in detecting crop diseases [18].

As stated in the preceding paragraph, the user will provide guidance in order for the segmentation system to extract the object of interest in interactive segmentation. The general process of interactive segmentation is summarized below:

Step 1: The user will provide information about the context and the object of interest.

Step 2: The segmentation system will generate a segmentation result based on the user's input.

Step 3: The user will evaluate the results, and if the user is satisfied, the process will be completed. Otherwise, the user will provide more background and object of interest information until the system produces a satisfactory segmented result.

Existing work [19] distinguishes between interactive and semi-automatic segmentation by involving the user in both the initialization and post-processing stages of the segmentation process iteratively, whereas semi-automatic segmentation only involves the user in the initialization stage. This study combines the two terms and defines interactive segmentation as any segmentation that requires user input. This study, on the other hand, will concentrate on the involvement of user input during the initialization stage.

Various input types are used in interactive segmentation to provide information about the background and object of interest. Some examples of these input formats are as follows:

- Strokes [20-24]: The user must apply stroke(s) to the image's object of interest and background.
- Seed point [25-29]: The seed points must be placed on the image's background and object of interest by the user.
- Bounding box [13, 30-34]: The user must position the bounding box around the object of interest within the image.

The following section explains Maximal Similarity-based Region Merging (MSRM) and Topology Preserved regular superpixels (TPRS).

A. Maximal Similarity-based Region Merging (MSRM)

Maximal Similarity-based Region Merging algorithm [11] is based on region merging. The image is first converted into superpixels using mean shift segmentation. The contour of the object is then extracted based on the labelling of non-marked regions as region of interest or background. Fig. 1(a) shows the superpixels of the image with strokes on the background and object of interest, and (b) shows the segmentation result.

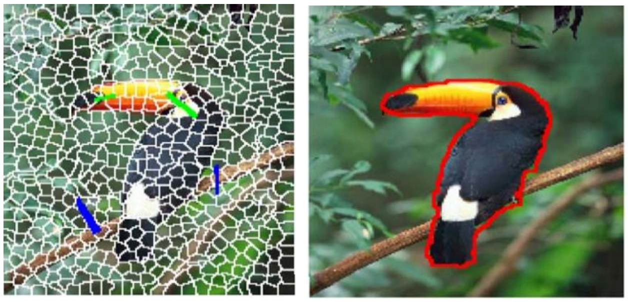

Fig. 1. The Algorithm's Segmentation Process [11]: (a) Superpixel Strokes Entered by users (b): The Segmentation Outcome.

B. Topology Preserved Regular Superpixel (TPRS)

Topology preserved regular superpixel (TPRS) [14] is a path-based method that partitions an image into superpixels by connecting seed points via pixel path. It begins by arranging initial seeds on a lattice grid and associating them with appropriate pixels on the boundary map. It then relocates each seed to the pixel with the highest locally maximal edge magnitudes, taking into account both the distance term and the probability term. Finally, it finds the local optimal path between vertical and horizontal seed pairs.

III. Experimental Setting

To determine the best superpixel size, TPRS will generate a test image with five superpixel sizes: 500, 1000, 1500, 2000, and 2500. Aside from that, each superpixel image will be paired with the following user input type:

- s1: 1 foreground stroke and 3 background strokes.
- s2: multiple foreground and background strokes.
- m2: 1 background bounding box and 2 foreground strokes.
- m3: 1 background bounding box and 2 foreground strokes.

The user input type and superpixel image as well as test image will be fed into the MSRM interactive segmentation algorithm in order to generate segmentation results. Fig. 2 shows some of test image with ground truth (see (a) and (b)). Aside from that, s1 and s2 input strokes from [35] were chosen, as shown in Fig. 2(c) and (d). Fig. 2(e) and (f) show the use of a bounding box with two and three foreground strokes, respectively. Fig. 3 shows the superpixel image generated by TPRS with sizes of 500 in (a) and 2500 in (b).

To assess the efficacy of superpixel algorithms in interactive segmentation, the error rate, F-score, and Jaccard indexes used by [31, 36-38]. Error rate (ERR) is the percentage of pixels placed in an incorrect region which is shown as below equation:

$$ERR = 1 - \left(\frac{TP+TN}{TP+TN+TP+FN}\right) \quad (1)$$

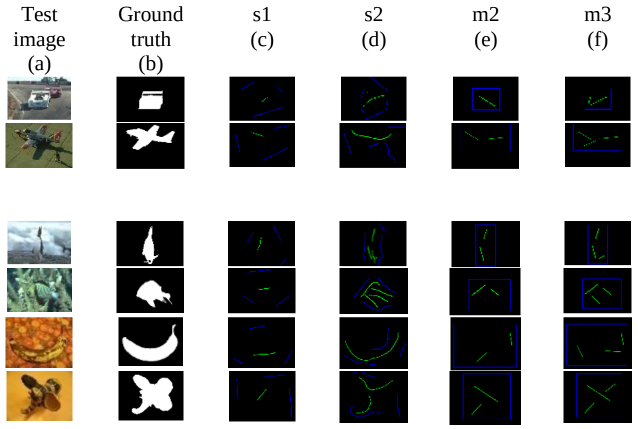

Fig. 2. (a) Test Image. (b) Ground Truth. (c) Simple Stroke. (d) Complex Stroke. (e) Bounding Box with Two Foreground Strokes. (f) Bounding Box with Three Foreground Strokes.

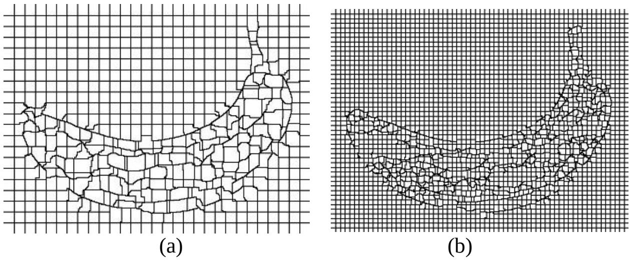

Fig. 3. Superpixel Image of Banana1 from the Dataset which had been Generated by TPRS. (a) 500 (b) 2500.

However, error rate takes into account the percentage of pixels that accurately map to the background information. As a result, the F-score and Jaccard Index are included.

F-score is equivalent to Dice Coefficient. The F-score is also known as the F1-Score or F-Measure. It is equal to 2 * the Area of Overlap divided by the total number of pixels in both images.

$$P = \frac{TP}{TP+FP} \qquad (2)$$

$$R = \frac{TP}{TP+FN} \qquad (3)$$

$$F = 2 * \left(\frac{P*R}{P+R}\right) \qquad (4)$$

The Jaccard index, also known as the Intersection over Union (IoU) metric. It is the ratio of the number of pixels that are shared by X and Y to the total number of pixels in X and Y. In this case, X and Y represent the segmented image and ground truth, respectively. The Jaccard index/ IoU formulation is depicted as follows:

$$J/IOU = \frac{TP}{TP+FP+FN} \qquad (5)$$

IV. Results and Discussion

To have better understanding of the result generated from various size as well as input type, the table below (see Table I) had divided the result based on the superpixel size, s and user input type, t. following by Error rate, e, f-score, f and Jaccard index, j. The error rate, F-score, and Jaccard index are also depicted graphically in Fig. 4 and 5.

TABLE I. Overall Image Segmentation Result based on Three Metrics: Error Rate, e; f, f-score; and Jaccard Index, j Performed by MSRM by using TPRS Superpixel Algorithms that Generated Different Numbers of Superpixels, s Ranging between 500, 1000, 1500, 2000, and 2500 by using Different Types of Input Types: m2 (Bounding Box with Two Foreground Strokes), m3 (Bounding Box with Three Foreground Strokes), s1 (Simple Strokes) and s2 (Complex Strokes)

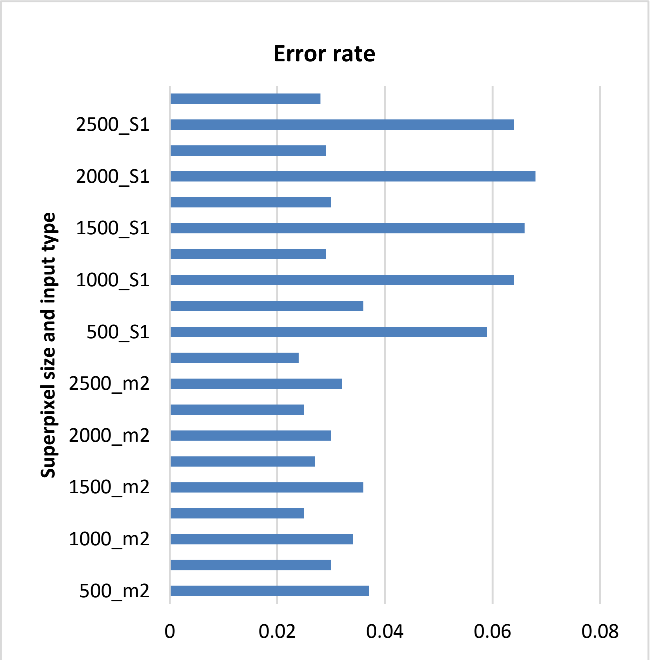

Fig. 4. Segmentation Results based on Error Rate using Various user Input T and Superpixel Size.

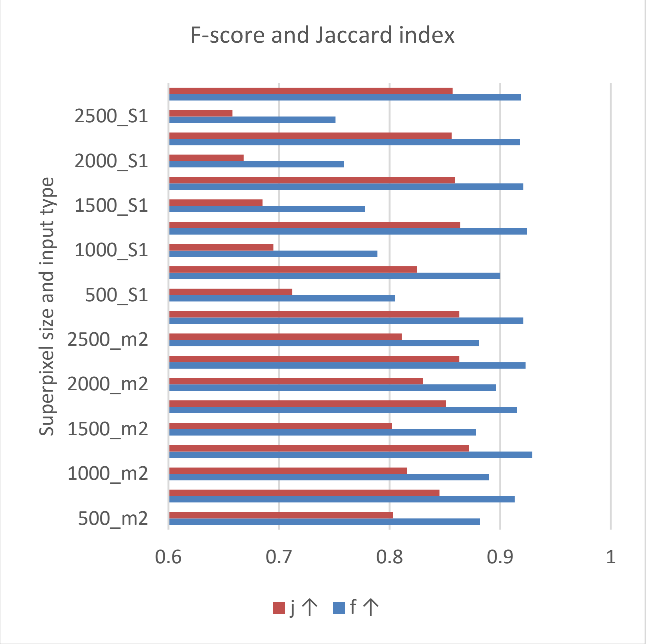

Fig. 5. Segmentation Results based on F-score and Jaccard Index using Various user Input Types and Superpixel Size.

From the Table I, it can summarize the finding of research study as below:

- In term of input type, bounding box input type had performed better than strokes with error rate 0.024 and 0.028, f-score 0.929 and 0.924, and Jaccard index 0.872, 0.864, respectively.
- Regardless of input type, superpixel size of 1000 had outperformed than other superpixel size in term of Jaccard index and F-score. On the other hand, if using error rate as a metric, size of 2500 is much better than size of 1000. However, the difference between only 0.001. Also, if comparing using f-score (0.005-0.008) and Jaccard index (0.007-0.009). It can conclude that size of 1000 should be an optimum size for TPRS.
- The increasing of input strokes for foreground had improved the segmentation results regardless of bounding box or strokes.
- The difference between the highest and lowest result for each category (s1, s2, m2, m3) of each matric are 0.006 and 0.009, error rate, 0.016 and 0.054, f-score and 0.024 and 0.054, Jaccard index.
- Overall, the difference between the highest and lowest result of all are 0.044, error rate, 0.178, f-score, and 0.214, Jaccard index.

The individual image results based on the 1000 and 2500 superpixels for strokes and bounding box categories shown in Table II. These two sizes from two categories were chosen due to the fact that they had achieved the best result among others. From the Table II, it is shown that 153077 had achieved high error rate (>0.1) if using bounding box while 189080 and stone2 if using strokes.

When compared to state-of-the-art interactive segmentation algorithms, 2500 m3 achieved 0.024, which is 0.001 higher than the best reference algorithm in the error rate category, which is a training-based algorithm (see Table III). It did, however, outperforms other training-based algorithms like Label propagation [43] (0.0321), Xia [44] (0.033), SBT with AT [44] (0.033,) RW with AT [45] (0.033), and DEEPGC [38] (0.034). Apart from this, in terms of the F-score (see Table III) and Jaccard index (see Table IV), there is a 4% difference between the best reference algorithm and our algorithm.

V. CONCLUSION AND FUTURE DIRECTION

The TPRS superpixels algorithm was used in this paper to generate various sizes of superpixels images on interactive segmentation algorithms, MSRM using strokes and a combination of bounding box with strokes as user input. The entire test images from the Grabcut dataset were used in the testing. Evaluation matrices such as error rate, e, f-score, f, and Jaccard index, J were used to evaluate the generated results. Overall, the interactive segmentation algorithm was able to achieve an optimal segmentation result by bounding the box with three strokes and using superpixel sizes of 1000 and 2500. This discovery will be useful for researchers who want to use superpixels, particularly on TPRS, with appropriate settings on the number of superpixels in an image on the interactive segmentation algorithm. The segmentation results, on the other hand, were compared to the results of the previous study, which determined that 500 is the optimal number of superpixels to use in interactive segmentation. The difference could be due to the number of test images used as well as the input types. Finally, we make several recommendations for future research:

- Comparative study of various types of superpixel algorithms with diverse input types on different interactive segmentation algorithms.
- Previous studies [49, 50] has found that image complexity can affect segmentation results. Existing interactive image segmentation algorithms have not addressed the relationship between image complexity and input type, as well as superpixel and size, and this can be investigated further.

ACKNOWLEDGMENT

The authors would like to thank Faculty of Computer Science and Information Technology, University of Malaysia Sarawak and Faculty of Science and Technology, i-CATS University College, for providing the facilities for this study.

***Abstract*—The intelligent fusion terminal in the distribution area usually adopts the mode of cooperation between the cloud and the edge, and the workload of manual operation and maintenance is large. Therefore, an intelligent fusion terminal system in the distribution area with fog computing capability based on a high-capacity CPU is proposed. Follow the “cloud pipe edge end” construction framework of smart IOT system, and take this framework as the edge computing node of distribution station area and power consumption side. Mt7622b chip in Linux operating system with openwrt firmware is used as the main control chip of edge agent gateway equipment, and the recursive least square method is used to realize the data fusion of power acquisition service in distribution station area and power distribution demand terminal. The test results show that the designed system can realize real-time monitoring of power consumption and distribution data and power quality management in the distribution station area, and the data processing delay is less than 100ms, which provides a reference for the intelligent fusion terminal system in the distribution station area.**

Keywords—Large-capacity CPU; fog computing capability; power distribution station area; intelligent integration; terminal; system design

I. INTRODUCTION

The communication demands of power users and the intelligent terminal equipment of the power grid are growing linearly. The communication network of many terminal devices in the distribution network station area needs to have a high level of manual operation and maintenance, which puts forward higher requirements for delay, bandwidth and communication flexibility [1]. The intelligent terminal in the station area is the core unit of measurement and control management in the current intelligent power distribution system. The intelligent terminal in the station area is usually installed on the side of the distribution transformer. It uses the intelligent terminal in the station area to realize the communication interaction of the main station system and the access of the lower-level intelligent equipment [2-3]. The intelligent terminal equipment in the station area is of high importance and has a huge impact on the power distribution system. The distribution station area is the junction of production and marketing. Both the production and marketing parties install distribution transformer terminals and concentrators on the station side based on business needs. There are problems such as non-sharing of data, duplication of functions, and increased operation and maintenance workload [4-5]. The intelligent fusion terminal device can realize the functions of the concentrator and the distribution terminal, reducing the cost of equipment procurement, reducing the workload of manual operation and maintenance, and saving the cost of operation and maintenance.

At present, there is much researches on terminal data analysis of power distribution systems. Literature [6] designs a remote terminal data acquisition system for intelligent power distribution automation. The author in [7] proposes an automatically test system for intelligent substation relay protection equipment based on information fusion, which can separately collect data from remote terminals of intelligent power distribution and automatic test of intelligent substation relay protection equipment. Although the above research has achieved certain results and has certain application performance, it does not have the function of improving the data processing efficiency of the intelligent fusion terminal in the distribution station area. To this end, a large-capacity CPU-based intelligent fusion terminal system with fog computing capability is proposed in the distribution station area. Fog computing is based on the concept of cloud computing. In the fog computing mode, the data processing of many intelligent terminals is concentrated on the network edge devices, which effectively improves the data processing efficiency [8]. Applying fog computing to data management in distribution station area can effectively reduce data transmission delay and improve data communication capabilities. The innovation of the research is to use fog computing and large-capacity CPU to improve the data processing capability and communication performance of the system, as an intelligent terminal management device with many functions such as power quality monitoring, distribution transformer detection, humidity and temperature monitoring, etc. It has a high degree of integration, many functions, realizes remote control of intelligent terminals, and has high applicability.

II. Intelligent Fusion Terminal System in Distribution Station Area with Large-capacity CPU with Fog Computing Capability

A. System Overall Structure

The designed intelligent fusion terminal system in the distribution station area has the functions of a concentrator and TTU, and can be used as the edge computing node in the distribution station area and the power consumption side. The distribution station area takes the intelligent fusion terminal system of the distribution station area as the core, and establishes an intelligent low-voltage distribution Internet of Things with distribution automation. The overall structure of the intelligent fusion terminal system in the power distribution station area with a large-capacity CPU designed with fog computing capability is shown in Fig. 1.

As can be seen from Fig. 1, the designed system follows the "cloud-pipe-side-end" construction framework of the smart IoT system, which can realize the intelligent integration of the power distribution station area's use and procurement services and power distribution requirements. The system supports the communication protocols of the mining system, power distribution and unified IoT management center. Using container technology, multiple containers can be run at the same time, data communication between containers is supported, and data exchange and sharing functions between containers. The marketing application in the distribution station area and the distribution application are installed in their respective containers, and all the functions of the system are realized by using the application APP they have.

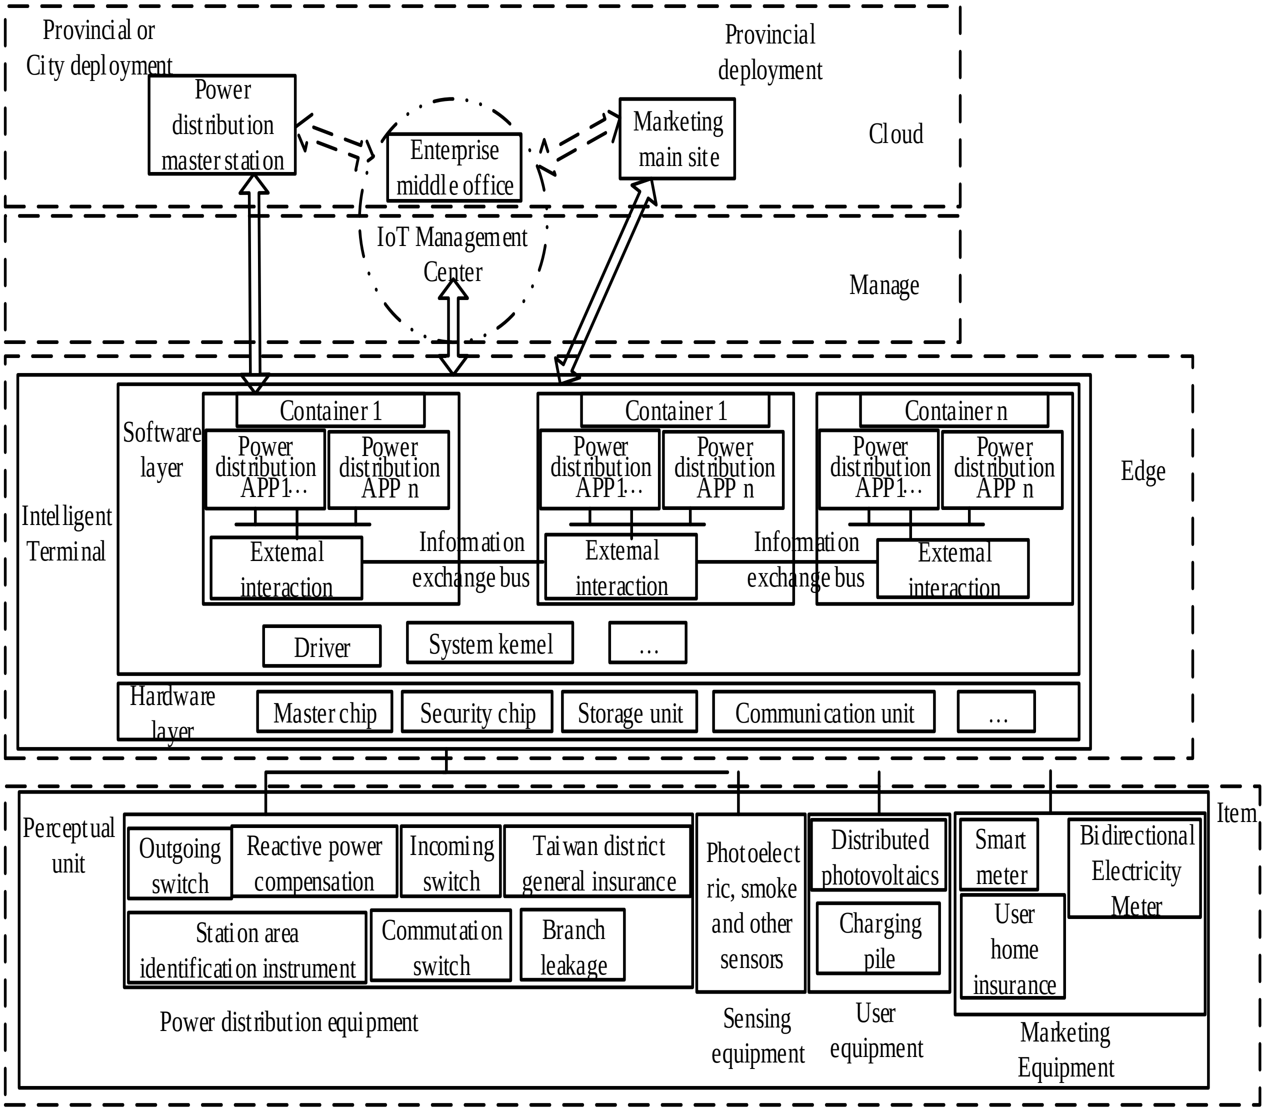

Fig. 1. System Overall Structure Diagram.

The system has external module communication data transmission application, container construction, data recording log and abnormal work log, running status monitoring, remote software and hardware information query, data recording and data statistics, event recording and reporting, parameter setting and query functions. The intelligent fusion terminal system has edge computing capabilities, and integrates the functions of power supply and consumption information collection in the distribution station area, energy meter or collection terminal data collection, equipment status monitoring and communication networking, local analysis and decision-making, and collaborative computing. The hardware adopts a platform-based design, supports the edge computing framework, and has fog computing capabilities [9], which can realize flexible expansion of functions through software-defined methods.

1) System hardware design: The hardware of the intelligent fusion terminal includes the basic core board, the main control board, the carrier module, the acquisition board, the power supply module, the single 4G module, and the dual 4G module. The hardware performance indicators of the fusion terminal are better than the reference standard requirements, and have good consistency. The hardware is designed based on the main control chip. The chip adopts the MT7622B architecture single-core 4-core processor, the main frequency is 1.35GHz, and the peripheral integrates 2GB DDR3 SDRAM and 8GM FLASH memory, two-way Gigabit Ethernet and other peripheral interfaces [10]. The software is based on an autonomous controllable operating system, Docker containers and autonomous orchestration technology.

The main control chip of the edge proxy gateway device adopts MT7622B, the peripheral is equipped with STM32 main control, and the MT7622B chip runs the OpenWRT operating system. It mainly realizes IO expansion and related acquisition functions. The software uses Ubuntu 16.04 operating system to compile openwrt firmware. Flash the compiled firmware into flash, and then run docker in the system to manage the entire application in a containerized manner. STM32 is developed with STM32 library to realize driver layer and application layer encapsulation.

The MT7622B chip adopts the Linux operating system of OpenWrt firmware. In order to ensure the normal and stable operation of the application, the firmware is cut and transplanted, and burned to the hardware platform. According to functional requirements, they increase or decrease related peripheral interface drivers, so that the overall system framework can meet the work requirements and be more streamlined. The main control chip has limited pins [11], and the terminal platform is equipped with an MCU chip as a data transfer hub. The MCU chip is used to connect the relevant peripheral modules, and communicate with the MT7622B main control chip through the communication interface, so that the main control chip can control the relevant peripheral modules.

MT7622B integrates dual ARM®Cortex-A53 cores, with a working frequency of up to 1.35GHz, with strong computing power and working stability. The high-speed DDR3 interface can be connected to high-capacity DRAM chips. It supports a variety of NAND Flash interfaces to realize mass storage control. The chip also includes various peripherals, including UART, SGMII, RGMII, PCIe2.0, USB2.0 (Host), USB3.0 (Host), and a 5-port 10/100 switch. It supports hardware router function, realizes 2.5Gbps HSGMII and 1Gbps RGMII Ethernet interface, embedded 5-port 10/100 switch and 802.11n 2.4GHz wireless. It can be supported by 802.11ac WLAN connection, and a variety of external network connection methods are available.

2) System software design: The system software platform provides a stable operating environment for the fusion terminal. The software platform is used to realize the decoupling of system software and hardware and software APP. The software platform includes the operating system and the edge computing framework.

The operating system completes the design of the root of trust and the chain of trust based on Linux. We have completed the driver design of all peripheral interfaces of the terminal, completed the kernel tailoring optimization and patch upgrade [12], and realized the kernel's support for the self-developed container management and terminal management platform.

The edge computing framework includes the container management engine Docker, system management, and various layers of components for edge-side application development, supporting various business applications. It has realized Docker's management of system-level single container and multiple APPs. It implements various functions such as container start, stop, uninstall, and deletion, APP start, stop, uninstall and deletion, and APP and container quota management.

B. Edge Proxy Gateway Device with Fog Computing Function

1) Edge proxy gateway device: Fog computing data processing and applications are concentrated in network edge devices rather than being stored in the cloud. The distribution station area is the intersection of production and marketing. Based on business needs, both production and marketing parties install distribution transformer terminals and concentrators on the side of the station area. There are problems such as non-sharing of data, duplication of functions, and increased operation and maintenance workload [13]. To solve such problems, the edge proxy gateway device with fog computing function is applied to the intelligent fusion terminal system in the distribution station area. The structure diagram of the edge proxy gateway device with fog computing function is shown in Fig. 2.

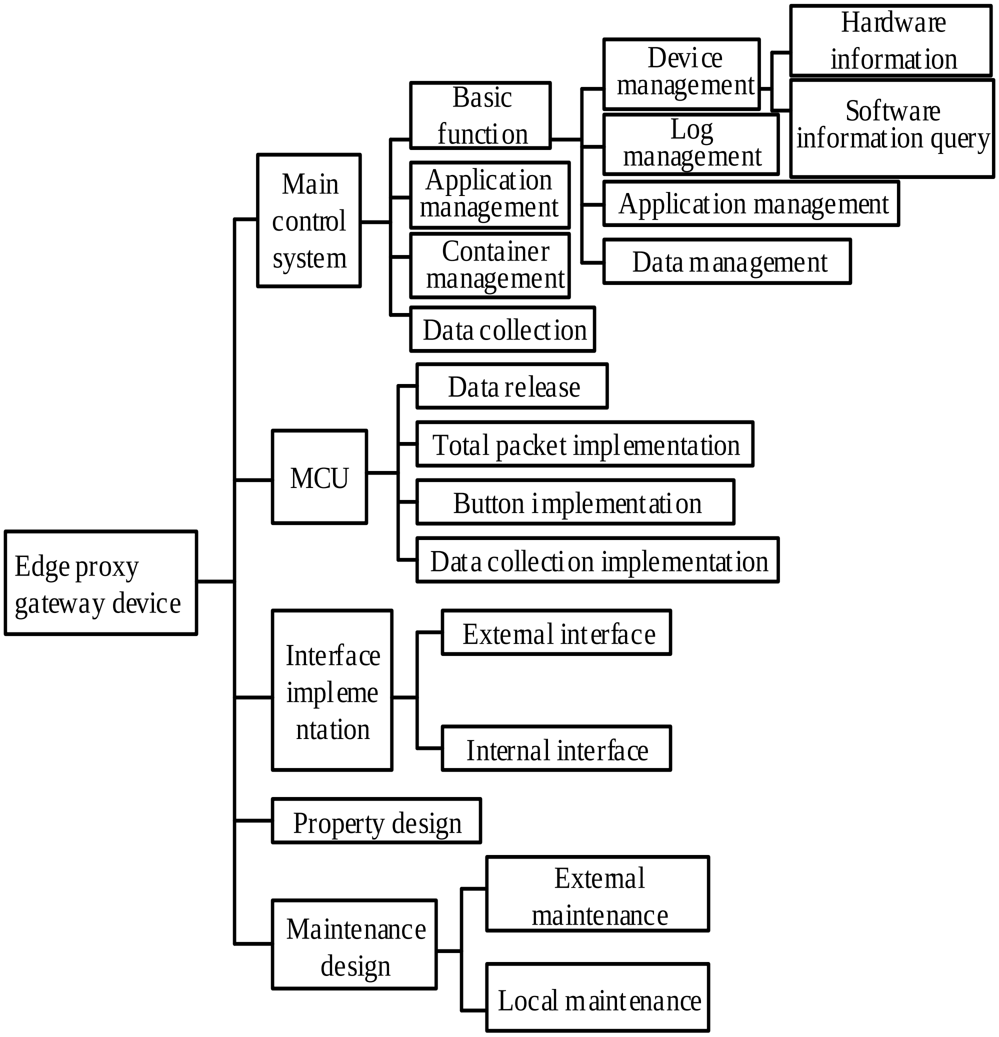

Fig. 2. Edge Proxy Gateway Device Structure Diagram.

The edge proxy gateway device includes a gateway system and a shell, and the gateway system includes a main control system, a single-chip microcomputer, an interface implementation, an attribute design and a system maintenance design. There is installation and positioning holes at the ends of the casing, and the installation and positioning holes are in a symmetrical state with respect to the central axis of the casing. A gas inlet window, a sequence area, a power button and a setting button are arranged on one side of the casing. The sequence area is located at the top of the gas inlet window, and the setting button is located between the sequence area and the power button. The edge proxy gateway device can monitor the devices in the distribution station area [14]. It can reduce the workload of equipment operation and maintenance, and reduce the input of manpower and material resources.

2) Network related skills reserve: The network-related skills reserves of the designed intelligent fusion terminal system in the distribution station area are as follows:

Layer 2 switch: Identify the MAC address information in the data packet. Forwarding is based on the MAC address, and the MAC address and the corresponding port are recorded in the internal address table.

Layer 3 switches: Layer 3 switches implement IP routing functions through a hardware switching mechanism. Its optimized routing software improves the efficiency of the routing process and solves the routing speed problem of traditional router software.

Link layer communication protocol: The data link layer provides services to the network layer based on the services provided by the physical layer. The most basic service is the reliable transmission of the source machine network layer data to the adjacent node target machine network layer.

Network layer communication protocol: The data link layer provides the data frame transmission function between two adjacent endpoints to manage network data communication. It transmits data from the source to the destination through several intermediate nodes, and provides end-to-end data transmission services to the transport layer [15].

DHCP: Dynamic Host Configuration Protocol (Dynamic Host Configuration Protocol), referred to as DHCP. It is a network protocol used in local area networks. This protocol allows servers to dynamically assign IP addresses and configuration information to clients.

DNS: Domain Name System (Domain Name System abbreviation DNS, Domain Name is translated as domain name) is the core service of the Internet. As a distributed database that can map domain names and IP addresses to each other, it makes Internet access more convenient without recording IP strings that can be read by machines.

LAN: Local Area Network (LAN) refers to a computer composed of multiple computers interconnected in a certain area.

WLAN: Wide Area Network (Wide Area Network), also known as a wide area network, external network or public network. The WAN is not the same as the Internet. It is a long-distance network that connects different local area networks or metropolitan area network computers to communicate, mainly using packet switching technology.

Docker container technology: A Linux container is a series of processes isolated from the rest of the system. All the files needed to run these processes are provided by another mirror. This means that Linux containers are portable and consistent from development to testing to production. Containers run faster than development pipelines that rely on repeating traditional test environments. Docker technology brings many new concepts and tools. It includes a simple command line interface to run and build new layered images, a server daemon, a library with prebuilt container images, and a registry server concept. Combining the above technologies, users can quickly build new layered containers and easily share containers with others.

3) Data fusion by recursive least squares: The edge computing layer of the system uses the recursive least squares method to realize the data fusion of the intelligent fusion terminal in the distribution station area. Assume that the number of smart terminals included in the distribution station area is n, and the measurement equation of smart terminal i is as follows:

$$Z_i = X + U_i \tag{1}$$

In equation (1), Z_i represents the i measurement value of the smart terminal. X represents the parameter value. U_i represents the noise value included in the data acquisition process.

The noise in the data collection process has no correlation, and the optimal weighting is based on a fixed criterion. According to the weight coefficient, the collected values of each intelligent terminal are multiplied to avoid the loss of information caused by removing the noise of data collection.

The weighting coefficient determination equation is as follows:

$$\hat{X} = \sum_{i=1}^{n} \alpha_i \times Z_i \tag{2}$$

In Equation (2), α_i represents a weighting coefficient.

The weighted estimated mean squared error equation is established as follows:

$$E = \sum_{i=1}^{n} \alpha_i^2 \delta_i^2 \times \hat{X} \tag{3}$$

In Equation (3), δ^2 represents the noise variance.

According to the conditional extreme value acquisition method of the above equation, the weighting coefficient equation that minimizes E is determined as follows:

$$f\left(\alpha_1, \alpha_2, \cdots, \alpha_n, \theta\right) = \sum_{i=1}^{n} \alpha_i^2 \delta_i^2 - \theta\left(\sum_{i=1}^{n} \alpha_i - 1\right) \tag{4}$$

In equation (4), θ represents the weight. The weighting coefficient equation is as follows:

$$\alpha_i = \frac{\delta_i^{-2}}{\sum_{i=1}^{n} \delta_i^{-2}} \tag{5}$$

The mean squared error equation to obtain the weighted estimate is as follows:

$$E\left[\left(X - \hat{X}\right)^2\right] = \frac{1}{\sum_{i=1}^{n} \delta_i^{-2}} \tag{6}$$

According to the determined optimal weights, the recursive relationship of the recursive least squares method is used to realize the data fusion of intelligent terminals in the distribution station area. The equation is as follows:

$$\begin{cases} P_{k+1} = P_k - P_k^2 / \left(1 + P_k\right) \\ \hat{Y}_{k+1} = \hat{Y}_k + P_{k+1}\left(\hat{X}_{k+1} - \hat{Y}_k\right) \end{cases} \tag{7}$$

In equation (7), $\hat{Y}_k$ and $\hat{Y}_{k+1}$ represent the data of the smart terminal at time k and $k+1$, respectively. Both P_k and P_{k+1} represent intermediate quantities. $\hat{X}_{k+1}$ represents the weighted estimated value of n intelligent terminals when time is $k+1$. Obtaining the fusion result by the recursive least squares method can ensure the minimum and unbiased estimated mean square error.

III. System Experimental Test

In order to verify the design of the large-capacity CPU with the ability of fog computing, the intelligent fusion terminal system management in the distribution station area and the effectiveness of monitoring the distribution station network. We use Matlab software to build the system in this paper, and select the distribution station area of a power company as the experimental object. The distribution station area includes distribution automation terminals, state monitoring intelligent terminals, power quality monitoring intelligent terminals, state monitoring sensors, secondary screen cabinets and many other intelligent terminals. In the distribution station area, the optical fiber network is used to realize communication.

After the system of this paper is adopted in the distribution station area, the emergency repair time when the fault occurs is calculated. The system in this paper is compared with the remote system [6] and the information fusion system [7]. The comparison results of the fault repair time are shown in Fig. 3.

It can be seen from the experimental results in Fig. 3 that the application of the system in this paper in the distribution station area can reduce the time of power failure and improve the reliability of power supply. The reliability of power supply in the distribution station area determines customer satisfaction and power supply revenue. After adopting the system in this paper, the dispatcher in the distribution station area can close the power outage switch at the first time in case of a fault, so as to reduce the outage time. It can notify the on-duty personnel to quickly repair, reduce the repair time, and improve the reliability of power supply.

At present, the residential voltage qualification rate cannot meet the residential electricity demand. The voltage qualification rate before the system in this distribution station area is not used is about 90%. After the system in this paper was applied to the distribution station area, the voltage quality of the distribution network from May to September 2019 was calculated. The method in this paper is compared with the remote system and the information fusion system. The comparison results are shown in Fig. 4.

It can be seen from the experimental results in Fig. 4 that after the system in this paper is adopted, the voltage qualification rate of the distribution station area is significantly improved. Within five months of operation, the system in this paper increased the voltage qualification rate of the distribution station area to more than 98.5%. The remote system and the information fusion system have a small improvement in the voltage qualification rate of the distribution station area, and the voltage qualification rate is lower than 95%. This system effectively monitors the voltage data of each integrated point. Through reasonable logical judgment, the comprehensive voltage regulation of the line voltage regulator is realized to ensure that the voltage of each node in the low-voltage line in the distribution network meets the voltage qualified value.

The real-time operation of the system is of great significance. The system in this paper adopts the fog computing architecture and has strong data processing and communication capabilities. Statistics The system in this paper is used to collect the refresh rate of the intelligent terminal equipment in the distribution station area. The statistical results are shown in Table I.

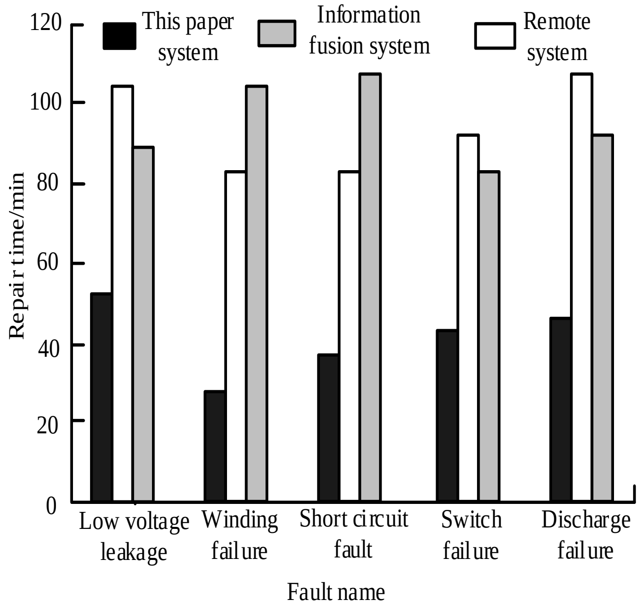

Fig. 3. Fault Repair Time Comparison.

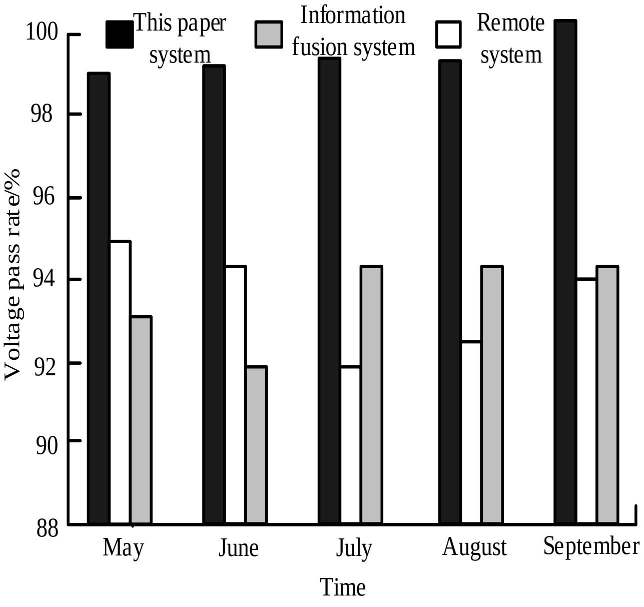

Fig. 4. Voltage Pass Rate Comparison.

TABLE I. Data Refresh Rate

System name	Fast data processing/(times/s)	Data collection/(times/s)
This paper system	120	30
Remote system	85	21
Information fusion system	94	19

It can be seen from the experimental results in Table I that the fast data refresh rate of the system in this paper is as high as 120 times/s. Intelligent terminal data collection refreshes data up to 30 times/s. The data refresh speed of the system in this paper is significantly higher than the other two systems, which verifies that the system in this paper has a higher data refresh speed. The system in this paper adopts fog computing architecture combined with large-capacity CPU, which has high communication performance and data transmission rate.

The monitoring time delay of the real-time monitoring of distribution data in the distribution station area is calculated using the system in this paper. The system in this paper is compared with the remote system and the information fusion system, and the comparison results are shown in Table II.

TABLE II. POWER DISTRIBUTION DATA MONITORING DELAY

Power distribution monitoring data name	This paper system/ms	Remote system/ms	Information fusion system/ms
Three-phase voltage	85	185	251
Electric current	91	165	234
Electrical energy	76	205	218
Tariff electricity	58	234	265
Total power	82	198	208
Voltage pass rate	94	152	234
Three-phase unbalance	84	184	218
Harmonic	76	235	269
Circuit breaker status	58	196	248
Capacitor switching state	64	184	235
Distribution terminal status	78	258	274

It can be seen from the experimental results in Table II that the monitoring delay of the system in this paper is less than 100ms. Using remote system and information fusion system to monitor the distribution of data monitoring delay in the distribution station area is higher than 150ms. The power distribution data monitoring delay of the system in this paper is significantly lower than that of the other two systems. The main reason is that the system in this paper adopts a fog computing architecture and a large-capacity CPU, which effectively improves the data processing capability of the system. The system meets the data acquisition and monitoring needs of the distribution station area.

Statistical data processing efficiency under different data volumes: The system in this paper is compared with the other two systems, and the comparison results are shown in Fig. 5.

As can be seen from the experimental results in Fig. 5, the data processing efficiency of the system in this paper is higher than 97% under different data volumes. The data processing efficiency of the other two systems is lower than 96% in the case of different data volumes. The fog computing architecture adopted in this system has high data processing efficiency. The previous cloud computing platform needs to transmit all the collected data to the computing center, and use the computing center to process the data, which cannot meet the delay requirement. The fog computing architecture can realize the analysis of data collected by the edge computing unit and improve the efficiency of data processing. The fog computing architecture can meet the low latency requirements of power communication networks. In the face of massive power data, it has high processing efficiency and can be used as a good solution in the distribution network.

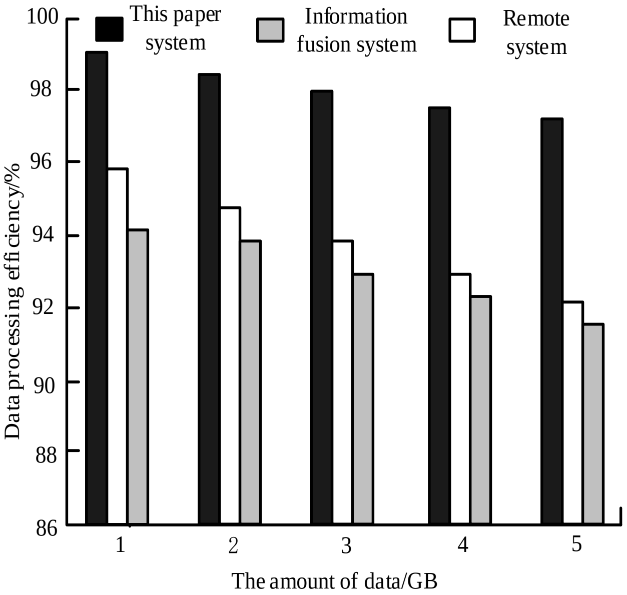

Fig. 5. Data Processing Efficiency Comparison Results.

After adopting the system in this paper, the cost of investing in secondary equipment in the distribution station area is calculated. The system in this paper is compared with the other two systems, and the comparison results are shown in Table III.

TABLE III. SECONDARY EQUIPMENT INVESTMENT ANALYSIS

Project	This paper system/million	Remote system/million	Information fusion system/million
Distribution automation terminal	3.5	4.2	4.3
Power quality monitoring terminal	2.4	2.6	2.5
Condition monitoring sensors	1.9	2.2	2.3
Condition monitoring unit	1.8	1.9	2.1
Fiber optic communication unit	0.9	1.1	1.1
Secondary screen cabinet	0.7	0.9	0.8
Total	11.2	12.9	13.1

From the experimental results in Table III, it can be seen that after using the system in this paper, the cost of investing in secondary equipment in the distribution station area is lower than the 17,000 yuan of the remote system and the 19,000 yuan of the information fusion system. The experimental results show that the system in this paper has a higher management effect of power distribution equipment. Applying the system in this paper to the distribution station area can effectively save the investment cost. It has high performance of intelligent terminal management in power distribution station area, which is helpful for the long-term development of electric power enterprises.

IV. Conclusion

Power grid technology has developed rapidly, and power infrastructure has been gradually improved. The primary and secondary equipment of the distribution network has gradually matured and stabilized. There are many intelligent terminals installed in the distribution network station area. Through the intelligent terminals, the power distribution data collection in the distribution station area and the online monitoring of the power consumption data can be realized. However, the functions of comprehensive management, comprehensive analysis and comprehensive control in the distribution station area are not perfect. We combined the fog computing mechanism with the large-capacity CPU to design an intelligent fusion terminal system in the distribution station area with fog computing capability based on the large-capacity CPU. And it is verified by experiments that the system has high practicability in the distribution station area. The researched system has a high level of automation and low input cost, which can help power companies to complete the goal of smart grid construction and realize smart grid functions. In the event of a power outage in the distribution station area, the researched system can transmit the terminal fault information data back to the system. The system sends information to equipment maintenance personnel. After receiving the information, the maintenance personnel can quickly reach the fault location, and the repair speed is fast, which improves customer satisfaction with electricity consumption.

V. Declaration

The authors declare that there are no conflicts of interest regarding the publication of this paper.

VI. Funding

The study was supported by “2018 quota station technology project of State Grid Corporation <Research on billing basis of UAV aerial survey technology application> (Grant NO. SGDE-LN-2018-02-003)” and “Science and technology project of State Grid Corporation <Research on monitoring and control optimization of power grid life cycle investment> (Grant NO. 2015YF-64)”.

A Blind Robust Image Watermarking on Selected DCT Coefficients for Copyright Protection

Majid Rahardi[1], Ferian Fauzi Abdulloh[2], Wahyu Sukestyastama Putra[3]
Faculty of Computer Science, Universitas Amikom Yogyakarta
Sleman, Indonesia[1, 2, 3]

***Abstract*—This paper proposes a blind and robust image watermarking technique using Discrete Cosine Transform (DCT) for copyright protection on color images called BRIW-DCT. Each channel of the host image is divided into non-overlapping image blocks with the size of 8×8 pixels. Each image block is transformed into a frequency domain using the DCT transformation. The watermark image is embedded into the host image by modifying the 11th to the 15th DCT coefficient. The experimental result shows that the watermarked image achieved a high PSNR value of 50.4489 dB and a high SSIM value of 0.9991. Furthermore, various attacks are performed on the watermarked image. BRIW-DCT can successfully recover the watermark image from the tampered image, which produces a high NC value of 0.7805 and a low BER value of 0.1126.**

Keywords*—Robust watermarking; copyright protection; discrete cosine transform; frequency domain; color image watermarking

I. Introduction

The development of internet technology in recent years has contributed to the birth of social media platforms. The advancement of the mobile operating system such as Android and iOS also contributes to the growth of social media users [1]–[4]. Everyone can share their data seamlessly across many social media platforms. One type of data is a multimedia image. The multimedia image is created using a camera and various available editing software [5]–[11]. The image itself is then uploaded to the social media platform. Everyone can download and re-upload the image on another platform. This action may violate the copyright and ownership of the image. In order to protect the ownership of the image, some artist commonly adds a visible watermark to the image. However, someone who has skill in image editing software may remove or replace the watermark on the image. As a result, the owner of the image has lost the intellectual property of that image. To solve this problem, researchers have developed an invisible watermark to protect the ownership of the image [12]–[18].

There are three categories of invisible image watermarking: robust, semi-fragile, and fragile image watermarking. A fragile image watermarking scheme embeds the watermark image into the host image in the original domain of the image, which is the spatial domain. The watermark embedding is performed on the Least Significant Bit (LSB) of the image. While semi-fragile and robust watermarking embed the watermark data in the transform domain, such as Discrete Cosine Transform (DCT) [19]–[28], Discrete Wavelet Transform (DWT) [29]–[37], and Singular Value Decomposition (SVD) [38]–[46]. Based on the objective, fragile and semi-fragile watermarking is commonly utilized for image authentication. In contrast, robust watermarking is widely used for copyright protection. In image authentication, the embedded watermark data must be sensitive to any modification to the image. Thus, if an image area is modified, the technique can localize the tampered area [47]–[50]. In contrast, in copyright protection, the watermark data must be preserved for any modification to the image, such as image compression [51]–[60]. Thus, it is called robust watermarking.

The watermarking process consists of two steps: embedding and extracting the watermark data [61]. The owner of the digital image does watermark embedding the first time the image is created. The image itself is then uploaded to the internet. If someone steals and modifies that image, then the owner can prove his ownership through watermark extraction from the modified image [62]. The extracted watermark then can be used as evidence in the court for justice. There are three techniques in the watermark extraction process: semi-blind, blind, and non-blind watermarking [63]. The non-blind technique requires the information from the host image and the watermark logo in the extraction process. The semi-blind technique requires additional information, such as the embedding region coordinates. In contrast, the blind technique does not require any information from the host image. Thus, the blind technique is the most efficient method in the robust image watermarking.

This paper proposes a blind and robust image watermarking scheme primarily used for copyright protection, namely BRIW-DCT. At first, the scheme divides the host image into three RGB channels. Each channel is divided into non-overlapping image blocks with the size of 8×8 pixels. Each block is then transformed into the frequency domain using the DCT. Each pixel of the watermark data is embedded into each block by modifying the 11th to the 15th DCT coefficient. The selected embedding location is considered the optimum for embedding without corrupting the host image. Once the watermark data is embedded, the inverse DCT is performed to reveal the watermarked image. The watermarked image can then be distributed safely through the internet. The evaluation of the watermarked image is computed using Structural Similarity Index Measure (SSIM) and Peak Signal to Noise Ratio (PSNR). While the extraction of the watermark data is measured using Normalized Cross-Correlation (NC) and Bit Error Rate (BER).

The rest of this article is organized as follows: Section II presents the related works of the existing robust watermarking techniques. The proposed method is explained in Section III. The experimental result and analysis are shown in Section IV. Finally, Section V concludes this research.

II. Related Work

Yousevi et al. [12] presented a blind robust image watermarking scheme on color images using the Integer Wavelet Transform (IWT). The scheme divided the color image into non-overlapping image blocks with the size of 4×4 pixels. Next, each block was transformed into a frequency domain using IWT. The low sub-band is selected as the embedding location of the watermark data to improve the watermarked image quality. The watermark data is embedded in a chaotic manner using the Lyapunov exponent. This process prevents the illegal extraction of the watermark data. Furthermore, the chaotic map is randomized using the Pseudo-Random Number Generator (PRNG). The experiments apply various attacks to the watermarked image, such as salt and pepper, low pass filtering, cropping, blurring, etc. The experimental result shows that the scheme successfully embeds the watermark data into the host image. However, the extracted watermark doesn't reach a satisfactory level of imperceptibility. Thus, the technique can be improved further.

Zermi et al. [13] presented a robust digital watermarking scheme using DWT and SVD for medical images. The host image is transformed into a frequency domain using DWT. Furthermore, the LL sub-band is transformed using SVD. The watermark data is then embedded into the SVD coefficient matrix. The watermark data itself is generated from the electronic patient record. The watermark data is then formatted into a binary sequence of data and hashed using the MD5 function. The experiment was performed using the Ocular Disease Intelligent Recognition (ODIR) database. The images are tampered with using various tampering methods such as JPEG compression, average filtering, gamma correction, sharpening, and scaling. The experimental results showed that the scheme could maintain the imperceptibility of the watermarked image. The scheme was also robust against several conventional attacks. However, the scheme has the limitation of usage on the medical images. The scheme can be further improved to support various types of multimedia images.

Begum et al. [14] presented a hybrid and robust watermarking scheme using DCT, DWT, and SVD. The Arnold map was used to encrypt the watermark image. The host image was transformed in the frequency domain using DCT followed by DWT and finalized using SVD. The experiment was conducted using various tampering attacks such as median filter and rotation attacks. The experimental result shows that the scheme achieved high robustness against multiple attacks. However, the utilization of two transform domains led to high computational costs. Thus, the scheme can further be improved to reduce the computational cost while maintaining robustness.

Fares et al. [15] presented a blind robust image watermarking based on the Fourier transform. Fourier transform is the first introduced frequency domain transformation in signal processing research. The scheme separated the color images into each RGB component. The Fourier transform is applied individually on each channel. Furthermore, multiple variants of the Fourier transform were utilized. Those variants are Fractional Fourier Transform (FFT), Quaternion Discrete Fourier Transform (QDFT), and Discrete Fourier Transform (DFT). The watermark image was inserted into the selected coefficient of the Fourier Transform. Once the watermark data was embedded, the inverse transformation was performed to produce the watermarked image. The experiment was done using multiple attack scenarios such as histogram equalization, blurring, rescaling, Gaussian noise, rotation, and JPEG compression. The experimental results showed that the scheme successfully embedded the watermark data into the host image. In addition, the scheme could also extract the watermark data under various attack scenarios. However, the extracted watermark quality can still be improved further.

Laxmanika and Singh [16] presented a robust image watermarking scheme using DWT, SVD, DCT, Particle Swarm Optimization (PSO), and Bi-dimensional Empirical Mode Decomposition (BEMD). The host image is decomposed using 2nd level DWT into sub-bands. The selected bands were then decomposed further using the BEMD. To optimize the searching of complex multidimensional data, the PSO was implemented. Furthermore, the DCT followed by SVD is applied to the selected band. In his research, the security key was utilized in the embedding process. The extraction process extracted the watermark data in reverse. The experimental result showed that the scheme was robust in restoring the watermark data after various attacks were applied to the watermarked image. However, excessive use of multiple transform domains led to a high computational cost. Therefore, the scheme can be further improved to reduce the computational time.

Thanki et al. [17] presented a blind watermarking scheme using Discrete Curvelet Transform (DCuT) and Redundant Discrete Wavelet Transform (RDWT). It combined two transformation domains to improve the imperceptibility of the watermarked image. A hybrid coefficient is selected from a single-level RDWT and the high-frequency DCuT. At first, the scheme implemented DCuT. The scheme then took the high-frequency coefficient and transformed it into RDWT. The watermark data was embedded into the LH sub-band of RDWT. The scheme also implemented Arnold Transform and Pseudo-random Noise (PN) sequences to scramble the watermark data. The scheme implemented multiple scaling factors between 5 and 40. In a lower scaling factor value, the scheme produced a high imperceptibility. However, the robustness was sacrificed. In contrast, the scheme achieved high robustness on a high scaling factor value while sacrificing imperceptibility. In addition, utilizing multiple transform domains has contributed to high computational complexity, reducing the watermark embedding speed. Thus, the scheme can be improved further.

Abdulrahman and Ozturk [18] presented a robust color image watermarking using DCT and DWT transformation. The DCT and DWT were applied to each of the RGB components. The scheme also used Arnold Transform to scramble the watermark data from a grayscale watermark image. Various image processing attacks are applied to the image, such as filtering, JPEG compression, resizing, and rotating. The experimental result has shown that the scheme can produce a high imperceptibility on a low scaling factor and high robustness on high scaling factors. However, the dual-domain approach has contributed to high computational costs. Hence, improvements are required.

III. Proposed Method

Eight color images from the SIPI-USC image database are utilized as the dataset for this research. University of Southern California (USC) provided this image for image processing research. Each image has a size of 512×512 pixels. Furthermore, many researchers used these images to experiment in the image watermarking field. The images are shown in Fig. 1.

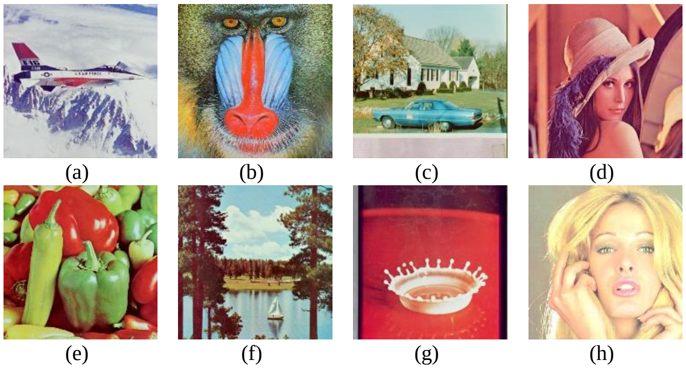

Fig. 1. The Host Images (a) Airplane (b) Baboon (c) House (d) Lena (e) Peppers (f) Sailboat (g) Splash (h) Tiffany.

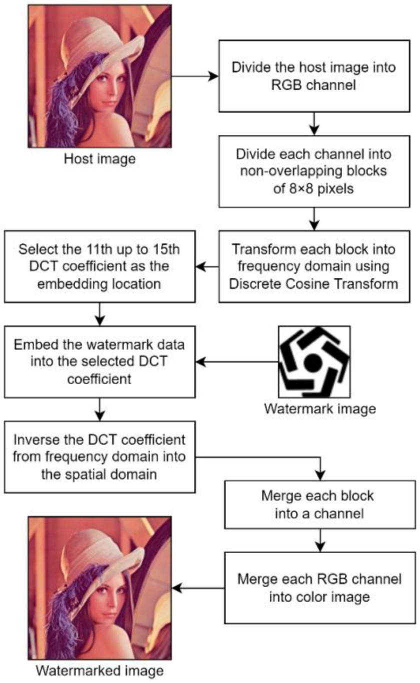
A. Watermark Embedding

The scheme embeds the watermark data into the host images. Each of the host images in Fig. 1 will undergo the watermark embedding process, as visualized in Fig. 2.



Host image
Divide the host image into RGB channel
Divide each channel into non-overlapping blocks of 8×8 pixels
Transform each block into frequency domain using Discrete Cosine Transform
Select the 11th up to 15th DCT coefficient as the embedding location
Embed the watermark data into the selected DCT coefficient
Watermark image
Inverse the DCT coefficient from frequency domain into the spatial domain
Merge each block into a channel
Merge each RGB channel into color image
Watermarked image

Fig. 2. BRIW-DCT Watermark Embedding Process.

According to Fig. 2, the embedding watermark process starts from the host image divided into RGB channels. Each channel is divided into non-overlapping image blocks with the size of 8×8 pixels. Next, each block is transformed using DCT into a frequency domain. The watermark data is then embedded into the selected DCT coefficient. The watermark itself is taken from the logo of Universitas Amikom Yogyakarta. The watermark image is stored in the binary black-and-white image with the size of 64×64 pixels. There are 64 coefficients for each block, as visualized in Fig. 3.

BRIW-DCT embeds the watermark data into the DCT coefficient, which has a low frequency between the 11th to the 15th. The purpose of the low-frequency selected DCT coefficient is to ensure the robustness of BRIW-DCT. Once the watermark data is embedded, the DCT coefficient is inverted into the spatial domain. Each block is then merged into a channel. And each channel is merged into the watermarked image. The watermark embedding process is also explained in Algorithm 1.

Algorithm 1. BRIW-DCT watermark embedding algorithm

```
Input: host, watermark
    [height, width, channel] = size(host);
    blockSize = 8;
    blockHeight = ceil(height / blockSize);
    blockWidth = ceil(width / blockSize);
    watermarked = zeros(height, width, channel, 'uint8');
    for y = 1:blockHeight
        yMax = y * blockSize;
        yMin = yMax - blockSize + 1;
        for x = 1:blockWidth
            xMax = x * blockSize;
            xMin = xMax - blockSize + 1;
            block = host(yMin:yMax, xMin:xMax, :);
            watermarked(yMin:yMax, xMin:xMax, :) =
            embedBlock(block, watermark(y, x));
        end
    end
    function output = embedBlock(input, wm)
        [~, ~, channel] = size(input);
        scale = 4;
        output = input;
        for c = 1:channel
            block = input(:, :, c);
            dct = dct2(block);
            dct(1, 5) = writeWm(dct(1, 5), scale, wm);
            dct(2, 4) = writeWm(dct(2, 4), scale, wm);
            dct(3, 3) = writeWm(dct(3, 3), scale, wm);
            dct(4, 2) = writeWm(dct(4, 2), scale, wm);
            dct(5, 1) = writeWm(dct(5, 1), scale, wm);
            idct = uint8(idct2(dct));
            output(:, :, c) = idct;
        end
    end
    function output = writeWm(input, scale, wm)
        base = (fix(input / scale) * scale);
        offset = (wm * scale / 2);
        output = base + offset;
    end
Output: watermarked
```

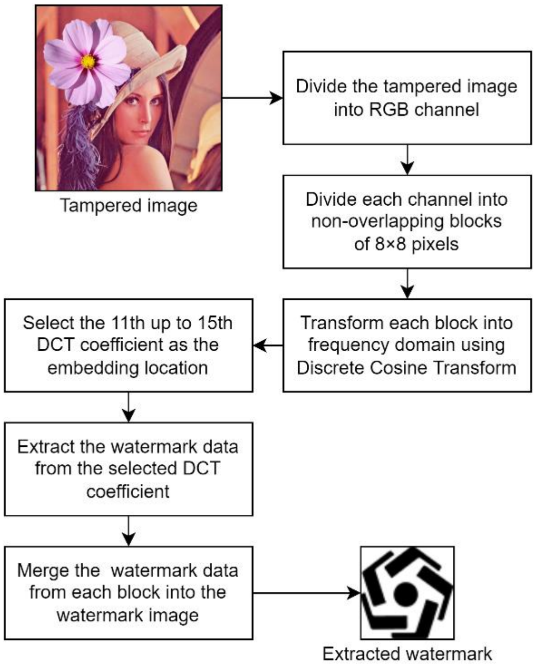
36	37	49	50	58	59	63	64

Fig. 3. Selected DCT Coefficients for Embedding.

According to Algorithm 1, the input of the algorithm is the host image and the watermark image. The output of the algorithm is the watermarked image. The watermark embedding is defined in the embedBlock() function. The DCT coefficient modification is defined in writeWm() function. The DCT transformation and inversion process are shown in Line 22 and 28, respectively. The watermark data is embedded in the five selected DCT coefficients on each RGB component for redundancy. Thus, if one watermark is broken, another watermark data can be extracted.

B. *Watermark Extraction*

Once the watermark data is successfully embedded into the host image, the watermarked image is ready to be distributed on the internet safely. If the image is misused and modified by an unauthorized user, the actual owner of the image can perform the extraction process to reveal the watermark data. The extraction process is explained in Fig. 4.



Tampered image
Divide the tampered image into RGB channel
Divide each channel into non-overlapping blocks of 8×8 pixels
Transform each block into frequency domain using Discrete Cosine Transform
Select the 11th up to 15th DCT coefficient as the embedding location
Extract the watermark data from the selected DCT coefficient
Merge the watermark data from each block into the watermark image
Extracted watermark

Fig. 4. BRIW-DCT Watermark Extraction Process.

Based on Fig. 4, the tampered image is divided into RGB channels. Each channel is then divided into non-overlapping blocks of 8×8 pixels. The tampered image is then transformed using DCT into the frequency domain. The scheme then selects the 11th up to 15th DCT coefficient of each block to extract the watermark bit. The watermark bit of each block is merged into 64×64 pixels of watermark data, producing a binary watermark image. The extraction process of the watermark image is also explained in Algorithm 2.

Algorithm 2: The watermark extraction algorithm

```
Input: tampered
1     [height, width, channel] = size(tampered);
2     blockSize = 8;
3     blockHeight = ceil(height / blockSize);
4     blockWidth = ceil(width / blockSize);
5     watermark = zeros(blockHeight, blockWidth, 'logical');
6     for y = 1:blockHeight
7      yMax = y * blockSize;
8      yMin = yMax - blockSize + 1;
9      for x = 1:blockWidth
10     xMax = x * blockSize;
11     xMin = xMax - blockSize + 1;
12     block = tampered(yMin:yMax, xMin:xMax, :);
13     watermark(yMin:yMax, xMin:xMax, :) = extractBlock(block);
14     end
15    end
16    function output = extractBlock (input)
17     [~, ~, channel] = size(input);
18     scale = 4;
19     out = zeros(channel, 1, 'logical');
20     for c = 1:channel
21     wm = zeros(1, 3, 'logical');
22     block = input(:, :, c);
23     dct = dct2(block);
24     wm(1) = readWm(dct(1, 5), scale);
25     wm(2) = readWm(dct(2, 4), scale);
26     wm(3) = readWm(dct(3, 3), scale);
27     wm(4) = readWm(dct(4, 2), scale);
28     wm(5) = readWm(dct(5, 1), scale);
29     out(c) = nnz(wm == 1) > 2;
30     end
31     output = nnz(out == 1) > 1;
32    end
33    function output = readWm (input, scale)
34     coef = mod(input, scale);
35     limit = scale / 4;
36     output = limit < coef && coef < limit * 3;
37    end
Output: watermark
```

Based on Algorithm 2, the input of the algorithm is the tampered image. The output of the algorithm is the watermark image. The watermark extraction is defined in the extractBlock() function. The selected DCT coefficient extraction process is defined in readWm() function. The DCT transformation process is shown in Line 23.

C. *Performance Evaluation*

In order to measure the imperceptibility of the watermarked image, the scheme computes the PSNR and SSIM of the watermarked image. A high PSNR and SSIM value represents an insignificant difference between the host and watermarked images. Both measurements are commonly used in the field of image watermarking. The PSNR is defined by:

$$MSE = \frac{1}{MN}\sum_{i=1}^{M}\sum_{j=1}^{N}\left(p(i,j) - q(i,j)\right)^2 \quad (1)$$

$$PSNR = 10\, log_{10}\left(\frac{255^2}{MSE}\right) \quad (2)$$

where p represents the host image, q represents the watermarked image, i and j represent the pixel coordinates. The PSNR values are represented in decibel (dB). Typically, the human visual system cannot distinguish two images with a PSNR value above 40 dB. The SSIM is defined by:

$$SSIM(i,j) = [l(i,j)]^{\alpha} \cdot [c(i,j)]^{\beta} \cdot [s(i,j)]^{\gamma} \quad (3)$$

$$l(p,q) = \frac{2\mu_p\mu_q + D_1}{\mu_p^2 + \mu_q^2 + D_1} \quad (4)$$

$$c(p,q) = \frac{2\sigma_p\sigma_q + D_2}{\sigma_p^2 + \sigma_q^2 + D_2} \quad (5)$$

$$s(p,q) = \frac{\sigma_{pq} + D_3}{\sigma_p\sigma_q + D_3} \quad (6)$$

where *l* is the luminance function to measure the closeness of the luminance of two images, *c* is the function of contrast to compute the contrast similarity of two images, *s* is the function of the structure to calculate the correlation coefficient between two images, D_1, D_2, and D_3 are constants with positive values. The SSIM utilizes the human visual system to measure the similarity between two images. Thus, it is considered more accurate compared to PSNR measurement. The robustness is measured using Bit Error Rate (BER) and Normalized Cross-Correlation (NC). The BER and NC are defined by:

$$BER = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N} w(i,j) \oplus e(i,j)}{M \times N} \quad (7)$$

$$NC = \frac{\sum_{i=1}^{M}\sum_{j=1}^{N} w(i,j).e(i,j)}{\sqrt{\sum_{i=1}^{M}\sum_{j=1}^{N} w(i,j)^2 \; \sum_{i=1}^{M}\sum_{j=1}^{N} e(i,j)^2}} \quad (8)$$

where *w* denotes the actual watermark image, *e* represents the watermark image that has been extracted from the tampered image. *M* and *N* denote the height and the width of the watermark image. A high NC value means the extracted watermark image is highly correlated to the actual watermark. While a high BER value denotes that the extracted watermark image has a higher error value than the actual watermark image, which frequently occurs when the image is under attack.

IV. Results and Analysis

The experiment in this research is evaluated using a computer with a 1.8 GHz octa-core AMD Ryzen 7 5700U processor, 32 GB memory, and a Windows 10 Home operating system. This experiment uses MATLAB 2021a as the programming language.

A. *The Performance of Imperceptibility*

In the process of watermark embedding, the watermark image is embedded in the DCT transformation domain. Thus, the watermarked image has invisible distortion when compared to the host image. The watermarked image and the host image of Lena are shown in Fig. 5.

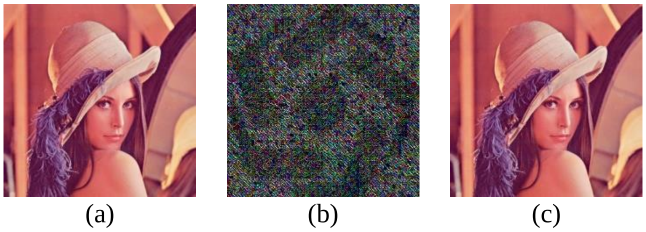


Fig. 5. The Lena Image (a) The Host Image (b) The Delta Image (c) The Watermarked Image.

According to Fig. 5, the scheme successfully embeds the watermark into the host image, as shown in Fig. 5(c). In addition, the watermark image is visually imperceptible from the watermarked image. The difference will only be visible if the delta image is brightened and sharpened into multiple levels, as shown in Fig. 4(b). Otherwise, the difference between the host and watermarked images is invisible to the human visual system. The watermarked image is evaluated using SSIM and PSNR. A higher SSIM and PSNR value means the watermarked image has less distortion compared to the actual image. On the other hand, a lower PSNR and SSIM value means the watermarked image suffers a significant error distortion compared to the host image. In addition, the computational time is also presented in this paper. It is expected to provide a complete picture of the performance of BRIW-DCT. The comparison of the imperceptibility is shown in Table I.

According to Table I, BRIW-DCT can maintain the watermarked image quality. The average watermarked image PSNR value is 50.4489 dB, while the average SSIM value is 0.9991. It proves that BRIW-DCT produces high imperceptibility in the watermark embedding process. In addition, BRIW-DCT requires less than one second to embed the watermark data. In order to show its full potential performance, this paper also compares the imperceptibility between BRIW-DCT and the existing scheme with similar watermarking techniques. Previously, Yousefi et al. [12] performed various experiments to protect the copyright of images. The scheme implemented various transform domains such as IWT, DWT, and CT. The result showed that the DWT method performed better in terms of PSNR and execution time. In terms of SSIM, the CT method has the highest imperceptibility. Another scheme by Thanki et al. [17] achieved the lowest imperceptibility in terms of PSNR value. The scheme also has the highest computational time to embed the watermark data due to implementing the dual-domain approach. However, the scheme by Thanki et al. [17] has a slightly better SSIM value than Yousefi et al. scheme [12]. The imperceptibility comparison with related work is presented in Table II.

Based on Table II, BRIW-DCT outperforms the previous method in terms of imperceptibility under PSNR and SSIM metrics. BRIW-DCT takes slightly more time to embed the watermark data. However, the execution time is highly dependent on the computer specification, which has a possibility of slight variation in the embedding speed. A computer with a higher clock rate and memory size can execute faster than the lower one. Thus, the execution time cannot be utilized as the main comparison between schemes.

TABLE I. THE IMPERCEPTIBILITY COMPARISON OF BRIW-DCT BETWEEN IMAGES

Image	PSNR (dB)	SSIM	Time (s)
Airplane	50.5074	0.9963	0.6719

Thanki et al. (DCuT & RDWT) [17]	47.6514	0.9953	1.5734
Proposed BRIW-DCT	**50.4489**	**0.9991**	0.7032

B. The Performance of Robustness

Various attack scenarios are implemented into the watermarked image to compute the robustness of BRIW-DCT. The watermark data is then extracted from the tampered image. At first, the watermarked image is tampered with using various tampering attacks. The attack scenarios are presented in Table III.

Table III shows multiple attack scenarios on the subject images to show the robustness of BRIW-DCT. The Airplane image is not modified with any tampering attack as the control. The Baboon image is modified using the Gaussian filter. The Gaussian noise is the most common attack applied to the image. The House image is modified using the salt & pepper noise. The Lena image is sharpened using the sharpen filter. The Pepper image is modified using median filtering. The sailboat image is attacked using the ripple mask. The splash image is modified using the mosaic filter. Finally, the tiffany image is modified using the unsharp filter. The tampered image quality is calculated using the PSNR and SSIM measurement against the host image. The tampered image has an average PSNR value of 36.3787 dB and an average SSIM value of 0.9771. The extracted watermark image is then compared to the actual watermark image. The extracted watermark image is shown in Fig. 6.

Based on Fig. 6, the mosaic filter in 6g dramatically affects the quality of the extracted watermark image. In contrast, the unsharp filter in 6h produces a less significant effect on the image. The Airplane image in 6a, which was used as the control image, can completely recover the watermark data, proven by the NC value of 1 and BER value of 0. Overall, the embedded watermark logo can be preserved under various tampering attacks. It proves that BRIW-DCT is robust in maintaining the watermark logo for copyright protection. The robustness comparison between images is presented in Table IV.

Table IV shows that the robustness varies between the images. It is highly affected by the type and the severity of the tampering attack. The average BER and NC values are 0.1226 and 0.7805, respectively. It proves the robustness of BRIW-DCT in the watermark extraction process. Furthermore, BRIW-DCT can extract the watermark image in under half a second, enabling it to implement in mobile devices with low computational power.

TABLE III. THE ATTACK SCENARIOS

Image	Attack	PSNR (dB)	SSIM
Airplane	No Attack	50.5074	0.9963
Baboon	Gaussian Filter	26.7028	0.9256
House	Salt & Pepper	32.5146	0.9382
Lena	Sharpen	41.1576	0.9980
Pepper	Median Filter	35.7176	0.9950
Sailboat	Ripple Mask	33.6158	0.9887
Splash	Mosaic Filter	30.7983	0.9777
Tiffany	Unsharp Filter	40.0151	0.9973
Average		36.3787	0.9771

V. Conclusion

This paper presented a blind and robust technique for color image watermarking based on DCT for copyright protection. Each image’s block has been transformed into the transform domain using the DCT. The watermark data has been embedded into the host image by modifying the 11th up to the 15th DCT coefficients. The experimental results conducted in this research have shown that the watermarked image achieved a high PSNR value of 50.4489 dB and a high SSIM value of 0.9991. Various attacks have been applied to the watermarked image to show the performance of BRIW-DCT. It shows that BRIW-DCT can achieve a high NC value of 0.7805 and a low BER value of 0.1126. In the future, BRIW-DCT can be improved by implementing the Arnold Transform to enhance the robustness against image tampering attacks.

Feedback Model when Applying the Evaluation by Indicators in the Development of Competences through Problem based Learning in a Systems Engineering Course

César Baluarte-Araya, Oscar Ramirez-Valdez
Departamento Académico de Ingeniería de Sistemas e Informática
Universidad Nacional de San Agustín de Arequipa
Arequipa, Perú

***Abstract*—Feedback can be very influential in students' learning, therefore, the university must be very clear about its procedures and rules on the time lapse of the response of the work done by them, and the comments made to positively influence in a sustained manner in the evaluation of learning. The present work shows the experience of applying the Problem Based Learning (PBL) methodology and also developing research competencies through Formative Research, and as a result of the evaluation of the learning of the Criteria and its Performance Indicators corresponding to the course Business Electronic which is taught by two teachers in theory and laboratory practices. The objective is to design a Feedback Model for the problems solved by the students in order to support the improvement of their learning. The methodology used is Problem Based Learning together with the Feedback Model, of real problems posed contemplating different contexts of the organisations; we have that from the Deliverable Report of each problem at the same time the incidences and observations are registered in the corresponding register and in this way the Feedback Report is elaborated. The results obtained reveal that the objectives of producing the Feedback Report are achieved, which should be sent as soon as possible to the students for analysis, to propose their own strategies for improving the shortcomings or errors, as well as having the motivation to continue progressing by accepting the suggestions or contributions of the teacher; as well as seeing an increase in knowledge, development of their competences, skills, attitudes, making their own judgements, and achieving the Student Results. In conclusion, the application of a well-planned active didactic strategy, the adequate evaluation of learning through the qualification of the indicators of each criterion, and the elaboration of a timely feedback report on the problems, will achieve the expected results for both the course and the student.**

Keywords*—*Problem based learning; competencies; evaluation; criteria; performance indicator; deliverable report; feedback report; skills; formative inquiry

I. Introduction

The Universidad Nacional de San Agustín de Arequipa [1], Arequipa - Peru, its Educational Model is based on professional training based on student competences, eliminating deficiencies in knowledge, soft skills and attitudes in students, and being able to use didactic strategies [2],[3],[4], adapting them to the nature of the same to achieve the training objectives and competences.

In 2021, the Professional School of Systems Engineering (EPIS) [5] underwent the evaluation process for accreditation by the Accreditation Board for Engineering and Technology (ABET) [6], one of its objectives being that the educational institution demonstrates that its graduates and those in the process of training achieve the expected student results, having good results and awaiting official certification.

The experience is developed in the subject Business Electronic (BE) which corresponds to the VIII semester of the Study Plan.

The objective is to design a feedback model of the problems solved by students in the Business Electronic course, in order to carry out an analysis of the recorded incidences, make decisions and take actions for improvement, which also allow the teacher to make decisions for continuous improvement in the teaching-learning process by solving problems by applying Problem Based Learning.

The research is descriptive, the methodology is based on the phases of the scientific method for problem solving [7], which states that the student has access to develop skills, and thus we would say greater knowledge of the problem area, procedures, attitudes and values.

As a result of working in groups and applying the PBL to the qualification of each of the problems posed, the students receive the Feedback Report of Evaluation of Deliverables together with the qualification matrix of the Criteria and their indicators involved to be analysed, discussed, reach conclusions on what to improve and determine their strategies to improve in the teaching-learning process. In addition to the statistics of the incidences derived from this.

The conclusion is that by applying PBL and evaluating the criteria and their indicators, together with a record of the incidents and the preparation of a Feedback Report for the students, which is sent to them as soon as possible, they help to correct mistakes or errors, increase their knowledge, strengthen the development of competences and soft skills, their attitudes, make their own judgements and assess the results of their work.

The article is organized in the Section II of Related Works - Context of the Experience, in Section III the Methodology is treated, in Section IV the Design of the Feedback Model is shown, in Section V the Method of Work is shown, in Section VI the Results of the work are shown, in Section VII the Discussion that is made is touched, that they worked or investigated others and of the result that is obtained, in Section VIII the conclusions of the work are shown, in Section IX the future works that can be carried out are shown.

II. Related Work – Context of the Experience

A. *Current Situation*

From 2019 we apply Formative Research adjacent to Active Didactic Strategies in the development of courses in the EPIS Given that the teaching learning process and competency based, training require feedback on the activities carried out by the students, this was done in a global way, not fulfilling the need to achieve significant and quality learning.

Thus, the evaluation of work, of each Deliverable Report, is based on the predefined criteria contemplated in the evaluation rubric, and thus a detailed, fair, real qualification, free as far as possible of subjectivities. This reflects the evolution and monitoring to be carried out on the group of students through adequate feedback. Thus, the problem is defined and will be considered in order to find a solution to the present work.

B. *Formative Research*

Formative research feeds research by training future researchers as stated by [8], that according to the professional training based on competences the student is at the centre of the process [9], with the teacher assuming the role of advisor with the rigor and demand in the development of the research.

In this sense, it is reiterated [10] that the mission of the university is to pay great attention to Formative Research, the actors directly involved are teachers and students, as it should be built throughout the process and thus deepen scientific research in the training of students for work performance in society.

There is experience in the EPIS of conducting Formative Research in courses such as Writing Articles and Research Reports (RAII), Research Methods and Writing, (MIR), Database, Business Electronic; the results are reflected in the Formative Research Report.

Applying active learning strategies; such as PBL; being participatory, whose focus is the student, generates methodological mechanisms to integrate it into the teaching-learning process [11], and develop research competences in the undergraduate whose role of Formative Inquiry is analysed by [12]. Together with the development of soft skills validated and evidenced by [13], it also contributes to developing the competences of the course.

C. *Student Competence Development*

All part of the educational model of the institution, in this case it is based on competences, which together with the Active Didactic Strategies as PBL make the competences to be developed appropriately by the students as referred by [14], we would say applied in different contexts.

Competence implies developing knowledge of an area of knowledge, skills and attitudes as referred to by [15]. If a methodology is also followed, as proposed by [16], the development of competences is demonstrated by solving problems of reality, discovering deficiencies or shortcomings, correcting weaknesses in the teaching learning process of engineering students supported by teachers. As well as valuing the achievements and learning from the experiences when carrying out research [17] by the students.

D. *Problem based Learning*

The training of students demands continuous updating so that when they graduate from the university they are able to work in different global contexts, to be part of multi- and trans disciplinary teams to solve problems of reality.

An alternative is to apply PBL, where the student is the centre of attention of the strategy [18], which in the area of engineering is used by offering interaction between teacher and student, and between students when working in groups of four to eight members. Working with PBL is based on the approach of a method such as that of [19] and [20] with steps to carry out the activities to be evaluated such as: reports, presentations, assessment of individual and team work as well as collaborative work, self-assessment, co-assessment, making judgements, critical thinking.

E. *Effective Evaluation*

If we start from the grade achieved in the resolution of a problem, task or work, this means approval, but it does not allow the student to know what his weaknesses and deficiencies are, which areas are weak in the subject treated, which concepts, methodologies, techniques, methods, the use of the appropriate tools, understanding his limitations, and what knowledge he should develop and deepen by researching in addition to what he has received in the class sessions.

In this regard [21] suggests that in order to have an effective evaluation, it must be:

- Valid; measuring what it should actually measure.
- Reliable; it must be consistent and fair.
- Transparent; that there are no tricks, traps or surprises.

The course contemplates and takes care that there is alignment between:

- Student Outcomes (SO).
- The defined contents to be covered in the course development.
- The learning activities in the theory and laboratory sessions to be carried out by the students.
- The evaluation method.
- The qualification tool that involves the general competences of the professional profile of the degree course, the course competences, the evaluation criteria

and their indicators, the qualification scales of the indicators.

F. Indicator based Evaluation of Learning

The assessment process generates information that when analysed, interpreted and then communicated generates knowledge with a value for action.

The assessment of learning should be a comprehensive and continuous process as discussed by [15] who considers basic questions such as What, How, When, Who to assess, the answers to which determine the type of assessment to be used, taking into account the context in which it takes place. This is also shared by [22] who highlights the finding of feedback as a formative act.

Thus, in the EPIS, professors apply Active Didactic Strategies that make it possible to evaluate student results in accordance with the ABET accreditation model, which works on the basis of criteria already defined for the courses of the Curricular Plan.

The Faculty of Production and Services Engineering (FIPS), to which the EPIS belongs, determined that the rubric should be used as an instrument, therefore in the present work the rubric [23, 24, 25, 26] was used to evaluate the criteria and its indicators related to student results, the achievement of increasing knowledge in the problem area, the development of competences, attitudes; for this purpose, rating scales are used according to the nature of the indicator to be rated in an objective and consistent manner.

It is through this assessment instrument that students are informed, in advance at the beginning of the course, which criteria are involved and must be fulfilled in order to reach the achievement levels of the Student Outcomes.

In the present work the BE course is taken as a case study applying the PBL in the laboratory sessions, taking as a result the evaluation of each Deliverable Report and recording and elaborating the Feedback Report addressed to the students.

G. Feedback in Learning

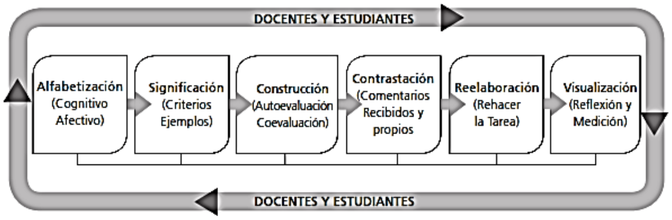
We have the contribution of [27] in the research of the literature review on feedback for learning. Thus it is considered the most salient as being:

a) Concept; citing Carless and Boud (2018) ... "deliver a definition of feedback from an understanding of a process through which learners use information to improve their work or learning strategies, this process being learner-driven in decision making to generate change (Dawson et al., 2019)".

b) Conceptual moments for Feedback.

- Feedback as a product; it is given by the teacher as the sole agent, it follows the idea of the corrective notion.
- Feedback as a dialogical act; the communication between teachers and students after the evaluation of a task based on criteria.
- Feedback as sustainable action; refers to interaction and dialogue as a support to the student in the tasks he/she performs; it is recursive in nature, it is delivered through cycles giving the opportunity to correct erroneous knowledge, leading to improvement, supported by clear criteria.

c) Feedback for Learning Model; providing feedback requires practice, through cycles in a sustainable way that allows learning beyond just completing the task. It is shown in Fig. 1.



DOCENTES Y ESTUDIANTES

Fig. 1. Feedback Model for Learning. Source: Quezada [27].

The definition of Feedback [28] is … Feedback is a process that helps to provide information about people's competencies, about what they know, what they do and how they act. Feedback allows us to describe how people think, feel and act in their environment and therefore allows us to know how it is performing and how it can be improved in the future."

In [29] citing Wiggins (2012) states characteristics that apply to the professor with respect to feedback such as:

a) Objective; the information given to the student should be related to the task being requested and conducive to learning.

b) Constructive; to consider the positive aspects, provide guidance, suggestions, how to overcome weaknesses, correct faults or mistakes.

c) Understandable; provide timely and detailed information on how to improve their learning.

d) Timely; the student receives feedback in time to improve their performance; or as we would say, to analyse and determine their strategies to improve their learning.

In educational evaluation, feedback is an essential component and is of great importance, as [30] points out that it is information that the student receives from each Deliverable Report of the BE course laboratory sessions about his or her performance. Having the following benefits it brings to providing the importance of feedback, such as:

- It clarifies the expected performance; the learning outcomes; based in our case on the analysis of the criteria and their indicators.
- It promotes dialogue between teacher and students, providing information about what has been achieved and allowing students to ask questions and thus improve their performance.
- Facilitates self-reflection; by instructing them to analyse the results of the scoring of the indicators of each criterion and thus address those where improvement is needed to achieve better results.
- Increases student motivation and self-esteem; students are motivated if through feedback they are shown the

positive aspects of their assessment and are told the level of marks they can achieve; they are also shown which points or aspects they need to improve and that they can make further progress, thus reinforcing their self-esteem.

The need arises for a procedure that provides students with a better feedback alternative in their course, compared to what is done in other courses in the curricula, and this is how the proposal of a simple and applicable feedback model arises, which has been maturing by applying the evaluation by indicators that make up a certain criterion.

III. Methodology

The methodological design is quasi-experimental, not employing a control group. The applied research is carried out to solve the problem of feedback through the Deliverable Evaluation Feedback Report. The research developed uses the feedback model generated, which involves the rubric instrument, the scoring tool for the indicators of each criterion of each defined competence of the subject.

IV. Design of the Feedback Model

The feedback model for learning should be delineated in dialogue, with the student gathering information from various sources about their performance and translating it into strategies for further improvement in their training.

The PBL uses a set of problems taken or adapted or posed by the professor, to be developed and solved by a group of students; for the course Business Electronic (BE) which is taken as a case for the present work.

Fig. 2 shows the Model developed and applied in semesters 2020 B and 2021 B in the BE course.

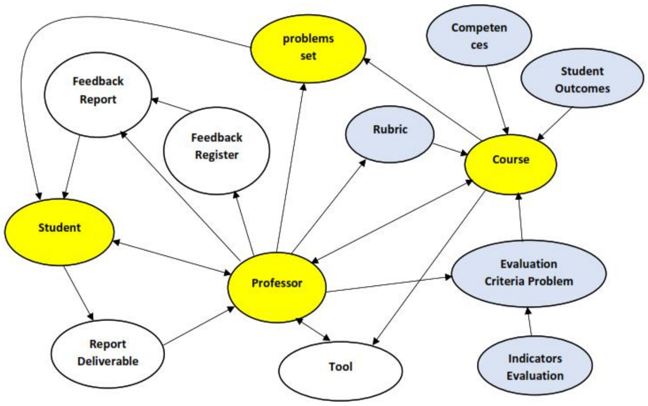

Fig. 2. Feedback Model. Source: Own Elaboration.

A. Reality of the Problem

Most of the evaluations carried out by professors teachers do not contain a documented record of the incidents, observations or suggestions made to the student or working group in the resolution of a problem that helps them to continuously improve in the development of the competences of the course involved.

B. Elements of the Model

The Feedback model includes the following elements:

1) Teacher
2) Student
3) Course
4) Competences
5) Student Outcomes to be assessed - criteria for SO
6) Evaluation Rubric - with criteria of the competences
7) Problem Evaluation Criteria
8) Evaluation Indicators of the Problem Evaluation Criteria
9) Problem Set
10) Qualification Tool
11) Deliverable Report
12) Deliverable Feedback Report Record
13) Deliverable Feedback Report.

The functions of each element of the model are detailed below:

- Professor
- Generates and updates the problem set
- Performs the grading of each Deliverable Report for each problem.
- Records the ratings in the Deliverable Feedback Report Log.
- Issues the Deliverable Feedback Report.

14) Student

- Form the working group for the academic semester.
- Work as a group to solve the proposed problems.
- Analyse, discuss the Deliverable Feedback Report, and make agreements for continuous improvement in the development of the course.

15) Course

- Contain the corresponding data and information for the development of the semester.

Involves a:

- Course competencies
- Student outcomes to be assessed - SO criteria
- Evaluation Rubric - with SO criteria
- Problem Evaluation Criteria
- Indicators of the problem's Evaluation Criteria.

16) Competences

- Contain the achievements to be attained by the students according to the general competences of the Professional Career Profile.

17) Student outcomes to be assessed - criteria of SO

- Contain the Student Outcomes expected to be achieved in the student's education in each course of the Curriculum.

*18)*Evaluation Rubric - with competency criteria

- Contain the evaluation criteria for each competency for the qualification of the Deliverable Report for each problem posed in the course.

*19)*Evaluation Criteria of the problem

- Generate the frame of reference for professors to evaluate the academic performance of students.
- Define the knowledge that students must acquire, what they have to learn to perform or create with such knowledge.
- They are those defined to be evaluated for each competence for the qualification of the Deliverable Report of each problem posed in the course.

*20)*Evaluation Indicators of the Evaluation Criteria of the problem

- Contain the indicators that are the most specific defined within a criterion and that will be evaluated from each Evaluation Criterion for the qualification of the Deliverable Report of each problem posed in the course.

*21)*Problem Set

- Contains the set of problems to be developed by the students during the semester.

*22)*Qualification Tool

Based on the Electronic Spreadsheet - EXCEL.

Involves:

- Course
- Course Competences
- Problem Evaluation Criteria
- Indicators of the Problem Evaluation Criteria.
- Indicator qualification scales.

Its responsibilities are to:

- Storing the marking data for the criteria indicators for each competency, for each proposed problem to be worked on.
- Calculate and record the continuous evaluation and examination marks for each semester evaluation period of the course.
- Calculate and record the marks for each Student Outcomes Criterion involved.

*23)*Deliverable Report

- Contain the development of the constituent parts of the Deliverable Report according to a predefined structure.

*24)*Deliverables Feedback Report Record

- Contain the observations, suggestions, contributions derived from the qualification of each indicator of each criterion of the Deliverable Report.

*25)*Deliverable Feedback Report

- Contain the observations, suggestions and inputs from the Feedback Report Register and from the qualification of the indicators of each criterion.

C. The Project

The design of the project contemplated the aspects considered in the professor's evaluation of the Deliverables Reports containing the criteria and their indicators, contemplating the application of the indicator-based evaluation system of [31]. And of the application of the system taking the results shown by [32] of the experience of evaluation based on indicators.

The developed project has the following characteristics:

- It contains problems of reality organisations or adaptations or case studies.
- The work team is made up of four or three students, taking into account the availability of time and timetables of its members, and also taking into account the other courses of study and personal interrelation, which provides very good results.
- The problems are developed during the academic semester, preparing the Deliverable Report for each one.
- Carry out the analysis of the Feedback Report and take actions for the continuous improvement of the Deliverable Reports to be elaborated in the following sessions.

D. Incidences

The table of incidences (observation) has been determined according to the evolution of the qualification of the indicators in the work done in the semesters involved, and what each teacher has found and how he/she has applied in the recording of incidences. Table I shows the incidences.

TABLE I. INCIDENCES

Codig	Description
1	Absent
2	Very incipient
3	Insufficient
4	Incomplete
5	No further explanation
6	No guard coherence
7	Stake out
8	Are not such
9	Inconsistent
10	Improve to reach excellent
11	To draft adequately

Source: Own Elaboration.

E. Follow-Up

Sessions are held to deliver the Deliverable Report during the semester, which contains the result of the problem, the presentation, the evaluation with the corresponding qualification of the indicators of each criterion, and at the same time the Feedback Report is drawn up. This is distributed to the members of the team involved so that in a joint session they can analyse the evaluation carried out by the teacher, and determine the shortcomings and weaknesses which must be corrected, taking into account the suggestions and opinions; and on this basis propose their strategies for continuous improvement in the development of the problems and therefore of the following deliverable reports.

As a principle of PBL, the teacher plays the role of a coach by providing suggestions, guidelines, pointing out shortcomings, giving guidance and comments to the students.

The qualification of the Deliverable Reports is carried out on the basis of the work done by [32] and at the same time, in parallel, the incidences of the indicators of each criterion are recorded in the Feedback Report of each group of students' work.

V. METHOD OF WORK

A. Conceptual Design

Having defined the Student Outcomes for each course of the Curriculum Plan, the teacher must propose the products, behaviours, actions or others that will be requested to the group of students in order to know the level of achievement.

The purpose is for the student to investigate, as referred to in [33] by carrying out research activities and using PBL to solve problems in order to discover more knowledge related to the problem area, reinforce other concepts, develop competences [33] soft and procedural skills, make their own judgements, and evaluate the results achieved.

The research for the development of the work is based on the stages of problem solving, of the scientific method, which associated with the active didactic strategy of PBL, the group of students develop each problem posed and elaborate the Deliverable Report following the stages of the project proposed by [32] in order for the professor to elaborate the Feedback Report.

In order to obtain the data on the students' assessment of the Feedback Model, the survey technique and its instrument, the questionnaire, are used, and then the results are systematised in order to analyse them and draw conclusions that can be used to make decisions regarding the continuous improvement of the teaching-learning process of the course.

Methodologies, Techniques and Instruments to be used

A Methodologies, Techniques and Instruments

- Problem Based Learning Methodology - PBL.
  - Problem solving, in sessions determined in the development of the course.
- Survey Technique
  - Questionnaire - Questionnaire of Assessment of the Feedback Model for the Application of Problem-Based Learning.

B Evidence

- Digital files, of the Reports of Deliverables of the laboratory work.
- Digital files, of the records of Incidents or Observations for the Deliverables Evaluation Feedback Report.
- Digital files of the Feedback Reports.
- Moodle, Virtual Classroom as a repository of the course work.

Evaluation Instruments

- Deliverable Report Qualification Tool.
- Evaluation rubrics.
  - Evaluation of Competences and Student Outcomes.

B. Participants

The BE course in the EPIS is taken as a case study, which is developed in the eighth semester (4th year), with five hours per week, three theoretical and two laboratory hours, in 17 weeks, the theory and laboratory practices were carried out by two professors. The students participated in the elaboration of the Deliverable Report, taking as a case study the semester 2020 B with 10 subgroups and a total of 35 students; the semester 2021 B with 15 subgroups and a total of 57 students.

C. Data Analysis Technique

From the registration of the incidences by the qualification of the indicators of each criterion of the developed problems, the data were systematised in the electronic spreadsheet EXCEL, visualising and analysing the results achieving frequencies, averages, tables, graphs.

D. Instruments

The following instruments are used:

- Template for the elaboration of the Feedback Report.
- Evaluation rubrics.
- Deliverable Report Qualification Tool.
- Feedback Model Valuation Questionnaire.

E. Techniques

Evaluation techniques are used:

- The rubric.
- The qualification scale.
- Survey.

F. Deliverables

It was established that the Feedback Report of the evaluation of the deliverables will be delivered to each working subgroup and stored in the repository of the virtual classroom.

The structure of the Feedback Report contains two parts:

- Feedback Report of each Deliverable Report
- Evaluation of Deliverable Report.

VI. RESULTS

The results of the Evaluation of the Deliverable Report are shown below; with a defined and used structure, based on the rubric defined for the BE course in semester 2020 B. Fig. 3 shows a sample of the course competences that are related to the general competences of the course, the criteria, the indicators of the criteria with the qualification scale determined for each one of them, and the qualification of the proposed problem of the working groups.

Then the results of the evaluation of the Deliverable Report are shown; which are reflected in the Feedback Report implemented in semester 2020 B showing the criteria and indicators with observation of the incidences found as the professor includes them always based on the defined rubric of the BE course. In Fig. 4 there is a sample, where the Feedback Report is included in the cover of the Deliverable Report for its registration and storage and its qualification resulting from applying the qualification tool of the proposed problem of the working group.

Fig. 4. Deliverable Report Including Rating Observations - Semester 2020 B. Source: Own Elaboration.

According to the analysis and conclusions reached from the development of semester 2020 B, the relevant modifications and inclusions were made to improve the grading tool, as well as the Feedback Report to make it more practical in its registration, by creating a coding of the criteria and indicators that serves for the systematisation of the same; and that serves as a better communication between the professor and the student, being clearer and more understandable, as shown in Fig. 5 and Fig. 6.

The results of the Evaluation of the Deliverable Report are shown below; with a structure determined and used, based on the defined rubric of the BE course of semester 2021 B. In Fig. 5 there is a sample, where the Competences of the course related to those of the degree course are shown, the inclusion of the Student Results to be achieved, the Criteria and the Indicators with the Qualification Scale determined for each one of them, and their qualification carried out of the problem proposed to the work groups; which at the end is reflected in the marks obtained for each student result, as well as the marks for the resolution of each problem posed.

Fig. 6 shows the results of the evaluation of the Deliverable Report; with the observations of the Incidences determined or found of the criteria and indicators involved and are reflected in the Feedback Report implemented in semester 2021 B, which in its design is more explicit and improves the communication between the professor and the students.

The Feedback Report that is sent to the members of each of the subgroups consists of the content of Fig. 6 Deliverable Report including incidents of the Feedback Report and of the Fig. 5 Evaluation of the Deliverable Report.

As a further result, Tables II and III reflect the performance results according to the level of ABET accreditation performance rating for the EPIS courses, which are at the satisfactory and outstanding level, showing that the Student Outcomes are achieved, as well as the development of the Competences and the Feedback Report plays an important role in achieving this.

VII. DISCUSSION

There are works on the application of didactic strategies such as that of [34] emphasising in his book the relevant explanations to achieve the objectives set out in each context where the teaching-learning process takes place.

The proposal of [35] is to go beyond a simple evaluation and use didactic teaching-learning strategies applied to the context of reality that contribute to student learning.

In the research, the application of PBL in the work of [32] has been achieved by having, at the moment of the qualification of the indicators of each criterion, the possibility of determining the incidences and observations to which it gives rise and registering them in the corresponding medium..

We have the results of the evaluation grades of the last four years, which show how the qualification based on indicators allow a fairer and more objective evaluation of each student's Deliverable Report, when applying PBL from 2019, which are shown in Table IV regarding the Mobile Business problem, being on average at an outstanding level according to the scale determined for the measurement of student performance (the minimum is 15) in the EPIS courses.

TABLE IV. GRADE POINT AVERAGE

Course	**Grade Point Average**			
	2018	***2019***	***2020***	***2021***
Business Electronics Theme: Mobile Business	15.17	16.15	17.4	15.10

Source: Own Elaboration.

Also [36] presents some general principles of effective feedback, and how, as he calls it, the Decalogue, helps students to improve and supports their self-esteem, which we consider a good contribution to be contemplated by the professor. Also taking into account what has been discussed by [37] regarding the principles of effective feedback.

VIII. CONCLUSION

The following conclusions have been reached:

The objectives of the Feedback Report have been achieved by reaching a better communication between the professor and the student so that they can formulate their strategies and take the relevant actions for continuous improvement.

The Student Outcomes determined for the course are achieved at an outstanding level; and students achieve through feedback a better development of their competences as well as those of the course, and thus also achieve the competences of the Professional School's syllabus.

Problem Based Learning as an active methodology and the Feedback Report allow; to increase motivation for autonomous learning, to increase knowledge on topics of the problems of the area, to apply the knowledge achieved, motivation for teamwork, to complement the development of soft and procedural skills, progressively improving their academic performance.

Through the evaluation of the Deliverable Report, students obtain an evaluation according to the qualification of each indicator in the criteria involved in each problem, which is more objective, fair, real and with less subjectivity on the part of the qualifier; students recognising that the feedback provided in the Feedback Report helps them to improve and perform better in teamwork.

Providing students with feedback in the Deliverable Reports on the reviews, qualifications and observations made by the professor, allows them to continuously improve in the work group.

IX. FUTURE WORK

To carry out comparative research on the application of PBL and others such as PrBL (Project Based Learning) in the courses of the Curriculum Plan using the evaluation by indicators and its Feedback Report.

The systematisation of the criteria and their indicators as well as the result of the work of [32] will allow the subsequent development of an evaluation and feedback system.

ACKNOWLEDGMENT

Our thanks to the Universidad Nacional de San Agustín de Arequipa for allowing and supporting the development of Formative Research and the application of the proposals for continuous improvement based on Active Didactic Strategies with the favourable results being of benefit to the students and the teaching-learning process.

Department of IT Education, Universitas Pendidikan Ganesha, Singaraja, Bali, Indonesia[1, 3]
Department of Electrical Education, Universitas Pendidikan Ganesha, Singaraja, Bali, Indonesia[2]

***Abstract*—This research had the main objective to provide information related to the innovation available in the form of an educational evaluation model that integrates the Discrepancy evaluation component, Tat Twam Asi concept, and TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) method in the framework of determining the dominant indicators triggering the effectiveness of implementing blended learning in IT vocational schools. The approach of this research was development research by an R & D development model that focused on four stages, including a) research and field data collection, b) planning, c) design development, d) initial trial, and e) revisions to the results of the initial trial. There were 34 subjects involved in the trial design of the evaluation model in this research, including two education experts, two informatics experts, and 30 IT vocational teachers in Bali. The instruments used in data collection were in the form of questionnaires, interview guidelines, and photo documentation. The analysis technique for the data that had been collected used quantitative descriptive techniques that referred to percentage descriptive calculations. The results of this research were Tat Twam Asi-based Discrepancy evaluation model design which was integrated with TOPSIS calculations and had been classified as excellent according to the eleven-scale categorization table.**

Keywords—Discrepancy; evaluation model; tat twam asi; TOPSIS

I. Introduction

Nowadays blended learning has become a vital requirement in the learning process at IT vocational schools because of the demands for flexibility, convenience, speed, and transparency in the educational field as a result of the appearance of industrial revolution 4.0. The fact shows that the blended learning implementation in some IT vocational schools was not optimal. It is following the statement of Mozelius and Rydell [1], who stated that “there were still many cases that show that blended learning has not been implemented well in the learning process”. Even though evaluation activities were often carried out in the blended learning implementation, the recommendations given were not yet precise regarding the target, especially in determining the dominant indicators that trigger the level of blended learning effectiveness. Several evaluation models have been used by educational evaluators to evaluate the blended learning implementation, including CSE-UCLA [2], CIPP [3], and Formative-Summative [4]. However, among those models, an exact model has not yet been found in determining the dominant indicators that trigger the effectiveness of blended learning based on the weighting equation given by evaluators to the defining, installation, process, and product components. One innovation to overcome those problems was to use the Tat Twam Asi-based Discrepancy evaluation model with an accurate and systematic calculation process using the TOPSIS method so that a dominant indicator can be determined as a trigger for the blended learning effectiveness. The discrepancy model can show the evaluation components, including definition, installation, process, and product. The concept of Tat Twam Asi (a local wisdom concept in Bali that means I am you) adheres to the philosophy of equality which can be used in determining the weighting equation given by evaluators. The TOPSIS method can be used to determine dominant indicators based on the highest preference value of each evaluation indicator. From the innovation findings in overcoming those problems, the research problem was “How was the design of Tat Twam Asi based Discrepancy evaluation model by TOPSIS calculation in determining the dominant indicators triggering the effectiveness of blended learning implementation in vocational high school (case study in Bali province)?”

This research was motivated by the results of the following studies, including (1) research in 2017 conducted by Embi et al. [5] showed that there was a deep assessment using the Kirkpatrick model in evaluating the implementation of multimedia-based blended learning. Limitation of the Embi et al.’s research has not yet shown in detail the assessment indicators that were the priority determinant of the multimedia-based blended learning effectiveness; (2) research conducted in 2018 by Istanbul and Supriadi [6] showed the use of the CIPP model to evaluate the blended learning implementation that supports the learning process at Widyatama University. The limitation shown in Istanbul and Supriadi’s research was that priority indicators have not been shown to trigger the successful implementation of blended learning in the learning process; (3) research conducted in 2019 by Agustina and Mukhtaruddin [7] basically showed four evaluation components that were the same as the evaluation components used in this research, including defining (same with Context component), installation (same with Input component), process (same with Process component), and product (same with Product component). The four components serve as the basis for evaluating the blended learning implementation that was used to support the integrated English learning process. The limitation of Agustina and Mukhtaruddin’s research was that they have not been able to show the most dominant indicators as triggers for the effectiveness of blended learning implementation; (4) research conducted in 2019 by Ngala et al. [8] showed the use of the CIPP model to evaluate the implementation of distance education based on e-learning and

*Corresponding Author

blended learning. The limitation of Ngala et al.'s research was not yet showing the evaluation standards in detail and had not been able to show the dominant indicators that trigger the successful implementation of distance education; (5) research conducted in 2019 by Siswadi et al. [9] showed the limitations of the CIPP model, especially on aspects in the context component and the input component used in evaluating national standards of nursing education. Besides, in research of Siswadi et al. also has not shown any aspects or indicators that trigger the effectiveness of learning in nursing education; (6) research conducted in 2020 by Sugianto [10] showed the utilization of the discrepancy model used to evaluate individual learning programs at junior high school level. The findings obtained in Sugianto's research were two aspects of individual learning programs that were unsuitable to program standards. Those aspects include: (a) aspects of the preparation and organization, and (b) aspects of the implementation and assessment. Besides, the limitations found in Sugianto's research was that it had not shown a dominant indicator that was the main cause of the success of the program implementation. Based on the problems that occur in the field, the innovations that were initiated, as well as the results and limitations of some previous studies, it was necessary to conduct more in-depth research related to the development of a Discrepancy model based on Tat Twam Asi combined with TOPSIS calculations to get a dominant indicator triggering the effectiveness of the blended learning implementation (case studies at several IT vocational schools in Bali Province).

II. Basic Theory

A. Discrepancy Evaluation Model

The discrepancy is an evaluation model that is used to determine the comparison between actual performance that occurs and standards that have been previously set in the evaluation [11]. The discrepancy is an evaluation model that consists of four evaluation components, including definition, installation, process, and product [12]. Based on those several definitions of discrepancy, a general conclusion is that discrepancy is one of the evaluation models comparing work results with existing standards to obtain the level of discrepancy using four stages/components of evaluation, including definition, installation, process, and product.

B. Tat Twam Asi

According to Evitasari and Wiranti, "Tat Twam Asi" is one of the Balinese local wisdom that teaches equality in the behavior of every human being in establishing a relationship to create harmony [13]. According to Perbowosari, the term "Tat Twam Asi" means I am you. This contains the concept of togetherness. Four elements need to be built to maintain togetherness, including 1) having the same vision, 2) not being selfish, 3) being willing to sacrifice, and 4) being humble [14,15]. Based on some of those statements, the general conclusion is that Tat Twam Asi is a concept that was born from the philosophy of local Balinese wisdom which shows equality, and alignment in authority so that later it can lead to harmony and effectiveness in living life.

C. TOPSIS

TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) is one of the multi-criteria of the decision-making methods, the principle of which works to find alternative choices by taking into account the closest distance from the positive ideal solution and the farthest from the negative ideal solution to determine the relative closeness between the optimal solutions with an alternative [16]. The steps to search for alternative options using TOPSIS can be described as follows [17]:

1) Make a normalized decision matrix.

2) Make a normalized weighted decision matrix.

3) Determine the matrix for the positive ideal solution and the matrix for the negative ideal solution.

4) Determine the distance between the values of each alternative and the matrix for positive ideal solutions and the matrix for negative ideal solutions.

5) Determine the preference value for each alternative.

TOPSIS requires a performance rating of each Ai alternative on each normalized Cj criteria, by the following formula [18].

$$r_{ij} = \frac{x_{ij}}{\sqrt{\sum_{i=1}^{m} x_{ij}^2}} \quad (1)$$

The positive ideal solution of A^+ and the negative ideal solution of A^- can be determined based on the normalized weight rating (y_{ij}), by the following formula [19].

$$y_{ij} = w_i r_{ij} \quad (2)$$

$$A^+ = \left(y_1^+, y_2^+, \cdots, y_n^+\right) \quad (3)$$

$$A^- = \left(y_1^-, y_2^-, \cdots, y_n^-\right) \quad (4)$$

Which:

$$y_j^+ = \begin{cases} \max_i y_{ij}; & \text{If j is the profit attribute} \\ \min_i y_{ij}; & \text{If j is a cost attribute} \end{cases}$$

$$y_j^- = \begin{cases} \min_i y_{ij}; & \text{If j is the profit attribute} \\ \max_i y_{ij}; & \text{If j is a cost attribute} \end{cases}$$

The distance between the A_i alternatives and the positive ideal solution is formulated as follows [20].

$$D_i^+ = \sqrt{\sum_{j=1}^{n} \left(y_i^+ - y_{ij}\right)^2} \quad (5)$$

The distance between the alternative A_i with a negative ideal solution is formulated as follows [21].

$$D_i^- = \sqrt{\sum_{j=1}^{n}\left(y_{ij} - y_i^-\right)^2} \tag{6}$$

The preference value for each alternative (V_i) is formulated as follows [22].

$$V_i = \frac{D_i^-}{D_i^- + D_i^+} \tag{7}$$

A greater value of V_i indicates that alternative A_i is preferred.

D. Blended Learning

Blended learning is a learning model that combines conventional learning that is carried out in the classroom and learning based on internet technology or other digital media, so that the learning process can be done quickly, easily, flexibly, and interaction between teachers and students through discussion in class and online outside the classroom [23]. Blended learning presents flexibility in place, time, and media used in the learning process without ignoring the elements of interaction that occur between teachers and students because the learning process can be done in the classroom or outside the classroom assisted by information technology [24,25]. Based on those statements, blended learning is a learning model that combines face-to-face learning directly in the room and outdoor learning assisted by information technology.

E. Discrepancy Evaluation Model based on Tat Twam Asi using TOPSIS Calculation

This model is a new breakthrough in developing the Discrepancy evaluation model that combines the concept of Tat Twam Asi with the TOPSIS method, making it easier to determine the dominant indicators that trigger the effectiveness of blended learning. The four components of discrepancy evaluation are given equal weight from evaluators based on the Tat Twam Asi concept reference then the weighting results are used in the TOPSIS calculation to obtain the preference value of each evaluation indicator so that later indicators can be obtained dominantly triggers the effectiveness of blended learning accurately.

III. Method

A. Research Approach

This research used a development approach by the Research and Development method. The research development model was Borg and Gall which consists of 10 stages of development [26-28], including: (1) research & field data collection; (2) planning; (3) design development; (4) initial trials; (5) revisions to the results of the initial trial; (6) field trial; (7) revision of the results of field trial; (8) usage trial; (9) final product revisions; (10) dissemination and implementation of the final product. Specifically, this paper focused on several stages undertaken to create a Tat Twam Asi-based Discrepancy evaluation model with TOPSIS calculations, including: (1) research & field data collection; (2) planning; (3) design development; (4) initial trial; and (5) revisions to initial trial results.

B. Research Subjects

The subjects involved in this research were two educational experts, two informatics experts, and 30 teachers, who would later be involved in conducting the initial trial. The education experts involved have a specific scientific field that was educational evaluation, while the informatics experts involved have a specific scientific field namely IT education.

C. Research Object

The object of research is the main topic that must be studied and solved. The object of this research was the design of a Discrepancy evaluation model based on Tat Twam Asi with TOPSIS calculation.

D. Research Location

The implementation of this research was located at IT vocational schools spread across six regencies in Bali. The six regencies include: Gianyar, Buleleng, Tabanan, Badung, Klungkung, and Denpasar.

E. Data Collection Instruments

Instruments used for collecting data in this research were in the form of questionnaires, photo documentation, and interview guidelines. The questionnaires were used to obtain primary data in the form of quantitative data from respondents as a basis for making decisions about the effectiveness percentage of the blended learning implementation. Interview guidelines were used to obtain secondary data as a basis for strengthening arguments qualitatively in supporting research findings. Photo documentation was used as proof that this research was indeed carried out and also used as valid evidence that showed the source of primary and secondary data obtained in this research.

F. Data Analysis Techniques

The technique used to analyze the data that had been collected was a quantitative descriptive technique through percentage descriptive calculation. The percentage descriptive calculation results were used as a basis for interpreting the research results on the Tat Twam Asi-based Discrepancy evaluation model. The percentage descriptive calculation is formulated as follows [29-35].

$$\text{Percentage } = \frac{\sum \text{(Answer} \times \text{Weight of Each Choice)}}{\text{n} \times \text{Highest Weight}} \times 100\% \tag{8}$$

Notes:

$\sum$ = Total; n = Number of all questionnaire items.

The percentage results were obtained from that formula and then converted into the eleven’s scale categorization. That categorization can be seen in Table I [36,37].

TABLE I. ELEVEN'S SCALE CATEGORIZATION

Effectiveness Percentage (%)	Category	Follow-up
95 to 100	Excellent	No needs revision
85 to 94	Very good	No needs revision
75 to 84	Good	No needs revision
65 to 74	More than enough	No needs revision
55 to 64	Enough	Revision
45 to 54	Almost enough	Revision
35 to 44	Minus	Revision
25 to 34	Very minus	Revision
15 to 24	Poor	Revision
5 to 14	Very poor	Revision
0 to 4	Highly poor	Revision

IV. RESULTS AND DISCUSSION

At the research stage and field data collection, several results were obtained, including aspects of evaluation standards, evaluation results in the field, and the weight of decision-makers. The full aspects related to standard evaluation can be seen in Table II, the evaluation results in the field can be seen in Table III, and the weight of decision-makers can be seen in Table IV.

Based on the data shown in Table III, there appears to be an imbalance that occurs between the percentage of effectiveness in field evaluation with the established effectiveness standards. Positive inequality occurs if the percentage of effectiveness in the field was higher than the percentage of effectiveness standards. Otherwise, if the percentage of effectiveness in the field was lower than percentage of effectiveness standards then negative inequality occurs. From Table III, several indicators were classified as negative inequality, including: indicators 11, 12, 13, 16, 18, 21, 22, 23, and 27. Indicators classified as positive inequality, including: indicators 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 15, 17, 19, 20, 24, 25, 26, 28, 29, 30, and 31.

TABLE II. THE EVALUATION STANDARD ASPECTS OF THE BLENDED LEARNING IMPLEMENTATION IN SEVERAL VOCATIONAL SCHOOLS IN BALI PROVINCE WHICH REFERRED TO THE DISCREPANCY MODEL

Evaluation Components	Aspects/Criteria of Evaluation		Indicators		Percentage of Effectiveness Standards
Definition	C1	The legality of conducting blended learning	I-1	Education service regulation regarding the needs of blended learning	88
			I-2	Principals' regulation regarding the implementation of blended learning	90
	C2	Academics support	I-3	Principals' agreement	88
			I-4	Developer team support	90
			I-5	Teacher enthusiasm	85
			I-6	Students enthusiasm	85
	C3	Community support	I-7	Support from board of trustees / school committees	87
			I-8	Support from students' parents	87
Installation	C4	Management team readiness	I-9	Suitability of academic qualifications and scientific fields of the management team	88
			I-10	Management team competence	88
	C5	Facility and infrastructure readiness	I-11	Availability of hardware with adequate specifications	88
			I-12	Availability of software / platforms that suit on the needs	88
			I-13	Adequate internet access availability	90
			I-14	Availability of supporting physical infrastructure (such as tables, chairs, air conditioners, LCD projectors, etc.) that are still suitable for use	87
	C6	User competency readiness	I-15	The ability of teachers in operating computers and accessing the internet	86

			I-16	The ability of teachers to prepare digital teaching materials to support blended learning	86
			I-17	Students' expertise in operating computers and accessing the internet	86
Processes	C7	The socialization of the procedures for using blended learning	I-18	There was a socialization to teachers about the procedures for making digital teaching materials	87
			I-19	There was a socialization of the use of blended learning to teachers and students	87
	C8	Implementation of learning using blended learning	I-20	The implementation time of learning is in accordance with the time agreed upon by students and teachers	88
			I-21	The quality of material transferred by the teacher through blended learning can be easily understood by students	88
Product	The effectiveness of implementing blended learning from several dimensions:				
	C9	Tangibles	I-22	The condition of the classroom/ lab that is used in the organization of blended learning	88
			I-23	The condition of digital teaching materials that is used in the learning process based on blended learning	88
	C10	Reliability	I-24	Speed in accessing a blended learning platform	88
			I-25	Ease of operating a blended learning platform	88
	C11	Responsiveness	I-26	Platform speed in responding to the process of data manipulation (input, edit, and delete digital teaching materials) into blended learning	87
			I-27	The speed of response given by the teacher when discussing with students through blended learning	86
	C12	Assurance	I-28	Security guarantees questions/tests which are provided by teachers in blended learning	90
			I-29	The security guarantee of each task deposited by students into blended learning	90
	C13	Empathy	I-30	The availability of facilities for giving advice/ complaints from students to the learning process through blended learning	90
			I-31	The availability of feedback facilities from teachers on existing suggestions/ complaints related to the learning process through blended learning	90

Average		**87.230**	

The data in Table IV shows the weighted value given by experts for each evaluation criteria. The weight value given to each evaluation criteria refers to the Tat Twam Asi concept. Tat Twam Asi was a concept that prioritizes equality/similarity of authority for each expert in providing a weighting assessment of each evaluation criteria. Therefore an average weight score calculation was performed to achieve the same authority of each expert. The weighted average results were then divided by the total number of weighted average, so we got a weight value that refers to Tat Twam Asi for each evaluation criteria. There were 14 evaluation criteria that were given weight referring to Tat Twam Asi.

TABLE IV. THE WEIGHTS GIVEN BY THE DECISION-MAKERS TO EACH EVALUATION CRITERIA REFERS TO THE TAT TWAM ASI CONCEPT

C14	2	3	3	2	2.50	0.042
∑					59.50	1.000

Notes:
• C1 to C13 were evaluation criteria as mentioned earlier in Table III.
• C14 was specifically an *Discrepancy* criteria.

At the planning stage, activities and time were regulated, as well as personnel involved in developing the evaluation model design. The details of activities and time needed in developing the design of a Tat Twam Asi-based Discrepancy evaluation model with a TOPSIS calculation can be seen in Table V. Personnel arrangements can be seen in Table VI.

At the design development stage, was made conceptual design and user interface design of the evaluation model. The design of the Discrepancy evaluation model based on Tat Twan Asi with TOPSIS calculation in finding dominant indicators that determine the success of blended learning implementation can be seen in Fig. 1 and user interface design in Fig. 2.

Fig. 1 shows the Discrepancy evaluation model consists of four evaluation components, including definition, installation, process, and product. From each of the evaluation components, there were several indicators used to measure the effectiveness of the blended learning implementation at the IT vocational schools. In Fig. 1, the evaluation indicators were displayed in the form of an indicator code. For more details about the description of each indicator's code can be seen in Table II. The results of the effectiveness percentage obtained in the field were then compared with the percentage of effectiveness standards. The inequality that occurs due to the process of comparing the effectiveness percentage, then it was used as one of the evaluation criteria from a total of 14 existing evaluation criteria. Those fourteen criteria were then given a weight value obtained from the weighting process of experts referring to the Tat Twam Asi concept. Based on the weight value given by the experts to each evaluation criteria, then the calculation process can be performed using the TOPSIS formula to determine the most dominant indicators as triggers for the success or effectiveness of blended learning implementation.

Fig. 2. User Interface Design of Discrepancy Evaluation Model based on Tat Twam Asi with TOPSIS Calculation in Finding Dominant Indicators that determine the Success of Blended Learning Implementation (Indonesian Version).

In the initial testing phase toward the accuracy of the use of the TOPSIS method in the evaluation model design, a simulation calculation of the TOPSIS formula was performed to determine the dominant indicator. There were two education experts, two informatics experts, and 30 teachers involved in the TOPSIS calculation simulation process. The data which was used in the complete TOPSIS calculation simulation can be seen in Table VII.

From the data shown in Table VII, it can be explained that the scores given by the black block in columns C1 to C13 were obtained from the percentage value of effectiveness in field evaluation for each evaluation indicator (as shown in Table III). Unblocked scores were obtained from the average value of the percentage of effectiveness in field evaluation (as shown in Table III). The score entered in column C14 (indicated by a gray block) was obtained from the inequality score also shown in Table III.

Based on the data shown in Table VII, the TOPSIS calculation process was then performed by following the steps as follows:

1) Determine the normalized matrix using the formula shown earlier in equation (1)

$$|x_1| = \sqrt{91.765^2 + 92.353^2 + 29(87.230)^2} = 487.454$$

$$r_{11} = \frac{x_{11}}{|x_1|} = \frac{91.765}{487.454} = 0.1883$$

$$r_{21} = \frac{x_{21}}{|x_1|} = \frac{92.353}{487.454} = 0.1895$$

$$r_{31} = \frac{x_{31}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{41} = \frac{x_{41}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{51} = \frac{x_{51}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{61} = \frac{x_{61}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{71} = \frac{x_{71}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{81} = \frac{x_{81}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{91} = \frac{x_{91}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{101} = \frac{x_{101}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{111} = \frac{x_{111}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{121} = \frac{x_{121}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{131} = \frac{x_{131}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{141} = \frac{x_{141}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{151} = \frac{x_{151}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{161} = \frac{x_{161}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

$$r_{171} = \frac{x_{171}}{|x_1|} = \frac{87.230}{487.454} = 0.1789$$

Fig. 3. R Matrix.

3) Determine the Y matrix: After the R matrix was obtained, then calculation was performed to determine the Y matrix. The Y matrix was the weighted normalized matrix. The way to get the Y matrix was to do a multiplication of the R matrix with expert weights referring to the Tat Twam Asi concept shown in Table IV. In general, the matrix multiplication to determine the Y matrix can be written as follows.

$$Y = [R] \times [0.080\ \ 0.071\ \ 0.071\ \ 0.080\ \ 0.071\ \ 0.071\ \ 0.076\ \ 0.063\ \ 0.076\ \ 0.076\ \ 0.076\ \ 0.080\ \ 0.042]$$

The complete results of the calculation of determining the Y matrix can be seen in Fig. 4.

$$Y = \begin{bmatrix}

Fig. 4. Y Matrix.

4) Determine the matrix for positive ideal solutions and the matrix for negative ideal solutions.

The matrix for positive and negative ideal solutions was strongly influenced by the classification of each evaluation criteria. The fourteen evaluation criteria in this research were classified as profit attributes. Based on those, it can be calculated the matrix for positive ideal solutions and the matrix for negative ideal solutions as follows.

a) The Matrix for Positive Ideal Solutions

y_1^+= max{0.01506; 0.01516; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431} = 0.01506

↓ same calculation up to y_{14}^+

y_{14}^+=max{0.00797; 0.00498; 0.00672; 0.00124; 0.00062; 0.00187; 0.00386; 0.00511; 0.00050; 0.00174; -0.01569; -0.00573; -0.00872; 0.00137; 0.00100; -0.01146; 0.00224; -0.02478; 0.00013; 0.00050; -0.01445; -0.00324; -0.01196; 0.00050; 0.00174; 0.00262; -0.00399; 0.00374; 0.00249; 0.00498; 0.00623} = 0.00797

A^+ = {0.01516; 0.01331; 0.01305; 0.01462; 0.01286; 0.01279; 0.01281; 0.01381; 0.01134; 0.01297; 0.01382; 0.01431; 0.01525; 0.00797}

b) The Matrix for Negative Ideal Solutions

y_1^- = min{0.01506; 0.01516; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431; 0.01431} = 0.01431

y_2^- = min{0.01273; 0.01273; 0.01331; 0.01322; 0.01245; 0.01254; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273; 0.01273} = 0.01245

↓ same calculation up to y_{14}^-

y_{14}^- =min{0.00797; 0.00498; 0.00672; 0.00124; 0.00062; 0.00187; 0.00386; 0.00511; 0.00050; 0.00174; -0.01569; -0.00573; -0.00872; 0.00137; 0.00100; -0.01146; 0.00224; -0.02478; 0.00013; 0.00050; -0.01445; -0.00324; -0.01196; 0.00050; 0.00174; 0.00262; -0.00399; 0.00374; 0.00249; 0.00498; 0.00623} = -0.02478

5) Determine the distance between the scores of each indicator with the matrix for a positive ideal solution and a negative ideal solution.

a) The distance between the scores of each indicator and the matrix for a positive ideal solution.

$$D_1^+ = \sqrt{(0.01506-0.01516)^2+(0.01273-0.01331)^2+(0.01274-0.01305)^2+(0.01435-0.01462)^2+} \ldots$$

$$\sqrt{..+(0.01279-0.01286)^2+(0.01279-0.01279)^2+(0.01281-0.01281)^2+(0.01365-0.01381)^2+\ \ldots}$$

$$\sqrt{..+(0.01134-0.01134)^2+(0.01274-0.01297)^2+(0.01366-0.01382)^2+(0.01360-0.01431)^2+} \ldots$$

$$\sqrt{..+(0.01431-0.01525)^2+(0.00797-0.00797)^2}$$

$= 0.00141$

↓ same calculation up to D_{31}^+

$$D_{31}^+ = \sqrt{(0.01431-0.01516)^2+(0.01273-0.01331)^2+(0.01274-0.01305)^2+(0.01435-0.01462)^2+} \ldots$$

$$\sqrt{..+(0.01279-0.01286)^2+(0.01279-0.01279)^2+(0.01281-0.01281)^2+(0.01365-0.01381)^2+\ \ldots}$$

$$\sqrt{..+(0.01134-0.01134)^2+(0.01274-0.01297)^2+(0.01366-0.01382)^2+(0.01360-0.01431)^2+} \ldots$$

$$\sqrt{..+(0.01525-0.01525)^2+(0.00623-0.00797)^2}$$

$= 0.00221$

b) The distance between the scores of each indicator and the matrix for negative ideal solutions

$$D_1^- = \sqrt{(0.01506-0.01431)^2+(0.01273-0.01245)^2+(0.01274-0.01274)^2+(0.01435-0.01435)^2+} \ldots$$

$$\sqrt{..+(0.01279-0.01182)^2+(0.01279-0.01181)^2+(0.01281-0.01105)^2+(0.01365-0.01348)^2+\ \ldots}$$

$$\sqrt{..+(0.01134-0.01070)^2+(0.01274-0.01274)^2+(0.01366-0.01317)^2+(0.01360-0.01360)^2+} \ldots$$

$$\sqrt{..+(0.01431-0.01431)^2+(0.00797-(-0.02478))^2}$$

= 0.03285

↓ same calculation up to D_{31}^-

$$D_{31}^- = \sqrt{(0.01431-0.01431)^2+(0.01273-0.01245)^2+(0.01274-0.01274)^2+(0.01435-0.01435)^2+\ldots}$$
$$\sqrt{..+(0.01279-0.01182)^2+(0.01279-0.01181)^2+(0.01281-0.01105)^2+(0.01365-0.01348)^2+\ \ldots}$$
$$\sqrt{..+(0.01134-0.01070)^2+(0.01274-0.01274)^2+(0.01366-0.01317)^2+(0.01360-0.01360)^2+\ldots}$$
$$\sqrt{..+(0.01525-0.01431)^2+(0.00623-(-0.02478))^2}$$
$$= 0.03112$$

6) Determine the preference score for each indicator.

$$V_1 = \frac{D_1^-}{D_1^- + D_1^+}$$
$$= \frac{0.03285}{0.03285+0.00141}$$
$$= 0.95880$$

↓ same calculation up to V_{31}

$$V_{31} = \frac{D_{31}^-}{D_{31}^- + D_{31}^+}$$
$$= \frac{0.03112}{0.03112+0.00221}$$
$$= 0.93381$$

7) Make decisions based on preference scores: Based on the results of the preference score, the most dominant indicator as a trigger for the success of blended learning implementation at IT vocational schools was V1, namely, I1 (the education service regulation regarding the need for blended learning).

At the revision stage of the initial trial results, there was nothing that needs to be revised in major related to the TOPSIS calculation process used in the design of the evaluation model. In addition, based on the results of the field evaluation shown in Table III, the effectiveness percentage was 87.230%. If that effectiveness percentage was matched with eleven's scale categorization (as shown in Table I) shows that the evaluation model design was included in the excellent category. So, In general, there was nothing that needs to revise in the evaluation model design. Therefore it can be concluded in general that the evaluation model design has been made optimally and the calculation simulation of the TOPSIS formula has been able to show an accurate calculation in determining the most dominant indicator as a trigger for the success of blended learning implementation at IT vocational schools.

Ma and Lee's research has similarities with this study in evaluating the effectiveness of blended learning implementation. However, the difference is in the uses of the evaluation model. Ma and Lee's research [38] used the ARCS (Attention, Relevance, Confidence, and Satisfaction) model, while this study in principle used the Discrepancy model. The limitation of Ma and Lee's research was it had not shown an accurate calculation process in determining the trigger indicators for the effectiveness of the blended learning implementation. Martín-Martínez et al.'s research have similarities with this study related to the object being evaluated, the difference is the evaluation mechanism. This study used a combination of the Discrepancy model, the TOPSIS method, and the Tat Twam Asi concept to determine the trigger indicators for the effectiveness of the blended learning implementation. The research of Martín-Martínez et al. [39] used a matrix of rotated factors to determine the level of effectiveness of the blended learning implementation. Sukirman et al.'s research have similarities with this study related to measuring the effectiveness of the blended learning implementation. The difference is the research approach. This study used an evaluative approach, while Sukirman et al.'s research [40] used an experimental study approach.

In general, this research has been able to give contributions to answering some of the limitations previously found in Embi et al.'s research, Istanbul and Supriadi's research, Agustina and Mukhtaruddin's research, Ngala et al.'s research, Siswadi et al.'s research, and Sugianto's research, through showing the dominant indicators that were the main cause of the successful implementation of the program (in this case blended learning at IT vocational schools in Bali Province) using the Discrepancy evaluation model based on Tat Twam Asi with TOPSIS calculation. Although this research was felt to solve the limitations of some previous studies, this research was also not perfect. There were several things found as limitations in this research, including 1) the indicators related to the readiness of funds in realizing blended learning have not been discussed in detail and 2) indicators related to the governance of the use of funds incurred in the blended learning administration have not been discussed in detail

V. Conclusion

The design of the Discrepancy evaluation model based on Tat Twam Asi with the TOPSIS calculation developed through this research was able to show the stages of structured evaluation and through an accurate calculation process in determining the dominant indicators that trigger the effectiveness/success of blended learning implementation in IT vocational schools in Bali Province. The evaluation stages used in this model were based on the Discrepancy model which has four evaluation components, including definition, installation, process, and product. The calculation process to determine the dominant indicators in this evaluation model uses the TOPSIS formula with the average weight given by experts for each criteria referring to the Tat Twam Asi concept that prioritizes equality of rights/authority. Future work that can be done to overcome the limitations found in this research is to include indicators of the readiness of funds in the installation component and include indicators of funding governance in the process components contained in the evaluation model.

Acknowledgment

The authors would like thank to the Directorate General of Research and Development, Ministry of Education, Culture, Research and Technology of the Republic of Indonesia which provided funding for this research through research grant number: 1219/UN48.16/LT/2022. The authors also would like to thank for Rector and Chair of the Research and Community Service Institute of Universitas Pendidikan Ganesha who provided the opportunity, guidance, and support to complete this research on time.

***Abstract*—The industry is subject to strong competition, and customer requirements which are increasingly strong in terms of quality, cost, and deadlines. Consequently, the companies must improve their competitiveness. Scheduling is an essential tool for improving business performance. The production scheduling problem is usually an NP-hard problem, its resolution requires optimization methods dedicated to its degree of difficulty. This paper aims to develop multi-hybridization of swarm intelligence techniques to solve job shop scheduling problems. The performance of recommended techniques is evaluated by applying them to all well-known benchmark instances and comparing their results with the results of other techniques obtainable in the literature. The experiment results are concordant with other studies that have shown that the multi hybridization of swarm intelligence techniques improve the effectiveness of the method and they show how these recommended techniques affect the resolution of the job shop scheduling problem.**

Keywords*—Scheduling; Job shop; Multi-hybridization; Swarm intelligence

I. Introduction

The profitability of a manufacturing company is generally achieved by minimizing production lead times, reducing stock costs, meeting deadlines, maximizing customer satisfaction and maximizing the use of machinery. These key performance indicators are dependent on effective scheduling.

Scheduling is the process of deciding how to allocate resources among the various potential job categories. The objective is to allocate resources over a period of time to complete a series of jobs. It has been the topic of a numerous publications in the area of operational research [1-4]. This is an important decision-making process in most sectors of manufacturing and services [5]. It may also be described as a decision-making process in order to optimize goals such as achieving and reducing makespan.

Scheduling problems may be modelled as allocation issues that represent a broad class of combinatorial optimization issues. In most such cases, it is very hard to come up with the optimum solution.

Job shop scheduling problem (JSSP) is a classic problem of operational search which has been regarded as a problem of combinatorial optimization difficult since the 1950s. As for the complexity of the calculations, the JSSP is an NP-hard in the strong sense of the term [6]. As a result, even in the case of very small JSSP instances, an optimum solution cannot be ensured.

In the general, job shop scheduling problem can be formulated as follows:

- There is a set of n jobs to be treated over a set of m machines.
- A job should not go on the same machine more than once.
- There are no constraints of precedence over the operations of the various jobs.
- The operations cannot be halted.
- Each machine can handle only one job at a time.
- Every job must pass through a specific sequence of predefined operations.

Every optimization issue should have an objective function that must be kept to a minimum or maximized in order to achieve a solution. In this case, the purpose of this paper is to reduce to a minimum the total time required to complete all jobs (makespan).

For job shop scheduling problems, there are numerous reference instances for the makespan minimization case:

1) FT (3) [7]: It is a collection of three instances of the combinations (n, m) ∈ {(6, 6), (10, 10), (20, 5)}.

2) LA (40) [8]: It is a collection of forty instances of which five instances of combinations (n, m) ∈ {(10, 5), (15, 5), (20, 5), (10, 10), (15, 10), (20, 10), (30, 10), (15, 15)}.

3) ABZ (5) [9]: It is a collection of five instances of the combinations (n, m) ∈ {(10, 10), (20, 15)}.

4) ORB (10) [10]: It is a collection of ten instances of the format (n, m) = (10, 10).

5) YN (4) [11]: It is a collection of four instances of the format (n, m) = (20, 20).

6) SWV (20) [12]: It is a collection of twenty instances of the combinations (n, m) ∈ {(20, 10), (20, 15), (50, 10), (50, 10)}.

*Corresponding Author

7) TA (80) [13]: It is a collection of eighty instances with ten instances for each of the formats (n, m) ∈ {(15, 15), (20, 15), (20, 20), (30, 15), (30, 30), (50, 15), (50, 20), (100, 20)}.

8) DMU (80) [14]: It is a collection of eighty instances of which ten instances for each of the combinations (n, m) ∈ {(20, 15), (20, 20), (30, 15), (30, 20), (40, 15), (40, 20), (50, 15), (50, 20)}.

Because of the NP-hard kind of job shop scheduling problems, the development of an optimum schedule is very expensive and impracticable. Hence, numerous techniques are developed for this problem.

A few contributions that have been made to solve the job shop scheduling problem are summarized in Fig. 1.

Several disadvantages have been encountered in solving the job shop scheduling problem, therefore, it became evident that concentrating on a single metaheuristic to solve the JSSP is rather limited.

A metaheuristic is rarely as powerful in diversification as it is in intensification, the solution consists in combining a technique characterized by a high exploration capability with a technique characterized by a good exploitation of the search space.

A good balance between diversification and intensification is required to obtain the optimum performance of a hybrid optimization method, hence its efficiency and success.

However, to the authors' best knowledge, very few articles can be found in the literature which investigate the multi hybridization of swarm intelligence techniques and conduct a thorough analysis.

The remainder of the paper is organized as follows: The material and method will be described in section II. The experimental findings and discussion are discussed in Section III. The conclusion is presented under Section IV.

Fig. 1. The Proposed Methods for Solving Job Shop Scheduling Problem in the Literature.

II. The Material and Method

Swarm Intelligence (SI) is considered to be one of the most important research fields that is applied by various scientists for problem-solving, computation, and solution optimization [4].

Swarm Intelligence is based on natural swarm systems and is defined as the collective problem resolution abilities of social animals. [30].

Swarm Intelligence is a direct outcome of self-organization in which the interactions of lower-level components establish an overall-level dynamic structure that can be considered intelligence [31].

Self-organization is established by four elements [30]:

1) Multiple interactions [31]: Information about food sources is shared between the employed bees and the onlooker bees on the dance floor to harvest and retrieve the food.

2) Positive feedback [31]: It is essentially a set of simple rules that assist in generating the complex structure. One example of this process is the recruitment of honeybees in a promising flower field.

3) Negative feedback [31]: Minimizes the impact of positive feedback and contributes to the creation of a counterbalance mechanism.

4) Fluctuation [31]: The scouts conduct research in the environment to randomly find the food source.

Various swarm intelligence methods have been proposed in the literature: Artificial Bee Colony (ABC) [32-35], Genetic Algorithm (GA) [36], Ant Colony Optimization (ACO) [37–40], Particle Swarm Optimization (PSO) [41], Cat Swarm (CSO) [42], Artificial Immune System [43], Bacterial Foraging [44], and Glowworm Swarm Optimization [45] and many more.

Swarm intelligence approaches are successfully used to solve many real issues and have yielded excellent results in comparison with other methods.

In this paper, the authors concentrate on two of the most popular swarm intelligence techniques, namely, Artificial Bee Colony (ABC) and Ant Colony Optimization (ACO).

A. Fundamentals of Artificial Bee Colony Algorithm (ABC)

The Artificial Bee Colony (ABC) is a population-based approach suggested by Karaboga and Basturk in 2007 [46] and an evolutionary algorithm based on the intelligent behavior of honeybees looking for food (nectar) [47, 48], which works by sharing information about food sources among bees in the nest.

Each position of the food source corresponds to one solution, the bees are ranked according to how they choose the food source to use. The phase of employed bee, onlooker bee and scout bee phase are the steps used in the suggested method.

The Artificial Bee Colony (ABC) algorithm has shown that it provides optimum solutions in the continuous and discreet field [1-4] [49-52] when it is confronted with noisy and multimodal optimization issues. A full overview of the use of the ABC technique is available in [47].

Analogous to other swarm techniques, the Artificial Bee Colony (ABC) method is a repetitive process.

The artificial bee colony technique (ABC) comes up with the best solution by applying four stages [53], until an end criterion is satisfied [54], these key steps of the ABC algorithm are outlined below:

1) Initialization step: It begins with a population of randomized solutions or food sources. The value of food sources determines by many factors such as their wealth, the ability to extract energy, the closeness of the nest and the amount of energy that's going to be collected from that food source.

2) Employed bee step: Every bee employed is given a source of food that it currently uses or operates. They bring together information about that particular source, their distance and direction from the nest, the cost-effectiveness of the source and they're sharing that information with some degree of probability. The number of employed honeybees will correspond to the number of food sources surrounding their beehives.

Unemployed bees wait in the nest and are seeking a source of food to explore, there are two kinds of bees unemployed:

a) Onlooker bee step: The Curious bees or Onlooker bees must look at the dance of the employed bees and then develop a source of food via information shared by the employed bees.

b) Scout bee step: Explorer or Scout bees are the ones whose source of food is abandoned and are seeking new food sources in the nesting environment. Once an adequate food source is found, scout bees become employed bees.

Register the best food source reached up to now.

From this algorithm, a colony of artificial bees (ABC) is established.

The Artificial Bee Colony (ABC) is also the same as other algorithms because it has pros and cons [55]:

1) The ABC method has a force in both local and global searches and it has been implemented with a number of optimization issues.

2) However, it has a number of parameters that need to be adjusted, randomly initialized and its local search are probabilistic.

B. Fundamentals of Ant Colony Optimization (ACO)

The Ant Colony Optimization technique (ACO) is another swarm intelligence approach based on ants' behavior looking for a food source from their nest with no visual information and using shortest pathways [56].

ACO is an optimization technique based on the population that Dorigo developed in 1992 [57] and has been successfully implemented to resolve various NP-hard combinatorial optimization issues that require to provide approximate solutions to the defined issue [58]. Algorithmically, the process of evaporating pheromones is helpful to prevent convergence towards a local optimal solution.

The steps involved in obtaining the best solution using the ant colony optimization technique are listed below [38]:

1) Building the solution space is made up of potential solutions with the help of the pheromone model.

2) These potential solutions are employed to update pheromone values in a manner that is considered to skew future sampling towards high quality solutions [59].

Ant behavior results in a self-reinforcement process: A pathway created by ants using the high level of pheromone is more followed by ants than the pathway with the low level of pheromone.

Numerous variations of ACO algorithms have been implemented in the literature [60].

C. The Proposed Methods

To enhance the original algorithms based on Swarm Intelligence, the researchers have generally hybridized them with other metaheuristics.

The Artificial Bee Colony (ABC) algorithm has the capacity to emerge from a local minimum and has a great ability to explore the global optimum which it is not immediately used, because the artificial bee colony (ABC) stocks it at every iteration.

The artificial bee colony (ABC) has been hybridized to increase its yields and effectiveness by balancing exploration and exploitation processes.

Swarm Intelligence's algorithms effectiveness is driven by two processes: exploration and exploitation [61]:

1) The exploration process: Allows the exploration of the search area in a more efficient way, and it can generate solutions that are sufficiently diverse.

2) The exploitation process: Utilizes all the information gathered from a defined problem to assist in finding new solutions that are better than the existing solutions.

An extensive exploitation and an insufficient exploration means that the system can have converge more quickly, but the likelihood of reaching the effective global optimum may be low. In addition, under-exploitation and over-exploration may result in very slow search paths to converge. Therefore, the balance between exploration and exploitation processes is crucial for achieving the optimum performance of the Swarm Intelligence method. In the literature, no non-hybridized

Swarm Intelligence algorithm is able to achieve this optimum equilibrium.

The multi-hybridization of ABC technique with ACO technique is proposed in this paper for getting a more powerful method that balances both processes, exploration and exploitation, harnesses and combines the benefits of Swarm Intelligence algorithms. The synchronous parallel hybridization [62] is applied in the proposed approach.

This approach, denoted as HABCACO involves integrating the ant colony optimization technique (ACO) into the employed bees step and/or in the onlooker bees step and/or in the scout bees step.

The HABCACO approach is described in Fig. 2.

HABCACO		
ABC	*Initialization step*	Uniform Random Generation
	Employed bee step	Add or do not add ACO method
	Onlooker bee step	Add or do not add ACO method
	Scout bee step	Add or do not add ACO method

Fig. 2. The HABCACO Approach.

Table I shown the configuration of the HABCACO techniques.

TABLE I. THE CONFIGURATION OF THE HABCACO TECHNIQUES

	ABC		
Hybrid ABC + ACO	***Employed bee phase***	***Onlooker bee phase***	***Scout bee phase***
HABCACO1	ACO		
HABCACO2	ACO	ACO	
HABCACO3	ACO	ACO	ACO
HABCACO4		ACO	
HABCACO5		ACO	ACO
HABCACO6			ACO
HABCACO7	ACO		ACO

The suggested approaches HABCACO has ABC technique as the primary algorithm that in its flow will call ACO technique for enhancement. ACO method refines the solution generated by the steps of ABC method (employed bees step and/or onlooker bees step and/or scout bees step) and produces a better solution to be used in the process of HABCACO.

The population of candidate solutions for these new approaches is initialized using the uniform random generation between a lower bound LB and an upper bound UB [63], this means that the potential solution frequently takes the form:

$$\mathrm{CS} = \mathrm{LB} + \alpha\,(\mathrm{UB} - \mathrm{LB}), \text{where } \alpha \in [0,1] \qquad (1)$$

The means to generate the candidate solution population affect an algorithm's efficiency.

Hence, the stepwise implementation of HABCACO2 and HABCACO7 are explained respectively in Fig. 3 and Fig. 4.

Initialization step:
Initialize input parameters.
Initialize the number of generations necessary for the termination criterion.
Initialize the number of solutions.
Initialize the employed bees' number (equal to solutions number)
Initialize the onlooker bees' number (equal to solutions number)
Initialize the number of scout bees
Initialize the possible solution populations by the uniform random generation.
Calculate the fitness value for each solution as follows:

$$fit_i = \frac{1}{(1+f_i)} \; if\ f_i \ \geq 0\ ;\ fit_i = 1 + \left|(f_i)\right| \; if\ f_i < 0$$

Where f_i is the value of the objective function of i^th solutions.
Identify the best solution.

Employed bee step:
For each employed bee
Create a new solution based on the function:

$$y_{ij} = x_{ij} + \emptyset_{ij}\left(x_{ij} + x_{kj}\right), k \neq i\ , i = \{1, 2\ \ldots, SN\},$$
$$j = \{1, 2\ \ldots, D\}\ , \emptyset_{ij} = Rand\ [-1, 1]$$

x_{min} , x_{max} are respectively the lower and upper boundaries of the search perimeter and y_{ij} is a new realizable dimension value of the solutions which is changed from the value of its previous solutions x_{ij}.
Apply ACO (new solution).
Determine the fitness value of these best solutions found by ACO.
Calculate the most appropriate solution.

Onlooker bee step:
For each onlooker bee
Create a new solution based on the function:

$$y_{ij} = x_{ij} + \emptyset_{ij}\left(x_{ij} + x_{kj}\right), k \neq i\ , i = \{1, 2\ \ldots, SN\},$$
$$j = \{1, 2\ \ldots, D\}\ , \emptyset_{ij} = Rand\ [-1, 1]$$

Choose the i^th solution associated with the probability value (p_i):

$$p_i = \frac{fit_i}{\sum_{k=1}^{SN} fit_k}$$

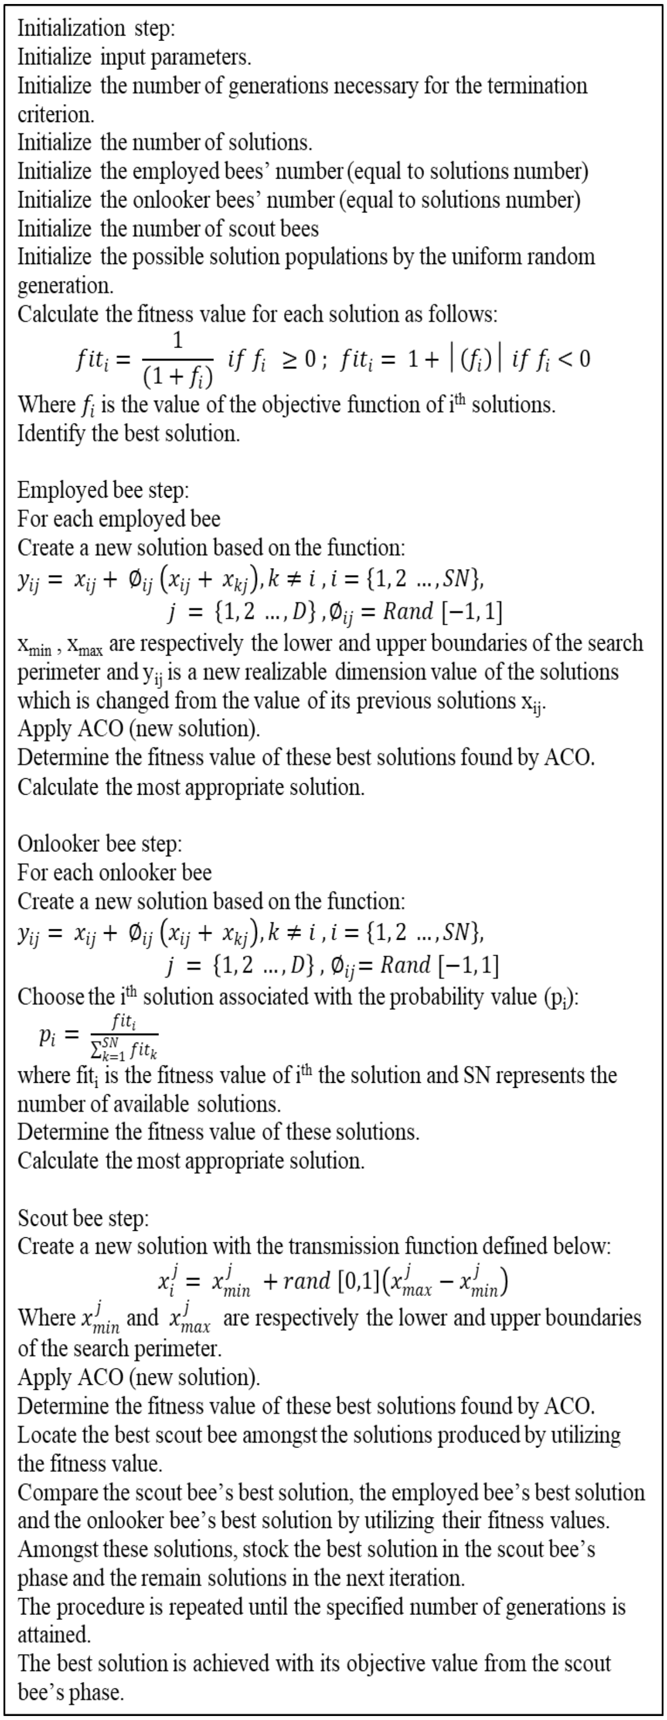
where fit_i is the fitness value of i^th the solution and SN represents the number of available solutions.
Apply ACO (new solution).
Determine the fitness value of these best solutions found by ACO.
Calculate the most appropriate solution.

Scout bee step:
Create a new solution with the transmission function defined below:

$$x_i^j = x_{min}^j + rand\ [0,1]\left(x_{max}^j - x_{min}^j\right)$$

Where x_{min}^j and x_{max}^j are respectively the lower and upper boundaries of the search perimeter.
Determine the fitness value of these solutions.
Locate the best scout bee amongst the solutions produced by utilizing the fitness value.
Compare the scout bee's best solution, the employed bee's best solution and the onlooker bee's best solution by utilizing their fitness values.
Amongst these solutions, stock the best solution in the scout bee's phase and the remain solutions in the next iteration.
The procedure is repeated until the specified number of generations is attained.
The best solution is achieved with its objective value from the scout bee's phase.

Fig. 3. The Procedure of HABCACO2.



```
Initialization step:
Initialize input parameters.
Initialize the number of generations necessary for the termination criterion.
Initialize the number of solutions.
Initialize the employed bees' number (equal to solutions number)
Initialize the onlooker bees' number (equal to solutions number)
Initialize the number of scout bees
Initialize the possible solution populations by the uniform random generation.
Calculate the fitness value for each solution as follows:
    $fit_i = \frac{1}{(1+f_i)}\ if\ f_i \geq 0\ ;\ fit_i = 1 + |(f_i)|\ if\ f_i < 0$
Where $f_i$ is the value of the objective function of i^th solutions.
Identify the best solution.

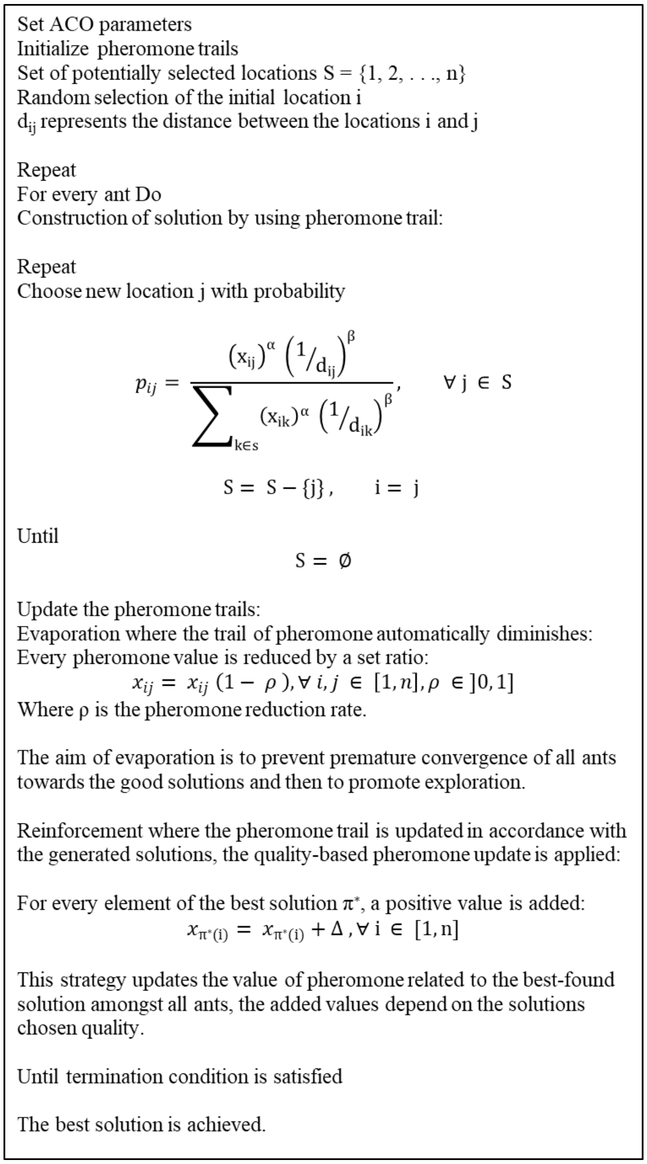
Employed bee step:
For each employed bee
Create a new solution based on the function:
$y_{ij} = x_{ij} + \emptyset_{ij}\left(x_{ij} + x_{kj}\right), k \neq i, i = \{1, 2\ \ldots, SN\},$
    $j = \{1, 2\ \ldots, D\}, \emptyset_{ij} = Rand\ [-1, 1]$
$x_{min}$, $x_{max}$ are respectively the lower and upper boundaries of the search perimeter and $y_{ij}$ is a new realizable dimension value of the solutions which is changed from the value of its previous solutions $x_{ij}$.
Apply ACO (new solution).
Determine the fitness value of these best solutions found by ACO.
Calculate the most appropriate solution.

Onlooker bee step:
For each onlooker bee
Create a new solution based on the function:
$y_{ij} = x_{ij} + \emptyset_{ij}\left(x_{ij} + x_{kj}\right), k \neq i, i = \{1, 2\ \ldots, SN\},$
    $j = \{1, 2\ \ldots, D\}, \emptyset_{ij} = Rand\ [-1, 1]$
Choose the i^th solution associated with the probability value ($p_i$):
    $p_i = \frac{fit_i}{\sum_{k=1}^{SN} fit_k}$
where $fit_i$ is the fitness value of i^th the solution and SN represents the number of available solutions.
Determine the fitness value of these solutions.
Calculate the most appropriate solution.

Scout bee step:
Create a new solution with the transmission function defined below:
    $x_i^j = x_{min}^j + rand\ [0,1]\left(x_{max}^j - x_{min}^j\right)$
Where $x_{min}^j$ and $x_{max}^j$ are respectively the lower and upper boundaries of the search perimeter.
Apply ACO (new solution).
Determine the fitness value of these best solutions found by ACO.
Locate the best scout bee amongst the solutions produced by utilizing the fitness value.
Compare the scout bee's best solution, the employed bee's best solution and the onlooker bee's best solution by utilizing their fitness values.
Amongst these solutions, stock the best solution in the scout bee's phase and the remain solutions in the next iteration.
The procedure is repeated until the specified number of generations is attained.
The best solution is achieved with its objective value from the scout bee's phase.
```

Fig. 4. The Procedure of HABCACO7.

The ant colony optimization technique (ACO) is primarily made up of two phases: construction of the solution and updating of pheromone. The algorithm of ant colony optimization (ACO) technique is described in Fig. 5:



```
Set ACO parameters
Initialize pheromone trails
Set of potentially selected locations S = {1, 2, . . ., n}
Random selection of the initial location i
$d_{ij}$ represents the distance between the locations i and j

Repeat
For every ant Do
Construction of solution by using pheromone trail:

Repeat
Choose new location j with probability

    $p_{ij} = \frac{(x_{ij})^{\alpha}\left({}^{1}/_{d_{ij}}\right)^{\beta}}{\sum_{k \in s}(x_{ik})^{\alpha}\left({}^{1}/_{d_{ik}}\right)^{\beta}}, \quad \forall j \in S$

    $S = S - \{j\}, \quad i = j$

Until
    $S = \emptyset$

Update the pheromone trails:
Evaporation where the trail of pheromone automatically diminishes:
Every pheromone value is reduced by a set ratio:
    $x_{ij} = x_{ij}\ (1 - \rho), \forall\ i, j \in [1, n], \rho \in ]0, 1]$
Where ρ is the pheromone reduction rate.

The aim of evaporation is to prevent premature convergence of all ants towards the good solutions and then to promote exploration.

Reinforcement where the pheromone trail is updated in accordance with the generated solutions, the quality-based pheromone update is applied:

For every element of the best solution $\pi^*$, a positive value is added:
    $x_{\pi^*(i)} = x_{\pi^*(i)} + \Delta, \forall\ i \in [1, n]$

This strategy updates the value of pheromone related to the best-found solution amongst all ants, the added values depend on the solutions chosen quality.

Until termination condition is satisfied

The best solution is achieved.
```

Fig. 5. The Procedure of ACO.

III. Results and Discussion

In order to justify the effectiveness of the proposed approaches HABCACO, they were simulated across a set of 250 benchmark instances from the job shop scheduling literature: FT [7], LA [8], ABZ [9], ORB [10], YN [11], SWV [12], TA [13], DMU [14], CAR [18], and compared with the best-known solution (BKS) obtained through other Techniques.

The performance of the HABCACO methods was also compared to two other advanced techniques available in the literature: HABCGA [2] and HABCPSOGA [3] to demonstrate the efficiency of HABCACO techniques in resolving job shop scheduling issues.

The HABCACO approaches have been implemented within Java and all calculation experiments were carried out on an Intel Core i7 computer with a speed of 2.5 GHz and 8 GB RAM memory under Windows 10.

All simulation and test processes were performed with the same configuration settings.

The results of the benchmark instances simulation are summarized in Table II.

The calculation results demonstrate that only the proposed HABCACO3 technique produced 100% of the best-known solution in all benchmark instances: FT (3), LA (40), ORB (10), SWV (20), ABZ (5), YN (4), TA (80), DMU (80) and CAR (8).

As shown in Table II:

1) All the suggested techniques HABCACO have given results that are 100% equal to the best-known solutions in FT (3), LA (40), ORB (10), SWV (20), ABZ (5), YN (4), and CAR (8).

2) Only the suggested techniques HABCACO3 and HABCACO7 produced 100% of the results equal to the best-known solutions in TA (80).

3) Only the suggested technique HABCACO3 produced 100% of the results equal to the best-known solutions in DMU (80).

The classification of the suggested HABCACO methods in terms of performance according to the hybridization number is illustrated in Table III.

From Table III, it can be concluded that:

1) The suggested HABCACO techniques provided the best results in comparison to the results achieved through other methods.

2) The suggested technique HABCACO hybridized in its three steps provided the best result.

3) The suggested techniques HABCACO hybridized in its two steps provided better results in comparison to the results achieved through the suggested techniques HABCACO hybridized in only one step.

4) The suggested technique HABCACO hybridized in its two steps (employed bees step and scout bees step) provided better results in comparison to the results achieved through the suggested techniques HABCACO hybridized in its two steps (onlooker bees step and scout bees step).

5) The suggested technique HABCACO hybridized in its two steps (employed bees step and scout bees step) provided better results in comparison to the results achieved through the suggested techniques HABCACO hybridized in its two steps (employed bees step and onlooker bees step).

6) The suggested technique HABCACO hybridized in its scout bees step provided better results in comparison to the results achieved through the suggested techniques HABCACO hybridized in its employed bees step or onlooker bees step.

7) The suggested technique HABCACO hybridized in its scout bees step provided better results in comparison with the results achieved through the suggested techniques HABCACO hybridized in its onlooker bees step.

The figures showed that the suggested techniques surpassed other methods with regard to the total number of benchmark instances successfully resolved and the quality of the solutions.

In order to confirm also the performance of the HABCACO technique in resolving job shop scheduling problems, it was compared to the HABCGA and HABCPSOGA methods available in the literature.

TABLE II. THE RESULTS OF BENCHMARK INSTANCES SIMULATION

TABLE III. THE RANKING OF THE PROPOSED TECHNIQUES HABCACO

Ranking	Hybridation number	HABCACO	ABC		
			Employed bee step	*Onlooker bee step*	*Scout bee step*
7	1	HABCACO1	ACO		
4	2	HABCACO2	ACO	ACO	
1	3	HABCACO3	ACO	ACO	ACO
6	1	HABCACO4		ACO	
3	2	HABCACO5		ACO	ACO
5	1	HABCACO6			ACO
2	2	HABCACO7	ACO		ACO

As shown in Table IV:

1) The suggested technique HABCACO hybridized in its three phases with ACO method provided similar result in comparison to the results achieved through HABCGA methods hybridized in its three phases with GA method.

2) The suggested technique HABCACO hybridized in its three steps with ACO method provided better result in comparison to the results achieved through HABCGA methods hybridized in its two steps with GA method.

3) The suggested technique HABCACO hybridized in its three steps with ACO method provided better result in comparison to the results achieved through HABCGA methods hybridized in its one step with GA method.

4) The suggested technique HABCACO hybridized in its two steps with ACO method (employed bee step and scout bee step) provided better result in comparison to the results achieved through HABCGA methods hybridized in its two steps (employed bee step and scout bee step) with GA method.

5) The suggested technique HABCACO hybridized in its two steps with ACO method (onlooker bee step and scout bee step) provided better result in comparison with the results achieved through HABCGA methods hybridized in its two steps (onlooker bee step and scout bee step) with GA method.

6) The suggested technique HABCACO hybridized in it scout bee step with ACO method provided better result in comparison to the results achieved through HABCGA methods hybridized in its scout bee step with GA method.

7) The suggested technique HABCACO hybridized in it onlooker bee step with ACO method provided better result in comparison with the results achieved through HABCGA methods hybridized in its onlooker bee step with GA method.

8) The HABCGA methods hybridized in its two steps with GA method (employed bee step and onlooker bee step) provided better result in comparison to the results achieved through the suggested technique HABCACO hybridized in its two steps (employed bee step and onlooker bee step) with ACO method.

9) The HABCGA methods hybridized in its employed bee steps with GA method provided better result in comparison to the results achieved through the suggested technique HABCACO hybridized in employed bee step with ACO method.

The classification of the suggested methods HABCACO and the HABCGA methods in terms of performance according to the hybridization number and the algorithm type hybridized is tabulated in Table V.

TABLE IV. THE PERFORMANCE COMPARISON OF PROPOSED METHODS HABCACO WITH THE OTHER OPTIMIZATION ALGORITHMS HABCGA

	Hybrid ABC (ACO)						Hybrid ABC (GA)					
Hybridation number	HABCACO	ABC				Ranking	HABCGA	ABC				Ranking
		Employed bee step	*Onlooker bee step*	*Scout bee step*				*Employed bee step*	*Onlooker bee step*	*Scout bee step*		
1	HABCACO1	ACO			94,80%	7	HABCGA1	GA			95,48%	5
2	HABCACO2	ACO	ACO		98,00%	4	HABCGA2	GA	GA		99,80%	2
3	HABCACO3	ACO	ACO	ACO	100,00%	1	HABCGA3	GA	GA	GA	100,00%	1
1	HABCACO4		ACO		96,00%	6	HABCGA4		GA		94,03%	7
2	HABCACO5		ACO	ACO	98,40%	3	HABCGA5		GA	GA	96,93%	4
1	HABCACO6			ACO	96,80%	5	HABCGA6			GA	95,35%	6
2	HABCACO7	ACO		ACO	99,20%	2	HABCGA7	GA		GA	98,40%	3

TABLE V. THE RANKING OF THE PROPOSED TECHNIQUES HABCACO AND HABCGA

Ranking	**Hybrid ABC (ACO) / Hybrid ABC (GA)**	**ABC**				**Hybridation number**
		Employed bee step	***Onlooker bee step***	***Scout bee step***		
1	HABCACO3	ACO	ACO	ACO	100,00%	3
1	HABCGA3	GA	GA	GA	100,00%	3
2	HABCGA2	GA	GA		99,80 %	2
3	HABCACO7	ACO		ACO	99,20 %	2
4	HABCACO5		ACO	ACO	98,40 %	2
4	HABCGA7	GA		GA	98,40 %	2
5	HABCACO2	ACO	ACO		98,00 %	2
6	HABCGA5		GA	GA	96,93 %	2
7	HABCACO6			ACO	96,80 %	1
8	HABCACO4		ACO		96,00 %	1
9	HABCGA1	GA			95,48 %	1
10	HABCGA6			GA	95,35 %	1
11	HABCACO1	ACO			94,80 %	1
12	HABCGA4		GA		94,03 %	1

From Table VI it can be concluded that:

1) The suggested technique HABCACO hybridized in its three steps with ACO method provided similar result in comparison to the results achieved through HABCPSOGA methods hybridized in its three steps with GA and PSO methods.

2) The suggested technique HABCACO hybridized in its three steps with ACO method provided better result in comparison to the results achieved through HABCPSOGA methods hybridized in its two steps with GA and PSO methods.

3) The suggested technique HABCACO hybridized in its two steps with ACO method (employed bee step and scout bee step) provided equal result in comparison to the results achieved through HABCPSOGA methods hybridized in its two steps (employed bee step by GA method and scout bee step PSO method).

4) The suggested technique HABCACO hybridized in its two steps with ACO method (employed bee step and scout bee step) provided better result in comparison to the results achieved through HABCPSOGA methods hybridized in its two steps (employed bee step by PSO method and scout bee step GA method).

5) The suggested technique HABCACO hybridized in its two steps with ACO method (onlooker bee step and scout bee step) provided better result in comparison to the results achieved through HABCPSOGA methods hybridized in its two steps (onlooker bee step by GA method and scout bee step by PSO method).

6) The suggested technique HABCACO hybridized in its two steps with ACO method (onlooker bee step and scout bee step) provided better result in comparison to the results achieved through HABCPSOGA methods hybridized in its two steps (onlooker bee step by PSO method and scout bee step by GA method).

7) The suggested technique HABCACO hybridized in its two steps with ACO method (employed bee step and onlooker bee step) provided better result in comparison to the results achieved through the suggested methods HABCPSOGA hybridized in its two steps (employed bee step by GA method and onlooker bee step by PSO method).

TABLE VI. THE PERFORMANCE COMPARISON OF PROPOSED METHODS HABCACO WITH THE OTHER OPTIMIZATION ALGORITHMS HABCPSOGA

	Hybrid ABC (ACO)						**Hybrid ABC (GA // PSO)**						
Hybridation number	**HABCACO**	**ABC**				**Ranking**	**HABCPSOGA**	**ABC**				**Ranking**	
		Employed bee step	***Onlooker bee step***	***Scout bee step***				***Employed bee step***	***Onlooker bee step***	***Scout bee step***			
2	HABCACO2	ACO	ACO		98,00%	4	HABCPSOGA4	GA	PSO		97,50%	7	
2	HABCACO2	ACO	ACO		98,00%	4	HABCPSOGA7	PSO	GA		98,48%	3	
3	HABCACO3	ACO	ACO	ACO	100,00%	1	HABCPSOGA2	GA	GA	PSO	100,00%	1	
3	HABCACO3	ACO	ACO	ACO	100,00%	1	HABCPSOGA6	GA	PSO	GA	100,00%	1	
3	HABCACO3	ACO	ACO	ACO	100,00%	1	HABCPSOGA9	PSO	GA	GA	100,00%	1	
2	HABCACO5		ACO	ACO	98,40%	3	HABCPSOGA1		GA	PSO	97,90%	5	
2	HABCACO5		ACO	ACO	98,40%	3	HABCPSOGA5		PSO	GA	97,85%	6	
2	HABCACO7	ACO		ACO	99,20%	2	HABCPSOGA3	GA		PSO	99,20%	2	
2	HABCACO7	ACO		ACO	99,20%	2	HABCPSOGA8	PSO		GA	98,40%	4	

8) The HABCPSOGA methods hybridized in its two steps (employed bee step by GA method and onlooker bee step by PSO method) provided better result in comparison to the results achieved through the suggested technique HABCACO hybridized in its two steps with ACO method (employed bee step and onlooker bee step).

The classification of the suggested methods HABCACO and the HABCPSOGA methods in terms of performance according to the hybridization number and the algorithm type hybridized is tabulated in Table VII.

As a result, it clearly demonstrated that HABCACO has the best performance compared to other methods HABCGA and HABCPSOGA.

The proposed approaches HABCACO are robust techniques that have the potential to solve job shop scheduling problems.

One of the main limitations of this research is that it only addresses the minimization of the total time required to perform all the jobs (makespan).

TABLE VII. THE RANKING OF THE PROPOSED TECHNIQUES HABCACO AND HABCPSOGA

Ranking	**Hybrid ABC (ACO) / Hybrid ABC (GA // PSO)**	**ABC**				**Hybridation number**
		Employed bee step	***Onlooker bee step***	***Scout bee step***		
1	HABCACO3	ACO	ACO	ACO	100,00%	3
1	HABCPSOGA2	GA	GA	PSO	100,00%	3
1	HABCPSOGA6	GA	PSO	GA	100,00%	3
1	HABCPSOGA9	PSO	GA	GA	100,00%	3
2	HABCACO7	ACO		ACO	99,20%	2
2	HABCPSOGA3	GA		PSO	99,20%	2
3	HABCPSOGA7	PSO	GA		98,48%	2
4	HABCACO5		ACO	ACO	98,40%	2
4	HABCPSOGA8	PSO		GA	98,40%	2
5	HABCACO2	ACO	ACO		98,00%	2
6	HABCPSOGA1		GA	PSO	97,90%	2
7	HABCPSOGA5		PSO	GA	97,85%	2
8	HABCPSOGA4	GA	PSO		97,50%	2

IV. CONCLUSION

Because of the high level of complexity of the job shop scheduling problems, powerful and hybrid approaches are essential to address these challenging NP issues.

A robust swarm intelligence multi-hybridization technique is the key to achieving maximum efficiency in the resolution of job shop scheduling issues.

In this article, the authors develop novel multi-hybridization approaches of swarm intelligence methods called HABCACO through hybridization of artificial bee colony (ABC) algorithm and ant colony optimization (ACO) technique in various ways to provide optimal or near optimal solutions to job shop scheduling problems.

In this new approach, HABCACO adjusts the standard artificial bee colony techniques (ABC) to balance the impact of exploration and exploitation processes in algorithm performance.

Balanced exploration and exploitation capacities can improve method performance in terms of solutions quality.

The assessment of HABCACO's performance was analyzed on 250 well-known benchmark instances of the classical OR-library of job shop scheduling problems.

The overall experimental findings clearly demonstrated that the proposed new technique surpassed other compared optimization algorithms in terms of the total number of successfully resolved benchmark instances and the global optimum attainment.

Furthermore, the experimental results clearly demonstrated that the approaches are robust, effective and reliable for solving job shop scheduling problems.

More importantly, the results showed that the suggested techniques HABCACO produced the best results in comparison to other optimization methods HABCGA and HABCPSOGA available in the literature.

Therefore, the suggested approaches are solid techniques which have the potential to solve the scheduling problem and can be applied to solve complex optimization issues.

As future research, the authors intend to apply these approaches developed in this article to another type of scheduling problems and complex optimization problems.

Abstract—**Safety is a serious concern that should be addressed carefully in different locations including homes, workplaces and educational buildings. The risk of fire is the most significant threat in many educational facilities such as schools, universities, offices, etc. The main goal of this work is developing an effective system that allows early managing of fires to avoid material and human losses. With the advent of the Internet of Things (IoT), the implementation of such system became possible. A low-cost system incorporating IoT sensors is constructed in this study to collect data (heat, the number of people at the fire scene, ...) in real time. The system provides a control panel that displays readings from all sensors on a single web page. When the collected values exceed a particular threshold, the system sends a message to the building keeper's phone, allowing him to notify the authorities or dispatch firemen in real time. One of the system's most important characteristics is that it keeps track of how many people are at the fire scene, simplifying the evacuation process and allowing civil defense authorities to efficiently manage resources. The system has been successfully tested in a variety of circumstances in an educational building (Al-Faisaliah female campus, University of Jeddah, Saudi Arabia).**

Keywords*—*Safety; fire; Internet of Things (IoT); sensors; cloud based platform; ThingSpeak

I. Introduction

Safety is defined as the condition of being protected from or unlikely to cause danger, risk, or injury. People are continuously exposed to dangers in their homes, workplace or roads. Occupants of Educational buildings such as students, educators and administrative staff have different awareness levels regarding safety practices and beliefs. Since educational buildings are continuously occupied, safety issues should be addressed properly and procedures used to reduce risks have to be implemented prior to unexpected accidents. The main objective of the present paper is to develop and implement a complete management system for monitoring safety. This can improve the safe conditions in educational buildings especially in Al-Faisaliah female campus, University of Jeddah, Saudi Arabia. To achieve the research objectives, a procedure including several steps will be implemented. The first step is dedicated to the study of safety requirements in educational buildings issued in official documents provided by civil defense authorities [1]. In the second step, to assess the commitment and awareness of the users of Al-Faisaliah Campus with health and safety conditions, an online survey was chosen to collect data because it can reach a large number of individuals and has a minimal risk of data inaccuracies.

Results of the survey conducted have shown that the safety culture inside Al-Faisaliah Campus is very poor. The results showed also that fire is the most dangerous threat that can occur. The official records have verified that fact. According to Saudi Civil Defense statistics [1], for the year 1440-1441 H, the number of firefighting operations was more than 42,000, equivalent to 119 firefighting operations per day. More than 14,000 were fires in the workplace, at a rate of 35.41%. The region of Mecca occupied the first place in the number of operations. Human losses are about 2000 cases, between 149 deaths and 1,809 injuries, and financial losses are more than 49 million Saudi Riyals (1 USD = 3.76 SAR).

The previous statistics have clearly indicated a rise in the daily rate of fires in workplaces such as schools and offices. The average rate of this kind of fires reached 42 fires per day. There are a multitude of causes for fires. According to the statistics, thermal demand was one of the most common causes of fires, with a percentage of 37.71%, equivalent to 45 fires per day. Next, 22.0% of the electricity is tampered with an average of 27 fires per day. Finally, the third cause of fire is the flaming heat source. From statistics above, the conclusion is that fires are big threats that may cause disasters in the studied educational building. In order to contribute to limit dangers, smart solutions relying on new technologies such as Internet of Things (IoT) should be developed and deployed. The proposed safety management system may help first educational building occupants in reacting immediately once a threat is initiated and second may assist civil defense authorities during their interventions. In addition, the safety department of the University should take benefit from the proposed system to remotely control the safety situation inside the campus.

Through using IoT technology, a complete low-cost smart solution that enables the management and monitoring of fire in real time was suggested. The building's status was remotely monitored via a friendly dashboard. This dashboard displays the data issued from sensors in one Web page. A message delivered to the building keeper's mobile phone is activated if a collected parameter exceeds its threshold. So that he can call the police or firefighters to arrive right away. A huge benefit of the system is its ability to count the number of individuals involved at the fire scene. This will ease the evacuation efforts.

The remaining of this paper is organized as follows. First, many studies related to safety issues including advantages and disadvantages of each approach will be summarized. Second, the proposed safety management system as well as its components and its operation will be detailed. finally, conclusions, recommendations and future work will be drawn.

II. Literature Review

A. Safety

This short literature review tries to cover the main aspects of safety that will be addressed in this study. Fire is considered as the most significant risk that has to be assessed regularly. In [2], qualitative approaches have been presented. The purpose was to identify and eliminate fire hazards. The study established that hotel utilities are of high risk. 76 items related to safety in hotels have been proposed and classified into seven main classes. The proposed methodical approach can be used by fire safety inspectors. Several tools including short oral survey, semi-structured interviews with subcontractors, etc. have been used to assess safety culture among investors working in the household construction sector in Australia [3]. Thus, a method of source causes analysis was employed to categorize the safety culture of subcontractors into seven different areas, including the building site, work procedures, equipment and materials. Recommendations drawn at the end of the study are built around free training of the subcontractors. The Cypriot manufacturing sector safety practices have been studied in [4] using a nation-wide survey in Nicosia. The opinion of managers regarding fire occurrence has been demonstrated to be influenced by several factors such as the no-smoking rule, the presence of fire alarms, and the practice of allowing employees to sleep on the job. Although the safety situation is generally good, there is still potential for enhancement, according to the study's findings. Since electricity is classified as a silent killer, identifying safety beliefs among Australian electrical workers has been addressed in [5]. The planned behavior concept has been used as a theoretical framework. Focus groups and interviews with 46 certified electrical professionals were analyzed according to advantages, disadvantages, referents, barriers and facilitators affecting respectively the safety beliefs and culture. In Saudi Arabia, few works have addressed the problem of safety. In reference [6], Saudi Arabia's safety regulations for worksites have been assessed by surveying the work being done on several projects. Protection assessment scores have been found to be typically superior across all categories for the large projects; whereas low assessment ratings, particularly in firefighting, healthcare, and comfort, were typical for small projects. Protection measures in residential building assessment procedures have been implemented . A field assessment study about fire awareness measures has been conducted in [7] through a survey in residential buildings. The obtained results showed that the safety awareness on fire is poor. Based on the observations, a number of strategies including effective codes and official requirements, designs taking into account safety and educational programs have been proposed as recommendation to improve safety awareness culture. In the same direction, the study in [8] has focused on the methods adopted by Saudi Arabia firms to solve safety issues when creating residential structures. The research concluded that safety design must be undertaken by qualified architects and engineers. Through a representative company survey conducted in Germany [9], workplace risk assessments have been studied. The frequency of patterns influencing OHS measures has been evaluated in N=6500 companies. The study suggested that more effort is to be deployed by the authorities to improve the safety practices and beliefs. In [10], it has been evaluated how the Hail region of Saudi Arabia views and employs electrical safety. Hail region level of electric safety awareness has been found to be 0.76 out of 4. This low score reflects a bad culture of electrical safety. Numerous suggestions covering numerous relevant parties have been put forth. From the above literature review about safety, it can be remarked that fire is the main concern since it may cause irreversible dangers that can affect human lives and properties in addition to its high impact on economy and social life [11]. For this reason, the study main focus will be fire safety management based on IoT technology.

B. Internet of Things (IoT)

The term "Internet of Things" (IoT) refers to a network of physical objects which are equipped with sensors, programs, as well as other tools that allow them to communicate with other objects and systems over the Internet. IoT is essential for raising living standards. Indeed, it is able to human well-being and the quality of life enhancement [12]. Fire is among the common problems that may be managed/solved by using solutions around IoT technology. In order to prevent the loss of priceless lives and critical infrastructure in the case of a fire, it is imperative to establish an early, and precise fire detection system. Integrating contemporary technology, such as IoT, advanced analytics, and WSN, can result in accurate fire detection systems for real-time monitoring and crisis management [13].

The abundance of sensors, which are small devices with environmental sensing capabilities, is what gives IoT its greatest strength. Technologies for detecting fire can be divided into those that detect temperature, gases, and flames. Early-fire detection is the main function of fire sensing devices. A good fire system imposes that sensors must Identify a fire issue in its early stages. Heat sensors function properly. But, they are not fast. Make them moving can increase their speed. Smoke detectors have a poor accuracy rate. They can perform better if a visual sensor system is added. Due to the irreversible nature, fragility, and poor selectivity of gas sensors, their usage is extremely restricted in buildings.

Currently, the emphasis is on employing robots to fight fire in critical cases. This procedure is always performed from the outside of the burning place. But robots are heavier due to sensor systems and fire suppression equipment mounted on them. This fact creates a difficulty with balance and high-speed movement for internal fire detection. Hence, more study is required to develop improved sensing systems [14].

C. Related Work

An review of various relevant Internet - of - things intelligent fire detection and management works is provided in this section. Reference [15] utilized numerous sensors to gather real-time readings. When an emergency arises, sensor data are examined to start a sprinkler system. This has an important issue which is the non-prevention of fire occurrence. The authors in [16] used a Raspberry Pi to create a fully coded fire warning framework. Whenever a fire is discovered, a tailored app sends out an alert along with a URL to a website that contains pictures captured by embedded cameras. A Convolutional Neural Network approach for identifying fire in real pictures was introduced in [17]. Results were superior than those suggested in the literature. The authors proposed a future improvement that would use videos rather than photos. The authors in [18] proposed a system that uses multiple sensors to collect readings. An artificial intelligence -based algorithm analyzes and processes the gathered data. In the event of fires, airflow and a water spray are then activated. This has a significant flaw since it can only function properly in enclosed spaces. The development of a smart ventilation and lighting solution that could recognize people and control lights was the subject of reference [19]. Additionally, heat and gases could be remotely measured and gathered. The fact that this equipment was only used in one chamber is among the drawbacks. More improvements and research may be required before it can be used on a wide basis. The Ubidots platform was utilized by the authors of [20] to create an improved forest fire monitoring system. A buzzer sounds to notify users whenever sensor readings cross a predetermined limit. One problem with the suggested solution is that sensors placed outside are inaccurate since weather conditions can alter them. Authors created a smart home inspection for fire prevention in [21] that incorporated a multitude of sensors in each connected home area. To quickly alert the user of a fire incident, they used the Global System for Mobile Communications (GSM). Experiment is performed using a Fire Dynamic Simulator. One problem with the suggested solution is how to effectively handle the enormous volume of data that has been gathered. Some of the proposed systems above include technical flaws, such as needless complexity and exorbitant costs. Therefore, this research suggests an intelligent system that provides real-time data collection and monitoring and alerting for the building occupants and any concerned authorities.

In order to make the system innovative and better than the previously developed systems, a comparative study based on several criteria has been conducted (Table I). The main criteria considered in this study are the types of:

- sensors
- the environment
- alarms
- dashboard
- new features
- processing (ML/IP/FL: ML for machine learning. IP for image processing. And IF for fuzzy logic)

Based on the previous comparison (Table I), the following conclusions can be noted:

TABLE I. Comparison between the Proposed System and Similar Ones

Criteria / Reference	[15]	[16]	[17]	[18]	[19]	[20]	[21]	The proposed system
Temperature	√	×	×	√	√	√	√	√
Smoke	√	×	×	√	√	×	√	√
Flame	×	√	×	√	√	×	√	×
Gas	√	×	×	√	√	×	√	×
PIR	×	×	×	×	×	√	×	√
Camera	×	√	√	×	×	×	×	×
Cloud dash-board	√	×	×	×	×	√	×	√
Indoor	√	√	√	√	√	×	×	√
ML/IP/FL	×	√	√	√	×	×	√	×
Counting People	×	×	×	×	×	×	×	√
alert	×	√	×	√	√	√	√	√

- Many of the systems above have technical limitations (unnecessary complexity).
- The largest error is trusting a single type of fire sensor. Doing so will lead to more false alerts.
- It is insufficient to just use an audible alarm to notify stakeholders. It may be necessary to warn the building guard via message whenever a fire arises in particular circumstances, such as when he is outdoors.
- Sending a message is not enough in case of emergencies. A dashboard is required to the surveillance of the building.
- Firefighters frequently don't know how many people are in the burning building. This makes the evacuation process exceedingly challenging. By keeping track of this number, fireman's work will be easily achieved and their resources will be used more effectively.

In this prototype, a multitude of sensors were used. This can ensure precise fire detection. Additionally, a buzzer and LED were employed to create an audible and a visual alarms in case of emergency. Then, two Passive Infrared (PIR) sensors for counting people entering and exiting were deployed. Finally, a dashboard that enables the surveillance of the building was implemented. When an emergency arises, a message will be automatically delivered to the building guard.

III. Design and Development

A. Study Area

The study area chosen for assessing performances of this low-cost fire monitoring station is Al-Faisaliah Campus (Female branch of the University of Jeddah: Fig. 1). More precisely, the experiments are conducted in Building 11 (see

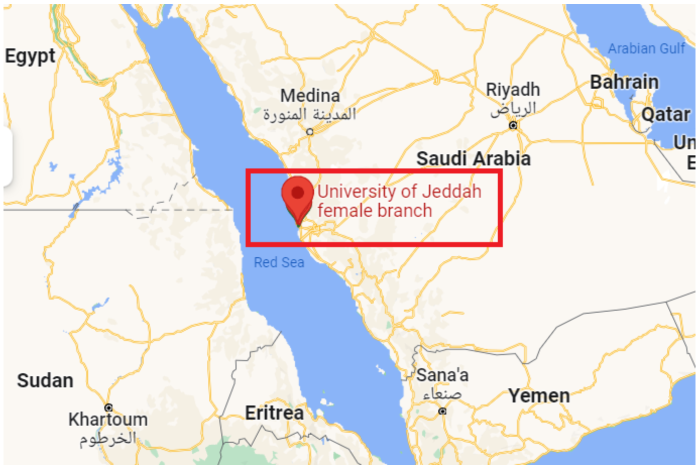

Fig. 1. Al-Faisaliah Campus (Female Branch of the University of Jeddah).

Classrooms:٣،٦،٧،١٤ gates : ١،٢،٣،٤،٥

Fig. 2. The Monitored Area (Building 11: in Red Square).

Fig. 2). For the development of this smart fire monitoring system, the work was divided into the following stages:

B. Functional and Non-Functional Requirements

The functional requirements specify what the proposed solution must perform during its operation. On the other hand, non-functional requirements are those characteristics of the device that can be observed throughout its execution. The following are the specified requirements:

1) Functional Requirements: The stakeholders are the building guard and the administrator.

- the building guard can view:
  1) sensors readings
  2) the number of persons in the fireplace
  3) any sudden changes in the monitored zone
- The administrator can determine:
  1) the temperature at which an alarm should be triggered
  2) the humidity which an alarm should be triggered
  3) the smoke t which an alarm should be triggered
- The system will be able to:
  1) display the dashboard
  2) determine how many people are in a building fire.
  3) issue different alerts during the early stages of a fire emergency

2) Non-Functional Requirements:

- Usability: The system shall be easy and simple to learn and use
- Portability: The system can be used in any indoor environment such as buildings, workplaces, hospitals, etc.
- Accuracy: The system should be accurate to avoid any faulty fire alarm.

C. Hardware Requirements

To make a prototype of an internet-of-things enabled intelligent fire surveillance system, one needs a microcontroller [22], sensors and a wifi module [23] for sending data from sensors to the internet. In this case, a micro controller integrating wifi which is NodeMCU [24] was chosen. Also, sensors [temperature (DHT11) [25], smoke (MQ2) [26]], a light emitting diode (LED) [27], a buzzer [28] and jumper wires [29] were deployed.

D. Block Diagram

The block diagram below serves as the foundation for the intelligent fire continuous monitoring system (Fig. 3).

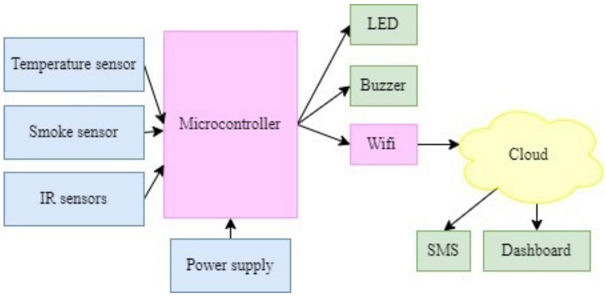

Fig. 3. Block Diagram.

The data issued from temperature, IR and gas sensors deployed in the monitored area are collected. Then transmitted to the microcontroller. Through wifi, sensors readings are displayed on a user-friendly dashboard. When readings are high and will cause a fire (cross a threshold), an alert message is sent to the building guard, a buzzer will beep accordingly and the LED will glow.

E. Circuit

Fig. 4 shows the circuit of the proposed smart system.

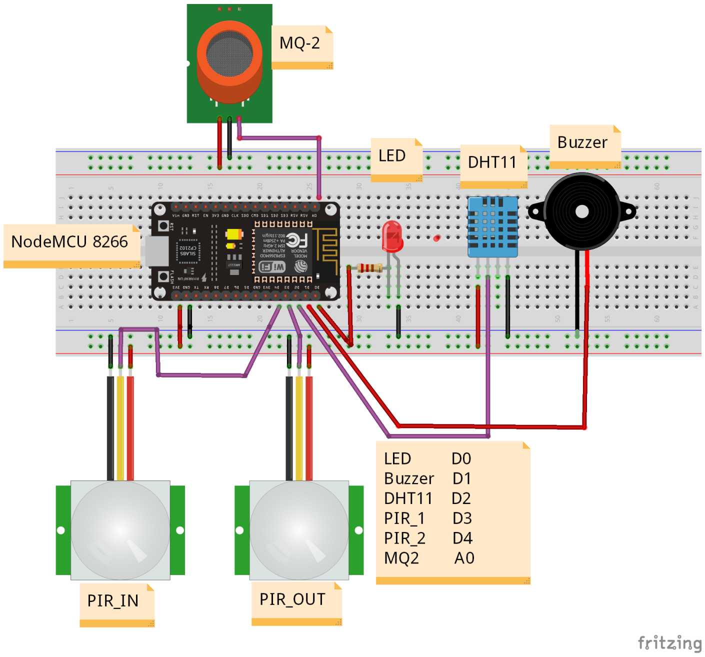

Fig. 4. Circuit Diagram.

F. Prototype

Fig. 5, Fig. 6, and Fig. 7 are a depiction of the exterior view, the exterior view without roof, and the interior view of the finalized system prototype, respectively.

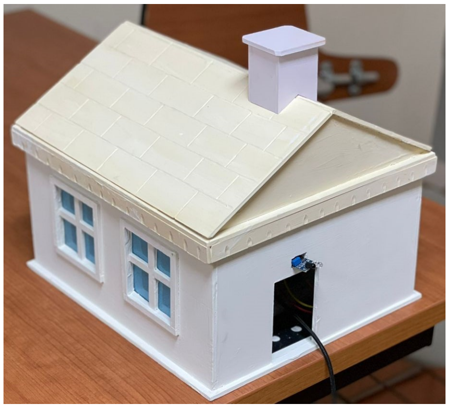

Fig. 5. View of the Developed Prototype from the Outside.

G. Fire Detection

According to Algorithm 1, temperature and smoke data are collected, sent to the cloud. End users are notified in the event that any parameter has abnormally high level.

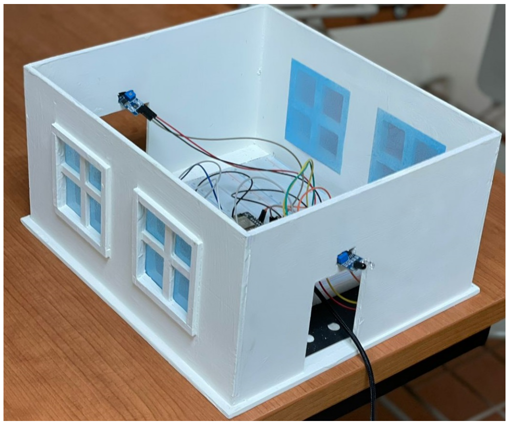

Fig. 6. View of the Developed Prototype from the Outside (without Roof).

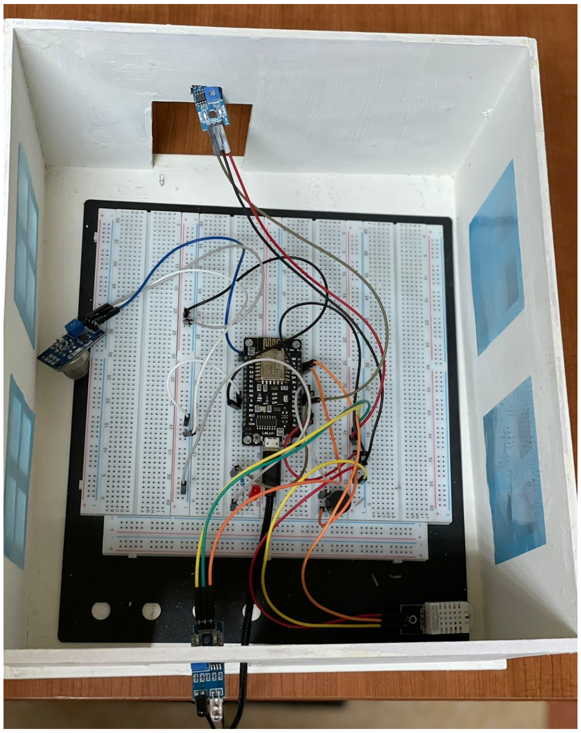

Fig. 7. A View of the Developed Prototype's Interior

IV. Results and Discussion

To visualize sensors' readings, Thingspeak [30] was used. ThingSpeak is a cloud service. This IoT analytics platform solution is really effective. The examination of real-time data streams is possible. Devices can continuously submit data to ThingSpeak. This can make instantaneous visualization of live data. It can also send alerts in emergency cases. The graphs below (Fig. 8, Fig. 9) show the results from the measured values taken from used sensors during an experiment conducted on site. In case of fire, an SMS is sent to the building guard automatically which can let him contacting firefighters immediately (Fig. 10).

Algorithm 1 Fire Detection

```
Require: Temperature sensor, Smoke sensor
Ensure: Warning notification
  Initialization:
  Set threshold for temperature $T_{TH}$
  Set threshold for smoke $S_{TH}$
  Capture temperature measured $T$ from target environment
  Capture smoke measured $S$ from target environment
  if ($T >= T_{TH}$) AND ($S >= S_{TH}$) then
    Red light (LED)
    sound alarm (Buzzer)
    notify the building guard (SMS)
  end if
```

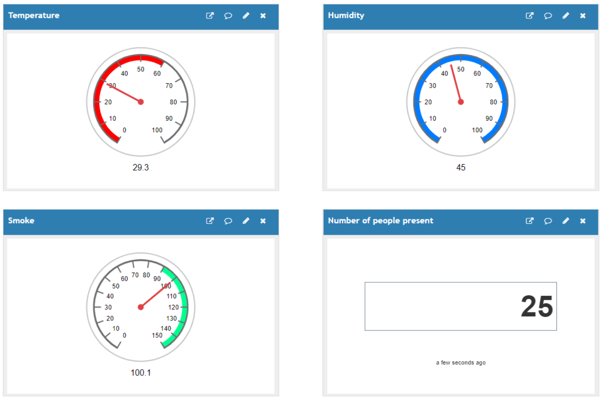

Fig. 8. Screenshot of the Continuous Monitoring in ThingSpeak.

V. Conclusion and Future Work

A cost effective smart fire system that provides real-time monitoring and data collection was deployed in this work. The suggested solution enables remote building status monitoring via a user-friendly dashboard that compiles sensor data into a single web page. A buzzer, a red light, and a message sent to the building keeper's mobile phone inform him whenever a collected parameter exceeds its threshold so that he can call authorities or firemen for assistance right away. The proposed technique has the important benefit of counting the number of persons at the building fire, which will speed up the evacuation procedure. Different scenarios have been successfully tested with the suggested system. The addition of an image processing method with a camera and real-time data analysis from sensors utilizing sophisticated algorithms can be considered as a future project. Another future work can be built around the deployment of a wireless sensor network to cover all the buildings existing in the campus. This can be performed by taking the advantages of the tremendous development that wireless communication technologies are experiencing today.

Acknowledgment

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-02-077-DR). The authors, therefore, acknowledge with thanks the University of Jeddah technical and financial support.

***Abstract*—Increasing postgraduate enrollments gives rise to many proposal documents required for vetting and human supervision. Reading and comprehension of large documents is a boring and somewhat difficult task for humans which can be delegated to machines. One way of assisting supervisors with this routine screening of academic proposals is to provide an artificial intelligent (AI) tool for initial *structural vetting* — checking if sections of proposals are complete and appear where they are supposed to. Natural Language Processing (NLP) techniques in AI for document vetting has been applied in legal and financial domains. However, in academia, available tools only perform tasks such as checking proposals for plagiarism, spellings or grammar, word editing, and not structural vetting of academic proposal. This paper presents a tool named Auto-proofreader that attempts to perform the task of structural document review of proposals on behalf of the human expert using formal techniques and document structure understanding hinged on context free grammar rules (CFGs). The experimental results on a corpus of 20 academic proposals using confusion matrix technique for evaluation gives an overall of 87% accuracy. This tool is expected to be a useful aid in postgraduate supervision for vetting students' academic proposals.**

***Keywords*—Document structure; context free grammar; postgraduate supervision; artificial intelligence; natural language processing**

I. Introduction

Natural language processing (NLP) has been applied in document vetting across domains such as legal practice [1], [2], [3]. These areas of research in extracting information, text summarising and text vetting of documents is a difficult task for humans when several pages of a document or many documents are involved or short time is available. Daramola [4] observed that postgraduate supervisors are faced with the salient task of vetting many students' proposals to conform to certain academic standards, amidst other key roles in the University and must find the right balance for work and effectiveness. In recent times, South Africa experienced an increasing headcount in the number of post-graduate students' enrollment, impacting on the process of screening of submitted proposals [5]. There are yet many sub-standard proposals submissions by postgraduate student novice writers which is impacting negatively on the screening, feedback and vetting time of the assigned supervisors [4], [6]. The timeliness and effectiveness of screening these proposals can be assisted by an intelligent tool performing the specific task of vetting proposals based on prescribed proposal format guideline constructed as context free grammar (CFG) rules.

A. Challenges Facing Supervisors in the Process of Vetting Academic Proposals

Supervision is a critical component of postgraduate studies and many supervisors continue to grapple with promoting research ideas in students' academic writing and students' writing standards [7]; especially when they are still novice writers and in the first year of research writing [4]. There is an increasing pressure on postgraduate supervision as the number of enrollments continue to increase exponentially and universities are under more pressure for more quality research output [8]. Supervisors continue to assess the preparedness and candidature of student enrollees with the vetting outcomes of their proposals. They observed that students often submit proposals that are unacceptable (often too long or too short, poorly written or not well organised and often *missing critical proposal sections*). This is attributed to students not reading or understanding the guideline/instruction format or other peculiar reasons [4], [7]. Supervisors are expected to play a multi-faceted role in their discharge of duties. They are stretched thin as they support students' handling responsibilities and other academic responsibilities for the university [4], [9]. A better approach is to reduce drudgery by introducing technological tools for replacing traditional approach in supervising students [10] and specifically for vetting the structure of academic proposals.

B. What has been done?

1) Support for Students to improve Writings before Proposal Submission: There are lots of approaches and support programmes for scholars to develop writing techniques in the best way possible. There are provisions for writing workshops [11], writing groups [11], informal and online support services [11], mentoring programmes [12], writing editors, various grammar and spell-check productivity tools [13], [14]. These were supports for scholars to improve their writings which is as important as support for supervision. The findings of a review of students and supervisors by Hey-Cunningham *et al.* [10] explained that providing innovative solutions to improve the feedback mechanism in supervision is very important.

2) Support Toolkit for Supervisors: A survey conducted by Hey-Cunningham *et al.* [10] expresses that the theme common to many supervisors was the need for enhancements of supervisory approaches to academic writing standards for which the authors proposed innovations for a timely and effective feedback in supervision. Supervisors engage many generalised tools (e.g. plagiarism checker, editor review tools and grammar cum spell check error tools) to provide revision

TABLE I. CATEGORY OF EXISTING TOOLS FOR POSTGRADUATE SUPERVISION

Supervision tool	**Functions**
Plagiarism checkers e.g. Turnitin	It performs only text extraction for similarity check index against other literature. It is not a self-check document tool.
Feedback review tools e.g. Microsoft's word reviewer	It can assist a human reviewer to perform a document self-check, but it can be time-consuming especially when reviewing proposals of many students.
Grammar and spell check tools e.g. Grammarly, document proWriting aid, etc.	It can only assist the human reviewer to proofread the content of a proposal but not the structure or format layout of the proposal document the proposal document.

supports when screening submitted proposals of students. The perceived functions of these tools are laid out in Table I

C. The New Norm of Technological Aids in Postgraduate Supervision

Productivity tools are replacing and improving traditional and unconventional methods of performing higher education supervision [15], [16]. The effect of COVID-19 pandemic has even made it more necessary. For instance, one-to-one supervision meetings now commonly take place virtually and proposal document review process are more commonly done with various online collaborative productivity tools [17], [18], [16]. Productivity tools has been very effective in engaging dialogue between supervisors and their students, but has been proven to be time-consuming and tiresome when examining a large batch of students' proposals on a computer [19]. Many grammar and spell-check tools are also used by students and supervisors for fine-tuning grammar and editing spelling errors that may not be easily tracked by the eyes of a human reviewer. Popular examples are Grammarly, Microsoft word spell check, pro-Writing aid and language tool.

D. Gap

Researchers have used various forms of text processing technique to automatically extract and analyse documents such as business documents [20], clinical notes [21], legal documents [2], [22] and so on. NLP techniques have been used to perform text information extraction [23], named entity recognition [24], language to SQL translator [25], [26], summarisation [27], classification and examination of other textual contents such as CVs [28], invoices [20] and social media texts [29]. These NLP techniques and others have been largely used around the text content of a document, and sometimes short-text based documents. We considered document understanding an AI task and we have found no tool for vetting of large-content academic text based document such as proposals or similar academic writings. The question then is: *"how can we aid the vetting of academic proposals using existing NLP techniques?"*

E. Proposed Solution

In this paper, we have designed an approach which breaks up a proposal document into `tokens` that are basic recognisable `symbolic parts` of an academic proposal document. We also determine if the input proposal document parts satisfies a valid structure, defined in a proposal guide, by constructing a CFG for the acceptance of a valid proposal structure and REGEX to accept valid terminal symbols. A simple parse tree representation for a proposal document is given in Fig. 1. The document itself as the root node of the parse tree contains Section parts of a proposal document. The algorithm for document parsing is implemented using an existing PDF library named `iTextSharp` Java PDF library.

Similar technique was used for CV slicing [28], metadata extraction of PDF books [30], meta-analysis of clinical notes [21], business invoice document processing [20] and legal documents [27].

F. Contribution to Knowledge

This paper contributes to knowledge in the following ways:

1) the production of a simplistic CFG for recognising an academic proposal structure,
2) design of an approach for the automatic discovery of the document's structure of academic proposals, useful for other large text based document,
3) it promotes further research on automatic slicing of text documents using grammar based rules,
4) design of an algorithm for end-to-end automatic vetting of the logical sections and elements (i.e. structure) of an academic proposal and
5) it describes the implementation and evaluation of a software tool for vetting of academic proposals.

The rest of this document is organised as follows. Section II explains some background to this research problem and related research efforts in text documents comprehension. Section III contains the design concept for this work, while Section IV shows the result of the test of the software tool on proposal documents and the output results generated. An evaluation of these results is done in Section V, while we conclude and state further future work in Section VI.

II. BACKGROUND AND RELATED WORK

There is no directly related research work in vetting academic proposals. This section only explains various related NLP techniques and examples in past research for information extraction and summarisation of documents in general. Then highlights on the formal grammar approaches that has been applied by various researchers for automatic document discovery of large text documents. bluelightAnd lastly discusses some existing proofreading tools.

A. Automatic Document Discovery

NLP has gained a lot of popularity using computational methods to process spoken or written form of text by humans, with applied use cases in various business and enterprise based applications [31]. This field in artificial intelligence (AI) is gaining a lot of momentum and one key applied use is in the area of text processing for information extraction, summarisation or classification [23]. It is used in legal field for similar case matching and text summarisation of legal documents [2]. NLP techniques has been applied successfully for automatic comprehension of clinical notes [21], slicing and information extraction from curriculum vitae (i.e. CVs) [28], understanding

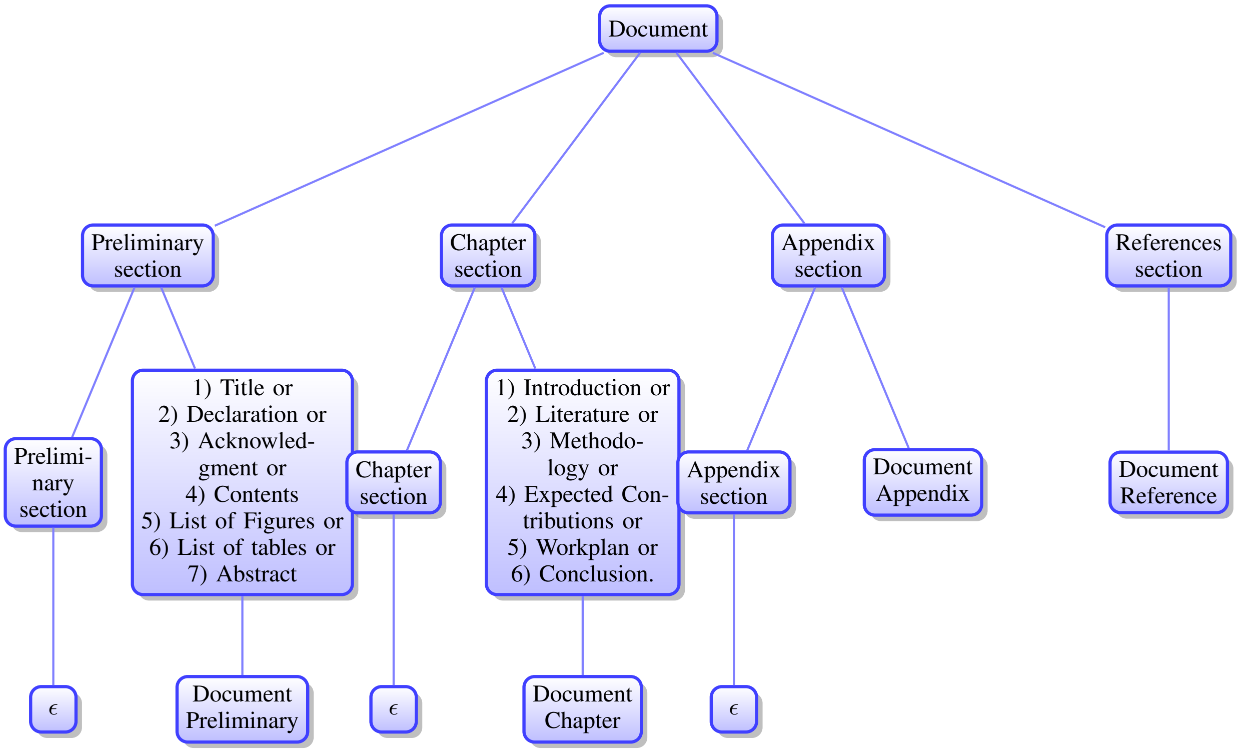

Fig. 1. Proposal Document Parse Tree.

and improvement of requirements documents [32], extracting parts of business (invoice) documents [20], finance chat messaging [33] and so on.

B. Related Work

1) Document Vetting of Legal Proceedings Document: Legal expert systems that use NLP for relevant information extraction and summarization for legal consumption now exist. The computational language processing of legal text documents has been very useful in drafting and analysing legal documents, classifying documents based on relevance to legal case and legal documents discovery and legal citations extractions [2], [3], [27]. More recently, a process tagged "Technology Assisted Review" is associated with the legal profession focused on categorizing legal documents and files based on relevance to case or legal information required [3]. It has become popular and replaced manual review of documents in the legal profession with a more effective automated approach.

2) Automatic Extraction from Business Documents: Glenda and Shilpa [1], implemented an NLP based document vetting process for Banks thereby reducing staff work load and increasing efficiency. NLP techniques have been successfully applied to processing business invoice documents [20], IT Projects system requirements document vetting [32] and automatic comprehension of business finance chats [33]. The applied use of NLP for document processing in finance has become very rapid and important.

3) Automatic Comprehension of Clinical Notes: Modern medicine has embraced NLP techniques for systematic reviews of several clinical trials with great measures of success, known as NLP-enhanced clinical trials research [34]. In a similar vein, a simple NLP translator was designed to decrypt clinical notes, creating friendly user plain texts from complex medical reports [21].

4) Automatic Slicing of CVs: Curriculum Vitae (CV) and resumes are structured documents that contain certain key elements information such as work experiences that talent-hunt specialist usually look out for in CVs during a job advert placement. Emil St. *et al.* [35] applied NLP text extraction techniques on several CV documents to determine candidate professional qualifications, which is useful for review and ease of vetting the relevance of the CV to the role advertised . At another instance, an NLP-based tool was designed to extract the logical sections of CVs using a set of CFG rules [28].

C. Some Background on Document Structure Parsing

The order of arrangement of a document largely explains its structure and can be described using a tree model or an hierarchical pattern [36], [37]. Anjewierden's [36] approach extracted the characteristics of text fonts and lines of text to discover the structure or document style by clustering tokens (in this case, a non-space characters or strings of the English alphabet identified in PDF document) into document elements identifiable on a document page. This was achieved using the characteristics of the token's dimensional co-ordinates on the document, which are upper left position co-ordinates of token and bottom right position co-ordinates on a document's page. These characteristics are syntactically analysed using rules by categorizing text into chunks of meaningful elements of the document that reveals the document structure. According to Anjewierden [36], a set of document object texts is sorted on

TABLE II. Existing Proofreading Tools and Techniques

	Tool	Main function	Technique
1.	Grammarly [38], [39], [40], [41]	Grammar, style and spell check	It combines rules, patterns and AI techniques in machine learning and deep learning
2.	Pro-write Aid [42]	Grammar, style and spell check	AI techniques in machine learning techniques
3.	Typely	Grammar, style and spell check	AI techniques in machine learning techniques aimed at high precision
4.	Custom-built proofreader tool e.g Chinese text automatic proofreader [43]	Grammar, style and spell check	entity recognition and Knowledge graph

their co-ordinate positions on a document page, then parsed through a set of shallow grammars to detect specific elements of the document's logical structure.

D. Discussion of Some Existing Proofreading Tools

There are quite a number of existing proofreader tools available as add-on or online tools for general writing problems on grammars, spellings and styles. Grammarly is quite popular for automatic proofreading in academic writing [38], [39], [40], [41]. Karyuatry and Rizqan [40] explains that Grammarly provides feedback on grammar errors and styling mistakes based on similarity patterns in real time. It is mainly available as a web based tool and built on AI system of a variety of natural language processing (NLP) statistic and machine learning based techniques. Pro-writing Aid is a similar proofreading tool for corrections in punctuation, grammar and style [42]. It is also available online and provides teachers and or students with feedback reports, with which they can improve writing. Proofreaders generally rely on AI techniques to come up with suggested corrections as feedback. Table II summarizes the functions and techniques of some existing tools. The table shows that existing proofreader tools have created a niche for improving writing by providing the feedback on grammar, punctuation and style. However, the novelty of our proposed tool seeks to provide feedback based on the organization (i.e. structure) and sections of an academic research proposal.

E. Definition of Terms

Definition 1: The document logical structure [36] is the layout for its constituents consisting of paragraphs, item lists, sections, tables etc which is easily identified by humans but has to be discovered computationally.

Definition 2: The document (logical) elements [36] is the proper thematic units that can be annotated and form part of the document logical structure, it is also referred to as document text segment. We can identify headings, sub-headings, paragraphs, tables, lists of information, page numbers and headers or footers as structural elements of a document.

Definition 3: A context free grammar (CFG) [44], [45] is a given grammar G defined by a four tuple given as
$G = (N, \Sigma, P, S)$ where:

1) N is a set of non-terminals,
2) Σ is a finite set of terminal symbols, which are the nodes of the grammar (such as symbols, alphabets and numbers),
3) P is a set of Productions and
4) S is a non-terminal start symbol.

.

Definition 4: Regular languages (RL) and regular expressions (REGEX) [44], [45] denotes regular languages. Both are represented by formulas involving the operations of concatenation, union and Kleene star. Regular languages are such languages that can be accepted by a finite automation. In formal terms, a regular language (L) for a given grammar over an alphabet set is Σ defined as any of the following:

1) a singleton language a where $a \in \Sigma$,
2) if A is a regular language, then kleene star of the language (A^*) is a regular language,
3) the empty set of a language A, denoted as $\{\}$ or $\{\lambda\}$ and
4) if A and B are regular languages, then $A \cup B$ the and $A \cap B$ are also regular languages.

III. Design

Fig. 2 describes the steps for structural vetting of academic proposals. The design presents an end-to-end technique of information extraction and vetting of an academic proposal.

A. Overview

An input proposal document is parsed (see Fig. 1 for parse tree structure), by an algorithm into meaningful document symbolic parts consisting of document's sections, chapters and pages. The leaf nodes of the parse tree structure are the document's pages symbols. In our implementation, a valid document page symbol acceptance is further determined by a REGEX parser for recognising and determining the *elements* within the symbolic string. Such elements that may be contained within a proposal document's page symbolic string are document's title, document's author, supervisor names, proposal date, section title, paragraph's heading, paragraph, figure and so on. *See Fig. 3 and 4 for the description of our proposal document elements*. The elements of a proposal document as presented in these figures are the building blocks for a proposal document organization. They appear in a predefined order for an organized paper. The structure of a proposal document is accepted or rejected after full parsing of the input proposal document into parts that validates its structure (i.e. arrangement). The correctness of the elements' structure is based on the CFG Production rules defined and successful passing by REGEX matching of elements contained in the document's parts.

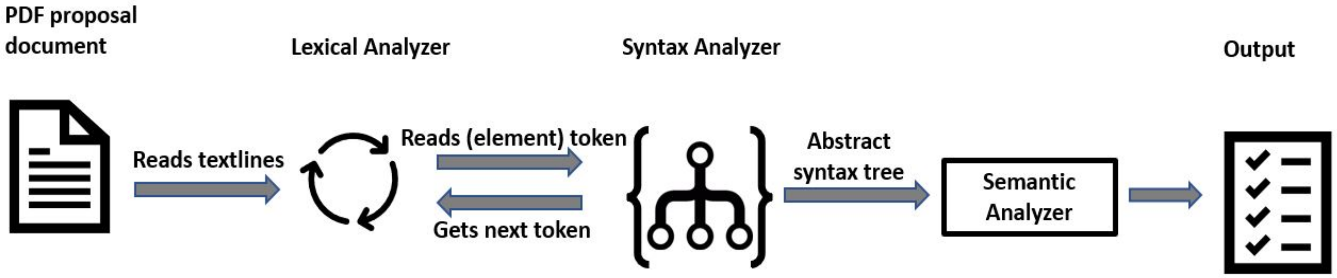

Fig. 2. Proposal Structural Vetting Design

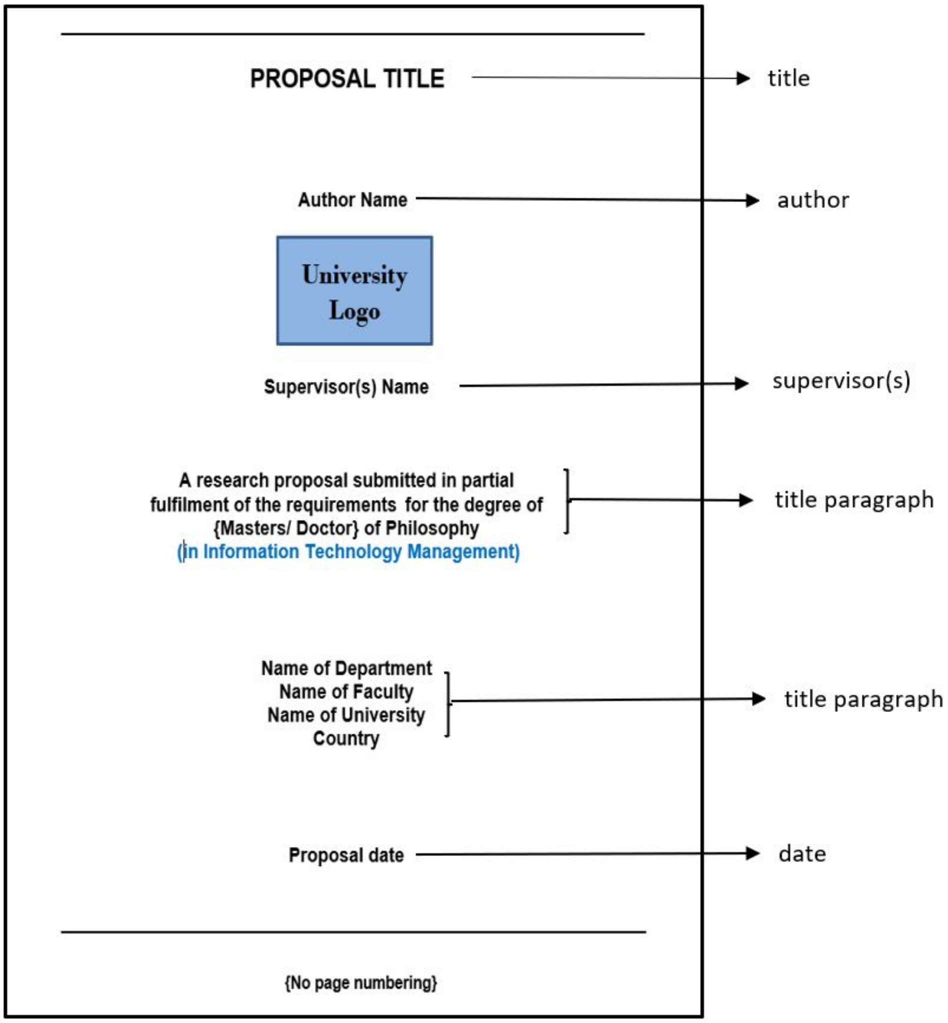

Fig. 3. Structure of Title Page

B. Lexical Analysis of PDF Proposal Document

The input document is tokenized into strings of texts identified by text line sequence on the document page. The text's feature (appearance) on the page described in the Table III is used to categorize text and "line of texts" of a page into meaningful document elements. For instance, a proposal document title is made up of line(s) of text in bold and appears on the first page of a proposal document. The input proposal is analyzed into all the elements that may be contained in a document and as described in Fig. 3 and 4.

Characteristics	Description
Font bold	the thickness of the text
Font size	text height
Line top spacing	height of space between the current line and the previous line.
Line bottom spacing	height of space between the current line and the next line.
Line left align	width of space between the document layout left indent and the line left co-ordinate position.
Line right align	width of space between the document layout right indent and the line right co-ordinate position
Line align type	determined as left, center or right based on the left and right indent

C. Description of Proposal Document Abstract Parse Tree using CFG

To explain the parse tree structure and its nodes, we implement a CFG with a four-tuple as given below:

$$G = (N, \Sigma, P, S) \tag{1}$$

with the following representations:

1) Set of non-terminal variables (N): a collection of all the non-terminal symbols for the production which represents proposal document's section. The symbols are described as Preliminary Section (S_p), Chapter Section (S_c), Appendix-Section (S_a) and References-Section(S_r). $N = \{S_p, S_c, S_a, S_r\}$.
2) Finite set of terminal symbols (Σ): a set of all symbols representing the proposal document terminals. These terminals are symbolic of proposal document pages and described as Title Page (t_p), Declaration Page (d_p), Acknowledgment Page (a_p), Content Page (c_p), List of Figures (l_f), List of Tables (l_t), Abstract Page (a_{bp}), Introduction Chapter Page (c_{intro}), Literature Chapter Page (c_{lit}), Methodology Chapter Page (c_{method}), Expected Contribution Page (c_{contr}), Workplan Chapter Page (c_{plan}), Conclusion Chapter Page (c_{concl}), Appendix Page (p_a) and Reference Page (p_r)

3) Set of Productions (P): are the Production rules (P) which defines the structure of the elements in the pages of the proposal document.

$$S_{doc} \longrightarrow S_p S_c S_a S_r \tag{2}$$

$$S_p \longrightarrow t_p(d_p|\lambda)(a_p|\lambda)c_p(l_f|\lambda)(l_t|\lambda)a_{bp} \tag{3}$$

$$S_c \longrightarrow c_{intro}{\cdot}c_{lit}{\cdot}c_{method}{\cdot}(c_{contr}|\lambda){\cdot}(c_{plan}|\lambda){\cdot}c_{concl} \tag{4}$$

$$S_a \longrightarrow p_a|p_a S_a|\lambda \tag{5}$$

$$S_r \longrightarrow p_r \tag{6}$$

4) Non-terminal start symbol (S): The start symbol for this grammar is the input document proposal, denoted by symbol S_{doc} .

D. REGEX for Terminal Symbols Matching

The terminal symbols of the CFG tuple are further broken down into regular expressions for recognising the page elements implemented by the symbols. The terminal symbols can be substituted with the following symbols in REGEX below.

$$t_p = e_t e_a e_s e_{tp}^{1,2} e_d \tag{7}$$

$$d_p = e_{st} e_p^{+} e_n \tag{8}$$

$$a_p = e_{st} e_p^{+} e_n \tag{9}$$

$$c_p = e_{st} e_{ta} e_n \tag{10}$$

$$l_f = e_{st}(e_i|e_{ta})e_n \tag{11}$$

$$l_t = e_{st}(e_i|e_{ta})e_n \tag{12}$$

$$a_{bp} = e_{st} e_p^{+} e_n \tag{13}$$

$$c_{intro} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{14}$$

$$c_{lit} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{15}$$

$$c_{method} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{16}$$

$$c_{contr} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{17}$$

$$c_{plan} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{18}$$

$$c_{concl} = e_{st}((e_p|e_{sst}|e_f|e_i|e_{ta})^{+} e_n)^{+} \tag{19}$$

$$p_a = e_{st} e_f^{+} e_n \tag{20}$$

$$p_r = e_{st} e_r^{+} e_n \tag{21}$$

The symbols \w, \s, \n, \d matches single word, single space, a newline character and single digit respectively

E. REGEX for Document Elements Matching

The elements contained in a proposal document's pages can be matched with corresponding regular expression defined in the Table IV. The regular expressions stated are used to represent the language of the structure in English alphabet strings for every element that may be contained in a proposal document. We define a language acceptor algorithm which accepts or rejects the element token based on the matching regular expression. The language acceptor determines if the element is well-formed and which element class it belongs to. The proposal document is vetted structurally correct if all the parsed elements are accepted by the language acceptor.

F. Document Parsing

This section explains possible derivations of a proposal document given the grammar defined and its set of Production rules. Given the input proposal document which is of the start symbol S as given below, then the document can be parsed as follows:

$$S_{doc} \Longrightarrow S_p \cdot S_c \cdot S_a \cdot S_r \quad (rule\ 2) \tag{22}$$

A proposal document can be made up of the following section parts: Preliminary Section(S_p), Chapter Section(S_c), Appendix Section(S_a), Reference Section(S_r).

$$\Longrightarrow t_p \cdot d_p \cdot c_p \cdot a_{bp} \cdot S_c \cdot S_a \cdot S_r \quad (rule\ 3) \tag{23}$$

The Preliminary Section can be made up of Title Page (t_p), Declaration Page (d_p), Contents Page (c_p) and Abstract Page (a_{bp})

$$\Longrightarrow t_p{\cdot}d_p{\cdot}c_p{\cdot}a_{bp}{\cdot}c_{intro}{\cdot}c_{lit}{\cdot}c_{method}{\cdot}c_{plan}{\cdot}c_{concl}{\cdot}S_a{\cdot}S_r \ (rule\ 4) \tag{24}$$

The Chapter Section can be made up of Introduction Chapter (c_{intro}), Literature Review Chapter (c_{lit}), Methodology Chapter (c_{method}), Workplan Chapter (c_{plan}) and the Conclusion Chapter (c_{concl}).

$$\Longrightarrow t_p{\cdot}d_p{\cdot}c_p{\cdot}a_{bp}{\cdot}c_{intro}{\cdot}c_{lit}{\cdot}c_{method}{\cdot}c_{plan}{\cdot}c_{concl}{\cdot}S_r \quad (rule\ 5) \tag{25}$$

The Proposal document may not contain an Appendix Section.

$$\Longrightarrow t_p{\cdot}d_p{\cdot}c_p{\cdot}a_{bp}{\cdot}c_{intro}{\cdot}c_{lit}{\cdot}c_{method}{\cdot}c_{plan}{\cdot}c_{concl}{\cdot}p_r \quad (rule\ 6) \tag{26}$$

The Derivation 26 is an instance of a valid proposal structure and has been successfully parsed by the four-tuple grammar defined for the structural vetting of a proposal document. The expressions contained in Derivations 22 to 26 shows the complete parsing. Further understanding of the document's structure is done by recognising the document *elements* contained in each symbolic string of the language generated by the parser, refer to Derivations 7 to 21. Elements are also matched by their corresponding REGEX description in Table IV

G. Algorithms

This algorithm for the automatic structural vetting of an academic proposal document takes as input, the proposal document, and outputs the document with highlights of any structural defects that may have been picked. We present the algorithm as given below:

Algorithm 1: Structural Vetting Algorithm

```
Data: PDF proposal document, $S_{doc}$
Result: Highlighted PDF proposal document, $S_{hl}$
Parse input document into document parts using
  PDFLibrary.Extract($S_{doc}$)
if ValidParse(Document parts) then
    if REGEX_Match(Elements contained in
      Document Parts) then
        if REGEX_Match(words contained in
          Document Elements) then
            PROCESS COMPLETE: Document
              verified successful

return Return $S_{hl}$
```

IV. Implementation and Results

The algorithms presented in this paper were implemented using C sharp Microsoft's .Net library. The software embeds an iTextSharp version 7.0 library used for PDF document tokenization and manipulation of text. The Auto-proofreader tool interface displaying its menu controls is presented in Fig. 5.

Table V shows the results from the implementation of a corpus of 20 academic proposals. All the results vary in the degree of the number of error or success feedback reported by the tool. All the elements in each document have been parsed against defined rules and REGEX patterns based on a given instruction format guide.

A. Description of Dataset

A corpus of ten (20) proposals collected from the online digital ecommons of various Universities was used to carry out the experimental result. The dataset consists of academic proposals of MSc and PhD post-graduate students in Information Systems' related discipline that were accessed on Universities institutional repository (IR) or available on online digital-common. These are academic proposal thesis submitted between year 2015 and 2021.

TABLE V. Results of Vetting of 20 Academic Proposals

S/N	Document Elements	TP	TN	FP	FN	Prec	Rec	Acc
1	Title	10	5	5	0	0.67	1.00	0.75
2	Author	5	5	9	1	0.36	0.83	0.50
3	Supervisor	15	5	0	0	1.00	1.00	1.00
4	Title-Paragraph	21	16	0	3	1.00	0.88	0.93
5	Section-Title	111	0	0	13	1.00	0.90	0.90
6	Sub-Section	2041	50	0	826	1.00	0.71	0.72
7	Paragraph	4019	255	0	538	1.00	0.88	0.88
8	Page-No	3011	0	0	0	1.00	1.00	1.00
9	Date	6	1	0	13	1.00	0.32	0.35
	Total	9239	337	14	1394	0.99	0.87	0.87

B. Result and Discussion

The difference in the number of correctly identified document elements by the tool differs significantly for some logical elements due to the complexities of computationally identifying them. The tool detected and proofread the structural items on the preliminary pages with better precision and accuracy. The overall tool precision and accuracy is given as 0.99 and 0.87, respectively. Refer to expressions given in Equation 27 and 29

Fig. 5. Autoproofreader Tool and Menus.

V. Evaluation

We present the evaluation for the tool in terms of accuracy for correctly classifying/ recognising syntactically right or wrong elements in the document. We present the confusion matrix model evaluation with the performance metrics of sensitivity, precision and accuracy given below. Table VI gives a brief explanation of how the confusion matrix is applied for evaluating the tool.

Overall Precision:

$$\frac{TP}{(TP+FP)} = \frac{9239}{(9239+14)} \approx 0.99 \tag{27}$$

Overall Recall:

$$\frac{TP}{(TP+FN)} = \frac{9239}{(9239+1394)} \approx 0.87 \tag{28}$$

Overall Accuracy:

$$\begin{aligned} & \frac{(TP+TN)}{(TP+TN+FP+FN)} \\ & = \frac{(9239+337)}{(9239+337+14+1394)} \approx 0.87 \end{aligned} \tag{29}$$

where:
TP = True Positives

[h!]

TABLE VI. Confusion Matrix Evaluation

Item	Auto-proofreader Tool(T/F)	Benchmark (P/N)	Description
TP	T = Identified	P = Correct Elements	Identified correct Elements
TN	T = Identified	N = Incorrect Elements	Identified incorrect Elements
FP	F = Did not identify	P = Correct Elements	Did not identified correct Elements
FN	F = Did not identify	N = Incorrect Elements	Did not identified incorrect Elements

TN = True Negatives
FP = False Positives
FN = False Negatives

VI. Conclusion and Future Work

Identifying errors in a (lengthy) textual document is an expert task that can be made into an artificial intelligent (AI) tool which can then assist human reviewers (i.e. Supervisors) to more effective and productive, especially when faced with many documents (i.e. academic proposals). The tool will not only be useful for academic proposals but can be refined for many varying template-based documents. In this paper, we have presented the technique and design of the tool for vetting an academic proposal for layout or structure-based errors. This technique slices a proposal document into its minute structural components (which we have termed as document elements contained a document section) and performs a check of correctness. The technique allows the slicing of the academic proposals into separate sections as documents and lastly allows the download of a **vetted** academic proposal document which can be used as a feedback to Students' candidate after an automatic vetting. The designed software tool was evaluated on twenty (20) proposal documents which gives an accuracy of 86%. The accuracy of the tool is only based on specific elements for evaluation but it can be made more robust with vetting more components (or elements) contained in a document section such as images (or figures) and tables. The software design is template specific but can be extended for various kind of template-driven text document vetting.

In the future, we will explore the structural vetting of more document logical elements: figures/images, tables and citations. We will also extend the tool to perform rule-based sentence level grammar vetting.

Mobile Application Prototype: Learning in the Programming Course in Computer Engineering Students

Lilian Ocares-Cunyarachi, Laberiano Andrade-Arenas
Facultad de Ciencias e Ingeniería
Universidad de Ciencias y Humanidades
Lima, Perú

Abstract—**Students need to continue with the learning process related to the world of programming because today are in the era of technological globalization. Therefore, it is very important to learn about it, since programming is used in different areas and as a result obtain software, electronic devices, among others. seek to design a mobile application that helps students learn much more about programming, since students in the first cycles of computer science and computer science have difficulties learning about different programming languages. That is why the application seeks to help the student by complementing their learning in such a way that they can obtain favorable results in their progress thanks to the development of the application. The objective is to design a mobile application for teaching programming in a didactic way that helps computer science students with learning difficulties. The methodology used is Design Thinking, because it is an agile methodology that is based on phases that help us understand and collect information about the problem encountered in order to provide a solution. As for the case study, the design of the mobile application and the detailed development of the prototype are shown. The result obtained is the prototype of the mobile application in which students with learning difficulties will benefit. In addition, a survey carried out at the University of Sciences and Humanities to students and teachers is shown, where very relevant data is obtained according to their learning.**

Keywords—Design thinking; learning; mobile application; students; programming.

I. Introduction

Due to The worldwide pandemic by the coronavirus or also called Covid-19 has led to a global rethinking as teaching either in schools or universities, around the world countries had to close student centers for several weeks due to the pandemic, therefore, technology has taken huge steps in a very surprising and significant way [1],[2],[3]. An important factor is programming; because websites, applications, software and everything have as a tool today to work from home or remotely or take classes from the comfort of home requires devices that are developed based on codes and that is where programming becomes of paramount importance worldwide [4],[5].

The education related to programming is very essential for the technological development in Latin America and around the world, this is because most of the organizations, in the labor and student field are subject to the applications that are created through codes coded in different programming languages performing their functionalities correctly [6]. However, programming is involved in the development of different industries [7]. Nowadays learning the art of programming has a high transcendence in the trade field as learning English, since nowadays it is very essential worldwide, therefore programming can not only be useful for computer engineers or computer technicians, because programming is present in everything that surrounds us, that is why it can be for everyone who has a university degree as well as for those who do not have one, it does not vary in the result of learning. It should be noted that the most interesting thing about a programmer is that he can create new things from 0 [8] by means of codes for the resolution of existing problems.

Unfortunately, the Latin American continent does not have enough experts to be a world power in the field of software or information technology in general [9]. Due to the fact that there is no incentive since childhood in the art of programming, so it is important to encourage children today as well as young people with seminars or courses to join their own research establishments related to computer science [10]. Being more and more innovative, having as direct consequence the economic and social growth of the country where an innovative method is applied in such a way to begin to create a better future [11],[12].

Several university students of the first cycles in the University of Sciences and Humanities return to take the course of Programming is why the importance of this research is to help students with this mobile application so they can learn more about programming in a didactic way since that is an advantage for students in the student subject. Likewise, Peruvian universities in an applicative approach in programming generate great uncertainty to their students of the first cycles, since, they only count on referring their grades. The most common problems in these students is the difficulty of learning programming languages. For all these reasons, the present investigation took as a reference the University of Sciences and Humanities in the faculty of computer engineering where students of the first three semesters are involved, identifying some problems of complication in programming.

The methodology to be implemented is Design Thinking, which is an innovative procedure to produce outstanding ideas with great effectiveness in understanding and offering a solution to the needs of the users in order to obtain favorable results.

The implementation of the mobile application is very important, so formulate the following question: How will it improve the learning of computer engineering students in the programming course?

The objective of this research work is to implement a prototype of a mobile application to improve learning in a didactic way with the students of the first cycles of the programming language course.

The paper is structured as follows: Section II describes in detail the literature review. Section III shows the methodology, Section IV shows the case study, Section V shows the results and discussion and finally, Section VI presents the conclusion and Section VII presents the future work.

II. Literature Review

This section presents an overview of different studies on learning programming in a way that is easier for students to understand. Not only using different methods but also explaining why the different methods should be used creatively depending on the results.

According to the author [13], he mentions that the development of mobile applications is a group of processes and procedures that relate to software for different wireless computing devices either small or large, such as smartphones among others.

Therefore, the author [14], refers that the development of web applications and mobile applications has its origin in open source development. However, a very important difference is that mobile applications are commonly written specifically to take advantage of the unique properties or functionalities of a mobile device. For example, a gaming application can take advantage of the phone's accelerometer, just as a health device can take full advantage of a smart watch's temperature sensor.

Likewise, the authors [15], highlight that the most important mobile platforms today are Apple's iOS and Google's Android plus an important fact is that Apple phones and tablets come preinstalled with essential applications, including a full web browser and the app store. Android devices also come preinstalled with similar applications through the Google Play Store now live in an era of technology agigantada, where interact daily with our mobile devices, in this context, this research project is aimed at developing an interactive mobile application to enhance the learning process to students through programming.

Education is very important for the formation of students in general, likewise it is advisable to integrate the use of mobile applications in the teaching-learning process of all other fields, to take advantage of the benefits brought by mobile technology and promote students to create a creative study habit [16]. Concluding that the optimal results have been obtained, successfully implemented in the learning process related to programming, thus having a significant impact on this type of implementation; obtaining a comfortable result.

Most first-year computer science students will find learning object-oriented programming difficult. Serious games have once been used as an approach to handle this problem. But most of them cannot be played on mobile devices. Obviously, this does not suit the era of mobile computing that aims to enable students to learn programming skills anytime, anywhere, thereby enhancing the learning of programming languages. A research project started more than a year ago and aims to create a serious gaming approach related to mobile devices along with an educational game for learning programming To date, the project has conducted a literature review to understand the existing work and identify problems in the field, conducted surveys to find out the needs of students for a mobile device based approach and then set up a serious mobile device based gaming approach with a developed prototype of the game [17]. It is expected that the presented project will be useful and helpful to integrate more effective approaches with didactic mobile games for learning object oriented programming in such a way to enhance the learning experience for university students.

Thus, the authors [18], describe that mobile technologies have a great impact on education and teaching of computer science programming, which leads to the development of tools to benefit this process in introductory courses. The increased use of cell phones makes it possible to encourage their use in programming courses using a mobile platform, seeking to improve classes with out-of-class support. It shows the structure and experience of use of Paepoo, Platform for Learning and Education of Object-Driven Programming, a mobile application where students, enthusiastic about the use of their cell phones, accept an active and committed role in their learning process, taking advantage of the support platform with great results and approval.

The authors [19], emphasize that to explicitly model complex dependencies between applications, adopt a dynamic graph structure to learn users' interests. First, extracted users' interests in each application usage graph using the hierarchical graph attention mechanism. Second, capture the time evolving user interests and generate the dynamic user embeddings by modeling the temporal dependencies among multiple application usage graphs. Finally, obtain the current user interests in the current application usage graph, merge the interests of multiple users, and generate comprehensive user embeddings for the next mobile application recommendation.

The authors [20], mention the rapid development of information technologies makes it possible to create and innovate more mobile devices. Most of the distance learning students require access to analysis materials such as communication tools and also extra learning media not only at home or at their workplace. The purpose of this article is to expose the modalities of mobile technology in computer science and programming education. According to the results of surveys conducted in elementary schools, high schools and universities. It is possible to mention that mobile devices are used more and more in relation to learning. The results of surveys and experiments show that mobile devices have the potential to improve education in computer science, programming and algorithms. The article explains the experience of teaching and development of mobile applications, for teaching and for users with special needs.

Likewise, the authors [21], researched and analyzed the development of a mobile application for the education of basic concepts such as programming. The purpose is to help students acquire skills while having fun and using their own devices. The mobile application was designed according to a cross-platform approach to reach the widest possible audience of students, saving development and maintenance time and effort. The code is fully shared between IOS, Android and Windows mobile platforms, allowing students to install the app on any device. The core application is based on a multivalent system to make the app interactive, flexible and dynamic and provide students with personalized instructions [22]. A prototype showing the main features of the application is presented.

In summary, the authors analyzed in their research conclude that over the years in the field of learning together with technology has been advancing rapidly so must adapt to the era of globalization using beneficial tools that help us to be able to do new things from 0 as is the programming applied in computer science.

III. Methodology

The Design Thinking process is made up of 5 phases and the Design Thinking methodology contains iterative processes, it is not linear, therefore it is a process that serves to address complicated challenges made up of the so called wicked problems or drawbacks, drawbacks that are complicated to conceptualize and solve as they was discovered during the practice of the process of the methodology. The most interesting thing is that at any time you can take steps forward or backward if required in the Design Thinking process, jumping even to non consecutive stages, collecting information and generating a huge proportion of content, which will grow or shrink depending on the stage in which are. Fig.1 shows the phases that implement next [23], by means of questions so that these are answered in an effective way in order to have good results.

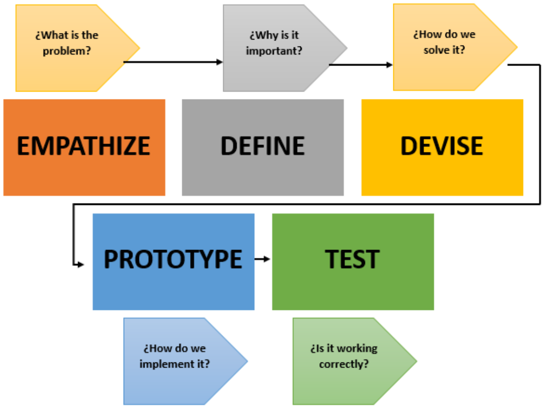

Fig. 1. Design Thinking.

Phases of Design Thinking

1) Empathy: As the first phase begins with understanding the needs, based on the requirements of the users, that is why in this first phase we must put ourselves in the situation of the users, so that from this we are able to create resolutions for a better lifestyle.

2) Define: As a second phase must process the information collected throughout the previous stage in such a way that are left with what really adds value to the research, therefore, it leads us to the scope of the perspectives. Therefore, identify drawbacks to solve the problem as a key point to obtain a satisfactory result, but above all innovative.

3) Ideation: As the third stage of Ideation, its purpose is to generate an infinite number of possibilities for the resolution of the problem encountered, which is why should not just go with the first thing that comes to mind, must analyze the situation well. At this stage, the requirements favor the creation of the application. Sometimes, the most extravagant ideas are the ones that produce creative resolutions.

4) Prototyping: As a fourth phase implement prototyping in which turn ideas into reality. That is, building prototypes directed towards the ideas helps us to visualize the probable resolutions. Therefore, at this stage can see the resources that must improve or modify in order to reach the final result.

5) Testing: Throughout the Testing stage, the prototypes will be tested with users based on the solution being implemented, therefore this stage is crucial which will allow us to detect improvements as well as failures to be solved, throughout this stage it evolves because it starts with the initiative until get to turn it into the solution were trying to find in such a way that return a properly developed final product.

IV. Case Study

1) Empathy: Applying the first stage collected detailed information by means of surveys with university students of the first cycles, in the first instance, in order to know if they had an elementary idea of what are the algorithms related to programming, therefore it was mentioned if they would use a didactic application to complement their learning in their classes. Likewise, in order to know and understand the inconveniences and problems that emerge in the students today and to understand their situation, in such a way to collect the case since it is of great importance for our inquiry and execution of this investigation. Tables I, II, and III were validated by expert judgment. Validation was of contents where the validation scale was low from 0 to 35%; from 35% to 70% medium; and from 70% to 100% high to medium. the evaluation criteria were relevance, coherence and clarity. Obtaining 85%, giving as approved by expert judgment. As it is observed in Table I, 3 questions were made to the students of first cycle of the career of computer science where the following questions were asked Do you like the art of programming? Do you have difficulties in understanding the different programming languages? And finally, is it difficult to learn to program? Thanks to these questions valuable information was collected.

TABLE I. Questions on the Taste of Programming

	Questions
Q1	¿Do you like the art of programming?
Q2	¿Do you have difficulties in understanding the different programming languages?
Q3	¿Do you find it difficult to learn to program?

2) Define: In this stage seek to detect a starting point based on the detailed information through the data obtained in the previous stage from the surveys, so that can propose the best solution for that need. As understand the student's need and have access to the different examples and tasks based on algorithms, as shown in Table II, 4 questions were asked based on stage where the following questions were asked: As a student, how important do you think algorithms are in the creation of something new? How do you create a programming algorithm? How do you develop a programming algorithm? What programming language do you often use? Thanks to these questions gathered important information.

TABLE II. QUESTIONS ON THE IMPORTANCE OF PROGRAMMING

	Questions
Q1	¿As a student, how important do you think algorithms are in the creation of something new?
Q2	¿How is a programming algorithm created?
Q3	¿How is a programming algorithm developed?
Q4	¿What programming language do you often use?

3) Ideation: Keeping in mind the two previous phases, which are empathizing and defining, several ideas were obtained to decide the functionality of the application. Likewise, the needs of the students will be aligned with the facilities provided by the implementation of the application. As shown in Table III, three questions were asked to students of the first cycle of computer science where the following questions were asked: How often do you use technological applications on your mobile device? Do you consider innovative the idea of creating a mobile application that helps to reinforce your knowledge related to programming? Do you think it would be helpful to use a mobile application to learn to program through algorithms? Thanks to these questions a clearer perspective was obtained.

TABLE III. QUESTIONS ON THE MOBILE APPLICATION

	Questions
Q1	¿How often do you use technological applications on your mobile device?
Q2	¿Do you consider innovative the idea of creating a mobile application that helps to reinforce your knowledge related to programming?
Q3	¿Do you think it would be helpful to use a mobile application to learn programming through algorithms?

4) Prototyping: Once the idea was clear, we designed the didactic application for learning programming based on the different programming languages, adding to this that is implemented with a virtual assistant (Chatbot) which will accompany and help the user to perform their learning correctly in such a way to obtain favorable results.

- Python: Python is a computer programming language widely used in the development world widely used in the development world for many different applications. many different applications. Widely used in scientific research and in fields ranging from finance to biomedicine, Python is from finance to biomedicine, Python is making inroads in many professions. many professions. The world ranking of the most popular and popular and popular programming languages shows that Python is among the top three Python is among the top three most preferred programming languages worldwide [24]. This is why it is important to introduce the Python language as a programming language in the computer and research and research centers in such a way that it can be applied in schools and in all in schools and in all Peruvian universities.

- Javascript: The JavaScript language was initially created for user-side programming in web browsers, nowadays its engine is included in various types of software programs, because the semantics of JavaScript are complex [25], especially thanks to its dynamic nature as the understanding and knowledge of JavaScript programs are challenging tasks for a programmer.

- Pseint: In introductory programming courses, students learn the logic for algorithm development. In these courses the usual methodology is to teach students the logic for the construction of algorithms in Spanish using paper, then in a second course a specific programming language is taught, usually C or Java. However, the syntax and instructions of the latter are in English [26]. This study analyzes the use of PSeInt as a support for teaching programming with syntax and instructions in Spanish.

- C#: The programs that are created have different types of formatting, i.e. the syntax that is used. The syntax in C# is a sequence of rules and processes that lead the composition of a procedure. These rules must be understood by the compiler that is executing the program in such a way as to produce a valid C# program, for example, they must implement how a line of C# code begins, how it ends and at what point to use, for example, quotation marks, brackets or braces [27]. The C# language excludes uppercase and lowercase letters, and the C# language is programmed in lowercase letters.

- Java: Nowadays we are in an environment of the Internet era, by means of the learning environment in this case of the university students suffering transcendental changes in their education, besides there has been a new change in the education, in which the learning by means of Internet became a tendency [28]. The java course is a must for every programmer, besides, it is worth mentioning that java is a very required platform, above all, safe and reliable for its development.

- Html: Learning Html presents challenges similar to those of learning a programming language, i.e. it is common for a beginner programmer to have a Html validator, and there are limited tools to help programmers who are just starting out in the programming world to fix bugs in their Html code. In this analysis, we used visualization techniques to show the structural and contextual information of Html code. looked at condensing and visually representing the relevant points of the Html code [29]. In other words, to allow novice programmers to obtain data about the composition of the Html code and to locate any semantic errors in corresponding syntax.

- Kotlin: Pure Kotlin code excludes the utilization of any java graphics library where it can be transpiled to JavaScript and realized on a web. Nonetheless, writing in Kotlin code will run without modification both in a web browser and also in jvm likewise being trivial in such a way precise adherence to a timely methodology is needed [30].
- Php 8: Php 8, was released at the end of 2020, being a fundamental update of one of the most famous programming languages so to speak so implemented in 4 out of 5 developed websites that use a server-side language also note that a free platform so the code is done on Linux, Windows. Php is subjectively easy to learn [31]. Many of the novel properties of PHP 8 where they make the code more efficient and accurate for a good development.

All the programming languages mentioned above are very essential to be able to program which is why these languages were chosen, because they are very required today in the labor market, also these languages will be implemented in the mobile application.

5) Testing: In this last phase verified in detail what was done, identifying each phase its good execution for the realization of the learning prototype related to the different programming languages, therefore a good performance was observed.

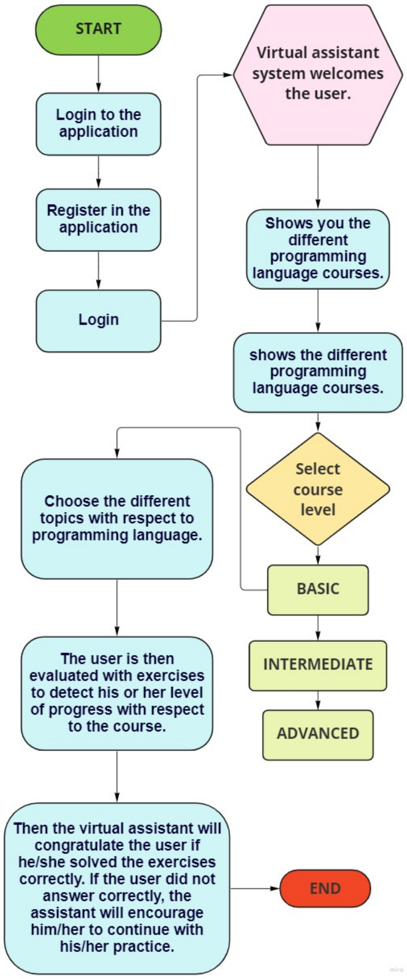
Fig. 2 shows the flowchart which begins by entering the application so that then be registered and then go to enter the application after the main screen where they will be attended by a virtual assistant who will welcome the registered user, for this the assistant will show the programming courses that are available for the user to choose any of them, you can also choose whether to start with the basic course, intermediate or advanced, Once the student has studied the selected programming language, he will go through a test of exercises where he will develop what he has learned. It is worth mentioning that if the student makes a mistake in the exercises, the virtual assistant will encourage him with some messages so that he keeps on trying, and if he solves the exercises correctly, he will be congratulated for what he has learned.

V. Results and Discussion

A) About the Case Study

In this section for the case study, it was carried out the design of the mobile application implemented with a chatbot for learning the programming course applied in computer science students as well as this application can be used by people who need to know more about the world of programming is why the implementation of the application is very beneficial because it helps to complement the knowledge acquired in addition to put them into practice as the system comes with a list of exercises so that they can be developed and increase the student's knowledge.

Fig. 3 shows the user's welcome and registration interface by entering their first name, last name, Gmail and password, and they can also log in directly from their Gmail email if they require it so that they can register in the application.



START
Login to the application
Register in the application
Login

EXCEPTION HANDLING

Excellent Lilian, keep it now we will put into practice what we have learned

Displays prime numbers between 1 and 100.

```
import java.util.Scanner;

public class sampleApp {

    public static void main(String[] args) {

        for (int i=1;i<=100;i++){

            int raiz=(int)Math.sqrt(i);
            int contador=0;

            for (int j=raiz;j>1;j--){
                if (i%j==0){
                    contador++;
                }
            }

            if (contador<1){
                System.out.println(i);
            }

        }
    }
}
```

Good job, congratulations keep it up

Fig. 6. Course Level.

they were also asked if they had difficulties in programming, thus obtaining 30%.

Fig. 8 shows the results as first question 36% answering that algorithms have great relevance in the creation of something new, as second question 18% mentioning that algorithms are created by means of sequences or processes that must be executed efficiently, as third question 18% were obtained by means of tools such as the different languages that exist, also as fourth question 28% were obtained where students mention that they use Java and Python.

In Fig. 9, we return with a 35% mentioning that students use their device most of the time, also as a second question obtained a 31% where students mentioned that they consider the innovative idea of using a mobile application to help reinforce their learning based on programming and finally as a third question obtained a 34% having as a result that if it would be very useful to use the mobile application to help them to increase their learning ability related to the different programming languages.

B) About the Methodology

The Design Thinking methodology has the possibility of approaching the creations in different fields in an adaptable and extreme way. Design Thinking also has a sequence of tools that are applied throughout the process of building the innovative product, therefore it can be used constantly because it is based on the resolution of problems from the customer's point of view, that is why the Design Thinking methodology was chosen because it is considered quite suitable to propose IT resolutions in process models in which prototypes are applied to clarify the requirements to the customer's satisfaction, some of these process models are used as prototypes for their solution. They allow a great relationship with the users, such as the construction and evaluation of the elaborated prototypes.

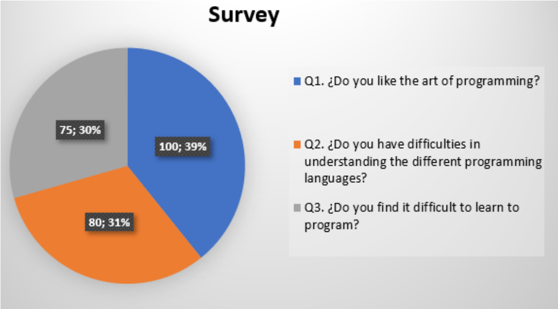

Fig. 7. Results on the Taste of Programming.

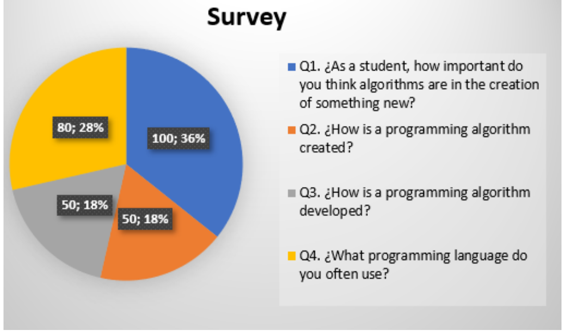

Fig. 8. Results on the Importance of Programming.

1) Advantages: One of the benefits of using this Design Thinking methodology is that it promotes the immediate solution to the problems that may arise during the development of the project. This is why the client is placed as the center of the construction process, in which the development is clear to overcome the challenges by guiding on the techniques and tools to use to solve a challenge both in an organization and in other spaces. It is necessary to emphasize that this methodology is people-centered, this means that it is a user-centered procedure whose fundamental potential is to solve real problems, also another benefit is that it adapts to the solution of the product and service through the customer's needs, thus excellent results are obtained.

2) Disadvantages: A disadvantage of the methodology is that it cannot be used for all types of projects, so it should be used in projects that require design thinking steps.

3) Comparison: Design Thinking is not only used by companies, in such a way that prestigious organizations have discovered its benefits and have incorporated it into their daily work because it designates the user as the main axis of the construction process before other approaches that try to move from thought to action. It also invites the user to be able to accept a more active role in the design of the required product, which involves the agents to dialogue between the user and the person in charge of making the innovative proposal, therefore the first approach of a team in innovation, it is essential to perform it in a focused way to a specific problem and then use the Design Thinking methodology offering a process where the stages have the possibility of being retaken and reiterated without further major limitations, In Scrum, you can work with a constant flow of projects that have to answer to the priorities through sprints, so there is a sequence of meetings and therefore there is a point where there may be a contrast, however, have the possibility to take certain resources of Scrum as prioritization, or adopt organizational points that contribute to group work.

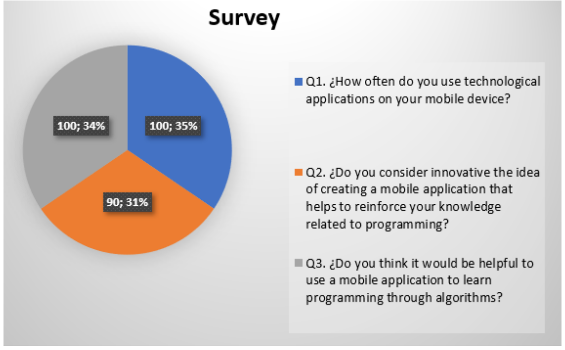

Fig. 9. Results on the Mobile Application.

TABLE IV. COMPARISON

Design Thinking	Cascade	Scrum
They focus on the users to obtain better results.	Clear structure of the methodology	It is required for large projects.
Team collaboration in such a way accelerates the cycle for the development of new solutions.	It presents difficulty in the required changes.	Provides a democratic approach.
Innovative ideas for good control and performance.	Excludes the customer or end user.	Requires a thorough homework review.
Reduces project costs and risks.	Determines the target immediately.	Requires those who use the scrum methodology, have a high level of qualification.

Table IV shows in detail the comparison of the Design Thinking, Cascade and Scrum methodologies, identifying that Design Thinking reduces risks at low cost and is adaptable to changes, and the cascade methodology presents difficulties when making required changes, and finally the scrum methodology requires a thorough review when performing tasks.

TABLE V. TRADITIONAL METHODOLOGY VS. AGILE METHODOLOGY

Traditional Methodology	Agile Methodology
The project is carried out without divisions.	The project is subdivided into different parts.
Extensive documentation is available.	There is little documentation.
Develops in a predictive manner.	It is developed in a way that is adaptable to the project
Software deliveries at the end of the project.	software deliveries are constant.
There is little communication with the client or user.	There is constant communication with the project.
Hide the error.	Immediately detects the error for resolution.

Table V shows the comparison of using an agile vs. traditional methodology, making reference that for this research the agile methodology was used since it fits the project and also has better processes to be implemented.

VI. Conclusion

In conclusion, the design of the application will help many students of the first cycles of the career of computer science and computing since they have various difficulties as shown in the survey is why it was analyzed in detail and devised the prototype of the mobile application working together with a chatbot which will help the user to perform their learning correctly in order to obtain favorable results, in addition, its teaching will be didactic which many students like the pedagogical and not the monotonous that are simple applications where they will not have motivation for learning and what is required is to help the student and facilitate their teaching complemented with the various courses of programming language for free that provides the application, on the other hand, The use of the Design Thinking methodology was satisfactory, because it focuses on the user and on the problems that may arise through the realization of the project, therefore, what made possible is the development of the prototype design of the application also obtaining data on the learning of programming in computer science students of the first cycles at the University of Sciences and Humanities. With this design of the application, it is intended in the future to have the implementation of the software to be able to implement it, in such a way to help many students or people who want to learn more about programming being in different countries benefiting their knowledge and being enriched every day more through the knowledge provided.

VII. Future Work

With this design of the application, it is intended in the future to have the implementation of the software to be able to implement it, in such a way to help many students or people who want to learn more about programming being in different countries benefiting their knowledge and being enriched every day more through the knowledge provided. With this design of the application, it is intended in the future to have the implementation of the software to be able to implement it, in such a way to help many students or people who want to learn more about programming being in different countries, benefiting their knowledge and getting richer every day through of the knowledge provided. In addition, it must be applied to other courses of complexity in learning; for this they must select a complexity course for their application.

Acknowledgment

Abstract—**During the spread of a pandemic such as COVID-19, the effort required of health institutions increases dramatically. Generally, Health systems' response and efficiency depend on monitoring vital signs such as blood oxygen level, heartbeat, and body temperature. At the same time, remote health monitoring and wearable health technologies have revolutionized the concept of effective healthcare provision from a distance. However, analyzing such a large amount of medical data in time to provide the decision-makers with necessary health procedures is still a challenge. In this research, a wearable device and monitoring system are developed to collect real data from more than 400 COVID-19 patients. Based on this data, three classifiers are implemented using two ensemble classification techniques (Adaptive Boosting and Adaptive Random Forest). The analysis of collected data showed a remarkable relationship between the patient's age and chronic disease on the one hand and the speed of recovery on the other. The experimental results indicate a highly accurate performance for Adaptive Boosting classifiers, reaching 99%, while the Adaptive Random Forest got a 91% accuracy metric.**

Keywords—Machine learning; COVID-19; wearable device

I. Introduction

Pandemics produced by infectious diseases always had a negative impact on the community at large. Currently, the globe is witnessing the advent of SARS linked to a novel coronavirus (SARSCov2) [1]. Patients with suspected exposure or symptoms should be identified as soon as possible. In respiratory infections, vital signs such as body temperature, heartbeat, and blood oxygen saturation are acknowledged as crucial strong indicators [2], [3]. Their monitoring is crucial for detecting early physiological abnormalities in patients who are deteriorating. They play a critical role in triaging patients for proper care and predicting whether they will improve or deteriorate [4], [5].

Approximately 82% of SARSCov2, also known as COVID-19, patients have minimal symptoms, recover quickly, and do not need to be hospitalized. 10 to 20% of patients who require hospitalization require care in intensive care units (ICUs), 3 to 10% require intubation, and the case fatality rate ranges from 2 to 5% [6]. Patients with mild illness are typically treated symptomatically, with home isolation as the last resort [7]. COVID-19's incubation period (the time between infection and beginning of symptoms) ranges from 2 to 14 days, with an average of (5 to 6) days [8]. Vital signs have to be monitored by the patients who have been assigned to a quarantine zone.

Wearable remote patient monitoring systems have made it possible to monitor vital indicators in a regular basis outside medical facilities and/or where mitigating contact with health workers is required [9]. However, with long-term monitoring and vital signs recording, a large amount of data is generated continuously, and health workers find it hard to extract information. This information is crucial to setting health policies and determining patient treatments. Thus advancements in machine learning combined with medical systems have resulted in a revolutionary discovery [5]. Commercial introductions of such gadgets without medical validation studies have occurred recently, rendering them inappropriate for medical use [10].

Generally, the classification process in data mining aims for the descriptive or predictive task. A descriptive analysis may be utilized to illustrate data relationships in a way that decision-makers can comprehend. In predictive analysis, the classification model can also be used for forecasting future values for the target class. One of the most popular data mining techniques is the decision tree DT. It is a simple and effective method that is used for both tasks. In [11], the proposed system presents a wearable device capable of monitoring the patient's vital signs (body temperature, oxygen saturation, heartbeat) and analyzing these data to predict the patient's recovery using ensemble classifiers with a DT as a based learner. The main contributions of this manuscript is:

- Utilizing an IoT-based monitoring health system to collect COVID-19 patients data set.
- Analysing the collected data and extracting crucial medical information using ensemble machine learning techniques.
- Evaluating and discussing the key findings of the main features of the medical data set.

The rest of this research is organized as follows: Section II reviews some related works. Section III describes the proposed classification system architecture along with the deigned wearable device. Section IV discuss the collected patient dataset and its characteristics, while Section V analyze this dataset and the performance of ensemble classifiers. Section VI discuss the results, limitations, and possible applications of the proposed system. Lastly, Section VII summarizes the main conclusions of this work.

II. Related Work

A. Health Monitoring Systems

Recent advancements in IoT and wearable device technologies enabled significant improvements in health applications, especially in the current pandemic that has become a global issue and threat to public health. For instance, Albassam $etal.$ Proposes an IoT-based health monitoring system for COVID-19 patients to measure various vital signs such as temperature, heart rate, oxygen saturation, and cough count, as well as to report patient GPS location data to medical authorities in real-time [12]. The system includes a wearable body sensor, web API, and a mobile application. The monitoring system is connected to the (IoT) cloud, where data is processed and analyzed.

Moreover, A real-time wearable monitoring system for the COVID-19 patient had been proposed [13]. A wearable chest patch and a pulse oximeter are used to send patients vital signals, including heart rate, respiration rate, and peripheral oxygen saturation, via wireless Android tablet devices to the nursing ward. The proposed system offers a technical wearable device (bracelet) to make it more unrestricted and give patients complete freedom of movement and do all activities without restrictions inside the home or hospital. The system added the technology of quarantine monitoring for those infected with the virus by adding GSM technology.

On the other hand, Mizher $et\,al.$ propose an internet of medical things (IoMT) based healthcare monitoring system that uses a wearable device [14]. This wearable device includes two sensors to measure blood oxygenation, temperature, and heart rate to monitor the health status of COVID-19 patient and limits virus spread. Their proposed system provides more services at a lower cost with the ability to change functions according to the requirements of medical staff, whether during the epidemic period or afterward.

Gloria.C $etal.$ [15] proposes a systematic review on accuracy and metrological characteristics of wrist-worn and chest-strap wearable devices. According to this system, aspects such as calibration procedure, number of test protocols, measured quantities, absolute error percentage, and correlation coefficient should be considered to evaluate the accuracy of wearable devices. The evaluation of the accuracy of wearable devices performed by a methodology was based on the calibration technique, the number of test protocols, measured quantities, absolute error rate, and correlation coefficient. However, in all the mentioned studies, either the wearable device design requires further efficiency or the produced health data lack a smart data analysis for this nontrivial big stream of data. This study aim to address this by proposing an efficient and smart health system.

B. Machine Learning in Health Applications

In order to extract or predict useful information from medical health dataset, many studies had proposed machine learning techniques. For instance, two machine learning techniques had been utilized for classifying COVID-19 against influenza data [16]. The first stage of their model was to make two clusters using Fuzzy C-Mean, then a Back Propagation classifier was built based on the clustering result. The implementation of their model included creating a mobile application that receives medical test data from the user and applies the classification within the mobile environment. Another classification framework proposed by [17] for detecting COVID-19 infection in the chest radiograph. X-ray images are classified using a convolutional neural network (CNN) and generative adversarial network (GAN) for data augmentation in their framework.

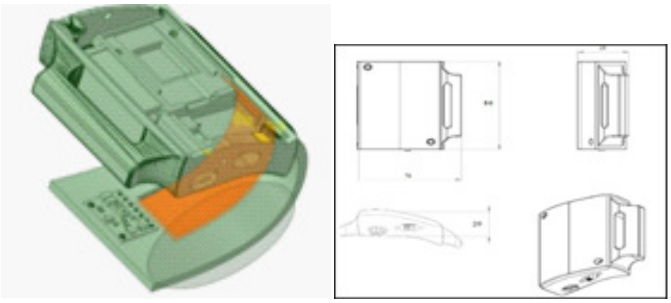
A smartphone-based recognition classifier is proposed by [18] for differentiating the normal coughs and uninfected persons from COVID-19 infected ones. Their work included a comparison of seven classification techniques, and the results showed that the neural network based on residual had the best performance. The author in [19] proposed a CNN classification model for classifying Computer Tomography (CT) images of COVID-19 patients. Their model required a low computational resource as it can be implemented in a personal computer without GPU acceleration. However, the works mentioned in this section are concerned with detecting COVID-19 infection, not the recovery status. In addition, two of them used medical images that are only available in the medical centers.

III. Proposed System Architecture

The proposed health classification system continuously records the sensors' output values alongside other medical information for COVID-19 patients and predicts their recovery. In addition, the system monitors the status of a patient; whenever the system recognizes a predefined critical level for any of the patient's vital signs, the system will send an alert to the responsible health staff. This system contains various components: (1) the Bracelet, which contains sensors for reading the patient's vital signs and passing them to the basic control unit, and (2) The Base Control Unit for receiving, analyzing, classifying, storing, and displaying data for each patient, (3) the user interface is designed to arrange and engage all system functions, inputs, and outputs for patients and users [9]. Moreover, it displays the instant patient vital signs to health workers.

A. Bracelet Design

Wearable electronics devices are starting to include many fundamental and even leisure functionalities due to market demands. In this research, the wearable device, which is the bracelet, has been designed to perform a vital task in the patient monitoring system. When constructing such systems, stability, durability, safety, and acceptable form factors must all be taken into account. Several layouts were implemented in this initial investigation, and the one illustrated in Fig. 1 was selected [20].



(a) (b)

Fig. 1. Bracelet Designed Layout.

The microprocessor, battery, sensors, and other components are all housed in the bracelet case, which measures (86 x 70 x 29) mm. Slots are cut into the lower and top parts of the bracelet so that the sensors can be placed on the skin with the needed accuracy, as shown in Fig. 1, the bracelet (container) is expertly created for patients of all ages and genders. The bracelet's exterior had an efficient technical curve that was made with a 3D printer with flexible materials to match the size and shape of most users' wrists. In addition, this design has shown the best accuracy in recording vital signs and communicating with the base station [20].

B. Building Ensemble Classifier

The data of a classification task with the size N consists of a set of features X $(x1, ..., xM)$ and Y, which is the class label vector, where N is the number of instances and M is the number of features. This task aims to build a model that can classify or predict the value of y depending on the given feature set X. The single model can produce unreliable predictions because of overfitting, so the ensemble classification includes building multiple weak classifiers (base learners) and merging their decisions to make one strong one. In the proposed system, the base learner is the decision tree consisting of two types of nodes; the internal node represents a condition on a data feature used to divide the data records. Only two branches produce from each internal node based on the condition in a binary tree, while the multi-branch DT can generate more than two branches from each internal node. A leaf node is a non-internal that holds a class label without any data splitting.

According to the mechanism of merging the base learners, ensemble classification is categorized as Boosting and Bagging, and both of them are used in the proposed system. AdaBoost refers to Adaptive Boosting [21]; it performs by assigning a higher weight to data records that are incorrectly classified and less weight to those that are already well-classified. This process is performed by many iterations, which is called the size of the ensemble, and it is equal to the number of base learners. For the initial iteration, the data subset is chosen randomly with the equal possibility of choosing each instance. In the following iterations, the weight of an instance will be increased if it was incorrectly classified in the previous iteration. AdaBoost predicts the unknown value for any new instance by using the weighted average of base learners' decisions. The weight of each learner is calculated base on its misclassification error. Fig. 2 illustrated steps of building the proposed ensemble classifier based on AdaBoost algorithm.

Random forest applies Bagging in which a random subsampling is chosen with a replacement in each iteration for the training set. In addition, a random subset of features will be selected in the splitting process of DT. Adaptive random forest ARF [22] is dedicated to dealing with data streams by applying a continual training method for the classification model to adjust to changes in data distribution. It uses a modified version of DT called Hoefding Tree of Very Fast Decision Tree, which can adapt itself as a response to changes in data distribution. Adaptive Window ADWIN is used in ARF for monitoring and detecting that change in a data stream.

IV. Patients Data Sample

The study sample in this research is made up of a voluntary group of individuals infected with COVID-19 found inside clinics designated to treat patients with COVID-19. In addition to the vital signs from the bracelet, the patient's medical history, how long they have been infected, and their symptoms are collected with the help of health workers in these clinics. Thus, each patient record is designed to show the pathological behavior of the virus throughout the infection period. Therefore, using data analysis techniques, information might be extracted to prevent patients from reaching critical conditions.

A. Sample Demography

The system was tested on a non-governmental voluntary sample targeting patients infected with the virus during the pandemic, which had mild or moderate symptoms while attending outpatient clinics in Iraq, in the capital, Baghdad. The sample included (408) infected individuals, and their information and medical history were recorded without mentioning their names in order to preserve privacy. The collected data has been divided into two datasets; the first one, entitled Covid19-IQ01, contains data from 313 patients, one record for each patient. The second dataset, Covid19-IQ02 created by monitoring 95 patients for five days, i.e., five records for each patient and 475 in total. In the Covid19-IQ01 data set, gender is fairly distributed, as shown in Table I. In addition, the sample data is categorized into six age groups, and since most of them suffered from high to moderate infection, the age group (60-69 years old) is the highest with (27.5%). Table I also shows that 55% of 313 patients have some kind of chronic disease, and this can provide the ability to indicate their impact on recovery period of COVID-19 patients.

TABLE I. The Demography Characteristics of Sample Patients

		Covid19-IQ01	**Covid19-IQ02**
Gender	Male	≈ 53%	≈ 45.2%
	Female	≈ 47%	≈ 44.8%
Age	10-19	≈ 16.6%	≈ 17.9%
	20-29	≈ 15.6%	≈ 12.6%
	30-39	≈ 14%	≈ 16.8%
	40-49	≈ 13.4%	≈ 16.8%
	50-59	≈ 12.8%	≈ 17.9%
	60-69	≈ 27.5%	≈ 17.9%
Chronic diseases	Hypertension	≈ 28.4%	≈ 27.3%
	Diabetes	≈ 28.4%	≈ 30.5%
	Others	≈ 8%	≈ 12.6%
	None	≈ 45.3%	≈ 46.3%
Symptoms	Exhaustion	≈ 55.5%	≈ 62%
	Dizziness	≈ 61%	≈ 65%
	Fast Heartbeat	≈ 59.1%	≈ 65%
	Depression	≈ 35.4%	≈ 69%

In addition, the system was tested on a sample of (95) volunteer participants, each of whom had (5) serial measurements starting from the fifth to the tenth day and had (mild or moderate) symptoms of infections. This is due to the fact that this period represents the tipping point for various complications, especially for older patients and those with chronic diseases, such as high blood pressure, diabetes, or other [23]. This sample is divided into (six age groups) from (10-70) years and two categories based on gender (43) males and (52) females. In addition, the medical history, and chronic diseases, of the patient were adopted, as the number of participants in the sample who had high blood pressure (26) participants, diabetes (29) participants, and other diseases (12) participants. Moreover, Health experts have classified the patient's status based on interviewing the patient into three categories: Recovered, recovering, and No sign of recovery. This classification is based on the persistence of symptoms associated with the disease due to infection. Taking into account the readings of vital signs, which are summarized in Table II, especially (body temperature and the oxygen saturation in the blood). These patient data records will be used in machine learning in the next sections.

V. Experiments Results

A. Data Analysis by Visualization

TABLE II. Summery of Numerical Features of Covid19-IQ01

Attribute	***Min.***	***Max.***	***Mean***	***STD***
Age	13	69	37.42	18.21
Body Temperature	36.2	38.4	37.29	0.62
Oxygen Saturation	90	97	94.62	1.5
Heartbeat Rate	55	86	69.62	6,17

In this section, we explore the patterns in the collected data Covid19-IQ01 and the relationship between the patient's condition on the one hand and age, chronic diseases, and vital signs on the other. In Fig. 3, 4, 5, 6, 7, 8, and 9,the color of the circle indicates the status of the patient, while the size of it relates incrementally to the age of the patient. RapidMiner platform [24] was used for analyzing and visualizing operations. Fig. 3 illustrates the relation between two common chronic diseases, Hypertension and Diabetes, with the progress of patient recovery. The figure showed clearly that patients with those two diseases have no sign of recovery, while there is a high ratio of recovered or recovering patients without Hypertension and Diabetes.

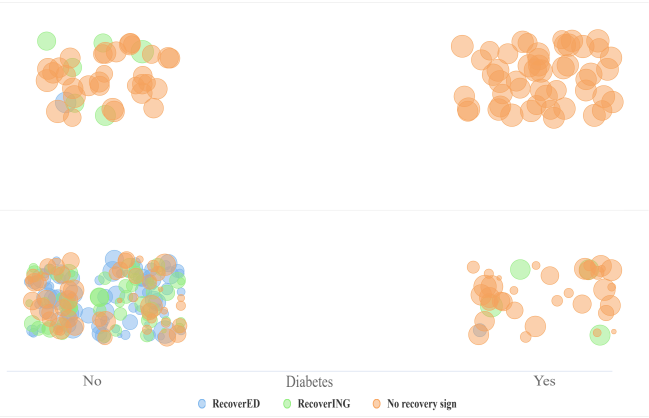

Fig. 3. Covid19-IQ01 Data Visualization: Hypertension and Diabetes

The impact of body temperature collected from the thermometer sensor on the recovery status is illustrated in Fig. 4 and Fig.5. Young Patients without Hypertension or Diabetes and 37 degrees or less of temperature mostly healed. In the case of having one of the two chronic diseases, most patients don't show a sign of recovery, although their body temperature is normal.

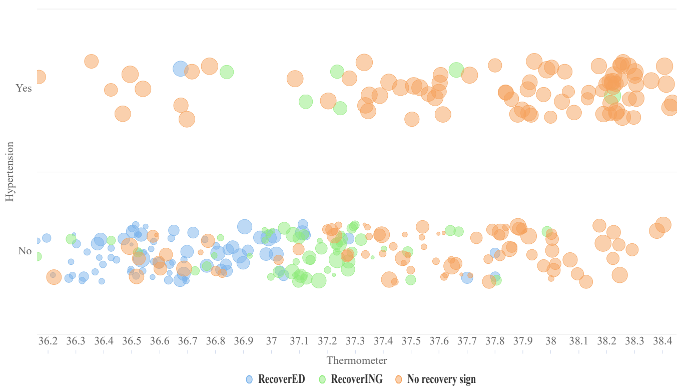

Fig. 4. Covid19-IQ01 Data Visualization: Hypertension and Thermometer.

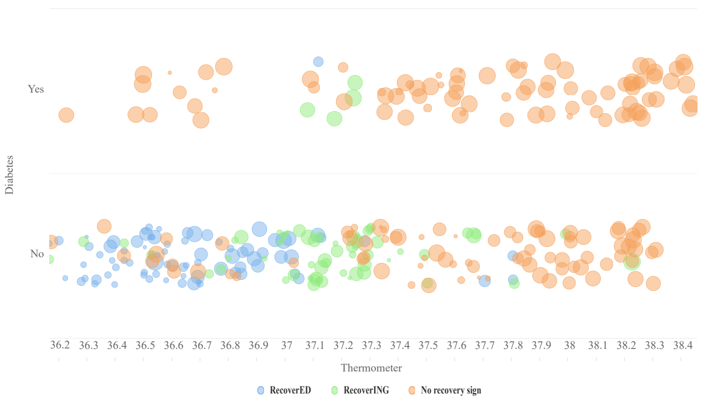

Fig. 5. Covid19-IQ01 Data Visualization: Diabetes and Thermometer.

Diabetes patients mostly have no sign of recovery regardless the age and their heartbeat rate, as shown in Fig. 6. Also, it indicates that Heartbeat rate is related to the recovery status of young patients without Diabetes. Adult patients with Hypertension mostly were not healing regardless of heartbeat rate, as shown in Fig. 7. In the normal range of heartbeat, most of the young patients were recovering or they already recovered. The same conclusions can be seen in Fig. 8 and Fig. 9 about the relation between the oxygen saturation, chronic diseases, and recovery from COVID-19.

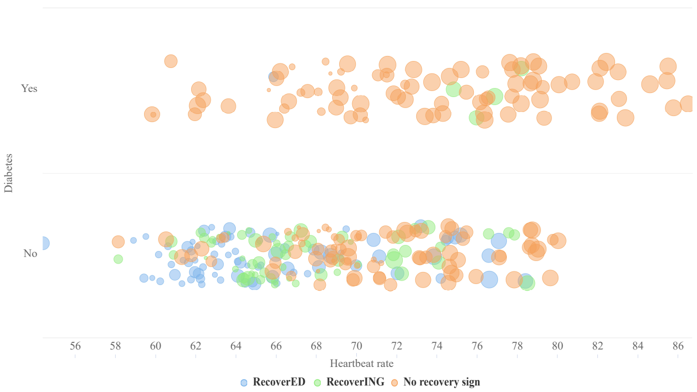

Fig. 6. Covid19-IQ01 Data Visualization: Diabetes and Heartbeat Rate.

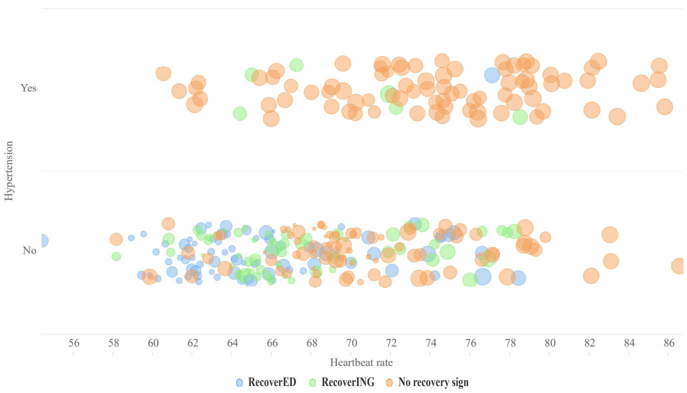

Fig. 7. Covid19-IQ01 Data Visualization: Hypertension and Heartbeat Rate.

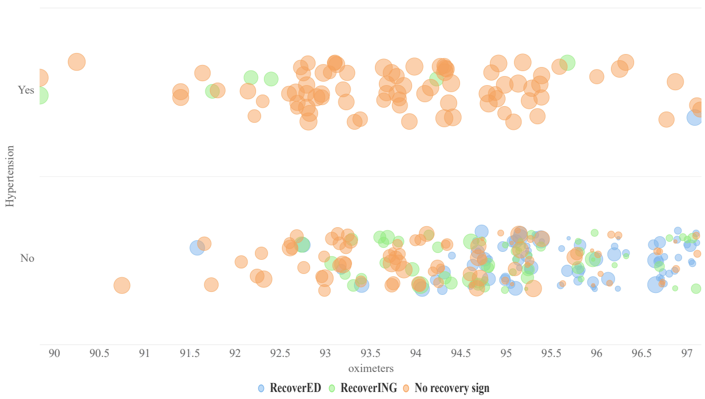

Fig. 8. Covid19-IQ01 Data Visualization: Hypertension and Oximeters.

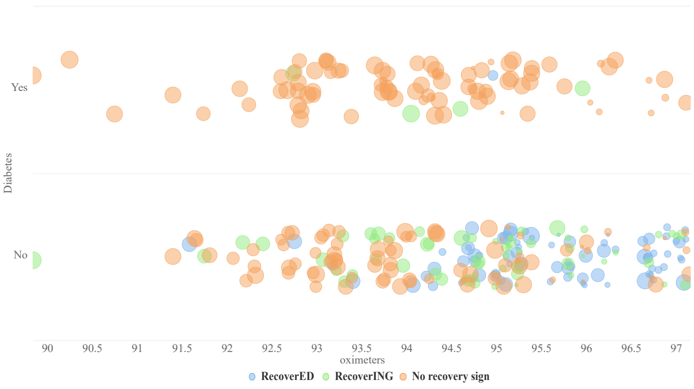

Fig. 9. Covid19-IQ01 Data Visualization: Diabetes and Oximeters.

B. Static Ensemble Classification

Waikato Environment for Knowledge Analysis [25] platform is used in this implementation for randomization, feature ranking, and classification. Implementing AdaBoost Ensemble classifier on both Covid19-IQ01 and Covid19-IQ02 datasets led to high accurate classification. The base learner for Adaboost was a J48 decision tree classifier that illustrated in Fig. 10 and Fig. 11. All the experiments in this section included 10-fold cross-validation to prevent bias, and the ensemble size was 20 for Covid19-IQ01 and 12 for Covid19-IQ02.

Tables III and IV represent the confusion matrix of AdaBoost with the two datasets; they show the correct predicted values in the bold numbers in the diagonal cells. The results in those tables indicate the accuracy of AdaBoost, especially in Table IV that contains only one record classified incorrectly.

TABLE III. CONFUSION MATRIX OF ADABOOST CLASSIFIER FOR COVID19-IQ01

	Predicted values		
Actual values	***Recovered***	***Recovering***	***No recovery sign***
Recovered	**72**	4	6
Recovering	3	**51**	9
No recovery sign	6	12	**150**

TABLE IV. CONFUSION MATRIX OF ADABOOST CLASSIFIER COVID19-IQ02

	Predicted values		
Actual values	***Recovered***	***Recovering***	***No recovery sign***
Recovered	**145**	0	0
Recovering	0	**120**	0
No recovery sign	1	0	**189**

A performance comparison is performed between AdaBoost and the other four popular classifiers. Three of them were a single classifier (J48, REPTree, and Hoeffding Tree), while the fourth is Random Forest which is an Ensemble classifier that uses bagging instead of boosting. The results of the comparison in Tables V and VI showed that Adaboost has the best results in both datasets compared with the other four classifiers based on five evaluation metrics (TP rate, FP rate, Precision, Recall, and F-Measure). Fig. 12 illustrates the importance of each feature in both datasets during the building of the AdaBoost classifier. It can be seen that AdaBoost chose a different subset from features in every dataset; only the Age feature had similar importance in both of them.

TABLE V. CLASSIFICATION PERFORMANCE OF FIVE CLASSIFIERS OF COVID19-IQ01

Technique	***TP Rate***	***FP Rate***	***Precision***	***Recall***	***F-Measure***
J48	0.837	0.103	0.838	0.837	0.838
REPTree	0.831	0.119	0.830	0.831	0.830
HoeffdingTree	0.655	0.198	0.644	0.6551	0.648
Random Forest	0.866	0.084	0.866	0.866	0.866
AdaBoost	**0.872**	**0.079**	**0.874**	**0.872**	**0.873**

TABLE VI. CLASSIFICATION PERFORMANCE OF FIVE CLASSIFIERS OF COVID19-IQ02

Technique	***TP Rate***	***FP Rate***	***Precision***	***Recall***	***F-Measure***
J48	0.977	0.010	0.977	0.977	0.977
REPTree	0.977	0.007	0.85	0.985	0.985
Hoeffding Tree	0.937	0.029	0.938	0.937	0.937
Random Forest	0.973	0.013	0.973	0.973	0.973
AdaBoost	**0.99**	**0.001**	**0.998**	**0.998**	**0.998**

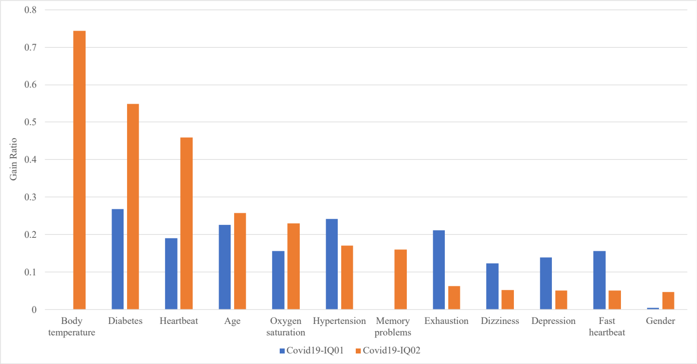

Fig. 12. Features Ranking of AdaBoost Classifer based on Gain Ratio.

C. Adaptive Ensemble Classification

Implementation of the second dataset, COVID10-IQ02, as a continuous data stream was performed in Massive Online Analysis platform and scikit-multiflow library in Python. Adaptive Random Forest ARF classifier, which is an adaptive ensemble classifier, had an incremental classification performance while receiving the stream samples with a size of 20 instances, as shown in Fig. 13. ARF obtained the best result compared with the other four adaptive classifiers by using ten base learners as shown in Fig. 14.

VI. Discussion

The COVID-19 pandemic has caused huge pressure on health systems in most countries due to a large number of infections. Thus, the focus of health institutions was to treat severe cases that needed breathing aids. Many patients were getting medical care at home in moderate and mild cases. Remote monitoring of the patient's recovery can reduce the necessary medical effort and speed up the return of the patient's normal life. This work proposes a classification system that determines whether or not a patient has recovered based on a set of patient biomedical and clinical data using machine learning techniques.

The process of collecting data on COVID-19 patients was one of the most difficult stages of this work due to the risks of transmission of the virus and continuous exposure to the virus. In addition, the quarantine laws for COVID-19 patients make them only accessible by certified health workers. Moreover, there was a challenge in finding COVID-19 patients health workers that are willing to volunteer for the study. This is due to the fact that volunteers require insurance and convincing that the proposed system guarantees security, ease of use, confidentiality, and effectiveness of using such health systems. In addition, due to the difficulty of gaining permission from governmental health intuitions to conduct this study, the focus was on private (non-governmental) medical clinics that were receiving patients, and they asked to use the bracelet to record their vital signs without using their names and any personal information using the proposed system.

The analysis of the collected data indicates that the vital signs data from the proposed wearable device sensors was more useful for the classification of the patients without chronic diseases. The patient's age significantly correlated with the recovery status, as the results showed. The younger patient tends to recover more than the adult and the elderly. However, a child or young person with a chronic disease is less likely to recover. Also, the impact of diabetes and its importance in building the classifiers, thereby predicting the recovery, was more than the impact of high blood pressure. However, the ranking of features during the process of building the classifier showed that the sensors data had more Gain ratio in the second dataset, which contains multiple readings (five) for each patient. In J48 classifier, which was the base learner for the two implementations, the root node was body temperature reading, and that can clarify the effectiveness of the proposed wearable device. Finally, as far as we know, this work is the first research analysis of COVID-19 patients' data using machine learning in Iraq. We look forward to extending the patients' sample and applying more improvements in data classification.

VII. Conclusion

Monitoring and home medical care contribute to focusing the medical effort on severe cases, especially during the spread of pandemics. The proposed system aims to design and implement a classifier capable of predicting a patient's recovery from COVID-19 and providing the medical staff with an immediate alert if the patient's condition declines. The implementation phase included collecting data from 408 patients, and the analysis of these data showed a significant correlation between the factors of chronic diseases, age, and patient recovery. The ensemble classification produced two classifiers. The first one was based on AdaBoost; it had the best accuracy of 0.874 compared with four classifiers with the first dataset and 0.998 with the second one. The second classifier was based on Adaptive Random Forest, which had the best accuracy of 0.919 compared with four adaptive classifiers. The ranking of features in AdaBoost classifiers showed more importance for the vital signs collected by the proposed system than the symptoms. Future works might include testing the the proposed classifier system on stream of data and provide instant predictions.

Acknowledgment

The authors would like to acknowledge the efforts of the medical staff in the private clinic of Dr. Abdullah Al-Rawiy in Alghazalyah in Baghdad for their efforts in collecting the data set.

Abstract—**During the COVID-19 pandemic, small clothing sales companies lost economic income and customers due to a lack of digital transformation, causing the dismissal of many employees. Due to this problem, our objective is to design an e-commerce mobile application for the sale of clothes, so that Small and medium-sized enterprises dedicated to this area generate income and retain their customers. For this, the Rational Unified Process (RUP) methodology was applied, because this methodology provides a structured way for companies or developers to visualize the development of the software, and for the validation by expert judgment, the survey and the questionnaire were used as instruments. Obtaining as a result a positive rating for the design of the mobile application and its acceptance to accommodate what is reflected. In conclusion, the e-commerce mobile application was successfully designed, backed by expert judgment, so that Small and medium-sized enterprises can offer their products and generate income, as well as build customer loyalty.**

Keywords—Mobile application; COVID-19; e-commerce; RUP; sale of clothes

I. Introduction

At present, worldwide, mobile applications have become elements of vital importance for electronic commerce. Since, during the pandemic, many companies have gone downhill, especially small companies due to lack of financial resources for digital transformation. Large companies, however, showed a slightly different result compared to small companies. This is due to the use of smartphones, which has generated a lot of innovation and with it, the creation of mobile applications, including the e-commerce application [1].

During the COVID-19 pandemic, mobile applications for online commerce or also called electronic commerce, gained a large number of new users, and in the same way, people's lifestyles have changed [2]. Therefore, today consumers choose to use these applications to make purchases from the comfort of their home. Because mobile applications have emerged as a form of innovation for the e-commerce business, since it provides convenience and ease to consumers by saving time and effort. In this sense, people prefer the use of electronic commerce applications, in particular to make purchases or orders, in this way, protect themselves from the COVID-19 coronavirus [3].

In addition, mobile e-commerce applications can help small businesses that sell clothes, and other sectors that have the home delivery modality, prosper. In the same way, it will allow consumers (customers) to make their purchases from the comfort and safety of their homes [4]. According to the study carried out in India, the habits adopted during the COVID-19 coronavirus pandemic are driving the growth of mobile applications related to electronic commerce. Because these applications help save time, resources and efforts for consumers. Therefore, it is one of the key reasons why small businesses can prosper [5]. Likewise, the use of the mobile application generates great benefits for the company, such as: quick and easy access to information, optimization of the average time in making and delivering purchases or orders and, consequently, improvement in customer loyalty.

For this reason, the present research work offers a viable solution to small companies dedicated to the sale of clothes, using an electronic commerce mobile application. In order to help small businesses prosper in the current market, to which they are directed.

Therefore, the proposed research will help automate and provide a solution to the problem of face-to-face clothing sales that currently exists, allowing customers to order or purchase with confidence and security from the mobile application.In this way, allow small businesses to provide services at home. Since the mobile application is key to continue generating income and sustain itself in the current market. Likewise, with this form of technological innovation, it not only benefits customers, but also small businesses and people who work as delivery people, since the mobile application is a system that helps the efficiency of the business and involves several people. that require a job. In the same way, the RUP methodology will be applied since this methodology provides a structured way to visualize software development. It also provides a detailed plan for each of the development phases.

The objective of the research is to design a mobile application for the sale of clothes through electronic commerce, applying the RUP methodology, which makes it easier for small businesses to generate income and retain their customers. The beneficiaries of the research are the people who sell clothing to generate income through the proposal of the mobile application, all through electronic commerce.

This research is made up as follows: Section II explains the review of the literature: analysis of different investigations related to the research work; Section III defines the RUP methodology and its different phases that were used in the research work; Section IV the development of the methodology; Section V presents the results; Section VI the discussions; Section VII the conclusions and finally Section VIII future work.

II. Literature Review

In the research work, the subject of e-commerce mobile applications was addressed. For this reason, in this section it will focus on analyzing the different investigations related to the research work, where it provides us with its objectives, methods, results and conclusions.

The author Hawa [6], states that the internet, applications and e-commerce allow consumers to be reached, since these mobiles allow the availability of clothing; therefore, sales increase. He developed the study with the aim of exploring the acceptance of personalizing clothing online, with the purpose of reaching the market through segmentation. Applying the qualitative method; the interview and questionnaire for data collection. The sample consists of 13 participants from diverse cultural backgrounds. Their findings contribute to a large-scale quantitative study. In addition, it is of interest to great executives of management and marketing of garments.

The author M.Subchan [7], manifest that electronic commerce allows consumers to carry out purchase and sale transactions in a simple and fast way. Likewise, it presents that the Muslim clothing store ayu fashion shops, offers a variety of Muslim clothing such as: hijab, tunic and couple; therefore, the purpose of the study is to create a sales system using electronic commerce technology, applying the waterfall methodology. Concluding that consumers of these online clothing stores can order from anywhere. Likewise, it provides the solution to the problems faced by Muslim fashion stores that are currently evolving.

The authors Purwaningtyas and Rahadi [8], in their study, aim to determine the factors that affect the sale of clothing through electronic commerce; To do this, they reviewed and came to a synthesis of 36 previous articles related to their research. Obtaining a result, that the factors that affect the sale of clothing through electronic commerce are the price, the design and style of the product, the promotion, the quality of the product, the availability of product information, the variety of products offered, ease of use and quality of service during the purchase. The study's findings are of great use to businesses selling garments on e-commerce platforms in Jakarta, Indonesia.

The authors BĂLĂȘESCU et al. [9], state that the development of electronic commerce platforms is of vital importance for the clothing sales market. The study analyzes clothing sales via e-commerce in Romania; For this, it is intended to know the opinions of clothing consumers, who use electronic commerce applications to make their purchases. In this way, determine the reasons why they choose to buy clothes online. Concluding that the results obtained in the study will be very useful for online clothing sales companies through applications, which will help improve their services. Likewise, for companies that want to enter the e-commerce business through their applications.

The authors Ramirez et al. [10], in the investigation present the development of an electronic commerce platform, to give the greatest flow of sales of sports and casual clothing. Similarly, they state that during the COVID-19 pandemic, many clothing sales businesses were affected; For this reason, the electronic commerce platform was developed, applying the Scrum methodology to solve the problem. According to the statistics they obtained, the acceptance by the clients was evidenced, since, from the moment it was put into service, the business obtained positive results. Concluding that e-commerce applications increase sales by making it easier for consumers to buy online.

The authors Soegoto et al. [11], state that there is a rapid development of technologies; one of them is the development of mobile applications as a means for the sale and purchase of a product. The purpose of the research is to design a mobile application for the sale and purchase of various types of Japanese anime t-shirts. Also, as a means of promotional marketing. For this, the qualitative descriptive analysis method was applied, in order to help Japanese anime fans to find different types of t-shirts. Likewise, it concludes that the mobile application facilitates the purchase and acts as an intermediary between consumers and the favorite anime product.

The authors Gomero-Fanny et al. [12] in their research work made a prototype of electronic commerce for the sale of clothes. To do this, they applied the scrum methodology. The objective was to design a web system for clothing sales under the agile SCRUM methodology. Which allowed them to design web system prototypes meeting the needs of the organization. The results were divided into 4 Sprint deliverables to analyze the user stories, where a maximum score of 21 and a minimum of 16 were obtained. Concluding that this system will focus on meeting the requirements of customers, with adaptations to the organization according to their needs, which will benefit the organization and its customers.

So also the authors Tupia-Astoray and Andrade-Arenas [13], state that currently Small and medium-sized enterprises (SMEs) have stalls and physical stores as the only means of sale. For this reason, in their study, e-commerce web prototypes for sale were made, applying the SCRUM methodology covering the established procedures, being a peculiar proposal and with a beneficial approach. Obtaining as a result, design of innovative prototypes complying with the procedures established under the SCRUM methodology. Therefore, the proposal made can be implemented by different SMEs that wish to improve their online sales, with a good management organization.

The authors Lazo-Amado et al. [14] mention in their research work that the COVID-19 pandemic generated a great loss of sales in the Peruvian market. For this reason, the objective of the study is to develop a model to optimize sales with the use of digital marketing, applying the DesignScrum methodology, which is a hybrid of Scrum and Design Thinking. To carry out the test, a survey was conducted with customers, who gave their opinion regarding the prototype. Then, the digital marketing proposal was raised. Concluding that the marketing model according to the needs of the company will benefit its sales through electronic business.

In summary, different research works have been studied and it was found that most of the authors focus on the development of web applications with attributes such as quality, design, reliability, price and various options associated with web applications. applications, and others focuses on the factors that influence customers to use the mobile application. However, they do not focus on the development of the mobile application, on the security that it can provide to the user. Likewise, they do not attribute the forms of payment to facilitate the consumer and can use them with confidence and security. Consequently, they are exposed to not achieving customer satisfaction and loyalty.

III. Methodology

This section focus on applying the RUP methodology, which is made up of phases.

A. Metodología RUP

The RUP methodology is a software development process that divides the process into four distinct phases, such as: start, build, build, and transition [15]. The four phases are as follows (see Fig. 1) :

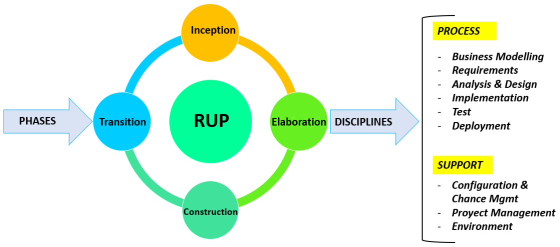

Fig. 1. Phases of the RUP Methodology.

1) Start: in this initiation phase, the project is defined. Likewise, it is determined if the project is feasible. In addition, the vision and objectives are defined, as well as the scope of the project. Similarly, it focuses on business modeling and identifying its requirements.

2) Elaboration: in this phase, the use cases are selected, which will allow defining the architecture of the system to be developed. Likewise, we proceed with the specification of each of the use cases and the analysis of the domain is carried out. In the same way, the design of the preliminary solution is carried out.

3) Construction: In this phase, the construction or coding of the software is carried out, which is carried out following a series of iterations. Afterwards, it begins with its implementation and proceeds with its respective tests, in order to find flaws or defects in the created software.

4) Transition: In this phase, the construction or coding of the software is carried out, which is carried out following a series of iterations. Afterwards, it begins with its implementation and proceeds with its respective tests, in order to find flaws or defects in the created software.

B. Design Tool

In this section, the design tools for the prototype of the mobile application were detailed.

1) Figma: In this project, the use of the Figma tool was used, an intuitive cloud-based application that allows designers to work without previously downloading the software [16]. It also allows the contribution of a work team in real time.

2) StarUML: This tool is developed under the Unified Modeling Language (UML) and Modeler Driven Architecture (MDA) standards, which allows modeling diagrams required for development and implementation in software projects. In the same way, it allows to obtain a better view of their operation [17].

C. Development Tools

In this section, the mobile application development tools were detailed.

1) Kotlin: Modern programming language, it is statically typed, capable of running on the Java Virtual Machine (JVM) platform. Likewise, it presents great advantages to the developer, such as: the reduction of the level of complexity of the code that is usually written during the development of the mobile application. In addition, it contains a large number of material design components that can be used to support UI/UX related interfaces [18]. Similarly, it is compatible with the java language, thanks to NativeScript.

2) SQLite: The chosen database engine is SQLite, developed under the sql language. This database manager is fast, highly reliable, self-contained, and small with big features [19]. Therefore, it allows you to store in a simple, fast and efficient way. Also, the implementation of this is very simple and light. Similarly, it is robust and totally free.

3) Android Studio IDE: Android Studio is free and open source software. Likewise, it is the software most used by developers for the development of Android mobile applications. In addition, it provides developers with the fastest tools to create applications for all types of Android devices. Also, the editing of the source code is world class. Since, it features debugging, performance tools, a very flexible build system. Which allow the developer to create unique and high-quality applications [20]. With this, scalable projects can be carried out quickly and efficiently.

IV. Development of the Methodology

In this section, the business model and the system model were developed to develop the mobile application.

A. Business Modeling

1) Current Business Process: Fig. 2 shows the current business model, which is working without the proposed mobile application.

2) Business use case Modeling:

- Business actor: Fig. 3 shows the actors of the business.
- Business use case diagram: Fig. 4 the business use cases.

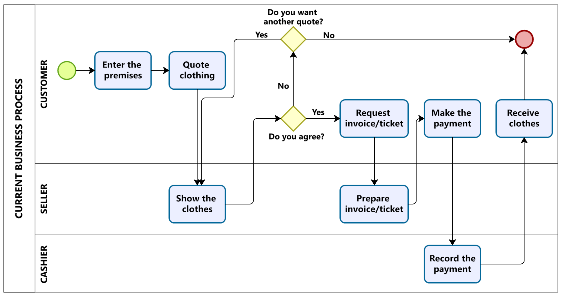

Fig. 2. Current Company Process.

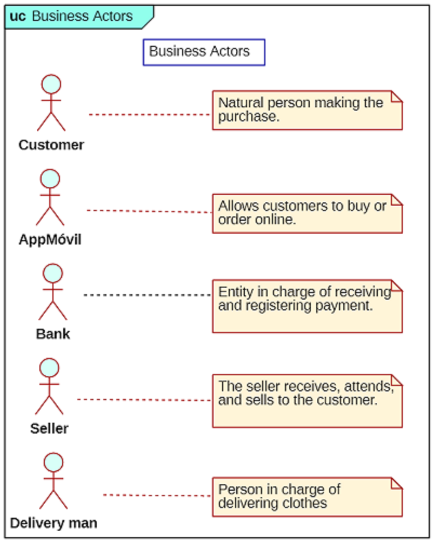

uc Business Actors
Business Actors
Customer
Natural person making the purchase.
AppMóvil
Allows customers to buy or order online.
Bank
Entity in charge of receiving and registering payment.
Seller
The seller receives, attends, and sells to the customer.
Delivery man
Person in charge of delivering clothes

Fig. 3. Business Actors.

3) Business Analysis Model:

- Business Sequence Diagram: Fig. 5 shows the sequence of business clothing sales steps.

B. Requirements Capture

- Functional Requirements: Table I shows the functional requirements of the mobile application for the sale of clothes.

TABLE I. FUNCTIONAL REQUIREMENTS

N°	Functional Requirements
1	User register
2	User authentication
3	List of products
4	Validate user
5	Search product
6	add to cart
7	generate payment
8	Register order
9	Search order
10	Cancel an order
11	Search category
12	Customer maintenance
13	Remove product from cart
14	Generate electronic bill
15	Print invoice

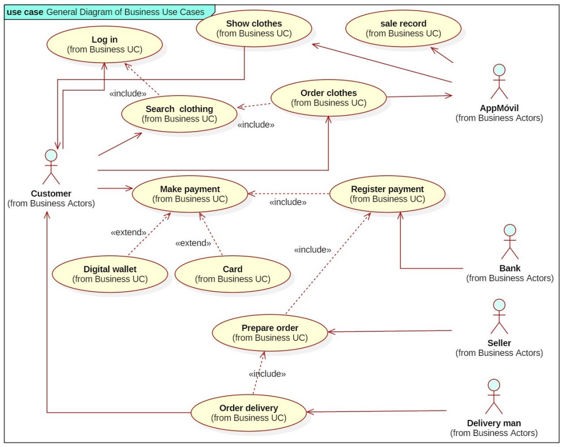

Fig. 4. Business Use Cases.

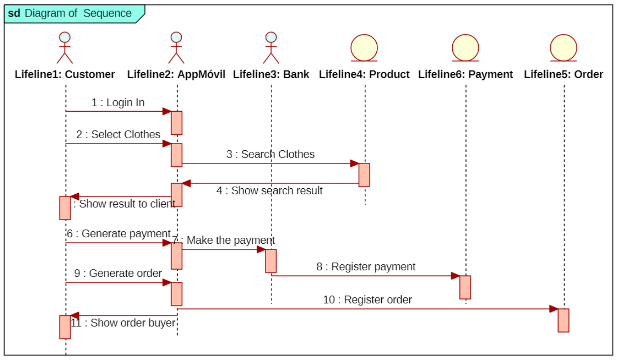

Fig. 5. Business Sequence Diagram.

- Non-Functional Requirements: Table II shows the non-functional requirements of the mobile application for the sale of clothes.

TABLE II. NON-FUNCTIONAL REQUIREMENT

N°	Non-Functional Requirement
1	The response time for order search is no more than 1 second.
2	Friendly, dynamic, descriptive and informative interface
3	Payment options
6	The system will have to be updated by users
5	The graphical interface of the system must be easy to read for the user
6	Allow remove product added from cart
7	Track purchase order with location in real time.
8	Request verification code when creating the account.
9	Request the password when deleting the account.
10	When creating the account you must accept the privacy terms
11	You must have the option to register with google.
12	You should have the option to log in without registering.

C. Modeling of System Use Cases

- System actor: Fig. 6 shows the actor that will interact with the mobile application.

- System use cases: Fig. 7 shows the use cases of the system.

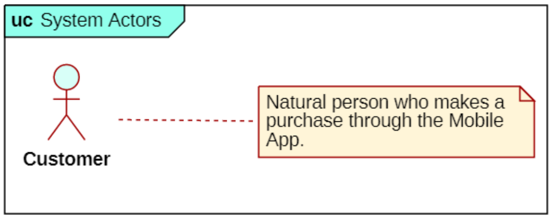

Fig. 6. System Actor.

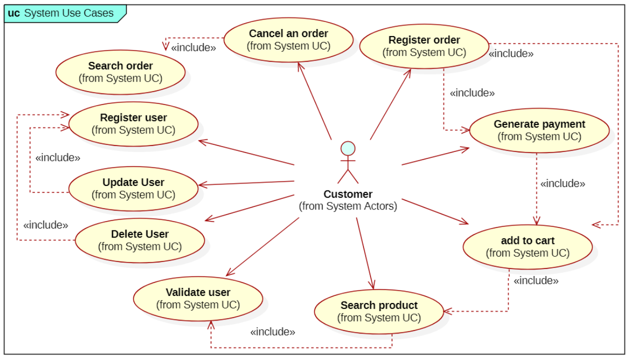

uc System Use Cases

V. Results

A. About the Prototype

Fig. 14 presents the login and user registration modules. The registration module allows you to create an account and by creating it, the user gets access to the virtual store. Similarly, the login module allows the user to validate their data for security reasons and make purchases with confidence.

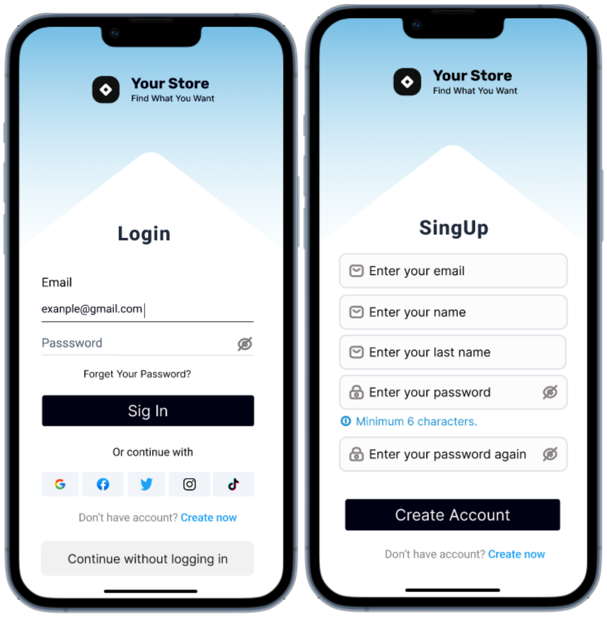

Fig. 14. Sign in and Sign up Prototype.

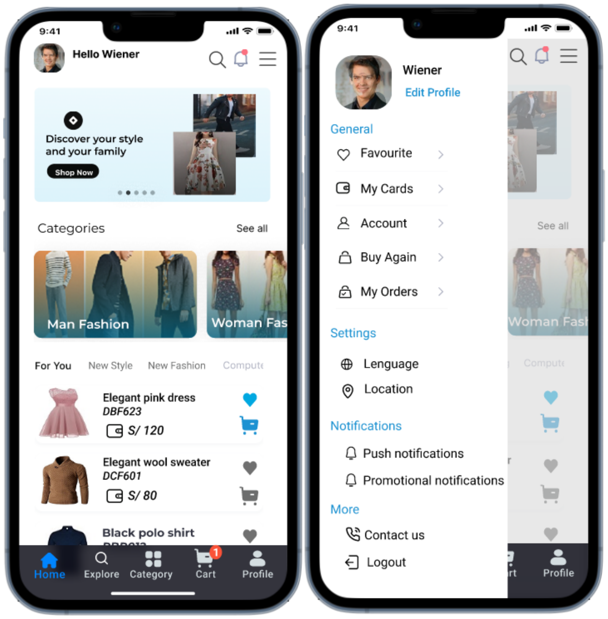

Fig. 15. Prototype Main Menu and Navigation Menu.

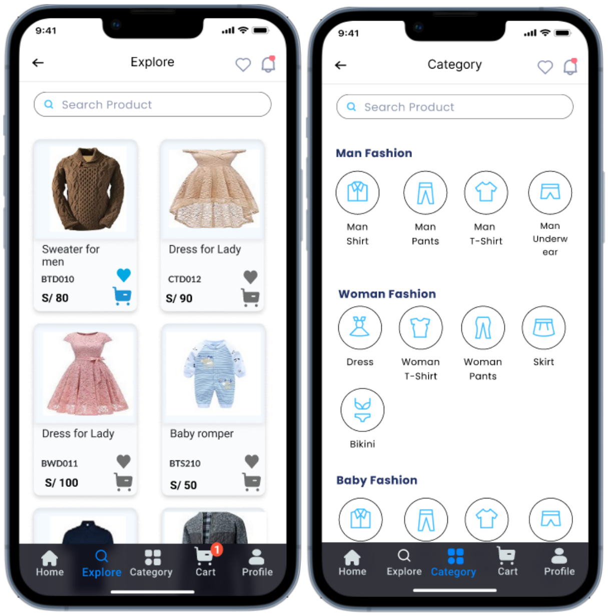

Fig. 16. Prototype Explore and Category.

In Fig. 15, the main menu and the navigation modules are presented. The main menu module shows the recently published products (clothes) with their respective prices and their shopping cart button to facilitate the user's choice. Likewise, the navigation menu module makes it easier for the user to navigate in the application by presenting different options in a simple way.

In Fig. 16, the exploration and category modules were presented. The explore module makes it easy for the user to search for the clothes they want and in the same way the module filters the product with its respective prices according to what the user is looking for. Likewise, the category module

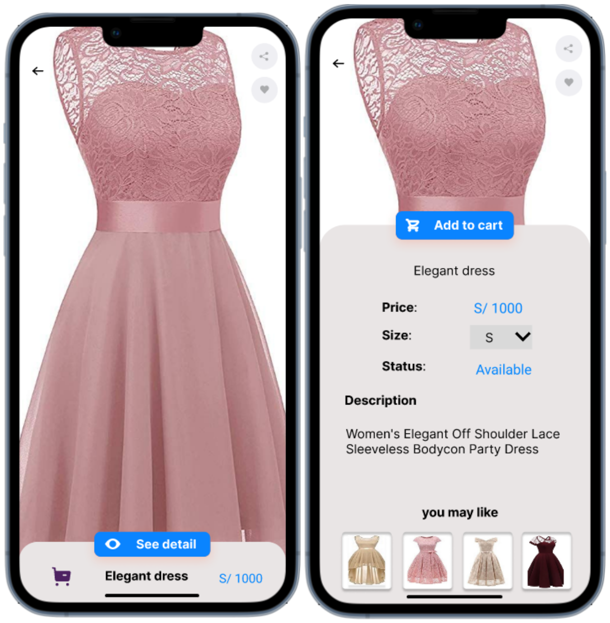

Fig. 17. Prototype to See and See in Detail.

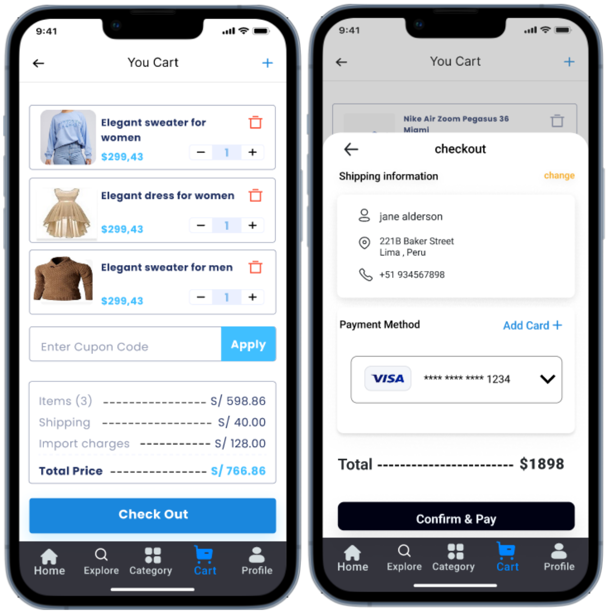

Fig. 18. Shopping Cart and Checkout Prototype.

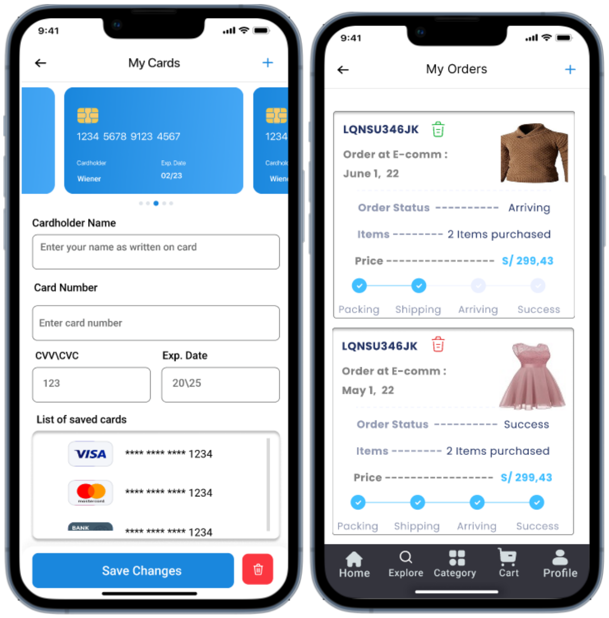

Fig. 19. Prototype of Cards and Purchase Order

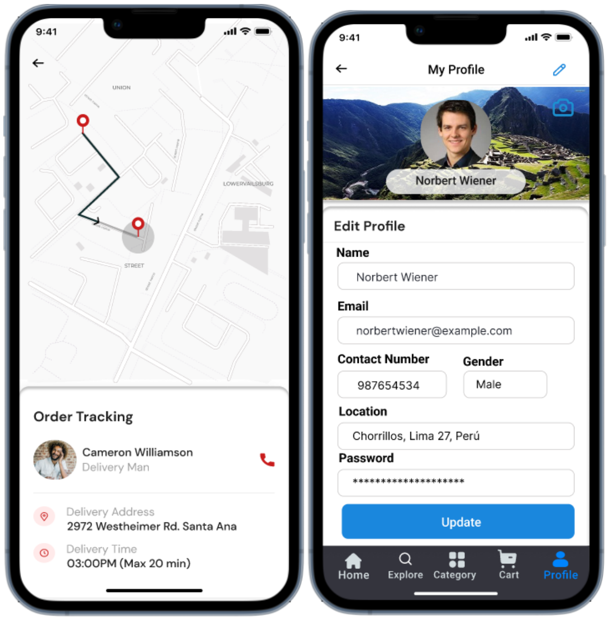

Fig. 20. Order Tracking and User Profile Prototype.

allows the user to search by category, classifying by gender and age.

In Fig. 17, the product view and detail view modules were presented. The product view module allows the user to view the clothing from different angles. Similarly, the detailed view module allows the user to review the information related to the product and make a decision when making the purchase.

In Fig. 18, the modules my cart and verify purchase were presented. The my cart module shows the user the summary or detail of their purchase such as: clothes to buy, quantity to buy, shipping cost, subtotal and total purchase. Similarly, the purchase verification module shows the information of the purchasing user, such as: name, delivery address and contact number. In addition, the form of payment and the total of the purchase to be confirmed.

In Fig. 19, the modules my cards and my orders were presented. The my card module allows the user to add their cards with which they can make payments for their purchases safely. On the other hand, the my orders module shows the status of the purchase and allows the user to track their purchase.

Fig. 20 shows the purchase tracking modules and the user profile. The purchase tracking module allows the user to follow their purchase through a map, which shows the location of the personnel in charge of delivering the purchase; as well as staff information, contact number and delivery time. While the profile module shows the user information. It also allows you to update your data.

B. About the Survey

For the survey, an evaluation questionnaire of 5 criteria or dimensions was elaborated, each one with 4 questions as shown in Table III. In which the evaluation of 10 experts was requested on the following criteria that the mobile application must meet: the design, usability, functionality, security and availability of the mobile application.

Regarding the items or questions for the evaluation, the three-point measurement scale was determined, in which Low, Medium and High must be evaluated according to the established criteria.

TABLE III. Evaluation Questions

Criterion	**Design**
P1	¿Does the application present a simple and neat user interface?
P2	¿Does the application present classified products?
P3	¿Does the application have simplified and clear navigation?
P4	¿Does the application present valuable content?
Criterion	**Usability**
P5	¿Is the application easy to understand and intuitive?
P6	¿Is the app easy to learn to use its features?
P7	¿Is ordering done quickly and easily in the app?
P8	¿Is the app easy and simple to navigate?
Criterion	**Functionality**
P9	Does the application have a simple and fast payment process?
P10	¿Does the application allow you to add or remove products from the shopping cart?
P11	. ¿Does the application filter products according to the searched product?
P12	¿Does the application allow the customer to have control of their order?
Criterion	**Security**
P13	¿Does the application request user authentication to make purchases?
P14	¿Does the application guarantee the integrity of customer data?
P15	¿Does the application maintain the availability of customer data?
P16	¿Does the application present a secure payment process and methods?
Criterion	**Availability**
P17	¿In the application the shopping cart is always visible?
P18	¿Does the application have payment methods commonly used in your online purchases?
P19	¿In the application is the description of the shipping options?
P20	¿Does the app show available products?

C. About Expert Evaluation

After evaluating the experts and analyzing their answers, the mean and standard deviation of each question were obtained. Also, according to the mean of the question, it was scored on a scale, which includes the following: 0 – 1 = Bass, 1.1 – 2 = Medium, 2.1 – 3 = High. Obtaining a result as shown in Table IV.

According to the results, in the Design criterion, in question 1, does the application present a simple and orderly user interface? An average of 3.00 or also called average was obtained, with a standard deviation of 0.000 to which the experts gave the average as High. Likewise, in the Usability criterion, in question 5, is the application easy to understand and intuitive? A mean of 2.70 with a standard deviation of 0.483 was obtained, to which the experts gave the mean as High.

TABLE IV. Result of the Evaluation of the Experts

Criterion	**Question**	**Half**	**SD**	**Scale**
Design	P1	3,00	0,000	High
	P2	2,90	0,316	High
	P3	2,90	0,316	High
	P4	2,90	0,316	High
Usability	P5	2,70	0,483	High
	P6	3,00	0,000	High
	P7	2,80	0,422	High
	P8	3,00	0,000	High
Functionality	P9	2,80	0,422	High
	P10	3,00	0,000	High
	P11	2,90	0,316	High
	P12	3,00	0,000	High
Availability	P13	3,00	0,000	High
	P14	3,00	0,000	High
	P15	3,00	0,000	High
	P16	3,00	0,000	High
Security	P17	3,00	0,000	High
	P18	2,90	0,316	High
	P19	2,80	0,422	High
	P20	3,00	0,000	High

D. About the Methodology

In this section, the comparison between the RUP, Extreme Programming (XP) and Rapid Application Development (RAD) methodologies will be made.

For the evaluation of the methodology, numbers from 1 to 5 were used, where (1) indicates that the practices are unfavorable for the correct development of the project. For its part, (5) indicates that the analyzed criterion is the one with the best compliance with respect to the practices for the development of the project. Obtaining a result as shown in Table V.

According to the results obtained, the RUP methodology has a score of 26, the XP methodology obtains a score of 20, and the RAD methodology obtains a score of 13. Which means that the RUP methodology is the most appropriate to develop the project.

TABLE V. Quantitative Selection Criteria

Criterion	**RUP**	**XP**	**RAD**
Budget available	3	4	3
Project size	5	2	1
Limited delivery times	2	4	2
Need for documentation	5	2	1
Staff needed	5	2	1
Adaptability, response to changes	2	4	2
Customer Impossibility	4	2	3
TOTAL	26	20	13

VI. Discussion

In the findings found in the investigation, it was through a survey of the experts, who qualified as high on a three-point measurement scale; low, medium and high. However, the authors' research [14] is different from ours, since they applied a survey to customers, who gave their opinion. Regarding the prototype and the methodology, the authors [12] developed the clothing sales web system applying the agile methodology such as SCRUM, if we compare it with the research carried out, it does not coincide because ours is focused on the design of a mobile application under the traditional methodology that is the RUP. Regarding the segmentation, the authors' research

[11] applies the development of the mobile application only for the sale of Japanese anime t-shirts, which is only for a community that likes anime t-shirt. For its part, our research focuses on the development of the application for the sale of all types of clothing, which is segmented for men, women, boys, girls and adolescents from different cultures. Finally, in our work we came to the conclusion that the e-commerce mobile application for the sale of clothing can generate economic income and help retain customers, in the same way help grow small businesses that are growing. ; agreeing with the authors [7] who conclude that the mobile application allows the customer to make purchases from anywhere, in the same way it helps Muslim fashion stores that are evolving or growing.

VII. Conclusion

In conclusion, in the present research work, it was possible to design a mobile application for electronic commerce in a satisfactory manner by users, backed by expert judgment based on 5 criteria: design, usability, functionality, security and availability; which guarantee that the application is of quality, applying the RUP methodology. In the same way, the application makes it easier for small companies or SMEs dedicated to the sale of clothing, to offer their products through electronic commerce, thus improving their economic income and building customer loyalty. Likewise, the RUP methodology is a method that ensures that the development is of the best quality and foresees the changes that occur during the development according to the requirements. In the same way, it shows a global vision and optimizes its development.

A limitation of the investigation was the technological one, due to the retractions that the hardware imposes on us when designing the mobile application. Since, when designing the application, you should think about whether the application will be installed satisfactorily on a wide range of mobile devices, since some are high-end and others are not.

VIII. Future Work

In addition, it is suggested as future work that this work should be completed with emerging technologies such as, artificial intelligence integrating the application such as chatbots (virtual assistant) to interact with customers. Likewise, automated personalization, so that the mobile application has the capacity to give recommendations to the client according to their interactions and purchases they make.

Comparative Analysis of Machine Learning Algorithms and Data Mining Techniques for Predicting the Existence of Heart Disease

Nourah Alotaibi[1], Mona Alzahrani[2]
Department of Information and Computer Science (ICS)
KFUPM
Dhahran, Saudi Arabia

***Abstract*—Heart diseases are considered one of the leading causes of death globally over the world. They are difficult to be predicted by a specialist physician as it is not an easy task which requires greater knowledge and expertise for prediction. With the variety of machine learning and deep learning algorithms, there exist many recent studies in the state of the art that have been done remarkable and practical works for predicting the presence of heart diseases. However, some of these works were affected by various drawbacks. Hence, this work aims to compare and analyze different classifiers, pre-processing, and dimensionality reduction techniques (feature selection and feature extraction) and study their effect on the prediction of heart diseases existence. Therefore, based on the resulting performance of several conducted experiments on the well-known Cleveland heart disease dataset, the findings of this study are: 1) the most significant subset of features to predict the existence of heart diseases are PES, EIA, CPT, MHR, THA, VCA, and OPK, 2) Naïve Bayes classifier gave the best performance prediction, and 3) Chi-squared feature selection was the data mining technique that reduced the number of features while maintained the same improved performance for predicting the presence of heart disease.**

***Keywords*—Heart disease; feature selection; feature extraction; dimensionality reduction; Chi-squared; Naïve Bayes; Cleveland dataset**

I. Introduction

Cardiovascular diseases (CVDs) [1] are when the heart and blood vessels affected by some diseases like coronary heart disease and heart failure disease. The statistics in Saudi Arabia that were collected over the past 40 years indicate that the deaths have increased from CVDs. Moreover, according to the World Health Organization (WHO)[1], 17.9 million deaths every year resulted of CVDs including different heart diseases such as cardiovascular disease, valvular heart disease, heart defects, heart infections or cardiomyopathy [2].

Correctly predicting a diagnosis, including predicting the Existence of Heart Disease (EHD), is essential to patient-centered care, equally in choosing healing plans and notifying patients as a basis for shared decision making [3]. In recent years, there have been plenty of studies on EHD prediction. However, EHD prediction research has passed through three different stages along with history. In 1979, two researchers [4] combined diverse results gained from examinations like stress electrocardiography and cardiotocography, and others into a diagnostic decision about the likelihood of getting a disease in a particular patient through Bayes' Theorem . While in 1998, the second stage started when Wilson et al. [5] established a new direction concerning heart diseases estimation by utilizing risk factor classes with the aid of logistic approaches and regression calculations. Nowadays, several researchers have developed various machine learning algorithms [3, 6–10] to predict the EHD on the publicly available datasets which are the focus of this work.

However, the machine learning-based studies were affected by various drawbacks. For example, using datasets without handling the imbalance classes [6, 10, 11], important features such as age were manually excluded from the experiments [6, 9, 10], no comparisons were made in terms of prediction methods [6] or the used dataset [6, 11, 12], various platforms were used for assessments [10], some important details were missing or not clear such as the number of selected features [7] or the number of samples per class [3, 8, 11]. Even more, surprisingly, no coloration exists between the selected features among these works [3, 6–10] even though some of them were using the same dataset. In addition, different machine learning algorithms were selected as the best classifiers in various works according to their experimented data mining approaches. To sum up, there is still a need to experimentally evaluate different classifiers with different data mining approaches to gain a final decision. Hence, inspired by the development of several machine learning-based models for improving the EHD prediction, this study contributes to the literature by providing a work that handles these drawbacks as follows:

- Study the effect of different balancing solutions such as oversampling and undersampling for EHD prediction to handle the imbalance classes issue that exist on Cleveland heart disease dataset.
- Explore the most significant subset of features for the EHD prediction by analyzing different data mining techniques.
- Investigate the best performed classifier for the EHD prediction by comparing different machine learning algorithms.
- Achieve the highest performance for EHD prediction compared to recent related works that experimented

on the well-known Cleveland heart disease dataset by training the best performed classifier with the most significant subset of features.

Consequently, the following set of research questions were explored:

- RQ1: What are the best-performing feature sets for the EHD prediction?
- RQ2: How can the prediction performance be improved using data mining?
- RQ3: What is the most appropriate classifier using the selected features for EHD prediction?

The remaining of this paper is organized as the following: Section II presents the related works which provide several EHD prediction machine learning-based models. Section III explains the proposed methodology. Section IV demonstrates the achieved outcomes and tackles the discussion in light of the findings. Finally, Section V concludes this study and discuses future works.

II. Literature Review

Several heart diagnosis studies in the state of the art [3, 6–14] have been done extraordinary works that contributed by providing different prediction approaches. These studies could be categorized based on the targeted prediction such as Heart Failure (HF) prediction [7], mortality or hospitalization prediction of the HF patient [3, 6], and EHD prediction [8–14]. In addition, they also could be categorized in terms of the investigated learning technique, whether it is supervised learning [3, 8, 11, 12], ensemble learning [6, 12], deep learning [7, 9] or even hybrid learning [10]. Table I summaries the recent related works [3, 6, 7, 10–12] in terms of their experimented datasets, pre-processing techniques, learning methodologies, performance evaluation and drawbacks.

For HF prediction, Maragatham et al. [7] took advantage of the availability of the intensive substantial historical information in Electronic Health Record (EHR) and related time stamped data, in which, the authors inspected whether the usage of deep learning would improve the model performance for early HF diagnosis. The tested data consists of 365,446 patients, where 4289 of them had HF. The examination of time stamped EHRs aided in identifying the relations between numerous diagnosis events and predicting when a patient is being examined for a disease. Medical concept vectors and Long Short-Term Memory (LSTM) network were used to determine the diagnosis events and HF prediction. The proposed model was trained using one-hot vectors and grouped code vectors. As an activation function, SiLU and tanh were used in the hidden layers, while in the output layer, Softmax was used. For weight optimization through the network, Bridgeout, a regularization technique was used. K-nearest neighbour (KNN) and SVM were implemented using Python Scikit-Learn version 0.16.1 while Theano 0.7 was used to implement LSTM network, multilayer perceptron (MLP), and Logistic Regression (LR) models. They conducted two different experiments according to the length of the prediction and observation windows; and the performance was compared to well-known supervised approaches such as LR, MLP, SVM and KNN. Specifically, the first experiment, when using 12-months and 6-months as observation and prediction windows respectively, gave an AUC of 0.797, and when using 18-months and 0-months gave 0.894 AUC.

While for mortality prediction of the HF patient, Adler et al. [6] developed MARKER-HF, a tool that computes a risk score between -1 and +1 to predict mortality of hospitalized and ambulatory HF patients as high risk or low risk mortality using ensemble learning. MARKER-HF is based on a machine learning model that is trained using AdaBoost which is a boosted decision tree algorithm that is implemented in the TMVA toolkit. They used eight features to train their models with data of 5822 patients taken from the A systems BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF) project, University of California San Diego (UCSD) and San Francisco (UCSF) Medical Centers. MARKER-HF results showed its ability to predict mortality consistently in three different datasets. For mortality prediction with a 95% confidence interval for the area under the ROC curve, they achieved AUC=0.88 using UCSD, AUC=0.84 using UCSF, and AUC=0.81 using BIOSTAT-CHF.

Moreover, Angraal et al. [3] compared five different supervised learning classifiers not only for mortality prediction but also for hospitalization of HF outpatients with preserved ejection fraction (HFpEF) through three years of follow-up. They trained the following five methods: two LR, one with a forward selection and one with a lasso regularization for feature selection, gradient descent boosting, Random Forest (RF) and Support Victor machine (SVM). They used a total of 86 candidate features to train their models, including demographic, clinical, laboratory and electrocardiography data, and KCCQ scores obtained from the patients. These patients' data are taken from the Treatment of Preserved Cardiac Function Heart Failure with an Aldosterone Antagonist (TOPCAT) trail. The authors used 5-fold cross-validation to divide the learning set into five subsets, where 80% of them were used for training and 20% for testing. They experimentally proved that RF is the best classifier with 95% confidence interval achieved AUC=0.72, and Brier score=0.17 for mortality prediction; and AUC=0.76 and Brier score=0.19 for HF hospitalization prediction. Even more, they found that the best features to predict mortality are the body mass index, BUN levels, and KCCQ scores; where BUN levels, hemoglobin level (H) and KCCQ scores are the best features to predict HF hospitalization.

On the other hand, most of the heart diagnosis studies were focused on predicting the EHD [8–14]. Ananey-Obiri and Sarku [11] investigated the traditional supervised learning algorithms and data mining techniques for EHD prediction. They investigated the following three supervised algorithms: decision tree (DT), LR, Gaussian Naïve Bayes (NB). They experimented the well-known Cleveland heart disease datasets with all of its 13 features shown in Table II which are age, sex, Resting Blood pressure (RBP), Chest Pain Type (CPT), Serum Cholesterol (SCH), Fasting Blood Sugar (FBS), Maximum Heart Rate achieved (MHR), Resting Electrocardiographic Results (RES), Exercise Induced Angina (EIA), Peak Exercise Slope (PES), Old Peak (OPK), Thallium Scan (THA) and number of major Vessels Colored by Fluoroscopy (VCA). The tested dataset contained 287 observations out of 303 after the duplicated, missing values and outliers were removed as a pre-processing step. In addition, they used feature normalization as a feature scaling technique, and single value decomposition (SVD) as feature extraction to reduce the number of features from 13 to 4. The data was labeled as absent or present of heart diseases. The authors used 10-fold cross-validation to divide the learning set into ten subsets, where nine of them were used for training and one of them for testing. The reported results were 79.31% accuracy and 0.81 AUC for DT model, 76% accuracy and 0.87 AUC for Gaussian NB model, and 82.75% accuracy and 0.86 AUC for LR model. Moreover, in the work conducted by Reddy et al. [12], ten different supervised and ensemble learning techniques were tested for EHD prediction. These techniques include NB, LR, Sequential minimal optimization (SMO), bootstrap aggregation, AdaBoost, JRip, RF, and KNN. Cleveland dataset was tested with 303 samples and 13 pre-mentioned features. Three different feature selection methods were used to enhance the performance, which are chi-squared, BestFirst search method and ReliefF. 11 out of 13 features were selected with the best performance result. As an evaluation scheme, 10-fold cross-validation was applied. The best result was 85.15% accuracy which was obtained using the SMO classifier with Chi-Squared feature selection technique. Even more, a hybrid learning approach was adapted by Abdeldjouad et al. [10], in which a hybrid approach of various machine learning methods was proposed to predict EHD. These methods include AdaBoostM1, LR, Fuzzy Unordered Rule Induction (FURIA), Multi-Objective Evolutionary Fuzzy Classifier (MOEFC), Fuzzy Hybrid Genetic Based Machine Learning (FH-GBML), and Genetic Fuzzy System-LogitBoost (GFS-LB). They also experimented Cleveland database for training and assessing their methods using 10-fold cross-validation. Two models were built in which the first model used AdaBoostM1, LR, and MOEFC with 14 features, and reduced to 12 by removing the personal information (e.g. age and sex) with the wrapper feature selection method. While the second model used FURIA, GFS-LB, and FH-GBML and reduced the features to 6 with Principal Component Analysis (PCA) as a dimensionality reduction technique. The first model was selected using the majority voting as the final best-performed model with 80.20% accuracy. For conducting this work, the Keel tool was used for feature selection, while the Weka tool was used for feature extraction.

However, the EHD prediction studies [8–14] have some drawbacks. For example, using datasets without handling the imbalance classes [6, 10, 11], important features such as age, were manually excluded [6, 9, 10], no comparisons were made in terms of prediction methods [6] or the used dataset [6, 11, 12], various platforms were used for assessments [10], some important details were missing or not clear such as the number of selected features [7] or the number of samples per class [3, 8, 11]. Even more, surprisingly, no coloration exists between the selected features among these works [3, 6–10] even though some of them were using the same dataset. In other words, the significant factors that cause variance in recent proposed works' performance are still not fully investigated. To sum up, there is still a need to experimentally evaluate different classifiers with different data mining approaches to gain a final decision. Hence, this study's primary goal is to compare and analyze different classifiers and data mining techniques (feature selection and feature extraction) and their effect on improving the EHD prediction.

III. Methodology

This work handled the previously mentioned drawbacks, in which it explored numerous solutions including the usage of different sampling techniques to overcome imbalanced datasets issue represented in [6, 10] with different dimensionality reduction techniques. Moreover, all the important features were taken into consideration which were excluded manually by [6, 9, 10]. Furthermore, some of the previous works [3, 6, 7] used different sets of performance metrics which make the comparison quite difficult, so the proposed approach was assessed by considering a full set of well-known performance metrics with clarifies details regarding the selected features and the number of samples per class to tackle what was missing in [3, 7, 8]. In addition, different machine learning algorithms were selected as the best classifiers in various works according to their experimented data mining approaches. To summarize, there is still a need to experimentally evaluate different classifiers with different data mining approaches to gain a final decision.

Consequently, the methodology shown in Fig. 1 which consists of seven main stages, was designed to conduct this study to ensure the proposed solutions. The first stage is *data collection* where the Cleveland heart disease dataset (Clev) [15] was selected in Section III-A to be investigated in this work. While in the second stage, a *data pre-processing* is performed in Section III-B using some data balancing techniques to generate two more balanced versions of the dataset. In Section III-C, *dimensionality reduction* was done as the third stage using some data mining techniques such as *feature selection*, and *feature extraction* to reduce the number of features, improve the performance and avoid overfitting. In Section III-D the fifth stage, which is *evaluation scheme preparing* was detailed. Then, seven well-known *classification algorithms* are selected in Section III-E for the purpose of comparison. Lastly, in the seventh stage, the conducted *comparative experiments* were designed in Section III-F.

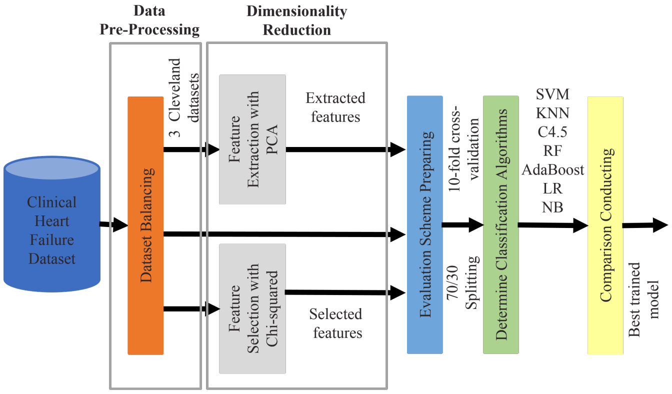

Fig. 1. The Proposed Methodology for EHD Prediction Comparison.

A. Dataset Collection

In this study, the well-known Clev heart disease dataset [15] was experimented since it is the most investigated dataset in this field by related works [8–11, 13, 14]. It is publicly available on an online machine learning and data mining repository of the University of California, Irvine (UCI). It contains

TABLE I. Summary of Various HF Prediction Techniques

	Reference	**Adler et al. [6]**	**Maragatham et al. [7]**	**Ananey-Obiri and Sarku [11]**	**Angraal et al. [3]**	**Reddy et al. [12]**	**Abdeldjouad et al. [10]**
Description	**Year**	2020	2019	2020	2020	2021	2020
	Main Goal	Mortality prediction of HF patients	HF prediction	EHD prediction	Mortality and hospitalization prediction of HF patients	EHD prediction	EHD prediction
Dataset	**Dataset Name**	UCSD	An arbitrary	Cleveland	TOPCAT	Cleveland	Cleveland
	# Samples	5822	4289	287	1,76	303	296
	Evaluation Scheme	50%|50% training|testing	6-fold cross-validation	10-fold cross-validation	5-fold cross-validation	10-fold cross-validation	10-fold cross-validation
Data Mining and Pre-Processing	**Technique**	- Exclusion of patients who had missing data, older than 80 years, with CIED device, died within 7 days of initial encounter, or had obvious medical record errors	Not clear	- Exclusion of patients who had missing or duplicated data - Feature scaling using normalization - Feature extraction using SVD	- Exclusion of features with 50% missing data - Feature selection using forward selection and a lasso regularization	- Feature selection using chi-squared, BestFirst search method and ReliefF	- Exclusion of patients who had missing data - Exclusion of personal features - Feature selection using a wrapper method - Feature extraction using PCA
	#Features	8	Not clear	4 out of 13	86	11 out of 13	13
	Features Names	Cr, RBP, H,BUN, platelets, WBC, RDW and albumin	Health info, tobacco usage, demographics and liquor consumption and lab test	Age, sex, RBP, CPT, SCH, FBS, MHR, RES, EIA, PES, OPK, THA and VCA	Demographic, clinical, laboratory and electrocardiography, and KCCQ scores features	Age, sex, RBP, CPT, SCH, FBS, MHR, RES, EIA, PES, OPK, THA and VCA	RBP, CPT, SCH, FBS, MHR, RES, EIA, PES, OPK, THA and VCA
Methodology	**Learning Category**	Ensemble learning	Deep learning	Supervised learning	Supervised and ensemble learning	Supervised and ensemble learning	Hybrid learning
	Prediction Methods	AdaBoost	LSTM	LR	LR with a forward selection, LR with a lasso regularization, RF, gradient descent boosting and SVM	SMO	A new hybrid approach of LR, AdaBoostM1, MOEFC, FURIA, GFS-LB and FH-GBML
Performance Evaluation	**Metrics**	ROC charts, and AUC	ROC charts, and AUC	CM, ACC, P, SE, F-score, ROC charts, and AUC	AUC, and Brier scores	ACC, MAE, SE, fallout, P, F-Score, SP, and ROC area	SE, SP, ACC, ER
	Results	AUC= 0.88	AUC= 0.894	ACC=82.75%, and AUC=0.86	Mortality prediction (AUC= 0.7, Brier score= 0.17) HF hospitalization prediction (AUC= 0.76, Brier score= 0.19)	ACC= 86.468%	ACC= 80.20%
Drawbacks	**In terms of** datasets, features, platforms, algorithms, and comparisons	- Imbalanced datasets - Exclusion of elderly patients above 80 years - No comparisons are made in terms of prediction methods	- Some important details are missing or not clear	- No. samples per class were not mentioned - Imbalanced datasets	- No. samples per class were not mentioned - No comparisons are made in terms of datasets - Dataset with missing data	- No comparisons are made in terms of the dataset	- Personal information is excluded manually (e.g age, sex) - Using various platforms - No comparisons are made in terms of the dataset - Imbalanced datasets

The evaluation metrics are P: Precision, CM: Confusion matrix, AUC: Area Under Curve, ROC: Receiver Operating Characteristic curve, ACC: Accuracy, SP: Specitivity, SE: Sensitivity, ER: Error Rate, MAE: Mean Absolute Error.
The features are RBP: Resting Blood pressure, CPT: Chest Pain Type, FBS: Fasting Blood Sugar, SCH: Serum Cholesterol, MHR: Maximum Heart Rate achieved, RES: Resting Electrocardiographic Results, EIA: Exercise Induced Angina, PES: Peak Exercise Slope, OPK: Old Peak, THA: Thallium Scan, VCA: Number of Major Vessels Colored by Fluoroscopy.

303 medical records of 165 patients with heart diseases and 138 are healthy. Moreover, it has 74 features, but 13 common features have been studied in the state of the art. Table II lists these features, their types and descriptions. The Clev originally contained five categorical classes (0, 1, 2, 3 and 4) where 0 refers to the absence of heart disease while the other four classes (1, 2, 3 and 4) refer to the presence of different heart diseases. However, most of the works [8–14] that used this dataset transferred these five categorical classes to a binary class for the purpose of distinguishing simplicity. The “class" field denotes the existence of heart disease in the patient. In which 0 means absence of heart disease (normal) and 1 means existence of heart disease.

B. Dataset Balancing

In the medical field, according to [10], the diagnosis of diseases is easier and quicker if data is balanced. The used Clev dataset contains 303 observations which present quite balanced positive and negative samples, with 165 and 138 observations respectively. But, machine learning techniques are very sensitive and the created prediction models are usually biased towards the larger class. However, the previous works [6, 10, 11] ignored this fact. Hence, to create an unbiased prediction model, reduce the gap between the two classes, and ensure equivalent balancing, dataset pre-processing is needed [9]. In this study, the class-imbalance problem in the original Cleveland dataset was solved by using oversampling and un-

TABLE II. Detailed Description of Cleveland Dataset's Features

#	Feature Name	Shortcut	Feature Type	Description
F1	Age	Age	Continuous	Age of the patient [years]
F2	Sex	Sex	Discrete	Sex of the patient [M: Male, F: Female]
F3	ChestPainType	CPT	Discrete	Chest pain type [TA: Typical Angina, ATA: Atypical Angina, NAP: Non-Anginal Pain, ASY: Asymptomatic]
F4	RestingBP	RBP	Continuous	Blood pressure at rest [mm Hg]
F5	Cholesterol	SCH	Continuous	Serum cholesterol [mm/dl]
F6	FastingBS	FBS	Discrete	Fasting blood sugar [1: if FastingBS >120 mg/dl, 0: otherwise]
F7	RestingECG	RES	Discrete	Resting electrocardiogram results [Normal: Normal, ST: having ST-T wave abnormality (T wave inversions and/or ST elevation or depression of >0.05 mV), LVH: showing probable or definite left ventricular hypertrophy by Estes' criteria]
F8	MaxHR	MHR	Continuous	Maximum heart rate achieved [Numeric value between 60 and 202]
F9	ExerciseAngina	EIA	Discrete	Exercise-induced angina [Y: Yes, N: No]
F10	Oldpeak	OPK	Continuous	Oldpeak = ST depression induced by exercise relative to rest [Numeric value measured in depression]
F11	ST_Slope	PES	Discrete	The slope of the peak exercise ST segment [Up: upsloping, Flat: flat, Down: downsloping]
F12	MajorVessels	VCA	Continuous	The number of major vessels colored by flourosopy [0-3]
F13	ThalliumScan	THA	Discrete	Type of defect [3 = normal; 6 = fixed defect; 7 = reversible defect]

dersampling techniques to create two balanced versions of the dataset. The first version is (*Oversampled Cleveland*) which was generated using the Synthetic Minority Oversampling Technique (SMOTE) [16] which is popularly used in the medical field to deal with class imbalanced data. SMOTE adds more samples to the smaller class observations by generating random synthetic ones from its nearest neighbors using the Euclidean distance [17]. SMOTE increased the original Cleveland dataset from 303 to 330 observations (165 for each class). While the second version is (*Undersampled Cleveland*) which was simply generated by randomly reducing the number of larger class observations. Undersampling reduced the original Cleveland dataset from 303 to 276 observations (138 for each class).

C. Dimensionality Reduction

It decreases the number of input features (dimensions) of the original problem using specific techniques to improve the learning performance. These techniques are categorized as *feature selection* and *feature extraction*. The key difference between them is that the feature selection selects a subset of features from the original features, while the feature extraction uses the original features to create a new set of features [18]. In this study, one technique from each of these categories was experimented in the following illustration:

1) Feature Selection: it is the process of selecting a group of relevant features from the original features according to specific criteria [10]. Some of its main goals are: 1) reduce the algorithm's computational time, 2) identify the relevant features, 3) improve the prediction performance, and 4) avoid the overfitting by limiting the number of selected features; because the overfitting could affect the model to loss its robustness when the model is used to test new unseen data [6, 19]. In this study, the Chi-squared [20] was used as a feature selection technique to determine the most relevant features. Chi-squared was selected among other feature selection techniques since it improves most of the classifiers' performances and achieves remarkable results in this field [12, 14, 20]. This study starts with the 13 most common features and end up with only seven features after applying Chi-squared. The seven selected features are PES, EIA, CPT, MHR, THA, VCA, and OPK.

2) Feature Extraction: as one of the dimensionality reduction methods, it reduces the number of dataset's features in which the reduced features are represented by a set of new features [10]. The main goal of this technique is to use fewer features, which results in a simpler model that may have better performance with new unseen data. In this study, the principal component analysis (PCA) was used. The reason behind selecting PCA is because it is considered as one of the most famous dimensionality reduction and feature (components) extraction techniques for the medical applications [10]. PCA works by creating novel factors that have the best valuable information by capturing the highest variance of these features [21]. Using PCA, 2, 8 and 8 new sets of features were extracted for the original Clev, Oversampled Clev, and Undersampled Clev, respectively.

D. Evaluation Scheme Preparing

All the three Cleveland versions were evaluated by two schemes which are 10-fold cross-validation and 70%|30% for training|testing data splitting.

E. Classification Algorithms Selection

Machine learning and classification techniques are a group of computational models that can be used to solve many kinds of problems easily. Various applications of computational intelligence exist in the pathology and medicine field [22, 23]. This work, compared the following seven classifiers: SVM [24], KNN [25], C4.5 [26], RF [27], AdaBoost [28], NB [29] and LR [30]. SVM is a supervised learning technique that demonstrates superb performance in the medical field [31]. It depends on kernel functions that transfer all instances to a upper dimensional space intending to find a linear decision boundary for data partitioning [24]. KNN is a simple but effective method for classification [25]. C4.5 decision tree was selected due to its low complexity in implementation and excellent explanation [26]. In addition, a decision tree was investigated as the main classifier in several EHD prediction research. RF decision tree [27], is one of the popular techniques for pattern recognition which has been efficiently applied as a strong and widespread tool for predicting and classifying medical data. NB [29] is based on Bayes' Theorem with an assumption of independence among predictors.

In this study, SVM was implemented via the LibSVM library using nu-SVC as SVM type and linear kernel [24]. KNN was implemented using IBk library where the number of neighbors K to inspect equals 1. C4.5 decision tree algorithm was implemented using the J48 classifier (C4.5 release 8 implemented with Java) [26]. AdaBoost [28] is a short term of Adaptive Boosting and was implemented using AdaBoostM1.

F. Comparison Conducting and Performance Measurements

The comparison experiments were conducted based on the three versions of the Clev dataset (original, oversampled, and undersampled Clev), each with three copies: 1) without dimensionality reduction, 1) after applying Chi-squared, 3) after applying PCA; which makes them a total of nine datasets to be experimented. Each dataset was used to build training models using the seven classifiers which are SVM [24], KNN [25], C4.5 [26], RF [27], AdaBoost [28], NB [29] and LR [30]. So, a total of 63 models (9 datasets * 7 classifiers) were experimented. Each model was tested using two evaluation schemes; 10-fold cross-validation and 70%|30% splitting. Hence, the entire experiment ended up with a total of 126 trails (63 training models * 2 evaluation schemes).

The building training models were evaluated via six measures, which are Matthews correlation coefficient (MCC) [8], accuracy (ACC), recall/sensitivity (SE), precision, F-Score (FM) [11], specificity (SP), error rate (ER) [10], and area under the curve (AUC) [7]. MCC is a measure that is frequently utilized for assessing the quality of binary classification. It ranged from -1 to 1, in which 1 indicates an excellent prediction, 0 means the classification is no better than a random prediction, and -1 indicates full disagreement between prediction and observation. The Receiver Operating Characteristic (ROC) chart is used for additional investigation, where it consists of two rates, the true positive rate (TPR) versus the false positive rate (FPR) for various thresholds. The best ROC is the chart with more area under the curve (AUC). AUC equal to 1 presents the ideal ROC which means that the model can perform with 100% sensitivity and 100% specificity [8]. ACC refers to the fraction of accurately classified samples. SE is the fraction of correctly classified heart disease patients. It is also known as True Positive Rate (TPR) or recall, while SP is the correctly classified healthy subjects. These measures are formulated as the following[2]:

$$Precision = \frac{TP}{TP + FP} \tag{1}$$

$$Recall/\ Sensitivity\ (SE) = \frac{TP}{TP + FN} \tag{2}$$

$$Specificity\ (SP) = \frac{TN}{TN + FP} \tag{3}$$

$$F\text{-}Score = \frac{2TP}{2TP + FP + FN} \tag{4}$$

$$Accuracy\ (ACC) = \frac{TP + TN}{TP + TN + FP + FN} \tag{5}$$

$$Error\ Rate\ (ER) = \frac{FP + FN}{P + N} \tag{6}$$

$$MCC = \frac{(TP * TN) - (FP * FN)}{\sqrt{(TP + FP) * (TP + FN)(TN + FP)(TN + FN)}} \tag{7}$$

All the implemented experiments including oversampling, feature extraction, feature selection, and performance evaluation were done using various libraries in WEKA version 3.8.5 [32]. The oversampling was implemented using the *SMOTE* technique that was proposed by [16] under the supervised filters where the nearest neighbors parameter was set to 5. While feature extraction was implemented using *Principal-Components* as attribute evaluator and *Ranker* as the search method. On the other hand, feature selection was implemented using *ChiSquaredAttributeEval* as an attribute evaluator and *Ranker* as a search method as well.

IV. Results and Discussion

Tables III and IV summarize the splitting and cross-validation results respectively. These results only present the best performed classifiers of the nine datasets that have been obtained from 126 trials. While Fig. 2 and 3 present the splitting and cross-validation results in terms of accuracy.

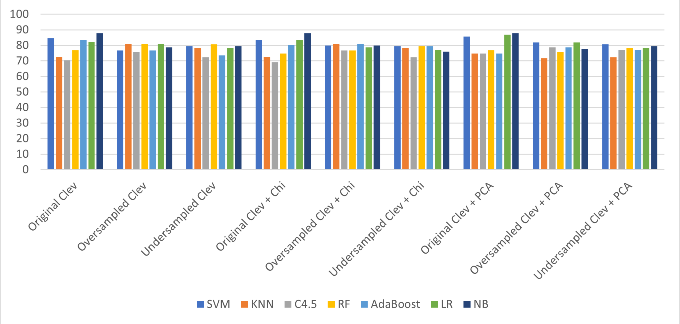

Fig. 2. The Accuracy of the Conducted Trails using 70%|30% Splitting.

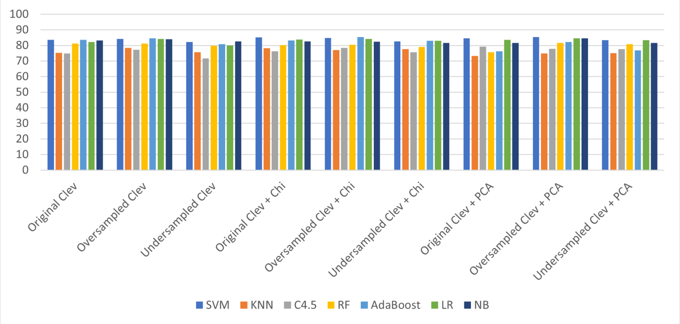

Fig. 3. The Accuracy of the Conducted Trails using 10-Fold Cross-Validation.

For *Original Clev dataset*, it can be noticed from the obtained accuracy in Fig. 2 of the splitting scheme that there are no significant differences between all the three versions of it (without processing, with Chi-squared, and with PCA) even though they contain different number of features. In fact, NB is the best performing classifier with ACC=87.91% and AUC=0.93, which is also summarized in Table III. C4.5 is the worst classifier, even when the number of features are changed. On the other hand, in terms of accuracy, when the cross-validation was used as shown in Fig. 3, SVM and AdaBoost were the best performing classifiers using all the 13 features with the same 83.5% accuracy. But SVM

* mean the classifier that gave the best performance in terms of accuracy.

outperformed the others when the features are reduced to 7 and 2 using Chi-squared (ACC=85.15% and AUC=0.84) and PCA (ACC=84.49% AUC=0.84).

For *Oversampled Clev dataset*, when the SMOTE technique is used to balance the data, the accuracy of the splitting scheme in Fig. 2 was significantly changed when the processing technique was changed (# of features) and with the evaluation scheme being changed. But the LR was the best classifier with ACC=81.82% when only the 8 features obtained from PCA were used. C4.5 and KNN gave the worst accuracy. However, in terms of AUCs, the RF and LR always outperformed other classifiers, even when the number of features being changed by 0.88 AUC for both classifiers. In addition, in terms of accuracy using cross-validation shown in Fig. 3, C4.5 and KNN again gave the worst accuracy. Where AdaBoost dominates the other classifiers by ACC=85.45%, when the original 8 or 7 features from Chi-squared and PCA were used, respectively. Moreover, in terms of AUCs, the best classifiers vary when the number of features being changed, but the worse classifiers were always C4.5 and KNN.

For *Undersampled Clev dataset*, Fig. 2 and 3, show that when the original Clev observations were reduced aiming for balancing, the obtained results were decreased compared with the above versions of the dataset. However, with the splitting scheme, it achieved 80.72% accuracy when using the 13 features with RF, and also when using the 8 features from PCA with SVM. Where with cross-validation scheme, it achieved 82.97% accuracy when using the 7 features from Chi-squared with AdaBoost. Furthermore, the LR and NB are the best classifiers in terms of AUCs, whatever the used features. Even with the splitting scheme, it achieved AUC=0.85 when using the 13 features with RF. Yet, with the cross-validation scheme, it achieved AUC=0.85 with whatever the used features.

According to the obtained results from the above experiments, the research questions were answered as follows: 1) seven features, which are PES, EIA, CPT, MHR, THA, VCA, and OPK, are the best performing features for predicting EHD, which were obtained from the Chi-squared feature selection technique; 2) it is noticeable that the best prediction performance ACC=87.91% and AUC=0.93 can be obtained whither the original features, the selected features, or the extracted features were used. Hence, the data mining techniques did not improve the prediction performance in terms of accuracy, however, they improved it in terms of reducing the number of features which lead to more computational efficiency; and 3) NB proves that it is the most appropriate classifier to be used with whatever feature sets to predict the EHD.

Furthermore, the availability of the Clev dataset allows many researchers to test their prediction models. For that reason, this work was compared to the recent related studies that used Clev dataset [11, 13, 14, 33]. Table V summarises their methods and obtained results along with this work. It is noticeable that these studies lack some important performance metrics such as MCC which play an important role in reporting balance or imbalanced data. Moreover, the effect of using different applied techniques such as data pre-processing, feature selection, and feature extraction techniques were also compared. This comparison proved that this work outperforms those studies by achieving higher performance with a margin of 2.20%.

V. Conclusion and Future Work

EHD prediction is a field where researchers propose new techniques that hopefully can facilitate the diagnosis of the existence of heart diseases and enhance the decision-making operations of physicians. In this work, an experimental comparison was conducted between seven famous classifiers, which are SVM, KNN, C4.5, RF, AdaBoost, NB, and LR with different data mining techniques including feature extraction, and feature selection. This work utilized a famous heart disease dataset called Cleveland, aiming to undergo a deeper investigation of the effective techniques that could improve EHD prediction. A methodology of seven basic stages was proposed to conduct this study, including data collection, data pre-processing, and balancing techniques (oversampling and undersampling). Dimensionality reduction such as Chi-squared feature selection and PCA feature extraction techniques were also investigated. The main concern of this paper is not only enhancing the accuracy of weak classifiers but also investigating the famous Clev dataset closely and studying the influence of different pre-processing techniques, in addition, to determining the number of best features that work better with Clev. However, this work, like other Cleveland dataset-based works [11, 13, 14, 33], suffers from the limited number of observations that could be handled in the future works by merging it with another EHD prediction dataset. Moreover, this study could be extended by exploring more data pre-processing techniques such as outlier detection, applying deep learning techniques, and tuning the hyperparameters.

***Abstract*—The Internet of Things can be defined as the network of physical objects that have sensors, software, and other technologies built into them in order to communicate and exchange data with other systems and devices over the internet. In intelligent agricultural advancements to increase the quality of agriculture, the Internet of Things (IoT) can be used. The manual monitoring of plant diseases is quite challenging. It demands enormous effort, expertise in the diseases of plants and the considerable time required for processing. The idea of automation in Smart Agriculture is implemented using the Internet of Things (IoT). They help monitor the plant leaf conditions, control water irrigation, gather images using installed IoT system which includes NodeMCU, cameras, soil moisture, temperature sensors and detect diseases in plants on the datasets collected from leaves. To detect plant diseases, image processing is applied. The detection of diseases comprises the acquisition of images, image pre-processing, segmenting an image, extracting and classifying features. In addition, the performance of two machine-learning techniques, such as a linear and polynomial kernel multi hidden extreme machine (MELM) and a support vector machine (SVM), has been studied. This paper discussed how plant diseases could be detected via images of their leaves. This analysis seeks to validate a proposed system for an appropriate solution to the IoT-based environmental surveillance, water irrigation system management and an efficient approach for leaf disease detection on plants. The proposed multi hidden layers extreme machine classification delivers good performance of 99.12% in the classification of leaf diseases in comparison to the Support Vector Machine classification, which gives 98%.**

I. Introduction

Agriculture is the primary livelihood of Indian villagers; more has been done to boost yields and help farmers address issues like agriculture and plant disease. There have been significant mechanical and chemical advances. In this industry, however, there is little or less digitization. With the IoT growth, it is hoped that the farmers will make a digital agriculture system that will assist farmers in making educated decisions on their farms and help them address undesirable issues earlier. It will therefore avail to increase crop quality and will also benefit farmers. This will help—early disease detection, which in agriculture is a great challenge. IoT sensor nodes play a significant role in collecting real-time information play a significant role in collecting real-time information [1], [2]. These nodes can make the system highly practical by gathering data from crop fields in real-time to specify the agriculture system precisely. Presently to make agriculture system more practical with the help of machine learning techniques. All of them are more beneficial in different domains. Multiple applications are developed in precision agriculture to update the farmers about the condition of the crop [3]. The precision agricultural model is usually made up of three primary phases, as illustrated in Fig. 1. In the first phase, the availability of the IoT sensor nodes and their monitoring conditions can be obtained for crop. Later in the second phase, the data gathered from all the sensors are sent to the fog node with a wireless module to further process the data for higher levels where it can be monitored. Finally, the analytic methods are applied in the third phase of architecture to understand the status of the fields.

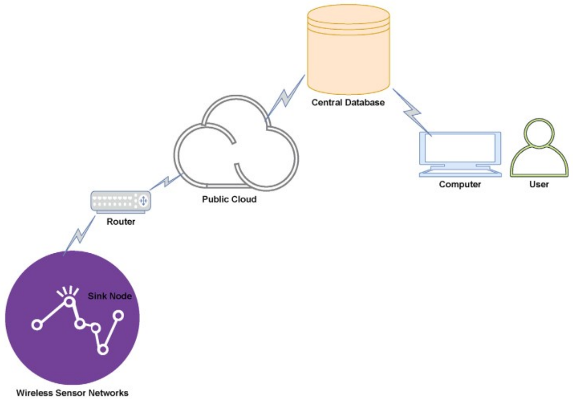

Fig. 1. Precision Agriculture Model.

An alert data is passed to the farmers to make them alert and take necessary precautions if any abnormal conditions are met, like dryness in the crop field, any leaves affected by diseases, with the help of deployed sensors. Therefore, there is continuous communication with the selector, which switches the dipping system on or off to allow the water for all the areas of the ground. Later, the farmers can use the required nitrogen, potassium, and phosphorus fertilizer to sustain plant growth and achieve crop yield. The response system is initiated by using analytics and actuators when any crucial situation is recognized (sensed/predicted). There are several IoT and WSN applications [4], some of which are discussed here. The applications for precision farming are shown in Fig. 2. The different implementation of greenhouses leads to specific significant planting problems and minor technical problems for the global conservation systems [5]—one of the primary issues employing temperature preservation. flies have also damaged greenhouses because they are covered in a structure that generates turbulence in the covered sheet for any reptile or flies. This turbulence can eventually cause a reduction in plant health, and even their growth can be affected. Because of these issues, the greenhouse practice has to be evaluated and technology integrated to address these concerns. This paper emphasises applying the internet of things (IoT) to solve temperature monitoring and leaf dataset detection in the plant. It will allow agribusiness, farmers, horticultural companies and potential investors to transform the internet from an existing greenhouse into an innovative greenhouse.

II. Related Work

Various literature works on the cloud and edge in the health service have emerged. A software approach for the automatic detection and classification of plant leaf diseases was suggested and experimentally verified in [6]. The proposed system developed includes four fundamental steps. In the first step, most of the coloured pixels are detected. Those pixels are subsequently masked using the Otsu method depending on specific threshold values, and predominantly green pixels are masked. The second step is to remove pixels with red, green, and blue nulls and the pixels on the edges of the infected cluster. The experiment results show that the technique provided is a robust method for detecting diseases from plant leaf images. The efficiency of the proposed algorithm may successfully detect and classify the diseases studied with accuracy from 83In [7], the authors trained a deep convolutional neural network to detect 14 plant classes and 26 diseases from 54,306 images of unhealthy and healthy plant leaf taken under controlled conditions (or absence thereof). The trained model obtains a 99.35% accuracy with a stable test set, which shows the practicality of the technique. The model still reaches an accuracy of 31.4% when tested on a collection of images acquired from reputable web sources, i.e. under conditions different from those for training. Although this accuracy is substantially higher than that due to random selection (2.6%), additional training data are required to improve overall accuracy. Essentially, the technique of deep learning models in increasingly large and open-ended image data sets presents a holistic path toward that massive global diagnosis of smartphone-assisted plant disease. In [8], the authors integrated thermal and visible light image data with information on the depth. They custom-made a machine learning system for remotely detecting plants with Oidium neolycopersici powdery tomato fungus. The results make evident that, by integrating this information with the depth data, the detection accuracy of unhealthy plants has improved dramatically from the image data. Furthermore, it has been demonstrated that a new feature set may detect plants that were not initially injected with the fungus at the beginning of the experiment but became diseased through standard transmission. In [9], the authors studied several computer vision ways that resulted in the detection of multiple algorithms. Phase one was taken using a typical digital camera to gather images of banana leaves. Phase two involves using several extraction methods to collect essential data for phase three when images are healthy or unhealthy. Extremely randomized trees have done their best in detecting diseases with 0. 96 AUC in banana bacterial wilts and 0.91 in the case of banana black Sigatoka (BBS) among the seven classifiers used in this study. Finally, based on the area under curve (AUC) analysis, the performance of various classifiers was evaluated, and the optimum approach for the automatic diagnosis of these banana conditions was then selected. In [10], the nonexistence of farmers in a country where around 58 percent of the people participates in farming, the best crop for the land is decided on by traditional and non-scientific techniques. Farmers were sometimes unable to choose the suitable soil crops, season and geographical location. This leads to suicide, to an abandonment of agriculture and urban living conditions. The authors have presented a technique to help farmers select the crop to overcome this problem by considering all elements, such as the soil's season and the crop's location. Moreover, precise agriculture is practised in emerging countries with current agriculture techniques, focusing on site-specific crop management. In order to accurately separate the disease symptoms from the clutter background, manual selection of the input dataset was utilised at the same time. In [11], Textual features can be extracted in two different methods. One method for calculating the energy, inertia, entropy, and homogeneity of textual features is to utilise a grey level co-occurrence matrix. The Gabor transform can also be used. Some studies employ descriptors based on colour. Area, perimeter, centroid, and diameter were once taken into consideration for shapes. Due to its high accuracy and reduced dimensionality problem, Support Vector Machine (SVM) is a favoured classification method. In [12], the CNN is a neural network technology that is frequently used today to train or analyse visual data. Convolution's matrix format is intended to filter the images. The input layer, convo layer, fully connected layer pooling layer, drop-out layer to form CNN, and finally linked dataset classification layer are all used in the Convolution Neural Network for data training. In [13], to extract the distinctive elements from an image, segmentation is an approach that takes into account the texture and colour of the image. In [14],the adoption of deep learning, more specifically Convolutional Neural Network (CNN), as a substitute method for creating a model for classifying diseases. In [15], in order to extract local features, the convolution layer convolves the input image (or the output of the previous layer) using configurable weight filters, or kernel. CNN extracts shift-

and scale-invariant local features from the input by using various weight filters. The object's translation invariance is acquired by the pooling layer, which summarises the results of the preceding layer. In [16], color, texture, and shape are some of the features that were taken from the image. Information about boundaries, spots, and broken areas is contained in the colour feature. The percentage of the lesion and its type are also included in the shape attribute. Uniformity, contrast, probability, variance, and correlation are all aspects of texture. The database is split into two sets of photos for training and testing using the identified features. In [17], building a model that can be utilised by developers to build smartphone or online applications to detect tomato leaf diseases using convolutional neural networks in order to illustrate, categorise, and provide solutions for plant problems. In [18], the tool for classification is a neural network. Target data is provided to the neural network as a class vector, and seven extracted features—Contrast, Correlation, Energy, Homogeneity, Mean, Standard Deviation, and Variance—are given as input. In this case, the data was classified using a back propagation neural network. Following the network's training, it displays the performance plot, confusion matrix, and error histogram plot. In [19], a pixel's intensity in relation to its surrounding pixels throughout the entire image is measured as contrast. The basis for contrast in visual observations of the real world is how the colour and brightness of an object change in comparison to other objects in the frame of reference. A constant image has a contrast value of 0.

III. Materials and Methods

In this work, we concentrate on monitoring humidity, temperature, and water flow to know the environmental conditions of the crop field with the help of IoT sensors connected to the server. In addition, the work involves the early detection of plant leaf diseases by capturing images periodically with the proper deployment of cameras and applying image processing techniques. Our work mainly contributes two-fold: Initially, a standalone system for monitoring and irrigation, as shown in Fig. 3. Second, the analysis and detection for plant leaf disease as shown in Fig. 4. Different sensors such as soil moisture, temperature, and camera are used to detect diseases on a leaf. Data from sensors is collected and transmitted to NodeMCU via wired or wireless devices. Data are checked and matched to the ideal data values such as temperature, humidity, and soil moisture on the server-side (Cloud database). If there is a discrepancy in the threshold value, send the notification on the mobile or website to the farmer. In the webpage and farmer, the output of the sensors is generated.

A. NodeMCU

NodeMCU is an IoT platform open source. The ESP-12 module includes both firmware that operates on the ESP 8266 Wi-Fi SoC and hardware. A 32-bit RISC CPU is clocked at 80 MHz and supports up to 16MB external flash storage for a significant RAM supplement. Thanks to its small size and built-in Wi-Fi capability, the gadget is particularly ideal for IoT applications.

B. DHT11 Temperature and Humidity Sensor

For hotness measurement and environmental impact, a temperature sensor is utilized. Humidity is the amount of water vapour in the air that the hygrometer can measure. For this, we used the DHT11 sensor, which can measure the temperature and humidity data. This sensor has compactness and operates at low voltages of 2.2V, and draws a few mA currents, thus suited for all temperatures and humidity conditions at a long transmission distance of 20m.

C. Water Flow Sensor

The water flow sensor has a plastic valve design, a Hall Effect sensor and a water rotor. The motion of the rotor with a changing rate of flow alters as the water flows along with the rotor rolling unit for each revolution. The process of recording the output 5 to 6 pulses for every litre of liquid that flows for 60secs. In this current work, we used a water flow sensor with a 20mm diameter and water pressure of 1.75 MPa and a flow range of 1 25L per minute.

D. Soil Moisture Sensor

Understanding the soil moisture in our fields is critical for optimal irrigation scheduling for precision irrigation. That's why we use intelligent and precise soil moisture sensors, which may be used to water our plants just when they're dry, avoiding over-or under-watering. A standard soil moisture sensor consists of two parts: A fork-shaped probe with two bare conductors inserted into the soil or anywhere else that water content is to be recorded. As previously stated, it operates as a variable resistor, with resistance that varies depending on soil moisture. An electronic module is also included with the sensor, which couples the probe to the NodeMCU. The module generates an output voltage based on the probe's resistance and provides access via an Analog Output (AO) pin. The module comes with a built potentiometer for adjusting the digital output's sensitivity. Using a potentiometer, we can configure a threshold setpoint such that when the moisture level is above the predefined threshold, the module will output level '0' (LOW), otherwise '1'. (HIGH). This design is highly beneficial when we want to initiate an action when a given limit is met. We can, for instance, activate a relay to start pumping water when the moisture level in the soil reaches a certain level.

E. VGA Camera Module

The operation of the installed camera in the crop field permits regular access with a 24-7 clock visual display of the crop field and plant conditions. A compact image sensor, low voltage module 'OV7670 Camera' allows a single chip, a VGA camera and an image processor to complete. The sensor can deliver the full-frame, samples, and different resolutions of up to eight data bits with SCCB bus controls. With the VGA image that has been inserted, it is possible to obtain frame rates of up to 30 frames per second. It takes the leaf images with high resolution in a suitable format that may be extensively controlled and effectively measured. This procedure includes image processing features, including the white balance and correction in saturation levels interface. SCCB programming interface.

F. Disease Detection Framework

This subsection shows how the leaf diseases detection process can be done on leaf dataset images by applying image processing operations using Matlab application. All the gathered images are in RGB format.

G. Image Acquisition

The camera captures the images of the plant leaf. In RGB (Red, Green and Blue), this image has been generated. For the RGB image, a colour transformation structure is constructed, and a device-independent colour transformation is performed to the design of colour transformation.

H. Image Pre-Processing

Different preprocessing methods are proposed to eliminate noise from the image or other object removal. Cropping of the image, i.e. leaf image, to get the region of interest (ROI) of the image relevant. Image smoothing is done with filter smoothing. Enhance the effectiveness to increase the contrast. The RGB images are converted into grey images by the equation (1).

$$f(x) = 0.2989 * R + 0.5870 * G + 0.114. * B \tag{1}$$

The histogram equalization that distributes the image intensities is then applied to improve images of plant disease. Intensity levels are distributed by a cumulative distribution function [20].

I. Image Segmentation

Segmentation implies dividing the image into different parts or with certain similarities. Segmentation can be performed with several approaches such as Otsu, k-means, RGB-image conversion in HIS, etc.

J. Segmentation using Boundary and Spot Detection Algorithm

The image of RGB is transformed into a HIS segmentation model. Identifying the boundary and spots helps discover the part of the infected leaf [21]. In this current study, the 8-pixel connection is considered for boundary detection, and the algorithm for boundary detection is used.

K. Adaptive K-Means Clustering Algorithm (AK-Means)

This approach uses the maximum connected domain technique for the K-means segmentation method to determine K values. After many tests, the K value ranges typically from 2 to 5. The K-means strategy solves the problem of “Maximization of Expectations” to apply the assignment mechanism to the necessary information points for the closest cluster, as shown in equation (2). We can also observe from equation (4), that when the data points belong to a cluster of xi, they belong to other clusters of k. Likewise, μ_j term denotes explicitly cluster centre xi. Interestingly, for the sake of closed clusters, we used Adaptive K-Means for the clustering process of leaf images which are unhealthy for further processing.

$$C = \sum_{i=1}^{y} \sum_{j=1}^{z} w_{ij} x^i - \mu_j^2 \tag{2}$$

$$\frac{\partial C}{\partial w_{ij}} = sum_{i=1}^{y} \sum_{j=1}^{z} x^i - \mu_j^2 \tag{3}$$

$$w_{ij} = \begin{cases} {}^{1ifk=argmin_i x^i - \mu_j^2} \\ \\ {}_{0else} \end{cases} \tag{4}$$

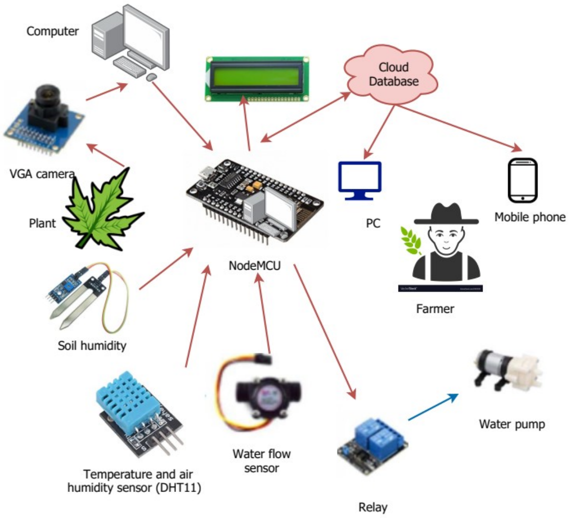

Fig. 3. Overview of Automated Monitoring and Irrigation System Hardware Design Architecture.

L. Feature Extraction

The extraction of features is a crucial element in object identification. The images were then removed by the Color Co-occurrence Method (CCM). The images were taken. The CCM consists of a matrix of pixel values distributed in the same way by the images at the provided offsets (grey scales or colours) in eq. (9). The features that can be employed to diagnose plant diseases are colour, texture, morphology, edges, etc. This method takes into consideration both colour and texture to create a unique image. The RGB is transformed to HSI translation for this purpose.

$$H = \begin{cases} {}^{\theta if B<G} \\ \\ {}_{360-\theta, B>G} \end{cases} \tag{5}$$

$$S = 1 - \frac{3}{(R+G+B)} \left[min\left(R, G, B\right) \right] \tag{6}$$

$$I = \frac{1}{3} \left(R + G + B\right) \tag{7}$$

The CCM approach employs SGDMs in which the CCM grey level is applied for doing the sampling process. The grey level is sampled in a way that is mainly associated with the other grey levels.

$$(p, q) = \sum_{x=1}^{n} \sum_{y=1}^{m} \begin{cases} {}^{ifl(x,y)=p,} \end{cases} 1, l\left(x + \Delta x, y + \Delta y = q\right)_{0else} \tag{8}$$

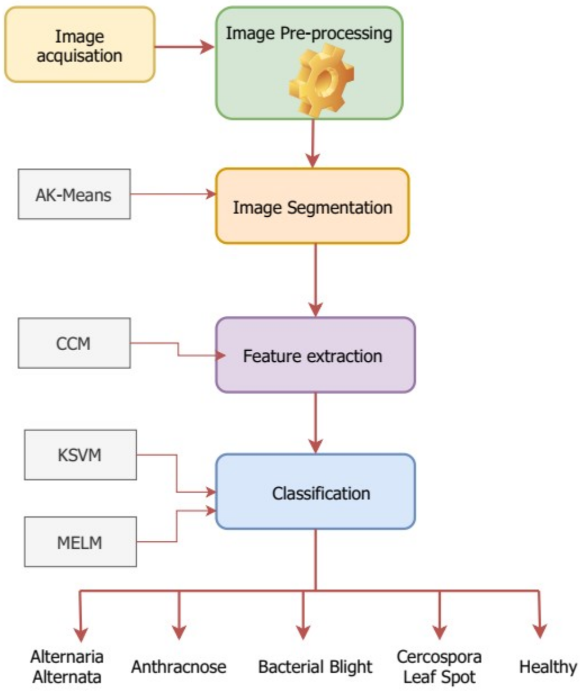

Fig. 4. Plant Leaf Disease Detection Process.

M. Leaf Color Extraction using H and B Components

Using an anisotropic diffusion approach, the input image is improved to preserve information of affected pixels before colour is separated from the base [22]. H and B components from the colour space of HIS and LAB are considered to discriminate between the grape leaf and the non-grape leaf.

N. Classification

After extracting features, the learning images from the learning database are classified using two separate machine learning algorithms: support vector machine and extreme learning machine. In addition, the SVM was used with two different kernels, linear and polynomial.

O. Support Vector Machine

The SVM supports a binary classifier that falls under machine learning. SVM is a binary classifier. The learning model is supervised and examines classification and regression data. Consequently, the most efficient hyperplanes selected for the SVM Classifier have been chosen, separating every input sample into two classes based on the two-class binary classification issue.

$$X = \left\{ \left(y^1, z^1\right), \left(y^2, z^2\right), ., \left(x^n, y^n\right) \right\} \tag{9}$$

The classification line is derived as:

$$X\left(n\right) = \left(w, n\right) + a \tag{10}$$

where z denotes X class label, and n is the high dimensional space-represented sample vector. The equation of the classification line is achieved with the help of w and a parameter. This work used 150 images of 5 different kinds of leaves to develop the SVM-based supervised machine learning classification with two different kernels. The test images of the NodeMCU and the camera were used to investigate the performance of the specified classifiers after the training procedure.

P. Proposed Multihidden-Layer ELML (MELM)

Fig. 5 illustrates the structure of the MELM (choose, for instance, the 3-level hidden layer ELM). Fig. 6 shows the workflow of the 3-level hidden layers using the MELM approach. To train the network, we provided the samples $\left\{X, T\right\} = \left\{xi, ti\right\}\left(i = 1, 2, 3, ..., Q\right)$ and constructed the network topology with hidden layers $\left(therearethreelayersineachofwhichhashiddenneurons\right)$ with activation function $g\left(x\right)$. Input layer, three hidden layers and output layer are available for the 3 level hidden layer structure of ELM. In this present work, we used three hidden layers placed with each other as two hidden layers. Thus the weight matrix β_{new} can be obtained from the second and output layers of the network. We can employ β weights, which enhance the overall ability of the network, depending on the number of actual samples. Then the MELM divides the previously combined three hidden levels and has three hidden layers for the MELM structure. This allows the predicted results of the third hidden layer $H3 = t\beta^+_{new}$ The β^+_{new} weight matrix is generalized inversely. The third MELM denotes the required matrix $W_HE1 = [B_2W_2]$ allows for the calculation of the formula (12) and formula $H3 = g\left(H_2W_2 + B_2\right) = g\left(W_{HE1}H_{E1}\right)$ acquired by the parameters of the third layer.

$$W_{HE1} = g^-1\left(H_3\right)H^1_{E1} \tag{11}$$

While H_2 denotes the second layer actual output, W_2 denotes the weight present in the second and the third hidden layer, B_2 denotes the third layer biasing factor, and H^+_{E1} denotes the inverse of the $H_{E1} = [1H_2]^T$ generation T, 1 is a one-column size Q vector with scalar unit elements 1. The $g^-1\left(x\right)$ notation denotes the opposite of $g\left(x\right)$ activation function. We use several activation functions for classification and regression to test the performance of the proposed MELM algorithm. We generally use the $g\left(x\right) = \frac{1}{(1+e^-x)}$ logistic sigmoid function. This determines the actual output of the third hidden layer:

$$H_4 = g\left(W_{HE1}H_{E1}\right) \tag{12}$$

Finally, the output new weights matrix β_new can be obtained from the third hidden and the output layer, the computation is as follows: If the number of hidden layer neurons is lower than the number of training samples β can be indicated as continues to follow:

$$\beta_{new} = \left(\frac{1}{\lambda} + H^T_4H_4\right)^- 1H^T_4T \tag{13}$$

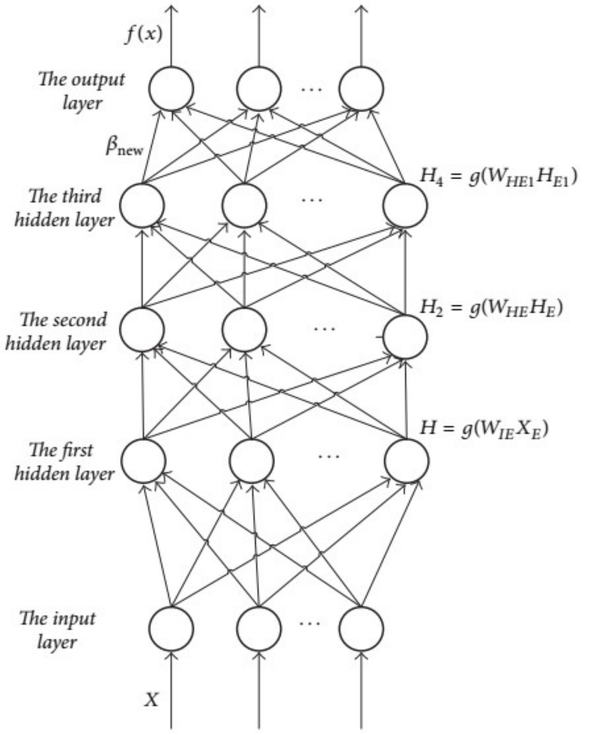

Fig. 5. Network Layers with 3-Level ELM

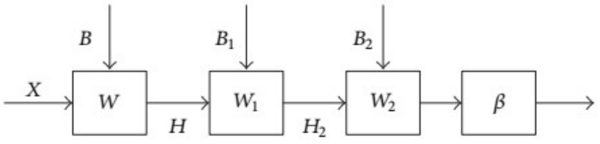

Fig. 6. The Workflow of the 3-Level Hidden-Layer of the ELM.

If the number of neurons in the hidden layer exceeds the number of training data, β is the following:

$$\beta_{new} = H_4^T \left(\frac{1}{\lambda} + H_4^T H_4\right)^{-} 1T \tag{14}$$

The actual output of the ELM network with three hidden levels can be described below:

$$f(x) = H_4 \beta_{new} \tag{15}$$

The operation phase is adjusting the network structural parameters from the second hidden layer to guarantee for Final hidden layer output be close to the estimated hidden layer performance for the total training time. Above is the estimated parameter for the ELM network of 3-level hidden layers, but our present work is intended to compute the ELM network variables from the multiple hidden layers and the final output of the MELM underlying network. The actual output of the ELM network of three hidden layers is as follows:

$$f(x) = H_4 \beta_{new} \tag{16}$$

The operation process optimises the network structure terms from the second hidden level to ensure that the actual hidden layer result is close to the estimated hidden layer output during the complete training time.

IV. Results and Discussion

In this study, the testing prototype and detecting plant leaf diseases are two phases of execution. The experimental prototype consists of the primary configuration and functioning of hardware components for necessary applications. Likewise, the analysis of plant leaf diseases detecting diseases from the images of the leaf dataset in question. There are two parts of system design, the primary is the sensor monitoring process, and the secondary is to predict the leaf diseases. The heart of the architecture is the NodeMCU microcontroller. The sensors are connected to the microcontroller, and gathered data is sent to the controller and received data will be further processed by the Matlab application for leaf disease detection. The sensors must capture the current environmental data. The early diagnosis of a disease depends on the image captured from the actual crop field using the MATLAB simulation tool. These images are the test cases for the identification process of plant disease.

A. Evaluation

The evaluation involves implementing a system of environmental monitoring sensors, including a software package required for deployed VGA cameras in the crop field to have precise agriculture for farmers. Database Description: The databases comprise 237 plant disease images from the leaf. The two most excellent plant disease image database websites collect five categories of images affected. Arkansas Plant Database and Reddit Plant Leaf Data Sets [14] [15] are used to acquiring images of diseases affected. Fig. 7 shows sample images of each form of plants leaf disease.

B. Evaluation of Segmentation

Two parts address the result section: first is the output of the segmentation of leaf diseases and the performance comparison of the segmentation in different parameters. The second part is detecting diseases from the collected images of the leaf dataset for the MELM and SVM classifications. For performance evaluation between the MELM segmentation output and the manual segmentation output, the Dice similarity coefficient (DSC), the mean square error (MSE) and the structural similarity index measure (SSIM) parameters were determined.

For the ten leaf samples, the average performance of the segmentation output, as shown in Table I, illustrates that the three parameters are acceptable for leaf disease detection.

TABLE I. Performance Parameter Values of the Segmentation Result

Disease Type	*DSC*	*MSE*	*SSIM*
Alternaria Alternata	0.97	0.014	0.97
Anthracnose	0.98	0.021	0.98
Bacterial Blight	0.95	0.047	0.96
Leaf Spot	0.96	0.011	0.94
Healthy	0.97	0.010	0.99

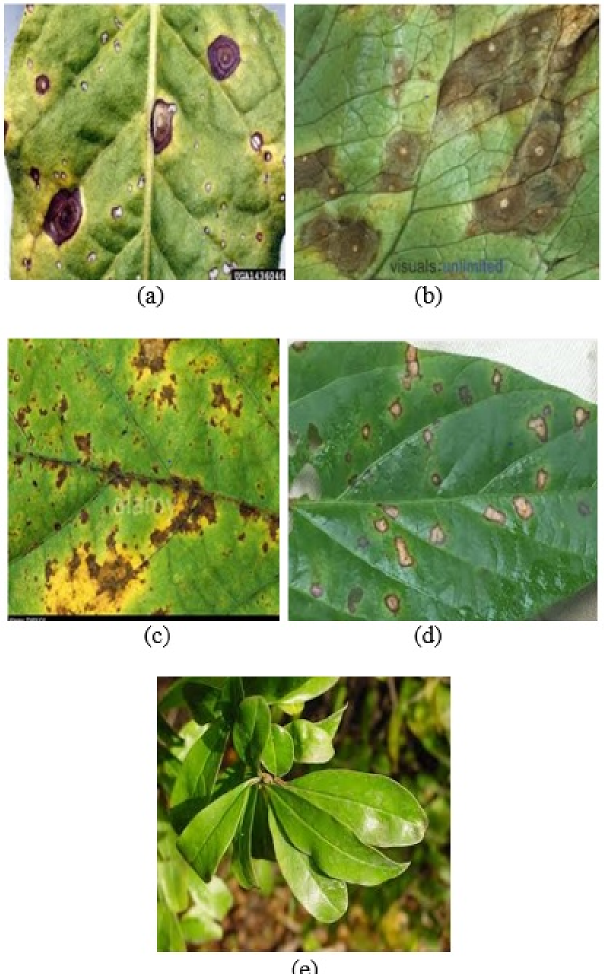

Fig. 7. Sample Images from the Database of Plant Disease: (a) Alternaria Alternata (b) Anthracnose (c) Bacterial Blight (d) Leaf Spot (e) Healthy

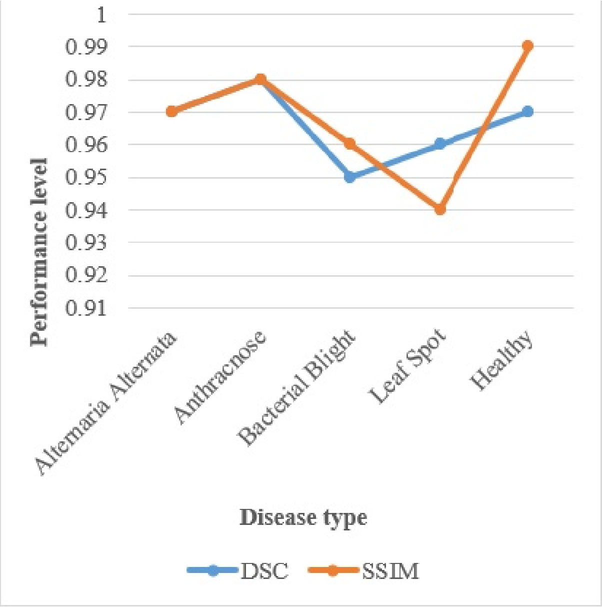

Fig. 8. Segmentation Result of the Parameters DSC and SSIM.

Fig. 8 shows that good segmentation with the proposed MELM techinique for five types of plant diseases having high DSC and SSIM values.

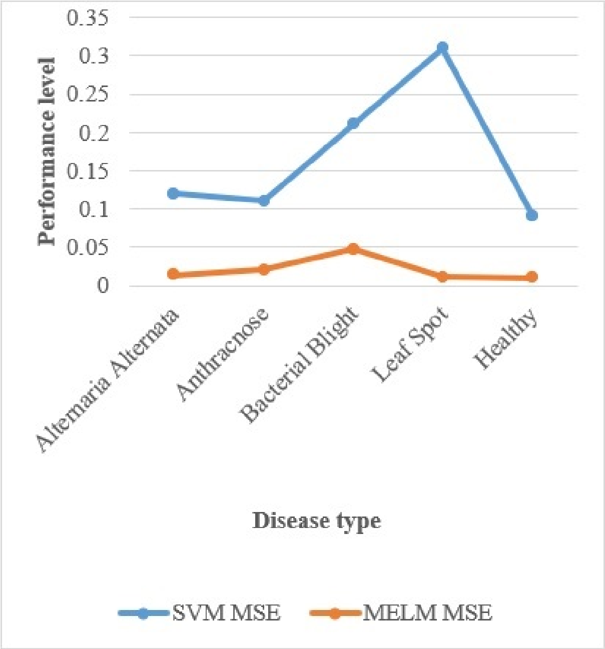

Fig. 9. Segmentation Result of the Parameter MSE of Two Classifiers

Fig. 9 illustrates good segmentation of five classes of plantation diseases with the minimum MSE values by the proposed MELM technique when SVM is poorly functioning owing to overfitting.Table II shows that the proposed MELM classification performs in classifying leaf diseases with other available approaches.

TABLE II. Performance Parameter Values of the Classification Result of Two Classifiers

Disease Type	*KSVM Accuracy*	*MELM Accuracy*
Alternaria Alternata	98.28	99.12
Anthracnose	97.32	98.92
Bacterial Blight	96.21	98.31
Leaf Spot	97.81	98.21
Healthy	98.21	99.14

The performance was evaluated of the two classifying models on the test data set, and the accuracy parameters for the performance assessment were calculated. The test data set includes 37 images with five different types of diseases. Fig. 10 demonstrates that the average five-class performance represents the average classification performance based on the test dataset after the individual classification performance is computed. The proposed multi hidden layers extreme machine classification delivers good performance of 99.12 in the classification of leaf diseases in comparison to the Support Vector Machine classification, which gives 98%.

V. Conclusion

The idea of detecting and monitoring leaf diseases of environmental conditions and irrigation systems is put into

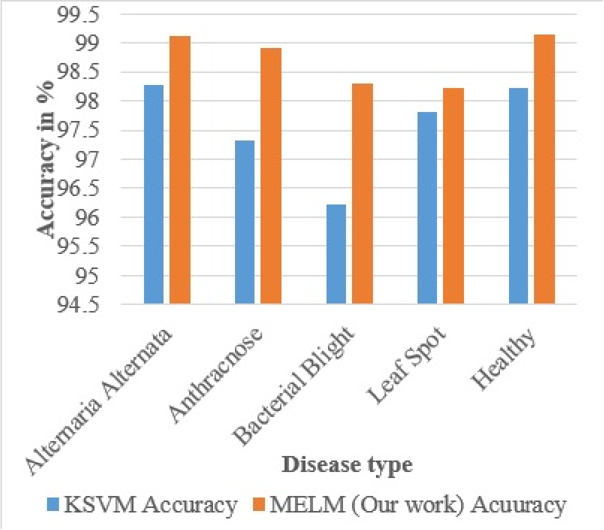

Fig. 10. Comparison of Classification Result of the Two Classifiers.

practice. For successful cultivation of crops, the correct detection and classification of the plant disease are crucial, and this may be done with image processing. This present study dealt explicitly with the adaptive K-Means clustering technique via various techniques for segments of the diseased part. This paper also explored several colour co-occurrence and classification methods for extracting the features of the diseased block and plant disease classification. The deployment of Multihidden Extreme Learning Machines can be efficiently employed for the classification of diseases in plants. The overall accuracy is considerably more significant for the multiple classifications than the ELM network structure. The MELM improves the network structure's performance in certain instances. In future, the data collected from Unmanned Ground Vehicles and Unmanned Aerial Vehicles can be applied to different ensemble algorithms.

Department of Electronics and Communication Engineering,
Koneru Lakshmaiah Education Foundation,
Vaddeswaram, India

***Abstract*—Person re-identification has been an extremely challenging task in computer vision which has been seen as a success with deep learning approaches. Despite successful models, there are gaps in the form of unbalanced labels, poor resolution, uncertain bounding box annotations, occlusions, and unlabelled datasets. Previous methods applied deep learning approaches based on feature representation, metric learning, and ranking optimization. In this work, we propose Global Average Attention Pooling (GAAP) on Resnet50 applied on four benchmark Re-ID datasets for classification tasks. We also perform an extensive evaluation on the proposed Attention module with different deep learning pipelines as backbone architecture. The four benchmark person Re-ID datasets used is Market-1501, RAiD, Partial-iLIDS, and RPIfield. We computed cumulative matching characteristics (CMC) and mean Average Precision (mAP) as the performance evaluation parameters of the proposed against the state of the art. The results obtained have shown that the added attention layer has improved the overall recognition precision over the baselines.**

***Keywords*—Person re-identification; attention network; ResNet50; global average attention**

I. Introduction

The goal of person re-identification (Pe-reID) is to identify and fetch a random person across mutually exclusive camera sources [1]. The objective of Pe-reID models is to determine whether a given query person has reappeared in the frame at a different point in time or in any other camera source at the same point in time [2]. The given query of the person can be an image [3], video [4] and also in text format describing some attribute of the query person [5]. The application range of Pe-reID spans surveillance systems with intelligence that can provide automated feedback on people's movements in real-time.

The Pe-reID pipelines are made up of 5 different tasks. They are arranged chronologically as data collection, bounding box creation, training data annotations, model design and person re-identification. According to [6], the above steps are being considered as a closed world Pe-reID system where the data is structured effectively during preparation. Whereas the open-world Pe-reID system will operate on raw datasets with no annotations and labels. Specifically, this work uses the closed world approach to the Pe-reID problem. The closed world setting is based on the following conditions:

1) Single modality video or image data has been used.
2) The annotations are fixed with persons in bounding boxes with same area identities.
3) The query person is extracted from the training data.
4) Finally, there is enough training data from annotations for supervised learning of person re-identification.

The above processes require expertise and domain knowledge for transforming a video surveillance security problem into a challenging person re-identification problem.

Pe-reID is still considered a super constrained problem. This is due to multiple challenges such as background clutter, low image resolution, poor image quality, partial occlusions, uneven bounding box annotations, human-object interactions [7], etc. Preliminary investigations on Pe-reID problems focused on the hand-crafted feature extraction methods such as Histogram of Oriented Gradients (HOG) and Local Binary Patterns (LBP). Similar Works considered body reconstruction models and distance metric learning [8]. In the last decade, the growth of AI-based approaches has captured the Pe-reID problem and has subsequently proved its potential with exceptionally good recognition accuracies across datasets [9]. However, the results obtained were nowhere close to the requirements of a real-time deployment pipeline.

In this work, we propose to redesign the regular deep learning approaches with additional layers to learn focused attention. The proposed attention model is called the Global Average Attention Pooling (GAAP) network. The GAAP learns by averaging the features extracted from previous convolutional layers in query, key and value channels. The output of the GAAP network is used to select features that contribute to making correct decisions about a given query person. The attention block has been created based on the non-local attention technique from [2] and the global average pooling is initiated on the attention features to generate a maximally discriminating learnable feature representation.

The proposed GAAP layers or block is integrated with the existing benchmark deep networks such as VGG, ResNet and Inception Net. All these models are trained from scratch on four different types of Pe-reID image datasets. The evaluation metrics used are Cumulative Matching Characteristics (CMC) and mean Average Precision (mAP). The proposed GAAP block is integrated at the last layer of the backbone networks as against the previous works where it was added in the primary layers. Experiments are designed to test and evaluate the GAAP block's performance in the identification of people in the test data.

The proposed GAAP integrated framework differs in three major areas from the existing baselines:

1) The addition of an attention-based GAAP layer after the convolutional layers in the backbone network ensures a maximally discriminating of learnable features for the dense layers.
2) The global average pooling is performed to mobilize feature space obtained from a large set of convolutional filters into a singular feature representation.
3) An attempt is made to validate the proposed GAAP integrated deep learning framework with cross dataset testing.

To develop the proposed GAAP block for Pe-reID problem, we propose the following objectives:

1) To restructure the datasets into training, testing and validation sets as input to the backbone networks with an integrated GAAP block.
2) To train the deep learning pipelines with an integrated GAAP layer and evaluate their performance.
3) To construct experiments for validating the proposed model.

The rest of the paper is organized as follows. The next section presents previous research performed on person re-identification problems. The third section gives an elaborated discussion on the construction, training and testing of the integrated GAAP network with backbone architectures. Experiments were built for validation and the obtained results are analyzed expensively for characterizing the model pipelines for Pe-reID. Finally, Section 5 concludes on the attained research outcomes with future direction.

II. Literature Review

Remarkably, the closed world Pe-reID problem [6] has been acknowledged previously through the following compositions: 1) Feature representational learning, 2) metric learning and 3) ranking optimization. In this section, we discuss the above approaches and their underlying research findings with their capabilities for providing better Pe-reID solutions. Feature representation learning has been implemented with three derivatives such as global, local and auxiliary. The global features represent the whole person's image for learning [10]. Contrastingly, the local feature learning approaches use parts of the image as input to the extraction algorithm [11]. However, in auxiliary feature representation, data generation models such as Generative Adversarial Networks (GAN) are used to learn variations in the existing datasets. The features of the entire person image are learned in the global feature representation model. These models used powerful deep learning architectures as a classifier for the identification of persons. A set of highly discriminating features were captured with single image representation and cross image representation on triplet loss embedding [12]. The other most popular Pe-reID models treated it as a multi-class classification problem [13] and multi-scale representation problem [14]. Though global feature representation learning has leveraged its full potential for giving good accuracies, it suffered from overfitting problems.

The overfitting problem occurred in global feature representation as the network learned mostly the background information rather than focusing on the person of interest. The global features also have an image misalignment problem that is induced because of the multiple views and person orientations in the training images. Part-based local feature representation has been proposed to overcome the misalignment and overfitting problems in global features. Two mechanisms were formulated in the form of pose-based [15] and rough horizontal-based [16] body part detection for training. In the automated body part detection models, the full body and part features were fused together for classification. Especially, part base local feature representation models such as multi-channel aggression [13], multi-scale context-aware convolutions [14], multi-stage feature decomposition [2], and bilinear pooling [3] have shown expedient performance. Moreover, the performance has been enhanced further by pose-driven [17] and pose-guided matching [18] methods. However, in horizontally divided part-based models, the part-based conventional baseline [18] has served as a building platform for part-based Siamese long short-term memory (LSTM) networks [3]. Other highly accurate models such as Interaction and Aggregated (IA) [19], and second-order nonlocal attention [3] have used reinforced feature learning approaches. The local feature representation learning approaches are limited by the use of noisy pose estimations and large background clutter. Some of the problems associated with both global and part-based feature learning models were maneuvered efficiently by using additional attributes in the training data. These additional attributes are generative datasets [3], semantic representations [20], viewpoint data [17] and data augmentation [18]. The above auxiliary features are found to provide additional data samples for training, which greatly enhanced their ability to identify persons. However, these auxiliaries are computationally expensive and required an additional pre-processing stage for input pairing.

Apart from image-based Pe-reID methods, some recent works have used video-based inputs to relocate a person in the multi-view video frames. Though the video representation has more information in the form of both spatial and temporal data, they fail to capture them accurately due to the unpredictable nature of the persons appearing in the video sequences. Predominantly, recurrent neural networks (RNN) were proposed to capture the temporal information [21] with a temporal pooling layer at the end of RNN. Mixed attributes of spatial and temporal information using sequential fusion are used to enumerate the frame-level feature representations for improved recognition [22]. A varying length video sequence is considered challenging in most video-based applications. In [19], long video sequences are divided into tiny snippets and are ranked in descending order to learn the compact embedding from the top – K segments.

In most of the works on Pe-reID, the backbone architecture is similar to that of the standard ones used for image classification tasks such as VGG-16 and ResNet50. Few works on Pe-reID have modified the ResNet backbone by introducing size 1 in the last convolutional layer or by adding adaptive average pooling in the last pooling layer [23]. However, a tremendous amount of design time can be curtailed by adopting AutoML models for Pe-reID as shown in [20]. The primary objective of all the above-discussed models is to improve the identification accuracy of the person. One such model which has improved the performance of the Pe-reID deep learning methods is deep metric learning (DML) [24]. The DML uses a metric loss function to calculate the distance between the features from within the class and between classes during training for generating a maximally discriminant feature vector for classification in the dense layers. The identity loss has been widely studied in multiple Pe-reId methods than any other models. The other type of DML model that has indeed improved the performance of the Pe-reID is triplet loss embedding, which starts by computing the distance between the positive class pairs and negative class pairs. The learning is initiated by maximizing the distance between the negative pairs and minimizing it between the positive pairs. The only shortcoming is during the pre-processing stage where the pairing process is performed between the samples from within the class and across classes. Moreover, this pairing complexity increases with the increase in the number of samples per class or an increase in the number of classes itself. Similar to the above DML model, ranking optimization has been shown to improve retrieval efficiency during the testing phase [25]. Very recently, attention-based models [2] have been shown to further strengthen the efficiency of Pe-reID models.

In this work, we propose a global average attention pooling (GAAP) layer at the end of the convolutional layers in ResNet backbone architectures and evaluate its performance against state-of-the-art models. We evaluate the importance of the proposed GAAP against various attention models and across two popular backbone architectures VGG and ResNet. Finally, we conclude by reasoning the significance of the GAAP layer in Pe-reID implementation through experimentation.

III. Methodology: Rank View Triplet Loss Embedding

Learning in Pe-reID is accomplished with D data samples $X_{Pe-reID} = \{x_i, y_i\}\ \forall\ i = 1\ to\ D$ with the goal of finding a mapping function between input x_i and their corresponding labels y_i. The objective of the Pe-reID deep learning neural networks is to learn a mapping function $\theta : X_{Pe-reID} \mapsto F$ that transforms the combined feature space $X_{Pe-reID}$ into F, in which the samples are highly discriminative. Given a set of test images T_{Pe_reID}, the learned mapping function θ will try to project the test images into constituent labels. The testing images and training images in this case are totally nonoverlapping. The primary challenge in the above model is in the learning process of the mapping function θ which in the previous works has been a simple image classifier. The mapping function in case of Pe-reID has to adapt to varying and insufficient training samples per class which results in inconsistent loss parameters during the training process. To regularize the loss function during training we propose to induce an attention layer with global averaging pooling as an architectural upgrade to the existing 50-layer ResNet model. In this subsection, we present the complete Global Average Attention Pooling (GAAP) network and deconstruct the entire pipeline implementation in tensorflow2.3.

A. GAAP Architecture

Global Average Attention Pooling (GAAP) is a network built on top of the existing ResNet50 model with an additional 4 layers. The first three layers in GAAP are convolutional layers, and the last one is a pooling layer. The overall GAAP model for Pe-reID has been illustrated in Fig. 1. A multiscale architecture such as ResNet50 is being used as the backbone network as it has become the state-of-the-art model in many previous works [14]. The proposed attention model has effectively shown to fuse the low level and high-level features to isolate the features of importance within a class label. The attention features are further averaged globally to regenerate a highly discriminative feature map for a particular class label. The model is end–to–end trained on the classification loss function only, which is categorical cross-entropy.

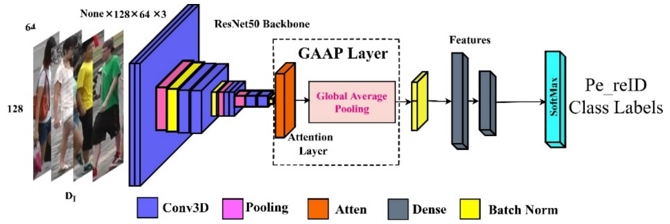

Fig. 1. Global Average Attention Pooling Network Illustration for Person Re-Identification.

The mark of a good person reidentification model is to retrieve accurately the query person image that closely matches the sample images in the class label. However, the previous models used different loss functions to attain close matches between the quey and training images. The two most commonly used loss functions are contrastive and triplet loss. The implementation of these loss functions requires enormous computation resources for training. The proposed GAAP attention framework adds only four layers to the existing network and therefore occupies uses comparatively lesser computational resources. Moreover, the total parameters of the GAAP architecture are lesser than the metric learning models.

The model in Fig. 1 takes input images in training data and transform them into features. The backbone network is Resnet with 50 layers with skip connections.The appearance images $A_n(x)\ \forall\ n = 1\ to\ N$ is divided into a length of N samples per class, the appearance sequence is a multidimensional tensor represented as $\mathrm{A} \in R^{r \times c \times 3}$. Here, (r, c) are RGB image height and width in three color channels. Since the GPU capacity is 8GB, the images are standardized to 128×64×3 across all datasets. This becomes the input to the RGB appearance stream $S_A \rightarrow A_n(None, x, y, c)$. The S_A stream is made from backbone ResNet consisting of multiple convolutional, maximum pooling with rectified linear activations and batch normalization layers. There is no padding in convolutional layers. This S_A stream will extract features from A using the trainable parameters Θ_{S_A} by optimizing the loss function L_{S_A} on the entire dataset

$$\Theta_{S_A} = \arg \min_{\Theta_{S_A}} L_{S_A}\left(\Theta_{S_A} : \mathrm{A}\left(x\right), y\right) \tag{1}$$

Here y denotes the class labels. The S_A stream is optimized using the categorical cross-entropy loss L_{S_A} defined as

$$L_{S_A} = -\sum_{i=1}^{C} \left(y_i \times \log\left(y_i\right) + \left(1 - y_i\right) \times \log\left(1 - y_i\right)\right) \tag{2}$$

The trained model M(Θ_{S_A}) will output at the end of i^{th} convolutional layer with j^{th} appearance feature map by using the expression

$$F_A^{ij}\left(x,y\right)=f_a\left(\sum_{p}\sum_{n=0}^{r-1}\sum_{m=0}^{c-1}\left(W_{ijp}^{nm}*\mathrm{A}_{(i-1)p}\left(x+n,y+m\right)\right)+b_{ij}\right)\quad(3)$$

Where, A is the person image and f_a is the activation function. W_{ijp}^{nm} are the weights at position (n,m) associated with p^{th} feature map in the $(i-1)^{th}$ layer of the CNN ResNet50 network. The parameter b_{ij} is the bias associated with each of the neurons. Eq'n (3) depicts the convolutional operation between the images and the weight matrix, which is updated sequentially during training of the network. The output RGB appearance features has the dimension $F_\mathrm{A}\in R^{r_j\times c_j\times 3\times C}$. Here, C is the channels or filter kernels applied in j^{th} convolutional layer. These features are further processed using the attention layers before being applied to the dense layers for classification.

B. Attention Layers and Global Average Pooling (GAAP Attention Module)

The proposed attention layers are shown in Fig. 2. The proposed model is inspired by self-attention in [11]. It consists of four 1×1 convolutional layers with stride 1 and one residual connection to preserve the original feature encodings. The dot product enhances the features that are important and discards the others that are least useful in the decision process. This allows the features to concentrate on the areas of the pixels that are highly discriminative in nature. The difference between self-attention in [12] and the proposed in Fig. 2 is that the latter takes input from different features within the class for computing the attention maps. Contrastingly, the self-attention model uses the same features of a single sample to calculate the attention map. The attention map in out proposed model is calculated between the $F_A^i\left(x,y\right)$of i^{th} feature of an image A_i in a class and the $F_A^j\left(x,y\right)$ of the j^{th} feature of the same image in the class. These features are obtained from the learned backbone network. This enables the network to learn similar appearances across the same image with different features computed using the learned filters in the feature mapping network. The proposed cross-feature attention (CFA) is defined as

$$CFA\left(f_i\right)=soft\max\left(\frac{\alpha Q_i.K_i^T+\left(1-\alpha\right)Q_jK_j^T}{\sqrt{d_k}}\right).V_i\quad(4)$$

Where $i,j\in 1,...,J$, with J is the number of filters in the convolutional layers and $\alpha=0.5$ is the set hyperparameter for all the layers. The (Q,K,V) are the query, key and value as three convolutional layers in the Fig. 2.

The dot product enhances the features that are important and discards the others that are The weighted sum of features are obtained from all possible positions using the following learning model.

$$a_i=W_a\times\theta\left(f_A^i\right)+f_A^i\quad(5)$$

Where, a_i is the attention maps obtained from the learned W_a with parameters θ of the network. The $+f_A^i$ is the residual connection. Finally, to capture the domain specific features, we apply global average pooling instead of maximum pooling used regularly. The global average pooling of attention features is formulated as

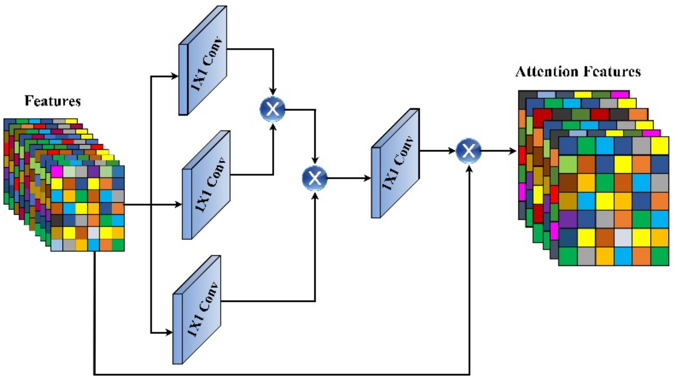

Fig. 2. Attention Layers and its Architecture.

$$f_{ga}=\left[f_1,f_2,......,f_K\right]^T=\left(\frac{1}{|F_k|}\sum_{f_i\in F_k}f_i\right)\quad(6)$$

Where, F_K is the total number of features in the feature maps with K features. f_k represents feature maps which are learned by the backbone and attention layers in the PereID pipeline using the backpropagation algorithm. Finally, the backbone Resnet50 is presented in Fig. 3.

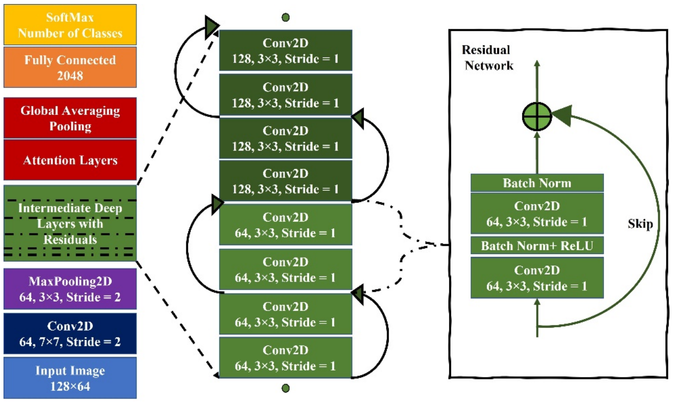

Fig. 3. The ResNet50 Architecture used as Backbone Network in the Proposed GAAP Model

Finally, the combined loss of the entire GAAP network is computed as

$$L_{GAAP}=\sum_{i=1}^{itr}L_{S_A}\left(\Theta\left(A_i\left(x\right);\theta\right),y_i\right)\quad(7)$$

Where, Θ is the trainable parameters of Resnet50 and θ are the learnable parameters of the attention network. The final feature representation is learned by minimizing the categorical cross entropy function L_{S_A} for classification. During testing only $A_i\left(x\right)$ are used for inferencing the trained model.

IV. Results and Discussion

The four benchmark person Re-ID datasets used in this work are Market-1501, RAiD, Partial-iLIDS and RPIfield. We evaluated the performance of the proposed method using the following parameters, computed cumulative matching characteristics (CMC) and mean Average Precision (mAP). This section gives details about the benchmark person re-identification datasets used for evaluation, the model configuration set for training and testing with in-depth assessment of attention framework.

A. Datasets for Pe-reID

This work has conducted extensive experimentation on four popular benchmark datasets, Market-1501 [1], RAiD [26], Partial-iLIDS [16] and RPIfield [27]. Market-1501 is the largest person re-identification image dataset containing 1501 identities captured with six camera angles and 32,668 bounding box persons that are annotated with deformable part model pedestrian detector. An average of 3.6 images are obtained per person per viewpoint. The training and testing sets have 750 and 751 classes respectively with 3368 additional query images. In this work, we train the model with 750 image classes and test with 750 classes. The training set is split into 15% validation. The image resolution is 128×64. Few training samples of the Market – 1501 are shown in Fig. 4. RAiD is developed in 2014 which has multiple person trajectories recorded using four static camera views. The data is primarily focused on persons on sidewalks and crosswalks. The images in the dataset appear cleaner in the background when compared to the other datasets used in this work. The RAiD dataset has 43 classes with 6290 image samples that are split into 0.7:0.15:0.15 for training, validation and testing. The image resolution is 128×64. Partial iLIDS has occluded person re-identification samples from 476 images from 119 classes. It contains four camera views with a varying resolution of the hand cropped images from the surveillance video data. However, the proposed work has set the resolution of all the images in the dataset as 128×64×3. The occlusions in the images are due to another person or luggage. The RPIfield is constituted in 2018 with 112 class identities with 12 non-overlapping camera viewpoints having 601581 samples is being shown in Fig. 4. The images are annotated using fast pyramid features for bounding box detection which is the reason for multiple resolutions across the dataset. However, the proposed work has normalized the use of image resolution to 128×64 across all the datasets and subsequently across the models used in this work.

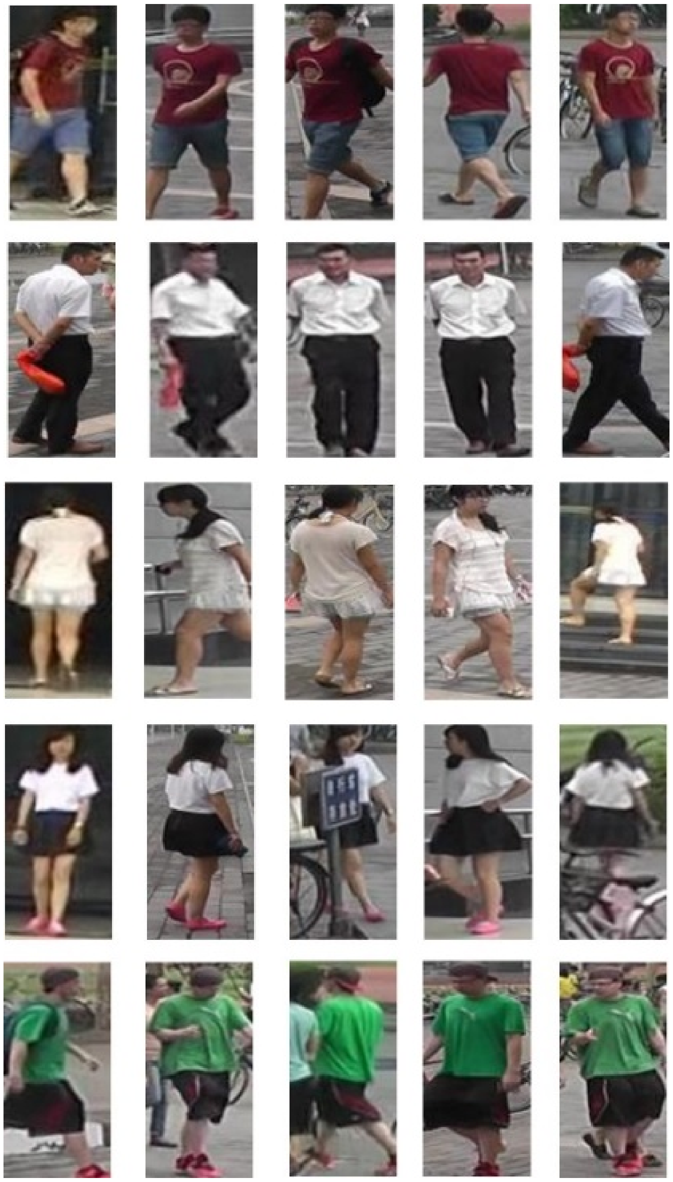

Fig. 4. Samples from Market – 1501 Dataset.

B. Model Configuration

For feature extraction we selected three Resent models as the backbone for feature extraction. The first was tiny ResNet-18 with the attention layers added before the dense layers. This model was used to train the model in a lightweight configuration for real time implementation. The feature extraction process was handled with the help of 8 convolution layers in ResNet-18. Similarly, we applied ResNet-34 with 32 and ResNet-50 with 48 convolutional layers each for feature extraction respectively. The ResNet-50 is deep with added 1×1 convolutions to preserve the input features and decrease the dimensionality of the feature vector. We also included the popular VGG – 16 and – 19 models to analyse the real time deployability as these models are highly recommended in this regard. To evaluate our proposed ResNet with attention layers, we adopted categorical cross entropy loss for optimization with Adam optimizer. This has resulted in providing level playing comparisons with the previous works. In the next subsection, evaluation protocols for the proposed model are being formulated.

C. Model Evaluation Protocols

All the backbone networks and the associated layers are trained from scratch on the benchmark datasets used in this work. Weights and biases were initialized using the standard zero mean 0.01 variance gaussian distribution function at the start of every training session. The network learns by updating weights and biases by optimizing the gradient losses that are backpropagated in reverse. The other training initialized hyperparameters would be learning rate, activations, momentum factor, frame dimensions, number of epochs, learning rate decay and minimum allowable loss of the trained classifier. The training set in each class is unbalanced in all the datasets and no attempt has been made to normalize the sample images in each class. However, data augmentation has been initiated on each image to increase the size of the dataset. Four types of augmentation were applied in the form of horizontal and vertical shifts, zoom and crop as shown in Fig. 5. The batch size was selected as 32 which means that there will be 32 images per training batch in each episode. The GAAP model with ResNet – 50 backbone was initialized with a learning rate of 0.0001 with a decay of 10% whenever the validation loss became constant for more than 4 epochs. The other backbones of ResNet were initialized with a higher learning rate to compensate for the lesser depth in features. The momentum factor has been considered as 0.8 across all networks and databases. The average number of training epochs were set at 25. Since the structure of the datasets has been unbalanced in the sample size, the image resolution is kept constant at 128×64 along with all other training initializers to maintain balanced evaluation.

Unseen training samples were used for testing the proposed GAAP network. The SoftMax outputs provide a statistical measure of the probability distribution of the test person image that closely matches the labels in the trained class. Here, we evaluate the global average pooling network with attached attention layers and their impact on the overall performance of the network across all datasets. Finally, we compare the proposed GAAP model with other Pe-reID methods and also perform a detailed ablation study to analyse the behaviour of the model under various test loads. All the models were trained and test on 8GB Nvidia A-4000 series with 16GB memory. The implementation has been done in TensorFlow and Keras packages.

D. Evaluation of the Proposed GAAP Model

The evaluation of the proposed method is conducted by calculation of cumulative matching characteristics (CMC) and mean Average Precision (mAP) across the training dataset. We computed single- and five-fold cross testing on all the datasets. We designed five backbone architectures to evaluate the models performance in identification of a person under various circumstances. Table I provides the results on all benchmark datasets with five backbone networks: VGG-16, VGG-19, ResNet-18, ResNet-34 and ResNet-50. The larger versions of ResNet such as ResNet-101 and ResNet-150 were not trained due to the GPU hardware insufficiency.

All the backbone networks were trained on exactly similar protocols as discussed in previous sections. The above table shows that VGG has failed to take advantage of the attention layers attached after the feature extraction convolutional layers. The reason for underperformance by VGG when compared to ResNet is the missing residual connections in the former model. The residual connections make the ResNet models to avoid overfitting and vanishing or exploding gradients problems. As the networks get deeper, the deep layers may sometimes get zero gradients as input which contributes to faulty decision making on the class labels. The success of ResNet – 50 is attributed to the fact that network is made deeper by adding 1×1 convolutions that help increase the feature quality and reduce the dimensionality.

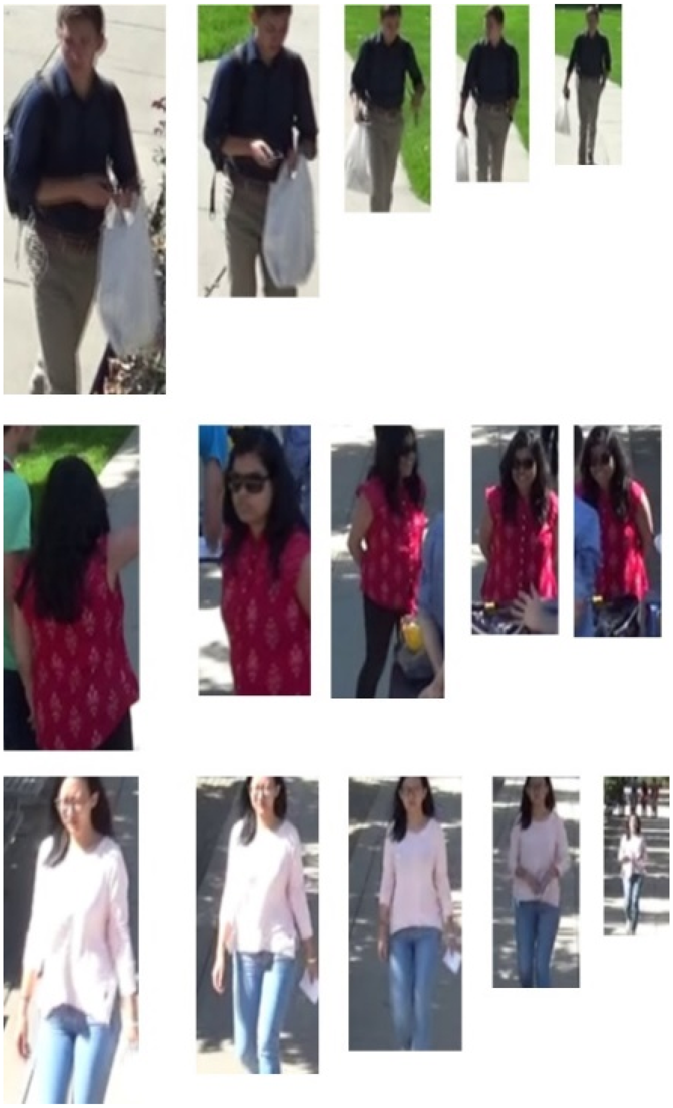

Fig. 5. Samples from RPIfield Pe-reID Dataset.

The results are as expected, and the overall recognition rate mRA with ResNet – 50 was averaged around 91.2% after 5-fold repetition. This is better than the other Pe-reID recognition frameworks in table I by an average of around 10%. The reason lies in the residual connections in ResNet - 50 and added attention module that highlighted the relationships between within-class samples to drive the appearance of the person in multiple cameras. RPIfield dataset has been shown to have maximum test accuracy due to the presence of large training data in all the considered datasets. In the next section, we evaluate the importance of the attention module.

E. Evaluation of Attention Layers

Table II shows the computed parameters on the test data with attention layers and without attention layers. The results show that the there is a 30% increase in network confidence for recognition with the proposed GAAP architecture when

compared to the traditional models. All the models are trained using the same initial conditions as discussed in the Section 4.3. The big jump in the proposed model is due to the ability of the network to train on the features that are important for classification. The use of attention layers guarantees highly discriminative features within a class label. In the next section, we evaluate the global average pooing of attention features against the traditional maximum pooling model used in previous works.

F. Evaluation of Global Average Pooling

Before evaluating the global average pooling layers in GAAP architecture with backbone CNN models, we present the attention maps obtained on Market – 1501 dataset with ResNet – 50 backbone CNN model in Fig. 6. The figures provide a visual confirmation of the concentration of features used for training the dense layers in the GAAP pipeline for recognition of persons in Market – 1501 dataset. We observed similar kind of results across all other datasets used in this work.

In the following Table III, we computed the performance parameters CMC and mRA for the proposed global average pooling and maximum pooling of attention features after the convolutional layers in all the backbone networks used in this work. The results show that the global average pooling results in an 10 ±2% increase in performance of the backbone network for recognition of persons when compared to the traditional maximum pooling model. In the traditional maximum pooling model, the largest values in the feature space on the batch size within a class label are pooled together for training on the dense layers. This procedure generates outlier features that are not concentrated on the person or object of interest in the entire feature space at all times. Hence, it is intuitive that the final feature space for dense layers may possibly miss some of the prominent features necessary for correct identification. This can be avoided by considering an averaging feature space across a batch size within a class label. Consequently, the global averaged features have shown to exhibit the characteristics of all prominent regions of interest across a batch size given a generalized representation of the person across the class label. This is observable in the Fig. 7 visualization of attention regions projected on the original images of Market – 1501 dataset. Finally, we compare our proposed GAAP with ResNet – 50 backbone with the state – of – the – art methods for Pe-reID on the benchmark datasets in the following section.

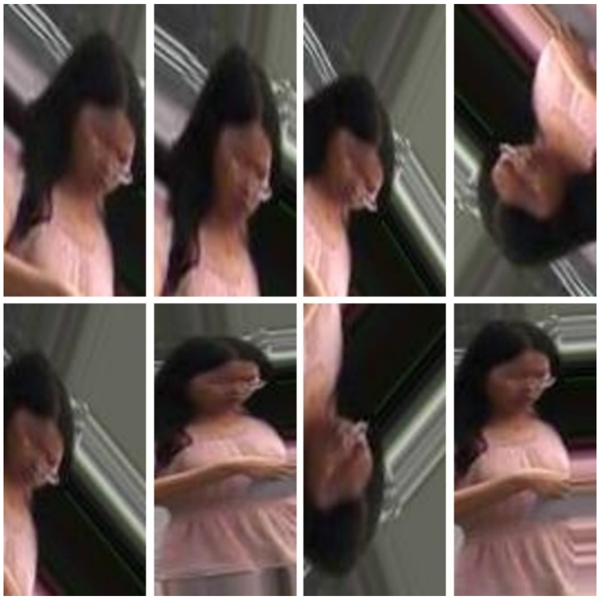

Fig. 6. Data Augmentation Applied on Market – 1501 Dataset.

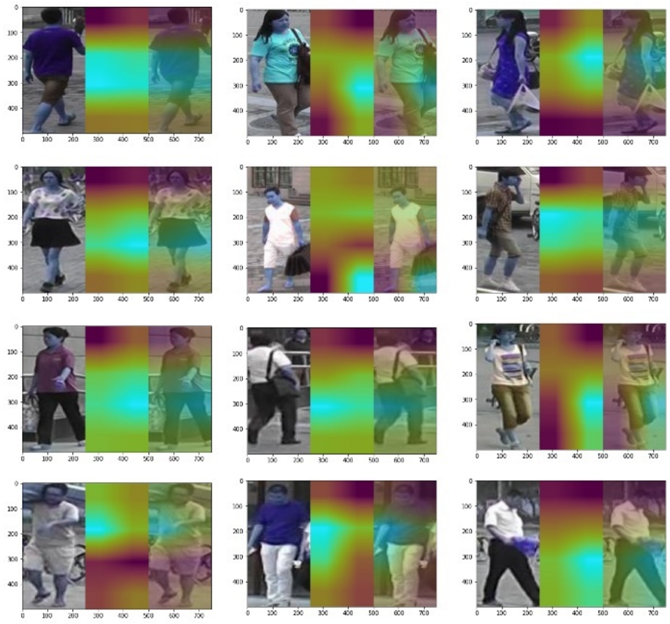

Fig. 7. Attention Maps Obtained from the Proposed GAAP Architecture on ResNet – 50 Backbone CNN Model.

G. Comparison with the State-of-the-Art Pe-reID Methods

This section draws comparisons of different Pe-reID methods against the proposed GAAP architecture. As can be observed from the above analysis that the ResNet – 50 backbone

has shown better performance when compared to other four models. Table IV records the performance of the models on benchmark datasets. All the models were trained from scratch on the same 8GB GPU with 16GB memory under similar initial conditions, except for the learning rate which has been selected differently to avoid overfitting. The stopping criteria is set as the flat validation error for more than 5 epochs and after two times decrease in learning rate.

The works in table IV are based on supervised and unsupervised methods that have clocked maximum mRA and CMC in the literature. We also compared with attention-based methods like AGW and the results show that the GAAP has indeed performed better than the AGW. The proposed GAAP has attention layers at the end of convolutional networks which enables the model to generate attention features for dense net classifier. However, the past attention-based methods used attention inside the convolutional layers that failed to capture the essential focused features for classification. We also found that the proposed model trains faster than the previous most popular triplet loss embedding with ResNet -50 backbone network. Fig. 8 and 9 shows the training accuracies and loss plots on Market – 1501 dataset for GAAP and DML with triplet loss respectively. Overall, our proposed GAAP model have shown good performance on RIPfiled Pe-reID dataset due to its rich multi view and multi resolution representation of the person images. Finally, the average recognition on all the benchmark datasets is around 84.12 which is 5% more than the previous methods.

V. Conclusion

In this work, we present an attention framework-based solution for person reidentification problem. The attention framework is built at the end of the feature extraction network and before the classifier dense network. Subsequently, the attention features are pooled using global averaging across the within class images. The proposed GAAP network is trained with ResNet – 50 as a backbone architecture for feature extraction. Consequently, extensive experimentation on four bench-

mark person Pe-reID datasets has shown that the proposed model performs better than state-of-the-art. Interestingly, the proposed model generated an average identification accuracy of around 84.12. Also, the proposed GAAP model trains in less time and achieves a competitive average validation accuracy on the benchmark datasets. However, the improvement of performance is achieved on large datasets with heterogeneous properties.

***Abstract*—The authors of this research paper present a mechanism for dealing with loanwords, missing words, and newly developed terms inclusion issues in WordNets. WordNet has evolved as one of the most prominent Natural Language Processing (NLP) toolkits. This mechanism can be used to improve the WordNet of any language. The authors chose to work with the Hindi and Gujarati languages in this research work to achieve a higher quality research aspect because these are the languages with major dialects. The research work used more than 5000 Hindi verse-based data corpus instead of a prose-based data corpus.As a result, nearly 14000 Hindi words were discovered that were not present in the popular Hindi IndoWordNet, accounting for 13.23 percent of the total existing word count of 105000+. Working with idioms was a distinct method for the Gujarati language. Around 3500 idioms data were used, and nearly 900 Gujarati terms were discovered that did not exist in the IndoWordNet, accounting for nearly 1.4 percent of the total of 64000+ Gujarati words in the IndoWordNet. It will also contribute almost 14000 Hindi words and around 900 Gujarati words to the IndoWordNet project.**

***Keywords*—Gujarati; Hindi; Indian language WordNet; IndoWordNet; loanwords; WordNet**

I. Introduction

Languages transmit knowledge from one generation to the next, as well as from one culture to another, through communication. There are multiple modes of communication, including speech, writing, and sign language. No matter what the communication medium is, Communication becomes a systematic process when using any language because each has its vocabulary, grammar, and components. There are 7151 different languages in the world [1], some of which are well-known while others are on the verge of extinction.

Hindi [2], a truly mellifluous Indo-Aryan language, is one of the most popular languages in the world, which is scripted using Devanagari [3] and is currently supported by The Unicode Standard [4]. Although Hindi is widely spoken throughout the world, it is mostly used in India, particularly in the Hindi Belt, which encompasses sections of India's four major zones: eastern, western, central, and northern [2]. The rich literature and long history of Hindi users make up the language's legacy. Hindi-based research and related efforts in relevant research disciplines are currently strongly emphasized.

Gujarati[5], like Hindi, is a sweet-sounding language that belongs to the Indo-Aryan language family. Although Gujarati is used by Gujaratis all over the world, it is especially utilised for communication in Gujarat, located in India's western region, which is considered the origin place of Gujarati. Gujarati is written in the Devanagari script as well and is currently supported by The Unicode Standard [6]. Gujarati is also thriving in terms of research and development in recent years [7], [8].

Natural languages are those that have evolved gradually and are used by humans to communicate. It is a well-known fact that computers don't understand natural languages. To make computers understand different kinds of languages, many research works are going on for different languages. Natural Language Processing (NLP) [9] is used to assist computers in understanding these languages. Computer Science (CS) [10], Computational Linguistics (CL) [11], and Artificial Intelligence (AI) [12] all intertwine in NLP. To grasp a language, computers, like humans, must understand the alphabet, words, meanings of words, pronunciation, vocabulary, sentence structure, context, and all grammatical rules associated with it.

Because computers lack cognitive intelligence, making them grasp any language is difficult. WordNet [13]–[15], a systematically managed correlated lexical database that usually consists of words and semantic relations with the words including synonyms, hyponyms, and meronyms, is commonly used to help computers overcome this limitation. As a practical matter, WordNet can be thought of as a hybrid of a dictionary and a thesaurus. There are various WordNet-based research projects underway [16], [17], some of which are language-specific exclusively and others that are multilingual.

The authors used IndoWordNet [18], [19], a well-known WordNet based on Indian regional languages, for this study. IndoWordNet is a WordNet that has a base of 18 different Indian languages. The Center for Indian Language Technology (CFILT) in the Computer Science and Engineering Department at IIT Bombay created IndoWordNet. Hindi is the default base language of this WordNet. The IndoWordNet is used in this research for both Hindi and Gujarati languages. Even when a well-built WordNet exists for popular languages [20], [21], there is always room for improvement.

The authors were motivated by the various WordNets they used and the difficulties they encountered while using them in different research studies due to missing or borrowed words. Current research is an attempt to address such concerns. This research will be useful in strengthening the WordNet and adding new words, loan words, and missing words.

Loanwords, missing words and newly developed terms are

*Corresponding authors.

several issues that must be addressed in the building of any language's WordNet. Each language typically has loanwords, which are words taken from other languages with slight or no alterations. Another challenge is dealing with words that are not in WordNet and dealing with the newly developed terms in the recent times. This research aims to efficiently address these issues in order to improve WordNets throughout time.

This research paper will also explain how to use WordNets to make effective use of information created by WordNets in order to strengthen WordNet research. The Section II, Literature Review will discuss various research works in a similar or related field to determine the research gap and the need for current research work. The Section III, Methodology segment describes the actual mechanism that can be used to continuously improve the WordNets. The Section IV, Results part will summarise the outcome of the applied mechanism for the Hindi and Gujarati languages utilising the IndoWordNet. The Section V, Conclusion portion will indicate how the improvements should be implemented and expanded. Finally, Section VI, Future Enhancement include some relevant and helpful remarks for upcoming research works.

II. Literature Review

The authors attempted to delve deeper into the WordNet research area first, as they were working with various WordNets and encountering issues with missing words from WordNets. WordNets are lexical hybrid resources that are an interconnected combination of a dictionary and a thesaurus built using different approaches for different languages. Professor George A. Miller[13], [14] oversaw the creation of the first WordNet for the English language at Princeton University's cognitive science lab. Following the development of Princeton's American English WordNet, a multilingual wordnet EuroWordNet[15] was created on similar principles during March 1996 to June 1999, specifically designed for the various European languages (Dutch, Italian, Spanish, German, French, Czech and Estonian). The development of WordNets for various Indian languages began in the early 2000s, spearheaded by the Hindi WordNet [16]. Later, in the direction of Bhattacharyya research project IndoWordNet [17] was expanded to include multiple Indian languages, and it now supports 18 languages (Assamese, Bangla, Bodo, Gujarati, Hindi, Kannada, Kashmiri, Konkani, Malayalam, Manipuri, Marathi, Nepali, Oriya, Punjabi, Sanskrit, Tamil, Telugu, Urdu).

Authors attempted to locate some advancement and improvement associated research works related to WordNet after exploring for foundation-related research works. Redkar et al. [18] attempted to create an online multilingual dictionary with 19 languages for researchers and non-researchers to utilise for various purposes. To access the IndoWordNet [17], Panjwani et al. created pyiwn [19], a python-based Application Programming Interface (API), pyiwn is used to access IndoWordNet in this study.

In other recent work, McCrae et al. [20] worked on English WordNet 2020, an open-source project to improve and extend the Princeton WordNet, which hasn't been updated in a long time. In other recent work, McCrae et al. worked on English WordNet 2020, an open-source project to improve and extend the Princeton WordNet, which hasn't been updated in a long time. They made around 15000 modifications since the last version was updated.

Kanojia et al. [21] worked on linking 18 different Indian Language WordNets to Princeton WordNet, which aids in the exchange of knowledge and comprehension of various terminologies and their meanings in a multilingual environment. Fellbaum [22] described the WordNet's latest approaches, which are focused on language mapping concepts. He also discusses Crosslinguistic WordNets, as well as all of the components of how WordNets are managed over time.

In an another introductory work, Bhensdadia et al. [23] reviewed the development of the Gujarati wordnet. That research was also a component of the IndoWordNet, and the source language for Gujarati language development was solely Hindi. As a result, the authors of the current study decided to conduct parallel research in both languages. Zankhana and Sajja [24] also worked on the issue of word sense disambiguation in the Gujarati language using a Knowledge-Based Approach and a Genetic Algorithm. Using the IndoWordNet, Modh and Saini attempted to contextually improve Gujarati machine translation [25]. They used the n-gram model and tests with varying frame sizes to try to enhance the translation of Gujarati idioms.

The authors reviewed numerous study works linked to WordNets of various languages, as well as improvement-related works and a few studies focusing on the trip of the WordNets' development thus far.The authors realised that there is still a need to identify some systematic technique that might aid streamline the process of improving and strengthening WordNets. Inclusion of loanwords, missing words, and newly formed terminology in any WordNet of any language around the world must be done in a systematic and organized way.

The authors also discovered that while most WordNet-based initiatives focus on prose-based content, verse-based content can also provide some noteworthy contributions. Using verse for such research purposes is still a challenge in and of itself. Languages with a greater number of dialects make such study even more difficult. Taking into account all of these factors, the authors decided to focus on developing a system for continual WordNet improvement and strengthening. The authors opted to work with Hindi and Gujarati languages since they have diverse dialects, and they chose to evaluate the mechanism's quality and efficacy with Hindi's verse-based literary content and Gujarati's idiom-based data.

Following an extensive literature review and identifying a pressing need of the hour while conducting research on metadata generation for Hindi poetry [26], [27] and a few other research works related to Hindi poetry [28] and Gujarati idioms [29] using WordNet, the findings indicate the need for a systematic approach to dealing with loanwords, missing words, and recently developed terminologies. Since there are so many dialects in Hindi and Gujarati, resolving such difficulties is more complicated; Intriguingly, the authors acknowledged this research as a challenging one.

III. Methodology

This proposed research revolves around the use of WordNet, specifically the use of WordNet to find words that aren't currently in the WordNet. Several phases of this research as represented in Fig. 1, Core Methodology includes:

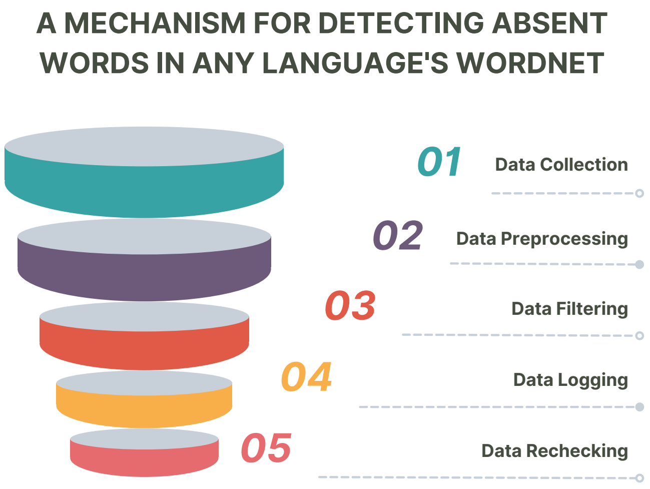

Fig. 1. Core Methodology

- III-A Data Collection
- III-B Data Preprocessing
- III-C Data Filtering
- III-D Data Logging
- III-E Data Rechecking

Authors incorporated transliteration and translation wherever non-English text is included, keeping in mind the international readership of the research work.

A. Data Collection

Special efforts were expended during the data collection phase for both Hindi and Gujarati. After analysing and brainstorming numerous types of data, the Hindi language poetic data and the Gujarati language idiom data were chosen with the goal of finding the most missing terms for a qualitative and quantitative contribution to the improvement of the respective languages' WordNets. Online websites and portals, as well as offline literature, were thoroughly examined for data collection. This study makes use of poetic data from Hindi literature. In Hindi poetry, verses play an important role. To write any type of verse, there are some specific rules that must be followed. Audichya and Saini's Hindi Verse dataset [30], as well as some additional data, were used. A total of 5011 poetic pieces of information were collected.

Example Hindi Data:

लग रहा है आज अम्बर, ज्यों उमड़ता सा समन्दर।
उठ चली चंचल हिलोंरे, आ रहे जैसे बवंडर।।

Transliteration of Example Hindi Data:

Lag rahā hai āj ambara, jyoan umadatā sā samandara.
uṭh chalī chanchal hilore, ā rahe jaise bavanḍara..

Translation of Example Hindi Data:

Looks like the sky today, as a rising sea.
Agitated tremors got up, like a tornado coming.

Gujarati data was obtained in the same way that Hindi data was, from various books and portals, along with some data which was directly acquired from the authors' previous research studies [31]. All of the standard Unicode-based data was collected, organised, and verified by specialists between December 2017 and April 2022.

Example Gujarati Data:

મોઢા પર મારવું

Transliteration of Example Gujarati Data:

Moḍhā par māravun

Translation of Example Gujarati Data:

Slap on face

B. Data Preprocessing

Following data collection, data processing takes place, which includes data preprocessing and cleaning. With the exception of the specific language's unicode range, which eventually removes unnecessary special symbols, emojis, junk characters, and so on, all unnecessary data is discarded first. Punctuation marks are also removed (Full Stop, Comma, Question Mark, Colan, Semicolon, Brackets, Exclamation Mark, Quotation Mark, Slash, and all irrelevant marks). The data is chunked into a list of words after the marks are removed and the preprocessing cleaning operation is completed. This procedure is known as Word Tokenization in the domain of NLP.

Preprocessed Hindi Data:

लग रहा है आज अम्बर ज्यों उमड़ता सा समन्दर उठ
चली चंचल हिलोंरे आ रहे जैसे बवंडर

Transliteration of Preprocessed Hindi Data:

Lag rahā hai āj ambara jyoan umadatā sā
samandara uṭh chalī chanchal hilore ā
rahe jaise bavanḍara

Translation of Preprocessed Hindi Data:

Looks dwell is today sky like surge as
sea rise walk fickle tremors come stay like
tornado

Preprocessed Gujarati Data:

મોઢા પર મારવું

Transliteration of Preprocessed Gujarati Data:

Moḍhā par māravun

Translation of Preprocessed Gujarati Data:

Slap on face

C. Data Filtering

The data preprocessing stage's list of words is now ready to be filtered. Let us first define filtering and its purpose. Every language has its own StopWords. Stopwords are commonly used words that have a little or no impact on the meaning of a sentence. Because this experiment uses Hindi language data, the authors used Hindi StopWords from a hybrid StopWords-based research of Hindi [32] and Gujarati[33] languages. StopWords from a specific language must be used in this stage to filter based on the language chosen for the implementation of this mechanism. StopWords were filtered while applying filtering to the list of words produced by the data processing stage.

Found Hindi Stop Words:

रहा है आज रहे जैसे

Transliteration of Hindi Stop Words:

rahā hai āj rahe jaise

Translation of Hindi Stop Words:

dwell is today stay like

Filtered Hindi Data:

लग अम्बर ज्यों उमड़ता सा समन्दर उठ चली चंचल

हिलोरे आ बवंडर

Transliteration of Filtered Hindi Data:

Lag ambara jyoan umadatā sā samandara

uṭh chalī chanchal hilore ā bavanḍara

Translation of Filtered Hindi Data:

Looks sky like surge as sea rise walk

fickle tremors come tornado

For the given Hindi example, five Hindi StopWords were filtered.

Found Gujarati Stop Word:

પર

par

Translation of Found Gujarati Stop Word:

on

Filtered Gujarati Data:

મોઢા મારવું

Transliteration of Filtered Gujarati Data:

Moḍhā māravun

Translation of Filtered Gujarati Data:

Slap face

For the given Gujarati example, a Gujarati StopWord was filtered. Data filtering is critical because it will assist us in reducing computational processing in subsequent stages. The remaining words will now go through the logging process.

D. Data Logging

The act of keeping a record of something is referred to as logging. Words from the filtered data list are checked in WordNet one by one at this stage. If a word is already in the WordNet, one can access all of the relevant properties of that word, such as Synsets, Synonyms, POS tags, Gloss, Example statements, and much more relevant information provided by the specific WordNet.

Now comes the crucial part of this research work: if any of the words are not found while checking the word's existence in the WordNet, some WordNets may produce an information message, while others may generate an error through exceptions. Such cases must be handled properly, and any words that are not found in WordNet must be logged and kept in a list of not found words.

The following words were not found in WordNet for the filter data from the data filtering stage.

Logged Hindi Data:

लग ज्यों उमड़ता सा उठ चली चंचल हिलोरे

Transliteration of Logged Hindi Data:

Lag jyoan umadatā sā uṭh chalī chanchal

hilore

Translation of Logged Hindi Data:

Looks like surge as rise walk fickle tremors

Logged Gujarati Data:

મોઢા

Transliteration of Logged Gujarati Data:

Moḍhā

Translation of Logged Gujarati Data:

face

This is a continuous process that can be repeated whenever a word is not found in WordNet. This entire mechanism can be embedded in any system that uses WordNet. All that remains is to integrate these various stages and keep track of words that are not found in WordNet while searching for various types of uses.

E. Data Rechecking

This is an optional step in reprocessing the logged data by rechecking it against WordNet. If this mechanism is integrated with any other system that uses WordNet, the logging stage will produce a large list of words that were not found over time.

Now, that list may contain some words that have already been added to WordNet in a later release, so to avoid those words from the logged data, the entire data can be rechecked with the most recent updated WordNet, and any duplicate words that have already been added to WordNet will be removed. Similarly, logged data can be filtered again with the updated StopWords if necessary.

The logged Hindi and Gujarati data example has been rechecked, and one word has been added in Hindi WordNet in the most recent update, so it has been removed from the data. Gujarati data remains as it is as the word is still not added in the Gujarati WordNet.

Rechecked Hindi Data:

लग ज्यों उमड़ता सा उठ चली हिलोरे

Transliteration of Logged Hindi Data:

Lag jyoan umadatā sā uṭh chalī hilore

Translation of Logged Hindi Data:

Looks like surge as rise walk tremors

Rechecked Gujarati Data:

મોઢા

Transliteration of Rechecked Gujarati Data:

Moḍhā

Translation of Rechecked Gujarati Data:

face

As a result, the data rechecking stage is for final checks before producing a clean list of data that are not available in WordNet. Let's take a look at the overall results of this study.

F. Discussion

If this mechanism is applied and followed in a systematic manner, this research will undoubtedly help to strengthen the various WordNet-based research works. This mechanism is useful for almost all WordNet-based projects, regardless of language. It was purposefully tested with Hindi language based poetic data and Gujarati idiom based data to determine its effectiveness because processing poems and idioms differs slightly from processing prose. That is the only explanation for such extraordinary results. There could be several reasons for the large number of words that were not found. It is possible to mention a few borrowed words, missing words, newly developed terminology, and combined or misspelt words. Because Hindi and Gujarati have so many dialects, there are more chances of borrowing words from neighbouring and sister languages.

IV. Results

This research was carried out over a long period of time, between December 2017 and April 2022. During this time, 5011 Unicode Hindi Verse-based poetic literature data and 3472 Gujarati idioms data were processed using this research methodology through all of the stages III-A. Data Collection, III-B. Data Preprocessing, III-C. Data Filtering, III-D. Data Logging, III-E. Data Rechecking as described in the III. Methodology section. Table I. Overall Results representing the different stats of current research work. As a result, the authors were able to populate a list [34] of 13,593 Hindi words which are not available in the Hindi WordNet section of Indian Languages WordNet (IndoWordNet). The total number of Hindi words in the IndoWordNet is 1,05,458, but through this research work, 13,953 new potential words were discovered, accounting for nearly 13.23 percent of the total number of words. In addition, 887 Gujarati words[35] were discovered while analysing 3,472 Gujarati idioms, accounting for 1.38 percent of the existing 64,300 Gujarati words in WordNet. This many words are more than enough to demonstrate the utility of this mechanism. Because there haven't been any similar research and datasets based on the Hindi and Gujarati languages, benchmarking isn't possible at this moment. Due to the limitation that there are currently no other comparable datasets available for both Hindi and Gujarati, future results may vary depending on the availability. If used, the current research methodology can yield significant results for various languages as well. This mechanism will undoubtedly aid in the improvement of WordNets in various languages around the world. While using this mechanism with other languages, the results may vary, but it will significantly improve any WordNet.

TABLE I. Overall Results

Sr. No.	**1**	**2**
Language	Hindi	Gujarati
Existing Words in IndoWordNet	105458	64300
Absent Words in IndoWordNet	13953	887
Absent Words %	13.23%	1.38%

V. Conclusion

To summarise, continual efforts are always required to strengthen the WordNets in order to accommodate freshly produced terms, loanwords, and missing words. Dealing with WordNets of languages with several dialects is difficult.Maintaining a log of words not found in WordNet while using any WordNet is usually beneficial. Later, processing those words with all of the WordNet's accessible words will yield a potential list of words. Such lists may be evaluated for inclusion in WordNet. On such words, the regular techniques for adding words to any language's WordNet can be used.

If these words are still not related to the specific language, they may have been borrowed from another language. In that scenario, these words can be cross-checked with WordNets from neighbouring languages from which they may have borrowed. For the continuing enhancement and strengthening of WordNet research projects, such methods and mechanisms can be included with practically every language's WordNet.

VI. Future Enhancement

The list of populated words after the data rechecking phase can be checked with the nearby and sister languages WordNets to identify the words in case some of the borrowed words belong to some nearby languages for future enhancement. Other studies, such as joint words or language detection related research, studies can also be conducted to check for missspelt and incorrect words.

Prediction of Diabetic Retinopathy using Convolutional Neural Networks

Manal Alsuwat, Hana Alalawi, Shema Alhazmi, Sarah Al-Shareef
Computer Science Department, College of Computer Science and Information System
Umm AlQura University, Makkah, 21955, Saudi Arabia

Abstract—**Diabetic retinopathy (DR) is among the most dangerous diabetic complications that can lead to lifelong blindness if left untreated. One of the essential difficulties in DR is early discovery, which is crucial for therapy progress. The accurate diagnosis of the DR stage is famously complicated and demands a skilled analysis by the expert being of fundus images. This paper detects DR and classifies its stage using retina images by applying conventional neural networks and transfer learning models. Three deep learning models were investigated: trained from scratch CNN and pre-trained InceptionV3 and EfficientNetsB5. Experiment results show that the proposed CNN model outperformed the pre-trained models with a 9 to 25% relative improvement in F1-score compared to pre-trained InceptionV3 and EfficientNetsB5, respectively.**

Keywords*—*CNN; convolutional neural networks; deep learning; transfer learning; medical imaging; diabetic retinopathy; retina fundus images

I. Introduction

Diabetic retinopathy (DR) is one of the diseases associated with diabetes and causes blindness to 4.4 million Americans over age 40 [1]. DR is an eye condition developed quickly in diabetes mellitus patients in type 1 or 2 [2]. DR often has no obvious symptoms in the early stages, but it becomes more pronounced as the disease progresses to more severe stages. An experienced ophthalmologist schedules a plan, which may run from weeks to months, to examine diabetic patients to determine their stage based on the retina's lesions and the severity level. Essentially, DR affects light-sensitive tissue blood vessels (i.e., retina) [3]. DR can be either nonproliferative or proliferative. In nonproliferative DR (NPDR), no abnormal blood vessel growth is found in the retina. Still, small outpouchings exist as the wall of retinal capillaries is weakened due to high blood glucose. These outpouchings are known as microaneurysms. NPDR can be mild, moderate, or severe based on the number of found microaneurysms and distortion of the blood vessels in the retinal exam. As the disease progresses, blood vessels may grow abnormally covering the retina; hence, DR becomes proliferative (PDR), leading to severe visual consequences.

In preventing blindness caused by the DR, detection, diagnosis, and treatment in earlier stages will control the disease and reduce vision loss. Diagnosis of the DR is complicated and requires high potential abilities [4]. One well-known obstacle for DR is that even for diabetic macular oedema, there are no early warning signs. Therefore, it is highly desirable to detect DR on time. Currently, DR diagnosis needs a well-trained doctor to diagnose the disease and manually evaluate digital images of the fundus of the retina. DR is recognised through identifying lesions connected with vascular malformations resulting from diabetes. This process may require longer time and effort depending on the experience and efficiency of the examiner doctor.

With the recent advancements in intelligent solutions, deep learning and transfer learning techniques showed significant success in object recognition and detection tasks. This research aims to automate DR diagnosis through exploiting convolutional neural networks (CNN) and transfer learning to identify DR from retina images. The Asia Pacific Tele-Ophthalmology Society (APTOS) dataset was used for blindness diagnosis and detection in this research. In addition, a comparison of the evaluation of different models to detect the disease effectively. This intelligent solution would help the health community diagnose the disease more efficiently, using less time and resources.

The remainder of this paper is organised as follows. In Section II, the related studies on the topic have been reviewed. Section III presents the research models used in this study followed by a description of the dataset used in the diagnosis DR in Section IV. Section V lays evaluation metrics and experimental design. Section VI presents the results of the experiments, and finally, the study is concluded in Section VII.

II. Related Work

Early DR detection is critical and time-consuming, and ophthalmologists are burdened. This attracted many researchers to develop early DR detectors and classifiers. Here, an overview of the deep learning techniques used in the previous literature is presented. Also, the used DR datasets in those studies are summarised. All of the reviewed literature detected DR from retinal fundus images. If detected, DR was classified into one of four severity levels: mild, moderate, severe NPDRs and PDR.

In the deep learning approach, CNN extracts features from input images and feeds them to the deeper layer in the model. Shan et al. [19] distinguished microaneurysms from fundus images using stacked sparse autoencoder (SSAE). Their model reached 91.3% for F1-score and an AUC of 96.2%. Singh et al. [20] employed a densely connected neural network architecture to detect the DR severity efficiently. Experimental findings showed that the DR severity could be successfully identified through the model with an accuracy of 83.6%.

Some researchers fine-tuned pre-trained models, known as transfer learning (TL), instead of training their models from scratch. These pre-trained models were initially trained using a large amount of out-of-domain data for object recognition and

detection. Then, only the output layer is replaced according to the given task and number of classes. Table I lists some of these studies along with the used pre-trained models and their performance. Whenever a study investigated more than one pre-trained model, an ensemble was applied to combine all these models and produce an optimal model.

Traditionally, the output layer of pre-trained models is replaced by a multi-layer neural network classifier and a softmax layer with a size equivalent to the number of classes to be recognised. Nevertheless, Taufiqurrahman et al.[11] suggested restructuring the MobileNetV2 model by replacing the fully connected layer with a Support Vector Machine (SVM) classifier. This modified version, MobileNetV2-SVM, obtained better performance than its original model. MobileNetV2-SVM achieved an accuracy of 85% and AUC of 92.8%. In a similar fashion, Khojasteh et al.[12] replaced the softmax layer with several classifiers: OPF, SVM, and KNN. Combing Resnet-50 and SVM outperformed other models with an accuracy of 98.2%, a sensitivity of 99%, and a specificity of 96%.

Several models can be combined using ensemble learning to improve prediction performance or reduce the bias in the learning process. Jiang et al. [17] introduced an image-based method to detect the DR early using an interpretable ensemble deep learning model. The proposed model is working on three main steps. Firstly, the fundus images preprocessing. Secondly, three different deep learning models have been used independently and trained sufficiently: Inception V3, Resnet152, and Inception-Resnet-V2. Finally, the Adaboost optimiser algorithm combined all the models' results to generate the final score. The integrated model proved a high performance in all evaluation metrics used: sensitivity, specificity, accuracy, AUC, 85.57%, 90.85%, 88.21%, and 0.946, respectively. Also, Tymchenko et al. [18] developed a DR detector using three-head CNN, which trained classification, regression and ordinal model. They used the output of these three heads for DR detection and achieved the sensitivity and specificity of 0.99.

As in the research, [17], [8], [6], [11], [7], this research aims to use InceptionV3, CNN, EfficientNetsB5 to detect DR due to their efficiency previous studies. However, these models will be validated using the same dataset to compare their results. Besides handling the issue of imbalanced distribution of classes on APTOS 2019 dataset, that not highlighted in previous researches.

III. Methodology

The purpose of this research is to classify a retinal fundus image whether it has a DR and at which severity. According to previous literature, deep learning and transfer learning models can solve this task. Transfer learning is a method that allows using the knowledge gained from other tasks to tackle new similar problems quickly and effectively. Hence, CNN models that are pre-trained will be fine-tuned utilizing domain dataset. Two pre-trained models will be selected for this study, InceptionV3 and EfficientNetsB5, for their effectiveness in diagnosing DR in the work of [17], [8], [6], [11], [7]. The performance of the fine-tuned pre-trained models will be compared with the performance of a CNN without pre-training.

A common issue in medical imaging datasets is the disparity in the number of samples within classes due to the difficulty of obtaining such samples. This problem is known as the class imbalance, and it pushes classifiers to prefer classes with higher training samples, reducing classification performance.

This section describes the techniques mentioned above.

A. Convolutional Neural Network (CNN)

Deep neural networks are artificial neural networks with more hidden layers to perform more complicated tasks and deal with massive amounts of data. The convolutional neural network (CNN) is one of the deep learning model networks with multiple layers such as convolution, pooling, fully connected, and non-linearity layer. CNN has been used with many applications, especially those that deal with spatial information, such as document analysis, image and video recognition, and computer vision [21]. The main aim of CNN is to increase or decrease the image dimensions into a more manageable form and extract the significant features, then process it to provide better predictions.

In this study, three convolution layers were employed with the same kernel size of (3,3). ReLU is used as an activation function with all layers, followed by a max-pooling layer with (2,2) pooling size to reduce the size of the large images. The results were flattened before the fully connected layer with a dropout of 0.2 to avoid overfitting. A softmax activation layer was used as the output layer. The architecture of the model is shown in Fig. 1. Some of the model's configurations were based on the work of [22], [23], [24].

B. Pre-Trained CNN Models

It has become customary to utilize a pre-trained CNN model and fine-tune it with in-domain dataset for the majority of computer vision applications. A pre-trained CNN model is a CNN model that has been trained on a large volume of data, such as ImageNet, for image classification [25]. Two pre-trained CNN models will be investigated in this paper: InceptionV3 and EfficientNetsB5.

Inception-v3 is a CNN architecture from the Inception family that contains 48 deep layers. Inception is characterised by implementing multiple kernels of different sizes in each layer (means become wider) instead of increasing the number of layers and going deeper in the network [26]. Each unit consists of four parallel operations: 1×1, 3×3, 5×5 conv layers and 3×3 max-pooling. All feature maps that come from different paths are concatenated together as the input of the next layer. Because in the image classification, the feature size of the image can diversify and deciding a fixed kernel size is difficult. Lager kernels are effective when the features are distributed over a wide area in the image. On the contrary, smaller kernels are useful and give excellent results in detecting small areas distributed across the image frame. To effectively recognise this variable size feature, kernels of different sizes are needed, which are provided in Inception models [27], [28].

EfficientNets family has a highly significant performance that achieves state-of-art on ImageNet, CIFAR-100, Flowers, and three other transfer learning datasets [29]. The architecture of the EfficientNets model involves convnet designs to reduce the space of the model with each layer to be scaled uniformly with a constant ratio to optimise the accuracy performance. It focuses on three aspects of scaling width, depth, and resolution. According to that, the EfficientNets family produces seven models with different image dimensions, and there is no change of layers operator of baseline network. This research proposes to apply EfficientNets B5 version.

C. Data Augmentation

Many approaches have been proposed to overcome the imbalanced dataset problem that can be classified into two categories: creating algorithms to resample the data and data preprocessing to generate new samples [30]. Resampling a dataset is a method used to balance the class distribution of the dataset. This is achieved by either adding samples to the minority class (oversampling) or removing samples from the majority class to balance the data (undersampling) [31]. However, data augmentation is a common technique used to generate new samples of the data to provide the image in a different representation.

Data augmentation techniques help improve the deep learning model's ability by generating artificial new images to achieve high variation in the training dataset and avoid overfitting problems. Many transform operations could be applied for data augmentation, such as random rotation, brightness, zoom, and image preprocessing techniques, such as Gaussian blur or CLAHE [32]. The data augmentation techniques included in this research are horizontal and vertical flip, zoom, and rotation. Fig. 2 shows a sample image from class 0 augmented after preprocessing image phase.

IV. Diabetic Retinopathy Dataset

Several datasets are available for the retina to detect DR and the vessels. Often these datasets are utilised for training,

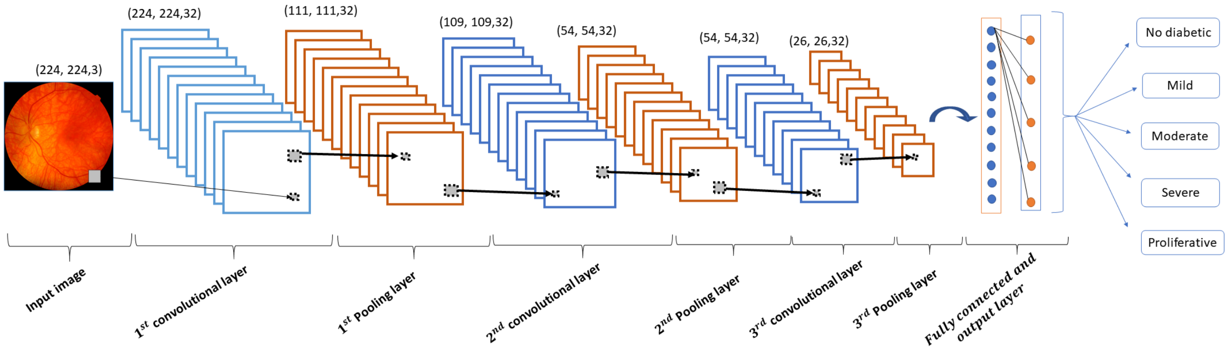

Fig. 1. CNN Module Architecture used in this Study.

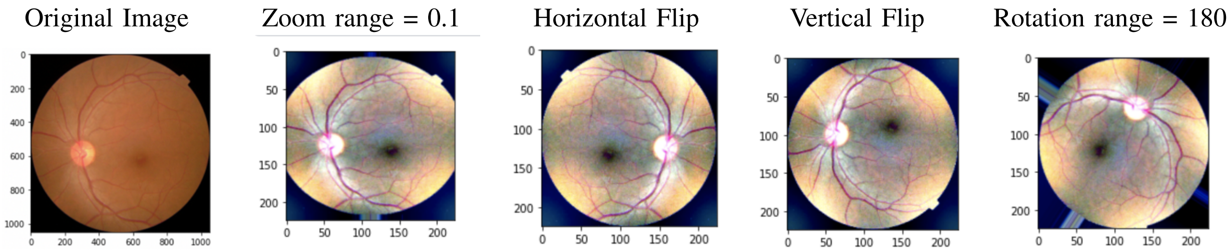

Fig. 2. Applying Data Augmentation Techniques in a Sample of Retinal Fundus Image.

validation, and testing deep learning models. The Asia Pacific Tele-Ophthalmology Society (APTOS) published this dataset in the second quarter of 2019. As shown in Table I, several studies used the APTOS2019 dataset [33] for blindness detection, containing a large set of retina images taken using fundus photography. Initially, two sets were published: labelled images, known as the train set, and unlabelled images, known as the test set. Only the labelled images were included in this study, consisting of 3662 fundus images. Each image was labelled into one of five classes, representing the severity of DR. Table II shows samples of each class and its characteristics that differentiate it from the others. As many of the medical dataset, APTOS2019 suffers from class imbalance as shown in Fig. 3 with majority of the cases towards healthy images without DR. However, there is a balance between the sum of all DR images regardless of their severity and healthy images.

The image size is a more critical factor that will impact the classification tasks. As shown in Fig. 4, there is a different distribution of image height and width, which suggests that not all images are in a perfect square shape.

V. Experiments

A. Experimental Design

All experiments were implemented and evaluated using Python [34] and leverage TensorFlow and Keras library [35] using Kaggle GPUs, Kaggle presents free access to NVidia K80 GPUs in kernels. In particular, these GPUs can be used to train deep learning models [33]. For this study, the labelled set was split into three homogeneous sets: training, validation and testing sets with a ratio of 68%, 20%, and 12%, respectively. The distribution of classes within each split is shown in Table III. Two sets of experiments were performed: fine-tuning and training using an imbalanced training set, 2489 samples, and a balanced training set after augmentation, 6158 samples.

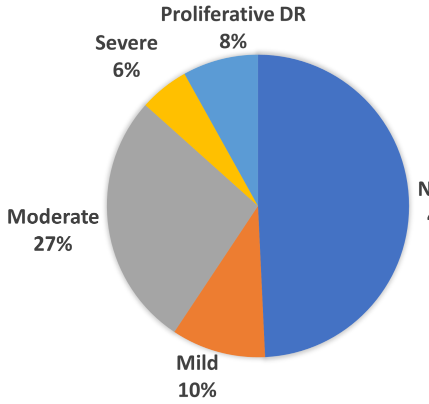

Fig. 3. Class Distribution among APTOS2019 Training Set.

B. Data Preprocessing

As most of the pre-trained models in this study were trained using images of size 224×224, images of APTOS2019 were rescaled accordingly. Moreover, images were converted into grayscale, which increases the visibility of some abnormalities. Following [18], [7], further image processing processes were applied: uninformative black areas were removed using circular crop, blending using Gaussian blur with alpha=4, beta=-4,

TABLE II. LABEL DESCRIPTION AND CHARACTERISTICS OF DR SEVERITY LEVELS WITH ITS SAMPLES FROM APTOS2019

Sample	Characteristics
 0 200 400 600 800 1000 0 500 1000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 500 1000 1500 0 500 1000 1500 2000 2500 0 200 400 600 800 1000 0 500 1000	**Label 0: No diabetic retinopathy (NoDR)**
 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 500 1000 1500 2000 0 1000 2000 3000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000	**Label 1: Mild nonproliferative retinopath**: In this early stage of the disease, small patches of balloon-like swelling in the small blood cells in the retina, known as microaneurysms. The fluid will leak into the retinas through these microaneurysms as shown in the left images.
 0 500 1000 1500 2000 0 1000 2000 3000 0 500 1000 1500 2000 0 1000 2000 3000 0 500 1000 1500 0 500 1000 1500 2000 2500 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000	**Label 2: Moderate nonproliferative retinopathy**: As the disease progresses, Blood vessels feeding the retina may swell and distort and also lose blood transportation capacity. These conditions cause significant changes to the appearance of the retina and can contribute to diabetic macular edema (DME) as shown in the left images.
 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000 0 250 500 750 1000 1250 1500 0 500 1000 1500 2000	**Label 3: Severe nonproliferative retinopathy**: Many further blood vessels are blocked, which deprive the retinal region of blood supply. These regions secrete growth factors that suggest that the retina is forming new blood vessels as shown in the left images.
 0 500 1000 1500 2000 0 1000 2000 3000 0 500 1000 1500 2000 2500 0 1000 2000 3000 0 500 1000 1500 0 500 1000 1500 2000 2500 0 250 500 750 1000 0 500 1000 1500	**Label 4: Proliferative diabetic retinopathy (PDR):** This more serious form called proliferative diabetic retinopathy. Damaged blood vessels are blocked in the retina in this case, causing the development of irregular new blood vessels, and can flow into the clear, jelly-like substance that fills the center of the eye (vitreous). Scar tissue stimulated through new blood vessel growth can gradually separate the retina from the posterior of the eye. Therefore, retinal detachment could lead to permanent eyesight loss as shown in the left images.

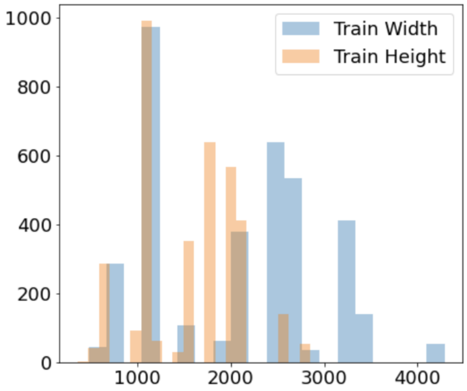

Fig. 4. Distribution of Image Width and Height in APTOS2019.

TABLE III. THE SPLIT OF APTOS2019 TRAIN SET USED IN THIS STUDY AND ITS CLASS DISTRIBUTION.

Class	Training set	Testing set	Validation set
No DR	1229	217	359
Mild	265	43	62
Moderate	670	124	205
Proliferative DR	132	25	36
Severe	193	31	71
Total	2489	440	733

and gamma=128. Consequently, the resulting images are not entirely greyscaled as modifications were applied separately on every pixel's colour channel. This helps improve the blood vessel's visibility and its growth in the eye, as shown in Fig. 5. All image preprocessing techniques was applied using Python (cv2) OpenCV library [36], [37].

C. Data Augmentation

Data augmentation was implemented using 'ImageDataGenerator' class from Keras library [35]. As shown in Fig. 3, the number of cases in each category varies significantly, with no_DR as the majority class (49.3% of total images). The number of the augmented images is different based on the number of the original images, as shown in Fig. 6. The augmentation phase enriched the diversities of the classes to provide high-quality images to the learning models. This operation was performed only on the training dataset. Image augmentation for the minority classes was applied via zooming, flipping, and rotation, which acquired a dataset three times larger than the original set.

D. Fine-Tuning the Pre-Trained CNN Models

For every pre-trained model included in this study, the input layer was set to be 224×224 and three channels. However, the output layer was modified to match the number of classes in this task, i.e. five classes. Then, all layers were frozen during the fine-tuning process except for the modified last layers. The last layers were trained using Adagrad optimiser with a learning rate of 0.01 and for 30 epochs. Similar training configurations were employed when training CNN model.

E. Evaluation Metrics

A multi-class classification task necessitates factors such as class balance and expected outcomes when picking the optimal metrics to evaluate the performance of a particular classifier against a given dataset. One performance metric may assess a classifier from a specific perspective while others can not, and vice versa. Hence, there is no standardised (unified) metric for defining the generalised performance measurement of the classifier. In this paper, several metrics are chosen to measure the models' performance: Accuracy, Precision, Recall and F1-score. Table IV. summarises how each of the first four metrics is calculated for a multi-class classifier with C classes, where TP_i and TN_i are the number of cases correctly diagnosed for class C_i or not, respectively. And FP_i and FN_i are the number of cases that were incorrectly diagnosed to the class C_i or not, respectively.

TABLE IV. EVALUATION METRICS AND THEIR FORMULAS.

Metric	Description	Formula
Accuracy	The average number of correct predictions.	$Acc = \frac{\sum_{i=1}^{C} \frac{TP_i+TN_i}{TP_i+FN_i+FP_i+TN_i}}{C}$
Precision	Capability of identifying the correct instances for each class.	$Pre = \frac{\frac{\sum_{i=1}^{C} TP_i}{\sum_{i=1}^{C} TP_i+FP_i}}{C}$
Recall	Capability to recognise the true positive out of the total true positive cases.	$Rec = \frac{\frac{\sum_{i=1}^{C} TP_i}{\sum_{i=1}^{C} TP_i+FN_i}}{C}$
F1-score	The harmonic average of precision and recall.	$F1 = 2 * \frac{Pre_M * Rec_M}{(Pre_M + Rec_M)}$

TABLE V. RESULTS WHEN TRAINING MODELS USING THE IMBALANCED DATASET.

	Precision	Recall	F1-score	Accuracy	kappa
	Training set				
CNN	61%	69%	69%	67%	61%
Inceptionv3	84%	71%	74 %	88%	84 %
EfficientNet B5	35%	34%	32%	62%	29%
	Validation set				
CNN	58%	65%	61%	65%	58 %
Inceptionv3	51%	51%	51%	76%	70%
EfficientNet B5	40%	36%	34%	64%	30%
	Testing set				
CNN	64%	71%	67%	73%	65%
Inceptionv3	62%	53%	54%	78%	72%
EfficientNet B5	30%	34%	31%	63%	30%

As one of the experiments uses an imbalanced dataset, Cohen's kappa was used as an additional metric. It can be computed as follows:

$$K = \frac{P_0 - P_e}{1 - P_e},$$

where P_0 denotes the overall accuracy and P_e denotes a measure of the probability of the agreement between the prediction class values and the actual class values as it occurs by chance [38]. $K = 1$ if classes are in complete agreement while $K = 0$ proves the opposite.

VI. RESULTS AND DISCUSSION

A. Training with Imbalanced Dataset

Each pre-trained model was fine-tuned using the imbalanced training set, with 2489 samples and no_DR as the majority class. When training the CNN model from scratch, the same imbalanced set was used for training. Table V. lists the results obtained during models training. Since accuracy is

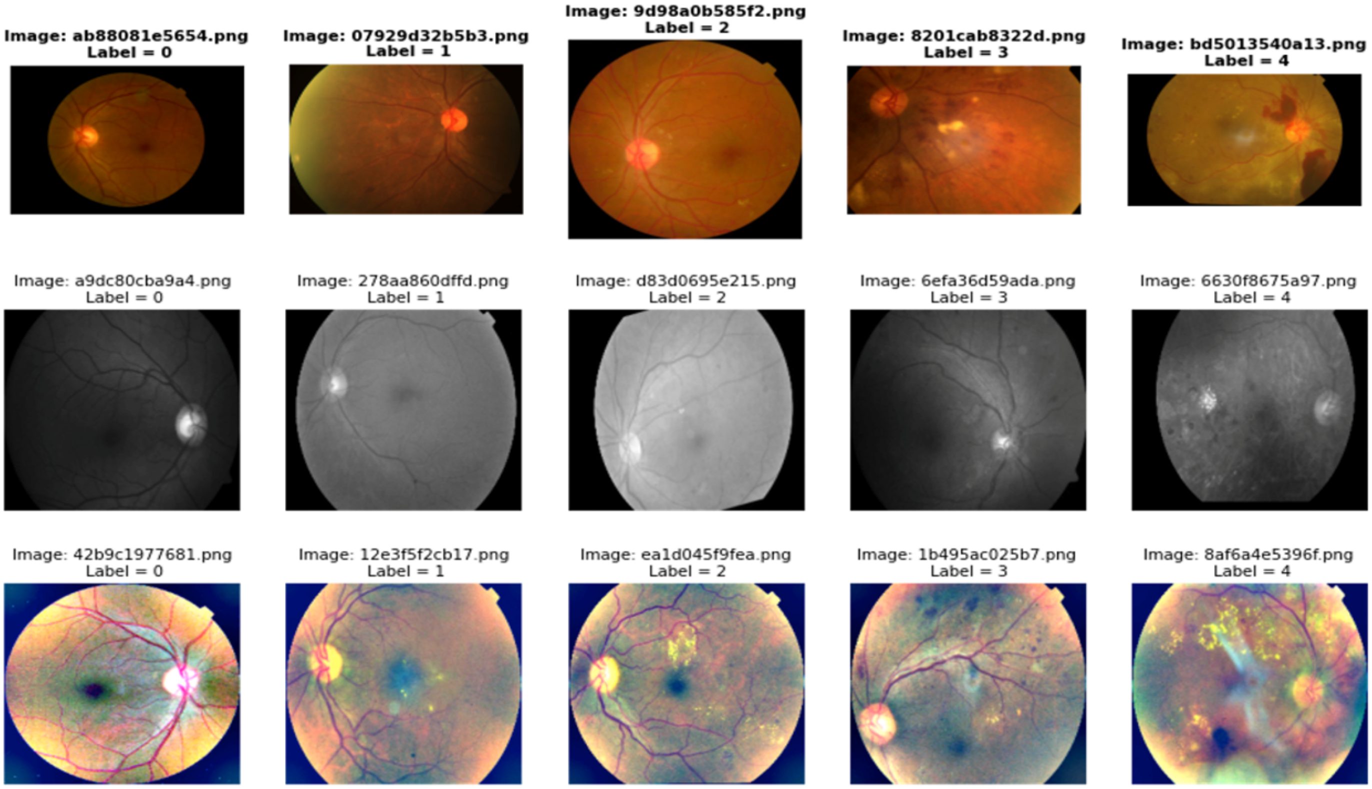

Fig. 5. Applying Image Preprocessing Techniques on Some Samples from APTOS2019. The First row Shows the Original Sample from each Class. The Second Row Shows the Same Samples after Converting them into Grayscale using the cvtColor Function and COLOR_BGR2GRAY as a Parameter. The Third Row Shows the Same Samples after Applying Gaussian Blur and Circular Cropping.

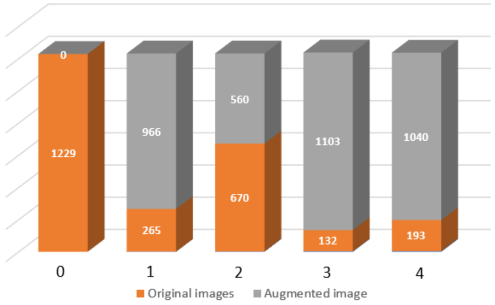

Fig. 6. Samples Per Class in APTOS2019 Training Set. Class 0 (no_DR) is the Majority Class so Other Classes were Augmented with Different Numbers of Samples to Obtain a Balanced Training Set.

unreliable when evaluating models trained on an imbalanced dataset, F1-score and kappa are the primary evaluating metric. CNN model achieves the highest F1-score with 67%, while the InceptionV3 model obtained 54%. On the other hand, the EfficientNetB5 model has the lowest performance.

To investigate the reasons for EfficientNetB5 performance, the learning curve for each of these models are depicted in Fig. 7. As shown in the figures, the learning curves of the CNN and InceptionV3 model in training and validation phases was improving smoothly, while the EfficientNetB5 model suffered from a high overfitting problem, which caused its low results.

Fig. 8 visualises the confusion matrix of these models, which indicates the number of predictions produced by the model where it classified the classes correctly or incorrectly. The diagonal expresses the correctly diagnosed states for each class, where the off-diagonal elements represent the misclassified samples. In general, all models have their best recognition for Class 0 (no_DR) and 2 (mild NPDR) aligned with the class majority shown in Fig. 3. with Class 0 and 2 with the largest samples, respectively. However, most confusion was between different classes of DR, not no_DR and any DR. This observation was accurate for all models. In other words, these models have good DR detection but poor severity level classification. The detection rate can be calculated by mapping all DR severity levels 1-4 to 1. Hence, the obtained detection rates are 90%, 96% and 83% for CNN, InceptionV3 and EfficientNetB5, respectively.

B. Training with Balanced Dataset

In this experiment, pre-trained models were fine-tuned using the balanced training set via augmentation, with 6158 samples. The same set was used for training when training the CNN model from scratch. Table VI lists the results obtained during models training. CNN model achieves the highest F1-score with 64%, while the InceptionV3 model obtained 58%. On the other hand, the EfficientNetB5 model has the lowest performance with a 48% F1-score. Looking at the learning curves for these models in Fig. 9. the performance of the validation set improved better than the training set for the CNN

EfficientNet B5	57%	46%	48%	73%	60%

model, which indicates that some samples were difficult for the models to learn from the features. However, this was not observed for InceptionV3 and EfficientNetB5 models, which means the performance of training and validation sets were approximate are similar.

Fig. 10 visualises the confusion matrix of these models. In general, all models could not recognise Class 4 (PDR) successfully compared to other classes. As in the previous experiment, most confusion was between different classes of DR, not no_DR and any DR. The obtained detection rates here are 84%, 95% and 90% for CNN, InceptionV3 and EfficientNetB5, respectively.

This study performed two experiments; the first was on a dataset imbalanced between classes and only processed by scaling and resizing the image. The second experiment was on a balanced dataset by utilising augmentation data and applying image preprocessing techniques. F1-score was used to measure and compare the performance in both experiments because it is a standard measure of imbalanced data classification, in addition to the rest metrics mentioned in Section V-E. The performance was improved when using balanced since the InceptionV3 and EfficientNetB5 models obtained higher results. InceptionV3 model's performance improved in Recall and F1-score when using a balanced training set while the results of the CNN model decreased in all measures. On the other hand, the results of the EfficientNetB5 model improved in all metrics when using a balanced training set. Hence, fine-tuning pre-trained models could benefit from the augmented samples and enhanced features, which was not the case for the CNN model.

Furthermore, the CNN model achieves the highest results in the two experiments which are 67% and 64% of F1-score, in the first and second experiments, respectively. When looking at their learning curves, overfitting was an issue in pre-trained models, indicating the need for more powerful regularisation for these advanced architectures. In other words, the more complex the architecture, the more prone to overfit.

In general, the detection ability of these models was better than its classification between DR severity levels. For EfficientNetB5, the DR detection was improved by 7% absolute when

using a balanced training set, while it was the opposite case for CNN as its detection accuracy dropped by 6% absolute.

VII. Conclusion

DR is currently one of the dominant diseases that significantly affect people with diabetes. The paper covers the details of the implementation and evaluation of several deep learning models: CNN, InceptionV3, and EfficientNetsB5 for classifying DR using the APTOS2019 dataset. Two different experiments were conducted, the first with the original images and the second after processing the images and balancing the classes. The InceptionV3 model performed the best accuracy on the dataset in both experiments, while the CNN model got the highest F1-score in both experiments. Using these prediction results, effective DR detection systems can be implemented using deep learning models so that the patient can be treated and dealt with in the early stages. The results of this research may not be the same as previous research due to the difference in the dataset used and the data processing method. This research's main challenges and limitations are that the image dataset was imbalanced, and there was a shortage of efficiency of the devices utilised in processing even when using online GPU, such as Kaggle, the allotted time was limited. For further work, this research can expand to address these deficiencies by using other methods to balance data and apply other pre-trained models to diagnose DR.

***Abstract*—Automatic License Plate Detection and Recognition (ALPR) is one of the most significant technologies in intelligent transportation and surveillance across the world. It has many challenges because it affects by many parameters such as the country's layout, colors, language, fonts, and several environmental conditions so, there isn't a consolidated ALPR system for all countries. Many ALPR methods have been proposed based on traditional image processing and machine learning algorithms since there aren't enough datasets, particularly in the Arabic language. In this paper, we proposed a real-time ALPR system for the Egyptian license plate (LP) detection and recognition using Tiny-YOLOV3. It consists of two deep convolutional neural networks. The experimental results in the first available publicly Egyptian Automatic License Plate (EALPR) dataset show the proposed system is more robust in detecting and recognizing the Egyptian license plates and gives mean average precision values of 97.89% and 92.46% for LP detection and character recognition, respectively.**

***Keywords*—Automatic license plate recognition; Egyptian license plate; Tiny-YOLOV3; CNN; eALPR dataset**

I. Introduction

Numerous applications, including traffic surveillance, automatic toll collection, parking, and theft prevention, depend on the automatic detection and recognition of licence plates [1]. The main objective of ALPR systems is to detect the location of the license plate in the vehicle image and recognize its characters and digits without involving massive human resources, and saving processing time.

The ALPR problem has been investigated over the last decades by many researchers, and several methods have been presented. However, the ALPR is still active due to several difficulties that are related to digital image processing, including the diversity of lighting, camera angles, distance from the camera, scales, complex backgrounds, etc. In addition to the license plate layout, each country defines a special plate structure, background, color, language, font type, and size, which differ from country to country. The majority of ALPR proposed methods are outside the Middle East (e.g. United States, China, Brazil, Taiwan, and Europe) [2]–[5].

Most of the previous works are based on traditional image processing techniques such as binarization, edge-based, character-based, color-based, texture-based, and template matching approaches, which are based on hand-engineered features. With the rapid development of the deep learning, the prediction performance of many computer vision tasks such as image classification, segmentation, and object detection has been greatly improved [6]. Many approaches have used deep Convolutional Neural Networks (CNN) to obtain state-of-the-art accuracy. However, the main drawback of deep learning models is that they need big datasets for the training stage. so, few deep learning works were presented in the Arabic region due to the lack of a publicly available dataset, especially for Egyptian license plates.

You Only Look Once (YOLO) [7] inspired models have made significant advancements in object detection problems. So we decided to use it in our proposed system. YOLOV3 [8] is the enhanced of YOLO and YOLOV2 [9] real time object detection algorithm that uses a model with 53 fully convolutional layers on the other side, Tiny-YOLOV3 is a light model focused on a speed / accuracy trade-off that uses eight convolutional and six max-pooling layers. Hence, Tiny-YOLOV3 is quicker but less accurate than YOLOv3.

In this paper, we propose a new real-time system for Egyptian license plate detection and recognition based on the Tiny-YOLOv3 object detection deep learning model. It consists of two stages : the first stage is responsible for detecting the license plate location from the input vehicle image and the second stage is recognizing the characters and digits from the detected license plate. The proposed system is used to evaluate the EALPR dataset that the first public Egyptian LP dataset.

our main contribution can be summarized as follows:

- A new real-time system for Egyptian license plate detection and recognition based on the Tiny-YOLOv3 deep learning model for both stages.
- Evaluation of the proposed system on the EALPR dataset, including 2450 vehicle images and more than 12,000 Arabic digits and characters.

The paper is organized as follows. We briefly review ALPR related works in Section II. Section III introduces the EALPR proposed system. We report the experimental results in Section IV, and finally, we present the conclusions and future work in Section V.

II. Related Work

ALPR is challenging because it depends on several factors, including the plate country's design, colors, environment, language, and texture. Both license plate detection and character recognition could be done using the object detection techniques. There are two approaches of object detection features, hand-engineered features (Haar, HOG, SIFT, SURF, ... etc.) and deep neural networks features based on convolutional neural networks (YOLO, SSD, Faster-RCNN, RefineDet, ... etc.). We briefly review some previous related work to the ALPR problem.

In [10], proposed a smart vehicle control system based on ALPR. The proposed method is color-based and extracts the region of the license plate based on some of the predefined colors like yellow and white, and applies histogram algorithms and morphological operations for rapid detection. This method uses a back-propagation neural network for character recognition. A total of 350 vehicles are used for testing the method and achieving a high success rate.

In [11], presented an ALPR system for the Egyptian license plates. A total of 221 images of classic Egyptian vehicle license plates were used in this study. The proposed method accuracy for plate detection is 78% using edge detection and morphological operations, 85% using the illumination model of YCbCr and wavelet transform, 85% for character segmentation, and 74% for character recognition.

In [2], developed an end-to-end deep learning system for Brazilian license plate detection and recognition in unconstrained scenarios. The developed system is based on deep convolutional neural networks (CNN). The authors used the public available Brazilian datasets. The accuracy of the license plate detection is 99%, and the recognition is 93%.

In [5], presented a two stages method for license plate detection and recognition. In the first stage, the author detected the vehicle region using a faster R-CNN method and in the second stage, they used the same algorithm with hierarchy sampling method for plate detection in the vehicle region. The proposed method is evaluated by Caltech dataset and achieved 98.39% as the precision rate.

In [3], proposed a real-time end-to-end ALP system based on the state-of-the-art YOLO object detection. They presented a fully annotated public dataset called FPR-ALP for Brazilian license plates. Fast-YOLO, YOLOV2, and CR-Net are used for plate detection and recognition respectively. The recognition accuracy of the system is 93.53% higher than both the commercial Sighthound and OpenALPR solutions.

III. Proposed System

A. System Overview

In Fig. 4, we show the main stages of the proposed ALPR system. The development of real-time object detection techniques is an important step for building a reliable ALPR system. We use two object detection models for license plate detection and recognition. The input to our proposed system is the vehicle image, whereas the output is the recognized license plate characters and digits. Tiny-YOLOV3 is the backbone architecture for both stages LP detection and recognition.

B. ELAPR Dataset

In this section, we introduce a new dataset for the Egyptian license plate called (EALPR). We scrap the EALPR dataset images from websites such as Instagram pages [12]–[15] and Facebook Marketplace [16] using web scraping Tools [17], [18]. It has 2,450, and 12,160 characters images including many types of vehicles such as cars, buses, trucks, microbuses, and mini-busses. Fig. 1 shows the characters and digits statistics. The vehicle images are captured using different cameras, at varying times, lighting, and background. Fig. 7 shows samples from EALPR. It is publicly available on https://github.com/ahmedramadan96/EALPR.

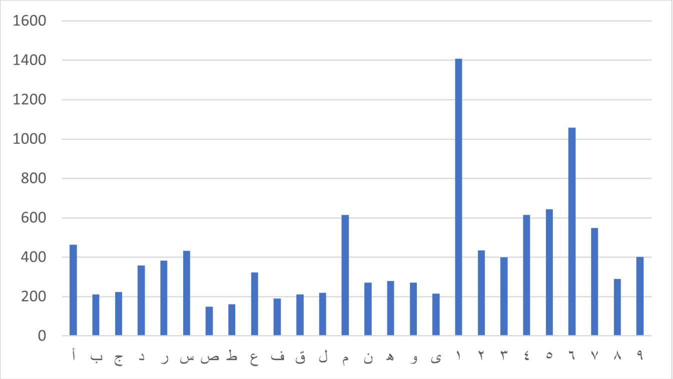

Fig. 1. Characters and Digits Statistics in the EALPR Dataset.

The Egyptian License Plate (LP) uses the Arabic digits and characters which is varying in several countries that use Latin letters such as Europe, Brazil, US, ... etc. It has a dimension 16 (height) X 40 (width) with aspect ratio 1:2 approximately [19]. its layout is divided into 3 regions: the country region contains the Egypt word in Arabic and English format, the character region includes plate characters, and the number region contains plate digits. Fig. 2 shows the Egyptian LP structure. It uses 10 Arabic digits and 17 Arabic characters. Fig. 3 illustrates the used license plate Arabic characters, digits, and their corresponding English format.

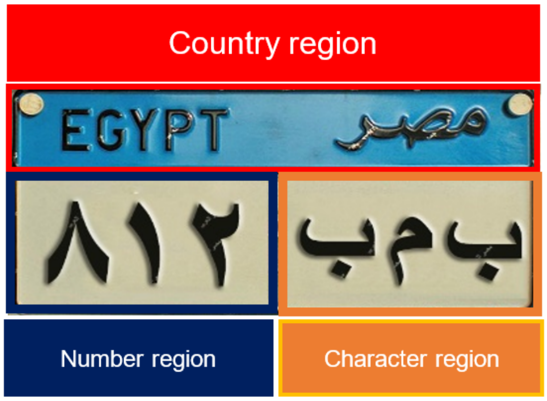

Fig. 2. Egyptian License Plate Structure.

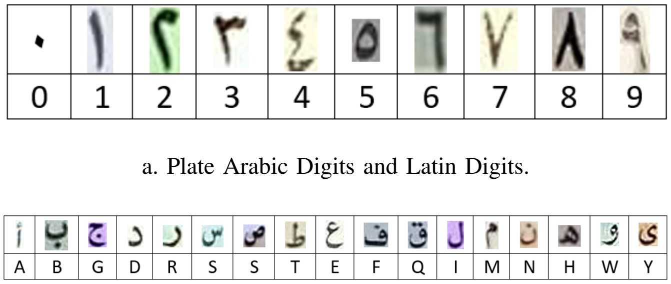
Dataset annotation is required for object detection YOLO models. After collecting EALPR dataset we manually annotate the vehicles, characters, and digits using Ybat tool [20] as shown in Fig. 5, and 6. Ybat provide the start and end coordinates (x_{min},x_{max}), (y_{min},y_{max}) respectively for each rectangle. The four values of YOLO bounding boxes is calculated using



a. Plate Arabic Digits and Latin Digits.

b. Plate Arabic Characters and Latin Characters.

Fig. 3. a. Plate Digits b. Plate Characters in Arabic (First Row) & English (Second Row).

equations (1)-(4)

$$b_{\mathrm{x}} = \frac{x_{\min} + x_{\max}}{2 \times w} \tag{1}$$

$$b_{\mathrm{y}} = \frac{y_{\min} + y_{\max}}{2 \times h} \tag{2}$$

$$b_{\mathrm{w}} = \frac{x_{\max} - x_{\min}}{w} \tag{3}$$

$$b_{\mathrm{h}} = \frac{y_{\max} - y_{\min}}{h} \tag{4}$$

where b_x,b_y,b_w,b_h representing the center point of the rectangle, width, and height, respectively.

C. *License Plate Detection Network **(LP-Net)***

LP-Net is responsible for taking the raw vehicle image as input and detecting the location of the plates. The plates are cropped based on the bounding boxes using OpenCV [21] and passed to the character model. A license plate is an object that may be detected using object detection algorithms. The main function of object detection algorithms is to detect the object locations at different scales (shapes and sizes). Deep learning object detection techniques work effectively in a variety of environments and with a large dataset. LP-Net is the same original Tiny-YOLOV3 network. Tiny-YOLOV3 consists of 8 convolutional and 6 max-pooling layers in the feature extractor block. The network architecture is shown in Table I. It uses small kernel sizes 3×3 and 1×1 for the convolutional layers and 2×2 for max-pooling layers. We changed the input image size from 416×416 to 608×608, which resulted in higher accuracy. We also changed the final convolutional layer to predict only one class label ("license_plate"). YOLO predicts bounding boxes using A anchor boxes (we choose A = 3) with four values (b_x,b_y,b_w,b_h), confidence, and C class probability, therefore the number of filters is 18 which is defined in Equation (5)

$$\#Filters = (Classes + 5) \times Anchors \tag{5}$$

TABLE I. Tiny-YOLOV3 Architecture

Layer	Type	Filters	Size/stride
0	Conv	16	3×3/1
1	Max		3×3/2
2	Conv	32	3×3/1
3	Max		3×3/2
4	Conv	64	3×3/1

20	Route 19,8		
21	Conv	256	3×3/1
22	Conv	33	3×3/1
23	Yolo loss		

D. *Character Recognition Network **(Char-Net)***

The main function of Char-Net is to detect the plate digits and characters and recognize them using deep object detection CNN. The input for this network is the cropped license plates that were detected from the previous network. We accept all cropped (LP)s with an aspect ratio of 1:2 and reject the small plates. Also, It has the same architecture of Tiny-YOLOV3 as shown in Table I with some changes. All plates are resized to be 384×192 to prevent the vanishing gradient in CNN layers. The architecture is changed to detect 27 digits and characters that are used in the Egyptian license plates. Fig. 3 show all used digits and character classes. The number of filter in the last convolutional layer is 96 which calculated using Equation 5

IV. Experimental Results and Evaluation

A. *Experimental Setup*

All experiments were performed on a personal computer with Windows 10 64-bit, Intel(R) Core(TM) i7-9750H 2.6GHZ CPU, 16GB memory, and NVIDIA GeForce GTX 1660Ti GPU. The proposed system is implemented using the darknet deep learning framework and OpenCV library. The YOLO implementation is available here [22]. As previously mentioned, the EALPR dataset vehicle images are collected from social networks with different environments and conditions. For plate and character networks, we resize the input image to be 608×608 and 384×192 respectively. 80% of the dataset is selected randomly for training our proposed system and the remaining 20% is used for testing purposes. In the training stage, we use the pre-trained Tiny-YOLOV3 model to initialize the network's weights. Both the plate and character networks were trained for 5000 epochs and 6000,54000 max batches respectively with a batch size of 64 images. We use the Leaky RELU activation function. The momentum is set to 0.9, the weight decay to 0.0005, and the learning rate started with 0.001 used for both networks. Table II summarizes all training parameters for both models.

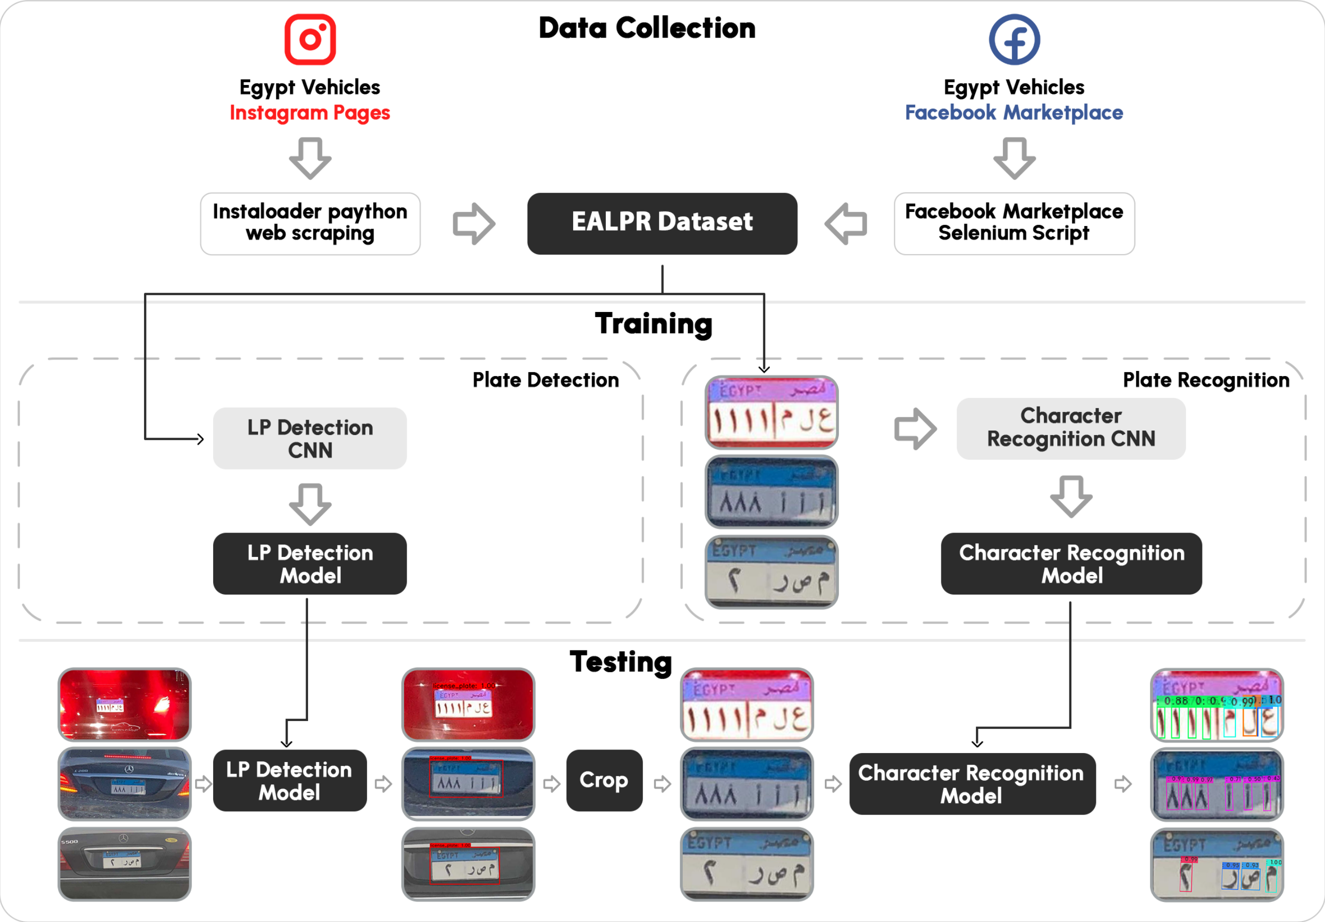

Fig. 4. Main Stages of the Proposed EALPR Approach.

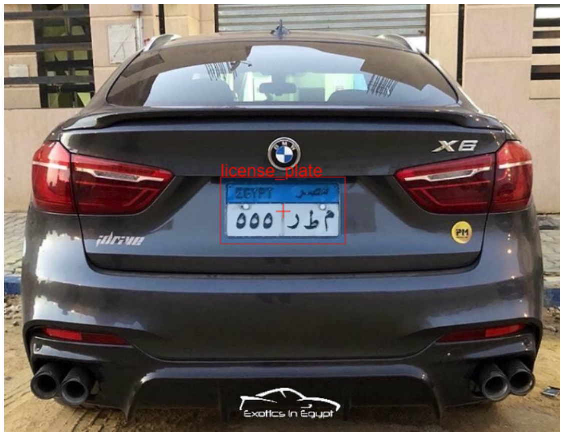

Fig. 5. Vehicle Plate Annotation.

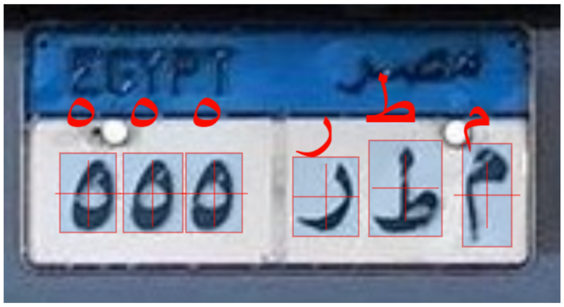

Fig. 6. Plate Characters Annotation.

B. Evaluation Metrics

The proposed system is evaluated using the mean average precision (mAP) value. The mAP value depends on precision and recall metrics [23] which are described in Equations (6) and (7).

$$Precision = \frac{TP}{TP + FP} \tag{6}$$

$$Recall = \frac{TP}{TP + FN} \tag{7}$$

where True Positive(TP), False Positive(FP), and False Negative(FN) means the number of correctly detected (plates

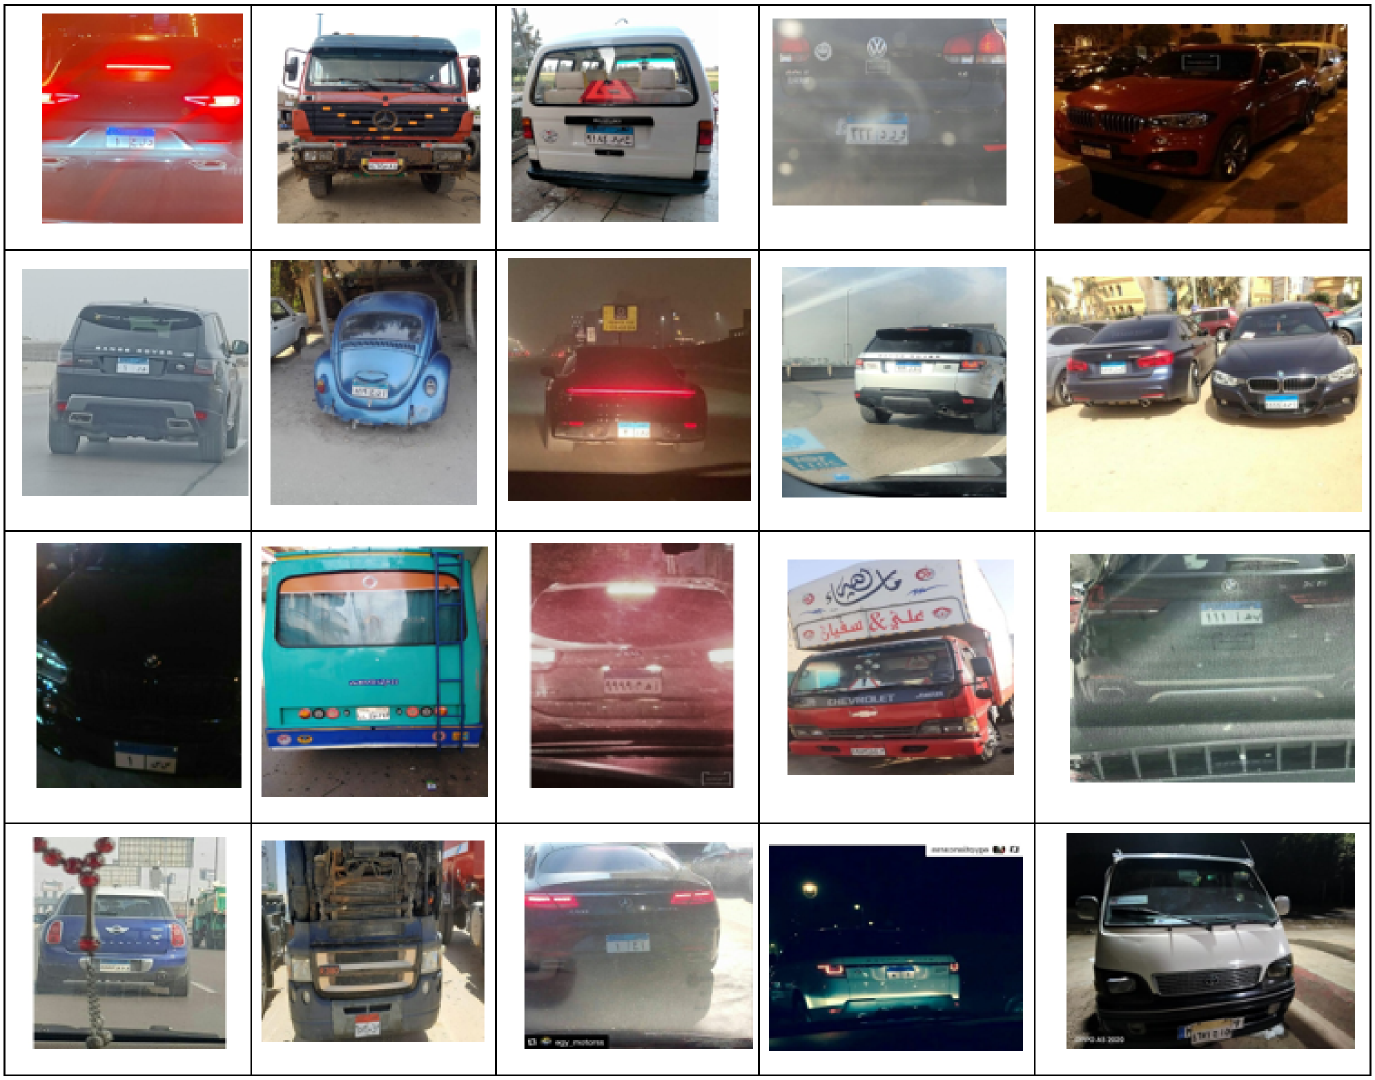

Fig. 7. Sample Images from EALPR Dataset.

TABLE II. TINY-YOLOV3 TRAINING PARAMETERS FOR LP-NET & CHAR-NET

Parameter	Value
Framework	Darketnet
Image Dimensions	608×608 (LP-Net) and 384×192 (Char-Net)
Channels	3
Activation Function	Leaky RELU
Policy	steps
Epoch	5000
Max batches	6000 (LP-Net) and 54000 (Char-Net)
Batch size	64
Subdivision	16
Learning rate	0.001
Decay	0.0005
Momentum	0.9

and characters), the number of negative correctly detected (plates and characters), and the number of not detected (plates and characters), respectively. Object detection correctly depends on the Intersection over Union (IoU) value that measures the similarity between the ground truth, and the predicted bounding box. We choose IOU = 0.5. The average precision (AP) is described in Equation (8) as the area under precision and recall values. AP is the standard evaluation way for object detection networks.

$$AP = \int_{0}^{1} P_{(\mathrm{R})} dR \tag{8}$$

where $P_{(R)}$ is the precision over recall. The mAP value is the average of all classes of AP.

C. Results Analysis

We evaluate the Performance of LP-Net and Char-Net using the mean average precision with the threshold value = 0.5. After training both networks with 5k epoch. The mAP of Let-Net is 97.89 %, while the Char-Net Performance is 92.46% to predict the bounding boxes with the ground truth. Fig. 8 and 9 show the results obtained from the experiments on both networks. In Fig. 8, the model result is the bounding boxes for each LP and LP class inside the vehicle image, while in Fig. 9 the result is the bounding boxes for each character and its class inside the detected license plate.

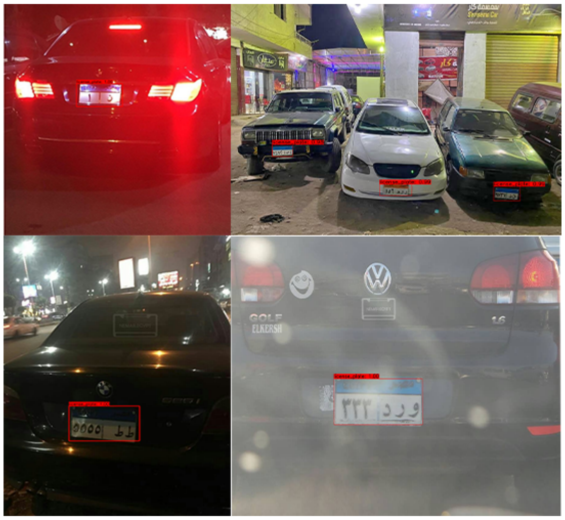

Fig. 8. LP-Net Results.

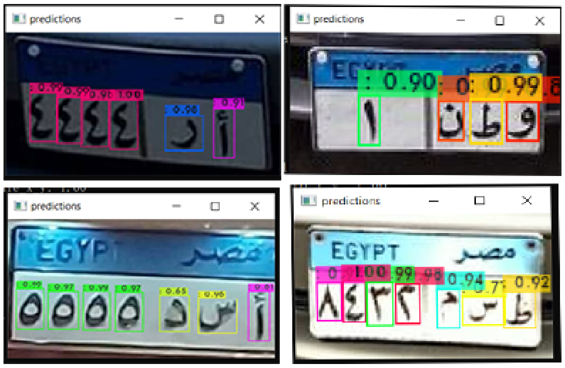

Fig. 9. Char-Net Results.

V. Conclusion

In this study, We present a real-time Egyptian license plate detection and recognition system. The proposed system is a pipeline of two deep convolutional neural networks. It can be deployed on GPU-less computing devices. The tiny-YOLOV3 model is the backbone for both networks. Also, We evaluated it on the publicly available Egyptian License plate (EALRP) dataset. The accuracy of the proposed system is 97.89% and 92.46% for license plate detection and character recognition, respectively. We suggest collecting more samples for the dataset with many variations and Implementing other YOLO model versions or Attention vision transformers to improve the accuracy of the proposed system.

Abstract—**Accurate diagnosis of patient conditions becomes challenging for medical practitioners in urban metropolitan cities. A variety of languages and spoken dialects impedes the diagnosis achieved through the exploratory journey a medical practitioner and patient go through. Natural language processing has been used in well-known applications, such as Google Translate, as a solution to reduce language barriers. Languages typically encountered in these applications provide the most commonly known, used or standardized dialect. The Arabic language can benefit from the common dialect, which is available in such applications. However, given the diversity of dialects in Arabic in the healthcare domain, there is a risk associated with incorrect interpretation of a dialect, which can impact the diagnosis or treatment of patients. Arabic language dialect corpuses published in recent research work can be applied to rule-based natural language applications. Our study aims to develop an approach to support medical practitioners by ensuring that the diagnosis is not impeded based on the misinterpretation of patient responses. Our initial approach reported in this work adopts the methods used by practitioners in the diagnosis carried out within the scope of the Emirati and Egyptian Arabic dialects. In this paper, we develop and provide a public Arabic Dialect Dataset (ADD), which is a corpus of audio samples related to healthcare. In order to train machine learning models, the dataset development is designed with multi-class labelling. Our work indicates that there is a clear risk of bias in datasets, which may come about when a large number of classes do not have enough training samples. Our crowd sourcing solution presented in this work may be an approach to overcome the sourcing of audio samples. Models trained with this dataset may be used to support the diagnosis made by medical practitioners.**

I. Introduction

Research into healthcare practices often highlight language barriers as a major hurdle that impedes a seamless doctor patient interaction and hinders the possibility of positive diagnostic outcomes [1], [2], [3]. In emergency rooms, where timing is critical and information exchange between the patient and the doctor can save lives, the language barrier is seen as an obstacle that must be overcome. It is important to understand the role that language plays, as there has been an increase in culturally and linguistically diverse populations among patients and practitioners [2]. As a result of this ongoing global migration and globalization, many societies all over the world have become multicultural, with many migrants who do not speak the official language of the host country. In the United Arab Emirates (UAE) in particular, the local citizens make up only about 11% of the population, with the rest being from various parts of the world, mostly from Southeast Asian countries and various Arab countries [4]. With this diversity in culture and population, it causes a communication gap in the healthcare service and creates challenges in providing quality individual and holistic healthcare [5].

A large number of published studies [6], [7] address the language barrier that exists between the doctor and the patient, resulting in a poor understanding of diagnosis, relevant investigations, and medication instructions [7]. Surveys, such as that conducted by [8], have shown that language barrier can also lead to poor comprehension and compliance with recommendations for follow-up and treatment. This increases the likelihood of the occurrence of adverse medical events, thereby lowering patient satisfaction. Hence, communication barriers must be considered as part of any strategy aimed at improving patient safety and risk management in healthcare organizations [9].

Attempts to solve this communication problem have been reported in [10], [11], [12], [13] by using Google Translate (GT) or an interpreter. However, when language is a barrier, GT remains the most easily accessible and a free initial mode of communication between the doctor and the patient [10]. A good medical interpreter needs to be able to accurately translate the complex medical terminology. Evidence in [14] suggests that when limited English proficiency patients have access to skilled professional interpreters or bilingual physicians, they have better communication, patient satisfaction, and outcomes, as well as fewer interpretation errors.

The limitations related to healthcare and diagnosis have been reported in [14], [15], [16]. GT has only 57.7% accuracy and should not be relied on for critical medical communications [10]. In [12], it is mentioned that those patients who require interpreters but do not receive them, have a poor self-reported understanding of their diagnosis and treatment. Ad hoc interpreters misinterpret or omit up to half of all physicians' questions and are more likely to make clinically significant errors. The three most commonly used forms of interpreters are ad hoc, professional, and telephone interpreters. For ad hoc interpreters, people commonly use friends or family members of the patient or staff in the work setting, such as housekeepers, secretaries, or medical personnel, who are untrained in interpreting. It is increasingly recognized that the use of untrained or ad hoc interpreters can lead to inaccurate communication and ethical breaches.

Language barrier leads to a communication breakdown between the patient and healthcare providers [6], [17]. Hence, it is critical for the doctor and the patient to communicate effectively, which is why it is advantageous if the doctor is fluent in the patient's language [18], [19]. However, doctors may not always be able to communicate in the patients' native language, which creates hurdles, as shown in [20].

Early health communication linguistic research [21] focused mainly on small datasets, such as language samples gathered from face-to-face clinical interactions or research interviews [22]. The main drawback of this was that the findings presented were based on limited datasets and hence, researchers have started to use corpus linguistic methods [23]. A corpus is a collection of authentic text or audio organized into datasets [24].

The Arabic language is classified into three forms: classical, modern standard and dialectal. Classical Arabic (CA) is the language used in both ancient history literary and religious texts. Modern Standard Arabic (MSA) is the "official" Arabic used in books, magazines, media, legal documents, etc. Dialectal Arabic (DA) is the informal Arabic that native speakers use to communicate in their daily lives. Research in [25], [26], [27], [28] focused on the development of an Arabic language corpus, such as Egyptian, Tunisian and Iraqi dialects.

Over the last decade, Arabic and its dialects have made growth in the field of Natural Language Processing (NLP) [29]. Dialects vary and mutate over the large geographical span of the Arab peninsula with popularity borne by the Egyptian dialect in a majority of countries in the Middle East and North African regions. The UAE population distribution provides the motivation for the work reported in this paper. Of the 40% Arab population in the UAE, Emirati and non-Emirati Arabic groups are almost in equal proportion. This allows us to focus our research efforts on the Emirati and Egyptian dialects based on the fact that the Egyptian dialect is the most spoken in the non-Emirati Arab community. Although research in [30] focused on developing a pediatric assistant that supported Arabic dialects, particularly Egyptian dialects, there is a lack of research for both Emirati and Egyptian dialects in the UAE healthcare sector.

With the growth of AI applications, researchers are looking for ways to use NLP (a strand of AI) to solve real-world problems related to language. So, a dataset that can enhance the functionality of NLP-based applications is highly desirable for researchers in this field and is a main contribution for science. Researchers working on language translation tools and chatbots will be very interested in such tools when focusing on the development of solutions for the healthcare industry. These datasets can be used to develop machine learning models to detect and classify linguistics.

In this work, the approach used by medical practitioners in the UAE were analyzed following some interviews with doctors representing the Dubai Health Authority (DHA). A database of questions was developed in the English Language and a platform was developed to allow users to record a translated version of the typical response to a question in their Arabic dialect (Emirati or Egyptian). These responses were labeled and stored as an audio dataset in a raw mp3 format for researchers to use. Recordings with poor audio quality were manually removed after an inspection. The development of AI-based tools can improve the diagnostic outcomes for patients and lead to a better care. Issues that are diagnosed early allow for treatments, which can lead to correct prognosis and timely interventions.

The remainder of this paper is organized as follows: Section II provides the related work in the field of Arabic NLP (ANLP); Section III discusses the DA challenges in healthcare; Section IV presents our approach and methodology for building a dataset to train a Machine Learning (ML) algorithm; Section V deals with the ML approach to which the dataset can be applied. Finally, Section VI provides the limitations of the work in addition to the social and ethical considerations. We conclude this paper with future directions of research that can be supported through this dataset and its enhancement.

II. Literature Review

A considerable amount of literature has been published on the growth of the DA, which has been recognized as the primary language for informal communication [31]. This growth has been aligned with the emerging trends in online social media platforms (e.g. Twitter, Snapchat, Facebook etc.). The online social media factor attributes to the varsity of DA, which has led to a wider use in offline social interaction. As highlighted in [32], the forms of DA differ depending on the geographic distribution and the socio-economic conditions of the speakers. Each form of DA is considered a divergence from the formal variety, the MSA. This divergence is evidenced in the challenges presented by [33], highlighting Arabic Internet users adopting a mixture of MSA and DA, thereby increasing the challenges related to text processing for machine translation through NLP.

The recent advances in computational power and processing of large data arrays have led to the enhancement of NLP as a technique to empower machines in gaining a better understanding of the human language [34]. Deep learning (DL), a consequence of the rise in computational power, has increased the opportunity for more tasks to be carried out by NLP. The Arabic NLP community (ANLP) [35] has yet to grasp the advantages offered by NLP with DL, despite the growth of DA aligned with social media platforms mentioned earlier. However, recent work published by [36] shows a new focus on ML and DL, based on lexicon and corpus approaches. Islam et al. [37] discuss the importance of NLP in the healthcare industry with researchers finding ways to improve diagnostics. Furthermore, automation for initial and informal diagnosis has been envisaged through the use of NLP to provide an on-demand self-service for patients [38]. The communication between a doctor and a patient usually involves personal questions, which reveal intimate information necessary for an accurate diagnosis [19]. These challenges are amplified in the Arabic culture and the framework of respect and politeness around the spoken dialogue [39]. To cater for these challenges, techniques used by practitioners have included the use of an interpreter [40]. However, the framework of politeness mentioned earlier also reduces the success of using an interpreter in the Arabic culture. Another

alternative approach used by doctors is known as code switching [41], where the bilingual capability of the practitioner can be used to combine English words and terms (of important medical consequence) and words in DA, which can provide an atmosphere of comfort and respect for the patient in the cultural setting. Although code switching has been reported to be a positive and useful approach, the bilingual capability is not ubiquitous, given the divergence of DA. Hence, approaches, which are supported by artificial intelligence (AI), play a role in bridging the gap. This gap is wider, where the growth in healthcare tourism [42] is supported by the deployment of practitioners accustomed to MSA or a different strand of DA [43].

Approaches in sentiment analysis, which apply NLP as reported in [44], have been used in healthcare based on text computation extracted from web sources, such as blogs and social media, and with no methodical approach used for the attainment. Again, the politeness of the Arabic culture plays a significant role in the level of accuracy that may be gained through these approaches, as there is a limited directness. Furthermore, online sources will also suffer from a lack of contextual information, which can be used to train models used in AI. Researches [31], [44], [45], [46] were developed using a corpus-based approach for sentiment analysis in healthcare. The techniques that have been used are Lexicon. There are several challenges mentioned in [45], [46] facing the sentiment analysis and evaluation process, especially in the medical domain. There are health related blogs and forums where people discuss their health issues, symptoms, diseases, medication, etc. [47]. These challenges become obstacles in analyzing the accurate meaning of sentiments and detecting the suitable sentiment polarity. The approaches used to overcome these challenges are discussed in [48].

ML implementations of audio analytics have gained popularity in applications, such as Alexa, Siri, Google Assistant and Google Home. The capabilities offered are founded on models, which can extract information from audio signals [49]. Audio processing capabilities supported by open-source codes and public big data have led to an accelerated development of applications, such as Shazam, which provides an audio similarity search capability [50]. Applications of audio analytics can range from customer sentiment analysis in recordings taken from call centers to media content monitoring for parental control. In the domain of healthcare, several ML-based approaches have been proposed to consider clinical decisions supported using text-free data [51]. In recent years, clinical speech and audio processing have offered new opportunities, such as automatic transcription of patient conversations, synthesis of clinical notes, as well as identification of disorders related to speech [52]. Chatbots, such as Babylon Health, have been developed for diagnosis and prevention of diseases. Such chatbots use speech recognition technologies to compare symptoms reported by the user with a database of diseases to recommend a course of actions based on the identified disease in addition to the patient history. In the special case of machine translation, there is currently limited evidence in the literature of the use of healthcare-oriented ML-based translators in clinical practice [53]. Instead, physicians commonly use either professional interpreters, who are usually costly, or digital translating services, such as GT, which are not tailored to properly function with a medical lexicon.

There are different techniques for processing the audio files for ML. The approaches used in the literature are audio spectrograms in [54] and Mel Frequency Cepstral Coefficients (MFCC) in [55]. In [56], the input of fixed length video segments of 10 seconds was converted to an audio spectrogram and fed into a Convolutional Neural Network (CNN) based on Alexnet [57] and VGG-16 [58] architectures. In [55], the use of audio spectrograms to feed into a CNN with the use of MFCCs was discussed. The authors also used a second approach, where the audio spectrogram was used as an input, using a modified VGG-16 architecture based on transfer learning [59]. Results in [55] showed that the accuracy using MFCC was higher than the spectrogram-based approach.

The approach proposed in this paper supports speech recognition (SR) under text and speech processing as a branch of NLP. Advances in SR through big data and DL have yielded significant gains through innovative approaches, as found in recent academic work [60], [61]. Limited work on the use of an audio corpus is referenced in [54], where voice recognition based on whole sentences without speech segmentation is done. To improve and innovate in the field of voice recognition for healthcare diagnosis in the DA, this corpus provides the big data component, which is labelled and can be used for supervised learning. The labelling approach of the corpus can support the development of voice recognition with DL for improvement in the healthcare diagnostic outcomes. The approach used to create the corpus is similar to Amazon Mechanical Turk. Other approaches, which use the crowd sourcing and labelling mechanism, are mentioned in Fig. 1.

III. Healthcare Challenges with DA

With the discovery of oil in the UAE in the late 1950s, a huge economic and social transformation began resulting in an increase of the need for foreign labor. Since then, the UAE has seen a huge number of expatriates trickling in to gain from the profitable economic bustle including trade, real estate, construction, and healthcare, thereby outnumbering the national population. While the nationals whose spoken language is Arabic only amount to 11.48% of the entire

TABLE I. SAME MEANING OF DIFFERENT HEALTHCARE WORDS IN EGYPTIAN AND EMIRATI DIALECTS

Egyptian Dialect	Emirati Dialect	Meaning
وجع	عوار	pain
غمَمان	لوعة	nausea
أرّجع	بزوع	I vomit
بتوجعني	يعورني	It hurts

TABLE II. EXAMPLES OF HEALTHCARE STATEMENTS IN DIFFERENT DAS WITH THEIR TRANSLATIONS IN ENGLISH

Questions/ Answers	Translation by GT	Correct Translation
زوري واجعني (Egyptian dialect)	visit and see me	my throat hurts
انا دايخ (Egyptian dialect)	I am deaf	I am dizzy
انا عيان (Egyptian dialect)	I am an eye	I am sick
شو رح يصير لو ما سويت هاي العملية؟ (Syrian dialect)	What would happen if you did not make this process happen?	What will happen if I do not get the surgery?
حاسة حالي تعبانة (Jordanian dialect)	My current sense is tired	I am tired
فيني لوعة (Emirati dialect)	Vinny is crazy	I feel nauseated

population in 2022, the expatriates total around 88.52% of the population, mainly coming from India, Pakistan, Bangladesh, Philippines, Iran, Egypt, Nepal, Sri Lanka and China [4]. As most of these migrants are non-Arabic speakers, the common communication language used in the different public and private service sectors in the UAE is English. The Arabic language has also been a barrier to Arabic speakers across the country, as the Arab migrants use different dialects or DAs, which diverge from the MSA, and are often classified regionally as Egyptian, North African, Levantine, Gulf, and Yemeni or sub-regionally as Tunisian, Algerian, Moroccan, Lebanese, Syrian, Jordanian, Saudi, Kuwaiti and Qatari [62]. Moreover, many of the Arabic speakers cannot use the English language to communicate efficiently with non-Arabic speakers. This suggests that the language in the UAE is a contributing factor to misinformation in several critical service providers including the healthcare sector.

In the UAE, the two mostly spoken Arabic dialects are Emirati (11.48%) and Egyptian (4.23%) [4]. While the majority of the Arabic speaking residents use these two dialects to communicate on a daily basis [63], hospitals are staffed mostly with physicians who speak exclusively English at workplace. Therefore, these physicians are frequently obliged to deal with Arabic speaking patients who have no language in common. Moreover, the diversity of the Arabic language through its several DAs poses another serious challenge that needs to be addressed [62]. Table I shows an example of several Arabic healthcare terms expressed differently in Emirati and Egyptian dialects, but having the same meaning. A situation of this kind, with barriers in language and medical understanding, creates serious problems for quality, security and equitability of medical care. Rosse et al. [64] defined a language barrier as “a communication barrier resulting from the parties concerned speaking different languages” and supported previous claims that these barriers pose a significant threat to quality of care and patient safety.

Therefore, the language barrier poses challenges for achieving high levels of satisfaction among physicians and patients, providing high-quality healthcare service, and maintaining patient safety. To address these challenges, several solutions are available today, but they all have their drawbacks. There has been recently a rising demand of English-Arabic translating services for medical, anatomy and healthcare lexicons in Arabic cosmopolitan countries, which usually attract multilingual/multidialectal expatriates [65]. Knowing that professional interpreters are very expensive and are not always available for some dialects, the framework of politeness in the Arab culture also reduces the success of using an interpreter for DA speakers. On the other hand, GT, increasingly often used when no other alternatives exist, is known to be unreliable for medical communication [66] and human interference is greatly needed to produce accurate and effective translation. For instance, an Egyptian patient reporting a pain in the leg, ””رجلي وجعاني , is interpreted as “My feet are hungry” instead of “My leg hurts”. Another example shows the inadequacy of GT, which fails to translate two different statements having the same meaning into the same expression. The two Egyptian dialect statements ””انا مصدع and ””انا عندي صداع ,which both report a headache, are construed as “I’m cracked” and “I have a headache”, respectively. Table II, which illustrates some examples of translation from several DAs to English, shows the inaccurate translation of GT when used in the healthcare sector.

All these factors lead us to explore and suggest a better solution to the language dilemma that physicians face in providing high-quality and safe care to DA-speaking patients with limited English proficiency in the UAE. Our work proposes a new approach of efficiently addressing this problem by using the crowd sourcing and labelling mechanism for the Emirati and Egyptian dialects in the medical diagnosis context. To our knowledge, no other work has followed this approach to address the challenge of English-Arabic interpretation in the medical field, specifically related to the emergency diagnosis questionnaire.

IV. APPROACH AND METHODOLOGY

The crowd sourcing approach used in this work is termed as “crowd labeling”. In this approach, an automated labeling implementation is developed, which allows for audio recordings to be labeled at the time they are recorded and uploaded by contributors.

A. Architecture Overview

Fig. 2 provides an overview of the application architecture using HTML, CSS, JavaScript, PHP and Google Developer APIs. Visitors to the webpage can see a landing page, which offers them the option to record their phrase in the Emirati or Egyptian dialect. The selection prompts a back-end process on the web server to get a random question and associated phrase from a pool, which is hosted in a Google sheets document. This is done using Google developer APIs.

The contributor records the phrase and uploads it to the audio sample database, which is hosted in Google drive. This repository is available for public access for other researchers. The audio files are labelled automatically. When a file is

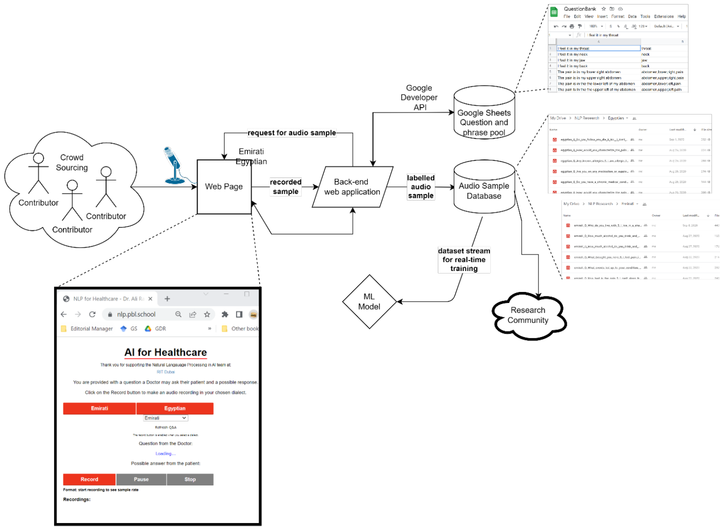

Fig. 2. High-Level Implementation Architecture.

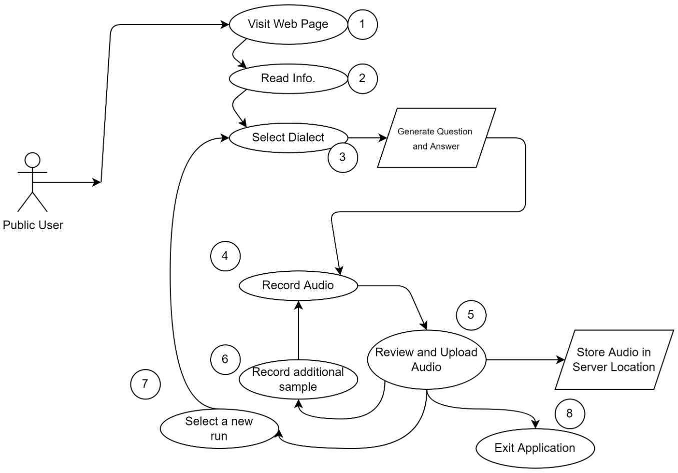

Fig. 3. Crowd Labeling Application Flow Diagram.

uploaded, the following attributes are included in the file name: <dialect>_Q_<possible question from Doctor> _S_<possible answer from patient>_L_ <predefined labels>.mp3

An example from the repository is provided here: emirati_Q_What_brought_you_here_S_I_feel_ pain_in_my_leg_L_leg_pain.mp3

The audio samples are recorded with a 48 MHz sampling rate and stored in the mp3 format.

B. Application Overview

Fig. 3 provides an overview of the implementation with a summary of the steps:

1) User visits the webpage (https://nlp.pbl.school/)
2) User reads the welcome note.
3) User selects the dialect they wish to contribute in.
4) Once the question-and-answer set is generated, the user records the audio.
5) The user reviews the recording quality and uploads it to the Google drive storage location. The user can proceed to step 7 to continue with contributions or proceed to step 8 and exit the application by closing their browser page.
6) If the audio sample is not clear, the user can decide to re-record it and return to step 5.
7) The user can choose to launch a new contribution and restart at step 3.
8) The user can choose to exit the application at any time.

C. Access to Repository

The repository of the collected audio files can be accessed from Google drive using the link below. As new recordings are published, this drive is automatically updated. Researchers have unlimited access to the ADD dataset:

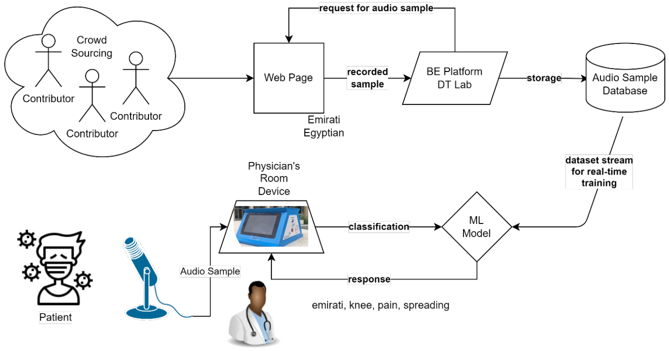

Fig. 4. Implementation of ML Pipeline for Patient-Doctor Diagnostic Device.

https://drive.google.com/drive/folders/160HE3q_ FcqNJMyC4M5Hx1e2SffKhDeW8?usp=sharing

Access to this repository can also be automated using Google drive APIs by researchers who intend to create a continuous ML pipeline. With this approach, each time a new file is uploaded, the ML pipeline implemented can fetch the file and update the ML algorithm. The current implementation of this is shown in Fig. 4. The implementation consists of a two-monitor device based on the Raspberry Pi 4, and placed in the room of a physician. The doctor can select a question, which is played in the dialect of the patient. The response from the patient is recorded and uploaded to the ML model for classification. The response from the ML model provides the physician with the phrase from the database that best matches the input from the patient.

Preliminary results on the accuracy of the classification have been produced, as described in Section V. We intend to publish detailed results in the future when the size of the corpus reaches a minimum threshold.

V. ML Proposed Applications

We address in this section the need for capacity development in this area by providing some conceptual ML methods

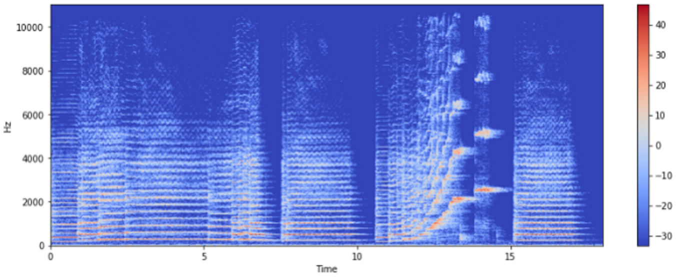

Fig. 5. Spectrogram of an Audio Clip with a Spectral Range of 0 kHz to 10 kHz.

for researchers to developing predictive algorithms for several healthcare speech recognition-related applications. Examples of such applications include speech tagging, dialect classification, diagnosis multi-labelling and language translation, using our freely available public ADD dataset for Emirati and Egyptian dialect lexicons.

Libraries, such as Librosa, provide useful tools for audio signal processing, using a Fourier Transform to convert an audio signal into a frequency domain from the time domain. Librosa supports the display, processing, and analysis of key spectral features, such as spectral-flux, spectral centroids and fundamental frequency components, which are essential features for ML-based spectral analysis [49]. Fig. 5 shows an implementation of Librosa's spectral display capabilities in which spectral images of our collected audio samples are generated. The image is normalized to a specific color profile and a frequency profile from 0 to 4 kHz, which aligns to the human speech audio range.

In a typical classification application, the images can be processed and numerically represented with the pixel color information being the input for each neuron in an Artificial Neural Network (ANN) or Convolutional Neural Network (CNN) model, such as AlexNet or GoogLeNet, as proposed by Boddapati et al. [67]. The training of the model will allow for classification of dialects and diagnosis types. This is summarized by the process pipeline shown in Fig. 6. In this section, we develop and test the proposed design process on the ADD dataset, as one possible approach of using the dataset for Arabic/English translation of the emergency diagnosis patient answers.

A. Audio Processing

A total of 301 recordings in the Egyptian dialect and 138 recordings in the Emirati dialect are collected as part of the ADD after manually removing the faulty audio samples from 12% of the Egyptian dialect recordings and 22% of the Emirati dialect recordings. The errors include wrong translation, blank recordings, and duplications. The maximum duration for an audio sample is 10 seconds, the minimum is 1 second, and the average is between 2 and 3 seconds.

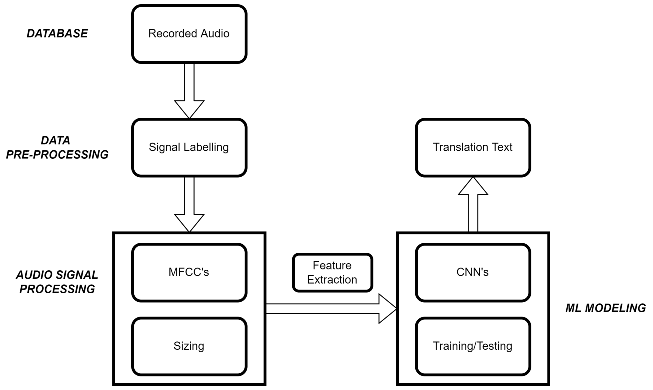

Fig. 6. Proposed Classification Pipeline.

Next, we consider the recorded raw audio samples, where a sample of an Egyptian dialect speech waveform is shown in Fig. 7. The waveform only shows the change of the signal's amplitude over time without giving any insight about the different frequency components pertaining to the recorded audio signal. Therefore, we convert the audio waveform to a spectrogram, which is a 2D image representing sequences of spectra with time along one axis, frequency along the other, and brightness or color indicating the strength of a frequency component at each time frame. This representation can thus be used with CNNs that are usually applied on images and can be applied directly to sound in this case. Moreover, learning more about the signal's frequencies gives us a better understanding of the recorded audio signal and allows us to filter out any unwanted disturbance, as distortion and noise can be visualized in a spectrogram.

B. Machine Learning Models

For speech classification, Mel Frequency Cepstral Coefficients (MFCCs) are commonly used for their classification and identification effectiveness, as they can describe concisely the shape of the spectral envelope expressed on a Mel-scale. However, MFCCs are also known as being "lossy" representations, which are preferably ruled out when working with a high-quality sound. Therefore, the spectrograms can be used directly as 2D images to feed pre-trained CNNs. In the case of a limited size dataset, transfer learning is used to relax the hypothesis that the training data must be large, independent and identically distributed with the test data. This motivates many work [68], [69], [70], [71], [72], [73] to use transfer learning in the presence of insufficient training data for speech and language classification. A network, which is pre-trained on a large-sized dataset, such as the ImageNet [74], will keep its structure and connection parameters, when used by a network-based deep transfer learning, to compute intermediate image representations for smaller-sized datasets. Therefore, a network, such as a CNN, is trained on the ImageNet to learn image representations that can be efficiently transferred to other visual recognition tasks with limited amount of training data. The front-layers of the network are operated as a feature extractor, where the extracted features are classified using ML classifiers, such as a support vector machine (SVM).

C. Preliminary Results

We propose a similar machine learning model for the spectrograms classification to identify the English translation of the corresponding Arabic audio sample. Fig. 8 shows the different steps followed in the described model. We perform

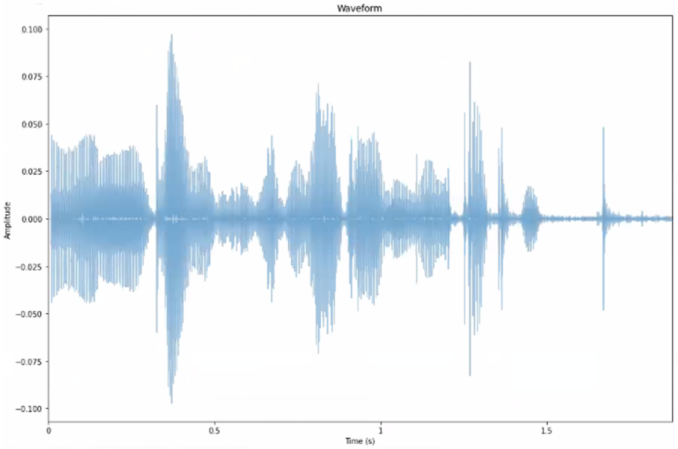

Fig. 7. Audio Waveform Sample of an Egyptian Dialect Recorded Answer.

identification experiments with a closed-set experimental protocol, where our model should predict the label to which the input image belongs. For experimentation, we use four classes of the dataset labeled as: "I smoke", "I do not smoke", "I live with my family", and "I live alone". The training set consists of 80% of the spectrogram images, while the testing set includes the remaining 20% of the images. Since the ADD dataset is relatively small, it is easy for the CNN model to over-fit and not generalize well on the testing data. To alleviate this problem, we augment the dataset with a factor of five by editing the pitch of the audio recordings to four different values. Other augmentation techniques are possible to use, such as time stretching or adding noise. We use the augmented training set of the resulting spectrograms on a VGG16 network. We extract features from different layers of the same network to explore the different classification accuracies. We perform an exhaustive search on the layers and report results with the layer that gives the highest accuracy. We find that the best performance corresponds to the last convolutional layer of VGG16. We use the extracted features to train a one-against-one multi-class linear SVM. The achieved recognition accuracy is of 78%.

Although the result might not look promising enough, it shows that the proposed model performs decently well for a small-sized dataset and proves to utilize the ADD in one of many ways to implement Emirati and Egyptian dialect sentences classification into their respective English translated expressions.

VI. Limitations, Social and Ethical Considerations

The main limitations of the approach presented in this work were the residual response bias of participants, the short period of time to conduct the research and failure to fully explore all the possible responses for both dialects.

The current work relies on translation crowdsourcing, which is particularly known for its innovative approach, combining the concept of crowdsourcing and that of natural and non-professional translation. The translation project that formed the basis of this work comprised of untrained translator

participants who were native speakers of the Arabic dialect with no previous experience of translation. Even though their contribution to the crowdsourcing platform, as native speakers, undoubtedly gave a high credibility to the correctness of the translated responses, there was still an obvious response bias in the research given that they were translator novices, with many participants translating the response differently based on their knowledge and background. The work shows that these limitations in volunteer translation suggest that one might bridge the gap between trained and untrained translators through collaboration and mutual training in this kind of projects as in [75].

To accommodate building the dataset and making it public to the community, only a short period of time was available for the research. The crowdsourcing platform and initial recordings were achieved in nine months. Participants were selected from the close network of school, family, and friends who spoke the Emirati and Egyptian dialects. Time restrictions limited the size of the dataset, which includes a total of 301 Egyptian and 138 Emirati dialects recordings. This resulted in an imbalanced dataset on multiple levels. The Egyptian dialect recordings are almost double the size of the Emirati ones, knowing that the acquaintances of the crowdsourcing developers consisted mainly of Egyptians. On the other hand, by looking at the participants gender figures, 95% of the Emirati participants are male, while 63% of the Egyptian participants are female. Finally, most of the participants (80%) are from the young generation, thereby minimizing the contribution of children, middle age and elder samples of the Emirati and Egyptian populations. This systemic inequity based on age and gender disparities has received a lot of attention recently in voice biometrics [76] and reveals that age and gender subgroups have a significant different voice characteristic. In fact, non-negligible gender disparities exist in speaker identification accuracy and show that the average accuracy can be significantly higher for female speakers than males due to mainly voice inherent characteristic difference [76]. The results in [77] also indicate a significant age effect on the voice acoustic parameters (fricative spectral center of gravity, spectral skewness, and speaking STSD) revealing that certain speech and voice features change with age.

Even though the research was deemed successful by curating the first medical diagnosis dataset for the Emirati and Egyptian dialects, it did fail to completely explore all the possible responses to the emergency diagnosis questionnaire, as not all the questions were presented to the participants in the crowdsourcing platform, and thus many responses missed being recorded in the Arabic dialects, at least in either one of them. In hindsight, participants should have been provided with a wide palette of different responses for them to translate before they were able to stop recording.

In order to protect the rights of the research participants and also to maintain scientific integrity, it was important to take ethical and social considerations into account [78]. The participants were therefore given the option of voluntary involvement, which allowed them to withdraw at any point without any obligations. It was also made clear to them that there were no negative consequences or repercussions to their refusal to participate. The identities of the research participants were kept anonymous, as no personal identifiable data were asked, such as their names, email addresses, phone numbers, photos and videos. The research used data pseudonymization, where the audio recordings of the participants were given artificial identifiers, such as sample001, sample002 etc.

VII. Conclusion

In this work, the implementation of a crowd labeling approach to develop an audio corpus is proposed. An application of the audio corpus to train an ML algorithm, which interfaces with a device in a physician's room is provided. Although results on the accuracy of the classification of this application are preliminary and incomplete due to the small size of the dataset, the implementation approach can be replicated by researchers by splitting the corpus into training and testing sets to evaluate different ML techniques or test a specific ML pipeline. The crowd labeling approach developed here can be extended to other applications, where data is collected from public contributors. Special care has been taken to ensure that no personal identifiable information about the contributors is collected or stored. The future proposed work will collect more audio samples and include additional Arabic dialects. A dashboard will be supporting the dataset to provide statistics on the collected audio samples.

Acknowledgment

The authors would like to thank Hana Abbas, Anan Hefny, Haneen Al Attar, Mohamed Dorrah, Amr Mohamed, Arjun Nair, Habiba Elshahat, and Sherif Reda for helping with this work.

Design of Higher-Dimensional Hyperchaotic System based on Combined Control and its Encryption Application

Kun Zhao, Jianbin He*
School of Mathematics and Statistics
Minnan Normal University, Zhangzhou 363000, China

Abstract—**According to the anti-control principle of chaos, a combined control method is proposed based on a class of asymptotically stable linear systems with multiple controllers. A higher-dimensional hyperchaotic system is investigated by the Lyapunov exponents method and equilibrium points analysis, and it exists the largest number of positive Lyapunov exponents. The chaotic pseudo-random sequences of the higher-dimensional hyperchaotic system can pass all NIST tests after preprocessing, and behave better chaotic characteristics. Meanwhile, a new encryption algorithm of image information with position scrambling, sequential diffusion and reverse diffusion is designed based on the chaotic pseudo-random sequences. The experiments of image information are given to verify the effectiveness and feasibility of the encryption algorithm. Finally, the security analyses are also discussed by the key sensitivity, differential attack and statistical analysis. It is shown that the encryption algorithm has large enough key space and can be applied to secure communication.**

Keywords—***Hyperchaotic system; positive lyapunov exponent; chaotic pseudo-random sequence; image encryption***

I. Introduction

With the rapid development of computer network technology and intelligent equipment, the digital information may be stolen or even destroyed by the attacker when it is transmitted through the public network, such as the personal privacy information, images and videos. In particular, some information is used in military, medical, political and other important fields, so it is very necessary to protect the integrity and confidentiality of the information transmission process. Information hiding and information encryption are two important information protection technologies. Information hiding is to hide information in another information carrier and transmit it through public channel, and it includes information hiding algorithm, digital watermarking, hidden channel technology and anonymous communication technology, etc. The information encryption is to design encryption algorithms to improve the security and efficiency by the characteristics of digital information. Usually, the image encryption includes uncompressed and compressed image encryption [1].

The chaos-based image encryption is one of widely used security method. It can not only prevent the loss of image information, but also convert original image into unrecognized encrypted image. The chaos-based image encryption generally includes two important steps: scrambling and diffusion encryption. The scrambling method can scramble the position of the plaintext image without changing the pixel value of the image, and it reduces the correlation between adjacent pixels of the image. The diffusion method changes the pixel value of the image through XOR operation, which makes the distribution of the encrypted image information more uniform and random. Therefore, the combination of scrambling and diffusion encryption is very effective for the image encryption.

Since Lorenz found the chaos from the mathematical model of meteorology, chaos theory has attracted extensive attention of scientists. Chaotic system is usually generated from a nonlinear dynamic system, and the characteristics of initial condition sensitivity, non-periodicity, long-term unpredictability and pseudo-randomness are very suitable for image encryption and other information encryption [2]–[7]. Moreover, some of the chaos-based encryption algorithms are analysed and may be not resist the chosen-plaintext attacks [8]. In [9], the security loopholes of an image encryption algorithm based on random walk and hyperchaotic systems are found, and the attack method is proposed to successfully break the encryption scheme. Therefore, the security of encryption algorithm based on chaotic system is one of the most important factors for information secure communication, and more secure chaos-based encryption algorithm need to be analysed and proposed. Compared with the lower-dimensional chaotic system, the higher-dimensional hyperchaotic system has more positive Lyapunov exponents, and the pseudo-random sequences generated by iteration are more complex chaotic characteristics. The encryption algorithm based on the higher-dimensional hyperchaotic system can be used for information secure communication [10]. The positive Lyapunov exponent is one of useful methods to show whether the nonlinear dynamic system exists chaos or not. Generally, the chaotic system has one positive Lyapunov exponent, while the hyperchaotic system has two or more positive Lyapunov exponents [11]. The number and size of positive Lyapunov exponents can reflect the chaotic characteristics of the system, and the hyperchaotic system with multiple positive Lyapunov exponents has more complex dynamic characteristics.

In recent years, the research on higher-dimensional hyperchaotic systems with multiple positive Lyapunov exponents has attracted much attention [12]–[14]. In [15], an effective image encryption algorithm of confusion and diffusion encryption is proposed based on chaotic system, and it is very sensitive to the initial variables. A new chaos-based image encryption algorithm is investigated in [16], and the security test shows

*Corresponding authors.

that the algorithm has good security performance and can resist a variety of special attacks. An image encryption algorithm based on chaotic system and DNA sequence operation is proposed, which not only has good encryption effect, but also can resist various typical attacks [17]. A S-box encryption algorithm based on chaotic system is designed for secure and fast image encryption, and NIST tests are used to verify the randomness of the sequences [18]. A color image encryption scheme is proposed based on non-uniform cellular automata and hyperchaos, the security analysis shows that the scheme has a very large key space and can resist various attacks [19]. A new image encryption algorithm is proposed by the confusion and diffusion based on chaos and SHA-256, and it can resist the chosen-plaintext attack and overcome the difficulty of key management in the "one-time password" encryption scheme [20]. A modified logistic chaotic map are created to designed encryption technique with better security and efficiency [21]. An image encryption algorithm is designed by combining fractional Fourier transform, DNA sequence operation and chaos theory, and the algorithm has good encryption effect, large key space and high key sensitivity [22]. A technique for encrypting RGB image components by using nonlinear chaotic function and DNA sequence is presented in [23]. In [24], the theoretical security of a medical privacy protection scheme based on DNA encoding and chaotic maps is reanalyzed, and the scheme is rigorously proven to be insecure against the chosen-plaintext attack. Based on a combination of multidimensional chaotic systems, an cryptosystem for the color image encryption is described in [25], and the level of security and the computational complexity is improved. By using higher-dimensional chaotic maps and some conventional cryptographic techniques, a class of chaotic cryptosystems is designed to enhance the security of cryptosystems [26].

The research of higher-dimensional hyperchaotic systems is one of hot topic. Some criteria and methods for constructing higher-dimensional hyperchaotic systems are proposed [27], [28]. In this paper, a higher-dimensional hyperchaotic system is investigated by the combination of multiple controllers, and a new 11-dimensional hyperchaotic system with nine positive Lyapunov exponents is designed. The main contributions of this paper are as follows: (1) Through the combination of multiple controllers, a class of higher-dimensional hyperchaotic systems with the largest number of positive Lyapunov exponents is studied; (2) Based on the chaotic sequences generated by the iteration of higher-dimensional hyperchaotic system, an encryption algorithm is proposed by combining the position scrambling, sequential diffusion and inverse diffusion. (3) The feasibility and security of the new encryption algorithm based on 11-dimensional hyperchaotic system are verified through the simulation experiments.

The rest of this paper is organized as follows. Section II is the design method of hyperchaotic system. Section III is the design of encryption algorithm. The security analysis of the encryption algorithm is given in Section IV. Section V concludes the paper.

II. Construction of Higher-Dimensional Hyperchaotic Systems

A. Chaotic Anti-Control System with Combined Controllers

According to the anti-control method of higher-dimensional hyperchaotic systems, a nominal asymptotically stable linear dynamical system is given by [29]

$$\dot{X} = PAP^{-1}X \tag{1}$$

where $X = (x_1, x_2, \cdots, x_n)$, the matrix A and the similarity transformation matrix P are given as follows:

$$\left\{ \begin{array}{l} A = \begin{pmatrix} A_1 & 0 & 0 & 0 & 0 \\ 0 & A_2 & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & A_{m-1} & 0 \\ 0 & 0 & \cdots & 0 & A_m \end{pmatrix}_{n\times n} \\ \qquad \text{if } n \text{ is even}, m = \dfrac{n}{2} \\ A = \begin{pmatrix} A_1 & 0 & 0 & 0 & 0 \\ 0 & A_2 & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & A_m & 0 \\ -1 & -1 & \cdots & -1 & \tau \end{pmatrix}_{n\times n} \\ \qquad \text{if } n \text{ is odd}, m = \dfrac{n-1}{2} \end{array} \right.$$

$$P = \begin{pmatrix} 0 & 1 & \cdots & 1 & 1 \\ 1 & 0 & \cdots & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & 0 & 1 \\ 1 & 1 & \cdots & 1 & 0 \end{pmatrix}_{n\times n}$$

and $A_i = \begin{pmatrix} \lambda_i & \psi_{i1} \\ \psi_{i2} & \lambda_i \end{pmatrix}$

is a block matrix, where $\psi_{i1} \times \psi_{i2} < 0, \tau < 0$.

Next, a uniformly bounded controller $f(\sigma X, \varepsilon)$ and control matrix C are designed for the system (1), such that

$$\dot{X} = PAP^{-1}X + Cf(\sigma X, \varepsilon) \tag{2}$$

The combination of controllers $f(\sigma X, \varepsilon)$ and the control matrix C are given by

$$f(\sigma X, \varepsilon) = \begin{pmatrix} \varepsilon_1 \sin(\sigma_1 x_1 + \varphi_1) + \varepsilon_2 \cos(\sigma_2 x_1 + \varphi_2) \\ \varepsilon_1 \sin(\sigma_1 x_2 + \varphi_1) + \varepsilon_2 \cos(\sigma_2 x_2 + \varphi_2) \\ \vdots \\ \varepsilon_1 \sin(\sigma_1 x_{n-1} + \varphi_1) + \varepsilon_2 \cos(\sigma_2 x_{n-1} + \varphi_2) \\ \varepsilon_1 \sin(\sigma_1 x_n + \varphi_1) + \varepsilon_2 \cos(\sigma_2 x_n + \varphi_2) \end{pmatrix}$$

$$C = \begin{pmatrix} 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & 1_{(i,j)} & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \cdots & 0 & 0 \end{pmatrix}_{n\times n}$$

where $\varepsilon_1, \sigma_1, \varphi_1, \varepsilon_2, \sigma_2, \varphi_2$ are controller parameters, $1_{(i,j)}$ denotes that the element in row i and column j is equal to 1, i.e., the controller is in the state of working.

When the dimension $n = 11$, the matrices A_i $(i = 1, 2, 3, 4, 5)$ are given by

$$\begin{cases} A_1 = \begin{pmatrix} -0.01 & 1.00 \\ -6.00 & -0.01 \end{pmatrix}, A_2 = \begin{pmatrix} -0.01 & 18.00 \\ -2 & -0.01 \end{pmatrix} \\ A_3 = \begin{pmatrix} -0.01 & 15.00 \\ -1.00 & -0.01 \end{pmatrix}, A_4 = \begin{pmatrix} -0.01 & 22.00 \\ -2.50 & -0.01 \end{pmatrix} \\ A_5 = \begin{pmatrix} -0.01 & 3.00 \\ -20.00 & -0.01 \end{pmatrix} \end{cases}$$

and $\tau = -0.01, \varepsilon_1 = 76, \sigma_1 = 8, \varphi_1 = 6, \varepsilon_2 = 68, \sigma_2 = 5, \varphi_2 = 4$, the control position $(i, j) = (11, 10)$, therefore, the controlled system is given as follows:

$$\dot{X} = PAP^{-1}X + \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ f(x_{10}) \end{bmatrix}_{11\times 1} \tag{3}$$

where the combined controller

$$f(x_{10}) = 76\sin(8x_{10} + 6) + 68\cos(5x_{10} + 4)$$

and it is shown in Fig. 1.

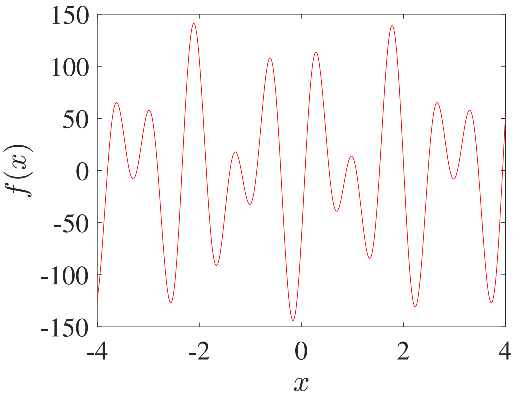

Fig. 1. The Function of Combined Controller $f(x_{10})$ (x Denotes x_{10})

B. Chaotic Attractors and Lyapunov Exponent

By the calculation on the software of Matlab R2021a, the Lyapunov exponents of system (3) are given by

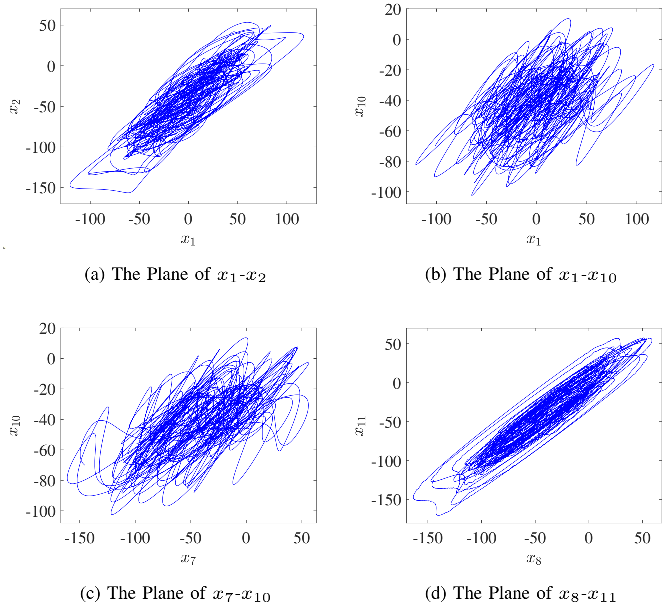
$$\begin{cases} \mathrm{LE}_1 = 4.37, \mathrm{LE}_2 = 0.49, \mathrm{LE}_3 = 0.41 \\ \mathrm{LE}_4 = 0.35, \mathrm{LE}_5 = 0.29, \mathrm{LE}_6 = 0.26 \\ \mathrm{LE}_7 = 0.22, \mathrm{LE}_8 = 0.16, \mathrm{LE}_9 = 0.02 \\ \mathrm{LE}_{10} = 0.00, \mathrm{LE}_{11} = -6.68 \end{cases}$$

Obviously, the 11-dimensional hyperchaotic system has 9 positive Lyapunov exponents, so it has strong chaotic characteristics.

Furthermore, the initial values

$$X(0) = (0.2, 0.1, 0.3, 0.1, 0.2, 0.1, 0.5, 0.6, 0.7, 0.4, 0.2)$$

then the phase diagrams of chaotic attractor are shown in Fig. 2.



(a) The Plane of x_1-x_2

(b) The Plane of x_1-x_{10}

(c) The Plane of x_7-x_{10}

(d) The Plane of x_8-x_{11}

Fig. 2. Attractor of the Controlled Hyperchaotic System (3)

C. Equilibrium Point Analysis of the Controlled System

Obviously, the only one equilibrium point of the system (1) is

$$X_e = (0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0)$$

and the corresponding eigenvalues of Jacobi matrix at the equilibrium point X_e are given by

$$\begin{cases} \lambda_{1,2} = -0.01 \pm 7.7460\mathrm{i} \\ \lambda_{3,4} = -0.01 \pm 7.4162\mathrm{i} \\ \lambda_{5,6} = -0.01 \pm 6.0000\mathrm{i} \\ \lambda_7 = -0.01 \\ \lambda_{8,9} = -0.01 \pm 3.8730\mathrm{i} \\ \lambda_{10,11} = -0.01 \pm 2.4495\mathrm{i} \end{cases}$$

Since all eigenvalues are negative, so the system (1) is asymptotically stable.

However, the controlled system (3) has multiple equilibrium points, and the equilibrium points of the controlled system (3) can be obtained by Eq. (4).

Therefore, the corresponding solutions can be obtained by the Cramer rule [11]:

$$\begin{aligned} x_i &= \frac{|E_i|}{|D|} \\ &= (-1)^{(11+i)} \frac{-f(x_{10})}{|D|} |M_{11,i}| \\ &\quad (i = 1, 2, \cdots, 11) \end{aligned}$$

where $D = PAP^{-1}$, E_i is the matrix that the ith column of the matrix D is replaced by the controller vector in right-

$$\begin{pmatrix} 2.74 & -0.25 & 22.75 & -19.25 & 5.25 & -12.25 & 3.75 & -15.25 & 4.75 & 1.75 & 8.75 \\ 3.75 & 1.74 & 4.75 & -17.25 & 7.25 & -10.25 & 5.75 & -13.25 & 6.75 & 3.75 & 10.75 \\ 1.45 & 2.45 & 22.44 & -19.55 & 4.95 & -12.55 & 3.45 & -15.55 & 4.45 & 1.45 & 8.45 \\ 2.00 & 0.00 & 23.00 & -19.01 & 3.00 & -12.00 & 4.00 & -15.00 & 5.00 & 2.00 & 9.00 \\ -0.45 & -2.45 & 20.55 & 0.55 & 3.04 & -14.45 & 1.55 & -17.45 & 2.55 & -0.45 & 6.55 \\ 1.85 & -0.15 & 22.85 & -19.15 & 5.35 & -12.16 & 2.85 & -15.15 & 4.85 & 1.85 & 8.85 \\ 0.25 & -1.75 & 21.25 & -20.75 & 3.75 & 1.25 & 2.24 & -16.75 & 3.25 & 0.25 & 7.25 \\ 1.95 & -0.05 & 22.95 & -19.05 & 5.45 & -12.05 & 3.95 & -15.06 & 2.95 & 1.95 & 8.95 \\ -0.05 & -2.05 & 20.95 & -21.05 & 3.45 & -14.05 & 1.95 & 0.95 & 2.94 & -0.05 & 6.95 \\ 2.35 & 0.35 & 23.35 & -18.65 & 5.85 & -11.65 & 4.35 & -14.65 & 5.35 & 2.34 & 3.35 \\ 1.65 & -0.35 & 22.65 & -19.35 & 5.15 & -12.35 & 3.65 & -15.35 & 4.65 & 2.65 & 8.64 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \\ x_7 \\ x_8 \\ x_9 \\ x_{10} \\ x_{11} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ f(x_{10}) \end{pmatrix} \tag{4}$$

hand side of the Eq. (4), and $M_{11,i}$ is the algebraic cofactor of E_i, i.e., the solutions x_i of the controlled system (3) are given by

$$\begin{cases} x_1 = \dfrac{11339f(x_{10})}{-106923}, & x_2 = \dfrac{10152750f(x_{10})}{106923} \\ x_3 = \dfrac{10156849f(x_{10})}{106923}, & x_4 = \dfrac{10155828f(x_{10})}{106923} \\ x_5 = \dfrac{10160590f(x_{10})}{106923}, & x_6 = \dfrac{10155606f(x_{10})}{106923} \\ x_7 = \dfrac{10167011f(x_{10})}{106923}, & x_8 = \dfrac{10155721f(x_{10})}{106923} \\ x_9 = \dfrac{10161661f(x_{10})}{106923}, & x_{10} = \dfrac{10252559f(x_{10})}{106923} \\ x_{11} = \dfrac{10157933f(x_{10})}{106923} \end{cases} \tag{5}$$

Hence, one has

$$\frac{106923}{10252559}x_{10} = -76\sin(8x_{10}+6) - 68\cos(5x_{10}+4)$$

if one lets

$$y_1 = \frac{106923}{10252559}x_{10}$$

and

$$y_2 = -76\sin(8x_{10}+6) - 68\cos(5x_{10}+4)$$

then the intersection points (x_{10}, y_1) of $y_1 = y_2$ are shown in Fig. 3, and the equilibrium points of the controlled system are given by Eq. (5).

III. Design of Encryption Algorithm

A. Data Preprocessing

An image encryption scheme is designed based on 11-dimensional hyperchaotic system. Firstly, the 4th-order Runge-Kutta method is used to discretize the 11-dimensional hyperchaotic system, where the Runge-Kutta formula is given by

$$\begin{cases} X_{i+1} = X_i + \dfrac{h}{6}(K_1 + 2K_2 + 2K_3 + K_4) \\ K_1 = f(t_i, X_i), K_2 = f(t_i + \dfrac{h}{2}, X_i + \dfrac{h}{2}K_1) \\ K_3 = f(t_i + \dfrac{h}{2}, X_i + \dfrac{h}{2}K_2), K_4 = f(t_i + h, X_i + hK_3) \\ \quad (i = 1, 2, \cdots n, \cdots) \end{cases}$$

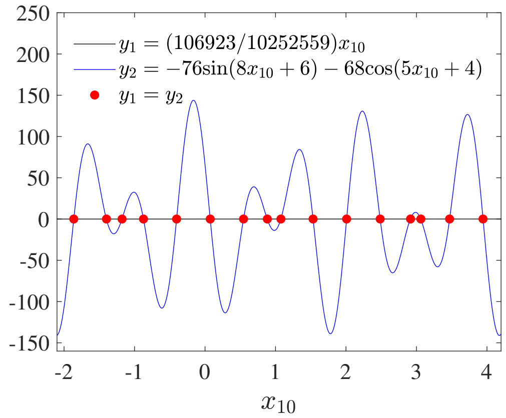


Fig. 3. The Intersection Points of y_1 and y_2 in Equation (4)

The initial values of the hyperchaotic system $X(0)$, and the step $h = 0.001$, then the image encryption algorithm are given as follows:

Step 1: The number of pre-iterations is equal to $\big(2000 + \mathrm{mod}(\mathrm{sum}, \sigma_1 \times \varepsilon_1 \times \varphi_1)\big)$ and it is used to counteract the transient effect of chaotic iteration, where sum is sum of pixel values of original image, mod is the modular function, and $\sigma_1, \varepsilon_1, \varphi_1$ are controller parameters. The pseudo-random sequences generated by the iteration of 11-dimensional hyperchaotic system are $X = (X_1, X_2, \cdots, X_{11})$.

Step 2: The operations of rounding, modulo and shifting are used to generate the pseudo-random sequences $Z =$

$(Z_1, Z_2, \cdots, Z_{11})$, i.e.,

$$\begin{cases} Z_1 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_1, 1) \times 10^{12}, 1) \times 10^9) \\ Z_2 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_2, 1) \times 10^{14}, 1) \times 10^9) \\ Z_3 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_3, 1) \times 10^{13}, 1) \times 10^9) \\ Z_4 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_4, 1) \times 10^{13}, 1) \times 10^9) \\ Z_5 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_5, 1) \times 10^{12}, 1) \times 10^9) \\ Z_6 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_6, 1) \times 10^{13}, 1) \times 10^9) \\ Z_7 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_7, 1) \times 10^{12}, 1) \times 10^9) \\ Z_8 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_8, 1) \times 10^{14}, 1) \times 10^9) \\ Z_9 = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_9, 1) \times 10^{11}, 1) \times 10^9) \\ Z_{10} = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_{10}, 1) \times 10^{13}, 1) \times 10^9) \\ Z_{11} = \mathrm{fix}(\mathrm{mod}(\mathrm{mod}(X_{11}, 1) \times 10^{15}, 1) \times 10^9) \end{cases}$$

where the function fix represents the rounding operation, and the pseudo-random sequences Z can pass most tests of NIST.

Step 3: In order to ensure that the encryption algorithm has better encryption effect, the pseudo-random sequences Z are further obtained by

$$\begin{cases} W_1 = \mathrm{mod}((Z_1 - Z_2 + Z_3), MN) + 1 \\ W_2 = \mathrm{mod}((Z_4 + Z_5), 256) \\ W_3 = \mathrm{mod}((Z_6 + Z_7 + 1), 256) \\ W_4 = \mathrm{mod}((Z_8 + Z_9 + 1), 256) \\ W_5 = \mathrm{mod}((Z_{10} + Z_{11}), 256) \end{cases}$$

Then the new pseudo-random sequences $W = (W_1, W_2, \cdots, W_5)$ can pass the NIST test, and they are given in Section V.

B. Encryption Algorithms

The encryption algorithms include scrambling encryption, sequential diffusion encryption and reverse diffusion encryption. The image information is chosen as an example, and the flow chart of information encryption is shown in Fig. 4.

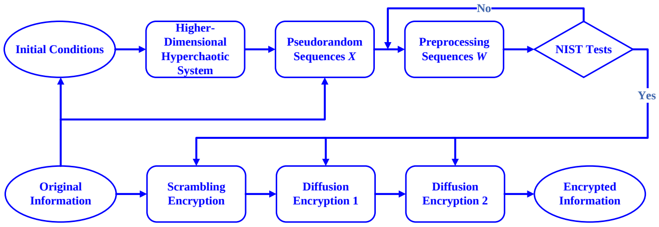

Fig. 4. The Flow Chart of Information Encryption

a) Position Scrambling Encryption

The original image P_1 is in the size of $M \times N$, and the pixel position of P_1 is scrambled based on the pseudo-random sequence W_1, then the scrambled image P_2 is obtained by

$$P_2(i) = P_1(W_1(i)), \ (i = 1, 2, \cdots, MN)$$

b) Sequential Diffusion Encryption

The scrambled image P_2 is encrypted by using pseudo-random sequences W_3 and W_4, and the steps of encryption are as follows:

Step 1: The first pixel value $P_2(1)$ of the scrambled image is encrypted by the first value $W_3(1)$ of the random sequence via the XOR operation, i.e.,

$$P_3(1) = P_2(1) \oplus W_3(1)$$

Step 2: Add the pseudo-random sequence $W_2(i)$ to the pixel values of scrambled image $P_2(i)$, and subtract the integer part of $P_2(i-1)/\varphi$, then the encrypted information $P_3'(i)$ is obtained by the modulus of 256, i.e.,

$$P_3'(i) = \mathrm{mod}((P_2(i) + W_2(i) - \mathrm{fix}(P_2(i-1)/\varphi)), 256) \\ (i = 2, 3, \cdots, MN)$$

Step 3: The sequence $P_3^{'}$ is encrypted with the random sequence W_3 by the XOR operation, and the encrypted image is given by

$$P_3(i) = P_3'(i) \oplus W_3(i), \quad (i = 2, 3, \cdots, MN)$$

c) Reverse Diffusion Encryption

Use the random sequence W_4 and W_5 to perform reverse diffusion encryption on the sequential diffusion encrypted image P_3, and the encryption steps are given as follows:

Step 1: The $P_3(MN)$ is encrypted by the pseudo-random sequence $W_5(MN)$, i.e.,

$$P_4(MN) = P_3(MN) \oplus W_5(MN).$$

Step 2: Through subtraction, multiplication and modulo operations, the pixel values of P_3 are encrypted from the pseudo-random sequence W_4, i.e.,

$$P_4'(i) = \mathrm{mod}(W_4(i) - P_3(i) + P_3(i+1), 256) \\ (i = MN-1, MN-2, \cdots, 1)$$

Step 3: Similarly, the P_4' is encrypted by the pseudo-random sequence W_5 by the XOR operation, one has

$$P_4(i) = P_4'(i) \oplus W_5(i), (i = MN-1, MN-2, \cdots, 1)$$

C. Decryption Process

The decryption is the inverse operation of the encryption, and it is given in follows:

Step 1: The $P_4(MN)$ and $W_5(MN)$ is used to obtain the value $P_3(MN)$ of sequential diffusion encryption, i.e.,

$$P_3(MN) = P_4(MN) \oplus W_5(MN)$$

Step 2: By addition, subtraction, multiplication and modulo operations, the P_3 is decrypted by the pseudo-random sequences W_4 and W_5, and it is given by

$$P_3(i) = \mathrm{mod}(W_4(i) + P_4(i+1) - (P_4(i) \oplus W_5(i)), 256) \\ (i = MN-1, MN-2, \cdots, 1)$$

Step 3: Similarly, the $P_2\left(1\right)$ of scrambled encrypted image is obtained by the XOR operation of $P_3\left(1\right)$ and $W_3\left(1\right)$, i.e.,

$$P_2(1) = P_3(1) \oplus W_3(1)$$

Step 4: By the XOR, addition, division, subtraction and modulo operation, the scrambled encrypted image P_2 is decrypted by the pseudo-random sequences W_2 and W_3, and it is given by

$$\begin{aligned} P_2(i) = \operatorname{mod}((&P_3(i) \oplus W_3(i) + fix(P_3(i-1)/\varphi) \\ &- W_2(i)), 256), \quad (i = 2, 3, \cdots, MN) \end{aligned}$$

Step 5: The pixel value $P_2(i)$ of the scrambled image is exchanged with the pseudo-random sequence $W_1(i)$, and then one can get the original imageP_1, i.e.,

$$P_1(i) = P_2(W_1(i)), \quad (i = MN, MN-1, \cdots, 1)$$

Therefore, the decryption process is completed, and the receivers can get the recovered information from the ciphertext.

IV. Experimental Results

Based on the 11-dimensional hyperchaotic system in Eq. (3), the numerical simulation results are given by the proposed encryption and decryption algorithm in Section III. The encryption algorithm is tested by the Lena image in Fig. 5 (a) with the size of 512×512 and the Cameraman image in Fig. 5 (e) with the size of 256×256 based on the Matlab software, and the sum of pixel values of Lena image and Cameraman image are 32515895 and 7780728, respectively. By the initial values

$$X(0) = (0.2, 0.1, 0.3, 0.1, 0.2, 0.1, 0.5, 0.6, 0.7, 0.4, 0.2)$$

and other parameters of controlled system in Eq. (3), the results of encryption and decryption are shown in Fig. 5. The encrypted images Fig. 5 (b) and (f) are chaotic and disordered, and the original information can not be distinguished, so the encryption algorithm is effective.

In the encryption algorithm, the sum of image pixel values is used to obtain the key of the encryption. Obviously, the sum of pixel values of different images is different, so the different images will generate different keys to the encryption, i.e., the cryptosystem has the effect of “one-time-pad”. Hence, one cannot get any information of the plaintext image from the encrypted image, and the encryption algorithm is effective for secure communication.

Meanwhile, the error images in Fig. 5 (d) and (h) show that the errors between the recovered image and the original image are equal to zero, and Fig. 5 (c) and (g) show the original information can be recovered successfully by the decryption algorithm.

The hyperchaotic system is highly sensitive to the initial values $X(0), A, P, \varepsilon_i, \sigma_i$ $(i = 1, 2)$, etc., and the initial values are used as the encryption keys. If one of the keys is wrong, the ciphertext image cannot be successfully recovered, because the different initial values will generate different chaotic sequences. For example, if the value of the controller parameter is changed from $\varepsilon_1 = 76$ to $\varepsilon_1 = 75$, then the Lena image is encrypted by the corresponding pseudo-random sequences W, but the experiments show that the Lena image cannot be recovered successfully. Similarly, if the initial values $X(0)$ are changed to

$$X(0) = (0.1, 0.1, 0.3, 0.1, 0.2, 0.1, 0.5, 0.6, 0.7, 0.4, 0.2)$$

the experimental results show that the Lena image cannot be recovered successfully, so the encryption algorithm is also sensitive to the initial values $X(0)$.

Fig. 5. Experiments Results of Image Encryption and Decryption

V. Security Analysis

A. Analysis of Key Sensitivity

A good encryption algorithm must be sensitive to the small change of the key, i.e., if there is a small change of the key, then the ciphertext image can not recovered completely. The key space is depended on the sensitivity of matrix A, similar transformation matrix P, controller parameter $\varepsilon_1, \sigma_1, \varphi_1$ and the initial values $X(0)$ of controlled system. As there are 121 elements in matrix A and similar transformation matrix P, one needs to keep other keys unchanged but change only one key with small error, and then the experimental results of decipher images are given in Fig. 6. Fig. 6 (a) shows the decrypted image obtained by using the correct keys, and the ciphertext image can be recovered successfully. Fig. 6 (b)-(d) shows the decrypted image with the small error key, but the ciphertext image cannot be recovered successfully. Through experimental tests, Table I shows the ciphertext can not be decrypted successfully when the errors of key is greater than or equal to the minimum values.

TABLE I. TEST RESULTS OF KEY SENSITIVITY

Error of key	Recovered successfully
$\lvert x_1 - x_1' \rvert \geqslant 10^{-16}$	No
$\lvert x_2 - x_2' \rvert \geqslant 10^{-15}$	No
$\lvert x_3 - x_3' \rvert \geqslant 10^{-16}$	No
$\lvert x_4 - x_4' \rvert \geqslant 10^{-17}$	No
$\lvert x_5 - x_5' \rvert \geqslant 10^{-16}$	No
$\lvert x_6 - x_6' \rvert \geqslant 10^{-16}$	No
$\lvert x_7 - x_7' \rvert \geqslant 10^{-16}$	No
$\lvert x_8 - x_8' \rvert \geqslant 10^{-15}$	No
$\lvert x_9 - x_9' \rvert \geqslant 10^{-16}$	No
$\lvert x_{10} - x_{10}' \rvert \geqslant 10^{-16}$	No
$\lvert x_{11} - x_{11}' \rvert \geqslant 10^{-15}$	No
$\lvert \sigma_1 - \sigma_1' \rvert \geqslant 10^{-15}$	No
$\lvert \varepsilon_1 - \varepsilon_1' \rvert \geqslant 10^{-14}$	No
$\lvert \varphi_1 - \varphi_1' \rvert \geqslant 10^{-15}$	No
$\lvert A(i,j) - A(i,j)' \rvert \geqslant 10^{-15}$, $(i,j = 1,2,\cdots,11)$	No
$\lvert P(i,j) - P(i,j)' \rvert \geqslant 10^{-15}$, $(i,j = 1,2,\cdots,11)$	No

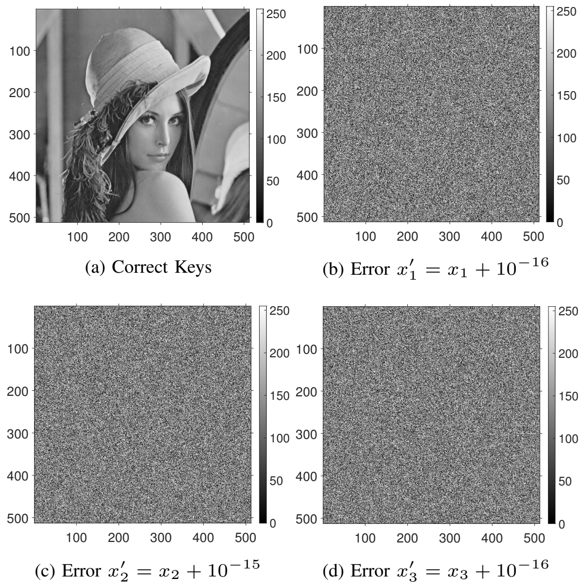
The experimental results show that the image can not be decrypted successfully by using the key with small error. In Table I, it can be estimated that the key space of the encryption algorithm is

$$\begin{aligned} KS &= 10^{14} \times (10^{15})^5 \times (10^{15})^{121} \times (10^{15})^{121} \times (10^{16})^7 \\ &\quad \times 10^{17} \\ &= 10^{3848} \gg 2^{210} \end{aligned}$$

B. Histogram and Chi-Square Test

Histogram describes the distribution of image pixel value. The more uniform the distribution of pixel value, the better the effect of the encryption algorithm. Fig. 7 shows the histograms of the plaintext image and the encrypted image, respectively.

In addition, the Chi-square test is used to illustrate that the cryptosystem has very good confusion characteristics [30].



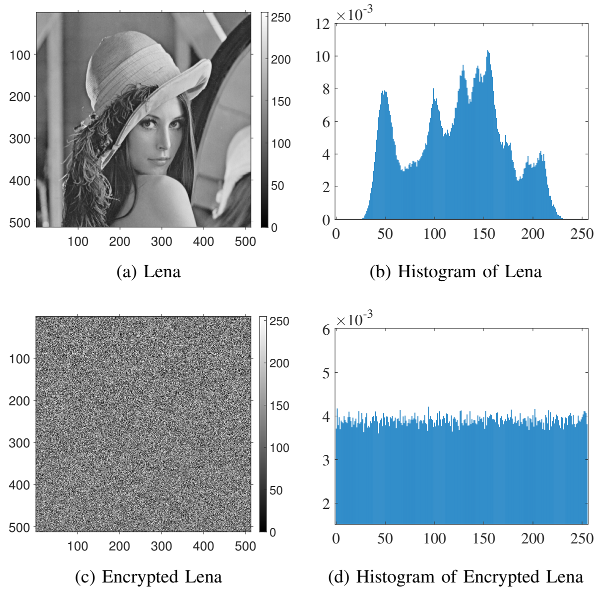
(a) Correct Keys

(b) Error $x_1' = x_1 + 10^{-16}$

(c) Error $x_2' = x_2 + 10^{-15}$

(d) Error $x_3' = x_3 + 10^{-16}$

Fig. 6. Decryption Results of Encrypted Image with Different Keys



(a) Lena

(b) Histogram of Lena

(c) Encrypted Lena

(d) Histogram of Encrypted Lena

Fig. 7. Histogram of Lena and the Corresponding Encrypted Image

The grayscale level of a grayscale image is 256, and then

$$\chi^2 = \sum_{i=0}^{255} \frac{(f_i - g_i)}{g_i}, \quad (i = 0, 1, 2, \cdots, 255)$$

where f_i is the frequency of each 0 to 255 pixel level in the histogram of the encrypted image, g_i is the ideal frequency of uniform distribution, i.e.,

$$g_i = \frac{MN}{256}, \ (i = 0, 1, \cdots, 255)$$

where M and N are the length and width of the image, respectively. If the χ^2 distribution with a degree of freedom of 255 and the significance level is 0.05, then $\chi^2_{0.05}(255) = 293.25$. In Table II, the χ^2 test of original images is significantly greater than 293.25, but the encrypted images are all less than 293.25. Therefore, the distribution of the histogram of the encrypted image is uniform, and it do not disclose any information by the statistical analysis.

TABLE II. χ^2 TESTS

Image	Lena	Cameraman	Barbara
Original Image	158350	110970	144100
Encrypted Image	223.64	238.89	215.80

C. Information Entropy

Information entropy is used to describe the randomness of image information, and it's defined as follows [31]:

$$H = -\sum_{i=1}^{n} p_i \log_2(p_i)$$

where p_i is the probability of the i-th gray value. For gray-scale images, the expected entropy of image information is equal to 8. The entropy of three different images and encrypted images are shown in Table III. The entropy of encrypted images is close to 8, so the encryption algorithm is suitable to encrypt the plaintext information and it has good encryption effect.

TABLE III. INFORMATION ENTROPY

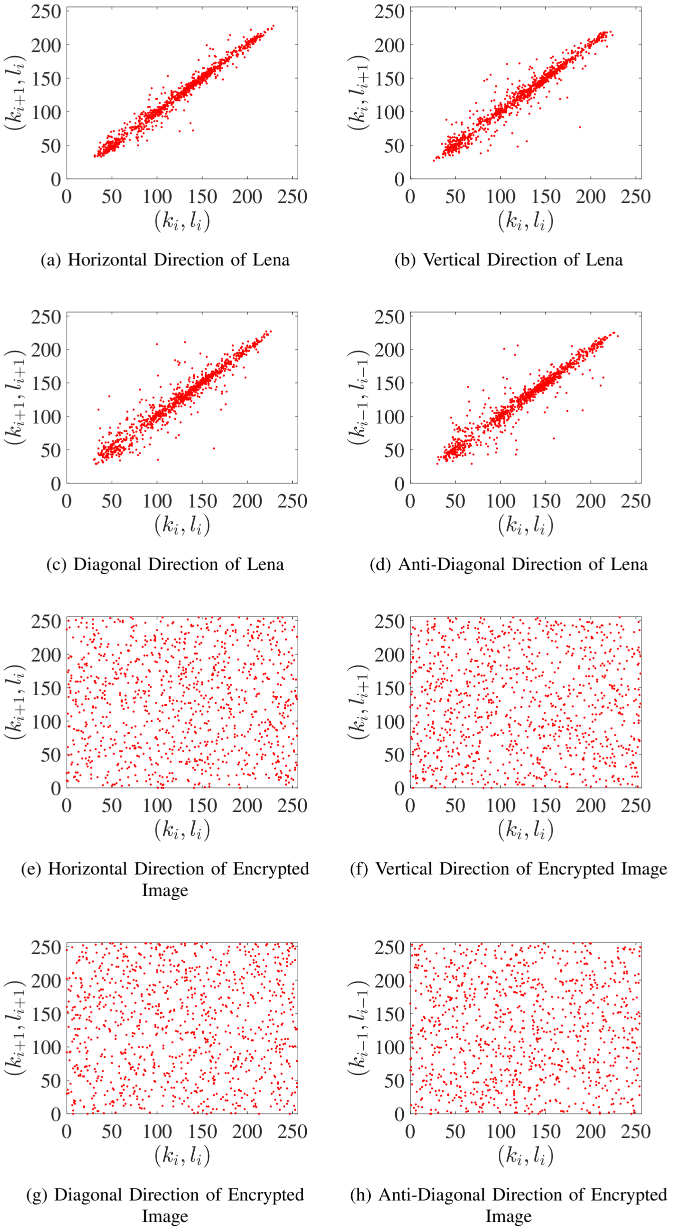
Image	Plaintext Image	Encrypted Image
Lena	7.4456	7.9915
Cameraman	7.0097	7.9902
Barbara	7.4664	7.9916
Lena in Ref. [32]	7.4456	7.9907
Lena in Ref. [33]	7.4456	7.9768

D. Analysis of Correlation Coefficient

The high correlation between the pixels of the plaintext image makes the image look clear and one may distinguish the image information. The correlation coefficient of unencrypted image is usually large, and the encryption algorithm will reduce the correlation between pixels to zero or close to zero. If N pairs of adjacent pixels are taken from the image and their gray value is (e_i, f_i) $(i = 1, 2, \cdots, N)$, the formula of correlation coefficient for vectors $\boldsymbol{e} = \{e_i\}$ and $\boldsymbol{f} = \{f_i\}$ is given as follows [34]:

$$\begin{cases} r_{\boldsymbol{ef}} = \dfrac{\operatorname{cov}(\boldsymbol{e}, \boldsymbol{f})}{\sqrt{D(\boldsymbol{e})}\sqrt{D(\boldsymbol{f})}} \\ \operatorname{cov}(\boldsymbol{e}, \boldsymbol{f}) = \dfrac{1}{N}\displaystyle\sum_{i=1}^{N} (e_i - E(\boldsymbol{e}))(f_i - E(\boldsymbol{f})) \\ D(\boldsymbol{e}) = \dfrac{1}{N}\displaystyle\sum_{i=1}^{N} (e_i - E(\boldsymbol{e}))^2, E(\boldsymbol{e}) = \dfrac{1}{N}\displaystyle\sum_{i=1}^{N} e_i \end{cases}$$

If the e_i denotes the pixel value in position (k_i, l_i), and the f_i denotes the pixel value in position (k_{i+1}, l_i), then the calculation result is the correlation coefficient in the horizontal direction. Similarly, 1000 pairs of pixel points of Lena are randomly selected in the vertical, horizontal, diagonal and anti-diagonal directions, and the corresponding correlation coefficients are shown in Table IV. Meanwhile, the correlations of Lena and the encrypted images are given in Fig. 8, the correlation coefficient of the encrypted image of proposed algorithm has been close to 0.



(a) Horizontal Direction of Lena

(b) Vertical Direction of Lena

(c) Diagonal Direction of Lena

(d) Anti-Diagonal Direction of Lena

(e) Horizontal Direction of Encrypted Image

(f) Vertical Direction of Encrypted Image

(g) Diagonal Direction of Encrypted Image

(h) Anti-Diagonal Direction of Encrypted Image

Fig. 8. Correlation Analysis of Lena Image

E. Differential Analysis

A secure cryptographic system should be highly sensitive to small changes in the key or plaintext image during encryption

TABLE IV. CORRELATION COEFFICIENTS OF PLAINTEXT AND CIPHERTEXT

Image	Horizontal	Vertical	Diagonal	Average
Lena	0.9831	0.9737	0.9666	0.9745
Encrypted	−0.0092	−0.0116	0.0114	0.0086
Ref. [35]	0.0141	0.0296	0.0054	0.0164
Ref. [36]	−0.0253	0.0026	0.0091	0.0123

and decryption. Especially, if the small changes in the plaintext image will produce completely different encrypted images, then it will be more effectively to resist chosen-plaintext attacks. NPCR and UACI are often used to analyze whether the encryption algorithm has a good encryption effect and security. NPCR is the proportion of different pixel numbers in all pixel points. UACI represents the average difference of the pixel values of the encrypted image when the original image is with one pixel (or some pixels) different in pixel values. The calculation formulas are given as follows [37]:

$$\begin{cases} \text{NPCR} = \dfrac{\sum\limits_{i=1}^{M}\sum\limits_{j=1}^{N} D_{(i,j)}}{M \times N} \times 100\% \\ D_{(i,j)} = \begin{cases} 1, x\left(i,j\right) \neq x'\left(i,j\right) \\ 0, x\left(i,j\right) = x'\left(i,j\right) \end{cases} \\ \text{UACI} = \dfrac{\sum\limits_{i=1}^{M}\sum\limits_{j=1}^{N} \frac{x(i,j)-x'(i,j)}{255}}{M \times N} \times 100\% \end{cases}$$

where x is the encrypted image, and x' is the new encrypted image when the plaintext is changed by one pixel or some pixels. If the 97 in 99-th pixel value of Lena image is changed to 98, the 132 in 99-th pixel value of Barbara image is changed to 133, and the 156 in 99-th pixel value of Cameraman image is changed to 157, then the NPCR and UACI of corresponding encrypted images are shown in Table V, and they are very close to the expected values (NPCR ≈ 99.6094%, UACI ≈ 33.4635%). So the encryption algorithm can resist plaintext attacks and has significant encryption effect.

TABLE V. NPCR AND UACI OF ENCRYPTED IMAGE(%)

F. NIST Test

NIST test is used to verify the random characteristics of random sequences, and it includes 15 tests, such as single bit frequency, longest-run-of-ones and non-overlapping template matching [40]. If the random sequence can pass all NIST test, i.e., the p-values are greater than 0.01, then the random sequence has good randomness. The pseudo-random sequences Z are obtained by the chaotic sequences X, and the results of NIST test for pseudo-random sequences Z are shown in Table VI, i.e., most tests of NIST are passed. Similarly, the results of NIST test for pseudo-random sequences W are shown in Table VII, and all the p-values are greater than 0.01, so the NIST test is passed.

VI. CONCLUSION

Through the combined controllers of trigonometric function, a class of asymptotically stable nominal linear systems are controlled to be hyperchaotic system, and a 11-dimensional hyperchaotic systems with 9 positive Lyapunov exponents is constructed. Meanwhile, an encryption algorithm of scrambling, sequential diffusion and inverse diffusion is designed based on the new hyperchaotic system. The encryption algorithm has many key parameters and initial values, and the key is related to plaintext information. To some extent, it has a large enough key space and can resist exhaustive attack and chosen-plaintext attack, etc. An example of image encryption is given by the simulation experiments, and it shows that the encryption algorithm based on higher-dimensional hyperchaotic system is feasible, effective and secure. Therefore, the chaos-based encryption algorithm can be applied to the secure communication in the near future, such as the encryption of images, video and other multimedia information.

ACKNOWLEDGMENT

The authors would like to thank the anonymous reviewers for their valuable comments and suggestions. ***Abstract*—Sound-event detection enables machines to detect when a particular sound event has occurred in addition to classifying the type of event. Successful detection of various sound events is paramount in building secure surveillance systems and other smart home appliances. However, noisy events and environments exacerbate the performance of many sound event detection models, rendering them ineffective in real-world scenarios. Hence, the need for robust sound event detection algorithms in noisy environments with low inference times arises. You Only Hear Once (YOHO) is a purely convolutional architecture that uses a regression-based approach for sound-event-detection instead of the more common, frame-wise classification-based approach. The YOHO architecture proved robust in noisy environments, outperforming convolutional recurrent neural networks popular in sound event detection systems. Additionally, different ways to enhance the performance of the YOHO architecture are explored, experimenting with different computer vision architectures, dynamic convolutional layers, pretrained audio neural networks and data augmentation methods to help improve the performance of the models on noisy data. Amongst several modifications to the YOHO architecture, the Frequency Dynamic Convolution Layers helped improve the internal model data representations by enforcing frequency-dependent convolution operations, which helped improve YOHO performance on noisy audios in outdoor and vehicular environments. Similarly, the FilterAugment data augmentation method and Convolutional Block Attention Module helped improve YOHO's performance on the VOICe dataset containing noisy audios by augmenting the data and improving internal model representations of the input audio data using attention, respectively.**

Keywords*—Sound Event Detection (SED); sound event classification; frequency dynamic convolution; audio processing; FilterAugment; data augmentation; vision transformers; Pretrained Audio Neural Networks (PANN); Convolutional Block Attention Module (CBAM)

I. Introduction

In machine learning, sound event detection (SED) identifies the different sounds in an audio file and identifies the start and end time of a particular sound event in the audio. Various applications use SED, such as speech recognition, audio surveillance [1], and context-based indexing and data retrieval in a multimedia database [2].

Most of the research and development in SED today is focused on building sound event detection systems that can be trained using weakly labelled data, i.e., audios without timestamps for the occurrence of each event or unlabelled data [3]–[5]. Hence, there is an increased focus on using models that employ semi-supervised learning [4], [6], [7] to learn from weakly labelled and unlabelled data. Moreover, most of these works use sequential models or transformer architectures to leverage the sequential nature of audio data [8]–[10].

However, the consequence of using sequential and transformer-based architectures is increased model complexity, machine computation requirements, and inference times. In addition, the audios from various sources are seldom devoid of any interfering noise or disturbance in real-life. Consequently, this makes such models unsuitable for deployment in smart devices, which have constraints on the compute available and often are required to make inferences in real-time, in addition to often operating in noisy environments. Architectures with short inference times, low model parameters, and high accuracy enable smart devices to deliver accurate insights more quickly.

The You Only Hear Once (YOHO) architecture proposed by S. Venkatesh et al. draws inspiration from the famous computer vision architecture - You Only Look Once (YOLO) [11] and only makes use of different forms of convolutions, with no sequential layers. The YOHO algorithm matches the performance of the various state-of-the-art algorithms on datasets such as Music Speech Detection Dataset [12], TUT Sound Event [13], and Urban-SED datasets [14] and at lower inference times. The fast inference can be ascribed to YOHO's regression-based approach, which takes the entire audio stream as input and predicts each audio event's start and end time using regression instead of performing framewise classification.

Hence, this work tests the performance of the You Only Hear Once (YOHO) [15] algorithm on noisy audio data from different acoustic environments like indoors, outdoors, and in vehicles. The experiments show that the standard YOHO architecture is better than other popular sound event detection architectures when tackling noisy audios. Thus, we used the regression-based sound event detection approach from YOHO and combined it with other computer vision architectures, pretrained audio neural networks and methods like attention, data augmentation and dynamic convolutions to increase model performance in noisy environments. However, it was difficult to improve on the standard YOHO architecture's F1 scores. In the end, we were able to improve the performance of YOHO on the VOICe dataset by replacing the standard convolutional layers in the architecture with frequency dynamic convolution layers which helped mitigate translational invariance along the frequency axis of the log-Mel spectrograms. We also made use of the FilterAugment data augmentation method and Convolutional Block Attention Module (CBAM) to improve YOHO's

F1 scores for specific noise environments. Hence, in the end we modified the novel, purely convolutional, regression-based architecture proposed by S. Venkatesh et al. [15] to use attention, better internal data representations and data augmentation to further improve YOHO's SED performance on noisy data with a negligible increase in the model parameters.

The first section, "Introduction" explains the motivation for undertaking this work. The second chapter, "Background Theory and Literature Review", deals with the different concepts used in this work and discusses relevant research. The third chapter, "Methodology and Implementation Details", elaborates on the architecture designs and the steps undertaken in the experiments. The fourth chapter, "Results and Analysis" delineates and analyses the results. The fifth and ultimate chapter, "Conclusion and Future Work" provides a gist of the future scope of the research and possible technical improvements.

II. Background Theory and Literature Review

This section discusses the current state of research in sound event detection. It also elaborates on the different architectures and techniques in addition to the dataset and various attention and activation functions used in this work.

A. State of Research in SED

Early approaches for SED had adapted techniques from music information retrieval and speech recognition, such as Hidden Markov Models (HMMs) and Gaussian Mixture Models (GMMs) [16]. However, HMMs could not deal with polyphonic audio containing co-occurring sound events.

The advent of deep learning demonstrated the adeptness of deep neural networks in multi-label sound event classification and dealing with polyphonic audio. While a simple feed-forward neural network (FFN) could perform multi-label classification, it was limited in its ability to model the temporal information in signals. Consequently, plain FNNs did not gain popularity for use in SED applications.

In 2017, Cakir et al. showed that the Convolutional Recurrent neural networks (CRNNs) [8] architectures were well suited for the SED task. The recurrent neural networks (RNNs) combined with convolutional neural networks (CNNs) could capture the audio's local and global context.

The following aspects helped the CRNN architecture perform well in the SED task:

- Using successive blocks of convolutional layers and non-linear transformations, the architecture learned distinguishing characteristics in the input log-Mel spectrograms and generated feature embeddings.
- The recurrent layers would then model the temporal dependencies in the feature embeddings from the convolutional layers.
- The framewise classification approach was used to predict the existence of audio events in each audio frame.

However, a drawback of the CRNN architecture was that processing times were higher, resulting from the sequential layers preventing the architecture from fully utilising GPUs' parallel computation.

To shorten inference durations without compromising high precision and recall, S. Venkatesh et al. introduced the You Only Hear Once (YOHO) architecture for SED [15]. The You Only Look Once (YOLO) algorithm, which is popular in Computer Vision, served as an inspiration for the YOHO algorithm. YOLO significantly reduced the processing durations for the input images and enabled real-time object recognition by changing the prediction of object bounding boxes from a classification problem to a regression problem. Similarly, YOHO transforms the frame-based, multi-label classification problem of acoustic boundary detection into a regression problem. To achieve this, multiple sets of three different output neurons were used, one for each class. The presence of an event class is detected by one neuron, and its start and endpoints are predicted by the other two in each set for the particular class. As a result, on numerous datasets, the YOHO article showed a higher F-measure and lower error rate than CRNNs [15].

The current focus of the majority of SED research and development is building sound event detection systems that can be trained using weakly labelled data (audios without timestamps for the occurrence of each event) or unlabelled data [3]–[5] As a result, semi-supervised learning models are being used more frequently [4], [6], [7] to learn from weakly labelled and unlabelled data. Additionally, the majority of these works take advantage of the sequential aspect of audio data by using sequential models or transformer architectures [7]–[9]. However, this work aims to explore the regression-based, supervised learning approach for SED; hence, semi-supervised learning approaches for SED are not a focus of this work.

B. VOICe Dataset

VOICe is a new dataset for developing and evaluating generalizable sound event detection and domain adaptation methods. VOICe is offered for sound event detection domain adaptation from one acoustic scene to another or between sound events with background and without background noise [17]. The VOICe dataset consists of 207 different audio mixtures containing audios with three different sound event labels:

1) babycry
2) gunshot
3) glassbreak

These audio events are then superimposed with audios from the following 3 acoustic scenes:

1) outdoor
2) indoor
3) vehicle

The noisy audios are mixed at 2 different sound-to-noise-ratio (SNR) levels:

1) -3 dB
2) -9 dB

The dataset also consists of 207 audio mixtures devoid of background noise. Consequently, there are a total of 1449 audio mixtures - 207 mixtures x 3 acoustic scenes x 2 SNRs

= 1242 noisy audios + 207 clean audios. These audio files are divided into “training”, “testing”, and “validation” sets. The testing and validation audio files are 60 seconds long, whereas the training audio files last about 180 seconds.

We used the noisier SNR -9 dB audios from the VOICe dataset [17] to assess the performance of YOHO and other architectures in this work on noisy audio. It is a dataset that has been artificially constructed utilising noise from various acoustic scenes and sound events from the TAU Urban Acoustic Scenes 2019 development set and TUT Rare Sound Events 2017 development set, respectively. We would have an algorithm that is resilient to noise and performs sound event recognition considerably faster than other contemporary algorithms if it can perform well on noisy data and provide scores at least matching the CRNN algorithm. Consequently, it would become a candidate model for portable sound event detection devices used in natural, noisy environments.

C. YOHO Algorithm

Instead of using the conventional, bigger YOLO architecture, S. Venkatesh et al. modified the final layers of the MobileNet [15] architecture to implement the YOHO architecture. As can be seen in Table I, YOHO is purely a convolutional neural network. The initial MobileNet architectural layers are retained in the initial half of the table. Layers adjusted for the target dataset are in the latter half.

Consequently, YOHO has faster inference times than designs with sequential layers like CRNNs because it is built as a solely convolutional neural network with no recurrent layers. The probability and the beginning and ending times of each event label are output from the neural network, which takes as input log-Mel spectrograms of the audios. In addition, because this end-to-end method directly predicts acoustic boundaries, it takes lesser time for post-processing and smoothing [18].

Log-Mel spectrograms are used as the YOHO model’s input. Next, a 3x3 2D convolution with a stride of 2 is performed after reshaping the input, halving the time and frequency dimensions. The MobileNet design uses depth-wise separable convolutions [19] with 3x3 filters, followed by point-wise convolutions [20] with 1x1 filters. All convolutions except the final layer were followed by batch normalisation [21] and ReLU activations [22]. Every time a stride of two is used, the time and frequency dimensions are halved.

D. PANNs: Large-scale Pretrained Audio Neural Networks for Audio Pattern Recognition

It is common practice in computer vision and natural language processing for systems to be pretrained on large-scale datasets. The pretrained systems then generalise well to several downstream tasks. However, the research on building pretrained neural networks trained on large-scale audio datasets is limited. Pretrained audio neural networks (PANNs) [23] are trained on the large-scale AudioSet dataset [24]. These PANNs are transferred to other downstream audio-related tasks. The best PANN system achieved mean average precision (mAP) of 0.439 on AudioSet tagging, outperforming the previous state-of-the-art result of 0.392 [23].

E. ViT: Vision Transformer

The Vision Transformer, or ViT [25], is a transformer-based model architecture for image classification. Each image is split into fixed-size patches. The patches are then converted to linear embeddings using a linear transformation. The linear embeddings are then added to the positional embedding, and the resulting sequence of vectors is fed to a standard Transformer encoder. Finally, an extra learnable “classification token” in the output sequence is used to perform image classification [25].

F. CoAtNet: Marrying convolution and Attention for All Data Sizes

Vanilla Vision Transformers lack the inductive biases that traditional convolutional networks possess. However, Vision transformers have the advantage of utilising attention over their input [26]. Hence, a model which uses convolution and attention in machine learning benefits from two fundamental aspects – higher generalisation and higher model capacity. Convolutional layers have better generalisation, while attention in the transformer layer yields higher model capacity. Hence CoAtNet [26] is a hybrid model based on two key insights:

1) By using simple relative attention, depth-wise convolution and self-attention can be naturally fused.
2) By stacking convolution layers and attention layers in a principled manner, generalisation, capacity, and efficiency are dramatically improved.

CoAtNet has the best of both convolution networks and Transformers. CoAtNet not only has the generalisation ability of convolution networks because of favourable inductive biases but also has the advantage of superior scalability from transformers resulting in faster convergence and improved efficiency [26].

G. KNNs: Kervolutional Neural Networks

KNNs [27] are an effort to establish convolution in non-linear space. Existing CNN architectures primarily leverage activation layers which only provide point-wise non-linearity. Kervolution (kernel convolution) was introduced to approximate complex behaviours of human perception systems by leveraging the kernel trick. It claims that using the kernel trick helps it generalise convolution, capture higher-order interactions of features via patch-wise kernel functions, and enhance the model capacity without introducing additional parameters. Extensive experiments showed that kervolutional neural networks (KNN) achieve higher accuracy and faster convergence than baseline CNN [27].

H. CBAM: Convolutional Block Attention Module

Convolutional Block Attention Module (CBAM) [28] is an attention module designed for convolutional neural networks. The module sequentially computes attention maps along the channel and spatial dimensions given an intermediate feature map. The input feature maps are then multiplied by the attention maps to refine the adaptive features [28].

I. Frequency Dynamic Convolutions

When a pattern moves along the time axis in the time-frequency domain, it sounds the same because the frequency components are the same, but the timing is different. On the other hand, because the frequency component that makes up the acoustic properties of the sound event changes as it moves along the frequency axis, it would sound different [29]. The Frequency Dynamic Convolutions paper [29] highlights that due to its nature, the standard 2D convolution operation wrongly enforces translational invariance along both the time and frequency dimensions of an input log-Mel spectrogram. In contrast, log-Mel spectrograms exhibit invariance only along the time axis but not the frequency axis.

Frequency dynamic convolution [29] uses a frequency-adaptive kernel to enforce frequency-dependency on 2D convolution and improve the physical consistency of the model with sound events' time-frequency patterns. The inputs have three axes - the frequency axes, the time axes and the parallel channels. From the input, it first derives frequency-adaptive attention weights. Average pooling along the time axis is followed by two 1D convolution layers which are applied along the channel axis the input. 1D convolution was used rather than fully-connected (FC) layers to take into account neighbouring frequency components. Batch normalisation and ReLU are applied between two 1D convolution layers. The channel dimension is compressed into the number of basis kernels using 1D convolution layers. The softmax activation function is then used to normalise the values of the frequency-adaptive attention weights between zero and one.

Additionally, Softmax sets each frequency bin's weight sum to one. A temperature of 31 was applied to the softmax to achieve stable training and homogeneous learning of basis kernels. Then, using frequency-adaptive attention weights, a weighted sum of basis kernels is used to produce frequency-adaptive convolution kernels. The obtained kernel is used for frequency dynamic convolution operation just like a regular 2D convolution.

J. FilterAugment Data Augmentation

FilterAugment [30] is an improved version of frequency masking compared to SpecAugment [31]. SpecAugment involved simply masking a small time and frequency range of Mel spectrograms. While the simplicity of the time and frequency masking makes it easily adoptable during model training, they are unforgiving as they completely remove portions of information from the spectrogram.

FilterAugment was proposed to regularize acoustic models over various acoustic environments by mimicking acoustic filters. It approximates acoustic filters by applying random weights on randomly determined frequency bands, i.e., randomly increasing or decreasing the energy of these random frequency ranges of the log Mel spectrograms.

Hence, FilterAugment is an effective regularization approach for acoustic models as it extracts sound information from a wider range of frequencies and it proved that generalising the SED model over a broader frequency range enhances SED performance by a significant margin.

K. Mish Activation Function

$$f(x) = x \cdot tanh(softplus(x)) \tag{1}$$

$$softplus(x) = ln(1 + e^x) \tag{2}$$

The Mish activation function outperforms ReLU [22]. The advantages of the Mish activation function are: It has unbounded upper limit and bounded lower limit. It is a non-monotonic, self-regularized function and a self-gated function. It is continuously differentiable with infinite order. It falls under the class of $C\infty$. In contrast, ReLU falls under the class of $C0$. However, a disadvantage of Mish is that it is computationally expensive [32].

L. SERF Activation Function

Serf, or Log-Softplus ERror activation Function, is a type of activation function which is self-regularized and nonmonotonic in nature.

$$f(x) = x \cdot erf(softplus(x)) \tag{3}$$

erf is the error function. SERF outperforms Mish and ReLU on a variety of tasks like image classification, object detection, machine translation and sentiment classification on multiple datasets [33].

III. Methodology and Implementation Details

The following section describes the different modification made to each architecture for the downstream tasks as well as the different hyperparameters set for different aspects of model training. The codes have been made available on Github[1].

A. Audio Processing

The following steps are performed to process the audio files and corresponding annotations:

1) Convert stereo audio with SNR -9 dB into mono audio.
2) Read mono audio at a sample rate of 44,100 Hz, then segment it into windows, where the window length is set to 2.56s and hop length is set to 1.96s.
3) Generate model compatible output format for each window's annotations.
4) Generate log-Mel spectrograms for each window using the following parameters:
    a) Number of Mel bins = 40
    b) Number of Fast Fourier Transform components = 2048
    c) Window length for generating spectrograms = 1764 sample points
    d) Hop length for generating spectrograms = 441 sample points
    e) Minimum frequency $fmin$ of 0 Hz
    f) Maximum frequency $fmax$ of 22,050 Hz
5) Save the log-Mel spectrograms and the model compatible outputs using the $.npy$ file format for use during model training and validation.

[1] https://github.com/sohamtiwari3120/YOHO-on-VOICe

6) At the time of model training, FilterAugment [30] is optionally used to augment the existing dataset. It randomly increases or decreases the energy of random frequency regions of the log-Mel spectrogram.

B. Model Training Settings

The random seed was fixed at 0. The batch size for training the model was set at 32. We used the -9 dB audios from the VOICe dataset for training.

While training, the Adam [34] optimiser with the default learning rate set to 10^{-3}, epsilon value set to 10^{-7} and default weight decay set to 0. Moreover, a call-back was used to reduce the learning rate of the model by half during training whenever the validation loss during training did not decrease for 5 epochs. Gradient clipping was used to clip/keep the global norm values of the gradients less than or equal to 0.5.

The number of epochs was not fixed, and Early Stopping [35] regularization was utilised to stop model training if the validation loss would not decrease for 10 or more epochs.

C. Working Changes to YOHO Architecture

Each audio file is first segmented into overlapping windows with a window length of 2.56s and a hop length of 1.96s. The model input dimensions are determined by the length of the audio example and the number of Mel bins. For the VOICe dataset, the input log-Mel spectrogram shape is (257, 40), where 257 is the number of time steps and 40 is the number of Mel bins.

As shown in Table I, the output of the last 2D convolution layer is reshaped by flattening the last two dimensions. The final 1D convolution layer consisting of nine filters of unit length yields an output matrix of shape 9x9. The first dimension of the output corresponds to the time axis, and the second dimension corresponds to three neurons for each of the three classes in the VOICe dataset. The input spectrogram is divided into nine bins along the time axis. Every row in the output matrix represents the audio events' start and end times in the input spectrogram's corresponding bin.

As seen in Fig. 1, the first, fourth and seventh neurons perform binary classification at each time step to detect the presence of the respective audio events. The second and third neurons use regression to predict the start and end times of the first audio-event class. Similarly, for the fifth, sixth, eighth and ninth neurons and their respective second and third audio-event classes.

Table I describes the YOHO architecture for the VOICe dataset. Each convolution layer in the architecture makes use of 'same' padding to keep the shape of the output of the convolution layer same as that of its input.

D. Working Changes to CoAtNet + CBAM Architecture

The CoAtNet architecture expects input images which have equal height and width and three channels. Since the size of the log-Mel spectrograms of the VOICe dataset was (257, 40) , i.e., (number of time frames, number of mel bins), a learnable transposed convolution layer [36] is included before the CoAtNet architecture. The transposed convolution layer would then reshape the input spectrogram to (257, 257) followed by a 2D convolutional layer which would increase the number of channels to 3. To this transformed input CBAM attention (with reduction factor of 2 and kernel size of 3) is applied before passing it onto the CoAtNet architecture. The "CCTT" variant [26] of CoAtNet architecture is used, i.e., two MobileNet Convolution Layers along with two Transformer layers. Finally, the output of the CoAtNet architecture is passed through a 1D Convolution layer to increase the number of channels to 9. The changes are described in Table II.

E. Working Changes to ViT Architecture

The Vision Transformer (ViT) expects input images with three channels and height and width of even values since it splits each image into fixed-size patches. In our code, the patch size for ViT was set to 8. The depth of the transformer layer was set to 6, the number of heads to 16, the dimension of transformer tensors to 1024 and that of the feed-forward neural network layer to 2048.

Table III shows that the input log-Mel spectrogram is passed through a 2D Convolutional layer. This layer increases the number of channels to 3 and reduces the height of the image to an even value. The ViT layer outputs a 1D vector of 1024 values and 161 channels. Consequently, the output is passed through two successive 1D convolutional layers to obtain the final output in the desired shape (9, 9).

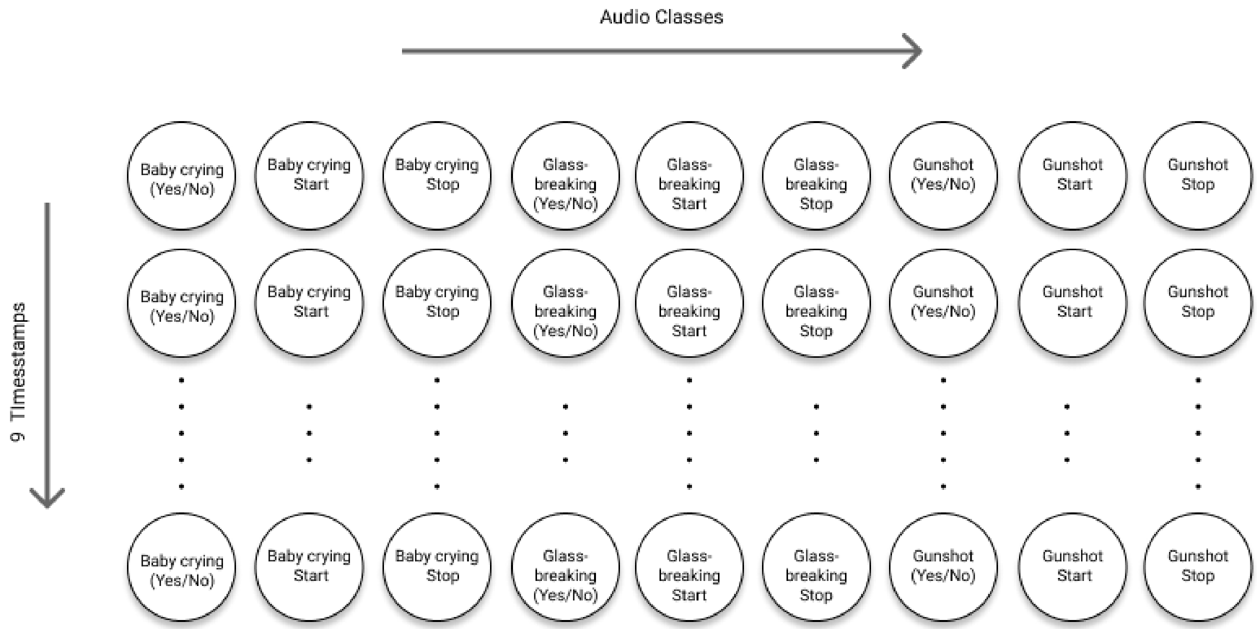

Fig. 1. Visualisation of Output Layer of YOHO for VOICe Dataset.

F. Working Changes to YOHO + KNN Architecture

The YOHO architecture was modified by replacing every standard 2D convolution layer in the architecture by a 2D kervolution layer with a linear kernel.

G. Working Changes to YOHO + PANN Architecture

The CNN10 [23] variant of the PANN architecture expects log-Mel spectrograms with 64 Mel bins as input. Hence as described in Table IV, the input is processed and made compatible with PANN. PANN's output is then passed through a couple of transpose convolution layers followed by a couple of convolution layers to make the output compatible for YOHO. During training and inference, the weights of PANN pretrained on the large-scale AudioSet dataset were used for the CNN10 architecture.

TABLE IV. WORKING CHANGES TO YOHO + PANN ARCHITECTURE

reduce_channels_2	Conv2d(...)	(1, 257, 40)
YOHO	YOHO(...)	(9, 9)

H. Working Changes to YOHO + CBAM Architecture

The YOHO architecture is modified by inserting a Convolutional Block Attention Module (CBAM) before the input to every 2D depth wise convolution layer. The reduction factor was set to 2 and the kernel size set to 3 for every CBAM layer. The number of channels for each cbam layer was set to the number of channels of the output from the previous layer.

I. Working Changes to YOHO + Custom Rectangular Kernel Architecture

In an attempt to mitigate the problem of convolutional neural networks wrongly enforcing translational invariance along the frequency axis of the log-Mel spectrograms, a custom convolutional layer with "rectangular kernels" was applied before being input to the YOHO architecture. Fig. 2 shows that the layer consisted of 4 parallel 2D convolution layers:

1) Conv2D layer with filter size (3, 3)
2) Conv2D layer with filter size (log-Mel height//4, 3)
3) Conv2D layer with filter size (log-Mel height//2, 3)
4) Conv2D layer with filter size (log-Mel height*3//4,3)

J. Working Changes to YOHO + FilterAugment Architecture

The YOHO architecture remains the same. The difference is during training, FilterAugment data augmentation is used. The decibel range was set to (-6, 6), the band number range to (3, 6), minimum bandwidth to 6 and a linear filter type was used. The same set of hyperparameters are used for all experiments using FilterAugment data augmentation.

K. Working Changes to YOHO + FDY Architecture

The YOHO architecture was modified by replacing every standard 2D convolutional layer in the architecture by a 2D frequency dynamic convolution layer with the number of basis

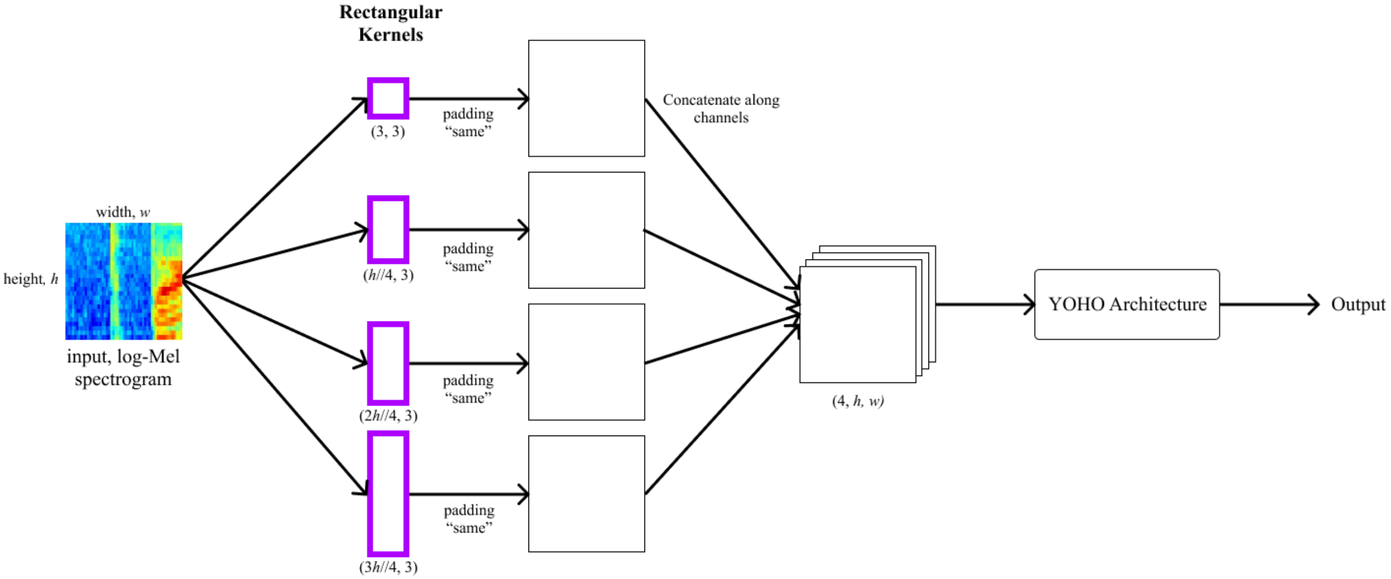

Fig. 2. Visualisation of Rectangular Kernel Layer Preceeding YOHO.

kernels set to 4 and the temperature set to 31 in every such layer. The same hyperparameters are used in all experiments using frequency dynamic convolutions.

L. Working Changes to YOHO + FDY + FilterAugment Architecture

The architecture is same as that described in the previous section, the difference being that the FilterAugment data augmentation method was being used during the training of the above architecture.

M. Working Changes to YOHO + FDY + FilterAugment + CBAM Architecture

The architecture is same as that described in the previous section, the difference being that the CBAM attention module (with reduction factor of 2 and kernel size of 3) is inserted before the input to every depth wise frequency dynamic convolutional layer.

IV. Results and Analysis

The results of all the experiments have been tabulated in Table V. More detailed results have been made available on Weights and Biases[2].

The results illustrate the following points:

1) YOHO, with an average F1 score of 0.8738, outperforms the CRNN architecture, which has an average F1 score of 0.7603, as given in [17].
2) The larger and more complex architectures, such as CoAtNet, ViT and PANN (with YOHO) with average F1 scores of 0.7589, 0.7966 and 0.8594 respectively are unable to match standard YOHO architecture's 0.8738 F1 score. This is surprising as these architectures are currently one of the best performing models in the multiple applications of Computer Vision and audio processing.
3) On average, the best performing architecture was the YOHO + CBAM architecture, with an average F1 score of 0.874. This architecture entailed adding attention to YOHO, which benefits from the inductive biases of a convolutional network. This is again surprising as the CoAtNet architecture, which combines the global attention of transformers and the inductive biases of the convolutional networks could not perform as well.
4) The proposed rectangular kernels layer (average F1 score of 0.8676), a simplistic approach to improve internal model representation of audio log-Mel spectrograms performed better than larger architectures like CoAtNet (average F1 score 0.7589), CRNN (average F1 score 0.7603), ViT (average F1 score 0.7966) and YOHO + PANN (average F1 score 0.8594) on the dataset.
5) YOHO modified with Kervolutional layers reported the lowest F1 scores in the Outdoor - 0.7883 and Vehicle - 0.8167 noise environments compared to all other variants of YOHO.
6) YOHO + FilterAugment reported the best F1 scores in the outdoor and the vehicle noise environments - 0.879 and 0.8918, respectively. In contrast, it performed the worst out of all architectures in the indoor noise environment, with an F1 score of 0.3871.
7) YOHO + FDY + FilterAugment reported very high scores in the outdoor and noise environments - 0.8746 and 0.8903, respectively. Moreover, frequency dynamic convolution layers seemed to counteract to some extent the drop in performance when using FilterAugment for indoor audios with an F1 score of 0.7681.
8) Combining YOHO + FDY + FilterAugment + CBAM did not perform as expected. Its F1 scores (0.8668, 0.8815 and 0.4534) are lesser than its individual

[2] https://wandb.ai/sohamtiwari3120/YOHO-on-VOICe?workspace=user-sohamtiwari3120

TABLE V. RESULTS OF ALL EXPERIMENTS

Architecture	**Outdoor F1**	**Vehicle F1**	**Indoor F1**	**Average F1**
CoAtNet	0.7566	0.7719	0.7483	0.7589
CRNN	0.7500	0.8004	0.7305	0.7603
ViT	0.7902	0.8223	0.7774	0.7966

YOHO + FDY + FILT_AUG	0.8746	0.8903	0.7681	0.8443
YOHO + FDY + FILT_AUG + CBAM	0.8668	0.8815	*0.4534*	0.7339

components - YOHO, YOHO + CBAM, YOHO + FilterAugment and YOHO + FDY + FilterAugment.

Table V shows that the standard YOHO architecture is adept at handling noisy audios, and few architectures and other variants of YOHO could improve upon the standard architecture's scores. It seems that complex architectures with a large number of parameters performed worse than standard YOHO on the VOICe dataset. One reason could be less training data, which large architectures usually require. The VOICe dataset could be sufficient for YOHO but insufficient for the more complex architectures.

Furthermore, architectures with sequential layers and transformers like CRNN and ViT performed worse than the purely convolutional YOHO architecture and its variants. Purely convolutional architectures can better utilise GPUs and hence train faster and longer. In addition, convolutional neural networks possess inductive biases, which help them generalise to unseen datasets. Hence, another reason sequential layer-based architectures did not perform well on noisy audios could be the lack of inductive biases and poor generalizability compared to YOHO. However, the reason why CoAtNet, which combines the inductive biases of convolutional layers and the attention of transformers, performed poorly on the dataset is unknown. The poor performance of CoAtNet is confounding, especially since YOHO combined with attention in the form of CBAM performed very well on audios from all three noise environments.

On the other hand, the experiments using convolutional block attention module (CBAM), FilterAugment and Frequency Dynamic Convolution (FDY) layers hint that improving internal model representations of the input audio data and data augmentation hold the key to achieving robust sound event detection on noisy audios.

V. CONCLUSION AND FUTURE WORK

The standard YOHO architecture is resilient to noise in audios, and its lightweight architecture with low inference times makes it a candidate model for use in portable sound event detection applications. Furthermore, this work found that combining the YOHO architecture with Frequency Dynamic Convolutions, Convolutional Block Attention Module, and FilterAugment data augmentation, helped obtain high F1 scores in specific noisy environments. This increase in performance can be attributed to improved internal model representations of the input audios with the help of data augmentation, which entailed a negligible increase in the number of parameters and model inference times.

The results suggest that improving audio representations in the model and data augmentation could help obtain better performance of SED models in noisy environments. Hence, future research can explore better representations for audios and research ways to mitigate the translational invariance along the frequency axis enforced by standard convolutional neural networks. This could involve improving the proposed rectangular kernels layer. Additionally, the models could be trained with representations from Google LEAF [37], which was one of the experiments we wanted to conduct. However, at the time of writing this paper, we could not find links to pretrained weights for the Google LEAF architecture and our compute and data were inadequate to train the architecture from scratch.

Another possible avenue of research could be to determine why the FilterAugment data augmentation method adversely affects only the audios containing noise from indoor environments while showing the opposite, helpful effects in audios containing vehicular and outdoor noise. This study could help unlock insights about noise in indoor environments and could help in the development of intelligent home audio devices.

Another direction of research would be to first train the larger and more complex architectures with more data to try and determine the ceiling for their performance in noisy environments. Furthermore, these experiments could help assess whether their performance can be improved using additional data or other factors that govern the model performance.

Finally, to determine why YOHO with convolutional block attention module performs so well and why CoAtNet does not. This could help us understand why CoAtNet's architecture, which benefits from inductive biases of convolutional networks and the global attention mechanism of transformer architectures, did not perform well in audios from noisy environments.

This work showed that the promising new regression-based, purely convolutional sound event detection architecture called You Only Hear Once can be effectively used in noisy environments. Furthermore, the regression-based approach was experimented with and used with other architectures and methods to find ways to better improve robustness to noise. The results indicate that better audio representations for the model and data augmentation techniques can help boost the performance of SED systems. Hopefully, this work will encourage more research in developing better audio representations and making audio-related models more robust to noise.

Acknowledgment

We want to thank the faculty of the Computer Science Department at Manipal Institute of Technology, Manipal, India, for their continued support and guidance. Special appreciation for Dr. Manjunath Mulimani (Email manjunath.mulimani@tuni.fi), who, during his tenure at Manipal Institute of Technology, guided us and helped us navigate various technical difficulties and advised possible research directions throughout the lifetime of this work. The authors would also like to thank Dr. Chng Eng Siong, Andrew Koh and Tanmay Khandelwal, part of the Speech Lab at Nanyang Technological University, Singapore.

Abstract—**The principal objective of this paper is to provide a parallel implementation focused on the main steps of the parameter-free clustering algorithm based on K-means (PFK-means) using the Spark framework and a machine learning-based model to process Big Data. Thus, the process consists of parallelizing the main tasks of the first stage of the PFK-means clustering algorithm using successive RDD functions. Then, the parallel K-means provided by Spark MLlib is invoked by setting the cluster centers and the number of clusters determined in the previous step as input parameters of the parallel K-means. Furthermore, a comparison between the parallel designed algorithm and the parallel K-means was conducted using UCI data sets in terms of the sum of squared errors and the processing time. The experimental results, performed locally using the Spark framework, demonstrate the efficiency of the proposed solution.**

Keywords*—*Clustering; big data; spark; parallel computing; parallel K-means

I. Introduction

Today's digital world is experiencing unprecedented progress, causing the generation of an immense amount of data presented in various formats and derived from many sources, including social networks, the internet of things, mobile apps, multimedia, financial services, and ERP systems. Hence, managing this huge amount of data requires efficient techniques and tools to ensure that the data is processed efficiently to make the right decision according to the application domain [1]. Researchers and scientists are constantly contributing to and developing new machine learning algorithms, as well as designing more efficient frameworks capable of dealing with the continuous flow of data generated each lapse of time [2] [3].

Cluster analysis is one of the appropriate data mining techniques for ensuring efficient Big Data processing [4] [5]. Indeed, the purpose of cluster analysis is to place similar data objects in the same group to construct disjoint clusters. The concept of similarity is firmly based on a distance measure depending on the characteristics of the data object's features. In the same context, several Big Data clustering algorithms were designed based on specific computing platforms aiming to either distribute the clustering tasks on several nodes to perform the necessary calculations in a parallel way or by using a server with high capacities in terms of CPUs, memories, and I/O resources [6] [7] [8].

This paper proposes a new parallel clustering algorithm based on Spark [9], designed to enhance the sequential PFK-means algorithm to leverage distributed systems and process big data. As a result, the proposed parallel implementation is carried out using open-source Hadoop, the Spark framework with RDDs, and a machine learning-based model. More specifically, the proposed algorithm aims to parallelize the two principal stages of the PFK-means algorithm using Spark RDDs functions. The first one consists of applying successive RDDs functions in order to perform the computation of the Euclidean distances, build the initial clusters, and finally update the different clusters to obtain the cluster centers and, consequently, the number k. The second stage invokes the use of the parallel K-means provided by Spark mLlib with as input parameters the cluster centers and the number of clusters discovered in the previous phase. In that respect, a comparison between the developed parallel algorithm and the parallel K-means provided by Spark mLlib was conducted on some UCI data sets based on the sum of the squared error measure and the processing time. The results obtained show that the suggested solution yields more efficient clustering compared to the parallel K-means with the random initialization mode. The main contributions of this paper are as follows:

- Improve the approach to determining the initial cluster centers of the cluster construction step
- Suggest a parallel implementation of the main steps of the PFK-means clustering algorithm based on spark RDDs in order to process big quantitative data.
- Establish a comparison between the designed algorithm and the parallel K-means algorithm provided by spark mLlib.

The remainder of this paper is organized as follows: Section II discusses a literature review. Section III gives a short presentation of parallel computing using the Spark framework. Section IV provides the design and implementation of the parallel developed algorithm. Section V shows the results of the experiment. Finally, Section VI concludes the paper and presents future perspectives.

II. Literature Review

Over the years, clustering algorithms have undergone several evolutions and improvements to face the challenges of managing heterogeneous and complex data generated from multiple and varied digital sources. In particular, K-means [10] [11] is one of the most widely used clustering algorithms due to its simplicity and efficiency in processing data. This algorithm has experienced several adaptations and improvements

*Corresponding authors.

to address initialization issues, exploit distributed systems and handle Big Data [12] [13] [14]. In this context, several research studies based on different parallel computing architectures have been carried out to give birth to powerful and scalable algorithms.

Among these algorithms, a parallel adaptive Canopy-K-means algorithm [15] aims to solve the manual selection problem for the distance threshold T2 in the Canopy process. In this regard, it is improved by adaptive parameter estimation using the MapReduce-based Model and the Spark framework. The clustering results on the Stanford Large Network Dataset Collection (SNAP) data set and self-built Dimension demonstrate the efficiency of the proposed solution.

Another improvement in the parallel K-means is introduced in [16], which is an improved K-Means Clustering Algorithm for Big Data Mining based on the density of data points to construct the corresponding clusters. Thus, the algorithm was parallelized on the Hadoop platform using the distributed database to improve its efficiency and decrease the running time. The simulation results prove that the enhanced solution outperforms the classical K-means and the DBSCAN algorithm in terms of clustering accuracy by 10%.

In the same context, a clustering center selection method [17] was developed to solve the issue of the random nature and limited quality of initial cluster center selection. In addition, a parallel implementation using the Spark computing framework was suggested to perform Big Data clustering and therefore obtain higher execution efficiency, accuracy, and good stability in big data.

More recently, another improved initialization method [18] for the K-means algorithm was implemented to enhance the initial points selection strategy using sparse reconstruction. Moreover, the parallel version of the algorithm was performed based on the MapReduce framework and Hadoop cluster using the real customer data from the JD Mall. The experimental results demonstrate its efficiency in processing large amounts of data.

Another contribution aiming to address the K-means algorithm initialization issue is a parallel clustering algorithm based on grid density [19]. Indeed, the process of the algorithm is based on specific strategies, including, locality sensitive hash function(DP-LSH), the adaptative grouping strategy (AGS), and the MapReduce framework to operate the cluster centers in parallel and therefore increase the performance of the proposed approach.

III. Parallel Computing using Spark Framework

Parallel computing is one of the efficient solutions to process large amounts of data using computing platforms. Indeed, these platforms allow the distribution of the calculations according to different architectures [20]. Such platforms can be either horizontally scaled platforms or vertically scaled platforms [7]. In particular, Spark is a horizontally scalable cluster computing framework [9], performing parallel processing for data-intensive applications with working sets. These applications are managed by the driver program, which allows them to execute the user's main function as well as the parallel operations in a cluster. Hence, it has the advantage of executing tasks by ensuring locality-aware scheduling, fault tolerance, and load balancing [9]. The spark is distinct from MapReduce since it handles iterative jobs and enables users to run queries on a Big Data set by loading into memory only the required data set. More specifically, the Spark framework is structured around two main abstractions: resilient distributed dataset (RDD) and shared variables. The RDD is a collection of items distributed through the cluster nodes that can persist in memory to be reused in the event of parallel operations. The shared variables are also used in parallel operations to share the necessary variables among jobs or between jobs and the driver program. In addition, Spark is powerful and outperforms the Hadoop MapReduce framework by 10× in interactive machine learning workloads. Fig. 1highlights the basics of spark architecture.

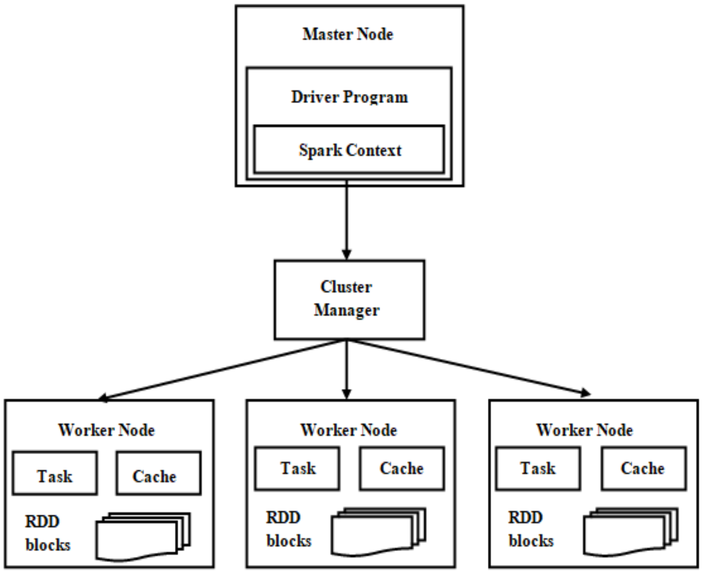

Fig. 1. Spark Architecture.

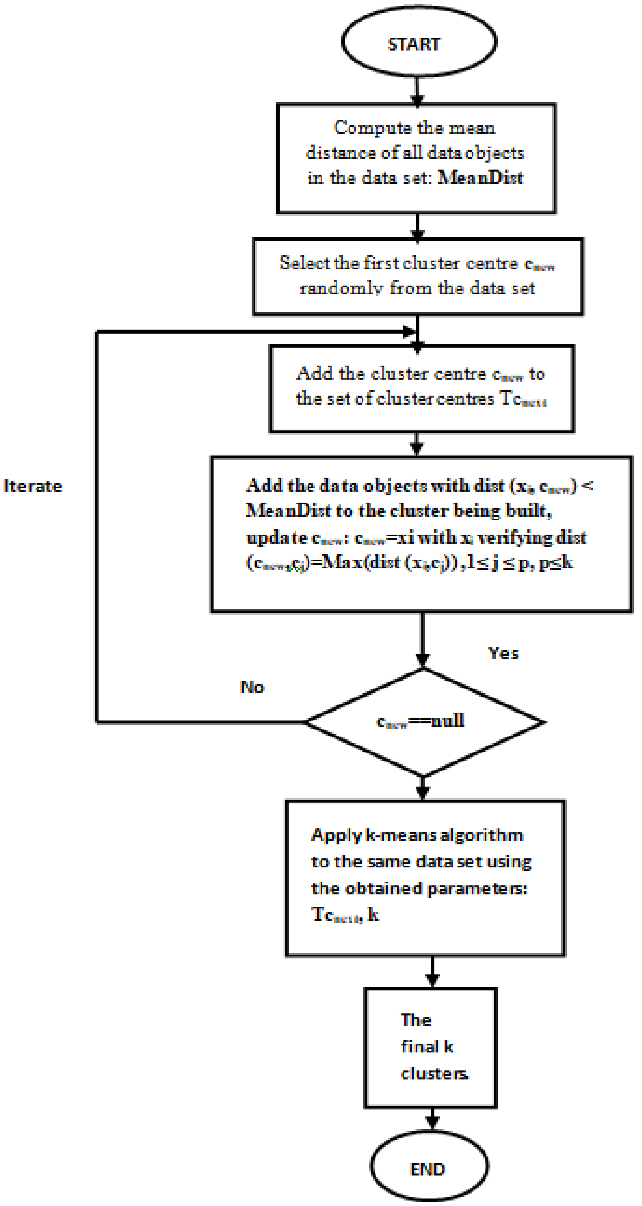
IV. The Proposed Parallel PFK-means

This section first introduces an overview of the PFK-means clustering algorithm for processing quantitative data, then gives a detailed description of the implementation of the parallel algorithm designed for Big Data processing, and finally presents the algorithm describing the various Spark RDD functions that allow the parallelization of the tasks of the suggested algorithm.

A. The Sequential PFK-means

The PFK-means algorithm [21] is a parameter-free clustering algorithm aiming to construct progressively homogeneous clusters until the appropriate number of clusters is automatically detected. This heuristic is a combination of the E-transitive heuristic [22] adjusted for quantitative data, and the traditional K-means [10] [11]. Indeed, the sequential version of the PFK-means algorithm performs a partitioning clustering based on two main stages. The first one aims to construct clusters successively based on the similarity between the cluster centers and the data objects using the Euclidean



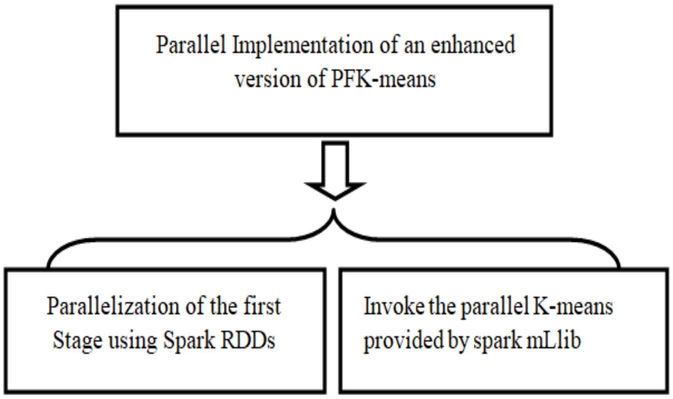
START
Compute the mean distance of all data objects in the data set: MeanDist
Select the first cluster centre c_new randomly from the data set
Add the cluster centre c_new to the set of cluster centres Tc_next
Iterate
Add the data objects with dist (x_i, c_new) < MeanDist to the cluster being built, update c_new: c_new=xi with x_i verifying dist (c_new,c_j)=Max(dist (x_i,c_j)) ,1≤ j ≤ p, p≤k
Yes
No
c_new==null
Apply k-means algorithm to the same data set using the obtained parameters: Tc_next, k
The final k clusters.
END

Fig. 2. Sequential PFK-means Flowchart.

distance calculation and consequently, gets the initial cluster centers and the number of clusters k, which are the two primary input parameters for the K-means algorithm. The second stage consists of applying the K-means algorithm to the same data set taking into consideration the cluster centers obtained and the number of clusters k reached in the first stage. The first stage of the PFK-means algorithm is an independent clustering algorithm that enables the discovery of clusters with appropriate cluster centers. The K-means algorithm is applied to enhance the quality of the clusters obtained. Fig. 2 resumes the main steps of the PFK-means algorithm.

B. Design and Implementation of the Parallel PFK-means

The PFK-means is a sequential and iterative clustering algorithm, suitable for processing unsupervised machine learning data sets. However, the efficiency of this algorithm will be restricted when dealing with a large amount of data. Among the solutions to improve the performance of this algorithm and make it suitable for processing Big Data is the parallelization of its tasks using the open-source Hadoop, Spark RDD, and Machine Learning-based Model. In that respect, the implementation of the parallel version of PFK-means consists of the parallelization of its two main stages. In this way, the first stage consists of the parallelization of three principal tasks, including the calculation of the total average of the Euclidean distances, the construction of the initial clusters, and assigning the data objects to the appropriate clusters as well as updating the discovered cluster centers. The next stage involves the use of the parallel K-means provided by spark mLlib, using as input parameters the discovered cluster centers as well as the number of clusters automatically detected in the first stage. Fig. 3 illustrates the design of the parallel implementation of the PFK-means. In the following, the steps of the initial stage will be thoroughly described.



Parallel Implementation of an enhanced version of PFK-means

Invoke the parallel K-means provided by spark mLlib

Fig. 3. The Design of the Parallel Implementation.

1) Calculation of the Total Average of the Euclidean distances: In order to compute the total average of the Euclidean distances, the process starts by reading the data set being processed locally into RDDs partitions since it is the first step. Then these RDDs' partitions are transformed using the Map function with the purpose of calculating the Euclidean distance between each two data objects, which is performed in several iterations. Therefore, in each iteration, the Reduce function sums the partial Euclidean distances for each partition Map. Then, after completing all the iterations, another Reduce function is applied to the final result, in order to obtain the total average of the Euclidean distances. Fig. 4 depicts the process of spark RDDs to compute the total average Euclidean distance of the processed data set.

Although the use of Spark is optimal since it avoids storing the data on a hard disk, the calculation of the average of the Euclidean distances of the data set is costly. It is, therefore, essential to optimize this calculation. The first way involves calculating the average of the Euclidean distances of a sample instead of processing the entire data set using the Map and Reduce functions. The second solution consists of first reordering the whole data set randomly and then applying the MapPartitions function, which allows decomposing the data

set into a specific number of partitions. Then, each partition performs the computation of the two-by-two Euclidean distances of a part of the data. Thus, the result produced by the MapPartitions function is transmitted to the Reducer, allowing the calculation of the total average of the Euclidean distances. In this solution, the MapPartitions and Reduce functions are invoked only once, so the calculation time is much reduced compared to the solution explained previously.

2) The Construction of the Initial Clusters: This step starts by choosing the first data object in the data set as the first cluster center. Then, the data objects similar to this cluster center are gathered in such a way that the Euclidean distance between this cluster center and each data object in the whole data set is less than the total average of the Euclidean distances calculated in the previous step. Contrary to the sequential version of the algorithm in which the construction of the first cluster is realized in n iterations, the construction of the first cluster in the parallel version of the algorithm is done using the filter function, which selects the elements similar to the cluster center by calculating the Euclidean distances in parallel. Subsequently, the cluster center of the second cluster is determined in such a way that the data object similar to the first cluster center whose Euclidean distance is the greatest is compared to the data objects not similar to the center, so the data object whose Euclidean distance yields an average value is chosen as the second cluster center. Consequently, the determination of the cluster center is realized using the filter function, which allows selecting the cluster center among the objects not similar to the first cluster center by calculating the Euclidean distances in parallel. In this way, the other cluster centers are determined successively to follow the same process. This process is finished when all the data objects are classified and there are no more data objects to choose from as a new cluster center. And lastly, it is important to mention that during the construction of the clusters, each data object can be placed in several clusters, and therefore the clusters achieved at the end of this step are overlapped. This allows for the enlargement of the size of the clusters and, accordingly, improves the quality of the cluster centers obtained. Fig. 5 shows the cluster construction process using the Spark RDDs functions.

Calculate the average of the data objects contained in the corresponding cluster, update Ci
The Set of clusters with the new cluster centres

Fig. 6. The Parallel Process of Updating Clusters.

3) Assigning the Data Objects to the Appropriate Clusters and Update Cluster Centers: After having built the initial clusters in the previous step, this step consists of assigning to each cluster center found in the previous step the data objects similar to it by using the filter function. This function selects the data objects by performing the calculations of the Euclidean distances in parallel. Then, the Reduce function is applied to the RDD returned by the Filter function to update the value of the cluster center by computing the average of the data objects contained in the corresponding cluster. In this step, each data object can be associated with only one cluster, and consequently, there will be no overlaps in the resultant clusters. Fig. 6 describes the process of obtaining the final hard clusters with the new cluster centers using the Filter and Reduce functions. Once the hard clusters with updated cluster centers and the number of cluster centers detected automatically have been obtained, the next step is to apply the parallel K-means provided by Spark mLlib with the input parameters obtained from the first stage, which are the cluster centers and the number of clusters.

C. The Parallel Proposed Algorithm

The following pseudo-code (Algorithm 1) describes the stages of the parallel implementation of the PFK-means algorithm. Hence, the process begins by reading the file containing the set of quantitative data (lines 1 and 2). Subsequently, it seeks to calculate the average of the Euclidean distances of the data set using one of the previously explained methods (line 3). The next step is to build the initial clusters to obtain the list of cluster centers to be used in the next step (from 4 to 17). Afterward, the process aims to assign the data objects to the appropriate centers and update the different centers (from 18 to 24). The last step intends to invoke the parallel K-means provided by Spark mLlib using the parameters obtained from the previous step (from 25 to 27).

Wine	178	13	3
Pima Indian Diabetes	768	8	2
Letter-Recognition(LR)	20000	16	26

V. Experiments

For the purpose of implementing the parallel version of PFK-means with Spark RDDs in stand-alone mode, a machine of 12GB memory and 1TB hard disk was configured with Spark (version 3.0.3) and Hadoop (2.7 version) and PyCharm IDE by installing useful Pyspark libraries (PySpark version is 3.9). Subsequently, the proposed algorithm was evaluated on real-world data sets extracted from the UCI machine learning repository based on the sum of squared errors and the execution time to measure the clustering performance. In addition, the parallel PFK-means were compared with the parallel K-means provided by the mLlib library to demonstrate the efficiency of the developed solution. It is also crucial to notice that the parallel implementation of PFK-means has been tested locally in the PyCharm IDE and, therefore, the size of the data sets has been limited.

A. Data Sets Description

Table I provides a short description of three real-world datasets, extracted from the UCI machine learning repository [23], serving to validate the efficiency of the parallel implementation of PFK-means, including Iris, Wine, and Letter Recognition (LR). In this way, each data set is represented by a data size, a determined number of clusters, and the number of attributes that constitutes the vectors of the data sets.

B. Results Achieved in Terms of the Sum of Squared Errors

One of the effective metrics to evaluate the quality of clustering is the sum of the squared errors. This measure is obtained by calculating the sum of the Euclidean distances between each cluster center and the set of data objects belonging to this cluster. Therefore, the sum of the results found corresponds to the sum of squared errors of the set of clusters. Accordingly, the more minimal this measure is, the better the result is achieved.

Table II reports the sum of squared errors of the clustering result obtained by running the parallel PFK-means and the parallel K-means provided by Spark mLlib on the Letter Recognition (LR) data set. The execution of parallel PFK-means performs clustering by automatically detecting the number of clusters that can be varied by changing the position of the new cluster center determined in each iteration of the cluster construction step of the algorithm. Thus, the reported results are obtained by iterating the parallel K-means one, three, and ten times, respectively. In other words, for the parallel PFK-means, the reiteration is applied just to the second phase of the algorithm, which consists of applying the parallel K-means implementation of Spark mLlib using the cluster centers and the number of clusters found in the first phase of the algorithm. In this respect, the acquired results are compared

TABLE II. The Sum of Squared Errors of the Clustering Results on Letter-Recognition Data Set

TABLE III. The Sum of Squared Errors of the Clustering Results on Iris, Wine, and Pima Data Sets

data set	parallel PFK-means	parallel K-means (mLlib)
Iris	**97.34**	97.70
Wine	**18889.14**	19015.23
Pima	**49403.81**	64315.08

with the parallel K-means of Spark mLlib using the random initialization mode.

By observing the results displayed in the Table II, it can be seen that the parallel PFK-means outperforms the parallel K-means in terms of the sum of squared errors, except for the tenth iteration with k = 24, for which the parallel K-means exceeds the proposed algorithm. It is also noteworthy that the PFK-means produces good results from the first iteration, implying that the cluster centers discovered in the first phase of the algorithm are well-positioned in comparison to the cluster centers discovered using the random initialization mode. Besides the fact that the parallel PFK-means allows discovering the number of clusters automatically, the result given by the developed algorithm is stable. Table III presents a comparison of the parallel PFK-means and the parallel K-means in terms of the sum of squared errors for the real-world data sets Iris, Wine, and Pima. The results clearly show that the execution of the parallel K-means after determining the input parameters (number of clusters and the cluster centers) from the first phase of the developed parallel algorithm consumes less time compared to the execution of parallel K-means with the random initialization mode for the three data sets used.

C. Results of the Processing Time

In order to evaluate the performance of the parallel PFK-means concerning running time, the second phase of the proposed algorithm has been compared with the parallel K-means of Spark mLlib using the random initialization mode, which allows to randomly generate the cluster centers. In this case, the number of clusters k used is the number detected by the first phase of the parallel PFK-means, and therefore the number of cluster centers must be fixed before the execution. On the other hand, by running the second phase of the PFK-means, the number of clusters is automatically detected and assigned to the parallel K-means as well as the cluster centers.

Fig. 7 illustrates the execution time of the second stage of the parallel PFK-means compared to the execution time of the parallel K-means on Iris, Wine, Pima, and Letter-Recognition data sets. Fig. 7 shows that the PFK-means outperforms the parallel K-means for all the data sets used.

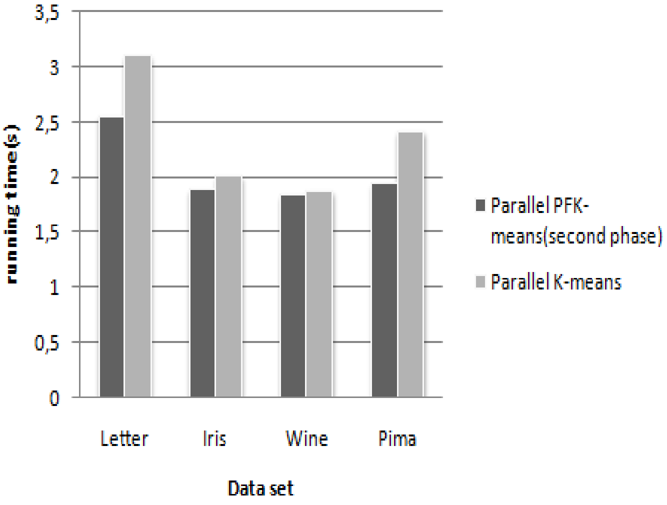

Fig. 7. Clustering Time on Real-world Data Sets.

D. Discussion of the Obtained Results

According to the experiments that were conducted on real-world data sets, it was proved that the proposed algorithm is a parameter-free clustering algorithm since it can automatically determine the set of cluster centers and the number of clusters without specifying any input parameters, and therefore the suggested solution is suitable for unsupervised learning. However, running the parallel version of k-means provided by Spark mLlib requires fixing the number of clusters as well as specifying the initial cluster centers. Moreover, the execution of the developed algorithm using real-world data sets gives significant results compared to the results achieved by the parallel implementation of K-means provided by Spark mLlib in terms of the sum of squared errors and execution time. In addition to that, the parallel implementation of the method allows the distribution of the tasks constituting the main steps of the algorithm on several nodes, which allows for the processing of very large files.

VI. Conclusion and Perspective

The main concern of this paper is to design a new parallel clustering algorithm based on the main steps of the PFK-means clustering algorithm for processing large quantitative data sets by bringing a significant improvement in the way of determining the initial cluster centers in the cluster construction step. Thus, it exposes a general presentation of the parallel computing platforms and the main process of the Spark framework. Moreover, this paper presents a preview of the sequential version of the PFK-means algorithm [21]as well as a detailed explanation of the proposed parallel algorithm. Furthermore, experiments based on UCI data sets were conducted based on the sum of squared errors and the execution time. The results have clearly shown that the suggested parallel algorithm is an efficient clustering algorithm as it can automatically construct the initial cluster centers as well as the number of clusters without having to specify any parameters beforehand. Besides, it has been demonstrated that the developed algorithm outperforms the parallel K-means provided by Spark mLlib in terms of squared errors and processing time.

In our future research, we intend to concentrate on creating a remote server configuration to distribute the different tasks of the algorithm on multiple nodes and therefore process very large files. In addition, we will establish a deep analysis to compare both the stand-alone mode implementation and cluster mode implementation. Furthermore, we will focus on the implementation of the proposed algorithm using other similarity measures and various data sets. It may also be possible to apply the proposed solution to perform real-time processing.

***Abstract*—Natural disasters such as earthquakes or mudslides destroy everything in their path, causing buildings to collapse, which can cause people to lose their lives or suffer permanent injuries. Rescuers and firefighters are responsible for entering these ruined buildings, this work being very dangerous for them because they can get trapped in the rubble or suffocate due to the harmful gases found inside these buildings. Taking into consideration the risk in this type of operations, technological innovations can be used to help in the exploration of ruined buildings and the rescue of people. Therefore, this article describes the development of TXRob, a low-cost teleoperated robot used in the exploration of post-disaster scenarios. TXRob has artificial vision, environmental gas recognition sensors, a real-time data display panel, is sized to enter buildings, and is capable of moving over uneven surfaces, such as debris or cracks, thanks to its track system. A human operator can remotely monitor and control the robot. The TXRob's versatility as well as sensors performance has been tested on uneven and harsh surfaces in a simulated disaster environment. These tests suggest that the designed robot is suitable for use in rescue situations.**

***Keywords*—Rescue robot; teleoperation; low cost robot; artificial vision**

I. Introduction

The Peruvian territory has suffered serious seismic episodes due to its location in the fire ring [1], [2]. Some of these earthquakes have occurred on June 23, 2001 with a magnitude of 8.4Mw (Moment scale), this event happened in Arequipa, leaving more than 240 dead, 70 people missing and 2400 injured [3]; in the province of Pisco on August 15, 2007, a 7.9Mw earthquake occurred, leaving 95 dead, 2,291 injured, 76,000 houses destroyed and uninhabitable and 431,000 people affected [4]; on May 26, 2019, an earthquake of 8.0Mw occurred in Alto Amazonas, which caused the death of 2 people and several injured people [5]. Due to these disasters, contingency procedures were developed to minimize the damage caused. In addition, systems capable of predicting these telluric movements have been created in order to minimize the post-disaster impact [6], but one must indeed have sufficient capacity to respond to a natural disaster, not only an earthquake, but also landslides or fires where the structure of the building of the place is affected.

After a disaster, access to the building is partially or totally inaccessible, so a teleoperated robot would assist with contingency programs in these hazardous situations, but the robot must be able to overcome obstacles and accurately locate potential survivors. For example, in the article [7] a rescue robot for miners trapped in a cave-in, equipped with cameras and sensors that detect toxic gas levels. Several robotics projects robotic projects have been designed with this approach, most of them remotely controlled to support human operators in SAR (search and rescue operations) tasks [8], [9].These robots work more efficiently and faster than a human human agent, which is reflected in the higher number of rescued people, this is the main objective of the robot. Rescue tasks are critical and are performed in dangerous environments for people, further reinforcing the need to employ this type of robots [10].

There are several approaches when designing a rescue robot. To understand and analyze the post-disaster environment, unmanned aerial vehicles (UAV) or unmanned ground vehicles (UGV) are used, an example of these vehicles is the Tactical Hazardous Operations Robot (THOR) [11]. In order to map a post-disaster scenario, SLAM (Visual Simultaneous Localization and Mapping) technology is used [12]. When rescuing survivors, the impact of the rescue robot on the survivor must be taken into account. Parameters such as the force induced by the robot and the speed of translation are important to analyze [13]. But these methods prove to be costly [14], this is why the development of a low-cost robot would be more accessible to the rescue teams.

In 2019, air pollution was considered the greatest environmental health risk. environmental health risk. The main sources of air pollution are large-scale burning of wood, biomass or crop residues, fuel adulteration, uncontrolled emissions from vehicles and factories, traffic congestion and accelerated construction. These sources cause smog and thus increase airborne particulate matter (PM_10, $PM_{2,5}$), NO_x, NH_3, SO_x , CO and other VOC (volatile organic compounds) in the air [15]. It is very likely that the concentration of gases after a disaster is not optimal for humans; this is due to gas leaks, fires caused by short circuits or ruptures of pipes inside buildings; there are several sensors that can detect these measurements but it is necessary to take these measurements remotely. Normally a gas sensor is incorporated to determine these parameters and thus secure the area for human intervention. These sensors are: CO_2 sensor, VOC sensor (Volatile Organic Compounds Sensor), NO_X sensor, PIR sensor, among others [16], [17].

Good body temperature control is vitally important in a survivor, because monitoring body temperature can predict stroke; sensors such as the UHF RFID temperature sensor are used to obtain a more accurate measurement [18], [19]. Estimating the maximum response time that can be expected is vital to prevent the survivor from suffering severe respiratory distress due to hypothermia, considered below 35C°, which could result in death [20]. There are several ways to detect life signs in survivors in a post-disaster scenario, considering that there is a 24-hour life time frame, these signs become a priority for the rescue robot operator. Sound acquisition serves as a possible support to other sensors in order to locate survivors quickly and efficiently [21], [22]. In today's technology, the use of infrared cameras is necessary for the detection of heat signatures within an environment to be explored. Due to the relevance of this tool in the exploration of environments for the detection of people, the processing of images from the camera is performed [23], [24].

The stereo vision has the advantage of being wireless, so it is the main component of the artificial vision modules of the detection systems in robots [25]. An application is the tracking of objects, where it is necessary to estimate the distance of the object, thus achieving a high accuracy in real time [26]. Being complementary to other systems such as ”leap motion” for interfaces ”man-robot” for applications in robots EOD (bomb disposal) [27].

An anti-shock system is used to assist the operator in manipulating the robot by avoiding obstacles that may pass unnoticed by the operator. The main components of this system are usually infrared sensors, ultrasonic sensors, among others [28].

In the communication with the robot and the control center there are several options, for example the Zigbee model which has a central coordinator, routers and end devices using as XBee-PRO ZB S2B module [29], but taking into account the low cost objective of the project, it is considered to create a local WiFi network configured with the Raspberry Pi 4 controller. Due to studies conducted on different platforms of the different versions of Raspberry, it is concluded that the latest versions support better the WiFi network [30].

This document is divided as follows: The Methodology is presented in Section II. Section III describes the development of TXRob. Section IV presents the development of the control center. Section V presents the results obtained. Finally, Section VI presents the conclusions of the research.

II. Methodology

This paper presents the development of an exploration robot for post-disaster areas, TXRob. The reason for the development of the TXRob robot is the great need of agents dedicated to the rescue of people trapped in ruins caused by a natural or human disaster. The main features of TXRob are:

- Ability to overcome rugged surfaces and debris, dust and moisture resistance, and teleoperated control.
- Perfect for simple fabrication due to its low cost.
- Weight less than 10Kg and dimensions of 20cm x 30cm x 15cm, according to the category of exploration robots.
- It has gas, audio and webcam sensors to collect data from the environment where it is located and transmit them to the operator through its graphic interface located in the control station.

Fig. 1 is the representation of the complete system in a block diagram. First, the control station generates a wifi server, the TXRob robot connects to this network as a client. Through this network, the robot sends the data from the sensors and the video captured in real time. The values obtained by the gas sensors will serve to determine the environmental conditions, while the video, the microphone and the ultrasound will allow the detection of people trapped in the rubble. Later, again at the control station, the operator visualizes this information on the user interface and through a command can generate instructions that control the movement of TXRob through the motor drivers. A bidirectional communication is generated between the robot and the control station.

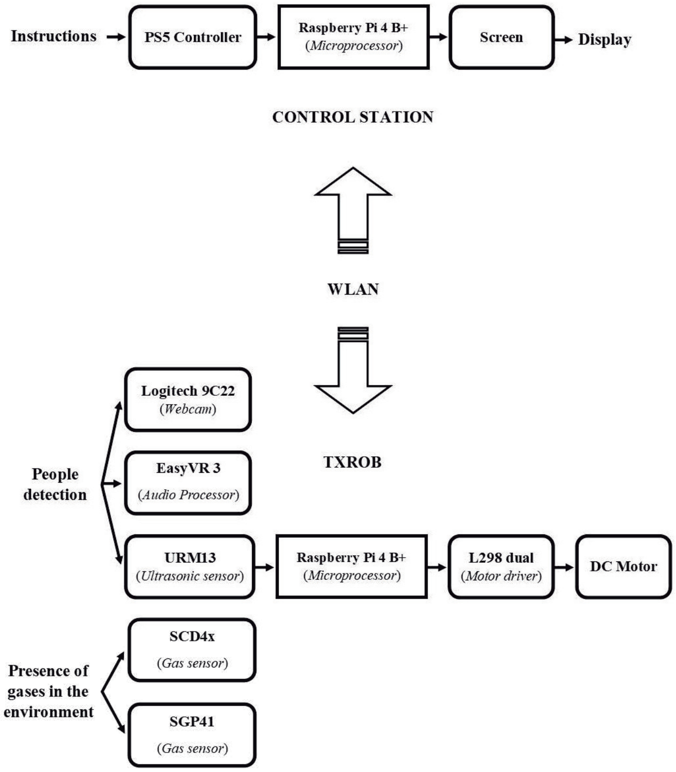

Fig. 1. System Block Diagram

The performance of the robot was measured in two evaluations, the first was an evaluation of the sensors in two different situations: an environment under normal conditions and an environment simulated under disaster conditions using a gradual and sustained increase in temperature, humidity and CO2. The second evaluation was focused on the versatility in displacement of TXRob on a flat surface and a rough surface, where the time needed to reach a given distance in meters was obtained.

III. TXRob Development

A. Mechanical Structure Design

SolidWorks software was used to produce the 3D design and generate the 2D drawings. The chassis of the robot is designed to be made of stainless steel, for its high durability and strength, so that the electronic components are fully protected. The motion system has a hybrid configuration between the rocket-buggie system, used in Martian rover explorers, and a crawler system, see Fig. 2 and 3. This rear-tracked configuration takes advantage of both systems; on the one hand, the left and right rocker suspensions are connected to the body through a differential balancing mechanism, which decreases chassis instability and pitching, while the tracked system is ideal for exploring rough terrain. The two front wheels allow for better handling and more efficient turns. Ultrasonic sensors are mounted front and rear to avoid collisions with the environment, and the top-mounted camera allows a greater field of vision.

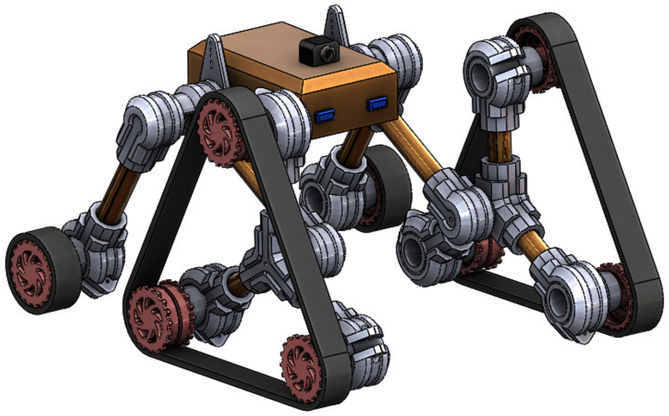

Fig. 2. Isometric View of the Mechanical Structure Design.

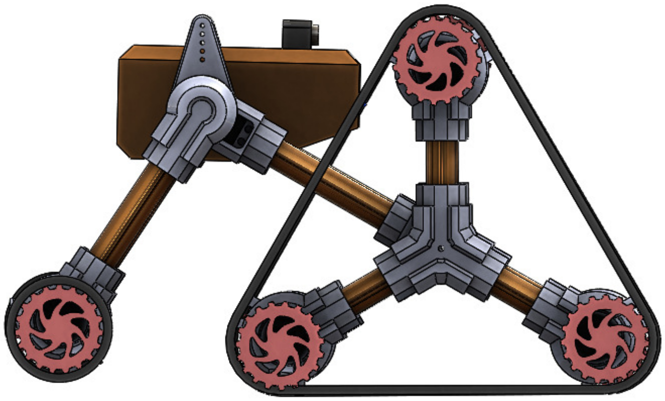

Fig. 3. Side View of the Mechanical Structure Design.

B. Electronic Circuit Assembly

For the development of the electronic and schematic design, the EasyEDA software with free license is used, available at the URL https://easyeda.com/es. This software has proven to have good performance and a fast learning curve at the basic and intermediate levels. Fig. 4 shows all the connections made for TXRob in addition to proper pin labeling. The component connections of the TXRob robot is centered on the Raspberry Pi 4 model B+ board, this Raspberry Pi model is the most recent on the market and has 8GB (gigabytes) of RAM, necessary to perform the video processing, data transmission and motion control of TXRob. This Raspberry Pi board is powered by a 7805 voltage regulator, shown at the beginning of the electronic diagram in Fig. 4, through pin 2, in addition this 5v power pin is also power supply for the sensors and webcam, and also provides a control level for the motor drivers (L298 dual). The L298 driver in addition to using 5v also requires a 12v source to power the motors, this voltage is supplied by the batteries through the VIN pin. The VIN pin is also the input to the 7805 regulator circuit.

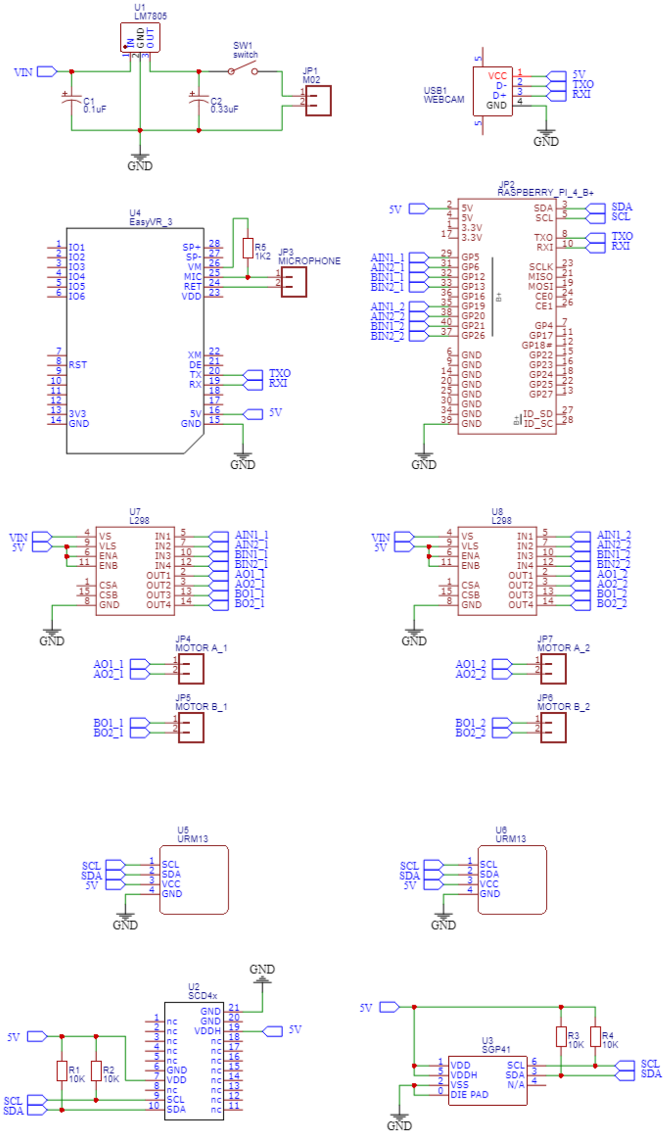

Fig. 4. Schematic Diagram.

1) Gas Sensors: In the exploration stage after a disaster, the environments are more closed, which increases the concentration of gases harmful to humans, so the measurement of these gases is a relevant point for rescuers.

- CO_2 Sensor: The CO_2 is not really a toxic gas but it produces the displacement of oxygen and in high concentrations of more than 30,000 ppm, it can produce asphyxiation. The use of this sensor will allow us to measure the ppm of the explored areas and to be able to analyze the different levels (See Table I). To determine the ppm values we have used the SCD41 sensor that allows us to measure a wider range, between 400 and 5000 ppm, has a typical minimum consumption of only 0.45mA at 3.3V and 0.36mA at 5V, which allows us to create CO2 meters with great autonomy.

TABLE I. CO_2 LEVELS

CO_2 **levels.**	**Air Quality**
250 -450 ppm	Typical atmospheric concentration
450-600 ppm	Acceptable concentration in the interior.
600-1000 ppm	Concentracion aceptable en el interior
1000-2500 ppm	Tolerable concentration. Drowsiness
2500-5000 ppm	Tolerable concentration. Headache. Stagnant air. Loss of concentration and attention.
6000-30000 ppm	Dangerous concentration, only light exposures.
30000-50000 ppm	Extreme concentration. Intoxicant
$>$ 50000 ppm	Extreme concentration. Permanent brain damage and death.

- Volatile Organic Compounds Sensor (VOC): Volatile Organic Compounds are air pollutants that, when mixed with nitrogen oxides, react to form ozone. The presence of high concentrations of ozone in the air we breath is very dangerous. The measurement of $VOCs$ is also relevant to the air quality in a space.
- NO_X Sensor: NO_2 is a toxic and irritating gas. Continued exposure to NO_2 is associated with various respiratory tract diseases.

For the measurement of VOC and NO_X, the SGP41 sensor was used, which has a measurement range from 0 to 1000ppm of ethanol equivalents and 0 to 100ppm of NO_2 equivalents, with a response time of less than 10s for VOC and less than 250s for NO_X necessary for real time sampling to determine the air quality of the area to be examined.

2) Ambiental Sensors:

- Temperature Sensor: The temperature in an environment is an essential indicator that can give us data, the presence of heat can give us to understand the presence of a person who is stuck in the debris.
- Humidity Sensor: Humidity is a factor that we must take into account, the excess of it in an environment can generate diseases or respiratory conditions.

3) Proximity Sensors: To support the teleoperation of the robot, it was decided to use these sensors, which allow us to measure distances and object detection. For the design, they were used for object detection and for an anti-shock system of the robotic structure.

- Infrared sensor: The infrared sensor is used in the market to measure distances in environments with absence of light which will allow us to detect obstacles within the area to be explored.
- Ultrasonic Sensor: The use of ultrasonic sensor as a support in the measurement of distances will help us to obtain more reliable values for the manipulation of the robot. The URM13 ultrasonic sensor has an excellent sensitivity with an effective measurement range of 15 cm to 900 cm with 1% accuracy and I2C communication.

4) DC Motor with Caterpillar: Greartisan DC motors are ideal for the movement of the robot. The proposed crawler system allows the robot to be transported over rough terrain and the powerful motors allow this system to be put into operation. The working voltage of the motors is 12v DC. The gearbox ratio is 1:22, with the specifications being: rated torque of 2.2Kg.cm, rotational speed of 200RPM and rated current of 100mA.

5) Camera: Vision is relevant in scanning robots in order to provide visual information of the operation environment. In addition, a camera was implemented to provide real-time video of the scanned scenario. Due to the costs, a USB camera was chosen. To achieve a teleoperation, through programming in Python language and the Flask framework, the real-time video display was converted to the WiFi network generated by the RaspBerry of the control station, i.e., the USB camera was configured to work as an IP camera, thus saving costs and obtaining the same benefits.

C. Motion Detection Algorithm

The developed detection algorithm performs a subtraction between a first frame captured by the camera ($t = n$) and the next frame ($t = n + 1$), when the value of each pixel obtained by this difference exceeds a threshold , considered threshold of 100 for presenting better results, the algorithm sends an alert to the operator, indicating that the robot has detected a person. Fig. 5 shows a person lying on the ground, which does not move, for that reason, the algorithm does not place red rectangles in the right window, and the left window is completely black. On the other hand, in Fig. 6, white areas are shown on the left, this is because the person has stood up, in addition, on the right there are six red rectangles around the person.

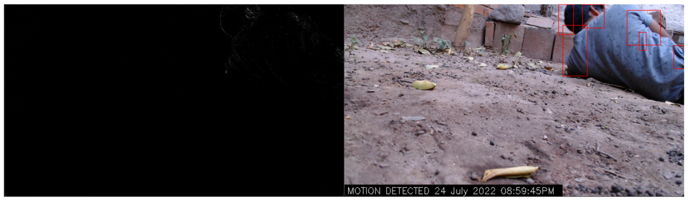
Fig. 5. Camera Frame without Motion Detection. a) Differential Window. b) Original Video Window Plus Motion Limiting Zones.



a) b)

Fig. 6. Camera Frame with Detected Motion. a) Differential Window. b) Original Video Window Plus Motion Limiting Zones.

IV. Control Station Development

A. Robot Control

The robot is controlled by a PS5 Dualshock5 controller connected to a Raspberry Pi (Control Station), which through wireless communication sends the instructions received by the controller to another Raspberry Pi located in the robot. The signal acquisition from the controller was made possible thanks to the implementation of Pydualsense, a package that uses the HID library to capture the controller signals, as well as offering the possibility to control various features of the controller such as LED activation, vibration level, etc.

B. Graphic Interface

The graphical interface refers to the video experience perceived by the user operating the robot. The interface shows the measurements collected by the different sensors, as well as relevant data and information about the system overlaying the video captured by the video camera. The interface was developed using Pygame and OpenCV for its versatility and ease of use.

C. Communication

For the reception and transmission of data between the control station and the robot, a local WiFi network was created in the control station, which handles server and client protocols in the data bus, in addition to this, the use of sockets is proposed for sending and receiving the values obtained from the different sensors.

V. Results

A. Sensor Evaluation

For the evaluation of the integrated sensors, it was proposed to make two measurements in two different conditions, the first one a simulation of disaster environment, where the robot will remain for 25 minutes to take the necessary measurements and a second measurement but in a clear environment under normal conditions for a human being. The results obtained are reflected in Fig. 7 for the measurements in disaster environment and in Fig. 8 for the measurements in normal environment.

The results obtained in a simulated disaster environment show a sustained increase of CO_2 and temperature values over time, which could be reflected in a hypothetical case of disaster, where a potential victim's health would be compromised in a very considerable time interval. The analysis of these data allows the generation of a standard regression curve in which an estimation of the maximum time in which the person would reach critical values is obtained, taking into account the permitted levels of CO_2 in a closed environment, see Table I.

The distance sensors were also evaluated to measure their reliability in providing information to the operator about the perceived distances in the environment. Measurements were made with the sensors as shown in the Table II below.

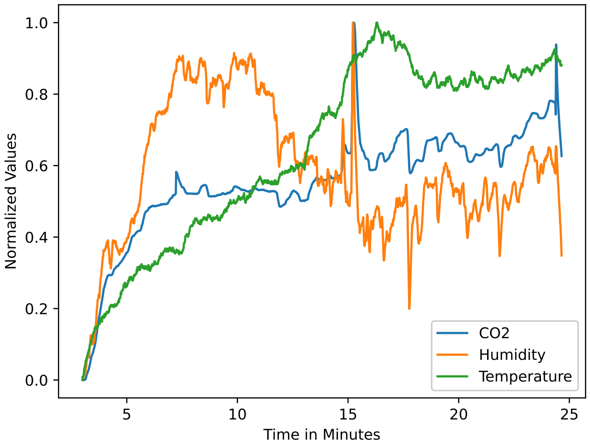


Fig. 7. Measurements taken by TXRob in a Simulated Disaster Environment.

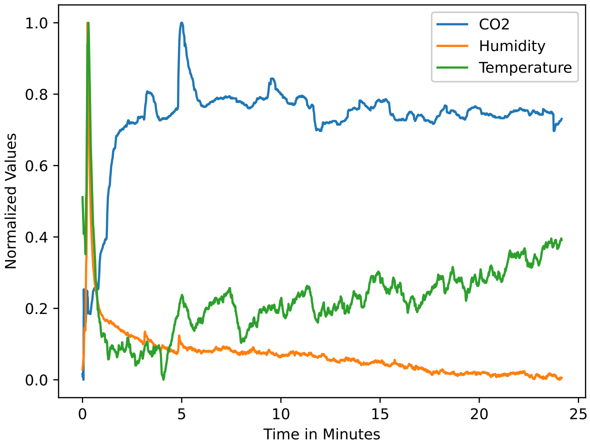

Fig. 8. Measurements taken by TXRob in a Normal Environment.

TABLE II. Measured Distances

Real	100cm	105cm	110cm	115cm	120cm	125cm	130cm
1	101cm	107cm	109cm	114cm	121cm	124cm	130cm
2	101cm	105cm	109cm	113cm	122cm	125cm	131cm
3	100cm	107cm	110cm	112cm	120cm	125cm	130cm
4	101cm	105cm	109cm	113cm	119cm	126cm	128cm
5	99cm	105cm	109cm	114cm	119cm	125cm	130cm
6	100cm	105cm	110cm	112cm	120cm	125cm	131cm
7	99cm	106cm	111cm	113cm	120cm	125cm	129cm
8	100cm	105cm	110cm	114cm	121cm	124cm	129cm
9	98cm	106cm	109cm	115cm	120cm	126cm	132cm
10	100cm	107cm	109cm	115cm	121cm	124cm	131cm

B. Robot Performance

Fig. 9 shows the graph of the time required for the robot to reach the place where the injured person is. From the results, the time required for TXRob to be able to reach the location is directly proportional to the distance it is for flat terrain with no slope. In Fig. 10 the time required for TXRob to reach the site is shown in the same way, but in this test an uneven terrain was considered, with rubble and a slightly steep slope (15 degree slope). It can be seen that for the second test the time increased, but this increase is not so great, so it is not a problem for the robot.

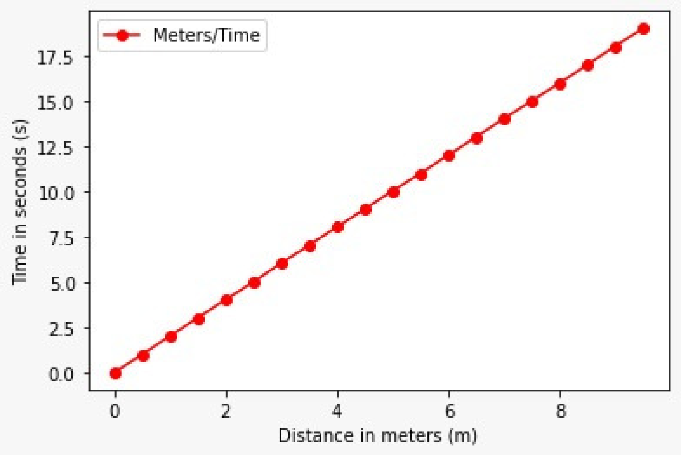

Fig. 9. Plot of the Time required for TXRob to reach the Location on Flat Ground.

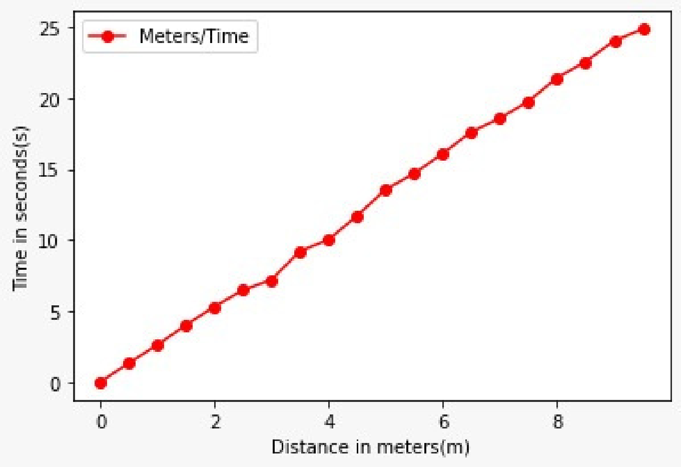

Fig. 10. Plot of the Time required for TXRob to reach the Site on Rough Terrain, with Rubble and a Slight Slope.

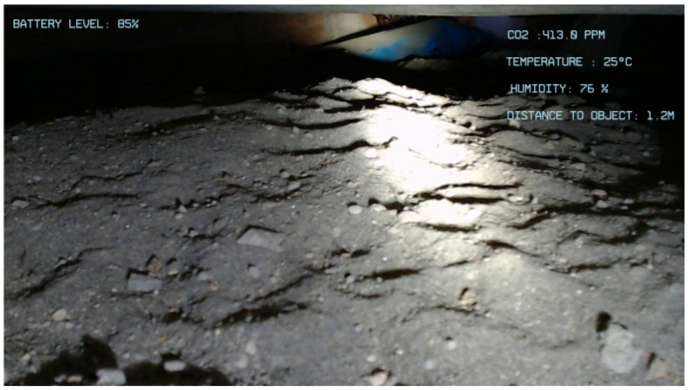
C. Display to User

The user display is composed of the video transmitted live by the camera in 720p resolution, together with the measurements obtained in real time by all the built-in sensors. The user display is shown in Fig. 11.

VI. Discussion

Based on the results obtained, the sensors measured and recorded satisfactorily the changes in temperature, humidity and CO_2 when they were subjected to a disaster environment, in the section of Robot Performance, TXRob reached the average speed of 0.47 m/s on a flat surface and 0.36 m/s on a rough surface, making possible the task of exploration in a hypothetical case of disaster where access to possible victims is very reduced due to obstacles, so it is possible to affirm that the measured characteristics of TXRob can fit perfectly in a low-cost robot for exploration and possible rescue work in areas of incidence of natural disasters such as landslides and earthquakes.



BATTERY LEVEL: 85%
CO2 :413.8 PPM
TEMPERATURE : 25°C
HUMIDITY: 76 %
DISTANCE TO OBJECT: 1.2M

Fig. 11. Display Shown to the User.

VII. Conclusion

This paper presents the successful development of a rescue robot for post-disaster scenarios (TXRob), capable of being remotely controlled, i.e. teleoperated. Demonstrating the reliability of the built-in WiFi network based on the Raspberry Pi4 platform. This robot has advantageous features, such as the ability to automatically detect the movement of potentially trapped or endangered people, analyze the environment and determine if it is suitable for rescue agents to enter, and has a suitable design that allows it to move over rough terrain and debris. TXRob also has the ability to avoid strikes by having proximity sensors that alarm the operator, with the results demonstrating the accuracy of the proximity sensors. In addition, its compact structure allows it to access areas inaccessible to humans, which means better exploration of landslides. From the experimental results we can conclude that TXRob can detect different concentrations of gases such as CO_2, NO_2, among others.At the same time that the data obtained by means of the sensors are satisfactorily shown on the display, being the object of future research to be shown in a virtual environment. Finally, it is demonstrated that the robot is able to move through rough terrain in a short time, in summary TXRob is a versatile robot for the rescue of people.

***Abstract*—The tariff fraction is the universal form of identifying a product. It is very useful because it helps to know the tariff that the product must pay when entering or leaving the country, in this case Mexico. Coffee is a complicated product to identify correctly due to its variants, which at first glance are not distinguishable, which can cause confusion and the tariff to be charged incorrectly. Therefore, the main objective of this project was to develop a system based on Deep Learning models, which allow to identify the tariff code of coffee to import or export this product through the analysis of digital images in real time, generating automatically a general report with this information for the customs broker. The developed system allows speeding up the process of assigning the tariff fraction, and also allows the correct assignment of the tariff fraction, avoiding confusion with other products and the wrong collection of the tariff. It is important to mention that the system, although for the moment it is focused on the country of Mexico, can be used in all customs offices since the tariff fraction is universal. The evaluation of the models was carried out with cross-validation, obtaining an effectiveness of more than 80%, and the tariff fraction assignment model had an effectiveness of 90%.**

***Keywords*—Machine learning; digital image processing; automation process**

I. Introduction

The Harmonized System (HS-code) of Tariff Nomenclature created by the World Customs Organization is widely applied to standardize the exchange of internationally traded goods. The code consists of six digits in general for all countries and in tariff fractions. The tariff fraction is an eight-digit code that represents a good within the Tariff of the General Import and Export Tax (TIGIE). Based on the assignment of the code, the tariff regulations that must be satisfied for the import or export of the goods are established. However, incorrect assignment of the HS-code can result not only in non-compliance with tariff regulations and restrictions, but can also lead to fines, infractions to customs agents or even seizure of the goods [1]. Among the products that are difficult to classify correctly for HS-codes assignment are coffee beans due to the varieties that exist and the different degrees of roasting. In general, coffee beans can be classified into four varieties: Arabica, Excelsa, Liberica and Robusta [2]. However, the classification process for unfamiliar people can be a very complicated task, even for an expert in the domain. This is explained by the fact that the shape and color of the different varieties look similar upon visual inspection. In the field of computational learning, different models have been evaluated to address the automatic classification of coffee beans [3], [4], [5]. This is especially useful for the correct assignment of HS-codes to avoid the negative consequences mentioned above. For this research, a modified basic deep learning architecture [6] was used, in which two layers of feature detection were incorporated. Two databases were integrated, first one consist of 200 images, 50 for each of the main coffee bean varieties: Arabica, Excelsa, Liberica, and Robusta. The second one, include 60 images for three categories of roasted: Not Roasted, Roasted and Dark Roasted. The model built was incorporated into a web-based system to assist in the process of correctly assigning tariff fractions. The performance achieved was 90% accuracy.

The paper is organized as follows: Section II provides a review of studies related to the application of machine learning models for HS-codes assignment as well as works that use this type of models to classify coffee beans with different purposes. Section III describes in detail the methodological strategy applied and the results obtained, as well as their discussion. In the final part, conclusions and future work are presented.

II. Related Work

In the international coffee marketing industry, several studies have been developed to improve the general correct assignment of HS-codes, identification of defects in the coffee beans and also correct class assignment of coffee beans.

In 2015 a paper was published related to the trading system for Singapore Customs, which was based on classifying accurately products and assigning HS-codes based on the text description of the declarations. The technique used was a Background Net. The actual transaction dataset after the pre-processing stage consisted of 40,861 records from chapter 22 and 83,830 records from chapter 90 according to the HS-code system. The data were split 60/40 for the training and testing phases, respectively. The results showed that the model employed had an accuracy greater than 90% for chapter 22 but significantly low for chapter 90 data with accuracy values of around 70% [7]. In another research, several machine learning models were explored to predict HS-code based on commodity descriptions entered by customers. The study followed the cross-industry data mining process methodology. The linear support vector machine model was able to achieve the highest accuracy of 76.3%. The dataset was provided by Dubai Customs through an Artificial Intelligence (AI) hackathon competition held in October 2019. This data consisted of 22,346,194 records where each record had two attributes; the Harmonized System Code (HS-Code) and the description of the user inputs. The machine learning models applied were: Naïve Bayes, K-Nearest Neighbor, Decision

Tree, Random Forest, Linear Support Vector Machine and Adaboost. The authors propose in their study that a hierarchical prediction could be built from the HS-Code header until all the subsections of the HS-Code are identified [8]. The issue of automatic classification of Hormonized System Codes (HS-codes) based on the descriptions provided by the users is also addressed by [9]. Three different Deep Learning architectures were evaluated in the experiment: Hierarchical logistic regression, Neural Machine Translator (NMT) and Long Short Tem Memory (LSTM), the latter two with and without hierarchical loss. Thus, 5 models were analyzed. The dataset consisted of eight months of shipments to a country via the DHL network, which included 1,156 million records. However, records of mask/kn95 shipments and blood samples were excluded so that the results would not be biased by the unusual shipment situation caused by the COVID-19 pandemic. The results showed that the NMT model with hierarchical loss obtained the best performance reaching an accuracy of 85%. In [10] is mentioned that deep learning can be defined as a waterfall that performs non-linear processing to learn multiple levels of data representations. In this context, the study by Lee et al. reports the application of a Deep Learning model to assist in the assignment of HS-codes in collaboration with Korea Customs Service. In the experiment 129, 084 cases were evaluated and the top-3 suggestions made by the model achieve an accuracy of 95.5% [11].

There have also been studies have also been carried out on the topic of coffee bean classification. In [3], measurements in the CIE L*a*b color space are used to characterize green Arabica coffee beans provided by growers in the State of Minas Gerais, Brazil. The algorithms used were a Multi Layer Perceptron feed-forward Artificial Neural Network (ANN) and Naïve-Bayes. The authors report an accuracy of 100%. The data set consisted of 20 samples of 50 grams, 30 images per color were obtained from the following groups: off-white, green, cane green and blue-green. In another study, feed-forward back propagation neural network and K-nearest neighbors algorithms were compared to classify coffee beans from different villages in Cavite, Philippines. The varieties included were Robusta, Excelsa and Liberica. The dataset consisted of 255 images, which were divided into 195 samples for training and 60 for the testing phase. Four morphology characteristics were used in the experiments: area, perimeter, equivalent diameter and percent roundness. The accuracy achieved was 96.66% with ANN and 82.56% with k= 4 for KNN [4]. In [5], 255 samples from the province of Cavite, Philippines were used. The data set included 85 samples per species, considering three species of green coffee: Robusta, Liberica and Excelsa. The images were converted to grayscale to extract morphological characteristics. The experiment included 22 classifier algorithms from 5 families: Decision Trees, Discriminant Analysis, Support Vector Machine, K-Nearest Neighbor and Ensembles. The results showed that Coarse Tree algorithm achieved the best result with 94.1% accuracy. Although in a previous work of the author an accuracy of 96.6% was obtained, it is explained that the Coarse Tree algorithm was faster in the time required for the training phase. Other research aimed to detect and classify Luwak coffee green beans purity into the following purity categories, very low (0-25%), low (25-50%), medium (50-75%), and high (75-100%). The research compared the performance of four pre-trained convolutional neural network (CNN) models: SqueezeNet, GoogLeNet, ResNet-50, and AlexNet. GoogLeNet obtained the best result in training and validation steps and achieve an acuraccy of 89.65% [12]. In the study of Walleign et al., the images of coffee bean samples were collected at Jimma Grading Center in Ethiopia, the beans from the 300 gram sample used for raw evaluation were used to prepare the dataset consisting of 1266 images of coffee beans from 12 quality grades. The dataset was divided into three sets for training (70%), validation (10%) and testing (20%) and accuracy of 89.1% was achieved on the test dataset [13]. In [14], 74 coffee beans of different origins were analyzed and separated into two species: Arabica and Robusta based on their fatty acid composition. The study was based on a Deep Learning approach using a conversion of the raw data into Z-score format. The authors comment that different types of conversion can affect the classification results of coffee species. Statistical analysis and Linear Discriminant Analysis were also used to extract robust features that influenced the Machine Learning process. The author [15] mentions that his article determines the species of coffee bean using the GLCM model (Gray Level Co-Occurrence Matrix) with the help of artificial neural networks. What this author does is create a new method to determine the different species of coffee beans: Arabica, Excelsa and Robusta. 120 images were used for training and 60 images for testing. This author concluded that image processing is effective in determining the quality of coffee bean variants, the ANN classifier had an experimental accuracy of 97.06% which shows that ANN classifier is reliable to classify which species of coffee beans.

On the other hand, several researches have been reported different methods to identification of defects in the coffee beans, for example, he work of Akbar and collaborators was based on the measurement of the quality of green Arabica coffee to classify the beans into five different levels of defects. The extraction of color and texture features of coffee beans was done through color histogram and local binary pattern. The machine learning techniques used were Random Forest and K-Nearest Neighbors, which achieved accuracies of 87.87% and 80.47%, respectively. The experiment included a balanced data set with a total of 900 RGB images for the five classes (defect levels). The data were divided in a 66/33 ratio for the training and testing stages. Authors mentioned that blurred images generated inconsistent values in feature extraction and could lead to incorrect predictions in the classification algorithms [16]. In [17], four models off CNN from Keras Framework were evaluated. The coffee roasting frames were divided into three classes that are Not Yet, Accepted, and Rejected, following the development of coffee bean during the roasting process. The dataset consisted of 4,464 images in Not Yet Class, 3,168 in Accepted, and 3,312 in Rejected. The dataset prepared for deep learning model training had a total of 10,944 images and they were processed into 60% training, 20% validation, and 20% test. The deep learning model training final result showed accuracy >97%. Other research, also focused on the development of more efficient methods to select coffee beans based on shape and particularly, on color descriptors achieved values >88% of accuracy. The techniques applied were Support Vector Machine (SVM), Deep Neural Network (DNN) and Random Forest (RF), to assess coffee beans' defects. Images of each class were taken separately, accounting for a total number of 635 samples (coffee beans) [18]. In other work, an AlexNet-based deep learning model was applied to detect eight types of defects in coffee beans with an accuracy ratio of 95.1%. The original dataset included 3261 samples but by rotation and data augmentation, 7203 images were acquired because the initial set contained few samples with defects [19]. Chou and collaborators proposes a model based on Deep Learning to inspect coffee beans and a Generative-adversarial network (GAN) for Structured Data Augmentation. The proposal aims to contribute to intelligent agriculture with the application of these techniques to remove beans with defects categorized by the SCAA (Specialty Coffee Association of America) and minimize human effort in the process of labeling coffee beans. The model reports an accuracy of over 80% [20]. Previous studies have shown the availability of image processing and machine learning techniques, in [21] is reported the application of techniques such as Convolutional neural networks (CNNs), Support vector machines (SVMs), and k-Nearest-neighbors (KNNs), for the classification of peaberries and normal beans. The separation of peaberries and normal coffee beans increases the value of both peaberries and normal coffee beans in the market. According to the authors, the combination of the CNN and Raspberry Pi 3 holds the promise of inexpensive peaberries and a normal bean sorting system for developing countries. The trained CNN could classify approximately 13.77 coffee bean images per second with 98.19% accuracy of the classification. In [22], an intelligent coffee bean quality inspection system based on deep learning (DL) and computer vision (CV) was developed to assist operators in detecting defects, including mold, fermentation, insect bites, and crushed beans. An open-source dataset of coffee bean images was used for testing. The dataset contains 4626 images of green coffee beans under the same light source, of the total there are 2150 and 2476 images of good and defective beans, respectively. In the experiment, the dataset was divided into a training set of 4000 images and a testing set of 626 images. The accuracy of the ResNet-18 model reached about 93% in the testing set. The student model achieve an accuracy of 79%. The author [23] makes mention in his research that he develops a system which, through convolutional neural networks, is capable of detecting defective coffee beans, for example beans that have some type of imperfection, this author also makes emphasis on that they performed five classifications of defective and non-defective beans better performance with CNN was obtained in all types of defects classification precision was more than 90%.

Finally, we identified some research focused in determine other kind of characteristic of the coffee, flavor and quality, among we can cited the follow: In [24] they mention that the aim of other research is to investigate the feasibility to train machine learning (ML) and deep learning (DL) models for predicting the flavors of specialty coffee using near-infrared spectra of ground coffee as the input. The authors mentioned that effective models provided moderate prediction for seven flavor categories based on 266 samples. The Machine Learning methods applied were Support vector machine and the Deep convolutional neural network (DCNN), which achieved similar performance, with the recall and accuracy being 70–73% and 75–77% respectively . Other study describe a method to classify the geographic origin of coffee beans, comparing popular machine learning methods, including convolutional neural network (CNN), linear discriminant analysis (LDA), and support vector machine (SVM) to obtain the best model. Principal component analysis (PCA) and Genetic algorithm (GA) were applied for LDA and SVM to reduce dimensionality. Ninety-six samples of Arabica coffee beans, representatives of three different geographical origins, were analyzed in the study. The results shown an accuracy of 90% in a prediction set achieved using a CNN method [25]. The author [26] mentions that the evaluation of the color of green coffee beans is an important process to define their quality and price in the market and that this process is normally carried out by means of a visual inspection, this causes some limitations. To solve this, they carry out a system capable of obtaining CIE measurements (Commission Internationale de l'Eclairage) of the coffee beans and in turn classify the beans of this product according to their color. Artificial Neural Networks (ANN) were used as the transformation model and the Bayes classifier was used to classify the coffee beans into four groups: whitish, cane green, green, and bluish-green. The neural networks models achieved a generalization error of 1.15% and the Bayesian classifier was able to classify all samples into their expected classes (100% accuracy).

The review shows that some of the related studies use machine learning models applied to the assignment of HS-codes but not precisely to classify coffee beans. In some cases, the accuracy is not higher than 70%. Experiments using Deep Learning techniques or hierarchical models are also reported, some even considering the top three classification suggestions to increase their performance. However, they either focus on coffee purity categories or defect levels for some variety of coffee beans, or they address only on the roasting process. On the other hand, they have approaches towards intelligent agriculture or the discrimination of peaberries and normal coffee beans, distinction of coffee flavors or identification of the geographical origin of the beans. It is necessary to mention that although one of the works reported 100% accuracy, it is possible that this was due to overfitting because only 20 samples were used. So, we propose the use a CNN model to resolve the problem of this research, classify the variety of coffee beans from digital image analysis. Some researches that report imaging classification from Deep Learning models are: [27] in where the authors make mention that the use of computer vision tools have had a strong impact on the industry given its varied applications and its ability to automate complex and demanding processes. One example of the applications of this kind of tools is the recommendation of clothing in online purchases, up to the characterization and generation of clothing statistics in physical stores. In [28], product recognition can be perceived as a particular research issue related to object detection. However, its application of product image recognition is still less perfect. Thereby, the relevance of our research is to propose a CNN model considering the assignment of tariff fraction for four varieties of coffee beans. There are two important issues to consider in the application of deep learning models. Deep learning algorithms have been used mainly in applications where the data sets were balanced or, as a workaround, in which synthetic data was added to achieve equity. Another concern is that deep learning relies predominantly on large amounts of training data. On the other hand, it is worth noting that the rise of deep learning has been strongly supported by major IT companies (e.g. Google, Facebook, and Baidu) who own a large number of patents in the field and major companies are backed substantially for data collection and processing.

Based on the above, the following differences of this work with those previously described can be highlighted:

- We do not seek to identify imperfections, which focuses on identifying shape features, but the work of [23] gives evidence that it is possible to extract features from images of coffee beans.
- The work of [26], it focuses on the distinction of colors identifiable with the naked eye, which does not happen when images of already toasted coffee beans are analyzed, which is common in a process of importing or exporting coffee in some country, that is, our problem is not reduced to distinguishing different categories of maturation of a coffee bean but to distinguish the variety of coffee from the analysis of a bean with a specific maturation.
- In [15] use an ANN, in our case you propose to take advantage of the advantages provided by the use of a CNN, in addition to including one more kind of coffee.

III. Results

The principal results of this research are reported in four parts, the data set of coffee beans image, the model to identify the variety of coffee beans, the model to determine the tariff fraction and the system to merge the models and generate the documentation related to specific variety of coffee identified.

A. Dataset of Coffee Beans Images

We searched images of coffee beans from several sources of Internet where it specifies the variety showed, and we also obtained real images of coffee beans that we obtained from a coffee beans shop, and then we built two data sets:

Dataset 1, for classifier model of coffee classes: This repository contains images of the four classes of coffee which are: Arabica with 50 images, Excelsa with 50, Liberica with 50 and Robusta with 50. Dataset 2, for classifier model of tariff fraction: The base for this model contains images of three classes of coffee which are: 60 Not Roasted, 60 Roasted and 60 Dark Roasted.

B. Deep Learning Model for Coffee Bean Variety Classification

Deep learning (DL) is a subset of a larger family of data representation-based machine learning algorithms.

The first DL model assigns the variety of coffee that corresponds to a certain image of coffee beans, which can be: Arabica, Excelsa, Liberica or Robusta. For this model, as for the one in the following section, we used the basic deep learning CNN architecture [6] with two feature detection layer. The base model is presented in Fig. 1, which considers input images of 150x150 pixels. The first convolution layer expands the information to 32 levels deep for convolutions, pooling reduces the visual information to a quarter of its size (75×75 pixels). 6x6 size filters were used. In the next stage, the information for convolution was duplicated, although with a smaller filter (4x4). Pooling was applied again, reducing the information from the previous layer to a quarter of its size (37×37 pixels). After that, the flattening layer was applied and the information was reduced to a vector of size 256. Finally, a Softmax layer was applied to describe the probabilities for each of the four classes (variety of coffee) to be predicted. Some changes were made due to the fact that satisfactory results were not obtained with the base architecture. Two layers were modified, one of convolution and one of reduction, in the same way an Adam optimizer was chosen, which is within the classification layer, this optimizer was chosen since it has a more effective error reduction. More details of the layers of the architecture used for the developed deep learning model are illustrated in Table I.

TABLE I. Summary of the Architecture used to Built Deep Learning Model for Coffee bean Variety Classification

Specs
Convolution layer (32) + Filter (6,6) + Height, Length (150)
Pooling
Convolution layer (64) + Filter (4,4)
Pooling
Classification layer (ReLu), 256 neurons, Softmax, Adam optimized

In more general terms, the first convolution layer will process images from coffe beans with a certain height and length (it will be resized to 150x150 px), and this layer will allow us to detect basic characteristics such as curves or lines, basic textures and so on from the images. For the first reduction layer we say that it will have a maxpooling and a certain pool size, this layer reduces the first convolution layer in order to gain some scale invariance in the input images. For the second convolution layer it is basically the same as the first one, except that in this image we will no longer assign a height, length, nor will it have any activation function. For the second layer of reduction we say that it will have a maxpooling and a 37×37 size of pool, to again, gain some extra invariance. This layer reduces the second layer of convolution. The classification layer contains a property which makes the image, which is now very deep and very small, will now become one-dimensional that contains all the information of our neural network, it also contains 256 neurons and the ReLu activation function, it does a dropout process which makes 50% of these neurons activate at each step (number of times the information is processed), this is done so that it not only learns a specific way to classify coffee and can adapt to new information (some kind of overfitting prevention) and the number of coffee classes which the model will contain in this case are four. Finally, this model in order to classify the variety of coffee beans required 22467300 parameters. In the two convolutions the number of parameters was 3488 and 32832 respectively. Once the network is flattened, the number of parameters to learn is 22429952. In the last classification layer, only 1028 parameters are required in order to detect four classes. A decimation function was performed to fit the images to the model input of $150 \times 150 \times 3$ pixels.

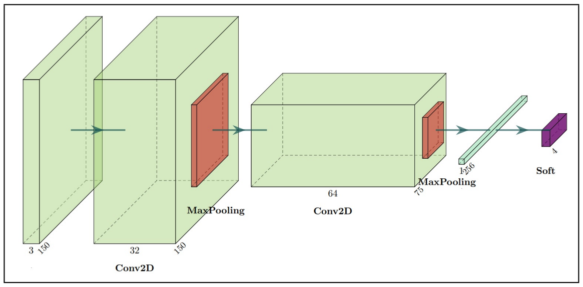

Fig. 1. Base Architecture of the Model used to Estimate the Four Classes of Coffee Beans. The Architecture that Estimates the Roasting Levels is Similar, having Three Classes in the Last Layer Instead of Four. More Details in the Tables I and II.

C. Deep Learning Model for the Identification of Tariff Fraction

The goal of this model is to classify the coffee into the following classes: Not Roasted, Roasted and Dark Roasted, once the coffee is classified within any of these, the model will assign a tariff fraction which is obtained from a database and it will generate detailed information of the product. In contrast as the previous model, the base architecture of CNN model was used, like show the Table II (note that, it is very similar to the corresponding architecture presented in Fig. 1). This is because, in this case, the classification focuses on color identification. In this second model, only the first convolution layer changes, reducing its number of parameters from the first convolution to 1568 (the first contains 3488). The final number of parameters therefore in this model was 22465380 parameters. These 22 million parameters were trained using a traditional Adam optimizer based on the Tensorflow library in the Python programming language. Since the training images consisted of a reduced dataset (due to the few examples found in the literature, even including our own examples), the model was not expensive to train locally. The effectiveness of the model (Section III-D) shows the results using a cross-validation technique, which could be done efficiently due to the few image examples mentioned above.

TABLE II. Summary of the Architecture used to Built Deep Learning Model for the Identification of Tariff Fraction

Specs
Convolution layer (32) + Filter (4,4) + Height, Length (150)
Pooling
Convolution layer (64) + Filter (4,4)
Pooling
Classification layer (ReLu), 256 neurons

D. Models Effectiveness Report

To validate the performance of the models we used 10 cross-validation, because the size of datasets, thereby we used 80% of data set to train the model and 20% for validation; this was applied to both models.

The obtained results (averages) are showed in Tables III and IV, performance of the model to identify the coffee class and performance of the model to identify the tariff fraction, respectively. The tables present precision, recall and f1-score measures, as well as the micro, macro and weighted measures.

TABLE III. Performance of the Coffee Variety Classifier Model

	Averages		
Class	Precision	Recall	f1-score
Arabica	72.70%	80.00%	75.60%
Excelsa	79.90%	90.00%	83.80%
Liberica	91.00%	78.00%	83.90%
Robusta	100.00%	90.00%	94.50%
		Macro	Weighted
Precision		86.00%	86.00%
Recall		84.60%	84.10%
F1-Score		84.30%	84.40%
Accuracy (Micro avg)	84.10%		

TABLE IV. Performance of the Tariff Fraction Classifier Model

	Averages		
Class	Precision	Recall	f1-score
Not Roasted	98.30%	98.00%	98.00%
Roasted	87.20%	88.00%	86.30%
Dark Roasted	89.20%	84.00%	85.40%
		Macro	Weighted
Precision		91.40%	91.40%
Recall		90.00%	90.00%
F1-Score		89.80%	89.80%
Accuracy (Micro avg)	90%		

The results of the Table III show that the model has a greater error when identifying the Arabica class, this is probably due to the fact that it has too much similarity, visually, to the Excelsa class. Fig. 2 shows the confusion matrix obtained for the results in Table III. The matrix shows more clearly the errors between the Arabica and Excelsa classes.

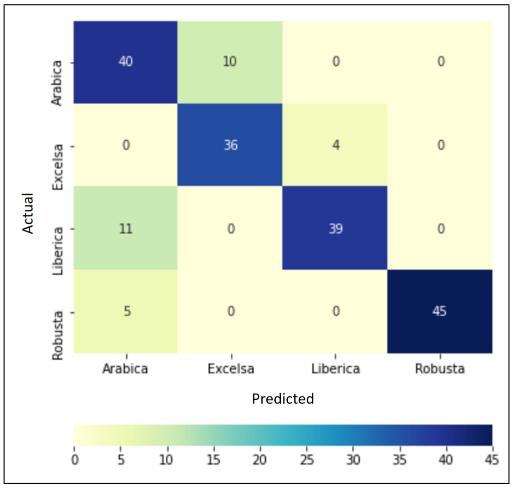

Fig. 2. Confusion Matrix of the Four Classes of Coffee Beans recognized by the Model. The Results show that Arabica Coffee is more difficult to Distinguish and is Confused with Liberica and Excelsa. Robusta is the Easiest Class of Coffee to Distinguish by the Model.

On the other hand, due to we have balanced classes, the measures micro, macro and weighted were similar, and we can take the micro measure as the Global Accuracy of the model. Thereby, the model have a global accuracy greater than 80% and the performance measured of each class show that the model is capable to distinguish the coffee beans class with good performance despite of visually them have the same color and shape.

OSTC is a system capable of analyzing the coffee bean by means of a photo to determine the tariff fraction and its description in an automatic way. If you wish to analyze the coffee to obtain the corresponding information, click on the button "Analyze Coffee".

The tariff fraction is the universal form of identification, this can be very useful to know the tariff that the product must pay when entering abroad, as well as to know the non-tariff regulations imposed by Mexico and the country with which you want to exchange merchandise. It is important to mention that the legal responsible for the correct tariff classification is the customs broker, in case it is considered that the goods can be classified in more than one tariff fraction, the customs authorities can be consulted by means of a written document.

Fraction: 9011101

Fig. 3. Sequence and Interfaces of Web System Usage. A) Main Interface, where a request of an Image to Analyse is Performed, B) Interface to Upload the Image to analyse by the Deep Learning Models, C) Interface where the System Presents the Class of Coffee Beans and the Tariff Fraction associated to them, and D) Final Report generated automatically by the System.

The results of the Table IV show that the model has a greater error when identifying the Roasted class, according to the performance measures for class, this is probably due to the fact that the roast sometimes has an identical tone to the dark roast and therefore the model becomes confused. Fig. 4 shows the confusion matrix for the results of Table IV. The difficulty in recognizing coffee beans with “roasted” and “dark roasted” levels can be seen more clearly.

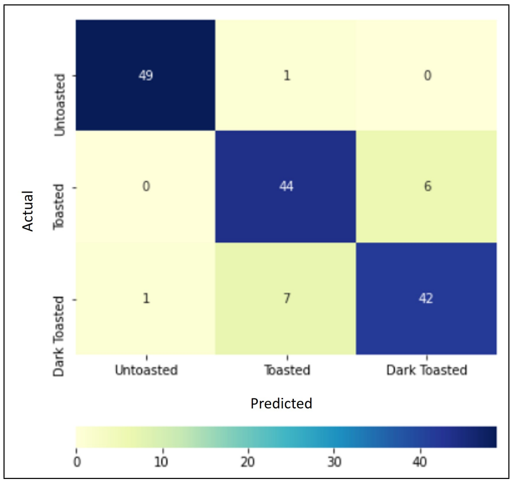

Fig. 4. Confusion Matrix of the Three Levels of Roasting. As Might be Expected, Roasted and Dark Roasted Classes are more difficult to Distinguish Since they have Similarities in Visual Appearance if Particular Coffee Beans are taken. These Results Reflect Visual Consistency for Coffee Roasting Levels.

In the same way that the other of our models, we can consider the micro measure like the global accuracy, 90%. This result is comparable to the similar work of [26] where their objective is to identify different types of coffee beans according the color of them, and they reported a global performance of 97.06%.

E. Web System

Finally, a web system was built, where the created Deep learning models were integrated, this system automatically assigns the tariff fraction of coffee beans from the analysis of a digital image, that image is entered into the first model and this determines the variety of coffee, then the second model determines if the coffee beans are roasted, dark roasted or not roasted in order to assign the corresponding tariff fraction. Finally, a document is automatically generated which contains the image uploaded by the user and the tariff item broken down in detail. The Fig. 3 shows images of the interfaces system and the general process to use it.

F. Discussion

This article presented the structure and model of a system that allows determining types of coffee beans as well as the roasting level in order to assign the tariff fraction as support in customs and, therefore, usable by customs brokers. It was noted that there is little information on visual datasets about coffee beans. Mostly concrete examples exist but not *many* image examples. This implied an interest in generating a small compendium of images generated by the authors of this work that allowed strengthening the results of the computer vision models presented. Computer vision models are based on Deep Learning techniques that, unlike the state of the art, present a lighter architecture in order to achieve finer recognition of coffee beans patterns that are usually difficult to identify with the naked eye. With the accuracy obtained from the models, the results were used to estimate the tariff fraction. These results, taken to a web system, facilitate the manual task of estimating said tariff fraction by people who are not familiar with agronomy and, in particular, with coffee beans varieties, or their roasting level. In addition, even when the main goal for this project is to facilitate the process of entering and leaving coffee from our country, since the system is web-based, it can be used ubiquitously by a diverse number of users, requiring only an Internet connection.

IV. Conclusion and Future Work

We have were present a novel system to automatically distinguish the variety of coffee from the analysis of a bean with a specific maturation, Arabica, Excelsa, Liberica, and Robusta, with a accuracy gather than of 80%, that is relevant in a process of importing or exporting coffee in some country, which helps to avoid the negative consequences of incorrect classification. Which is one of the main differences with similar works, given that these works only report the development of machine learning models but do not report their implementation in any tool that is easy to use by end users.

So, we described the deep learning models built and the accuracy of them, 84.1% for model for coffee bean variety classification and 90% by model the identification of tariff fraction respectively. These results are comparable with research in the state of the art. In this way, this results support the feasibility of the application of these model to the tariff fraction assign process.

The base architecture used for the development of Deep Learning models was very useful since not many changes had to be made for model classify of coffee, and no changes were done for the tariff fraction assign model.

The assessment made by end users was good and they consider that the system meets the needs of customs agents. In addition to the fact that the system is fast and innovative, so we consider that we not only obtained Deep Learning models, but we integrated them to a web system for use them in a simple way.

Finally, and as a future work, we consider to improve the performance of both model, but specifically the classify of coffee model, first increasing the size of the datasets, and second, carrying out other changes in the CNN architecture base used, for example, add a third convolutional layer, or even to probe other architectures like LeNet or Alexnet.

***Abstract*—The popularity of social media has led to a substantial increase of data. The task of fake news detection is very important, because the authenticity of posts cannot be guaranteed. In recent years, fake news detection combining multi-modal information such as images and videos has attracted wide attention from scholars. However, the majority of research work only focuses on the fusion of multi-modal information, while neglecting the role of external evidences. To address this challenge, this paper proposes a fake news detection method based on multi-modal and multi-task learning. When learning the representation of the news posts, this paper models the interaction between images and texts in posts and external evidences through a multi-level attention mechanism, and uses evidence veracity classification as an auxiliary task, so as to improve the task of fake news detection. Authors conduct comprehensive experiments on a public dataset, and demonstrate that the proposed method outperforms several state-of-the-art baselines. The ablation experiment proves the effectiveness of the auxiliary task of evidence veracity in fake news detection.**

I. Introduction

Social media is an important platform for people to share and obtain information, and has become an indispensable part of people's daily life. But at the same time, the characteristics of easy access and manipulation of social media information also promote the proliferation of fake news. Fake news on social media not only affects public opinion, but also does serious harm to the economy [1], politics [2], public health [3] and society. Therefore, fake news detection has become an important research issue.

The purpose of fake news detection is to automatically determine whether the statements in news posts are true or false. Some news posts contain videos or images besides words, which are more attractive and deceptive than textual news [4]. According to statistics, the average forwarding times of posts containing images are about 11 times that of posts without images [5]. Multi-modal fake news usually contains some distorted or confusing images [6]. As shown in Fig. 1, the upper image is obviously processed by tools, while the image in the lower is a misleading image that is inconsistent with the text.

Recent works have made lots of attempts on multi-modal fake news detection [7]. Some researches simply combine textual features with visual features to obtain multi-modal features [8]. Wang et al. [9] use Text-CNN and VGG-19 to extract text and image features respectively, and then simply concatenate them to classify the news. Sing et al. [10] manually design textual and visual features from four dimensions: content, organization, emotion and manipulation, and then concatenate them to detect fake news. In order to capture the interactions of multi-modal features, Wu et al. [11] stack multiple co-attention layers to fuse the multi-modal features. Qi et al. [12] extract three kinds of text-image correlations to capture multi-modal clues. However, the above methods only use the information of the news itself and neglect the use of external evidence.

To this end, this paper proposes a fake news detection method via Multi-modal and Multi-task Learning (MML). Different from previous studies, the classification of evidence veracity is used as an auxiliary task of fake news detection. MML first extracts the features of the image by a multi-layer CNN model, and then obtains evidence representations through claim-evidence correlation representation learning. Finally, the representations of image and image-related evidence are fused through the co-attention mechanism. Specifically, this paper jointly trains fake news detection and evidence classification, the two tasks share the representation of evidence.

The main contributions of the paper are as follows:

1) This paper proposes an end-to-end neural network to detect multi-modal fake news on social media by simultaneously learning the deep correlations between the image, claim and the evidence.

2) This paper extracts the image-related evidence and improves the performance of fake news detection through a multi-task learning framework.

3) Authors design detailed experiments to prove the effectiveness of the proposed model, and verify the effectiveness of multi-modal learning and multi-task learning in this task.

The remaining sections of the paper are structured as follows: Section II introduces the literature survey in the field of fake news detection and multi-task learning. After that, Section III explains the methodology. Then, Section IV describes the results and discussion followed by Section V conclusion and future enhancements.

II. Literature Survey

This section briefly summarizes the existing work in the field of fake news detection and multi-task learning.

A. Fake News Detection

For news that only contains texts, besides the text information, the propagation structure of news on social networks is commonly used to detect fake news. Liu et al. [13] presented a kernel graph attention network, which performed more fine-grained fact verification based on kernel-based attentions. Zhong et al. [14] applied semantic role labeling to parse each evidence sentence and established links between arguments to build a graph structure for information detection. Different from the graph structure constructed in the above methods, Ma et al. [15] and Bian et al. [16] modelled the propagation of posts on the Weibo platform by tree structures. Some researchers have different opinions about the research direction of fake news. They think it is very important to study the interpretability of fake news detection. Shu et al. [17] developed a joint attention graph to capture the top K interpretable sentences and user comments. Wu et al. [18] proposed a dual-view model based on collective cognition and individual cognition for interpretative claim verification.

While for multi-modal news, various methods have been proposed to utilize the multi-modal information and detect fake news. Vo et al. [19] proposed to use images as a supplement to news content, and used text matching layer and visual matching layer to detect text and images respectively. Jin et al. [20] treated each image or video as a topic and used the credibility of these topics as a new feature to detect fake news. However, a key problem with using multi-modal information for fake news detection is that the multi-modal information usually comes from another real event, and the content seems to correspond to the text in the fake news. At this point, although the image itself is real, it does not actually match the text content. The above methods ignore this problem and do not fully integrate text and multimedia content. Based on this, Wu et al. [11] proposed a joint multi-modal attention network to integrate the text features and visual features of fake news. Qi et al. [12] captured the correlation between text features and visual features by extracting three kinds of text-image features. However, these methods ignore the use of external evidence. Wen et al. [21] leveraged the semantic similarity between news and external evidence to capture the mismatch between text content and multi-modal information. However, this method did not fuse the physical features of image. To overcome the above limitations, this paper proposes a method to capture the physical features of image, and learns the deep correlations between the image, claim and the evidence.

B. Multi-Task Learning

Multi-task learning refers to the joint learning of related tasks that share representation information, so that these tasks can achieve better results than training a single task. In recent years, multi-task learning has been proved to be effective in various NLP tasks, including fake news detection. Kochkina et al. [22] constructed a multi-task learning framework consisting of three tasks: veracity classification, stance classification and rumor detection. The proposed method was represented by a shared LSTM layer (hard parameter sharing), followed by many task-specific layers. Ma et al. [23] jointly modelled rumor detection and stance classification by using two RNN-based architectures with shared layers. Wu et al. [24] explored a sharing layer of gate mechanism and attention mechanism, which can selectively capture valuable sharing features for fake news detection and stance detection. Li at al. [25] proposed a neural network model for multi-task learning of rumor detection and stance classification, including a shared layer and two task-specific layers. However, all the above multi-task learning methods are based on the joint training of fake news detection and stance detection. To the best of author's knowledge, this paper makes the first attempt to jointly model fake news detection and evidence veracity classification in multi-task learning.

III. Methodology

A. Overview

This paper proposes a Multi-modal and Multi-task Learning method for fake news detection (MML). As shown in Fig. 2, the proposed model mainly contains three parts: visual representation learning, textual representation learning, and fake news classification.

The problem definition is as follows. Suppose that $P = (p_1, \ldots, p_n)$ is a set of multi-modal news posts from social media, the text in the news is denoted as a claim C_j where $j \in [1, n]$. $E_i = \{e_i^1, e_i^2, \ldots, e_i^m\}$ is a set of evidence for news p_i, composed of the titles of web pages searched from Google. Given a news post p_i and the corresponding evidence set E_i, the main task aims to predict whether p_i is a fake news based on its multi-modal representation learned from MML. For the task of evidence veracity classification, in the training stage, this paper uses the label of evidence to learn the representation of evidence and shares it with the main task.

B. Visual Representation Learning

Since the fake-news images are often re-compressed images or tampered images, they are different from real-news

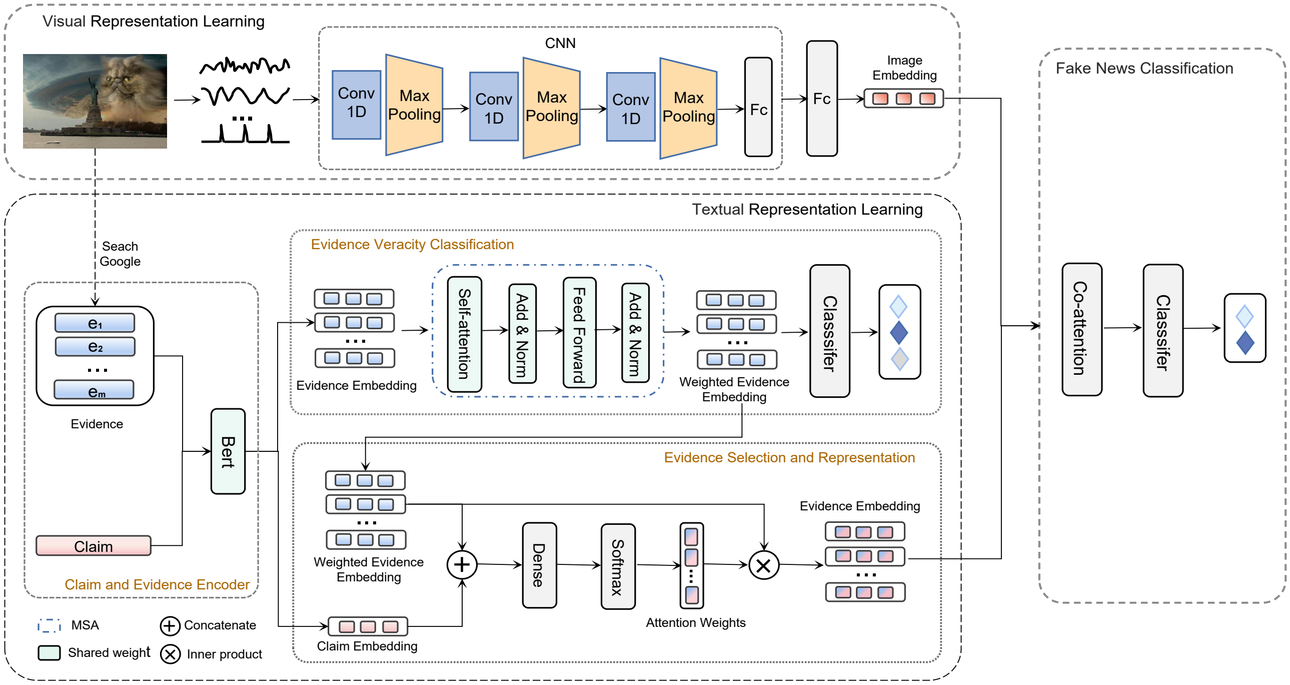

Fig. 2 Illustration of the Proposed Model MML.

images in frequency domain, which are usually periodic. Inspired by Qi et al. [26], the discrete cosine transform (DCT) is first used to transform the image in the news post from spatial domain to frequency domain, to obtain 64 hisograms, which can be represented by 64 vectors $V_0, V_1, \ldots, V_{63}$ with a fixed size. After that, this paper feeds each vector to the multi-layer CNN model consisting of three convolution blocks and a fully connected layer, where each convolution block contains a one-dimensional convolution layer and a max-pooling layer. Finally, a fully connected layer with ReLU activation function (denoted as “Fc” in Fig. 2) is added to get the feature representation of image R_v.

C. Textual Representation Learning

To capture the correlations of the semantics and visual information of the news posts, MML extracts image related web pages from Google to serve as the evidence of the claim. At the same time, in order to make a selection of evidence, MML uses the evidence veracity classification task to assist the fake news detection task. In this part, the claim and the evidence are first fed into a BERT-based encoder, then through the evidence veracity classification task, the importance of evidence is learned. Finally, the textual representation is learned based on the co-attention of claim and the evidence.

1) Claim and Evidence Encoder: This paper uses BERT to obtain the representations of claim and its corresponding m related evidences. The BERT model is a bidirectional coding representation model based on the transformer structure proposed by Devlin et al. [27]. Compared with the traditional Recurrent Neural Network (RNN) and Long Short-Term Memory networks (LSTM) used for NLP tasks, the transformer structure is more powerful in encoding texts. It consists of six encoder-decoders stacked with the same structure. Each encoder consists of two sub-layers, i.e., a feedforward layer and a multi-head attention layer, and each decoder consists of three sub-layers: a feedforward layer, a multi-head attention layer and a masked multi-head attention layer. In addition, add and normalization functions are added to each sub-layer. The BERT model achieves better performance in existing models by stacking twelve-layer Transformer Encoders.

Given a claim C and a set of evidences $E = \{e_1, e_2, \ldots, e_m\}$ corresponding to the claim, BERT model is used to generate the representations of the claim and each evidence:

$$R_c = BERT(C) \tag{1}$$

$$h_j = BERT(e_j) \tag{2}$$

where e_j is the *j*-th evidence corresponding to the claim C. Next, the total evidence representation H is obtained by concatenating the representation of each evidence:

$$H = h_1 \oplus h_2 \oplus \cdots \oplus h_m \tag{3}$$

where m represents the number of evidence corresponding to the claim C.

2) Evidence Veracity Classification: Since there are a lot of web pages searched from Google, it is of great significance for fake news detection that how to find the “useful evidences” and make use of them. Taking the evidence representation H as input, the Transformer encoder is used to capture the correlations of evidences, and a Multi-layer Perceptron (MLP) is used to classify the evidence into three pre-defined categories: True, False and Unverified.

The objective of evidence veracity classification task is to minimize the cross-entropy loss function:

$$\mathcal{L}_e = -\sum_{i=1}^{m} q_i log p_i \tag{4}$$

where p_i denotes predicted probability of evidence i, q_i refers to the ground-truth label of evidence i. By classifying the veracity of evidences, this paper can use transformer to learn the correlations of evidences and share it with the fake news detection task.

3) Evidence Selection and Representation: After obtaining the weighted evidence representations from the auxiliary task, this paper uses attention mechanism to select important evidences related to the claim. Given the claim representation R_c and evidence representation $\{h_1, h_2, \ldots, h_m\}$, this paper concatenates claim representation with each evidence representation:

$$a_j = R_c \oplus h_j \tag{5}$$

where h_j is the *j*-th evidence representation corresponding to claim.

This paper performs a linear and a softmax to calculate the attention score between the claim and the *j*-th evidence, and gains the evidence weighted representation based on claim-evidence attention R_e:

$$\alpha_j = \frac{exp(a_j W^T + b)}{\sum_j exp(a_j W^T + b)} \tag{6}$$

$$R_e = [\alpha_1 \cdot h_1, \ldots, \alpha_j \cdot h_j, \ldots, \alpha_m \cdot h_m] \tag{7}$$

where W^T denotes the weight matrix and b is the bias term, α_j is the attention score between the *j*-th evidence and the claim.

D. Fake News Classification

Given the visual representation and the textual representation, this paper uses a co-attention block to fuse the image representation R_v and image-related evidence representation R_e and obtains R'. The structure of the co-attention block is as follows:

$$R = R_e + MHA(R_e, R_v, R_v) \tag{8}$$

$$R' = R + FFN(R) \tag{9}$$

This paper feeds R' into a MLP layer to predict whether the news post is fake or not. The loss function of this part $\mathcal{L}_n$ is as follows:

$$\mathcal{L}_n = -\sum_{i}^{n} [y_i * log(\hat{y}_i) + (1 - y_i) * log(1 - \hat{y}_i)] \tag{10}$$

where y_i denotes the ground-truth label of post i and $\hat{y}_i$ indicates the predicted probability of being fake news.

The overall objective function consists of two parts: evidence classification loss and news classification loss. According to Equations 4 and 10, the objective function of MML can be defined as:

$$\mathcal{L}_{final} = \lambda \mathcal{L}_e + \mathcal{L}_n \tag{11}$$

where $\mathcal{L}_e$ denotes the evidence classification loss, $\mathcal{L}_n$ represents the news classification loss, and λ is a hyperparameter used to balance these two losses.

IV. Experimental Results and Discussion

In this section, authors conduct experiments to evaluate the effectiveness of the proposed MML. Specifically, the section aims to answer the following research questions: EQ1: Can MML improve the performance of multi-modal fake news detection? EQ2: Are visual representation and multi-task learning useful for fake news detection task? If so, how much can it improve? EQ3: Is MML model sensitive to different parameter settings?

A. Dataset

Authors evaluate the proposed MML model on the CCMR dataset, which is a multimedia fake news verification dataset with 17 events in total [21]. The dataset consists of 15,629 tweets with multimedia information, 4,625 webpages from Google and 2,506 webpages from Baidu that share similar multimedia content. Among them, this paper only uses the tweets and webpages from Google in the dataset to perform the experiment. Table I shows the statistical information of the CCMR dataset.

B. Baseline Methods

This section compares the proposed MML model with the following state-of-the-art methods:

1) **SpotFake+:** Singhal et al. [28] build a multi-modal fake news detection method based on transfer learning. The model extracts the features of text and image respectively, and then feeds the feature vectors to a fully connected layer for classification.

2) **IDM-FND:** Singhal et al. [29] develop a fake news detection framework based on inter-modality inconsistency. Firstly, the framework captures the relationship (inconsistency) among various components in news articles. Then, the features of text and image features are extracted and concatenated to detect fake news.

3) **MVNN:** Qi et al. [26] propose a multi-domain visual neural network framework, which extracts and fuses the features of frequency domain and pixel domain of images to detect fake news.

4) **MCAN:** Wu et al. [11] propose a multi-modal co-attention network to fuse the features of textual and visual features. Firstly, the network uses BERT to extract features. Secondly, the spatial domain and frequency domain features of the image are captured respectively. Finally, the multi-modal features are fused by stacking four co-attention layers.

5) **TFG:** Wen et al. [21] use cosine similarity and agreement classifiers to obtain the classification features. The network leverages the multimedia information to find the consistency and inconsistency among news from different social media platforms but sharing similar visual contents.

TABLE I. Statistics of the CCMR Dataset

ID	Event	Twitter	Google
01	Hurricane Sandy	10222	2204
02	Boston Marathon bombing	533	722
03	Sochi Olympics	274	347
04	MA flight 370	310	323
05	Bring Back Our Girls	131	108
06	Columbian Chemicals	185	63
07	Passport hoax	44	26
08	Rock Elephant	13	20
09	Underwater bedroom	113	59
10	Livr mobile app	9	15
11	Pig fish	14	20
12	Solar Eclipse	277	143
13	Girl with Samurai boots	218	60
14	Nepal Earthquake	1360	424
15	Garissa Attack	79	63
16	Syrian boy	1786	8
17	Varoufakis and zdf	61	20
	Total	15629	4625

C. Evaluating Metrics

To evaluate the performance of the proposed MML model, this paper uses four commonly used evaluation metrics: Accuracy, Precision, Recall and F1-score. Accuracy is a relatively intuitive evaluation index, which indicates the proportion of correctly classified samples in the total number of samples. Precision (P) represents the probability that the samples predicted to be true are real positive samples. Recall (R) represents the probability that positive examples in the sample are predicted to be correct. In practical evaluation of a model, both Precision and Recall should be considered, but it is difficult to compare the two values in a balanced way. The F1-score (F1) is a common method of integrating two values for evaluation:

$$F1 = \frac{2 * P * R}{P + R} \tag{12}$$

D. Implementation Details

This paper uses event 1-11 for training and event 12-17 for testing according to Wen et al. [21]. This paper sets the number of hidden layers in the Transformer encoder and the number of attention heads to 12. The maximum sequence length is set to 512. The learning rate is set to 1e-5 and the batch size is set to 8. The dropout of each layer is 0.1. The hyperparameter λ is 0.2.

E. Experimental Results and Analysis

This section compares the performance of the proposed model MML with the above baselines. From the results in Table II, authors can draw the following conclusions:

TABLE II. Results of MML Model and Baseline Models

Methods	Accuracy	Precision	Recall	F1-score
SpotFake+	0.7615	0.8212	0.7652	0.7921
IDM-FND	0.7937	0.7849	0.8231	0.8035
MVNN	0.8399	0.8173	0.8461	0.8315
MCAN	0.8573	0.8632	0.8347	0.8487
TFG	0.8912	0.8813	0.9254	0.9029
MML	**0.9225**	**0.9169**	**0.9262**	**0.9215**

TABLE III. Evaluation Results of the MML Model and Two Variants

Methods	Accuracy	Precision	Recall	F1-score
MML	**0.9225**	**0.9169**	**0.9262**	**0.9215**
MML-*w/o* Visual Representation	0.8501	0.8742	0.8439	0.8588
MML-*w/o* Evidence Veracity Classification	0.8651	0.8673	0.8426	0.8548

1) The MML model performs significantly better than all baseline models, achieving the Accuracy of 0.9225 and F1-score of 0.9215. Compared with SpotFake+ and IDM-FND, which simply combine the multi-modal features, MML achieves the greatest improvement, 16.1% in Accuracy and 12.9% in F1-score.

2) Compared with other multi-modal models MVNN and MCAN, the proposed MML model improves the Accuracy by 8.2% and 6.5%, respectively. It can be speculated that external evidence can effectively identify the correlations between text and image, and help improve fake news detection.

3) Compared with TFG, which also uses external evidence to detect fake news, MML is 3.1% and 1.8% higher in Accuracy and F1-score, respectively. This is because MML has advantages in extracting physical features of images and selecting important evidences.

F. Ablation Experiment

In this section, authors discuss the contribution of different components in the model, including visual representation learning and evidence veracity classification task. Authors remove the above two modules from MML model to obtain the following two variants: **MML- w/o Visual Representation**, which denotes MML only models the textual representation, and **MML- w/o Evidence Veracity Classification**, representing MML without multi-task learning.

The results of the two variants are shown in Table III. When the visual representation learning module is removed, the Accuracy and F1-scores drop to 0.8501 and 0.8588, respectively, showing the importance of visual representation for multi-modal fake news detection. By comparing MML with the

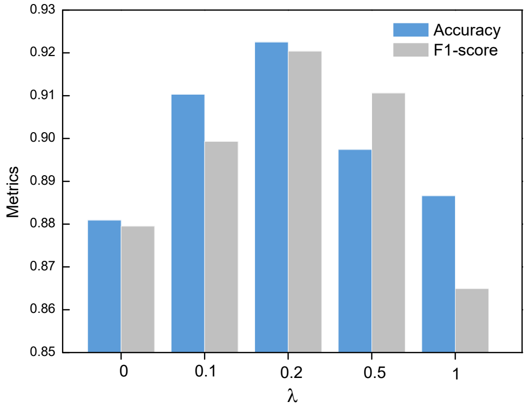

Fig. 3. Results of different Hyperparameter λ.

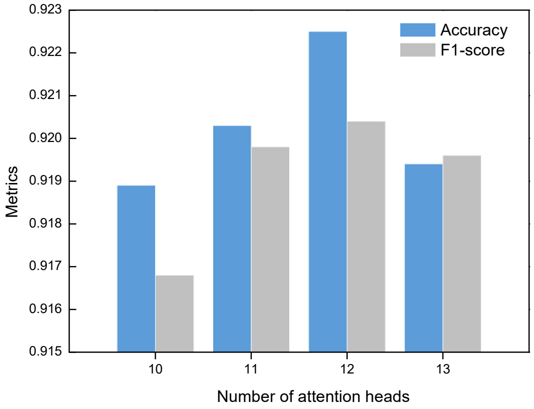

Fig. 4. Results of different Number of Attention Heads.

variant without evidence veracity classification task, authors can observe that all the evaluating metrics decreased greatly, which demonstrates the effectiveness of multi-task learning and the necessity of evidence selection and representation.

G. Parameter Sensitivity Analysis

To analyze the influence of hyperparameters on model performance, authors conduct the following two parameter sensitivity experiments.

1) Effects of hyperparameter λ: Note that λ is a weight parameter for balancing the evidence classification loss $\mathcal{L}_e$ and the news classification loss $\mathcal{L}_n$. In other words, the larger λ is, the greater the effect of evidence weight learning on fake news detection. This paper sets λ to 1, 0.5, 0.2, 0.1 and 0. The Accuracy and F1-score of different hyperparameter λ are shown in Fig. 3. Authors find that the model achieves the best performance when λ is 0.2, while the evidence classification loss brings an improvement of 5% on F1-score for the proposed MML model (λ=0, without evidence classification loss). This proves the effectiveness of the model by introducing evidence classification loss.

2) Number of attention heads: As shown in Fig. 4, authors can clearly see that the performance of the proposed model varies with the number of attention heads (i.e. 10, 11, 12 and 13). With the increase of the number of attention heads, the Accuracy and F1-score firstly increase and then decrease, and the best effect is achieved when the number of heads is 12.

V. Conclusion and Future Enhancements

This paper proposes a Multi-model Multi-task Learning model (MML) to detect multi-modal fake news on social media by modeling the image, claim and image-related evidence. By comparing MML with other competitive baseline methods, authors find that it is effective to use external evidence in this task, with an accuracy of 92.2%. In addition, besides the news classification loss, MML also introduces evidence classification loss to further optimize the model performance. By testing MML with different settings, authors observe that the proper setting of evidence classification loss can improve the performance of fake news detection. Finally, the results of the ablation experiments show that visual feature representation and evidence representation learning are beneficial to improve the fake news detection results, and the model is improved by 7.2% and 5.7%, respectively.

In the future, the authors are willing to extract the visual entity of the image and the text embedded in the image, and model them with the news text to further capture the correlation between the image and the text in multi-modal news.

A Model Driven Approach for Unifying User Interfaces Development

Henoc Soude
Institut de Mathématiques et des
Sciences Physiques, BENIN

Kefil Koussonda
Epitech, FRANCE

***Abstract*—In this paper, we dealt with the rapid development of client web applications (frontend) in a context where development frameworks are legion. In effect with the digital transformation due to the COVID-19 pandemic we are witnessing an ever-increasing demand of the application development in a relatively short time. To this is added the lack of skilled developers on constantly evolving technologies. We therefore offer a low-code platform for the automatic generation of client web applications, regardless of the platform or framework chosen. First, we defined an interface design methodology based on a portal. We then implemented our model driven architecture which consisted of defining a modeling and templating language, centered on user data, flexible enough to not only be used in various fields but also be easily used by a citizen developer.**

Keywords*—*Model driven; user interface; modeling language; templating language; low code; citizen developer

I. Introduction

Over the past two decades, web applications have evolved and are now used in all areas of everyday life: medical, transport, e-commerce and social networks. One of the reasons for their success is that they can be used on all our devices like laptops, smart phones, tablets and desktops. The interfaces are determining elements in the acceptance of a web application [1], [2]; their development is therefore of paramount importance hence the multiplicity of frameworks in the market. For some years the frameworks *javascript* have spread widely to the point of becoming indispensable in the development of modern applications. By the way Sacha Greif et al. [3] have launched an annual survey since 2016 to analyze developments and trends in *javascript* frameworks by focusing on based data from more than 20,000 developers spread over more than 100 country. This study shows us, among other things, the most used frameworks (react, angular, vue) but doesn't give us any information on how they choose, knowing that they have different learning curves more or less complex. Indeed, the COVID-19 pandemic requires us to rapidly develop more and more complex applications, in the context of a global shortage of developers [4], [5].

Model-based development (MDD) has been used in the literature [6]–[8] in order to simplify the development of applications and increase productivity. It is a development paradigm which according to Stephen et al. [9], consists in building the model of a system and then generate a real instance of this system from the obtained model. MDD was quickly adopted by the Object Management Group (OMG) which standardized model-based architecture (MDA) and is composed of several levels, two of which are essential in our development context of web application: platform independent model (PIM); used to describe the system and platform specific model (PSM); used to generate an instance actual system. The PIM and PSM models are described using languages that are either standardized or domain-specific (DSL). Most of these languages are neither suitable, nor flexible enough and too complex [10], in terms of learning curve.

One of the solutions to address the problems related to developer shortage is the use of low-code platforms [11], which in addition to using model-based approaches, use graphical or high-level languages to make development accessible to all. According to a Gartner report more than 50% of companies will adopt them as a solution strategic by 2023 [12]. There are many low code [13]–[15] which agrees with generating interfaces from models. They have the particularity of either generating code for their own platform or to use languages specific to their domain wich most of the time are difficult to handle. Added to this is the fact that the adoption of low-code platforms by citizen developers is conditioned by the simplicity and accessibility of the underlying models.

This work is part of a more global project to implement a low code [16] platform to automate the development of tasks in various fields. For the sake of consistency, all projects share not just the same development languages: *c/c++* and exchange data: *json*, but also the same automation system; the generator must generate codes in several domains without requiring the intervention of expert developers.

The general research question of our work is: *How can we unify user interface (UI) development?*. Whatever framework used: Mithril, React, Vue, the development process must be identical and the learning curve should be as simple as possible even for a person without any developing skills (citizen developer). The solution we propose is to automatically generate the code for the different platforms from a single model, defined by the user. It comes in the form of the following contributions:

- the development of a portal and the definition of an UI design methodology based on a portal. It allows to gain in productivity and to make the implementation of UI simpler since their navigation elements have to be configured.
- the development of a cloud-based graphic editor for UI modeling
- the definiton of a modeling language which has simple structure; all its elements have the same basic,

and flexible structure; it can be extended for new platforms.

- the development of a code generation system consisting of an engine and a template language.

The rest of the document is organized as follows: Section II presents state of the art. Then we described our model-based approach to Section III. Our interface modeling language and our template language are described in Sections IV and V. In Section VI we presented a general discussion of work then we concluded with the Section VII

II. Related Work

Whatever platform or model-based approach used, they are distinguished by the modeling language and the generation system used.

A. UI Modeling Language

The principle of modeling a user interface consists in finding an abstract representation of the constituent elements of the interface. This representation usually contains information relating to the organization, the description of the elements in the interface and interactions with users. This explains the multiplicity of modeling languages that differ depending on the type and storage of the information they contain.

UIML [17] is the first universal modeling language independent of the platforms and technologies used. It is an XML dialect which describes an interface in five sections: the description, the structure, the data, the style, and the event. Subsequently the language was standardized by OASIS group. USIXML [18] is another language based on XML and standardized by the World Wide Web Consortium (W3C) whose particularity is to describe the multimodal interfaces. The proposed language in our work differs from the two languages presented by the format of the definition of models; we use the *json* format unlike the XML used in most templates [19], [20].

Brambilla *et al.* [21] present interaction flow modeling language (IFML) which was quickly adopted as a standard by OMG. Language allows to describe the structure and interactions with end users via a set of visual components representing the different elements of an interface. This concept of visual modeling has greatly appealed whether in the academic world or that of industry [22]–[26]. The language has introduced a high level of abstraction that makes an element of the model we can match several components of an interface. This ambiguity is resolved by the language when generating the interface, since the user provides these correspondence elements. This constitutes a real problem in the works as shown where we have no idea of the interface that the end user wants to generate: we cannot provide a mapping that will satisfy all users.

More recently Moldovan *et al.* [27] presented a model-based approach for developing user interfaces f' or multi-target applications. They first define their modeling language (OpenUIDL) whose syntax is based on the JSON format. Then they present the different stages of their approach for the development of interfaces: the design, the generation and the deployment of the interface. Although dealing with the same problem with an almost identical approach, our work differs mainly in the level of the semantics of the modeling language and the process of generation. In order to improve the problem of limited accessiblity to defintions of modeling languages (cf. [27]), we propose a model of a simpler and more intuitive level than the authors of [27]. Indeed in their model a node can be of type static value, dynamic reference, element, conditional, repeat, slot, nested-styled and its content is specified through the attribute of the same name. So you need at least two objects *json* nested to define an element of an interface then in our model the equivalent of the node directly represents an element of the interface. Their code generation model remains limited to web interfaces and cannot allow ”citizen developers” to generate code or data in specific areas contrary to what we propose.

B. Code Generation

In the context of automatic web interface generation, two approaches are often used: that based on the structures tree abstracts [27] and that of the engines template. The major drawback of the first approach is that it requires having technical skills if you want to generate code in a language other than the original one. We are indeed in need of a system that allows seasoned users or not to generate code or documents in various fields.

The second approach is more appropriate in our context since the engines offer a template description language; the user will only have to describe his new model through this language. Most languages used for the development of java web interfaces (freemaker [28]), python (jinja2 [29]) and javascript(mustache [30]) all have template engines whose languages does not tell us nor inhibit us from defining the models of views whose structure is not known during design. XSLT [31] is a language standardized by W3C which allows you to transform XML documents into another format (HTML, XML, js,etc.). It easily solves the problem mentioned above thanks to these directives*template* and *apply*; unfortunately there remains a verbose language and very complex to handle.

III. Model based Approach

The objective of our work is to allow developers to implement web applications without worrying about platforms or frameworks available in the market. For this we propose, as indicated in the Fig. 1 a three-step approach: design, build, and refinement of the interface after deployment. Except for the refinement, the other two steps are MDD classics. The distinctiveness of our solution lies in the methodology, the concepts, the languages and tools we use in the different stages.

A. UI Design

The first principle of our design approach is that the user doesn't waste time implementing common and recurring concepts in web applications: menu navigation and operation application on user data. For this we have implemented an application portal which not only is an application receptacle but also has mechanisms for specifying menu and application-related actions. As shown, Figure 2, is divided into five parts: (i) the main bar which indicates the name of the current application and different menus drop-down such as the list

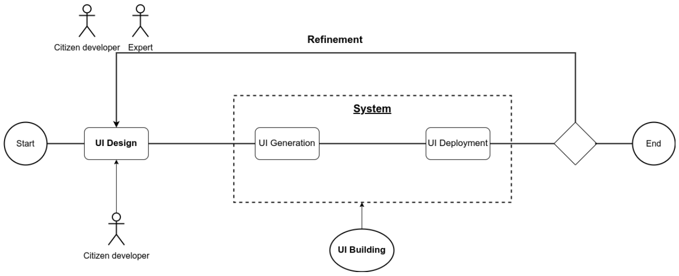

Fig. 1. The Different Steps of our Model-based Approach.

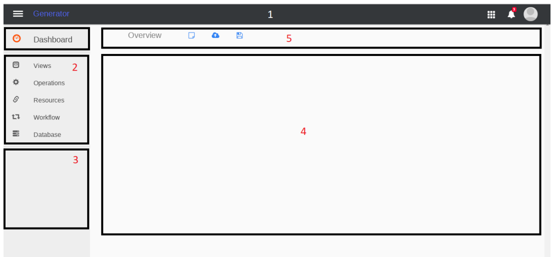

Fig. 2. The Structure of our Application Portal.

of applications, (ii) represents the elements of menu of the current application, (iii) represents the list of applications related to the current application, (iv) represents the workspace in which the different views of the application will be hosted and (v) represents the action bar which indicates the possible operations on a given view. The design of an application's interfaces therefore consists of identifying and declaring the set of views or interfaces that compose it and for each of it to define its content and its operations.

The second principle of our approach is that of the separation of concerns that we have implemented in our editor interface graphic: users of different level techniques will be able to intervene on different parts as shown in Fig. 3 the design is divided into six sections: *view*, *template*, *variables*, *functions*, *actions* and *lifecycle*.

The *view* section describes the organization of a view in the application portal. The form elements `inside menu`, `role` and `icon` allow resp. to specify whether the view is accessible or not in the application menu, the role needed to access the view and view icon in the menu. The `modal` attribute indicates that the view can be imported by another view.

The *template* section describes the contents of a view. The user uses the different predefined elements to describe the content of its view. The `tag` can be used to specify non-predefined elements. Every Adding of an element, the user can choose either to see the preview (tab interface) or to see the generated model (tree tab). At any moment of the design the user can select an element of the model and modify its properties.

The *variables* section describes the variables used by the different view elements. They are usually created by the user which can also associate test values to then. The *functions* section describes user-defined methods. The *actions* section describes sight operations. The user must provide the icon as well as the method to call. Finally the *lifecycle* section describes the mechanisms of *javascript* component status notification.

Fig. 3. The Interface Confuguration of a View.

B. UI Building

The user does not intervene in the process of generating the views even if he is the instigator. As shown in Fig. 4, our template takes as parameter the view model and the mapping of the elements of the seen. The mapping of an element corresponds to its html template for a support given. We have therefore provided the mapping of all the predefined elements of our editor for the following frameworks: mithril.js, react.js, vue.js. An example of mapping is presented in Section V-B.

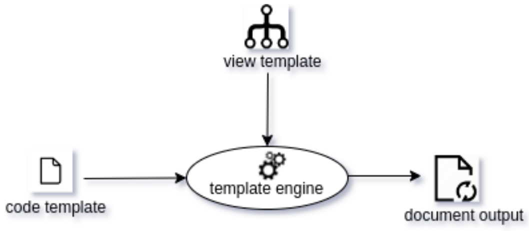

Fig. 4. Our Code Generation Process.

In addition to specificities related to the generation of web applications our build system needs to be flexible enough to not only allow generation in multiple domains but also allow citizen developers to edit their own model for specific needs. For this we have proposed a model language based on text and simple substitution directives, intuitive and non-verbose. We have also decided to limit the number of instructions to make it easier to get started. We have implemented a simple and adaptable algorithm to all situations. The algorithm consists of traversing a tree structure (in *json* format) and each node of the tree generates the corresponding code by retrieving the associated template to its type. This implies that any *json* object passed as a parameter must have the `type` attribute.

C. UI Refinement

After the generation of the interfaces, the user can deploy the application on our beta server to be tested by all connected users. This mechanism allows us to integrate the Agile principles in our view generation process: the end users or team members can make feedback that will be integrated during this phase.

The positive point of our refinement mechanism associated with principle of the separation of concerns developed during the phase of design is that it is possible for a citizen developer to design the organizational aspect of the views: positioning of the different interface elements. Once his work has been validated then a user with technical skills will be able to finalize the views during the refinement phase.

IV. UI Modeling Language

The most natural representation of an interface is that of a tree in which a node corresponds to an element of the interface. The Fig. 5 is a representation in the form of a tree of the html component `table`: it has `tr` elements which, in turn, have `td` elements. Our modeling therefore consists in defining in a format *json* the structure of interfaces. The nodes of the description tree are represented by the objects*json* whose structures are defined via their json schema.

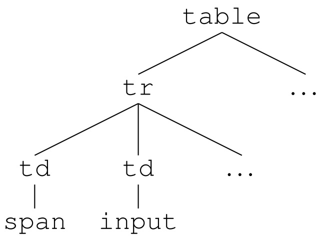

Fig. 5. Representation of `table` Component as a Tree.

A. Syntax of Models

Fig. 6 presents the schema *json* of the basic structure of elements of an interface. An element is described by its type and by either its value or its descendants. All other properties of the element are optional; our generator is able to generate values for them by default. The `type` attribute is a character string whose value is the name of the element with which the object is associated. The `children` attribute is an array that describes the children of an element. The attribute `value` is a character string containing the value of an element. The semantics of the value of an element depending on its type. For example the value of a `button` is the text that accompanies it while the value of a `span` represents its content.

```
{
  "$id": "schema/base",
  "type": "object",
  "properties": {
    "type":    {"type": "string"},
    "value":   {"type": "string"},
    "children":{"type": "array",
    "items":   {"$ref": "#"}}
  },
   "required": ["type",
     {"oneOf": ["value", "children"]}]
 }
```

Fig. 6. The Basic Structure of an Element of our Model.

The value of an element can either be literal or come from a variable. For this reason we use a formatting which consists of preceding the value of the attribute `value` by one of the following characters: `$, #, %` . When the attribute value is not prefixed for any of these characters then the value is used as such. When preceded by the character`#` then it should be treated as given *json*. When she is preceded by the character `$` then the value of the element comes from a variable, defined inside the html component, whose name is the value of the attribute without the prefix character. When the attribute value is preceded by the character `%` then the value of the element comes from a variable passed as a parameter to the html component. In the following example {``a": ``foobar", ``b": ``$foo", ``c": ``%bar", ``d": ``#{}"}, a, b, c, d have the respective value `foobar`, the value of the variable`foo`, the variable of the variable `bar` passed as component parameter and an empty json object.

```
{
    "$id": "schema/view",
    "type": "object",
    "properties": {
        "type": {"type": "string"},
        "imports":  {"type": "array",
            "items": {"$ref": "#/$defs/keyval"}},
        "variables":{"type": "array",
            "items": {"$ref": "#/$defs/keyval"}},
         "functions":{"type": "array",
             "items": {"$ref": "#/$defs/keyval"}},
         "template": {"type": "object",
             "properties": {"$ref": "schema/base"}},
         "oninit":   {"type": "string"},
         "oncreate": {"type": "string"},
         "onupdate": {"type": "string"},
         "onremove": {"type": "string"}
     },
     "required": ["type", "variables",
                 "modals", "functions", "template"],
     "$defs": {"keyval":{
         "type": "object",
         "properties": {
           "name"  {"type":"string"},
           "value" {"type":"string"}
         }
     }}
 }
```

         "type": "object",
         "properties": {
           "name" {"type":"string"},
           "content" {"type":"string"}
         }
     }}
 }
```

Fig. 11. Metamodel of Wizard Component.

B. Components

We have predefined a number of interface elements which we have organized into three categories:

- *simple*; they have no child elements. hr, hx, img, span,radio, label, icon, input, button, select, checkbox, textarea.
- *container*; they have child elements. nav, tab, link, list, form, group, table, accordion, dropdown, paragraph.
- *widgets*; these are non-standard html elements; wizard, treeview, carousel, display.

We have not implemented all the elements of an interface but rather those that come up regularly in web applications. Nevertheless the tag element can be used to implement elements not predefined.

In the rest of the document we present only the special components (view and tag) and one component per category due to the simplicity of the model.

a) view: An element of type view is a special element allowing to model the organization of interfaces in the application portal (see section III-A). As shown in its json schema, in Figure 7, the attributes variables, imports, functions and template are mandatory. The template attribute is an object representing the content of sight. The attributes variables, imports and functions represent respectively the variables, the imported elements and the user-declared functions.

b) input: Fig. 8 represents the model definition of a input. The attributes value and subtype are required. This model represents multiple types of input via the subtype attribute; other attributes are added to the model depending on the type chosen. The label and the placeholder can also be specified via attributes of the same name. The user can specify the action to perform when changing the value via the onchange attribute.

c) tag: The tag type element is used to model dynamic attribute (unknown at design time) or non-predefined elements. As shown in Fig. 9 the attributes value and children are mandatory. The children attribute contains the definition of the element's children given while the attribute value represents the real no of the element. The element name can be assigned literally or via a variable (cf. Section IV-A).

d) list: The list type element is used to model components from a repetitive action; this is the case for example of the elements dl, ul and table. As shown in Fig. 10 the attributes data and children are required. children contains the definition of the elements that are repeated according to the data coming from the data attribute which must be an array. The root attribute when present becomes the parent element containing the repeated elements. The iterator attribute represents the name of the iterator to use in the code for traversing data in data.

e) wizard: Fig. 11 represents the model definition of a wizard. The attribute data is mandatory and represents all the pages of the wizard. Pages are defined by an object whose attribute name represents the page name and the content attribute represents the content of the page. The content of a page is a reference that is resolved when generated. The action to be performed after the process is completed is specified via the done attribute.

V. Template Language

The language that we propose must not only make it possible to write the model codes of our web interfaces but also be sufficiently simple and flexible to allow a citizen developer to write their own models in various areas. For this we have chosen a language composed of texts: they are copied as such by the template engine, and substitution directives: they are replaced by the value of the variables or expressions they represent.

In order to make the language simple and accessible, the transformation of directives is solely based on user data; unlike some languages [28], [31], ours does not allow for defining variables or functions in our models.

User data is passed as a parameter to the template engine as an object of *json* (see Fig. 12) whose attributes are the variables used by the substitution directives. The language uses the symbols `{,},[,]` as block delimiters, the character `%` to escape special characters and the character `$` to introduce directives.

```
{
  "string": "foobar", "number": 12.23,
  "bool": false, "null": null,
  "object": {"key": "val"},
  "array":  [10,20,30]
}
```

Fig. 12. An Example of User Data.

A. Directives

a) content: This directive is used to retrieve the value of an attribute of the data passed as a parameter to the engine.

$$\$ < attribut >< . < attribut_1 >< \cdots . < attribut_n >>> \tag{1}$$

$$\$ < attribut > [< index >] \tag{2}$$

Its syntax is presented by the expression 1 where $< attribute >$ represents the attribute whose value we are looking for. Considering the data of Fig. 12, the directives $\$string$, $\$number$, $\$bool$, $\$ull$, $\$object$ and $\$array$ respectively have the value foobar, 12.23, false, null, an empty string and an empty string. The directives $\$object$ and $\$array$ have the value of empty strings since we must specify the element that is sought within them. With regard to the directive $\$object$ we use the optional part of the expression 1 by preceding the name of the element with the character .. The $\$object.key$ directive is used to retrieve the value of the key. The expression notation 2 is used for arrays. The pattern $< index >$ indicates the position of the element of the array that we are looking for; in our example $\$array[2]$ and $\$array[\$number]$ have the value 20 and an empty string since $\$number$ is not an integer.

The evaluator of a directive returns the Boolean value false which indicates that an error occurred while evaluating and the value true in the opposite case. In case of error the evaluator generates an empty string.

b) alternative: This directive allows you to choose between two models. The expression 3 presents its syntax where $||$ represents the separator of the two patterns. The model $< model1 >$ is generated when it tests true while model $< model2 >$ is generated when it tests true when the first shows false. In considering the Figure data 12 the guidelines $\$string||\$number$ and $\$foo||nothing$ have the value foobar and nothing.

$$< model1 > || < model2 > \tag{3}$$

c) test: This directive makes it possible to choose between two models according to the value of a variable. The expressions 4 and 5 present its syntax.

$$\$ < attribut > \{< model1 >\}\{< model2 >\} \tag{4}$$

$$\$ < attribut >< CMP >< VAL > \{< model1 >\}\{< model2 >\} \tag{5}$$

In the expression 4 the test is implicit; the model $< model1 >$ is generated if attribute attribute is true else $< model2 >$ is generated. The attribute is considered true when it exists and value is neither false nor null. In the expression 5 we specify the comparator as well as the reference value. The comparator can be one of the operators following: $=, <, >, >=, <=, ! =$. Considering the data of Fig. 12 the directives $\$foo\{found\}\{not\ \ found\}$ and $\$number = 12.23\{equal\}\{not\ \ equal\}$ have value not found and equal.

d) repeat: This directive makes it possible to repeat the generation of the model according to the number elements in an array variable. The expression 6 presents its syntax where $< attribute >$ must be of type array.

$$\$ < attribut > *\{< model1 >\} \tag{6}$$

$$\$\$ < . < attribut >> \tag{7}$$

The expression 7 presents the iteration variable notation that represents an array element. When the element is an object then we use the optional part of the expression in order to specify the attribute to be to find the value. Considering the data in Figure 12 the directive $\$array * \{\$\$\}$ has the value 102030.

e) separator: This directive is used to automatically generate separators in the context of the *repeat* directive. The expression 8 presents its notation where $< SEPATOR >$ is the separator character. Considering the data of the Fig. 12 the directive $\$array * \{\$\$\$:\}$ has the value 10:20:30.

$$\$ < SEPATOR > \tag{8}$$

f) only if: This directive is used to generate a model if and only if all its directives evaluate to true. The expression 9 presents its notation. Considering the data in Fig. 12 the directives $[\$string\ has\ \$number]$ and $[\$name\ has\ \$foo]$ have for value foobar has 12.23 and an empty string.

$$[< model >] \tag{9}$$

g) built-ins: These are language variables whose notation is present by the expression 10 where $< func >$ represents the name of the variable and $< arg_i >$ represent the arguments associated with the variable. Arguments are optional and allow to change the behavior of the variable.

$$\$ < func ><, < arg_1 >, \cdot, < arg_n >> \$ \tag{10}$$

The variable `$index$` is used in a context of the directive *repeat* and returns the iteration number. The directive $\$array*$

$\{\$index\$\}$ has the value `012` if we consider the data of the Fig. 12.

The variable `$call$` is used in a context of the directive *repeat* and allows recursively calling the template engine on the elements of a table. Elements must be objects that have at least one attribute *type*.

The variable `$href$` is used when we want to retrieve data on media different from the object passed as a parameter to the engine. The data user must contain an *urn* attribute that describes the exact location of the data. The *urn* is composed of fragment separated by the character `:`. The first fragment can take the value `file`, `db`, `rest` depending on whether the data comes from a file, a database or a rest resource. The variable `$count$` is used in a context of the directive *repeat*; it returns the number of elements in an array. The directive $\$array * \{\$count\$\}$ has the value `3` if we consider the data of the Fig. 12.

The variable `$sum$` is used in a context of the directive *repeat*; it returns the sum of the elements in an array. The directive $\$array * \{\$sum\$\}$ has the value `60` if we consider the data of the Fig. 12.

h) Arithmetic operations: The language allows performing arithmetic operations only on the user data according to the syntax of the expression 11 where $< OP >$ Represents an operation among `+,-,/,*,%` and $< VAL >$ represents a whole value. Operations are only allowed for attributes of type *number* Or *string*. Only the addition operation is possible on strings; that is to reduce, from the beginning, the size of the string by the number $< VAL >$. The directives $\$string + 3$ and $name + 3$ have the value `bar` and `name+2`.

$$\$ < attribut >< OP >< VAL > \tag{11}$$

```
module.export= ()=>{
  $modals*{var $$.name%=$href$;}
  $variables*{var $$.name%=$$.value;}
  var $name%_cls = function(){
  return {
    $functions*{$$.name:$$.code$,}
  };}();
  return {
    oninit:(vnode)=>{
      app.setActions($noaction{null}{
        %[$actions*{$call$$,}%]
      });
      $oninit
    },
    [oncreate:(vnode)=>%{$oncreate%},]
    [onupdate:(vnode)=>%{$onupdate%},]
    view:(vnode)=>{
     return $template*{$call$};
    }
    [,onremove: (vnode)=>{$onremove}]
  };
}
```

    }
  },
  computed: {
    $functions*{$$.name$$.code$,}
  },
  beforeCreate(){
    app.setActions($noaction{null}{
      %[$actions*{$call$$,}%]
    });
    $oninit
  },
  [created(){$oncreate},]
  [updated(){$onupdate},]
  [destroyed(){$onremove}]
};
</script>
```

Fig. 14. Mapping of `view` Component for vue Framework.

B. Mapping

Mapping consists of using the language to describe the structure of the code to be generated for each element of our model. Here we present only the Mapping of the `view` element, as an example. Fig. 13 and 14 present the code structure of `view` For mithril and vue frameworks. Users can provide their mapping during the init phase of the engine.

VI. Discussion

How do we assess the learning curve of our modeling method Views? We compared our modeling approach to the one presented by Moldovan *et al.* [27] and that based on IFML. All the three approaches use graphic elements in order to simplify the Modelization. However, the other two approaches introduce new concepts, in addition to the components of an interface.

Why are we talking about unification when we have not limited ourselves on only three frameworks? We talk about unification because our system allows you to add other platforms or frameworks. Just provide the mapping (cf. section V-B) of the predefined elements for the said platform.

Is our built system as simple as claimed? We submitted, to fifteen students, the writing of templates in different fields using our language and XSLT. After analyzing their return from experience it appears that our work was preferred because of its syntax compact and its low learning curve.

Is our build system flexible enough to be used in different areas? Unlike the work of Moldovan *and Al.* [27] which use one generator per target, we use the same generator ourselves regardless of the target; only the mapping changes. Furthermore our generator was used to generate unit tests in some of our projects.

VII. Conclusion

In this work we presented a model-based approach for the development of web interfaces, whatever the platform and have implemented an application portal to simplify the Modeling work. All elements common to interfaces are implemented in the portal and configured during modeling. Then we implemented a cloud-based graphic editor for the modeling of interfaces. The elements of the interface are described via our model *json* whose flexibility allows implementing the abstraction of elements of different platforms without introducing new concepts. Finally we implemented an automatic code generation system for frameworks Mithril, React, Vue. The system is composed of a template language, with a low learning curve, and a template engine focused on user data: the generator determines the model to generate based on the type of the data. Their association make the generation system suitable for different areas.

To further reduce interface development time, we would like to generate them from their draft.

***Abstract*—YouTube has been recognized as an important information source for the millennial generation. This paper aims to identify the factors affecting Malaysian higher education students' acceptance of YouTube for Islamic information acquisition and to investigate if any notable distinction that exists between the students' path coefficients in Islamic academic discipline and the other disciplines. Employing the Unified Theory of Acceptance and Use of Technology model (UTAUT) as its theoretical foundation, data were collected by distributing a self-administered survey to 795 students actively using YouTube for information seeking. Partial least squares structural equation modelling (PLS-SEM) and multi-group analysis (MGA) in SmartPLS 3.2.7 software were used to analyze the data. Three constructs of the UTAUT model, performance expectancy, effort expectancy and social influences, were found to significantly and positively influence behavioural intention to use YouTube for Islamic information acquisition in both groups of students. Facilitating conditions demonstrates significantly negative relationship with YouTube acceptance for students in other academic disciplines than for Islamic academic discipline. Additionally, the MGA analysis' findings suggest that determinants' factor coefficients of YouTube acceptance for Islamic information acquisition are not significantly different between students in Islamic academic disciplines and the other disciplines. This study validates the UTAUT model to understand the determinant of social media application usage in a new study context.**

Keywords—Unified Theory of Acceptance and Use of Technology (UTAUT); YouTube; information acquisition; student knowledge; Partial Least Square

I. INTRODUCTION

YouTube resembles a social media platform that specializes in online videos. It is available in over 100 countries, with 400 hours of video added per minute in 80 languages [1]. With 2.3 billion users worldwide, the YouTube site has increased in popularity [2]. However, with no requirements or defined certification criteria, creators worldwide can submit an infinite number of videos to YouTube, meaning that video accuracy and quality might differ widely [3, 4]. This is because the content quality and content validity would depend on the knowledge and experience of video creators [5]. However, despite these facts, YouTube has been recognized as the first and essential source for millennial generations when they want to acquire new information and express their opinion [6-8]. Remarkably, the most popular search-related term on YouTube is "How to" [9].

There is an expanding literature body that has investigated YouTube as an information source predominantly pertaining to health-related information [10-13]. The findings of these studies, together with others, have highlighted the quality and reliability of shared health information. For example, Kocyigit et al. [13] and Ng et al. [11] found that most YouTube videos were high quality and provided useful information. However, several studies indicated that YouTube is not an appropriate source of information [10, 12]. Nevertheless, despite the fact of contrary evidence regarding specialized health information, the number of users obtaining health information from internet-based sources is rapidly increasing [13]. One explanation is that users have experienced enjoyable and valuable times when YouTube is used as a source of health information [14]. Nevertheless, studies on the usage of YouTube for Islamic information are scarcely found in the literature.

Traditionally, Islamic knowledge learning is usually performed through face-to-face interactions known as talaqqi and takes place in mosques, madrasahs, or other specific places [15, 16]. However, researchers have long been concerned about digital religious learning [17], which has motivated the present study. In general, as observed from prior studies, several studies highlighted the motivations of online Islamic information. For instance, Ishak [18] found that social media are uncomplicated and beneficial for Malaysian Muslims to obtain Islamic information to increase their religious beliefs. This is consistent with a recent study of Islamic information-seeking behavior in Saudi Arabia [19] and Indonesia [20].

However, most studies were conducted on general Internet or social media applications, and a specific study for YouTube has not been attempted.

The literature shows that UTAUT researching students' YouTube usage is being validated to describe and anticipate user behaviors behavioral and intention with regard to technology acceptance [21]–[26]. In contrast, Venkatesh et al. [28] proposed that it is crucial to evaluate UTAUT in a variety of technological contexts, settings, and cultural contexts since factors that affect technology adoption may differ depending on the technological context, cultural context, and user population. In this context, it was projected that the variables affecting students' use of YouTube for information acquisition could vary from contexts for using information systems generally, and that the UTAUT would need to be applied in diverse situations [26].

The objective of this study is twofold. First, to investigate the determinants of YouTube acceptance for Islamic information acquisition among Muslim university students in the margin of UTAUT. In order to fully grasp students' acceptance of YouTube, the four basic UTAUT constructs (performance expectancy, effort expectancy, social influence, and facilitating conditions) were utilized. Second, despite the numerous studies on YouTube adoption within various academic disciplines in Higher Education, such as medical sciences [29, 30], language literacy [31, 32], and business management [33, 34], the objective of our work is to fill the gap of the effect of academic disciplines on YouTube Islamic information acquisition.

This paper’s remaining section is like the following. As Section II describes the hypotheses development and conceptual framework, Section III explains the methodology for this study. Section IV discusses the results of the measurement model, structural model and multi-group analysis. Furthermore, Section V presents the study’s findings, and Section VI provides the paper’s conclusion.

II. Literature Review

A. Conceptual Framework

The Unified Theory of Acceptance and Use of Technology (UTAUT) model was chosen as the theoretical guideline for this research because it explains the elements that influence technology acceptance and usage [27]. Furthermore, several prior YouTube studies' usage in educational settings has empirically validated UTAUT for validity and reliability [23], [35–37]. Furthermore, UTAUT is a robust approach because it incorporates eight various models [27], encompassing the Theory of Reasoned Action [38, 39], Theory of Planned Behavior [40], Technology Acceptance Model [41], motivational model [42], the personal computer utilization model [43], an integrated model of planned behavior and technology acceptance [44], Social Cognitive Theory [45] as well as Innovation Diffusion Theory [46]. Moreover, facilitating conditions, social influence, effort expectancy, and performance expectancy are the four key variables that impact actual use and behavioral intention [27]. Therefore, three independent variables (social influence, effort expectancy, and performance expectancy) are suggested as behavioral intention direct determinants by UTAUT, whereas behavioral intention and facilitating condition determine actual usage. Hence, we suggest the conceptual framework provided in Fig. 1 for this research.

B. Hypotheses Development

Performance expectancy denotes a person's belief that technology will improve their performance in specific tasks [27]. Performance expectancy will be explored in connection to information acquisition activities in this research. The performance expectancy factor has been proven to possess a major effect on the behavioral intention of social media usage in education [23][47-50]. Thus, the research theorizes that the higher students perceive YouTube as an advantageous source of Islamic information acquisition, the higher their behavioral intention to use the application.

H1. Performance expectancy is a significant predictor of the behavioral intention to use YouTube for Islamic information acquisition.

The level of easiness connected with the technology used is referred to as effort expectancy [27]. Effort expectancy signifies a person's expectation of obtaining Islamic information from YouTube without much effort, as YouTube is a social media application. Researchers have found that the easiness of social media in educational settings positively influences the behavioral intentions to utilize the applications [47-49]. Hence, this research hypothesizes that the students' intention to utilize a YouTube video for Islamic information acquisition will increase with an advance in the searching easiness and handling of the YouTube functions.

H2. Effort expectancy is a significant predictor of the behavioral intention to use YouTube for Islamic information acquisition.

Social influence refers to a person's understanding of how others are relevant (e.g., peers, friends) and considers them utilizing technology [27]. Several research on social media acceptance has found that the influence of others is a strong predictor of social media behavioral intention for learning purposes [23][47-50].

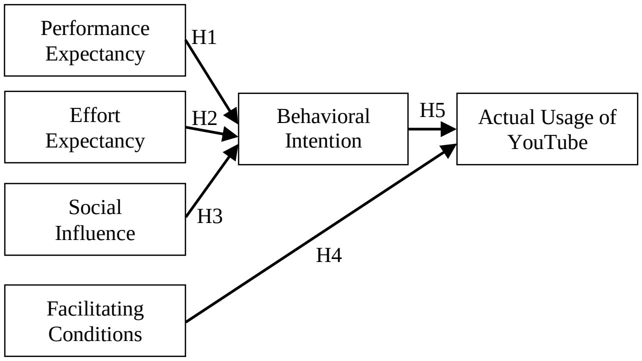

Fig. 1. The Research Framework and Hypotheses.

Therefore, individuals will be motivated to accept social media in educational settings if social influencers also utilize it. Hence, this work hypothesizes that the students' intentions to use YouTube for Islamic information acquisition increase when the social influence level increases (for instance, imposed by significant people, family, or peers).

H3. Social influence is a significant predictor of the behavioral intention to use YouTube for Islamic information acquisition.

The extent to which a person senses that technological infrastructure and an organizational sustains to ease the system's use is termed facilitating conditions [27]. Facilitating conditions were expressed in the context of this research as students' views of whether they have access to the tools and assistance they need to utilize YouTube for Islamic information acquisition. Several social media researchers have found that the facilitating conditions are a reliable predictor of intention to utilize social media apps [47][50]. Therefore, this research hypothesizes that when the ease of facilitating conditions improves, the student's use of YouTube videos for Islamic knowledge will develop.

H4: Facilitating conditions are a significant predictor of the behavioral intention to use YouTube for Islamic information acquisition.

Behavioral intention signifies the motivational factors that affect the probability of performing certain behavior [40]. The behavioral intention has been identified as a mediating element in users' use and acceptance of technology [27]. In the framework of this research, behavioral intention assesses students' inclinations, as well as intentions of using YouTube to get Islamic information. According to the UTAUT, behavioral intention is a powerful indicator of actual technology utilization. The behavioral intention has also been found to be a key predictor of social media application usage in several research on social media [23][47, 48][50]. Therefore, this study hypothesizes that behavioral intention is pivotal to YouTube's actual use of Islamic information.

H5: Behavioral intention is a significant predictor of students' actual usage of YouTube for Islamic information acquisition.

III. Methods

A. Samples

Referring to the UTAUT by Venkatesh et al. [27], this research adopts a quantitative method to assess all the variables in the study hypothesis model. The participants in the research are the younger generation of Muslims in Malaysia among undergraduate students at public universities aged between 20 to 30 years. The rationale for selecting university students is because they are active users of YouTube and utilize the platform for information seeking.

As per the Ministry of Higher Education Malaysia's report, there were 584,576 public university students in 2020 [51]. The sample size was selected according to the method prescribed for Partial Least Squares-Structural Equation Modelling (PLS-SEM) analysis. Based on the minimum sample size requirement suggested by Hair et al. [52], we would need a minimum 619 sample size to render the corresponding effect significant at 5% when the minimum path coefficient is expected to be signed between 0.11 and 0.20. This study targeted 800 students randomly selected from five areas in Malaysia at six public universities. Data were collected through online surveys assisted by the program coordinator in each selected university. Initially, 800 surveys were collected; 795 students were used for the analysis after removing the outliers.

B. Measures

The questionnaire consists of demographics, YouTube usage patterns, and five variables taken from UTAUT and administered in the Malay language. The measurement instrument is presented in Appendix A. The interval scale was used to six variables measure: performance expectancy (Cronbach’s Alpha=0.886), effort expectancy (Cronbach’s Alpha=0.935), social influence (Cronbach’s Alpha=0.917), facilitating conditions (Cronbach’s Alpha=0.939), behavioral intentions (Cronbach’s Alpha=0.926), as well as actual usage (Cronbach’s Alpha=0.909). In the pre-test research, they all had high construct reliability.

C. Data Analysis

The partial least squares structural equation modelling (PLS-SEM) was used for this investigation due to its ideal for theory prediction and exploration [53]. SmartPLS version 3.2.7 [54] was used. The following actions were taken during data analysis: to see if any demographic variables differed between Islamic and other academic disciplines, a chi-squared test was utilized alongside IBM SPSS 26.0. The model was subsequently verified using a two-stage analytical PLS-SEM procedure [55]. PLS-SEM has the additional benefit of evaluating both the measurement and structural models, which is additionally best suited to performing multi-group analysis [54][57].

The first stage involves testing the measurement model to assess the internal consistency reliability, convergent validity and discriminant validity of the constructs used in this study. Composite reliability of more than 0.70 [55] was used to analyze the reliability. Compared to Cronbach's Alpha, composite reliability is better suited for PLS-SEM [53]. In addition, the average variance extracted, and factor loading was utilized to evaluate convergent validity. Meanwhile, the Heterotrait-Monotrait ratio (HTMT) and the Fornell-Larcker criterion were used to determine discriminant validity [56]. Finally, an invariance test was also carried out to identify if the construct measurements were equally comprehended all across two groups of different academic disciplines before performing a multi-group analysis (MGA).

The second stage involves examining the structural model to test the hypotheses. The structural model defined the casual relationships between the model's constructs (the coefficient of determination, R^2 value and path coefficients). The R^2 and the path coefficients (significance and beta) together demonstrate how well the data are consistent with the proposed model [55][57]. The bootstrapping method involving a resampling of 5000 was employed to calculate the path coefficient's significance. According to the literature, this study additionally evaluated the path model's predictive relevance (Q^2 value), which includes blindfolding procedure [55][57]. Additionally, effect sizes (f^2) were evaluated to identify if an exogenous latent construct has a weak, moderate, or substantial influence on an endogenous latent construct [52]. Lastly, the multi-group analysis is carried out to establish the differences in path coefficients between two groups.

IV. Results

A. Sample Profiles

The chi-squared test discovered substantial differences (p<0.05) between students in Islamic academic discipline and other academic disciplines in gender, university, year of study, and age (Table I). Questions with multiple-choice answers were used to examine YouTube search behavior is shown in Table II.

TABLE I. Sample Profiles

Variables	***Profiles***	**Full Dataset n (%)**	**Islamic Academic Discipline Dataset n (%)**	**Other Academic Disciplines Dataset n (%)**	***Chi-Square***	***p Value***
Gender	Male	317 (39.9)	97 (30.6)	220 (69.4)	18.357	0.000
	Female	478 (60.1)	202 (42.3)	276 (57.7)		
University	USIM	200 (25.1)	99 (49.5)	101 (50.5)	300.509	0.000
	UMK	100 (12.6)	0 (0.0)	100 (100.0)		
	UMS	100 (12.6)	0 (0.0)	100 (100.0)		
	UKM	100 (12.6)	100 (100.0)	0 (0.0)		
	UNIMAP	100 (12.6)	0 (0.00)	100 (100.0)		
	UIA	195 (24.5)	100 (51.3)	95 (48.7)		
Study Year	Year 1	167 (21.0)	70 (41.9)	97 (58.1)	21.813	0.000
	Year 2	204 (25.7)	53 (26.0)	151 (74.0)		
	Year 3	291 (36.6)	107 (36.8)	184 (63.2)		
	Year 4	133 (16.7)	69 (51.9)	64 (48.1)		
Age	18 to 21	517 (53.0)	124 (24.0)	393 (76.0)	38.935	0.001
	22 to 24	402 (41.2)	161 (40.0)	241 (60.0)		
	25 to 27	48 (4.92)	13 (27.0)	35 (73.0)		
	28 to 30	8 (0.82)	1 (12.5)	7 (87.5)		

Almost all students actively used YouTube to get religious information based on self-initiative (94.0%). Searching keywords are based on topics (54.6%), current issues (51.2%), religious figures (45.9%), and religious law (33.0%). Students actively search YouTube on campus (77.6%), at home (58.3%), and others (10.8%) using smartphones (79.2%), notebooks (46.4%), and tablet (12.3%).

B. Measurement Invariance Test

A measurement invariance test assesses if item measurements vary between groups [55].

TABLE II. YouTube Searching Behavior

Variables	**Full Dataset n (%)**	**Islamic Academic Discipline Dataset n (%)**	**Other Academic Disciplines Dataset n (%)**
Using YouTube for religious information on own initiatives:	748 (94.0)	290 (38.8)	458 (61.2)
Keywords used for searching religious information:			
Topics	434 (54.6)	175 (40.3)	259 (59.7)
Current Issues	407 (51.2)	163 (40.0)	245 (60.0)
Religious Figures	365 (45.9)	141 (38.6)	224 (61.4)
Religious Law	262 (33.0)	108 (41.2)	154 (58.8)
Access YouTube from:			
Campus Network	617 (77.6)	261 (42.3)	356 (57.7)
Home	464 (58.3)	163 (35.1)	301 (64.9)
Others	86 (10.8)	30 (34.9)	56 (65.1)
Device Accessing YouTube:			
Smartphone	630 (79.2)	247 (39.2)	383 (60.8)
Notebook	369 (46.4)	156 (42.3)	213 (57.7)
Tablet	98 (12.3)	32 (32.7)	66 (67.3)

When executing multi-group analysis, this is a key step [58]. The initial examination found that full measurement invariance was not possible. We discovered that one indicator of effort expectancy (EE2) has distinct implications across the groups and excluded this indication. All construct measures were invariant between Islamic academic discipline and other academic disciplines dataset once the initial model was purified; there was no substantial distinction between those two. The findings of the investigation revealed well-developed measurement invariance (Table III).

C. Measurement Model

Assessment of the measurement model was done through construct reliability as well as validity.

For construct reliability, this study tested the individual composite reliability (CR) values to evaluate the reliability of each of the measurement model's key variables [55]. The results indicate that all the composite reliability (CR) values range from 0.799 to 0.894 in the full data set, 0.773 to 0.94 in the Islamic discipline group, and 0.827 to 0.938 in the other disciplines group, respectively. These values were higher than 0.7 [39], which, as demonstrated in Table IV, sufficiently demonstrates that construct reliability is met.

TABLE III. MEASUREMENT INVARIANCE TEST

Construct	**Indicator**	**Outer Loadings Differences**	***p Value***
Performance Expectancy (PE)	PE1	0.023	0.372
	PE2	0.023	0.225
	PE3	0.245	0.669
	PE4	0.285	0.636
	PE5	0.001	0.969
Effort Expectancy (EE)	EE1	0.128	0.619
	EE3	0.049	0.847
	EE4	0.216	0.917
	EE5	0.209	0.178
Social Influence (SI)	SI1	0.185	0.537
	SI2	0.189	0.677
	SI3	0.200	0.287
	SI4	0.281	0.148
Facilitating Conditions (FC)	FC1	0.056	0.403
	FC2	0.101	0.875
	FC3	0.021	0.735
	FC4	0.111	0.813
	FC5	0.042	0.739
Behavioral Intention (BI)	BI1	0.006	0.685
	BI2	0.025	0.221
	BI3	0.005	0.692
	BI4	0.024	0.538
Actual Usage (AU)	AU	0.000	0.671

Indicator reliability was examined using factor loading. High loadings on a construct show that the related indicators appear to have similarities which what the construct captures [55]. Factor loadings of 0.50 were regarded as highly significant [55]. As indicated in Table IV, all items' loadings were higher than the recommended value of 0.5, with the exception of item FC2 in three different data sets and SI4 in the Islamic academic discipline group. These items were retained because they not affect internal consistency and reliability [52]. However, items EE1 and FC4 were deleted to improve the composite reliability.

This study employed the average variance extracted (AVE) to examine convergent validity (the degree to which a measure correlates favourably with different measures of the same concept), and it found that all AVE values exceeded the recommended value of 0.50 [55]. As a result, the convergent validity for all constructs in the three datasets has been well met. Thus, sufficient convergent validity is exhibited, as shown in Table IV. The full dataset indicates values of AVE from 0.551 to 0.793, Islamic academic discipline data pointed the values ranging from 0.540 to 0.797, and other academic disciplines data indicated the values of AVE from 0.556 to 0.791.

Two metrics, Fornell-Larcker and the Heterotrait-Monotrait (HTMT) ratio, were used to evaluate the discriminant validity of the measurement model (the extent to which items differ between constructs or measure various concepts). The results of discriminant validity using the Fornell-Larcker criterion for the full dataset are presented in Table V, in which the square root of the AVEs on the diagonals, as denoted by the bolded values, are higher than the correlations between constructs (column values and corresponding row). This suggests that the constructs have an excellent discriminant validity because they are substantially associated to their respective indicators when compared to other model constructs [59]. Moreover, the correlation between exogenous constructs is lower than 0.85 [59]. Additionally, the constructs' Fornell-Larcker criterion for the Islamic academic discipline dataset (Table VI) and other academic disciplines dataset (Table VII) also suggested good discriminant validity.

However, Henseler et al. [56] mentioned that the lack of discriminant validity in most study scenarios is not accurately revealed by the Fornell-Larcker criterion. Therefore, a new approach has been introduced to solve this sensitivity problem, which uses the HTMT ratio of correlations based on the multitrait-multimethod matrix. The results for discriminant validity using the HTMT ratio are presented in Table V (full dataset), Table VI (Islamic academic discipline dataset) and Table VII (other academic disciplines dataset).The conservative approach’s HTMT threshold is <0.85, whereas for the liberal approach’s threshold is <0.90 [38]. The liberal approach was used in the current study to evaluate discriminant validity. The findings demonstrate a lack of discriminant validity since all construct values in the three datasets are less than 0.90. In conclusion, based on the tests of both validity and reliability, the measurement model in three datasets has been validated successfully.

D. Structural Model

The structural model defined the causal relationships between the constructs in the model (the coefficient of determination, R^2 value and path coefficients). Both the path coefficients (significance and β) and the R^2 display excellent ways that the data is supporting the hypothesized model [55][57]. Table VIII presents the path coefficients for the entire sample. After analysis, it was discovered that behavioural intention (BI) was positively and significantly associated to effort expectancy (EE), performance expectancy (PE), and social influence (SI) for all datasets. Table VIII also displays the results in detail for each academic discipline. Most notably, both the academic disciplines datasets and the entire datasets offer empirical support for H1, H2, and H3, respectively.

With regard to the relationship between facilitating condition (FC) and actual usage (AU), the full and other academic disciplines datasets were discovered to possess a negative significant outcome. Thus, H4 is strongly supported, except for the dataset for Islamic academic discipline. The R^2 values in Table IX for this relationship were above the desired 0.5 threshold and considered moderate [55], accounting for 51% of behavioural intention (BI) variance. However, there is no empirical support for the impact of behavioural intention (BI) on actual usage (AU) for all datasets.

This study also evaluated the path model's predictive relevance (Q^2 value) via the blindfolding procedure. Every data point of the indicators in the reflective measurement model of endogenous constructs is systematically deleted and predicted during the blindfolding procedure, which is a resampling technique [55]. The original values and the forecasted values are compared using this procedure. The path model has good predictive accuracy if the prediction is close to the original values (for example, the prediction error is minimal). If the value of Q^2 is greater than 0, then the predictive relevance of the proposed model exists for a certain endogenous construct [55], [59]. The findings for all datasets reveal that the Q^2 values are all greater than 0, verifying the prediction model as shown in Table IX.

Finally, this study assessed the f^2 effect sizes. It identifies if an exogenous latent construct possess a weak, moderate, or substantial impact on an endogenous latent construct [51]. Hair et al. [55] suggest testing the R^2 value's changes. On the other hand, Cohen [61] recommend a magnitude of f^2 at 0.35 (large effects), 0.15 (medium effects) and 0.02 (small effects) as a guideline measure. Following the rules of thumb, the result of f^2 as Table IX shows the relationships with large effects on behavioural intention (BI) of the total dataset but small effect sizes on actual usage (AU).

E. Multi-group Analysis (MGA)

Using MGA, the analysis concludes by determining if the differences in path coefficients between the Islamic academic discipline dataset and other academic disciplines dataset are significant. The results in Table X indicate no substantial differences between the two groups were observed in any pathways. This indicates that there is no significant difference between the two different groups of academic disciplines in terms of the effect of performance expectancy (PE), effort expectancy (EE), and social influence (SI) on behavioural intention (BI) to use YouTube for Islamic information acquisition. This study also indicates that there is no significant difference between two different groups of academic disciplines in terms of the effect of facilitating condition (FC) and behavioural intention (BI) on the actual usage (AU) of YouTube for Islamic information acquisition.

V. Discussion

This study used the UTAUT model as a guiding concept to analyze the factors that influence students' behavioral intentions to utilize YouTube for Islamic information acquisition.

TABLE X. Path Differences by Academic Disciplines

Relationships	**Path Coefficients Differences**	***t Value***	***p Value***
PE → BI	0.100	1.199	0.231
EE → BI	0.117	1.316	0.189
SI → BI	0.077	1.030	0.303
FC → AU	0.027	0.336	0.737
BI → AU	0.071	0.852	0.394

Notes: PE: performance expectancy; SI: social influence; EE: effort expectancy; FC: facilitating condition; BI: behavioral intention; AU: actual usage.

It also looked at how academic disciplines affected these relationships. The PLS-SEM approach's empirical outcomes showed that the relevance and relative significance of influencing elements in the UTAUT on behavioral intention and usage is not distinguished between students in Islamic and other academic disciplines.

Significant relationships exist between performance expectations and students' behavioral intentions to use YouTube for Islamic information acquisition, supporting H1 as anticipated. The path coefficients did not vary significantly between the Islamic academic discipline and other academic discipline groups of students. The easy access to YouTube among students might explain that video on Islamic material is available anywhere, anytime, on various devices. Hence, this result aligns with earlier studies that used UTAUT in YouTube research contexts for information acquisition [23].

Parallel to the hypothesized relationship, effort expectancy affects students' use of YouTube for Islamic Information acquisition for both groups in different academic disciplines. Thus, H2 is upheld. This result has also been a decisive factor in the intention to use social media for learning in previous studies [47-49]. For this study, it may be assumed that the students' use of YouTube for Islamic learning does not necessitate any intellectual, physical, emotional, or psychological effort on their part. In other words, YouTube apps are simple to use for information acquisition.

Regarding social influence on behavioural intention to use YouTube for Islamic information, this research's findings portrayed that students do emphasize this, and hence H3 is supported. This research's results are consistent with previous studies in UTAUT, which explain that social influence factors are closely related to a person's behavioral intentions to use YouTube [23][47-50]. Furthermore, the effect of social influences on the YouTube use intention was greater for students in Islamic discipline than for other academic disciplines. This interesting result might come from an increased number of Muslim preachers utilizing YouTube to spread their message [62, 63]. This study, even so, found that the difference in path coefficients between the two groups was insignificant.

The existence of facilitating conditions positively affects students' actual usage of YouTube for Islamic Information overall and other academic disciplines students. Hence, H4 was sustained. However, it was not a determinant for Islamic academic disciplines students. This predictor's path coefficients on YouTube usage appeared to be higher among other academic disciplines students. Nonetheless, in this study, there were no significant differences in the path coefficients of the two groups. This finding is both enlightening and controversial. The explanation for this might be due to the enabling condition's limited effect size on other academic disciplines of student usage. Furthermore, there were no variations in the effect size of the facilitating conditions among the two groups. The result is along the lines of earlier literature [23] that found that facilitating condition was not a predictor of students' willingness to use YouTube application for learning.

Unlikely, the behavioral intention was not significantly related to the YouTube usage for either Islamic or other academic discipline students; there was no substantial difference between the two groups. This intriguing outcome might be since using YouTube to obtain Islamic material is a voluntary use of technology. However, several research that deemed social media use for learning to be mandatory disputed these findings [23][47].

This research presents a statistically verified UTAUT model to explain the different usage between students of Islamic and other academic disciplines. In the context of disseminating Islamic information on online platforms, this study corroborates the UTAUT's ability to predict students' behavioral intentions regardless of their academic background. The students of nowadays are known as ‘digital natives,’ who are accustomed to incorporating technology into every aspect of their lives, including religious activities. They exploited YouTube as a search engine to discover information in formal and informal learning [8]. However, previous research discovered obstacles to misinformation and disinformation of Islamic information on social media [20]. Given these results, Muslim preachers should utilize this platform to disseminate Islamic information as the video's credibility depends on them. Furthermore, YouTube potentially encourages interactivity among users and preachers because it has tools that facilitate interaction.

Finally, this study has limitations that may suggest future research directions. First, possible latent variables that may enhance the prediction of students' behavioral intentions, such as ambiguity of information [64] and students' religiosity, should be considered in future research. Second, the study examined just Malaysian students; results obtained in other countries may differ. Lastly, this research depended on respondents' self-reported measures of actual usage, which might be skewed by common method bias. Assessing students' usage in a longitudinal study and controlling for real YouTube usage would be a more precise estimate.

VI. Conclusion

This research's primary goal was to observe the factors influencing students' behavior when it comes to YouTube usage for Islamic information acquisition established on the UTAUT research framework. This research also analyzes the differences between Islamic academic disciplines and other academic disciplines groups of students in the usage of YouTube for Islamic information acquisition. The findings imply that for both groups, students' behavioral intentions to YouTube for these specific purposes are predicted by social influences, effort expectancy, and performance expectancy. The results also found that that facilitating conditions were not a significant predictor of Islamic academic disciplines students' actual YouTube usage. Nonetheless, for both groups, behavioral intention was not a substantial predictor of actual YouTube usage for Islamic information acquisition. Overall, results of the multi-group analysis of PLS-SEM showed that there were no substantial differences were observed in any path coefficient between the two groups. The research's theoretical contribution is to verify the UTAUT model in the usage of YouTube among students in higher education for specific information acquisition.

APPENDIX A

Constructs	**Items**	
Performance Expectancy	PE1	I would find YouTube useful for me to acquire Islamic information.
	PE2	Using YouTube increases my daily religious practice.
	PE3	Using YouTube enables me to understand Islamic knowledge more quickly.
	PE4	Using YouTube increases my religious faith.
	PE5	Using YouTube enables me to solve uncertainty in Islamic information.
Effort Expectancy	EE1	Learning to operate YouTube for Islamic information acquisition is easy for me.
	EE2	My interaction with YouTube on Islamic information acquisition would be clear and understandable.
	EE3	I would find YouTube easy to use for religious purposes.
	EE4	It would be easy for me to become skillful at using YouTube to find Islamic information.
	EE5	I would find YouTube easy to use for Islamic information acquisition.
Social Influence	SI1	People who are important to me think I should use YouTube for Islamic information acquisition.
	SI2	People who influence my behavior think I should use YouTube for Islamic information acquisition.
	SI3	My peers have been helpful in using YouTube for Islamic information acquisition.
	SI4	In general, most people have supported using YouTube for Islamic information acquisition.
Facilitating Conditions	FC1	I have the resources necessary to use YouTube.
	FC2	It would be comfortable for me to surf YouTube for Islamic information acquisition.
	FC3	I have the knowledge necessary to use YouTube.
	FC4	YouTube is compatible with any gadgets I use.
	FC5	A specific person is available for assistance with the YouTube difficulties.
Behavioral Intention	BI1	I plan to use YouTube for Islamic information acquisition soon.
	BI2	I predict I would use YouTube every day for religious benefit.
	BI3	I intend to use YouTube more often to acquire Islamic information.
	BI4	I want to share Islamic information on YouTube with my friends.
Actual Usage	Using YouTube for religious information on my own initiatives.
