Wang et al. [18] discussed in his paper that a coloured image rectification approach that utilizes non-linear functionality conversion by the brightness-reflection model and multi-scale concept is presented to enhance the flexibility of visualization in images with low illumination. The initial RGB image is altered to HSV color space before extracting the illuminating part of the illustration utilizing the multi-scale Gaussian function. The setting parameters of the image-enhancing mechanism are then adaptively adjusted depending on the spatial distribution characteristics of the lighting elements to produce two images. The correction mechanism is then built using the Weber-Fechner law. The features underlying the two images are then extracted using an image fusion approach. The suggested technique, when compared to the traditional method, can enhance an image's total contrast and brightness while lessening the effects of unequal brightness. The improved images are crisp, inevitable and precise. This paper's lack of brightness is its fundamental flaw.

Greater detail is available in high-quality MR images, enabling accurate diagnosis and statistical image analysis [19]. A deep CNN has demonstrated its potential capacity for super-resolution imaging given LR images. The underlying texturing of various sizes, the highly correlated edges, and the backdrop that is less instructive are a few visual traits that the LR MR images often have in common. Although the backdrop is smoother, multiple scales structural details are instructive for image restoration. The majority of earlier CNN-based SR techniques treat all spatially pixels identically and employ an individual field of reception. For superior MR image SR, it fails to detect the full space and extract a variety of attributes from the input. To solve these issues, a wide weighted attention multi-scale network (W2 AMSN) is suggested for precise MR image SR. On the opposite, the broad multi-scale branching may be used to extract the characteristics of various sizes. On the contrary, in order to continually calibrate feature reactions, a non-reduction attentiveness technique. This focus maintains ongoing cross-channel contact and concentrates on areas that are more relevant. The accessible weighting factors, however, dynamically combine recorded characteristics. A recurrent foundation and a global system for attention are used to incorporate the encapsulated W2AMSB numerous evaluations and a variety of research on ablation demonstrate the usefulness of the suggested W2 AMSN, that outperforms cutting-edge techniques on the majority of common MR image SR standards both numerically and subjectively. On actual MR images, this method still provides greater accuracy and flexibility.

SISR has been shown to greatly benefit from CNN [20]. Previous studies, nevertheless, have not fully used multi-scale characteristics and have disregarded the inter-scale relationship among various up sampling parameters, leading to poor results. It is devoted to mining image characteristics and

discovering the inter-scale relationship among various expanding variables rather than only raising the level of the network irrationally. A MDCN is used to do this, which delivers outstanding efficiency with fewer settings and shorter processing time. DRB, HFDB, and MDCBs make up MDCN. They include DRB, which aims to reconstruct SR images with various up sampling variables within a single model, and MDCB, which concentrates on automatically recalibrating channel-wise feature reactions in order to accomplish feature the distillation process. It's important to note that each of these modules has autonomous operation. To enhance the accuracy of the model, these components may be selectively integrated into any CNN model. Numerous investigations demonstrate that MDCN performs competitively in SISR, particularly when it comes to reconstruction tasks involving numerous up sampling values. On GitHub, the code is available under the name MIVRC/MDCN-PyTorch.

The interpretation of medical images has greatly increased in recent years due to machine learning, especially deep learning, but labelled data is still hard to come by. Researchers have developed a unique self-supervised learning method based on backdrop restoration to overcome this problem. Additionally, researchers have studied state-of-the-art unsupervised and semi-supervised deep learning approaches. Deep learning has proven crucial in a variety of medical imaging applications, including illness diagnosis. Meanwhile, the combination of deep learning and machine learning has produced smart imaging devices that increase the precision and effectiveness of the interpretation of medical images. Medical image security is an issue, and to improve image safety, a zero-watermarking technique utilizing DTCWT-DCT has been developed. Moreover, image denoising is crucial for medical imaging, and noise reduction is achieved using an optimization-based technique based on bilateral filters. Furthermore, maintaining the integrity of images is essential in telehealth, and to avoid distortions, a robust solution to reversible watermarking has been created. Particularly in the context of COVID-19, AI has advanced significantly in radiology, with image-based AI being essential for controlling the severity of sickness. Deep CNNs have demonstrated potential for super-resolution imaging, and an inventive method of image correction improves image visibility. Finally, a multi-scale network method that offers faster processing times and more efficiency is suggested for image super-resolution. In a number of respects, these developments are spearheading the revolution in medical imaging and healthcare.

## III. PROBLEM STATEMENT

The above discussed literatures states that, in healthcare, the effectiveness of medical imaging is crucial for precise diagnosis, treatment planning, and continuing condition monitoring. Despite significant advancements in image restoration methods, there are still two significant problems. First, it is necessary to protect important spatial elements without losing context-related data, which is frequently lost during restoration methods. Second, while maintaining exact location precision might be challenging, creating linguistically sound outputs is essential. This paper presents an MSDL-RNN to overcome these problems and enhance medical imaging.

The MSDL-RNN uses various scales during model development, in contrast to typical RNN-based techniques that frequently depend on both full-resolution and gradually reduced-resolution approximations. A comprehensive solution to increase medical image restoration and enhancement across many modalities is provided by this ground-breaking multi-scale technique, which efficiently uses deep learning capabilities to address issues including noise reduction, defect elimination, and overall image quality enhancement [21].

The selection of the suggested approach is supported by a number of elements that make it extremely suitable for handling the particular issue at hand. First off, the segmentation process is made more flexible and precise by using the ABC optimization method. This is especially important for medical image analysis, since precise identification of regions of interest is critical. Second, applying a median filter during the pre-processing phase guarantees that noise is efficiently minimized, maintaining crucial image features and enhancing the quality of the input data a feature that is especially helpful for medical images that are frequently tainted by noise. Moreover, the application of the GLCM for feature extraction yields a thorough

comprehension of the textural and structural characteristics present in the images, which is an essential component of medical image analysis. However, the constraints of current approaches, such as basic pre-processing's limited noise reduction capabilities and classic segmentation techniques' lack of flexibility, make them ill-suited for the complexity and requirements of medical image analysis. These drawbacks highlight the need for the integrated approach of the suggested strategy, which combines these deficiencies and makes it a strong option for the given situation.

## IV. PROPOSED ABC-RNN METHODOLOGY

The second dataset for training and testing is the Kaggle dataset. This is employed to show the efficacy of the analysis and to find the diseases in patients. Pre-processing is used to eliminate unwanted noise distortions and improve specific qualities that are essential for the process. Correspondingly, the standard MSDL-RNN technique is employed to restore and enhance the medical image. Furthermore, it is employed to attain a better accuracy value. Fig. 1 shows the architecture of the proposed MSDL-RNN.

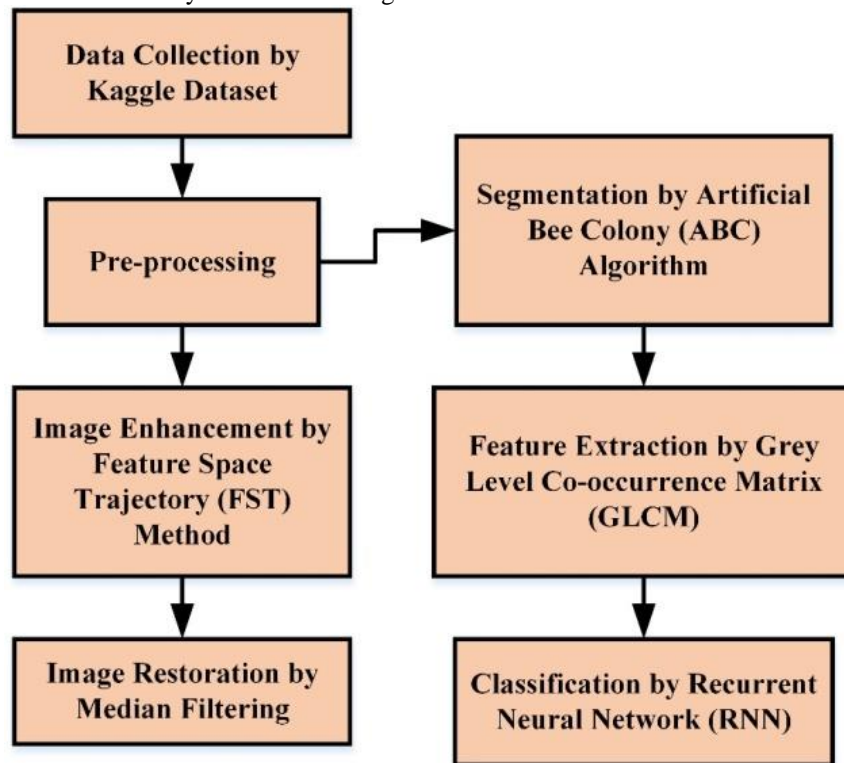

Fig. 1.   Proposed ABC-RNN architecture.

### A. Data Collection

The dataset used here is the Kaggle dataset [22]. Nearly, 10,000 datasets are used. From this, 50% of the datasets are second-hand for the training process and the other 50% for the testing process.

### B. Median Filter for Pre-processing

Pre-processing is done to remove unwanted noise, eliminate defects, and ensure the comprehensive quality of

images. Here, pre-processing is used to improve and improve the image quality. The image enhancement is done by Feature Space Trajectory (FST) method. The route or trajectory data points taken when traversing the space of features is referred to as the FST   [23]. The space determined by the data's characteristics or qualities is referred to as feature space in the arenas of machine learning and data analysis. The exact location of every data point in the space of features is determined by the set of value features that represent it. And

also, the image restoration is done by Median filtering [24]. The steps and equations of the median filtering are given below:

Step 1: Give an input image that is represented as J

Step 2: The image's channels is divided, and the highest and lowest P pixels in every channel are determined in (1) and (2)

$$minimum = minimum_{(i,j)} P(i,j) \qquad (1)$$

$$maximum = maximum_{(i,j)} P(i,j) \qquad (2)$$

Step 3: The channel of the image is non-linearly modified as seen below in (3)

$$P_1(i,j) = minimum - (maximum - minimum) \times \left( \frac{(P(i,j) - minimum)}{maximum - minimum} \right)^{\beta} \qquad (3)$$

The change in wavelength is comparable to the beta transformation but is not the same. The result of the transformation, which is the input image, does not change the image when $\beta=1$ is applied. When $\beta \neq 1$, the transformation may extend or conceal the image's pixel values, boost contrast and recover high-frequency elements that disappeared because of border data and the distance, among other capabilities. When $\beta<1$, extending the low-pixel frequency band and decreasing the high-pixel frequency band is possible In this instance, it is possible to efficiently recover the minute details of the deeper portion of the image while also improving the local brightness of the darker region of the image and the effect of the stronger lighting on the image. When $\beta > 1$, low-pixel data can be muted by stretching the spectrum of high-pixel data. In this scenario, it is possible to efficiently recover the minute details of the brightest portion of the image by increasing the local brightness of the brightest section. So, grounded on the image's circumstances that need improvement, one can select the c value. Stronger lighting will result in poorer image pixel values.

Step 4: The image was transformed logarithmically, as displayed in the resulting manner given below in (4),

$$P_2 = log(P_1 + n) \qquad (4)$$

The alteration can broaden the image's low-pixel frequency spectrum, boost the darker image's contrast, which helps to recover the darker image's features more effectively and is more suitable for outdoor locations with lower light levels. Nevertheless, logarithmic treatment significantly diminishes the image's luminosity and reduces the high-pixel frequency. To compensate for this, the image's luminosity can be somewhat improved by setting an even amount preceding the logarithmic adjustment.

Step 5: The image is normalized to have pixel values that range from 0 to 255. Eq. (5) provides the particular conversion.

$$P_3 = \frac{(P_2 - minimum) \times 255}{(maximum - minimum)} \qquad (5)$$

## C. Segmentation using Artificial Bee Colony Optimization Algorithm

Segmentation has become more important in various aspects of image processing, especially classification, image recovery and object recognition [25]. It is an essential step in numerous applications. The suggested approach employs Artificial Bee Colony Optimisation (ABC) to discover similar regions and appropriately inspect every section once images have been segregated following the pre-processing stage.

The ABC algorithm, which stands for Artificial Bee Colony, is an optimization method that mimics the honey bee's feeding behavior and has been effectively used to solve several real-world issues. The class of algorithms for swarm intelligence includes ABC. A group of honey bees known as a swarm can work together to complete activities effectively [26]. Additionally, the ABC method has three different kinds of bees: working bees, observers and scouting bees. The recruited bees searching for food nearby the food resource in their memories while informing the spectator bees about these food sources. Despite the food resources discovered by the worker bees, the onlooker bees frequently select the best ones. The likelihood that the onlooker bees will select the nourishment basis with better quality (fitness) is much greater than the likelihood that they would choose the one with a lower level of quality. Scout-type bees are derived from a trivial number of worker bees that leave their nourishment foundations and look for new ones. The employed bees make up the initial part of the swarm in the ABC algorithm, and the onlooker bees make up the second half. The total number of solutions in the swarm is equivalent to the number of engaged bees or observers.

This study aims to investigate the effects of ABC parameters in a Multi-Scale Deep Learning-Based Recurrent Neural Network on Medical Image Restoration and Enhancement. ABC is an optimization method that carefully adjusts the hyper parameters of the network. The model's overall performance is significantly impacted by the meticulous selection of ABC parameters, such as colony size, convergence criterion, and exploration rate. When these parameters are optimized with expertise, the network is able to perform very well in the complex field of medical image restoration and enhancement, leading to better denoising and sharpening of medical images. The careful choice of ABC parameters results in improved image quality as well as increased network accuracy when it comes to medical image restoration. This significantly increases the Multi-Scale Deep Learning-Based Recurrent Neural Network's overall efficacy in the field of medical image processing.

The ABC algorithm creates a starting population with a uniform distribution of randomness. Every solution $y_j$ (j = 1, 2..., SN) in this group has a solution number (SN). The formula for ABC optimization is given in (6) below:

$$y_j^i = y_{minimum}^i + random\,(0.1)\left(y_{maximum}^i - y_{minimum}^i\right), \forall\, i = 1,2,...V \qquad (6)$$

Where, $y_j$ stands for the $j^{th}$ source of nourishment in the starting community; $y_{maximum}^i$ and $y_{minimum}^i$ are the boundaries of $y_j$ in the $i^{th}$ route.

According to the nectar's efficiency data, the hired bee stage improves the hired bee's present strategy. This also comprises modifying the location of the nourishment basis according to its output and its calculation is given in (7). If it is discovered to be smaller than the previous one, the food sources with significant quantities are upgraded; otherwise, they are eliminated.

$$u_{ji} = y_{ji} + \emptyset_{ji}(y_{ji} - y_{li}) \qquad (7)$$

Where, $\emptyset_{ji}(y_{ji} - y_{li})$ is denoted as the step size; $\in \{1,2, \ldots SN\}$ , $i \in \{1,2, \ldots V\}$ are represented as the indices that are chosen randomly; $\emptyset_{ji}$ belongs to the range [-1,1].

The observer bee phase evaluates the collective nectar fitness and positional data provided by worker bees and according to the fitness chance and it selects the optimum course of action. The location of the worker bees is updated by the greater fitness chance and is given in (8) below:

$$q_j = \frac{g_j}{\sum_{i=1}^{SN} g_i} \qquad (8)$$

Where, $g_j$ denotes the $j^{th}$ fitness solution.

The hunter-bee phase starts looking for additional food sources when the food supply is depleted. This condition occurs if a source of nourishment disappears and its location has not been verified for the required number of cycles. A scout bee begins creating novel food sources in the surroundings and has a connection with discarded food. Nevertheless, in its simplest form, the ABC approach struggles with efficiency when handling challenging issues with a large search area. It demands a lot of fitness assessments and gets caught in regional minima. ABC also excels in discovery but struggles with the harvest. Many researchers were motivated by these flaws to suggest ABC versions for resolving various actual, empirical restrictions.

### D. Feature Extraction by GLCM

Feature extraction is selecting and highlighting raw data's most important information or characteristics [27]. It transforms the basic data into a more streamlined and practical form that might be used for tasks demanding simulation or further analysis. In machine learning and pattern recognition software, feature extraction is widely utilized to enhance computational effectiveness and presentation. This research uses a Gray-Level Co-Occurrence Matrix (GLCM) to extract features. In extracting features, the initial information is changed into mathematical topography that is devoid of any construction of alterations in the strange datasets, and its features are based on its pixels. It employs multiple parameters, such as energy, correlation, contrast, homogeneity, entropy, etc., which are second-order image characteristics to remove the statistically significant texture characteristics from the image.

*1) Energy:* The squares with regularly greater grayscale and erratic image concentration standards are summated to generate energy. In (9), the energy formula is shown.

$$\text{Energy} = \sum i \sum j \{N(i,j)\}^2 \qquad (9)$$

Here, N is denoted as the images; (i, i) is represented as the squares of the image.

*2) Contrast:* The regional intensity of an image is calculated using characteristics and is expected to be lower when the value of attentiveness is even. The comprehensive grayscale data of the original image is then displayed and its calculation is given in as (10).

$$\text{Contrast} = \sum_{x=0}^{H_j} x^2 \left\{ \sum_{i=1}^{H_j} \sum_{j=1}^{H_j} N(i,j) \right\} \qquad (10)$$

Here, H stands for the grayscale images; N is represented as the images; (i, j) is represented as the square of the greyscale image.

*3) Correlation:* By using the correlational features, it is feasible to adjust the mathematical links among the parameters and the inverse relationship of the grey levels on pixels. Its calculation is indicated in (11).

$$\text{Correlation} = \frac{\sum_i \sum_j (i,j) N(i,j) - \mu_p \mu_q}{\sigma_p \sigma_q} \qquad (11)$$

The images' $\mu_p$, $\mu_q$, $\sigma_p$, and $\sigma_q$ values for the average and the standard deviation are denoted as row and column correspondingly.

*4) Entropy:* The anticipated substantial amount of the randomness of the distribution of grey levels is entropy and its calculation is shown in (12).

$$\text{Entropy} = - \sum_i \sum_j N(i,j) \log(N(i,j)) \qquad (12)$$

---

**Algorithm 1:** *Pseudo code for ABC Optimization*

The problem should be defined initially.
Prioritize the ABC algorithms parameters.
Develop the colony of the worker bees.
Then the estimation of all the bee's fitness values should be done.
**Repeat** the process
M=0
**Repeat** the process
(l=a result in the locality of j)
($\emptyset$ = a random number in the range $[-1,1]$)
Develop novel results using Eqn. (7)
Then the process of greedy selection is applied.
The likelihood functional values are estimated using Eqn. (8)
Next the onlooker bees are assigned.
**Do** $\forall$ onlooker bees.
Again, the process of greedy selection is applied.
If the fitness worth of the onlooker bees is lesser than the fitness worth of the worker bees
Exchange it with the worker bees.
**End**
**End**
**If** the fitness of the best onlooker bees is lesser than the fitness of the best bee
Exchange all with the superior results.
**End**
M=M+1
**Until** (M=Number of the worker bee)
Define the rejected result with Eqn. (6)
**If** the scout bees result is superior to the worker bees result, replace it with the scout bees' result.
**Until** the maximum iteration

---

### E. Classification using RNN

The results from positive nodes can impact upcoming inputs to exact similar nodes via a recurrent neural network (RNN), an intimate of artificial neural networks whose interconnections among vertices can create a loop [28]. It can show continuous fluctuation. RNNs originated from feedforward neural networks and can handle classifications of inputs of various lengths by using their internal state. They can be used for applications like linked, not segmented recognition of handwriting or speech. A recurrent neural network describes networks with an infinite impulse response. The behavior of RNNs is temporally unpredictable. The architecture of RNN is shown in Fig. 2, followed by the algorithm of ABC optimization is given below. Fig. 3 displays the illustration of the proposed MSDL-RNN technique.

Fig. 2. Architectural diagram of RNN.

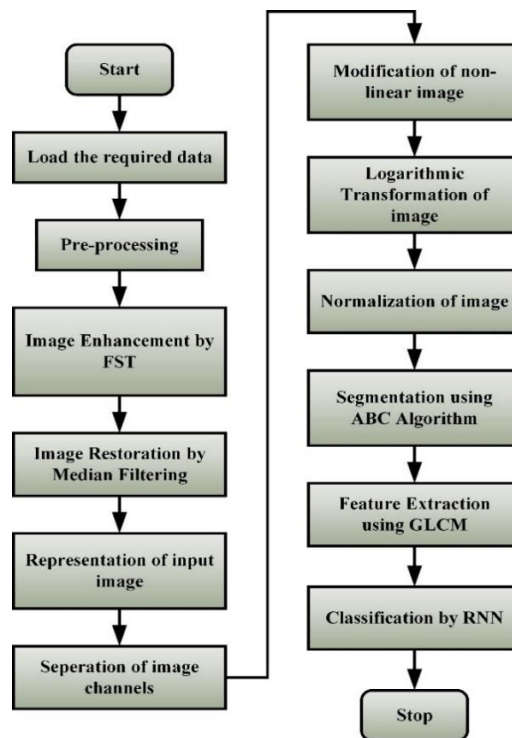

Fig. 3. Flowchart of proposed MSDL-RNN.

## V. RESULTS

The planned method has been investigated by using some datasets. Here, the Multi-Scale Deep Learning Based Recurrent Neural Network is used in this research for the procedure of image restoration and image enhancement. The description of the planned model is discussed by some parameters such as Accuracy, Recall, Precision, F1 Score, MSE, PSNR, and SSIM.

### A. Performance Metrics Evaluation

*1) Accuracy:* The easiest metric to comprehend is accuracy, which measures how many examples in a dataset have been correctly categorized as a percentage of all instances. It offers a broad gauge of overall accuracy. The accuracy calculation is given in (13) below:

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \qquad (13)$$

*2) Precision:* The percentage of cases that were correctly foretold as positive compared to every instance is what precision measures. It gauges the framework's capacity for avoiding erroneous positive results. For precision, use the formula which is shown in (14) below:

$$Precision = \frac{TP}{(TP+FP)} \qquad (14)$$

*3) Recall:* Recall counts how many advantageous circumstances were properly predicted out of all the favorable instances. It measures how well the model can find every instance of positivity. The recall equation is given in (15) below:

$$Recall = \frac{TP}{TP+FN} \qquad (15)$$

*4) F1-Score:* Precision and recall are harmonically summed to produce the F1 score. It yields a single value by combining the two metrics, giving a fair assessment of the efficacy of a model. The formula for F1-Score is given in (16) below:

$$F1 - Score = 2 \times \frac{(Precision \times Recall)}{(Precision + Recall)} \qquad (16)$$

*5) Mean Square Error (MSE):* An average square variance among the values of the pixels of the underlying and altered images are calculated by MSE. Lower scores suggest higher levels of quality in the restoration or enhancement process, and it estimates the overall appearance reconstruction inaccuracy. The calculation for MSE is given in (17) below:

$$MSE = \frac{1}{MN}\sum_{n=0}^{M}\sum_{m=1}^{N}[\hat{g}(n,m) - g(n,m)]^2 \qquad (17)$$

Where M and N are represented as the total number of pixels in the images; the $\sum$ is represented as the summation; $\hat{g}(n,m)$ is represented as the original pixel value image; $g(n,m)$ is represented as the pixel value of the processed image.

*6) Peak Signal Noise Ratio (PSNR):* The PSNR scale gauges the difference between the highest possible signal power and the strength of corrupted interference. Contrasting the initial and modified images is a common way to gauge how well the image restoration or enhancement techniques perform. Greater PSNR readings indicate greater image quality. The calculation of PSNR is given in (18) below.

$$PSNR = \frac{10 \, log_{10} \, (peak \, value)^2}{MSE} \qquad (18)$$

*7) Structural Similarity Index Metric (SSIM):* A statistic called SSIM evaluates how structurally two images are similar. It verifies perceived image quality by considering contrast, brightness, and structural data. The range of the SSIM is 0 to 1, with readings nearer to 1 and that suggests higher resemblance. The calculation of SSIM is given in (19) below.

$$SSIM = [l(x,y)]^\alpha \times [c(x,y)]^\beta \times [s(x,y)]^\gamma \qquad (19)$$

Where $l$ is represented as the luminance, c is represented as the contrast and s is represented as the structure.

Fig. 4. Comparison graph of accuracy.

The Table I presents a comparative examination of the accuracy, precision, recall, and F1-score performance measures of several approaches and it is depicted in Fig. 4. It analyse four approaches: Desnet, AGnet, Efficient NetB0, and Proposed ABC-RNN. Desnet obtains an F1-score of 94.53%, an accuracy of 95.11%, a precision of 98.77%, and a recall of 94.56%. With precision and recall both above 96% and high accuracy of 98.20 per cent, AGnet has an F1-score of 98.13%. Efficiency NetB0 has a 92.93% accuracy, a 98.32% precision, a 90% recall, and an 88% F1-score. With extraordinary accuracy of 99.23%, precision of 99.10%, recall of 98.65%, and an F1-score of 99%, the proposed ABC-RNN approach beats others.

TABLE I. COMPARISON OF PERFORMANCE METRICS

| Method | Accuracy (%) | Precision (%) | Recall (%) | F1-Score (%) |
|---|---|---|---|---|
| Desnet [29] | 95.11 | 98.77 | 94.56 | 94.53 |
| AGnet [30] | 98.20 | 96.45 | 98.13 | 98.13 |
| Efficient NetB0 [31] | 92.93 | 98.32 | 90 | 88 |
| Proposed MSDL-RNN | 99.23 | 99.10 | 98.65 | 99 |

Fig. 5. Comparison graph of MSE.

Table II and Fig. 5 show the evaluation and performance estimation of MSE. When associating the MSE of the planned technique with the following three existing methods, i) DS-RD-Net [32] ii) UIEC2-Net [33] iii) DCT [34], the proposed MSDL-RNN algorithm produces a lower MSE of about 1.04.

TABLE II. COMPARISON TABLE OF MSE

| Method | MSE (%) |
|---|---|
| DS-RD-Net [32] | 19.34 |
| UIEC2-Net [33] | 11.26 |
| DCT [34] | 4.15 |
| Proposed Method | 1.04 |

Fig. 6. Comparison graph of PSNR.

Table III and Fig. 6 show the evaluation and performance estimation of PSNR. When associating the PSNR of the planned technique with the following three existing methods, i) DS-RD-Net [32] ii) UIEC2-Net [33] iii) DCT [34], the proposed MSDL-RNN algorithm produces a greater PSNR of about 93.12 dB.

TABLE III. COMPARISON TABLE OF PSNR

| Method | PSNR (dB) |
|---|---|
| DS-RD-Net [32] | 36.21 |
| UIEC2-Net [33] | 20.54 |
| DCT [34] | 89.97 |
| Proposed Method | 93.12 |

Fig. 7. Comparison graph of SSIM.

Table IV and Fig. 7 show the evaluation and performance estimation of SSIM. When associating the SSIM of the planned technique with the following three existing methods, i) DS-RD-Net [32] ii) UIEC2-Net [33] iii) DCT [34], the proposed MSDL-RNN algorithm produces a greater SSIM of about 0.99.

TABLE IV. COMPARISON TABLE OF SSIM

| Method | SSIM |
|---|---|
| DS-RD-Net [32] | 0.96 |
| UIEC2-Net [33] | 0.84 |
| DCT [34] | 0.97 |
| Proposed Method | 0.99 |

## VI. DISCUSSIONS

The efficiency of the recommended MSDL-RNN strategy is higher when compared to earlier-used methods like Desnet, AGnet, and Efficient NetB0. The proposed methods' MSE value range is lesser than the other DS-RD-Net, UIEC2-Net and DCT methods values. The PSNR and SSIM values range higher than the other DS-RD-Net, UIEC2-Net and DCT methods. The anticipated technique's accuracy is greater than the efficacy determined by MSDL-RNN alone. The accuracy level achieved by utilizing this model is 99.23%. This

suggests the multi-scale deep learning-based recurrent neural network will enhance and restore medical images. The Kaggle dataset was utilized in this instance. The pre-processing approach is employed to lessen noise, eliminate corrupted images and enhance the superiority of the images. The FST technique is used to improve the image, and median filtering is used to restore it. After that segmentation is completed. ABC optimization performs segmentation, splitting an image or a bigger dataset into unique, significant segments or areas. The GLCM approach is used for feature extraction, choosing and emphasizing the most crucial details or traits from raw data. The classifying procedure is finished at that point. A machine learning model must first be trained to classify or categorize data into pre-set categories or groups. RNN handles it. The ABC algorithm's fictitious code is then presented. It now gets to the section where results and discussions take place. The proposed method is shown to have superior outcome statistics than every other approach when accuracy, recall, precision, f1-score, MSE, PSNR and SSIM are evaluated. The research then presented its findings and plans for the future.

## VII. CONCLUSION AND FUTURE WORK

The findings of this study underline how crucial it is to improve medical image quality for precise diagnosis, treatment planning, and ongoing condition monitoring in healthcare applications. By restoring lost high-quality data, the restoration of damaged input images constitutes a crucial step in accomplishing these goals. Despite substantial advancements in the field of image restoration, this work addresses two enduring problems. An innovative response to these problems is provided with the launch of the MSDL-RNN. MSDL-RNN differs from traditional RNN-based algorithms that depend on both full-resolution and gradually reduced-resolution approximations by using a multi-scale approach during model development. Deep learning is used in this breakthrough to efficiently solve problems including noise reduction, defect eradication, and the improvement of overall image quality. The MSDL-RNN technique's combination of local and global data enables the enhancement and recovery of a variety of medical imaging modalities. Despite these encouraging results, a noteworthy drawback of this work is that it largely concentrates on the improvement of image quality, leaving opportunity for potential future research in real-time applications and computing efficiency. Future studies should focus on reducing the processing requirements of the model to enable a smooth incorporation into clinical operations. The results of this study set the way for substantial developments in the field of medical imaging by providing a solid answer to problems relating to image quality improvement. The results of this study offer significant potential for enhancing patient care, diagnostic precision, and the general usability of medical images in healthcare applications, since the healthcare sector continues to rely heavily on them.

# Cold Chain Logistics Path Planning and Design Method based on Multi-source Visual Information Fusion Technology

Ke XUE[1], Bing Han[2]

School of Logistics and e-Commerce, Henan University of Animal Husbandry and Economy, Zhengzhou, 450044, China

*Abstract*—**Complete cold chain logistics is needed to control the whole temperature of refrigerated and frozen food, including the closed environment, storage and transportation when loading and unloading goods. Studying how to optimize vehicle scheduling and reduce transportation time and transportation costs is very important. The research object of this paper is the path planning of urban cold chain logistics. This paper will consider the cold chain distribution of multi-vehicle coexistence, build an integer programming model, design a targeted ACO (Ant Colony Optimization) solution model, and verify it with an example. Based on multi-source visual information fusion technology, these independent heterogeneous data sources are accessed through cloud computing resource integration technology to establish a unified data integration middleware. The pheromone update model selected in this paper is the ant week model, which uses global information to record the optimal path of ants. The results show that the satisfaction of delivery time is far behind, and even the average satisfaction of key customers with high value is only 55.1%, which is 18.3% higher than that of the planning without considering value. This method can provide a real-time optimized path in an effective time range and improve the efficiency of distribution services, which has certain theoretical significance and practical value.**

*Keywords—Multi-source visual information fusion; cold chain logistics road; path planning; ant colony optimization*

## I. Introduction

Effective distribution has become the key link of cold chain logistics because agricultural products are greatly affected by natural conditions and easily spoiled. Logistics operations such as low-temperature production, low-temperature transportation and low-temperature storage are selected in the cold chain logistics distribution process, which is a key logistics project supported by the state in recent years [1]. At the present stage of China's development, the logistics platforms of various industries have become perfect, and only cold chain logistics is still in a new developing position. Then the demand for cold chain logistics for the Chinese market is objective, and the overall growth rate of the cold chain logistics market is gradually increasing. However, some fresh agricultural products have caused huge losses in the process of circulation and consumption due to their special quality, and people's requirements for cold chain logistics and transportation are constantly improving. The development of China's cold chain is facing unprecedented challenges.

The role of cold chain logistics in industries such as food, medical, and chemical is increasingly prominent. Ensuring that cold chain items are not damaged during the continuous process from production to consumption in low temperature environments is the core task of cold chain logistics. However, in practical operation, cold chain logistics faces many challenges, such as unreasonable path planning, high energy consumption, and insufficient real-time monitoring. To address these issues, this study applies multi-source visual information fusion technology to cold chain logistics path planning and design, aiming to improve the efficiency and reliability of cold chain logistics. Multi source visual information fusion technology is a method that comprehensively utilizes computer vision, image processing, and pattern recognition technologies to obtain and integrate visual information from multiple sources. In the field of cold chain logistics, multi-source visual information fusion technology can obtain multiple information such as temperature, humidity, and location of goods, and based on this information, path planning and design can be carried out to achieve optimal resource allocation. This model will obtain real-time status information of goods through computer vision and image processing technology, and classify and analyze the information through pattern recognition technology. Then, based on the obtained information, the model will use optimization algorithms for path planning and design, ensuring that the goods reach their destination with the shortest path and lowest energy consumption, while meeting temperature and other conditions.

In the cold chain delivery where multiple vehicles coexist, the contribution points of the integer programming model based on multi-source visual information fusion technology are as follows:

*1) By* integrating multi-source visual information, this model can obtain more comprehensive information on goods and vehicles, thereby better planning distribution routes. This helps to reduce transportation costs, reduce energy consumption, and improve on-time delivery rates and customer satisfaction.

*2) Multi* source visual information fusion technology can monitor the status and location of goods in real time, detect potential problems in a timely manner, and provide early warnings. This helps to reduce cargo losses, ensure food safety, and provide better customer service.

*3) Through* integer programming models, the number of vehicles, loading capacity and route arrangement can be optimized to improve resource utilization efficiency. In addition, different vehicles can collaborate and cooperate to achieve more efficient delivery and improve overall operational efficiency.

Section I of this study elaborates on the background of cold chain logistics to control the closed environment of refrigerated and frozen food, as well as the storage and transportation of goods during loading and unloading. Section II elaborates on the research achievements of scholars who have become a hot topic in cold chain logistics distribution. Section III considers the cold chain distribution of multiple vehicles coexisting, establishes an integer programming model, and designs a targeted ant colony optimization (ACO) solution model. Section IV accesses these independent heterogeneous data sources through cloud computing resource integration technology to establish a unified data integration middleware. The pheromone update model chosen in this article is the Ant Week model, which utilizes global information to record the optimal path of ants. The results show that this method can provide real-time optimization paths within an effective time range. Section V summarizes the entire article. The integer programming model based on multi-source visual information fusion technology is an innovative method that can promote technological progress and industrial upgrading in the cold chain logistics industry.

## II. RELATED WORK

In recent years, cold chain logistics and distribution has become a research hotspot, mainly focusing on single vehicle route optimization, such as Bittencourt et al. accurately depict the distribution scene and study the impact of real-time traffic on the cold chain logistics route optimization in the road network [2]; Ouyang comprehensively considered time window, food spoilage, equipment-energy consumption and traffic congestion, and to get the optimal vehicle route distribution scheme, a stochastic vehicle route model with time window was constructed [3]. Amaruchkul put forward a mixed integer linear programming model, which combined the food production chain and quality loss, and analyzed the application value of this model with a case [4]. Established a model based on perishable property and time constraint, which had a significant impact on the cost, and solved it by tabu search algorithm [5]; In view of the problems existing in Yu's cold chain logistics and distribution, some effective suggestions are put forward. While improving the distribution efficiency, we should also ensure the quality and safety of products and optimize the process from the whole [6]; Li et al. deduced the calculation formula of algorithm convergence based on the related theoretical research of multi-objective generalized ACO (Ant Colony Optimization) and verified the correctness of the convergence and time complexity theory of multi-objective generalized ACO according to two given examples [7]. Zhang et al. analyzed the optimization problem of the cold chain logistics distribution path with the process of return and recovery. They provided a reference for the decision-making operation of cold chain transportation and distribution enterprises [8]. Chen took into account the timeliness

requirements of fresh products and, based on customer information feedback, studied and analyzed the feasibility of simultaneous delivery and pick-up processes to prevent the transport vehicles from driving back with no load [9]. Zhang et al. proved that the improved Dijkstra algorithm has better solution efficiency, and the quality of the final solution is improved compared with the traditional algorithm through simulation experiments [10]. Song et al. gave an effective distribution model to solve the distribution problem of cold chain perishable products in economically poor areas [11]. The purpose of the improved vehicle routing problem and optimal allocation is to reduce the pain and hunger in poor areas, not the distance and time.

In order to ensure the safety of food, a complete cold chain logistics is needed to control the whole temperature of refrigerated and frozen food, including the closed environment, storage and transportation when loading and unloading goods. In reality, due to the difference in delivery time and other factors, the delivery time may change, and the research of dynamic vehicle scheduling problems is still in the initial stage. The information on vehicle dynamic scheduling problem optimization is related to the travel time and the running speed of vehicles [12], [13]. Generally speaking, there is a positive correlation between vehicle transportation cost and vehicle mileage. Reasonable planning of vehicle transportation routes and minimizing vehicle mileage are the primary ways to reduce vehicle transportation costs. It is very important to study how to optimize vehicle scheduling, reduce transportation time and transportation cost [14].

Multi source visual information includes various information, such as vehicle position, speed, and cargo status is of great significance for path planning and design. However, in previous studies, this information was not fully utilized, resulting in the model being unable to make optimal decisions based on actual situations. Cold chain logistics has its unique characteristics, such as temperature control, shelf life of goods, etc. These characteristics have a significant impact on path planning and design. In cold chain logistics, the number of vehicles and goods that need to be considered may be very large, so efficient algorithms are needed to solve the problem. Therefore, it is of great practical significance to study vehicle optimal scheduling and route optimization as important contents. This paper will consider the cold chain distribution situation of multi-vehicle coexistence, build an integer programming model based on multi-source visual information fusion technology, design a targeted ACO solution model, and verify it with an example.

## III. RESEARCH METHOD

### A. Logistics VRP Analysis

The process of cold chain logistics includes four aspects: frozen processing, frozen storage, refrigerated transportation and distribution, and frozen sales [15], [16]. Logistics VRP(Vehicle Routes Planning) is generally defined as giving the location, distance, demand and other related information of one (or more) warehouses and multiple customers, seeking appropriate driving routes, so that vehicles can complete the delivery or pick-up work through them in an orderly manner, and achieve a certain purpose.

The products distributed in the cold chain logistics are generally fresh products, which are corrosive. Fresh product sellers often make a prior agreement on the delivery time of the products and restrict the distributor from delivering the goods within the agreed period. Therefore, cold chain logistics distributors must consider the change in air temperature when delivering. Cold chain logistics not only requires the minimization of the cost in circulation but also has certain requirements for time, and its response to the market should be sensitive.

VRP problem is the most studied VRP problem at present. Firstly, the basic elements of the transportation problem, the corresponding constraints, the total cost value target that the logistics enterprise hopes to achieve, etc., are defined. The artificial intelligence algorithm approaches the optimal solution step by step and has strong applicability in dealing with large-scale and multi-node transportation path problems [17]. The new hybrid algorithm and structure greatly improve the efficiency of problem-solving and enrich the feasibility of theoretical results and practical applications. In the context of the close combination of traditional algorithms, it is also helpful to discover the advantages, disadvantages and application scope of traditional nature-imitating algorithms. The inspiration for particle swarm optimization comes from this method.

The VRP problem is based on the TSP (Traveling Salesman Problem) problem, which assumes that the distance between customers is known and the quantity of goods delivered by vehicles to customers is the same. Then, the route is reasonably planned to make the total distribution route the shortest. The specific situation is shown in Fig. 1:

Fig. 1. Schematic diagram of vehicle scheduling problem.

It is the most basic carrier of cargo transportation and information transmission, and its main attributes include the maximum cargo load, the longest driving distance, whether it can be returned halfway, etc. The longest transportation distance of vehicles directly determines the coverage and size of the transportation network. With the distribution center as

the dot, the radius of serviceable demand points and the longest distance between various demand points directly affect the number of serviceable demand points [18], [19]. Different types of distribution centers have different supporting facilities, different service targets and different service scopes, which can be aimed at a certain type of customer or a variety of customers. In violation of the time constraint, the customer has a certain probability of refusing to deliver the transport vehicle.

The vehicle routing optimization problem is based on the travelling salesperson problem with some restrictions, including limiting the quantity of product demand, delivery time, loading quantity of vehicles, driving distance of vehicles, etc. When multiple customer numbering schemes are selected to solve the problem, a satisfactory solution with higher quality can usually be obtained, but the amount of calculation will be doubled.

*B. Multi-source Data Information Analysis of Cold Chain Logistics VRP*

Logistics informatization refers to a series of processing such as collecting, classifying, querying, tracking and summarizing the information generated in the logistics distribution process by using Internet technology and modern information technology in the logistics supply chain, with the development of e-commerce and virtual business in modern enterprises. Cold chain logistics distribution center refers to the intermediate storage base set up to promote the rapid circulation of fresh products from the place of production to the place of sale. Enterprises or individuals hope to visit the optimized best-driving route in cold chain logistics distribution anytime and anywhere. At the same time, they also hope that the platform for optimizing the route can be dynamically upgraded.

There is a maximum cargo capacity of the vehicle, and there may be a time limit for delivery. It is necessary to arrange the picking-up time reasonably, organize the appropriate driving route so that the user's needs can be met, and at the same time, a certain cost function can be minimized, such as the minimum total working time, the shortest route and the minimum cost [20].

The ant colony system represents the feasible solution by the ant colony's advancing route, and each route of the ant colony's advancing route constitutes the solution space. The pheromones released by ants with shorter routes are more and move continuously. Under the action of positive feedback, the ant colony will take the optimal route, and the solution at this time is the optimal solution.

When the ant colony is moving, the pheromone is constantly evaporating, assuming that the parameter $\rho(0 < \rho < 1)$ represents the rate of pheromone volatilization, that is:

$$\begin{cases} \tau_{ij}(t+1) = (1-p)\tau_{ij}(t) + \Delta\tau_{ij} \\ \Delta\tau_{ij} = \sum_{k=1}^{n}\Delta\tau_{ij}^{k} \end{cases} p \in (0,1) \qquad (1)$$

In the formula, $\Delta\tau_{ij}^{k}$ represents the pheromone concentration released by the $k$th ant between the route of town $i$ and town $j$; $\Delta\tau_{ij}$ represents the sum of pheromone

concentrations released by all ants between the route of Town $i$ and town $j$.

The determination of the distribution type of random variables is often the assumption of the distribution type after preprocessing the collected data. The theoretical distribution of many random variables in the system can be directly determined by experience. A triangle is a continuous probability distribution with the lower limit of $a$, the mode of $b$ and the upper limit of $c$.

$$f(x|a,b,c) = \begin{cases} \frac{2(x-a)}{(b-a)(c-a)}, & a \leq x \leq b \\ \frac{2(b-x)}{(b-a)(b-c)}, & b \leq x \leq c \\ 0, & other \end{cases} \quad (2)$$

The mathematical expected value of the random variable $x$ is:

$$E(X) = \frac{a+b+c}{3} \quad (3)$$

When using GPS data of floating cars to calculate road weight, the influence of invalid data points must be considered. Then, an average speed estimation model based on travel time is selected to calculate the average speed of each road section. At the same time, road quality and energy consumption loss are considered. Finally, the estimation method of road weight is obtained by combining these kinds of information. The estimation formula for the road weight of a single section is:

$$w(i) = \alpha \frac{L_i}{V_i} \beta Level_i \quad (4)$$

Where $w(i)$ is the road weight of the road section $i$, $L_i$ is the distance travelled by the floating car in the road section $i$, $V_i$ is the average speed of the road section $i$, and $Level_i$ is the evaluation function of the comprehensive quality of the road section; $\alpha, \beta$ is the correlation coefficient.

New information will constantly appear, which will affect the driving path of vehicles to varying degrees. The quality of refrigerated products changes with the passage of time, weather and seasons, the traffic conditions during rush hour and the penalty cost when the distribution violates the time window. The traffic volume of different sections in a day also changes with time.

At present, the development direction of information processing mainly includes integration and fusion. Among them, the former is the basic premise and material basis of an information fusion system. Therefore, the realization of a multi-source visual information fusion service in the process of logistics distribution can effectively solve objective problems such as collaborative scheduling between the logistics center and logistics distribution, optimization of the logistics distribution path, logistics tracking and value-added information service under uncertain conditions.

The multi-source data information of the cold chain vehicle route optimization model is provided by different application resources of the cloud computing center, and the data formats of these different resources are quite different. These independent heterogeneous data sources are accessed through cloud computing resource integration technology to establish a unified data integration middleware as shown in Fig. 2.

The terminal acquisition layer is the data resources on which this information system relies, including the RFID system (to obtain goods information) and the GPS system (to obtain real-time in-transit position information of vehicles) under the unified management of the database management and control system.

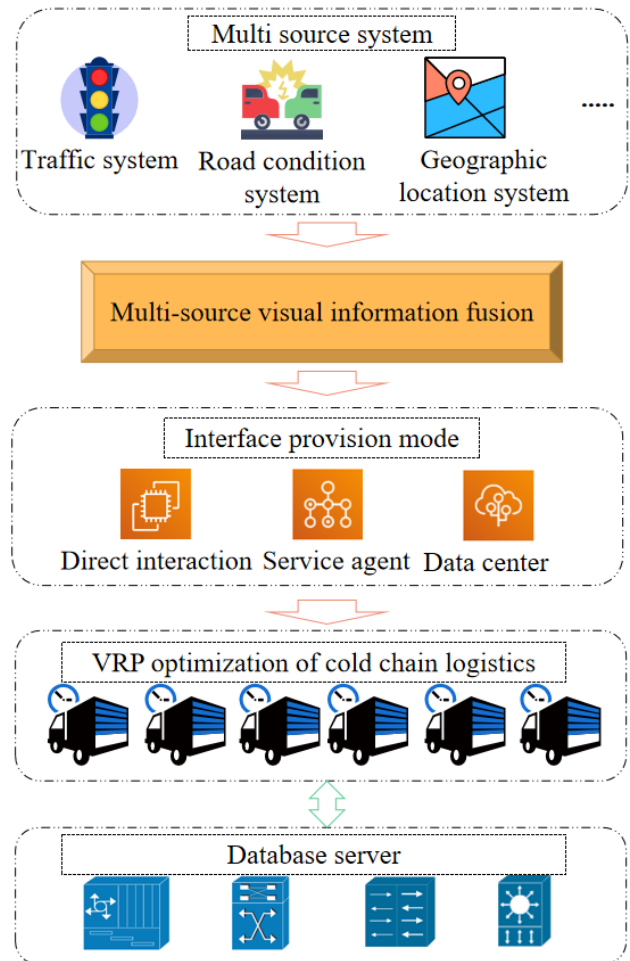

Fig. 2. Vehicle dynamic optimization model based on multi-source visual information fusion technology.

On the one hand, the system can plan the best route with time as a consideration; On the other hand, by sending different recommended routes to vehicles, the traffic efficiency is maximized, and the fuel loss caused by frequent braking and starting of vehicles is reduced, the waste of transportation resources is effectively reduced, and the environment is protected at the same time. These multi-source data can provide real-time data and make the calculated optimal path closer to the actual distribution service.

### C. Vehicle Trajectory Analysis and Matching

The research object of this paper is the path planning of urban cold chain logistics, and its model is based on one or more logistics centers meeting multiple customer points in the region. In practice, the running unit is a truck with refrigeration

equipment to transport fresh products. Make the objective function closer to reality according to the actual situation, and get further optimization.

A penalty function is introduced if refrigerated trucks deliver goods to customers over time. If it is delivered in advance, a reward function is introduced. Generally speaking, refrigerated vehicles' cost includes fixed and variable costs. In this paper, the former refers specifically to the precipitation cost of allowing each distribution vehicle to run normally, which is basically linearly proportional to the total time travelled by the vehicle, generally including wages, maintenance, fuel costs, etc., and is a known constant.

Which increases with the increase in transportation distance, and the two are in direct proportion.

Department:

$$C_1 = \sum_{i \in N} \sum_{j \in N} \sum_{k \in K} tcost_k * x_{ijk} * d_{ij} \qquad (5)$$

$tcost_k$ represents the unit transportation cost of transport vehicle $k$, $d_{ij}$ represents the distance from customer $i$ to customer $j$, $tcost_k$, $d_{ij}$ is known, $x_{ijk}$ is a variable of 0-1, which represents the process of vehicle $k$ from point $i$ to point $j$, if there is this process, it is 1; otherwise it is 0.

Set the upper and lower limits of the customer's patience time, and establish the correlation function between time and compensation within this time limit. Once the customer exceeds the lower limit of his time limit, the penalty will be calculated automatically. The Equation (6) is the general calculation formula of penalty cost:

$$K(t)_{ij} = \begin{pmatrix} 0, & t_{ik} < a \\ M(j)(t_{ik} - a), & t_{ik} > a \end{pmatrix} \qquad (6)$$

Where, $K(t)_{ij}$ represents the time window penalty cost of the $i$th car serving customer $j$; $M(j)$ represents the penalty cost to be paid per unit time after exceeding customer $j$ time tolerance. $t_{ik}$ indicates the time when the $k$th car arrives at customer $i$.

In cold chain logistics, the main factors that cause goods damage are time, including transportation time and unloading time, and the cost of goods damage at node $i$ is transportation loss cost plus unloading loss cost. Therefore, the total cost of goods damage can be expressed as:

$$Z = \sum_{i=1}^{N} C_{goods} \times q_i \times (\rho_1 D_{0 \to i} + \rho_2 D_{off_i}) \qquad (7)$$

$\rho, \rho_2$ is the loss ratio of transportation and unloading, and $D_{0 \to i}$, $D_{off_i}$ is the time spent on transportation and unloading.

Customers' demand is often affected by factors such as the brand, quality, marketing methods, personal preferences, different seasons, after-sales and so on of dairy products, resulting in uncertain changes. In this paper, the demand for urban dairy cold chain logistics distribution is regarded as a random variable, and the premise of its optimization is to obey the normal distribution of customer demand. When the customer demand is higher than the actual vehicle load, the order will be cancelled, and at the same time, customer satisfaction will be reduced, resulting in out-of-stock costs. The specific formula is as follows:

$$C = \tau \sum_{k=1}^{m} max\{d_k - s_k\} \qquad (8)$$

Where, $\tau$ is the shortage cost per unit cold chain product; $d_k$ the actual total demand of the retailers served by the $k$-car; $s_k$ is the actual load capacity of the vehicle $k$.

Time is very important for customers, and customers hope that goods can be delivered on time within the agreed time. In this paper, it is assumed that the service attitude satisfaction of the delivery staff is 1, and the customer's satisfaction with the delivery time is calculated according to the customer's requirements for the delivery time window.

In this paper, it is assumed that customer satisfaction is linearly related to time, when the vehicle arrives in the best time window agreed by the customer, $e_j \leq t_j \leq l_j$, and when the vehicle arrives at the customer point outside the best time window of the customer point $E_j \leq t_j \leq e_j, l_j \leq t_j \leq L_j$. The delivery time satisfaction expression can be expressed as:

$$U(S_j) = \begin{cases} \left(\frac{t_j - E_j}{e_j - E_j}\right)^\alpha, & E_j \leq t_j < e_j \\ 100\%, & e_j \leq t_j < l_j \\ \left(\frac{L_j - t_j}{L_j - l_j}\right)^\alpha, & l_j \leq t_j < L_j \end{cases} \qquad (9)$$

Where $[e_j, l_j]$ is the customer's expected time window, $[E_j, L_j]$ is the customer's acceptable time window, and $\alpha$ is the customer's sensitivity coefficient to time.

The methods for solving objective programming problems can be divided into exact and heuristic algorithms. It is an important idea of a modern, improved heuristic algorithm to search the neighborhood of the current solution many times according to a fixed search strategy. It constantly feeds back the results of the solution to improve the process of the initial solution continuously.

The remaining pheromones on the road section will gradually weaken with the continuous accumulation of time. Every time each ant visits all the cities, the number of pheromones on the road section will change accordingly. The following formula can describe the change and adjustment of pheromones on the path, namely:

$$\tau_{ij} = (t + 1) = (1 - \rho)\tau_{ij}(t) + \Delta\tau_{ij} \qquad (10)$$

$\rho$ is the attenuation coefficient of pheromone, and $\Delta\tau_{ij}$ is the amount of pheromone released by ants from node $i$ to node $j$.

In this paper, the mathematical model of dairy products' logistics and transportation problems is established, and the best path selection scheme is obtained by solving the problem model with related algorithms. ACO has the advantages of fewer iterations, a relatively stable solution process and relatively high solution quality in this paper.

Generally speaking, many models can calculate the pheromone concentration. This paper takes the ant week model as the basic model.

$$\Delta\tau_{ij}^k = \begin{cases} \frac{Q}{L_k}, & \text{If the kth ant passes through } sec\,tion\,(i,j) \text{ in this cycle} \\ 0, & other \end{cases}$$

$$(11)$$

ACO is inspired by the behavior of ants seeking the shortest path to get food in the foraging process. The simple behavior rules of ants make the whole ant colony present intelligent behavior, which makes it diverse and positive. In the process of foraging, diversity can prevent ants from entering a dead end and falling into an infinite cycle.

It has a unique positive feedback mechanism of iteration results and parallel calculation method, strong compatibility between algorithms, stable iteration results, etc. The specific implementation process of the improved ACO is shown in Fig. 3.

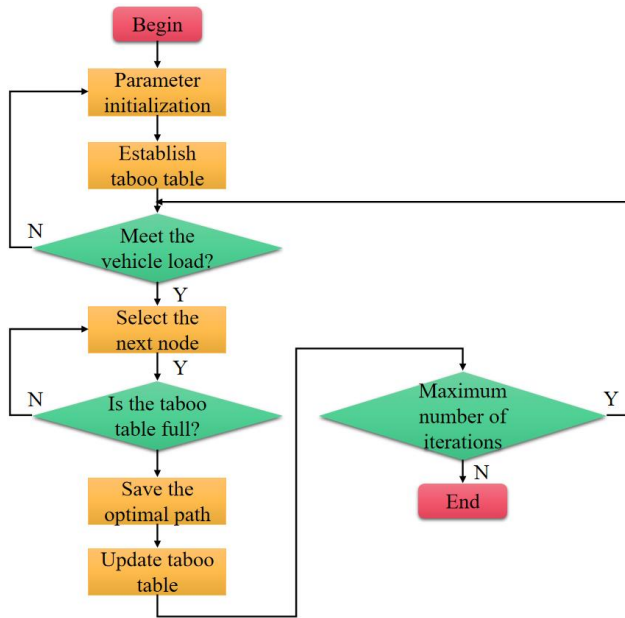

Fig. 3. Improve the calculation process of post-ACO.

Therefore, in order to make it more likely that customers with shorter waiting times will be selected as the next transportation point when selecting the next customer point, the waiting factor is added to the rules for selecting the next node.

$$w_{ijk} = \frac{1}{rt_j - t_{ik}} \tag{12}$$

$t_{ik}$ is the moment when the $k$ -th car arrives at point $i$.

The pheromone update model selected in this paper is the ant week model. Using the global information, the pheromone increment is only related to the overall search route and has nothing to do with the specific route. After all the ants have gone through one traversal, the best route for recording the ants is $L\_best$, and the pheromone matrix is updated:

$$Tau = Rho * Tau + \Delta Tau \tag{13}$$

$$\Delta Tau = \Delta Tau + \frac{Q}{L\_best} \tag{14}$$

$Rho$ represents the pheromone residual coefficient, $\Delta Tau(i,j)$ represents the pheromone increment of all ants on

the route from the $i$th city to the $j$th city, and $Q$ represents the pheromone increase intensity coefficient.

The core idea of vehicle trajectory analysis and matching is to fully consider and analyze the relationship between the front positioning point. When the GPS positioning point of the floating car is far away from the road intersection, it is a common situation to determine the optimal road section that matches it through the weight calculation model, which is the most common in map matching.

Assuming that the two endpoints of the road section are $P_1(x_1, y_1), P_2(x_2, y_2)$ and the position coordinates of the current GPS positioning point are $P_0(x_0, y_0)$, the distance between the positioning point and the road section to be matched can be directly obtained by using the distance formula from point to line, which is marked as $dis$. Then the function of calculating the distance weight through this distance is as follows:

$$w_{dis} = h_1 * f(dis) \tag{15}$$

Where $h_1$ is the distance weight coefficient, and $f(dis)$ is the quantization function of the distance weight.

In this paper, the objective function is a combination of the lowest cost and the largest repurchase degree, so the objective function is directly defined as the fitness function. The fitness function is defined as:

$$f_i = z_i = \sqrt[2]{d_1 d_2} \tag{16}$$

$f_i$ represents the fitness of the $i$th chromosome and $z_i$ is its corresponding function value.

## IV. RESULT ANALYSIS

On the basis of the optimization mentioned above analysis, model construction and algorithm research and analysis of urban dairy products logistics distribution under uncertain demand, this paper selects F enterprise as an example to analyze its demand for dairy products distribution optimization, understand its distribution reality, and introduce MATLAB software to program ACO, then make a solution, and finally verify the scientificity of the algorithm and the effectiveness of the model.

Take a certain distribution service as an example. The F Enterprise Distribution Center provides distribution services for its 15 stores, and the distribution center has 8 refrigerated trucks. The more ants there are, the more accurate the optimal solution will be. As the algorithm converges closer to the optimal solution, the positive feedback of information decreases, resulting in a large number of repeated solutions, which consumes resources and increases the time complexity.

In this paper, the number of ants is set to 50. Before the service, the potential value of each customer is mainly determined by the breadth and depth of their social circle. Therefore, when classifying customers, the potential value of customers is determined by the product of the coverage of the customer's social circle and the importance of the customer in the social circle.

First of all, we set the geographic location information. For the convenience of calculation, we set the origin of the plane's geographic coordinates as the logistics center itself. Please see Table I below.

The dynamic data taken in the simulation refers to the road conditions, traffic congestion and vehicle speed. These changes in dynamic data may cause changes in the delivery time and cost of refrigerated vehicles, and the dynamic data of each journey can be obtained periodically. Fig. 4 shows the speed of the vehicle in a certain period of time.

TABLE I.    GEOGRAPHICAL LOCATION INFORMATION OF A LOGISTICS COMPANY AND ITS CUSTOMERS

| Customer name | Geographic information |
|---|---|
| Logistics centre | (0,0) |
| A customer | (30.1,2.1) |
| B customer | (22.6,-2.2) |
| C customer | (35,0) |
| D customer | (24.1,5.5) |
| E customer | (29.8,2.3) |
| F customer | (31.5,1.8) |
| G customer | (33.6,1.5) |
| H customer | (30.8,2.7) |
| I customer | (29.5,2.2) |

Fig. 4.    Vehicle speed map.

TABLE II.    TIME WINDOW ARRANGEMENT AND SERVICE TIME OF EACH CUSTOMER

| Distributor number | Time window | Service time |
|---|---|---|
| 0 | 6:00-12:00 | 0 |
| 1 | 7:00-10:00 | 22 |
| 2 | 7:00-10:00 | 29 |
| 3 | 7:00-90:30 | 30 |
| 4 | 7:10-8:00 | 13 |
| 5 | 8:00-10:00 | 24 |
| 6 | 7:00-8:30 | 16 |
| 7 | 7:00-8:00 | 28 |
| 8 | 7:00-9:00 | 11 |
| 9 | 7:00-11:00 | 23 |
| 10 | 7:00-8:50 | 35 |

The goods are distributed as daily necessities for citizens, such as fresh shrimp, ice cream, fresh milk and other perishable products. And ensure that it will not smell bad within 12 hours. The maximum loading capacity of each incubator is about 80 kg, i.e., 0.0 8 tons. In the case of freezing, three cold accumulators are needed, and in the case of refrigerating, two cold accumulators are needed. The holding time is 12 hours. For the distribution of products at room temperature, there is no need to use an incubator. The time window arrangement and service time of each customer are shown in Table II.

The logistics center operation system is a queuing system, and the random arrival of orders accords with the characteristics of the exponential distribution. See Table III for the occurrence times of order arrival time intervals obtained through actual observation.

TABLE III.    NUMBER OF NUMERICAL OCCURRENCES OF ORDER ARRIVAL TIME INTERVAL

| Arrival time interval (min) | Frequency of occurrence | Arrival time interval(min) | Frequency of occurrence |
|---|---|---|---|
| 1 | 7 | 11 | 1 |
| 2 | 2 | 12 | 3 |
| 3 | 4 | 13 | 3 |
| 4 | 5 | 14 | 2 |
| 5 | 5 | 15 | 1 |
| 6 | 4 | 16 | 3 |
| 7 | 10 | 17 | 1 |
| 8 | 4 | 18 | 1 |
| 9 | 3 | 19 | 2 |
| 10 | 6 | 20 | 3 |

After the histogram is used to determine the theoretical distribution of sample data, it is necessary to judge how close the observed sample distribution is to the estimated theoretical distribution, that is, to determine the fitting degree of the estimated theoretical distribution. Fig. 5 shows the comparison between the histogram and probability density curve.

Fig. 5.    Compare with histogram and probability density curve.

It can be seen from the Fig. 5 that the estimated exponential distribution is in good agreement with the observed samples, so

the exponential distribution function can be used to set the parameters of the model and simulate the real system.

According to the basic ACO principle and algorithm flow, this model is solved by MATLAB programming. The best results in 10 experiments are shown in Fig. 6 and 7 below.

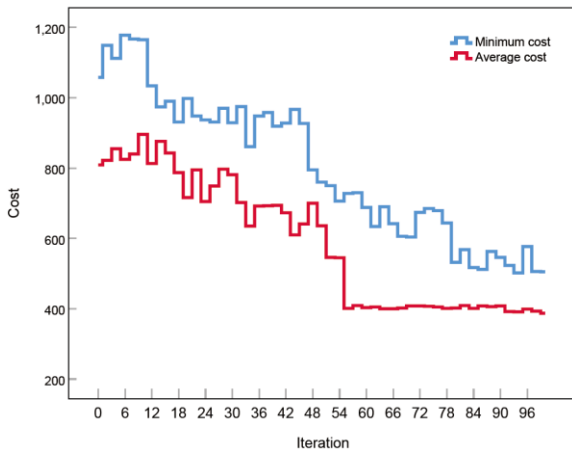

Fig. 6.    Basic ACO iterative process.

Fig. 7.    Basic ACO optimal path.

At the beginning of the algorithm iteration, with the increase in iteration times, the quality of the current optimal solution rises sharply. The total cost of the current optimal solution changes relatively little after the $20^{th}$ iteration until the total cost of the current optimal solution stops decreasing at the $55^{th}$ iteration, and the global optimal solution is obtained.

Taking the processed target benefit function as the final goal, after running in MATLAB, the display results are shown in Fig. 8.

Compared with VRP, which does not consider customer value, VRP, which does not consider customer value lags far behind in customer satisfaction with delivery time. Even the average satisfaction of key customers with high value is only 55.1%, which is 18.3% higher than that of the planning that does not consider value. The improvement in resource allocation efficiency is obvious.

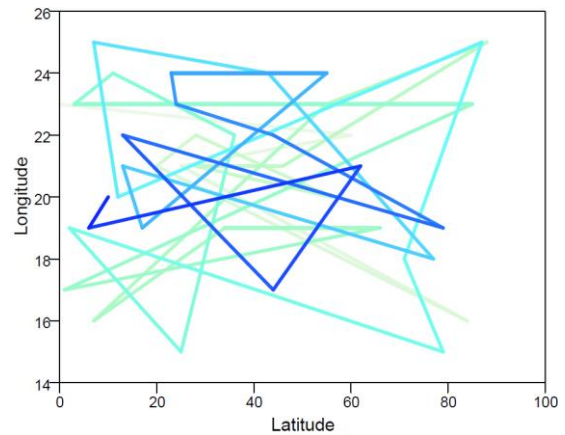

Fig. 8.    Vehicle distribution route considering customer value.

It can be seen that the time and expense of the calculated results are different according to the degree of attention to vehicle delivery cost and delivery time. The evolutionary algebra of the improved ACO model solution and the classical ACO solution in the cloud computing environment are shown in Fig. 9.

Fig. 9.    Comparison between improved ACO and classic ACO.

When different processors are used, the execution time of the algorithm is different. To a certain extent, the more processors, the shorter the calculation time. It is proved that the shortest path calculation is correct, which can effectively solve the path planning problem on the road network with traffic rules.

In practical applications, we can evaluate the performance of models by comparing the performance of different algorithms. However, for cold chain logistics, due to issues related to food quality, safety, and other aspects, we still need to consider some additional factors. For example, different foods have different temperature requirements, and some foods need to be stored or transported at specific temperatures, otherwise it may affect their quality or safety. Therefore, when establishing integer programming models and designing targeted ant colony optimization (ACO) solving models, we

need to fully consider these factors to ensure that the model can meet practical needs.

In addition, we should also note that the ant colony optimization algorithm itself has some limitations. For example, during the ant search process, they may fall into local optima and cannot find global optima. Therefore, when designing targeted ant colony optimization (ACO) solving models, we need to take some measures to avoid this situation. For example, suitable heuristic information can be set to guide ants in their search direction, or random factors can be introduced to jump out of the local optimal solution.

## V. CONCLUSION

Logistics operations such as low-temperature production, low-temperature transportation and low-temperature storage are selected in the cold chain logistics distribution process, which is a key logistics project supported by the state in recent years. In reality, the delivery time may change due to the difference in delivery time and other factors, and the research on dynamic vehicle scheduling problems is still in the initial stage. The information on vehicle dynamic scheduling problem optimization is related to the travel time and speed of vehicles. This paper will consider the cold chain distribution situation of multi-vehicle coexistence, build an integer programming model based on multi-source visual information fusion technology, design a targeted ACO solution model, and verify it with an example. The results show that the satisfaction of delivery time is far behind, and even the average satisfaction of key customers with high value is only 55.1%, which is 18.3% higher than that of planning without considering value. The improvement in resource allocation efficiency is obvious. And it shows the correctness in calculating the shortest path, which can effectively solve the problem of cold chain logistics path planning with traffic rules constraints.

However, this study still has certain limitations. The acquisition and processing of multi-source visual information requires a large amount of manpower and technical support. Planning models may involve complex algorithms and data processing processes, resulting in reduced interpretability of the model. This may affect the user's trust and acceptance of the model results. In the future, while ensuring model performance, try to simplify the complexity and computational complexity of the model as much as possible. Visualization techniques and interpretive algorithms can be used to make the model results more intuitive and understandable. In addition, domain experts can also be invited to evaluate and validate the model, improving its credibility and acceptance.

# CDCA: Transparent Cache Architecture to Improve Content Delivery by Internet Service Providers

Alwi M Bamhdi

Umm Al-Qura University, College of Computing, Al-Qunfudah, KSA

*Abstract*—The popularity of on-demand multimedia such as video streaming services has been rapidly increasing the overall Internet traffic volume in the world. As of the beginning of 2023, almost 82% of this global Internet traffic came from video transmission through on-demand online services, trending towards changing the Internet paradigm from location-based to content-based, culminating in a new paradigm of Information-Centric Networking (ICN). ICN focuses on content distribution based on name rather than location, allowing Internet Service Providers (ISP) to implement local content caching systems for faster delivery and reduced transmission delays and unnoticeable jitter or distortions. ICN can be implemented over a Software-Defined Networking (SDN) infrastructure. SDN enables flexible programming and implementation of forwarding packet rules within a network domain seamlessly. This paper proposes a hybrid architecture that combines ICN and SDN to create a transparent in-network caching system for content distribution over the traditional IP network. The architecture aims to improve the performance of Video-on-Demand (VoD) services for customers while efficiently utilizing network provider resources. A prototype called CDCA was developed and evaluated in a Mininet emulation environment. The results of the evaluation demonstrate that the CDCA hybrid architecture to create a caching system for content distribution enhances VoD service performance and optimizes network resource utilization.

*Keywords*—*Content caching; content delivery network; content search algorithm; information-centric networking; multimedia; network function virtualization; software defined networks*

## I. INTRODUCTION

The integration of the Web, ICN, SDN and NFV, juxtaposed the *archaic* Internet. By combining these technologies, there is the potential to enable seamless placement and retrieval of multimedia content by multiple users. The integration of these technologies allows internet network service providers to leverage local caching mechanisms to deliver content to multiple users simultaneously. This unique CDCA approach of a system represents a novel and innovative way of optimizing content distribution and improving the overall user experience. The specific details and benefits of this novel approach are further elucidated in this paper.

### A. Summary of the CDCA Solution

This paper presents a content delivery-based caching framework architecture system called CDCA that typically resides inside network providers' premises, i.e., Internet Service Providers (ISP), using SDN, which is completely transparent for users, content provider applications and network providers. Transparency is applied to all actors: the user, the content provider and the ISP network, which neither needs to modify any application and network equipment. In essence, the SDN/NFV module within the CDCA architecture permits forwarding data packets to the content cache or to the content source server transparently.

The key features and advantages of the CDCA architecture provide for in-network caching. The architecture is applicable to any application communication protocol that follows the client-server model and identifies content using unique logical names, such as HTTP URLs. The combination of the SDN control plane, Proxy, and Cache components enables the orchestration of a distributed caching framework. CDCA ensures that content is transparently delivered as close to the user as possible without any modifications to communication protocols or user clients.

CDCA is designed with horizontal scalability and high manageability in mind, adopting the principles of the microservice architectural pattern style that structures an application as a collection of services. This design approach provides elevated deployment flexibility and high levels of availability, regardless of the network's operational state. Content management within the architecture is driven by rule-based policies, facilitated by distributed decision-making mechanisms and multiple caches distributed throughout the network. These components interact with the SDN centralized control plane to ensure efficient content delivery. Although this topic is relevant and interesting and outside the scope of this paper, it will be addressed in-depth in future research works.

CDCA is designed to be deployed and supported by the ISP premises on the client side. In CDN architecture, the service must be contracted and paid for by the content provider. And also, if the CDN server is not located within the ISP network, it will be not worth it, since it will have to pay for the high bandwidth requested by multiple users' content downloads.

### B. Rest of the Paper

The CDCA architecture is distinct from a traditional Content Delivery Network (CDN) infrastructure. They are not comparable. The unique aspects and differences of the CDCA solution are elaborated in Section IV.

The rest of the paper is structured as follows. Section II covers the background to the concepts and issues related to the topic of this paper. Section III presents the literature review of related works. Section IV presents the CDCA

architecture and in Section V the evaluation and results from the experiments are presented. Section VI discusses some important open issues and challenges to consider for future research related to the CDCA architecture and its content delivery operations, and finally, Section VII concludes the paper.

## II. BACKGROUND

It is a remarkable transformation of the Internet from its humble beginnings as a point-to-point communication network for users to becoming a ubiquitous and essential infrastructure for global everyday communication. Over its nearly 54-year history, commencing as ARPANET, the Internet has evolved and gained popularity, becoming a highly successful and effective communication system that continues to rapidly advance. With the increasing volume of traffic and the complexity of modern services such as file sharing, VoIP, social networking, e-commerce, online gaming, and multimedia streaming, the inadequacies of the Internet's original design have become apparent. The architecture of the Internet has undergone numerous amendments to accommodate these evolving needs, resulting in a progressively more complex system at each stage of its development. This growing complexity poses challenges in terms of implementation, maintenance, and management of new networking services and applications. The costs associated with these tasks continue to rise as the Internet becomes more sophisticated and intricate. However, innovation in information communication and internetworking philosophies helps to mitigate the phenomenon of ossification [1], whilst acknowledging the challenges posed by the limitations of the original design and recognizing the ongoing efforts to innovate and adapt to meet the demands of modern communication and networking needs.

The evolving nature of Internet applications, particularly the significant growth in video streaming services, including both live broadcasts and on-demand content is increasing exponentially. According to Cisco, it has seen a massive buildup of Internet traffic in the order of 4.8 zettabytes during 2022, which is over three times the 2017 rate, led by a combination of increased use of cloud computing, IoT device traffic, video viewing, and the sheer number of new users coming onboard every day. The video traffic constituted 82% of the total Internet traffic in 2021, a substantial increase from over 70% in 2017, excluding video exchanged through Peer-to-Peer (P2P) file sharing [2]. The forecast indicates that Internet video traffic will grow at a rate of more than 31% per year, while online gaming, which is part of the audio/video mix, is expected to grow at a rate of over 50% plus per year until 2025. Currently, most content distribution platforms handle content requests individually, resulting in a unicast delivery paradigm where each user receives content from a Content Delivery Network (CDN) infrastructure separately [43]. However, this approach overlooks the fact that much of the content requested by users is identical to content requested by others just moments ago. As a result, a substantial amount of redundant content is delivered repeatedly over the same network segment, leading to unnecessary strain on service providers' transmission capacity and bandwidth. This inefficiency becomes more significant as the number of users

and unicast content continues to grow. Consequently, new approaches are needed to improve and optimize the efficiency of content distribution.

The ongoing modifications and improvements to the Internet's architecture to accommodate new applications demand faster infrastructure and versatile middleware. However, the modern web still faces many challenges due to incompatibilities inherited from the original design of the Internet. The shift in user behaviour is highlighted, with Internet users now seeking specific content *("what")* rather than focusing on the location of that content *("where")*. This shift necessitates more than simple unicast communication for modern web applications [44]. As a result, network architectures need to be smarter and more flexible to support the exponential growth resulting from the dynamic nature of multimedia content availability and online delivery. This trend is expected to persist in the foreseeable future. To emphasize the magnitude of this growth, a comparison between the content data produced in 2008 amounted to 500 exabytes compared to the present-day zettabyte scale [3]. This example illustrates the substantial increase in content generation and consumption over the years. The need for smarter and more flexible network architectures to support the dynamic nature of content availability and delivery on the modern web is a must with the significant growth in content data generation and consumption.

In recent years, some proposals tried to change the current end-to-end IP packet networking and web search engines to innovate enhanced content-based network architecture, called Information-Centric Networking (ICN) [4]. ICN is based on the principle that the Internet should prioritize the data needed by users rather than focusing on the physical location from which the data can be retrieved. In contrast, the current Internet architecture is host-based and was initially designed to facilitate communication between a limited number of fixed computers and geographically dispersed users. Although ICN offers significant advantages, implementing it as a replacement for the existing Internet backbone would require a radical and impractical overhaul. Consequently, various research efforts have focused on adapting ICN architectures to operate within the constraints of the legacy Internet infrastructure. One approach involves integrating ICN with Software-Defined Networking (SDN) and the OpenFlow protocol, allowing for the implementation of ICN concepts while leveraging the programmability and flexibility of SDN to make it compatible with the current Internet backbone [5]–[8].

The concept of a *"programmable network"* originated as a result of the SDN principles and architecture. The concept of a programmable network was initially driven by the introduction of OpenFlow, an open protocol that enables the configuration of packet forwarding tables in switches. With OpenFlow, network users can actively modify these tables, providing a level of control over the network's behaviour [9]. By utilizing OpenFlow and similar technologies, a programmable network introduces an abstraction layer for switches, allowing the separation of the data and control planes. In this context, the switch functions as a hardware fabric that primarily focuses on transparently forwarding data.

The policy management for handling data content is then handled by software through the control plane functions and mechanisms. This decoupling of data and control planes enables greater flexibility and programmability in network management and configuration.

Over the last few years, Network Functions Virtualization (NFV) [10] has shown the most promising results in the development of advanced computer networking. NFV offers a new approach to developing network services by utilizing programmable software and virtualization means. It replaces traditional proprietary hardware network elements and appliances that perform various network functions, such as Network Address Translation (NAT), Intrusion Detection and Prevention System (IDPS), caching, and more. With NFV, these network functions are implemented as Virtualized Network Functions (VNFs) using software and deployed within Virtual Machines (VMs). This approach enables more flexible and efficient networking and network service deployment. By utilizing NFV, network services can be customized according to specific business needs, allowing for greater agility in serving the ever-changing demands of service providers and end-users. Additionally, NFV brings significant cost savings by eliminating the reliance on expensive proprietary hardware and enabling more efficient resource utilization.

## III. Literature Review

Ooka et al. propose the OpenFlow-CCN, a system architecture joining Content-Centric Network (CCN) and OpenFlow mechanisms to achieve content end-to-end forwarding [6]. In their proposal, the content names are mapped to hierarchical structure hash values and the long prefix matching. In an OpenFlow network, the content packet is forwarded by a unique IP address based on the content name hash value. The architecture was evaluated on the Trema Controller in an OpenFlow network. Their proposal is quite interesting because it does not impose any modification to either the OpenFlow protocol or CCN. CDCA does not require a CCN infrastructure because it uses a traditional IP network.

Nguyen et al. propose an improvement in CCN caching strategy that uses SDN [7]. They implement a wrapper between CCNx software and OpenFlow switch to decode and hash the content name in CCN messages into parameters that an OpenFlow switch can forward, e.g., IP address or port number. They argue that the large naming space offered by these fields restricts the collision probability between two different contentnames. The evaluation shows that the wrapper does not affect forwarding performance but might have name-space problems. CDCA does not require a CCN infrastructure.

Chandra et al., proposed a caching architecture specifically for HTTP on an SDN infrastructure [11]. They concluded that while the OpenFlow protocol maintains an abstraction of control and forwarding planes, it presents challenges when dealing with ICN because it lacks content abstractions. In response to this limitation, Chandra et al. proposed an architecture that utilizes a unique Proxy and multiple caches distributed across the OpenFlow network. In comparison to the CDCA solution provided in this paper, it employs the concept of deploying a Proxy to determine whether content should be fetched from the Cache or the server and it introduces a distributed Proxy and Cache architecture to enhance scalability and resilience. This means that the CDCA Cache architecture is designed to accommodate scalability and provide better fault tolerance and resilience.

Georgopoulos et al. presented OpenCache, an in-network caching system designed specifically for Video-on-Demand (VoD) applications using OpenFlow technology [12]. OpenCache consists of two main components: the OpenCache Node (OCN) and the OpenCache Controller (OCC). The OCC is responsible for determining which videos should be cached, while the OCN handles the storage necessary for video caching. The experiments conducted on OpenCache have demonstrated positive results in terms of video start-up delay, external link usage, and video quality. However, it is noted that these experiments were conducted with a single video client, which may not fully represent the behaviour and performance of OpenCache in real-world production networks with multiple user accesses.

The CDCA concept and solution offered in this paper of finding the Cache that is nearest to the user overcomes the deficiencies from other comparative approaches in so far as making Cache decisions based on user requests in an *on-demand* fashion, rather than relying solely on operator decisions.

## IV. CDCA: Content Delivery Cache Architecture

The CDCA architecture aligns with the SDN principle of having a centralized control plane, which is responsible for controlling and directing the forwarding of data packets within the network. In this architecture, the centralized control plane is designed to handle cacheable requests that adhere to the client-server model, similar to the distributed content Cache architecture embedded inside the provider datacenter [13], but going one step further by deploying the distributed content Cache system inside the ISP infrastructure closest to the end-user, offering better response time and server load-balancing. By leveraging the capabilities of the centralized control plane, the architecture enables efficient management of cacheable requests. The control plane can make decisions regarding content caching based on various factors, such as user demand, network conditions, or predefined rules. These decisions are then communicated to the versatile device responsible for managing the caching process. Overall, the architecture combines the benefits of SDN's centralized control plane with the ability to handle cacheable requests in a client-server model. This integration allows for effective management and optimization of caching operations within the network.

The CDCA operational framework architecture is shown in Fig. 1. It is based on two fundamental components: the Proxy and the Cache. The SDN Controller identifies a potential content flow, such as an HTTP request to a VoD provider via the destination IP address and TCP port information. Once identified, the content flow is redirected to the Proxy component. Within the Proxy, the traffic of interest (content) is mapped to the content re-director module

responsible for forwarding the content request to an appropriate Cache instance where the content is stored. The Cache instance can be located within the same network or distributed across multiple locations. By redirecting the content request to the Cache instance, the CDCA aims to retrieve the content from the Cache instead of fetching it from the original source, thereby reducing latency and network traffic. This mechanism improves the overall efficiency of content delivery by serving frequently requested content from nearby caches. This approach enables faster and more efficient content delivery by leveraging caching capabilities within the network.

Note that the Proxy searches in the DHT to find if the content is cached, then, forward the requests to the Cache or to the Content Server. Fig. 1 illustrates the Cache-missed example shown on the left side, and the successful Cache hit case shown on the right side.

Fig. 1. CDCA system operational framework architecture.

The CDCA architecture implements an on-demand caching scheme for video-on-demand (VoD) services. In this architecture, larger content files can lead to longer transfer delays and higher processing overhead for caching operations, such as storing an entire file in the Cache and delivering it to the user while small files do not need chunking. To overcome this issue, large content files are divided into smaller parts called content chunks. Each chunk is handled independently, allowing for more efficient caching and delivery. This chunk-based delivery approach is specifically designed to handle the delivery of content in smaller segments rather than delivering the entire file at once. All VoD providers analyzed in this work used chunk-based delivery. This indicates that dividing content into smaller chunks is a common practice in the industry, likely due to the advantages it offers in terms of caching, delivery efficiency, and user experience. By adopting this chunk-based delivery approach and caching content chunks on-demand, the CDCA architecture aims to optimize the delivery of VoD content while minimizing transfer delays and processing overhead associated with caching operations.

Chunk-based caching [45] offers several advantages over file-based content caching. By dividing a content file into smaller chunks, it becomes possible to deliver different chunks from multiple caches, improving the efficiency of content delivery. One of the key benefits of chunk-based caching is increased storage efficiency. Instead of storing and replacing entire content files, the caching system can focus on

individual chunks. This fine-grained approach allows for precise caching decisions, reducing the amount of storage required and improving overall Cache utilization. But the distribution of chunks within the network becomes a crucial decision in chunk-based Cache delivery since the placement of chunks across caches can significantly impact the performance and effectiveness of the caching system. Optimizing the distribution of chunks involves considering factors such as Cache proximity to users, network congestion, and popularity of specific content chunks. Efficient chunk distribution strategies typically enhance the caching system's ability to serve content quickly and reduce network traffic. Techniques such as content popularity analysis, adaptive caching algorithms, and dynamic chunk placement are employed to ensure effective distribution and retrieval of content chunks from caches. Furthermore, chunk-based caching has many advantages over file-based content caching. Different chunks of the same content can be delivered from multiple caches. Replacing some chunks instead of a whole content file may increase storage inefficiency. However, careful consideration must be given to the distribution of chunks within the network to optimize performance and achieve efficient content delivery.

In the CDCA architecture, the selection of caches is determined based on either the shortest path to the content or a set of custom rule-based policies. The forwarding decision is made by the Proxy that may receive information from the network management system and server state. Based on this information, the Proxy chooses the best Cache instance. For instance, when a content request is received by the Proxy, it checks if the requested content is already cached in a Cache instance. If a Cache hit occurs, meaning that the content is present in the Cache. This allows for fast and efficient content delivery without the need to retrieve the content from an external source. However, if the requested content is not present in any Cache, resulting in a missed Cache, the Proxy will then forward the request to the nearest Cache. The closest Cache is determined based on factors such as network proximity or predefined routing policies. This Cache, in turn, will request the content from the external Content Server, retrieve and Cache the content locally, and finally serve the user's request. This mechanism ensures that frequently requested content is cached closer to the users, reducing the need for content retrieval from remote servers and improving the overall response time and user experience. By leveraging caching and intelligent Cache selection, the architecture minimizes the latency associated with content delivery, optimizing the use of network resources and enhancing the efficiency of the system. In summary, the Proxy in the CDCA architecture determines Cache hits and misses for content requests. Cache hits allow for direct content delivery, while Cache misses triggering the retrieval of content from the closest Cache or the external Content Server, enabling efficient content caching and delivery to users.

In the CDCA architectural operating scheme, it is possible for multiple instances of the Proxy to be deployed across the network infrastructure "world", where each instance is responsible for coordinating a "Cache island", a group of Cache servers under same management domain. This

distributed deployment allows for efficient content delivery and load balancing. The SDN Controller plays a crucial role in the architecture by receiving network state information from the network management system. Based on this information, the SDN Controller makes forward decisions, determining the best Proxy instance to handle a content request. The goal is to minimize congestion, optimize transfer times, and enhance throughput by selecting the closest Proxy to the requesting user. Each Proxy instance is part of a Distributed Hash Table (DHT) in the overlay network. The DHT network facilitates the storage and retrieval of content-Cache instance mappings throughout the entire network. This distributed approach ensures that the mapping information is accessible and maintained across the network, enabling efficient Cache selection and content delivery. The Cache component, associated with each Proxy instance, is responsible for storing and serving cacheable objects triggered by any user's request within the network. When a cacheable object is requested, the Cache component determines if the object is already stored in the Cache. If it is present, the content is served directly from the Cache, minimizing latency. If the object is not in the Cache, the Cache component retrieves it from the appropriate source (e.g., external Content Server) and stores it in the Cache for future requests. By deploying this strategy of multiple Proxy instances, leveraging SDN-based forward decision-making, and utilizing a DHT overlay network, the CDCA architecture optimizes content delivery, reduces network congestion, and enhances the overall performance of the system.

The CDCA architecture was designed to accentuate high level of scalability and manageability at runtime to accommodate the dynamic nature of network environments. To achieve this, a logically centralized platform, such as a distributed SDN Controller system, is employed to provide scalability and resilience at the SDN layer [14]. While the specific analysis of the distributed SDN Controller system is not within the scope of the paper, it serves as a foundational component for the overall architecture.

Multiple instances of the Proxy and Cache components can be dynamically added or removed at runtime, facilitated by a cloud orchestration platform like OpenStack. This allows for an elastic and flexible solution where the system can adapt to changing demands and resource requirements. The management system, which could be integrated with the cloud orchestration platform, plays a vital role in monitoring the server's response time and making decisions regarding the deployment or termination of Proxy and Cache instances.

Similar to cloud management, the management of the Proxy and Cache instances follows principles of scalability and flexibility. The system can scale up or down based on the workload and user demands, ensuring optimal performance and resource utilization. Cloud management practices can serve as a reference for managing the Proxy and Cache components, but further exploration and research in this area are needed.

Of particular note to address the scalability issues mentioned in Section II, the CDCA architecture deploys many Proxy and Cache instances horizontally to assure a desired response time for any user by taking an integrated distributed Proxy approach to solve the unique Proxy limitation of the Chandra et al. proposal [11]. This CDCA approach directive offers several advantages in utilizing NFV in real-time network orchestration, particularly in optimizing runtime processing, transfer times, and scalability. Here are some benefits of using NFV in this context:

*1) Flexibility and agility*: NFV enables the virtualization of network functions, allowing them to be deployed and scaled as needed. This flexibility enables dynamic resource allocation and efficient utilization of infrastructure based on the current workload. It allows for quick deployment and adjustment of network services, leading to improved agility in responding to changing network demands.

*2) Scalability*: NFV provides scalability by allowing network functions to be dynamically instantiated and scaled according to the workload. During peak times, when network traffic is high, additional instances of network functions can be provisioned to handle the increased load, ensuring smooth operation and optimal performance. Similarly, during low-traffic periods, unnecessary instances can be scaled down or deactivated, saving resources.

*3) Resource optimization*: NFV allows for efficient utilization of hardware resources by consolidating multiple network functions onto virtualized infrastructure. This consolidation eliminates the need for dedicated hardware for each network function, leading to cost savings and improved resource utilization. Additionally, NFV enables the sharing of resources among different network functions, optimizing resource usage based on demand.

*4) Faster deployment and service innovation*: NFV decouples network functions from proprietary hardware, allowing them to run on general-purpose servers or cloud infrastructure. This decoupling simplifies the deployment process and reduces the time required to introduce new services or update existing ones. It enables service providers to rapidly deploy and scale network functions, promoting faster innovation and time-to-market for new services.

*5) Cost efficiency*: NFV can result in cost savings by reducing the need for expensive proprietary hardware appliances. Instead, virtualized network functions can be run on standard servers or cloud infrastructure, which are typically more cost-effective. NFV also enables service providers to adopt a pay-as-you-grow model, scaling their infrastructure based on actual demand, thereby optimizing costs.

By leveraging NFV in real-time network orchestration, service providers can achieve optimum runtime processing, reduce transfer times, and achieve high scalability, allowing them to efficiently handle variable network workloads and provide a better quality of service to their users.

Overall, the CDCA architecture aims to provide a scalable and manageable solution by exploiting distributed SDN controllers, dynamic deployment of Proxy and Cache instances, and integration with cloud orchestration platforms. Future work can delve deeper into the management aspects,

drawing inspiration from cloud management practices to enhance the efficiency and effectiveness of the system.

Algorithm 1 gives the core logical idea behind the operational aspects of the CDCA architecture, describing how the Proxy and Cache instances work together. Both components have a specific task in the processing of user requests. The Proxy is responsible for identifying and deciding *where* and *which* requests are going to be cached, while the Cache is responsible for providing the storage resources in order to Cache the contents according to the network policy. The details of the operational aspects of each component are described in the next subsections.

---

**Algorithm 1:** CDCA architecture operation

---

**1** The user triggers a content request;

**2** The SDN Controller forwards the request to the closest Proxy *cPrx*;

**3** *cPrx* checks its shared index if there is a content copy under its domain;

**4 if** *there is a content copy* **then**

**5**     *cPrx* forwards the request to the Cache *cCh* thatholds the content copy;

**6**     *cCh* delivers the cached content to the user;

**7 end**

**8 else**

**9**     *cPrx* forwards the request to the closest Cache *cCh*;

**10**     *cCh* retrieves the content from the original ContentServer;

**11**     *cCh* delivers the content to the User;

**12**     *cCh* stores the content for next User;

**13**     *cCh* notifies *cPrx* that a new content has beencached;

**14**     *cPrx* updates the index;

**15 end**

---

### A. Content Forwarding

The dependency on the SDN infrastructure in the CDCA solution for content dispatching offers several advantages, particularly in terms of efficiency and transparency. Some key points related to this dependency:

*1) Transparent request forwarding*: SDN allows for the transparent forwarding of content requests to cacheable content and Proxy instances on the network. By leveraging the OpenFlow protocol or similar SDN technologies, it becomes possible to create traffic flows on the switches that map specific TCP or UDP ports of applications. This enables the SDN Controller to direct requests to the appropriate Cache or Proxy without modifying the IP packet header. This transparency ensures that the communication between clients and the requested content or Proxy remains seamless and unaffected.

*2) Efficient traffic steering*: With the help of SDN, traffic can be efficiently steered to the desired destinations. By leveraging the programmability and control capabilities of SDN, the SDN Controller can dynamically analyse network conditions, load distribution, and Cache availability to make intelligent decisions on how to direct traffic. This enables the system to optimize content delivery by sending requests to Cache instances or the closest Proxy, minimizing latency and improving overall network performance.

*3) Flexibility and adaptability*: The use of SDN provides flexibility and adaptability to the solution. Since the forwarding, behaviour of switches can be dynamically controlled by the SDN Controller, changes in the network topology or caching infrastructure can be easily accommodated. New Cache instances or Proxy nodes can be added, removed, or reconfigured without requiring changes in the underlying network infrastructure. This flexibility allows the solution to scale and adapt to changing demands and evolving network conditions.

*4) Enhanced network visibility and control*: SDN offers centralized network management and control, providing enhanced visibility and control over network traffic. By having a centralized SDN Controller, network administrators can monitor and manage content dispatching, Cache utilization, and overall network performance from a single point of control. This centralized control enables efficient decision-making and troubleshooting, leading to improved network efficiency and performance.

Typically, the SDN infrastructure for content dispatching brings efficiency, transparency, flexibility, and enhanced control to the CDCA solution. By using SDN technologies like the OpenFlow protocol, it becomes possible to transparently forward requests to cacheable content and Proxy instances on the network without the need to modify IP packet headers. This enables efficient traffic steering and dynamic adaptability, leading to improved content delivery and network performance.

In the CDCA architecture, two approaches are used for creating flows in the SDN switches: proactive and reactive [15]. Here are the characteristics and considerations associated with each approach:

*1) Proactive approach*: In the proactive approach, the OpenFlow Controller configures all the necessary flows from the users to the nearest Proxy instance before any request is made to a server. This means that the flows are pre-installed in the switches based on anticipated traffic patterns. The advantage of this approach is that it avoids the need for switches to request the Controller for each new flow, thereby reducing forwarding delay. However, one drawback is that all data packets are routed through the same network segment or domain path, which can potentially lead to congestion on that path.

*2) Reactive approach*: In the reactive approach, flows are created on-demand, meaning that they are installed in the switches only when a request is made by a user. When a switch receives a packet for which there is no pre-installed flow, it sends a request to the Controller, which then installs the appropriate flow and forwards the packet accordingly. This approach introduces some latency as switches need to

contact the Controller for each new flow. However, it provides the opportunity to use load-balancing techniques to set alternate paths, thereby reducing congestion and improving network performance.

In the CDCA architecture, the Controller sets a path to the nearest Proxy instance in a reactive manner, meaning that flows are installed on-demand as requests are made by users. This allows for dynamic path determination based on the current network conditions and load distribution. On the other hand, the path from the user to the Cache or external network is set proactively, meaning that the necessary flows are pre-installed to optimize the forwarding of user traffic. This proactive approach helps minimize latency and optimize link usage. Remember that the NFV module establishes a new path for each new user request, providing scalability and load balancing.

By combining the proactive and reactive approaches, the CDCA architecture aims to achieve an efficient and balanced network operation. The reactive approach mapping users' requests to the nearest Proxy minimizes latency by dynamically determining the optimal path based on current network conditions. Meanwhile, the proactive approach setting the path from the user to the Cache or external network to ensure efficient forwarding without switches requires the Controller the path for each new flow [15].

It is important to note that the choice between proactive and reactive approaches may depend on specific network conditions, traffic patterns, and performance requirements. Both approaches have their advantages and trade-offs, and the decision should be made based on the specific needs and constraints of the network deployment.

When the SDN Controller receives an HTTP request, it sets a flow from the user to the Proxy. The forwarding is based on the destination IP address, i.e., the Content Provider IP, destination HTTP port (typically port 80) and the user's IP address to select the best Proxy to be used, e.g., closest to the user. The Proxy element is necessary because the SDN only analyses IP header fields, not HTTP requests. The Proxy analyzes the HTTP GET header and checks if the content is cached in its DHT index table. Then, it forwards, i.e., sets the flow in network switches, to connect the user to Cache. From this moment onwards, the user interacts only with the Cache until a new request is done, minimizing Proxy processing. In big content delivery, e.g., VoD services, a user maintains a long-time connection with a Cache.

Once a request arrives at a Proxy, it performs a deep inspection of the request to decide to which Cache this request should be forwarded. This inspection is possible for requests using the HTTP protocol, as the packet payload can be read by the Proxy. However, for requests using the HTTPS protocol, which provides encryption and security, performing deep inspections on the packet payload is not feasible and would risk breaching security.

When the Proxy needs to determine the path from the user to the closest Cache, it sends a command to the SDN Controller using a Representational State Transfer (REST) Application Programming Interface (API). The API allows the Proxy to communicate with the SDN Controller and provide the necessary information to install the required flows on the switches that belong to the network path connecting the user to the closest Cache.

This process of sending commands to the SDN Controller and installing flows on the switches ensures that the traffic is directed efficiently and transparently, optimizing the content delivery process. Fig. 2 provides an illustration of this timeline flow process, highlighting the interactions between the Proxy, SDN Controller, and switches in the network path as follows:

*1) Content request identification*: The SDN Controller identifies content requests from users within the network.

*2) Forwarding to proxy*: The SDN Controller forwards the content requests to the Proxy component responsible for handling Cache-related operations.

*3) Checking cache availability*: The Proxy checks if the requested content is already cached within the network.

*4) Forwarding to cache*: If the content is already cached, the Proxy forwards the request to the appropriate Cache instance that stores the content. This allows for direct content delivery from the Cache to the user.

*5) Flow path configuration*: The SDN Controller configures a data flow path from the Cache to the user, establishing a direct transmission route for efficient content delivery.

Fig. 2. Content forwarding sequence flow steps.

The CDCA approach ensures a transparent Cache handling for users without requiring any changes to their application implementations. The underlying transport protocol, TCP, necessitates that both the Proxy and Cache nodes are aware of connection handling details, as the connection state needs to be exchanged between them by SDN Controller that knows all Cache and clients address [16]. This awareness allows for the seamless transfer of connections from the Proxy to the Cache.

The use of SDN in implementing a transparent forwarding mechanism is also discussed in the work by Koulouzis et al [17]. Their research focuses on enhancing the transfer of data-intensive scientific applications by leveraging SDN network programmability.

By incorporating SDN principles and applying the REST API and SDN architecture, the CDCA architecture enables dynamic and controlled flow management, allowing for efficient content caching and delivery while respecting security considerations and the limitations imposed by the HTTPS protocol.

The release of HTTP/2 introduces improvements and new challenges to the Web. Its specification was published in May 2015 [18], and its adoption has been growing. The HTTP/2 decreases latency and improves web browsers' load speed and video delivery by implementing many new features [19]: (1) compression of HTTP headers; (2) inclusion of HTTP/2 Server Push; (3) multiplexing and pipelining of multiple requests over a single TCP connection; and, (4) fixing of blocking problem in HTTP/1.1. The HTTP/2 specification recommends cryptography using TLS 1.2, but it is not mandatory. For video streaming, HTTP/2 Server Push relieves the Proxy processing, and the video chunks should be delivered unencrypted to reduce the encryption overhead of video files.

The CDCA architecture supports HTTP/1.1 and HTTP/2 offering seamless smooth ambiance effect video viewing without side effects, because the request are initiated at the client side. In HTTP/1.1, with no Server Push, the performance is lower than HTTP/2. In general, most of the contemporaries, like CDCA researcher, consider encrypted video to be unfeasible for normal viewing because each browser would need a different crypt-key per connection. However, if cryptography is required for whatever reasons, CDCA system is easily capable of providing any publicly available standard encryption/decryption module such as a Deep Packet Inspection (DPI) module, which will be addressed in another article.

Content identification is the initial most important task performed in the Proxy. The architecture does not Cache all kinds of information, but only large and reusable content, e.g., video and music on demand, software installers, or sizable images.

The most important, big, and reusable content object application on the Internet is VoD. A plethora of VoD providers exist. All of them use similar approaches to provide a variety of content delivery services. Most of them use Flash and HTML5 as video player. In the CDCA experiment, HTML5 was chosen since it is better for identifying video characteristics. The video stream encoder is mostly H.264/MPEG-4, and the video stream is not encrypted to reduce server and client overhead. This fact is very important for the CDCA architecture because there are some outstanding security issues regarding encrypted content, which should be readable only by the first user. And, of course, we suppose the multimedia videos are royalty-free to permit distribution to all users, which, in reality, might be different in business-oriented provider networks with regard to payment to owners of the content or to their nominated agents, such as the service provider.

Currently, the transport protocol for video streaming on the Internet is accomplished by using either TCP or UDP. The delivery of live video streaming with *on-the-fly* encoding, like IPTV, is mostly UDP based, but the delivery of pre-encoded video, called VoD, essentially uses TCP [20]. In the CDCA architecture, the focus is on VoD services over TCP. For the evaluation, YouTube is considered since it is the most prominent VoD portal, which handles more than several billion video streams daily. While the YouTube site itself operates over HTTPS, the actual video stream requests and delivery are performed using HTTP. This allows for the identification of unencrypted HTTP requests and the corresponding HTTP objects are easily identified using pattern-matching techniques [21]. It is worth noting that the architecture is designed to handle TCP-based VoD services and can be adapted to support other VoD providers with minor modifications. The future intention is to analyze and adapt the CDCA solution for various VoD platforms, applying the same approach used for YouTube.

For instance, considering a YouTube video URL, the web page provides the link for different formats, e.g., *href="http://www.youtube.com/watch?v=yXc8KCxyEyQ"* for standard format, *href="http://m.youtube.com/watch?v=yXc8KCxyEyQ"* for hand-held devices, and also for specific devices, like Android, *href="android-app://com.google.android.youtube/http/www.youtube.com/watch?v=yXc8KCxyEyQ"*.

It seems that Google implements some techniques to restrict the direct access to video in a lot of ways. It is possible to see some interesting fields in the URLs, e.g., "?part=" and "?range=," which permit identifying of each downloaded chunk and storing it in the correct order. The process to retrieve a Youtube video requires reverse engineering to extract chunk information from the URL, a technique used by some "Youtube downloaders", which is very common nowadays.

YouTube employs various mechanisms, including DNS translation and URL redirection, to optimize the delivery of video content. These mechanisms help distribute the video's chunk files across multiple caching servers, allowing for load balancing of the transmission.

The YouTube video delivery name is composed of three key components [22]:

*1) Video ID space*: Each video on YouTube is assigned a unique video ID, which serves as an identifier for the specific video content.

*2) Hierarchical logical video server*: YouTube utilizes a hierarchical logical video server structure to organize and manage video content. This structure helps ensure efficient content management and delivery across the platform.

*3) Physical server cache hierarchy*: The physical server Cache hierarchy represents the distribution of caching servers used by YouTube. The chunk files of the videos are stored in these caching servers, which are strategically located to optimize content delivery and minimize latency for users.

By employing DNS translation, URL redirection, and a well-structured video delivery name, YouTube can efficiently distribute and deliver video content, providing a seamless streaming experience to its vast user base as:

*a) YouTube Video Id Space:* Each YouTube video is uniquely identified using a fixed-length flat identifier with random (nonsensical) characters, e.g., something like *yXc8KCxyEyQ*.

*b) Hierarchical Cache Server DNS Namespaces:*

YouTube defines multiple DNS namespaces representing a group of logical video servers related to the video format and resolution. The DNS namespace forms a hierarchical structure of logical video servers that are mapped to an IP address where the video file is stored, e.g., http://b8u-4vge.googlevideo.com

*c) Physical Cache Servers:* In the case of YouTube, the logical Cache servers are represented by a unique logical namespace in the DNS names. However, each DNS resolution of this namespace can map to a large set of IP addresses, which correspond to the physical Cache servers. For example, if we consider the hostname *http://b8u-4vge.googlevideo.com,* the primary namespace represents the logical Cache server. However, depending on factors such as the user's location and the load balancing policy in place, multiple IP addresses can be associated with this hostname. These IP addresses correspond to the physical Cache servers that store and serve the video content.

YouTube uses HTTP to deliver videos to users in order to reduce the cryptography overheads. Even under an HTTPS connection, the HTTP request can be easily seen. Analyzing the URL, we can identify the video name (Video Id Space) and the format and resolution for a specific device (Hierarchical Cache Server DNS Namespaces). In the CDCA architecture, the *Physical Cache Server* component does not give away any useful information.

### B. Proxy Design

The Proxy component acts as an intelligent intermediary between users and Cache nodes, ensuring efficient content delivery and load balancing within the network. It plays a crucial role in the CDCA architecture as it handles users' requests and ensures the delivery of the requested content to the nearest available Cache. Its main function is to determine the appropriate Cache node to serve the content based on a mapping index.

When a user makes a content request, the Proxy checks whether there is an existing copy of the requested content in the network. If a copy is available, the Proxy forwards the request to the Cache node that holds the content. This minimizes the latency and improves the response time for the user. In cases where the requested content is not available in any Cache node, the Proxy identifies the Cache node closest to the user and forwards the request to that node. This Cache node becomes a aspirant for holding a copy of the requested content. If there are multiple Cache nodes with the same distance from the user, the Proxy employs a round-robin operation. This load-balancing technique distributes the requests among the Cache nodes equally, ensuring efficient utilization of resources and preventing any single Cache node from becoming overloaded.

Since it is possible that many Proxies exist over the network, each Proxy instance participates in a DHT to share the content index. This DHT serves as a Distributed Forwarding Unit (DFU) that allows efficient content lookup and forwarding among the proxies.

While there are multiple Proxy instances distributed throughout the network, it is important to note that each user's requests will always be handled by the same Proxy node nearest to it. This selection of the closest Proxy node to the user ensures proximity-based routing and minimizes latency in the content delivery process.

By maintaining the user's requests consistently routed to the same Proxy node, it offers several advantages. Firstly, it provides a predictable and reliable user experience as the user interacts with the system through a specific Proxy node. Secondly, it allows the Proxy node to maintain the context and state of the user's requests, facilitating personalized content delivery and improving overall efficiency.

The sharing of the DHT among the Proxy instances enables efficient content indexing and lookup. When a user request arrives at a Proxy node, it can quickly query the DHT to determine if the requested content is available in the network and identify the Proxy node that holds a copy of the content. This ensures effective content retrieval and delivery to the user.

The forward decision is taken by the SDN Controller that receives the network state information from the network management system, choosing the best Proxy instance. Because any new user's request is processed by the SDN Controller, it should choose the optimal Proxy *on-the-fly* based on the network status. Generally, the closest Proxy will be the perfect solution because it will have the minimum delay. It also does not store any content and only looks at a DHT table. However, if one Proxy processes more requests than another, it is possible to redirect the requests to load balance the system considering network and server status.

The Proxy and Cache instances maintain a virtual overlay network configuration schema, which enables them to exchange Cache states and commands seamlessly. When a Proxy decides to forward a user's request to a Cache instance, it sends a command to the chosen Cache, specifying the request and the user. This command instructs the Cache to serve the requested content to the user.

Upon sending the command, the Proxy listens for an acknowledgment from the Cache. This acknowledgment confirms that the content has been successfully cached by the Cache instance. It allows the Proxy to update its index, which maps content names to Cache instances. This updated index enables the Proxy to efficiently forward future requests for the same content to the same Cache instance, enhancing caching effectiveness and reducing content retrieval latency.

Additionally, the acknowledgment may provide information about the content's lifetime. The Cache instance specifies the maximum duration for which the content will be cached. Once the Cache lifetime expires, the corresponding index entry for the content is automatically removed from the DHT, ensuring that outdated content is not unnecessarily stored in the network.

By maintaining an efficient and synchronized index across Proxy and Cache instances, the architecture optimizes content caching, improves content availability, and ensures that the most relevant content is stored and served efficiently.

The content caching mechanism is designed to be transparent and efficient, allowing any Proxy to forward a request to a Cache instance that already holds the requested content. This means that even if a Proxy is responsible for managing a specific Cache instance, it can still forward requests to other Cache instances that have the desired content.

As an example, for instance, where Proxy 'A' manages Cache 'A' and Proxy 'B' manages Cache 'B', if a user near Proxy 'A' requests content 'C', Proxy 'A' would handle the request. However, since Proxy 'A' knows that Cache 'B' has a copy of content 'C' (as indicated by the DHT index), it would forward the user's request to Cache 'B' to fetch the content. This behaviour enables efficient utilization of the caching infrastructure, as any available Cache instance can serve content to users, regardless of the Proxy managing it, thus optimizing content retrieval and delivery, ensuring that users can access the content efficiently from the nearest available Cache instance. This approach enhances the overall performance of the caching system and improves user experience.

Usually, choosing the optimal Cache or deciding to fetch content from an external server is most desirable in content delivery systems. The choice between fetching content from an in-network Cache or from an external server depends on various factors, such as Cache proximity, network conditions, content availability, and delivery requirements.

In the CDCA architecture, the decision of whether to fetch content from an in-network Cache or from an external server is not explicitly addressed. However, future works and research can focus on developing intelligent policies or algorithms to determine the best Cache to use within the network or when it is more efficient to fetch content from an external server. These policies could take into account factors such as Cache proximity, network congestion, content popularity, Cache availability, and other performance metrics. By considering these factors, the system can dynamically adapt and make better decisions based on the current network conditions and optimize content delivery for the best user experience.

Overall, this Proxy design scheme enhances the scalability, reliability, and performance of the CDCA architecture.

### C. Cache Design

The Cache component plays a vital role in serving user requests and optimizing content delivery. When a request reaches a Cache instance, it first checks its local memory using a Hash Table for the fast lookup to see if the requested content is already stored. If the content is found in the Cache, it can immediately send the requested content back to the user through the previously configured OpenFlow path. This enables fast and efficient delivery of content from the Cache without the need to retrieve it from the original server.

However, if the content is not available in the Cache, the Cache acts as a Proxy and forwards the user's request to the target server specified in the request. This behaviour is similar to a standard client-server interaction without caching. When the target server responds to the request, the Cache immediately sends the response back to the user.

Additionally, the Cache performs a deep packet inspection on the response received from the target server. This inspection helps determine if the response is cacheable or not. The Cache examines the nature of the protocol being used (such as HTTP) and looks for specific headers, like the Cache-Control header in the case of HTTP. The Cache-Control header provides instructions to consumers (in this case, the Cache) on how the response can be cached, including the duration for which it can be cached or whether caching is prohibited by the server.

When the Cache determines that the fetched content is cacheable, it immediately notifies the Proxy that it now holds a copy of the content. This ensures that subsequent requests for the same content can be efficiently served from the Cache. Additionally, the Cache may include a Cache lifetime value, which indicates the maximum duration for which the content should be considered valid in the Cache. The determination of the Cache lifetime value depends on the characteristics of the media, such as its freshness requirements or expiration policies.

In cases where the content is deemed non-cacheable, such as very small content that may not benefit from caching, the Cache simply sends the response directly to the user without storing it. This prevents unnecessary utilization of Cache space and avoids the need for DHT updates related to that particular content.

Setting the Cache lifetime value appropriately is crucial for optimizing system performance. It allows balancing between serving stale content and the overhead of fetching fresh content from the server. The specific Cache lifetime values and policies can be defined by the content provider according to their own requirements and policies.

### D. Cache Management

Separating the data storage layer from the control function of Cache instances offers flexibility and scalability in the deployment of the caching system. By decoupling these two functions, each Cache instance can operate independently without interfering with the others in the storage layer.

This separation allows for various deployment scenarios, each with its own characteristics. For example, multiple Cache instances can be deployed on different physical servers or virtual machines, enabling distribution across different geographical locations or network segments. Each Cache instance can have its own storage resources, such as disk space or memory, dedicated to serving content requests. For instance, an ISP may deploy a number of caches over their network, configuring 70% of the instances to use their RAM memory while the other 30% are configured to use SSD disks. The decision about the type of storage that will be used by the Cache instances and where they are deployed is a decision that must be taken by the network operator since there are many strategical decisions involved.

The separation of data and control also enables the implementation of different caching strategies or policies within each Cache instance. This means that each Cache

instance can have its own set of rules and algorithms for content eviction, replacement, or caching optimization, tailored to specific requirements or objectives, allowing for efficient and independent operation of each Cache instance within the caching system.

The decision of whether to store content in memory or on local disks within a Cache instance is an important aspect that can significantly impact caching performance and efficiency. Both options have their advantages and considerations.

Using an in-memory approach provides faster access to cached content due to the high speed of memory. It is particularly suitable for frequently accessed or hot content that requires low-latency delivery. However, memory capacity is typically limited compared to disk capacity, which means that the Cache can store a smaller amount of content in memory. This can lead to a higher likelihood of Cache eviction for less frequently accessed or cold content, resulting in potential Cache misses and increased latency.

On the other hand, storing content on local disks provides a larger storage capacity, allowing the Cache to accommodate a larger volume of content. This is advantageous for caching less frequently accessed or larger files. Disk-based storage can be especially useful for VoD (Video on Demand) services that deal with pre-encoded videos, where the content size can be substantial. However, accessing content from disks is generally slower compared to memory, which can introduce additional latency.

The choice between in-memory and disk-based storage depends on various factors, including the nature of the content, the expected workload, and the network administrator's policy. If the network administrator prioritizes fast access to frequently accessed content, an in-memory approach might be preferred. Conversely, if accommodating a larger volume of content is crucial, disk-based storage is more suitable.

Additionally, the eviction policy is an essential consideration in Cache design. It determines how content is selected for eviction when the Cache reaches its capacity limit. There are various eviction algorithms, such as LRU (Least Recently Used), LFU (Least Frequently Used), and Random Replacement, each with its own trade-offs in terms of Cache efficiency and performance. The network administrator can choose the most suitable eviction algorithm based on factors such as content popularity, access patterns, and the desired Cache hit rate.

The CDCA architecture is flexible such that it can be configured to use any eviction algorithm by an open API, i.e.; the network administrator can choose the best algorithm according to the user's profile. Cache eviction policies are well discussed in Balamash [23] and Wang [24].

It is possible to use a hybrid approach when dealing with the decision to store the content in memory or on disk. For instance, a hybrid approach combining both memory (M1) and disk (M2) storage can provide a balance between fast access and larger storage capacity. This approach takes advantage of both memory and disk to optimize caching performance.

In the hybrid approach, frequently accessed or hot data is stored in the M1 Cache, which is the faster memory component. This ensures that popular content is readily available for fast retrieval and reduces latency for frequently requested items. The M1 Cache acts as a high-speed Cache tier that can quickly serve content without accessing the slower disk storage.

On the other hand, less frequently accessed or cold data is stored in the M2 Cache, which resides on a disk. The M2 Cache provides a larger storage capacity compared to memory, allowing the Cache to accommodate a broader range of content. Although accessing content from the M2 Cache may introduce additional latency, the presence of frequently accessed items in the M1 Cache minimizes the impact on overall performance.

To optimize the hybrid approach, a managing schema algorithm is employed to determine which data should reside in the M1 Cache and which should be stored in the M2 Cache. This algorithm can monitor access patterns, frequency of requests, and other relevant metrics to make informed decisions about data placement. For example, if a content item in the M2 Cache starts to experience increased access frequency, the managing schema algorithm can dynamically promote it to the M1 Cache to improve access time.

The reconfigurability of the Cache instance is a valuable feature that allows for dynamic adjustments and fine-tuning of the Cache's parameters to meet changing demands and optimize performance. By deploying the Cache instance within a Virtual Machine (VM), it becomes possible to modify various aspects of the Cache configuration during runtime.

One such configurable parameter is the storage capacity, which includes both memory and disk space. As the workload increases and the Cache approaches its capacity limit, it may become necessary to adjust the available storage resources to accommodate additional data. This can be achieved by dynamically increasing the memory allocation or expanding the disk space assigned to the Cache VM.

In addition to storage capacity, other parameters such as eviction policies can also be tuned. The eviction policy determines which content items are evicted from the Cache when it reaches its capacity limit. By adjusting the eviction policy, the Cache manager can prioritize certain content or employ different strategies to optimize Cache utilization and improve hit rates.

When the Cache becomes saturated and the eviction rate surpasses a predefined threshold, the Cache manager can take proactive measures to address the situation. This may involve automatically attaching a new VM to distribute the caching load, increasing the available memory to accommodate more content in the M1 Cache, or modifying the eviction policy to better manage the Cache's content.

The ability to make such adjustments dynamically (on-the-fly) and in a dynamic manner allows the Cache instance to adapt to varying workloads and optimize its performance in real time. This flexibility ensures that the Cache can efficiently handle increasing demands and effectively utilize available resources, ultimately enhancing the overall

efficiency and responsiveness of the caching system.

*E. Cache Policy Management*

Designing a system that can cater to various business needs and network traffic patterns requires careful consideration of policy management. Different organizations and network environments may have specific requirements, priorities, and constraints that need to be taken into account. Therefore, the system project incorporates design strategies to enable efficient content delivery while also accommodating complex real-world policies.

Policy management encompasses various aspects, including caching policies, eviction policies, load balancing policies, content placement policies, and more. These policies define how the system operates, makes decisions, and prioritizes tasks. By incorporating flexibility in policy management, the system can be customized and tailored to meet specific requirements.

One important design strategy is to provide configurable parameters and APIs that allow administrators or users to define and modify policies according to their needs. This flexibility empowers organizations to adapt the system to their unique business rules and network traffic patterns. For example, administrators can define caching policies based on content popularity, user preferences, or other relevant factors.

Furthermore, the system project may offer a range of pre-defined policy templates or algorithms that serve as a starting point for administrators to choose from. These templates can be based on industry best practices or research findings, providing guidance for policy selection. Administrators can then fine-tune and customize these templates to align with their specific requirements.

Additionally, the system may provide monitoring and analytics capabilities to gather data on network traffic, content usage patterns, performance metrics, and other relevant information. This data can be used to evaluate the effectiveness of existing policies and make informed decisions for policy adjustments or optimizations.

By considering policy management as an integral part of the system design, the project aimed to provide a flexible and adaptable solution that can cater to diverse business needs and network scenarios. This approach acknowledges that different organizations may have unique policies and requirements, and it offers the means to configure and manage these policies effectively to achieve optimum performance and content delivery outcomes.

The policy management function being performed on the Proxy component is a logical and efficient choice. As the decision-maker responsible for managing a set of caching instances, the Proxy is well-positioned to handle policy management tasks. Since all requests from a subset of network nodes pass through the Proxy, it has the necessary visibility and control to implement and enforce caching policies effectively.

By extending the Proxy's content inspection capabilities, it becomes possible to deeply analyse the content's data and incorporate manageable aspects into the policy management process. This allows the Proxy to make intelligent decisions about which content should be cached based on specific criteria or conditions.

In the current stage of proposal development and experimentation, the system has addressed five caching policies to provide adaptability to different workloads commonly encountered in practice:

*1) Cache everything*: This policy implies caching all content without any specific filtering or criteria. It ensures that all requested content is stored in the Cache for future retrieval.

*2) Cache only content whose name matches any given regular expression set*: This policy allows administrators to define a set of regular expressions to match content names. Only content with names that match these expressions will be cached, while others will be bypassed.

*3) Cache only content whose size matches certain file criteria*: This policy focuses on caching content based on their file size. Administrators can define specific criteria (e.g., minimum or maximum file size) to determine which content should be cached.

*4) Cache only content served by a specific set of target domains*: This policy restricts caching to content served by designated domains. Administrators can specify a list of target domains, and only content from these domains will be eligible for caching.

*5) Cache-only content of a given type (audio, video, etc.)*: This policy enables selective caching based on content types. Administrators can specify the types of content (e.g., audio, video, images) that should be cached, while excluding others.

The system utilizes a pipeline processing approach to handle multiple sets of distinct policies in an efficient manner. This approach allows the policies to be applied in a combinatorial fashion, starting from the most restrictive to the least restrictive that serves as a set of policy filters to derive an optimal management solution.

When a request reaches the Proxy, it undergoes a deep inspection phase to gather relevant information about the content. Following this, the request is processed through the policy pipeline, which consists of sequentially applying the defined policies to determine whether the content should be cached or not.

The policy pipeline filters the requests based on the defined rules, allowing or denying caching of the requested content. If a request is denied by any policy rule in the pipeline, the Proxy sends a forward command to the Cache instance without expecting Cache confirmation or acknowledgment. In this case, the content will have a flag indicating that it cannot be cached by that specific Cache instance.

The algorithm presented in Algorithm 2 serves as an example of how the policy pipeline operates for Caching, determining the caching behaviour based on the policies:

*1)* Initialize the request
*2)* Perform deep inspection on the request

*3)* Set caching_allowed = True

*4) For each policy in the policy pipeline*: a. Apply the policy rule to the request b. If the policy denies caching: - Set caching_allowed = False - Break the pipeline loop

*5) If caching_allowed is True*: a. Forward the request to the closest Cache instance to the user b. Expect Cache confirmation/acknowledgment

*6) If caching_allowed is False*: a. Send a forward command to the Cache instance b. Set the content's "*cacheability"* flag to indicate no caching

By processing requests through this policy pipeline, the system can effectively filter and determine the caching behaviour based on the defined policies. The pipeline approach allows for flexible and customizable policy management, enabling administrators to derive an optimal caching solution based on their specific requirements and policies.

In some cases, certain requests cannot enter the processing pipeline until they have been served by the originating server. For example, in HTTP requests, the requester may allow the receipt of both text and video responses, but the actual response will determine the content type by inspecting the ContentType header. Similarly, the content's size may not be known until the response has been completely received.

In such cases, the same processing pipeline can be applied at the Cache instances, but only in specific scenarios where the request can be fully inspected and the necessary information is available. The Cache instances can run the policy pipeline to determine the caching behaviour based on the received response.

It's important to note that if the Proxy's flag command allows caching, it prevents the Cache from overriding any previous decision made by the Proxy. This ensures that the caching behaviour determined by the Proxy is maintained and not altered by the Cache instances.

By allowing the processing pipeline to run at both the Proxy and Cache instances, the system can ensure consistent caching decisions and policies across the network, taking into account the specific characteristics and information available at each stage of the request-response cycle.

---

**Algorithm 2:** Policy processing method

**Data:** The content request *cRqst*; and a set of filters *polFltr[]*

**Result:** 1 if the content should be cached, 0 otherwise

1 **foreach** *p in polFltr[]* **do**
2     **if** *p(cRqst) == 0* **then**
3         **return** 0;
4     **end**
5 **end**
6 **return** 1;

---

*F. System Scalability*

Scalability is a crucial aspect of the CDCA architectural system, and it involves the SDN Controller, proxies, and caches. To ensure scalability and address availability concerns, the architecture allows for the deployment of new instances of these components in the network on the fly. One key factor in achieving scalability is the use of a stateless OpenFlow control. This enables simple load balancing across multiple Controller devices, ensuring that the control plane can handle increasing demands and distribute the workload effectively [9]. By distributing the control plane functionality, scalability and redundancy are improved, as multiple controllers can handle the control tasks in a distributed manner. In the context of SD-ICN, scalability becomes an even more significant concern due to the introduction of in-network caching and content-based communication. To address the control plane scalability challenge, Gao et al. propose the Scalable Area-based Hierarchical Architecture (SAHA) [25]. SAHA is designed to handle the control plane scalability problem specific to SD-ICN environments and provides a hierarchical architecture that enables efficient management and scalability.

Several distributed architectures have been CDCA to enhance OpenFlow scalability and redundancy. Examples include Disco [26], ElastiCon [27], and Onos [28]. These architectures aim to distribute control plane functionality, improve scalability, and provide redundancy mechanisms to ensure high availability.

By leveraging these scalable and distributed architectures, the CDCA system can handle increasing demands, distribute control tasks effectively, and provide redundancy to ensure system availability. This enables the system to accommodate a growing number of users, requests, and caching instances while maintaining efficient control plane operations.

Analyzing the Proxy design, it is possible to notice that its main idea is to simply forward the request to the appropriate Cache, thus it relies on the DHT index to get all information it needs about the caching state, which is spread over all Proxy instances of the network topology. The most costly operation that the Proxy does (determine where content was previously cached) basically relies on a DHT lookup operation, which is the operation that can constrain the Proxy scalability. Since the chosen DHT implementation is in conformance with Chord [29], a lookup operation needs just $O(logN)$ messages to find any key in the table and $O(log^2N)$ messages to update any key, where $N$ is the number of proxies deployed in the network. While the Proxy relies on a DHT to find the appropriate Cache to forward requests, the Cache itself is a simple solution that only relies on a Hash Table to look up cached contents locally, so all its operations require $O(1)$ time. The main concern about the Cache is simply its memory capacity, which obviously will limit the amount of data that can be stored in that network node.

Along with the individual characteristics of each component, the overall architecture is also important. The decision of using a microservice architectural pattern was furthermore taken based on the scalability opportunities that such design offers. Many modern systems built incloud environments take this same direction when scalability is a major nonfunctional requirement. The main characteristic of microservices comes from its own definition, which states that a microservice should do one thing, and do it well. Such an

idea allows that a system with multiple functional components can be developed, tested and deployed separately. It makes easy as operational actions that must be taken in response to business and network requirements. The CDCA solution has these characteristics, allowing, for instance; the number of proxies, caches, or controllers can be changed over time independently of each other to satisfy any demand.

The CDCA architecture has been designed with flexibility in mind, and considering how the architecture's components could be used and reused in real-world production provider networks. The architecture considers the business needs, the technical issues, and the most important constraints that concern network providers on a daily basis. As previously mentioned, the idea to use SDN and NFV brings several deployment possibilities, and the architecture has been designed to accommodate these different deployment possibilities. The network administrator can deploy the system according to the exact business and technical needs. The idea is to create autonomous *islands* responsible for handling the in-network content caching in a specific network segment/domain. These islands may contain several Cache instances and few Proxy instances, each of them operating independently, yet sharing the same data content across the DHT index at the proxies. The network segment/domain could be composed of any arbitrary set of users and/or network devices, each of them sharing common features, like geographical region, traffic patterns, etc.

## V. RESULT ANALYSIS OF THE CDCA SYSTEM

The experiments have been conducted to evaluate the effectiveness of the CDCA architecture and prototype operational system. By conducting these experiments, one can gain valuable insights into the performance, scalability, and feasibility of deploying the system in real-time production networks.

Evaluating the system in a realistic environment helps identify any potential challenges, bottlenecks, or areas for improvement. It also allows you to gather empirical data on the system's performance, such as response times, caching efficiency, and resource utilization. By conducting experiments and gathering insights, one can refine and optimize the CDCA architecture, ensuring that it meets the requirements and expectations of real-world deployment scenarios. Additionally, sharing the results of these experiments and promoting further research and development in this subject area can contribute to the advancement of the field and drive innovation in content delivery networks beyond today's technical achievements.

In all experiments, the CDCA solution is compared against a *legacy* network, i.e., a traditional Internet environment where the content is delivered directly from the content server to the user.

The main objective of the experiment is to evaluate the effectiveness of the users, considering the network provider and the content provider resources. To this extent, the first experiment aims to analyze how long a set of users would wait to retrieve arbitrary contents with different chunk sizes from an external server. The second experiment aims to verify how many data packets and bytes are exchanged within the network provider's infrastructure when requests for contents with distinct sizes are performed by several users. Finally, the third experiment checks the throughput at the content provider's server at different hit rates and Cache storage capacities when requests for content with distinct sizes are performed by many users.

### A. Experimental Environment Evaluation

The evaluation of the prototype using an emulation methodology provides a controlled and reproducible environment to assess the performance and behavior of the CDCA architecture. Mininet, a virtualized network platform, was chosen as the basis for the evaluation, offering the ability to create interconnected virtual devices such as hosts, switches, and controllers [30].

The evaluation scenario of the topology experiments was implemented within a c3.2xlarge Amazon EC2 VM, which provided sufficient resources including 8 virtual CPUs, 15GB of RAM, and 2 x 80GB of SSD storage. The virtualized devices in Mininet communicated with each other via virtual interfaces, enabling the execution of real protocol stacks in a virtual network.

The network topology used in the experiment is composed of one content server, one SDN Controller and six islands with three users each as shown in Fig. 3. The network driver and switching delay considered in Mininet environment are not shown. The latency stated in the figure is only the fiber propagation delay.

To control the traffic flow in the network, an OpenFlow Controller was employed. The Floodlight OpenFlow Controller was selected for its simplicity and development flexibility, which facilitated the implementation and management of the network environment [31]. The evaluation took into account the latency of a 1 Gbps Ethernet board driver (100 µs) and the switching latency in the Linux Open vSwitch. These latency values were set to be greater than those typically found in real network infrastructures to ensure the worst case scenario for evaluation purposes of the results.

The flexibility of Mininet allowed configuring parameters such as link bandwidth and delaying strategies, enabling the emulation of various network conditions and scenarios similar to production networks. This flexibility enhanced the accuracy and applicability of the evaluation results.

It is worth mentioning that the evaluation utilized OpenFlow version 1.0, as it was deemed sufficient for assessing the CDCA architecture. Subsequent versions of OpenFlow did not offer any new features or fields that would significantly impact the evaluation of the proposal.

By conducting the evaluation in this controlled environment, the researchers were able to gather data on the performance, scalability, and feasibility of the prototype. These insights help validate the effectiveness of the CDCA architecture and provide valuable information for further refinement and improvement. It has allowed for a comprehensive assessment of the CDCA architecture's capabilities in a realistic network setting.
Fig. 3.    Evaluation topology of the experiment.

The experiment involved the initiation of multiple applications running over HTTP, encompassing a variety of content types ranging from plain text websites to multimedia video streams. The content response chunk sizes were varied in the range of 10 to 3200 kilobytes.

The methodology employed in the experiment drew inspiration from the work of Augustin et al. [32], who extensively analysed the bandwidth usage of Web 2.0 applications. By adopting a similar approach, the experiment aimed to evaluate the CDCA architecture's ability to handle a diverse range of applications and their associated bandwidth requirements. This experimental method was selected because it demonstrated success in addressing a wide spectrum of applications, including email and on-demand video streams. This approach also permitted gathering meaningful statistics and insights into the performance and efficiency of the CDCA architecture in handling different types of content and application scenarios. It also allowed conducting experiments with various content response chunk sizes and a diverse set of applications to assess the scalability, efficiency, and effectiveness of the CDCA architecture in accommodating different bandwidth demands and traffic patterns as well as providing valuable insights into its performance and potential benefits in practical deployment scenarios.

In the experiment, each user was implemented in Java using Apache's HTTP Client library to perform HTTP requests. Each user was single-threaded, and all users concurrently sent their requests.

To simulate realistic user behaviour, the Cache hit rate was set at 70%, meaning that 70% of the requests made by the users were expected to be found in the Cache and result in Cache hits. The CDN's Cache hit rate is variable and depends on the content and user profile. The literature typically regard CDN's hit rate estimate to be in the range from 60% to 90%, so an intermediate value was used. As we used emulation, the chunks were randomly generated and the client's hit rate was

set to 70%.

To optimize network resource utilization, each client used HTTP pipelining, which allows multiple requests to be sent over a single TCP connection without waiting for individual responses. This approach maximizes the use of network capacity by reducing the overhead of opening and closing TCP connections for each request. Each client was configured to have a maximum of 10 pipelined requests without responses, meaning that a client could have several pending requests in transit simultaneously, even though each client was single-threaded.

The perceived delay experienced by users was measured as a roundtrip time, starting from the moment a user sent an HTTP request until the corresponding response was received by the same user. This metric captured the overall time required for a user to receive a response and reflected the user's perceived delay in accessing the requested content.

To gather statistics on bytes and data packets, the OpenFlow Controller was utilized. After each experiment round, the OpenFlow Controller obtained the counter values for each port of the OpenFlow switches through StatsRequest messages [33]. This allowed collection of information on the amount of data transmitted and the number of packets exchanged within the network under realistic conditions. This approach provided insights into the system's ability to handle concurrent user requests, optimize network resources, and deliver content with reduced perceived delay.

In the first experiment, caches with a capacity of 1GB were used. This means that each Cache instance had the ability to store up to 1GB of content. The experiment aimed to evaluate the system's performance and effectiveness with this limited Cache capacity.

The second experiment involved two Cache instances, each with a capacity of 1GB. This setup allowed for a total Cache capacity of 2GB. By increasing the number of Cache instances, the system aimed to assess the impact of distributed caching on performance and content availability.

In the third experiment, Cache capacities varied from 2GB to 6GB. This range of capacities allowed the researchers to investigate the scalability and performance of the system as the Cache capacity increased. The experiment aimed to understand how increasing Cache capacity influenced Cache hit rates, perceived delay, and overall system efficiency.

In all three experiments, the caches were configured to use the Least Frequently Used (LFU) eviction policy. LFU is a Cache replacement policy that selects the least frequently used content for eviction when the Cache reaches its capacity limit. This policy is based on the assumption that content popularity is a significant factor in Cache usage, and frequently accessed content is more likely to be accessed again in the future.

Additionally, the caches in these experiments used an in-memory approach, meaning that the content was stored in the Cache's memory rather than on disk. This allowed for faster access times but limited the overall storage capacity compared to using disk-based storage.

The decision to use an LFU eviction policy and an in-

memory approach was based on previous research by Famaey et al. [34], which highlighted the effectiveness of popularity-based Cache replacement strategies for Video-on-Demand (VoD) services. Adopting LFU and an in-memory approach, allowed them to align the experiments with existing literature for comparison purposes and leverage the benefits of these strategies in their system.

### B. Experimental Results

In the first experiment, the user's average delay when requesting content from a server was evaluated. Each experiment was executed 10 times with different chunk sizes and hit rate of 70%, showing overall results of an average of 95% confidence interval as shown in Fig. 4. It demonstrates the effectiveness of the CDCA architecture in improving the user's delay perception.

The graph illustrates that the CDCA architecture led to a significant improvement in the user's delay, regardless of the content's size. On average, the delay was reduced by nearly 75% compared to traditional approaches. This improvement indicates that the CDCA architecture effectively optimizes content delivery and reduces the perceived delay from the user's perspective.

Furthermore, the result for 3200 kilobytes of contents showed an even higher improvement of almost 80%. This suggests that the CDCA solution not only enhances the user's delay but also reduces network traffic. By utilizing caching and efficient content delivery mechanisms, the CDCA architecture minimizes the need for repeated content requests, leading to reduced network congestion and improved overall performance.

These findings support the effectiveness of the CDCA architecture in improving user experience by reducing delay and optimizing content delivery, irrespective of the content's size.

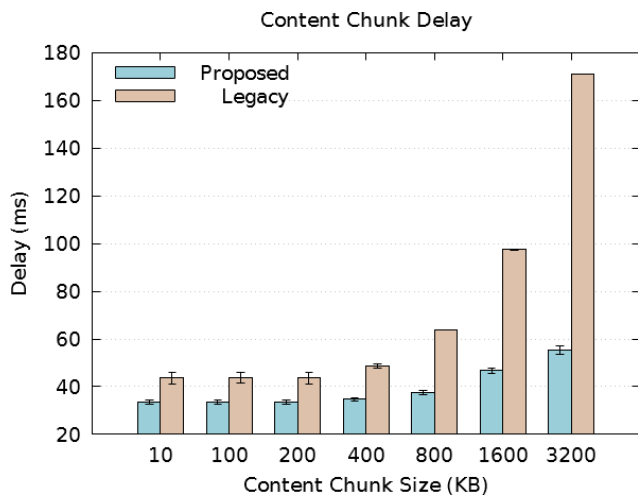

Fig. 4. User's observed delay with responses with different chunk sizes.

Fig. 5 displays the number of bytes transferred after the execution of the second experiment of the sum total of the number of bytes transferred through all switches at each network interface within the network topology. It compares the CDCA solution against traditional approaches. Both

values, for all content sizes, show a reduction in the number of bytes transferred when using the CDCA solution. This reduction can be attributed to the architecture's ability to deliver content closer to the users through caching. By caching content in proximity to the users, the need to transfer the same content repeatedly over the network is minimized. This result in a more efficient utilization of network resources and a reduction in the overall data transferred.

Fig. 5. Sum total of the number of bytes transferred through all switches.

The results show that the CDCA architecture effectively reduces the amount of data transferred, leading to more efficient network resource utilization and improved Quality of Experience (QoE) for users by reducing delay, as observed in the previous experiment, but also optimizes the use of network resources. The results highlight the positive impact of the CDCA architecture by minimizing data transfer and efficiently delivering content, the CDCA solution helps networks become more effective, ultimately reducing operational costs associated with bandwidth usage.

Fig. 6 and Fig. 7 show the results of the third experiment respectively.

From Fig. 6 it can be observed that operating with 2 caches storing 1GB of data the Cache hit rates increases and the throughput at the server decreases. This trend indicates that the CDCA architecture effectively reduces the number of requests which reaches the destination server as the Cache hit rate increases. This reduction in server requests is independent of the chunk size of the content. The results demonstrate that the caching mechanism of the CDCA architecture successfully offloads traffic from the server, improving its throughput.

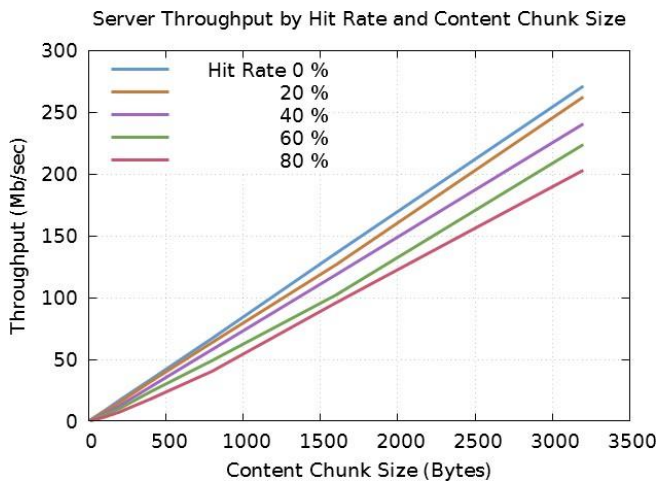
Fig. 7 focuses on the influence of Cache capacity on server throughput at different Cache hit rates with response sizes of 3200 kilobytes. The graph shows that Cache capacity plays a significant role in the server's throughput, particularly at higher Cache hit rates. For example, at a hit rate of 40%, there is a noticeable difference of around 30 Mb/sec in server throughput when the Cache capacity increases by just 4GB. This difference becomes even more significant, reaching 100 Mb/sec, as the hit rates increase to 80%. These findings highlight the importance of Cache capacity in effectively reducing the load on the server and improving its throughput.


Fig. 6.    Server throughput at different Cache hit rates and response sizes.

With a larger Cache capacity, more content can be stored and served directly from the Cache, resulting in a reduced burden on the server. As a result, the CDCA architecture demonstrates its ability to alleviate the server's load and improve its performance, especially when higher Cache hit rates are achieved. The CDCA architecture successfully compels caching to offload traffic from the server and optimize its performance, leading to more efficient content delivery and enhanced network scalability.

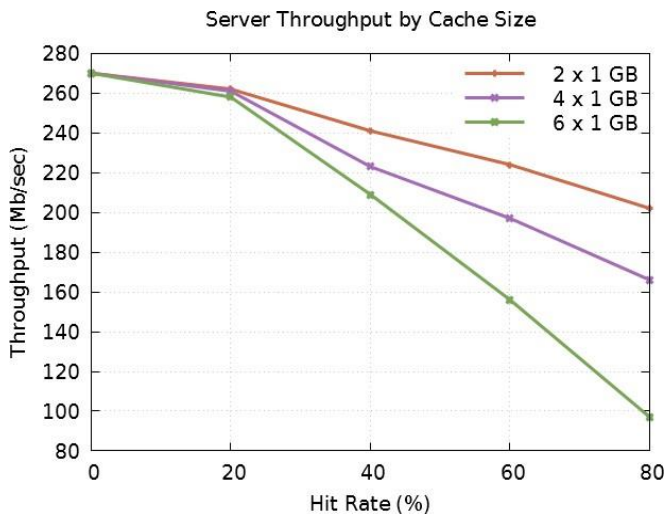

Fig. 7.    Server throughput with different Cache hit rates and capacities.

The consistent improvement patterns observed in both users' QoE metrics and network metrics, regardless of the content size, are indeed interesting findings. The CDCA solution, by caching content near users at high speeds, effectively reduces transmission time and improves overall performance, regardless of the size of the content being delivered.

This result suggests that the CDCA architecture efficiently utilizes caching mechanisms to deliver content to users, irrespective of the content's size. The proximity of the cached content to the users, combined with the optimized delivery process, minimizes the impact of content size on transmission time. Consequently, users experience similar levels of

improvement in QoE metrics, such as reduced delay and improved perceived performance, regardless of whether they are accessing small or large content.

Furthermore, improvements were also observed regarding server throughput and data transfer, reinforcing the effectiveness and validation of the CDCA architectural solution. By offloading traffic from the server and optimizing content delivery through caching, the architecture efficiently utilizes network resources, leading to reduced server load, decreased transferred bytes, and improved overall network operational efficiency while optimizing network performance and resource utilization.

*C.  Discussion of the Results*

In all three experiments, we can notice that the CDCA architecture has been effective in reducing the user's perceived delay, reducing the network data transfer, and reducing the network traffic at the content provider's server. The improvement on the user's QoE is intrinsically connected to the network data transfer reduction since fewer network segments need to be traversed in order to serve the content requests. As a result, if several requests are being handled by the Cache nodes spread over the network, then fewer requests need to be forwarded to the external content server, reducing the amount of data exchanged.

Fig. 7 provides valuable insights into the impact of Cache capacity on the system's performance. As the Cache capacity increases, the hit rate improves, resulting in a higher proportion of content being served from the Cache instead of the content server. This reduces the load on the server and improves overall throughput. Conversely, when the Cache capacity is low, frequent evictions occur, leading to more requests being forwarded to the content server. This not only increases the load on the server but also decreases the overall throughput, as observed in the results.

The findings suggest that the Cache capacity should be carefully considered during system deployment. Insufficient Cache capacity may result in higher eviction rates and increased dependence on the content server, ultimately affecting user experience and server performance. It is important to allocate an appropriate amount of Cache storage to accommodate the expected workload and ensure efficient content caching.

Furthermore, implementing a policy that selectively caches specific types of content, such as popular videos or audio, can optimize Cache utilization and prevent waste of resources. By focusing caching efforts on high-demand content, the Cache capacity can be effectively utilized to serve the most frequently requested content, enhancing overall performance and reducing the strain on the system.

These insights highlight the importance of careful Cache capacity planning and policy management in real-world deployments. By considering the workload characteristics, content popularity, and resource constraints, ISPs can design caching solutions that maximize the benefits of caching while efficiently utilizing Cache resources.

As depicted in Fig. 4 and Fig. 7, bigger content chunk

sizes and Cache storage leads to better results, indicating that large caches improve the system's performance. Nowadays, storage capacity is not a considerable problem since the ever-increasing capacity and decreasing prices of RAM and Flash memory provide affordable storage for huge capacity data (or files) resulting in superior overall system performance. And also, the system performance could be influenced by the Cache eviction policy used.

An initial approach for the ontology taxonomy utilizes four categories: (1) Content Type, (2) Content Identification, (3) Content Location, and (4) Content Chunk.

Content Type considers the content media type. There are two main categories of multimedia: time-sensitive media, e.g., video and audio, and non-time-sensitive media, e.g., documents and software. In the CDCA architecture, the time-sensitive content has to be treated in a different way in order to maintain the seamless delivery rate and guarantee the user real-time QoE. The video and audio parameters, i.e., resolution and CODEC, are used to quantify the required media rate in order to set the network provision once the end-user file is selected, preferably through the ontology search and found mechanism.

Content Identification is used to identify the content name, version, date and hash. This information is important for checking the content version to ensure that the most updated content version is delivered to the end user.

Finally, the use of multiple SDN controllers, proxies and caches, provides scalability by growing infrastructure horizontally. The Proxy and Cache implementation using a stateless *microservice* framework helps to meet all the scalability requirements. However, further studies will be necessary to determine any limitations in a large-scale deployment.

## VI. Open Research Issues, Challenges and Future R&D Directions

The CDCA architecture provides a transparent Cache system to improve the delivery of content objects inside an ISP infrastructure. Although outside the scope of this paper, there are still some open research issues that need to be considered before the CDCA system could be safely and practically deployed.

### A. Ontology Issues

The engine should offer the end-user the ability to find any content in a topic-specific manner, within a very short response time. In a real-life service production environment, it is possible for the network provider to host millions of content objects. To find topic-specific content with the correct version and date, it is necessary to organize the content index in an effective and efficient way, which should be approached through the use of some kind of dynamically updating knowledge-based ontology and deep machine learning techniques [35].

Several works have investigated the theory and practice of the semantic web and CDCA ontologies to organize the content classification [36]. However, most of these proposals focused on classifying the content to help the end-user find specific information, e.g., sport, business, travel, and so on. Nevertheless, in the CDCA solution, this kind of classification alone is not very useful because, for resourceful Cache management, it is not relevant whether the video is about sport or about travel, because the resolution, transmission rate and content chunk size are far more critical and significant for the optimization, sustainability and scalability. This does not mean that the content sought by the end-user is not important, but the selected optimum delivery of cached parts is the main consideration. The twin objectives of optimal seeking and delivery are crucial in formulating ontology.

Content-Location is important for finding the best geographic content distribution location point in order to improve the content QoE and the load balancing criteria during transmission.

The Content Chunk defines how the content chunk is divided and organized to improve the overall delivery and system performance. The content chunk is an atomic particle and it is the main element in the design of the CDCA architecture. The definition of its length is important to satisfy optimum delivery and system performance.

In a content-based network, the same content may have different names due to various reasons such as alternate naming strategies, load balancing, content distribution strategies, or user location-based routing. This can result in duplicate copies of the same content being stored in caches, leading to wastage of memory and storage resources.

To address this issue and avoid unnecessary hosting and caching of duplicate content, a hash mechanism can be employed. By calculating a hash value based on the content's data, such as using hash functions like MD5 or SHA-1, it becomes possible to determine whether multiple requests refer to identical content or not. The hash value serves as a unique identifier for the content, regardless of its name or location.

When a request is received, the system can calculate the hash value of the requested content and compare it with the existing Cache entries. If a matching hash value is found, it indicates that the content is already cached, and there is no need to store another copy. Instead, the existing cached copy can be retrieved and served to the requesting user.

By using a hash mechanism, the CDCA architecture can effectively identify and eliminate duplicate copies of content, thereby optimizing memory and storage resources in caches. It ensures that only one copy of the content is stored, regardless of the different names or variations associated with it due to load balancing or other factors. This approach helps in reducing storage overhead and improving the overall efficiency of the content delivery system.

### B. Optimization Issues

Although the CDCA architecture shows improvements in the response time of content requests and in the reduction of traffic from an external content provider, many aspects can be improved, as discussed in Section IV-C. We also envisage that it is possible to improve the content inspection algorithm to optimize searching and the application of a load-balancing mechanism. Although the system seems to

be scalable, further studies are necessary to determine any limitations in a large-scale system.

As noted earlier, the CDCA architecture utilized OpenFlow 1.0 because more recent versions do not offer any new field to improve the CDCA system. However, if a future version of the OpenFlow protocol implements matches in the HTTP Content-Type field, it will be able to forward certain specific MIME requests, for example, "video/mp4", direct to the Cache, avoiding the need for a Proxy. Even so, the content lookup should be done by the OpenFlow Controller instead of the Proxy. The lookup inside the switch diverges from the OpenFlow philosophy to maintain simplicity.

The issues mentioned in Section IV-C can be resolved by the configurable architecture. The configurable software approach means that the network administrator can deploy new VMs or adjust VM configuration, i.e., allocate memory and disk capacity when needed. This function can be accomplished by a cloud management and orchestration system. The CDCA prototype provides an open API that offers the capacity to change the eviction algorithm *on-the-fly*. The evaluation utilized the Least Frequently Used (LFU) eviction algorithm over RAM memory, as described in Section IV-D. In future research work it will compare the system behavior using various cache policies.

A critical issue, that should be investigated in the future, is the popularity prediction of User Generated Content (UGC). This is a valuable tool for content providers and advertisers. As the cached content is delivered inside the own ISP, the content provider could not get access to the user's profile. An interesting approach is proposed by Figueiredo et al [37].

It tackles the popularity prediction trend of a UGC object as early as possible to infer the user behavior. The results obtained by using YouTube datasets show an improvement of 38% in classification effectiveness, compared to the baseline approaches. Using this approach, the ISP can collect the user's information and notify the content provider.

### C. Security Issues

The CDCA system deployment within an ISP opens an opportunity with varying degrees of risk for external and internal security attacks of various kinds. It is possible that the CDCA critical infrastructure is susceptible to Distributed Denial of Service (DDoS) attacks affecting server provision and slowing down (or completely shutting down) the service, thereby frustrating the end user [38]. The distributed and open structure of a Cache system and its associated services can make it an attractive target for potential cyber-attacks. As with any system connected to the Internet, it is important to consider security measures to protect against intruders and mitigate the risks associated with cyber-attacks. These intruders can masquerade and manipulate various types of multimedia content, and therefore a supporting set of safety measures and security mechanisms and services would be needed to prevent intrusions and breaches. This would require a versatile, collaborative Intrusion Detection and Prevention System (IDPS) which must be flexible enough to guarantee smooth optimized streaming throughput flows with near-zero

(minimum) glitches.

Given the openness, and transparent nature of the mix-mode multimedia content delivery caching SDN architecture, traditional IDPS mechanisms would be fundamentally inefficient and ineffective [39]. In particular, it would be extremely difficult to detect intrusions in transparent multimedia content, hence preventing subsequent intrusions without employing a smart IDPS. It must involve advanced machine learning and computational intelligence techniques and the use of the five fundamental principles of autonomic self-management computing, knowledge base and ontology, risk management, fuzzy theory, and advanced artificial intelligence techniques [40] to leverage and satisfy the detection and prevention security capabilities of a Cache system. By incorporating these advanced techniques and concepts, the Cache system can enhance its ability to detect and prevent cyber-attacks, improve threat response mechanisms, and optimize overall security operations [41] [42]. However, it's important to consider the specific requirements and constraints of the Cache system via proper risk assessment and adapt these techniques accordingly to achieve effective and efficient operational and security outcomes.

HTTP/2 includes encryption as an optional facility. It is not mandatory because encryption can result in unnecessary jitter and distortion of the smooth viewing flow of videos. Many experts consider encryption unfeasible for ordinary large run-of-the-mill content delivery of videos. However, when and where cryptography is required, we also observe other major safety measures (security, privacy, trust, ID management, Digital Rights Management (DRM), digital *blockchaining* (virtual currencies), audit, digital forensic, non-copyediting, copyright infringement, permission to use, royalties, payments, etc.), and in particular issues related to the hiding of secret information using steganography will have to go beyond HTTP/2 specification. The complexities of these sets of safety measures are best accommodated by a comprehensive ontology.

### D. Copyright Infringement and Payment Issues

Another issue of importance and concern is that the CDCA architecture considers all content to be public without any restriction to distribution, which, however, makes the CDCA architecture unsuitable to deliver protected and paid content, such as required by some VoDs. Another example would be the rights of the content owner or their agent to be paid for documentaries, films, or music. Such content should typically be encrypted and the VoD provider can provide a temporary digital security key to the subscriber to decrypt the content for a certain period of time based on a payment scheme and without allowing copying of the content for further illegal distribution. This can be potentially achieved by activating the signature timeout period in conjunction with monitoring if the user attempts to copy the content. After this expiry period, the key is invariably disallowed, requiring the subscriber to renew the key to access the content. Implementing these security and protection measures requires careful consideration of technical, legal, and business aspects. It involves collaboration between content providers, payment service providers, DRM vendors, and security experts to

design and deploy a comprehensive and effective solution. This suggested scenario requires intensive research to fully define and design a secure payment mechanism that also curtails illegal copying, as well as verify and validate the mechanism for business deployment.

## VII. Conclusion and Future Work

This research has described a content-based transparent caching architecture in SDN. It provides a highly available, reliable and scalable caching of named content on SDN-based ISP networks, independent of specific underlying applications and middleware protocols. The research has also demonstrated that the caching mechanisms are driven by business policy needs and can be deployed in any networks, using the NFV approach and the microservice-based framework architecture. One notable aspect of the CDCA architecture is its support for the HTTP protocol, which remains the primary protocol for content delivery over the Internet. Rather than replacing HTTP, the system complements it by introducing transparent caching mechanisms that enhance content delivery and improve QoE for users.

The experimental evaluation conducted in the research demonstrates the effectiveness of the CDCA system. It shows improvements in user QoE and various QoS network metrics related to delivery times and scalability. This validation reinforces the benefits of the architecture and its potential to enhance content delivery in real-world network scenarios.

The CDCA architectural system has some important outstanding issues that should be addressed in future research and development work. At present, there is no effort by content providers and related industry players to develop a standardized naming scheme for content, which is crucial for efficient and optimum search and delivery of content, as well as for avoiding duplication of names and content hosted all throughout the provider network. In addition, the new naming scheme should avoid the same content with different names being downloaded multiple times. It is important for content providers and industry players to recognize the significance of a standardized naming scheme and work toward its development and adoption.

In future research work, the intent is to address many of the issues mentioned in the previous section. In addition, further research work is planned to perform analyses of several other video content providers, other than YouTube, to adapt the CDCA solution, if necessary. Another critical issue, which will be investigated, is the *popularity prediction* of UGC, which is a valuable tool for content providers and advertisers for revenue generation.

Finally, another area for future work involves system security. In the CDCA architecture, the ISP acts as a content provider, and it could suffer external and internal DDoS attacks, affecting servers slowing/shutting down the service and frustrating users. Further, multimedia content could be manipulated for illegal cybercrime activities, which should be avoided through the proper implementation of safety measures. Traditional IDPS is largely inefficient for the CDCA environment due to its architecture and virtualization. A new IDPS paradigm should be designed to achieve a high level of security health in the service provider network. In addition, we have highlighted issues related to secure payment and royalty awarding schemes for content that is primarily declared as public but that requires payment to intellectual property owners or their agents. Property rights issues also involve various safety measures. These system security challenges require creative solutions and therefore offer opportunities for further research.

*Abstract*—**Due to the increasing demand for unmanned in the hotel industry in recent years, how to efficiently use hotel service robots to further improve the efficiency of the hotel industry has become a hot research issue. To solve the problems of lengthy path-finding time and poor route security in conventional service robots in complex environments, the current study provides an improved A\* path-finding algorithm for application in the hotel environment. Firstly, the conventional A\* algorithm is combined with bidirectional search and Jump Point Search (JSP) algorithm, which makes the search more effective. Secondly, the traditional A\* algorithm is combined with the security weight square matrix to make the path trajectory safer. A cubic spline interpolation is chosen to smoothen the transitions at the corners planned by the improved A\* algorithm. Simulation experiments were done on grid maps with 10\*10, 20\*20 and 50\*50 sizes. Compared with the conventional A\* algorithm, the search time were decreased by 67%, 77% and 95% respectively. The number of search nodes was decreased by 80%, 76% and 95%, respectively. Meanwhile the distance between the robot and the obstacles was increased. The results indicate that the improved A\* algorithm suggested in the present research can ensure the path trajectory safer while keeping the path search efficiency higher.**

*Keywords—Path planning; bidirectional A\* algorithm; JPS algorithm; security weight square matrix; cubic spline interpolation method*

## I. INTRODUCTION

Path planning is an important technology to ensure the hotel service robot can complete the corresponding tasks; the purpose is to plan a reasonable and safe route from the starting point to the target point without collision based on the corresponding task requirements [1]. For the hotel scene with high real-time requirements and a complex environment, it is necessary to design an algorithm to consider both real-time and security and increase the operation efficiency of the service robot. This research aims to investigate the A\* algorithm [2] for a fast and secure path planning problem.

Many scholars have done various investigations on the path planning of mobile robots. Regarding various search environment information, the planning is classified into global and local path planning. Among them, A\* algorithm [3], Dijkstra algorithm [4], RRT\* algorithm [5] are relatively common global path planning algorithms, while local path planning algorithms include dynamic window method, artificial potential field method and genetic algorithm [6], [7]. Although several researchers have researched this subject,

many deficiencies still exist. For example, in [8], a novel fusion algorithm of jump-A∗ algorithm and Dynamic Window Approach (DWA) was presented to satisfy global optimality and path smoothness performance requirements in robot path planning. However, the security of the planning path is unsatisfactory. To make robot movements safe in a realistic environment, Zhang et al. [9] considered node-to-obstacle distances in the A\* extension node and used the threat generation value to assess node cost. That algorithm guarantees the safety of the path, and its computation time is also increased. Some three-path smoothers have been designed by Song et al. [10] for optimizing the paths, but the algorithm's time complexity is sensitive to the scale of the node number. In [11], a Bi-directional Adaptive Probabilistic Method having a Triangular Segmented Interpolation was developed to increase the real-time performance of path search by an Adaptive-RRT approach and a Bi-directional scheme. However, there are still too many redundant nodes. We synthesize the solutions involved in the above literatures, and organize their methods, advantages and disadvantages in the Table I.

TABLE I. ADVANTAGES AND DISADVANTAGES OF EXISTING METHODS

| Method | Advantages (well considered) | Disadvantages (not fully considered) |
|---|---|---|
| fusion of jump-A\* algorithm and DWA | computation time and path smoothness | security |
| A∗ algorithm taking the safety cost into account | safety and smoothness | computation time |
| A∗ algorithm with three path smoothers | Path smoothness | computation time |
| Bi-directional adaptive probabilistic method | computation time and path smoothness | redundant nodes |

As shown in Table I, the related research work of other scholars on the path planning algorithm have been comprehensively studied and improved from the aspects of real-time, security and smoothness, and satisfactory results have been achieved. Thus, the research in this paper adopts a new improved way to achieve better performance of A\* algorithm in the hotel environment. To realize that the hotel service robot can travel in the globally optimal path and keep a safer distance from obstructions, this paper proposes a new solution. A global path planning algorithm combined with bidirectional search and Jump Point Search (JSP) algorithm, also combined with the security weight square matrix is suggested in the present study in terms of improved A\*.

The contributions of the improved hybrid algorithm recommended in the present research to the path planning

problem are as follows.1) The concept of bidirectional search [12] and JPS jump point search [13], [14] is used to promote the searching efficacy of the traditional A* algorithm. 2) The security weight square matrix with the idea of multi-neighborhood search [15], [16] is suggested as a new method for helping the robots prevent temporary obstacles in the global path. According to the requirements of different safety distances, that manner sets the corresponding neighbourhood matrix to complete the detection of obstacles, making the path trajectory safer. 3) Cubic spline interpolation is employed to improve the smoothness of the path [17], which is unsmooth at the corner.

The remaining of the paper is as follows. Section II first reviews the traditional A* algorithm, then discusses the bidirectional A* algorithm regarding Jump Point Search and presents a cubic spline interpolation method to smooth the turning of the path. Thirdly, it introduces the security weight square matrix. Finally, the steps of the improved hybrid A* algorithm proposed in the present article are summed. Section III represents the experimental results of the simulation. Section IV concludes the whole research in summary and provides future research directions.

## II. IMPROVED A* ALGORITHM

### A. Traditional A* algorithm

A* algorithm [18], [19] is a heuristic search algorithm relying on the cost function. It can be considered as the most efficient direct search method to solve the shortest path in static road networks, usually used in global planning grid map scenes. The algorithm can evaluate the cost value of nodes around the existent path and find the node with the lowest cost value as the next moving point, and so on, until the robot reaches the target point. The formula of the cost function is defined in Equation (1):

$$F(n) = G(n) + H(n) \qquad (1)$$

Where F(n) is the cost value of the current moving node, G (n) represents the cost value from the starting node to the current moving node, and H (n) represents the cost value from the current moving node to the target node.

### B. Real-Time Improvement of A* Algorithm

The traditional A* algorithm searches from the starting point to the target point, but its search effectiveness is not optimal. Hence, an improved A* algorithm is suggested by some scholars [20]–[23] that changes the one-way search of the primary algorithm to the bi-directional search. The improved A* algorithm searches from the starting point and the target point simultaneously, which greatly enhances the search effectiveness. The specific formula is as follows.

$$\begin{cases} F_1(n) = G_1(n) + H_1(n) \\ F_2(n) = G_2(n) + H_2(n) \end{cases} \quad (2)$$

Where $F_1(n)$ is the cost value from the starting point to the target point and $F_2(n)$ is the cost value from the target point to the starting point. When one party detects the checked node of the other party, the value of $F_1(n) + F_2(n)$ is the minimum and the search ends.

For the bidirectional search, it is easy to form a parallel search range while the obstacles exist between the starting and target points, increasing traversal nodes. Hence, this work mixes the JPS algorithm with the A* algorithm, greatly reducing traversal nodes by selecting corresponding hop points. OpenList1 and OpenList2 are established in this paper, respectively, representing the search from the starting point to the target point and vice versa. When searching the path, the two search directions are carried out alternately. The jump point is added to Openlist1 when searching in the forward direction. Then, the forward search is stopped and changed to the reverse direction. When searching in the reverse direction, the jump point is added to Openlist2, then stop the reverse direction search and start the forward direction search again. Carry out the forward and reverse search alternately until the same jump point is added to Openlist1 and Openlist2, which means the optimum path is found.

The improved A* algorithm can search a suitable path quickly, but a large turning point still exists at the corner. A relatively smooth turning is usually required for the specific complex hotel scenario. The present paper selects the cubic spline interpolation [24], [25] method to smoothen the turning trajectory in the improved A* algorithm. Its detailed definition is shown as follows.

For a piecewise function S(x), if $S(x) = S_i(x)$ is a cubic polynomial in every interval $[x_i, x_{i+1}]$ $(i = 0,1,2,3, \cdots, n-1)$ composed of n + 1 discrete points and $S(x_i) = y_i (i = 0,1,2,3, \cdots, n)$ is satisfied at each point, this function S(x) is a cubic spline interpolation function. Since S(x) is a second derivative and the second derivative is continuous in the continuous interval $[m, n]$, the S (x) curve can be understood as a smooth curve, so the path it fits at the corner is naturally smooth.

Fig. 1. Traditional A* algorithm.

Fig. 2. A* algorithm integrated with JPS and bidirectional search.

Fig. 1 and Fig. 2 show the simulation experiments of the traditional A* algorithm and the A* algorithm integrating JPS and bidirectional search, where the black square shows the obstacle, the pink square represents the search node, and the green line refers to the planned path. The simulation experiments above demonstrate that the improved algorithm has fewer search nodes and better real-time performance. Although it smooths the turning of the path, a big risk of collision between the hotel service robot and obstacles still exists because of the close distance. Therefore, how to promote security is a crucial problem.

*C. Security Improvement of A* Algorithm*

In a traditional A* algorithm, the path planning situation shown in Fig. 3 usually occurs where the green S square denotes the starting point, the red G square denotes the target point, the black square denotes the obstacle, and the blue line denotes the planned path. However, it ignores the volume of the robot in practical application, which easily causes a false collision at the position marked X. This paper introduces the idea of a security weight square matrix for ensuring that the mobile robot can effectively keep a safe distance from obstacles, to increase the security of the algorithm.

Fig. 3.    Path planned via A* algorithm before security improvement.

Fig. 4.    Path planned via A* algorithm with security improvement.

According to the multi-neighbourhood search idea, the present work designs a corresponding neighbourhood matrix to complete the detection of obstacles according to the requirements of different safety distances. Because the map environment type in this paper is a grid map, the minimum safe distance from obstacles is set as the distance of a grid, and the size of the corresponding neighbourhood matrix is 3*3, which is also known as the basic comparison matrix. Taking the basic comparison square matrix as an example, the central element of the square matrix is set as the current path node with a value of 0 and other position values are set to 1, which can be shown in the following matrix.

$$B = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 1 \end{pmatrix} \quad (3)$$

In the process of path search, if an obstacle is detected within the range of the matrix, the element value of the corresponding position should be changed from 1 to 2 to generate a security weight square matrix, indicating that there is an obstacle. For example, for the path node X in Fig. 3, its security weight square matrix is.

$$X_B = \begin{pmatrix} 2 & 2 & 1 \\ 2 & 0 & 1 \\ 1 & 1 & 1 \end{pmatrix} \quad (4)$$

Set $d$ as the safety factor. If $d$ is larger, the degree of path safety is higher. If there exists 2 in the square matrix, set $d$ to 5 (the actual situation can be selected on its own), indicating obstacles near the current node. Otherwise, $d$ is 0. The detailed expression can be written as follows.

$$d = \begin{cases} 5 & \exists X_{B_{ij}} = 2 \\ 0 & \forall X_{B_{ij}} \neq 2 \end{cases} \quad (5)$$

The functional cost of the improved A* algorithm is shown in formula (6), where m is the number of 2 in the statistical basis comparison matrix, also known as the obstacle influence factor. The larger its value is, the more obstacles near the current node. As shown in Fig. 4, due to the increase in the cost value for the original path node, the path node is re-selected to keep the path away from obstacles.

$$f(n) = g(n) + h(n) + md \quad (6)$$

The matrix transformation can be based on the basic comparison matrix to set other safety distances. Using formula (8) with the transformation matrix A, the comparison matrix C of k*k (k is odd) with the central element value of 0 and the remaining elements value of 1 is obtained.

$$A = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ & \cdots & \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}_{k \times 3} \quad (7)$$

$$\begin{cases} C = \frac{1}{8} ABA^T \\ C_{\frac{k}{2}+1 \ \frac{k}{2}+1} = 0 \end{cases} \quad (8)$$

According to formula (4), the comparison square matrix C generates the security weight square matrix and the path node is re-selected. The flowchart of security improvement for the A* algorithm is shown in Fig. 5.

Fig. 5.    A* algorithm security improvement flow chart.

## D. *Improvement of Hybrid A* Algorithm*

To effectively promote the path planning algorithm in a specific service robot in the hotel environment, the present study mixes a bi-directional A* algorithm with a JPS algorithm to enhance its real-time performance. Simultaneously, it combines the idea of a security weight square matrix to enhance the algorithm's security. Finally, the cubic spline interpolation method is applied to smooth the improved A* algorithm at the path corner to construct the improved A* global path planning algorithm. The flow chart of the improved A* algorithm is represented in Fig. 6. The detailed steps include:

*1)* Create a grid map, initialize the corresponding parameters, starting point position and target point position, establish OpenList1 and OpenList2, select the first hop point and add it to OpenList1.

*2)* Set the safety distance. This paper uniformly sets the safety distance to facilitate comparison as 1 grid distance.

*3)* Compare the distance between the hop point to be selected and the obstacle, and add it to OpenList1 if it meets the conditions during the forward search.

*4)* Judge whether the jump point exists in OpenList2. If so, smooth the turning of the path. If not, stop the forward search and change to the reverse search.

*5)* Compare the distance between the jump point to be selected and the obstacle, and add it to OpenList2 if it meets the conditions during the reverse search.

*6)* Judge whether the jump point exists in OpenList1. If so, smooth the turning of the path. If not, stop the reverse search and change to the forward search.

*7)* Loop steps 3 to 6.

*8)* Output the optimal path.

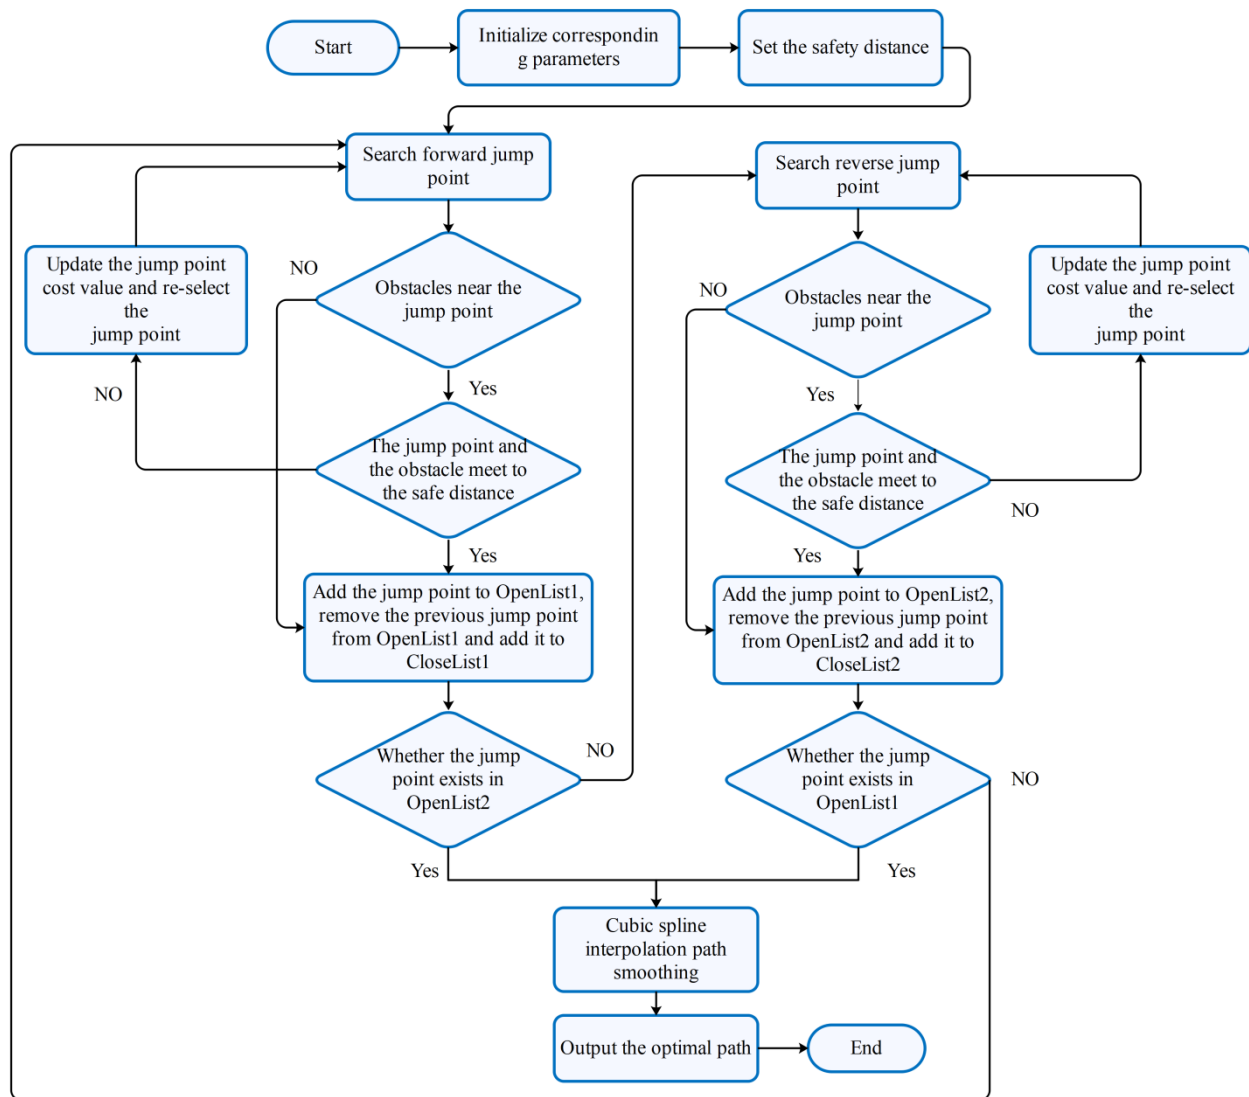

Fig. 6. Flow chart of improved A* algorithm.

## III. SIMULATION EXPERIMENTAL ANALYSIS

### A. Simulation Scenarios and Conditions

Simulation experiments are done in this part to validate the improved A* algorithm in mobile robots' authentic path-planning process. The computer parameters of the simulation environment are system Windows 10, CPU Intel Core i5 4210h, memory 8GB, compilation environment MATLAB 2016b. Since the research work of this paper comes from a real hotel robot project, we simulate three sets of grid map environments with different sizes and several sparse obstacles. These grid maps are associated with a real hotel scene and the sizes of them are 10 * 10, 20 * 20, 50 * 50 grids, respectively.

### B. Results and Discussion

The simulation results have been presented in Fig. 7 to 9, where the black square shows the obstacle, the pink square indicates the search node, and the green line refers to the planned path. The test of each group presents an analytical contrast between the results of these two methods based on the nodes and path length.

As shown in Fig. 7, the improved hybrid A* algorithm reduces the number of nodes from 61 to 12 compared with the traditional algorithm. In the middle size map as shown in Fig. 8, the improved hybrid A* algorithm reduces the number of nodes from 139 to 33, and in the large map as shown in Fig. 8, the number of nodes is reduced from 787 to 42. It can

be seen from the comparison of Fig. 7(a) and Fig. 7(b), the safe distance from the obstacle is increased about 1 grid and the path is smoother in the simulation results for the improved hybrid A* algorithm, and the same results can also be obtained from Fig. 8 and Fig. 9.

Total counts of nodes, path lengths and search time are further used to evaluate the improved algorithm's efficacy, as shown in Table II. It can be seen that compared with the traditional algorithm, the search time of the improved A* algorithm for 10 * 10, 20 * 20, 50 * 50 environmental raster maps are reduced from 0.082 s to 0.027 s, from 0.198 s to 0.046 s, and from 1.211 s to 0.065 s, respectively. Although the path length increased, the search time and the number of nodes have decreased. By comparing the results shown in Table I, it can also be seen that the improved A*algorithm has obvious priority regarding search time and node number with the expansion of the map area. Although the path planning length is relatively long, it can guarantee the safety of the path trajectory.

Consequently, from the previous analysis of the results, we can conclude that the improved A* algorithm suggested has fewer search nodes and less search time while keeping safe distance compared with traditional A* algorithm. It is proved that the algorithm presented in the paper enables the search for an optimum path under the condition of ensuring safety and shows good robustness and real-time performance.

TABLE II. DATA COMPARISON BETWEEN TRADITIONAL A* ALGORITHM AND IMPROVED HYBRID A* ALGORITHM

| Map size | Search time /s | | Number of nodes | | Path length | |
|---|---|---|---|---|---|---|
| | *Traditional* | *Improved* | *Traditional* | *Improved* | *Traditional* | *Improved* |
| 10*10 | 0.082 | 0.027 | 61 | 12 | 14.5 | 23.1 |
| 20*20 | 0.198 | 0.046 | 139 | 33 | 28.6 | 29.9 |
| 50*50 | 1.211 | 0.065 | 787 | 42 | 82.7 | 87.0 |

## IV. CONCLUSION

In the complex regional environment of the hotel, even though the traditional A* algorithm is proper to plan a reasonable shortest path, several inflection points are available in the path. That makes the hotel service robot too close to the obstacle during driving and will seriously influence the safe movement of mobile robots. Numerous nodes are evaluated in the process of path planning simultaneously, which makes its real-time performance not good enough. To overcome such problems, the current paper suggests an improved A* algorithm. First, the conventional A* algorithm combines bidirectional search and JPS hop point selection to enhance search efficiency. Then, the traditional A* algorithm is combined with the security weight square matrix to make the path trajectory safer. Finally, cubic spline interpolation is employed to smoothen the turning path trajectory. The experimental results show that the improved algorithm is productive and better than the conventional A* algorithm in the number of search path nodes, path security and path smoothness.

The limits of the proposed algorithm is that it is only applicable to static environment, and does not have the ability to avoid dynamic obstacles. Since there are still dynamic areas in the hotel environment, such as pedestrians and other dynamic obstacles, we will study how to embed dynamic path planning into this algorithm to meet the specific needs of the hotel mission in future studies.

# Innovative Practice of Virtual Reality Technology in Animation Production

He Huixuan[1], Xiang Yuan[2]

Shijiazhuang University of Applied Technology, Animation Academy, Shijiazhuang City, Hebei Province, 050031, China

*Abstract*—In order to make the users who watch animation look better, the innovative practice research of virtual reality technology in animation production is proposed. According to the object structure information, the method uses 3ds Max software to complete the production of 3D animated character models. It completes the character prototype texture feature extraction through the character prototype boundary contour extraction, image hat height transformation, and discrete grid projection. The OpenGL texture mapping is used to complete the mapping of 3D animated character models. After the boundary optimization of texture seams, the best 3D animated character modeling effect is obtained. Geometric modeling technology and DOF nodes are used to build static and dynamic scene entity models to complete the construction of a 3D animation scene. The interactive visualization platform based on space is introduced to complete the visualization processing of the interactive animation scene, and the animation scene is regarded as the image base. The points with equal arc length are selected according to the curve points, and the camera is switched in combination with the roaming speed to realize the real-time roaming of 3D animation scenes and complete the innovative, practical application of virtual reality technology in animation production. Experimental results show that this method improves the smoothness, integrity, and authenticity of animation, improves the smoothness of motion, and ensures the real-time roaming effect.

## I. INTRODUCTION

Virtual reality is a new world created by computer and electronic technology. It is a seemingly real simulation environment. Through a variety of sensor devices [1], [2], users can use people's natural skills to investigate and operate objects in the virtual world according to their feelings, participate in events in the virtual world, and provide intuitive and natural real-time perception of seeing, listening, and touching, and make participants "immerse" in the simulation environment [3]. 3D animation modeling technology is to create the structure and shape of objects involved in animation in the process of animation production. The modeling process requires the analysis of the shape characteristics of the object. The existing shape in the computer can be expanded and changed to meet the requirements of realistic modeling. In addition, the structure should also be linked with the geometry in reality. Through the analysis of object categories, different methods of model building and detail modification can be carried out [4].

Many researchers have conducted research on the application of virtual reality technology in animation production, such as Kokaram A et al. [5], who studied motion-based frame interpolation in film and television production. Frame interpolation is the process of synthesizing new frames between existing frames in image sequences. The difference frame is used as a key algorithm module in movie production to improve the effect of movie production. But motion-based frame interpolation usually requires a lot of computation and processing, especially in high-resolution image sequences. This may lead to excessive consumption of computing resources, reduce real-time performance, and increase production costs. For example, Khalid N et al. [6], to improve the accuracy of character modeling in the animation, through the Gaussian mixture model, each pixel of different human body parts is assigned a specific label to achieve better animation character modeling. However, this method has high requirements on the quality of input images. For low-quality, fuzzy or noisy images, the accuracy of joint extraction and pixel-level marking may decrease, thus affecting the accuracy of character modeling. Perez Perez Y et al. [7], to better complete the animation scene, proposed an environment modeling method based on joint semantic and geometric features, based on Markov random field (MRF), strengthen the consistency between environmental semantics (e. g., beam, column, wall, ceiling, floor, pipe), and geometric labels (example, horizontal, vertical, cylindrical), and use the neighborhood context to improve the accuracy of semantic labels, improve the accuracy of environment modeling, provide effective environment modeling basis for animation. However, when the environment is more complex or there are subtle changes, such as texture differences, lighting changes, etc., the method may encounter challenges in the consistency of semantic and geometric labels, resulting in a decline in the accuracy of modeling results.

Aiming at the problems existing in the above methods in 3D animation modeling, this paper combines virtual reality technology to study the innovative practice of virtual reality technology in animation production to provide users with a better 3D animation perception. The research structure of this article includes:

*1) Provide* a detailed introduction to the process and steps of using 3DsMax software to create character models, explain the methods of extracting texture features from character prototypes, including boundary contour extraction, image high-low hat transformation, and discrete mesh projection, and explain the application of OpenGL texture mapping technology and boundary optimization texture seam method;

*2) Explain* the application of geometric modeling technology and the construction process of DOF nodes, and

introduce the establishment of static and dynamic scene entity models;

*3) Deeply* explain the application of spatial based interactive visualization platforms and discuss the interactivity and visualization processing methods of animation scenes;

*4) Introduce* the concept and methods of treating animation scenes as image bases, and explain the application of techniques such as curve point filtering, camera switching, and roaming speed;

*5) Verify* the effectiveness of the techniques presented in this article through experiments;

*6) Discuss* the research results and point out future research directions.

## II. ANIMATION PRODUCTION BASED ON VIRTUAL REALITY TECHNOLOGY

### A. 3D Character Modeling

*1)* 3D animated character model based on 3ds Max*:* To build 3D models of related objects in animation, first, we need to analyze the structural characteristics of objects. The objects in 3D animation can be generally divided into two types: regular objects and irregular objects. There are two main modeling methods for animated 3D characters: the stacking modeling method and the subdivision modeling method. The stacking modeling method creates characters from details to the whole, while the subdivision modeling method first creates an object's overall shape and then carves details [8].

Regular objects are suitable for stacking modeling because of their regular shape. Its modeling process is to split complex objects into some basic components, then use the basic molding command to make these small parts and stack them together. Animation designers must grasp the model's size-scale relationship and spatial location. Common tools include insert, extrusion, turning, chamfering, FFD deformation tools, etc.

Irregular objects are more suitable for the subdivision modeling method; that is, the basic geometry is used to complete the large shape of the object first, and then the model details are subdivided by editing polygons or mesh editing tools. This modeling method is similar to drawing sketches or sculpture's construction process. Generally, we use subdivision modeling to complete the modeling of 3D characters, cartoon characters, or surface object bodies. Common tools include edit mesh, edit polygon, symmetry, mesh smoothing, etc. The specific process is shown in Fig. 1.

After determining the construction method, this paper completes the production of a 3D animated character model by applying the 3ds Max software, obtains the rough image by stretching and changing the graphics tools contained in the 3ds Max software, and then modifies the details with the modification tools, to establish a more accurate and intuitive model.

*2) Character prototype texture extraction:* The texture is an important feature of the scenery. It is generally believed that texture is a certain regularity of grayscale or color distribution on the image, which has different characteristics in complex textures. Texture can be roughly divided into two categories: regular and irregular. The extraction of irregular regional textures is an important part of image processing technology, so it has become a research hotspot of computer application technology.

Fig. 1. Animation character modeling process.

*a)* Boundary contour extraction*:* The mathematical expression of the object contour obtained from the object image is called contour extraction [9], which is one of the basic steps in image processing, computer vision, and medical images.

This paper uses a method based on an improved model to extract the contour of the character prototype. Firstly, the method of combining some algorithms with the circumscribed rectangle is used to realize the automatic setting of the control points of the initial contour line of the model and then improve the gradient energy function to introduce the gradient vector flow operator so that the contour can better converge to the target depression, and adjust the weight of other energy function terms according to the actual situation. Finally, the target contour line is obtained through the neighborhood greedy algorithm when the total energy is minimized.

*b) Image preprocessing:* This paper combines high hat transform, and low hat transform to process the image. Add the high hat transform image to the original image, and then subtract the low hat transform image to get the enhanced image. Using the original image plus the result of the high hat transform can make the area with a larger gray value brighter, and subtracting the result of the low hat transform can make the smaller gray value darker. In this paper, the morphological reconstruction method is defined as:

$$C_{top}(f) = S_f(f) + 1 \tag{1}$$

$$I = thresh\left(S_f(f)\right) \tag{2}$$

Among them $S_f(f)$ is from the enhancement diagram at the start of the reconstruction operation, which is equivalent to subtracting a constant from the grayscale of the enhancement image $S_f(f) = f - h$, denoted by $S_f(f - h)$. Here is a marked graph. This paper binarizes the reconstructed result graph to get the marked graph. Because of the filtering effect of the reconstruction operation, many of the original images after the reconstruction operation are smaller than all the small peaks that will be "flattened". The value represents the size of the filtering amount [10]. In terms of filtering effect, reconstruction filtering is low-pass filtering, which flattens the peaks in the image. The peak in the image is the high-frequency part, and flattening the peak is equivalent to filtering out part of the high-frequency part. The low-frequency part is retained to form a low-pass effect.

The dual operation of reconstruction transformation is expressed as, according to the principle of dual operation, $S_f * (f + h)$ the role of will fill the low valley in the image. After operation $S_f * (f + h)$, it will be less than fill in the original low valley and form a platform at the original low valley. The combination of morphological and dual reconstruction can flatten the peak and fill the valley, leaving only the middle part of the image that is neither high nor low. The function of the parameter is to control the contrast. Generally, the contrast in the signal is less than all fluctuations that $2hh$are filtered out.

Reconstruction filtering is essentially an efficient nonlinear filtering, and the filtering effect is similar to median filtering, but the effect is better. The purpose of morphological reconstruction is to extract the maximum value and bright top of the region to smooth the interior of each target and extract the maximum value within the target range.

*c) Texture extraction:* Generally, texture images are stored and represented rectangularly [11]. This exactly corresponds to the discrete grid of the surface, which is the points on the discrete grid are projected onto the image, and the color information of the image is extracted so that the texture is arranged in the form of a discrete grid, but this is too sparse. Therefore, the mesh needs to be refined. Each refined mesh point corresponds to a pixel on the texture image. Original geometric mesh size is $4 \times 3$, to extract texture, each geometric mesh is further uniformly refined $4 \times 4$. The size of the whole refined mesh is $16 \times 12$. Each vertex on the mesh corresponds to a pixel of each vertex that is re-projected onto the image (in the actual solution process, both the vertical grid line and the horizontal grid line corresponding to the grid point can be projected onto the image to find the intersection point on the image). The color information of the point on the image is obtained to form a texture image [12]. The coordinate value of the thinned image point is usually a floating point number. If the color value of one of its neighboring pixels is directly taken as the color value of the current point, the extracted texture will become more blurred.

Therefore, in this paper, color information is extracted in a weighted way according to the position of the current point and the proximity of the four adjacent pixels around it, as shown in Fig. 2, $(x, y)$ is the pixel coordinate of the current image point,

$(x_1, y_0)$ is the coordinate of four adjacent pixels (the coordinate value is an integer).

Fig. 2.  Weighted center of gravity.

Set $f(x, y)$ is a point the texture extraction based on barycentric coordinates can be expressed as:

$$f(x,y) = \frac{C_{top}(f)}{I}\frac{V_{00}}{V} f(x_0, y_0) + \frac{V_{01}}{V} f(x_0, y_1) \qquad (3)$$
$$+ \frac{V_{10}}{V} f(x_1, y_0) + \frac{V_{11}}{V} f(x_1, y_1)$$

The whole surface is projected onto the front view, and the barycentric weighted texture extraction method can be used to obtain the image's texture. For the texture data matrix [13] outside the specified area, please give it a uniform value of 0 and give the part of the texture data matrix outside the texture outline in the specified area a value of 1. This aims to facilitate the storage of irregular regional textures and the subsequent mapping of 3D models.

*3) Model mapping and optimization*

*a)* Model mapping based on OpenGL texture mapping: After getting the texture image and 3D model, we need to use its projection relationship to give the corresponding texture information to the corresponding part of the image on the surface of the 3D model, that is, local texture mapping. Texture mapping technology is also called texture mapping technology [14]. In 3D graphics, texture mapping methods are widely used, especially to describe realistic objects. The work of local texture mapping is to correctly back project an acquired texture image onto the surface of the 3D model.

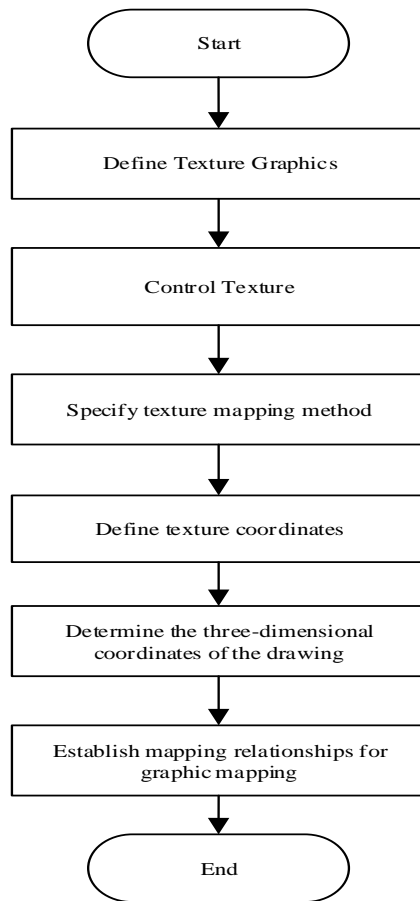
This paper uses OpenGL texture mapping technology to map 3D models. The technology of texture mapping of the texture image refers to mapping the texture image to the surface of a three-dimensional object, that is, predefine the texture pattern on the texture space of a plane area and then establish the mapping relationship between the object surface space and the coordinates of the texture pattern. When the visible points of the object's surface are determined, the texture pattern can be attached to the object's surface according to the value of the corresponding points in the texture space. The general steps of texture mapping are shown in Fig. 3.


Fig. 3. Texture mapping steps.

Fig. 4. Schematic diagram of concave-convex texture processing.

For relatively flat model areas, texture mapping is relatively easy to implement. This paper introduces merging adjacent triangular patches to deal with irregular mapping areas. Its algorithm idea takes the included angle between the normal vectors of adjacent triangular patches as the object of study. The included angle will remain unchanged if it exceeds a set closed value. If the included angle is less than a certain idle value, it will merge two triangular patches, and so on repeatedly. However, since the included angles of multiple triangular patches may accumulate in the same direction during the merging process, if it is possible to simplify the larger surface into a plane according to the above principles, limiting the size of the composite surface is necessary. When the area of the plane is greater than a set value, the merging stops. According to the corresponding texture area of the model surface, the merged plane can use the trilinear filtering texture filtering technology to operate it in OpenGL to achieve relatively flat texture mapping of the model area. To map the bump model surface, it is necessary to comprehensively consider the texture's stretching, scaling, bending, and the change of gray value. See Fig. 4 for details.

As shown in Fig. 4, a texture segment $O * P *$ is for the curve segment of the bump model; the texture segments attach to the curve segment $O * P *$, assume that in the curve segment: $O * Q *= w, Q * R *= v, R * P *= u$.

To stretch a texture segment $OP$, which also means reducing the length of the distance between and $P *$. Make line segment $OP$ and $O *$ and $P *$ the included angle between is $\theta$, then represent:

$$\sin \theta = \frac{|OP|}{|O*P*|} = \frac{f(x,y)\sqrt{(x_1-x_2)^2(y_1-y_2)^2}}{\sqrt{(x_1*-x_2*)^2(y_1*-y_2*)^2(z_1*-z_2*)^2}} \quad (4)$$

To make the length of texture deformation the same as the curve, the interpolation coefficient is introduced here. Setting rules are as follows:

When a surface moves from a point to point $Q *$, take $s = o$;

When a surface moves from a point to point $R *$, take $s = q$;

When a surface moves from a point to point $P *$, take $s = r$;

And:

$$ow + qv + ur = |OP| \quad (5)$$

$$o + q + r = 1 \quad (6)$$

Can get

$$\sin \theta = \frac{|OP|}{|O*P*|} = \frac{ow+qv+ur}{\sqrt{(x_1*-x_2*)^2(y_1*-y_2*)^2(z_1*-z_2*)^2}} \quad (7)$$

After the above transformation, the texture space coordinates can be mapping area coordinates with the bump model one-to-one correspondence to better realize bump model mapping.

*b)* Boundary optimization*: Because of the color difference of the texture at the back boundary of the texture mapping of the 3D character model, it is easy to have color discontinuity between the texture regions; that is, texture seams when rendering realistically. If not properly handled, it will greatly impact the reality of the 3D modeling of the character. Therefore, the purpose of processing texture boundaries is to eliminate texture seams in the display effect as far as possible.

The parameterization method is used to map the mesh model to the plane domain or other domains to process the model with some mature technologies in the parameter domain [15]. Parameterization is to establish a one-to-one correspondence between the vertices of the mesh model and the points on the parameter domain and ensure that the mesh formed by the vertices on the parameter domain is not folded. The deformation of the parameterized mesh is smaller than that of the original mesh. According to the different parameter domains, parameterization can be plane and spherical.

Planar parameterization is to spread the mesh model into a planar mesh. Each triangle uniquely corresponds to a triangle in the planar domain, which is helpful for texture mapping of the mesh. Spherical parameterization can map the completely closed mesh to the spherical domain, which is conducive to mesh simplification, shape gradient, and other processing.

According to the idea of parameterization, the implementation steps of texture seam processing at the back boundary of 3D character model texture mapping can be established: locate the triangle mesh belt on both sides of each boundary. The grid belt is parameterized in two dimensions; In parameter domain, texture is constructed by weighted interpolation method to achieve natural transition [16]. So far, this paper has completed the optimization of texture mapping.

### B. 3D Animation Scene Construction based on Virtual Reality

The 3D solid model in a virtual scene generally includes static and dynamic solid modeling. Static refers to solid models of terrain and ground objects, ranging from houses, pavilions, and launchers to roadside flowers and trees. Dynamic solid models refer to various simulation solid models with motion attributes, such as pedestrians, robots, swing booms, etc.

*1) Construction of scene static entity:* The physical building is the main part of the virtual scene and the most important scene content. The modeling of static entities mainly uses geometric modeling technology [17]. Geometric modeling studies basic problems such as graphic data structure and deals with the representation of polygons, triangles, and points of objects' geometry and morphology, as well as their appearance, textures, materials, and colors. In the geometric modeling of solid buildings, it is required that the real and accurate space position and surface texture be used to represent the objective object of buildings to create an environment in which the observer can feel immersive and immersive. Geometric modeling is mainly realized by corresponding modeling software such as 3DMAX, AutoCAD, etc. 3D modeling of buildings is carried out in combination with AutoCAD and 3DMax [18]. The overall process includes total station acquisition of characteristic data points, importing AutoCAD and AutoLISP software to form wireframes, importing 3DMax to establish 3D models, 3DMax texture mapping, and model output. The overall process is shown in Fig. 5.

Fig. 5.   Building 3D modeling based on AutoCAD and 3DMax.

*2) Construction of dynamic entities:* The modeling of moving parts should first construct moving objects. The construction of moving objects may change the initially built internal organization [19], that is, add DOF nodes of moving parts in the file formed by modeling, set corresponding local coordinates and locate them, and carry out the kinematic relationship (Link analysis) on multiple moving parts based on DOF to determine the kinematic traction relationship, determine and publish the main parts. The process of non-publicly distributed sub-components and traction equation is shown in Fig. 6.

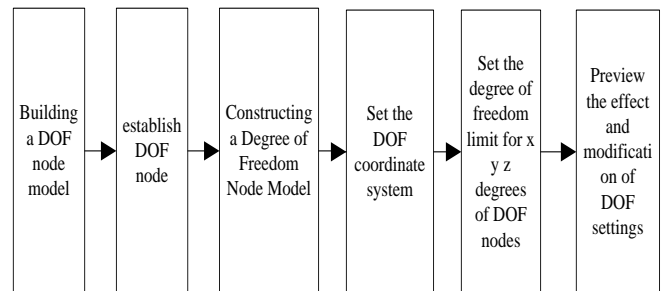

Fig. 6.   General process of establishing DOF nodes.

### C. Interactive Animation Scene Visualization

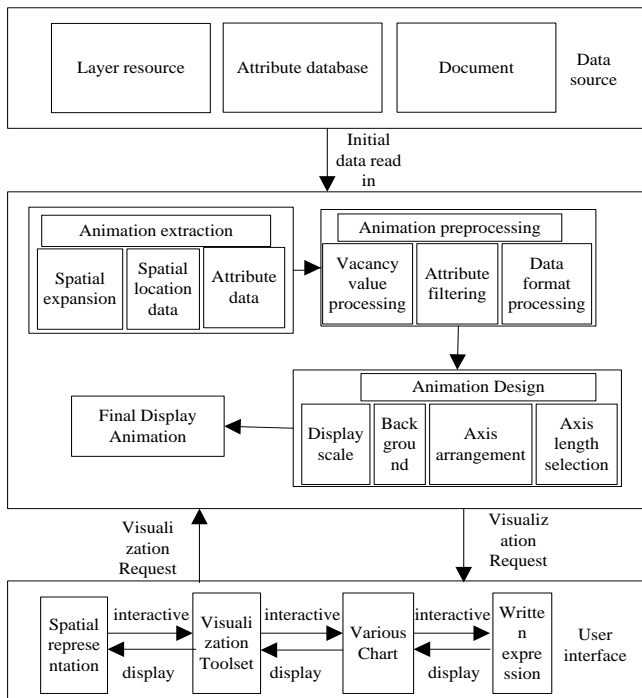
Animation design aims to establish a spatially based interactive visualization platform [20], integrating relational databases, spatial location files, component modules, various multi-dimensional graphical visualization tools, and common graphical expression tools. The above module takes relational data as the analysis object, applies spatial spatial analysis principles and methods to extract spatial information, and displays it as layers. The object is further analyzed and transformed through graphical visualization methods, such as a parallel coordinate method, to explore the inherent abstract rules of spatial data. These abstract rules are just beyond the reach of traditional spatial analysis and expert experience. Finally, appropriate visualization technology is selected to express the rules so that the rules or patterns contained in the data can be transformed into graphics that are easy to understand and recognize and visualized through animation. Fig. 7 is the visualization structure diagram of an interactive animation scene.


Fig. 7. Interactive animation scene visualization structure diagram.

As shown in Fig. 8, the main function of the space module is to provide a layer-calling function and a simple layer-editing function, such as refreshing, mouse response, highlighting, etc.; The main function of the visualization toolset module is to focus on implementing HyperTree and parallel coordinate method and provide a toolset management function to add or delete tools dynamically; The main function of the interaction function module is to realize the interaction between visualization tools and spatial layers, as well as between visualization tools.

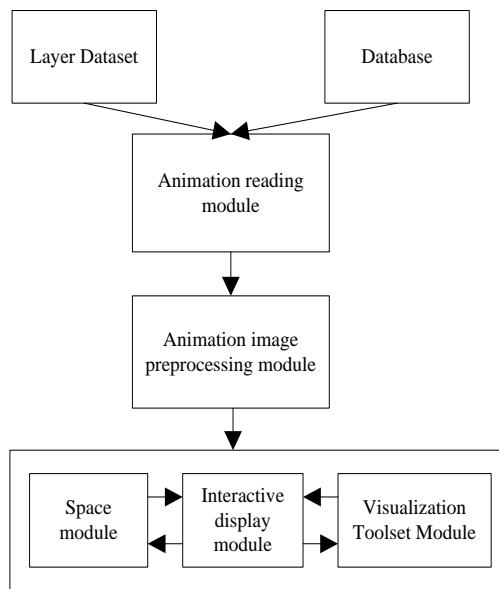

Fig. 8. Functional module structure diagram.

Layers and various multidimensional visualization tools each play an important role in interactive animation scene visualization. Layers display animation data and express spatial attributes of spatial objects. Graphic visualization tools are suitable for expressing nonspatial multidimensional attributes. Interactive animation scene visualization focuses on combining layers and multidimensional visualization tools [21] to develop their interactive functions. The interactive function in interactive animation scene visualization is shown in the following points:

*1) HyperTree* is used to manage hierarchical layer resources;

*2) HyperTree* highlighted nodes interact with corresponding layers [22];

*3) The* highlighted area on the layer interacts with the parallel coordinate, which displays the nonspatial attribute data of the area;

*4) HyperTree highlights nodes to interact with parallel coordinates, which express the attribute information of corresponding layers;*

*5) The* parallel coordinate method is used to compare and analyze the attribute data of each region on each layer [23].

To summarize, the layer you see, the highlighted node in the center of HyperTree, and the parallel coordinate visualization tool are all aimed at the same animation target object. After realizing interactive expression among layers, HyperTree expression, parallel coordinate expression, and common charts, the user's thinking is more coherent, and various tools give full play to their due advantages, showing a more advantageous interactive animation scene visualization effect.

### D. Real-time Roaming of 3D Animation Scene

In the process of real-time roaming of the animation scene, first select three animation scenes in the three-dimensional space to form an image base, calculate the image overlap area, fuse the area, use this as the basis for image stitching [24], extract the color information of the animation scene image, calculate the sampled image data [25], obtain the curve points of the scene image, and filter points with equal arc length according to the curve points, Switch the camera according to the points with equal arc length and the roaming speed to complete the real-time roaming of 3D animation scene. The specific steps are detailed as follows:

Assumed represents 3D global coordinates, $(x'_1, x'_2)$ represents two-dimensional plane coordinates, $e$ represent the time variable, then use equation (8) to select three animation scenes in three-dimensional space to form an image base, calculate the overlapping area between images, and use equation (8) to express

$$\partial * (\mu) = \frac{[X'_1, X'_2, X'_3] \otimes (x'_1, x'_2)}{sin\,\theta\, e\sigma[\gamma]} \qquad (8)$$

Where $\sigma[\gamma]$ represents an image sequence.

Assumed represents the position of a point in the scene from the viewpoint, $a$ represents the distance between the agreed viewpoint and the object, represents the brightness

difference of two adjacent images, then use Formula (9) to fuse the regions and sew the images according to this:

$$\overline{m}(G) = \frac{A(\wp)\times\eta}{a\times\partial} - \partial*(\mu)\mu(\alpha) \otimes [\Gamma(\theta)] \quad (9)$$

Where $\partial$ represents the tensor parameter, the camera position, and any point in the viewpoint grid.

Hypothesi $n$ represents any time of roaming $\overline{m}(T)$ represents a viewpoint, the coordinates of this point determine a point on the image taken by the lens, and the color of this point is defined as the pixel color corresponding to the point expressed by Formula (10):

$$m*(\delta) = \frac{\overline{m}(T)\times n\overline{m}(G)}{\partial(\Upsilon)} \quad (10)$$

Where $\partial(\Upsilon)$ represents the pixel values of different image regions, $t(b)$ represents the color value between unit squares.

Assume the edge represents boundary conditions, Represents the tangent value of the curve, calculate the sampled image data using Equation (11), obtain the curve points of the scene image, and filter points with equal arc length according to the curve points:

$$g(c) = \frac{\theta(l)\times\Gamma m*(\delta)}{L(\sigma)} \times \varphi(\gamma)*\Phi(\mu) \quad (11)$$

Where $L(\sigma)$ represents the camera storage format, the arc length curve point set, and the jitter state in the walkthrough.

Assumed that represents the rotation angle of image coordinates, $\delta(j)$ represent the density value of curve points, use formula (12) to switch cameras according to points with equal arc length and roaming speed to complete real-time roaming of 3D animation scene:

$$\eta(\overline{m}) = g(c)\frac{\delta(j)*M(K)}{C(\mu)} \times \xi(\vartheta) \quad (12)$$

Where $\xi(\vartheta)$ represents roaming parameters, $C(\mu)$ represents the cumulative distance between points.

The above method is the principle of real-time roaming of 3D animation scenes, which is used to complete real-time roaming of 3D animation scenes [26].

## III. EXPERIMENTAL ANALYSIS

To verify the innovative practice effect of this method in animation production, take the Judy police officer role and animation scene in the "Crazy Animal City" animation as an example; use this method to model, texture map, and virtual roaming interaction, and give the Judy police officer and scene produced by this method, as shown in Fig. 9.

(a) Character modeling

(b) Scene modeling

Fig. 9.   Effect of the method mapping in this article.

It can be seen from the analysis of Fig. 9 that this method uses OpenGL texture mapping technology for mapping, which improves the effect of 3D animation design of characters and scene modeling, making both clearer and more realistic.

The method in this paper is used to conduct real-time roaming experiments on some scenes and characters in Crazy Animals to verify the practicability of animation scene construction, and the effect is shown in Fig. 10.

(a) 15 frames

(b) 25 frames

(c) 35 frames

(d) 45 frames

Fig. 10. Real-time roaming rendering.

As can be seen from Fig. 10, this paper selects three animation scenes in the three-dimensional space to form an image base. It combines the roaming speed to switch the camera and the points with the middle arc length of the image curve points to achieve real-time roaming to ensure the practical effect of real-time roaming.

The texture mapping of the character model is optimized by optimizing the boundary processing method in this paper to eliminate the texture seams in the display effect. The effect before and after optimization is shown in Fig. 11.

(a) Pre optimization rendering

(b) Optimized rendering

Fig. 11. Effect before and after optimization.

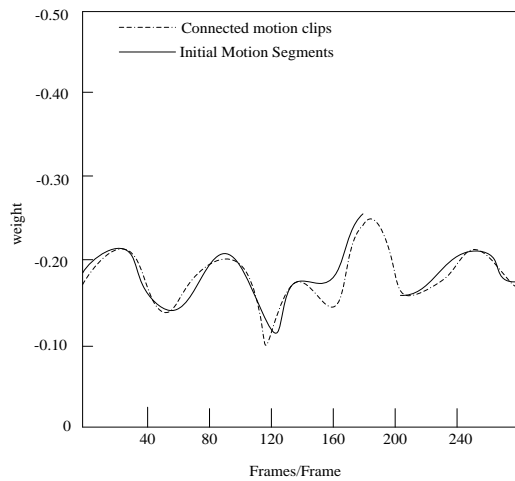
By analyzing Fig. 11, it can be seen that the boundary optimization method in this paper has a good effect on eliminating texture seams. It is clearer for the expression of the appearance and texture of animated characters, enhances the texture of animated characters, and verifies that the texture mapping map in this paper is more practical, making the animation effect smoother and giving users a better impression.

To verify the collision detection performance of the method in this paper, the experiment conducted collision detection on a virtual scene, and the results are shown in Fig. 12.

It can be seen from Fig. 12 that collision detection for real-time roaming in the virtual scene is carried out by the method in this paper. The detection time is only 4ms, and the detection time is less than 10ms. It can be seen that this method has good performance in collision detection of virtual scenes.

Fig. 12. Collision detection time and collision detection rate.

To verify the smoothness of the motion connection of the 3D animated character model in this method, the motion process of Police Officer Judy was tested. There are 30 frames in each motion clip, and the number of clips is 8, totaling 240 frames. The connection smoothness in the ear joint and eye rotation motion segment of police officer Judy in the post-application test of this method is shown in Fig. 13.



(a) The Movement Process of Ear Cartilage Joints

(b) The movement process of eye rotation

Fig. 13. Connection smoothness of two motion segments.

From the analysis of Fig. 13, it can be seen that through the method in this paper, the connection between the two motion segments is relatively smooth, and the initial motion is also retained accordingly. The experimental results show that the connection smoothness of each part of the motion segment is high under the method in this paper. Applying this method to animation production can enhance the visual perception of animation and bring a good visual experience.

## IV. CONCLUSION

Aiming at the problems of low fluency and rough models in 3D modeling animation production, the innovative practice of virtual reality technology in animation production is studied to improve the animation user perception. Animated character modeling, image texture extraction, mapping, and optimization are realized through 3ds Max software. The animation scene is constructed from the two entry points of dynamic entity and static entity, and through interactive animation scene visualization design and 3D animation scene real-time roaming design, the innovative practice of virtual reality technology in animation production is finally realized. Through experimental verification, this method can improve the quality of animation production and enhance the visual perception of users. In addition, in future animation production, researchers can work to introduce more complex and realistic physical effects, such as cloth simulation and liquid simulation, to provide more realistic visual effects for animation production, and enhance the user's immersion and viewing experience.

*Abstract*—In this research work, we have presented a machine learning strategy for Bengali speech emotion categorization with a focus on Mel-frequency cepstral coefficients (MFCC) as features. The commonly utilized method of MFCC in speech processing has proved effective in obtaining crucial phoneme-specific data. This paper analyzes the efficacy of four machine learning algorithms: Random Forest, XGBoost, CatBoost, and Gradient Boosting, and tackles the paucity of research on emotion categorization in non-English languages, particularly Bengali. With CatBoost obtaining the greatest accuracy of 82.85%, Gradient Boosting coming in second with 81.19%, XGBoost coming in third with 80.03%, and Random Forest coming in fourth with 80.01%, experimental evaluation shows encouraging outcomes. MFCC features improve classification precision and offer insightful information on the distinctive qualities of emotions expressed in Bengali speech. By demonstrating how well MFCC characteristics can identify emotions in Bengali speech, this study advances the field of emotion classification. Future research can investigate more sophisticated feature extraction methods, look into how temporal dynamics are incorporated into emotion classification models, and investigate practical uses for emotion detection systems in Bengali speech. This study advances our knowledge of emotion classification and paves the way for more effective emotion identification systems in Bengali speech by utilizing MFCC and machine learning techniques. Our work addresses the need for thorough and efficient techniques to recognize and classify emotions in speech signals in the context of emotion categorization. Understanding emotions is essential for many applications, as they are a basic component of human communication. By investigating cutting-edge strategies that show promise for enhancing the precision and effectiveness of emotion recognition, this study advances the field of emotion classification.

*Keywords—XgBoost; gradient boosting; CatBoost; random forest; MFCC*

## I. INTRODUCTION

Emotions significantly impact people's attitudes and decision-making processes in various everyday activities, making them a crucial aspect of communication among individuals. Emotional understanding promotes mutual understanding and contributes to a fulfilling social life [1]. In today's technologically advanced world, where voice commands and manual instructions are exchanged between humans and machines, the ability of artificial intelligence or machine learning to identify and assess someone's emotional state from their voice has emerged as a pressing challenge [2][3]. There is little study on emotion classification in non-English languages like Bengali, which presents particular difficulties for speech analysis. Systems currently in use frequently struggle with linguistic diversity and cultural subtleties. In order to solve these problems, our research advances the area by introducing a machine learning technique that improves the accuracy of emotion recognition. Our objective is to enhance emotional intelligence and human-machine communication, especially in underrepresented languages.

The contributions of this paper are twofold. Firstly, we provide a comprehensive investigation into the application of machine learning algorithms for emotion classification in Bengali speech, which is a relatively unexplored area of research. This study addresses the need for emotion recognition systems tailored to Bengali, which can enhance communication and human-machine interactions within Bengali-speaking populations. Secondly, we offer insights into the performance of Random Forest, XGBoost, CatBoost, and Gradient Boosting models in the context of emotion classification in Bengali speech. By comparing and evaluating the results of these models, we aim to identify the most effective approach for accurate emotion recognition.

Overall, our research aims to contribute to the advancement of speech emotion recognition, specifically in the Bengali language, and pave the way for improved human-machine interactions, affective computing applications, and speech therapy within Bengali-speaking communities.

This paper is organized logically and cogently. It starts with an introduction that sets the scene by supplying the backdrop and rationale for the research, outlining the goals of the study in detail, and highlighting its importance. The literature review section that follows conducts a detailed examination of earlier work on speech emotion identification, discusses several methods for categorizing emotions, and identifies the research gap in Bengali speech emotion categorization. The basis for the following sections is laid by this. Details regarding the Bengali speech dataset used in the study are provided in the dataset and data collecting section,

along with information on the methods used for data collection and participant selection, as well as the preprocessing procedures performed on the speech data. The feature extraction section emphasizes the importance of Mel-frequency cepstral coefficients (MFCC) features in the categorization of emotions by emphasizing their extraction from the preprocessed speech data. In the section on machine learning algorithms, the algorithms Random Forest, XGBoost, CatBoost, and Gradient Boosting are introduced and discussed, along with details on their implementation and parameter settings. The experimental setup, evaluation measures, and results of the implemented algorithms are examined in the experimental evaluation section. The discussion part concludes by interpreting the results, outlining any ramifications, and addressing any study limitations.

The motivation section underlines the importance of emotions in human communication and draws attention to the dearth of research on emotion classification in non-English languages, particularly Bengali. The Speech Emotion Recognition (SER) methodology—which includes data collection, preprocessing, feature extraction, model selection, training, evaluation, optimization, and deployment—is the primary topic of discussion in Section IV. With the goal of accurately detecting emotions, enhancing human-machine interactions, and enhancing emotional comprehension, the project focuses on creating a machine learning technique for Bengali speech emotion categorization.

In Section V, we go over the steps involved in classifying emotions in Bengali speech. These include gathering data, analyzing dataset properties, extracting features using MFCC, and applying machine learning algorithms (Random Forest, XGBoost, CatBoost, and Gradient Boosting) to the classification process. The diversity of the dataset, the value of MFCC in capturing emotional information, and the prowess of each classification method in handling complex patterns are all emphasized in this section.

## II. MOTIVATION

The need to address the dearth of studies concentrating on non-English languages, notably Bengali, in the field of emotion classification led to the research on "A Machine Learning Approach for Emotion Classification in Bengali Speech". Despite the importance of emotions in human communication, the majority of study so far has focused on English or other commonly used languages. This investigation into the categorization of emotions in Bengali speech tries to close this gap.

The major goal is to create a machine learning model that can recognize emotions in Bengali speech that is accurate and efficient. A useful tool for deciphering and comprehending emotions communicated in Bengali would be provided by such a model. It has applications in areas including sentiment analysis for Bengali-based platforms and services, human-computer interaction, and virtual assistants.

The study also recognizes the diversity of languages and cultures found among Bengali speakers. For effective emotion classification, Bengali's limited linguistic resources, dialectal variances, and pronunciation quirks present special

difficulties. In order to create emotion recognition algorithms that are both culturally diverse and contextually pertinent, the project intends to solve these issues.

Studies on the identification of emotions from Bangla speech data are scarce [4],[24]-[27]. 25 MFCCs were suggested by researchers who investigated the optimum number of MFCCs for emotion recognition in speech data in [4]. To categorize user comments on Facebook pages, a deep neural network model based on Gated Recurrent Units was created in [24]. 5126 comments in Bangla were gathered, and these were divided into six categories: incitement, political, religious, hate speech, communal attack, and incitement. The accuracy of the GRU-based model was 70.10%. With an accuracy of 51.33%, a Recurrent Neural Network (RNN) was used in [25] to categorize six emotions in Bangla speech: joy, sadness, anger, surprise, fear, and disgust. [26] used a vocabulary of 500 distinct words using the Gaussian Mixture Model-Hidden Markov Model and Deep Neural Network-Hidden Markov Model to identify emotions in 49 distinct speakers. Using Word Error Rate to gauge model performance, they discovered that the GMM-HMM had 3.96% WER while the DNN-HMM had 5.30% WER. In [27], speech data was subjected to emotion categorization using an ensemble method that used multiple supervised classifiers, with an accuracy rate of 70%. It is clear that the level of accuracy attained by previous studies in audio-based emotion detection and recognition has not been very high.

In conclusion, the research is driven by the need to enhance communication technology, enable applications that can better recognize, interpret, and react to human emotions within the Bengali-speaking community, and advance our understanding of emotions in Bengali speech.

## III. RELATED WORK

While there have been extensive research studies conducted in the field of Speech Emotion Recognition (SER) for various languages, particularly English, only limited efforts have been made to establish SER for Bengali (Bangla). In 2018, Rahman et al. introduced a method for Bangla emotion classification using Dynamic Time Warping (DTW) assisted Support Vector Machines (SVM) [5]. The features utilized for classification were the first and second derivatives of Mel-frequency Cepstral Coefficients (MFCC). The proposed system achieved an average accuracy of 86.08% on a small dataset consisting of only 200 words.

N. Kholodna et al. [6] constructed a machine-learning model to automate the detection of emotions from speech, to monitor public emotions. They selected a manually annotated dataset and transformed it into a textual representation using a vectorization technique. Deep learning approaches, including convolutional neural networks (CNNs), recurrent neural networks (RNNs), and perceptron models, were employed to identify emotions from the textual data. The classification accuracy of the resulting model was found to be relatively low, with random forest achieving 77%, regression achieving 74%, and the naive Bayesian classifier achieving 73.5%.

Some researchers work with Bengali speech. That study employs pitch and MFCC variables to identify emotions in

Bengali speech [7]. The suggested method produced an accuracy rate of 87.50% on a self-created dataset of Bengali emotional speech, with accuracies of 80.00% for joyful, 75.00% for sad, 85.00% for angry, and 75.00% for neutral emotions. For a thorough evaluation of the study, further information is required.

A. Majeed et al. [8], a system was created by the authors to detect emotions from Roman Urdu text. They constructed a comprehensive corpus comprising 18k sentences, sourced from various domains, and annotated it with six different emotion classes. The authors further employed baseline algorithms such as K-Nearest Neighbors (KNN), Decision Tree, Support Vector Machine (SVM), and Random Forest on their corpus. The achieved accuracy rate was 69.4%, with an F-measure of 0.69

S. Cunningham et al. [9], the authors introduced an Artificial Neural Network (ANN) approach for predicting emotions in the domain of Music Emotion Recognition. A total of 167 voices were analyzed, and 76 features were extracted from the International Affective Digital Sounds Dataset (IADS). To facilitate model training and evaluation, the audio dataset was partitioned into three segments: training (70%), validation (15%), and testing (15%). During the prediction phase, the ANN model achieved accuracy rates of 64.4% for arousal and 65.4% for valence. These results indicated that the shallow neural network outperformed the regression model in terms of performance.

In our study, we were successful in classifying Bengali speech emotions with a high degree of accuracy. We achieved outstanding results by utilizing cutting-edge machine learning methods including Random Forest, XGBoost, CatBoost, and Gradient Boosting. Our top accuracy score was 82.85%. This outstanding performance demonstrates how well our method works at correctly identifying and categorizing emotions in Bengali speech. These findings help Bengali language emotion recognition technology progress and present prospects for real-world applications in numerous fields.

## IV. SPEECH EMOTION RECOGNITION

The goal of speech emotion recognition (SER), a crucial field of study, is to automatically identify and categorize the emotions indicated in speech signals. To process and analyze the voice data properly, the system includes a number of crucial steps. In the beginning, a dataset of labeled speech recordings is gathered, capturing emotions displayed in regulated or naturalistic settings. To improve their quality and retrieve pertinent information, the speech signals go through preprocessing procedures such as segmentation and noise removal. The preprocessed signals are used to extract acoustic features such as Mel Frequency Cepstral Coefficients (MFCCs), energy-based features, and prosodic features. These characteristics act as clear illustrations of the emotional content. When deep learning or machine learning models like Support Vector Machines, Convolutional Neural Networks, or Long Short-Term Memory networks are used for classification, model selection is critical. The models are developed using the labeled data, tuned using hyperparameters, and their performance is assessed. In the end, the trained models can be used to predict emotions from speech data that hasn't been seen, which will help with applications like affective computing, human-computer interaction, and speech therapy. The processes of data collection, preprocessing, feature extraction, model selection, training, assessment, optimization, and deployment are all included in speech-emotion recognition systems. This study aims to investigate a machine learning method for Bengali speech emotion classification. The work seeks to accomplish accurate emotion detection using methods like MFCC-based feature extraction and models like Random Forest, XGBoost, CatBoost, and Gradient Boosting. Understanding and creating efficient speech emotion detection algorithms have the potential to significantly improve human-machine interactions, and emotional comprehension, and facilitate applications in many other fields.

## V. THE MATERIALS AND METHOD

To identify the proper emotional state, our suggested system goes through several significant phases, including generating a dataset for Bengali speech, feature extraction, feature classification, and decision-making based on extracted features and classifications. Fig. 1 is the process of emotion classification.

Fig. 1. Process of emotion classification.

### A. Preparing Datasets

*1) The* technique of collecting the data for Bengali speech's classification of emotions requires several processes and meticulous planning. A total of 40 sentences were originally composed, and 25 of them were chosen for recording. Following this, these lines were uttered and recorded by people ranging in age from 9 to 48, creating a total of 25 distinct recordings. The clips ranged in length from 2 to 4 seconds, with an average of about 3 seconds, and each recording was converted to the mp3 format.

A Sample of data -

Bangla- তোমার নাম কি?

English – What is your name?

Phonemic- Tomar name ki?

Fig. 2 shows the audio frequency of each emotion.

(a) Audio frequency output (angry)

(b) Audio frequency output (happy)

(c) Audio frequency output (neutral)

(d) Audio frequency output (sad)
Fig. 2.   Audio frequency output (angry, happy, neutral, sad).

Our Bengali speech dataset's main sources include unrestrained or natural emotions, performed or driven emotions, and elicited or created emotions [10]. Happy, Sad, Natural, and Angry were the four main emotions that were the focus of the data gathering. 14 speakers, including both male and female speakers, were enlisted to take part in the recording process to capture a wide spectrum of emotions. When compared to comparable datasets like the BanglaSER database, our dataset has a considerable volume [11]. This research produced a sizable dataset of 1400 audio recordings, 350 of which were assigned to each emotion group. Fig. 3 represents the total dataset and accuracy of each algorithm.

| SL | Name of Algorithm | Number of data | Accuracy (%) |
|----|-------------------|----------------|--------------|
| 1 | Random Forest | 350 | 80.01 |
| 2 | XGBoost | 350 | 80.03 |
| 3 | Gradient Boosting | 350 | 81.19 |
| 4 | CatBoost | 350 | 82.85 |

Fig. 3.   Total Number of dataset and accuracy of each algorithm.

The data collection method required a lot of time and effort because the participants were not actors but rather members of the general public. In order to capture a realistic depiction of genuine emotional expression, it was essential to guarantee the speaker's independence. The dataset is important because it is diverse in terms of speakers and emotions. The dataset offers a wide range of vocal qualities and expressions with four female voices and ten male sounds. An 80-20 split was used to ensure the dataset's usefulness, with 80% of the data (1120 clips) going toward training the models and the other 20% (280 clips) going toward testing and assessment.

### B. Extraction of Features

Feature extraction is the process of taking a little amount of information from a speech signal in order to address each speaker separately [12]. Mel-frequency cepstral coefficients (MFCC) are a frequently employed method for feature extraction, which is a vital stage in the analysis and classification of speech data. In order to extract pertinent acoustic features that capture the unique qualities of the audio signals, MFCC is used in the context of emotion categorization in Bengali speech. Parts of human speech production and perception are represented by MFCC. The human auditory system's logarithmic perception of loudness and pitch is depicted by MFCC [13].

MFCC features are based on human hearing perception [14]. The first step in the MFCC feature extraction procedure is to split the recorded speech data into brief frames, which typically last 20–40 milliseconds and have a minimal amount of overlap. The next step is to perform a series of operations on each frame to determine the MFCC coefficients. A full diagram of MFCC is given in Fig. 4.

The average frequency perception capability of humans is over the range of 1KHz [15]. To lessen spectral leakage, the speech signal is first divided into manageable chunks, and a windowing function, such as the Hamming window, is then applied. The signal is then transformed from the time domain to the frequency domain on each segment using the Fast Fourier Transform (FFT).

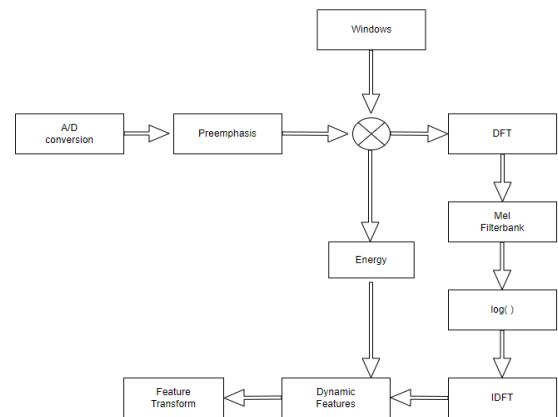

Fig. 4.   Block diagram of MFCC.

The resulting frequency spectrum is then altered using a Mel filter bank to simulate the non-linear perception of sound by the human auditory system. The purpose of this filter bank is to simulate how sensitive different frequencies are to the human ear. The magnitude of the spectral components is represented by the logarithm of the energy contained within each Mel filterbank.

The Discrete Cosine Transform (DCT) is used to decorrelate the Mel-frequency coefficients as the last stage in the MFCC feature extraction process. This treatment decreases

dimensionality, compresses the data, and keeps the most important information.

The signal produced by our speech often comprises a large number of criteria that indicate the signs of different emotions. Pitch, energy, format, as well as spectral features including Mel-frequency cepstrum coefficients (MFCC), are recovered in this study. The approach known as MFCC (Mel-frequency cepstral coefficients) is commonly used in speech recognition and voice emotion recognition. It is predicated on the knowledge that speech impulses are not linearly processed by the human auditory system. A non-linear Mel scale filter bank is used, which amplifies the lower frequencies while attenuating the higher ones, to capture the phoneme-specific information included in the lower frequency components of speech.

The short-term power spectrum of a speech frame is represented by the Mel frequency cepstrum in speech processing. It can be found by taking the logarithm of the power spectrum on a Mel frequency scale and performing a linear cosine transform. The formula m = 2595 * log10(f/700+1) converts the normal frequency (f) to the Mel frequency (m). We are able to convert any frequency to its Mel equivalent using the presented equation. [16].

$$m = 2595 log10(\frac{f}{700} + 1)$$

### C. Classification Method

Four well-known algorithms were used to categorize emotions in Bengali speech using machine learning: Random Forest, XGBoost, CatBoost, and Gradient Boosting. These algorithms were selected because they handled classification jobs well and could identify intricate patterns in the data. Many of the researchers use many algorithms but small work with those algorithms.

*1) Random forest:* An ensemble learning system called Random Forest mixes various decision trees to produce predictions. Each tree in the forest is trained using a portion of the data, and the combined forecasts of all the individual trees are used to make the final prediction. Fig. 5 shows the Random Forest architecture. Double randomness is the random forest's primary attribute [17]. Random Forest is renowned for its resistance to overfitting and capacity for handling large-scale, multidimensional data. In Fig. 7, it shows the confusion matrix of Random Forest.

Fig. 5.   RF classifier  architecture.

*2) XGBoost:* It is an ensemble machine-learning technique based on decision trees that makes use of an improved gradient-boosting framework [18]. Due to its outstanding results in numerous machine learning contests, the gradient boosting technique known as XGBoost (Extreme Gradient Boosting) has become increasingly popular. In Fig. 6, Gradient descent is used to incrementally improve an ensemble of poor prediction models, such as decision trees. The capacity of XGBoost to handle intricate relationships and identify non-linear patterns in the data is well known. The major benefit of this algorithm is its regularization technique [19]. Fig. 8 shows the confusion matrix of XGBoost.

Fig. 6.   XGBoost architecture.

*3) CatBoost:* Another gradient boosting method created specifically to handle category features effectively is CatBoost. It combines ordered boosting and gradient-based optimization techniques to obtain high accuracy in classification applications. When working with datasets that combine numerical and categorical variables, CatBoost is especially helpful. By applying the process of encoding, this method is able to handle the many types of data in the form as they emerge. Such a category can be handled without difficulty by Catboost [20]. Fig. 9 shows the confusion matrix of CatBoost.

*4) Gradient boosting:* A broad ensemble learning approach called gradient boosting combines several weak learners to produce a powerful predictive model. It is among the effective models created for making predictions. Three components make up the technique [21]. A decision tree to strengthen weak learners, a differentiable loss function, and an additive model to help choose the best decision tree model [22]. Each decision tree's nodes use a unique subset of characteristics to determine the appropriate split. In this method, each tree is distinct and capable of extracting a distinctive signal from the data points. Additionally, every new tree is built on top of the mistakes made by the prior tree, and all of these procedures are carried out sequentially [23]. In Fig. 10, it shows the confusion matrix of Gradient Boosting.

### VI.   RESULT AND DISCUSSION

An experimental study was carried out to gauge how well the machine learning approach performed in classifying emotions in Bengali speech. The dataset used for this assessment was made up of recorded Bengali speech samples from different people, covering a variety of emotions including happy, sad, natural, and angry.

For the emotion categorization challenge, four well-known machine learning algorithms—Random Forest, XGBoost, CatBoost, and Gradient Boosting—were used. Using features taken from the Bengali speech samples, such as Mel-frequency cepstral coefficients (MFCC), each algorithm was trained on the training subset. Following the training phase, the classification models were used to forecast the emotions present in the Bengali speech samples using the testing subset. The accuracy of each algorithm was determined by contrasting the anticipated labels of the test samples with their actual labels.

### A. Accuracy

A model's overall accuracy in foretelling both positive and negative events is measured by accuracy. It is determined by dividing the total number of forecasts by the number of correct guesses. Although accuracy offers a broad evaluation of model performance, it may not be appropriate when classes are unbalanced.

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN}$$

### B. Precision

Precision measures a model's ability to categorize positive cases among all instances that it properly predicted as positive. It is determined by dividing the total number of true positives (positives that were successfully predicted) by the sum of true positives and false positives (positives that were mistakenly forecasted). The model's precision indicates its capacity to prevent false positives.

$$Precision = \frac{TP}{TP + FP}$$

### C. Recall

The capacity of a model to properly identify every positive case is measured by the recall. It is determined by dividing the total number of true positives by the total number of false negatives, which are positives that were mistakenly labeled as negatives. Recall shows how well the model can prevent false negatives.

$$Recall = \frac{TP}{TP + FN}$$

### D. F-1 score

The F1 score is a statistic that combines precision and recall. By using the harmonic mean of precision and recall, it offers a fair evaluation of the model's performance. The F1 score is calculated as 2 * ((precision * recall) / (precision + recall)). It has a scale of 0 to 1, with 1 representing the highest attainable score.

$$F - 1\ Score = 2 * \frac{Recall * Precision}{Recall + Precision}$$

These findings show how well Bengali speech can be classified according to emotions using machine learning. The most accurate results came from CatBoost, which demonstrated a great capacity to identify underlying patterns and relationships in the data. The ability of Gradient Boosting, XGBoost, and Random Forest to correctly predict emotions in

Bengali speech was also demonstrated by their respectable performance.

Fig. 7. Confusion matrix of random forest.

Fig. 8. Confusion matrix of XGBoost.

Fig. 9. Confusion matrix of CatBoost.
Fig. 10. Confusion matrix of gradient boosting.

TABLE I. CONFUSION MATRIX

| ML Model | Emotion | Precision | Recall | F1-score | Average accuracy |
|---|---|---|---|---|---|
| Random Forest | angry | 0.86 | 0.83 | 0.85 | 0.80 |
| | happy | 0.75 | 0.80 | 0.77 | |
| | neutral | 0.73 | 0.83 | 0.77 | |
| | sad | 0.86 | 0.75 | 0.80 | |
| XGBoost | angry | 0.86 | 0.78 | 0.81 | 0.80 |
| | happy | 0.75 | 0.80 | 0.77 | |
| | neutral | 0.74 | 0.75 | 0.74 | |
| | sad | 0.85 | 0.87 | 0.86 | |
| Gradient | angry | 0.77 | 0.88 | 0.82 | 0.81 |
| | happy | 0.81 | 0.77 | 0.79 | |
| | neutral | 0.79 | 0.77 | 0.78 | |
| | sad | 0.87 | 0.83 | 0.85 | |
| CatBoost | angry | 0.77 | 0.88 | 0.82 | 0.82 |
| | happy | 0.81 | 0.77 | 0.79 | |
| | neutral | 0.79 | 0.77 | 0.78 | |
| | sad | 0.87 | 0.83 | 0.85 | |
| | | | | | |

The experimental evaluation sheds important light on the effectiveness of various algorithms and emphasizes the significance of choosing the right machine-learning methods for Bengali speech emotion categorization. To acquire a deeper knowledge of the models' performance, additional research and assessment could be conducted to study different evaluation measures, such as precision, recall, and F1 score.

We shall start by outlining the judicial system of our suggested model. We have taken into account the Table I accuracy, precision, recall, and F-1 score.

The experimental results showed how each algorithm performed in terms of accuracy. Gradient Boosting, CatBoost, Random Forest, and XGBoost all produced results with

accuracy higher than 81.19%, 82.85%, 80.01%, and 80.03% respectively.

Overall, the experimental findings support the effectiveness of the machine learning method for correctly detecting emotions in Bengali speech, advancing emotion identification systems designed for the Bengali language.

## VII. CONCLUSION AND FUTURE WORK

In conclusion, this research focused on developing a machine-learning approach for emotion classification in Bengali speech. The experimental evaluation demonstrated the effectiveness of the Random Forest, XGBoost, CatBoost, and Gradient Boosting algorithms in accurately predicting emotions in Bengali speech samples. The achieved accuracy rates ranged from 80% to 83%, with CatBoost exhibiting the highest accuracy. This research contributes to addressing the scarcity of studies on emotion classification in non-English languages, specifically Bengali, and provides valuable insights into the potential of machine learning algorithms for capturing emotions in Bengali speech.

Incorporating sequence modeling techniques, such as recurrent neural networks or transformers, as well as taking into account the temporal dynamics of emotions in a speech could capture the temporal dependencies and boost the precision of emotion classification.

We realize that our study has some limitations. There are a total of seven different emotional categories; initially, we concentrated on the classification of four distinct emotions. Second, while MFCC was the main methodology we used for feature extraction, there are other feature extraction methods like LPC and PLP that can provide different insights and advantages.

In future work, we plan to expand our approach by incorporating a broader range of algorithms for emotion classification. Additionally, we intend to explore additional feature extraction techniques, including LPC and PLP, to enhance the robustness and accuracy of our emotion classification system.

# Hybrid Integrated Aquila Optimizer for Efficient Service Composition with Quality of Service Guarantees in Cloud Computing

Xiaofei Liu[1]*

School of Computer and Information, Anqing Normal University
Anqing 246133, Anhui, China

*Abstract*—The prompt evolution of cloud computing technology has given rise to the emergence of countless cloud-based services. However, guaranteeing Quality of Service (QoS) awareness in service composition poses a substantial difficulty in cloud computing. A solitary service cannot effectively handle the complicated requests and varied demands of real-world situations. In some instances, one service alone may not be enough to fulfill users' particular requirements, prompting the integration of several services to satisfy these needs. As an NP-hard problem, service composition has been addressed using many metaheuristic algorithms. In this context, the proposed methodology presents a new blended technique, referred to as Integrated Aquila Optimizer (IAO), which amalgamates conventional Aquila Optimizer (AO) and Particle Swarm Optimization (PSO) algorithm. The central objective of this hybridization is to tackle the shortcomings confronted by both AO and PSO algorithms. Specifically, these algorithms are known to get stuck in local search areas and show limited solution variety. To address these challenges, the proposed method introduces a novel transition mechanism that facilitates suitable adjustments between the search operators, ensuring continual improvements in the solutions. The transition mechanism allows the algorithm to switch between AO and PSO when any of them gets stuck or when the diversity of solutions decreases. This adaptability enhances the overall performance and effectiveness of the hybrid approach. The proposed IAO method is exhaustively tested through experiments conducted using the Cloudsim simulation platform. The numerical findings confirm the effectiveness of the suggested approach regarding dependability, accessibility, and expenses, which are essential factors of cloud computing.

*Keywords—Cloud computing; service composition; Particle Swarm Optimization; Aquila optimizer*

## I. INTRODUCTION

Cloud computing is a prevalent method for providing on-demand resources and services. Its pay-as-you-go strategy has attracted considerable attention from businesses and research institutions, particularly in areas that require substantial and intricate computing tasks, such as aerospace, bioinformatics, and physics [1]. Elastic computing capabilities are provided to cloud users through cloud computing, encapsulating these capabilities as Virtual Machines (VMs) deployed on Physical Hosts (PHs) controlled by the management center. These resources are fabricated and made accessible to users based on their availability and the required quality parameters [2]. Cloud computing has become a popular choice for large institutions and IT companies for its reliability, cost-effectiveness, and security. The rise of dependable and credible cloud providers has greatly diminished concerns about embracing this method [3, 4].

However, two significant challenges must be addressed regarding service accessibility and efficient allocation prospects. Predicting all the necessary services, particularly in software services, is a challenging task [5]. To tackle this issue, providing simple and fundamental services that can be combined to form more complex services is essential [6]. Different service providers can contribute to these building block services, making it easier to address the diverse needs of users. The second hurdle is selecting the ideal combination of mandatory and individual services, each supplied by different suppliers with variable quality of service (QoS) features [7]. This involves optimizing the formation of complex services while considering a vast number of similar single services offered by different providers. As an NP-hard problem, this presents a formidable computational challenge. Service composition has emerged as one of the most effective approaches proposed and utilized by cloud providers and researchers alike. This approach simultaneously resolves both of the aforementioned challenges. This technique aims to ensure service user satisfaction by choosing appropriate services from a pool, adhering to service composition restrictions, analyzing important QoS metrics, and accounting for the unpredictable nature of changing service features and network conditions [8].

The integration of the Internet of Things (IoT), machine learning, deep learning, and neural networks represents a transformative paradigm in addressing the complex challenges of cloud service composition. IoT devices generate vast amounts of data, often in diverse formats and characteristics [9-11]. Machine learning techniques provide the ability to extract valuable insights from this data, facilitating intelligent decision-making in the cloud service composition process [12, 13]. Deep learning, a subset of machine learning, excels at handling complex, unstructured data, such as images, text, and speech, enabling the automatic recognition of patterns and correlations in the cloud service context [14, 15]. Neural networks, inspired by the human brain's interconnected neurons, offer powerful tools for modeling and optimizing the intricate relationships between various cloud services,

enhancing the accuracy of service composition while adapting to dynamic and unpredictable conditions [16, 17].

Meta-heuristic algorithms are vital to solving complicated challenges associated with cloud service composition. These algorithms, known for their adaptability and problem-solving versatility, offer effective strategies to optimize the selection and arrangement of diverse cloud-based services, ensuring QoS requirements are met, and performance is maximized within complex cloud computing environments. By efficiently navigating the vast solution spaces, meta-heuristic algorithms contribute significantly to achieving optimal service combinations, which are essential for fulfilling the dynamic and multifaceted demands of cloud users [18]. This paper proposes a swarm intelligence-based method for service composition in cloud computing called Integrated Aquila Optimizer (IAO). IAO merges the traditional AO and Particle Swarm Optimization (PSO) algorithms to overcome their individual constraints. Specifically, IAO addresses the issues of having low solution diversity and being stuck in local search areas. The proposed method incorporates a new transition mechanism to maintain improvements and enhance performance. This mechanism enables appropriate transitions between search operators, allowing the algorithm to switch between AO and PSO when any algorithm becomes stuck or solution diversity decreases. This paper contributes the following:

- QoS criteria determine the optimal selection of services. This ensures that the user's objectives are met effectively.

- Reductions in response times and cost-of-service choices lead to faster service composition.

- Power consumption is decreased compared to other metaheuristic algorithms.

The rest of the paper in arranged in the following manner. Section ii reviews the related work. Section III explains the problem statement. Section IV discusses the proposed method. Simulation results are reported in Section V. Finally, Section VI concludes the paper and suggests some hints for upcoming research.

## II. RELATED WORK

Bao, et al. [19] proposed a new approach called the Evolutionary Multitasking Algorithm for Cloud Computing Service Composition Problem (EMA-CCSC). EMA-CCSC stands out due to its capacity to optimize two service composition tasks concurrently, unlike traditional solvers that handle composite service requests one at a time after pooling them in a waiting queue. This enhanced optimization capability allows EMA-CCSC to handle a greater number of tasks more quickly, leading to improved efficiency. To evaluate the performance of EMA-CCSC, the researchers conducted experiments using the QWS dataset. They resolved a series of randomly generated service composition tasks varying in size and structure. Experiments suggest that EMA-CCSC is superior to other algorithms with varying properties. Notably, EMA-CCSC achieves this performance while spending only half of its computational expenses. Qi, et al. [20] introduce

models for evaluating Quality of Service (QoS) and propose a mathematical model for optimizing Web service composition regarding QoS. Additionally, a knowledge-driven differential evolution process is presented for optimizing Web service composition. By incorporating structural knowledge, this algorithm significantly enhances the convergence velocity. The research includes simulation experiments and an evaluation methodology, with results demonstrating that KDE (knowledge-based differential evolution) outperforms the PSO algorithm and original differential evolution for Web service composition.

Hosseinzadeh, et al. [21] have presented a novel integrated approach termed the Artificial Neural Network-based Particle Swarm Optimization (ANN-PSO) Algorithm, which is tailored to augment the Quality of Service (QoS) attributes within cloud-edge computing. The crux of their contribution lies in introducing a formal verification technique that employs labeled transition systems to evaluate crucial linear temporal logic equations systematically. This verification process bolsters the efficacy of candidate composite services and optimizes various QoS parameters within the context of the hybrid algorithm. The outcomes of the experiment exhibit the exceptional effectiveness of the proposed model, highlighted by its minimal verification time, low memory consumption, and capability to ensure critical specifications based on Linear Temporal Logic (LTL) formulas. Furthermore, they noted that the recommended model exceeds other service composition algorithms, attaining the ideal timing, reliability, and cost. Souri, et al. [22] introduced a hybrid formal verification approach to evaluate service composition in multi-cloud environments. The objective was to enhance the ultimate service configuration by reducing the number of cloud vendors involved while maintaining a high QoS. Their method involved a behavioral model to analyze request flow, selection of services, and combination within a varied cloud situation. The suggested procedure utilized model checking using Multi-Labeled Transition Systems (MLTS) and process algebra using Pi-Calculus to perform the analysis of service composition. These techniques were employed to monitor performance characteristics to measure the quality of service. The authors conducted experiments to validate the feasibility of their proposed approach, utilizing performance evaluations and confirmation setups. The experimental results demonstrated the effectiveness and viability of the approach in achieving optimized multi-cloud service composition with reliable QoS standards.

Wang and Liu [23] introduced an inventive approach by fusing the firefly optimization algorithm (FOA) with fuzzy logic, presenting a methodology adept at effectively harmonizing multiple QoS parameters while adhering to connectivity limitations in service composition. The crux of their contribution lies in the introduction of a novel metric, termed the model maturity metric, designed to assess the lifecycle of simulation models across various cloud scenarios. This study dynamically computes the maturity score for the amalgamated model, factoring in the collaborative relationships between model services. The authors further devised a new algorithm that integrates FOA and fuzzy logic to optimize and synthesize cloud model services. Empirical

findings underscored the efficacy of the proposed technique. It showcased a superior performance compared to previous methodologies in key aspects like energy consumption, availability, and response time. This substantiates the efficiency of the suggested approach in significantly enhancing the Quality of Service (QoS) within the realm of cloud service composition. Mohapatra, et al. [24] introduced a Multi-Criteria Decision-Making methodology that employs the Simple Additive Weighting (SAW) technique. This methodology assists customers in determining the preferable cloud service from a range of available services based on their individual satisfaction criteria.

Additionally, they proposed an enhanced approach called Eagle Strategy with Whale Optimization algorithm (ESWOA). This enhanced technique helps balance local and global optima, ensuring efficient optimization of cloud services. The system proposes time-saving, dependable, and trustworthy cloud services from the available pool by combining these methodologies. This recommendation system aids customers in finding the appropriate cloud services to satisfy their specific demands.

## III. PROBLEM STATEMENT

Service composition identifies the most suitable set of Cloud-based Services (CSs) from an array of available services to enhance user experience while adhering to QoS constraints. In Fig. 1, the formal definition of service composition is presented. It assumes that from a total of m candidate services available in the cloud, $n$ services ($X_1, X_2, \cdots, X_n$) must be combined to achieve the desired QoS and meet the user's requirements. There are various ways to combine a set of services, but evaluating all possible combinations and selecting the optimal method is time-consuming. This paper addresses the service combining issue using IAO. The system model for cloud service composition consists of several key components, including Cloud Providers (CPs), service requirements, QoS constraints, and types of composite service profiles. Different CP partners must collaborate and work together in a supply chain format to meet all service requirements. This collaboration allows them to leverage their unique strengths and capabilities, creating an optimal package of services that fulfills the customer's needs and ensures the highest QoS. Effective communication and coordination among CP partners are essential for a successful collaboration. CPs may offer multiple services, each involving one or more CPs. To meet the complex needs of customers, services from different commercial independent cloud platforms can be combined through mutual communication. This flexibility in combining services from various sources enhances the ability to satisfy customers' diverse and evolving requirements effectively.

In QoS-aware service composition, the cloud user initially provides a list of abstract services that describe the application requirements for a specific task. The cloud provider then composes these abstract services into a concrete and executable workflow, which is deployed within the cloud environment. The cloud provider considers the user's specified QoS constraints throughout this composition process, such as performance, reliability, and cost. These constraints play a crucial role in ensuring that the composed services meet the user's needs while optimizing the resulting workflow's cost, performance, and reliability. To achieve this optimization, the cloud provider evaluates and weighs the different QoS requirements against each other. By doing so, they can make informed decisions to select the most suitable composition of services that best aligns with the user's goals and fulfills the specified QoS constraints. Consider a set of n customer service requirements represented as $R = (R_1, R_2, ..., R_i, R_n)$ $(1 \leq i \leq n)$. Each abstract service $S_i$ $(1 \leq i \leq n)$ can satisfy a specific requirement $R_i$ in a particular order, adhering to the user's preferences and priorities for service composition. Cloud pools offer services catering to clients' diverse needs from numerous providers, aiming to boost their profitability. As client needs can be complex, they may require the compilation and orchestration of multiple services. Service composition aims to combine and organize these various services into a formalized workflow that efficiently processes client requests. Figure 2 illustrates the process of composing a cloud service, where n tasks represent the client's request. Each workflow task is matched with candidate services during service discovery. An optimization algorithm is employed to select the most suitable services to create a coherent path that fulfills the client's requirements.

Fig. 1. Service composition model.

A workflow in this context represents a client request comprising n tasks and a list of $m$ candidate services. These workflows are represented using directed acyclic graphs (DAGs) with five tuples. $V = (T_1, T_2, ..., T_n)$ represents the workflow of n tasks, and each task includes a list of candidate services denoted as $(S_1^1, S_2^2, ..., S_n^m)$, where $S_i^j$ $(1 \leq i \leq n, 1 \leq j \leq m)$ represents the $j^{th}$ service for the $i^{th}$ task. An association between the services and QoS parameters is represented by $E$. The QoS parameters for the $j^{th}$ service are denoted as $(P_{1,i}^1, P_{2,i}^2, ..., P_{Q,n}^m$, where $P_{r,i}^j (1 \leq r \leq Q)$ represents the $r^{th}$ QoS parameter for the $j^{th}$ service. Here, $C$ represents the values of the QoS parameters, represented as $C = (C_1, C_2, ..., C_Q)$. The workflow patterns can be loop, conditional, parallel, or sequential, and they are denoted as $P$. $Q$ denotes the number of QoS parameters in the system. Furthermore, $W$ represents the clients' QoS desires, represented as $W = (W_1, W_2, ..., W_Q)$, indicating the specific values and priorities the clients require for the QoS parameters.

In the given formulation, there are multiple potential solutions in the form of infinite paths, with a total of less than

m solutions. However, the results obtained from optimization algorithms reveal that only one solution stands out as the best among all others. Hence, the service composition problem can be seen as a multi-objective optimization problem, as the goal is to find a single optimal solution. In the context of mobile cloud computing environments, the battery life of mobile devices is a critical factor. Therefore, three QoS factors, namely cost, response time, and energy, play a significant role in determining the optimal service composition. These QoS parameters are further divided into positive and negative factors. Positive factors, such as availability and throughput, are most beneficial to users when their values increase. On the other hand, negative factors, such as energy consumption and response time, benefit the user when their values are decreased. Optimization algorithms are employed to calculate the solution's fitness based on the following formula, which

considers the various QoS parameters and their effect on user satisfaction.

$$
\begin{aligned}
Fitness\ function &= W_1.Responsetime0 \\
&+ W_2.Energy + W_3.Cost
\end{aligned} \tag{1}
$$

In Eq. (1), the values of $W_1$, $W_2$, and $W_3$ are constrained to range from 0 to 1, and their sum is equal to 1. The proposed algorithm aims to select a composite service that yields the lowest fitness value. Table I illustrate the existing QoS factors, calculated using sum and product operations and then normalized to fall from 0 to 1. This normalization process ensures that all the QoS factors are on a comparable scale, allowing the algorithm to make a fair assessment and selection of the composite service with the most favorable QoS attributes.

TABLE I.        QOS AGGREGAATION FORMULAS AND WORKFLOW PATTERNS

| QoS parameter | Loop | Fork | Branch | Sequential |
|---|---|---|---|---|
| Cost | $\left(\prod_{i=1}^{n} C(a_i)\right)^k$ | $min_{i=1}^{P} C(s_i^f)$ | $\sum_{i=1}^{m} P_i.C(s_i^b)$ | $\prod_{i=1}^{m} C(a_i)$ |
| Energy consumption | $k.\sum_{i=1}^{n} E(a_i)$ | $max_{i=1}^{P} E(s_i^f)$ | $\sum_{i=1}^{m} P_i.E(s_i^b)$ | $\sum_{i=1}^{n} E(a_i)$ |
| Response time | $k.\sum_{i=1}^{n} T(a_i)$ | $max_{i=1}^{P} T(s_i^f)$ | $\sum_{i=1}^{m} P_i.T(s_i^b)$ | $\sum_{i=1}^{n} T(a_i)$ |

## IV. INTEGRATED AQUILA OPTIMIZER FOR SERVICE COMPOSITION

### A. Aquila Optimizer

The Aquila Optimization (AO) algorithm draws inspiration from the hunting behaviors of the Aquila (eagle) during its pursuit of prey. The hunting process involves four steps: expanded exploration, narrowed exploration, expanded exploitation, and narrowed exploitation. To transition from the exploration stage to the exploitation stage, the AO algorithm incorporates various behaviors. In the initial two-thirds of iterations, the algorithm replicates the exploration phase, followed by the emulation of the exploitation phase in the concluding one-third of iterations. Mathematically, the AO algorithm can be described as follows:

Initializing: A total of *N* solutions are strategically distributed within a D-dimensional exploration domain, delimited by a predetermined range denoted as *[L, U]*. This allocation is accomplished through the utilization of Eq. (2), where $X_{i,j}$ denotes the value in the $j^{th}$ dimension of the $i^{th}$ solution. Here, $L_j$ and $U_j$ signify the lower and upper boundary values pertaining to the $j^{th}$ dimension within the exploration space, while $r$ signifies a randomly generated value within the range of 0 to 1. The spatial coordinates of these solutions are meticulously recorded in a matrix denoted as $X_{N \times D}$. Subsequently, the fitness value for each individual solution is computed through the function $f(X_i)$.

$$X_{i,j} = L_j + r \times (U_j - L_j) \tag{2}$$

Expanded exploration: An Aquila, or eagle, employs a distinct strategy for locating potential prey by identifying regions of interest and strategically selecting optimal hunting locations through a combination of high soaring and vertical stooping. This behavior enables the bird to survey the search area from elevated vantage points, aiding in the estimation of potential prey locations. The AO algorithm simulates this approach to expand exploration, as captured by Eq. (3). This simulation occurs when the ongoing iteration count is less than two-thirds of the total maximum iterations, and a randomly generated value falls below 0.5. Within Eq. (3), $X_1(iter + 1)$ corresponds to the solution generated from the prime method, intended for utilization in the subsequent iteration. $X_{best}(iter)$ designates the best solution discovered up to the current iteration, serving as an approximation of the prey's position. The term $(1 - \frac{iter}{MaxIter})$ is employed to regulate the extent of exploration based on the progression of iterations. Here, *iter* denotes the current iteration count, and *MaxIter* represents the total number of iterations. In the $iter^{th}$ iteration, $X_M(iter)$ represents the mean of the presently available solutions, computed using Eq. (4). This mean value acts as a guide for the exploration process, providing a directional influence for the algorithm as it navigates the search space in pursuit of the optimal solution.

$$
\begin{aligned}
X_1(iter + 1) = X_{best}(iter) \times \left(1 - \frac{iter}{MaxIter}\right) \\
+ (X_M(iter) - X_{best}(iter) \times r)
\end{aligned} \tag{3}
$$

$$X_M(iter) = \frac{1}{N}\sum_{i=1}^{N} X_i(iter), \forall j = 1,2,\dots,D \tag{4}$$

In Eq. (4), the variable $N$ denotes the total number of solutions within the population, while $D$ signifies the dimensionality of the search space.

Narrowed exploration: The hunting behavior of the Aquila, referred to as "contour flight" or "short glide attack," involves the bird hovering over its intended prey, descending swiftly upon spotting the prey from an elevated position. This tactic allows the Aquila to explore a designated region with precision thoroughly. The AO algorithm emulates this focused exploration strategy through Eq. (5), enacted when the ongoing iteration count remains less than two-thirds of the maximum iterations and a randomly generated value exceeds 0.5. In Eq. (5), $X_2(iter + 1)$ represents the solution generated by the narrowed exploration technique. $X_R(iter)$ denotes a solution randomly selected from the entire set of solutions during the iter-th iteration.

Additionally, *Levy(D)* signifies the Levy flight distribution function, calculated via Eq. (6). The Levy flight distribution function, as defined in Eq. (6), exerts an influence on the movement of solutions during the narrowed exploration phase. By introducing controlled random deviations, this distribution facilitates dynamic and efficient exploration of the search space. This stochastic behavior enables the algorithm to focus on specific areas of interest during the narrowed exploration phase, potentially leading to the discovery of promising solutions.

$$X_2(iter + 1) = X_{best}(iter) \times Levy(D) + X_R(iter) \\ + (y - x) \times r \tag{5}$$

$$Levy(D) = s \times \frac{u \times \sigma}{|v|^{\frac{1}{\beta}}}, \sigma = \left(\frac{\Gamma(1 + \beta) \times \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1 + \beta}{2}) \times \beta \times 2^{(\frac{\beta-1}{2})}}\right) \tag{6}$$

Eq. (6) delineates the parameter values as follows: $\beta = 1.5$ and $s = 0.01$. In addition, the variables $u$ and $v$ are integer values randomly generated within the range of 0 to 1. Moving to Eq. (5), the spiral pattern is depicted through the variables $y$ and $x$, which are computed using Eq. (7). Eq. (7) relies on the calculations of the variables $r$ and $\theta$. The value of $r$ is established using Eq. (8), while the value of $\theta$ is computed through Eq. (9). In Eq. (8) and Eq. (9), the number of search cycles is determined by the random number $r_1$, which assumes values between 1 and 20. $D_1$ denotes an integer value ranging from 1 to $D$, where $D$ signifies the dimensionality of the search space. $U$ is a constant set to 0.0056, and $\omega$ is another constant established at 0.005. These parameters collectively contribute to the computation of the spiral form in Eq. (7), playing a pivotal role in shaping the movement and exploration patterns of solutions during the narrowed exploration phase within the framework of the AO algorithm.

$$y = p \times \cos(\theta), x = p \times \sin(\theta) \tag{7}$$

$$p = r_1 + U \times D_1 \tag{8}$$

$$\theta = -\omega \times D_1 + \theta_1, \theta_1 = \frac{3 \times \pi}{2} \tag{9}$$

Expanded exploitation: Aquila adopts the "low-flying descent attack" tactic to capture its target in the expanded exploitation phase. After carefully identifying the prey zone, the Aquila prepares to descend and attack. It descends vertically and executes the first strike to gauge how the prey would respond. The AO algorithm simulates this low-flying descent attack behavior using Eq. (10). It is performed when the current iteration is greater than two-thirds of the maximum iterations and a randomly generated value is less than 0.5. Eq. (10) introduces $X_3(iter + 1)$ as the solutions generated through the expanded exploitation approach. The parameters governing exploitation adjustment, $\alpha$ and $\delta$, are both fixed at a value of 0.1. These parameters play a role in fine-tuning the exploration and exploitation balance during the expanded exploitation stage. The values of $\alpha$ and $\delta$ help control the level of exploitation, influencing how the algorithm explores the promising regions discovered earlier and refines the solutions to find the optimal solution more effectively.

$$X_3(iter + 1) = \left(X_{best}(iter) - X_M(iter)\right) \times \alpha - r \\ + ((U - L) \times r + L) \times \delta \tag{10}$$

Narrowed exploitation: In the narrower exploitation phase, the Aquila adopts a "walking and grabbing the prey" strategy, characterized by a randomized approach towards the prey followed by an attack. This action is executed when the current iteration is greater than two-thirds of the maximum iterations and a randomly generated value is greater than 0.5. This behavior is simulated using Eq. (11). In Eq. (11), $X_4(iter + 1)$ signifies the fourth search solution generated, $X(iter)$ denotes the current solution during the $iter^{th}$ iteration, and a quality function referred to as $QF$ is computed using Eq. (12) to regulate and balance the search strategy. To determine the values of $G_1$ and $G_2$, which represent the Aquila's prey tracking movements, Eq. (13) and Eq. (14) are utilized.

$$X_4(iter + 1) = QF(iter) \times X_{best}(iter) \\ - (G_1 \times X(iter) \times r) - G_2 \\ \times Levy(D) + r \times G_1 \tag{11}$$

$$QF(iter) = t^{\frac{2 \times r - 1}{(1 - MaxIter)^2}} \tag{12}$$

$$G_1 = 2 \times r - 1 \tag{13}$$

$$G_2 = 2 \times (1 - \frac{iter}{MaxIter}) \tag{14}$$

### B. Particle Swarm Optimization

PSO is an intelligent, biologically inspired algorithm that draws its origins from the study of avian predatory behavior. At its core, PSO operates on the principle of identifying optimal solutions through collaborative interaction and the exchange of information among individual members within a group. In PSO, each individual is represented as a bird, and their positions and speeds are treated as independent variables. The objective function value at each location is related to the food density, and the goal is to find the optimal location with the highest food density, which corresponds to the optimal solution to the problem. Each bird adjusts its search direction and speed based on the difference between its historical best position and the best position found by the entire population. By continuously updating their positions and speeds and sharing information with each other, the bird swarm gradually

converges toward the optimal population location. This collective effort leads to finding the optimal solution called problem convergence.

Within the realm of optimization, the PSO algorithm is often conceptualized as a stochastic search challenge occurring in a D-dimensional space. The central aim is to optimize a given objective function. In this D-dimensional environment, a population of *n* particles are denoted as $p_i = (p_{i1}, p_{i2}, ..., p_{iD})^T$, where each $i^{th}$ particle is composed of a d-dimensional position vector $x_i = (x_{i1}, x_{i2}, ..., x_{id})^T$ and a velocity vector $v_i = (v_{i1}, v_{i2}, ..., v_{id})T$. The PSO algorithm commences with each particle initiating its search within the D-dimensional space, leveraging an initial set of randomized particles. Through a series of iterative updates, the particle embarks on a quest to identify an optimal solution. During this continuous exploration, the particle maintains its present optimal position, $p_i = (p_{i1}, p_{i2}, ..., p_{id})^T$, representing its local optimum, and its velocity $v_i = (v_{i1}, v_{i2}, ..., v_{id})^T$. The global optimal solution, $p_g = (p_{g1}, p_{g2}, ..., p_{gd})T$, signifies the finest solution collectively discovered by the entire particle swarm during optimization. In each iteration, the particle refines its position and velocity by considering two distinct "optimal solutions": its local best position and the global best position. By updating its position and velocity using the specified equations outlined in Eq. (15) and Eq. (16), the particle navigates towards its local best position while being influenced by the superior global best position identified by the swarm as a whole. The PSO algorithm recurrently applies these updates, fostering the gradual convergence of particles towards the global optimal solution. This iterative process orchestrates the collective efforts of particles, ultimately yielding optimization of the objective function and culminating in the discovery of the paramount solution for the given optimization quandary.

$$v_{id}(t + 1) = \omega v_{id}(t) + c_1 r_1 \big(p_{id}(t) - x_{id}(t)\big) + c_2 r_2 \big(p_{gd}(t) - x_{id}(t)\big) \tag{15}$$

$$x_{id}(t + 1) = x(t) + v_{id}(t + 1), \quad i = 1,2,...,N; d = 1,2,...,D \tag{16}$$

### C. Proposed IAO Algorithm

The IAO incorporates two main search methods, namely the Aquila Optimizer and Particle Swarm Optimizer, to enhance its search capabilities. A novel transition mechanism (TM) is employed to balance the search process and preserve the diversity of solutions. This transition mechanism, as shown in Eq. (17), aims to prevent the algorithm from getting trapped in local optima and improve the quality of the candidate solutions. By combining the strengths of both the Aquila Optimizer and Particle Swarm Optimizer and using the transition mechanism, the proposed IAO method aims to achieve more robust and efficient optimization performance.

$$TM = \frac{1}{2} Sin \left( \pi + 2\pi \times \frac{t}{T} \right) + rand \tag{17}$$

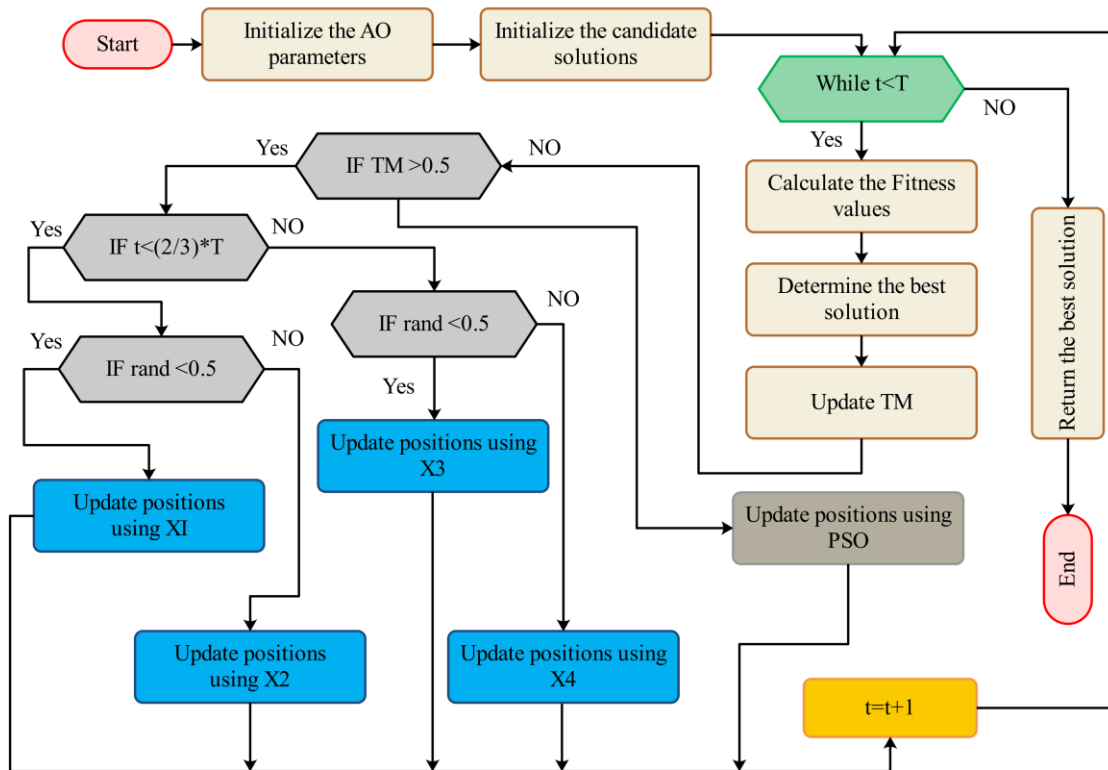

Fig. 2. The flowchart of the proposed method.

Fig. 2 illustrates the general procedure of the proposed IAO method. The method begins by initializing the solutions and defining the required parameters, including the transition parameter (TM). The TM is crucial in determining the

optimization process used in each iteration. During the optimization process, if the value of the TM is greater than the current iteration number (t), the algorithm utilizes the Aquila Optimizer's operators for updating the solutions. On the other hand, if the TM is less than or equal to the current iteration number (t), the Particle Swarm Optimizer's operators are employed for updating the solutions. By dynamically switching between the two search methods based on the TM, the proposed IAO method enhances the diversity of the solutions. It avoids getting trapped in specific search areas, especially local search areas. This approach allows the algorithm to balance exploration and exploitation effectively, leading to improved overall performance and better convergence toward the optimal solution.

## V. SIMULATION

To assess the superiority of the IAO method in solving large-scale cloud service composition problems, its performance is compared with several other algorithms: Genetic Algorithm (GA), Max-Min Ant System (MMAS), Artificial Bee Colony (ABC), and PSO. The comparison is conducted using two large-scale problems denoted by the task scale *T(n, m)*, where *n* represents the number of subtasks equal to 30, *m* represents the number of candidate services for each subtask, with $m \in \{100, 300\}$. For instance, *T(30, 300)* indicates 30 subtasks and 300 candidate services. In this comparison, the QoS evaluation index is normalized.

Fig. 3 and Fig. 4 present the box plots of the average QoS fitness values obtained from the experimental data for each cloud service composition problem scale. These box plots allow for a visual comparison of the performance of different algorithms, showcasing the distribution and variation in their average fitness values. Fig. 5 shows the average time consumption for each algorithm during the experiment. Based on the computational results, it is evident that the IAO method outperforms the other algorithms regarding the maximum fitness values obtained. In the *T (30, 100)* problems, the

maximum values in all five algorithms are relatively similar. However, as the scale of the problem increases, a noticeable gap starts to emerge between IAO and the other algorithms. IAO consistently performs at the top, GA and PSO at the bottom, and MMAS and ABC in the middle. The IAO method demonstrates faster optimization time compared to MMAS as the scale of the problem increases. This advantage becomes more pronounced for larger and more complex cloud service composition problems. IAO's faster optimization lies in its incorporation of GA to optimize the solutions generated by the ant colony algorithm. By combining these two optimization techniques, IAO can dynamically adjust and fine-tune the solutions, fully leveraging the strengths of the genetic algorithm.

The stability of the optimal solution is indeed superior in both IAO and MMAS compared to other algorithms, such as GA and PSO. The key reason behind this enhanced stability is that IAO and MMAS are designed to effectively avoid local optima during optimization. Ant-colony algorithms, including MMAS, utilize pheromone-based communication and exploration, which allows them to strike a balance between exploitation and exploration. This helps prevent premature convergence to local optima and encourages the algorithm to explore a more diverse and promising search space. On the other hand, GA and PSO are more prone to premature convergence, especially in complex optimization problems. This can lead to less stable solutions as they might get trapped in local optima, failing to explore other potential regions of the search space. It is evident from the results that IAO outperforms the other algorithms in terms of accuracy, especially as the scale of the problem increases. The higher accuracy achieved by IAO can be attributed to the strengths of the ant algorithm in searching large spaces. The AO is particularly well-suited for exploring complex and vast search spaces, as it leverages pheromone-based communication and dynamic adjustments to navigate the problem domain efficiently.

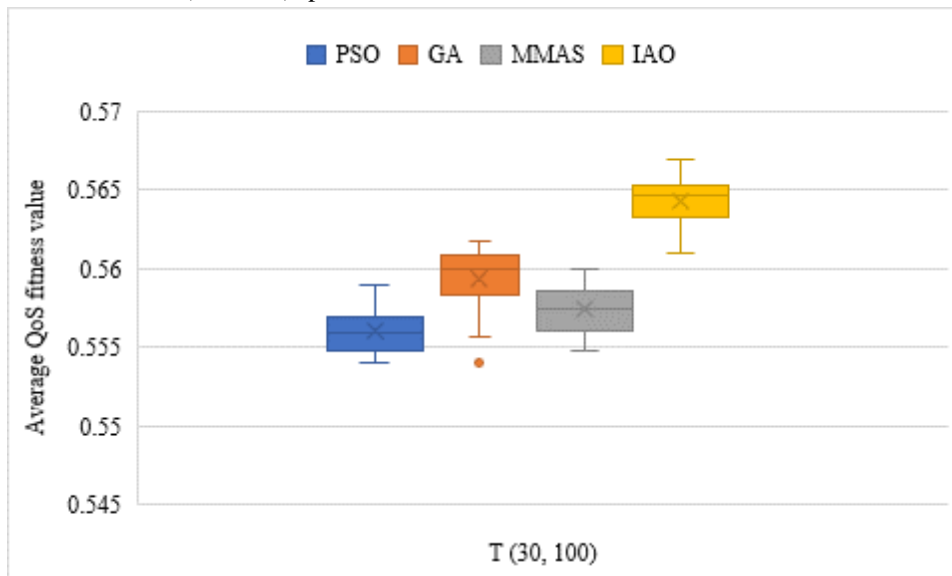

Fig. 3. Box plot of the optimal solution for 100 candidate services.
Fig. 4. Box plot of the optimal solution for 300 candidate services.

Fig. 5. Time consumption comparison.

Additionally, the iterative adjustment threshold and increased ant population size introduced in the IAO algorithm contribute to its improved accuracy. These modifications help fine-tune the search process and facilitate more thorough exploration, which enables IAOs to find high-quality solutions more effectively. As the scale of the problem grows, the advantage of IAO becomes more pronounced, as it can consistently deliver more accurate solutions compared to other algorithms like MMAS and GA. This demonstrates the capability of IAO as a robust and accurate optimization method, making it a promising choice for tackling large-scale cloud service composition problems and other complex optimization challenges.

## VI. CONCLUSION

Cloud computing has gained immense popularity due to its numerous benefits, such as cost-effectiveness and the ability to offer a wide range of hardware and software services. However, composing different services to fulfill complex requests poses challenging Np-hard problems. To overcome this, service composition becomes essential for creating more extensive services with enhanced functionalities. This paper introduced a novel hybrid method called IAO, which combines the strengths of both the conventional AO and PSO algorithms. By combining AO and PSO, this hybridization aims to address their weaknesses, such as low solution diversity and being trapped in local search. To tackle these challenges, the proposed IAO method incorporates a unique transition mechanism that enables seamless changes between search operators. This mechanism allows the algorithm to switch between AO and PSO when necessary, especially when either algorithm gets stuck, or the diversity of solutions declines. This adaptability enhances the overall performance and effectiveness of the hybrid approach. The performance of the

IAO method is extensively tested through experiments on the Cloudsim simulation platform. Comparative experiments are conducted, and the results demonstrate that IAO significantly improves the accuracy and stability of large-scale cloud service composition problems. Moreover, the time consumption of the algorithm is also optimized, showcasing its efficiency in solving complex optimization problems.

In future research, this work can be extended in several directions. First, a deeper exploration of the scalability and adaptability of the IAO in larger, more complex cloud environments could offer valuable insights. Additionally, investigating the integration of IAO with emerging technologies like edge computing or hybrid cloud setups could enhance its applicability across diverse computing landscapes. Further research could refine the transition mechanism of IAO to dynamically adapt to changing network conditions and varying service demands in real-time. Moreover, exploring the impact of IAO in multi-objective optimization scenarios to simultaneously optimize conflicting QoS metrics would be a compelling avenue for advancement. Lastly, a thorough investigation into the security implications and resilience of IAO against potential attacks or failures within cloud environments could be a pivotal direction for future improvement.

*Abstract*—**Cloud computing has become a viable option for many organizations due to its flexibility and scalability in providing virtualized resources via the Internet. It offers the possibility of hosting pervasive applications in the consumer, scientific, and business domains utilizing a pay-as-you-go model. This makes cloud computing a cost-effective solution for businesses as it eliminates the need for large investments in hardware and software infrastructure. Furthermore, cloud computing enables organizations to quickly and easily scale their services to meet the demands of their customers. Resource allocation is a major challenge in cloud computing. It is known as the NP-hard problem and can be solved using meth-heuristic algorithms. This study optimizes resource allocation using the Particle Swarm Optimization (PSO) algorithm and fuzzy logic system developed under the proposed time and cost models in the cloud computing environment. Receiving, processing, and waiting time are included in the time model. The cost model incorporates processing and receiving costs. Two experiments demonstrate the performance of the proposed algorithm. The simulation results demonstrate the potential of our mechanism, demonstrating improved performance over previous approaches in aspects such as providers' total income, users' total revenue, resource utilization, and energy consumption.**

*Keywords—Cloud computing; resource allocation; scheduling; PSO; fuzzy logic*

## I. INTRODUCTION

Cloud computing offers on-demand access to various computing resources, including software, platforms, and storage [1]. Coupled with IoT and big data applications, it has revolutionized information technology operations, becoming the enabling technology for next-generation communications [2]. Energy consumption is a significant challenge for cloud data centers, given the substantial and constantly evolving size of cloud computing infrastructures and the rapidly growing number of users [3]. From 2005 to 2010, there has been an average annual increase of 12% in energy consumption, which has intensified over the past few years [4]. Excessive energy consumption produces excessive heat emissions and increases costs, resulting in a degradation of system reliability and performance [5]. As energy costs rise and availability diminishes, data center resource management should be optimized for energy efficiency while ensuring high service levels [6]. Consequently, cloud service providers must guarantee that rising energy costs do not adversely affect their profit margins. Rising energy costs seriously threaten cloud infrastructures as they increase the Total Cost of Ownership (TCO) and reduce the Return on Investment (ROI) [7].

Energy efficiency in data centers is a complex problem since computing applications and data grow rapidly, and larger servers and disks are required to meet the processing times [8]. Green cloud computing aims to optimize the processing and management of computing infrastructure while reducing energy consumption [9]. The success of cloud computing depends on the sustainability of its future growth. The advent of cloud computing with increasingly pervasive frontend client devices interacting with backend data centers could cause energy consumption to skyrocket [10]. To promote green cloud computing, data centers should be operated efficiently. Cloud resources should be allocated according to user-specified Quality of Service (QoS) criteria via Service Level Agreements (SLAs) and minimize energy consumption. Multiple subscribers are served by combining the resources in the cloud [11]. Using a multi-tenancy model, the provider dynamically multiplexes the resources (physical and virtual) according to the requirements of each tenant [12]. Based on the lease and SLA agreement, the number of virtual resources will be assigned based on the needs of each client. As a result, as cloud service demand has grown, providers have had to scale up the number of resources and capabilities of cloud-based services to handle the increasing resource demands [13]. Fig. 1 shows a process for allocating resources in a cloud environment.

Integrating Internet of Things (IoT), machine learning, deep learning, and neural networks within cloud resource allocation marks a transformative shift in addressing the complexities of modern computing landscapes [14]. The IoT introduces a vast network of interconnected devices and sensors, generating copious data streams requiring efficient processing and resource allocation [15, 16]. Machine learning, especially when combined with deep learning and neural networks, enables cloud systems to learn, adapt, and make data-driven decisions, facilitating predictive analytics for demand forecasting and user behavior analysis [17, 18]. These technologies empower cloud resource allocation mechanisms by automating decision-making processes, optimizing resource distribution, and enhancing the scalability of computing systems [19]. Neural networks, a subset of deep learning, allow for pattern recognition, predictive modeling, and intelligent decision-

making, ensuring more accurate and adaptive resource allocation strategies [20, 21]. Leveraging IoT data and machine learning capabilities within cloud resource allocation not only enhances system efficiency but also allows for dynamic adjustments, adaptive resource scaling, and predictive provisioning, ultimately leading to improved QoS and streamlined cloud operations in a rapidly evolving technological landscape [22].

The significance of meta-heuristic algorithms in cloud resource allocation lies in their capacity to efficiently navigate cloud environments' complex, dynamic, and constantly evolving landscape, offering optimized solutions amidst varying user demands and operational challenges. This paper introduces a hybrid optimization algorithm to address the issues in multi-cloud resource allocation. Particle Swarm Optimization (PSO) algorithm and fuzzy logic system are combined as a hybrid approach to reduce the problems in multi-cloud resource allocation. The selected optimization algorithms are known for their optimal global solutions and rapid convergence characteristics. While PSO exhibits robust optimization capabilities, the integration of fuzzy logic manages the uncertainties and imprecisions inherent in the dynamic nature of cloud environments. Fuzzy logic enhances the adaptability and robustness of decision-making, particularly

in scenarios involving vague or uncertain data, thereby augmenting resource allocation's overall accuracy and effectiveness. This combined approach prioritizes QoS criteria and energy efficiency in cloud data center resource allocation. The principal contributions of this paper can be summarized as follows:

- Combining the PSO algorithm and fuzzy logic system for solving the resource allocation problem in cloud computing.

- Enhancing resource utilization and reducing the execution time of the resource allocation problem.

- Increasing user and provider utility and reducing the generational distance of the resource allocation problem.

This paper presents an efficient resource allocation model that takes advantage of the benefits of optimization algorithms. The remainder of the paper is organized in the following manner. Section II reviews the previous cloud resource allocation approaches. Section III describes the proposed cloud resource allocation mechanism. Experimental results are reported in Section IV. Section V concludes the paper.

Fig. 1. Cloud resource allocation process.

## II. RELATED WORK

Wang and Su [23] developed an algorithm for dynamically allocating resources among numerous cloud nodes operating in a big data context. Based on computing power and storage factors, this algorithm uses fuzzy pattern recognition to divide nodes and tasks into distinct levels. Therefore, a dynamic mapping between tasks and nodes is generated. Upon the arrival of a new task, only the nodes corresponding to the task level will join the bid. The algorithm uses a hierarchical approach to minimize communication traffic during resource allocation. Based on the results of experiments, the presented algorithm is more efficient regarding makes span and communication traffic than the Min-Min algorithm.

The cloud-based disassembly proposed by Jiang, et al. [24] abstracts the disassembly factory as a disassembly resource, allowing it to be allocated to disassembly tasks. Based on this

model, a cloud-based disassembly solution is developed that offers users a disassembly service tailored to their needs. Disassembly services are execution plans for tasks derived from scheduling and allocating disassembly tasks. The paper uses a mathematical model to describe the disassembly service formally by taking into account the uncertainty associated with disassembly processes and the precedence relationships between tasks involved.

Mousavi, et al. [25] presented a hybrid approach to load balancing that integrates Grey Wolves Optimization (GWO) and Teaching-Learning-Based Optimization (TLBO) algorithms, aiming to maximize throughput by balancing virtual machine loads and avoiding a local optimum trap. The algorithm is evaluated on eleven benchmark functions, and comparisons are made with particle swarm optimization (PSO), biogeography-based optimization (BBO), and GWO.

Cloud computing is characterized by elasticity, distinguishing it from other paradigms, such as cluster and grid computing. Based on the bio-inspired coral-reef optimization paradigm, Ficco, et al. [26] developed a meta-heuristic approach to cloud resource allocation. The resource reallocation schema was optimized using classic Game Theory based on cloud provider optimization objectives and customer requirements expressed through fuzzy linguistic SLAs.

Chen, et al. [27] presented a self-adapting resource allocation methodology that consists of several feedback loops, each involving a PSO-based runtime decision algorithm and an iterative QoS prediction model. Each iteration of the algorithm improves QoS values. Future resource allocation operations are determined based on the predicted QoS value and the PSO-based runtime decision algorithm. As the PSO-based algorithm iterates, no further improvements are suggested compared to current resource allocations. The proposed method is evaluated on the RUBiS benchmark, highlighting a 20% improvement in QoS prediction accuracy compared to the current state of the art based on the same historical data.

Singhal and Singhal [28] developed a Feedback-based Combinatorial Fair Economical Double Auction Resource Allocation Model (FCFEDARA) to determine provider genuineness based on the prices offered and feedback from customers. The proposed framework enables customers to access resources from different providers at the best prices and prioritizes genuine providers with good feedback over non-genuine providers with bad reviews. Providers and customers submit bundle bids and resource lists in the combinatorial double auction model. By assessing provider truthfulness, penalizing market spoilers, and giving preference to providers with positive feedback from customers, the proposed model takes care of the truthfulness of providers.

Thakur and Goraya [29] introduced a novel metaheuristic-based resource allocation approach for load balancing in cloud environments. The goal is to effectively reduce the uneven distribution of workloads between physical machines in addition to their resource capabilities. Consequently, the over- or under-loading of active physical machines is prevented. To develop a suitable resource allocation strategy for load balancing, dragonfly and PSO algorithms are combined. The proposed algorithm is superior to PSO, dragonfly algorithm, and comprehensive learning PSO in determining optimal resource allocation.

## III. PROPOSED METHOD

A new PSO algorithm is used in this paper to select the best member of the population. This algorithm outperforms existing multi-objective optimization techniques regarding calculation time, reasonable undefeated solutions distribution, and Pareto front convergence. Moreover, the Fuzzy set theory is used in this paper to select the best adaptive solution.

### A. Mathematical Formulation of the Problem

Each user requests a combination of the requested resources with different attributes, the required number of the resources, and a proposed cost to buy all the resources in a bundle form. Each provider presents a combination of the resources with different attributes, the number of the presented

resources, and a proposed cost to sell all the resources in a bundle form. The bundle is a request to buy with all bought products and a sell request with all products. Moreover, the meaning of a specific attribute of the requested items is the number showing the processor processing power, the accumulator capacity, bandwidth, and so on. The total number of requested resources should equal or less than the total number of all the presented resources. All the users requested resources' attributes should be equal to or less than all the presented attributes by the cloud presenter to assign the resources. After determining which provider can meet the user's requests, the cost that the user should pay to the provider is determined by a costing model. The costing model should be fair and beneficial for the provider and the user. The costing model used in this paper is the presented method in [30] and [31]. Table I lists the symbols and variables used in the equations.

TABLE I. SYMBOLS AND VARIABLES

| Symbol | Definition |
|---|---|
| N | Population size |
| n | Number of iterations |
| D | Number of dimensions |
| Rq | Users' requests |
| Sq | Providers' services |
| Rc | Average cost per user |
| Sc | The average cost for each provider |
| RSc | Average business cost |
| $C_u^p$ | The paid cost by the user u to the provider p |

Eq. (1) and Eq. (2) show the total number of a user's requested and presented items by the provider. Eq. (3) allows for dividing the user's suggested cost by the total number of requested products to determine the average cost per user. The average cost for each provider is the division of the proposed cost by the provider on the total number of provider items shown in Eq. (4). The average business cost of provider p and user u is determined based on the users and the provider's average costs using Eq. (5). The paid cost by the user u to the provider p is estimated through the number of assigned resources using Eq. (6). The earnings of each provider are presented in Eq. (7), which is equal to the paid cost minus the proposed cost in Eq. (6). The higher cost received by the provider for its resources than the expected cost leads to higher earnings by the provider.

Moreover, in each user's income, Eq. (8) equals the proposed cost of the user minus its paid in Eq. (6). It is also clear that more paid cost by the user to rent the requested resources to the provider than its proposed cost makes more earning for the user. The resource utilization rate in Eq. (9) is equal to the ratio of the total number of requested items by a user to the total items presented by the provider. Objective functions in Eq. (10), Eq. (11), and Eq. (12) show the total earnings of the providers, the total income of the users, and total resource utilization, respectively. The objective area in the proposed algorithm is three-dimensional, as shown in Eq. (13).

Moreover, the requested resources should not be more than the provided resources controlled by Eq. (14).

$$Rq_u = \sum_{l=1}^{k} q_k^{u} \qquad (1)$$

$$Sq_p = \sum_{l=1}^{k} q_k^{p} \qquad (2)$$

$$Rc_u = \frac{cost_u}{Rq_u} \qquad (3)$$

$$Sc_p = \frac{cost_p}{Sq_p} \qquad (4)$$

$$RSc_u^{p} = \left( \frac{Rc_u + Sc_p}{2} \right) \qquad (5)$$

$$c_u^{p} = RSc_u^{p} \times Rq_u \qquad (6)$$

$$Submitcost_p = c_u^{p} - cost_p \qquad (7)$$

$$Requestcost_u = cost_u - c_u^{p} \qquad (8)$$

$$quantity_p = \frac{Rq_u}{sq_p} \qquad (9)$$

$$f_1 = \sum_{p=1}^{m} (Submitcost_p) \qquad (10)$$

$$f_2 = \sum_{u=1}^{n} (Requestcost_u) \qquad (11)$$

$$f_3 = \sum_{u=1}^{n} \sum_{p=1}^{m} (quantity) \qquad (12)$$

$$Finess = [f_1\ f_2\ f_3] \qquad (13)$$

$$\sum_{u=1}^{n} \sum_{l=1}^{k} (q_k^{u} \le q_k^{p}\ and\ a_k^{u} \le a_k^{p}) \qquad (14)$$

### B. The Proposed Method for Cloud Resource Assignment

The proposed multi-objective method is proposed based on the PSO algorithm. Here, the algorithm and the way of making it multi-objective are explained. Then, the steps of the proposed method are presented:

*1) Particle swarm optimization algorithm:* The PSO algorithm employs a population-based stochastic process.

Particles move through the search space of an optimization problem. Particles' positions represent potential solutions. The particles search the search space for better positions by modifying their velocities under rules derived from behavior models of flocking birds. The PSO algorithm is known for its adeptness at approaching near-optimal solutions, a characteristic pivotal in addressing resource allocation concerns within cloud computing environments. The time complexity of the PSO algorithm typically operates at O(n*N), where n represents the number of iterations and N stands for the population size or number of particles in the swarm. In terms of space complexity, it generally stands at O(N*D), with D representing the number of dimensions in the given problem space.

*2) Multi-objective particle swarm optimization algorithm:* In MOPSO, a concept called the hall of fame or repository is used so that from the investigated best answers, the best of them that are undefeated answers are stored in a repository. These repository members are an approximation of the Pareto front. Each particle in MOPSO selects one repository's member as a leader when it wants to move. It is the experimented best position of that particle. However, the answers are distributed on a multi-dimensional plate. Vertical and horizontal lines should be used to tabulate the area initially. The cells in the space are then identified, including the repository members. Some cells may have repository members, but the priority is for the cells with less population because of maintaining diversity. One of the less congested cells is selected using the Roulette Wheel Selection method, and then one of the cell's members is selected as leader randomly. Each particle moves using Eq. (15) and Eq. (16).

$$v_{i\ (it+1)} = wv_i^{(it)} + c_1 r_1 (pbest_i^{(it)} - X_i^{(it)}) + c_2 r_2 (gbest^{(it)} - X_i^{(it)}) \qquad (15)$$

$$X_i^{(it+1)} = X_i^{(it)} + v_i^{(it+1)} \qquad (16)$$

The following comparisons should be made between the new role and the top memory: 1) If the new position beats the best memory, the new position replaces the best memory. 2) Nothing is performed if the best memory beats the new position. 3) If none of them is defeated, one of the positions is considered the best memory randomly. Then, undefeated members of the current population are the elites. Now, the quality of the response is controlled. Selecting the repository's member to remove is performed using the Roulette Wheel Selection method, but the cell with fewer roles in the diversity of the answers is selected. Here, the priority is for the cells with more population. The lack of memory has a limit on the repository size. The new members should be removed using the Roulette Wheel Selection method, depending on the crowded cells if the number of repository members exceeds the calculated capacity. A multi-objective problem that requires an agent in every square inch of space is being explored, and the PSO is an algorithm with a high convergence speed. As a

result, a mutation operator slows down convergence to ensure the entire space is thoroughly examined [31].

*3)* The proposed multi-objective particle swarm optimization algorithm through crowding distance

A new particle swarm optimization algorithm called $MOPSO - CD$ is proposed in [32]. A mutation operator is used in this algorithm, like the $MOPSO$ algorithm. Moreover, the crowding distance approach used in this algorithm is proposed in [33] and used in the $NSGA - II$ algorithm. This method is also used in $MOPSO - CD$ to find the optimal answers. The crowding distance for each answer approximates the answers' density around it. The studied problem has three objective functions. At first, the objective function values of each dimension are sorted decreasingly. Then, the previous and next points are selected rather than the problem's objective functions. The fractions of the dimension covered by the ith member of the population in the first, second, and third objective functions are obtained by Eq. (17), (18), and (19), and the crowding distance is obtained by Eq. (20).

$$d_i^1 = \frac{\left| f_1^{i+1} - f_1^{i-1} \right|}{f_1^{max} - f_1^{min}} \tag{17}$$

$$d_i^2 = \frac{\left| f_2^{i+1} - f_2^{i-1} \right|}{f_2^{max} - f_2^{min}} \tag{18}$$

$$d_i^3 = \frac{\left| f_3^{i+1} - f_3^{i-1} \right|}{f_3^{max} - f_3^{min}} \tag{19}$$

$$d_i = d_i^1 + d_i^2 + d_i^3 \tag{20}$$

It is beneficial if the population's ith member covers a bigger area. Hence, the higher priority is for the undefeated answers with higher crowding distance in the PSO algorithm. The undefeated answers in the external repository are sorted through the decreasing crowding distance decreasingly. Then, in each step, one of the top 10% of answers is selected randomly. If the repository is full, one of the last 10% of answers is selected randomly, and the new undefeated answer found in the last iteration replaces it. Algorithm 1 shows different steps of the PSO algorithm. Before the start of the main loop of the algorithm, the users' requests list and the providers' offerings, including the attributes, number, and proposed cost, should be received. Moreover, in the proposed algorithm, the particles' positions are defined as follows:

---

**Algorithm 1.** PSO algorithm

1. Initialize the population:

  1.1. Generate Xi

  1.2. Set particle velocity vi to zero (vi=0)

  1.3. Evaluate the fitness value of particle Xi

  1.4. Set the best position of each particle as Pbesti = Xi

  1.5. Update the global best position gbest with the best particle Xi

---

2. Initialize the number of iterations it = 0

3. Save undefeated answers of Xi in rep

4. Begin iteration:

  4.1. Calculate the crowding distance for each undefeated answer in rep

  4.2. Sort undefeated answers in rep based on their crowding distance in decreasing order

  4.3. For each particle Xi from 1 to nPop:

    4.3.1. Randomly select an optimal guide from the top 10% of the sorted rep for particle Xi and update its position in gbest

    4.3.2. Compute the new speed of each particle using equations (3-15) with c1=1 and c2=1

    4.3.3. Calculate the new position of each particle using equations (3-16)

    4.3.4. Adjust variable values of Xi to fit within the determined limits; if Xi exceeds the limits, reverse its particle speed by multiplying it by -1

    4.3.5. Implement a mutation operation on Xi

    4.3.6. Evaluate the objective function of Xi

  4.4. Update undefeated answers in rep:

    4.4.1. Calculate the crowding distance for each undefeated answer in rep

    4.4.2. Sort the undefeated answers in rep based on crowding distance in decreasing order

    4.4.3. Randomly replace one of the lower 10% of the sorted rep with the new answer Xi

  4.5. Update the best position of each particle if the new position defeats the stored position in memory

  4.6. Increment the iteration count it

5. Repeat steps 3 to 4 until the maximum number of iterations is reached

---

*4) The fuzzy-based approach for the adaptive solution:* Multi-objective optimization algorithms do not result in only one answer; a set of undefeated answers is obtained, the approximations of the first front. If a final answer is required, one of the answers should be selected as the resource allocation objective. To this aim, different methods are presented and used now, like the Fuzzy Set theory *[34]*. A membership function for each objective function is considered in *[35]*, given by Eq. (23).

$$\mu_o^s = \begin{cases} 1 & F_o \leq F_o^{min} \\ \dfrac{F_o^{max} - f_o^s}{F_o^{max} - F_o^{min}} & F_o^{min} < f_o^s < F_o^{max} \\ 0 & F_o \geq F_o^{max} \end{cases} \tag{23}$$

A normalized membership function is obtained using Eq. (24) for each undefeated solution. The best adaptive solution is the answer with the most value for $\mu^s$.

$$\mu^s = \frac{\sum_{o=1}^{Nobj} \mu_o^s}{\sum_{s=1}^{S} \sum_{o=1}^{Nobj} \mu_o^s} \qquad (24)$$

## IV. SIMULATION

The proposed algorithm is simulated on a Microsoft Windows system using Matlab. Experiments are divided into three categories: Small-Scale (SS), Middle-Scale (MS), and Large-Scale (LS). The total number of users and providers related to the three experiments is (20, 5), (15, 50), and (30, 100), respectively. The population size is 75, the maximum number of repetitions is 100, and the personal and collective learning coefficients are 1. The Inertia Weight is W=0.4, and the mutation rate is mu=0.5. The resource attributes are as follows:

- The power and speed of the computer processor are measured by Million Instruction per Second (MIPS) with the range of [220, 1000].

- The memory shows the amount of memory in MB with the range of [256, 512, 1024, 2048].

- The accumulator shows the amount of accumulator in MB with the range of [1500, 40000].

- Bandwidth shows the amount of bandwidth in bits per second with the range of [120, 1000].

- The proposed cost is expressed as the cost unit per million instructions with the range of [0.012-0.1046].

### A. Performance Measures

The performance measures of this work are as follows:

- Total earnings of the provider: proportional to Eq. (10)

- Total incomes of the users: proportional to Eq. (11).

- Total resource utilization: proportional to Eq. (12).

- Generation distance: proportional to the presented model in [26].

- The distance: proportional to the model in [27].

### B. The Experimental Results

Two distinct experiments are conducted in this study. Each experiment compares the performance of the suggested method with that of the other methods.

*1) First experiment:* In this experiment, the proposed method performance is compared with NSGA-II *[36]* and MOPSO *[37]* algorithms in terms of the answers' quality, generation distance, distance, and execution time. Tables II to IV show the comparison of these three algorithms comparisons through the previously explained six measures for three types of experiments. Based on three types of experiments, the results for the provider's total earnings, the total users' income, the total resource utilization, and the generation distance for each algorithm are shown in Fig. 2 to Fig. 5. The performance of the proposed algorithm is superior to those of the other three algorithms. Fig. 6 to Fig. 7 illustrate the distance and execution time results for the mentioned algorithms. The proposed algorithm had an average improvement rate of 51% in total resource utilization, 50% in generation distance, and 16.5% in execution time when compared with MOPSO.

*2) Second experiment:* Here, the proposed method's performance is compared with the Artificial Fish Swarm Optimization algorithm (AFSO) [38]. This experiment examines the proposed method's time, cost, and energy efficiency. Fig. 8 illustrates the performance of the proposed method. As the number of tasks increases, the execution time will also increase. Fig. 9 illustrates an analysis of the performance in terms of cost. System performance is affected by the maximum cost. Fig. 10 also illustrates performance in terms of energy consumption. An increase in energy means an increase in cost as well. The proposed algorithm improved the total execution time by 22%, cost by 9%, and energy consumption by 21% compared with AFSO.

TABLE II. STATISTICAL COMPARISON FOR SMALL-SCALE

| Parameters | NSGA-II | MOPSO | PSO-fuzzy |
|---|---|---|---|
| Total earnings of the provider | 0.0852 | 0.01123 | 0.1952 |
| Total incomes of the users | 0.2962 | 0.3740 | 0.5124 |
| Total resource utilization | 5.5175 | 7.0364 | 12.212 |
| Generation distance | 0.0385 | 0.022 | 0.00931 |
| The distance | 0.0545 | 0.0928 | 0.03012 |
| Execution time (sec) | 64.51 | 18.74 | 11.12 |

TABLE III.    STATISTICAL COMPARISON FOR MIDDLE-SCALE

| Parameters | NSGA-II | MOPSO | PSO-fuzzy |
|---|---|---|---|
| Total earnings of the provider | 0.1786 | 0.2340 | 0.561 |
| Total incomes of the users | 0.5908 | 0.7710 | 2.1325 |
| Total resource utilization | 15.7246 | 19.2885 | 42.124 |
| Generation distance | 0.0067 | 0.0043 | 0.0012 |
| The distance | 0.0197 | 0.0394 | 0.00124 |
| Execution time (sec) | 68.187565 | 22.224956 | 15.324 |

TABLE IV.    STATISTICAL COMPARISON FOR LARGE-SCALE

| Parameters | NSGA-II | MOPSO | PSO-fuzzy |
|---|---|---|---|
| Total earnings of the provider | 1.0241 | 1.3480 | 2.125 |
| Total incomes of the users | 1.3848 | 2.0113 | 3.163 |
| Total resource utilization | 31.2672 | 42.2504 | 65.260 |
| Generation distance | 0.0124 | 0.0062 | 0.00325 |
| The distance | 0.0421 | 0.0784 | 0.0231 |
| Execution time (sec) | 87.255300 | 28.799435 | 18.215 |
Fig. 2.   Total earnings of the provider comparison.
Fig. 3.   Total incomes of the user's comparison.
Fig. 4.   Total resource utilization comparison.

Fig. 5.   Generation distance comparison.

Fig. 6.   The distance comparison.
Fig. 7.   Execution time comparison.

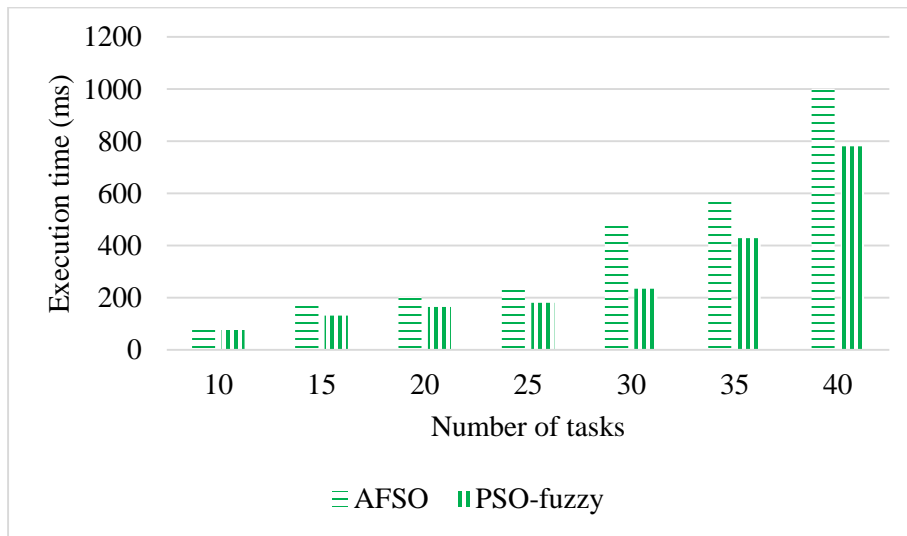

Fig. 8.   Execution time comparison.

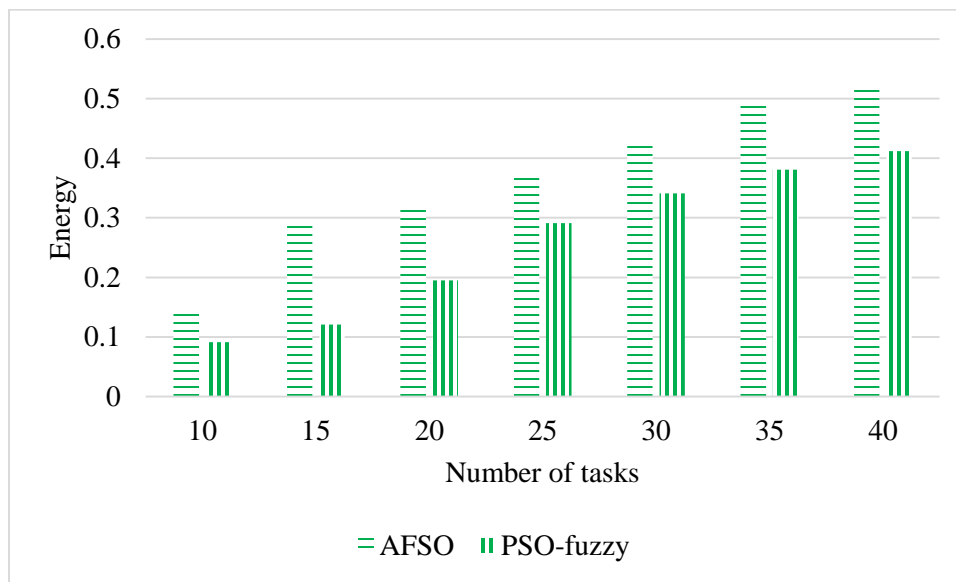
Fig. 9.   Cost comparison.


Fig. 10. Energy consumption comparison.

Performance measures expressed proportionally through specific mathematical models encompass key indicators such as total provider earnings, user incomes, resource utilization, generation distance, and execution time. In the first experiment, the PSO-fuzzy algorithm's performance is benchmarked against NSGA-II and MOPSO algorithms, showcasing superior results across various metrics. Notably, the proposed algorithm exhibits an average improvement of 51% in resource utilization, a 50% enhancement in generation distance, and a substantial 16.5% reduction in execution time compared to MOPSO. The PSO-fuzzy methodology is pitted against the Artificial Fish Swarm Optimization (AFSO) algorithm in the second experiment. The results highlight a marked improvement in execution time by 22%, cost efficiency by 9%, and a notable 21% reduction in energy consumption when compared to AFSO. These findings underscore the robustness and efficiency of the PSO-fuzzy algorithm in optimizing resource allocation and cost management across varying scales and scenarios within cloud computing environments.

## V. CONCLUSIONS

This paper proposed an optimal resource allocation method combining the PSO algorithm and fuzzy logic system based on the presented time and cost models in the cloud computing environment. The time model includes receiving, processing, and waiting times. Costs associated with processing and receiving are included in the cost model. The PSO algorithm was applied to the cloud environment for optimal resource allocation. The fuzzy logic system was used to evaluate the time and cost models. The proposed algorithm's efficacy was clearly demonstrated through a series of meticulously designed experiments. In the initial experiment, comparative analysis against established algorithms, namely NSGA-II and MOPSO, revealed the superiority of our method concerning providers' total income, users' total revenue, and resource utilization. Subsequently, the second experiment showcased the algorithm's superior performance in execution time, cost-

effectiveness, and energy consumption when juxtaposed with the AFSO algorithm. These results unequivocally establish the proposed algorithm's prowess, emphasizing its effectiveness in both performance and efficiency metrics. The outcomes affirm the superiority of our algorithm for scheduling within cloud computing systems, surpassing existing methodologies. The success of this approach not only underscores its potential in addressing the resource allocation challenge but also signifies a significant stride toward optimizing cloud computing operations. However, while these results are promising, future work should delve into further validation across a more extensive range of scenarios and consider real-world implementations to solidify the algorithm's robustness and applicability in diverse cloud environments.

# Efficient Cloud Workflow Scheduling with Inverted Ant Colony Optimization Algorithm

Hongwei DING, Ying ZHANG*

Hebei Software Institute, Hebei, Bao ding, 071000, China

*Abstract*—Cloud computing has risen as a prominent paradigm, offering users on-demand access to computing resources and services via the Internet. In cloud environments, workflow scheduling plays a vital role in optimizing resource utilization, reducing execution time, and minimizing overall costs. As workflows comprise interdependent tasks that need to be assigned to Virtual Machines (VMs), the complexity of the scheduling problem increases in proportion to workflow size and VM availability. Due to its NP-hard nature, finding an optimal scheduling solution for workflows remains a challenging task. To address this problem, researchers have turned to metaheuristic approaches, which have shown promise in finding near-optimal solutions for complex combinatorial optimization problems. This paper proposes a novel metaheuristic algorithm called Inverted Ant Colony Optimization (IACO) for workflow scheduling in cloud environments. IACO is a variation of the traditional ACO algorithm, where the updated pheromone has an inverted influence on the path chosen by the ants. By leveraging the complementary nature of these two algorithms, our proposed algorithm aims to achieve superior workflow scheduling performance regarding total execution time and cost, surpassing existing approaches.

*Keywords—Cloud computing; workflow scheduling; virtualization; task allocation; swarm intelligence; optimization*

## I. INTRODUCTION

Cloud computing is a technological advancement that harnesses the capabilities of the Internet and distant centralized servers to supply users with flexible services. These services are delivered using a diverse range of distributed resources, catering to various quality of service (QoS) requirements [1]. Prominent cloud computing platforms include Aneka, Microsoft Azure, Google App Engine, and Amazon EC2. Clouds are generally classified into several types: public, private, community, hybrid, and cloud federation [2]. Public clouds are accessible to the general public and are owned and managed by external entities known as independent cloud service providers. Computing resources, like applications, storage, and servers, are available to an array of businesses or individuals [3].

In contrast, private clouds are owned by an individual organization and are either hosted internally or handled exclusively by an external provider for that organization's use [4]. Community clouds are shared among multiple organizations with similar interests or requirements. These clouds are designed to cater to the specific needs of a particular community, such as government agencies, educational institutions, or healthcare providers [5]. Hybrid clouds integrate elements from both public and private clouds. In this

model, organizations can distribute applications and data across multiple cloud deployment models, interconnected to function as a cohesive infrastructure. Cloud federation involves the interconnection and collaboration of multiple cloud infrastructures to work as a single unified cloud environment. It enables seamless movement of workloads and data among different cloud providers, enhancing flexibility and scalability in cloud computing [6].

Cloud computing is categorized into three primary service models: Software-as-a-Service (SaaS), Platform-as-a-Service (PaaS), and Infrastructure-as-a-Service (IaaS) [7]. In SaaS, software applications are delivered to users online through subscriptions. Users can use these services remotely without installation or local device maintenance. The responsibility for hosting, maintenance, and updates lies with the SaaS provider. PaaS offers a platform for developers to build, deploy, and manage applications with no need for infrastructure management. PaaS provides developers with access to a set of development tools, programming languages, and runtime environments, facilitating the creation and execution of applications. In IaaS, users subscribe to virtual machines, servers, networking components, and other infrastructure resources from a cloud provider. IaaS gives customers enhanced control over infrastructure without requiring them to invest in physical hardware and its maintenance [8].

Virtualization is a critical technology in cloud computing that enables the coexistence of multiple Virtual Machines (VMs) on a single physical machine. A VM is a simulated computer system that executes tasks assigned by users. This capacity for VM instantiation empowers users to run their applications across resources that encompass diverse functionality and cost attributes. Orchestrating this arrangement within each physical machine or server is a software layer, colloquially referred to as the hypervisor or VM monitor. The hypervisor serves as a facilitator for VM creation and ensures their isolated execution, allowing multiple VMs to operate independently and securely on the same physical hardware. The hypervisor is responsible for efficiently managing the allocation of resources and providing a seamless and robust virtualization environment for cloud computing [9].

Workflow scheduling poses a substantial challenge within the context of cloud computing, entailing the intricate assignment of workflow tasks to VMs based on a multitude of operational and technical requisites [10]. Workflows are constructed from an array of interdependent tasks, interlinked by either data or functional dependencies, necessitating meticulous consideration during the scheduling endeavor. Nonetheless, the task of workflow scheduling in cloud

environments is classified as an NP-hard optimization problem, rendering the attainment of an optimal schedule a formidable undertaking [11]. The cloud environment typically encompasses a multitude of VMs, engendering intricacies in orchestrating an array of user tasks while accounting for diverse scheduling objectives and elements. For instance, a scheduling scheme may prioritize supporting Service Level Agreements (SLAs), predetermined timeframes, and cost limitations. Additionally, scheduling strategies may take into account parameters like the availability of cloud resources and services, load balancing, and resource utilization to make informed scheduling plans.

The integration of cutting-edge technologies such as the Internet of Things (IoT), machine learning, deep learning, and neural networks has revolutionized workflow scheduling, particularly in cloud environments. The IoT facilitates the interconnectedness of devices and sensors, offering real-time data collection and sharing [12, 13]. Machine learning techniques, including supervised and unsupervised algorithms, analyze this data to predict and optimize workflow patterns [14, 15]. Deep learning, a subset of machine learning, uses intricate neural network architectures to process complex data representations, making it adept at recognizing patterns and optimizing scheduling decisions [16]. Neural networks, inspired by the human brain's structure, excel in learning from data and making informed decisions based on this acquired knowledge [17]. Their application in workflow scheduling involves predictive analysis, resource allocation, and task optimization [18]. Collectively, these technologies enable intelligent decision-making, predictive scheduling, and adaptive allocation of tasks within cloud environments. By harnessing IoT data with machine learning, deep learning, and neural networks, workflow scheduling becomes more agile, responsive, and adept at handling the dynamic and complex demands of cloud-based applications, ultimately improving efficiency, resource utilization, and overall performance. Their integration not only streamlines operations but also paves the way for self-optimizing and self-adapting systems in cloud workflow management [19, 20].

Meta-heuristic algorithms are key to workflow scheduling within cloud computing due to the inherent complexity of task allocation. These algorithms, by their nature of adaptive and efficient search strategies, offer an effective way to navigate the vast solution space, addressing the NP-hard nature of scheduling problems [21]. They enable the optimization of resource allocation, contributing significantly to reduced execution times, minimized costs, and improved overall efficiency in cloud-based workflow management. Inverted Ant Colony Optimization (IACO) represents a deviation from the conventional ACO algorithm, which is a metaheuristic derived from the foraging behavior of real ants. In ACO, ants construct solutions by probabilistically choosing paths in a graph based on pheromone trails and heuristic information. The pheromone trails reflect the attractiveness of edges in the graph, and ants deposit pheromones on the paths they traverse. Over time, paths with higher pheromone concentrations become more attractive to other ants, leading to the emergence of high-quality solutions. The IACO algorithm introduces a novel concept to the ACO framework called "inversion." In the traditional ACO, the pheromone trail is reinforced for successful paths, and it is evaporated gradually to encourage exploration. However, in IACO, the pheromone trail on the best path (i.e., the path with the highest desirability) is reduced instead of increased during the pheromone update process. This reduction is referred to as "inversion". The core idea behind the inversion mechanism in IACO is to enhance exploration capabilities. By reducing the pheromone level on the best path, the algorithm encourages ants to explore alternative routes rather than always favoring the currently best-known path. This helps in diversifying the search space and prevents the algorithm from getting stuck in local optima. For workflow scheduling in cloud computing, IACO is applied to find an optimized allocation of tasks to VMs, aiming to lower the total execution time and overall costs. In this context, the graph represents the task dependency graph, and ants traverse paths by assigning tasks to available virtual machines. The main contributions of the study can be summarized as follows:

- Adaptation of traditional ACO algorithm with an inversion mechanism to enhance exploration capabilities and prevent local optima convergence.

- Improvement in the allocation of tasks to VMs, leading to reduced total execution time and minimized costs in cloud-based workflow scheduling.

- Establishment of a pioneering approach that sets a potential benchmark for optimization in cloud computing, influencing future research and practical implementations.

## II. RELATED WORK

Choudhary, et al. [22] combined the Heterogeneous Earliest Finish Time (HEFT) heuristic and the Gravitational Search Algorithm (GSA) for workflow scheduling. The GSA is a powerful meta-heuristic that imitates the law of gravity to search for optimal solutions, while HEFT is a widely used heuristic that schedules tasks based on their earliest finish times on heterogeneous resources. One of the key contributions of their work is the introduction of a new factor called "cost time equivalence," which enhances the realism of the bi-objective optimization process. By considering the monetary cost ratio (MCR) and the schedule length ratio (SLR) as performance metrics, they compare the proposed algorithm's performance with existing algorithms. To validate their results, rigorous experiments are conducted over various scientific workflows. They demonstrate the effectiveness of their proposed algorithm by comparing it with standard GSA, Hybrid Genetic Algorithm (HGA), and HEFT. Statistical tests, such as Analysis of Variance (ANOVA), are utilized to validate the results. The simulation results consistently show that the proposed approach outperforms the existing algorithms in terms of both makespan and cost optimization. The algorithm's effectiveness is demonstrated across different workflow scenarios, providing robust evidence of its superiority over the compared algorithms.

Elsherbiny, et al. [23] introduced a novel algorithm that extends the Intelligent Water Drops (IWD) algorithm, a nature-inspired optimization method, to optimize the scheduling of workflows in cloud computing environments. The suggested

algorithm is applied and incorporated into the workflow simulation toolkit, allowing for comprehensive testing in various simulated cloud environments with different cost models. The results of the experiments demonstrate that the proposed IWD-based algorithm outperforms classical workflow scheduling algorithms in terms of both performance and cost. They conducted a thorough comparison with several well-known scheduling algorithms. In most situations, the proposed IWD-based algorithm exhibited noticeable enhancements in terms of both performance and cost, outperforming the alternative algorithms. This showcases the effectiveness and efficiency of the IWD-based approach in optimizing workflow scheduling for cloud computing environments.

Ismayilov and Topcuoglu [24] address the intricate challenge of dynamic workflow scheduling within the context of a Dynamic Multi-Objective Optimization Problem (DMOP). This dynamic aspect arises from two primary sources: resource failures (manifested as software or hardware faults) and the inherent variability in the number of objectives during the execution of workflows in real-world cloud computing scenarios. To surmount this intricate problem, the authors propose an innovative prediction-based dynamic multi-objective evolutionary algorithm named NN-DNSGA-II. This algorithm ingeniously combines the capabilities of an artificial neural network with the NSGA-II algorithm, allowing it to make informed predictions concerning the evolving objectives and subsequently adapt its strategies accordingly. The study also involves the adaptation of five prominent non-prediction-based dynamic algorithms from the existing literature, with the overarching goal of addressing the dynamic workflow scheduling dilemma. The NN-DNSGA-II algorithm is thoughtfully designed to encompass six distinct objectives within the scheduling process. It aims to minimize critical aspects such as makespan, cost, energy consumption, and degree of imbalance while simultaneously maximizing attributes like reliability and utilization. To assess its efficacy, the authors conducted comprehensive empirical studies employing real-world applications sourced from the Pegasus workflow management system. This rigorous evaluation entails a range of metrics tailored for DMOPs characterized by unknown true Pareto-optimal fronts. Metrics include considerations such as the number of non-dominated solutions, Schott's spacing, and the Hypervolume indicator. The findings derived from the empirical investigation reveal the remarkable performance of the NN-DNSGA-II algorithm. It consistently outperforms alternative algorithms across various scenarios, underlining its supremacy in effectively managing dynamic workflow scheduling imbued with multiple objectives and unknown true Pareto-optimal fronts.

Mangalampalli, et al. [25] introduced a novel workflow-scheduling mechanism that incorporates task priorities to schedule tasks onto appropriate virtual resources efficiently. The Whale Optimization Algorithm (WOA) was used as the methodology to model this algorithm. Extensive simulations were conducted using the workflow simulator to evaluate the proposed mechanism's performance. The mechanism was compared against existing algorithms, including PSO, CS, ACO, and GA. The simulation results revealed significant improvements in makespan, migration time, and energy consumption when using the proposed mechanism. These improvements indicate the effectiveness of the WOA-based workflow-scheduling approach in optimizing task scheduling in cloud computing environments. By considering task priorities, the proposed mechanism is able to make more informed and efficient scheduling decisions, leading to reduced makespan (total execution time), migration time (task relocation between resources), and energy consumption. These improvements are crucial for enhancing the overall performance and resource utilization in cloud-based workflow management.

Zeedan, et al. [26] introduced an innovative approach termed Enhanced Binary Artificial Bee Colony-based Pareto Front (EBABC-PF) for optimizing workflow scheduling in cloud computing environments. The proposed approach involves a sequence of strategic steps aimed at achieving efficient task scheduling. The initial step of the approach involves task prioritization using the HEFT algorithm. HEFT organizes tasks based on their earliest finish times across heterogeneous resources, thereby establishing a prioritized sequence. Subsequently, an initial solution is constructed using the Greedy Randomized Adaptive Search Procedure (GRASP), a constructive metaheuristic approach renowned for its optimization capabilities. The core task scheduling phase is executed through the utilization of the enhanced Binary Artificial Bee Colony (BABC) algorithm. This modified version of the BABC algorithm integrates several enhancements specifically targeted at refining the local search process. The process incorporates circular shift and mutation operators, which are applied to the population's food sources while considering the improvement rate. These enhancements contribute to augmenting the algorithm's search capacity and effectiveness. The proposed EBABC-PF approach is simulated and implemented using WorkflowSim, an extension of the CloudSim tool designed to manage workflows within cloud environments. To assess its performance, the approach is rigorously compared against a range of other scheduling algorithms, which include HEFT, Deadline Heterogeneous Earliest Finish Time (DHEFT), Non-dominated Sort Genetic Algorithm (NSGA-II), and the standard BABC algorithm. This comparative analysis is conducted across diverse task sizes and benchmark workflows. The simulation results obtained exhibit the exceptional efficiency of the proposed EBABC-PF approach across multiple performance metrics. It notably outperforms the alternative algorithms in terms of makespan (total execution time), processing cost, and resource utilization. This finding underscores the approach's effectiveness in optimizing workflow scheduling within cloud computing environments, rendering it a superior choice for this intricate task.

## III. Proposed Approach

### A. Problem Statement

In the domain of cloud computing, workflow scheduling involves the representation of workflows as Directed Acyclic Graphs (DAGs), denoted as $G = (V, E)$. $V$ refers to a collection of vertices, each representing an individual task within the workflow. $E$, on the other hand, denotes the set of edges

signifying task dependencies. In this setup, tasks must be executed in a specific order, where parent tasks precede the execution of their child tasks. Fig. 1 offers a concrete illustration of task dependencies spanning from $T_1$ to $T_{10}$. Serving as the root node, $T_1$ takes the lead as the first task to be executed. Once $T_1$ is finished, tasks $T_2$ and $T_3$, located on the first tier of the DAG, are initiated. In a parallel manner, once task $T_2$ is accomplished, tasks $T_4$ and $T_5$ are set into motion.

Additionally, the execution of task $T_6$ is contingent upon the completion of task $T_3$, thus establishing $T_3$ as the necessary precursor to $T_6$. Scientific workflows encompass a specialized class of workflows extensively utilized across a range of scientific fields, such as astronomy, biology, and gravitational waves, among others. Prominent instances of practical scientific workflows include SIPHT, LIGO, Epigenomics, CyberShake, and Montage, all meticulously cataloged by the Pegasus project. The structural depiction of these scientific workflows is presented in Fig. 2. The scheduling of workflows can be perceived as a mapping function, allocating numerous interdependent tasks to available virtual machines. A sample mapping is illustrated in Fig. 3, demonstrating the allocation of n tasks to m VMs. In such instances, when employing a brute

force algorithm, there emerge $m*n$ potential combinations. Consequently, the intricacy of workflow scheduling is acknowledged, and achieving a solution within polynomial time is not attainable. Consequently, the pursuit of a nearly optimal resolution to the workflow scheduling predicament proves advantageous and attainable through the assistance of meta-heuristic algorithms.

Fig. 2. The structural depiction of scientific workflows.
Fig. 3. Task mapping model.

## B. Fitness Function

The optimization algorithm aims to enhance specific parameters within the fitness function. In this context, we have employed two distinct fitness functions, labeled *F1* and *F2*, which are the focal points of optimization through the proposed algorithm. The initial fitness function, *F1*, encompasses a synthesis of the Total Execution Time (TET), whereas the subsequent fitness function, *F2*, is constructed from the Total Execution Cost (TEC). The precise formulations of TET and TEC are outlined in Eq. (1) and Eq. (5), respectively.

$$Fitness\ (F_1) = Total\ Execution\ Cost\ (TEC) \tag{1}$$

The total execution time, often referred to as the makespan, signifies the longest duration taken by tasks within the workflow to reach completion. But it quantifies the time necessary for accomplishing all tasks distributed among various VMs. The mathematical expression to compute the makespan of the workflow can be deduced from Eq. (2), where $CT_i$ symbolizes the completion time of task $T_i$ within the workflow. The completion time of a task encompasses its entire execution duration, and in cases where task dependencies exist, the waiting time of preceding tasks is also considered. The calculation of completion time is presented in Eq. (3). The waiting time for task $T_i$ is established as the utmost completion time among all predecessor tasks within the workflow, as delineated in Eq. (4). Furthermore, the execution time of task $T_i$ on $j^{th}$ VM can be evaluated using Eq. (5). Here, $SZ_{Task}$ signifies the size of task $T_i$, quantified in million instructions (MI), $Num\ (PE_j)$ represents the count of cores allocated to $j^{th}$ VM, and $PE_{Unit}$ denotes the magnitude of each core in Millions of Instructions per Second (MIPS).

$$TET_W = \max\{CT_t | 1,2,\dots,m\} \tag{2}$$

$$CT_i = \begin{cases} ET_i & if\ pred(T_i) = \emptyset \\ WK_i + ET_i & if\ pred(T_i) \neq \emptyset \end{cases} \tag{3}$$

$$WK_i = \begin{cases} 0 & if\ pred(T_i) = \emptyset \\ \max(CT_i) & if\ pred(T_i) \neq \emptyset \end{cases} \tag{4}$$

$$ET_{i,j} = \frac{SZ_{Task}}{Num(PE_j) \times PE_{Unit}} \tag{5}$$

Eq. (6) delineates the process for calculating TEC. The TEC for the $i^{th}$ VM is derived by calculating the disparity between the Least End Time (LET) and the Least Start Time (LST) of that specific VM. The cost associated with the $i^{th}$ VM, denoted as *C[i]*, is uniformly set at 1 across all VMs. To provide further clarity, Eq. (7) and Eq. (8) elucidate the mechanics behind computing the LET and LST, respectively. LET pertaining to the $i^{th}$ VM corresponds to the highest execution time among all tasks executed on that particular VM. Conversely, LST is determined as the minimum execution time of tasks in progress on the $i^{th}$ VM.

$$Total\ Execution\ Cost\ (TEC) = \sum_{i=0}^{VM} C[i] \times (LET[i] - LST[i] \tag{6}$$

$$LET[i] = \max(ET[i]) \tag{7}$$

$$LST[i] = \min(ET[i]) \tag{8}$$

## C. Proposed Algorithm

ACO algorithms harness a populace of ants to collaboratively address optimization challenges, navigating graphs to discover paths of minimal cost while upholding specific constraints. The behavior of these ants encompasses two distinct groups: a smaller ensemble lays down pheromone trails, while the other contingent diligently tracks these trails, reinforcing them while circumventing impulsive moves. As time elapses, the potency of these trails diminishes, leading to a waning allure for the ants. Let *G = (V, E)* symbolize the graph that underpins the optimization conundrum, where *V* denotes vertices and *E* signifies edges. On this graph, viable pathways correspond to potential resolutions for the optimization predicament. While in pursuit of the shortest path, the ants deposit pheromones along their journey, cultivating an enduring memory of the exploration process. Furthermore, heuristic values might be attributed to the graph's edges, derived from antecedent knowledge or real-time feedback, exerting influence over the ants' conduct.

The decision-making process of the ants is probabilistic in nature and relies on their memory, the constraints of the problem, and the ant-routing table, a localized data structure housing pheromone trails and heuristic values. Pheromone updates transpire through two distinct mechanisms: an online step-by-step update involving the deposition of pheromone by the ant while traversing an edge and an online delayed update, which involves adjusting pheromone trails after discovering a solution and retracing the path in reverse. Additional processes for updating pheromone trails include daemon actions and pheromone evaporation. Daemon actions, while discretionary, enable ants to execute actions that are beyond their individual capacities, often involving centralized actions. Pheromone evaporation entails a gradual reduction in the strength of

pheromone trails over time. This mechanism prevents the convergence toward suboptimal regions and promotes the exploration of novel areas within the graph.

**Algorithm. 1.** Generic ACO algorithm

Initialize

**While** stop criteria are not met **do**

   **For all** ant $a$ in $A$ **do**

     Position a in startNode

   End for

   Repeat

     **For all** ant $a$ in $A$ **do**

       Choose nextNode

       Pheromone$_{(currentNode,nextNode)}$+=Update

     End for

   **Until** every ant has a solution

   **For all** edge $e$ in $B$ **do**

     Pheromone$_e$+=Deposit

   End for

   **For all** edge $e$ in $E$ **do**

     Pheromone$_e$-=Evaporation

   End for

End while

Eq. (9) calculates the probability of an ant selecting a particular path. It depends on the number of pheromones$\tau_{i,j}$, present on the path between nodes $i$ and $j$ and the reverse of the distance ($\eta_{i,j}$) between these two nodes. The parameters $\alpha$ and $\beta$ are control parameters that influence the relative importance of pheromones and distance in the probability calculation.

$$p_{i,j}^{k} = \frac{[\tau_{i,j}]^{\alpha}[n_{i,j}]^{\beta}}{\sum_{l=j_i}[\tau_{i,l}]^{\alpha}[n_{i,l}]^{\beta}} \qquad (9)$$

The ants act like scouts, searching for food (appropriate service corresponding to user demands) in the environment. Once they find food, they return to their nests, dropping pheromones on the trails they have traversed. These

pheromones serve as a form of communication for other ants, indicating the quality of the path. The pheromone trail amount can either increase when ants deposit pheromone or decrease over time due to pheromone evaporation. Eq. (10) calculates the pheromone evaporation rate, where $1 - \omega$ is the pheromone declining rate.

$$\tau_{i,j} = (1 - \omega) \times \tau_{i,j} + \sum_{r=1} \Delta\tau^{r}i,j \qquad (10)$$

In the ACO algorithm, other ants tend to follow paths with a high amount of pheromone, as it indicates better solutions. There are two main approaches to updating the pheromone trails. The first approach involves selecting the best-so-far solutions (iteration best) and using them to update the pheromone matrices for each objective. These best solutions represent the most promising paths found so far in the search process. The second approach revolves around gathering and storing non-dominated solutions in an external set. Only the solutions in this non-dominated set are allowed to update the pheromone trails. Non-dominated solutions are those that cannot be improved in one objective without worsening at least one other objective. This approach helps maintain a diverse set of optimal solutions. Once the ants find food, they return to their nests, dropping pheromones on the trail they traveled. This pheromone serves as a signal for other ants to explore the same path, thus collectively reinforcing good solutions. Ants make local decisions based on their observations and the information available in their local environment. Instead of directly communicating with each other, ants use indirect forms of communication, which is referred to as "stigmergy." The pheromones left by ants' act as a form of stigmergic communication, guiding other ants to explore the most promising paths. Over time, the pheromones evaporate, which allows the algorithm to explore new areas and avoid convergence to sub-optimal solutions. The rate of pheromone evaporation is higher when returning to the nest takes a longer time, promoting the exploration of alternative paths. At intersections in the graph, each ant chooses one of the branches to continue its path. Ants tend to select shorter branches to return home faster, resulting in more pheromone accumulation on these shorter paths.

Fig. 4. Path selection by ants.

In the presented scenario (see Fig. 4), the ants encounter three paths: $A{\to}B{\to}C{\to}E$, $A{\to}B{\to}E$, and $A{\to}B{\to}D{\to}E$. Initially, due to the shorter distance, the shortest path $A{\to}B{\to}E$ will have a higher pheromone density. As the ants make their choices, they select paths based on the pheromone densities present on the branches. Consequently, most ants will opt for the shortest path, $A{\to}B{\to}E$. The main focus of the article is on the IACO algorithm for workflow scheduling in cloud computing. This algorithm combines the principles of ACO with a constrained optimization approach, which is suitable for solving single-objective discrete optimization problems. By leveraging pheromone communication and making local decisions based on observed pheromone densities, the IACO algorithm effectively guides ants to converge toward the shortest and most feasible paths in the search space.

Indeed, the IACO method exhibits several significant differences in each ant's behavior compared to the traditional ACO. The main distinctions between ACO and IACO are as follows:

- Pheromone functionality: In the ACO, the pheromones produced by ants serve only the function of attraction. Pheromones act as a positive signal, guiding ants to explore paths with higher pheromone densities. In contrast, the pheromones in the IACO method serve a dual purpose. Besides attraction, they also act as a form of repulsion. This repulsive nature of pheromones helps to alleviate the pressure on certain paths or nodes. It discourages ants from over-converging on a specific route or node.

- Role of nodes: In the ACO, nodes do not directly influence the algorithm. The focus lies primarily on paths and the pheromones present on those paths as important parameters.

- IACO Method: In the IACO, nodes play a significant role as influencing parameters. They store the number of pheromones present. If the pheromone count exceeds a specific value, the node acts as a blockade, preventing other ants from passing through it. This approach is designed to reduce pressure on certain nodes and is directly linked to the pheromone value.

- Consideration of route capacity: ACO does not explicitly consider the maximum capacity on a path when updating pheromones. In the IACO, the pheromone's evaporation process takes into account both the length of the route and the maximum capacity of the route. This consideration helps to ensure that the algorithm avoids routes that may become congested due to excessive pheromones.

These differences in behavior and parameterization between ACO and IACO allow the IACO method to address complex optimization problems more effectively, especially in scenarios where path congestion and capacity constraints are crucial considerations. By combining both attractive and repulsive properties of pheromones and incorporating node-based mechanisms, IACO offers an enhanced approach for finding optimal or near-optimal solutions in constrained optimization problems.

## IV. PERFORMANCE EVALUATION

In the experiments conducted to verify the performance of the proposed method, we used the WorkflowSim toolkit. The implementations of strategies were implemented in Java and run on a computer with an Intel Core i5 processor running at 2.8 GHz and equipped with 4 GB of RAM. The WorkflowSim toolkit is an extension of CloudSim, designed specifically to simulate an environment for executing scientific workflows. In pursuit of an equitable comparison of outcomes, the simulations involving the proposed approach and other established methods were orchestrated under identical conditions. This systematic parity in experimentation conditions serves to objectively gauge the performance and efficacy of the proposed approach in contrast to alternative methodologies. The experimental trials were conducted utilizing three distinct real-world workflow applications, each hailing from diverse scientific domains. Noteworthy among these is the Montage workflow applied within the realm of astronomical physics. Furthermore, the Cybershake workflow was harnessed to analyze earthquake hazards, while the Ligo workflows were instrumental in the quest for gravitational wave detection.

The configuration of VMs is based on the specifications of Amazon EC2 instances, which are commonly used in cloud computing environments. Within the simulation model, it is assumed that the storage capacity of every VM is generously sufficient to host all the allocated tasks. Nonetheless, the mean bandwidth linking distinct virtual machines exhibits variability across three distinct scenarios: 5 Gb/s, 10 Gb/s, and 25 Gb/s. The variation in bandwidth represents different network capacities and performance levels that can affect task execution and communication between VMs. Additionally, the virtual machine preparation time is taken into consideration during the simulations. This preparation time represents the overhead required to set up and configure a VM before it can start executing tasks. The temporal interval required for VM preparation is modeled to fluctuate within the range of 1 second to 1.5 seconds. During the evaluation process of the proposed IACO algorithm, a comprehensive comparison is conducted against three alternative algorithms: standard ACO, FR-MOS, and PEFT-ACO algorithms.

In the first series of experiments, the algorithms were evaluated independently for each objective, i.e., cost and makespan. The experiments were performed on three different types of workflows: Montage, Cybershake, and Ligo, with varying numbers of tasks (100 and 300). The results averaged over 100 executions for each workflow type, are presented in Table I. It is observed that the traditional ACO algorithm performs poorly in both the total cost and makespan across all three workflow types. On the other hand, the IACO algorithm is superior to both PEFT-ACO and FR-MOS regarding cost and makespan across all workflow types. The discernible distinction in performance is especially pronounced with regard to makespan. This indicates that IACO is more efficient and effective in exploring the solution space and finding globally optimal or near-optimal solutions. Fig. 5 and Fig. 6 provide visualizations of the average results for makespan and cost when the number of tasks is set to 500.

TABLE I.  OBTAINED RESULTS FOR COST AND MAKESPAN

| Workflow | Tasks count | IACO | | FR-MOS | | PEFT-ACO | | ACO | |
|---|---|---|---|---|---|---|---|---|---|
| | | Cost ($/h) | Make span (s) | Cost ($/h) | Make span (s) | Cost ($/h) | Make span (s) | Cost ($/h) | Make span (s) |
| Montage | 100 | 14.1 | 468.2 | 15.9 | 614.7 | 25.6 | 625.8 | 52.2 | 654.3 |
| | 300 | 9.2 | 584.7 | 13.8 | 679.4 | 20.1 | 693.5 | 30.1 | 708.3 |
| Cybershake | 100 | 21.8 | 489.5 | 40.7 | 513.7 | 57.7 | 578.5 | 70.2 | 695 |
| | 300 | 19.8 | 627.1 | 32.1 | 659.4 | 43.9 | 701.8 | 53.7 | 872.4 |
| Ligo | 100 | 31.5 | 559.1 | 46.9 | 609.5 | 69.7 | 695.8 | 78.7 | 710.8 |
| | 300 | 26.9 | 697.4 | 42.8 | 823.4 | 64.4 | 888.1 | 77.2 | 896.7 |

Fig. 5.  Makespan comparison.

## V.  CONCLUSION

Cloud computing has emerged as a revolutionary concept in the field of distributed systems, providing efficient and scalable solutions for high-performance and distributed computing needs. Its dynamic nature, virtual resource provisioning, and pay-per-use model have contributed to its widespread popularity among organizations and research laboratories. In this context, workflow scheduling plays a crucial role in optimizing the execution of applications in cloud environments. Workflows model processes as a sequence of steps, and scheduling involves assigning each task of the workflow to an appropriate processing resource while adhering to specific workflow rules and constraints. This paper proposed a novel

workflow scheduling approach called Inverted ACO (IACO). The IACO algorithm leverages the principles of the ACO algorithm but introduces unique modifications to improve its performance in cloud-based workflow scheduling scenarios. The experiments were carried out utilizing instances from the Amazon EC2 cloud platform, encompassing three distinct real-world workflow types originating from various scientific domains.

In the comparative analysis, IACO was assessed against established methodologies in the field, namely standard FR-MOS, PEFT-ACO, and ACO algorithms. The results of the experiments show that IACO outperforms all other algorithms in most tests, particularly in terms of the trade-off between makespan and cost. This work could explore how the IACO algorithm adapts dynamically to varying cloud environments, taking into account factors like workload fluctuations and cloud structure diversity. Additionally, exploring the integration of IACO with machine learning or other metaheuristic approaches could expand its efficiency and applicability. Moreover, investigating the scalability of IACO in hybrid cloud settings or its adaptability to real-time workflow changes could significantly advance its practical implementation. Furthermore, assessing the robustness of IACO against various cloud constraints, including resource limitations or network latency, would contribute to a more comprehensive understanding of its performance under diverse cloud scenarios.

*Abstract*—Due to the popularity of digital games, there is a growing interest in using games as therapeutic interventions. The ability of games to capture attention can be beneficial to distract patients from pain. In this paper, we investigate the impact of visual parameters (color, shapes, and animation) on users' awareness of their surroundings in virtual reality. We conducted a user study in which experiments included a visual search task using a virtual reality game. Through the game, the participants were asked to find a target among distraction objects. The results showed that the different visual representations of the target among distraction objects could affect the users' awareness of their surroundings. The least awareness of the surroundings occurred when the target and distractors shared similar features. Further, the conjunction of low similarity between distractors-distractors and high similarity between target-distractors provided less awareness of the surroundings. Additionally, results revealed that there is a strong positive correlation between search time and awareness of the surroundings. Less awareness of the surroundings while playing a game implies that users are positively engaged in that game. These results offered a set of criteria that can be applied to future virtual reality interventions for medical pain distraction.

*Keywords*—*Virtual reality; visual distraction; attention; awareness*

## I. Introduction

Game playing was recognized as the most attractive activity for individuals all over the world. The success of games is highly dependent on their ability to keep their players engaged [1]. Despite some of the negative aspects of playing games, there is growing research demonstrating the positive effects that game playing can provide. If games succeed to activate users' attentional engagement and motivation, they can be of valuable therapeutic benefits [2]. Playing games offers a promising non-pharmacological distraction technique for pain control by diverting attention away from painful stimuli [3]. The logic behind distraction is that pain requires attention and humans have limited information-processing resources [4]. Therefore, the more attentional resources a distraction intervention consumes, the fewer resources are available for pain perception [3]. The research work conducted by [5] [5] highlights that high attentional engagement during games demonstrates a significant analgesic effect on pain distraction.

Distraction interventions can engage one or more sensory modalities. Each modality could have an impact on the distraction level to attract focused attention. In the range of sensory modalities, vision is the most important in its capacity and utility in terms of perception [6]. Besides, distraction using visual tasks was confirmed to significantly reduces pain compared to other modalities [7], [8]. Numerous studies demonstrated that

the majority of processing information comes from the visual modality *(visual dominance)* [9]. A wide range of research supported that our vision captures the most percentage of our attentional resources [10]. Recently, virtual reality (VR) becomes one of the major tools that affect visual perception by offering a highly immersive and tangible interaction experience [11]. Experimental research showed that immersive environments build strong user engagement compared to screen-based environments [11]. VR technologies provide a higher degree of presence through increased interactivity and hence increase the user's attention to the virtual environment [11]. The unique characteristics of VR encouraged researchers to conduct numerous studies, [12], [13], to investigate the effect of VR as a non-pharmacological tool for pain management.

We believe that understanding the visual parameters affecting humans' awareness of their surroundings in VR is valuable. Less awareness of the surroundings increases engagement and immersion in the visual activity. High engagement demands a greater amount of user's focused attention. This is critical for many applications such as game-based learning [14], engagement in games [15], and pain distraction [16]. Tasks that require subjects to detect a particular target among distractors gained a great interest in the research of vision and attention [17]. The results of these tasks depend on the features of the target and distractors. Different features might have different capabilities to guide users' attention in a given task [17]. The efficiency of a visual search can be assessed based on changes in performance such as search time or accuracy [17]. Many studies [18], [19], have presented theories to discuss the factors that affect visual search efficiency in 2D, such as the *feature integration theory* and the *similarity theory*.

In this paper, we provide a user study to measure the impact of different visual parameters on users' awareness of their surroundings and task search time in VR. Experiments in this study focus on the principle of visual search using a simple VR game. Numerous studies proved that using the illusion of VR significantly reduces the perception of pain. Although, to our knowledge, no studies were conducted to determine the impact of visual parameters that affect the users' awareness of their surroundings. The less awareness of the surroundings implies that the VR intervention engages much of a user's attentional capacity. This is valuable, especially when developing VR interventions for pain distraction. Results from this study will be considered in designing future VR interventions for medical pain distraction.

Through the following sections, this paper discusses the background of VR distraction for managing pain in Section II. Then, Section III presents the conducted user study. Further-

more, in Section IV we summarize the main findings of the study. Finally, the discussion and conclusion are included in Sections V and VI, respectively.

## II. BACKGROUND

This section discusses in detail the related work of using VR distraction for pain management. Section II(A) provides some background on VR technology. Section II(B) discusses some applied VR research for pain distraction and reduction.

### A. Virtual Reality

With advances in wearable technology, VR became popular across various industries due to its ability to engage users in a multisensory environment. There are several definitions of VR, but the most appropriate one "it is defined as a real or simulated environment in which a user experiences telepresence". This definition is chosen as it describes VR without any implications of technology [20]. VR offers a combination of three effects: *1) Fully immersion*, users wear a headset that visually isolates them from the real world, *2) Stereoscopic vision*, the simulation of the real world in three dimensions, and *3) Motion capture*, allows the tracking of head position and controllers with three or six degrees of freedom [21]. These effects enable VR to provide users with a unique visualization tool to explore, manipulate, and interact with their data.

VR is unique in that it allows a multisensory experience that involves visual, auditory, and tangible senses [22]. The VR characteristics of immersion, presence, and interactivity provide users with a greater sense of engagement. These three factors may subsequently prompt better distraction outcomes from a VR intervention via increased engagement. Presence describes the subjective experience of being in one place or environment, even when one is physically situated in another [23]. There are two points of view for immersion definition; the first is based on the state of mind (feeling caught up in and absorbed by the virtual world) and the second is based on the technological capability of a VR system (1)Fully immersive, using a head-mounted display (HMD), (2)Semi-immersive, using large projection screens, (3)Minimal-immersive, using window-based display) [24]. Interactivity describes the degree to which users can influence the content of the virtual environment [24]. According to [25], growing improvements in hardware and software make VR technology more affordable for the scientific and commercial community.

### B. Virtual Reality Distraction

Various studies have shown that VR distraction is more effective in reducing pain and anxiety than typical distraction techniques such as deep breathing, listening to music, watching a favorite video, and hypnosis [13]. The last decade has witnessed exponential growth in using VR interventions for pain management with encouraging results that recommend VR distraction to enhance treatment outcomes [26]. Numerous studies were conducted to investigate the effectiveness of VR distraction in reducing different types of pain. Research in this area [16], [27], indicates that VR is a promising adjunct for controlling acute and chronic pain.

Patients with severe burn injuries frequently experience extreme pain related to the injury itself or its wound care procedures. VR distraction provided a strong non-opioid pain control technique for both pediatric and adult burn patients even in the Intensive Care Unit [28]. Also, adding VR to the rehabilitation program of pediatric burn patients had a significant effect on decreasing pain [29]. The main finding from these studies is that VR significantly reduces pain and other uncomfortable symptoms experienced by burn patients [30]. Also, the findings of the chronic pain studies supported the efficacy of VR distraction. Patients reported a significant decrease in pain ratings when using VR interventions compared to the control condition [31]. However, the studies focused on the area of using VR with chronic pain were few [13], and further investigations are needed to ensure its feasibility.

Moreover, VR succeeded to offer a powerful distraction tool for patients who suffer from cancer pain. Cancer patients experience pain associated with the disease itself and/or pain caused by examinations and treatments such as chemotherapy. Several studies showed that VR interventions are effective in reducing pain and other chemotherapy-related symptoms in both adult and pediatric patients suffering from different types of cancer [26], [32]. Patients receiving VR during their chemotherapy session reported less time thinking about pain and also an underestimation of the treatment session duration [33]. VR distraction can help cancer patients accept and tolerate the treatment procedures and hence accelerate the recovery process.

Further to the above category of studies that investigated the efficacy of VR distraction, other studies investigated whether VR distraction will provide a larger analgesic effect when used repeatedly during treatment sessions [28], [34]–[36]. Results indicated that VR efficacy did not diminish with repeated use and pain intensity levels dropped significantly. Previous research, as indicated by both [34] and [36], suggested that receiving VR for a longer treatment duration is more effective than the shorter duration.

Moreover, few studies have investigated the impact of low-cost VR technology on pain tolerance [37], [38]. For both studies, participants were suffering from severe burn injuries and results showed that low-cost VR technology succeeded to achieve a promising pain reduction level. This key finding will open the door to conducting further research to generalize using cost-effective technology with many more patients and different types of pain. Finally, VR interventions can also be used effectively to distract young children aged less than four years during their wound care procedure [39]. This study used a projector-based VR system and the results indicated that VR significantly reduced children's acute pain.

Results from the scientific literature support the adjunctive use of VR distraction for pain management. However, it remains unclear what is the impact of different visual parameters such as color, shapes, and animation on users' awareness of their surroundings. Understanding the impact of such parameters on the awareness of the surrounding is valuable in developing powerful VR therapeutic interventions. To this aim, we conducted a study that included a VR game where players searched for a target among distractors. One study has investigated the impact of color congruency on task search time in VR. This study measured the search task performance when target and distractors were varied

concerning congruency [40]. Moreover, the study examined the impact of using a flanker item as a visual distraction from completing task flow. Participants were asked to search for daily items on a virtual kitchen countertop and ignore flanker items. Results indicated that the search time became longer when the target and distractors shared color.

Regarding 2D applications, many studies examined the impact of visual representations of the target and distractors on task search time. Treisman et al. [18] provided a framework that explained the hypotheses of the feature integration theory. This theory hypothesized that the search task will proceed slowly when the target and distractors share features. The theory suggested that the human visual system maintains a set of feature maps for different visual attributes (such as color or shape). When the target has a unique feature, one feature map will be accessed and hence leading to a fast response time. Another research work suggested that the amount of difference between the target-distractors and distractors-distractors will affect the search time [19]. This theory hypothesizes that if the "target-distractors" similarity is high, then search efficiency decreases and search time increases. Besides, if the "distractors-distractors" similarity is low, then search efficiency decreases and search time increases.

These researches showed that the presented visual features could significantly affect users' focus of attention and engagement in search tasks. However, one important gap in the literature on virtual reality analgesia is that no studies explored the impact of different visual parameters such as color, shapes, and animation on users' awareness of their surroundings. To address this gap, we performed a user study to determine the impact of these visual parameters on users' awareness of their surroundings and task search time. Moreover, we are also interested in exploring whether there is a correlation between task search time and awareness of the surrounding. The results from this study will help to develop effective VR interventions that engage most of the patient's attention and hence feel less pain.

## III. METHODS

This study was designed to help in developing a future VR game for medical pain distraction. To provide more distraction effects, it is valuable to determine the impact of different visual parameters on users' awareness of their surroundings while in VR. We found that visual components such as color, shape, and animation are commonly included in any digital game. Accordingly, we focused on determining the impact of these visual components on users' awareness of their surroundings. Experiments in this study focus on the principle of visual search using a simple VR game. We examined the impact of different visual representations of the target and distractors on the search performance and awareness of the surroundings.

### A. User Study

The study used a within-subject design where each participant experienced different conditions. These conditions varied with respect to some visual parameters such as color, shape, and animation. The participants were asked to perform a primary visual task, finding a target cube among distraction objects as fast as possible. Moreover, external disruptions (audio or vibration) were generated randomly while performing the search task. These disruptions were used to measure their awareness of the surroundings without affecting the completion of the primary task. The number of these disruptions was fixed among participants, but the order of them was randomized. Each condition consisted of twenty-five trials and had a duration of about three minutes. At the end of each condition, a compulsory break time was offered. During the break, each participant had to fill in a simple questionnaire that asked about the time duration and the observed disruptions - e.g., "How long did you feel the condition take?", and "Did you observe any disruption?".

If they answered "yes" to the latter question, they have to provide which types occur and the number of their occurrence frequency. The experiment took around forty-five minutes per participant including breaks. For all conditions, we recorded the completion time and the generated disruptions. Through the study, we examined task completion time and disturbance awareness for each of the study's conditions. We measured the awareness and illusion errors that were reported by the participants. Awareness error is the number of missed disruptions, while illusion error is the number of disruptions that never happened. These data were collected to measure the participants' awareness of the surrounding environment.

### B. Participants

A total of 31 undergraduate students (19 females) (12 males) aged (18-24) years participated in the study. Participants were recruited via a university announcement for voluntary inclusion in the study. All participants were eligible with respect to the criteria determined for the study (had normal visual and normal color vision). Five participants were excluded as they suffered from VR-induced motion sickness. So, a total of 26 healthy participants were included in the study analysis. Informed consent for the publication of identifying information/images in an online open-access platform and for participation in the study was provided by all participants before the experiment. The study was approved by the ethical committee in the Faculty of Computers and Artificial Intelligence, Benha University. All methods were carried out in accordance with relevant guidelines and regulations. The flow of participants is shown in the flow diagram (see Fig. 1).

### C. Equipment

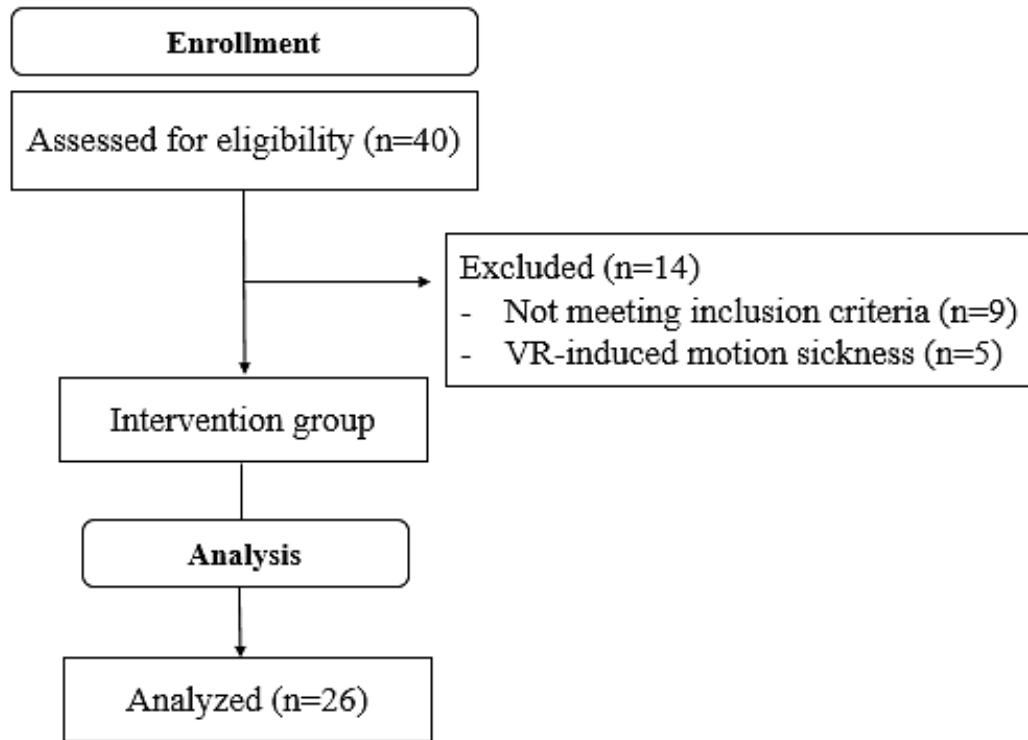
We carried out the experiments of the study using a controlled room. Participants delivered the VR experience using a *Xiaomi MI VR* headset with a Samsung Galaxy Note3 phone and a handheld controller as an interaction device. We used this head-mounted display to be able to use a variety of mobile phones. The Samsung Galaxy Note3 phone was attached to the HMD and was used for recording the completion time of the condition. Another mobile phone was used and attached to the participant's left arm. This phone was also used to generate random disruptions and save them. The participants were able to look around and navigate the virtual environment using their heads. The VR application was developed using the Unity engine and the Android application using Android Studio. The condition started once the participant wore the HMD and ended when the twenty-five trials ended. Fig. 2 shows the hardware components used in the experiment besides one of the participant's trials.


Fig. 1. Flow of participants.

Fig. 2. Experiment hardware components (left), and a participant trial (right).

### D. Stimuli

Participants were situated in a full virtual closed room surrounded by a number of distractive objects. There was only one real target cube which was always spawned randomly at the eye level of the user. The size of the objects was scaled according to their distance away from the camera's location (size was around 10 % of the display width and 22 % of its height). The distractive objects were spawned at fixed random locations within the room. Colors were defined by the following RGB values: target (R=0, G=255, B=118), in conditions 2 and 5 distractor's red color (R=255, G=0, B=0), in conditions 3, 4, and 6 the colors of the cubes were generated randomly while spheres in condition 6 used the same target color. The environment was populated with 20 distractive objects. The experiment took around forty-five minutes per participant. Each participant performed 150 trials: 6 conditions × 25 trials per condition.

### E. Study Design

The study was carried out in immersive VR and included six different conditions with the same task. The participants were asked to find a target object in the presented VR condition. Each condition included a different visual representation of the target and distraction objects, which is our study's independent variable. This differentiation among conditions is used to investigate the different visual parameters and their impact on users' awareness of their surroundings. The following are our study's conditions:

1) Condition1: Single-cube.
2) Condition2: One-color cubes.
3) Condition3: Multi-color cubes.
4) Condition4: Animated cubes.
5) Condition5: Spheres.
6) Condition6: Cubes-spheres.

All conditions included one target green cube along with other distraction objects spheres or cubes. The order of exploring the conditions was randomized among the participants. We previously conducted a pilot study to determine the best visual design for the conditions. Also, the pilot study helped us to determine the break time duration which was set to five minutes.

Fig. 3 shows our study's six conditions, where the visual representation of the target and distraction objects varied between them. Fig. 3(a) shows "Condition1" that included the target green cube only with no distraction objects. Fig. 3(b) shows "Condition2" with one-color distraction objects. Participants were asked to find the target green cube which was allocated randomly with the fixed distraction red cubes. Fig. 3(c) shows "Condition3" with a fixed multi-color distraction objects. The participants had to find the target green cube out of the multi-color presented cubes. Fig. 3(d) shows "Condition4" with animated multi-color cubes as distraction objects. Condition4 included an extra effect which was animation. Fig. 3(e) shows "Condition5" in which participants had to find the target green cube hidden between fixed red spheres. Condition5 included different shapes as distraction objects. Fig. 3(f) shows "Condition6" in which participants had to find the target green cube which was surrounded by fixed one-color spheres (the same target color) and fixed multi-color cubes.

The participants were asked to complete the six conditions. The completion time and the generated disruptions were recorded for each condition by the application. The *completion time* was automatically recorded from the start of the condition till the participant finished the twenty-five trials. The completion time represented the total time taken to finish the condition. Moreover, we recorded the response time taken to find the target in each trial. We calculated the *search time* for the condition as the average of the twenty-five trials' response time. The completion time was saved on the mobile attached to the HMD, while the generated disruptions were saved on the other mobile phone. On the other hand, the estimated time and errors were reported by the participants via the questionnaire that was filled out after each condition. All of the data was recorded and transcribed to a computer spreadsheet for later analysis.

### F. Procedure

Prior to running the study, we had explained many rules and cautions to the participants. We told them to take off the HMD and stop running the condition if they felt any VR-induced motion sickness during their running. We showed an example display of the conditions to explain how to play. The participants heard the audio disruptions and felt the vibrations to get familiar with them. We had two types of audio disruptions (*ringtone and beep*) and two types of vibrations that varied in duration *(short: one second and long: three seconds)*. After getting ready the participant wore the HMD, hold the handheld controller, and attached the other mobile phone to his/her left arm to start the condition. The participants used the handheld controller to press on the target green cube when found.

The primary purpose of the study was to determine the impact of different visual parameters on users' awareness of their surroundings in VR. The conditions varied according to many parameters such as color, shape, and animation. The main task was to search for the green target cube and find it as fast as possible. When the target fell into the participant's view, he/she focused the cursor of the handheld controller on the target and place a single click. Finding the target indicated the end of a trial and the start of a new one. After the click, the target disappeared and a new target object was randomly located in another location within the same room. Through each condition, the mobile attached to the participant's left arm randomly generated *four* disruptions. The type and occurrence frequency of these four disruptions were used to measure both the awareness and illusion errors. We supported different types of disruption to measure the participants' awareness of the surrounding environment. The number of disruptions (four) was fixed among conditions and participants. After twenty-five trials, the current condition was ended and the compulsory break time must be taken.

During break time, the participants were offered to take off the HMD and were asked to fill out the user-experience questionnaire. The participants were asked to report the estimated time duration of the condition in minutes. Also, they were asked to report the observed disruptions that occurred during running the condition. After the break time, the participants return back to continue running the study and repeat the same procedure with a new condition. Each participant completed a block of six conditions. The order of experiencing the conditions was randomized among the participants.

## IV. EXPERIMENTAL RESULTS

Analyses of the sample data (N = 26) were conducted using IBM SPSS Statistics v25. For all analyses, an alpha level of 0.05 was used unless otherwise specified.

### A. Completion Time

We ran the study to measure if the visual parameters affect the task completion time or/and users' awareness of the surroundings in VR. We recorded the data as we calculated the time difference values by subtracting the completion time (automatically recorded) from the estimated time (reported by the participant). This time difference was used to generate the *less_than* and *greater_than* values. *Less_than* indicated
Fig. 3. Example displays for (a) Condition1, (b) Condition2, (c) Condition3, (d) Condition4, (e) Condition5, and (f) Condition6.

Fig. 4. Condition's mean values less_than and greater_than.

Fig. 5. Time difference per condition.

that the participant reported time less than the actual time, while *greater_than* indicated the opposite. Then we calculated *less_than* as the negative value in the time difference and *greater_than* as the positive value. We used the absolute value for all of the time differences, *less_than*, and *greater_than* values. For each condition, we ran paired samples t-Test between the *less_than* and *greater_than* values to determine the significant condition. The results showed there was a significant difference between *less_than* and *greater_than*, but with a high mean for *greater_than* values (see Fig. 4).

We ran the time difference values through one-way repeated measures ANOVA. Mauchly's test indicated that the assumption of sphericity had not been violated, but when it was violated, the Greenhouse-Geisser corrected tests were reported, $\chi^2(14) = 19.06, p = 0.165$. The results showed that there was a significant main effect of the different visual param-

eters (color, shape, and animation) on the time difference, $F(5, 125) = 2.51, p = 0.034$. Fisher's Least Significant Difference (LSD) post hoc analysis of the results showed that participants significantly overestimated the time duration of cubes-spheres condition ($mean = 1.39; SD = 1.53$) compared to the single-cube condition ($mean = 0.78; SD = 0.80; p = 0.018$) and the spheres condition ($mean = 0.93; SD = 0.99; p = 0.020$). There was no significant difference between the other pairs of conditions. Fig. 5 shows the mean values by condition for the time difference.

We ran the study's search time results values through one-way repeated measures ANOVA. Mauchly's test indicated that the assumption of sphericity was met, $\chi^2(14) = 21.72, p = 0.086$. The results showed that there was no significant main effect of the different visual parameters on search time, $F(5, 125) = 0.393, p = 0.853$. Fig. 6 shows the mean values by condition for the search time.
Fig. 6. Search time per condition.

Fig. 7. Mean values for the awareness and illusion errors.

### B. Task Errors

Following in the two sections we are presenting the analysis results for the awareness and illusion errors reported by the participants. Awareness error is the number of missed disruptions, while illusion is the number of disruptions that never happened. These errors were collected to measure the participants' awareness of the surrounding environment.

*1) Awareness error:* For each condition, we ran the awareness error through one-way repeated measures ANOVA. Mauchly's test indicated that the assumption of sphericity was met, $\chi^2(14) = 15.19, p = 0.368$. The results showed that there was a significant main effect of the different visual parameters on the awareness error, $F(5, 125) = 1.29, p = 0.273$. LSD post hoc analysis of the results showed that participants were significantly less aware of their surroundings in the cubes-spheres condition ($mean = 1.38; SD = 1.28$) compared to the single-cube condition ($mean = 0.81; SD = 0.89, p = 0.037$).

*2) Illusion error:* For each condition, we ran the illusion error through one-way repeated measures ANOVA. Mauchly's test indicated that the assumption of sphericity was met, $\chi^2(14) = 16.57, p = 0.282$. The results showed that there was a significant main effect of the different visual parameters on the illusion error, $F(5, 125) = 1.77, p = 0.124$. LSD post hoc analysis of the results showed that participants were significantly less aware of their surroundings in the cubes-spheres condition ($mean = 0.88; SD = 1.14$) compared to the single-cube condition ($mean = 0.38; SD = 0.63, p = 0.030$) and the one-color cubes condition ($mean = 0.31; SD = 0.54, p = 0.041$). Fig. 7 represents the mean values of awareness and illusion errors by condition.

### C. Search Time and Awareness of Surroundings

We ran Spearman's correlation test to determine if there is a relationship between participants' search time and the awareness error. The results showed that search time and awareness error have a statistically significant relationship ($r_s = 0.886, p = 0.019$). The direction of the relationship is positive where search time and error rate are positively correlated, meaning that these variables tend to increase together. The magnitude of the association is strong ($0.5 < |r| < 1.0$).
A Spearman's correlation test again was computed to assess the relationship between participants' search time and illusion error. There was a positive correlation between the two variables ($r_s = 0.829, p = 0.042$). Overall, there was a strong, positive correlation between search time and illusion error. Increases in search time were correlated with increases in the rating of illusion error.

### V. Discussion

The goal of this experiment was to determine the impact of different visual parameters on the users' awareness of their surroundings. The least awareness of the surroundings means that the user is highly engaged in the VR content. High engagement increases the levels of immersive experience, thus, increasing the impact of future VR interventions for medical pain distraction.

### A. Completion Time

Based on the study analysis, the time difference (estimated - actual) data revealed that there is a significant difference between the cubes-spheres condition and both the single-cube and the spheres conditions. These results indicated that more attentional resources were engaged in the cube-spheres condition and hence the passage of time got distorted. This implies that the cubes-spheres condition affected the users' perception of time in VR. Due to the visual representation of the target and distractors in the cubes-spheres condition, participants focused their attention on detecting the target and hence failed to judge the time duration.

We further measured the search time of each condition. The analysis showed that there was no significant difference between the six conditions. However, the cubes-spheres condition required more search time to detect the target compared to the remaining conditions. Results revealed that the search time increases when it is hard to identify the target among distractor objects. This implies that the visual representations of the target and distractors affect the search time in VR. Our results revealed that the spheres condition was the lower-order condition against the cubes-spheres condition with the higher-order. The target in the spheres condition had unique

features color and shape, so participants were able to detect it easily. The cubes-spheres condition is the highest due to sharing multiple features color and shape with the distracting objects. Sharing similar features between target and distractors increased the response time for the search task. Our finding comes in line with the conducted research in other 2D and 3D platforms [40], [18]. Fig. 6 shows the mean values of search time for the six conditions.

Another important issue is that the similarity between the (target-distractors) and (distractors-distractors) also affected the search time. In the spheres condition the similarity between the target and distractors was low accompanied by the high similarity between distractors-distractors and in turn, search time decreased. On contrary the target-distractors similarity in the cubes-spheres condition was high and the distractors-distractors similarity was low. Thus, participants in the cubes-spheres condition required more time and also more focused attention to identifying the target. This finding is aligned with the finding presented in [19]. Overall, our findings indicated that the search time was higher when the target and distractors shared similar features. Further, the conjunction of low similarity between distractors-distractors and high similarity between target-distractors provided a long search time. This finding shows a similarity in results between the task search time in VR and desktop 2D platforms.

Finally, it may be worth considering the qualitative data. It is interesting to state that the comments from the participants further supported the statistical findings. For the overestimation of time, participants claimed that the task completion time influenced their judgment of the estimated time. Therefore, as the task became longer the total time was assumed to become longer. This explains why participants overestimated the time duration of the conditions.

### B. Task Errors

The analysis of awareness error showed that there was a significant difference between the cubes-spheres condition and the single-cube condition. As shown in Fig. 7, the cubes-spheres condition has the highest awareness error rate. We found that participants in this condition required more of their focused attention to identifying the target among distractors. Therefore, participants were less aware of their surroundings in this condition compared to the others. Participants missed observation of many auditory and vibration distractions in this condition. As indicated, the cubes-spheres condition included conjunctions of many visual factors that led to increased engagement. Sharing similar features between the target and distractors demanded more attentional resources and hence decreased the participants' awareness of their surroundings. Moreover, participants were less aware of their surroundings when the similarity between target-distractors was high and the similarity between distractors-distractors was low. In line with the previous analysis, the condition that provides more distraction from surroundings is that of the longest search time and the highest awareness error.

Regarding the illusion error, the results showed that participants in the cubes-spheres condition were less aware of their surroundings compared to the single-cube condition and the one-color cube condition. Participants in the cubes-spheres condition reported a significant number of disruptions that never happened, which implies that their focus attention was affected by the visual representations of this condition. Similar to awareness error, participants' attention was significantly engaged in the cubes-spheres condition. The superiority of that condition as an influence on awareness and illusion errors strongly suggests that this condition effectively decreased the participants' awareness of their surroundings. Participants in the cubes-spheres condition consumed a high capacity of attentional resources to detect the target compared to other conditions. This implies that the participants were highly engaged in that condition. In our VR game, the least awareness of the surroundings was provided when the target shared similar features with distractors along with the conjunction of low similarity between distractors-distractors and high similarity between target-distractors. Thus, these visual representations of the target and distraction objects should be considered when developing a VR intervention for pain distraction.

### C. Search Time and Awareness of Surroundings

Regarding the results of search time and task errors (awareness and illusion), there was a strong positive correlation between search time and awareness of the surroundings in immersive VR. When the search task requires more time, the awareness of the surroundings decreases. The awareness of the surroundings is represented by the awareness error and illusion error. Notably, participants lost awareness of their surroundings when the search task required more of their focused attention. Therefore, they missed the observation of many disruptions that were generated during playing the game. The logic behind this is that humans' attentional resources are limited. When the search task requires more time, a great amount of these resources will be captured to perform the task. Thus, less attention is available to process incoming signals from the surroundings. This finding offers potential, especially for medical applications that can make benefit from using VR interventions for pain distraction. Future VR interventions should employ these findings to maximize distraction effects and provide more reduction in pain intensity.

We would like to highlight the following limitations, which should be thoughtfully considered within the context of the study's findings. Firstly, our participant pool was comprised of individuals aged 18 to 24 years, who had minimal experience of using VR. To enhance the generalizability of our findings, future research should encompass more diverse participant populations, spanning various age groups and educational backgrounds. Furthermore, future studies should examine gender and age differences, the outcomes may be linked to variables such as gender and age. Another limitation is related to the relatively short duration of each condition which led to participant overestimation of the time duration. To address this limitation, future studies should consider implementing longer VR interventions. Lastly, this study was limited to examining the main components of visualization however, later we need to examine the combination of these components.

### VI. CONCLUSION

There is solid evidence from controlled research that VR distraction is effective for pain distraction. Based on our knowledge, none of the previous controlled studies has

examined the impact of the different visual parameters on users' awareness of their surroundings in VR, so our study examined in-depth the visual parameters and their impact on users' awareness of their surroundings. Results showed that when the search task required more time, the awareness and illusion errors were high. High errors indicate less awareness of the surroundings and more engagement in the game. Moreover, results revealed visual features that affect search time and capture a viewer's focus of attention in 2D games are also feasible in VR. This key finding in addition to immersion renders VR an effective tool for pain distraction. This study is an elementary study conducted to determine the visual representation of target and distractors that provides the least awareness of the surroundings in VR. This visual representation will be employed in our next VR game designed for distracting patients from pain. By using VR technology we may make a significant step towards increasing the therapeutic benefits of VR for pain management.

# A Comparative Study of Deep Learning Algorithms for Forecasting Indian Stock Market Trends

Mrinal Kanti Paul, Purnendu Das

Department of Computer Science, Assam University, Silchar, Assam, India-788011

*Abstract*—This research underscores the vital significance of providing investors with timely and dependable information within the dynamic landscape of today's stock market. It delves into the expanding utilization of data science and machine learning methods for anticipating stock market movements. The study conducts a comprehensive analysis of past research to pinpoint effective predictive models, with a specific focus on widely acknowledged algorithms. By employing an extensive dataset spanning 27 years of NIFTY 50 index data from the National Stock Exchange (NSE), the research facilitates a thorough comparative investigation. The primary goal is to support both investors and researchers in navigating the intricate domain of stock market prediction. Stock price prediction is challenging due to numerous influencing factors, and identifying the optimal deep learning model and parameters is a complex task. This objective is accomplished by harnessing the capabilities of deep learning, thereby contributing to well-informed decision-making and the efficient utilization of predictive tools. The paper scrupulously examines prior contributions from fellow researchers in stock prediction and implements established deep learning algorithms on the NIFTY 50 dataset to assess their predictive accuracy. The study extensively analyzes NIFTY 50 data to anticipate market trends. It employs three distinct deep learning models—RNN, SLSTM, and BiLSTM. The results underscore SLSTM as the most effective model for predicting the NIFTY 50 index, achieving an impressive accuracy of 99.10%. It's worth noting that the accuracy of BiLSTM falls short when compared to RNN and SLSTM.

*Keyword*—*Stock prediction; machine learning technique; deep learning; stock market; National Stock Exchange*

## I. Introduction

Scholars have been actively engaged in researching the prediction of stock trends due to the stock market's pivotal role as a significant investment avenue across various financial instruments. The goal of stock portfolio selection is to allocate investment funds across multiple stocks in the market, aiming to maximize returns for investors [1]. Investors encounter two broad categories of challenges when creating stock portfolios "The selection of stocks by an investor" and "Allocating funds across various major sectors"

With the advent of faster and high-performance computers, data transfer in the modern computing world has become effortless, making the stock market more accessible to global investors. The internet revolution of the last decade further increased accessibility, as it provides crucial event information that directly or indirectly influences the stock market, leading to the emergence of important tasks like strategy formulation and decision-making support using this information.

Data science (DS) and machine learning (ML) algorithms have become powerful tools in the financial domain, sig-

nificantly improving stock investments' efficiency. They are extensively utilized to develop innovative ideas and modes that simplify the process of creating stock portfolios for investors [2].

This paper delves into the growing interest among financial researchers in Machine Learning (ML) owing to its success in various domains. It focuses on exploring and comparing the latest prediction algorithms and techniques proposed by researchers for forecasting stock market trends and behavior in both academic and industry settings.

This paper encompasses a concise overview of both Machine Learning (ML) and Deep Learning algorithms. It goes on to conduct a thorough examination of a wide array of algorithms, coupled with an extensive survey of correlated research. This inclusive approach serves to fortify the theoretical underpinnings of the study while also delving into pertinent algorithmic issues. Moreover, the research delves into the practical application of existing work and prevalent deep learning algorithms, commonly employed as the bedrock of numerous researchers' investigations. A pivotal aspect of this study involves a comprehensive comparative analysis of the outcomes achieved through these algorithms.

To accomplish our research objectives, we conducted an extensive survey of prior studies on stock market prediction utilizing data science and machine learning. We meticulously analyzed the methodologies and algorithms employed by various researchers to forecast stock prices. Moreover, we assembled an extensive dataset of NIFTY 50 data obtained from the National Stock Exchange India, covering a period of 27 years. This dataset facilitated a comprehensive evaluation of prediction models across a range of market scenarios.

This study involves a comparative analysis of well-known algorithms: LSTM, BiLSTM, SVM, and RNN. The analysis utilizes a collected dataset as training data to predict NIFTY 50 stock index movement accurately. The primary goal is to identify the algorithm that performs best in terms of predictive accuracy. The algorithms are trained on the dataset, and their performances are evaluated using appropriate metrics. The study aims to offer insights into which algorithm is most effective for predicting NIFTY 50 movement, aiding in more informed decision-making within the financial realm. The study focuses on four algorithms: SLSTM (Stacked Long Short-Term Memory), BiLSTM (Bidirectional Long Short-Term Memory) and RNN (Recurrent Neural Network). Fig. 1 depicts the process flow of our study.

In the upcoming sections of this paper, we will delve into various aspects of our study. Section II will be dedicated to discussing the related work that has shaped the foundation of

our research. Moving forward to Section III, we will provide an in-depth description of our implementation plan. Within Section III , specifically in subsection III(A) and III(A)(1), we detail our meticulous implementation process using the RNN model. Furthermore, we will present a comprehensive analysis of the results derived from this implementation. Transitioning to subsection III(B) and III(B)(1), we will outline the steps taken for the implementation of the SLSTM model. Alongside this, we will conduct a thorough examination of the results obtained from this implementation. Similarly, in subsection III(C) and III(C)(1), we will provide insights into our implementation approach for the BiLSTM model and present a comprehensive analysis of the results.

Advancing to Section IV, our focus will shift towards conducting a Comparative Study of the results derived from our various implementations. This section will not only provide a comprehensive comparison of the implementation outcomes but will also identify potential avenues for Future Research Opportunities, illuminating areas that warrant further exploration. As we reach the concluding stages of this paper, Section V will encapsulate our findings and insights. This concluding section will succinctly summarize the key takeaways from our research journey, offering a cohesive wrap-up to our study.

## II. Related Works

In the history of the stock market, researchers have employed algorithms like Neural Networks (NN), Support Vector Machines (SVM), Genetic Algorithms (GA), Linear Regression (LR) and Case based Reasoning (CR) for predicting market trends. However, Neural Networks (NN) have gained prominence recently due to their consistent superiority in various scenarios. Their ability to capture intricate patterns in financial data has led to more accurate and adaptable predictions of market behavior, making them the preferred choice among these algorithms [3].

White's implementation of the Feed Forward Neural Network (FFNN) was the pioneering stock market prediction model, inspiring many researchers to develop accurate models for predicting share market trends. Despite continuous efforts, achieving 100% accuracy in stock market forecasting remains elusive due to historical data reliance and external factors' impact on stock prices, driving persistent research in this domain [3].

Earlier research emphasized optimizing learning algorithms but overlooked dimensionality reduction and eliminating irrelevant patterns. To overcome this, Kyoung-jae Kim and Ingoo Han introduced a hybrid model in the early 2000s, blending Artificial Neural Networks (ANN) and Genetic Algorithm (GA). Their model incorporated daily direction of change and technical indicators for Korea Stock Price Index prediction, yet it had limitations in fixed processing elements, input features and optimization objectives in the hidden layer (set at 12) [4].

Mingyue Qiu et al a hybrid solution, GA-ANN, aimed at forecasting the Japanese Stock Market. Their method involved integrating Genetic Algorithms (GA) with a refined Artificial Neural Network (ANN) model, resulting in an enhanced predictive model. This approach combined the strengths of both techniques to achieve improved forecasting outcomes for the Japanese Stock Market [5].

M.R. Hassan and B. Nath proposed the use of Hidden Markov Model (HMM) for predicting unknown values in time-series stock market data. They applied this model to forecast stock prices for four airlines, utilizing a partitioned approach that involved four distinct states for more accurate predictions [6]. The paper's noteworthy aspect is that it doesn't require any specialized knowledge to construct the model. However, the study's limitations are that it's restricted to Airline Industries and was evaluated using a relatively small-scale dataset, which might not result in a general prediction model.

Ming-Chi Lee's paper introduced a Support Vector Machine based prediction model with a hybrid feature selection approach that combined Supported Sequential Forward Search (FSSFS) and F-score filtering wrapping methods. This fusion aimed to identify an optimal feature subset for improved prediction. The study acknowledges feature selection's impact on SVM performance and highlights the need for further investigation into SVM generalization and performance measurement guidelines [7].

Justin Sirignano and Rama Cont introduced a model utilizing Deep Learning on a large-scale, high-frequency dataset from NASDAQ stocks. Their approach involves a Neural Network with three layers, including LSTM, a feed-forward layer with rectified linear units (ReLUs) and the Stochastic Gradient Descent (SGD) algorithm for optimization [8]. The model developed by the authors was regarded as a universal solution but incurred high training costs. They observed that conducting feature selection before training would have been more beneficial, effectively lowering computational complexity.

Li-Ping Ni et al. suggested a predictive model for the Shanghai Stock Exchange Index (SSECI) daily trends. They combined a fractal feature selection method with SVM and compared it against five common feature selection approaches, demonstrating superior prediction accuracy with their method and surpassing both no feature selection and the other five methods [9]. The authors' model, based solely on a technical indicator, should be assessed with additional factors that influence stock prices, given the multifaceted nature of stock price dynamics.

Sean McNally et al. devised a model predicting Bitcoin's USD price using Bayesian-optimized LSTM and RNN networks. LSTM achieved 52% accuracy and 8% RMSE. Comparing to ARIMA, their deep learning models excelled. GPU training surpassed CPU by 67.7%, underscoring research strength in optimization and feature engineering, with implications for dataset processing advancements [10].

Bin Wenga et al. Martinez created a short-term stock price prediction model employing machine learning techniques including Random Forest Regression (RFR), Support Vector Regression Ensemble (SVRE), Neural Network Regression Ensemble (NNRE) and Boosted Regression Trees (BRT) [11].

Yakup Kara et al. utilized ANN and SVM to predict the stock price index, using time series data from Istanbul Stock Exchange between January 1997 and December 2007. Their study lacked clear performance comparisons with prior models. They employed diverse data sets from various sources, including open-source APIs and the Technical Training Rules (TTR) R package, for training their research model [12].

Xinyi Li and colleagues introduced DP-LSTM, an innovative deep neural network for predicting stock prices. By integrating differential privacy, sentiment-ARMA modeling, LSTM, VADER model, and multiple news sources, the approach minimizes prediction errors, enhances robustness, and demonstrates significant advancements in accuracy and Mean Squared Error (MSE) improvement for forecasting the S&P 500 market index [13].

Sidra Mehtab et al. conducted a study using NIFTY 50 index data from India's NSE, covering December 2014 to July 2020. They initially trained on NIFTY 50 data from December 2014 to December 2018, developing eight regression models. Subsequently, they forecasted NIFTY 50 open values from December 2018 to July 2020, employing four LSTM-based deep learning regression models with walk-forward validation. Their research highlighted the efficacy of a univariate LSTM model in predicting NIFTY 50 open values for the following week, utilizing the preceding week's data as input, leading to enhanced predictive accuracy [14].

Hadi NekoeiQachkanloo et al. introduced an artificial stock counselor trading system, combining support vector regression for stock value prediction with portfolio theory and fuzzy investment counsel for optimal budget allocation. Their approach encompasses optimization-based technical analysis and fuzzy logic incorporating technical and fundamental aspects, demonstrating efficacy through experimental results on the NYSE [15].

In their study, M. Nabipour et al. explored the accuracy of tree-based models (Decision Tree, Bagging, Random Forest, Adaboost, Gradient Boosting, XGBoost) and neural networks (ANN, RNN, LSTM) in predicting values for four stock market sectors using regression. Forecasting was done across different time horizons (1, 2, 5, 10, 15, 20, and 30 days ahead), employing exponentially smoothed technical indicators as inputs. The research found that LSTM outperformed other methods, showcasing the highest performance and notably improving the accuracy of stock market predictions within this context [16].

Hiransha M et al. employed MLP, RNN, LSTM, and CNN deep learning architectures to predict stock prices across NSE and NYSE. Using TATA MOTORS' NSE data, these models accurately forecasted prices for MARUTI, HCL, AXIS BANK (NSE), as well as BANK OF AMERICA and CHESAPEAKE ENERGY (NYSE). The study demonstrated the models' ability to identify patterns in both markets, revealing shared dynamics. DL models outperformed ARIMA and CNN excelled in capturing sudden changes, although the research did not explore hybrid network approaches for further improvement [17].

Manuel R. Vargas et al. proposed a deep learning approach combining financial news titles and technical indicators for predicting intraday directional movements of the S&P 500 index. Their study emphasized Convolutional Neural Networks (CNN) for extracting text meaning and Recurrent Neural Networks (RNN) for capturing context and temporal trends, achieving improved results over similar prior work. Notably, the model's utilization of news from the preceding day underscored the short-term impact of news articles on financial market predictions [18].

Qingfu Liu et al. innovatively treat stock price charts as images and utilize deep learning neural networks (DLNNs) to predict short-term price movements by integrating price charts and stock fundamentals. The study highlights the supremacy of deep learning over single-layer models in forecasting the Chinese stock market, underlining the importance of historical price trends in predicting future price changes compared to stock fundamentals [19].

Somenath Mukherjee et al. introduced a pair of approaches for predicting stock market trends. The first utilized a Feed-forward Neural Network with backpropagation, achieving 97.66% prediction accuracy but facing challenges with data volume and overfitting. Regularization was applied to address these issues. The second approach employed a Convolutional Neural Network, offering a more efficient solution with improved accuracy (98.92%) on a smaller dataset and training time, outperforming the initial model [20].

Yanli Zhao et al. proposed an innovative LSTM-based model enriched with sentiment analysis to predict stock market trends, acknowledging the impact of investor psychology. The study integrated sentiment indexes to capture emotional facets, utilizing Sentiment Analysis (SA) to convert textual content into daily sentiment indexes. The model's refinement with Denoising Autoencoders (DAE) improved its performance by extracting crucial information [21].

Abdul Quadir Md and collaborators present an innovative strategy for stock price prediction that employs a Multi-Layer Sequential Long Short Term Memory (MLS LSTM) model integrated with the Adam optimizer. This technique involves dividing normalized time series data into discrete time steps, effectively capturing historical and future associations and yielding remarkable prediction accuracy rates of 95.9% and 98.1% on the test dataset, outperforming alternative deep learning approaches. [22].

Arsalan Dezhkam et al. introduced HHT-XGB, a novel model that merges Hilbert-Huang Transform (HHT) for feature engineering and extreme gradient boost (XGBoost) for close price trend classification, facilitating the prediction of changing trends in upcoming close stock prices. The model's output sequence optimizing portfolio weights demonstrated a remarkable 99.8% improvement over raw financial data, surpassing benchmark strategies even in challenging market conditions, substantiated through back-testing results [23].

Liheng Zhang et al. introduced the State Frequency Memory recurrent network, designed to capture diverse trading patterns and enhance short and long-term stock predictions. Their novel approach demonstrates superior performance compared to conventional methods in real market data analyses [24].

Guanzhi Li et al. presented a novel framework consisting of Pearson Correlation Coefficient (PCC) and Bayesian Regularized Neural Network Least Squares (BLS), applied for short-term stock price prediction in Shenzhen and Shanghai Stock Exchanges. The approach involved using PCC to select relevant input variables from a pool of 35 variables, followed by training the BLS model with these chosen combinations. The PCC-BLS model demonstrated superior accuracy compared to ten other machine learning methods, as evidenced by results across five evaluation metrics [25].

Shouvik Banik et al. created an LSTM-based Decision Support System for accurate stock value prediction, catering to swing traders. The system generates comprehensive reports with forecasts for the next 30 days, incorporating technical indicators like MFI, RSI, Support and Resistance levels, Fibonacci retracement levels, and MACD analysis. The model's strong performance, boasting low error values, underscores its superiority over existing methods [26].

Stock prices are impacted by politics, economics, news, and investors use fundamental and technical analysis for predictions [27]. Fundamental analysis of a company's stock involves evaluating historical performance, anticipated future growth, and key factors such as profits, product quality, industry competition, financial balance, and cash flow projections [28]. Technical analysis involves predicting stock price trends through market trends and statistical data, addressing questions like optimal buying and selling times. It relies on tables, charts, and coefficients to make short-term and long-term predictions for specific stocks [28]. The review of existing studies and comparisons highlights the success of deep learning models like LSTM, ANN, RNN, SVM, SLSTM and BiLSTM in achieving accurate stock price predictions with minimal error. This prompts our exploration into studying these algorithms for potential research opportunities. We did a comparative study of all the machine learning algorithms used till date in financial instruments.

### III. IMPLEMENTATION

#### A. Experimental Setup

In this research paper, our focus lies in implementing and comparing three distinct models: RNN, SLSTM, and BiLSTM. Our primary goal revolves around evaluating and contrasting their performance utilizing data sourced from the National Stock Exchange. Specifically, we're utilizing the NIFTY 50 index dataset, which covers a substantial 27-year timeframe, ranging from January 1, 1997, to December 31, 2021. This dataset comprises an extensive record of over 6000 days, detailing NIFTY 50 movements. The dataset includes data attributes such as Opening, High, Low, and Closing values. However, our primary attention within this study is focused on the Closing value, as our objective centers on forecasting daily index movements.

Fig. 1. Process flow diagram.

Throughout our experimental setup, we've meticulously partitioned the dataset into two segments: 70% for training and the remaining 30% for rigorous testing and validation purposes. This meticulous division allows us to methodically appraise the predictive prowess of the RNN, SLSTM, and BiLSTM models when applied to the NIFTY 50 dataset.

It's essential to note that during the data preprocessing phase, we've diligently filtered out records with missing closing values or date fields, as well as those with incorrect data types. This meticulous approach ensures the dataset's uniformity and consistency, providing a solid foundation for our models' assessments. Fig. 2 on page 935 displays the NIFTY 50 closing values from 1997 to 2021.

Fig. 2. NIFTY 50 movement from 1997 to 2021.

The Fig. 3 on page 936 illustrates the sequential process of our experimental framework, which is specifically designed for predicting the closing movements of NIFTY 50. Our approach involves the utilization of the deep learning model mentioned previously. In our experimentation, we systematically evaluated these models across three distinct setups. Our aim was to derive valuable rules from these evaluations and ultimately identify a model and combination of factors that not only yield high predictive accuracy but also enhance efficiency in forecasting NIFTY 50 closing movements.

#### B. Implementation of Recurrent Neural Network on Nifty 50 Index Dataset

RNNs are a Neural Network variant that handles sequences by utilizing the previous step's output as the current step's input. The standout feature is the hidden state, acting as memory, which preserves sequence information. This memory state, also called the Memory State, empowers the network to grasp sequential relationships and patterns in data. While Recurrent Neural Networks (RNNs) share the input-output structure with other deep neural architectures, they diverge in how information flows. Unlike traditional architectures with distinct weight matrices per layer, RNNs maintain consistent weights across the network. They compute hidden states $(H_i)$ for inputs $(X_i)$ using specific formulas, allowing the network to retain memory across sequences.

We employed the RNN algorithm for predicting NIFTY 50 index movements, utilizing a dataset spanning January 1, 1997, to December 31, 2021. Our strategy centered on forecasting closing values based on historical closing points. The structure consisted of four layers of regressors with a dropout rate of 0.2. Moreover, we integrated a dense layer housing a single neuron. Optimization was achieved through the utilization of the Adam optimizer, aiming to elevate the overall performance of the deep learning model. We systematically endeavored to enhance the model's predictive abilities through 12 diverse
Fig. 3. Overall experimental framework.

TABLE I. RNN PREDICTION RESULTS

| Sr. | Number of Neurons in RNN | Batch Size | Number of Neuron in Dense Layer | Epoch | Sequence Length | Training Time | Mean Absolute Percentage Error | Prediction Accuracy |
|---|---|---|---|---|---|---|---|---|
| 1 | 16 | 10 | 1 | 10 | 15 | 104.81 | 1.97 | 98.03 |
| 2 | 32 | 10 | 1 | 10 | 15 | 122.66 | 2.38 | 97.62 |
| 3 | 64 | 10 | 1 | 10 | 15 | 143.77 | 2.02 | 97.98 |
| 4 | 16 | 10 | 1 | 50 | 15 | 487.67 | 2.33 | 97.66 |
| 5 | 32 | 10 | 1 | 50 | 15 | 588.08 | 1.75 | 98.25 |
| 6 | 64 | 10 | 1 | 50 | 15 | 643.61 | 3.7 | 96.3 |
| 7 | 16 | 32 | 1 | 10 | 15 | 44.19 | 4.06 | 95.94 |
| 8 | 32 | 32 | 1 | 10 | 15 | 49.04 | 1.60 | 98.40 |
| 9 | 64 | 32 | 1 | 10 | 15 | 58.62 | 1.59 | 98.41 |
| 10 | 16 | 32 | 1 | 50 | 15 | 193.112 | 1.77 | 98.23 |

combinations of neuron counts, batch sizes, and epochs. Here, epochs refer to the total number of complete passes made through the training dataset. The accompanying Table I on page 936 visually presents the outcomes of our tests, offering insights into the predictive efficacy of the RNN models across various configurations.

*1) Result analysis:* After a comprehensive analysis of the NIFTY 50 closing movement predictions using RNN across 12 distinct configurations (as outlined in Table I on page 936), we have identified a standout performer. Specifically, the RNN model with 64 neurons, a batch size of 32, and 50 training epochs consistently outperformed all other combinations in terms of prediction accuracy. Impressively, this configuration achieved an average prediction accuracy of 98.65%, demonstrating its robust performance. Additionally, the training time for this model was deemed satisfactory.

In Fig. 4(a), we present a visual comparison between the predicted and actual movement of NIFTY 50 closing prices, along with the associated differences. This graphical representation showcases the alignment of the predicted movement with the real data. Furthermore, Fig. 4(c) illustrates the training data's movement and provides a detailed comparison between the predicted and actual movements. The chart in Fig. 4(b) provides insights into the prediction accuracy versus error

analysis, showcasing the model's proficiency in estimating values.

Graphs depicting the loss vs. epoch are a valuable tool for visualizing the training progress of a neural network. This graphical representation involves plotting the loss metric on the vertical axis against the number of training epochs on the horizontal axis. Each point along the line represents the loss value recorded in consecutive epochs. In this context, the Fig. 4(d) illustrates the loss vs. epoch graph for the RNN model that achieved the highest accuracy in predicting the movement. This visual representation allows for a clear understanding of how the model's loss evolves throughout the training process, offering insights into its learning dynamics and convergence.

### C. Implementation of Stacked Long Short-Term Memory on Nifty 50 Index Dataset

LSTM (Long Short-Term Memory) stands out as a highly potent solution for tackling sequence prediction challenges. Its strength lies in its ability to retain past information, a critical factor for predicting future trends and records in daily QC items. Unlike traditional RNNs, LSTM networks effectively mitigate the issues of forgetting and gradient vanishing through the incorporation of self-loops and a unique internal gate structure. LSTM's unique architecture is characterized by four

(a) Prediction vs. actual vs. difference.

(b) Accuracy percentage vs. MAPE.

(c) RNN model implementation data.

(d) Losses vs. epoch.

Fig. 4. RNN model testing matrix (a) Prediction vs. actual vs. difference, (b) Accuracy Percentage vs. MAPE, (c) RNN model implementation data, (d) Losses vs. epoch.

essential gates: Input Gate, Cell State, Forget Gate and Output Gate. The forget gate plays a crucial role in determining which information is allowed to pass through the cell. Subsequently, the input gate decides how much new information should be incorporated into the cell state. Finally, the output gate regulates the information that is used for generating the output message. The development of the LSTM network was motivated by the necessity to address the challenge of vanishing gradients. The critical breakthrough in the design of LSTM involves incorporating non-linear, data-dependent controls into the RNN cell. These controls are trainable elements that serve the purpose of preventing the gradient of the objective function from diminishing in relation to the state signal. This innovation significantly boosts the network's ability to learn during training and enhance its predictive potential [29].

A SLSTM, an extension of the LSTM architecture, involves layering multiple LSTM units to process sequential data. Each layer in the stack handles output sequences from the preceding one, enabling the model to grasp intricate patterns. This layered structure enhances the model's ability to learn hierarchical features and representations in the data, similar to deep neural networks. Stacked LSTMs excel in capturing complex temporal patterns in sequences, making them valuable for tasks like time series prediction, natural language processing, and speech recognition. The accompanying Table II on page 938 visually presents the outcomes of our tests, offering insights into the predictive efficacy of the SLSTM models across various configurations.

*1) Result analysis:* Upon conducting a comprehensive analysis of NIFTY 50 closing movement predictions using SLSTM across 12 distinct configurations (as detailed in Table II on page 938), a clear standout has emerged. Specifically, the LSTM model featuring 32 neurons, a batch size of 10, and 50 training epochs consistently demonstrated superior predictive accuracy compared to all other parameter combinations. Notably, this configuration achieved an impressive average prediction accuracy of 99.10%, underscoring its robust performance. Moreover, the training time for this model was deemed satisfactory. Similarly, the model with 64 neurons, 50 epochs, and batch sizes of 10 and 32 yielded comparable accuracy rates of 99.01% and 99.08%, respectively. The analysis revealed that even the lowest achieved prediction accuracy was 98.03%. It's noteworthy that all 12 tested LSTM configurations yielded prediction accuracies exceeding 98%.

To provide a visual representation of our findings, Fig. 5(a) offers a comparison between predicted and actual NIFTY 50 closing price movements, along with the corresponding discrepancies. This graphical presentation effectively showcases the alignment between predicted and actual trends. Additionally, Fig. 5(c) highlights the movement in the training data and offers a comprehensive juxtaposition of predicted and actual trends. Finally, Fig. 5(b) presents a chart depicting the relationship between prediction accuracy and error, further demonstrating the model's adeptness at value estimation. Fig. 5(d) illustrates the loss vs. epoch graph for the SLSTM model that achieved the highest accuracy in predicting the movement.

TABLE II. SLSTM PREDICTION RESULTS

| Sr. | Number of Neurons in SLSTM | Batch Size | Number of Neuron in Dense Layer | Epoch | Sequence Length | Training Time | Mean Absolute Percentage Error | Prediction Accuracy |
|---|---|---|---|---|---|---|---|---|
| 1 | 16 | 10 | 16, 1 | 10 | 15 | 30.60 | 1.70 | 98.3 |
| 2 | 32 | 10 | 16, 1 | 10 | 15 | 30.14 | 1.70 | 98.30 |
| 3 | 64 | 10 | 16. 1 | 10 | 15 | 34.19 | 1.00 | 99.00 |
| 4 | 16 | 10 | 16, 1 | 50 | 15 | 148.07 | 1.10 | 98.90 |
| 5 | 32 | 10 | 16, 1 | 50 | 15 | 156.50 | 0.9 | 99.10 |
| 6 | 64 | 10 | 16, 1 | 50 | 15 | 185.01 | 0.99 | 99.01 |
| 7 | 16 | 32 | 16, 1 | 10 | 15 | 15.94 | 1.60 | 98.40 |
| 8 | 32 | 32 | 16, 1 | 10 | 15 | 15.46 | 1.40 | 98.60 |
| 9 | 64 | 32 | 16, 1 | 10 | 15 | 19.08 | 1.37 | 98.63 |
| 10 | 16 | 32 | 16, 1 | 50 | 15 | 66.77 | 1.04 | 98.96 |
| 11 | 32 | 32 | 16, 1 | 50 | 15 | 68.68 | 1.02 | 98.98 |
| 12 | 64 | 32 | 16, 1 | 50 | 15 | 87.23 | 0.92 | 99.08 |

(a) Prediction vs. actual vs. difference.

(b) Accuracy percentage vs. MAPE.

(c) SLSTM model implementation data.

Fig. 5. SLSTM model testing matrix (a) Prediction vs. actual vs. difference, (b) Accuracy percentage vs. MAPE, (c) SLSTM model implementation data, (d) Losses vs. epoch.

### D. Implementation of Bidirectional Long Short-Term Memory on Nifty 50 Index Dataset

A Bidirectional LSTM, abbreviated as BiLSTM, is a sequence processing architecture composed of two LSTMs. One LSTM processes input data in the forward direction, while the other processes it in reverse. This dual approach significantly enhances the information accessible to the network, thereby enriching the contextual understanding of the algorithm. For instance, in text analysis, a BiLSTM comprehends not only the current word but also the words that follow and precede it in a sentence, amplifying its contextual awareness. The accompanying Table III on page 939 visually presents the

outcomes of our tests, offering insights into the predictive efficacy of the BiLSTM models across various configurations.

*1) Result analysis:* After a comprehensive evaluation of NIFTY 50 closing movement predictions using BiLSTM across 12 distinct configurations (as outlined in Table III on page 939), a prominent frontrunner has surfaced. Specifically, the BiLSTM model with 64 neurons, a batch size of 32, and 50 training epochs consistently exhibited superior predictive accuracy compared to all other parameter combinations. This configuration notably achieved an impressive average prediction accuracy of 96.27%, highlighting its robust performance. Additionally, the training time for this model was satisfactory.

TABLE III. BiLSTM PREDICTION RESULTS

| Sr. | Number of Neurons in BiLSTM | Batch Size | Number of Neuron in Dense Layer | Epoch | Sequence Length | Training Time (Seconds) | Mean Absolute Percentage Error | Prediction Accuracy |
|---|---|---|---|---|---|---|---|---|
| 1 | 16 | 10 | 10,5,1 | 10 | 20 | 81.76 | 20.99 | 79.01 |
| 2 | 32 | 10 | 10,5,1 | 10 | 20 | 66.44 | 47.90 | 52.10 |
| 3 | 64 | 10 | 10,5,1 | 10 | 20 | 177.06 | 51.10 | 49.90 |
| 4 | 16 | 10 | 10,5,1 | 50 | 20 | 335.74 | 12.97 | 87.03 |
| 5 | 32 | 10 | 10,5,1 | 50 | 20 | 313.74 | 13.43 | 86.57 |
| 6 | 64 | 10 | 10,5,1 | 50 | 20 | 677.32 | 45.25 | 54.75 |
| 7 | 16 | 32 | 10,5,1 | 10 | 20 | 32.86 | 7.72 | 92.28 |
| 8 | 32 | 32 | 10,5,1 | 10 | 20 | 28.88 | 4.19 | 95.81 |
| 9 | 64 | 32 | 10,5,1 | 10 | 20 | 96.95 | 4.69 | 95.31 |
| 10 | 16 | 32 | 10,5,1 | 50 | 20 | 114.81 | 4.87 | 95.13 |
| 11 | 32 | 32 | 10,5,1 | 50 | 20 | 117.90 | 6.49 | 93.51 |
| 12 | 64 | 32 | 10,5,1 | 50 | 20 | 377.99 | 3.73 | 96.27 |

However, it's worth noting that the model with 32 neurons, 10 epochs, and batch size of 10 indicated underfitting, while the model with 64 neurons, batch sizes of 10 and 32, and epochs of 10 and 50 demonstrated overfitting. These outcomes yielded prediction accuracies that were suboptimal for our NIFTY 50 trend prediction dataset.

To visually depict our conclusions, Fig. 6(a) provides a comparative view of predicted and actual NIFTY 50 closing price movements, along with discrepancies. Fig. 6(c) presents the movement in training data, effectively comparing predicted and actual trends. Fig. 6(b) offers a chart illustrating the connection between prediction accuracy and error, underscoring the model's proficiency in value estimation. Additionally, Fig. 6(d) showcases the loss vs. epoch graph for the RNN model with the highest predictive accuracy. In summary, the identified BiLSTM configuration demonstrates significant promise for NIFTY 50 trend prediction.

## IV. COMPARATIVE STUDY AND FUTURE RESEARCH OPPORTUNITIES

Based on our analysis of the RNN, SLSTM, and BiLSTM models, the SLSTM model emerged as the standout performer for predicting NIFTY 50 closing movement, achieving an impressive prediction accuracy of 99.10%. The RNN model also showcased strong predictive capabilities, yielding an average accuracy of 98.65%.

However, in contrast, the BiLSTM model did not demonstrate consistent success across various cases. In its most favorable scenario, the BiLSTM model achieved an average accuracy of 96.27%. It's noteworthy that the training time of the BiLSTM model was comparatively higher when compared to SLSTM and RNN. Additionally, the BiLSTM model was more susceptible to issues of both underfitting and overfitting. In summary, the SLSTM model showcased remarkable predictive prowess, while the RNN model also performed well. On the other hand, the BiLSTM model faced challenges and did not consistently match the accuracy levels achieved by the other two models. Fig. 7(a) illustrates the comparison of predicte values, while Fig. 7(b) depicts the accuracy of predicted movements of the models.

This study has advanced our understanding of stock market prediction but also highlights several promising directions for future research. Enhancing prediction accuracy through the refinement of existing models, including the integration of external data sources, is a key avenue. Exploring alternative deep learning architectures and hybrid models holds potential for improved results. Moreover, incorporating sentiment analysis from various sources such as financial news, social media, and macroeconomic factors can offer a more comprehensive understanding of market movements. Investigating the interpretability of deep learning models and their capacity to capture underlying market dynamics is essential for their practical acceptance and use in the real world.

## V. CONCLUSION

After a thorough exploration of diverse algorithms, we have uncovered their significant relevance within stock markets. Given the intricate interplay of factors shaping stock market dynamics, there exists a compelling opportunity to refine and elevate the algorithms and models employed for predicting stock prices. Our comparative analysis has illuminated the robust performance of deep learning models, including LSTM, ANN, RNN, SLSTM, and BiLSTM, in efficiently forecasting stock prices with minimal errors. To delve deeper, we focused on implementing RNN, SLSTM, and BiLSTM deep learning models within this study, harnessing a comprehensive 27-year dataset of NIFTY 50 data as our input. Our methodology allocated 70% of the dataset for model training, reserving the remaining 30% for validation purposes.

During the validation phase, our findings emphatically underscored the superior predictive capabilities of the SLSTM model. It consistently outperformed the other three models in accurately predicting the closing movement of the NIFTY 50 index, achieving an impressive average accuracy of 99.10%. Our analysis further unveiled captivating behaviors inherent in deep learning models, presenting avenues for subsequent exploration and model refinement. By enhancing the consistency of error patterns and elevating accuracy, these models' efficacy can be further amplified. Furthermore, our research lays the groundwork for extending prediction prowess to both short-term and long-term future movements. The scope of its applicability can be expanded to encompass stock prices within other sectors, thereby fostering new realms of inquiry.

# Detection of Dyslexia Through Images of Handwriting using Hybrid AI Approach

Norah Dhafer Alqahtani[1], Bander Alzahrani[2], Muhammad Sher Ramzan[3]

Faculty of Computing and Information Technology, King Abdulaziz University, Jeddah 21589, Saudi Arabia[1,2,3]

Information Systems, King Khaled University, Abha 61421, Saudi Arabia[1]

*Abstract*—Dyslexia is a neurodevelopmental disorder characterized by difficulties with acquiring reading skills, despite the presence of appropriate learning opportunities, sufficient education, and a suitable sociocultural context. Dyslexia negatively affects children's educational development and their acquisition of language, as well as their writing. Therefore, early detection of dyslexia is of great importance. The prediction of dyslexia through handwriting is an active research field of almost five years' standing. In this paper, we propose hybrid models (CNN-SVM) and (CNN-RF) to reveal dyslexia through images of handwriting. The paper aimed to develop a CNN model to extract features from images of handwriting where CNN is highly reliable in extracting features from images, and to use SVM as a classifier due to its generalization abilities as well as using random forest (RF) as a classifier in (CNN-RF). The study aimed to combine a deep learning (DL) model and a machine learning (ML) model to improve model performance. Data sets that consisted of 176,673 images of handwriting were used in this study. The hyperparameter of the model was adjusted and examined in order to classify the three categories of handwriting. The CNN model that was built demonstrated an outstanding accuracy rate of 98.71% in effectively categorizing three distinct types of handwriting—99.33% with SVM, and 98.44% in the CNN-RF model. The aim of recognizing dyslexic handwriting through CNN-SVM was successfully attained, and our model outperformed all previous models.

*Keywords—Dyslexia; dyslexia detection; deep learning; dyslexia classification; CNN model; SVM model; random forest model*

## I. INTRODUCTION

Dyslexia is a language-based, neurobiological, developmental learning disorder that affects how people learn to read (in terms of accuracy and speed) and how they learn to spell. As a result of impairments in the phonological component of language, individuals with dyslexia struggle to connect spoken language with the written word [1]. Difficulty accurately and fluently deciphering words can impact reading and vocabulary development [2].

Although dyslexia is neither a sign nor an indicator of low intelligence, it may cause a person to perform poorly academically and to become frustrated. A person may drop out of education entirely. Detecting dyslexia in children as early as possible and using assistance tools and intervention programs may improve their skills and learning performance. In recent years, a greater awareness of dyslexia and other learning difficulties has developed.

Traditional diagnostic tools and tests have been used to detect these disorders and assist individuals based on the results of diagnostic tests. These detection techniques have focused on behavioural elements, such as proficiency in reading and writing and working memory and have also included IQ tests.

They are generally standardized tests [3]. Since every individual with dyslexia has a unique experience of the disorder, this approach can be time-consuming and runs the risk of missing cases or providing inaccurate diagnoses. Traditional machine learning methods and deep learning algorithms are being increasingly used in dyslexia and biomarker detection and have proven their effectiveness in making diagnoses. One of the deep learning models is Convolutional Neural Network (CNN), which has the ability to deal with images and extract features from them. This paper aims to enrich research in this field; our study is considered the sixth study in predicting dyslexia by looking at handwriting using DL models. In addition, the study developed CNN model to raise its ability in extracting features. Moreover, It builds hybrid models based on CNN; (CNN-SVM and CNN-RF) for developing dyslexia detection through the use of machine learning (ML) and deep learning (DL). Better classification accuracy can be achieved when the DL and ML models are combined than when they are used separately, as noted in [4], where the first (DL) can automatically extract useful spatial characteristics, while the second (ML) can classify the features that have been extracted by DL mode (CNN) . The paper is organized into five sections: Section II details the related work, noting studies that have examined the detection of dyslexia through children's handwriting and their key results. Section III introduces the phases that will be followed in this study, Section IV presents suggested models that will be used in this study. Section V illustrates the steps of the experiment, starting from data set acquisition to classification phase. Section VI explores the results of this study. Section VII is the conclusion.

## II. RELATED WORK

The advent of AI and its various capabilities have opened up possibilities for automating methods of diagnosis and early detection of dyslexia through the use of ML and DL. Existing methods of detecting dyslexia have included detection using Magnetic Resonance Imaging (MRI), Electroencephalogram (EEG) signals, and eye-tracking, as well as Electrooculogram (EOG) signals. The ML method and computer vision can help with dyslexia classification as illustrated in [5]. Although earlier methods achieved good accuracy, it was time-consuming and expensive to collect the required neurological data. Dyslexic children have irregular handwriting and reverse their letters. This feature (inverted letters) helped Spoon et al. [3] to look at a new method for dyslexia prediction¬—the use of images of handwriting. They attempted to collect samples to investigate if there was a possibility of diagnosing dyslexia through handwriting samples using the CNN model. They achieved 55.71.4% accuracy on average—better than

the random standard of 50%. These preliminary outcomes nevertheless showed promise, with the detection rate much higher than that able to be achieved by instructors and parents at that time. These results encouraged researchers and led them to prove this concept in their study [6]. They used 100 samples of handwriting and built CNN models for prediction. The result was 77.6%—higher than the previous result. In another study, Isa et al. developed an automated handwriting recognition framework using an image-processing and pattern-recognition technique through the use of MATLAB to build an Artificial Nural Network (ANN) model—a method for processing information that was inspired by how biological neural systems process information [7]. The study employed four letters—'f,' 'p,' 'b,' and 'c'—as well as four numbers—'5,' '2,' '6,' and '7'. These samples were chosen because dyslexic people are often confused about the shape of these figures. The samples were used to train and test a suggested model —ANN—to extract features from images and utilized MLP as a features classifier. The model achieved accuracy of 73.33%, which was still considered low, due to the lack of samples. This study was followed by an Indian study that aimed to determine whether it was possible to detect dyslexia in Indian handwriting [8]. The researchers were able to collect approximately 267 pictures from the participants' textbooks and process them. The CNN model was used to extract features from the images and predict dyslexia in children; here it was able to automatically find strong features by using Keras and TensorFlow—the accuracy average was 86.14%. All previous studies suffered from the small-scale size of the data sets and the problem of an imbalanced class, which affected the performance of the DL models as well as well as their tend to the large-scale class. In the study [9] researchers put more effort into building a dyslexia data set that could be utilized by other researchers in the future, they used these data sets to build different CNN models to compare the performance of these models. They employed data augmentation techniques to maximize the scale of data sets and solve the class imbalance problem. Different CNN models, like CNN-1, CNN-2, CNN-3, and LeNet-5, were used and compared in this study. The CNN-1 model achieved high accuracy compared with other models, which reached 87% in the classification process. The transfer learning technique was used to develop the performance of the DL model for classification purposes in [1]. The study utilized the same data set as the previous study and built a CNN model based on the well-known handwriting detection architecture of LeNet-5. The suggested model achieved an outstanding accuracy of 95.34% in the three classes of classification. These studies have some limitations which illustrated in Table I.

This study presents the following contributions: (i) Develop the CNN model to raise its performance in feature extraction from the handwriting model; (ii) assessing the performance of SVM and RF classifiers, as well as a CNN classifier, in terms of their ability to utilize CNN feature extraction for improving diagnosis accuracy. These models will use the dataset that has been used by the last two studies after removing the redundancy from it, and the classes will be balanced.

## III. METHODOLOGY

The study passes through three phases: the first phase relates to data preprocessing and dividing the dataset (training, validation, and testing) before used by the CNN model. In the second stage, the CNN model will be built and used a dataset that has been processed in phase 1(training, validation) to train the model in extracting features from the handwriting images till reach the required accuracy. In the last stage, training and validation data will be used as one data set to train the different classifiers, then test data will be used to test the performance of different classifiers. Fig. 1The workflow of the proposed method. illustrates the workflow of this study. The primary objective of the research is to introduce and evaluate hybrid models, specifically (CNN-SVM) and (CNN-RF), for the effective detection of dyslexia through images of handwriting. The research leverages Convolutional Neural Networks (CNN) to extract meaningful features from the handwriting images, exploiting the well-known reliability of CNNs in image feature extraction. In addition, Support Vector Machines (SVM) are chosen as classifiers due to their strong generalization capabilities. The (CNN-RF) model introduces Random Forest (RF) as an alternative classifier, enriching the model diversity. This hybrid approach combines deep learning (DL) models, such as CNN, with machine learning (ML) models like SVM and RF, with the intention of enhancing overall model performance.

## IV. SUGGESTED APPROACHES

The study suggested hybrid models based on CNN model for classifying data in this study (CNN-SVM and CNN-RF). In addition, developing CNN model that have been used in the literature to raise its ability in extracting features and the raise the performance in the prediction of dyslexia.

### A. Convolutional Neural Network

The CNN model is a DL technique that is specifically designed for the task of image classification. It operates on two-dimensional (2D) images as input data. Similar to ANNs, the CNN model exhibits a hierarchical architecture consisting of multiple layers, where the output of each preceding layer is systematically linked to the input of the subsequent layer. A traditional ANN structure is paired with a stage for extracting spatial features using a sequence of convolutional filters [4]. The architectural design of the CNN model typically encompasses three primary, interconnected layers—namely, the convolutional layer, pooling layer, and fully connected layer. The initial step in the convolutional layer involves the computation of weights through the application of a convolution filter. This filter performs a dot product operation on either the 2D input data or the outputs of preceding layers within a localized region [4]. Feature maps are generated by using a nonlinear activation function, such as a Sigmoid, Tanh and Rectified Linear Unit (ReLU), which is what was utilized in this study. The pooling layer is utilized to condense the retrieved features into representative values, such as maximum or mean values, in order to simplify the information. The utilization of the max pooling layer has been extensively employed in the classification process of CNNs [10]. The two layers (convolutional and pooling) are sequentially arranged in an alternating manner until higher-level features are obtained. Once the convolutional and pooling processes have been performed to extract the high-level features, the resulting feature maps are converted into a one-dimensional vector and subsequently passed to the fully connected layer. Typically, the final, fully connected

TABLE I. LIMITATIONS OF THE RELATED WORKS

| Study | Limitation |
|---|---|
| [3] | 1) They achieved 55.7% accuracy, and the baseline was 50%, there was no significant improvement.<br>2) To improve the outcomes, more data are needed, particularly data from dyslexic pupils. |
| [6] | 1) They achieved 77.6% accuracy results, still, there is a chance to improve it.<br>2) Their dataset consists of 100 samples, which are considered small-scale data. CNN does not perform well with small-scale data. |
| [7] | 1) The data set is small and focused on specific small letters 'b', 'c', 'f', 'p'.<br>2) The performance of the classification accuracy does not exceed 75%. This is because the ANN needs a lot of samples to get high. |
| [8] | 1) In this study, the letters are cropped manually, which required improvement, Handwritten recognition by using (OCR) can be used, or cursive and skew methods.<br>2) The dataset used in the experiments is small. More data is required to study the results further. |
| [9] | 1) The imbalance class problem is still in this study although data augmentation techniques have been applied, in addition to the presence of some duplicate images in the dataset.<br>2) The study requires more dyslexic handwriting images for the test set (real dataset) in examining the performance of the model. |
| [10] | 1) The imbalance class problem is still in this study although data augmentation techniques have been applied, in addition to the presence of some duplicate images in the dataset.<br>2) Other data augmentation techniques can be applied where the study focused on the rotation technique. The transfer learning effectiveness from sources was not explained well.<br>3) It can be improved classification tasks by using other methods and rise the model performance. |

layer of a neural network is responsible for normalizing the network's output. This normalization process involves utilizing a SoftMax function to get probability values corresponding to the expected output classes. Ultimately, the categorization outcome is determined through the use of the maximum probability rule [4]. CNN has produced outstanding results in the field of computer vision and pattern recognition [11], for example in visual recognition [12], image retrieval [13], and scene annotation [14]. This model has been effectively implemented for character recognition in handwritten images. It has been successfully used in offline, handwritten Javanese character recognition [15]. In the study [12], CNN achieved 88% in the Arabic data set, and high accuracy in MODI (ancient Indian script) character recognition [16]. According to [17], modifying the CNN with two different types of training input—reconstruction feedback and classification feedback—was able to achieve an accuracy rate of 99.59% on the MNIST data set. Some of the research tweaks CNN in a number of ways to improve its performance and accuracy rate. Other research alters the input data to enhance the accuracy rate of the CNN model.

### B. Support Vector Machine

SVM is a supervised learning model with corresponding learning algorithms that analyze data utilized for classification and analysis of regression. This model is considered one of the most solid prediction methods, which depend on statistical learning frameworks. It can be utilized to solve different problems in the real world; for example, it is useful in the categorization of text and hypertext, the recognition of handwritten characters [18], face detection, and satellite data classification. There are two kinds of SVM: linear and nonlinear. The first is utilized for linearly separable data. A data set is said to be linearly separable if it can be divided into two classes using a single straight line; the classifier used is known as a linear SVM classifier. However, if the data set cannot be classified using a straight line, such data is known as nonlinear data, and the classifier applied is called nonlinear. The basic idea of SVM is to get the best hyperplane, which maximizes the hyperplane margin. A good generalization is achieved by a hyperplane with a maximum margin.

CNN is an extension model of multilayer perceptrons (MLP), since its theoretical learning technique is the same as MLPs'. The MLP learning algorithm tries to reduce errors in the training set: it depends on empirical risk minimization (ERM). When the backpropagation method discovers the first separating hyperplane, whether it is a global or local minima, the training operation ends. The MLP learning algorithm does not continue to enhance the separating hyperplane solution. Further, the SVM classifier utilizes a structural risk minimization (SRM) precept on unseen data to minimize the errors of generalization, with a constant distribution for the training set [19]. Therefore, SVM generalization ability is much better than that of MLP. According to [20]–[23], the SVM method has high generalization performance, which means it can correctly classify data that has never been seen before. One paper [24] advised using the SVM classifier as an end classifier because it has better generalization ability than neural networks on standard CNN.

### C. Random Forest

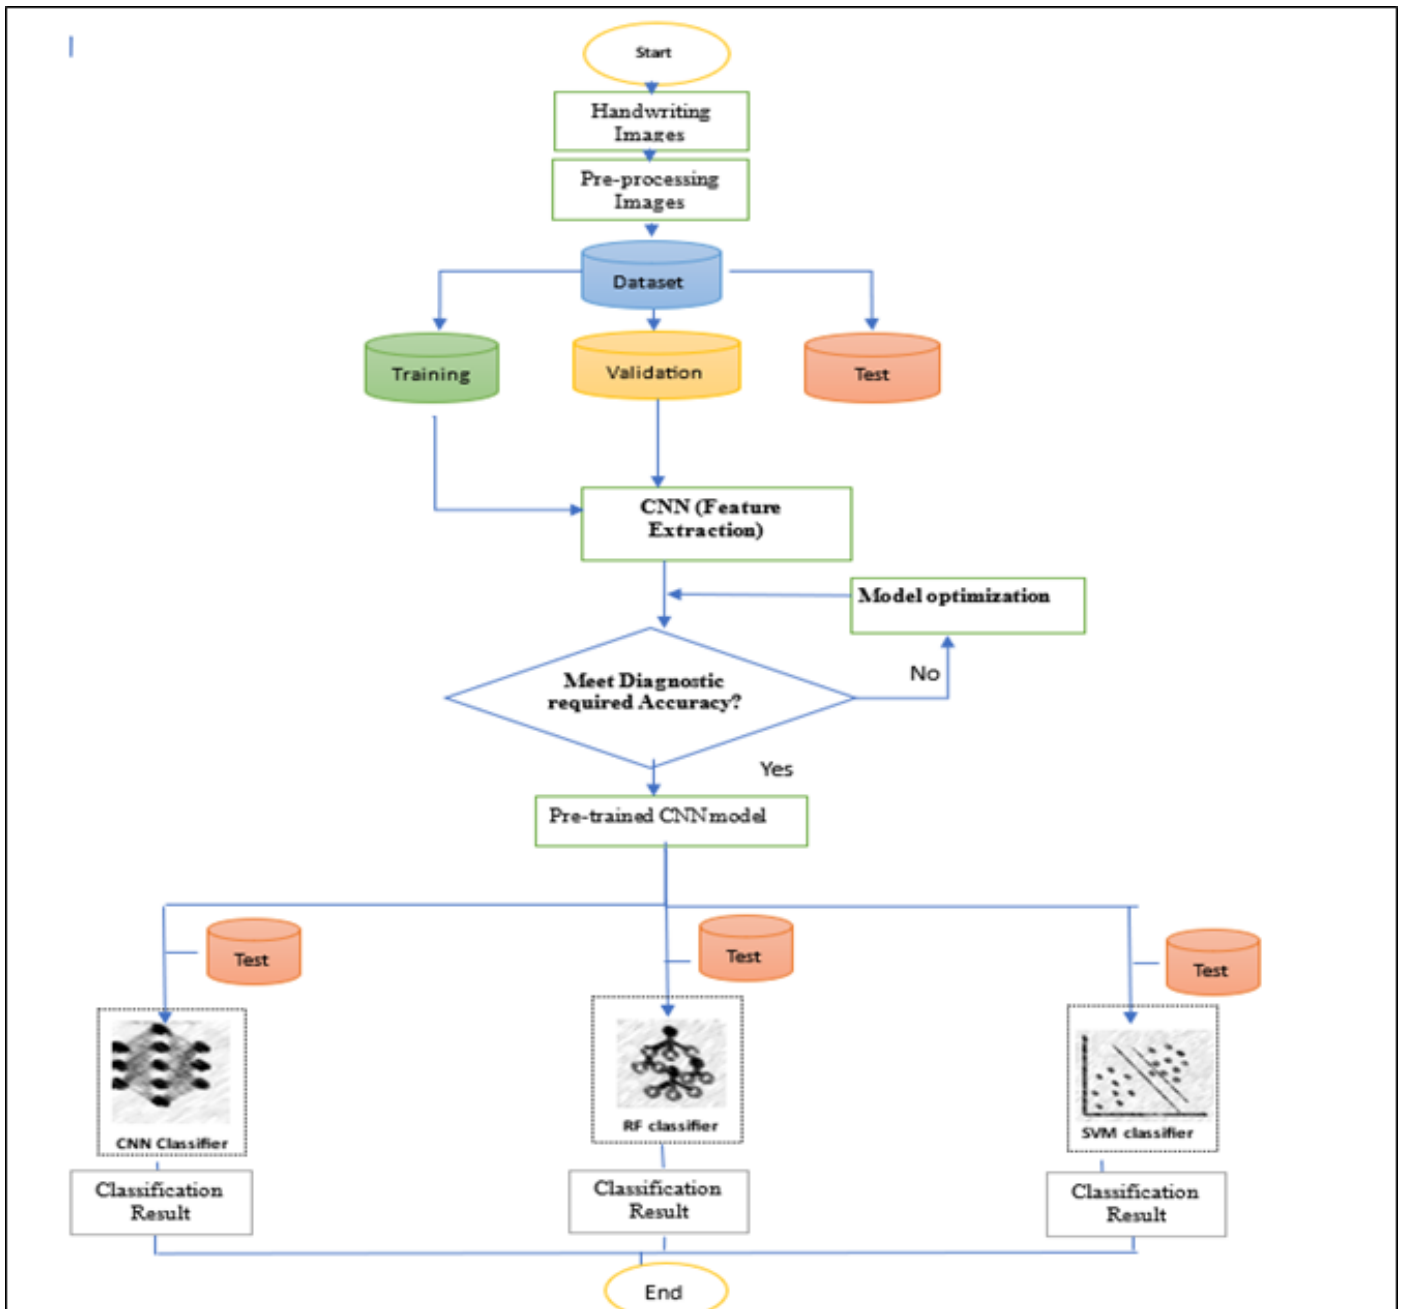
RF is widely utilised in the field of machine learning and falls under the category of supervised learning techniques. ML can utilise this technique for both regression and classification tasks. The approach is rooted in the principle of ensemble learning, wherein many classifiers are integrated to address intricate problems and enhance the model's performance [25]. The classifier known as "Random Forest" is so named because it consists of many decision trees that are constructed using different subsets of the provided dataset. By taking the average of the predictions made by these decision trees, the RF classifier aims to enhance the accuracy of its predictions for the supplied dataset. The random forest algorithm utilises an ensemble approach by aggregating predictions from several decision trees. By considering the majority vote among these predictions, the random forest algorithm generates the final output. We chose these classifiers for this study for two reasons: previous studies relied on this CNN classifier to classify dyslexia, and its use here after its development shows an increase in the performance of the model compared to the previous one. In addition, RF is considered an effective and robust algorithm due to the avoidance of over-fitting, its high level of accuracy of classification, its ability to assess the


Fig. 1. The workflow of the proposed method.

relevance of variables [26] and its ability to operate effectively on huge databases [27] as well as the ability of SVM in generalization as we explained before.

## V. EXPERIMENT

### A. Data Set Used

The data set used in this study was images of the handwriting of three classes: reversal (dyslexics), normal, and corrected handwriting suggested by Susan Barton, founder of Bright Solutions for Dyslexia [28]. This data is publicly available in [29] which is obtained from three distinct sources. The uppercase letters were sourced from the NIST Special Database 19 [30] while the lowercase letters were obtained from the Kaggle data set [31]. Additionally, certain data sets for testing purposes were collected from dyslexic students attending Seberang Jaya primary school by researchers in [9]. This data set consisted of 176,673 images. In the context of the reversal class, the normal handwriting data set underwent a mirroring process, resulting in the creation of reversal data sets through horizontal flipping as mentioned in study [9] as well as apply rotation and noise injection techniques after horizontal flipping. This data set has been used by the last two studies in this field [9], [1]. Samples of this data set are shown in Fig. 2Samples of datasets used., where A is a sample of the reversal class, B is a sample of the normal class, and C is sample of

corrected writing.

### B. Pre-processing

The data sets needed to be processed before feeding the classifier by them. A foreground-background swap was adopted to reduce computational overhead, as training an image with more white points (value 1) than black points (value 0) consumes more power and memory [32]. This procedure alters the background color to black while leaving the handwriting white. The subsequent action is the process of cropping the image to isolate the section containing the written content. This procedure involves the removal of undesired sections of an image, specifically from the bottom and top, and the right and left sides. The resulting image will be centered on the alphabet, thereby emphasizing it. In our study, the photos underwent a resizing process to dimensions of 32×32 pixels, ensuring uniformity across all data sets. This was done to facilitate their use as input for the CNN model. Ultimately, the entire data set was converted into a .csv file based on the one-hot encoding technique. The data sets were divided into 70% handwriting data sets for training objectives, 15% for validation, and 15% for testing objectives.

### C. Feature Extraction

Feature extraction from the handwriting data sets was done through the CNN layers, which consisted of four convolutional layers, two max-pooling layers, and a flattened layer. Fig. 2 shows these layers. Convolutional layers act as a feature extractor; they receive the feature representations of the input pictures, and the trainable convolutional kernel adjusts its kernel weights automatically during the backpropagation training process [33], [34]. The pooling layer works to alter the input feature into a statistical picture of the surrounding feature, hence making the next feature smaller than the one before it [34]. As shown in Fig. 3, a batch normalization layer subsequent to each convolutional layer is suggested. This is used in neural networks to normalize the activation values of hidden units. Normalization ensures that the activations maintain consistent behavior during training, leading to improved accuracy and faster training [35]. Moreover, to prevent overfitting of the model, we utilized a dropout layer, which implements a regulatory mechanism wherein a subset of neurons is randomly disregarded during the training process. After being built, the model required fine tuning to raise performance and therefore accuracy in the training data sets. According to our objectives in the three class classifications to predict dyslexia, we preferred to utilize the RLU as an activation function, as it addresses the issue of gradient vanishing that arises due to the utilization of sigmoid and tanh activation functions in deep neural networks [36]. Moreover, it enhances the intricacy of the neural network by incorporating non-linearity, hence enabling the network to acquire more intricate representations of the data, thereby increasing the performance of the model. The features extraction vector has generated from the convolution operation, the pooling operation as well ReLU function, as shown below equation,

$$O_{x,x} = \sum_x \sum_y f[l,k] * [x-l][y-k]$$
$$F_{x,y} = \max(0, F\_O_{x,y})$$

(1)

The handwriting images are fed via CNN layers starting from convolutional layer for extracting significant features. The given input consists of a two-dimensional matrix with a rank of 2. The matrix has M rows and N columns, where the indices for the rows and columns are denoted as (x, y). It is important to note that the values of x and y should satisfy the condition $0 \le x \le M$ and $0 \le y \le N$. The convolutional operation layer produces the final feature map values, denoted as Fx,y which are deemed to be significant for the task at hand. The utilization of an activation function is implemented at every layer in order to enable the model to effectively address nonlinear problems, as demonstrated in Eq. 1. Additionally, the incorporation of dropout and max pooling techniques serves to reduce the computing burden associated with the model.

The Adam optimizer was also used; the Adam optimization technique has gained wider acceptance in recent years for its application in deep learning tasks related to computer vision and natural language processing. It combines the advantages of AdaGrad and the RMSProp optimizer. One of the setup parameters utilized in the Adam optimization algorithm is the learning rate, which is assigned a value of 0.001. The last feature map undergoes a transformation so as to be represented as a vector with a single column. The recognition experiment involves feeding a single-column feature vector, which consists of identifiable features, to the classifier (a soft max layer of CNN, SVM, and RF) as shown in Fig. 3.

### D. Classification

Following the completion of the pre-processing and feature extraction procedures, we classified the handwritten digit images using the different classifiers. Different classifiers were trained by utilizing feature vectors stored in a matrix format. The evaluation of the numerical value was conducted using the outcomes obtained from the training process. The hyperparameter of SVM employed an RBF function as its kernel, the cost parameter C = 1 and degree = 3. The RF was used to evaluate the model classification with hyperparameter (n_estimators), which was equal to 50 in this study, and to evaluate classifications with a fully connected layer in the CNN with a batch size = 64 and number of epochs = 40.

### VI. RESULTS DISCUSSION AND OBSERVATIONS

In this section we evaluate the performance of the three models: the CNN model, the CNN-RF model, and the CNN-SVM model.

Loss and accuracy: The evaluation of a CNN model's performance in extracting features is determined by measuring the loss and accuracy on both the training and validation data sets. The testing dataset will be used in classification stage after the training all classifier as we explained in methodology section. The analysis and interpretation of this loss value provide insights into the model's effectiveness on these two sets. The error aggregation is computed as the cumulative aggregate of errors made for each individual example within the training or validation sets. The loss value refers to the degree of performance exhibited by a model following each iteration of optimization. As seen in Fig. 4Loss of a CNN model., the training loss in the CNN model was 0.0407, while the validation loss was 0.0384.
Fig. 2. Samples of datasets used.

Fig. 4. Loss of a CNN model.

Fig. 5. Accuracy of CNN model.

The evaluation of a model's accuracy often occurs subsequent to the estimation of its parameters and is quantified as a percentage. The accuracy of a model's predictions is determined by its ability to closely align with the actual data. Fig. 5Accuracy of CNN model. clarifies the accuracy of the CNN model, which reached above 98.59% in feature extraction with batch size = 64 and number of epochs = 40.

Confusion matrix:A confusion matrix is a tabular representation that provides a concise summary of the predictive performance of an ML model when evaluated against a specific set of test data. Measurement of classification model performance
Fig. 3. CNN layers.

is frequently employed to assess the accuracy of predicting categorical labels for input instances. This provides a means of comparing the observed values with the values that were forecasted or estimated. The confusion matrix of the CNN model is shown in Fig. 6CNN confusion matrix. and 7CNN report of confusion matrix., where 0 denotes normal, 1 point denotes corrected, and 2 points denote reversal. This matrix is particularly useful for measuring important metrics: recall, precision, specificity, and accuracy. The elements within the matrix are classified as true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). A TP occurs when an observation is classified as positive and is correctly expected to be positive. An FN occurs when an observation is determined to be positive but is incorrectly anticipated to be negative. A TN occurs when the observed outcome is negative and is accurately anticipated to be negative. An FP

occurs when an observation is determined to be negative but is incorrectly anticipated to be positive.

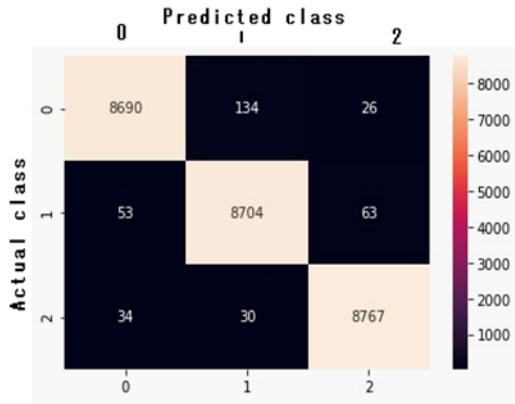
$$
\begin{aligned}
\text{Accuracy} &= \frac{TP + TN}{TP + TN + FP + FN} \\
\text{Precision} &= \frac{TP}{TP + FP} \\
\text{Recall} &= \frac{TP}{TP + FN} \\
\text{F1-Score} &= \frac{2 * \text{precision} * \text{recall}}{\text{precision} + \text{Recall}}
\end{aligned}
\tag{2}
$$


Fig. 6. CNN confusion matrix.

Fig. 9. CNN-RF confusion matrix.

The CNN-SVM model achieved high accuracy—99.33%—as illustrated in Fig. 10CNN-SVM report of confusion matrix. and 11CNN-SVM confusion matrix.. This proves what noted in [21]–[24] that SVM classifiers have a strong generalization ability.

| CNN-SVM | 0.9933 |

## VII. CONCLUSION

In the field of image identification, the DL architecture known as CNN is becoming remarkably more significant. It has been utilized in all previous studies to recognize dyslexia through handwriting. Its performance has varied, starting at 55% and going up to 95% accuracy. This has been due to factors such as the small-scale size of the data set as well as problems with imbalanced classes. Our paper targeted developing the CNN model to maximize the performance in feature extraction and therefore classification and leveraging the combination of the DL and ML models to improve the prediction of dyslexia through handwriting image models, in terms of loss and accuracy, in the training model test. CNN-SVM outperformed CNN and CNN-RF, which reached 98.59% and 98.44%, respectively, while CNN-SVM achieved 99.33% in multiclass classification. Expanding research and the development of applications based on the identification of dyslexia through online handwriting is possible with the development of DL. We encourage researchers to seek to build a handwriting data set for children with dyslexia, as there is no collection currently available, except for those to whom the research has been applied.

*Abstract*—Recent years, edge computing has been getting increased attention due to its ultra-low delay service deliveries. Plenty of works have focused on the performance improvement of edge computing by e.g., edge server deployment, edge caching, and task offloading. While, there is a lack of work on improving the investment cost for building or upgrading the edge site deployment by making a decision on which places edge sites are deployed. In this paper, we focus on the edge site deployment problem (ESDP) to maximize user coverage with fewest edge sites. We first formulate ESDP into a binary nonlinear programming with two optimization objectives of user coverage maximization and edge site minimization, and prove that ESDP is NP-complete. Then, we propose a hybrid meta-heuristic algorithm to solve ESDP with polynomial time complexity, which combining the crossover and mutation operators of genetic algorithm with self- and social-cognition of particle swarm optimization. At last, we conduct extensive simulated experiment based on a real data set to evaluate the performance of our proposed algorithm. The results show that our algorithm achieves 100% user coverage with much fewer edge sites than other seven meta-heuristic algorithms, and has a good scalability.

*Keywords*—*Edge computing; edge deployment; GA; PSO; meta-heuristic*

## I. INTRODUCTION

Over the past two decades, cloud computing has been applied in all fields, due to its numerous benefits, e.g., on-demand, flexibility, reliability [1]. But in recent years, cloud computing alone cannot satisfy real time requirements of many user requests [2], especially in mobile networks. This is mainly because cloud resources are shared by users around the world and cloud computing platforms provide services over Wide Area Networks (WAN) that generally have high latencies. In addition, more and more users request services by mobile devices nowadays [3] with the rapid development of communication and network technologies, which results in a highly dynamic locations where requests are initiated and thus a much fluctuating communication performance between users and cloud computing platforms.

Therefore, in recent years, edge computing is becoming more and more popular in both industry and academia, because it can efficiently compensate for the shortcomings of cloud computing [4], [5]. In edge computing, some computing and storage resources are deployed close to user devices, and thus ultra-low latency services can be provided for users. While, due to the distribution and heterogeneity of limited edge resources,

it is a very challenging work to provide high quality services for all users. Many works have focused on addressing the challenge in various aspects including edge server placement [6], [7], edge caching [8], [9], task offloading [10], [11] and so on. While, all of works assume that edge sites have been deployed, where edge resources are placed and used for processing requests. For each request, it can be accepted by closely located edge sites, because edge sites provide Local Area Network (LAN) connections for users usually by wireless networks in a short distance. Thus, the locations of edge sites have an effect on the service quality, by deciding which edge resources can be used for processing every request. Therefore, in this paper, we focus on the edge site deployment problem (ESDP) that is deciding which of multiple candidate places to be edge sites.

For a user, if it is not covered by the network signal of any edge site, then it cannot communicate with any edge site. In such case, the user's requests cannot received by an edge site, and thus cannot be processed by edge resources, which can cause major performance degradation of these requests. Therefore, in this paper, we identify maximizing user coverage as a major objective, which is maximizing the number of users that are covered by the network signal of at least one edge site. As the profit maximization is the first aim of service providers, in this paper, we consider the deployment cost as the second optimization objective by minimizing the number of deployed edge site.

Due to geographical characteristics and urban planning, candidate places generally are dispersive. This leads to that ESDP is a discrete optimization problem and hard to be solved precisely. Therefore, in this paper, we exploit meta-heuristic algorithms for solving ESDP, due to their powerful search ability [12]. To be specific, we consider to exploit Genetic Algorithm (GA) and Particle Swarm Optimization (PSO), which are most representative evolutionary algorithm and swarm intelligence, respectively. GA, inspired by Darwin's theory of evolution, has powerful global search ability by evolutionary operators but usually convergences slowly [13]. PSO is designed based on the movements of birds for foraging, which has high convergence speed but is easily trapping into local best positions [14]. Thus, GA and PSO are complement each other, and we design a hybrid meta-heuristic algorithm by combining their advantages for providing a ESDP solution with maximized user coverage and minimized monetary cost. In brief, the contributions of this paper are as followings.

- First, ESDP is formulated as a binary non-linear programming, and its hardness is proven. The objectives include the user coverage maximization and the monetary cost minimization.

- Then, a hybrid meta-heuristic algorithm is proposed for solve ESDP in polynomial time complexity by combining GA and PSO. The hybrid algorithm uses the swarm evolving framework of PSO to exploit the self- and social-cognitions, and employs the mutation and crossover operators of GA to ensure the population diversity for a powerful global search ability.

- At last, the performance of proposed algorithm is evaluated by extensive simulated experiments that are designed based on a real data set. Experiment results show that the proposed algorithm achieves 100% user coverage and requires much less edge sites than several other meta-heuristic and hybrid algorithms.

The rest of this paper is organized as followings. Section II presents the formulation of ESDP. Section III illustrates the proposed meta-heuristic algorithm, and section IV shows the performance evaluation results. Section V discusses the related works. At last, Section VI concludes this work.

## II. PROBLEM STATEMENT

In this paper, we consider to select part of multiple candidate places to deploy edge sites for providing edge computing services. Assuming that there are $P$ candidate places represented as $p_i, 1 \leq i \leq P$. For candidate place $p_i$, its location is $(l_{i,1}^P, l_{i,2}^P)$, which can be either latitude and longitude in geographic coordinate or horizontal and vertical values in Cartesian coordinate. When an edge site is decided to be deployed on $p_i$, there will be $m_i$ monetary cost. For each edge site, the maximal distance of network signal is $S$. This is meaning that a user is covered by an edge site or a candidate place if and only if their distance is smaller than $S$. The edge site deployment decisions can be indicated by binary variables $x_i, 1 \leq i \leq P$, where $x_i = 1$ means $p_i$ is selected for deploying an edge site, and $x_i = 0$ means not. In this case, the total monetary cost $C$ can be calculated by Eq. (1).

$$C = \sum_{i=1}^{P}(m_i x_i) \qquad (1)$$

In the considered edge computing, there are $U$ users $(u_j, 1 \leq i \leq U)$. The location of $u_j$ is $(l_{j,1}^U, l_{j,2}^U)$. Then, the distance $(d)$ between users and candidate places can be calculated by Eq. (2) and (3), respectively, when using geographic and Cartesian coordinate systems. Where $R$ is the earth radius, which is usually set as 6371.393 kilometres.

$$\begin{aligned} d_{i,j} = \ & R \arccos(\cos l_{i,1}^U \cos l_{j,1}^P \cos(l_{i,2}^P - l_{j,2}^U) \\ & + \sin l_{i,1}^P \sin l_{j,1}^U) \end{aligned} \qquad (2)$$

$$d_{i,j} = \sqrt{(l_{i,1}^P - l_{j,1}^U)^2 + (l_{i,2}^P - l_{j,2}^U)^2} \qquad (3)$$

Then, the cover between users and candidate places can be achieved by Eq. (4), where $c_{i,j} = 1$ represents $u_j$ is covered by $p_i$, and $u_j$ can be served by the edge site deployed on $p_i$ during

the operation of edge computing. And, we can get the set of covered users for each candidate places, $\mathbb{C}_i = \{u_j | c_{i,j} = 1\}$, and the set of all covered tasks by selected candidate places, $\mathbb{C} = \cup_{x_i=1} \mathbb{C}_i$. Now, we can calculate the overall user coverage by Eq. (5).

$$c_{i,j} = \begin{cases} 1, & \text{if } d_{i,j} \leq S \\ 0, & \text{if } d_{i,j} > S \end{cases} \qquad (4)$$

$$Q = \frac{|\mathbb{C}|}{U} \times 100\% \qquad (5)$$

Based on above formulations, we can now model ESDP as following optimization problem. The two objectives are maximizing the user coverage (Eq. (6)) and minimizing the cost of deployed edge sites (Eq. (7)), respectively. Decision variables include $x_i, 1 \leq i \leq P$, which are all binary. As the nonlinear of Eq. (5), the ESDP is a binary nonlinear programming.

$$\text{maximizing} \quad Q, \qquad (6)$$
$$\text{minimizing} \quad C. \qquad (7)$$

In this paper, we consider coverage maximization as the major objective. Then, the two objectives Eq. (6) and Eq. (7) can be convert into one, as shown in Eq. (8). $UQ = |\mathcal{C}|$ is the number of covered users. $\sum_{i=1}^{P} m_i$ is the total cost when all candidate places are selected for deploying edge sites, which is greater than or equal to $C$, and thus $\frac{C}{\sum_{i=1}^{P} m_i} \leq 1$.

$$\text{maximizing } O = UQ - \frac{C}{\sum_{i=1}^{P} m_i} \qquad (8)$$

Next, we proof that ESDP is NP-Complete, which means no polynomial algorithm can exactly solve it unless P=NP, and in the next section, we will present a hybrid meta-heuristic algorithm to solving it in a polynomial algorithm with global search abilities of GA and PSO. Considering an instance of ESDP, all user can be covered and costs of edge site deployments on all candidate places are identical. Then, the ESDP instance is to minimize the number of deployed edge sites with 100% user coverage, which can be formulated following optimization problem. Objective (9) is minimizing the number of selected candidate places for deploying edge sites. Constraints (11) require that every user must be covered by at least one selected candidate place or deployed edge site. Constraints (11) represent that decision variables are binary. Therefore, the ESDP instance is binary linear programming which has been proven as NP-complete [15]. Thus, ESDP is NP-complete.

$$\text{minimizing } \sum_{i=1}^{P} x_i, \qquad (9)$$

subject to,

$$\sum_{i=1}^{P} c_{i,j} x_i \geq 1, 1 \leq j \leq U, \qquad (10)$$

$$x_i \in \{0,1\}, 1 \leq i \leq P. \qquad (11)$$

## III. Hybrid GA and PSO for Edge Site Deployment

In this section, we propose a hybrid meta-heuristic algorithm aiming to search a global best solution for ESDP. In this paper, we choose to employ GA and PSO, and will exploit other meta-heuristics for more powerful global search ability and efficiency. The reasons of choosing GA and PSO are two-fold. One is that both GA and PSO are most representative meta-heuristic algorithms and have widely used in various fields due to their good performance and easily implementations [14], [16]. Another is that one's advantage can make up another's disadvantage for GA and PSO, as GA has powerful global search ability but slow convergence speed, and on the contrary, PSO has fast convergence speed but is easily trapping into local optima. Fig. 1 gives the flow chart of our proposed hybrid meta-heuristic algorithm for ESDP, which is represented by PGSAO.

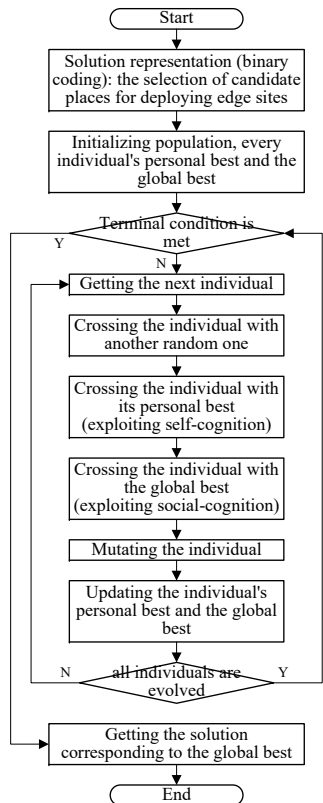

Fig. 1. The algorithm flow chart of the hybrid GA and PSO for edge site deployment.

As shown in Fig. 1, at first, PGSAO employs a binary coding method to establish the solution space for meta-heuristic algorithms' searching. A solution of ESDP is represented as a $P$-dimensional vector, $\langle x_1, x_2, ..., x_P \rangle$, where values in all dimensions are binary, indicating whether edge sites are deployed on the corresponding places. During the search, there is a fitness function used for evaluating the goodness for each individual/solution. In this paper, we identify user coverage maximization as the major objective and deployed edge site number as the minor objective. Thus, the fitness function of

PGSAO is defined as Eq. (12).

$$f = |\mathbb{C}| + \frac{\sum_{i=1}^{P} x_i}{P}. \tag{12}$$

Given the solution space and the fitness function, PGSAO first initializes a population consisting of multiple individuals (chromosomes, particles), where every individual is a solution, by randomly setting a value on each dimension of every individual. Then, for each individual, PGSAO evaluates its fitness, and records itself as its personal best. After the fitness evaluation, PGSAO finds the individual with the highest fitness, and records it as the global best. Now, PGSAO proceeds to the evolutionary stage to upgrade individuals for retrieving better or even global best solutions.

In the evolutionary stage, PGSAO repeats upgrading the population by performing crossover and mutation operators on every individual as following steps until the terminal condition is met. (1) The individual is crossed with another one that is selected randomly with the crossover probability, which is same to GA. (2) The individual is crossed with its personal best with the crossover probability, which is exploiting the self-cognition of PSO. (3) The individual is crossed with the global best with the crossover probability for employing the social-cognition of PSO. (4) The individual is mutated with the mutation probability, as done by GA for increasing the population diversity. (5) For each individual, by three crossover operators (steps 1, 2, and 3) and one mutation operator (step 4), total seven offspring are produced (two for a crossover and one for a mutation). At the end of each individual's evolution, its personal best and global best are updated as the best offspring when an offspring has better fitness.

In this paper, to ensure the population diversity, PGSAO employs the uniform crossover and the uniform mutation operators. The uniform crossover operator is to swap the values on every dimension of two individuals with a probability, which represents exchanging the selection states of a candidate place between two solutions. By the uniform mutation operator for an individual, each dimension is changed from one value (0/1) to another one (1/0) with a probability, which represents changing the selections of candidate places on the solution.

PGSAO is terminated when the repeat time reaches the predefined threshold or there is no change on the global best a few times continuously. And PGSAO returns the solution corresponding to the global best.

## IV. Performance Evaluation

To evaluate the performance of PGSAO, we conduct extensive simulated experiments based on a real data set, EUA [17], [18], which includes locations of 9318 LTE base station sites and 131312 users in the Melbourne CBD area. We consider LTE base station sites as candidate places in ESDP. In our experiment, we convert the geographic coordinate into a Cartesian coordinate system by setting one degree as 1000 metres in both longitude and latitude for just simplifying the calculation of distances, and set the coverage of each edge site as 100 metres referring to existing related works.

The performance metrics used for evaluating PGSAO include the user coverage and the number of selected candidate

places for edge site deployment. For the first metric, it is better for a greater value, and 100% is the best value. For the second one, a smaller number is better, which indicates a lower cost for edge site deployment.

To prove the superiority of our method, we compare PGSAO with five classical and widely used meta-heuristic algorithms, GA [16], Differential Evolution (DE) [19], Artificial Bee Colony (ABC) [20], PSO [14] and Multi-Verse Optimizer (MVO) [21], and two hybrid meta-heuristic algorithms (GAPSO [22] and PSOGA) in solving ESDP. GAPSO is to perform GA in the first half of the evolutionary stage, and PSO in the second half. PSOGA reverses the order of GA and PSO for GAPSO.

### A. Overall Performance

For each experiment, we repeat eight times and show results by the box-plot. In our experiment, all algorithms achieve 100% user coverage, which verifies the powerful search ability of meta-heuristics. In Fig. 2, we present the number of deployed edge sites when applying various algorithms. From the figure, we can see that PGSAO requires the fewest edge sites for full user coverage, and thus the minimal deployment cost. On average, PGSAO requires to deploy 16.0%–31.7% fewer edge sites than other methods. This verifies that the performance superiority of PGSAO in the global optimization, compared with other [hybrid] meta-heuristic algorithms. This is mainly because of the efficient fusion of GA and PSO in the following two aspects. First, hybrid meta-heuristic algorithms, GAPSO, PSOGA, and PGSAO, achieve better performance than single meta-heuristic algorithms, GA, DE, ABC, PSO, and MVO, in minimizing the number of deployed edge sites, which verifies the validity of combining different meta-heuristic algorithms for a better performance. Second, PGSAO needs fewer deployed edge sites than GAPSO and PSOGA. This proves that the high efficiency of the combination strategy exploited by PGSAO, as GAPSO, PSOGA, and PGSAO are all combining GA and PSO.

Fig. 2. The number of deployed edge sites for user coverage maximization when applying various algorithms.

We also perform t-test to verify the statistical difference of our method to others in optimizing deployed edge site number, and present the test results in Table I. As shown in the table, the $p$-values of all t-test are much smaller than 0.01. Thus, PGSAO has significantly different performance to other algorithms, which confirms the superiority of PGSAO further.

TABLE I. $p$-VALUES OF T-TEST ON THE STATISTICAL EQUALITY OF PGSAO TO OTHER ALGORITHMS

| Method | $p$-value |
|--------|-----------|
| GA | $1.33 \times 10^{-15}$ |
| DE | $2.60 \times 10^{-20}$ |
| ABC | $3.41 \times 10^{-20}$ |
| PSO | $9.72 \times 10^{-19}$ |
| MVO | $3.89 \times 10^{-14}$ |
| GAPSO | $1.32 \times 10^{-12}$ |
| PSOGA | $7.94 \times 10^{-21}$ |

In the next, we compare the time consumed by various algorithms, where the results are shown in Fig. 3. The time is tested on a personal computer with Window 11, Intel(R) Core(TM) i7-4770 CPU @ 3.40GHz, and 24 GiB RAM. As shown in the figure, PGSAO consumes about five times time of others, where the increased time is mainly consumed for exploiting self- and social cognitions by crossover operators of PGSAO. Even so, it is absolutely a worthwhile trade-off for a much lower deployment cost, noticing the following observation. The edge deployment strategy is stable. There are mainly two cases in which service providers need edge deployment solutions, building or upgrading edge computing on some new or original areas when providers decide to develop new business or user traffics are increased greatly. For both cases, it generally takes a long time, e.g., months or years, for changing the edge deployment solution. Thus, service providers prefer to consume more hours for an edge deployment solution with much lower cost.

Fig. 3. The time consumed by different algorithms.

### B. Performance Varied with User Number

Now, we exam the performance variations with the user number for different algorithms. Fig. 4 and 5 give such variations when the user number is changed from 10,000 to 100,000. The user coverage is always 100% for every algorithm in any case. As shown in Fig. 4, we can see that the number of required edge site for the full user coverage is stable with varied user number for every algorithm. This is mainly because the area size instead of the user number determine the number of required edge site for a full coverage, given the fixed coverage range of each edge site. From Fig. 4, PGSAO always requires minimal number of edge sites than others, and thus has the best performance in minimizing the deployment cost.

As shown in Fig. 5, we can see that every algorithm consumes time increased linearly with the increase of the user number in overall. This is mainly because all users are traversed once for calculating the fitness for each individual. This verifies that all algorithms including ours have good scalability in solving various scale ESDP, and thus have good usability.

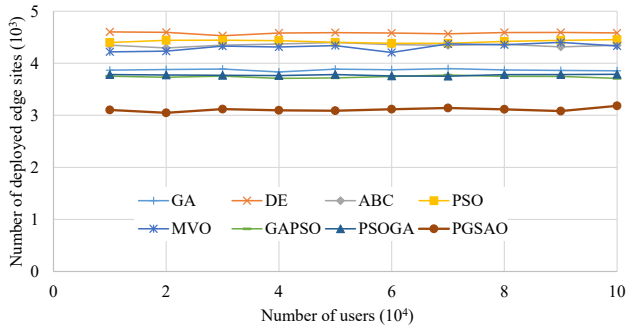

Fig. 4. The number of deployed edge sites required by various algorithms with varied user numbers.

Fig. 5. The time consumed by different algorithms with varied user numbers.

### C. Performance Varied with Candidate Site Number

We also evaluate the performance variations with the candidate place number for each algorithm on solving ESDP, and present results in Fig. 6 and 7, where the number of candidate places is in the range from 1000 to 9000. Same to previous results, all algorithms can achieve 100% user coverage, confirming the effectiveness of their search strategies. From Fig. 6, we can see that as the number of candidate places increases, more edge sites are required for deployment for every algorithm, i.e., the performance is degraded. This is mainly because as the number of candidate places increases, the search space is exponentially increased, and thus it is more and more difficult to retrieve the global best solution.

As shown in Fig. 7, the consumed time is stable as the number of candidate places is varied for every algorithm, as the main time overhead is consumed for the population evolution and thus mainly decided by population size and iteration number. This phenomenon further confirms the good scalability of our algorithm.

Fig. 6. The number of deployed edge sites required by various algorithms with varied candidate places.

Fig. 7. The time consumption changed with varied number of candidate places for each algorithm.

## V. Related Works

Edge-cloud computing has attract more and more attention from both industry and academia due to its huge advantage by combing edge and cloud computing. Several works have aimed at designing edge server placement approaches, edge service/data caching strategies, and task offloading algorithms to improve the efficiency and effectiveness of edge-clouds, which are discussed as follows, respectively.

Given the edge site deployment solution, edge server placement is to decide which sites edge servers (resources) are placed to maximize the overall performance with restricted edge resources. Zhang et al. [23] proposed a niche PSO to minimize the overall respond time considering the placement as a multimodal optimization problem, which divides similar individuals into a niche during the population upgrade. Li et al. [24] and Zhang et al. [25] employed K-means++ to cluster edge sites into $k$ classes, and deploy $k$ edge servers on the sites closest to theses classes' centres. These works assumed that all edge sites have been deployed, and thus our work is complementary to them. These works only considered to improve request processing performance with fixed number of edge servers, without concerning the investment cost improvement for building edge computing platforms.

During operation of edge computing, as resources configured in each edge site are restricted, there is no enough room for storing all services or data requested by users in the edge. Therefore, an edge caching strategy decides which

service data that are deployed (cached) on every edge site for processing corresponding requests, and affect the performance by determining whether or not a request can be processed in edge servers. There mainly two kinds of edge caching, static and dynamic strategies. Static strategies provide a solution that the placement of services or data on edge sites is not changed, e.g., [26], [27], [28], while dynamic strategies adjust the placement over time, e.g., [29], [30], [31].

Another key work to tune the performance of operating edge computing is task offloading/scheduling that decides the resource that every request task is processed on. Laboni et al. [32] proposed a two-layer hyper heuristic algorithm to determinate the server and router path for each request's processing for optimizing processing delay and load balance. They exploited ant colony optimization as the high-level algorithm for selecting the low-level algorithm employed for each population evolution, and Whale optimization, sine-cosine algorithm as well as Henry gas solubility optimization as low-level algorithms. Zhang and Yu [33] proposed a hybrid task offloading algorithm by combining ABC and PSO, to improving processing delay and energy consumption. Concerned about service caching, Zhang et al. [34] formulated the task offloading problem into a mixed-integer non-linear programming, and exploited non-cooperative game to iteratively solving the problem by the interaction between wireless characteristics and mobile users. Both edge caching and task offloading are used for improving performance during the operation of edge computing, and thus requires that the edge sites and resources have been deployed. Therefore, our work focusing on ESDP is complement with these existing related works.

## VI. Conclusion

In this paper, we focus on the edge site deployment problem (ESDP) to improve the build/upgrade cost to provide ESDP solution for service providers to expand their businesses. To achieve this goal, we first formulate ESDP into a binary non-linear programming problem with two objectives, user coverage maximization and edge site number minimization. And we prove the NP-complete of ESDP by establishing an ESDP instance that is binary linear programming. Then, we propose a hybrid GA and PSO algorithm aiming to retrieve the global best solution of ESDP. The proposed algorithm combines the global search ability of GA and cognitions exploited by PSO, to achieve a more efficient search strategy. In the end, we evaluate the performance of our proposed algorithm based on a real data set, and confirm the superiority of our algorithm in various aspects.

[2]FPT Polytechnic, Can Tho City, Vietnam

*Abstract*— The escalating demand for blood and its derivatives in the medical field underpins its indispensable nature for disease diagnosis and therapy. Such essential life-giving components are irreplaceable, necessitating a continuous reliance on voluntary blood donors. Existing methodologies primarily address the challenges of blood storage and its logistical distribution among healthcare centers. These conventional strategies lean towards centralized systems, often compromising data transparency and accessibility. Notably, there remains a significant gap in incentivizing and raising awareness among potential and existing donors regarding the life-saving act of blood donation. Recognizing these challenges, we introduce a robust and innovative framework that harnesses the potential of Blockchain technology, coupled with the power of smart contracts. Furthermore, to foster a sustainable blood donation ecosystem, we advocate the shift from traditional paper-based recognition to digitized donor acknowledgment using Non-Fungible Tokens (NFTs). Our novel approach encapsulates four key areas: (a) Introduction of a supply chain oversight mechanism for blood and its derivatives through Blockchain and smart contracts; (b) Development of a digital certification system for blood donors utilizing NFTs; (c) Execution of our suggested framework via smart contracts, offering a tangible proof-of-concept; and (d) Assessment and implementation of the proof-of-concept across four prominent platforms: ERC721 (ETH's NFT), and the Ethereum Virtual Machine (EVM) employing the Solidity language – this encompasses the BNB Smart Chain, Fantom, Polygon, and Celo, aiming to discern the optimal platform compatible with our innovative framework.

*Keywords—Blood donation; blockchain; ethereum; blood products supply chain; smart contract; NFT; ethereum; fantom; polygon; binance smart chain*

## I. INTRODUCTION

Supply chain management, an interdisciplinary field that interlinks various sectors, has witnessed transformational shifts in the digital age, with implications spread across delivery [1], [2], [3], payment systems [4], [5], [6], project dynamics [7], product movement [2], [8], and even ecological waste disposal [9]. One of its paramount manifestations is within the medical landscape, particularly in ensuring the efficient and safe management of blood and its associated products.

Historically, the majority of supply chain models, while sophisticated, have been grounded in traditional logistics and storage paradigms. When we delve into the intricacies of managing biological resources like blood, these models often fall short. Blood, unlike other commodities, has unique storage

requisites, from maintaining a specific temperature range to ensuring an optimal humidity environment, and most critically, adhering to its limited shelf life [10]. These nuances underscore the inadequacies of conventional supply chain mechanisms and highlight an urgent need for innovation.

Enter blockchain technology and smart contracts. Beyond the mainstream applications in finance and business, these technologies harbor immense potential for healthcare. In ensuring a transparent, immutable, and decentralized storage and access system, they promise an enriched donor-recipient relationship. Every single unit of blood can be tracked, from its origin to its end-use, ensuring complete transparency and trustworthiness in the system [11]. But technology alone, as history often reminds us, is insufficient to drive societal change.

Across the globe, the act of blood donation remains both a noble endeavor and a logistical challenge. How does one not only encourage a first-time donation but ensure that the donor returns, given the physiological restrictions that mandate waiting periods between donations? Current incentive structures, while well-intentioned, often falter in ensuring sustained donor engagement. And with medical innovations surging, the demand for blood and its derivatives amplifies, rendering the challenge even more pronounced [12].

It is within this complex mosaic of challenges and opportunities that our research emerges, aiming to not merely innovate but to transform. Our work, grounded in the principles of blockchain, smart contracts, and the dynamism of Non-Fungible Tokens (NFTs), envisions a holistic reimagining of the blood donation landscape.

Our pivotal contributions are:

- Redefining Blood Supply Chain Mechanisms: By integrating blockchain and smart contract technologies, we introduce a more transparent, efficient, and secure system for managing the blood supply chain.

- NFT-driven Electronic Certification: Venturing beyond conventional incentive models, we harness the capabilities of NFTs to create a robust electronic certification system for blood donors. These digital tokens, being unique and easily transferable, provide an innovative solution to the tangible certificate's pitfalls, offering

donors a secure and lasting acknowledgment of their invaluable contribution.

- Proof-of-Concept Realization: Our theoretical formulations are translated into tangible, executable smart contracts, reinforcing the practical viability and applicability of our proposed systems.

- Platform Exploration and Optimization: Conscious of the economic implications, our solutions undergo rigorous deployment trials across platforms supporting the Ethereum Virtual Machine (EVM) infrastructure. Our endeavor seeks not just feasibility but also cost-effectiveness, ensuring that our solutions remain both cutting-edge and accessible.[1]

The undercurrent binding our contributions is the conviction that technology, when thoughtfully applied, can drive societal transformations. By augmenting the blood donation landscape, our research does more than introduce technological innovations; it touches lives, accelerates medical interventions, and champions a cause of profound societal significance.

## II. RELATED WORK

### A. Prior Art in Blood Supply Chain Management via Blockchain

In recent years, Blockchain technology's transformative potential has been tapped to address challenges in blood supply chain management. Notably, Nga et al. [13] pioneered this integration, showcasing a working model implemented on the Hyperledger Fabric platform. Their primary innovation was the facilitation of healthcare professionals to log and secure data directly on the blockchain. Shifting from a centralized storage protocol to a decentralized one, this framework places significant emphasis on ensuring robust security mechanisms. Particularly, as documented by [14], they engineered an authorization process that offers exclusive access to sensitive donor and recipient data only to authenticated users, preserving the privacy sanctity system-wide.

Supplementing this innovative stride, Kim et al. [15] extended the application of Hyperledger Fabric in designing a holistic blood supply chain management system. Their model prioritizes privacy, constructing a well-contained system that oversees the entire blood supply trajectory—from collection to final distribution to medical institutions. Another salient feature they introduced is a donor identification technique to streamline communication for future blood donation drives. However, a noticeable void in their proposal is the absence of granular management processes tailored to distinct blood components, each demanding specific preservation methods and having unique shelf lives.

Lakshminarayanan et al. [16] further explored the Hyperledger Fabric's capabilities, proposing a model accentuating transparency in blood transportation from donors to end recipients. Another intriguing convergence of technologies was demonstrated by Toyoda et al. [17], where they synergized blockchain with Radio Frequency Identification (RFID). In this model, upon blood donation, each unit gets a unique RFID tag,

simplifying access to comprehensive blood-related data, like donation time and location, for both healthcare professionals and recipients.

While many have gravitated towards the Hyperledger Fabric, Ethereum's potential hasn't been overlooked. A compelling use case, delineated by [10], presents an Ethereum-centric decentralized architecture. This structure exclusively empowers certified blood donation centers (CBDC) to manage blood and its components through deployable smart contracts. This system ensures procedural fidelity and plugs potential logistical gaps. An added advantage is the donor's ability to interface with the system using unique identifiers, such as social security numbers, paired with secure passwords.

Zooming into specific blood components, Peltoniemi et al. [18] analyzed the efficacy of decentralized blockchains in plasma management. Their approach ensures meticulous documentation of donor data prior to plasma extraction. Post extraction, an analytical assessment discerns the plasma quality.

In light of the foregoing exploration of blockchain-powered blood supply chain solutions, it's evident that while tremendous progress has been made in rectifying traditional system pitfalls, one persistent challenge remains unaddressed: incentivizing recurring blood donations. Our contribution to this discourse is a multifaceted model amalgamating Blockchain (specifically Ethereum), Smart Contracts, and Non-Fungible Tokens (NFTs). This model doesn't just oversee the blood supply chain but also introduces digital recognition mechanisms, like electronic donor certificates. An in-depth exposition of our model is detailed in the subsequent section.

### B. Blockchain-based Medical Systems

Healthcare has always been a fundamental aspect of human life. With the advancement of technology and a growing concern for patients' data privacy and the immediate need for accessing data during emergencies, blockchain technology has emerged as a promising solution for many of the challenges faced by modern healthcare systems.

*a) Emergency access in healthcare systems:* Son et al. [19] stressed the importance of personal health records (PHR) due to their sensitivity and significance in healthcare. The authors identified the challenges faced during emergencies when it becomes cumbersome for patients to grant medical personnel access to their critical health records. They proposed an emergency access control management system built on the permissioned Hyperledger Fabric blockchain. The system leverages smart contracts to define rules and timeframes to handle emergencies, ensuring patients can restrict data access time.

Similarly, Le [20] introduced the Patient-Chain platform, a blockchain-based patient-centered healthcare system also built on Hyperledger Fabric. The system aims to protect patients' data during emergencies and provides a systematic approach to allow authorized personnel to access patient data during time-sensitive situations.

*b) Medical waste management:* The demand for medical equipment spiked significantly during the COVID-19 pandemic. However, the subsequent waste treatment processes

---

[1]We consciously eschew ETH owing to its exorbitant smart contract execution expenses.

often went overlooked. Le et al. [9] highlighted the independent waste treatment processes in hospitals that lack coordination and data sharing. The authors proposed the Medical-Waste Chain, a decentralized system built using Hyperledger Fabric technology. This system manages the waste treatment processes for used medical equipment and supplies, promoting transparent and efficient interactions between all involved stakeholders.

*c) Blood supply chain management:* With a rising demand for blood supply due to demographic shifts, traditional blood management information systems face challenges, such as the lack of detailed blood data, making the quality, supply, and demand management for blood quite challenging. In response, Le [14] introduced BloodChain, a blockchain-based system that improves blood information management. The system, constructed on Hyperledger Fabric, provides detailed data, including blood consumption and disposal metrics.

Quynh et al. [13] echoed similar sentiments about the changing population structure and its impact on blood supply. They introduced a novel system on Hyperledger Fabric to manage blood information effectively, addressing supply and demand challenges faced by national institutions.

*d) Patient-centered healthcare systems:* Duong [21] identified challenges in current healthcare systems regarding the privacy and sharing of medical data. The authors highlighted the necessity for a secure transaction mechanism to allow patients to monitor and control their health records. Proposing a solution, they introduced a patient-centered healthcare system using smart contracts via blockchain technology, releasing the complete code solution on GitHub to promote reproducibility and further improvement.

In another contribution, Duong [22] proposed a patient-centric system based on smart contracts. Emphasizing patients' control over their health records, the authors used Smart Contract on both Hyperledger Fabric and Ethereum Blockchain to improve care coordination. Through six algorithms, they interacted with different components of the healthcare system, showcasing the system's efficiency through simulation results.

In summary, while blockchain technology offers a plethora of solutions to address various challenges in the healthcare sector, from managing blood supply chains to medical waste, its paramount feature remains in ensuring the privacy and security of patient data. Future research might look into integrating these blockchain-based systems with other emerging technologies to further improve healthcare operations and patient experiences.

## III. METHODOLOGY

This section elucidates the conventional models of blood donation and its associated documentation methods. We further introduce a novel methodology incorporating Blockchain technology, smart contracts, and Non-Fungible Tokens (NFTs) to modernize the system of transporting, storing, and authenticating blood products.

### A. Conventional Blood Donation and Management Process

As depicted in Fig. 1, the conventional blood donation system operates through four primary channels. Donors, de-

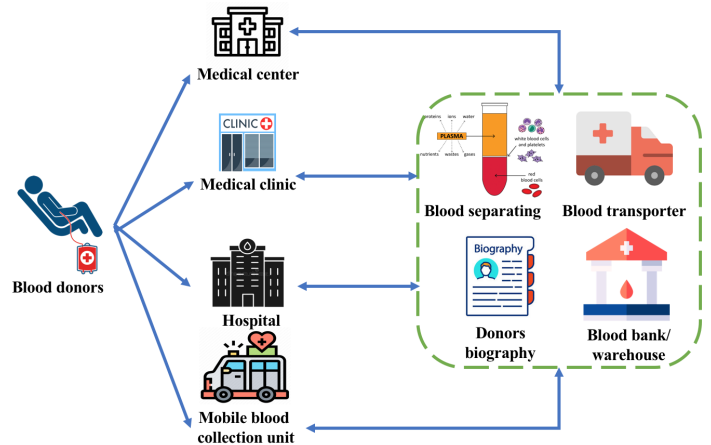

Fig. 1. Conventional system of blood donation and management.

pending on their geographical proximity, have the option to donate at: (a) healthcare centers; (b) medical facilities; (c) hospitals; or (d) portable blood collection stations [23]. The fourth option, (d), is a transient solution such as pop-up stations during weekends or holidays. This approach is not only geared towards encouraging potential donors but also addresses challenges in regions where there are obstacles to blood collection using the first three methods. Once the blood is collected, it is transported to specialized facilities or institutions equipped with blood storage systems. This collected blood undergoes separation into components like red and white blood cells, platelets, and plasma. Simultaneously, donor data is recorded and stored securely for communication purposes.

Fig. 2. Conventional blood donor certification.

In terms of documentation, Fig. 2 elucidates the process of obtaining a donor certificate from an institution, such as a hematology center. Such certificates serve as a moral boost for donors. Moreover, they ensure that donors receive equivalent blood volume in situations where they might require it due to certain health conditions. Detailed critiques and evaluations regarding the shortcomings of this method have been discussed in the Introduction[2]. The subsequent subsection outlines our innovative proposal that leverages blockchain, smart contracts, and NFT technology.

### B. Revolutionizing Blood Donation and Management via Blockchain, Smart Contracts, and NFT

The core objective of our research is to formulate an advanced system that enhances blood utilization across med-

---

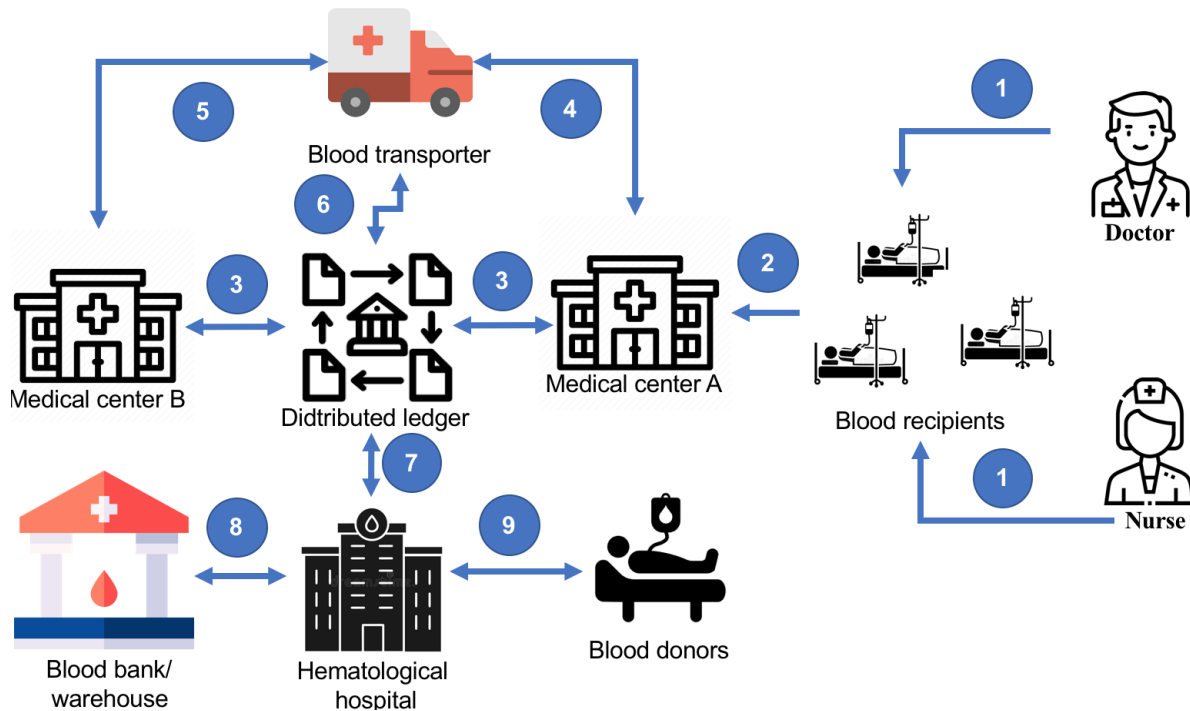
[2]Refer to our earlier publications for a deeper dive into the challenges of conventional methodologies [14].


Fig. 3. A novel blood donation and management paradigm utilizing blockchain, smart contract, and NFT technologies.

ical establishments and offers inventive means to motivate individuals to regularly donate. In this context, we propose a dual model that harnesses the capabilities of blockchain, smart contracts, and NFTs to circumvent existing limitations.

Fig. 3 suggests an interconnected model for blood donation and its management among healthcare facilities within a specified region, e.g., a city. The first step encompasses clinical examinations and treatments offered by physicians to their patients, who might be potential recipients of blood. Should there be a necessity for blood, a requisition is forwarded to the concerned institution. Two scenarios can arise: either the institution has an adequate blood stock or faces a shortage. In the latter scenario, the requirement is logged onto a distributed digital ledger. This system then scans affiliated institutions for the requisite blood type. Upon locating a matching facility, a carrier is mobilized. Vital data points such as timings and locations are recorded onto the digital ledger. In situations where local healthcare facilities are devoid of the needed blood type, the system communicates with specialized hematology centers or scans regional blood banks. If there still remains a deficiency, potential donors are contacted for collections.

Fig. 4 delineates the procedure for NFT issuance which serves as a digital blood donation certificate. Before the NFT's generation, donor's consent and institutional validation (e.g., from a hematology center) are imperative. We extend distinct services to each stakeholder, culminating in the creation of a digitalized version of the donor certificate. This data, alongside pertinent documentation, is recorded on the distributed ledger, leading to the production of an NFT via predefined functions in the smart contract.

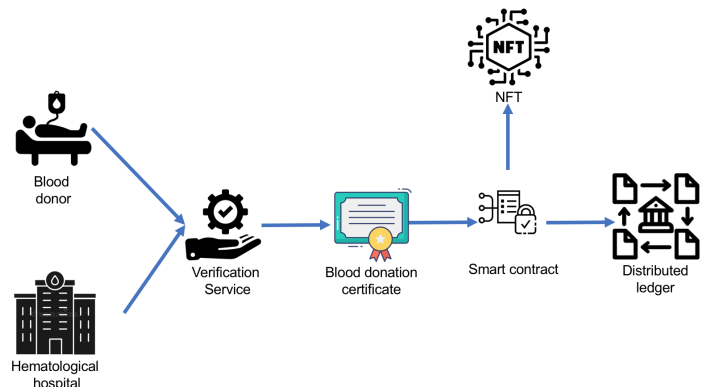

Fig. 4. Process of issuing digital blood donation certificates leveraging NFT technology.

## IV. IMPLEMENTATION

This practical model serves dual purposes: (i) management of blood and its by-products data on the blockchain platform encompassing creation, querying, and updates, (ii) instantiation of NFTs for donor contributions, serving as a motivation for continued blood donation. Moreover, we present the sample of the managing blood resources leveraging on Binance Smart Chain as a deployment sample.

### A. Data and NFT Initialization

As depicted in Fig. 5, the process begins by generating comprehensive data on blood and its derivatives. This encompasses details about the donors, their contact specifics (e.g., address, unique identification code), specifics about blood and its components, and their respective shelf lives. Given the
Fig. 5. Process of data and NFT initialization.

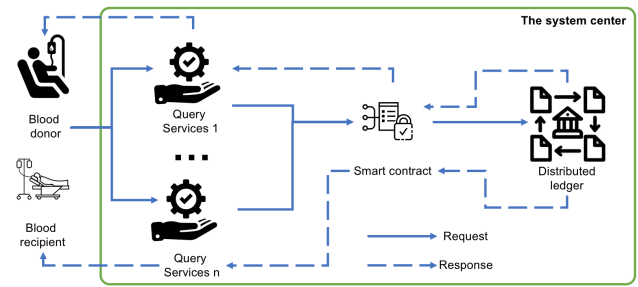

Fig. 6. Data retrieval process.

varying storage needs and lifespans of different blood products, categorization is vital. Moreover, the system archives details about the recipients, blood type requirements, and the medical professionals overseeing the procedures. Concurrent storage support is enabled on the distributed ledger, allowing multiple users to engage simultaneously, thereby reducing latency.

The data structure for a blood component, such as red blood cells, is represented as:

```
redBloodCellsData = {
"donorID": donorID,
"medicalStaffID": medicalStaffID,
"bloodType": blood type,
"institutionID": institutionID,
"volume": volume,
"validityPeriod": validity period,
"packageID": packageID,
"timestamp": timestamp,
"location": current location,
"status": null,
};
```

Besides the primary data attributes, the system monitors the real-time status of blood components in storage. This status attribute indicates if the blood product is in storage or has been dispatched for medical use. This dynamic tracking, combined with time and location data, aids in real-time logistics management.

For initializing NFTs, the structure encapsulates the blood donation details as:

```
NFTBloodDonation = {
"donorID": donorID,
"bloodType": blood type,
"donationCount": donation occurrences,
"totalVolume": accumulated volume donated,
"lastDonationDate": most recent donation date,
"blockchainAddress": blockchain address
};
```

This ensures a comprehensive, immutable record of each donation, aiding in efficient management and donor recognition.

### B. Data Retrieval

Fig. 6 outlines the steps involved in the data retrieval mechanism. Leveraging a distributed model, it permits multiple users to concurrently access the system. Donors and recipients might seek insights into storage processes, donation frequency, or upcoming donation schedules. Medical professionals, on the other hand, might access donor details for outreach or future donation drives.

### C. Data Update Mechanism

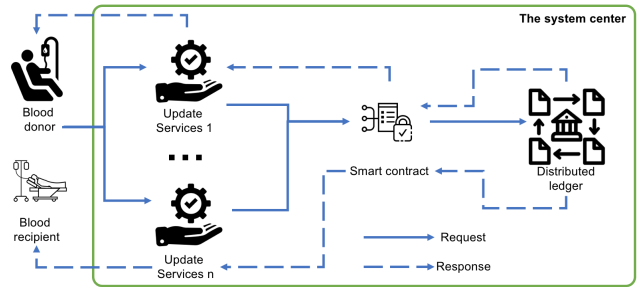

Fig. 7. Procedure for data updates.

As demonstrated in Fig. 7, the data updating procedure only commences post data verification. If the sought data isn't present on the blockchain, a non-availability message is relayed to the user. In case of updates, the process fetches existing data and modifies relevant attributes such as blood volume or donation frequency. For NFTs, any major update triggers the generation of a new NFT, ensuring historical records remain untouched.

### D. Managing Blood Resources using Binance Smart Chain

The Binance Smart Chain (BSC) has been identified as an ideal candidate for managing blood resources, given its compatibility with the Ethereum Virtual Machine (EVM) and its optimized transaction performance. As such, the proposed model is primarily evaluated and implemented on BSC, but compatibility with other platforms is also maintained. Here, we discuss the specifics of the implementation on BSC, showcasing transaction details, NFT creation, and the process of NFT transfers.

Fig. 8 details our deployment of the system on BSC. It showcases attributes essential for evaluating and comparing transaction performance across different blockchain platforms. This snapshot is a representative case, with similar settings applied when deploying on other platforms. Transaction details like the transaction fee, gas limit, and gas price provide a

Fig. 8. A snapshot illustrating transaction details on Binance Smart Chain. The attributes highlight the cost implications and performance of a transaction, specifically for our blood management use case.

Fig. 9. Depicting the NFT creation process on BSC. This highlights the structured format of our NFTs, tailored to represent blood donations and their associated attributes.

comprehensive insight into the cost-effectiveness of operations on the chain.

The NFT creation process, visualized in Fig. 9, follows a structured format. Each NFT is intricately designed to represent blood donations, capturing essential details like the donor's information, blood type, and donation history. Such a tokenized representation not only ensures data integrity and authenticity but also promotes transparency in the system.

Fig. 10. A detailed representation of NFT transfer operations on BSC. The process ensures secure, transparent, and traceable transfer of NFT ownership.

The transfer of NFTs, especially in a sensitive domain like blood resource management, demands high levels of security and traceability. Fig. 10 provides a comprehensive overview of the NFT transfer operations. Leveraging the ERC721 standard ensures that each NFT transfer is not just secure but also accompanied by clear traceability, promoting trust among participants.

While Binance Smart Chain plays a pivotal role in our implementation, it's essential to recognize the versatility of our model. We have deployed and evaluated the system on several EVM-compatible platforms, including Binance Smart Chain[3], Polygon[4], Fantom[5], and Celo[6]. Implementations and results across these platforms, especially focusing on cost metrics like transaction fees and gas utilization, are detailed in the ensuing Evaluation section.

## V. EVALUATION SCENARIOS

### A. Transaction Fee Analysis

Table I showcases the transaction fees of distinct operations, namely Contract Creation, NFT Creation, and NFT Transfer, across four pivotal blockchain platforms: BNB Smart Chain, Fantom, Polygon, and Celo. These platforms, known for their support of the Ethereum Virtual Machine (EVM), differ significantly in their fee structures.

Contract creation, a foundational operation for initiating any decentralized application, bears varying costs across platforms. BNB Smart Chain requires approximately 0.02731136 BNB, equating to $8.37. This competitive fee is attributed to the Binance Smart Chain's infrastructure and its optimization for reduced costs. Conversely, Fantom, known for its efficient contract deployment, charges a lower fee of 0.009576826 FTM or about $0.001860. Polygon, a Layer-2 scaling solution, boasts an even more affordable rate at 0.006840590024626124 MATIC ($0.01), emphasizing its aptitude for micro-transactions. Finally, Celo, focusing on mobile-centric blockchain solutions, demands a modest 0.0070973136 CELO, translating to around $0.004.

The surge in NFT (Non-Fungible Token) popularity necessitates a comprehension of minting costs. On the Binance Smart Chain, a fee of 0.00109162 BNB or $0.33 is levied for this operation. Fantom's fee structure is notably lower for the same, standing at 0.000405167 FTM ($0.000079). Polygon, with its emphasis on affordable transactions, charges a mere 0.00028940500115762 MATIC, a negligible amount in fiat terms. Celo's rate for NFT creation is comparably minimal at 0.0002840812 CELO or roughly $0.000.

Transferring ownership of NFTs, a procedure that consumes computational resources for validation and recording, also incurs diverse costs across these platforms. BNB Smart Chain's fee is 0.00057003 BNB or $0.18. Fantom's cost stands at 0.0002380105 FTM, approximately $0.000046. Polygon continues its trend of affordable operations, charging 0.000170007500612027 MATIC, which is negligible in fiat currency. Similarly, Celo's fee for this process is 0.0001554878 CELO, equating to about $0.000.

In sum, this detailed exploration of Table I underscores the variable costs of primary blockchain operations across different platforms. It's paramount for stakeholders to not just consider these transaction fees, but also weigh other platform-specific factors, such as security, scalability, and community backing, when determining the most suitable blockchain for their endeavors.

### B. Gas Limit Analysis

Table II distinctly portrays the gas limits for crucial blockchain operations across four salient platforms: BNB Smart Chain, Fantom, Polygon, and Celo. The gas limit is a quintessential parameter, representing the maximum amount of gas units that a sender is willing to expend on a transaction. It's a protective mechanism to ensure that transactions don't unintentionally consume all the sender's funds due to errors in contract logic or malicious intentions.

Starting with the Contract Creation, a cardinal operation that establishes the foundation for decentralized applications:

TABLE I. TRANSACTION FEE

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 0.02731136 BNB ($8.37) | 0.00109162 BNB ($0.33) | 0.00057003 BNB ($0.18) |
| Fantom | 0.009576826 FTM ($0.001860) | 0.000405167 FTM ($0.000079) | 0.0002380105 FTM ($0.000046) |
| Polygon | 0.006840590024626124 MATIC($0.01) | 0.00028940500115762 MATIC($0.00) | 0.000170007500612027 MATIC($0.00) |
| Celo | 0.0070973136 CELO ($0.004 ) | 0.0002840812 CELO ($0.000 ) | 0.0001554878 CELO ($0.000 ) |

TABLE II. GAS LIMIT

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 2,731,136 | 109,162 | 72,003 |
| Fantom | 2,736,236 | 115,762 | 72,803 |
| Polygon | 2,736,236 | 115,762 | 72,803 |
| Celo | 3,548,656 | 142,040 | 85,673 |

TABLE III. GAS USED BY TRANSACTION

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 2,731,136 (100%) | 109.162 (100%) | 57,003 (79.17%) |
| Fantom | 2,736,236 (100%) | 115,762 (100%) | 68,003 (93.41%) |
| Polygon | 2,736,236 (100%) | 115,762 (100%) | 68,003 (93.41%) |
| Celo | 2,729,736 (76.92%) | 109.262 (76.92%) | 59,803 (69.8%) |

- BNB Smart Chain has set its gas limit at 2,731,136. This platform's optimization for rapid and cost-efficient transactions is manifested in its relatively streamlined gas limit, ensuring the smooth deployment of smart contracts without unnecessary overheads.

- Fantom and Polygon, both with a gas limit of 2,736,236 for this operation, have nearly identical values. The similarity might stem from their shared objective of optimizing EVM compatibility and transaction efficiency, ensuring developers migrating from Ethereum find a familiar environment.

- Celo, with a more generous gas limit of 3,548,656, emphasizes flexibility. This platform, renowned for its mobile-centric approach, might accommodate more comprehensive contracts with intricate features, necessitating a higher gas allowance.

Moving to the realm of NFTs, a booming sector within the blockchain industry:

- For NFT Creation, BNB Smart Chain allocates a gas limit of 109,162. Given the proliferation of NFTs on this chain, a harmonized gas limit helps stabilize the costs associated with minting.

- Both Fantom and Polygon, with their synchronized limits of 115,762, demonstrate an equilibrium in accommodating the minting processes, potentially reflecting common optimization strategies.

- Celo, in line with its previously observed trend, sets its limit at 142,040, granting developers more leeway for intricate NFT-related operations.

Lastly, for NFT Transfer:

- BNB Smart Chain, maintaining its ethos of streamlined operations, sets a limit of 72,003, balancing efficiency with the necessary computational power.

- Fantom and Polygon, true to their aforementioned synchronization, both allocate 72,803 units. This congruence underscores their shared emphasis on facilitating swift and seamless NFT transfers without incurring undue costs.

- Celo's value stands at 85,673, slightly higher than the others. This platform's propensity for granting a broader gas berth might be to ensure all encompassing NFT functionalities, including meta-transactions and layered transfers, are seamlessly accommodated.

Table II elucidates the diverse gas limits across blockchain platforms. These figures are not just mere numbers; they embody each platform's philosophy, optimization strategies, and focus areas, guiding developers and stakeholders in their blockchain endeavors.

### C. Gas Used by Transaction Analysis

Table III provides an intricate breakdown of the gas consumption for pivotal operations across BNB Smart Chain, Fantom, Polygon, and Celo platforms. The values illustrate the proportion of the gas limit consumed by each operation, revealing the actual computational overheads associated with the actions. Notably, an operation's efficiency can be deduced by its gas consumption percentage. Lower percentages indicate optimized contract functions, while higher values may hint at the operation's complexity or inefficiencies.

Starting with the pivotal operation of Contract Creation:

- BNB Smart Chain, Fantom, and Polygon all exhibit a consumption of 100%. This denotes that these platforms optimally utilize the gas limit for the operation, ensuring that the smart contracts are deployed efficiently without wastage or excess.

- Celo stands at 76.92%, suggesting that the platform's contract creation process might be optimized further or that the operations contain redundant computations, consuming lesser than the allocated gas limit.

Delving into the NFT realm:

- For NFT Creation, both BNB Smart Chain and Celo consume 76.92% of the gas. It could indicate shared optimization techniques or similar contract structures.

- Fantom and Polygon, with a consumption rate of 100%, indicate an exhaustive use of the allocated gas, mirroring their performance in contract creation. Their contracts for NFT creation might be exhaustive

or meticulously tailored to use the entirety of the allocated gas.

When it comes to NFT Transfer:

- BNB Smart Chain has a consumption rate of 79.17%. This indicates a reasonably efficient transfer operation, ensuring a smooth transition of assets across addresses.

- Fantom and Polygon, with identical figures of 93.41%, suggest a higher computational need or a more comprehensive process to ensure asset security during transfer.

- Celo consumes 69.8% of the gas. This might denote an optimized transfer mechanism or a more straightforward procedure compared to other platforms, leaving a portion of the allocated gas unutilized.

To encapsulate, Table III unearths the intricacies of gas consumption patterns across platforms, serving as a barometer to gauge operational efficiencies and offering invaluable insights to developers and users alike.

### D. Gas Price Analysis

The cost of executing a transaction on a blockchain is determined by the gas price, which is multiplied by the gas used. Gas prices essentially dictate the fee paid to miners or validators for transaction inclusion in a block. Table IV elucidates the set gas prices for different operations on various blockchain platforms.

BNB Smart Chain:

- The gas price remains consistent across all operations, being set at 10 Gwei (or 0.00000001 BNB). Given BNB Smart Chain's commitment to providing scalable and low-cost transactions, a stable gas price ensures predictability for users and developers.

Fantom:

- At 3.5 Gwei (or 0.0000000035 FTM) for all operations, Fantom offers an even lower gas price than BNB Smart Chain. The consistent pricing reflects Fantom's operational efficiency and its design geared towards a high throughput.

Polygon:

- Polygon's gas prices, though varied minutely, hover around 2.5 Gwei. The slight variations, albeit minor, could be due to the inherent floating-point imprecisions or perhaps due to a dynamic gas price setting algorithm, though the former seems more plausible.

Celo:

- The gas prices for Celo operations are set at approximately 2.6 Gwei (0.0000000026 CELO). Interestingly, the maximum fee per gas, capped at 2.7 Gwei, gives users a ceiling for potential fluctuations, ensuring transaction costs remain within predictable bounds.

In summation, gas prices are pivotal in determining the overall cost of a transaction. As platforms strive for mass adoption, ensuring competitive, consistent, and transparent gas prices is essential. It not only fosters trust but also encourages application development and user participation by making operations financially feasible.

## VI. DISCUSSION

The exploration and comparison of the gas metrics across various blockchain platforms, specifically BNB Smart Chain, Fantom, Polygon, and Celo, provide a compelling view of the operational efficiencies, cost structures, and user experiences offered by each. These metrics, while technical, carry profound implications for the broader blockchain ecosystem, developers, and end-users alike. Here, we delve deeper into the repercussions and broader perspectives.

### A. Operational Efficiencies and Scalability

Gas prices: A consistent gas price, as seen in BNB Smart Chain and Fantom, speaks volumes about a platform's predictability. While lower gas prices are invariably attractive for users and developers, consistency ensures that users can predict costs, allowing for better financial planning and resource allocation. The minute variation in Polygon's gas price could be indicative of a more dynamic approach to network congestion and resource management, although this merits further investigation.

Gas used: The efficiency of a blockchain platform can also be gauged by looking at the gas used for each operation. A higher percentage indicates a more efficient utilization of resources, whereas a significantly lower percentage may suggest that transactions are either too complex or the network overestimates the required gas.

### B. Cost Structures

Economic implications: Low and predictable transaction costs, like those of BNB Smart Chain and Fantom, can be major drivers for mass adoption. High transaction costs can deter users, especially for micro-transactions or frequent operations. Economically, for blockchain platforms to find widespread use in daily applications—be it in finance, gaming, or supply chain—keeping transaction costs low is paramount.

Developer attraction: For developers, the economic viability of deploying and running applications on a blockchain platform is essential. Platforms that offer competitive gas prices and consistent cost structures are likely to attract more developers, fostering a richer ecosystem of decentralized applications (DApps).

### C. User Experience and Predictability

The end-user experience is invariably tied to costs. Unexpectedly high transaction costs can deter users, leading to a lack of trust in the platform. As seen with Celo's capped maximum fee per gas, providing users with a cost ceiling ensures that they are not caught off guard by potential price spikes, thus enhancing user trust and experience.

TABLE IV. GAS PRICE

| | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 0.00000001 BNB (10 Gwei) | 0.00000001 BNB (10 Gwei) | 0.00000001 BNB (10 Gwei) |
| Fantom | 0.0000000035 FTM (3.5 Gwei) | 0.0000000035 FTM (3.5 Gwei) | 0.0000000035 FTM (3.5 Gwei) |
| Polygon | 0.000000002500000009 MATIC (2.500000009 Gwei) | 0.00000000250000001 MATIC (2.50000001 Gwei) | 0.000000002500000009 MATIC (2.500000009 Gwei) |
| Celo | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) |

### D. Future Directions

Broadening the scope for mainstream acceptance: As we venture into the broader adoption of blockchain technology, an imperative is to ensure transactions remain swift and economically viable. The present data from the four platforms hints at the directionality of this progression. However, while these platforms seem poised for mainstream integration, there is an evident need for extended empirical studies on a variety of use-cases to further this claim.

Innovations and evolutions on platforms: The dynamism of the blockchain sphere cannot be overstated. Our current analysis captures just a fleeting moment in its evolution. Anticipating the future, it's plausible to expect innovations that can redefine cost structures, enhance scalability, and introduce pioneering pricing strategies. The adaptability of these platforms will be tested, necessitating agile and proactive advancements to keep pace.

Harmonizing cross-platform dynamics: The imminent expansion of the blockchain ecosystem suggests an escalation in inter-platform operations. A profound understanding of individual platform cost structures is essential to streamline these multi-chain interactions and ensure economically efficient cross-communication.

Future Explorations and Implementations:

### E. A Glimpse into the Upcoming Endeavors: Future Explorations and Implementations

#### 1) Delving into Advanced Algorithms and Data Structures:

- Purpose: To probe deeper into the blockchain dynamics and bring to light the implications of more sophisticated processes on transactional overheads.

- Highlight: A particular emphasis will be placed on encryption mechanisms. Given their significance in ensuring data security and confidentiality, it's imperative to understand their transactional costs in the blockchain realm.

#### 2) Real-world Deployment of Our Proposed Model:

- Objective: To transition from theoretical frameworks to real-world applications, offering tangible solutions that can be assessed and refined.

- Case in point: We're gearing up to integrate a recommendation system on the FTM mainnet. This move seeks to harness the potential of the platform while testing the feasibility and efficiency of our model in a live environment.

#### 3) Addressing Privacy-Related Complexities:

- Context: In today's digital age, user privacy and data protection have soared in importance. However, our current research hasn't delved deeply into this domain.

- Future directions: We'll be diving into:
  - Access control mechanisms [24], [25]: Exploring how permissions are granted or denied within the blockchain, ensuring only authorized entities can access pertinent information.
  - Dynamic policy frameworks [26], [27]: Understanding how policies that govern data access and usage can be dynamically altered, offering flexibility while maintaining security.

#### 4) Infrastructure-Driven Approaches: Amplifying User Interactivity and System Efficiency:

- Objective: To enhance the user experience, making it more interactive, efficient, and user-centric.

- Strategies under consideration include:
  - gRPC [28], [29]: A high-performance, open-source framework that can potentially supercharge remote procedure calls, ensuring seamless communication between services.
  - Microservices architecture [30], [31]: Breaking down an application into small, loosely coupled services, each running its process, enabling swift deployments and scaling.
  - Dynamic message transmissions [32]: Adapting the mode and format of message transmissions based on real-time requirements and constraints.
  - Brokerless systems [33]: Direct communication mechanisms eliminating intermediaries, aiming to reduce latencies and enhance data transmission rates.

At its core, the incorporation of these systems and approaches is about amplifying user interactions, making the systems more intuitive, responsive, and efficient, potentially through strategies such as API-driven calls.

In sum, the implications of our current gas metrics study pave the way for a host of future explorations. As we advance, the amalgamation of these findings will be instrumental in tailoring platform strategies, aligning developer priorities, and refining user experiences.

## VII. CONCLUSION

By harnessing the transformative capabilities of blockchain technology, smart contracts, and Non-Fungible Tokens (NFTs),

our work offers an innovative reimagination of the blood donation paradigm. Our contributions, including the integration of blockchain in the blood supply chain, the introduction of NFT-driven electronic certification for donors, and the realization of these concepts through proof-of-concept smart contracts, underscore the promise our solutions hold.

Additionally, our commitment to platform optimization, particularly through rigorous deployment trials across Ethereum Virtual Machine (EVM) supportive platforms, emphasizes the tangible and practical significance of our research. Our decision to sidestep Ethereum due to its high cost implications epitomizes our dedication to ensuring that our innovations are not just technologically advanced, but economically viable and accessible.

In sum, our research transcends mere technological advancements. By intertwining technology with a cause as noble as blood donation, we aspire to drive change, save lives, and amplify the significance of every donor's invaluable contribution. As we look forward, we remain optimistic about the transformative impact of our work, not just on the medical landscape but on society at large.

*Abstract*—The global transportation of goods has evolved in response to varied economic demands. The rapid progression of modern scientific and technological innovations offers a shift from traditional shipping paradigms. Current systems, whether domestic like Cash-on-Delivery (CoD) or international such as Letter-of-Credit, necessitate trust-building through an intermediary—be it a carrier or a financial institution. While these conventional systems provide certain benefits, they inherently present several challenges and potential vulnerabilities, affecting both sellers and buyers. The introduction of blockchain technology and smart contracts has been explored as a viable alternative to bypass these intermediaries. However, simply removing the shipping intermediary presents its own set of issues, particularly when disputes arise. Notably, the shipper remains unaffected in situations of contention. Consequently, some models are now incorporating the shipper's role, either as a singular entity or in collaboration with others. Yet, a considerable number of these models still depend on an external trusted party for conflict resolution. Our study introduces a unique framework, blending the robustness of blockchain, the enforceability of smart contracts, and the authenticity assurance of NFTs. This system creates a streamlined CoD operation encompassing the seller, shipper, and buyer, using NFTs to produce digital receipts, guaranteeing both proof-of-purchase and a security deposit. Furthermore, our system provides an inherent mechanism for dispute resolution. Key contributions of our work including i) The design of a novel CoD system anchored on blockchain and smart contract capabilities; ii) The incorporation of Ethereum-based NFT (specifically, ERC721) for securely logging package information; iii) The development of smart contracts that facilitate NFT generation and transfer between transactional entities; and iv) Performance evaluation and deployment of these contracts across multiple EVM-compatible platforms such as BNB Smartchain, Fantom, Celo, and Polygon, establishing the optimal environment for our innovative system.

## I. Introduction

The intricate world of shipping and logistics has always revolved around trust and verifiability, historically hinging on the foundational rapport either between buyer and seller or embedded within the trust framework of a shipping entity, notably the shipper [1]. Regrettably, within these traditional paradigms, numerous challenges have surfaced, casting a shadow on the reliability of transactions, especially in the context of international trade.

For instance, consider the Letter-of-Credit (LoC) model, a time-tested mechanism used in international trade. To elucidate, let's sketch a scenario involving a Vietnamese exporter, specializing in cashew nuts, and an importing entity situated in Italy. While seemingly straightforward, the mechanics of their transaction heavily rely on a neutral third party, conventionally a bank, to validate and authenticate the dealings.[1] The fragile nature of this process becomes glaringly evident when crucial documents, say the LoC, go missing. The consequences can be dire, as evidenced by a 2021 event involving potential financial losses in a Vietnamese cashew shipment to Italy, all precipitated by the unavailability of requisite documents.[2] Fortunately, swift diplomatic intervention averted a crisis. Yet, the incident remains a poignant testimony to inherent systemic frailties.

On the domestic front, where the Cash-on-Delivery (CoD) model reigns supreme, sellers are ensnared in a web of dependency on shipping companies. Under this system, profits from goods sold are typically remitted to the sellers either periodically or upon hitting predetermined financial ceilings. However, this trust-dependent system has shown its flaws. A poignant case from Vietnam during 2017-2018 involving GNN Express highlighted the vulnerability, as funds intended for sellers were misused by the shipping entity.[3]

Such systemic vulnerabilities have instigated an earnest quest for robust, technology-driven mechanisms in the shipping sector. The genesis of Bitcoin in 2009 marked a paradigm shift, championing a decentralized, transparent Peer-to-Peer transactional ecosystem reinforced by the Proof-of-Work (PoW) consensus mechanism [2].

Building on this momentum, Ethereum entered the scene, revolutionizing the landscape with the introduction of smart contracts—autonomous, self-regulating contracts, where contractual terms and conditions transmute into programmable code lines.[4] This technological marvel birthed transactional frameworks such as localEthereum in 2017, advocating for

---

[1]For reasons aligned with information security and confidentiality, we have intentionally refrained from naming the specific companies involved in these transactions from Vietnam and Italy.

[2]https://vietnamnet.vn/en/100-containers-of-cashew-nuts-exported-to-italy-suspected-of-being-scammed-821553.html

[3]https://vir.com.vn/gnn-scandal-rocks-delivery-segment-62710.html

[4]https://ethereum.org/en/whitepaper/

payment paradigms rooted in the Solidity language.[5] While several innovative models sprouted, Ethereum's technological acumen found resonance in other platforms, leading to the creation of EVM-integrated platforms, heralding a new era of smart contract adaptability.

Yet, the path is not devoid of hurdles. A recurring critique of many frameworks has been their apparent sidelining of a crucial player in the shipping process: the shipper. Excluding them could muddle dispute resolution processes between sellers and buyers [3]. Recognizing this gap, subsequent studies championed the seamless incorporation of shippers via blockchain and smart contracts [4]. However, integrating shippers isn't the panacea; challenges like potential package damages during transit loom large [5].

Addressing this multifaceted issue is our primary research impetus. We harness the potential of NFT technology to meticulously encapsulate package particulars, ensuring a transparent and accountable transfer process from sellers to buyers, with shippers playing a pivotal role. The cornerstones of our research are: (a) architecting a holistic shipping framework anchored in blockchain technology and enriched with smart contracts; (b) engineering a meticulous Ethereum-based NFT mechanism (specifically ERC721) for comprehensive package information cataloging; (c) the meticulous design and deployment of NFT-empowered smart contracts, enabling seamless transactional experiences between stakeholders; and (d) rigorously assessing the performance of these smart contracts across a spectrum of EVM platforms - specifically, we install a recommendation system on four popular blockchain platforms today, supporting Ethereum Virtual Machine (EVM), including Binance Smart Chain (BNB Smart Chain)[6]; Polygon [7]; Fantom [8]; and Celo [9]. [10]

## II. PRELIMINARIES

### A. Understanding Blockchain

Blockchain gained prominence with Bitcoin's debut in 2008, presented by Nakamoto [2]. It serves as a distributed, credible, and transparent ledger. Within a peer-to-peer network, a blockchain system distributes transaction information across multiple computing devices. This facilitates a robust link between transaction participants, eliminating traditional intermediaries like banks [6].

Presently, blockchains are categorized into Public, Private, and Consortium. Public blockchains, like Bitcoin and Ethereum, are open for all, even anonymous participants, to validate transactions, introduce new ones, and ensure the authenticity of existing data. In contrast, private blockchains like GemOS, MultiChain, Ripple, and Eris restrict participation to authorized members. Consortium blockchains merge attributes from both types. They are designed for business needs, balancing openness with security. Examples include Hyperledger Fabric [7] and the private configurations of Ethereum [8].

[8]https://whitepaper.io/document/438/fantom-whitepaper

[9]https://celo.org/papers/whitepaper

[10]The ETH platform was consciously excluded due to the prohibitive costs associated with smart contract operations.

### B. Key Blockchain Platforms

*1) Ethereum:* Ethereum, as described in [9], is a distributed platform that facilitates the execution of smart contracts using the Solidity language. Powered by the Ethereum Virtual Machine (EVM), Ethereum extends its capabilities to decentralized finance (DeFi), establishing protocol-bound conditions.

*2) Hyperledger fabric:* Hyperledger Fabric, an open-source solution [7], is tailored for enterprise requirements. With its distinct architecture, it supports dual modes—public and private blockchains. Unlike Ethereum's reliance on EVM, Fabric employs Docker containers termed "ChainCode" for smart contract execution, offering compatibility with Java and Go, which simplifies development and lowers operational costs.

*3) Celo:* Celo is a decentralized platform prioritizing mobile access and stability of value. While it is EVM-compatible, it differentiates itself with a mobile-first approach. The platform incorporates stable-value tokens, ensuring that transaction fees are predictable.

*4) Fantom:* Fantom is a high-performance, scalable, and secure smart contract platform. Leveraging its unique Lachesis Protocol, it guarantees low time-to-finality. Being EVM-compatible means developers familiar with Ethereum can easily transition to Fantom.

*5) Matic (Polygon):* Polygon, formerly known as Matic, offers a scalable and interoperable framework. While it started as an Ethereum sidechain, it has evolved to support multiple chains. Its EVM compatibility and commitment to scalability make it a preferred choice for many decentralized applications.

### C. Decentralized Logic: Smart Contracts

Smart contracts, known as chaincode in Hyperledger Fabric, digitally facilitate, verify, or enforce credible transactions. These self-executing contracts embed the terms directly within the code. In decentralized applications, they serve as algorithmic agents, functioning like traditional contracts.

*1) Distinctive features:* Smart contracts exhibit several traits:

- Decentralization: Stored across the Ethereum network, contrasting centralized solutions.

- Predictability: Act only under stipulated conditions, maintaining consistent outcomes.

- Autonomy: Automate tasks, staying dormant until activated.

- Immutable Nature: Once deployed, they're unchangeable. However, they can be rendered inactive if preprogrammed.

- Versatility: Programmable before deployment, they cater to diverse decentralized applications.

- Trustless Operations: Enable interactions without mutual trust, as blockchain validates data accuracy.

- Openness: Being on a public ledger, their code is visible to all but remains unalterable.

*2) Functionality overview:* A smart contract's functionality parallels that of a vending machine. It awaits the right conditions, then executes. Assets and terms are encrypted into a blockchain block. Upon activation, the contract follows the encoded logic, autonomously ensuring term adherence.

*3) Advantages:*

- Efficient Cost Structures: Smart contracts streamline processes that conventionally demand intermediaries. By eliminating middlemen, like banks or notaries, there's a direct reduction in associated costs and fees. Transactions are executed automatically when predetermined conditions are met, ensuring that users only bear the essential costs of the contract's execution.

- Adaptive Terms for User Convenience: Smart contracts are designed to be programmable, granting them a degree of flexibility unparalleled by traditional contracts. This adaptability allows parties to customize terms according to their specific needs. Whether it's payment schedules, compliance criteria, or conditional operations, smart contracts can be tailored to handle diverse scenarios, enhancing user experience and satisfaction.

- Complete Transparency and Clarity in Transactions: Being on a blockchain, every smart contract's terms and transactions are transparent to all involved parties. This ensures that every stakeholder can verify transaction details, reducing ambiguities and mistrust. The open nature of public blockchains further enhances transparency, as any external observer can validate the contract's operation, fostering trust and collaboration.

- Unwavering Reliability and Minimal External Interference: Once deployed on the blockchain, a smart contract is immutable. This means that without the consensus of network participants, it cannot be altered, ensuring its credibility. The decentralized nature of blockchains also ensures that no single entity has control over the contract, making it resistant to censorship, fraud, and undue interference.

- Speedy, Straightforward Deployment and Execution: Traditional contracts can be time-consuming due to manual processes, verifications, and approvals. In contrast, smart contracts automatically execute when their conditions are met. This automation, combined with the power of blockchain technology, leads to faster transactions and contract completions. Tools like Remix simplify the development and deployment, further accelerating the entire process.

*4) Solidity and related tools:* Solidity, inspired by languages like JavaScript, C++, and Python, caters to smart contract creation for the EVM. It supports complex types, inheritance, and libraries.

Web3.js serves as a bridge for Ethereum interactions, akin to how jQuery interacts with web servers. It facilitates Ether transfers, smart contract interactions, and more, relying on JSON RPC to communicate with Ethereum nodes.

Remix, a development environment for Solidity, assists in contract drafting, compilation, and debugging. It provides tools for contract deployment and transaction simulations.

### D. Chosen Platforms for Implementation

Our research showcases the Letter-of-credit Chain's proof-of-concept on Ethereum, Binance Smart Chain, and Fantom.

*1) Binance Smart Chain:* Binance Smart Chain (BSC) is an evolution of the original Binance Chain, designed to run parallelly. Like Ethereum, BSC extends its capabilities to DApps and can be deployed on EVM-compatible platforms. BSC employs the Proof of Staked Authority (PoSA) model, a combination of Proof of Authority and Proof of Stake. Validators stake BNB tokens and earn rewards for validations. The seamless integration between Binance Chain and BSC ensures asset interoperability, benefiting from fast transactions and EVM's capabilities.

*2) Celo:* Celo emphasizes on financial tools accessible via mobile phones. Supporting EVM-compatible smart contracts, its primary aim is to diminish financial barriers and simplify access.

*3) Fantom:* Prioritizing speed and security, Fantom provides a scalable smart contract platform. It ensures swift transaction confirmations using its Lachesis Protocol, making it a viable option for various decentralized applications.

*4) Matic (Polygon):* Polygon provides a framework for building and linking Ethereum-compatible blockchain networks. Its primary focus lies in scalability and instant blockchain transactions, catering to a multitude of DApps.

### III. RELATED WORK

Blockchain technology has increasingly found applications in domains requiring secure and transparent interactions among multiple stakeholders. This section provides an overview of these applications, culminating in the emergence of blockchain-based freight models that incorporate Non-Fungible Tokens (NFTs).

### A. Blockchain in Delivery and Transactional Systems

Historically, blockchain has been explored as a solution to problems in various delivery systems. Some notable examples include:

- *Cash-on-Delivery*: Blockchain has been employed to address challenges in cash-on-delivery systems, ensuring both payment security and delivery assurance [10], [11].

- *Letter-of-Credit*: Blockchain's immutability and transparency features make it suitable for modernizing Letter-of-Credit mechanisms, enhancing trust among parties [12], [13].

- *Traditional Delivery*: The technology also aids in streamlining traditional delivery processes by creating clear, tamper-proof records [5], [14].

## B. Blockchain in Healthcare

Beyond delivery systems, the need for transparency and security has made blockchain a favorite for healthcare applications:

- Traditional healthcare systems leverage blockchain for securely storing and accessing patient records, ensuring both patient privacy and data integrity [15], [16].

- Blockchain's transparent and immutable nature has led to its use in the supply chain management for blood and related products, ensuring traceability and accountability [17], [18].

- There are also systems in place that give patients control over their information, promoting a patient-centric approach to healthcare [19].

## C. Bitcoin and its Limitations

Introduced in 2009, Bitcoin was a pioneering system that facilitated trust-less peer-to-peer payments [20]. However, Bitcoin's reliance on the Proof-of-Work (PoW) consensus algorithm led to significant operational costs, both monetary and environmental [21]. The system's constraints, particularly its limited throughput and associated high fees for transaction validations, led to the search for alternative blockchain solutions.

## D. Emergence of Ethereum and Smart Contracts

In response to Bitcoin's limitations, Ethereum emerged as a versatile platform, introducing the concept of smart contracts. These self-executing contracts, with terms directly written into code, enabled more sophisticated and customizable transactions. Ethereum's introduction of the Solidity programming language further empowered developers to create advanced applications on the blockchain. Additionally, Ethereum showcased improved system performance compared to Bitcoin [4].

## E. Decentralized Exchange Platforms

Platforms like Local Ethereum [22] and Open Bazaar [23] aimed to facilitate trust-less exchanges between buyers and sellers. While Local Ethereum focused on a direct barter system, Open Bazaar introduced a third-party, the moderator, enhancing transactional trust. These platforms emphasized transparency, ensuring all members could monitor ongoing transactions, even if not directly involved.

However, these systems' reliance on predefined smart contracts meant inflexibility in the transaction process. Any dispute would require an external trusted party for resolution. This limitation prompted the exploration of adaptable smart contract solutions like the "middleman" [24], offering dynamic contracts with penalties for breaches.

## F. Broadening the Scope: Beyond Traditional Buyer-Seller Models

Ethereum's decentralized applications (Dapps) started considering more participants in transactional models, like shippers or shipping companies [25]. This shift in perspective highlighted the pivotal role of shippers in the transactional ecosystem. However, these models also introduced complexities in arbitration, requiring parties to post deposits as assurance against potential disputes [3], [26].

## G. Our Contribution

In light of the aforementioned challenges and developments, we propose a novel blockchain-based freight model integrating NFT certificates. In our model, unique NFTs are generated upon item shipment, creating a secure, transparent, and traceable record of each transaction.

## IV. Approach

### A. Preliminary: Traditional Freight Transport Modalities

In specific regions, the logistics and shipment processes are overseen and authorized by specialized transport entities. These entities may perform diverse roles—either solely ensuring product delivery or overseeing the financial exchange from the consumer to the vendor. In the model depicted in Fig. 1, the consumer commits the entire invoice payment upfront. This model signifies that the transportation company's primary responsibility is the physical delivery, devoid of any financial intermediation. The outlined process seamlessly moves from invoice consolidation to packaging, and finally, product distribution to the end consumer.

Conversely, the Cash-on-Delivery (CoD) model, prevalent in several regions, is more vendor-centric. Here, transportation companies play a pivotal role in not just delivering but also managing payment collections, as illustrated in Fig. 2. Although the CoD model ensures payment upon successful delivery, it brings forth specific risks for the merchants.

As delineated in the preceding sections, traditional freight systems possess inherent challenges. Our novel contribution aims at an intricate blend of blockchain, NFTs, and smart contracts to modernize and secure the transportation model, safeguarding against potential discrepancies among stakeholders (e.g., vendor, consumer, courier).

### B. Revolutionizing Freight: The Blockchain, NFT, and Smart Contract Fusion

Our proposal, visualized in Fig. 3, hinges on three pivotal technologies: blockchain for transparent and immutable transaction recording, NFTs as digital certificates vouching for consensual agreements, and smart contracts automating contractual obligations. This amalgamation targets the eradication of reliance on central trust entities, even in conflict scenarios.

The process initiates with the vendor, who is mandated to deposit a security amount. This ensures that the product aligns with the information and quality delineated in the smart contract. The logistics company, responsible for managing couriers, deposits a fee to safeguard against potential risks like misplacement, product damage, or insolvency. The consumer's deposit encompasses the logistics fee and a partial product deposit, the latter serving as a safeguard against arbitrary purchase cancellations.

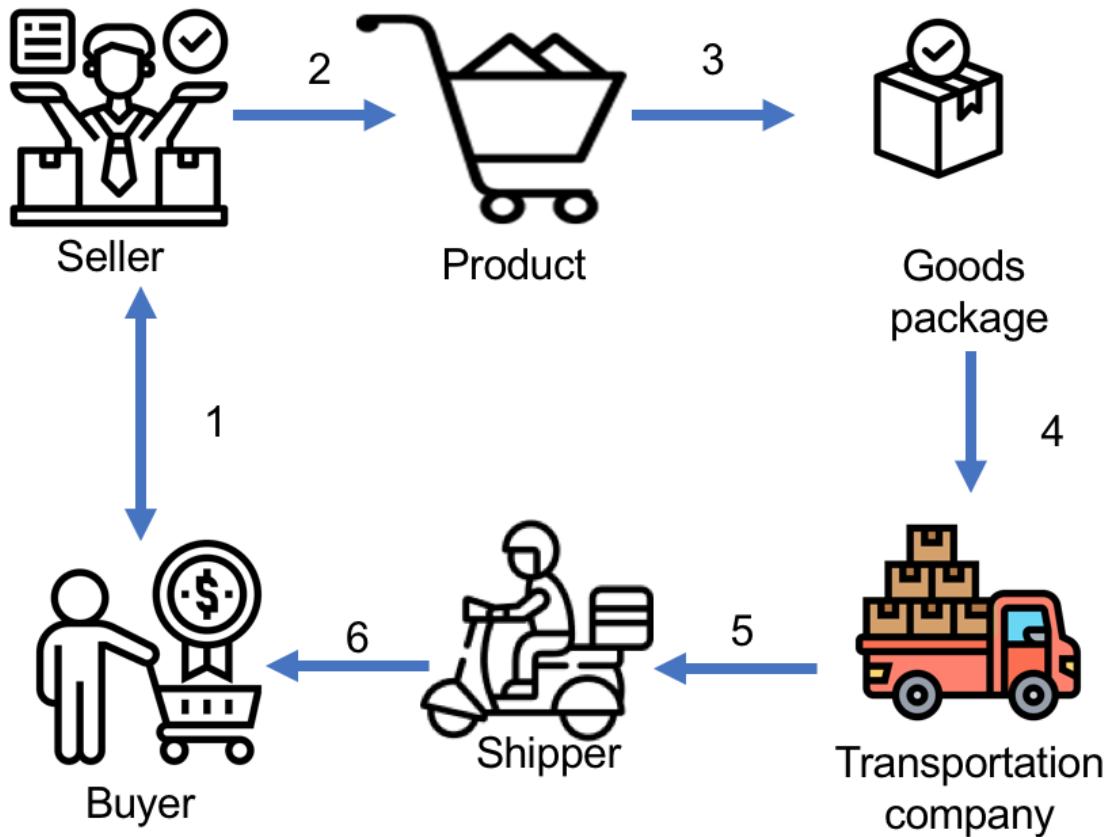
As Fig. 3 suggests, the vendor initiates the process by cataloging the product's specifics (e.g. weight, unit price,


Fig. 1. Traditional framework involving a transportation entity in freight movement.

Fig. 2. Conventional Cash-on-Delivery (CoD) mechanism in freight transport.

type) into the system. Leveraging these details, the system's underlying smart contract crafts a shipment contract. Once this agreement is in place, an appropriate logistics partner is chosen. All agreements and stipulations are meticulously recorded within an NFT, consented upon by all involved entities (i.e. vendor, consumer, logistics entity).

The physical shipment process, potentially involving multiple couriers, is orchestrated by the logistics company. Upon reaching the consumer and obtaining an affirmation of product integrity, the NFT records this validation. The final transactional phase sees the consumer settle any outstanding product payments, the logistics entity obtaining their fees and security deposits, and the vendor procuring the product sales revenue. Any discrepancies or contractual breaches get resolved based on the smart contract's predefined conditions, ensuring transparency and fairness.

In culmination, all transactions get appended to the distributed ledger, making them immutable and transparent, and the system resets, readying for the next shipment cycle.

## V. Implementation Process for Advanced Patient-Centric Medical Test Record Management

The core objective of our research paper is to leverage the innate capabilities of the blockchain, especially in the realm of Non-Fungible Tokens (NFTs), to provide a seamless experience for patients managing and sharing their medical test results. The very design of our proposed model, which emphasizes intuitive patient-centric management of test results, coupled with the ease of sharing these results with any desired entity, underscores the need to opt for EVM-enabled blockchain platforms, eschewing the Hyperledger ecosystem, to enable broader accessibility.

In this vein, our efforts have been directed towards discerning the most apt platform that can seamlessly host our model. Our search and subsequent evaluations led us to focus on four of the contemporary leading blockchain platforms, each supporting the Ethereum Virtual Machine (EVM) - Binance Smart Chain (BNB Smart Chain)[11], Polygon[12], Fantom[13], and Celo[14].

Our contributions to this domain have been further enriched by sharing the implementation details on these platforms, thus, fostering a transparent discourse around transaction costs asso-

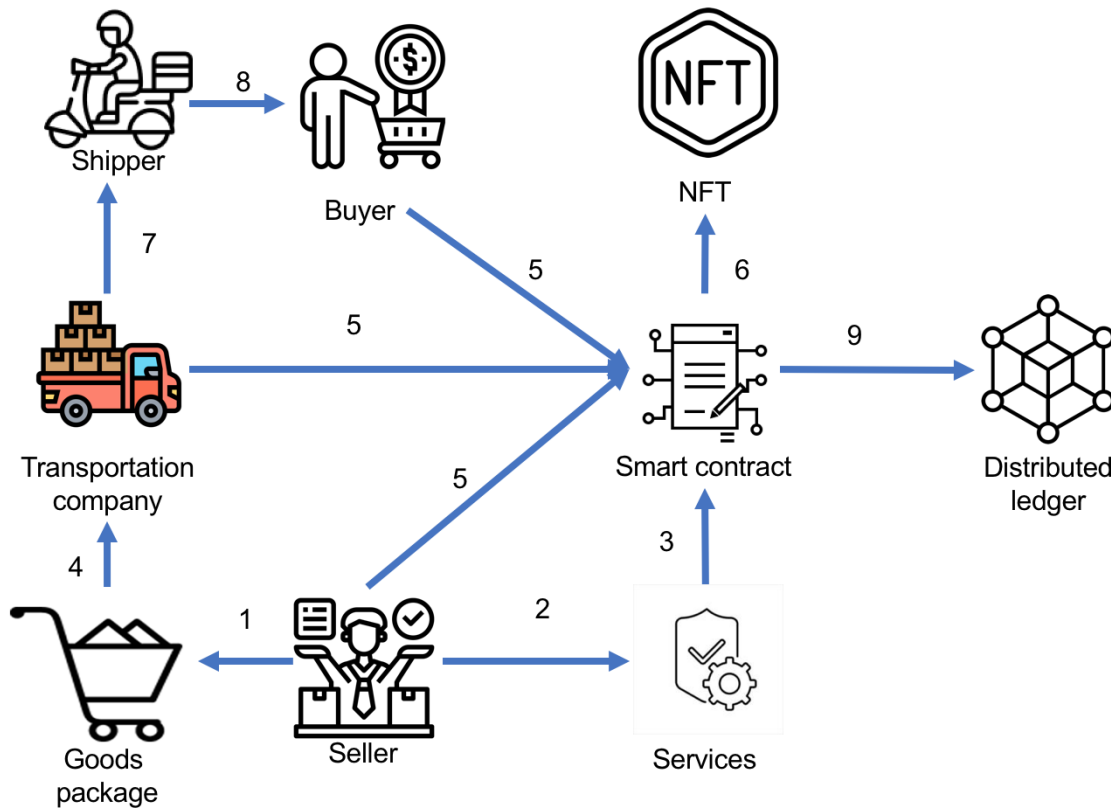
[14] https://celo.org/papers/whitepaper


Fig. 3. Innovative freight model harnessing Blockchain, Smart Contracts, and NFTs.

ciated with these platforms' native tokens[15], namely, BNB[16], MATIC[17], FTM[18], and CELO[19].

The culmination of our assessments was directed towards ascertaining the cost-effectiveness of executing smart contracts, designed leveraging the Solidity language, on the testnet environments of these platforms. This would be instrumental in guiding our decision on the optimal platform for deployment.

### A. Deployment on EVM-compatible Platforms with a Spotlight on BNB

The blockchain realm, especially platforms compatible with the Ethereum Virtual Machine (EVM), offers versatility that serves a range of applications. In discussing a tripartite model involving sellers, shippers, and buyers and bolstered with an integrated consensus protocol for payments, the superiority of EVM-compatible platforms is evident.

This section provides an intricate look at our model's integration on these platforms, emphasizing its deployment on the Binance Smart Chain (BNB) - Fig. 4.

---

[15]Our models were released on 11/24/2022, 8:44:53 AM UTC

Fig. 4. Snapshot of transaction details, specifically from BNB smart chain.

This figure is a snapshot highlighting transaction details on the Binance Smart Chain (BNB). Within this image, users would observe an interface displaying transaction IDs, timestamps of transactions, sender and receiver addresses, and the amount transferred. Furthermore, it likely showcases the transaction's status (whether it's pending, failed, or successful), gas fees associated, and possibly even a link to the block where this transaction is recorded. By analyzing this snapshot, one can discern the efficiency and speed of transactions on the BNB Smart Chain and understand its user-friendly interface.

In Fig. 5, the visualization concentrates on the non-fungible token (NFT) creation process. This graphical representation likely delineates the steps involved in minting an NFT, from selecting the digital asset, inputting metadata, determining rarity or attributes, to finally issuing or minting it on the blockchain. The figure may also exhibit the interaction with smart contracts during the NFT creation and any gas fees or computational resources required. The graphical elements emphasize the uniqueness and immutable nature of NFTs and

Fig. 5. Visualization of the NFT creation process.

the efficiency of the BNB Smart Chain in facilitating their creation.

Fig. 6. Demonstration of NFT transfer mechanics.

The focus of Fig. 6 is on the intricacies of NFT transfers, especially concerning the ERC-721 token standard. This diagram likely presents an NFT's journey from one digital wallet to another, illustrating the security protocols, verification processes, and blockchain confirmations involved. An integral aspect might also include the interaction with the underlying ERC-721 smart contract, ensuring the asset's authenticity and ownership transfer. This figure aims to highlight the seamlessness and secure nature of transferring unique digital assets on platforms that adhere to the ERC-721 standard.

Continuing from earlier, our goal is to benchmark our system against four premier EVM-compatible platforms. By sharing our insights on these platforms, we aim to enlighten the community and gather actionable data. Through a meticulous analysis of smart contract execution costs in these testnet environments, we seek the platform that blends optimal cost-efficiency with performance for tangible deployments.

Our implementation model focuses on two main purposes i) data manipulation (i.e. package) - initialization, query and update - on blockchain platform and ii) generation of NFTs for each order goods for easy retrieval by sellers and buyers (i.e. product reviews before and after delivery).

### B. Data and NFT Initialization Procedure

The intricacies of initializing package data, from its inception to the eventual registration on the blockchain, are portrayed in Figure 7. This diagram offers an overview of the process and helps comprehend the significance of each step.

Package data is a conglomerate of multiple parameters:

- Sender's Details: This pertains to the individual or entity dispatching the goods. It includes crucial aspects such as the sender's address, the weight of the package, and specifics about the item being sent.

- Recipient's Details: It's essential to ascertain where the package is headed. Data includes the recipient's address and an estimated time of arrival.

- Security Deposits: The financial security mechanisms are indispensable in maintaining the integrity of the system. Each of the three key participants - sender, recipient, and shipper - deposits an amount that acts as a safeguard, facilitating automatic resolution of potential disputes via the smart contract.

- Metadata of the Package: Further granular details about the package are recorded, such as which shipping company is responsible, when and where it's to be delivered or picked up, etc. This becomes exceedingly crucial in scenarios involving multiple shippers, which could either belong to the same logistics company or different entities.

To fortify data consistency and system efficiency, the platform employs a distributed ledger model. This supports concurrent storage, mimicking a peer-to-peer network structure, enabling multiple users to store data simultaneously, thereby diminishing system latency.

The structure of package data can be understood by examining the following data representation:

```
goodsObject = {
"goodsID": goodsID,
"deliveryCompanyID": deliveryCompanyID,
"shipperID": shipperID,
"type": type of goods,
"buyerID": buyerID,
"sellerID": sellerID,
"quantity": quantity,
"unit": unit,
"packageID": packageID,
"addressReceived": received address,
"addressDelivery": delivery address,
"time": time,
"location": location,
"state": Null
};
```

Within this structure:

- The "state" parameter is a dynamic attribute, commencing as a Null value. A change to 1 signifies the shipping company has taken possession of the goods, whereas a 0 implies it's awaiting collection by the shipper.

- The "unit" denotes the order's quantity. An adjunct "packageID" helps in tracking the particular package associated with the order.

Post the collection of packages from sellers, the onus falls on shippers to ensure the items are consistent with the listed details. Post verification, they're held in a temporary digital storage before getting committed to the blockchain.

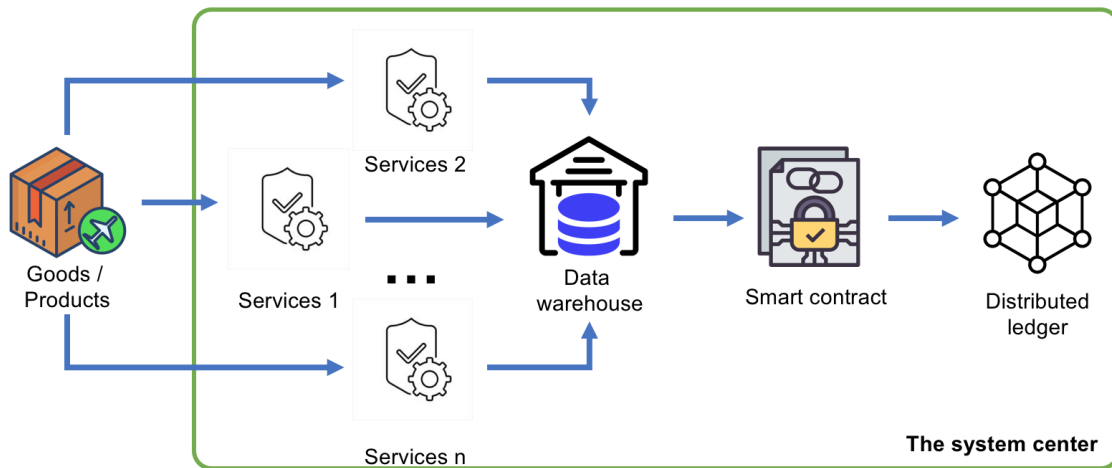
The verification process is paramount, for any discrepancies or damages can directly impact the shipping procedure. Furthermore, it establishes a foundation for resolving conflicts that might arise during the transportation of goods.


Fig. 7. Procedure to initialize data and NFT for goods.

NFTs, in this context, encapsulate distinct attributes of each order. Beyond the conventional details, they also record financial commitments in the form of deposits from each party involved. The NFT structure is as such:

```
NFT PACKAGE = {
"shipperID": shipperID,
"sellerID": sellerID,
"buyerID": buyerID,
"packageID": packageID,
"type": type of goods,
"quantity": quantity,
"addressReceived": received address,
"addressDelivery": delivery address,
"depositShipper": deposit of shipper,
"depositSeller": deposit of seller,
"depositBuyer": deposit of buyer,
"time": estimated delivery time
};
```

NFTs offer a transparent mechanism to track goods and ensure accountability. For instance, in cases of delivery delays, the embedded information within the NFT provides a clear path for conflict resolution.

For more nuanced interpretations of stakeholder deposits and related topics, our preceding research works and articles offer a comprehensive discussion.

### C. In-depth Examination of Data Query Process

The data query process, depicted in Fig. 8, is as intricate as the data initialization phase, and its operations are molded to accommodate multiple simultaneous participants. The overarching principle is the distributed model, which caters to an environment where several users can query data concurrently, ensuring the system's scalability and flexibility.

Different stakeholders have distinct query requirements:

1) Shippers: Their primary focus is on logistical details. They query data to obtain specifics like the

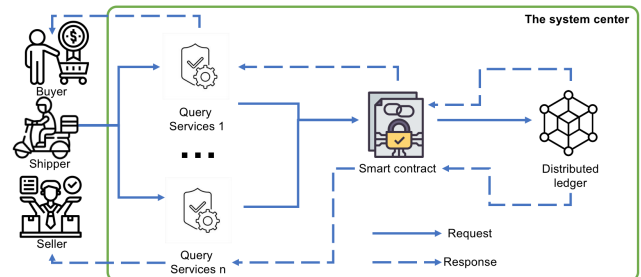

Fig. 8. Illustration of the data query process.

consignee's particulars and their corresponding addresses. Such information is pivotal to ensure the seamless delivery of goods to the right destinations.

2) Sellers/Buyers: Their queries are more customer-centric. Sellers and buyers are keen on tracking the status of their orders, particularly post-dispatch and receipt. Furthermore, if any discrepancies or issues arise—be it delays or damages—they would resort to this system to glean insights and possibly initiate conflict resolution processes.

The data retrieval mechanism can be delineated as follows:

- Users, be it shippers or sellers/buyers, initiate their query through a predefined service, often implemented as an API call. These calls are essentially instructions directed at smart contracts present in the blockchain system. Each smart contract has specific functions tailored to handle a variety of tasks, and in this context, it deals with fetching the requisite data from the distributed ledger.

- Every query isn't just a fleeting transaction; it's logged within the system. This implies that all retrieval requests metamorphose into a query history, which is associated with the respective individual or organization. Such a chronicle can be instrumental for audit trails or to understand behavioral patterns of users over time.

A point of intrigue in this system is the handling of more complex shipping processes. When a package's journey isn't a straightforward 'A to B' route, but rather involves multiple intermediary stops with various shippers handling the goods, the complexity grows. In such multi-hop scenarios, where several shippers—either from the same or different logistics companies—are involved, NFTs play a crucial role. They act as verifiable digital tokens at each handover point, ensuring transparency and traceability.

However, the system is designed to be robust but not infallible. Instances might arise where queries return no results, possibly due to erroneous inputs like an incorrect ID. In such scenarios, the system is intuitive enough to relay a 'not found' message, ensuring users are promptly informed.

Lastly, when it comes to NFT-based queries, they are seamlessly integrated with the overarching system. All necessary services to handle NFT inquiries are provided as APIs, facilitating easy and efficient interactions for users.

### D. An In-depth Exploration of the Data Update Mechanism

Fig. 9. Illustration of the data update mechanism.

Updating data within the blockchain requires utmost precision, given the immutability of records once entered. This process is not simply about making amendments; it's about ensuring the integrity of the entire system.

Before any data can be updated, there's a prerequisite: the data in question must exist. This might sound simple, but it's a crucial step. This is ensured by invoking the data query procedure beforehand. In simpler terms, before attempting any changes, the system checks if the data entry to be updated is actually present. If it isn't, the user is promptly notified with a message, as detailed in the previous Section V-C.

The architecture to support data updates is structured and methodical:

- API Integration: Similar to the mechanisms for data querying and initialization, the update services are provided through APIs. These Application Programming Interfaces act as gateways. They allow users to submit their update requests, which are then funneled to the appropriate part of the system for further action.

- Smart Contract Interaction: Once the API receives an update request, it communicates with a designated smart contract. Smart contracts are like automated intermediaries, each with specific functions to ensure that the processes within the blockchain are executed

correctly. In this context, the smart contract handles the updating of data based on the request received.

- Purpose and Implications: The main objective of the update process is multifaceted. One primary role is to track and record the evolving status of packages as they move through various transit points. But it goes beyond mere tracking; it also addresses anomalies or issues. If something isn't right - maybe there's damage, or a package goes missing - the system can initiate conflict resolution mechanisms. This is achieved through a combination of smart contract logic and the attributes of Non-Fungible Tokens (NFTs).

Fig. 9 offers a visual representation of this intricate dance of data updates. When it comes to the realm of NFTs, the update dynamics take a slightly different hue. An NFT, by its very nature, is unique and cannot be replicated. Therefore, updating an NFT doesn't mean modifying its existing attributes. Instead, when details associated with an NFT need to be changed, the system creates a brand-new NFT to capture those updates. On the surface, this might seem like a mere transfer, like moving an NFT from one owner's address to another. But underneath, it ensures the veracity and traceability of each unique digital asset, as further explained in subsection V-B.

## VI. IN-DEPTH EVALUATION OF CONTRACT OPERATIONS

In our thorough evaluation, we scrutinize the intricacies of the expenses tied to blockchain operations, such as contract creation, NFT generation, and the dynamic transfer or retrieval of NFTs. These operations, illustrated in Fig. 5 and 6, bring with them costs. We categorize these costs under four main subsections: i) Transaction Fee; ii) Gas limit; iii) Gas Used by Transaction; and iv) Gas Price. Each of these sections offers a lens into the underlying costs and efficiencies of the blockchain processes.

Blockchain operations are often lauded for their immutable record-keeping and decentralized nature, but it's equally essential to understand the associated costs. Contract creation, NFT generation, and transfer each have their own set of expenses. These costs ensure the sustainability of the network, compensate for the computational effort, and can also act as a deterrent against frivolous or malicious activities. A closer examination of these costs can offer insights into the economic viability of blockchain-based systems.

### A. Transaction Fee Analysis

The transaction fee is a fundamental aspect of our evaluation. It acts as a "price" for the computational and operational services provided by the blockchain. To showcase the relative costs across various platforms, we present a detailed breakdown in Table I.

From Table I, we can infer a few pivotal insights:

- Variability across Chains: There's a noticeable difference in transaction fees across different chains. For instance, the BNB Smart Chain's contract creation is significantly higher than that of Fantom or Polygon. Such variations can be attributed to the underlying architecture, consensus mechanism, network congestion, and other chain-specific factors.

TABLE I. TRANSACTION FEE

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 0.02731184 BNB ($8.32) | 0.00109162 BNB ($0.33) | 0.00057003 BNB ($0.17) |
| Fantom | 0.009576994 FTM ($0.001850) | 0.0002405167 FTM ($0.000078) | 0.0002380105 FTM ($0.000046) |
| Polygon | 0.006840710032835408 MATIC($0.01) | 0.0002894050001852192 MATIC($0.00) | 0.000170007501088048 MATIC($0.00) |
| Celo | 0.0070974384 CELO ($0.004 ) | 0.0002840812 CELO ($0.000 ) | 0.0001554878 CELO ($0.000 ) |

- Cost Gradient in Operations: Contract creation typically incurs a higher fee than other operations across all chains. This indicates the relative computational complexity and resources utilized during this process.

- Micro-transactions: Some fees, especially on chains like Polygon and Fantom, are incredibly minute, hinting at their potential suitability for high-frequency, low-value transactions.

Understanding these nuances is crucial for both developers and users, as it helps in making informed decisions about which chain to use, especially when balancing between operational costs and performance requirements.

### B. Diving into Gas Limit Values

Gas limit refers to the maximum amount of units of gas the sender is willing to spend on a transaction or contract execution. It is a protective mechanism to ensure that a process doesn't run indefinitely, especially if something goes wrong. The Table II provides a clear breakdown of the gas limits set for three distinct operations across four blockchain platforms.

Table II distinguishes the gas limit values for three types of operations: Contract Creation, NFT Creation, and NFT Transfer across the BNB Smart Chain, Fantom, Polygon, and Celo blockchain platforms.

**Detailed Insights**:

BNB Smart Chain:

- The gas limit for contract creation stands at 2,731,184.

- For creating an NFT, the gas limit is considerably lower at 109,162.

- Interestingly, transferring an NFT requires a higher gas limit of 3,000,000, which is the highest among the three operations on this chain.

Fantom & Polygon:

- Both Fantom and Polygon have identical gas limits for the operations showcased.

- Contract creation requires a gas limit of 2,736,284.

- Creating an NFT comes in at 115,762.

- Transferring an NFT consumes the least gas limit, set at 72,803.

Celo:

- Celo has a distinctively higher gas limit for contract creation, which is 3,548,719, making it the highest among the platforms presented.

- The gas limit for NFT creation is 142,040.

- NFT transfer operations require 85,673 as the gas limit, which, similar to the trend in Fantom and Polygon, is less than the gas limit for NFT creation.

**General Observations**:

- Comparative Gas Limits: Across platforms, the gas limit for contract creation is consistently higher than that of creating an NFT, indicating the relative complexity of the contract creation process.

- NFT Transfers: The gas limits for NFT transfers differ significantly between chains. For instance, on the BNB Smart Chain, the limit is exceptionally high, whereas, on Fantom and Polygon, it's much lower. This suggests varying computational demands and efficiencies in the transfer process across these platforms

- Consistency between Fantom and Polygon: The identical gas limits for Fantom and Polygon for all three operations might indicate similarities in their underlying architecture or processing mechanisms for these specific operations.

In general, understanding the gas limit is essential for blockchain developers and users as it provides insights into transactional and operational costs. The values in Table II offer a comparative view of the efficiency and computational demands of different operations across various blockchain platforms.

### C. Insight into Gas Consumption

Table III provides a comprehensive analysis of the gas utilized for various operations across four blockchain platforms. Unlike the gas limit which signifies the maximum gas units that could potentially be spent, "Gas Used by Transaction" indicates the actual gas consumed by an operation, thus giving a clearer picture of efficiency.

Table III showcases the gas consumed in units and as a percentage of the gas limit for three main operations: Contract Creation, NFT Creation, and NFT Transfer. These operations are evaluated across BNB Smart Chain, Fantom, Polygon, and Celo blockchain platforms.

**Detailed Breakdown:**

BNB Smart Chain:

- The contract creation operation uses all its gas limit, consuming 2,731,184 units, which equates to 100% utilization.

- Creating an NFT also exhausts its set gas limit, utilizing 109,162 units or 100

TABLE II. GAS LIMIT

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 2,731,184 | 109,162 | 3,000,000 |
| Fantom | 2,736,284 | 115,762 | 72,803 |
| Polygon | 2,736,284 | 115,762 | 72,803 |
| Celo | 3,548,719 | 142,040 | 85,673 |

TABLE III. GAS USED BY TRANSACTION

|  | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 2,731,184 (100%) | 109,162 (100%) | 57,003 (1.9%) |
| Fantom | 2,736,284 (100%) | 115,762 (100%) | 68,003 (93.41%) |
| Polygon | 2,736,284 (100%) | 115,762 (100%) | 68,003 (93.41%) |
| Celo | 2,729,784 (76.92%) | 109,262 (76.92%) | 59,803 (69.8%) |

- In contrast, NFT transfer is highly efficient, consuming only 57,003 units, which is just 1.9% of its gas limit.

Fantom & Polygon:

- Both Fantom and Polygon have matching gas utilization statistics.

- Contract creation and NFT creation operations use up their entire gas limit, consuming 2,736,284 and 115,762 units respectively, which translates to 100% utilization for both.

- The NFT transfer operation, however, uses 68,003 units, or 93.41% of its gas limit, indicating a high efficiency but not as optimal as the previous two operations.

Celo:

- For contract creation, 2,729,784 units of gas are used, translating to 76.92% utilization of its gas limit.

- Creating an NFT follows the same pattern with 109,262 units consumed, equating to 76.92

- The NFT transfer operation on Celo uses 59,803 units, or 69.8% of its allocated gas limit.

**Observations:**

- Full Utilization on BNB Smart Chain, Fantom, and Polygon: For the operations of contract creation and NFT creation, both the BNB Smart Chain and Fantom-Polygon duo show a 100% gas utilization, indicating that these operations are maximally optimized or perhaps the gas limits set are just adequate for these operations.

- Diversity in NFT Transfer Efficiency: The efficiency of the NFT transfer operation varies significantly across platforms. BNB Smart Chain is highly efficient, utilizing only a small fraction of its gas limit, while Fantom and Polygon use over 90%. Celo falls in between, using just under 70%.

- Celo's Consistent Utilization Pattern: Celo displays a consistent pattern of gas consumption across the operations, with both contract and NFT creation operations having identical utilization percentages. This

could hint at a standard optimization mechanism or architectural decision inherent to the Celo platform.

In essence, Table III offers an in-depth perspective on the operational efficiency of various tasks across different blockchains. Such insights are invaluable for developers and users to understand the performance and optimization levels of each platform for specific operations.

### D. Gas Price Analysis Across Blockchain Platforms

Table IV delves into the nuances of gas prices associated with specific blockchain transactions. Gas prices are critical as they are the cost per unit of gas, and thus dictate the transaction fee users will pay for their actions on a given blockchain network. By understanding these prices, users can gauge the economic feasibility of their operations on each platform. This table enumerates the gas prices for three primary blockchain operations: Contract Creation, NFT Creation, and NFT Transfer. These prices are examined across four prominent blockchain platforms: BNB Smart Chain, Fantom, Polygon, and Celo.

- BNB Smart Chain: Across all three operations, the gas price remains consistent at 0.00000001 BNB, equivalent to 10 Gwei. This uniformity suggests a standardized price point for transactions on this platform, regardless of the operation's nature.

- Fantom: Fantom too demonstrates a steady gas price for all operations at 0.0000000035 FTM, equating to 3.5 Gwei. This price is lower than BNB Smart Chain, hinting at more economical transactions on the Fantom network.

- Polygon: Polygon's gas prices for each operation are consistent at the microscopic level of 0.000000002500000012 MATIC and 0.000000002500000016 MATIC, which translate to 2.500000012 Gwei and 2.500000016 Gwei, respectively. While there are slight variations in the gas price between the operations, they are marginal and may result from intricate calculations or rounding mechanisms inherent to the Polygon platform.

- Celo: Celo's gas prices for all three operations are set at 0.0000000026 CELO. These prices correlate with a Max Fee per Gas of 2.7 Gwei. The "Max Fee per Gas" metric in Celo might indicate a pricing cap or standard set by the platform to ensure price stability.

TABLE IV. GAS PRICE

| | Contract Creation | Create NFT | Transfer NFT |
|---|---|---|---|
| BNB Smart Chain | 0.00000001 BNB (10 Gwei) | 0.00000001 BNB (10 Gwei) | 0.00000001 BNB (10 Gwei) |
| Fantom | 0.0000000035 FTM (3.5 Gwei) | 0.0000000035 FTM (3.5 Gwei) | 0.0000000035 FTM (3.5 Gwei) |
| Polygon | 0.000000002500000012 MATIC (2.500000012 Gwei) | 0.000000002500000016 MATIC (2.500000016 Gwei) | 0.000000002500000016 MATIC (2.500000016 Gwei) |
| Celo | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) | 0.0000000026 CELO (Max Fee per Gas: 2.7 Gwei) |

**Insights:**

- Uniformity Across Platforms: Both BNB Smart Chain and Fantom showcase a uniform gas price across all operations, while Polygon and Celo exhibit minimal variations. Such consistency can help users predict their transaction costs with higher accuracy.

- Comparative Economy: When juxtaposing the platforms, Fantom and Polygon present themselves as the more economical options, with gas prices lower than BNB Smart Chain. Celo, while being slightly higher than Polygon, still offers a competitive rate, especially when compared to BNB Smart Chain.

- Gwei Representation: Representing gas prices in Gwei offers a standardized lens to compare across blockchains. Gwei is a common denomination used in the context of Ethereum-based blockchains, making it a familiar reference point for many users.

In conclusion, Table IV serves as a valuable resource for users to understand and compare the financial implications of their actions on different blockchain platforms. By staying informed on these gas prices, users can make more informed decisions about where and when to transact.

## VII. DISCUSSION

### A. Threats to Validity

Our study, while comprehensive in its approach, acknowledges potential threats to its validity. One prominent challenge is the dynamic nature of gas prices. They are known to fluctuate based on network congestion, overall demand, and blockchain-specific factors, meaning our analysis, which captures a specific moment in time, might not remain representative in the future. Furthermore, each blockchain platform has its unique mechanisms, such as gas auctions, that can introduce variations in gas prices and potentially lead to disparities in the actual transaction costs. External economic factors also play a pivotal role. The volatile nature of cryptocurrency valuations means the conversion of gas prices to traditional currency can vary greatly, impacting the real-world perception of operational costs. Lastly, our findings focus on a select group of operations and platforms, raising questions about the generalizability of our conclusions to other operations or nascent blockchain platforms.

### B. Observations and Findings

Several key observations emerge from our analysis. Platforms like the BNB Smart Chain and Fantom exhibit a remarkable uniformity in their pricing structure across operations, which could potentially simplify cost predictions for users.

There's also an evident economic disparity between platforms. For instance, when observing gas prices, Fantom and Polygon present themselves as more economical choices compared to the BNB Smart Chain. Notably, the consistent use of Gwei as a unit for expressing gas prices provides a standard frame of reference, which aids in drawing comparative conclusions across diverse blockchains.

### C. Future Work

The future direction of our research aims to address some of the identified limitations and expand the horizons of our current findings. A temporal analysis could be beneficial, wherein tracking gas prices over extended periods might help identify patterns like peak congestion periods or times conducive to economical transactions. As the blockchain ecosystem grows, incorporating newer platforms into our analysis can offer a holistic view of the evolving landscape. A deeper dive into the economic models driving each blockchain platform might provide clarity on the reasons behind the observed gas prices. Furthermore, examining user behavior in response to fluctuating gas prices can offer invaluable insights into transaction patterns, platform preferences, and challenges hindering blockchain adoption.

The delineation of our subsequent directions in research is pivotal for contextual understanding. We are inclined to delve deeper into the introduction of *intricate methods and algorithms*, specifically those related to encryption and decryption. Such operations, foundational to preserving data integrity and security in blockchain platforms, offer a paradigm to examine the pecuniary ramifications of safeguarding transactional data on the blockchain [27], [28]. Parallel to this, the exploration of *complex data structures* presents a unique lens, offering insights into the interplay between data intricacies and transactional efficiency. The impetus to deploy our proposed model in a tangible, operational realm is palpable. The very act of *transposing our recommendation system onto the FTM mainnet* would be a leap from a sandboxed environment to a live ecosystem pulsating with real transactions. A discernible lacuna in our present analysis is our oversight of the multifaceted dimensions of user privacy policies. With citations underscoring the imperatives of access control and dynamic policy [29], [30], [31], [32], we're inclined to probe the nuances of how these privacy constructs shape transaction costs. Future vistas beckon us towards a slew of *infrastructure-centric methodologies*. The confluence of modernist paradigms like gRPC [33], [34], Microservices [35], [36], adaptive messaging systems, and broker-less architectures [37] presents a promising trajectory. A pivot towards an *API-call-centric* interface may very well be the linchpin, bridging users with a system that seamlessly obfuscates its underlying complexities while offering a user-centric experience.

## VIII. CONCLUSION

Motivated by the pressing need to bridge this gap, our research ventured into the realm of NFTs, harnessing their potential to encapsulate package specifics. Our multi-pronged approach aimed at architecting a robust shipping paradigm anchored in blockchain, enriched with the finesse of smart contracts, and enhanced by NFTs. The meticulous design and deployment of NFT-empowered smart contracts have laid the groundwork for transparent, accountable, and seamless interactions among all stakeholders, including shippers. Our empirical assessment, spanning several leading EVM platforms, not only corroborates the viability of our proposed model but also underscores the transformative potential it holds for reshaping the shipping and logistics sector.

In conclusion, while blockchain technology and smart contracts herald a promising dawn, the path to holistic and inclusive transactional frameworks demands continuous innovation and introspection. Our endeavor stands testament to this, striving to chart a course where trust is not merely assumed but systematically engineered.

# Recognition of Human Interactions in Still Images using AdaptiveDRNet with Multi-level Attention

Arnab Dey[1], Samit Biswas[2], Dac-Nhoung Le[3]

Computer Science and Technology,
Indian Institute of Engineering Science and Technology, Shibpur, Howrah, 711103, India[1, 2]
Faculty of Information Technology, Haiphong University, Haiphong, 180000, Vietnam[3]

*Abstract*—Human-Human Interaction Recognition (H2HIR) is a multidisciplinary field that combines computer vision, deep learning, and psychology. Its primary objective is to decode and understand the intricacies of human-human interactions. H2HIR holds significant importance across various domains as it enables machines to perceive, comprehend, and respond to human social behaviors, gestures, and communication patterns. This study aims to identify human-human interactions from just one frame, i.e. from an image. Diverging from the realm of video-based interaction recognition, a well-established research domain that relies on the utilization of spatio-temporal information, the complexity of the task escalates significantly when dealing with still images due to the absence of these intrinsic spatio-temporal features. This research introduces a novel deep learning model called AdaptiveDRNet with Multi-level Attention to recognize Human-Human (H2H) interactions. Our proposed method demonstrates outstanding performance on the Human-Human Interaction Image dataset (H2HID), encompassing 4049 meticulously curated images representing fifteen distinct human interactions and on the publicly accessible HII and HIIv2 related benchmark datasets. Notably, our proposed model excels with a validation accuracy of 97.20% in the classification of human-human interaction images, surpassing the performance of EfficientNet, InceptionResNetV2, NASNet Mobile, ConvXNet, ResNet50, and VGG-16 models. H2H interaction recognition's significance lies in its capacity to enhance communication, improve decision-making, and ultimately contribute to the well-being and efficiency of individuals and society as a whole.

*Keywords*—*Human interaction recognition; still images; adaptiveDRNet; multi level attention; human interactions*

## I. INTRODUCTION

Human-human interactions are the fundamental building blocks of human society, influencing various aspects of our lives, from personal relationships to collaborative efforts in professional settings. The study of these interactions has garnered increasing attention in recent years, driven by advancements in social psychology [1], communication sciences, and technology. Human-human interaction recognition from still images using deep learning has emerged as a compelling and cutting-edge research area with profound implications for a wide range of applications. In an era characterized by the ubiquity of image data and the growing demand for automated systems capable of understanding human behaviors, this field stands at the forefront of technological innovation.

In real-life scenarios, deep learning-based frameworks for recognizing human interactions in still images [2] find application in diverse fields. They play a crucial role in social

behavior analysis [3] by detecting and deciphering subtle cues in body language and gestures, facilitating a deeper understanding of human interactions. They also find utility in educational settings, specifically identifying classroom interactions. Analyzing human interactions yields valuable behavioral data, facilitating data-driven decision-making across diverse industries. Enabling systems to understand user behavior and intentions through images can create more intuitive interfaces across applications, from gaming to virtual reality, seamlessly adapting technology to human interaction and preferences. Furthermore, these frameworks assist in automated content tagging on social media and content-sharing platforms, enhancing content discoverability.

The proposed AdaptiveDRNet with Multi-level Attention model represents a significant advancement in human interaction recognition from still images, standing out for its distinctive architectural features. The proposed network combines the multi-level attention mechanism and an adaptive deep residual network to enhance its ability to recognize human-human interactions in images. The term "Adaptive" signifies the model's dynamic ability to adjust its focus and attention within the input data. This adaptiveness is facilitated by the Multi-level self-attention mechanism that allows the model to intelligently prioritize important information, enhancing its capacity to discern complex human interactions. Instead of relying on a single, global attention mechanism, the model employs multiple attention levels. This approach enables the model to adaptively focus on salient image regions, capturing fine-grained spatial dependencies and intricate patterns crucial for accurate recognition. The residual connections help capture and propagate important information through the network. Additionally, the model incorporates depthwise separable convolution, batch normalization, and the Swish activation function. This combination improves computational efficiency and bolsters generalization, enabling the model to adapt effectively to diverse interaction scenarios. The Swish activation enhances non-linearity, and batch normalization aids in stable training, reducing overfitting risks. The proposed model offers a distinct advantage over other existing deep learning models for H2H Interaction recognition from images by incorporating the GELU (Gaussian Error Linear Unit) activation function instead of the traditional ReLU (Rectified Linear Unit) in the fully connected Dense layers. GELU activation, known for its smoothness and non-linearity, provides an essential edge to this model. In contrast to ReLU, which can suffer from vanishing gradients in deeper networks, GELU maintains gradient flow, facilitating the learning process in a deeper architecture.

Combining multi-level self-attention, efficient convolutional operations, and enhanced activations, this model excels in capturing nuanced details and spatial relationships, offering superior generalization for human interaction recognition from images, surpassing existing models in this field.

The proposed model mainly classifies the Human-Human Interaction images into fifteen categories: Celebrating, Dancing, Dining, Handshaking, Hugging, Protesting, Punching, Pointing, Waving, Kicking, Kissing, Highfive, RaisingHands, Talking, Teaching.

The main contributions of this research are: (a) Creation of a novel image dataset for the recognition of Human-Human Interactions (H2HID) with comprehensive data labelling. (b) Recognition of Human-Human Interaction in images is carried out using the proposed AdaptiveDRNet with Multi-level Attention. (c) Introduction of Regularized Categorical Cross-entropy (RCCE) Loss Function. (d) The model proposed in this study is assessed on three related standard benchmark datasets, HII, HIIv2 and Stanford40. (e) Result analysis with various well-established deep learning models based on accuracy and trainable parameters.

The structure of this research paper can be outlined as follows: The comprehensive exploration of related works is discussed in Section II. Section III delves into the intricacies of our proposed method, meticulously detailing our approach, which encompasses data preparation, the network architecture of the proposed model, and details of the loss function utilized. Section IV delves into the experimental results with various standard models on our curated H2HID dataset using various performance metrics and analysis of results with various available related datasets based on accuracy and the number of trainable parameters. The final section summarizes our unique contributions, emphasizing significance and discusses the future scope of this research.

## II. RELATED WORKS

The study of human-human interactions (HHI), human-object interactions (HOI), human-computer [4] interaction (HCI) and human actions has been a prominent research focus [5] in the analysis of video sequences. However, it is noteworthy that there has been a noticeable decrease in the volume of research dedicated to exploring these topics when shifting the focus from video sequences to static still images. Tanisik et al. [6] introduced a range of facial region-based descriptors in their research. Their experiments revealed that while these facial descriptors offer valuable insights, their standalone use yields less effective results. However, when integrated with global scene features, particularly deep features, the proposed facial descriptors exhibited enhanced recognition performance and demonstrated the capability to recognize human interactions in static images. The authors have attained 80.11% accuracy using their collected Human Interaction image dataset. Gong et al. [7] introduced a new image dataset containing four distinct categories of human interactions. Li et al. [8] proposed a new method for transferring knowledge from images to videos, which adapts well to video data with limited training samples. They employ class-specific spatial attention maps within Convolutional Neural Networks (CNNs) to transform video frames into a condensed feature representation. Their ap-

proach incorporates a new Siamese EnergyNet framework, optimizing two loss functions to enhance attention maps aligned with ground truth concepts. They have attained 96.8% accuracy on HII data using the fine-tuned ResNet101 model. In another study, Tanisik et al. [9] delved into the significance of human poses in discerning human interactions within still images. Their novel approach introduces a multi-stream convolutional neural network architecture, harmonizing diverse human pose information to enhance human interaction recognition. Various pose-based representations are scrutinized, and extensive experimentation on an expanded benchmark dataset validates the efficacy of their multi-stream pose CNN in distinguishing a broad spectrum of human interactions and poses. When coupled with contextual information, it serves as a valuable tool for discriminative insights into human-human interactions. They have attained 92.78% accuracy in recognizing human interactions. Verma et al. [10] have employed a feature-based neural network to identify human interactions in images. Tang et al. [11] devised a novel approach to enhance vision-based safety compliance checks by explicitly categorizing worker-tool interactions. Their human-object interaction recognition model, built upon this detector and dataset, also delivered impressive results. On the other hand, Zhou et al. [12] tackled the detection and recognition of Human-object interactions (HOI) in images. They introduced a cascaded parsing net (CP-HOI) that employs a multi-stage, structured approach for HOI understanding. CP-HOI refines HOI proposals through instance detection and structured interaction reasoning (SIR) modules, utilizing a graph parsing neural network (GPNN) to represent HOI structures as interconnected graphs, enhancing contextual information extraction for better interaction comprehension.

On the contrary, there is a substantial body of literature dedicated to the recognition of human interactions in video streams. Numerous references, such as Zhou et al. [13] and Tapaswi et al. [14], have extensively explored this domain by utilizing traditional classification techniques. Nguyen et al. [15] utilize handcrafted features in conjunction with a three-layer convolutional neural network for model training. Yan et al. [16] introduce a CNN-based network to extract features, while Shu et al. introduce Hierarchical Long Short-Term Memory (HLSTM) network [17] to handle temporal information. Alazrai et al. [18] introduced an H2H interaction video dataset having 12 interactions giving more focus on the Pointing, Kicking and Punching interaction. Lee et al. [19] have recognized eight different interactions. Guerdelli et al. [20] provided a comprehensive overview of interpersonal relation recognition datasets and well-established methods, aiding researchers in gaining deeper insights into their characteristics.

Human interaction recognition is a specific area within the broader field of human action recognition. Thus, in addition to our focus on human interaction, we have also listed some notable and relevant existing research and studies in the field of action recognition. Zhang et al. [21] introduced an approach for recognizing actions in static images while minimizing the need for extensive annotations. Luo et al. [22] employed an improved EfficientNet framework to recognize human behaviours. In another study, Yu et al. [23] have proposed a deep ensemble learning model to recognize human actions in still images. In our prior research endeavours focused on Action Recognition, our primary objective was to predict various workout actions from still images [24], subsequently

classifying them into ten distinct workout categories. It's worth highlighting that the proposed WorkoutNet model showcased a remarkable validation accuracy of 92.75% when rigorously assessed on our WAId dataset. Siyal et al. [25] have proposed a Residual CNN model for feature extraction and SVM as a classifier to categorize human actions in still images. Saif et al. [26] have proposed an InceptionResNetV2-based CNN-LSTM model to recognize actions in videos.

Existing standard image datasets HII [27] and HIIv2 [6] have been pivotal in driving progress in the field of human interaction recognition. However, these publicly available datasets often lack specificity in terms of interaction types. The publicly available HII [27] dataset initially focused on four distinct human interaction categories, while the HIIv2 [6] dataset expanded this scope to include ten different human interaction classes. To further enhance the resources available for researchers and practitioners in the field, we have introduced the Human-Human Interactions Image dataset (H2HId), which comprises fifteen diverse types of human interactions. Our primary objective is to furnish the research community and professionals with valuable assets that can be utilized to develop and assess models designed to classify and recognize human interactions depicted in images accurately. This dataset will contribute to enhancing the generalization capabilities and real-world applicability of Human-human interaction recognition models, particularly in the context of interaction recognition.

The proposed AdaptiveDRNet model revolutionizes human interaction recognition from still images with multi-level self-attention, efficient convolution, and GELU activation. It dynamically adapts focus, captures fine details, and maintains gradient flow, outperforming traditional models.

## III. PROPOSED METHOD

The method commenced by gathering human interaction images and standardizing them to a consistent size with augmentation. Subsequently, the curated dataset underwent division into training, validation, and test sets. Data augmentation was employed to enhance the training data. The proposed model, integrated with Callback functions, facilitated model training and extraction of image features. Ultimately, human-human interactions were categorized using the last layer of the proposed model, specifically the Softmax layer. The illustration of the proposed method can be visualized from Fig. 1.

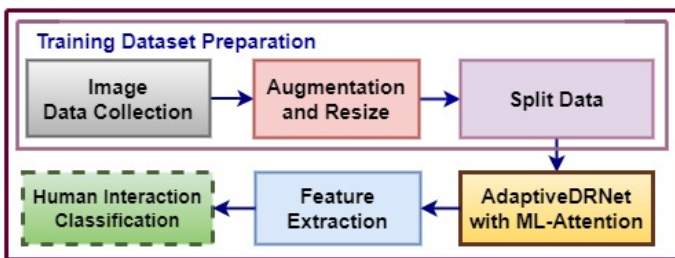

Fig. 1. Illustration of the proposed approach's workflow.

Recognizing the need for research methodologies that can perform efficiently with limited computational resources, this study introduces the AdaptiveDRNet with Multi-level

Attention to recognize various human interactions in still images. The subsequent sections provide detailed insights into the following aspects: a) Training dataset preparation, b) *AdaptiveDRNet with ML-Attention*: Model Architecture, c) Description of the employed loss function, and d) Advantage of AdaptiveDRNet ML-Attention model.

### A. Dataset Preparation

The dataset capturing Human-human interactions (H2HId) has been meticulously curated, enhanced through augmentation techniques, and then resized all images to a uniform resolution of 224 x 224. The collected images are in RGB. There are a total of 15 different human interaction categories. Some sample images of the collected H2HId dataset are highlighted in Fig. 2. The dataset details are given in Section IV(A).

Fig. 2. H2HId data sample.

Recognizing the significant demand for ample training data in deep learning models, we employed the data augmentation technique to bolster the overall performance of the AdaptiveDRNet with ML-Attention model. This approach entailed enlarging the training dataset and mitigating the risk of overfitting. We introduced random transformations, including a zoom range of 0.18, a contrast range of 0.23, rotations ranging from 0 to 25 degrees, and horizontal flips. These random transformations effectively generated additional training data, thereby exposing the training model to a wider array of potential data distribution characteristics. Furthermore, the H2HId dataset has been methodically split into three separate subsets following a precise distribution: 61% of the data is assigned for training, 20% for validation, and 19% for testing. This partitioning strategy adheres to established best practices in deep learning.

### B. AdaptiveDRNet with ML-Attention: Model Architecture

The proposed Adaptive Deep Residual Network (Adaptive-DRNet) with Multi-level Attention model architecture comprises an initial convolutional layer with 32 filters, followed by three sets of residual blocks with attention mechanisms. The model begins with an input layer configured to accept RGB images with dimensions of 224x224 pixels. The initial layer is a 2D convolutional layer with a 3x3 kernel, utilizing 32 filters and applying the GELU activation function, followed

by batch normalization. Subsequently, three residual blocks with Self-Attention mechanisms are employed. Each block encompasses a depthwise convolution layer with a 3x3 kernel and either a stride of 1 (for the first block) or 2 (for subsequent blocks), maintaining spatial dimensions with 'same' padding. Batch normalization and Swish activation functions follow. The block also features a 1x1 convolutional bottleneck with varying filter sizes (64, 128, and 256, respectively, for each block) to capture and transform features. Self-Attention layers are introduced to capture long-range dependencies within the data. The model also comprises a Global Average Pooling (GAP) layer, succeeded by two dense layers consisting of 128 and 256 units, both utilizing GELU activation and dropout with a rate of 0.15 for regularization. Finally, the output layer is a dense layer employing the softmax activation function for classification into 15 human interaction classes. The model has 419,279 trainable parameters. This architecture offers a versatile and customizable framework for image classification tasks, with the flexibility to fine-tune hyperparameters based on specific datasets and requirements. The layered diagram representing the proposed AdaptiveDRNet with ML-Attention model, which is employed to implement the proposed work, is illustrated in Fig. 3.

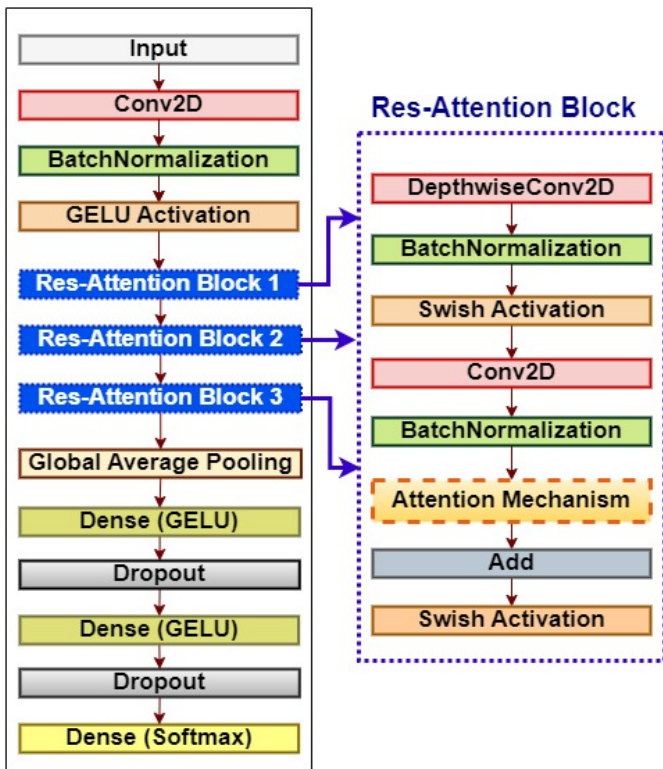

Fig. 3. Proposed adaptiveDRNet ML-attention model.

The proposed AdaptiveDRNet ML-Attention model architecture is outlined as follows:

Input Layer: The model takes input images with a shape of 224x224 pixels and three color channels (RGB).

Initial Convolution Layer: The input images are processed by a convolutional layer with 3x3 kernels having 32 filters, batch normalization (BatchNorm) layer, and a GELU activation function. This layer extracts basic features from the input

images. The choice of a GELU activation function is pivotal, as it captures non-linearities more effectively than traditional activation functions. This layer's primary role is to extract low-level features from input images while maintaining spatial dimensions. Batch normalization aids in faster convergence and mitigating overfitting, ensuring smoother training. The first convolution layer applies a set of filters to the input, followed by batch normalization and a GELU activation function, which introduces non-linearity. The 2D convolution operation is represented as illustrated in Eq. (1). Here, $y(q, r)$ is the output at position $(q, r)$ denotes the feature map, $x(q, r)$ represents the input feature map, $w(l, m)$ are the convolutional filter weights and $b$ denotes the bias term.

$$y(q,r) = \sum_{l=0}^{L-1} \sum_{m=0}^{M-1} x(q+l, r+m) \cdot w(l,m) + b \quad (1)$$

Batch Normalization Layer (BatchNorm): Batch Normalization is a method employed to standardize the output of a layer. This process involves subtracting the mean of the batch and dividing it by the batch standard deviation. This process can be mathematically represented as illustrated in Eq. (2). In this equation, $y_B$ represents the normalized output, $I$ is the input to the BatchNorm layer, $\mu$ denotes the batch mean, $\sigma^2$ stands for the batch variance, $\beta$ denotes the shifting parameter (learnable), $\epsilon$ is a small constant added for numerical stability, $\gamma$ represents scaling parameter (learnable).

$$y_B = \frac{I - \mu}{\sqrt{\sigma^2 + \epsilon}} \cdot \gamma + \beta \quad (2)$$

Res-Attention Block: The proposed model comprises three Residual Attention (Res-Attention) blocks that serve as a powerful feature extraction unit. This block consists of several key layers, starting with a depthwise separable convolutional layer, followed by the BatchNorm layer and the Swish activation. Each block follows a consistent pattern, commencing with depthwise convolution, which performs spatial convolutions independently for each channel, preserving spatial dimensions. This is particularly beneficial for capturing fine-grained details in the image.

The DepthwiseConv2D layer performs a depthwise convolution operation, where each input channel is convolved separately with its own set of learnable filters. The DepthwiseConv2D operation can be represented as illustrated in Eq. (3) The operation is performed independently for each input channel, resulting in an output with the same number of channels as the input. Here, $Y_{i,j,k}$ is the value of the output feature map at position $(i, j)$ and channel $k$, $X_{(i+d-1),(j+e-1),k}$ is the value of the input feature map at position $(i + d - 1, j + e - 1)$ and channel $k$, $K_{d,e,k}$ is the value of the depthwise convolution filter at position $(d, e)$ and channel $k$, $B_k$ is the bias term for channel $k$ and the summation is over the filter size $D$ and both spatial dimensions.

$$Y_{i,j,k} = \sum_{d=1}^{D} \sum_{e=1}^{D} X_{(i+d-1),(j+e-1),k} \cdot K_{d,e,k} + B_k \quad (3)$$

The proposed model incorporates Swish activation functions [28], a choice made due to their well-known smoothness

characteristics and effectiveness in enhancing overall model performance. Subsequently, a 1x1 convolutional bottleneck further processes the features. The distinctive feature is the Self-Attention Layer, which calculates attention scores between spatial locations, allowing the block to weigh the significance of different regions and capture global dependencies. Like the residual blocks, the Attention Block includes a residual connection that adds the Self-Attention output to the original input feature map. This combination of residual connections and Self-Attention enables the block to effectively capture both local and long-range contextual information, making it a valuable building block for image recognition tasks where understanding spatial relationships and context is crucial for accurate classification.

Attention Mechanism: The role of the attention mechanism is pivotal in augmenting the performance of the proposed AdaptiveDRNet model. The attention mechanism, based on the scaled dot-product attention mechanism, is employed to selectively emphasize and de-emphasize features within the intermediate representations of the network. Its importance lies in its ability to capture and focus on crucial information while discarding less relevant details. The attention mechanism is represented using mathematical equations illustrated in Eq. (4), Eq. (5) and Eq. (6).

At first, the Query (Q), Key (K), and Value (V) are obtained by projecting the input (X) using learnable weight matrices $W_q$, $W_k$, and $W_v$, respectively.

$$Q = X \cdot W_q \quad K = X \cdot W_k \quad V = X \cdot W_v \qquad (4)$$

The attention logits are calculated as the dot product of Q and K, scaled by the square root of the dimension of K. Here, $d_k$ denotes the dimension of the key vectors.

$$Att_{Logits} = \frac{Q \cdot K^T}{\sqrt{d_k}} \qquad (5)$$

The attention weights are computed by applying the softmax function to the attention logits ($Att_{Logits}$) as illustrated in Eq. (6).

$$Att_{Weights} = \text{softmax}(Att_{Logits}) \qquad (6)$$

Finally, the attention output is obtained by taking the weighted summation of the values (V) utilizing the attention weights ($Att_{Weights}$) as illustrated in Eq. (7).

$$Att_{Output} = \text{Att Weights} \cdot V \qquad (7)$$

Here, the "Multi-level Attention" aptly characterizes the attention mechanism within our proposed model due to its ability to operate on multiple levels or scales of information. This means that it can simultaneously focus on fine-grained details and broader context within the input data. It's not limited to a single level of attention but rather incorporates various levels, making it a versatile tool for capturing nuanced relationships and patterns in the data. The attention mechanism's significance in the proposed model is multifaceted.

Firstly, it aids in the model's ability to focus on relevant regions of the input, thereby improving feature selection. Secondly, it enhances feature refinement by amplifying important information. Lastly, it facilitates gradient flow during training, as it provides a clear path for gradients to propagate through the network.

Global Average Pooling (GAP) Layer: After the residual attention blocks, GAP is performed, which reduces the spatial dimensions to a single vector for each feature map while retaining essential information. This operation helps in creating a fixed-size representation of the features extracted by the previous layers. GAP calculates the average value of each feature map, effectively summarizing the presence of specific features across the entire image. This is essential for making the model translation-invariant, allowing it to recognize objects regardless of their position in the image. GAP contributes to reducing the model's computational complexity and parameters, making it more efficient. The GAP operation is represented using Eq. (8). Here, $GAP(Y_3)[c]$ represents the spatial average value of channel $c$ in the feature map $Y_3$, which is the output of Res-Attention Block 3 in the model. $K$ and $L$ are the spatial dimensions of the feature map, and $C$ is the number of channels. The GAP operation is applied independently to each channel, calculating the spatial average of values across the entire spatial region of $Y_3$.

$$GAP(Y_3)[c] = \frac{1}{K \cdot L} \sum_{i=1}^{K} \sum_{j=1}^{L} Y_3[i,j,c] \qquad (8)$$

Fully Connected Layers: The proposed model comprises two dense layers (fully connected) with GELU activation. The initial dense layer comprises 128 units, succeeded by a dropout layer configured having a 0.15 dropout rate, strategically employed to mitigate overfitting. The subsequent dense layer consists of 256 units, accompanied by yet another dropout layer with an identical dropout rate. These layers enable the model to learn complex patterns and relationships in the feature representations produced by the earlier layers. The dropout layers further prevent overfitting by randomly deactivating a fraction of neurons during training.

The GELU activation function applied to the fully connected dense layer is mathematically represented using Eq. (9). This activation function introduces a layer of non-linearity into the network, enabling it to capture intricate relations and patterns within the data. Let's denote the input to the fully connected layer as I, which is a vector of activations from the previous layer. The GELU activation denoted by G(I) is applied element-wise to each element of the input I. In Eq. (9) and Eq. (10), I represents the input to the fully connected layer, $\tanh$ is the hyperbolic tangent function, $\sqrt{\frac{2}{\pi}}$ is a constant and 0.044715 is a constant. GELU helps with the vanishing gradient problem and is utilized in the proposed model for improved performance.

$$G(I) = \frac{1}{2}I\left(1 + \tanh(R1)\right) \qquad (9)$$

$$R1 = \left(\sqrt{\frac{2}{\pi}}\left(I + 0.044715I^3\right)\right) \qquad (10)$$

Output Layer: The ultimate layer of the proposed model consists of a dense layer comprising 15 units, as there are 15 human interaction categories. It employs softmax activation to produce probabilities for each human interaction class, making it suitable for multi-class classification.

The illustration in Fig. 4 emphasizes the filter outputs stemming from an image belonging to the 'Pointing' interaction class. Specifically, it highlights the outputs originating from the 1st DepthwiseConv2D layer (1st Res-Attention block), the 2nd DepthwiseConv2D layer (2nd Res-Attention block), and the 3rd Conv2D layer (2nd Res-Attention block). It's worth noting that the numbering of these layers aligns with the sequence provided in the layered diagram of the model, which is depicted in Fig. 3.

Fig. 4. Feature map visualization of some layers.

Thus, this model architecture incorporates convolutional layers for feature extraction, deep residual blocks with attention mechanisms to capture important features, global average pooling to reduce spatial dimensions, and fully connected layers with dropout enable classification. The attention mechanism between the convolutional layers allows the model to focus on relevant image regions, which can be crucial for tasks with complex visual patterns. The final output layer provides class probabilities for making predictions.

The proposed AdaptiveDRNet model architecture is meticulously designed to capture features at different levels, from low-level details to high-level contextual information with Multi-level Self Attention. The Self-Attention mechanism is a key innovation, enhancing the model's ability to capture spatial relationships, making it well-suited for image classification tasks where context and object dependencies are critical. The Multi-level Attention mechanism enables the model to adaptively focus on important features within the data, enhancing feature selection and representation learning.

### C. Loss Function Details

In addressing the multi-class nature of this study, the Regularized categorical cross-entropy (RCCE) loss function is employed to quantify the error that the model seeks to decrease throughout its training. The Standard categorical cross-entropy loss ($SCCE_{Loss}$) is expressed as illustrated in Eq. (11). Here, $y_{\text{tp}}^{(k)}$ represents actual probability of class $k$ and $y_{\text{pp}}^{(k)}$ represents the anticipated probability of class $k$.

$$SCCE_{Loss} = -\sum_{k=1}^{M=15} y_{\text{tp}}^{(k)} \cdot \log(y_{\text{pp}}^{(k)}) \qquad (11)$$

The $RCCE_{Loss}$ function adds an extra term, which is the L2 regularization [29] term (LT), to the standard loss as mathematically illustrated in Eq. (12).

$$RCCE_{Loss} = SCCE_{Loss} + LT \qquad (12)$$

The L2 regularization term (LT) is mathematically expressed as shown in Eq. (13). Here, $y_{\text{tp}}$ denote the true probability distribution (one-hot encoded labels) of class membership, $y_{\text{p}}$ denote the predicted probability distribution (model's output) of class membership and value of $M$ is 15 which denotes the number of interaction classes in the dataset.

$$LT = \sum_{k=1}^{M=15} (y_{\text{tp}}^{(k)} - y_{\text{pp}}^{(k)})^2 \qquad (13)$$

The Nadam optimizer is then utilized with an initial learning rate set at 0.001 to effectively reduce the error function linked to the proposed model.

### D. Advantage of AdaptiveDRNet ML-Attention Model

In the proposed model, three residual blocks with attention having varying filter sizes (64, 128, 256) help in hierarchical feature extraction. The use of multiple residual blocks with increasing filter sizes allows the model to learn hierarchical features from low-level to high-level representations. Smaller filter sizes (64) in the initial layers help capture fine-grained details and edges, while larger filter sizes (128 and 256) in subsequent layers capture more abstract and complex features. Each residual block typically includes a convolutional layer with a stride greater than 1, which downsamples the spatial dimensions of the feature maps. Starting with a stride of 2 in the first block and possibly increasing it in later blocks helps reduce the spatial resolution of the feature maps. This downsampling reduces computational complexity and increases the receptive field of the network. By using progressively larger filter sizes, the model increases its capacity to learn more complex patterns and features in the data. The skip connections in residual networks enable the reuse of features from prior layers. With multiple blocks, each incorporating its attention mechanism, the model can selectively leverage features from different network stages. This allows the model to focus on fine-grained and high-level features, improving prediction. Therefore, the design choice of three residual blocks with attention and varying filter sizes facilitates efficient feature learning and representation across different scales and complexities.

## IV. EXPERIMENTAL RESULTS

This proposed research is conducted in Google Colab using Python programming, emphasising resource efficiency without utilizing any GPU. It leverages an Intel-Xeon CPU with 2.3GHz clock speed, 13GB of RAM, and approximately 80GB of disk space, diverging from the current practice of relying on GPUs for deep learning tasks. In this section, we have provided the details of our curated H2HId dataset, including available datasets, thorough performance evaluation, and comprehensive analysis of the results.

### A. Dataset Details

Several publicly accessible datasets related to human interactions include HII [27], HIIv2 [6], and Stanford40 [30]. In this work, we have introduced a substantial dataset called the Human-Human Interaction Image dataset (H2HId) [1], a comprehensive collection of images sourced from a variety of online platforms and social media. To ensure effective categorization, images depicting diverse human interaction scenarios were systematically organized into distinct directories. The H2HId dataset is noteworthy for its unbiased representation of human interactions across various individuals and scenarios, aiming for universality without demographic, ethnic, or regional bias. The proposed dataset encompasses a diverse range of human interactions, encompassing 15 distinct categories and containing a total of 4,049 images. The human interaction categories considered are *Celebrating*, *Dancing*, *Dining*, *Handshaking*, *Hugging*, *Protesting*, *Punching*, *Pointing*, *Waving*, *Kicking*, *Kissing*, *Highfive*, *RaisingHands*, *Talking*, *Teaching*.

### B. Performance Evaluation

The effectiveness of the proposed research is assessed through a range of metrics, including measures like training and validation accuracy, F1-score ($F1_s$), AUC-score, classification performance, and the analysis of the confusion matrix.

Fig. 5. Accuracy curve of proposed adaptiveDRNet attention model.

Fig. 5 illustrates the proposed model's training and validation accuracy curve. It is seen from the curve that the proposed model shows 99.57% train accuracy and 97.20% validation accuracy. After 28 epochs, the performance of the proposed model did not improve much, so we stopped the

---
[1]H2HId Dataset Link: https://sites.google.com/view/h2hid/home

training process at that point by utilizing the callback functions. The hyperparameters of the proposed AdaptiveDRNet ML-Attention model are highlighted in Table I.

TABLE I. HYPERPARAMETERS OF PROPOSED MODEL

| Parameter(s) | Considered Value |
|---|---|
| Input Shape | 224X224 |
| Batch Size | 5 |
| Epochs | 28 |
| No. of Classes | 15 |
| Kernel | 3X3 |
| Initial Learning Rate | 0.001 |
| Loss Function | Regularized CCE |
| Metrics | Accuracy |
| Optimizer | Nadam |

The proposed work has been evaluated with several benchmark deep learning models, all of which were trained from scratch. Table II presents the training accuracy (Train Acc) and validation accuracy (Val. Acc) and F1-Score ($F1_s$) of VGG-16, ResNet50, InceptionResNetV2, NASNet Mobile, ConvXNet, EfficientNet [22], and our proposed model on the H2HId dataset. The proposed model significantly outperforms the benchmark deep models in terms of accuracy and achieves an impressive 97.20% accuracy on the validation data, surpassing the performance of the EfficientNet [22], NASNet Mobile, ConvXNet, InceptionResNetV2, ResNet50 and VGG-16 model. Additionally, the InceptionResNetV2, NASNet Mobile, ConvXNet and EfficientNet [22] models also exhibited strong performance in classifying the images of the H2HId dataset, achieving validation accuracies (Val. Acc) of 95.30%, 94.76%, 94.60%, and 96.52% respectively.

TABLE II. ASSESSMENT OF DEEP LEARNING MODELS' PERFORMANCE ON H2HID DATASET

| Model | Train Acc | Val. Acc | $F1_s$ | AUC |
|---|---|---|---|---|
| VGG-16 | 96.21% | 94.27% | 0.92 | 0.95 |
| ResNet50 | 97.08% | 94.54% | 0.93 | 0.96 |
| InceptionResNetV2 | 97.61% | 95.30% | 0.95 | 0.98 |
| NASNet Mobile | 97.85% | 94.76% | 0.94 | 0.97 |
| ConvXNet | 98.28% | 94.60% | 0.94 | 0.97 |
| EfficientNet [22] | 98.70% | 96.52% | 0.95 | 0.98 |
| **Proposed Model** | **99.57%** | **97.20%** | **0.96** | **1.0** |

When considering the F1-score ($F1_s$), the Proposed Model performed exceptionally well, achieving the highest $F1_s$ of 0.96, whereas the EfficientNet [22], and InceptionResNetV2 model achieved the second highest $F1_s$ of 0.95 on our H2HId dataset. This indicates that the proposed model exhibits a balanced combination of precision and recall score, making it highly effective in human interaction classification. However, it's worth noting that the proposed model maintains its high $F1_s$ while simultaneously achieving the highest validation accuracy, demonstrating its consistency and robustness in performance. In evaluating deep learning models on the H2HId dataset, their performance was further assessed using Area Under Curve (AUC) scores [31], a crucial metric for measuring their ability to discriminate between positive and negative instances. The results revealed that the Proposed Model stands

out as the top performer with a perfect AUC score 1.0. This achievement showcases its exceptional capability in effectively distinguishing between classes. Following closely, the EfficientNet [22] and InceptionResNetV2 model exhibited strong performance with an AUC score of 0.98. In comparison, the other models, including InceptionResNetV2, NASNet Mobile, ConvXNet, ResNet50, and VGG-16, demonstrated descending levels of AUC scores, with the VGG-16 model having the lowest AUC score at 0.95. These findings emphasize the superiority of the proposed model and EfficientNet [22] in terms of their ability to discriminate between positive and negative instances on the H2HId dataset.

Confusion Matrix: It provides a clear and informative snapshot of a model's predictions aligning with actual ground truth values. In this visualization, the rows represent the true or actual classes, while the columns depict the predicted classes. Each cell in the matrix indicates the number of instances that fall into a particular category. The confusion matrix of the H2HId dataset utilizing the proposed model is depicted in Fig. 6. It serves as a powerful tool for fine-tuning and optimizing classification models.

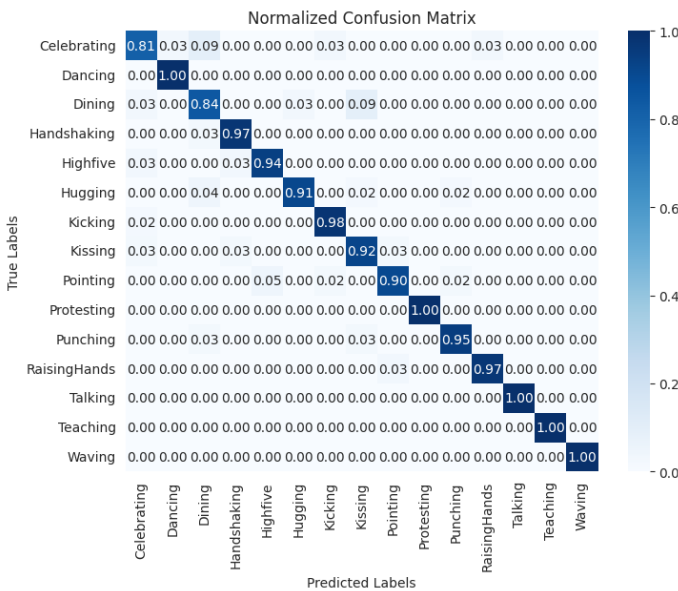

Fig. 6. Confusion matrix of H2HId dataset utilizing proposed model.

Classification Performance: The performance of our Proposed model in classifying human interactions is visually depicted in Fig. 7, showcasing the F1-scores ($F1_s$) for the H2HId dataset.

It is observed that most of the interaction categories in the H2HId dataset exhibit high $F1_s$, exceeding 0.95. However, a few categories, such as "Celebrating" (0.85 $F1_s$), "Dining" (0.90 $F1_s$), "Hugging" (0.93 $F1_s$), and "Pointing" (0.92 $F1_s$), demonstrate slightly lower but still respectable $F1_s$. The proposed AdaptiveDRNet with Multi-level Attention model demonstrates outstanding classification performance on the H2HId dataset. The proposed AdaptiveDRNet model has accurately predicted all the human-human interaction test image samples taken for further evaluation as depicted in Fig. 8.

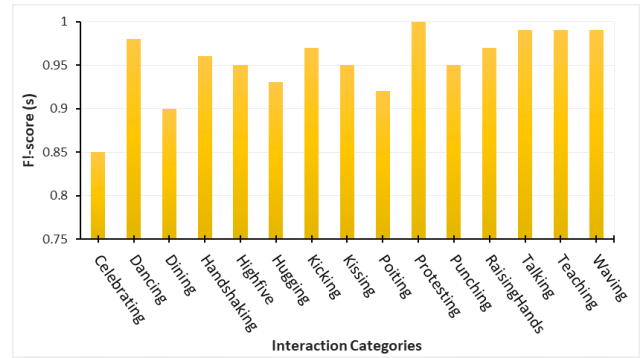

Fig. 7. Classification score of H2HId dataset utilizing proposed model.

Fig. 8. Test result of proposed model.

### C. Result Analysis

The analysis of results with the proposed AdaptiveDRNet with Multi-level Attention model on various Optimizers is depicted in Table III. In this context, the remaining model parameters, including a fixed learning rate (LR) of 0.001, the utilization of the Regularized Cross-entropy loss (RCCE) as the loss function (Loss Func.), a consistent number of training epochs set to 28, and a batch size of 5, were maintained unchanged throughout the optimizer analysis.

TABLE III. ASSESSMENT OF PROPOSED MODEL ON VARIOUS OPTIMIZERS

| Optimizer | Epochs | Loss Fun. | Val. Acc | MCC Val. |
|---|---|---|---|---|
| SGD | 28 | RCCE | 94.20% | 0.9447 |
| RMS | 28 | RCCE | 94.60% | 0.9509 |
| Adagrad | 28 | RCCE | 95.35% | 0.9517 |
| Adam | 28 | RCCE | 96.43% | 0.9640 |
| **Nadam** | **28** | **RCCE** | **97.20%** | **0.9726** |

In the assessment of the proposed model's performance on the H2HId dataset using various optimizers, a nuanced understanding of the optimizer's impact on model accuracy becomes evident. Starting with Stochastic Gradient Descent

(SGD), which achieved a Validation accuracy (Val. Acc) of 94.20%, we observed steady progress with Root Mean Square Propagation (RMS) and Adagrad, reaching Val. accuracies of 94.60% and 95.35%, respectively. However, the Adam optimiser notably improved the model's accuracy, achieving 96.43%. It is observed that the best performance is produced by the use of the Nadam optimizer, which stood out among the optimizers with a remarkable accuracy of 97.20%. These results emphasize the significance of optimizer selection in fine-tuning deep learning models, with Nadam proving to be the most effective choice for maximizing the model's accuracy on the H2HId dataset. Further, the optimizers' performance in the proposed model is evaluated utilizing the Matthews Correlation Coefficient (MCC) values [32] to gauge the quality of multi-class human-human interaction classifications. This metric is crucial in evaluating the model's ability to provide precise predictions while considering both false positives and false negatives. Upon examining the MCC values (MCC Val.) for each optimizer, a clear trend emerged. The Nadam optimizer outshone others, securing the highest 0.9726 MCC value. This achievement signifies a remarkable level of agreement between the model's predictions and the true labels. The Nadam optimizer stands out as the top performer, demonstrating exceptional classification capabilities. This emphasizes the significant influence of optimizer selection on a model's ability to generalize and make accurate predictions.

The proposed technique is compared with various standard CNN models to test the efficacy, as demonstrated in Table IV. It depicts the accuracy results of different deep learning-based models with various benchmark datasets, namely HII [27], HIIv2 [6] and our H2HId dataset. Among all the models considered for evaluation, the proposed model attained the top-most accuracy of 96.38% on the HII dataset, followed by the EfficientNet [22] and EnsembleNet [33] models with 95.83% and 95.37% accuracy, respectively. Our method demonstrated high classification performance on the two benchmark datasets, namely the HII and HIIv2, yielding remarkable accuracies.

TABLE IV. COMPARATIVE EVALUATION OF DEEP LEARNING MODELS IN HUMAN INTERACTION RECOGNITION

| Method(s) | HII | HIIv2 | H2HId | TP (M) |
|---|---|---|---|---|
| VGG-16 | 93.20% | 81.36% | 94.27% | 134.70 |
| ResNet-50 | 93.56% | 81.20% | 94.54% | 25.60 |
| MobileNetv2 | 94.54% | 82.16% | 94.67% | 3.50 |
| DELVS1 [23] | 94.20% | 82.28% | 95.82% | >140 |
| IncepResNetV2 | 95.24% | 82.67% | 95.30% | 55.90 |
| EnsembleNet[33] | 95.37% | 82.40% | 96.21% | – |
| EfficientNet [22] | 95.83% | 83.17% | 96.52% | 1.03 |
| **Proposed Model** | **96.38%** | **83.42%** | **97.20%** | **0.41** |

Notably, the proposed model achieved the highest accuracy across all three datasets, showcasing its exceptional ability to accurately identify human interactions. The proposed model attained 96.38% on HII, 83.42% on HIIv2, and 97.20% on H2HId datasets. On the HIIv2 dataset, EfficientNet [22] and EnsembleNet [33] attain 83.17% and 82.40% accuracy respec-

tively. The InceptionResNetV2 (IncepResNetV2), DELVS1 [23], and EfficientNet [22] model attain 95.30%, 95.82% and 96.52% accuracy, respectively on our H2HId dataset. let's consider the comparison based on the number of trainable parameters (TP). The proposed model features a comparatively streamlined design, comprising merely 0.41 million (M) TP. In contrast, some of the benchmark models have significantly larger numbers of trainable parameters. For instance, VGG-16 and ResNet50 have 134.70 million and 25.60 million TP, respectively. DELVS1 [23] model has $140+$ million TP, IncepResNetV2 has 55.90 M, MobileNetv2 has 3.50 M, and EfficientNet [22] has 1.03 million TP. The proposed model's advantage lies in its ability to achieve superior accuracy while maintaining significantly smaller trainable parameters than these well-established benchmark models. This is particularly important in real-world applications where computational efficiency and memory constraints are critical factors.

The F1-Score ($F1_s$) on both the Stanford40 [30] and the HII [27] datasets demonstrates strong classification performance across multiple established deep learning models, as depicted in Fig. 9. Stanford40 is a still image action dataset with 40 action categories, which is also considered in the analysis.

Fig. 9. Performance analysis of various models on stanford40 and HII datasets.

The proposed model emerges as the top performer, showcasing its outstanding classification performance with 0.83 $F1_s$ on the Stanford40 dataset and an impressive 0.96 $F1_s$ on our HII dataset. This model consistently demonstrates superior classification capabilities in recognizing human interactions and actions. Both the EfficientNet [22] and EnsembleNet [33] model attains 0.95 $F1_s$ on HII dataset. The InceptionResNetV2 model achieves 0.81 $F1_s$ on Stanford40, whereas the EnsembleNet [33] model achieves 0.83 $F1_s$ on Stanford40 dataset, and both these model attains $F1_s$ above 0.95 on HII dataset.

## V. CONCLUSION AND FUTURE SCOPE

Human-human interaction recognition from still images using deep learning is a rapidly evolving field with vast implications across various domains. Recognizing complex human interactions from static visual cues using the proposed model finds applications in social behavior analysis, surveillance, market research, education, content tagging, and human-robot interactions. The proposed network in this research combines multi-level attention mechanisms and residual networks to

enhance its ability to recognize human interactions, allowing it to focus on relevant features within images automatically. This approach aims to improve accuracy and effectiveness in recognizing intricate human-human interactions, making it valuable in computer vision and video analysis. The study's main contributions include the development of a new dataset for Human-Human Interaction Recognition (H2HID) with comprehensive labelling, the introduction of a novel AdaptiveDRNet Multi-level Attention Network for recognizing human interactions in images, and an extensive result analysis involving various well-established deep learning models based on accuracy and the number of trainable parameters, utilizing established related benchmark datasets for a comprehensive evaluation. The Multi-level Attention in our model excels by operating on multiple information scales, enabling simultaneous focus on fine-grained details and broader context. Its versatility lies in its ability to encompass attention at various levels, capturing nuanced relationships and data patterns. The suggested model is suitable for operation on devices with limited resources since it employs minimal trainable parameters. This research underscores the potential of deep learning in advancing our understanding of human interactions from visual data and its wide-ranging applications in diverse fields.

The future scope of this research encompasses several promising avenues for further exploration and enhancement. Firstly, there is a significant potential for expanding the dataset size used in this study. A larger dataset would not only increase the diversity and representativeness of human interactions but also enable the model to generalize better across various scenarios. Furthermore, the inclusion of additional and more diverse human interaction categories within the dataset would enhance the model's capability to recognize a broader spectrum of interactions. Another important direction for future research involves the creation of improved classifiers that prioritize energy efficiency to ensure the feasibility and scalability of the proposed work in real-world settings.

*Abstract*—Due to the rapid expansion of information and online sources, automatic keyphrase extraction remains an important and challenging problem in the field of current study. The use of keyphrases is extremely beneficial for many tasks, including information retrieval (IR) systems and natural language processing (NLP). It is essential to extract the features of those keyphrases for extracting the most significant keyphrases as well as summarizing the texts to the highest standard. In order to analyze the distance between keyphrases in news articles as a feature of keyphrases, this research proposed a region-based unsupervised keyphrase distance analysis (KDA) technique. The proposed method is broken down into eight steps: gathering data, data preprocessing, data processing, searching keyphrases, distance calculation, averaging distance, curve plotting, and lastly, the curve fitting technique. The proposed approach begins by gathering two distinct datasets containing the news items, which are then used in the data preprocessing step, which makes use of a few preprocessing techniques. This preprocessed data is then employed in the data processing phase, where it is routed to the keyphrase searching, distance computation, and distance averaging phases. Finally, the curve fitting method is used after applying a curve plotting analysis. These two benchmark datasets are then used to evaluate and test the performance of the proposed approach. The proposed approach is then contrasted with different approaches to show how effective, advantageous, and significant it is. The results of the evaluation also proved that the proposed technique considerably improved the efficiency of keyphrase extraction techniques. It produces an F1-score value of 96.91% whereas its present keyphrases are 94.55%.

*Keywords*—*Curve fitting technique; data pre-processing; data processing; feature extraction; KDA technique; keyphrase extraction*

## I. INTRODUCTION

In the past fifteen years, the paradigm for consuming news has changed from traditional print newspapers to individualized online news aggregation platforms like Google News, News360, and Yahoo! News. These systems gather a lot of news from many sources, aggregating it and presenting it on their respective mobile apps and websites [1], [2]. But now, the dramatic increase in textual news and the continual development of technology make it far more difficult to manage such a vast volume of news. People could just handle this enormous amount of news manually, which took a lot of time before technology was developed [3]. Developing automated keyword extraction techniques that replace manual tasks by utilizing the extraordinary computing power of computers is due to the difficulty of handling this huge amount of news [4], [5]. High-level keyphrases are extracted from news articles using automatic keyphrase extraction techniques. The keyphrase often offers a high level of document characterization, summarization, and description, which is important for numerous NLP features like content categorization, clustering, and segmentation [3]. However, they are utilized in a variety of online information processing applications, including contextual advertising, recommended systems, digital content management, and information retrieval. It is suitable for use in media searches, legal information retrieval, geographic information retrieval, search engines, and digital libraries [5].

To meet the aforementioned applications, a wide range of keyphrase extraction techniques have already been created, including [6], [7], [8], [9], [10]. Some of them, like domain-specific strategies [6], call for application domain knowledge; others, like linguistic techniques [9], [10], demand language competence. As a result, they are unable to solve issues in different fields, languages, or disciplines. According to [11], supervised machine learning algorithms need a large portion of datasets for training to extract high-quality keyphrases, and they generalize ineffectively beyond the range of trained data. Additionally, it made the system less understandable, required more storage and calculation, and was computationally expensive [12], [4], [13]. Due to the enormous number of complex processes, statistical unsupervised methods like [14], [15], [16] seem to be computationally very expensive. The graph-based unsupervised techniques underperform due to their inability to identify coherence between the many words that make up a keyword [17], [18], [19], [20], [21]. Last but not least,

TeKET [22] is incredibly flexible and behaves similarly to the TF-IDF if the data length is short.

Feature extraction is an essential technique in keyphrase extraction for those who want high-quality keyphrases. It is the process of acquiring characteristics (also referred to as features) that distinguish keyphrases or keywords from other terms [23]. These features also affect the effectiveness of various supervised and unsupervised keyphrase extraction methods. Keyphrase distance analysis (KDA) is important for all of those keyphrase extraction methods as a feature that helps to take top-level keyphrases from any article. The KDA technique is used as a feature of such keyphrase extraction techniques to extract keyphrases. Without applying high-quality features, the keyphrase extraction method cannot extract high-quality keyphrases [5]. As an outcome of the previous discussion, it has been determined that keyphrase feature extraction continues to be a crucial research field for the study. So, a region-based unsupervised KDA technique is proposed in this paper for news articles, which led to the following important achievements:

- The proposed technique called keyphrase distance analysis (KDA) introduced new features of keyphrases to calculate the distance of keyphrases from the center point of the news article.

- The proposed technique is corpus-independent, domain-independent, and language-independent.

- The proposed technique can be used by both unsupervised and supervised techniques.

- The proposed technique doesn't depend on document length means that it is a length-free technique.

- Two (2) standard news datasets are utilized to test as well as evaluate the performance of our proposed technique.

The remainder of this article is organized as follows: The various strategies are discussed in Section II along with their advantages and disadvantages, highlighting the demand for a fresh approach. Following that, a region-based unsupervised KDA technique is provided in Section III for figuring out the distance of keyphrases in each region of a news article. The phase of experiments is then thoroughly discussed in Section IV, including information about the datasets, evaluation metrics, and implementation details. The efficiency of the system was then assessed on two (2) standard datasets, and the suggested strategy was compared to existing methods to ascertain its advantages and disadvantages, which are discussed briefly in Section V. Lastly, in Section VI, the research's contributions, follow-up research, as well as flaws, were noted.

## II. RELATED WORKS

The proposed keyphrase distance analysis (KDA) method from news articles can be used as an attribute or characteristic for keyphrase extraction methods [24], [25]. Therefore, similar strategies are covered in this section. There are two common types of keyphrase extraction techniques, depending on the training dataset. One is unsupervised, and the other is supervised. Both techniques can make use of feature extraction methods [3]. The essential components of both techniques will be covered in the following subsections:

### A. Unsupervised Techniques

These techniques, which are categorized as statistical or graph-based techniques, are used to extract keyphrases from documents without any prior knowledge. They are thought to be a ranking issue [26]. PositionRank is a PageRank enhancement that enhances performance by combining word locations and frequency. However, it performs quite poorly, as evidenced by [20]. Another keyphrase extraction method that outperforms TextRank's constraints is TopicRank. Additionally, it has an issue of error propagation, according to [18]. TextRank's extension is SingleRank. Only noun phrases can be correctly extracted from a document. However, it is unable to accurately extract the keywords from the compiled ranked phrases [17]. A method called MultipartiteRank addresses the issue of topic rank, such as error propagation. There is an error in clustering [21]. TeKET is a more famous key extraction method that does not depend on a language or a domain. It requires only basic statistical knowledge. It offers a great deal of versatility, even though it performs better than others [22]. The KP-Miner is used to overcome the problem of preferring single phrases. Despite outperforming TF-IDF, it suffers a decline in performance on a worldwide scale. It is also expensive computationally [14], [27]. Another better technology that can solve the IDF issue is YAKE. For N-grams, however, the computing complexity rises linearly [16].

### B. Supervised Techniques

The extracted keyphrases from any articles using supervised techniques are categorized in a binary fashion, with some candidate keyphrases being labeled as keyphrases and others as non-keyphrases [26]. The classification problem can be solved using a number of well-known methods, including support vector machines (SVM) [28], decision trees (DT), naive bayes [29], neural networks (NN) [23], [30], and so forth. The KEA utilizes the Naive Bayes technique, which uses TFxIDF with the first occurrence location as a feature. However, it may yield subpar results and rely on the training dataset [31]. First appearance position, length of keyphrase, and term frequency (TF) are all automatically taken into account by the Genitor Extractor (GenEx) as features. This system does not make use of the TFxIDF method [26]. The Maui algorithm extended the KEA technique to combine data from Wikipedia. Its primary flaw is a lack of assessment abilities [32]. Informingness, keyphraseness, length of candidate terms, beginning occurrence position, and term position are among the characteristics used by HUMB. Even though it has only used academic papers, it has had positive results across a variety of data sets [33], [25]. The first position of words, relative Pos, POS, keyphraseness, and TFxIDF are all features used by CeKE. It could make keyphrase extraction better [34]. The KeyEx Method significantly improves the quality of the retrieved key. Additionally, this method works better than other consecutive pattern mining methods [35].

The aforementioned discussions demonstrate that supervised and unsupervised keyphrase extraction approaches have a number of distinct disadvantages that prevent them from performing as well as they could. As a result, the proposed KDA technique will assist in minimizing the observed shortcomings and extracting high-quality keyphrases from news articles.
Fig. 1. The architectural flow diagram of proposed KDA technique.

## III. MATERIAL AND METHODS

The eight steps of the proposed KDA technique are depicted in Fig. 1: data collection, data preprocessing, data processing, searching keyphrases or goldkeys, distance computation, averaging distance, curve plotting, and the last, the curve fitting technique. The next subsections explore the proposed approach in more detail.

### A. Data Collection

The suggested technique gathered a total of two datasets that contained news in this phase. The two datasets are 110-PT-BN-KP and 500N-KPCrowd, which contain 610 news articles that cover the languages (English and Portuguese) [36]. Every dataset consists of two different types of files: the "keys file" (which contains keyphrases with the name "goldkeys") and the "documents file" (which has the name "docsutf8" and contains the articles/papers). In Section IV-A, the dataset is described in depth.

### B. Data Pre-processing

After that, the data pre-processing phase receives the collected datasets. The suggested system then separates the

key files and the docsutf8 files. The key files contain several critical keys, and the docsutf8 files contain numerous crucial documents or articles. The docsutf8 files and key files are then read, and they are saved as text files (named text and key, respectively). Afterward, normalization is required to apply to these files, which entails four procedures, such as text conversion to lowercase, removing all the punctuation marks from the text, eliminating empty or white spaces by using the strip() function (delaying all the leading and ending spaces), and removing digits (using regular expressions, non-relevant numbers are removed).

### C. Data Processing

After the data pre-processing phase, the proposed technique tries to determine the total goldkeys depending on the Newline (\n) method from the key files. After that, the proposed approach uses the first appearance keyphrase, assumes the length of the document has eight regions, and then determines the midpoint of each document to calculate the distance of keyphrases from the midpoint.

### D. Goldkey Searching

The proposed method then attempts to determine each goldkeys location *(Loc)* inside the document by taking into account their first occurrence. If the document has the location of Goldkey, it advances to the next phase. If the location of the goldkey cannot be found, try looking for the next goldkey in the document's key file. This procedure will continue until the key file (goldkeys) has been finished for a single document as well as for a single dataset. The exact same process will go on for all datasets.

### E. Distance Calculation

In this phase, the proposed technique must compute the distance *(Dist)* between the document's midpoint and the goldkey location after the data searching step and preserve this *Dist* value in the relevant region of the document. Be aware that this value is preserved in a two-dimensional *(2-D)* array, where each column shows the number of document regions and each row shows the number of goldkeys [25].

### F. Distance Averaging

After distance calculation, it is an important stage. This step involves calculating the distance average *(AVG)* between every region for a document and storing the results in a new *(2-D)* array with the same columns for article regions and rows for the total number of papers in the dataset. Then, until all documents for a particular dataset are finished, this procedure will continue. Similarly, for all documents in a dataset, calculate the distance average for every region in a manner similar to that described before, and then store the result in another *2-D* array, where the column represents the document region's number and the row indicates the total number of datasets. "Then, until all datasets have been completed, this AVG distance-calculating process will continue. Lastly, determine the AVG distance for each region across all datasets" [25].

### G. Curve Plotting (CP)

The CP is a graphical method for representing the collected data. It effectively enables the creation of thoughts that do not emerge from a list of values and visually depicts the link between variables. In data statistics and analysis, CP is crucial. This technique is used to get the idea that keyphrase distance from the document's center depends on the article region in our proposed method. This is the justification for plotting the average or mean distance value of every dataset and the mean distance value for all datasets [25].

### H. Curve Fitting Technique (CFT)

One of the most effective and often used analysis tools is curve fitting, which may be applied to linear, polygonal, and nonlinear curves. Most frequently, it involves creating a mathematical equation or curve that best fits a set of data points that are oriented toward limitations. The suggested approach uses CFT to generate a mathematical equation as well as a curve to determine the distance of keyphrases from the documents' centers and their density in each area. The CFT is then applied to the entire dataset's average value, and the suggested system gets a negative exponential curve as a result.

## IV. Experimental Setup

In this section, the proposed technique explains the experimental setting, the details of the corpus, the evaluation metrics, and the details of how it will be used. The details of how it will be used are explained in more depth in the next subsection. This then anticipates the discussion of the findings in Section V.

### A. Corpus Details

The performance of the suggested technique has been tested on two (2) different datasets. In this proposed system, typical collections like 500N-KPCrowd and 110-PT-BN-KP are used [36]. The datasets have been briefly described in the earlier Section III-A. A table that is shown in Table I explains the number of languages, categories of documents, document's number, goldkey's number, present goldkey's number, the number of present-and-absent goldkeys per document (%), and execution/processing time for each datasets [5], [2].

The dataset named *110-PT-BN-KP*, is a television (TV) broadcast news (BN) related dataset. The European Portuguese ALERT BN corpus contains 110 scripts from eight TV broadcast news programs. These programs cover a wide range of topics, such as banking, sports, and politics" [3]. All terms that made up text content summaries were removed using a tagger, yielding 24.44 goldkeys per document. There are 72 keyphrases that are missing and 2616 keyphrases that are present; processing took 0.047 seconds.

A dataset of broadcast news transcriptions is called the *500N-KPCrowd*. This dataset consists of 500 English-language broadcast news articles from ten different categories, each of which has 50 articles (art and culture, crime, fashion, business, health, world politics, politics, sports, science, and technology) [36]. Along with the processing time of 0.203 sec, it also includes the keyphrases 2265, which is absent, and 22345, which is the keyphrase that is present.

### B. Evaluation Metrics

In our proposed method, the three most significant and relevant measures are used to contrast performance with alternative methods: *Precision, recall, and F1-score*. Here, *Precision* refers to the proportion of correctly predicted values to all positively predicted values. In other words, it is used to determine the positive patterns in a positive class that are successfully anticipated out of the overall projected patterns [5], [2]. The following equation (1) can be used to calculate it:

$$Precision = \frac{Key_{corrected}}{Key_{predicted}} \qquad (1)$$

Where $Key_{corrected}$ is the total correctly predicted keyphrases that are matched with standard keyphrases and $Key_{predicted}$ is the total predicted keyphrases. Similarly, the ratio of precisely expected positive values to actual positive values is known as *Recall*, and it may be calculated using the equation (2):

$$Recall = \frac{Key_{corrected}}{Key_{standard}} \qquad (2)$$

TABLE I. AN OVERVIEW OF THE NEWS DATASET USED TO ANALYZE THE PRESENT AND ABSENT KEYPHRASE / GOLDKEY WITH EXECUTION / PROCESSING TIME

| News Dataset | Language Types | Total Docs | Total Gold-Keys | Total Present Goldkey | Present Goldkey per doc (%) | Absent Goldkey per doc (%) | Processing Time (sec) |
|---|---|---|---|---|---|---|---|
| 110-PT-BN-KP | PT | 110 | 2688 | 2616 | 98.66% | 1.34% | 0.047 |
| 500N-KPCrowd | EN | 500 | 24610 | 22345 | 90.45% | 9.55% | 0.203 |

Where $Key_{standard}$ is the total keyphrases in the standard keyphrase list. Lastly, the weighted average of Precision and Recall is known as *F1-score*. The *F1-score* is calculated by utilizing the below equation (3).

$$F1 - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \qquad (3)$$

### C. Implementation Details

The suggested approach is put into practice using Python 3.6 and the Spyder IDE. Python is very simple and easy to use as well as learn. It's an object-oriented and high-level programming language. It offers a flexible data format that is user-friendly and backed by a number of libraries. It boosts productivity, is interpretive and dynamically typed, and is open-source and free. Python is used in many different fields, such as machine learning, big data, and cloud computing. The computer is outfitted with a 256GB SSD drive, 12GB of RAM, an Intel Core i7 processor, and Win-10 OS [2].

## V. RESULTS AND DISCUSSION

This section discusses the in-depth study of the outcomes of the experiments. If the region's number is raised to more than eight in our proposed technique, the first region is found to have a relatively shorter AVG distance and fewer goldkeys. Likewise, if the region's number is decreased to less than eight, the first region has a bigger AVG distance and more goldkeys. The proposed technique therefore considers the text length to be eight regions rather than varying the number of regions because its goal is to analyze the keyphrase distance from news articles. In this section, the performance of the suggested method is examined under various headings (such as the Results of Dataset Analysis, the Results of Curve Plotting (CP) Analysis, the Results of Curve Fitting Technique, and finally Comparisons of the Suggested Method) that are described in the following subsections.

### A. Result of Dataset Analysis

Two independent datasets (described in IV-A) were used to examine and assess the performance of the proposed approach. The proposed technique attempts to determine the processing time for each dataset from the dataset analysis. It also determines the total of documents, the total of goldkeys, the number of present-absent goldkeys, and the total present-absent keyphrases or goldkeys per document in percentage that are existent in each dataset, as shown in Table I. Based on this investigation, the proposed method takes an average of 0.13 seconds to process, has an AVG presence rate of 94.55% for keyphrases, and an AVG absence rate of 5.45% per document.

### B. Result of Curve Plotting (CP) Analysis

According to the prior discussion, since the datasets contain an average of 94.55% of keyphrases/goldkeys per document that are actually present, all results in this work have been conducted based on that percentage of goldkey. The suggested method then tries to plot the average distance of each dataset and all datasets' average values together to represent the distance between each region by considering the first occurrence keyphrase and length of documents as eight (8) regions. The proposed KDA technique analyzes keyphrase distance and is depicted in Fig. 2. This study confirms that the first region of the document, followed by the second region, and so on, has the highest average distance and most frequent keyphrases. Because the plotted curves are negatively exponential, which can be seen in Fig. 2.

### C. Result of Curve Fitting Technique (CFT)

Following the inspection of the plots, the CFT is adjusted to take into account the value of the average distance across all datasets. The suggested approach then seeks to identify the fitting curve as well as an exponential equation that is negative for that AVG distance value. Fig. 3 illustrates the analysis of the curve fitting technique in every region for the proposed KDA process while taking into account the eight regions for the documents and offers the negatively exponential curve and equation denoted in the following (4). Since this fitted curve is likewise negative exponential, as shown in Fig. 3, it is proven from this study that the highest number of keyphrases and the greatest distance are located in the 1st region of the document, then the second portion or region, and so forth.

$$y = b * e^{-cx} + d \qquad (4)$$

*where, $b = 12834.22$, $c = 1.59$, and $d = 339.30$.* Lastly, the proposed system also attempted to demonstrate the region-based keyphrase distance analysis (KDA) from news articles using curve plotting analysis as well as curve-fitting analysis.

### D. Comparison of Proposed Technique

This step involves two different kinds of comparisons, which are detailed in the next sub-subsection: comparisons to identify a superior dataset as well as comparisons to identify a superior model or technique.

*1) Comparison to Identify a Superior Dataset:* The suggested method measures the effectiveness of each dataset and identifies the best one, as shown in Table II, using evaluation criteria (such as precision, recall, and f1-score). From this
Fig. 2. The analysis of keyphrases distance by considering 1st occurrence and eight regions.

Fig. 3. The curve fitting analysis for the proposed KDA technique based on 8 regions.

table, the dataset named "110-PT-BN-KP" has a higher F1-score of 98.64% and a recall value of 97.32% than the "500N-KP-Crowd" dataset. It is indicated that the dataset "110-PT-BN-KP" performs better than the "500N-KP-Crowd" dataset.

*2) Comparison to Identify a Superior Technique:* As there is only one current method and the proposed KDA method is a novel method, it can be contrasted with the existing technique in this section. The comparison of our proposed

KDA technique is exhibited in Table III. Based on Table III, the proposed KDA technique provides a higher recall value of 94.06% and a higher F1-score of 96.91% than the existing technique. Here, the proposed approach considers average performance measurements.

## VI. CONCLUSION

In many computer science applications, feature extraction of keyphrases has now become crucial. This article proposes

TABLE II. THE DATASET'S PERFORMANCE COMPARISON FOR FINDING A BETTER ONE

| Dataset | Average Performance Measurements | | |
|---------|-----------|--------|----------|
| Name | Precision | Recall | F1_Score |
| 110-PT-BN-KP | 100% | 97.32% | 98.64% |
| 500N-KPCrowd | 100% | 90.80% | 95.18% |

TABLE III. COMPARISON OF OUR PROPOSED KDA TECHNIQUE

| Existing | Average Performance Measurements | | |
|----------|-----------|--------|----------|
| Techniques | Precision | Recall | F1_Score |
| RDAK Technique [25] | 100% | 69.31% | 80.09% |
| Proposed KDA Technique | 100% | 94.06% | 96.91% |

a region-based keyphrase distance analysis (KDA), a technique for automatic unsupervised feature extraction that is independent of domain and language and necessitates little statistical expertise and training data. Data collection, data preprocessing, data processing, searching keyphrases, distance computation, averaging distance, curve plotting, and lastly, the curve fitting technique, are the steps that make up the process of our proposed approach. After that, the KDA technique was tested and evaluated on two benchmark datasets to determine its effectiveness. Then it has produced a negative exponential equation and curve for the distance value, indicating that greater distance as well as more gold keys appear in the first region of documents. The proposed technique finally produced an accuracy/recall value of 94.06%, an F1-score of 96.91%, and a total present keyphrase of 94.55%. The proposed method also identifies *110-PT-BN-KP* as a better dataset, with a maximum recall value of 97.32% and the highest F1-score value of 98.64% than any other dataset. With the more statistical aspects given in this work, we intend to create a powerful keyphrase extraction technique in the future. The limitation of our research is that for the absent or missing keyphrase, the distance value is zero. For this reason, we are currently addressing the issue of missing goldkeys or keyphrases, such as when a large number of explicitly provided keyphrases are lacking from the document itself.

# Gamification in Physical Activity: State-of-the-Art

Majed Hariri[1], Richard Stone[2]

HCI Department, Iowa State University, Iowa State University, Ames, USA[1]

Industrial and Manufacturing Systems Engineering Department, Iowa State University, Ames, USA[2]

*Abstract*—Physical activity is decreasing globally, and more people are becoming sedentary, which is associated with numerous adverse health outcomes. To counter this trend, gamification emerges as a promising strategy for enhancing participation in physical activity interventions. The review investigates the influence of gamified systems on the promotion of physical activity and examines associated behavioral and psychological outcomes. The analysis incorporates empirical studies focused on adult participants, published in peer-reviewed English-language journals over the last five years. Several critical aspects are considered in the analysis, including specific types of physical activity targeted, employed gamification systems, involved motivational features, and behavioral and psychological outcomes, thus offering a state-of-the-art overview of gamification and physical activity. Findings confirm that gamification serves as an effective mechanism for promoting physical activity. To address gaps in existing research, recommendations for future work include broadening the range of metrics used for measuring physical activity and investigating the psychological benefits of gamification in physical activity interventions. Moreover, future research could benefit from leveraging addictive game design elements and utilizing artificial intelligence and computer vision models to monitor user progress and suggest appropriate challenges. In conclusion, the review outlines the considerable potential of gamification to positively affect participation in physical activity, highlighting the need for additional research to fully realize this potential.

## I. Introduction

The increase in sedentary behaviors and lack of physical activity have significantly impacted global health, highlighting the growing problem of obesity [1]. Obesity is associated with various health risks, particularly cardiovascular problems [2]. Research has shown that weight loss can effectively reduce these cardiovascular risks [3]. Furthermore, obesity-related complications are serious and can lead to severe outcomes such as heart attacks and strokes [4]. In addition, obesity is often associated with comorbid conditions such as diabetes, a metabolic disorder that increases blood glucose levels and can lead to various complications like nerve damage, kidney failure, and vision loss [5]. Moreover, being overweight increases the likelihood of experiencing problems such as osteoarthritis [6]. There is also evidence linking obesity to various types of cancer [4]. Additionally, obese individuals are at increased risk of obstructive sleep apnea due to airway blockage caused by excess fat tissue [6]. Obese individuals have a higher incidence of depression, along with challenges in social interactions and stigma [7]. Obesity has significant implications for mental health. Moreover, obesity places a heavy burden on healthcare systems, leading to increased healthcare costs and reduced productivity in the workforce [8],

[9].

Maintaining a regular exercise routine can be challenging for many individuals despite its numerous benefits in terms of health and well-being [10]. Time constraints have been identified as one significant obstacle to consistent physical activity [10]. Another notable barrier is the concern about potential injuries during exercise, which has been emphasized [11]. Inadequate knowledge regarding effective workout strategies also contributes to inconsistent engagement in physical activity [12]. Additionally, societal pressures and cultural norms can negatively influence exercise habits [13]. Given the prevailing sedentary lifestyle prevalent today and its associated risks to health, there is an urgent need for viable solutions.

The concept of gamification offers a unique and positive approach to promoting behavioral change. By incorporating game design elements like points, rewards, and challenges, gamification enhances user engagement and motivation in non-game contexts [14]. There are mainly two ways to implement gamification. The first way is to infuse game-like features into an existing system, like incorporating a point system in physical activity programs. The second involves designing the activity as a game from scratch, which requires a more comprehensive resource commitment but offers a compelling avenue to control and manipulate the game mechanics to drive specific behaviors and outcomes. Research in various sectors has shown differing degrees of success with gamification. For instance, a study conducted on the implementation of gamification in healthcare discovered that integrating game elements into the system enhanced the collection and analysis of data, increased patient involvement and knowledge, promoted professional growth and reputation, as well as improved care for both practitioners and patients [15]. Evidence from a separate study suggests that incorporating game elements into a computer programming course can strengthen students' motivation and overall learning journey [16]. Moreover, a thorough examination of 103 existing gamified fitness tracker apps revealed promising potential for innovative approaches that seamlessly blend game mechanics in engaging and enjoyable manners instead of solely relying on conventional gamification elements and leaderboards [17]. Moreover, a research study examined the impact of gamification on users' adoption of personal finance management applications and discovered that incorporating game elements fulfilled users' desires for competence and autonomy, resulting in an increased intrinsic motivation to use gamified apps [18]. Furthermore, research on the utilization of gamification in luxury goods revealed that incorporating elements and mechanisms of game design into experiences resulted in elevated levels of brand recognition, customer loyalty, and sales [19].

Understanding the role of gamification as a tool to boost physical activity is crucial. The theoretical groundwork that guides the creation, roll-out, and evaluation of such gamified interventions falls into three main categories [20]. The first is the principle of motivation and impact, which pulls from a range of theories, including self-determination, flow, goal-setting, and self-efficacy. This principle stresses the need for developing gamified interventions tailored to the user's motivational triggers and interests. The second guiding principle focuses on behavior, drawing upon theories like activity, reinforcement, reasoned action, and planned behavior, to name a few. This aspect emphasizes the critical role of creating interventions that effectively drive behavioral outcomes. Lastly, the principle of learning incorporates theories such as experiential learning, constructivist learning, and cognitive load and highlights the importance of developing interventions that facilitate learning. A thorough examination was carried out to analyze theories related to motivation and effectiveness, providing valuable insights into the potential impact of gamification in promoting physical activity. A comprehensive evaluation was conducted on these principles and their practical implementations.

The remainder of the paper is organized as follows:

- Theoretical Background: Provides foundational theories and principles that guide the use of gamification in promoting physical activity.

- Literature Review: Dive into previous research on the subject, covering different aspects such as types of physical activity, technological platforms, and psychological outcomes, among others.

- Limitations and Shortcomings: Discusses the limitations of the review.

- Discussion: A discussion of the findings and their implications.

- Conclusion and Future Work: The key findings and suggestions for future research.

The provided framework intends to thoroughly evaluate how gamification contributes to the promotion of physical activity, pinpointing areas where current research is lacking and proposing potential future paths for exploration.

## II. THEORETICAL BACKGROUND

Gamification is a concept that draws inspiration from motivational psychology and seeks to leverage both intrinsic and extrinsic motivators. Incorporating game elements into a non-game intervention stimulates user participation in specific activities. Intrinsic motivation is driven by an individual's internal desires, such as the innate urge to explore, learn, and derive pleasure from the activity. This form of motivation enables self-regulation, as individuals are guided by their interests without needing external rewards [21]. On the other hand, extrinsic motivation is characterized by the pursuit of external rewards like financial incentives or social recognition [22]. Self-determination theory has provided valuable insights into these motivational aspects. This theory posits that the psychological needs for autonomy, competence, and relatedness are fundamental to enhancing motivation and, by

extension, well-being [23]. Within this framework, autonomy relates to individual control over actions, competence focuses on the individual's effectiveness in their pursuits, and relatedness involves feeling supported and connected to others [24], [25]. Game elements have been extensively studied in the context of gamification, offering insights into how game mechanisms can boost motivation and engagement [26], [20].

Gamification has the potential to impact users' experiences in numerous ways, with one of the most noteworthy being the flow experience [27]. Flow experience stems from psychology and refers to a mental state where individuals become fully absorbed in an activity that they lose awareness of time passing and external distractions [28]. In order to achieve a state of flow, certain conditions must be met. There needs to be an appropriate level of challenge that aligns with the individual's skill level. This balance ensures that the person remains engaged in the activity without feeling bored or overwhelmed [29]. Using gamified interventions is crucial in attaining and sustaining the state of flow. These interventions are emphasized due to the various elements present, such as points, badges, leaderboards, and challenges. Each element is designed specifically to maintain user engagement. With advancements in game engines, these interventions have evolved further by dynamically adjusting to challenge levels and providing immediate rewards. Ensuring that participants stay fully engaged and motivated throughout their experience, making the gamified intervention more enjoyable and effective [30], [31].

In the realm of gamification, game elements such as badges, progress bars, and levels are not merely decorative features but vital motivational tools. These elements serve to inspire users, compelling them to engage more deeply with the activity and work steadily towards accomplishing a goal [14], [32]. This motivational structure is intrinsically goal-oriented. It provides users with a roadmap, offering clear objectives to pursue or granting them the freedom to set their own goals [33]. The adoption of a goal-oriented approach is backed by the widely recognized goal-setting theory, which posits that specific and challenging goals can substantially improve performance and motivation [34], [35]. The goal-setting theory has been effectively deployed for over two decades to enhance outcomes in work-related tasks [33]. Several principles must be observed to maximize the effectiveness of goals within a gamified environment. Firstly, the goals should be explicit and well-defined to remove ambiguity. Secondly, they should be sufficiently challenging to engage the users. Thirdly, these goals should resonate with the users' interests or aspirations to ensure acceptance. Fourthly, continuous feedback mechanisms must be in place to keep the users informed about their progress. Lastly, an optimal level of complexity should be maintained to keep users intrigued and prevent disengagement [36]. It is important to note that game elements are routinely utilized to implement these principles effectively. For instance, badges and levels act as unmistakable indicators of progress, rewarding the user and providing motivation. Progress bars, on the other hand, offer real-time feedback, enabling users to gauge their advancement toward set objectives [37], [38].

Motivating users is a common objective in gamification, and one concept that enriches our understanding of motivation is self-efficacy [39], [40]. Self-efficacy refers to an individual's

belief in their capability to successfully complete specific tasks or achieve particular goals. This belief significantly contributes to encouraging and sustaining positive behaviors, especially within health-related contexts. When individuals have a strong sense of self-efficacy, they are more willing to take on challenges and develop strategies for overcoming them. Their confidence in their abilities inspires them to tackle complex tasks with focus and resilience, even in the face of obstacles [41]. Importantly, self-efficacy goes beyond just the skills needed for task completion; it also includes an individual's conviction in their ability to successfully perform the task [42]. The theory provides individuals with a framework for what they can potentially achieve, irrespective of their current skill level or perception [35]. Gamification often employs game elements such as levels, badges, and progress bars to foster self-efficacy. Research has shown that setting both short-term and long-term goals within a gamified system can significantly enhance an individual's self-efficacy [43]. Such game elements offer users a tangible measure of their progress, bolstering their confidence and spurring them to continue participating in the gamified experience [44].

Achievement goal theory provides essential insights into how game elements can effectively motivate users [45]. Achievement goal theory differentiates between two primary types of goal orientation: mastery-approach and performance-approach [46], [47], [48]. The former prioritizes skill development and focuses on avoiding failure, while the latter is more concerned with self-esteem and demonstrating ability relative to others, all while steering clear of perceived incompetence. By employing achievement goal theory, designers of gamified interventions can better understand and target the unique motivational needs of different users. One practical application of achievement goal theory in gamification is the customization of interventions to align with a user's specific goal orientation. Game elements such as badges, feedback, and challenges can be adapted to foster a sense of achievement, tailored to mastery or performance-approach orientations [49]. Goal customization enhances the motivational aspects of gamified experiences, making them more effective and engaging. Furthermore, understanding achievement goal theory can help recognize factors that might negatively impact intrinsic motivation [50]. For example, excessive focus on social comparison, particularly among individuals with performance-avoidance goals, can be detrimental. In such instances, gamified intervention designers often employ leaderboards and other game elements cautiously to encourage competence without fueling harmful social comparisons [50].

Social comparison theory suggests that individuals have an innate tendency to gauge their opinions and abilities by contrasting them with those of others [51]. Social comparison framework allows people to validate their perception of reality and serves as a basis for self-evaluation [52]. In the context of gamification, leaderboards serve as a practical tool that enables this form of social comparison. Leaderboards, which prominently display the performance and ranks of participants, serve as tangible representations of social comparison in gamified environments [53]. Game elements encourage individuals to evaluate or enhance specific aspects of their abilities through comparison, particularly with others they deem similar. However, the utility of leaderboards and other status-indicating elements is nuanced. Research has indicated that such features can have a dual impact: either boost or hinder motivation and performance [54], [55].

## III. Literature Review

The purpose of this literature review is to explore the potential of gamification as a tool to promote physical activity. The focus is primarily on empirical studies published in peer-reviewed journals. This exploration will shed light on the existing evidence and indicate areas that require further research.

### A. Step 1: Previous Literature

The increasing interest in gamified interventions, specifically in the context of physical activity interventions, has opened up avenues for research and academic exploration. A comprehensive study evaluated the impact of gamified interventions on physical activity and sedentary behavior [56]. Through an analysis of 16 randomized controlled trials, the results indicated that gamification had a small to medium effect on modifying physical activity behavior. These interventions were found to be more effective compared to control groups without gamified approaches. However, it was also observed that the long-term sustainability of these behavioral changes posed a challenge, as they tended to diminish over time. The study emphasized the need for standardized methodologies and further research in addressing sedentary behaviors alongside physical activity interventions.

The effectiveness of longitudinal Active Video Game interventions in maintaining increased physical activity levels was examined by [57]. Their review included 25 studies and highlighted the role of AVGs in promoting a moderate increase in overall physical activity. Consistent with previous research, their findings emphasized the inconsistencies in methodologies and called for more standardized approaches. The study also recommended further exploration of long-term effects and complexities involved in AVG interventions, indicating a need to revisit and improve research strategies.

On the other hand, another study examined the different aspects of gamification implemented in interventions and their resulting effects [58]. The research involved a thorough analysis of 16 studies, all of which emphasized the effectiveness of gamification in promoting physical activity. Key elements such as points, feedback systems, leaderboards, and challenges were found to significantly influence positive behavioral changes. However, limitations such as age group exclusions and the need for stronger research methods were identified by this study.

Another study explored the design features of gamified fitness tracker apps [59]. By examining 103 different applications, they discovered that certain game elements, such as goals, social influences, and challenges, were prevalent in these apps. However, their findings indicated that there is room for innovation by combining different game mechanics to create more captivating and impactful fitness applications.

The importance of incorporating gamification in health and well-being applications was discussed in a recent study [60]. Through a comprehensive review of 19 papers, the

researchers found that gamification does have a positive impact on health-related behaviors, but the level of empirical evidence supporting its benefits is moderate. The study calls for further high-quality research to determine the effectiveness of gamification across different outcomes.

The existing literature presents a positive yet complex depiction of gamified interventions. The clear advantages are undeniable; however, there remain uncertainties surrounding long-term effects, varying research approaches, and unexplored areas. This review aims to explore the potential of gamification in promoting physical activity by analyzing empirical studies published in peer-reviewed journals. By doing so, it offers a more nuanced interpretation of gamified interventions.

### B. Step 2: Database Search

An extensive search was carried out using the Scopus database to conduct a comprehensive search on the implementation of gamification in physical activity. The Scopus database was chosen for its reputation as a reliable source of high-quality, peer-reviewed articles covering various disciplines. A systematic and well-structured strategy was employed to filter through the Scopus database. Specific parameters revolved around gamification's influence on physical activity to ensure the search was both targeted and exhaustive. The search was conducted using keywords such as "gamif*" which encompassed variations like "gamification" and "gamified" in addition to terms like "fitness," "physical activity," and "exercise". The selection of these keywords was done diligently, ensuring a balance between including relevant studies and maintaining a strong alignment with the objective of this review.

### C. Step 3: Focused Result

The systematic search was conducted on 09/2022 and yielded 1347 records from the Scopus database. During Stage 2, this number decreased to 676 after excluding duplicates, conference papers, and books. Subsequent date restrictions were implemented in Stage 3, resulting in 338 records. In Stage 4, articles written in languages other than English were eliminated, leaving behind 212 records. During the initial screening process, titles and abstracts were carefully reviewed. At the end of Stage 5, 153 articles were excluded for various reasons, such as unavailability for download or needing to be empirical studies. As a result, there were 59 remaining records after this selection process was completed. During Stage 6, a comprehensive evaluation of the full-text documents was conducted. Forty-three articles were excluded as they needed to meet certain criteria, such as having study populations below 18 years of age or failing to adhere to the specified framework stating that motivational affordance leads to psychological and behavioral outcomes [61]. After this thorough assessment, only sixteen records remained for further consideration. In the end, only 12 records remained after excluding educational articles. These remaining articles were carefully selected to ensure that only the most relevant and reliable findings could contribute to understanding how gamification can promote physical activity. (See Fig. 1).

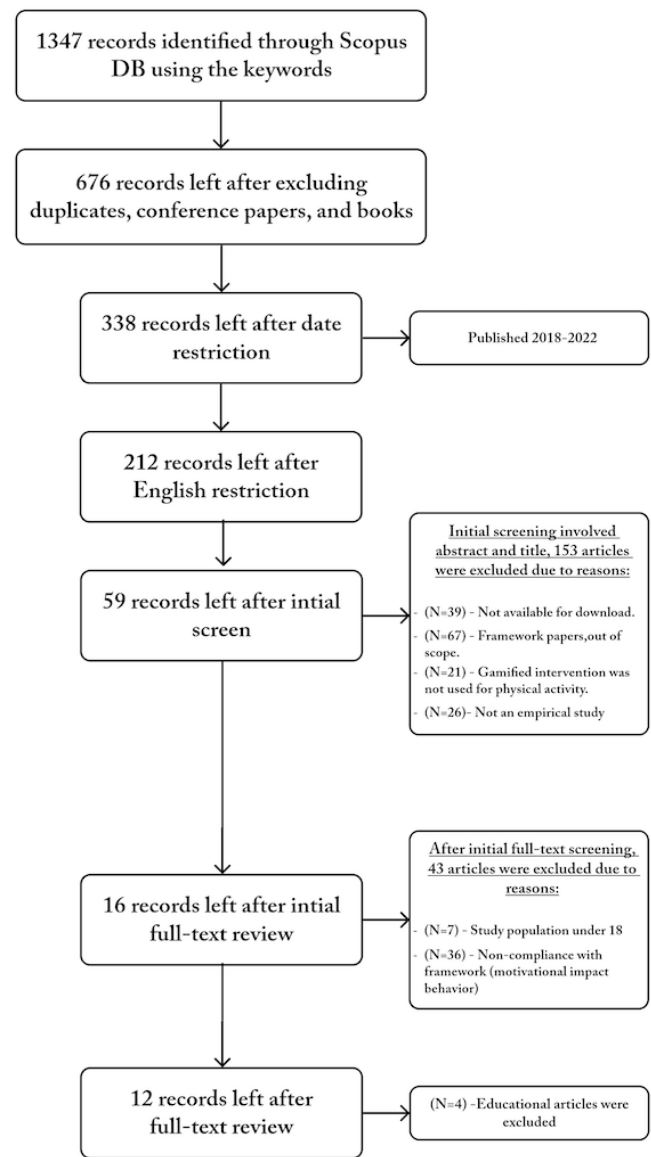

Fig. 1. Flowchart of the review process.

### D. Step 4: Analysis and Categorization

To effectively assess the impact of gamification on physical activity, this study considers six key aspects:

1) Types of Physical Activity: The analysis includes different sorts of exercises.
2) Technological Platforms: The research examines the types of technology used, such as mobile apps or wearables.
3) Motivational Elements: Key gamification elements like badges, leaderboards, and stories are given priority to find out what motivates users the most.
4) Psychological and Behavioral Outcomes: The review assesses the impact of interventions that incorporate gamification on psychological and behavioral aspects.
5) Incentive Mechanisms: Both tangible and intangible rewards are evaluated to gauge their role in user engagement.

6) *Reported Outcomes:* The review also considers the tangible results from the studies analyzed.

This focused examination helps in understanding not only the current state of the field but also offers directions for future studies.

### E. Types of Physical Activity

In the reviewed studies, walking emerged as the dominant focus, with 9 out of 12 studies aiming to boost daily step counts [62], [63], [64], [65], [66], [67], [68], [69], [70]. Other activities that have been gamified include cardio, 2 out of 12, have allowed the users to choose from a wide range of activities, such as running and swimming, which is a popular approach used in the market by companies like Fitbit and Apple [71], [72]. Finally, one study has adopted cycling as the physical activity of interest to investigate the long-term effectiveness of gamification in physical activity interventions [73] (See Fig. 2). The analyzed studies tended to rely on increasing step counts, distance traveled, and other cardio-related metrics as the main outcomes of interest. The means of collecting the data were also quite different across the studies. Some of the studies relied on in-device sensors such as accelerometers and pedometers, which are popular among the current wearables and phones. Other studies have relied on self-reported data assessed online or through a paper application.

Fig. 2. Type of physical activity measured.

### F. Technological Platforms

The reviewed studies employed varying systems for gamification interventions. These systems were categorized in terms of the utilization of an existing system, such as WeChat, Playpluse, and Way to Health, to gamify physical activities. Likewise included in this category was the utilization of technology to create a new system, such as through building games or fitness trackers to promote physical activity. While the majority of the studies, 7 out of 12, have utilized the technology to create a custom system for the purpose of the study [62], [65], [66], [67], [69], [71], [72]. 5 out of 12, have utilized existing platforms and services to gamify physical activities [64], [63], [68], [70], [73]. Most of the analyzed studies utilized technology in the form of a watch as an extension of the system deployed [62], [65], [64], [63], [66], [67], [68], [71], [72], [73]. Others relied on phones to feed the system data related to the user's physical activity [69], [70](See Fig. 3). Most studies that were analyzed have created their custom system, which gave them advantages when designing the gamification interventions. It allowed them to tailor the experience to the needs of the target population. This precision maximizes motivation and engagement with the game or activity. Also, it allowed for better integration of the system with other aspects of users' lives, such as social media and work-life balance. Ultimately, it allowed for better tracking and monitoring of user data, which can provide valuable insights for researchers.

Fig. 3. System used.

### G. Motivational Elements

In the reviewed studies, points were featured in 9 out of the 12 examined studies [62], [65], [64], [63], [66], [69], [70], [71], [72]. Points are generally awarded for completing certain tasks or goals and can be redeemed for rewards. They provide a sense of progress to users and can help keep them engaged in the game or activity. The progress bar is the second most popular motivational element used in the studies. It was used in 5 out of 12 studies as a way to motivate individuals to be physically active, and within those studies, it was often paired with points or other elements [62], [69], [71], [72], [73]. The progress bar is an indicator of the percentage of completion of a task or goal. It represents how close users are to earning rewards or reaching a milestone. Challenges are the third motivational element used in the studies. It was used in 4 out of 12 studies as a mechanism to encourage

individuals to be physically active, and within those studies, it was often paired with points or other elements [62], [67], [71], [72]. Challenges are tasks or goals one must complete to gain rewards or reach milestones. Levels are the fourth motivational element used in the studies. It was found in 4 out of 12 studies to encourage physical activity [65], [64], [63], [70]. Levels are milestones one must reach by accumulating a certain number of points or completing a specific challenge (e.g., completing three tasks on Level 1 unlocks Level 2). The leaderboard is the fifth motivational element used in the studies and was found in 3 out of 12 studies as a way to encourage individuals to be physically active [62], [66], [71]. It ranks users based on their progress toward reaching certain goals or milestones. Feedback is the sixth motivational element used in the studies and was found in 3 out of 12 studies to motivate individuals to be physically active [65], [63], [70]. It is a mechanism to help users make sense of their progress and give them insight into how they can improve. Competition is the seventh motivational element used in the studies and was found in 3 out of 12 studies to motivate individuals to be physically active [63], [68], [69]. It is a technique developed to encourage users to outperform their peers by beating them at certain tasks or goals, which can be facilitated by different game elements such as leaderboards, points, and a progress bar. Rewards are the eighth motivational element used in the studies, which was found in 3 out of 12 studies to motivate individuals to be physically active[62], [68], [71]. Rewards can be tangible or intangible and can be given once a particular task, goal, or milestone is completed. They can be given for each task or goal accomplished based on cumulative points(See Fig. 4). It is worth noting that only a few studies comment on the underlying mechanism of the game elements they employed, with most focusing more on the outcomes rather than the actual design process.

Fig. 4. Game elements used.

## H. Psychological and Behavioral Outcomes

The review also encompassed the categorization of outcomes into behavioral and psychological dimensions. Behavioral outcomes in physical activities can be easily measured with activity time, distance traveled, number of steps taken, and calories burned. These results are beneficial because they provide concrete evidence of the positive effects of the game elements on users' physical activity. Psychological outcomes are subjective outcomes that are more challenging to measure, such as users' self-esteem, level of satisfaction, improved mood, reduced stress, and self-confidence. However, they are also important outcomes because they help us determine how much users were motivated by the game elements to be active, how enjoyable it was for them, and whether or not they will continue engaging in physical activity. Overall, the studies we analyzed measured only the behavioral outcome of the game elements' effect on physical activity via various sensors such as pedometers, GPS, and accelerometers or via self-reported measures [62], [65], [64], [63], [66], [67], [68], [69], [70], [71], [72], [73]. The studies did not discuss the psychological outcomes that could provide insight into the users' attitudes and beliefs in relation to being physically active.

## I. Incentive Mechanisms

In the review studies, incentives or rewards were examined and categorized as either tangible or intangible. Tangible incentives, which consist of monetary or material rewards, were employed in 5 out of 12 studies [62], [65], [64], [69], [70]. Intangible incentives, such as points and badges, were utilized in 7 out of 12 studies [63], [66], [67], [68], [71], [72], [73]. The preponderance of intangible rewards is attributable to their lower cost and ease of implementation, as they do not necessitate additional financial resources. However, it is crucial to recognize the potential downsides of tangible rewards. Among the studies utilizing tangible rewards, 40% reported that these failed to maintain engagement in follow-up periods, while 20% did not evaluate long-term impacts. The remaining 40% observed enduring positive effects, potentially due to the intermittent provision of rewards until the study's conclusion (See Fig. 5).

## J. Reported Outcomes

The outcomes of the studies were closely reviewed, revealing that 33% of the analyzed papers focused on participants who were overweight or obese [64], [63], [66], [70]. This could be due to the fact that researchers usually use this population as a proxy for participants with low levels of physical activity, which is a limitation of the existing studies. However, this could also be explained by researchers' intentions to help people who are more likely to suffer from health problems due to their being inactive. In addition, we found that 58% of the studies did not have a follow-up period. The lack of a follow-up period is likely due to the difficulty in getting participants to return for a follow-up session. Even if researchers can get participants to complete the follow-up session, it may only be for a short period, making it difficult to discern how effective the intervention was in the long term. However, one study was the exception, which investigated the impact of their intervention over two
Fig. 5. Long-term effect of tangible rewards.

Fig. 6. Participant characteristics.

years [69]. They designed the game to have a challenge at six-week intervals, which can encourage participants to join for one interval and then stop and rejoin the next interval. Furthermore, it is critical to recognize that in the exceptional study, financial rewards were periodically given to participants to maintain the intervention's impact over an extended duration, which could clarify the intervention's sustainability(See Fig. 6). Regarding short-term, the results were classified into two categories in the analyzed studies: positive and no effects. Positive results can be determined by the game elements' effect on behavioral outcomes, whereas a lack of behavioral outcomes change indicates no effects. As reported in the 3.4 section, none of the studies measured the psychological outcomes that could provide insight into how the game elements may have influenced users' attitudes and beliefs in relation to physical activity. Therefore, we could not determine whether the psychological outcomes were positive or negative. Out of 12 studies that measured behavioral outcomes, four reported no effects [63], [70], [71], [73], and eight reported positive effects [62], [65], [64], [66], [67], [68], [69], [72]. Overall, the reported results of the studies indicate that using game elements to promote physical activity can lead to positive outcomes for participants. While some studies did not report any effects, the preponderance of evidence supports positive outcomes, indicating that this method could stimulate individuals to increase their physical activity. To ensure the long-term sustainability of physical activity interventions that incorporate game elements, researchers must measure the psychological impact of such interventions. By doing so, a better understanding of the long-term effects can be obtained, which can help maintain individuals' motivation to remain physically active over time.

## IV. Limitations and Shortcomings

In the review of the existing literature, several limitations and shortcomings in the approach become apparent. First,

the context of this review was limited to physical activity interventions incorporating gamification elements. However, the results may not be generalized to other contexts and areas. Additional reviews in varying fields like mental well-being are advised for a more comprehensive understanding of gamification's influence on physical activity. Second, due to a lack of empirical evidence, the analysis did not involve theoretical frameworks, which may help to understand the findings of this review better. Other theories and frameworks may provide further insight into how game elements influence physical activity. Third, linguistic constraints are evident as the focus was solely on English-language articles. This limitation potentially omits valuable research published in other languages. Fourth, for quality assurance, only articles from peer-reviewed journals were considered. This criterion excludes other types of scholarly work, such as reports or theses, thus narrowing the review's breadth. Fifth, the review is exclusive to studies targeting adults 18 years of age or older due to their unique psychological characteristics. Hence, the findings may not be applicable to younger demographics, including adolescents and children. Sixth, accessibility issues arise due to the utilization of articles available through Iowa State University Library's Scopus database license. Articles inaccessible through this source may exist but were excluded from the present study. Ultimately, the examination is constrained by time and focuses solely on articles that have been published in the past five years. This means that valuable older research may be disregarded despite its potential significance. Though this review has acknowledged its limitations, it serves as a foundational study that explores the potential of gamification as a tool to promote physical activity.

## V. Discussion

By analyzing the studies, the review brings forth important findings regarding various aspects such as the different types of

physical activities conducted, technological platforms utilized, motivational factors involved, psychological and behavioral results, incentive strategies employed, and reported outcomes. The review of existing literature indicates that current gamified interventions mainly concentrate on step counts as a parameter for measuring physical activity [62], [63], [64], [65], [66], [67], [68], [69], [70]. The narrow focus on step counts suggests that other types of physical activities still need to be thoroughly investigated. Although step counting is convenient, the step count approach has its limitations. The step count approach may not comprehensively assess an individual's overall activity level, particularly if step-tracking devices are not consistently used. Additionally, relying solely on step counts may not be the most effective way to achieve optimal calorie expenditure or overall health benefits through exercise. Accordingly, the reviewed studies revealed that technological platforms can influence the effectiveness of gamification interventions. The reviewed studies have shown a preference for wearable devices over smartphones in the gamified interventions [62], [65], [64], [63], [66], [67], [68], [71], [72], [73]. While the findings overall were positive, highlighting the effectiveness of game elements in short-term physical activity promotion, they were not without limitations. Moreover, to effectively promote long-term physical activity, it is crucial to have a comprehensive understanding of the psychological processes underlying behavioral metrics. Furthermore, It is worth noting that while tangible rewards can be effective in motivating individuals, they also have the potential to negatively impact intrinsic motivation over time. Therefore, gamified interventions should carefully consider a balanced approach. Lastly, although the reviewed studies did not incorporate advanced technologies such as artificial intelligence or machine learning models, their integration could provide promising opportunities to personalize gamification features. By using artificial intelligence or machine learning models, dynamic and personalized challenges could be created, resulting in increased user engagement and overall effectiveness of the gamified intervention.

## VI. Conclusion and Future Work

The current state of gamification within physical activity interventions is still in its nascent stages, and further development is necessary. The existing literature reveals limitations, especially when relying on constant positive reinforcement and motivation. Such strategies eventually deplete the will to continue and blunt sensitivity to rewards. To create more sustainable interventions, learning from digital game design is essential, particularly regarding reward systems. Emphasis should also be on the strategic deployment of both positive and negative feedback mechanisms to sustain user engagement. The future of this field could benefit greatly from the incorporation of artificial intelligence and computer vision models, not only for optimizing difficulty and rewards but also for tracking various metrics. In terms of the types of physical activities considered, most studies primarily target metrics related to cardio exercises like step counts and distance traveled. These studies often employ in-device sensors, such as accelerometers and pedometers, or rely on self-reported data collected either online or via paper applications. This suggests an opportunity for broadening the scope of research to include activities like weightlifting and

other forms of resistance training using a computer vision model to monitor the progress. Moreover, the studies largely bypass any discussion of psychological outcomes. Attitudinal and belief systems related to physical activity offer invaluable insights and should be incorporated into future research efforts. These metrics can help inform the creation of interventions that are not only physically effective but also psychologically motivating.

## Disclosure of interest

The authors report there are no competing interests to declare.

*Abstract*—Despite the plethora and diversity of research on Natural Language Processing (NLP). As a technique allowing computers to understand, generate, and manipulate human language; It still remains insufficient, especially with regard to the processing of Arabic texts and their dialects which are widely used. The proposed approach focuses on the application of machine learning techniques taking into account evaluation criteria such as training to comments expressed in Mauritanian dialect, published on social media notably Facebook, and compares results generated by three algorithms which we applied such as the Random Forest (RF), Naïve Bayes Multinominal (NBM), and Logistic Regression (LR) algorithm. Additionally, We then study the effect of machine learning techniques when different stemmers are combined with other features such as the tokenizers used to process the dataset. Although major challenges exist such as the morphology of Arabic is completely different from Latin letter languages, and there is no pre-existing dataset or dictionary to train the algorithms, the result we obtained after the experiments carried out on Weka shows that the RF and NBM algorithms are more efficient when applied with ArbicStemmerKhoja giving results respectively 96.37% and 71.40%; However, Logistic gets better performance results with Null Stemme is 81.65%. Results obtained by the three techniques applied with a light Arabic stemmer were more than 70%. This article presents a contribution to NLP based on Machine learning, descript also an important study that can determine the best Arabic classifier.*

*Keywords*—*Machine learning; Natural Language Processing; Arabic text classification; HASSANIYA dialect; Weka; stemming*

## I. INTRODUCTION

Mauritania, like other countries around the world, has been invaded by new technology, which has given rise to exchange platforms commonly known as social media, through which inter-family exchanges on the one hand, and inter-governmental and two-way exchanges between government agencies and the public (citizens) on the other, can take place. Thereafter a data stream in dialect Mauritania and Arabic language will be generated reflecting the citizens' sentiment. Whereas, Sentiment analysis is an approach that uses natural language processing (NLP) [1], machine learning analysis methods [2] [3], or other lexicon-based methods [4] to extract, convert, and interpret opinions from a text and classify them into positive, negative, or neutral sentiments. However, the emergence of new technologies will allow governments and companies to take into account the opinions of their public via social media, which would help them make better decisions. Thus, artificial intelligence (AI) within other technologies has solved the challenges of business practice and introduced the application of Business Intelligence (BI) that has promoted the transformation of information. In this sense, several processing techniques have been used to classify large volumes of data (Big Data) for example regression analysis, Naïve Bayes (NB), Support Vector Machine (SVM), and Neural Network (NN) [5]. So far, most research work has been done to classify text using Machine Learning for various languages like English more than Arabic sometimes when Arabic native speakers are more than non-Arabic according to [4].

We consider dialectal Arabic to be a new field of research in the field of text classification, for several reasons: firstly, dialect is widely used in social networks, which generates a large amount of data; secondly, dialect, whether HASSANIYA or others, is generally more widely used than the main language, even if this is not an official case. Moreover, the Mauritanian dialect has an alphabet and script that are those of Arabic, which means that dialect has become an important area of research; Regarding the complexity of HAASANIYA, justified by the reasons listed above, in this work, we propose an approach that gives a clear view of the classification of HASSANIYA text using machine learning algorithms and comparing the archived result. To implement the proposed approach, we use WAKE, which implements several filters and classifiers from machine learning algorithms [6].

The differences between Standard Arabic and dialectal Arabic are minimal in terms of derivation and grammar, as well as termination. On this basis, we decided to study the classification of Mauritanian dialectal texts taking into account the effect of the stemmer method. The goal of this work is to identify the best Machine Learning for dialect classification and the effect of stemming and tokenization on text classification, particularly the HASSANIYA dialect; nevertheless, we fusion deference filters for building our property models.

More specifically, a HASSANIYA dataset was collected on Facebook and contains comments posted on popular pages in Mauritania such as bloggers' pages or government pages (the Ministry of Hydraulics, the Ministry of the Interior and Decentralization, Ministry of Housing and Urban Development) that

we prepared in order to prove the stemmer method on dialectal text. To experiment, three types of stemmer were adopted in this work such as light stemming, null stemming, and heavy stemming in this case we use khoja, and every one of these three types is fusionned with another filter to make a new method. We tested three Machine Learning algorithms individually on the models built mentioned above. Machine Learning techniques applied are NVM, RF, and logistic regression.

The main contributions of this paper are:

- scraping data from Facebook pages to build a HAS-SANIYA dialect dataset;
- proving the classification of the HASSANIYA dialect text with Machine Learning techniques;
- applying and comparing different types of Stemmer to improve text classification.

The paper is organized as follows: an introduction followed by a state of the art and literature review gives an overview of the Arabic language and its dialects, then we explain our research methodologies followed in this paper and finally, we discuss the results obtained and give a conclusion.

## II. Related Works

Text classification presents an amazing field in the data analysis area, and still rich in terms of scientific research, increasing domain due to what we let know. Many researchers studied these cases and realized more articles, but the Arabic language and its dialects still need more work.

In this context, several studies have been carried out such as the approach [4] gives an approach for the classification of Arabic texts using various algorithms, and showed an enhancement in the accuracy of classifier models.

Authors in the article [7] explored a comparative system on two different datasets based on the machine learning technique, classification models are compared in terms of accuracy for each dataset.

Another study [8] applied six variations of the Bayes classifier on Arabic data, after analyzing their results were compared, and showed that the best values were generated successively from Naïve Bayes and Naïve Baye Update, in another way Naïve Bayes Multinomial Text generated the worst results.

Proposed [9] a contribution to big data processing which is considered a challenging stage of data analysis ax, so a solution proved for the challenges in four stages: data collection, cleaning, enrichment, and availability. they looked to convert social media data to computation-based data after it was source-based.

The author [10] Proposed a model for text dialectal classification, they prepared a dataset of Marocain dialect scraped from Twitter comments and a combination of extraction(n-grames), weighting schema(Bow, TF-IDF), and word embedding was applied in order to prove the Marocain dialect classification and get the best classify model. the Machine Learning techniques which they applied are following: Naive Bayes, Random Fest, support Vector Machine, Logistic Regression, and a Deep Learning Model such as Long Short term

Memory (LSTM). the experimental work showed that the SVM achieved an accuracy equal to 70%.

This paper [11] proposed a new algorithm to generate all potential derivation roots of an Arabic word, without deleting initial affixes. the author seeks to address the weaknesses and errors of existing algorithms in order to improve the accuracy of Arabic Natural language Processing. they used in this study a data set that includes a collection of roots, patterns, and affixes. by matching the derived word to identify the root. and then, they get an average accuracy rate of 96%.

This study [12] proposed a model as a novel assembly of CNNs for analysis of the task of Arabic dialect classification from spontaneous Arabic speech dataset. this model is based on a fusion of linguistic and acoustic features and uses pre-trained bidirectional encoder representation from the transformed (BERT) Model. the proposed approach achieves an accuracy of 82.44% for the identification task of five Arabic dialects.

The author [13] proposes an approach to improve P-Stemmer by combining it with various classifiers such as Naïve Bayes, Random Forest, Support Vector Machines, K-Nearest Neighbor, and K-Star. In this study they used a data set synthesized from various online news pages and did the experience on Weka tools, which is achieving the result showed that the P stemmer has Improved when using NB.

## III. Review of Arabic and its Dialects

Arabic is one of the major languages used in the world, it is used by all Muslims because is the language of the holy book of Islam [6], [14], as well, Arabic divided into three categories according to [14] as follows: First, Classical Arabic (CA) is considered the oldest type it is the Arabic literature, The Holy Quran; Second, Modern Standard Arabic (MSA) can be defined as a simplified version of Classical Arabic to be comprehensible by whole people and be became largely used; and then, exists a third type called Arabic Dialect use the same Arabic characters for writing, this one used more than two above types in daily life.

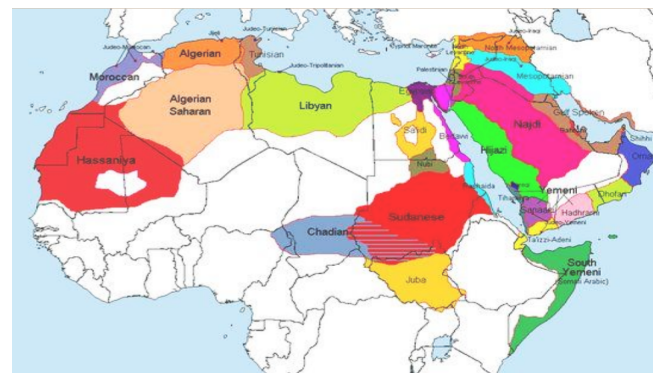

Fig. 1. Arabic dialect Map.

The Arabic dialect is divided into several types, as shown in Fig. 1; for instance:

- Moroccan Dialect: The Moroccan dialect commonly Diarj [10];

- Egyptian Dialect: The Egyptian dialect is spoken in Egypt;
- North African Dialect: The North African dialect is spoken in Algeria, Libya, and Morocco [12];
- Tunisian Dialect: Tunisian [15], and others are also Arabic dialects [16];
- Mauritania Dialect: This is named HISSANIYA dialect and is spoken mainly in the middle Mougreb region, more specifically in Mauritania country.

*Mauritania Dialect:* The Mauritanian dialect named HASSANIYA is a local dialect and a variety of Maghrebi Arabic spoken by Mauritanian Arabs widely used in daily life not only to change between families but also to indicate or share feelings and opinions on social media and to interact with others' posts. The operation of HASSANIYA text classification is becoming increasingly complicated, for three reasons: firstly, HASSINIYA is an Arabic dialect that has the same letters of the alphabet for writing, with changes in pronunciation and meaning depending on their diacritics, and ambiguity between words' root and their derivation; secondly, it is an unstructured language; thirdly, there is no data set or dictionary pre-exists.

In Table I, we segment an example of a Hassaniya word into sub-segments that show its basic construction; as mentioned above, this dialect uses Arabic letters and can be conjugated with all subjects and tenses; as shown in the following table, the word HISSANIYA has an affix such as prefix, suffix, and postfix determined by usage.

TABLE I. EXAMPLE OF A HASSANIYA « ماخَلَّيْتُو » WORD WHICH HAS DIFFERENT AFFIXES ATTACHED TO A ROOT WORD

| Word | تُو | يْ | خَلَّ | ما |
|---|---|---|---|---|
| Meaning | Pronoun '' You '' | Termination of conjugation | let | Negation like "Don't" |
| Affixes | Postfix | Suffix | Root | Prefix |

## IV. MATERIALS AND METHODS

The main stages in our proposed Methodology are data collection, preprocessing, building technique, classification, and Evaluation stages will be described in the following. This approach was applied using Weka tools. For the sake of a better selection of dialectal words, we adopt in this work a methodology consisting of phases shown in Fig. 2.

Fig. 2. Proposed architecture

### A. DataSet Description

Social media data is the main source of our Data set. We have built our own Data set which contains words and sentences in HASSANIYA by gathering hundreds of comments from Facebook pages using scrap tools that present cytosine's reaction to government activities and then annotating them according to their polarity. We annotated each comment extracted according to his opinion hidden behind the writing.

The corpus of the dataset is present in the below Table 2.

TABLE II. DATASET

| Class | Comment |
|---|---|
| Positive | 321 |
| Negative | 348 |
| Neutre | 337 |
| **Total** | 1006 |

Based on our knowledge of the local language, we divided the corpus into three categories looking at opinions reflected as positive, negative, and neutral as well as shown in Fig. 3. Moreover, we loaded comments on Interim storage as a CSV file after converting it to ARFF format for use on Weka.

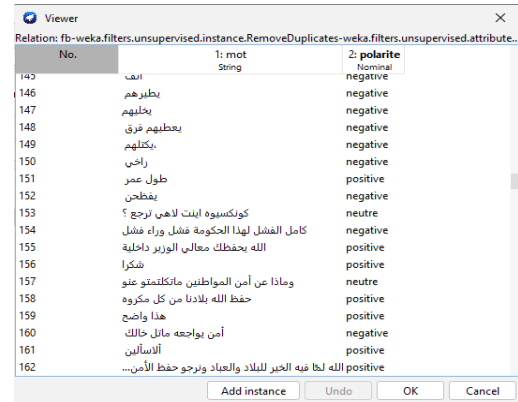

Fig. 3. DataSet example annotated.

The data was balanced by the Smote method as well as shown in the following Fig. 4.

Fig. 4. DataSet balanced.

## B. Pre-processing

Pre-processing is the first step in the data analysis process and that is a crucial step when dealing with Arabic documents [17]. In order to convert input data to a performed text clearly and useful for machine analyses, we were using in this work a process consisting of various steps presented in the following. thus, these steps and filtering are offered by the Weka tool.

*Tokenization :* Tokenization is a technique that divides and transforms the word into tokens while preserving the meaning of the words by removing spaces, punctuation, and non-Arabic words [18]; in this case, the document is also reduced to words.

*Normalisation :* Word normalization means giving a format where some letters appear differently [19] for instance, ١, can appear in different forms like أ, آ and إ .

*StopWordsHandler :* stop word is used to eliminate everything not part of the word's root.

*Stemming :* The streaming method is an essential step in Natural Language Processing or text classification, which converts the word into its corresponding root or stem. stem is the combination of a root and its derivation which is a suffix prefix and postfix [16]. There are two main types of stemming in Arabic, namely Stem or Light Stemming and root-based stemming, the first one can be explained by removing the suffix and prefixes from the word in order to obtain its root; The second type is divided into three sub-categories. according to [17] such as (i) Dictionary Based when using a file dictionary; like khoja. (ii) no-dictionary bases, and hybrid that is shown in Fig. 5. There are several Stemming approaches applied to the Arabic language the following is a non-exhaustive type.

*Light stemmer :* Light stemmer is one category of stemming approach that aims to reduce words to their stem by means of removing the most frequent word's prefix and/or suffix [20], [21], [19] .

*Heavy Stemmer :* Heavy stemming is the process of eliminating affixes and changing certain letters in words to obtain the root word [22].

Fig. 5. Stemming structure approach.

*SetMinTermFreq() :* The SetMinTermFreq() method is used to define the minimum frequency threshold of a term (word) to be taken into account in the feature vector; In Weka, the StringToWordVector filter allows us to convert a collection of text documents into a set of numerical features, where each feature represents the frequency of a specific word in the document. In this study, you have used a minimum frequency equal to 2.

## C. WEKA tools

WEKA is a machine learning framework with a graphical user interface, making it easy to use for beginners. it also includes a large collection of machine learning models such as Neural Networks, Decision Trees, and K-means. provides implementations of learning algorithms that can be applied for data analysis purposes [23].

Weka covers tools for transforming datasets, such as discretization and sampling algorithms for pre-processing a dataset, integrating it into a learning scheme, and analyzing the resulting classifier and its performance.

## D. Machine Learning Algorithms

*1) Naive Bayes Multinominal :* Naïve Bayes (NB) is a data mining algorithm dedicated to data classification [24]. It is used to deduce the probability of a datum belonging to a class, based on the assumption that all attributes are independent of each other given the class [25]. In this work, we use Multinomial Naive Bayes to assign texts to classes based on statistical analysis of their content. This algorithm offers an alternative to the often cumbersome semantic analysis based on artificial intelligence and considerably simplifies the classification of textual data. It aims to classify by assigning text fragments to classes while determining the probability of a document belonging to the class in other documents with the same subject.

*2) Random Forest :* According to [26] RF is a set of decision trees where each tree is built from a bootstrap version of the training data set. Each tree is built according to the principle of repetitive partitioning: starting from the root node, the same node-splitting procedure is applied repeatedly until certain stopping rules are met. Its predictive power comes from the aggregation of many weaker learners (decision trees). Performance is particularly good if correlations between forest trees are low.

*3) Logistic :* Logistic regression is an important technique in the field of artificial intelligence and machine learning for data analysis that uses mathematics to find relationships between two data factors. It then uses this relationship to predict the value of one of these factors as a function of the other. The prediction usually has a finite number of outcomes, such as yes or no. Logistic regression belongs to the family of supervised machine learning models. It is also considered a discriminative model, meaning that it attempts to distinguish between classes (or categories) [27].

## E. Evaluation Metrics

Text classification models are evaluated using well-defined essential criteria. This set was used to evaluate our models [28]. To evaluate the accuracy of our Models', a confusion metric is defined by [10] as a tool to evaluate the accuracy of ML models' predictions and compare their predictions to reality. Since We have three classes to be classified, six important terms will have come into the evaluation process as shown

in Fig. 6. Results obtained are assessed using the F1 score, precision, accuracy, and recall.

*Tp:* here is true Positive, where the prediction is positive, and the actual values are positive also.

*Fp:* here is a False positive, where the prediction is positive, but the actual values are Negative or Neutral.

*Tng:* here is true Negative, where the prediction is negative, and the actual values are negative.

*Fng:* here is a false negative, where the prediction is negative, but the actual values are positive or neutral.

*Tn:* here is true Neutral, where the prediction is neutral, and the actual values are Neutral also.

*Fn:* here is a false Neutral, where the prediction is neutral, but the actual values are positive or negative also.

*Precision :* Precision (P) measures how many of the "positive" predictions are made correctly by the model. The mathematical formula is as follows :

$$P = \frac{\mathcal{T_P}}{\mathcal{T_P} + \mathcal{F_P} + \mathcal{F_P}} \tag{1}$$

*Recall :* Recall(R) measures how many of the positive class samples present in the dataset were correctly identified by the model. calculated by the following mathematical formula:

$$\mathcal{R} = \frac{\mathcal{TP}}{\mathcal{TP} + \mathcal{F_{Ne}} + \mathcal{F_N}} \tag{2}$$

*F-Measure :* F-Measure or F1 score is a machine-learning evaluation metric that measures a model's accuracy. It combines the precision and recall scores of a model. given by the formula:

$$\mathcal{F}1 = 2 * \frac{P * \mathcal{R}}{P + \mathcal{R}} \tag{3}$$

*Accuracy :* The accuracy metric computes how many times a model made a correct prediction across the entire dataset.

$$Accuracy = \frac{\mathcal{T_P} + \mathcal{T_N} + \mathcal{T_{Ng}}}{\mathcal{F_N} + \mathcal{T_N} + \mathcal{T_P} + \mathcal{F_P} + \mathcal{T_{Ng}} + \mathcal{F_{Ng}}} \tag{4}$$

Fig. 6. Confusion metrics for three classes.

## V. RESULTS AND DISCUSSION

There are three experimental works carried out using Weka tools are shown in Table III, in order to investigate the stemmer method effect in Mauritania dialectal classification and to compare the performance of the Machine Learning techniques applied. In the first EXP (i), we combined the ArabicStemmerkhoja, the MultiStopwords, and the word tokenizer in order to construct an appropriate feature; Exp (ii) is the result of a combination of ArabicLightStemmer, multistop-word, and word tokenizer; The last one EXP(iii) was done of null Stemmer combined with multi Stop Words, and WordTokenizer. The accuracy of the three experimental works is illustrated in Fig. 7 and Table VII, which shows that three machine learning techniques (Random Forest, Logistic Regression, and Naive Bays Multinomial) were tested using training data at three different stages, with the result changing according to features used.

TABLE III. COMBINED FEATURES

| Exp | Feature set |
|---|---|
| i | WordTokenize + ArbicStemmerKhoja + MultiStopWords |
| ii | WordTokenize + Arabic light Stemmer + MultiStopWords |
| iii | WordsTokenize + Null Stemmer + MultiStopWords |

Tables IV, V, and VI shows the results obtained by the Random Forest, NBM, and logistic techniques on the basis of the training data. It can be seen that the three classifiers managed to classify the positive class more than the others with better data by RF with Ligth StemmerArabic equal 98,5%; moreover, RF gets better results than others classified in three cases.

TABLE IV. EXP(I) CLASSIFICATION RESULTS OF EACH CLASS USING STEM-BASED (LIGTH STEMMERARABIC)

| | | Class | | |
|---|---|---|---|---|
| | | Positive | Negative | Neutral |
| NBM | Precision | 0,768 | 0,685 | 0,694 |
| | Recall | 0,731 | 0,726 | 0,686 |
| | F-Measure | 0,749 | 0,705 | 0,690 |
| RF | Precision | 0,985 | 0,974 | 0,934 |
| | Recall | 0,974 | 0,938 | 0,979 |
| | F-Measure | 0,980 | 0,956 | 0,956 |
| Logistic | Precision | 0,841 | 0,761 | 0,768 |
| | Recall | 0,840 | 0,776 | 0, 755 |
| | F-Measure | 0,841 | 0,768 | 0,762 |

The results obtained from exp(i) with Light Stemmer Arabic are shown in Table IV; this shows the performance evaluation measure for each selected class or sentiment (positive, negative, and neutral), so positive sentiment was ranked higher by RF.

Table V shows the results obtained when using Arabic Stemmer Khoja. This experience shows RF arrives at a significant number classified in all classes, followed by Logistic which is better for the positive, and negative classes than the neutral.

The results obtained during the exp(iii) indicated in Table VI show that RF and Logistic in terms of classification than NBM. However, the correctly classified number of the neutral class is less important here than the other classes.

TABLE V. EXP(II) CLASSIFICATION RESULTS OF EACH CLASS USING ROOT-BASED (ARABIC STEMMER KHOJA)

| | | Class | | |
|---|---|---|---|---|
| | | Positive | Negative | Neutral |
| NBM | Precision | 0,766 | 0,681 | 0,679 |
| | Recall | 0,705 | 0,749 | 0,665 |
| | F-Measure | 0,734 | 0,713 | 0,672 |
| RF | Precision | 0,982 | 0,951 | 0,952 |
| | Recall | 0,968 | 0,956 | 0,961 |
| | F-Measure | 0,975 | 0,953 | 0,956 |
| Logistic | Precision | 0,863 | 0,812 | 0,755 |
| | Recall | 0,796 | 0,951 | 0,801 |
| | F-Measure | 0,945 | 0,804 | 0,777 |

TABLE VI. EXP(III) CLASSIFICATION RESULTS OF EACH CLASS USING NULL STEMMER)

| | | Class | | |
|---|---|---|---|---|
| | | Positive | Negative | Neutral |
| NBM | Precision | 0,787 | 0,674 | 0,688 |
| | Recall | 0,705 | 0,746 | 0,686 |
| | F-Measure | 0,744 | 0,708 | 0,687 |
| RF | Precision | 0,985 | 0,945 | 0,946 |
| | Recall | 0,965 | 0,953 | 0,958 |
| | F-Measure | 0,975 | 0,949 | 0,952 |
| Logistic | Precision | 0,872 | 0,820 | 0,762 |
| | Recall | 0,853 | 0,796 | 0, 801 |
| | F-Measure | 0,862 | 0,808 | 0,781 |

Metric in the three experiments for the three classes given with the NMB and Logistic, it shows that the technique used is good for predicting the positive class, especially in experiment (i), and bad for predicting the negative class. Unlike RF who managed to predict all classes.

Fig. 7. Accuracy performance of the three algorithms.

Fig. 7 illustrates the Accuracy of algorithms given respectively by the three experiments applied.

TABLE VII. MODELS PERFORMANCE

| | Accuracy | | |
|---|---|---|---|
| EXP | RF | NBM | LOGISTIC |
| (i) | 96.37 | 71.40 | 79.02 |
| (ii) | 96.14 | 70.63 | 80.79 |
| (iii) | 95.84 | 71.24 | 81.65 |

As shown in Table VII above RF and NBM algorithm was better in performance when using ArbicStemmerKhoja; however, Logistic gets better performance results with Null Stemmer. Overall, with the Light Stemmer Arabic feature, the RF algorithm had the highest accuracy rate compared to the NBM and Logistic algorithms.

TABLE VIII. COMPARISON OF EXPERIMENTAL RESULTS

| Paper | Dataset | Classification Algorithm | Best Accuracy |
|---|---|---|---|
| [29] | Scrapping from tweets comments | SVM, NB, and K-nearest neighbour | 67.19% |
| [30] | Moroccan sentiment analysis corpus | NB, SVM , and Maximum Entropy (ME) | 82.5% |
| [31] | Tunisian sentiment analysis corpus | SVM, and NB | 76.41% |
| **Our approach** | **Mauritania dialect analysis corpus** | **NBM, RF , and Logistic Regression** | **96.37%** |

Table VIII illustrates the results obtained with previous work, which focuses on different dialects; Likewise, our approach also studies a dialect. However, the experimental study in this approach gave a result of 96.37% higher than those obtained by existing studies. Therefore it is a successful approach.

Diacritization and derivation or rootization of Arabic words are the limitations of this approach. We recommend that future research enhance algorithms by taking diacritization and all possible word lengths into account; So that the correct word meaning can be processed.

## VI. CONCLUSION

This study essentially focuses on the Mauritanian dialect, looking at its morphology, structure, and meaning, with the aim of analyzing it using Machine Learning algorithms. In order to prove the classification of the Mauritanian dialect using ML algorithms, we experimented on a corpus of dialect words that gave satisfactory results, however, the study proved that the results obtained are influenced by the effect of stemmer methods;

In this article, three types of stemmer were tested with the objective of measuring and comparing their effect on the classification of dialect text, this process showed that the stemmer method "ArbicStemmerKhoja" is the most efficient with the NBM and RF algorithms in terms of prediction, unlike logistic which gives a better performance without stemmer.

These results will guide us to a deeper study of the language data in order to uncover sentiments behind his comments written in the Mauritanian dialect and find an accurate prediction.

*Abstract*—In today's era of escalating digital threats and the growing need for safeguarding sensitive information, this research strives to advance the field of information concealment by introducing a pioneering steganography methodology. Our approach goes beyond the conventional boundaries of image security by seamlessly integrating classical image processing techniques with the cutting-edge realm of quantum encoding. The foundation of our technique lies in the meticulous identification of distinctive features within the cover image, a crucial step achieved through the utilization of SIFT (Scale-Invariant Feature Transform). These identified key points are further organized into coherent clusters employing the K-means clustering algorithm, forming a structured basis for our covert communication process. The core innovation of this research resides in the transformation of the concealed message into a NEQR (Novel Enhanced Quantum Representation) code, a quantum encoding framework that leverages the power of quantum circuits. This transformative step ensures not only the secrecy but also the integrity of the hidden information, making it highly resistant to even the most sophisticated decryption attempts. The strategic placement of the quantum circuit representing the concealed message at the centroids of the clusters generated by the K-means algorithm conceals it within the cover image seamlessly. This fusion of classical image processing and quantum encoding results in an unprecedented level of security for the embedded information, rendering it virtually impervious to unauthorized access. Empirical findings from extensive experimentation affirm the robustness and efficacy of our proposed strategy.

## I. INTRODUCTION

Digital document transfer via networks is vulnerable to a number of security threats, including attacker interception and modification. Different methods have been developed to safeguard the transfer of digital documents in order to reduce risk. Steganography is one such method, which entails concealing a message within another message or a tangible item. Researchers have recently put forth a number of steganography methods that mix classical and quantum computing methods. For instance, the hybrid quantum k-means algorithms described by Poggiali et al. [9] and DiAdamo et al. [8] combine classical and quantum clustering methods. Jiang and Wang [10] suggested a unique, safe, keyless steganography method based on the Moiré pattern for pictures on quantum computers. Li and Lu [7] introduced a brand-new LSB-based steganography for colored quantum pictures that makes use of reflected Gray coding. Even while these methods have showed potential, steganography still has limitations.

For instance, The secret message may be discovered if the steganography algorithm is known or if the cover item is subjected to statistical analysis [21]. This paper introduces a unique method of picture steganography that combines traditional image processing methods with quantum computing in order to overcome these constraints. The proposed method leverages Scale-Invariant Feature Transform (SIFT) for keypoint detection and K-means clustering [6]for image processing before encoding the secret message using quantum circuits. The secret message is then encoded into a Novel-Enhanced Quantum Representation (NEQR) code, providing an additional security layer. The suggested method is used to conceal a hidden message in a handwritten manuscript and document image. The main contribution of this approach lies in its innovative combination of classical image processing techniques with quantum computing to enhance the security and imperceptibility of steganography. Specifically, K-mean clustering introduces It provides an efficient way to group similar keypoints detected by SIFT and group them to find the optimal number of centroids of keypoints in the cover image. This ensures that the secret message is encrypted in a secure and efficient way. Followed by encoding the secret message using quantum circuits and NEQR coding. This not only enhances the security of the hidden message but also maintains the aesthetic quality of the original image. To overcome the limitations of steganography techniques, k-means unsupervised learning algorithm can be used to hide large data sets. It assumes that the detector parameters and K-means are completely synchronized between sender and receiver and that the quantum circuit used for encryption can be transmitted securely. The remainder of this paper is divided into the following sections. For background, in Section II, we review prior initiatives in the field of imagine steganography. We fully describe the methods we want to utilize in Section III. Experimental results demonstrating our approach's effectiveness are described in Section IV. Section V concludes the essay and discusses what happens next.

## II. RELATED WORKS

An area of study that is expanding quickly and has gotten a lot of attention lately is quantum image processing and information concealing. In order to improve the embedding capability, visual quality, and security of quantum image steganography, researchers have proposed forth several novel techniques for hiding information within quantum images. These techniques include Fourier's Quantum Information Processing [1], Image processing in quantum computers [2], turtle

shell algorithm [3], and least significant bit (LSB) replacement [4]. The publication "A novel quantum color image steganography algorithm based on the turtle shell and LSB" [3] describes one noteworthy technique. In order to increase visual quality and security, the authors provide a novel quantum color picture steganography technique that makes use of the human vision system (HVS) model and validates codes. To conceal secret information, the algorithm randomly chooses two channels from each color carrier pixel's red (R), green (G), and blue (B) channels with varying probability. The grayscale values of the two selected channels line up with a spot in the reference matrix based on a turtle shell. Either the LSB substitution technique or the turtle shell algorithm is used to embed the secret information, depending on whether the point is near the border of the reference matrix or not. The technique of the authors' unique system is better explained through the use of specialized quantum circuits. According to experimental findings, their algorithm is workable and performs better than competing techniques in terms of security, embedding ability, and imperceptibility. The article "LSB-based Steganography Using Reflected Gray Code for Color Quantum Images" [7] presents another intriguing technique. In order to increase embedding capacity and security for color quantum pictures, this research suggests an LSB-based steganography approach employing reflected Gray code. The authors include four hidden qubits into each pixel of the cover picture using the NEQR encoding for quantum images. In order to lessen distortion in the stego picture and make detection more challenging, they additionally use reflected Gray coding. Mario Mastriani's works and others are connected. The author in [1], who first up the idea of quantum Fourier transformation and investigated how it affected entanglement, teleportation, and quantum secret sharing. The author in [2] investigates how Quantum Image Processing (QIP) may be used to more effectively represent pictures by storing N bits of classical information in just log2 N quantum bits (qubits) and by using a brand-new LSB-based quantum image steganography algorithm. The many facets of quantum image processing and clustering approaches have also been examined in certain related publications. For instance, [8] provided a useful quantum k-means clustering method and examined its effectiveness and potential uses for classifying energy grids. This research showed how useful quantum clustering methods may be in real-world applications. In contrast to prior studies, our technique first processes the image before encoding the secret message using SIFT (Scale-Invariant Feature Transform) and K-means clustering. K-means is a clustering technique used to divide data into groups, whereas SIFT is an algorithm that finds and characterizes local features in photographs. You use quantum circuits to encrypt a secret message after utilizing SIFT to identify keypoints in a cover picture and K-means clustering to organize them into clusters. The result is a NEQR code. By changing the pixel values of the cover image, you may finally encrypt the secret message in the picture. The main difference between our approach and these related works is that our methodology concentrates on processing the image using SIFT and K-means clustering before encoding the secret message, whereas these works concentrate on improving the embedding capacity, visual quality, and security of LSB-based quantum image steganography or improving the efficiency of k-means clustering through quantum parallelism. Furthermore, unlike previous comparable research, our suggested approach includes machine learning techniques. With regard to your information concealment technique, we specifically use machine learning methods or models like K-means clustering for keypoint grouping or other pertinent activities. In comparison to conventional steganography approaches, our proposed work offers improved performance and flexibility by using machine learning techniques. The efficiency and efficacy of the information-hiding process are increased thanks to machine learning models' ability to recognize patterns, improve settings, and adjust to changing circumstances. In spite of these developments, there are still several issues and research gaps in this area. For instance, utilizing security metrics like entropy, correlation coefficient, chi-square test, etc. A more thorough security study and comparison with other quantum picture steganography systems already in use are required. Researchers must also take into account how assaults or quantum noise may impair the resilience and dependability of these solutions. Additionally, it is necessary to provide clearer descriptions of how models like HVS are used to choose channels for information concealment as well as their adaptability to various picture kinds and color schemes. To prove practicality and applicability, further experimental findings on real-world pictures or applications are required.

## III. Proposed Approach

### A. Image Pre-processing

Noise reduction, contrast enhancement, and edge detection techniques will be used on cover images to enhance their steganography. Edge detection will identify the edges of the image, contrast enhancement will change its brightness and blackness, and noise reduction will eliminate any extraneous pixels or imperfections. the things in the picture. The cover picture is then loaded and made grayscale. The keypoints detection technique only functions on grayscale pictures, hence the conversion to grayscale is required.

### B. Detection of Key Points

The Scale-Invariant Feature Transform (SIFT) technique will next be used to find relevant regions in the cover picture [24]. Here These strategic places will offer suitable hiding spots for the hidden message. In order to identify, describe, and match local characteristics in pictures, David Lowe created the SIFT algorithm in 1999 [5]. SIFT identifies and characterizes local features in images. It is a reliable option for key point identification since it is invariant to scale, orientation, and affine distortion. SIFT is used by our suggested technique to find key points in the cover picture. Key points are interesting areas of a picture that remain constant despite changes in scale and direction. The scale space of the input image is initially built as part of the SIFT algorithm's operation. This is accomplished by creating a collection of smoothed pictures by convolving the image with Gaussian filters at various scales. Next, neighboring smoothed pictures in the scale space are subtracted to determine the Difference of Gaussians (DoG). The local extrema (maxima and minima) are looked for across scales and spatial dimensions in the DoG pictures. These extremes might serve as important points. After possible key points have been discovered, they are refined by removing edge responses and low-contrast key points. The prevailing gradient direction in each key point's immediate vicinity is

then used to determine its orientation. The local image patch of each key point is used to construct a description for each of them. Equation [1] shows how the scale space is built using a Gaussian function:

$$G(x, y, \sigma) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \qquad (1)$$

where:

- $x$ and $y$ are the pixel coordinates.

- $\sigma$ is the scale parameter.

### C. Clustering of Key Points

In the suggested method, we employed the K-means clustering technique to organize the key points that were identified in the cover picture into clusters [19], [22]. This process is used to locate areas in the image where the hidden message could be hidden. The last places to implant the hidden message will be in the centroids of these clusters (10 centroids were employed can seen in Fig. 1). Unsupervised machine learning technique known as K-means divides a set of data points into K clusters [23]. Stuart Lloyd made the initial suggestion in 1957, and James MacQueen subsequently published it in 1967 [20]. The method updates the cluster centers based on the mean of the data points given to each cluster after repeatedly allocating each data point to the closest cluster center. When the cluster assignments stop changing, the algorithm has reached its convergence. Let $C = \{c_1, c_2, \ldots, c_k\}$ be the set of cluster centers and $\{X = x_1, x_2, \ldots, x_n\}$ be the collection of data points in mathematics. The within-cluster sum of squares (WCSS) [11], which is determined by Eq. (2), is the objective of K-means:

$$\sum_{i=1}^{k} \sum_{x \in C_i} \|x - c_i\|^2, \qquad (2)$$

where:

- $C_i$: the set of data points assigned to cluster $i$.

- $i$, and $\|x - c_i\|$: the Euclidean distance between data point $x$ and cluster center $c_i$.

The key points from the cover picture that were recognized by our suggested method were grouped into clusters using K-means clustering. The K-means method seeks to identify a clustering of the key points such that the key points within each cluster are as near as feasible to one another (in terms of their Euclidean distance) by minimizing the WCSS. As a consequence, a collection of neatly spaced-out key point clusters is produced. These clusters may then be utilized to find possible locations for the hidden message to be embedded. For instance, we may decide to place the hidden message in the pixels that correspond to the cluster centers or those that are a specific distance away from the cluster centers. We can make sure that the embedding spots are selected in a way that will probably retain the aesthetic quality of the cover picture by using K-means clustering to divide the key points into clusters.

Fig. 1. Identification of the embedding positions.

### D. Encoding of Messages

In our suggested method, we harness the power of quantum circuits and keypoint clustering to safely insert a hidden message into a picture. We can find the best places to integrate messages while still maintaining the aesthetic appeal of the cover picture by utilizing keypoint clustering. The K-means technique was used to create these clusters, which may be used to find possible locations for the secret message to be embedded. For instance, we may decide to place the hidden message in the pixels that correspond to the cluster centers or those that are a specific distance away from the cluster centers. We begin by employing SIFT and K-means clustering to find and group the key points, then we use quantum circuits to encrypt the secret message and produce a Novel-Enhanced Quantum Representation (NEQR) coding for the message. This technique is an illustration of the Proposed KeyPoints Clustering and Quantum Circuits technique. First, translate the hidden message into binary form. To do this, transform each character in the secret message to its corresponding ASCII code before converting it to an 8-bit binary string. Let's propose that we have a binary secret message (B message) and a quantum circuit $Q$ with $n = 144$ qubits initialized to the $|0\rangle$ state.

A tensor combination of the several qubit states may be used to describe the starting state of the quantum circuit in Eq. (3):

$$|\psi\rangle = |0\rangle \otimes |0\rangle \otimes \ldots \otimes |0\rangle, \qquad (3)$$

Fig. 2. Overview of the process of encoding messages.

The size of the binary secret message divided by $n$ will determine the number of qubits in the quantum circuit that will be created subsequently. This flips the state of that qubit from $|0\rangle$ to $|1\rangle$. The binary secret message is first encoded into the quantum circuit, and then it is changed into a gate to produce the NEQR code for the secret message. This would produce a gate called neqr_code that would reflect the secret message's NEQR code. Then, using the appropriate files, we load this NEQR code into the cover picture and cluster centers. The cover graphic then contains red markers for the cluster centers. Then, according to each pixel value's binary representation,

the binary secret message is concealed in the least significant bit (LSB). This is accomplished by iteratively going through each pixel and changing the value of the blue channel to encode one bit of the binary secret message. A file is then created with the finished stego image. Instead of adding a new signal on top of the cover data, this method provides an extra degree of protection by enclosing the secret message inside the image itself. It is harder for an enemy to discover the hidden message when it is concealed inside the image itself. Furthermore, Fig. 2 illustrates how even if an enemy were to discover its existence, they would still need to understand how it was encoded in order to decode it and obtain the information. Because it is challenging to identify the secret message in the cover image, the system is safe. Each ASCII character's LSB only differs by one bit, making it incredibly challenging to identify. The plan also employs a random scrambling process to further muddle the secret message. The approach is especially effective because it doesn't necessitate sending a lot of extra data. The secret message's ASCII representation is the only extra information that is necessary. NEQR (new enhanced quantum representation), a novel enhanced quantum representation for digital pictures, was put out as an enhancement to the Flexible Representation of Quantum pictures (FRQI) paradigm [12]. Instead of using a qubit's probability amplitude, as in FRQI, the NEQR model stores the basic state of a qubit sequence as the initial gray-scale value for each pixel in an image. The NEQR quantum image can differentiate between several gray scales because the basic states of a qubit sequence are orthogonal [12]. A quadratic speedup in quantum picture preparation, a 1.5X improvement in quantum image compression, and reliable digital image retrieval from quantum images are all demonstrated by NEQR in performance comparisons with FRQI. NEQR also makes it easier to conduct other quantum image operations linked to the picture's grayscale data, such as partial and statistical color operations. As a result, compared to existing models in the literature, the proposed NEQR quantum image model is more adaptable and more suitable for quantum picture representation. The NEQR (new enhanced quantum representation) coding and LSB (least significant bit) replacement are utilized in the proposed method to add another level of security to the encoded communication. While the cover picture's cluster centers are colored red using NEQR coding, the secret message's binary representation is encoded into the pixel values of the stego image using LSB substitution. This provides a way to indicate specific locations where the secret message can be found in the cover image. There are various advantages of using NEQR coding in this project. For instance, it could be harder for an attacker to figure out whether the image contains a secret message. In order to effectively decode the secret message, an attacker has to be familiar with both LSB substitution and NEQR coding. NEQR coding can also give a mechanism to check the message's integrity after it has been encoded. The NEQR code identifies precise spots in the cover picture where the hidden message may be identified (extraction algorithm), and by comparing these marked sites to the original cluster centers, it is possible to identify any alterations made to these locations (for example, as a result of image compression or editing).

**Algorithm 1** Clustering of Proposed KeyPoints and Quantum Circuits

---

**Require:** Cover Image (CI), Secret Message (SM)
1: CI: Cover Image
2: SI: Stego Image
3: SM: Secret Message
4: BSM: Binary Secret Message
5: NEQR: Novel-Enhanced Quantum Representation
6: **Output:** Stego Image, Decoded Message
7: **Step 1: Detect Keypoints in the CI**
8: Load the CI using OpenCV library.
9: Create a SIFT object.
10: Detect keypoints in the CI using SIFT.
11: Save the keypoints information to a file.
12: **Step 2: Cluster the Detected Keypoints**
13: Load the keypoints file.
14: Convert the keypoints information.
15: Create a K-means object with desired clusters.
16: Perform K-means clustering.
17: Save cluster centers to a file.
18: **Step 3: Encode the Secret Message using Quantum Circuits**
19: Convert the SM into binary.
20: Create a quantum circuit with qubits equal to BSM length.
21: **for** each qubit **do**
22:    Check bit value of BSM.
23:    **if** bit is '1' **then**
24:       Apply an X gate.
25:    **end if**
26: **end for**
27: Convert the circuit to a NEQR gate.
28: **Step 4: Encode the Secret Message in the CI**
29: Load the CI again.
30: Load cluster centers.
31: Mark centers in the CI with red color.
32: Create SI copy.
33: Get SI dimensions.
34: Initialize binary index to 0.
35: **for** each pixel in SI **do**
36:    Get pixel value.
37:    **if** binary index $<$ BSM length **then**
38:       Calculate new pixel value.
39:       Set blue channel to original value minus LSB plus BSM bit.
40:       Update SI pixel.
41:       Increment binary index.
42:    **end if**
43: **end for**
44: Save SI to a file.

---

*E. Secret Message Extraction and Decoding*

The original secret message is obtained by extracting the NEQR code from the stego picture. In order to decode the NEQR code, one must first measure the quantum circuit, then take the least significant bit from each pixel value in the stego picture and combine it with other bits to create a binary string. To extract the original secret message, this binary string may then be transformed into a character string. This is how Eq.

TABLE I. STRUCTURAL SIMILARITY INDEX METRICS (SSIM)

| Benchmarks | PSNR |

(4) should be written:

$$b = p \mod 2, \tag{4}$$

## IV. EXPERIMENTAL RESULTS

This section presents the outcomes of evaluations conducted on the proposed steganography system. The system was assessed regarding imperceptibility and robustness using widely accepted techniques such as Peak signal-to-noise ratio (PSNR), SSIM, BER techniques, and histogram analysis.

### A. Context and Parameters

The proposed algorithm included several vital parameters, such as the number of octaves and the number of scale levels within each octave in the scale. In k-mean, the primary parameter is the number of clusters(K) that have been determined and then applied to the set of squares within the double WCSS set for a range of K values. The quantum circuit parameters are the number of qubits determined by the length and state of the binary secret message.

### B. Datasets

In the conducted experiments, a selection of renowned handwriting datasets was employed. These encompass the EMNIST dataset [13], the MNIST database, the IAM handwriting database [14], CASIA Handwriting Database [15], and the Chars74k dataset. These particular datasets furnish an extensive assortment of handwritten characters and digits, thereby serving as a robust testing ground for the algorithm under scrutiny.

### C. Imperceptibility

We evaluated the imperceptibility of our steganography system using three metrics: PSNR, SSIM, and histogram analysis. Image quality is quantified by the Peak Signal-to-Noise Ratio (PSNR) [16]. The ratio of the signal's highest achievable power to the noise's power affects the accuracy of the representation [16]. The following Eq. (5). can be used to determine the PSNR, which is typically reported in dB

$$PSNR = 10 \cdot \log_{10}\left(\frac{MAX^2}{MSE}\right), \tag{5}$$

Where MAX is the maximum possible pixel value of the image (e.g. 255 for 8-bit images) and MSE is the mean squared error between the cover image and the stego image. We calculated the PSNR values for several datasets using this equation (Table I).

The Structural Similarity Index Metrics (SSIM), measures the structural similarity between two images. It is designed to capture the perceived change in structural information between two images. The formula for determining the SSIM is as follows [17](6):

$$SSIM(x,y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{xy} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)}$$

c represents the cover image, and s represents the stego image. $\mu_c$ and $\mu_s$ are the average pixel values of images $c$ and $s$, respectively. These values are used to compare the luminance of the two images. $\sigma_c^2$ and $\sigma_s^2$ are the variances of images $c$ and $s$, respectively. These values are used to compare the contrast of the two images. $\sigma_{cs}$ is the covariance of images $c$ and $s$. This value is used to compare the structure of the two images. We calculated the SSIM values for several datasets using this equation. And since the resulting number of SSIM ranges from -1 to 1, with one indicating that the cover and stego images are identical. A higher SSIM value that achieved (0.99) indicates that the structural similarity between the cover and stego images is high.

### D. Histogram Analysis

It was performed to evaluate the distribution of pixel intensities in the stego images compared to the original cover images. The results displayed in Fig. 3 confirms that the histograms of the cover and the image of Stego were very similar since our steganography system does not introduce significant changes to the histograms of the images. To determine the differences between cover images and stego, we performed a histogram analysis of the pixel difference (PDH) between document images, handwritten manuscripts four benchmarks: man from Standard test images(c1), Tobacoo800(c2), L3iDocCopies(c3) and EMNIST(c4) and the resulting stego images-histogram, respectively (s1, s2,s3,s4) man, Tobacoo800, L3iDocCopies and EMNIST (Table II). The difference values between the cover images and the resulting stego were minimal, which confirms the superiority of our proposed approach in achieving the minimum level of distortion during the data embedding. The images show that our proposed system has a minimal visual impact on the paper, which preserves readability while making it difficult to determine the exact locations of the embedded message. Fig. 4 presents document images and stego manuscripts resulting from the use of the proposed system in including the secret message for three types of dataset used, where it can be seen that the documents remain clear because our system did not affect the image of the document in a way that prevents discovering the location of the secret message being included in it. In addition, the evaluation of our proposed system includes a comparison between SSIM and PISNR in Fig. 5. These results were obtained using ten images from the data set used in evaluating the system, including images of handwritten documents and manuscripts, which show that 54.62 and 0.99 are the average values of PSNR and SSIM of our proposed system, respectively. The maximum values of both PSNR and SSIM are 1, and thus our approach produces high quality images of Stego documents. Fig. 6 presents a comparison of the PSNR of our proposed system with related works, including standard least significant bits (LSB) [3], [Li, Panchi, and Aiping Lu] [7], and [Zhou, Ri-Gui, et al.] [4].

Through this comparison, it can be seen that the method of [3] is superior to other related researches, except for the technique used in Our proposed approach. This confirms the validity of high image quality, which reduces the chances of detecting the Human Visual System (HVS).

TABLE II. COVER-STEGO-DOCUMENT PIXEL DIFFERENCE HISTOGRAM ANALYSIS

| Benchmark | Cover image | Stego image | (PDH) analysis |
|---|---|---|---|
| Standard test images (Man) | C1 | S1 | 0.18 |
| Tobacco800 | C2 | S2 | 0.21 |
| L3iDocCopies | C3 | S3 | 0.22 |
| EMNIST | C4 | S4 | 0.29 |

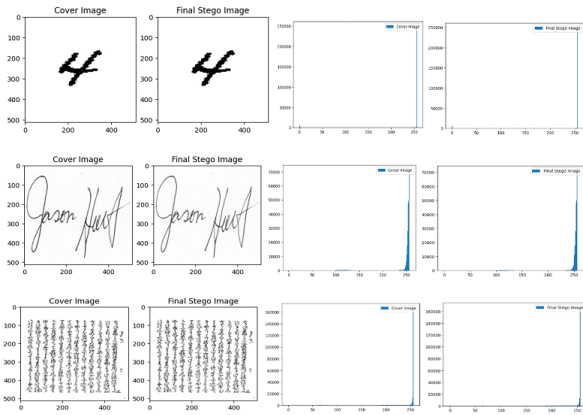

Fig. 3. Histograms of similarity the cover and stego images.

### E. Robustness Evaluation

Due to possible rotational distortion brought on by printing and scanning disturbances, the original form of the encoded document must be restored before hidden message detection. That the accuracy ratio of extracted message bits is evaluated using the Bit Error Ratio (BER), which is also used further to evaluate the robustness of the extracted secret message. The Bit Error Rate (BER) measures how accurately a secret message can be extracted from a stego image. It is the ratio between the number of incorrect bits in the extracted message and the total number of bits in the original message [18]. A lower BER value indicates a better resistance to errors or alterations in the stego image as referred in Table III.

TABLE III. BIT ERROR RATE (BER) FOR DIFFERENT BENCHMARKS

| Benchmarks | BER |
|---|---|
| Lena | 0.0037 |
| Baboon | 0.00601 |
| Cameraman | 0.0031 |
| Tobacco800 | 0.00234 |
| MNIST | 0.0027 |
| IAM dataset | 0.0073 |
| CASIA Handwriting dataset | 0.00741 |
| EMNIST | 0.0041 |
| Signature dataset | 0.0087 |
| Dataset-1 | 0.0076 |

The table demonstrates that our steganography system consistently produced low BER values across multiple datasets, showing that the bit error rate is minimal and the secret

Fig. 4. Stego documents samples

message can be accurately recovered from the stego pictures. In conclusion, the testing findings from our steganography technology demonstrate its high levels of stealth and durability. The method can conceal information in high-quality and structurally comparable images with a low bit error rate.

Fig. 5. PSNR and SSIM of ten stego document image quality.

### F. Comparison with Related Works

To evaluate the performance of our steganography method compared to the related works, we conducted experiments using specific datasets and measured the PSNR values. The results are summarized in the Table IV:

TABLE IV. COMPARISON AMONG VARIOUS WORKS AND OUR PROPOSED WORK

| Dataset | Our Proposed Work | Wang et al. (3) | Li et al. (7) | Zhou et al. (4) |
|---|---|---|---|---|
| Lena | 54.2827 | 54.59 | 50.58 | 50.21 |
| Baboon | 50.674221 | 54.59 | - | - |
| Cameraman | 51.410 | - | - | 50.19 |

As can be seen from the table, our steganography system achieved competitive PSNR values compared to existing methods on several datasets. These results indicate that our system can hide secret messages in images with high image quality. In summary, our experimental results show that our

steganography system achieves high imperceptibility in terms of PSNR. The system can hide secret messages in images with high image quality as measured by this metric.

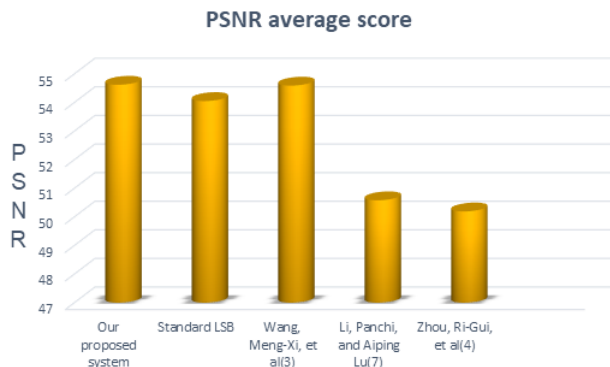

Fig. 6. A comparison of the proposed approach based on peak signal to noise ratio PSNR with state of the art methods.

## V. Conclusion

In this paper, we presented a novel steganography system that combines quantum circuits and classical image processing techniques to hide secret messages in images. Our system uses the Scale-Invariant Feature Transform (SIFT) algorithm to detect keypoints in the cover image and K-means clustering to group the detected keypoints into clusters. The secret message is then encoded using quantum circuits, and a NEQR code is created for the message. The NEQR code is embedded in the cover image by modifying the cluster centers' pixel values. This quantum error-correcting code can be used to protect secret messages from noise. The stego image is then created by combining the modified cover image with the NEQR code. The scheme was implemented using the Python programming language and the qiskit library. We evaluated our steganography system regarding imperceptibility and robustness using several metrics. Our experimental results show that our system achieves high imperceptibility as measured by PSNR, SSIM, and histogram analysis. The system also achieves high robustness as measured by BER. Our steganography system provides a novel and practical approach to hiding secret messages in images with high imperceptibility and robustness. The system has potential applications in secure communication and data hiding.

# Development of Interactive Data Visualization System in Three-Dimensional Immersive Space

Shah Murtaza Rashid Al Masud, Homaira Adiba, Tamzid Hossain, Aloke Kumar Saha, Rashik Rahman*

Computer Science and Engineering, University of Asia Pacific, Dhaka, Bangladesh

*Abstract*—Today's data-driven environments require innovative tools and methods to analyze and present data. The growth of data across many domains and remarkable technological advances have necessitated a shift from 2D data representations. The rapid growth in dataset scale, variety, and speed has revealed the limitations of conventional charts and graphs. Significant progress has been made in the domain of interactive, three-dimensional data visualizations as a means to address this challenge. The integration of Virtual Reality (VR) and Augmented Reality (AR) technologies enables users to achieve a heightened level of immersion in a simulated environment, where data is transformed into physical and interactive creatures. Recent research in the domain of immersive analytics has provided evidence that virtual reality (VR) and augmented reality (AR) technologies possess the capacity to provide succinct multiple layouts, facilitate collaborative data exploration, enable immersive multiview maps, establish spatial environments, enhance spatial memory, and enable interactions in three dimensions. The primary aim of this research is to design and implement a sophisticated data visualization system that integrates the development of a data pipeline within the Unity 3D framework, with the specific goal of aggregating data. The resulting system will enable the presentation of data from CSV files within a three-dimensional immersive environment. The prospective ramifications of this development have the capacity to yield good effects in diverse domains, including E-commerce analysis, financial services, engineering technology, medical services, data analysis, and interactive data display, among others. The proposed system presents a methodical framework for the development of a 3D data visualization system that integrates virtual reality (VR) technologies, Unity, and Python, with the aim of redefining the process of data exploration within a VR environment. This paper examines the integration of continuous testing methodologies within the context of Python API and virtual reality (VR) environments. It also allows for the creation of an interesting and immersive experience that meets user needs.

*Keywords*—*Immersive space; data visualization; VR system; python API; unity 3D*

## I. Introduction

The need for reliable tools and cutting-edge methodologies to analyze, assess, and present datasets has witnessed a substantial increase in the modern era. Technology and the availability of massive data sources across many disciplines enabled the growth. Two-dimensional (2D) charts and graphs are inadequate for revealing intricate patterns and relationships in increasingly large and complex datasets. As the quantity, variety, and speed of data continue to expand at an exponential rate, this constraint becomes more evident.

To address the aforementioned formidable task, significant progress has been made in the field of three-dimensional (3D) interactive data visualization systems. The emergence of these novel technologies has facilitated the ability of researchers, analysts, and other professionals to fully immerse themselves in a domain where data points are converted into tangible entities that can be actively engaged with. The current transformation is helped by the combination of augmented reality (AR) and virtual reality (VR) technologies, which allow individuals to interact with data in a way that is both intuitive and fascinating. Recent studies have shown the significant benefits that virtual reality (VR) and augmented reality (AR) can potentially provide in certain data exploration scenarios, as demonstrated by the existing collection of research in the field of immersive analytics in recent times. The advantages mentioned above encompass a diverse array of subjects, such as the utilization of small multiple layouts [1], the facilitation of collaborative data exploration [2]–[6], the implementation of immersive multiview map systems [4], [7], the provision of boundless spatial environments [1], [7], [8], grouping (clustering) and spatial (dimension reduction) [9], [10], the enhancement of spatial memory retention [11], and the enablement of three-dimensional spatial interactions [3], [10], [12], among various other benefits.

The primary objective of this research endeavor is to introduce and showcase an advanced data visualization system that effectively harnesses the vast capabilities of a three-dimensional immersive environment. This objective is achieved through the integration of computer graphics, data visualization, and human-computer interaction in a mutually advantageous manner. The objective is to provide an extensively interactive setting that facilitates the exploration and analysis of data beyond the limitations imposed by conventional two-dimensional representations. By providing users with the ability to deeply engage with the data, this novel technology aims to exceed the constraints of traditional visualization methods, therefore enhancing users' understanding and facilitating informed decision-making.

The contribution of the research paper can be summarized as follows:

- The proposed system effectively accomplishes the objective of developing a superior user interface within the domain of 3D data visualization, thus attaining excellence in this field. By blending simplicity and accessibility, people of all backgrounds and technological abilities may easily interact with data in an immersive 3D setting. This work serves to enhance the inclusivity and user-friendliness of data visualization.

- The presentation and implementation of advanced visualization techniques tailored for three-dimensional (3D) scenarios have made a significant and noteworthy

contribution. The application of customized visualization methods enhances the representation of complex data relationships and patterns that could otherwise provide difficulties in their recognition. This feature enables users to gain valuable insights from their data within a three-dimensional framework.

- The proposed system facilitates an enhanced level of interactivity by incorporating a wide range of interactive components. This enables users to actively engage with and examine real-time data within a fully immersive 3D setting. The incorporation of functionalities such as data filtering, grouping, and linking facilitates users in effectively managing and analyzing their datasets. The significance of this work resides in the provision of robust tools that enable users to manipulate and explore data effectively within a three-dimensional (3D) spatial context.

- The research work provides a practical contribution by elucidating the process of integrating a Python application programming interface (API) for the purpose of aggregating data into the Unity 3D development environment. This interface enables the smooth conversion of data from a Comma-Separated Values (CSV) file into a three-dimensional (3D) visualization environment, thereby augmenting the level of immersion and engagement. This study focuses on a crucial element of data transmission, aiming to facilitate a seamless and effective transfer from two-dimensional data sources to three-dimensional representation.

The subsequent sections of the document are organized in the following manner: Section II provides an overview and analysis of the existing literature and research studies that are relevant to the topic. The approach adopted is outlined in Section III, while Section IV gives a detailed explanation of the dataset. Section V provides a detailed explanation of the experimental configuration and the methodology employed for interacting with the data. Section VI provides an in-depth look of qualitative results, while Section VII encompasses the concluding remarks. Additionally, Section VIII outlines our upcoming research in this field. The remaining section consists of acknowledgment and references.

## II. RELATED WORKS

Numerous research inquiries have been conducted in the realm of immersive technologies and data visualization, thereby enhancing our comprehension of the various facets and potentialities of this emerging topic. The comprehensive and innovative research carried out over a prolonged period has greatly clarified the numerous applications of immersive technology and its ramifications across several fields of study. This summary offers a brief outline of the significant contributions made by researchers in these studies, clarifying their primary discoveries and ramifications.

In 2017, Ens, Barret [8] introduced the concept of Situated Analytics Interfaces (SAIs) on Head-Worn Displays (HWDs). Their groundbreaking work clarified the advantages of SAIs over traditional mobile interfaces as well as the implementation difficulties present in this developing field. In 2019, Taehoon K. *et al.* [13] conducted a thorough investigation

of the effectiveness of 3D immersive stereoscopic virtual reality technology in producing tactile sensations. Their research produced a significant finding: when compared to the haptic 3D visualization method shown on traditional 3D flat screens, the haptic 3D visualization method presented in a 3D stereoscopic space through headsets displayed superior qualities of intuitiveness, accuracy, and immersion. This result highlighted the immersive technology's transformative potential in boosting sensory engagement with data. Utilizing this knowledge, Alfaro, Luis, *et al.* [14] investigated the state-of-the-art immersive technologies, exploring their significant contributions to the creation of cognitive knowledge. Their research emphasized the potential for immersive technology to completely transform pedagogical methods while illuminating the crucial role it plays in the creation of teaching and learning activities.

Liu *et al.* [1] thorough investigation of the functionality and preferences of various tiny multiples layouts in immersive settings was carried out in the following year of 2020. Their thorough analysis, which covered designs including Flat, Quarter-Circle, and Half-Circle, with a focus on easing combinatorial difficulties through horizontal curvature, yielded insightful results. Their meticulous study did, however, recognize the intricacy of user preferences and performance in immersive tiny multiple visualizations and encourage further investigation of other elements. Simultaneously, Lee *et al.* [2] showed the benefits of utilizing shared surfaces and spaces in the cooperative field of data visualization. Their study emphasized how these collaborative environments create greater spatial awareness, increased collaboration, and improved communication. Lee and colleagues wisely understood the necessity for continued validation and further uses of shared surfaces and spaces in addition to their findings. In-depth research on immersive multiview map systems was conducted by Satriadi, K. A. *et al.* [7], who clarified their potential advantages for tasks including map browsing, search, comparison, and route-planning. While they correctly stressed the need for more study to support their findings and compare the effectiveness of immersive multiview maps to conventional single-view exploration techniques, their observations shed light on the exciting prospects of these systems.

Shifting the focus to navigation strategies in virtual worlds, Yang, Y. *et al.* [15] investigated the effectiveness of two different approaches: overview+detail and zooming in 3D scatterplots. Their comparison investigation, which covered four situations, shed light on the subtle differences between user engagement and comprehension in immersive environments. Yang, Y. *et al.* [3] research on visualization techniques was expanded upon, notably about the use of area-linked data in immersive settings. They gave important insights into the relative efficacy of conventional 2D choropleth maps versus 3D prism maps and colorful prism maps in virtual reality (VR) through thorough controlled tests.

The study of the difficulties in this new field by Ens, B. *et al.* [16] in 2021 was a turning point in the development of immersive analytics. Incorporating visualization, immersive environments, and human-computer interaction, their article covered 17 different difficulties that were categorized into four main categories. These difficulties paved the way for additional research and advancement in the area of immersive

analytics. The dynamics of collaboration modes and user position arrangements in a VR learning environment supporting immersive collaborative tasks were investigated concurrently by Chen, L. *et al.* [17] Their findings suggested that in cooperative VR learning settings, shared views and particular user locations could significantly improve task performance and user experience.

Reichherzer *et al.* [11] conducted a study in the field of law to explore the potential applications of immersive virtual reconstructions, particularly virtual reality (VR), in aiding juries during trial hearings. The study unveiled fascinating possibilities for the integration of immersive technology inside the court system. Newbury *et al.* [12] conducted a research investigation on the concept of embodied engagement in immersive maps. Their study shed light on the perceptual intricacies associated with maps as objects in three-dimensional space, as well as the utilization of consistent physical principles during the process of map design.

In the year 2022, Luo, W. *et al.* [18] initiated a scholarly discourse concerning the transformative capacity of augmented reality (AR) in reshaping forthcoming work environments. The researchers conducted a meticulous investigation on the impact of office environments and work practices on the organization of virtual material, specifically about the process of sensemaking using augmented reality. Liu *et al.* [19] conducted a comprehensive examination of immersive approaches for interactive Information Visualization (InfoVis), including diverse data kinds. The user did not provide any text to rewrite. The researchers' findings indicated potential shifts in data browsing behaviors through a comparison of immersive and non-immersive data visualization methods. It is hypothesized that non-immersive approaches may supplant immersive techniques in handling extensive data sets.

The aforementioned collaborative efforts exemplify a diverse array of research initiatives that have contributed to the discourse around immersive technologies and data visualization. These endeavors have yielded valuable insights, shedding light on many aspects of this rapidly evolving field and paving the way for novel avenues of investigation.

## III. METHODOLOGY

Fig. 1. (a) 2D DataBlocks and (b) 3D Immersive Space View

The principal methodology adopted in this research involves the development and application of a three-dimensional data visualization system. To address this matter, a block dimension and a layout design have been devised. The chosen configuration for the immersive area depicted in Fig. 1 involves a 2D block dimension and a 3D horizontal layout design. This arrangement aims to expand the possibilities for interactive data exploration and analysis within the dynamic realm of a 3D immersive environment. The aforementioned methodology signifies a fundamental change in our strategies for interacting with and deriving insights from intricate datasets, hence creating a significant impact on the field of data visualization. The system makes use of the Meta Quest 2 virtual reality (VR) headset, which has been specifically created to use the Python API and Unity software in order to provide data in a visually realistic manner.

As depicted in Fig. 2, the methodology is structured into three discrete subsections, each of which centers on a crucial facet of the system's development and implementation. The subsections are the following:

*1) Python API:* The utilization of a data backend API is used to streamline the process of data processing and retrieval. The Pandas library, which is a powerful tool for manipulating data, is employed to do data processing. The utilization of Flask, a web framework, is incorporated into the codebase to facilitate the transformation of the processed data into an API that can be effectively utilized. JSON (JavaScript Object Notation) is widely regarded as the optimum format for efficient data interchange, particularly for rapid data transportation.

The data frame is imported from a CSV file, serving as the primary data source. The Flask framework hosts two distinct APIs inside a single application. The first API offers a compilation of numeric data columns that may be plotted and are easily accessible. The inclusion of a user-defined column as a route parameter in the second API streamlines the process of user-driven data selection.

Upon completion of the data aggregation process, the selected column becomes linked to the predetermined column labeled "Major Category". The plot data gathered and given consists of aggregated data points, which comprise the necessary index values for constructing a bar plot. The accumulated data is advantageous in determining the relative proportions for pie charts.

The primary objective of these API is to collect and analyze data before transmitting it to the Unity platform to generate graphical representations.

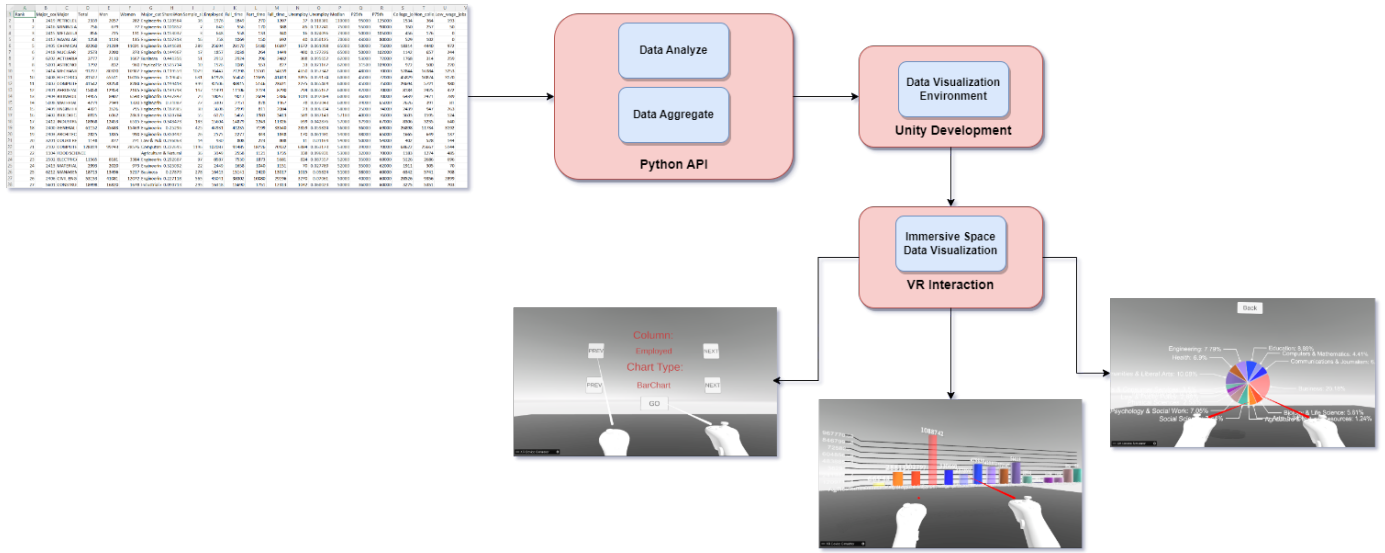
*2) Unity Development:* Within the Unity environment, the utilization of 3D prefabricated objects is employed to graphically represent bar charts and pie charts in a manner that is highly compatible with the VR context. The prefabricated structures serve as the foundational framework for the representation and interpretation of data within the immersive virtual reality setting. The data acquired from the Python application programming interfaces (APIs) is dynamically integrated into the Unity project at runtime. The process of accessing pertinent data is expedited through the utilization of user-input columns as integral elements within URLs. The data acquired through the application programming interface (API) is associated with the pre-existing objects within the Unity software environment. A dictionary is employed as a data structure to aid the organizing of data by establishing a relationship between columns and their related values. The


Fig. 2. Proposed data flow and unity visualization model in immersive space.

utilization of data mapping is employed in order to ensure that the preconstructed three-dimensional representations accurately and efficiently display the selected data. Ultimately, this process reaches its completion in the production of the expected data visualizations.

*3) VR Interaction:* The incorporation of Virtual Reality (VR) technology into the Unity project represents a crucial milestone in the pursuit of creating a fully immersive data visualization experience. The project has been designed to facilitate VR interactions, with a specific emphasis on the Oculus VR platform. The incorporation of VR controllers serves to augment the user's experience within the immersive environment. The XR Interaction Toolkit plays a crucial role in enabling virtual reality interactions and behaviors. The process of continuously testing and gathering feedback from users is of utmost importance in the iterative refinement of a system, as it aids in enhancing its usability and alignment with the desired objectives. The use of the Oculus VR platform is employed for the implementation of the data visualization project that relies on virtual reality technology, guaranteeing compatibility and achieving optimal performance inside the virtual reality environment.

This study presents a systematic approach to developing a 3D data visualization system that effectively combines Python API, Unity, and VR technologies. This methodology aims to offer a new and efficient way of data exploration and presentation inside a virtual reality setting by employing meticulous data processing, dynamic data transmission, and immersive visualization techniques. The process of continuous testing and refining plays a crucial role in ensuring that the system remains in line with user expectations and provides a captivating immersive experience.

## IV. Dataset

The dataset included in this study is derived from an article entitled "The Economic Guide to Picking a College Major", accessible on the well-recognized data-centric platform 538.

The information under consideration offers significant statistical insights into the median incomes linked with different college degrees. The dataset utilized in this study was carefully selected and retrieved from the previously stated publication. It serves as a solid basis for the empirical analysis conducted in this research. The dataset is supplied in the well-recognized CSV format and was obtained from a publicly accessible GitHub repository[1].

A notable characteristic of this dataset is its specific emphasis on individuals who have just completed their education. The intentional emphasis on individuals who have just completed their education is supplemented by the incorporation of gender-specific data, making it a highly beneficial tool for undertaking a thorough and diverse investigation.

The dataset illustrates the substantial financial disparities that might arise as a result of selecting a certain academic degree. It contains a thorough structure consisting of 21 attributes and 173 rows, providing a wealth of information about the economic aspects of college major choices. The structural complexity of the dataset not only facilitates a comprehensive analysis of median wages but also facilitates the identification of possible patterns and complexities that may arise among different academic disciplines, particularly among those who have just graduated from college.

## V. VR Prototype Implementation

The virtual reality prototype that has been constructed in this study serves as a tool for investigating the design aspects of immersive spatial data display.

### A. Experimental Setup

In our study, we employed the Oculus Meta Quest 2, a room-scale VR device, together with the Unity version 2021.3.16f1. The prototype operates on a personal computer

---

[1]https://github.com/fivethirtyeight/data/tree/master/college-majors

running the Windows 10 operating system. The computer is equipped with an Intel(R) Core(TM) i7-7500U CPU, which has a clock speed of 2.70GHz and can reach a maximum speed of 2.90GHz. The prototype also utilizes VRTK XR interaction to enable interactive components.

### B. Interacting with the data

The proposed system aims to combine a framework for visualizing three-dimensional data with a virtual reality system. The system provides users with a menu-based interface that allows them to select attributes from a dataset stored in a CSV file. Users can also choose the required chart styles to visualize their data in a personalized manner. The user's input demonstrates a connection between the Python API and a specific attribute called "Major Category".

This feature serves to identify the main fields of study undertaken by graduates. To improve the narrative coherence, it is important to employ a consistent structural element. Based on the provided options, the aggregate data is utilized to generate the required charts.

## VI. RESULT AND DISCUSSION

This section presents the findings of this particular research study. Based on the information provided in Section IV, it can be inferred that the dataset under consideration pertains to recent graduates, encompassing 21 attributes and 173 rows. We chose to analyze the qualities of "Employed" and "Full-time" employed among the graduates and represented the data using both a bar chart and a pie chart.

Within this system, the user has the ability to choose a certain column and chart type based on their preferences.

In Fig. 3, the user chooses the "Employed" column and selects the Bar Chart type. This option leads to the creation of a Bar chart plot, as seen in Fig. 4.

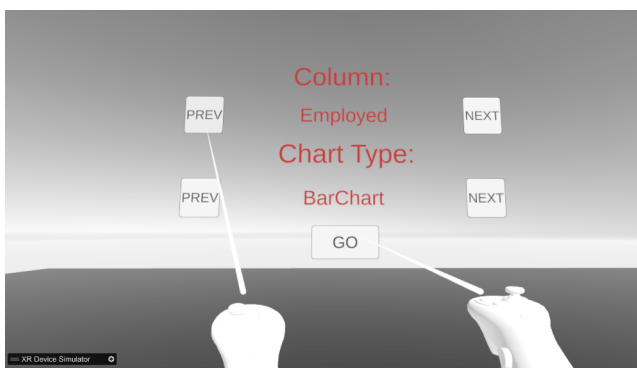

Fig. 3. Selecting employed column and bar chart type.

In Fig. 5, the user opted for the same column as previously and selected a different chart style, namely, a pie chart. Consequently, Fig. 6 displays the final plot in the form of a pie chart.

In Fig. 7, the user opted for the "Full-time" column and picked the Bar Chart type. Subsequently, Fig. 8 displays the outcome in the form of a Bar chart.

Fig. 4. Bar chart for employed graduates.

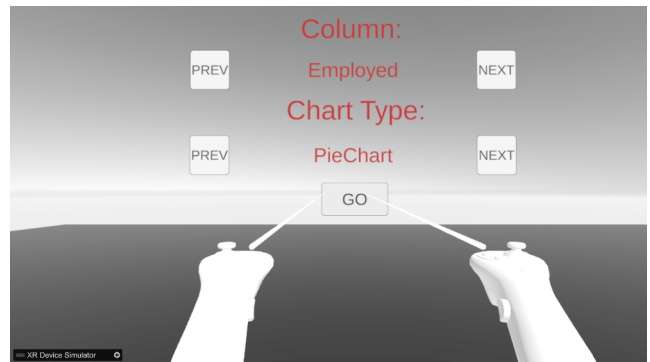

Fig. 5. Selecting "employed" column and pie chart type.

Fig. 6. Pie chart for employed graduates.

In Fig. 9, the user selected the Pie Chart type using the same column as previously. Subsequently, Fig. 10 displays the outcome in the form of a Pie chart.

## VII. CONCLUSION

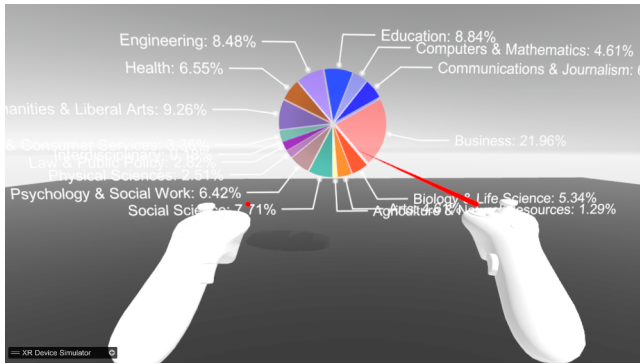
With the swift progression of technology, our research has effectively made the transition from conventional two-dimensional (2D) data representations to immersive three-dimensional (3D) data visualization. The solution we have developed provides users with an interactive platform, that allows them to access and visualize datasets within a 3D immersive environment using Python APIs. The objectives have been successfully achieved through the expansion of


Fig. 10. Pie chart for full-time employed graduates.

Fig. 7. Selecting "full-time" column and bar chart type.

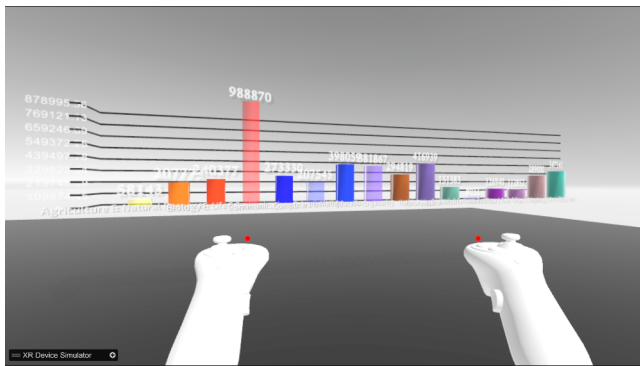

Fig. 8. Bar chart for full-time employed graduates.

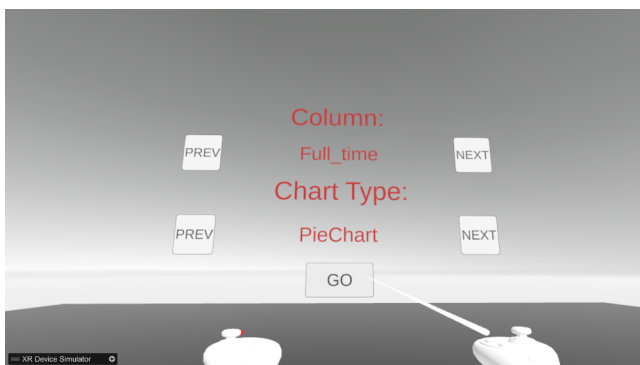

Fig. 9. Selecting "full-time" column and pie chart type.

interactive data exploration opportunities within the dynamic 3D immersive arena.

## VIII. Future Work

Our forthcoming study intends to improve the visualization of data by integrating a broader array of interactive chart formats. Furthermore, our objective will be to promote collaboration through the establishment of a communal immersive environment that enables multiple users to engage in data exploration and analysis concurrently.

DeepVerse Technology (Shanghai) Ltd, ShangHai, China[5]

*Abstract*—The use of social media has proliferated dramatically in recent years due to its increasing reach and ease of use. Along with this enlarged influence of social media platforms and the relative anonymity afforded to content contributors, an increasingly significant proportion of social media is composed of untruthful or "fake" news. Hence for various reasons of personal and national security, it is essential to be able to identify and eliminate fake news sources. The automated detection of fake news is complicated by the fact that most news posts on social media takes very diverse forms, including text, images, and videos. Most existing multimodal fake news detection models are structurally complex and not interpretable; the main reason for this is the difficulty of identifying essential features which characterize fake social media posts, leading to different models focusing on multiple different aspects of the news detection task. In this paper, we show that contrasting the *different and similar* (DS) features of social media posts serves as an important identifying marker for their authenticity, with the consequence that we only need to direct our attention to this aspect when designing a multimodal fake news detector. To address this challenge, we propose the Fine-Grained Differences-Similarities Enhancement Network (FG-DSEN), which improves detection with a simple and interpretable structure to enhance the DS aspect between images and text. Our proposed method was evaluated on two different language social media datasets, Weibo in Chinese and Twitter in English. It achieved accuracies 3% and 3.8% higher than other state-of-the-art methods, respectively.

*Keywords—Fake news detection; social media; pre-training model; multimodal; transformer*

## I. INTRODUCTION

Despite the challenges posed by the pandemic and current economic climate, virtual social media platforms have flourished in recent years, resulting in a significant increase in information volume. A large number of consumers tend to acquire news exclusively through social media platforms instead of conventional sources. However, most platforms lack timely and effective supervision, making it easy for people to publish unverified news [1]. Furthermore, in contrast to the linear dissemination mode of traditional media, social media's dissemination characteristics facilitate the rapid spread of information, directly resulting in explosive growth of disseminated fake news and subsequently broader negative impacts with greater potential for social harm. Early research on fake news often used a vague definition that could include hoaxes, satires, or clickbaits as fake news. This study describes fake news as "news articles that are intentionally and verifiably false and could mislead readers" [2].

Apart from its rates of spread, social media news items are often multimodal and include text, images, and videos. Posts containing multimodal information are more appealing to readers, and studies have shown that news with images is, on average, 11 times more probable to be shared than text-only news [3]. However, the multimodal of most social media news items poses a significant obstacle to fake news detection [4]. The determination of news veracity based solely on text or images brings a challenge. Therefore, the development of models capable of integrating multimodal information is crucial for effective fake news detection.

Fake news has been a concern for researchers for some years. Due to the increasing realization of fake news' effects on society, work on fake news detection has dramatically intensified in recent years [5], [6]. With multimodal features proving effective in enhancing detection rates, so has research on fake news detection increasingly focussed on multimodal integration. Most multimodal methods involve feature interactions that are very complex, with multiple overlapping fusion modules, with the consequence that the final models are often very involved and are not amenable to extensions or improvements. This also leads to the difficulty in explaining these models, and it tends to neglect a very important feature of fake news: the differences and similarities between the text and image components of fake news [7]. This, in turn, contributes to the suboptimal performance of fake news detection. An emphasis on considering these differences and similarities can highlight distinctions between fake and real posts, thereby improving the discriminative power of the final classifier.

Based on these considerations and in contrast to most prevailing fake news detection networks, our work uses a simple structure to extract similar and dissimilar information among different modalities to enhance features and improve detection performance. Our structure is similar to the co-attention transformer [8], [9], but the performance is better. It can establish connections between similar and dissimilar points among features of different modalities while ensuring the purity of the original information to achieve the best detection performance. Earlier studies either overlooked this crucial connection or employed overly intricate interaction modules that compromised the integrity of the original information. The detection accuracy is at least 3% higher than the best method on two datasets.In concrete terms, we introduce the *Fine-Grained Differences-Similarities Enhancement Network (FG-DSEN)* to detect fake news. The architecture comprises four main components: two fine-grained feature extractors, a differences-

similarities enhancement network, and a fake news classifier. Our work makes the following contributions:

- We propose an effective detection method for fake news that emphasizes the differences and similarities (DS) between true and fake news items in terms of their textual and visual modalities. We find that these predominant features serve as accurate evaluation metrics for truthfulness. Our method avoids overcomplicating the task by requiring only text and image information.

- To effectively detect fake news via DS detection, we design a deep learning model called FG-DSEN. The proposed method extracts fine-grained features using an optimized pre-trained model. The differences-similarities information of these features are enhanced and used for classification, allowing the model to achieve higher accuracies than the baselines.

- We evaluate on two standard datasets and is able to achieve state-of-the-art performance on both. For purposes of comparison we have included a significant number of SOTA baselines from very recent works. We also perform extensive ablation studies on our model and conclude that its efficacy is indeed due to emphasis on the difference-similarity contrast of extracted news features.

The paper is structured into five sections. Section I provides an introduction to the study. Section II summarizes early research in the field. Section III provides a detailed description of the proposed methodology. Section IV covers the experimental aspect, including datasets introduction, parameter settings, comparative and ablation experiments, as well as corresponding result analysis. Finally, Section V concludes the work and discusses future directions.

## II. RELATED WORK

This study investigates approaches to detecting fake news using machine learning and deep learning methods, and additionally categorizing the latter into single-and multimodal methods.

### A. Machine Learning-based Fake News Detection

Early works on fake news detection typically employed hand-crafted features combined with machine learning models. Among the widely studied hand-crafted features are text-specific content features such as punctuation [10], [11], [12], textual sentiment polarity [3], [13], and personal pronouns [3], [10], [11]. Propagating features, such as the root degree in the propagation tree and the average degree of leaf nodes [3], [10], are significant indicators. User features like user's following and followed [3], [10], [12], [14] and account profile completeness [15]. These hand-crafted features can then be utilized to train machine learning models, including decision trees and SVMs. Castillo et al. [10] crawled hot news on Twitter for approximately two months and constructed a decision tree for news credibility determination. Pérez-Rosas et al. [11] manually curated features related to language, including punctuation, psycholinguistic features, and syntactic

rules. These methods necessitate researchers to possess extensive knowledge of linguistics and to know which features effectively distinguish true from false news, which is a difficult task.

### B. Deep Learning-based Fake News Detection

*1) Single-modal approaches to fake news detection:* With the advent of deep learning models, researchers have discovered that they outperform traditional machine learning models and no longer necessitate intricate hand-crafted features. Kaliyar et al. [16] introduced a deep convolutional neural network (FNDNet) for fake news detection, which takes as input a word embedding vector produced by GloVe. Sahoo et al. [17] present a technique for detecting the authenticity of news content by combining user profiles. The exBAKE model presented by Jwa et al. [18] uses weighted cross-entropy to classify the data, which mitigates the issue of data imbalance in BERT [19].

*2) Multimodal approaches to fake news detection:* News images contain abundant information, so an increasing number of researchers are focusing on fake news detection methods that fuse multimodal features. Singhal et al. [20] proposed Spotfake, a multimodal approach for detecting fake news, which employs VGG-19 to extract image features and BERT to extract textual features. Wang et al. [21] proposed an Event Adversarial Neural Network (EANN) that utilizes event discrimination as an auxiliary task. The att-RNN framework proposed by Jin et al. [22] leverages an attention mechanism to enhance modal information, integrates social context features, and feeds the fused multimodal information into the classifier for classification. Wu et al. [23] proposed a Multimodal Co-attentive Networks (MCAN), and Qian et al. [24] proposed a Hierarchical Multi-modal Contextual Attention Network (HM-CAN). Both approaches utilize transformer-based attention modules to combine features from various modalities or layers, thereby aiding detection. Jing et al. [25] presented a Multi-modal Progressive Fusion Networks (MPFN) to retain shallow information by sampling and fusing features at different levels. Although previous works have achieved superior results in fake news detection tasks, they neglected the extraction of fine-grained features and mapping alignment and failed to exploit similarities and differences of features when fusing in depth.

## III. METHODOLOGY

### A. Model Overview

The present study establishes the task of detecting fake news as follows: given a multimodal news post $S = (T, V)$ containing text $T$ and images $V$. Training a model then implies a mapping $f : S \rightarrow Y$, where our predefined classes $Y \in \{0, 1\}$ with $Y = 0$ implying that a news post $S$ is fake and $Y = 1$ implying that it is true. More details about the model will be provided in the later subsections.

The proposed FG-DSEN is shown in Fig. 1. The model consists of

- Two fine-grained feature extractors: We utilize the VGG-19 [26] and 1D convolution to extract fine-grained features from images; for text we employ BERT and a BiLSTM;

- A differences-similarities enhancement network: Two self-attention modules are applied in parallel to extract feature similarities and differences. The attention module is able to capture correlation between these;

- A fake news classifier: We connect a simple fully-connected feedforward network to perform classification of the fused features.

Fig. 1. The proposed model architecture.

### B. Text Feature Extractor

Fake news detection conventionally employs static word embedding models. In our case, in order to context information explicitly into account, we use a pre-trained BERT model which has excellent performance in dynamic word embedding tasks. Texts $T$ of social media news posts have the general structure $T_i = [x_1, x_2, \ldots, x_n]$, where $x_j \in T_i$, $j \in \{1, 2, \ldots, n\}$ is the $j$th word in the $i$th text corpus. We then obtain the dynamically extracted word vector, representing the fine-grained word-level features, via a BERT model. These are input into a BiLSTM to generate the text fine-grained feature $F^T$ containing global text information, as shown in Eq. (1).

$$F^T = \text{BiLSTM}\left(\text{BERT}\left(t_i; \Theta_{\text{BERT}}\right); \Theta_{\text{BiLSTM}}\right), \quad (1)$$

where $\Theta_{\text{BERT}}$ and $\Theta_{\text{BiLSTM}}$ are the BERT and BiLSTM model parameters, respectively.

### C. Image Feature Extractor

We utilize the VGG-19 as an image feature extractor by eliminating the average pooling and classification layers. We also remove the final 2D Max-pooling layer in the feature extraction part to reduce the loss of image information and facilitate alignment with text features. Image $i_j$ of news posts is input to the modified VGG-19 to obtain the fine-grained pixel-level features.

$$\mathbf{f}_{\text{VGG-19}} = \text{VGG-19}\left(V_j; \Theta_{\text{VGG-19}}\right) \quad (2)$$

Subsequently, these are aligned with text fine-grained features through reshaping and 1D convolution to obtain fine-grained image features, as shown in Eq. (3).

$$F^V = \text{Conv1d}\left(\text{Reshape}(\mathbf{f}_{\text{VGG-19}})\right). \quad (3)$$

### D. Differences-Similarities (DS) Enhancement Network

A differences-similarities (DS) enhancement network was designed based on ideas on feature processing involving fusion of fine-grained feature similarities and differences before classification [25]. Firstly, $F^T$ and $F^V$ are concatenated, as shown in Eq. (4). The direct concatenation of fine-grained features at the word-level and pixel-level is equivalent to modal alignment, hence establishing a link between word vector and feature map. Subsequently, a fully connected layer with the `LeakyReLU` activation function is applied to map the concatenated features into the same semantic space, as shown in Eq. (5).

$$F^{VT} = \text{Concat}(F^T, F^V) \quad (4)$$
$$P^{VT} = \max(0, W_F F^{VT}) + 0.01 * \min(0, W_F F^{VT}) \quad (5)$$

where $F^{VT}$ represents the stitching feature, $P^{VT}$ represents the stitching projection feature, and $W_F$ denotes the fully connected layer's weight. $F^T$ and $F^V$ are connected after subtracting and finding the Hadamard product, respectively, as shown in Eq. (6). Subtraction yields the different points between image and text features, while the Hadamard product amplifies the similar points of image and text features. Then a fully connected layer with the `LeakyReLU` activation function maps text and image differences-similarities features into the same semantic space, as shown in Eq. (7).

$$FC^{VT} = \text{Concat}((F^T - F^V), (F^T \odot F^V)) \quad (6)$$
$$PC^{VT} = \max(0, W_{FC} FC^{VT}) + 0.01 * \min(0, W_{FC} FC^{VT}) \quad (7)$$

where $FC^{VT}$ represents the differences-similarities feature, $PC^{VT}$ represents the differences-similarities projection feature, and $W_F$ denotes the fully connected layer's weight.

After deep-fusing $P^{VT}$ through the self-attention module, we obtain the union attention feature $S^U$. Similarly, $PC^{VT}$ is passed through another self-attention module to obtain the DS attention feature $S^C$. The DS attention feature is used to help distinguish fake news by interacting with the similar and dissimilar parts of the two modalities. The union attention feature then ensures that the original multimodal information is not lost after enhancement by the differences-similarities enhancement network to help the model comprehend the whole news. An example of obtaining a union attention feature is shown in Eq. (8)-(11).

$$S_1^U = \text{Softmax}\left(\frac{Q_U K_U^T}{\sqrt{d_k}}\right) V_U \quad (8)$$
$$S_2^U = \text{Layer\_norm}\left(P^{VT} + S_1^U\right) \quad (9)$$
$$FFN\left(S_2^U\right) = \max\left(0, W_1 S_2^U\right) W_2 \quad (10)$$
$$S^U = \text{Layer\_norm}(S_2^U + FFN\left(S_2^U\right)) \quad (11)$$

where $Q_U = P^{VT} W_Q, K_U = P^{VT} W_K, V_U = P^{VT} W_V$, This indicates that after inputting $P^{VT}$, the $Q_U, K_U, V_U$ required to calculate the self-attention are obtained by multiplying with

their respective weight matrices $W_Q, W_K, W_V$. The denominator in Eq. (8) is a scale factor controlling the magnitude of the attention fraction, where $d_k$ represents the dimension of Q. $W_1$ and $W_2$ are the two weight matrices in the position-wise feed-forward networks. `Layer_norm` refers to layer normalization. Finally, $S^U$ and $S^C$ are reconnected after mean-pooling to obtain the enhanced feature $S^{UC}$, as shown in Eq. (12).

$$S^{UC} = \texttt{Concat}(\texttt{MeanPooling}(S^U), \texttt{MeanPooling}(S^C)) \tag{12}$$

### E. Fake News Classifier

The fake news classifier employed in this study is a MLP consisting of two fully connected layers. The association between characteristics and classifications is accomplished via the softmax activation function applied to the output layer of the MLP upon feeding $S^{UC}$. This is demonstrated in Eq. (13) and (14).

$$MLP_1 = \max(0, W_{s1}S^{UC}) + 0.01 * \min(0, W_{s1}S^{UC}) \tag{13}$$

$$P = \texttt{Softmax}(W_P MLP_1 + b_P) \tag{14}$$

In the fully connected layer above, $W_{s1}$ and $W_P$ represent the weight matrix and $b_P$ represents the bias term. This study uses cross-entropy as the loss function.

## IV. EXPERIMENTS

This section presents the results of numerical experiments performed on our proposed model, evaluated on two well-known social media datasets (Weibo and Twitter). We introduce these datasets and discuss some state-of-the-art baseline models. Then FG-DSEN is compared with these methods and we show that it achieves SOTA results compared to the baselines. Finally we present results from ablation experiments and analyze and interpret the findings derived from our experiments.

### A. Datasets

- Twitter: The dataset [27] contains the text of news posts, additional images, and corresponding IDs, and includes a development and a test set. The former comprises about 5,000 real and 6,000 fake news posts. The latter contains about 2,000 news posts. We retained only those news samples that contained both text and images and used Google Translate to standardize the language of the tweets to English.

- Weibo: Jin et al. [22] collected and published this dataset. Fake news posts were sourced from all news articles published by the official Weibo platform disinformation system between May 2012 and January 2016, which had been verified as fake. The system enlists reputable users to review tweets reported by regular users to determine their veracity. The real news posts were sourced from posts verified by the official Xinhua News Agency. During dataset processing, we remove news samples containing only text or images in the dataset and eliminate duplicate or low-quality images. Table I presents detailed statistics for both datasets.

TABLE I. STATISTICS OF TWO DATASETS

| Dataset | Label | Number | Total |
|---|---|---|---|
| Weibo | Fake | 4749 | 9528 |
| | Real | 4779 | |
| Twitter | Fake | 7021 | 12995 |
| | Real | 5974 | |

TABLE II. DIFFERENT HYPERPARAMETERS ON TWO DATASETS

| Hyperparameter | Value | |
|---|---|---|
| | Weibo | Twitter |
| Sentence length | 192 | 87 |
| BERT vision | BERT_base_chinese | BERT_base_uncased |
| Minibatch size | 70 | 128 |
| Epoch | 150 | 100 |
| Learning rate | 0.00005 | 0.0001 |

### B. Data Preprocessing and Experimental Settings

Text sequences were converted to dynamic word vectors using BERT-base with a dimension of 768. For image data, we resized images to $224 \times 224 \times 3$ and fed them to the modified VGG-19 model for fine-grained feature extraction, yielding a dimensionality of 100352. We froze the parameters of both BERT and VGG-19 models to prevent overfitting. The BiLSTM had a dropout rate of 0.4 and a dimension of 256; the convolution kernel size of the 1D convolution is set to 1, with a stride of 1 and an output channel count equal to the length of the text sequence. The two transformer encoders of the self-attention module are identical, with dimensions of 256, 8 attention heads, and a dropout rate of 0.4. We optimize parameters utilizing the Adam optimizer. The hyperparameters that were different on the two datasets during training are presented in Table II.

### C. Evaluation

We compare FG-DSEN with other single- and multimodal methods to evaluate its performance on fake news detection tasks.

#### 1) Single-modal based approaches:

- Text: We omit the image embedding component from the FG-DSEN. After extracting text fine-grained features using BERT and BiLSTM and performing differences-similarities feature extraction, we input to a self-attention module and perform fake news classification via a MLP layer;

- Images: Similar to the processing of text-only news classification, we exclude the text embedding layer from the FG-DSEN and use VGG-19 and a Conv1d to extract fine-grained image features before directly feeding them into a self-attention module and MLP for classification.

#### 2) Multimodal-based approaches:

- Att_RNN [22]: Att_RNN is a recurrent neural network incorporating an attention mechanism for modal fusion in rumor detection. To ensure a fair comparison

with our approach, we utilize only text and image features in our experiments and remove the components that deal with social context information;

- EANN [21]: Event Adversarial Neural Networks(EANN) extract event-invariant features by adding an event discriminator as a secondary task to help better detect fake news. For our experiments, we utilize EANN with the event discriminator component removed;

- MVAE [28]: The Multimodal Variational Autoencoder (MVAE) consists of a bimodal variational autoencoder and a binary classifier. It employs pre-trained VGG-19 and BiLSTM to mine features from images and text;

- SpotFake [20]: SpotFake is a multimodal framework developed for the detection of fake news. The framework employs VGG-19 to extract image features and a pre-trained language model, BERT, to extract text features;

- SpotFake+ [29]: SpotFake+ is built on top of Spot-Fake, which utilizes a pre-trained XLNet model instead of BERT to extract text features and employs richer fully-connected layers to assist in modal fusion;

- SAFE [30]: SAFE is a multimodal fake news detection approach based on perceptual similarity. The framework introduces auxiliary objective functions to measure text and image similarity, aiding in detecting fake news by incorporating measures beyond simply splicing multimodal features together;

- HMCAN [24]: Hierarchical Multimodal Contextual Attention Network (HMCAN) captures hierarchical semantic information through a hierarchical coding network. Multimodal contextual attention networks are used to fuse inter-modality and intra-modality relationships;

- MPFN [25]: the Multimodal Progressive Fusion Network (MPFN) uses Swin Transformer to extract multi-level visual features from images, VGG-19 to extract additional frequency domain features from images, and BERT to extract text features.

### D. Results and Analysis

We conducted broad experiments on two public datasets to evaluate our model's effectiveness and generalization ability. Table III shows that the overall performance of the FG-DSEN surpasses that of the baseline approach. Based on these results, the following conclusions can be drawn:

- For both single-modal methods, neither perform as well as the original FG-DSEN. However, the text single-modal method's accuracy in the Weibo dataset surpasses all other multimodal methods except our proposed method. This demonstrates that text fine-grained features with the self-attention module are highly effective for news classification. Its accuracy in the Twitter dataset is second only to HMCAN, probably because the text in the Twitter dataset is short, and some of the text needs to be translated with

high quality, which impacts performance. The image single-modal approach has the lowest accuracy on the Weibo dataset. At the same time, it outperforms all multimodal approaches except our proposed method in the Twitter dataset, which proves that fine-grained image features with the self-attention module can sometimes be very effective;

- Both att-RNN and EANN methods exhibit diminished performance after excluding additional social background information and auxiliary tasks. This indicates that incorporating auxiliary tasks or additional features can enhance fake news detection performance. Nevertheless, the overall effect falls short of that achieved by a model designed specifically for various multimodal feature fusion;

- The inferior performance of MVAE compared to Spot-Fake demonstrates that the improvement brought by auxiliary tasks is not as effective as using pre-trained models. The fact that SpotFake is less effective than SpotFake+ suggests that using a better pre-trained model can enhance fake news detection;

- MPFN and HMCAN extract image and text features hierarchically and design a complex fusion network for hierarchical feature fusion abd therefore better utilizing shallow-level features. However, multiple complex fusion networks increase the computational cost and do not focus on the similarities and differences between different modal features, resulting in suboptimal detection of fake news;

- The Precision, Recall, and F1-Score of real and fake news on the Weibo dataset are equal for the FG-DSEN; we investigate them by confusion matrix, as presented in Table IV. We can see that the cause of the equivalence is that false positives and negatives happen to be equal;

- Our proposed method's overall performance on the Weibo and Twitter datasets surpasses other baselines, and additionally, We have a simple structure with fewer parameters to train. Therefore, our method extracts fine-grained features to better and more efficiently capture the images and text information in the news. The differences-similarities attention feature can better extract each modality's similar and dissimilar information. The union attention feature can ensure the fusion of the original multimodal information.

### E. Model Ablation

This section presents ablation experiments conducted on FG-DSEN and compares them with a variant using the co-attention transformer to determine its effectiveness.

- No transformer: The stitching projection features and differences-similarities projection features are connected and input to the fake news classifier for experiment ①;

- One transformer: We utilize a single self-attention module within the DS enhancement network. Three distinct experiments are conducted: ② inputting only

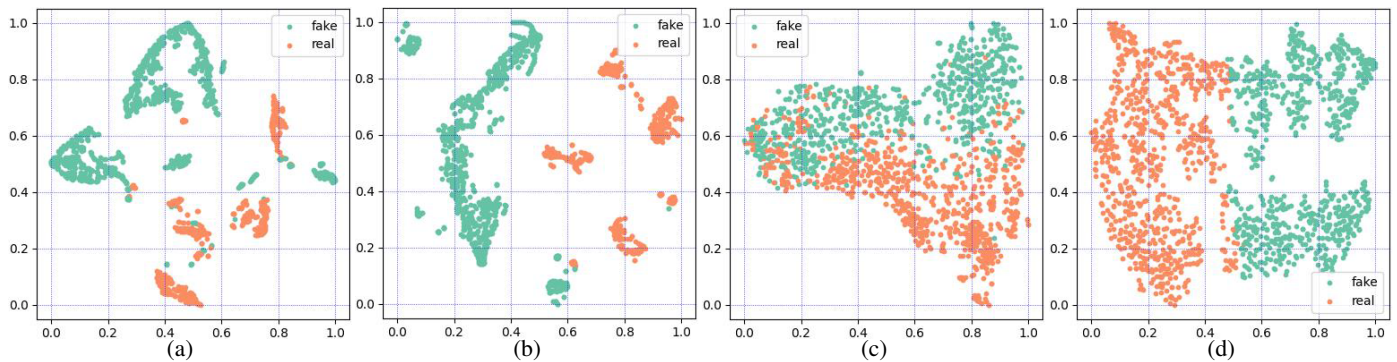

Fig. 3. (a) and (b) depict two features from the Twitter dataset, while (c) and (d) depict two features from the Weibo dataset. (a) and (c) represent features that have not undergone differences-similarities enhancement network processing, while figures (b) and (d) represent those that have.

sion as the stitching projection features.

Table V and Fig. 2 present the results of these ablation experiments.

The overall impact of the DS enhancement network is demonstrated by comparing the features before and after the network on the two datasets, see Fig. 3. We can find that after passing through the differences-similarities enhancement network, samples from each category are more closely clustered and exhibit distinct boundaries.

Based on Experiment ①, it is evident that the classification performance deteriorates in the absence of the DS enhancement network. Within the DS enhancement network, we compare experiments ②, ③, and ④ and find that only DS projection features work best on the Weibo dataset, and only stitching projection features work best on the Twitter dataset. This indicates that each of the two features is effective. However, directly connecting stitching projection features and DS projection features and inputting them into the self-attention module for enhancement proves to be ineffective. A

possible explanation is that the two features are not in the same semantic space and represent original and DS information. Excessive fusion can have a detrimental effect and contaminate the extracted features. Experiment ⑤ indicates a slight decrease in model performance due to a reduction in the number of parameters. However, the shared weight model was the most effective in the ablation experiments, except for the original model, and outperformed all other baseline models in the previous subsection in performance. From experiments ⑥, ⑦, we can see that two self-attention modules in parallel work much better than a single co-attention transformer, despite having the same number of parameters. Additionally, directly inputting text fine-grained features and image fine-grained features of the same dimension does not effectively capture DS information in news content and is not conducive to detecting fake news. These experiments validate the rationality of our designed DS enhancement network.

## V. Conclusion

This study proposes a fine-grained differences-similarities (DS) enhancement network for fake news detection. Initially, the model extracts fine-grained features from text and images using a modified pre-training model to minimize the loss of valid information in news posts. The DS enhancement network is then employed to enhance both the stitching features and DS features of the news, ensuring interaction between original modal information while highlighting DS information in news content to aid in fake news detection. The improvement achieved by using the DS enhancement network is more significant than that achieved by adding auxiliary tasks or extracting multi-level features. Experiments demonstrate that the FG-DSEN proposed in this paper outperforms state-of-the-art methods on two public and popular social media datasets.

This study has certain limitations, as it cannot be directly applied when one of the modalities is missing. In scenarios where news articles solely comprise of textual or visual content, models exhibit limited performance in handling such cases. Additionally, if manipulated images or artificially generated deceptive images are employed to align with fake news narratives, it is possible that the extraction of DS features could be compromised, leading to potential challenges in detecting fake news.

For future work, we aim to enhance the model's capabilities in the detection of fake news in scenarios where modalities are missing. This would enable the model to be more versatile in detecting both single-modal and multimodal fake news. Furthermore, we plan to augment the feature extraction process to address manipulated images or artificially generated deceptive images, incorporating them into the construction of DS features. This enhancement is expected to fortify the model's robustness and improve its overall performance.

# Detecting and Unmasking AI-Generated Texts through Explainable Artificial Intelligence using Stylistic Features

Aditya Shah*, Prateek Ranka†, Urmi Dedhia‡, Shruti Prasad§, Siddhi Muni¶ and Kiran Bhowmick‖
Department of Computer Engineering, Dwarkadas J. College of Engineering
Mumbai, India

*Abstract*—In recent years, Artificial Intelligence (AI) has significantly transformed various aspects of human activities, including text composition. The advancements in AI technology have enabled computers to generate text that closely mimics human writing which is raising concerns about misinformation, identity theft, and security vulnerabilities. To address these challenges, understanding the underlying patterns of AI-generated text is essential. This research focuses on uncovering these patterns to establish ethical guidelines for distinguishing between AI-generated and human-generated text. This research contributes to the ongoing discourse on AI-generated content by elucidating methodologies for distinguishing between human and machine-generated text. The research delves into parameters such as syllable count, word length, sentence structure, functional word usage, and punctuation ratios to detect AI-generated text. Furthermore, the research integrates Explainable AI (xAI) techniques—LIME and SHAP—to enhance the interpretability of machine learning model predictions. The model demonstrated excellent efficacy, showing an accuracy of 93%.Leveraging xAI techniques, further uncovering that pivotal attributes such as Herdan's C, MaaS, and Simpson's Index played a dominant role in the classification process.

## I. INTRODUCTION

Artificial Intelligence (AI) has had a significant impact on how humans perform daily tasks [1], such as composing text, in recent years. The technology behind it has improved to the point that computers are now capable of generating text that closely resembles human writing. This has resulted in issues such as circulating false information and stealing identities. It's also made things less apparent, which could be dangerous for security. Given the importance of these dangers and issues [2], it is critical that the underlying patterns used by various text generation techniques are uncovered. The research paper sets ethical guidelines for emulating human styles or perspectives by distinguishing AI-generated writing from human-generated language or examining the patterns formed by AI.

Researchers have tried several methods to understand how AI generates material. Curvature-based hypothesis and perturbation discrepancy detection of machine-generated text. The hypothesis argues that machine-generated text will be at the negative curvature and human-generated text will be at the positive curvature.If the perturbation discrepancy is more than 0, the text is machine-generated; if it goes to 0, it is human-generated [3].

As input, many textual properties such as length, punctuation, and word choice are utilized. On five models, an ensemble technique with Logistic Regression is used for binary classification (text is either human or machine-generated). Three models are utilized directly without cross-validation for multiclass classification (to determine which deep neural model was used for text synthesis) [4].

The primary focus for detecting AI-generated text is linguistic analysis [5], which breaks out syntactic patterns, word choices, and sentence structures. When a person uses too many words, repeats the same thing, or breaks the rules, this is a red signal. Investigating AI prompts and replies that don't match is crucial. If the AI model doesn't make sense or changes style, a machine may be implicated. Metadata is another option. AI creation may be indicated by unusual timestamps or IP addresses. Anomaly detection methods point out when language patterns are broken. Machine learning models trained to spot anomalies can distinguish AI writing from human-written language. Determining if writing was created by AI is complicated and ever-changing. Linguistic signals, inconsistency analysis, information inspection, stylometric quirks, bias identification, outliers, and purpose-built models are crucial.

Detecting AI-generated text remains an evolving effort, with several uncharted areas that demand attention for more robust and accurate identification. Firstly, there's a need to collect a diverse and thorough corpus of training data, spanning various AI models, linguistic styles, and genres, to ensure the detection system's adaptability. Fine-tuning detection models for specific AI language generators could improve precision by honing in on the unique attributes of each model. Contextual understanding remains a problem, as AI-generated text often lacks coherence. Developing methods that examine contextual disparities and irregularities could support the detection of AI-generated text. The rise of multimodal AI-generated content demands the development of detection models that can study and correlate text, images, and videos, expanding the scope of accurate identification. To counter evolving AI models, adversarial approaches must be adaptive, having a constant back-and-forth development between detection and generation. Ensuring real-time detection capabilities is crucial, especially for online platforms, necessitating the creation of lightweight, quick-response systems that analyze text as it's created.

This research paper aims to explore various methods for

identifying AI-generated text. The paper discusses various factors that need to be considered while detecting AI-generated text. These include parameters such as average syllable count, average word length, average sentence length by word, count of functional words, punctuation count ratio, and many more. Further, it implements xAI techniques which are LIME and SHAP to assist in interpreting and comprehending the predictions provided by the machine learning models.It contributes to the continuing discussion concerning AI-generated material by throwing light on the methodologies and approaches used to distinguish between human and machine-generated text.

Section II covers a wide range of techniques for detecting and understanding AI-generated text. The section provides insights into various approaches used to differentiate between machine and human-generated content, underscoring the evolving nature of this research. Section III provides a comprehensive overview of the technologies employed in this research and Section IV discusses the proposed model. In Section V, experimentation done using fine-tuning of hyperparameters is discussed and Section VI discusses the results with the conclusion in Section VII followed by future scope in Section VIII.

## II. Review of Literature

Various features extracted from the text, such as length, punctuation, and word choice, are used as input. For binary classification (text is whether human or machine generated), an ensemble technique with Logistic Regression is applied to five models().For multiclass classification (to determine which deep neural model was used for text generation), three models are used directly without cross-validation [4].

The paper explores various detection methods, including classifiers trained from scratch, zero-shot classifiers utilizing pre-trained TGMs, and fine-tuning pre-trained languages models like RoBERTa and GROVER. While the RoBERTa detector shows promising results, it requires a substantial number of training examples, making it less practical (). The paper highlights the difficulties faced by the state-of-the-art RoBERTa detector, including identifying short and fluent MGT instances, factual errors, spurious entities, contradictions, and violations of common sense reasoning [6].

In the context of text recognition using the GLTR model, the underlying assumption of their methods is to generate natural-looking text. Most systems sample from the head of the distribution through max sampling, k-max sampling, beam search,temperature-modulated sampling, or even implicitly with rule-based templated approaches. [7].

A curvature-based criterion that makes use of hypothesis and perturbation discrepancy to detect machine-generated text. The hypothesis states that if the text is machine-generated, then it will lie at the negative curvature and if it is human-generated, then it will occupy the positive curvature. If the perturbation discrepancy is greater than 0, it implies that the text is machine-generated and if the perturbation discrepancy tends to 0, it implies that the text is human-generated [3].

The author in [8] explores various approaches such as Multimodal Explanation, Deep Visual Explanation, and Deep Tensor Networks to create models that can provide explanations for their decisions using visual and textual modalities. In the context of understanding and interpreting AI models and their decisions, the paper emphasizes the crucial role of xAI. It emphasizes the need for AI systems to provide explanations for their decisions in sensitive areas like healthcare. It also presents different approaches for the explainability of AI models. The paper concludes by discussing the importance of xAI.

Researchers collected a dataset of 500 data points by gathering responses from computer science students for essay and programming assignments [9]. Each response was labeled as either Human-written or machine-generated. To analyze the text, they used a technique called Term Frequency-Inverse Document Frequency (TF-IDF) for feature extraction, which converts the text into numerical representations that machine learning models can understand.

The researchers created an open dataset for the Russian language consisting of long texts generated by different models with varying parameters and sampling methods, balanced with human-written text, and experiments with data mixing which shows that blending samples from different generative models improved the generalization ability of the detector models particularly helping RoBERTa-based models in detecting machine-generated text [10]. They further increased the input length sequence which then improved the model's understanding of the context and led to better detection performance and Multi-Task learning where the model simultaneously trains on multiple tasks, proved beneficial for improving the quality of the discriminator.

This research work focused on improving the stability of the LIME algorithm in xAI. LIME (Local Interpretable Model-Agnostic Explanations) is used to explain AI algorithms [11]. The researchers identified two main stability issues with LIME which are Segment Ordering and Region Flipping and to improve LIME's stability, they proposed two strategies: High Sample size and Average Segment Weights.

The paper [12] provides a guided tutorial of the xAI implementation in the field of Software Engineering. It provides an introduction to xAI. Further, it provides fundamental knowledge of defect prediction models. It addresses three successful case studies where xAI is used in defect prediction models.

The authors explore challenges in distinguishing Large Language Models (LLMs) and human-generated text. They derive complexity bound for detecting AI-generated text, indicating a number of samples needed for detection [13]. The researchers also discuss different existing approaches for detecting AI-generated text, highlighting the ethical concerns related to the misuse of LLMs.

In the study [14], various methods for detecting AI-generated text are explored. There are several techniques that include analyzing word pair frequency, linguistic characteristics, lexicographical features, and many more. The paper provides details on the methodology and results of each method. Further, it concludes that there is no single best method, and further evaluation of standardized datasets is necessary.

In the research, three decoding strategies are examined. They show that the improvement in these methods is for fooling humans, rather than difficult detectable text. These decoding strategies include top-k and untruncated random

sampling [15]. The authors emphasize the importance of using both human and automatic detection methods to assess the humanness of text generation systems. They call for further research in improving language models, building better automatic detectors, and developing tools to improve human detection of machine-generated text.

The research proposes a classification model for detecting essays generated by ChatGPT [16]. The model is based on XGBoost. It is trained and further evaluated on a dataset generated by ChatGPT and written by humans. It also explores feature engineering for better results. It specifically explores TF-IDF and other hand-crafted features.

The research examines various Machine Translation methods and assesses the linguistic complexity of their translations in terms of both vocabulary and grammar [17]. The study uses different metrics to measure diversity, such as lexical richness and morphological variety and applies these metrics to translations produced by MT models.

This study evaluates 13 lexical diversity metrics for tracking the progression of French learners' written productions. [18]They used a semi-longitudinal corpus of learners' essays and applied random forests to predict the production wave. The metrics show varying correlations and the ability to detect differences between productions achieving 69% accuracy in predicting production waves

The study presents a variety of techniques, including linguistic analysis, frequency counting, perplexity-based filtering, and more. [14]These methods leverage different aspects of the text, such as syntactic patterns, linguistic features, and statistical properties, to differentiate between human-written and machine-generated content.

In order to analyze complex machine learning models, the study introduces a unifying framework termed SHAP. The framework determines the significance of each feature in a model for a certain prediction [19]. The framework introduces new ways and unites six current methods to enhance computational efficiency and compatibility with human intuition. To illustrate how well SHAP works at understanding model predictions, the paper includes theoretical findings, computational experiments, and user studies.

The authors of this scientific study suggest a categorization method for categorising research paper abstracts using several machine-learning approaches. The goal is to automatically classify the papers into three categories: business, social science, and science [20]. Four machine learning techniques are tested by the authors: Support Vector Machines (SVM), Naive Bayes, K-Nearest Neighbour (KNN), and Decision Tree. Tokenization, stemming, and stop word removal are used in the pre-processing of the abstracts. For feature extraction, Bag of Words and TF-IDF vectorization techniques are applied. The authors contend that the algorithm could function even better with more data. Overall, the study shows that machine learning approaches may successfully categorize research articles based on their abstracts.

The article proposes a GPT language model and investigates its Python code-writing capabilities [21]. In contrast to GPT-3's performance of 0% and GPT-J's performance of

11.4%, the researchers are able to provide better results. Furthermore, they find that frequent sampling from the model is an extremely effective technique for coming up with workable solutions to difficult problems. The model has a number of faults, including problems with binding operations to variables and docstrings that provide detailed information. Finally, the paper goes over the wider effects that utilizing strong code generation methods might have on safety, security, and economics.

In summary, the literature survey illuminates the complexities and multifaceted nature of AI-generated text analysis, revealing that advancements in the field are often accompanied by intricate challenges and unexplored areas. This research paper endeavors to offer a comprehensive solution to the intricate challenge of detecting text that originates from artificial intelligence (AI) systems.

## III. OVERVIEW OF TECHNOLOGIES USED

Technologies used in this research can be broadly classified into three groups:

### A. Machine Learning Algorithms

For AI-generated text detection, various machine learning models were chosen such as Decision Tree, Random Forest, Logistic Regression, and Support Vector Machine (SVM), Gradient Boosting. These models were chosen with the specific intention of utilizing xAI.

The selection of these models for xAI was driven by several key considerations such as:

1) Interpretability: For eg, Decision Trees provide a clear and intuitive decision-making structure represented by tree-like diagrams making it easier to understand. Interpretable coefficients provided by models like Logistic Regression and SVM indicate the impact of each feature on the outcome.

2) Balancing complexity: These models strike a balance between performance and complexity. While more complex models like neural networks may help in achieving higher accuracy, they are difficult to interpret. The chosen models provide a reasonable trade-off between predictive power and interpretability.

(A) Logistic Regression [22]: It is a statistical method used for binary classification tasks by making use of the logistic function also known as sigmoid function, which transforms a linear combination of predictor variables into a value between 0 and 1. The logistic regression is expressed by:

$$P(Y=1|X) = \frac{1}{1+e^{-(\beta_0+\beta_1 X_1+\beta_2 X_2+...+\beta_p X_p)}} \tag{1}$$

(B) Decision Tree [23]: It employees the Gini index to make informed decisions during the process of creating a tree like structure for classification tasks. It uses a recursive process to partition the feature space into regions to minimise impurity and improve classification accuracy. The Gini index is a measure of impurity and

its formula is given by:

$$Gini(t) = 1 - \sum_{i=1}^{C} (p(i|t))^2 \qquad (2)$$

(C) Gradient Boosting [24]: It is an advanced machine learning method that builds a strong predictive model by combining multiple weak learners. It makes use of Gradient Descent optimization to minimise the predictive errors.

$$F(x) = \sum_{m=1}^{M} \gamma \times f_m(x_i) \qquad (3)$$

(D) Support Vector Machines (SVM) [25]: It is a powerful classification technique that aims to find a hyperplane in a high-dimensional feature space that best separates different classes of data points. The main idea behind SVM is to maximise the margin between the classes, which is the distance between the hyperplane and the nearest data points of each class.

$$h(x) = sign(\sum_{i=1}^{n_{SV}} a_i y_i \times K(x_1 x_i) + b) \qquad (4)$$

(E) Random Forest [26]: It is an ensemble learning method that combines multiple decision trees to improve the classification accuracy. It uses random subsets of data and features to build diverse trees , thus making independent predictions.

$$\hat{y} = \frac{1}{N} \sum_{i=1}^{N} f_i(x) \qquad (5)$$

*B. xAI Libraries*

xAI for classification refers to the application of techniques that provide transparent and interpretable explanations for the predictions made by classification models. It also refers to the concepts and techniques used to make artificial intelligence models more transparent and interpretable to humans. In classification tasks, where the model assigns input data to specific categories or classes, xAI techniques focus on revealing the contributing factors that led to a particular classification outcome. Commonly used techniques and models include LIME, feature importance, PDP(Partial Dependency Plots), and SHAP.

1) LIME - It is a technique designed to explain the predictions made by complex ML models, particularly "black-box" models, in a more understandable and interpretable way. LIME helps bridge the gap between the often opaque nature of advanced ML algorithms and the need for human-understandable explanations.

2) SHAP - SHAP, which stands for "SHapley Additive exPlanations," is a powerful technique used in machine learning to explain the predictions of various models. It provides a unified framework for explaining the output of any machine learning model by assigning "importance" values to each feature in a prediction. SHAP values are based on cooperative game theory and offer a comprehensive understanding of feature contributions to individual predictions.

*C. Stylistic features*

TABLE I. STYLISTIC FEATURES AND VARIOUS SCORES CALCULATED FOR THE DATA POINTS

| Linguistic Features | Scores | Description |
|---|---|---|
| Lexical Features | Average Word Length [27] | This gives us the average word length of the concerned text in terms of the number of characters used. |
| | Average Sentence Length By Word [28] | This gives us the average number of syllables used per word in the concerned text. |
| | Functional Words Count [29] | Functional words are grammatical connectors or mood-defining words within phrases, lacking significant linguistic value on their own. |
| | Punctuation Count | This gives us the ratio of the number of punctuations used to the number of characters used in the concerned text. |
| Readability Score | Flesch Reading Ease [30] | This metric assesses a text's readability by analyzing its ease of comprehension. Score Range: The scores range from 0 to 100. Text with a higher score is more likely to be easier to read. |
| | Flesch-Kincaid Grade Level [31] | This metric estimates the U.S. school grade level required to grasp the material. Score Range: Scores can be any value greater than zero. Lower scores suggest that comprehension is possible at lower grade levels. |
| | Gunning Fog Index [32] | The Gunning Fog Index determines how many years of official schooling are required for a person to fully understand a text. Score Range: The scores range from 0 to 20. Lower scores indicate simpler text. |
| | Dale-Chall Readability Formula [33] | Dale-Chall The readability formula considers a set of well-known words and uses their presence to determine the readability of the text. Score Range: Approximately similar to US grade levels. Lower scores imply that the text is easier to read. |

The research uses various stylistic features which are calculated for every text in the data set. These features include lexical features, readability, and diversity and richness of vocabulary. These features are important and used further in the research for model training and to discover patterns and information regarding the text that are not visible and perceptible to the human eye. Table I and Table II explain the various features that are noted and calculated for the texts present in the data set.

IV. PROPOSED METHODOLOGY

The proposed methodology for this research consists of two major pipelines:

1) Dataset Generation Pipeline
2) Model Training and xAI Pipeline

All the steps occurring in both pipelines are explained in detail below.

*A. Dataset generation pipeline*

Fig. 1 represents the flow for the creation of the two datasets used in this research.

1) Prompt generation for every data point: The proposed model's datasets are constructed using introductions from Wikipedia articles, specifically human-generated texts.

TABLE II. Stylistic features and various scores calculated for the data points (Diversity and Richness of Vocabulary)

| Linguistic Features | Scores | Description |
|---|---|---|
| Diversity and Richness of Vocabulary | Yule's Characteristic K [34] | Yule's Characteristic K measures text "disorderliness" by analyzing word frequency distribution, calculating the ratio of total words to the square root of its inverse. A lower value indicates greater vocabulary diversity, while a higher value suggests more word repetition and lower vocabulary richness. |
| | Herdan's C [35] | Herdan's C quantifies word frequency distribution in a text by subtracting the logarithm of total words from the logarithm of unique words. It offers insights into the text's vocabulary distribution. |
| | Maas [36] | Maas is a measure derived using a formula by Mueller involving variables like "logeV0," representing vocabulary expansion, where natural logarithm is employed, and incorporating variables a, logV0, and V to indicate proportional vocabulary expansion across the text. |
| | Mean segmental TTR(Type Token Ratio) (MSTTR) [37] | Mean Segmental TTR (MSTTR) calculates the average Type-Token Ratio (TTR) over consecutive text segments, where TTR is the ratio of unique words to total words in a segment. It detects shifts in vocabulary diversity within the text. |
| | Simpson's Index [38] | Measure that quantifies the likelihood of two words randomly selected from a text being identical. The scale spans from 0, representing a state of high diversity, to 1, indicating a state of low diversity. |

Fig. 1. Dataset creation pipeline

The creation process involves employing a prompt in the format "200-word Wikipedia-style introduction on 'title' starter_text." Here, 'title' represents the Wikipedia page title, and 'starter_text' comprises the first seven words from the introduction paragraph of the respective article.

2) LLMs used to generate text: Two large language models, namely "ggml-gpt4all-j-v1.3-groovy" [39]and "orca-mini-3b.ggmlv3.q4_0.bin" [39], are utilized to generate a set of 10,000 data points for each model. These data points are then combined with the human-generated text, resulting in two separate datasets, each containing 20,000 data points. The final datasets are created by shuffling the data points independently for each of the models along with the human-generated text.

3) AI text generation: Both LLMs then produce 10000 AI-generated texts each for a better variety and spread of data.

4) Combining the data: All the AI-generated texts from both LLMs are then combined with 10,000 human-generated texts individually from the two LLMs.

5) Shuffling data: All of these data points are then shuffled so that the machine learning models used ahead do not learn

any unintended patterns from the data, thereby impeding the performance of the model. This step denotes the creation of an intermediate datasets for this research.

6) Calculating Scores & Final Datasets: Every data point in the intermediate datasets, undergoes a series of calculations that help determine various style characteristics and linguistic features of the text such as readability, richness and correctness of vocabulary, and semantic spread of the text, and lexical features that are not lucid and discernible to the human eye. Each of these characteristics has been attributed to various scores that help determine such features in the text. These scores are then appended to the intermediate dataset thus completing the dataset generation process and thereby creating two datasets for the LLMs used.

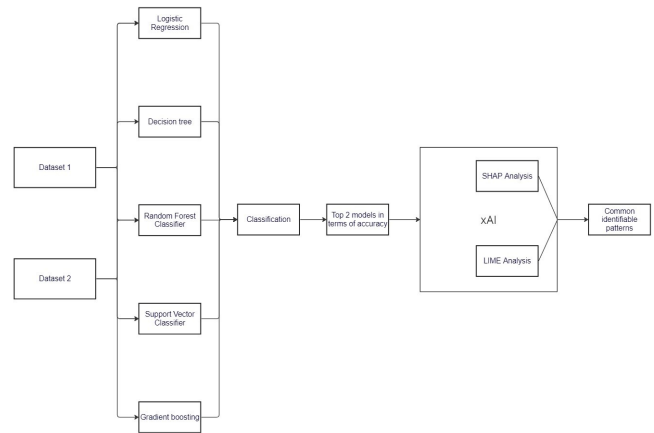

Fig. 2. Model Training and xAI pipeline

Following is the brief of all the scores used to extract the stylistic features later on in this research.

(A) Lexical Features: One of the ways in which AI generated text and human text can be distinctly identified is by its lexical structure. Usually, human text is erroneous in terms of appropriate punctuation - punctuation marks are fairly missed or used improperly. Similarly, there are disparities in other areas of lexical architectures such as the differences in word lengths and thus the number of syllables (AI tends to use heavier words), differences in typical sentence lengths, the varied usage of functional words such as she, these, or, and, etc. and so on. Hence, these factors are calculated for both classes of texts and used in this research paper to identify the trends for the same.

(B) Readability Scores: Readability scores seek to identify the reading level of a particular text, usually in terms of the minimum education level required to read the text with ease. Since human texts and AI texts are bound to differ in terms of readability ease, this paper made use of the following readability metric formulae to quantitatively identify the reading ease of human and AI generated text both:

a) Flesch Reading Ease:

$$206.835 - 1.015(\frac{totalwords}{totalsentences}) - 84.6(\frac{totalsyllables}{totalwords})$$
(6)

b) Flesch-Kincaid Grade Level:

$$0.39(\frac{totalwords}{totalsentences}) + 11.8(\frac{totalsyllables}{totalwords}) - 15.59$$
(7)

c) Gunning Fog Index:

$$0.4 \cdot [(\frac{totalwords}{totalsentences}) + 100(\frac{complexwords}{totalwords})]$$ (8)

d) Dale-Chall Readability Formula: The Dale-Chall Formula compares its wordlist to the provided text and then determines the U.S. grade level based on the number of difficult words and average sentence length.

(C) Diversity and richness of the vocabulary: The vocabulary used by AI to generate texts and that used by human writers is vastly different. Human text considers several other factors apart from the meaning and semantics while selecting a word, such as cultural relevance, formal/informal style, text's context and usage, etc. AI on the other hand tends to focus more on the textbook definition rather than these factors, thus causing a disparity with human text even between sentences meant to convey the same meaning. The following vocabulary richness and diversity metric formulae were used in determining the vocabulary levels for both the classes of texts:

a) Yule's Characteristic K:

$$K = \frac{10^4}{N^2} \sum_{i=1}^{V} (n_i - c)^2$$
(9)

Where,
N is the total number of words in the text.
V is the vocabulary size (the number of distinct terms/words).
$n_i$ is the frequency of the ith word.
c is the mean frequency of all words.

b) Herdan's C:
$$C = \frac{\log(V)}{\log(N)}$$
(10)

Where:
V is the vocabulary size (the number of distinct terms/words).
N is the total number of words in the text.

c) Maas:
$$a^2 = \frac{\log(N) - \log(V)}{\log(N^2)}$$
(11)

$$\log V_0 = \frac{\log V}{\sqrt{1 - \frac{\log V^2}{\log N}}}$$
(12)

The term "logeV0" is equivalent to 'logV0", but it should be noted that the natural logarithm (with base $e$) is employed for the logarithmic computations. Furthermore, the computations incorporate the variables $a$, $\log(V_0)$ (which exhibit dissimilarity from their prior values), and $V'$, which function as indicators of the proportional expansion of vocabulary across the text.

d) Mean segmental TTR(Type Token Ratio) (MSTTR):

$$\text{Mean Segmental TTR} = \frac{\text{Total TTR in all segments}}{\text{Number of segments}}$$

e) Moving Average TTR(Type Token Ratio) (MATTR): The formula remains the same as for MSTTR, however MATTR computes the average Type-Token Ratio (TTR) by considering a sliding window of words instead of mutually exclusive segments as in MSTTR.

f) Simpson's Index:

$$D = 1 - \sum_{i=1}^{V} (\frac{n_i}{N})^2$$
(13)

Where:
V is the vocabulary size (the number of distinct terms/words).
$n_i$ is the frequency of the ith word.
N is the total number of words in the text

### B. Model Training and xAI Pipeline

Fig. 2 demonstrates the classification and xAI pipeline as a whole which includes training of the datasets on various machine learning models and then using xAI libraries like LIME and SHAP to get various insights regarding the data points.

1) Machine Learning and Classification: Both generated datasets are trained on classification models such as Logistic Regression, Decision Tree Classifier, Random Forest, Support Vector Machines, and Gradient Boosting. This is done to see which model will perform better on these data sets. The classification task is whether a given text is AI-generated or human-generated.

2) Top Model Selection: The best two of the five models trained before are chosen for xAI analysis using LIME and SHAP as these models will provide better insights than the others. The top two models are selected on the basis of classification metrics such as accuracy,f1-score, precision, and recall.

3) xAI Analysis: Arbitrary data points of AI-generated are chosen and LIME and SHAP analysis is implemented. Model weights of the two best machine learning algorithms are used. The same is done for human-generated text as well. How LIME and SHAP were used in this research is discussed later.

4) Identifying Common Patterns: Upon conducting these xAI techniques, the ensuing analysis reports offer a wealth of insights. These insights are subsequently juxtaposed, whereupon commonalities amongst the patterns identified by various models are isolated. This convergence of identified features in both AI and human-generated text serves as a critical juncture, underpinning the suggestion of a preferred technique for discerning between AI-generated and human-generated text.

### C. xAI

*1) LIME(Local Interpretable Model-agnostic Explanations):* LIME is effectively implemented to interpret models used to classify between AI-generated and human-generated text in a dataset. In this scenario, the goal is to understand

how the model distinguishes between texts created by artificial intelligence systems and those written by humans. LIME can provide insights into which features or patterns the model relies on for making such distinctions.

In this research, LIME is implemented on various test data points to check which features were chosen by a particular model for classification. To implement LIME, a subset of data points is chosen randomly, comprising both AI-generated and human-generated text samples. Then LIME is used to identify the prevailing scores and metrics, and subsequently patterns congruous to AI as well as human-generated texts are studied and determined. These patterns are discussed later in this research.

*2) SHAP (SHapley Additive exPlanations):* SHAP is a powerful method that, like LIME, is used to interpret classification models for human-generated and AI-generated text. It helps in figuring out which parts of the text or words are most important to model's prediction of whether a piece of text was written by a person or an AI system i.e. it can be used to reveal the important factors influencing the model's conclusions when classifying AI-generated and human-generated text.

To use SHAP, a similar method of choosing a subset of data points is used that includes both types of text examples. SHAP then generates perturbed versions of these data points, similar to what LIME does. But instead of fitting a separate model that can be understood, SHAP uses an idea from cooperative game theory called Shapley values. These numbers tell how much each feature contributes to the prediction for a certain instance. The following are some SHAP visualization techniques that are

TABLE III. Hyperparameters tuned for Orca and GPT-J dataset

| Models | Hyperparameters tuned and tuned values for Orca dataset | Hyperparameters tuned and tuned values for GPT-J dataset |
|---|---|---|
| Logistic Regression | 'C' (Regularisation Strength):90.68 | 'C' (Regularisation Strength): 33.27 |
| Random Forest | n_estimators': 212, 'max_depth': 30,'min_samples_leaf': 2, 'min_samples_split': 4, 'bootstrap': False | n_estimators': 761, 'max_depth': 35, 'min_samples_leaf': 8, 'min_samples_split': 4, 'bootstrap': False |
| Gradient Boosting | 'n_estimators': 351, 'learning_rate': 0.18896, 'max_depth': 5, 'min_samples_leaf':8, 'min_samples_split': 8 | 'n_estimators': 486, 'learning_rate': 0.20436, 'max_depth': 9, 'min_samples_leaf': 7, 'min_samples_split': 3 |
| SVM | 'C' (Regularization Parameter): 9.05764, 'kernel': 'linear', 'degree': 2, 'gamma': 0.01 | 'C'(Regularization Parameter): 5.185706911647028, 'kernel': 'rbf', 'degree': 3, 'gamma': 0.1 |

used in this research to analyze the importance of individual features in the model's decision process:

1) Summary Plots: These graphs show how important each trait is across the whole dataset. They show the Shapley values for each feature, which show how they make the model's prediction move away from the average (base) estimate.
2) Waterfall Plots: Waterfall plots show how the Shapley value of each feature adds to the final prediction for a single instance. It makes it easier to see how the contributions add up.
3) Force Plots: Force plots are made to show how predictions can be made for specific cases. They show how the value

of each attribute and its Shapley value interact to affect the final prediction.

## V. Experimentation

### A. Parameter tuning

All the models were subjected to hyperparameter tuning to optimize the performance of various machine-learning models for AI-generated text detection. The process involved systematically searching and evaluating different combinations of hyperparameters to give the best set of hyperparameters that maximized the model's accuracy. For each model, a range of hyperparameter values was specified and RandomizedSearchCV was used which effectively sampled and cross-validated these values. This meticulous process enabled the models to better capture the patterns, resulting in improved accuracy and predictive capabilities. Table III shows the various hyperparameters used and their respective "best" values for model training to boost the accuracy of the models.

TABLE IV. Classification metrics for Orca generated dataset

| Model Name | Accuracy | F1-Score | Precision | Recall |
|---|---|---|---|---|
| **Logistic Regression** | **0.92** | **0.92** | **0.93** | **0.93** |
| Decision Tree | 0.80 | 0.79 | 0.80 | 0.77 |
| **Support Vector Classifier** | **0.91** | **0.92** | **0.93** | **0.92** |
| Random Forest | 0.86 | 0.86 | 0.84 | 0.89 |
| Gradient Boosting | 0.89 | 0.89 | 0.88 | 0.90 |

TABLE V. Classification metrics for GPT-J generated dataset

| Model Name | Accuracy | F1-Score | Precision | Recall |
|---|---|---|---|---|
| Logistic Regression | 0.67 | 0.68 | 0.65 | 0.66 |
| **Decision Tree** | **0.78** | **0.76** | **0.75** | **0.76** |
| **Support Vector Classifier** | **0.71** | **0.71** | **0.69** | **0.70** |
| Random Forest | 0.70 | 0.69 | 0.70 | 0.71 |
| Gradient Boosting | 0.65 | 0.65 | 0.64 | 0.61 |

From the above models, an ensemble model was created combining the predictions of various models using a weighted average based on their accuracy scores. The weights were determined by normalizing the accuracy scores, ensuring their sum equals 1.

## VI. Results and Discussion

### A. Classification Results

Both the datasets, the ones generated by GPT-J and Orca were trained on the various classification models mentioned above — Logistic Regression, Decision Tree, Random Forest, Support Vector Classifier, and Gradient Boosting. Both datasets had varied accuracies for the models trained. The various classification metrics such as accuracy, F1-Score, precision, and recall [40] for both datasets are illustrated in Table IV and Table V.

### B. xAI Results and Inferences

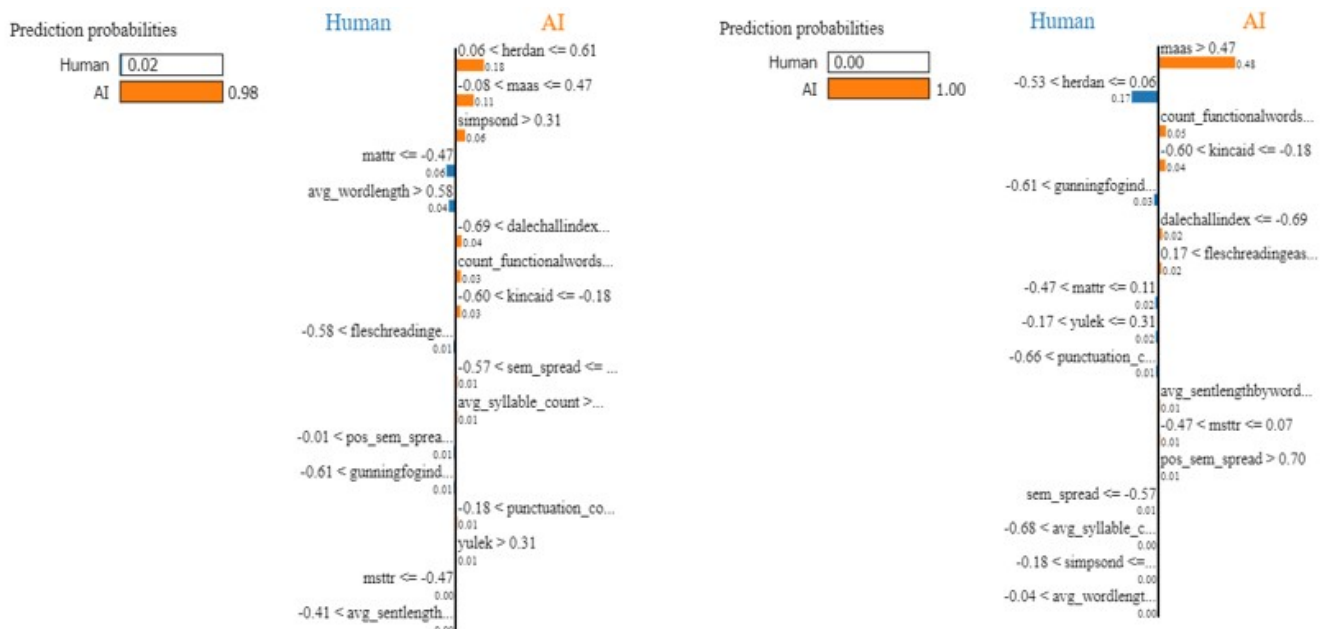
xAI was then implemented to determine which features are dominating and have a higher impact in determining the class label of a particular data point.


Fig. 3. LIME Interpretability Graphs for arbitrary AI-generated texts

LIME was then implemented on the Orca-generated dataset as it yielded better results to determine which features played an important role in how the model classified a data point as either human-generated or AI-generated text. This feature importance identification then helps in identifying what kinds of lexical and other features related to text are prominent in AI-generated and human-generated text.

The Fig. 3 has two LIME graphs for two separate AI-generated text data points. In the first image— on the left— LIME has Herdan's C [35], MaaS [36], and Simpson's index [38] have an abundant positive effect on the classification of this data point as an AI-generated text whereas MATTR and the average_word_length feature has a negative impact on the classification. From looking at various LIME graphs for data points being classified as AI generated the most dominant features were Herdans C, MaaS, and the Simpson's Index.

Herdan's C was one of the features which highly impacted the classification. Herdan's C metric is used to determine a text's vocabulary richness and diversity. It computes the proportion of unique words relative to the total number of words in the text. A higher Herdan's C value indicates a more diverse vocabulary, whereas a lower value indicates a repetitious or restricted vocabulary. It was observed from a sample of AI-generated data points that most of AI-generated text has a high value of this metric, meaning having a rich diversity of vocabulary was present. This is because the language model used to generate the data was pre-trained on massive datasets containing a wide range of text sources(3 billion parameters for Orca). But, there might be cases where the richness is abated because the dataset on which that language model was trained must not be up to standards.

The Simpson's Index can be used to measure the diversity of words in a given text within the context of text analysis. A higher Simpson's Index value would indicate less word diversity, indicating that a small number of words are repeated frequently. A lesser Simpson's Index value indicates greater word diversity or the use of a greater variety of words. Furthermore, for Simpson's Index, the values were high i.e. they were between 0.65 to almost reaching 1. This indicates that the phrases or words in the text are repeated often. Consequently, the diversity decreases. This is because AI models, particularly language models, can occasionally generate text that tends to reuse certain phrases or patterns, resulting in a relatively smaller vocabulary. These models may generate coherent text, but they may lack the inherent variability and creativity of human-generated text [41]. However, it's important to note that this can vary based on the specific AI model, the input data it was trained on, and the prompt given for text generation [42].

Fig. 4 illustrates a set of examples of LIME interpretability graphs for human-generated text. Many data points were interpreted and the results were mostly opposite to the ones inferred by the AI-generated ones. For instance, the Herdans C constant was relatively low for various human-generated text data points. It was either relatively low or it negatively influenced the classification.

Fig. 5, Fig. 6, and Fig. 7 illustrate the summary, waterfall, and force plots respectively generated by SHAP for the ORCA dataset. Table VI shows some feature values characteristic to AI and Human-generated texts.

TABLE VI. Some feature values characteristic to AI and Human-generated texts

| Feature | AI-Generated | Human Generated |
|---|---|---|
| Herdan's C | 0.9214 | 0.8901 |
| Simpson's Index | 0.016 | 0.013 |
| MATTR | 0.9548 | 0.9203 |
| Maas | 0.0180 | 0.0196 |
| Flesch-Kincaid grade level | 37.07 | 52.96 |
| Gunning Fog Index | 41.32 | 56.99 |

## VII. CONCLUSION

In conclusion, this research delves into the intricate realm of AI-generated text analysis and its differentiation from human-generated text. As Artificial Intelligence continues to revolutionize various facets of human activities, including text composition, the challenges of identifying AI-generated content have become increasingly pertinent due to concerns about misinformation, security vulnerabilities, and identity theft. The research methodology is multifaceted, combining linguistic analysis, readability metrics, semantic spread measurements, and vocabulary richness assessments to uncover essential textual attributes. By leveraging a composite ensemble of machine learning models, including Logistic Regression, Decision Tree, Random Forest, Support Vector Classifier, and Gradient Boosting, the research demonstrates impressive efficacy with an accuracy of up to 93% in classifying AI-generated and human-generated text.

Moreover, the integration of xAI techniques, such as LIME and SHAP, provides invaluable insights into the features and patterns that influence the model's classification decisions. These insights reveal that certain attributes, such as Herdan's C, MaaS, and Simpson's Index, play pivotal roles in distinguishing AI-generated text from human-written content. These features highlight the richness of vocabulary, repetition of certain phrases, and syntactic patterns that are characteristic of AI-generated text.

The paper's limitation lies in its reliance on non-state-of-the-art models due to computational constraints, which may not fully represent the latest advancements in the field. These constraints, including limitations in computational resources and data availability, result in a performance gap compared to more advanced models. However, this limitation serves as a catalyst for future research that can harness the power of deep learning architectures and explainable AI (xAI) to delve into AI-generated text with greater sophistication. Additionally, it highlights the need to address ethical concerns and practical applicability as AI models evolve, making this paper a foundational stepping stone for deeper explorations in the future.

## VIII. FUTURE SCOPE

The research's future directions revolve around advancing AI-generated text analysis comprehensively. This entails harnessing larger and more diverse datasets spanning various domains, crucial for enhancing the detection system's real-world applicability. Alongside this, optimizing processing power to expedite analysis processes tied to xAI techniques like SHAP is essential. Incorporating additional style criteria such as linguistic tendencies and sentiment analysis aims to refine the methodology, deepening the grasp of distinguishing AI text styles from human language. This extends to evaluating a wider range of AI models beyond GPT-J and ORCA. Diversification of Machine Learning algorithms like K-Nearest Neighbors, Naive Bayes, and Neural Networks, as well as integration of Deep Learning algorithms like Transformer-based models, enhances AI text recognition. To fathom model decision-making, XAI methods like Grad-CAM and Integrated Gradients will be employed. Rigorous validation of authentic AI text data will test the proposed approach, collectively advancing differentiation between AI-generated and human-composed texts and propelling the field forward.

*Abstract*—This paper demonstrates the feasibility of a database reconstruction attack on open-source database engines and presents a defense method against it. We launch a Flush+Reload attack on SQLite, which returns approximate, noisy volumes returned by range queries for a private database. Given the volumes, our database reconstruction uses two algorithms, a Modified Clique-Finding algorithm and Match-Extension algorithm, to recover the database. Experiments show that an attacker can reconstruct the victim's database with a size of 10,000 and a range of 12 with an error rate of up to 0.07% at most. To mitigate the attack, a small dummy data is added to the result volumes of range queries, which makes the approximation more confused. Experimental results show that by adding about 1% of dummy data, an attack success rate (in terms of the number of reconstructed volumes in the database) is reduced to 60% from 100% and an error rate increases to 15% from 0.07%. It is also observed that by adding about 2% of dummy data, the reconstruction is completely failed.

*Keywords*—*Attack; cache attack; side-channel attack; security; database reconstruction; privacy; clique-finding; database volume*

## I. INTRODUCTION

Data processing continues to become more common in the cloud, and cloud computing is embedded in the business model of popular services such as Google's G Suite, Microsoft's Office 365, Adobe Creative Cloud [1]. In addition to cloud use by industry, federal agencies are also now leveraging cloud services, even for the storage and analysis of sensitive data. Microsoft, for example, won a $10 billion contract from US government that creates a secured cloud for the Pentagon.

One of the most significant security challenges in the cloud is on processing sensitive information. In extreme cases, cloud servers that handle sensitive information may not be trusted because they are presumed to be malicious. In this case, since the data must be encrypted, additional time is required to calculate the encrypted data [2], [3]. In this paper, it is assumed that a trusted server handles sensitive data, but a spying process is also running on the same public server. When the spy process is located in the same physical space as the victim, it shares hardware such as cache, which may act as a side channel. Our assumption is quite reasonable in a realworld setting because leading companies in the cloud service spend great amount of money to show that their servers are trusted.

The goal of this paper is to investigate the impact of side-channels on open-source database engines, to address the risks, and to present a method for defense. The model of the paper assumes that an external user requests a query a private database stored in the victim Virtual Machine (VM), and that the victim VM uses SQLite to process the query and returns the result to the external user. An attacker cannot make a query request directly to the database or observe the results of the query. The attacker is running a spy VM in the cloud with the victim VM, so it can monitor the shared cache to bring in side channel leaks. The attacker's goal is to reconstruct the volume of the victim's database. Reconstruction of the database here refers to recovering the volume rather than finding out all the information correctly. Suppose that a school's student database stores data from <Alice, Bob, Charlie> for grade $A$, <Dave, Eve> for grade $B$, <Frank, George, Henry, Ivan> for grade $C$, for example. The reconstruction is to restore the volume of three rows for grade $A$, two rows for grade $B$, and four rows for grade $C$.

This paper introduces a conventional side-channel attack that captures information leakage in the cache shared by victim VMs and a spy VM using SQLite. This recovers approximate volumes of database including some noise values. We also introduce a database reconstruction attack that uses a clique finding algorithm. It recovers database volumes by constructing a graph based on correct and noiseless volumes of the range queries. In order to make it deal with the approximate, noisy volumes, this paper shows its extension. The extended algorithm includes two sub algorithms. In a modified clique finding algorithm, a concept of noise budget is introduced and utilized in a edge creation step of the clique finding algorithm. A match-extension algorithm handles such a case that the modified algorithm sometimes fails to find a maximum clique in a given graph. Experimental results show that our database reconstruction can recover almost 100% volumes of database with low error rate (0.2-0.7%).

To mitigate the database reconstruction attack, this paper introduces a stratey to add noise to data. The intution behind the strategy is that the clique finding algorithm is an NP-Hard problem. The complexity of the algorithm grows quickly with the size of the range. Thus, adding a small number of nodes to a graph can significantly increase the time required to reconfigure the database; it can even cause the algorithm to fail completely. Technically, a small dummy data is added to the results of range queries. This approach is reasonable in that approximate volume data obtained from the side-channel attack is only exposed to attackers and they are not aware of the existence of dummy data. Regular users (in victim VMs) is able to access raw data and easily seperate the dummies before processing further. Experiments were conducted to investigate

the impact of the noise (dummy data) on performance of database reconstruction. With 1% of dummy data, only 60% of database were recovered with up to 15% of error rate. When adding 2% of dummy data, no databased was constructed at all; the database construction attack was completely failed.

The rest of the paper is organized as follows. Section II reviews previous research outcomes in cache attacks and database construction attacks. Section III describes a threat model, a cache side-channel attack, that this paper addresses. In Section IV, we introduce a database construction attack that aims to recover the volume of orginal database given noisy data obtained from the cache side-channel attack. Section V introduces a mitigations strategy, which is followed by experiments and results in Section VI. Finally, Section VII concludes the paper.

## II. RELATED WORKS

Cache attack is performed based on attacker's ability to monitor cache accesses made by the victim in a shared physical system as in virtualized environment or a type of cloud service [4]. Tsunoo et al. [5] introduced it first by showing a timing attack caused by collisions in the memory lookups on a block cipher. Osvik et al. [6] revealed an inter-process leakage via cache's state and showed key extraction of AES. Acıiçmez [7] showed that instruction cache could be a target for attacks. Ristenpart et al. [8] explored the feasibility of side channel attacks on cloud; they demonstrated that an attacker could penetrate VM isolation and harm confidentiality of victim VMs. In [9], authors introduced a cache side-channel attack technique, Flush+Reload, that exploited weakness of memory pages shared among processes. Cache behaves in a way to leak information on a victim's access to memory lines in shared pages; so that an attack can determine what victim does and infer the data the victim operates on. They also showed that the technique could be used to extract cryptographic keys for RSA. By using the Flush+Reload, Yarom and Benger [10] demonstrated that the ECDSA leaked the nonce and the secret key of the signer, allowing unlimited forgeries. Moghimi et al. [11] introduced an attack tool, CacheZoom, that could allow an attacker to monitor all memory accesses of SGX enclaves with high resolution. They demonstrated the feasibility of AES key recovery. Authors in [12], [13], [14] showed possibility of cache side-channel attacks by monitoring critical operations in AES T-table entry and other operations such as modular exponentiation, multiplication, or memory accesses. Yan et al. [15] used Prime+Probe and Flush+Reload for the cache side channel and successfully obtained a DNN's architecture that was considered a major commercial asset in a business. Hong et al. [16] showed a DNN fingerprinting attack where an attacker followed function invocations corresponding to architecture attributes of the victim network and thus fingerprinted the entire network.

In database reconstruction, Kellaris et al. [17] demonstrated reconstruction attacks on securely outsourcing database storage systems implementing searchable symmetric encryption or order-preserving encryption. Their attacks were developed for a weak adversarial model where underlying query distribution was only known to an attacker. He does not directly query a database and not need to know any of queries nor answers; he may observe encrypted resonses of queries. They identified that

either access pattern or communication volume was leaked for range queries. A reconstruction attack run with the auxiliary information in $N^4$ queries, where $N$ is a domain size, which recovered the number of records having each specific value in a database, i.e., database counts. Lacharité et al. [18] considered a setting where access pattern (a set of records matched by each query) and rank information (the position of a record in a sorted list of records) were leaked. They presented three attacks, full reconstruction, approximate reconstruction, and reconstruction using auxiliary information, that recovered values in different levels of accuracy. Grubbs et al. [19] presented a database reconstruction attack given the volume leakage of the response of range queries. Their attack used a graph-theoretic approach; they reduced database reconstruction to finding a clique in a graph constructed from the volume information. In the graph, volumes were represented as nodes, and an edge connected two nodes when their absolute difference was represented as a node. After multiple iterations of adding and deleting nodes, their algorithm returned the counts of all values in the database. Shahverdi et al. [20], unlike prior a threat model, considered an honest cloud server on which an adversary virtual machine and a victim one co-located. The adversary could not issue queries to the victim's database but obtain information leaked via a shared cache. This implies that he could not obtain response volumes of range queries accurately; instead, obtaining noisy volumes. In this scenario, authors presented a database reconstruction attack by extending the Grubbs's algorithm [19] and by developing a noise reduction algorithm.

Naveed et al. [21] showed attacks on database systems capturing property-preserving encryption. Using encrypted database columns and publicly known auxiliary informtion, they could recover certain encrypted attributes by up to 80%. Kornaropoulos et al. [22] considers an encrypted spatial database that handles data in a geometric space and k-nearest neighbor (kNN) queries that return the nearest k points in the database for a given query point based on distances between points. Authors exploited a query leakage profile and used a convex polytope to characterize a set of reconstructions. The attack could recover values of the database with approximation error of 2.9% to 0.003%. The same authors in [23] developed a reconstruction attack without assumptions about the knowledge of query distribution and the data. The attack exploited search-pattern leakage, computed distances between encrypted values, and eventually recovered plaintext values.

## III. THREAT MODEL: CACHE SIDE-CHANNEL ATTACK

A threat model in this paper assumes multiple users in a cloud server, each of which has access to its own database. For instance, it is assumed that user 1 can access database 1, user 2 can access database 2, and server is a trusted server. Once one of the users becomes an attacker with a malicious intend, he can abuse physical properties of the model; his VM is in the same cloud server and shares the cache with victim VMs. Although an attacker cannot directly query the database of a victim, he can interact with the server to obtain some information about the inaccessible database.

The attacker does not know what range of queries were requested and what rows were returned exactly. This means that only an approximate volume with noise can be obtained.
Fig. 1. A general cache architecture.

It is noted that the side-channel attack proceeds regardless of whether the victim's database is encrypted or not, as it proceeds by approximating the volume of range queries. An attack is possible as long as the spy VM can see the code line that the database engine executes for each record returned in the range query.

### A. Cache Architecture

Cache is a memory located at the top of the memory hierarchy. It is much smaller in size than the main memory and is very expensive, but it is characterized by a very fast speed. The cache is placed between the CPU and the main memory as shown in Fig.**??**. Data in the main memory is loaded into the cache memory, and performance can be expected to be improved by allowing the CPU to access the cache memory first instead of the main memory with relatively slow access time. The cache serves as a buffer to reduce the speed gap between the CPU and the main memory.

Typical modern CPUs have multiple levels of cache to reduce access time to the main memory. Level 1 cache is the smallest and fastest, while Level 3 cache forms the slowest and largest hierarchical structure. Level 1 cache is divided into two caches, one to store data and the other to hold instructions. In higher-level caches, data and instructions are kept in the same cache. Level 3 cache is a shared memory space where data and instructions are kept in the same cache and is the Last Level Cache (LLC). The LLC includes all lower level architectures, which means that all data present in Level 1 and Level 2 also exists in the LLC. Each cache consists of multiple sets, each set containing multiple cache lines. Each line in the main memory is mapped to a unique set of caches. However, within this set, memory lines can be mapped to cache lines. Typically, each cache line stores 64 bytes of data. If it's already full, we have to decide which memory lines to be removed when writing new lines. This decision is called the Replacement Policy and depends on a cache structure. The most popular replacement policy is the Least-Recently Used (LRU), which replaces the least recently used items with new ones.

### B. Flush + Reload Attack

Cache is vulnerable to information leakage because an attacker that is with the victim on the same process can access meaningful information about activities of the victim. In particular, an attacker can monitor and use his own access time to the cache to guess whether the victim has accessed specific memory lines. The reason why such an attack is possible is that the attacker and the victim share the same resource, that is, the cache. Moreover, in a setting where the attacker and victim share the library, both will have access to the physical memory location where a single copy of the library is stored. An attacker can explicitly remove lines corresponding to shared physical memory from the cache. In order to exploit the shared physical memory in a useful way, this paper uses a *Flush+Reload* attack introduced by Yarom and Falkner [9].

This attack method takes advantage of the fact that the access time to cache memory is shorter than that to main memory, and targets the L3 cache line shared by a victim and an attacker. An attacker uses a special command called `clflush` to remove a monitored line from the cache. This command removes the monitored line from the L1, L2, and L3 caches. As mentioned earlier, L3 includes L1 and L2. Thus, if L3 is removed, the lines that are removed are removed from all other caches. The attacker then allows the victim to continue running a program. After a certain period of time, the attacker regains control and measures the memory access time to determine whether the monitored line still remains in the cache. If the reload runs quickly, the monitored line is still in the cache. Then, an attacker deduces that the victim accessed the same line during execution. If the reload runs slowly, the monitored line is not in the cache. Then, the attacker infers that the victim did not access the line while running. Thus, an attacker can know whether the victim has accessed a particular line. To perform the *Flush+Reload* attack, this paper used a package provided in the Mastik framework [24]. Mastik is a toolkit for experimenting with micro-architectural side-channel attacks and provides implementations of published attack and analysis techniques.

### C. Detecting Two Lines to Monitor

This paper uses SQLite [25], a popular open-source database engine that uses the BTree data structure to store columns. We looked into the SQLite program and used a `gcov` command to detect a line being called once in each iteration of the range query. It is possible to determine query response volume by monitoring the number of times these rows are called. It should be noted that the duration of each query can also be measured and used as an indicator of the volume. However, there is no reliable way to convert time to volume, resulting in introducing big noise. So we decided to count the numbers explicitly. The library was compiled using the `-fprofile-arcs` and `-ftest-coverage` flags to obtain the number of times each line runs. We, then, ran the range query command and used the `gcov` command to count the number of times each line was executed in the main.c and sqlite3.c files. After finding more lines in the SQLite program, two lines are monitored simultaneously to improve measurement accuracy. The advantage of monitoring two lines is as follow. Even if an attack code may fail to detect activity on one of the lines due to overlap between the attacker reload and victim access, it is still likely to see activity on the second line. There may be some false positives due to the mismatch of hits on the two lines, which is mitigated by considering the number of proximity hits to be from the same activity.
Fig. 2. We launched the Flush+Reload attack on SQLite and showed one sample measurement; the two monitored lines are shown in blue and red.

### D. Using Mastik Toolkit

After detecting a line leaking query volume, we, by using the Mastik Toolkit, monitor the lines while SQLite processes range queries. Fig. **??** draws results of one sample measurement. The two lines being monitored are colored blue and red. The x-axis represents the sample point at which the reload occurs, and the y-axis represents the time required to reload the monitored line from memory on that time instance. Because two lines are being monitored, there are two sets of measurements for each time instance.

A `FR-trace` utility in Mastik automatically starts measuring when it detects a hit on one of the lines monitored by the SQLite program. When Mastik does not detect more activities for a while, the measurement automatically end. There are samples with reload time of less than 100 cycles during the interval in which the range query runs. These sample points are recorded when SQLite accesses the line the attacker is monitoring, so the attacker sees a small reload time. Then the number of hits in blue or red measurements are calculated. The number of hits corresponds to the inquiry volume. It is also important to monitor the associated cache lines in order to detect when/whether the range query is executed. Because the measurement is not a noise-free environment, the number of hits counted may differ from the actual value of the volume. Some of the sources of noise are explained below.

*False Positive (FP)*. Instruction to be executed are brought into the cache before memory lines are executed. In the case of the Flus+Reload attack, it still looks that this instruction was executed because of the fast access. In general, true hit counts occur at fixed time intervals. If observing a hit that occurred much earlier than the expected hit time, it is likely a FP. It is presumed to have occurred by speculative execution, and it is not considered to be hit.

*False Negative (FN)*. A FN occurs when the victim accesses the monitored code line after the spy process reloads the line and before the spy process flushes the line. This paper attempts to detect FNs only algorithmically; an asymmetric window around each observed volume is used to compensate for the fact that the actual volume is usually larger than the observed volume. In our experiments, we assign 90% of the window width to a value larger than the observed volume.

### E. Approximate Noisy Volumes

A single trace is collected by randomly selecting and executing a range query [a, b] while simultaneously monitoring the line using Mastik FR-trace. This experiment is repeated several times to collect enough traces. We count, for each trace, the number of times that one of the two lines represents a hit, mitigate the FP problem, and then report the number of hits as a range query volume for that trace. Some volumes are observed much more frequently than others, and their values are stored as approximations to the expected volumes. It is expected to see $\binom{N}{2} + N$ values at most in a noiseless setting. There are some traces noted *good enough* but with incorrect volume. By putting all traces together, the effect of such instances would be minimal and the exact approximation of the volume would be distinguishable. It is noted that the volume being recovered is an approximate volume of the database, not a correct volume.

## IV. DATABASE RECONSTRUCTION

Given a set of volume of database recovered from the cache side-channel attack, the attacker aims at reconstructing the database. This section explains our database reconstruction based on a clique finding algorithm. It shows, first, the Grubbs' work [19] that constructs a graph based on the observed correct and noiseless volumes of the range queries. Note that each volume is represented by a node in a graph. Then, an extention of the clique finding algorithm to handle noisy volumes [20] is introduced.

### A. Clique Finding without Noise

The clique finding algorithm has two main parts for graph construction: node creation and edge creation.

*1) Creating Nodes:* Given a set of recovered volumes V, this part creates a node representing each volume and labels the node with that volume. This means that node $v_i$ has volume $v_i$.

A recovered volume refers to a volume that has been reconstructed through an attack. Suppose that we have a <5,10,15,20> database of size 4. A query request with a range of 1 will return 5 rows, and a query request with a range of 1 to 2 will return 5 + 10 = 15 rows. It returns 10 + 15 + 20 = 45 rows if a user asks for a query of 2 to 4. From the attacker's point of view, it is not possible to know exactly what range the query request is, but it can be seen that the volume returned is {5,10,15,20,25,30,35}. These volume sets are called recovered volumes.

*2) Creating Edges:* This part creates an undirected edge between two nodes $v_i, v_j \in V$ if there exists a node $v_i \in V$, where $v_i = v_j + v_k$.

A volume can be recovered by running a clique finding algorithm on the constructed graph. Assuming the value ranges from 1 to N, there are $\binom{N}{2} + N = \frac{N(N+1)}{2}$ possible ranges, so the graph shows $\frac{N(N+1)}{2}$ nodes. Each range $[i, j]$ for $1 \le i \le j \le N$ is denoted by a node. In other words, node $[i, j]$ means
Fig. 3. A graph constructed with nodes of ranges.

Fig. 4. A graph constructed with nodes of volumes corresponding to Fig. **??**.

that the range of the query is $i$ to $j$. Nodes corresponding to ranges of of the form $[1, i]$ for $1 \leq i \leq N$, i.e., base volumes, forms a clique for pairs of ranges of $[1, i]$ and $[1, j]$ ($1 \leq i \leq j \leq N$). There is a range of $[i + 1, j]$. This means that there exists an edge between $[1, i]$ and $[1, j]$ due to the way the graph is constructed. The clique finding algorithm finds nodes $[1, i]$, $1 \leq i \leq N$. In order to recover the original range of form $[i, i]$, we simply sort the nodes based on labels and subtract them sequentially because $|[i, i]| = |[1, i]| - |[1, i - 1]|$, $1 < i \leq N$.

| Student name | Alice | Bob | Charlie | Dave | Eve | Frank | George |
|---|---|---|---|---|---|---|---|
| Grade | 1 | 2 | 2 | 2 | 2 | 3 | 3 |

For instance, suppose a student database shown in Table I. A set of known ranges and corresponding observed volumes are $[1, 1] = 1$, $[2, 2] = 4$, $[3, 3] = 2$, $[1, 2] = 5$, $[2, 3] = 6$, $[1, 3] = 7$. Fig.**??** shows that a graph is constructed based these data, where each node represents a range. The edge creation part created lines connecting two nodes. Since $|[1, 2]| = |[1, 1]| + |[2, 2]|$ and there exists a node $[2, 2]$ connecting $[1, 1]$ and $[1, 2]$, the two nodes are connected via a line. Similarly, $|[1, 3]| = |[1, 2]| + |[3, 3]|$, so there is a connection between $[1, 3]$ and $[3, 3]$.

It is observed that three nodes $[1, 1]$, $[1, 2]$, and $[1, 3]$ in the graph are connected each other and form a complete graph. A subset of nodes in which every two different nodes in an undirected graph are connected is called a clique. Among the cliques that can be found, the largest clique becomes the clique of the graph. Upon finding the clique, $[2, 2]$ can be obtained by subtracting $[1, 1]$ from $[1, 2]$, and $[3, 3]$ by subtracting $[1, 2]$ from $[1, 3]$. This allows us to reconstruct the database easily. Although the exact range is unknown, if the $\{1, 4, 2, 5, 6, 7\}$ volume set is recovered through an attack, it is possible to find $1, 5, 7$ cliques as shown in Fig. **??** and reconstruct the database in the same way.

### B. Modified Clique Finding with Noise

From the cache side-channel attack in Section III, correct volumes may not be recovered; that is, recovered ones are approximate and noisy volumes. Therefore, a conventional clique finding algorithm that assumes noiseless volumes (described in

Section IV-A) does not find cliques of sufficiently large size. This happens because the condition for connecting nodes $v_i$ and $v_j$ almost always fails since it is not possible to find the third volume $v_k$, where the equation $v_i = v_j + v_k$ is satisfied. This implies that too many edges are missing in the constructed graph to form large cliques.

To mitigate the effect of noise, our method modifies the second parts (Creating Edges) in the clique finding algorithm, a *Modified Clique-Finding algorithm*. Because traces are noisy, it may not possible to obtain the correct volume. The recovered volume is close to the correct volume, and error ranges can be calculated. Here, we define a *noise ratio* as (the recovered volume / the correct volume). An attacker, at the first step, performs a preprocessing by launching an attack on a database known to the attacker. The attacker then examines the recovered volume, selects a noise ratio, and compares it with the actual volume, from which he evaluates the accuracy of the traces to find an approximate value for the noise ratio. Based on all the noise ratios, the attacker then sets a value for *noise budget* - the average of the noise ratios observed across all volumes. The attacker, once the noise budget is fixed, then creates a window of acceptable values around it for each recovered volume. The window is created around $v_i$ using lower bound of $v_i \times (1 - 0.1 \cdot noise\ budget)$ and upper bound of $v_i \times (1 + 0.9 \cdot noise\ budget)$. The window is asymmetric with 90% of the width on the right side because the noisy volume is usually smaller than the actual volume. For volume $v_i$, the window is denoted as $w(v_i)$. The modified part in the clique finding algorithm that enables to construct a graph from nosiy volumes is as follow.

- *Creating Edges (Modified):* This part creates an undirected edge between two nodes $v_i, v_j \in V$ if there exists a node $v_k \in V$, where $|v_i - v_j| \in w(v_k)$.

### C. Match-Extension

Although the noise budget is appropriately adjusted, the Modified Clique-Finding algorithm sometimes fails to find the maximum clique of size $N$. This section describes an improvement of the algorithm to handle such a case. First, note that in the clique finding algorithm, a graph corresponding to the volume in the range $[1, i]$ for $1 \leq i \leq N$ should have a clique if there is a full range of volumes present in the data.
Fig. 5. A graph constructed from noiseless volumes in the database <30, 100, 80, 30, 60>. The maximum cliques corresponds to $N$, 5. The maximum cliques found are shown in bold connections.

Fig. 7. Given a graph missing edges, the Modified Clique-Finding algorithm returns a clique of size 4 (less than $N$ = 5) with values {29, 128, 209, 239}.

Fig. 6. A graph constructed from noisy volumes in the database <30, 100, 80, 30, 60>. A missing edge in the maximum clique is represented in the dotted line.

Now suppose we are given an approximate, noisy volume corresponding to the range $[i, j]$. $|[1, i]| \approx |[1, i-1]| + |[i, j]|$ should have a connection, but the connection from node $[1,j]$ to node $[1,i-1]$ is missing. A maximum clique of size $N$ is not formed as a result of missing connections. Executing the clique finding algorithm on data with missing volumes returns cliques of size smaller than $N$ and recovers the candidate database for each clique. The algorithm then merges information from these small databases to create a larger database.

*1) Observation:* This subsection explains the idea of this improvement with an example. Consider a database with a range of 5 possible values (i.e., $N$ = 5), <30, 100, 80, 30, 60>. This means $|[1, 1]| = 30$, $|[2, 2]| = 100$, $|[3, 3]| = 80$, $|[4, 4]| = 30$, $|[5, 5]| = 60$. A set of possible values for the volume of range queries $V$ is, then, {30, 60, 80, 90, 100, 110, 130, 170, 180, 210, 240, 270, 300}. For instance, $|[1, 2]| = 130$. A graph constructed for these volumes is shown in Fig. 5. The maximum cliques found by the algorithm are shown in bold connections. The nodes {30, 130, 210, 240, 300} are returned, and a database <30, 100, 80, 30, 60> is reconstructed.

Now, assume that the recovered volume has noise and that a set of possible values for the volume of range queries $V$ is {29, 58, 79, 89, 98, 108, 128, 160, 209, 239, 268, 299} as shown in Fig. 6. Almost all the noisy volumes are close to the true values; exceptionally volume 160 is far from the correct volume 170. In this setting, our method uses the Modified Clique-Finding algorithm to construct a graph. It first uses a window around a volume $v_i$ allowing to have lower and upper bounds of $v_i - 1$ and $v_i + 3$, respectively. Some connections will be missing due to measurement errors. For example, a connection from node 299 to node 128 will not be formed because there is no window containing 171 anymore. If our method runs the algorithm on the new graph, the result will be a smaller clique (less than $N$ = 5). As shown in Fig. 7, the algorithm returns cliques whose size is 4 with values {29, 128, 209, 239}, which creates a database $< 29, 99, 81, 30 >$. In the next, we describe main steps in the Match-Extension algorithm to reconstruct a database from noisy volumes.

*2) Finding cliques:* This step aims at finding all the cliques in the constructed graph.

**Maximum Clique**. The first stage is to find the maximum clique in the graph. Let $K$ be the size of the maximum clique recovered in this stage. If multiple cliques with the same maximum size are found, one of them is chosen randomly. Once a clique is found, a corresponding database is reconstructed. We call this database an initialized solution, `initSolution`. If the size of the maximum clique found in this stage is $N$, it is done; the database is successfully reconstructed. Otherwise, the rest parts of the algorithm extend this `initSolution`.

**All Other Cliques**. The next stage recovers all cliques of sizes $K, K - 1, K - 2, \ldots,$ and $K - l$, and sorts them from the largest size to the smallest size. For each clique, a corresponding database is reconstructed and referred to as a candidate solution `candSolution`. It is in the form of a sorted list of volumes corresponding to contiguous ranges in the database. The cliques found in this stage are not limited to ranges of the form $[1, 1], [1, 2], \ldots, [1, K]$ for some $K$. Note that this holds true even in the noiseless setting. Any set of volumes in the range of $[i, i_1], [i, i_2], \ldots, [i, i_k]$, where $i \leq i_1 < i_2 < \cdots < i_k$, forms a clique of size $k$ if all
Fig. 8. The Modified Clique-Finding algorithm returns a clique with values
$\{29, 209, 239, 299\}$ (size = 4), which creates a database $\langle 29, 180, 30, 60 \rangle$

.

differences in volumes corresponding to the ranges exist in the data. This fact allows this algorithm to recover the original database by discovering the volumes of different parts of the actual database and combining those parts.

*3) Combining solutions:* Given the `initSolution` and a `candSolution` in the form of lists of volumes, in this step, the Match-Extension algoriithm *combines* the information in them into one large solution.

**Longest Common Substring** The first stage is to find the longest common substring of the two solutions; it is the longest contiguous list of volumes where the two solutions match. We call this substring `lcList`. To find it, our method uses a modified standard longest common substring algorithm where the elements of the substring are approximately equal to the corresponding elements of `initSolution` and `candSolution`. This stage returns the `lcList` and the starting and ending indices (locations) of `lcList` in two given solutions. However, even after the first stage, there may be volumes where `initSolution` and `candSolution` match, which are not recognized in the first stage. In order to show an example, we take the previous sample from Fig. 7 and let the `initSolution` $\langle 29, 99, 81, 30 \rangle$. `candSolution` is $\langle 29, 180, 30, 60 \rangle$ (see Fig.8 for its construction). In this case, `lcList` can be found as $\langle 29 \rangle$, but it is observed that the two solutions match at $\langle 99, 81 \rangle$. This information is presented as a volume of a range $\langle 180 \rangle$ that is the union of two adjacent ranges in `initSolution`.

**Extension** Our combine algorithm identifies such a case and extends `lcList` accordingly in the next stage. It searches for cases where a particular volume $v_i$ next to the end of `lcList` in one solution (say `initSolution`) is approximately equal to the sum of the volumes $u_j, u_{j+1}, \ldots, u_{j+r}$ if $r \geq 0$ next to the end of `lcList` of the other solution (e.g. `candSolution`). The algorithm, then, extends the `lcList` by adding $\langle u_j, u_{j+1}, \ldots, u_{j+r} \rangle$ and changing the endpoints of the `lcList` in `initSolution` and `candSolution`. In the database example above, the combine algorithm examines the neighbors of $\langle 29 \rangle$ and finds that $180 \approx 99 + 81$, and extends the `lcList` to $\langle 29, 99, 81 \rangle$. It again examines the

neighbors of $\langle 29, 99, 81 \rangle$ and finds $30 \approx 30$, extending the `lcList` to $\langle \mathbf{29, 99, 81, 30} \rangle$. It is noted that while the values in the example are exactly the same (e.g., $180 = 99 + 81$) by chance, the algorithm also accepts the case where values are approximately equal.

```
initSolution = ⟨prefix1, lcList, suffix1⟩
candSolution = ⟨prefix2, lcList, suffix2⟩
```

After the `lcList` is maximally extended, the two solutions have the form above. Any of prefixes and/or suffixes can be empty. The algorithm then performs one of four options:

(a)   If `prefix1` and/or `suffix1` is empty, then it extends the `lcList` to `lcList = prefix2||lcList` and/or to `lcList||suffix2`.

(b)   If `prefix2` and/or `suffix2` is empty, then it extends the `lcList` to `lcList = prefix1||lcList` and/or to `lcList||suffix1`.

(c)   If the lengths of both `prefix1` and `prefix2` are 1 (say, their volumes are $a$ and $b$, with $a < b$), and if the absolute value of difference appears in the volume measurement, then `lcList = ⟨b−a, a⟩||lcList`. This option also applies to the case when the lengths of both `suffix1` and `suffix2` are 1.

(d)   Otherwise, the algorithm stops combining and repeats stages for another `candSolution`.

Back to our example, we found the `lcList` to be $\langle \mathbf{29, 99, 81, 30} \rangle$. The last stage has `initSolution` $= \langle \text{lcList} \rangle$ and `candSolution` $= \langle \text{lcList}, 60 \rangle$. This is the case of option (a) where `suffix1` is empty. Thus, the algorithm adds `suffix2` $= \langle 60 \rangle$ to `lcList` and returns `initSolution` $= \langle \mathbf{29, 99, 81, 30, 60} \rangle$ as a solution.

*4) Finding best solution:* Once a combine is successful, two solutions are merged and one larger solution is created. The clique finding algorithm may not discover this large solution in the first place because some volumes or connections in the graph were missing, preventing potential cliques corresponding to this solution from being formed. Whenever two solutions are combined, it identifies the number of missing volumes that prevented finding the combined solution. In fact, if the missing volumes could be added to the graph and starts the algorithm, we could get the combined solution in all listed solutions. Therefore, the number of missing volumes is used as a metric to evaluate how good a candidate solution is. On one hand, showing few missing volumes indicates that the `initSolution` and `candSolution` match on many volumes in the database and therefore are compatible. On the other hand, a large number of missing volumes suggests that two solutions may have different information about the volumes. At this, last step finds a candidate solution among all cliques having the lowest number of missing volumes with respect to being combined with the `initSolution`.

## V. MITIGATION STRATEGY

Given noisy volumes, the Modified Clique-Finding algorithm described in the previous section shows a high attack success rate (as will be shown in Section VI); that is, it finds
Fig. 9. A graph constructed from noisy volumes in the database
$\langle 30, 100, 80, 30, 60 \rangle$ when 6 dummy elements are added to the query
responses.

the maximum clique, finds the longest common substring to combine subsolutions, and eventually reconstructs the victim's database correctly with high probability. However, it is noted that the clique finding algorithm is an NP-Hard problem that can be only solved by checking the numbers of all cases one by one, not by polynomial solutions. The complexity of the algorithm grows quickly with the size of the range. We figure out that it works well for the ranges up to size 15 in practice. Adding a small number of nodes to a graph can significantly increase the time required to reconfigure the database; it can even cause the algorithm to fail completely. It is also important to remind that the goal of the attack is to reconstruct the volume, the size of columns on which a victim is making range queries, not exact records.

Based on the observation, this paper proposes to add noise to mitigate the reconstruction attack. Technically, dummy elements are added to results of range queries, which makes it more difficult for an attack to recover approximate volumes in the side-channel attack. The increased size of volume may create edges that should not exist or not create edges that is essential to recover a database. This directly causes the first step to find incorrect cliques; say, the size of the maximum clique found may be greater than $N$. The next step is also affected; it may fail to find the longest common substring or result in reconstructing a wrong database eventually. This approach works because the attacker is concerned only about the volume where the elements are not exposed obviously. However, regular users (i.e., victims) are not confused with the additional elements because they can access exact records in query responses and discern such elements immediately.

Back to our example of database, $\langle 30, 100, 80, 30, 60 \rangle$ in Fig.5. Remind that $\|[1,1]\| = 30$, $\|[2,2]\| = 100$, $\|[3,3]\| = 80$, $\|[4,4]\| = 30$, $\|[5,5]\| = 60$, and a set of possible values for the volume of range queries $V$ is {30, 60, 80, 90, 100, 110, 130, 170, 180, 210, 240, 270, 300}. Now, suppose that 6 dummy elements are added to the response of each range query. Then, $\|[1,1]\| = 36$, $\|[2,2]\| = 106$, $\|[3,3]\| = 86$, $\|[4,4]\| = 36$, $\|[5,5]\| = 66$, and $V = \{36, 66, 86, 96, 106, 116, 136,$

176, 186, 216, 246, 276, 306}. It is noted that $\|[1,2]\| = 136$ (= 130 + 6), not $\|[1,2]\| + \|[2,2]\| = 36 + 106 = 142$, because 6 dummy rows are being added to the result. Fig. **??** shows a graph constructed from the given volumes when 6 dummy elements are added. Comparing the edges in black to Fig. 6, it is observed that new connections are formed (solid bold lines) and some connections are missing (dotted bold lines). The edges in red correspond to the clique found in Fig. 7. It is observed that a connection between node 35 and node 114 (a dotted red line) is not formed and thus the clique is not found in the algorithm. Missing one clique implies that we lose a string information (a contiguous list of volumes) in it, which hiders from finding `lcList` and eventually leads to the failure of the combining step. The algorithm may find another clique and successfully reconstruct a database, but it must be far from the original database.

## VI. EXPERIMENTS AND RESULTS

This section performs experiments for four sets in total and shows their results. The first two sets (I and II) are the cases where an attacker launches a cache side-channel attack to measure approximate noisy volumes and then performs database reconstruction to recover a victim's database. In experiment I, distribution over all the possible queries are uniform; that is, each range are queried with equal probability. Experiment II performs non-uniform range queries. Although each range must be queried at minimum number of times, the query distribution do not need to be uniform. For this, `rand()` function is used in our system. The rest of settings are the same for I and II. In the rest two sets (III and IV), our countermeasure strategy is applied with different percentages of additional dummy elements and with different query distributions. With results, we assess their effects on the database reconstruction attack.

### A. Preliminary

For experiments, this paper uses the Nationwide Inpatient Sample (NIS) 2008 dataset [26]. The NIS is part of the Healthcare Cost and Utilization Project (HCUP) used to analyze national trends in healthcare. This data is collected annually and it has approximately 5 to 8 million hospitalization records. Since data is in an SPSS file format, we use IBM SPSS Statistics [27] to read it. Then, 10 SQLite database is created by selecting 10,000 records randomly out of 8 million ones. We perform range queries on the AMONTH element, an "admission month coded from (1) January to (12) December" (refer to [26] for the full description of elements). The list of ranges are $[1, 1], [1, 2], \ldots [1, 12], [2, 1], [2, 2], \ldots [12, 11], [12, 12]$ and possible values in the range are $N = 12$. For the non-uniform range queries, ranges $[i, j]$ are set by randomly selecting $i$ and $j$ in $1 \le i, j \le 12$. For each set, experiments are repeated 10 times and average values are returned.

We run experiments on a desktop computer with Intel Core i5-9400F CPU @ 2.90 GHz running Ubuntu 16.04. The capacities of the L1, L2, and L3 caches are 384 KB, 1.5 MB, and 9 MB, respectively. For a database engine, we use the SQLite Amalgamation version 3.20.1 with a single large file of C-code named `sqlite3.c` [28]. Table II summarizes information of our setup. We found in a heuristic manner that when approximately 120 measurements are collected for

TABLE II. Setup Information for Experiments

| Dataset | NIS 2008 database [26] |
|---|---|
| Noise budget | 0.002 |
| Possible values in the range | 12 |
| Total number of records | 10,000 |
| Capacities (L1, L2, L3) | 384KB, 1.5MB, 9MB |

TABLE III. Results (Success Rate and Error Rate) from Experiments I and II

| | Exp. I | Exp. II |
|---|---|---|
| Success rate [%] | 100 % | 100 % |
| Error rate [%] | 0.4-0.7 % | 0.2-0.7 % |

a range query, the aggregated measurements in the cache side-channel show a peak regarding the approximate volume. Because there are 78 different range queries for our data, around 10,000 traces are collected first to see if the traces for each range are sufficient so that we can check a peak for each approximate volume.

### B. Database Reconstruction from Noisy Volumes

For Experiments I and II, this paper collects 10,000 traces corresponding to 10,000 range queries; that is, 1 trace for each query. It then processes all of those traces to get a set of approximate, noisy volumes, with which the Modified Clique-Finding algorithm and the Match-Extension algorithm are performed. This returns an output of reconstructed database. The former algorithm runs with different values for the noise budget, whereas the latter algorithm is with a fixed value 0.002 of noise budget. For each value in $1, 2, \ldots, 12$, it is expected to recover a candidate volume that corresponds to the number of records in the database using that value.

For a database of size $N$, a *success rate* is defined as the number of candidate volumes recovered out of $N$. For instance, if our method recovers 10 candidate values in our experiments with the range of size $N = 12$, the success rate is $\left(\frac{10}{12}\right) \times 100$ [%]. It is noted that an attacker can distinguish between successful and unsuccessful attacks because he knows $N$, the size of the database that needs to be recovered. We also define an *error rate* of a recovered volume. For each candidate volume $\tilde{v}$ recovered, we compare it to the corresponding value $v$ in the actual database and report the error rate of $\left(\frac{|\tilde{v}-v|}{v}\right) \times 100$ [%]. For example, if the actual volume is 1,000 and the recovered volume is 980, then the error rate is reported as 0.2%. If our database reconstruction recovers 10 values out of 12, error rates only for the recovered 10 values are reported.

From experiments, it is observed that increasing a noise budget increases the average error rate and the confidence interval for the Modified Clique-Finding algorithm. For noise budgets of 0.005, some of the databases recovered in Experiment I were very far from the true database, resulting in much larger error intervals. In short, increasing the noise budget seems to have helped increase the success rate, but as the error rate increases, the quality of the recovered database decreases. It is also noted that its average running time increases with the size of the noise budget. In the case of the Match-Extension algorithm, the average error and the width of the error interval are similar to those in the Modified Clique-Finding algorithm. But, it achieves much higher success rate with a small noise budget. Experiments in this paper fix the noise budget of 0.002 and thus the average running time remains low. The Modified Clique-Finding algorithm with a noise budget of 0.006 shows better success rate than with a smaller noise budget, and is selected as an algorithm

comparable to the Match-Extension algorithm. For Experiment II, this paper performed non-uniform range queries and used the same sets of database as in Experiment I. As mentioned earlier, we need approximately 120 measurements for a range query to detect approximate, noisy volumes from the cache side-channel. This do not require that the query distribution be uniform. Technically, this experiment tests an hypothesis that the success of a database reconstruction attack relies on the capability of identifying peaks corresponding to the volumes of range queries. In this sense, a query distribution in which a peak disappears as its neighboring peaks dominate it could be challenging to attackers. One setting for the challenging distribution, for instance, is that a range [a, b] is queried more often than a range [c, d] when two ranges have close volumes (i.e., close peaks). Our random setting generate this distribution with probability, given requirement that each query be observed at least 120 times.

Table III shows our results from Experiments I and II. For Experimental I with uniform distribution for all queries, it was possible to reconstruct all 10 databases with the error rate of up to 0.7%, which is considerable in accuracy. Even in the case of Experiment II, where the query range was not uniform, we succeeded in reconstructing 10 databases correctly. The error rate was also within 0.7%. It can be seen that our database reconstruction attack has 100% success rate with low error.

### C. Database Reconstruction with Dummy Data

For Experiments III and IV, our method adds dummy data to response volumes returned by range queries. The rest of settings are same to those in Experiments I and II. Experiment III and IV perform uniform and non-uniform range queries, respectively and use approximate, noisy volumes. The database used in the experiment has 10,000 rows, and the range of the AMONTH attribute is 1 to 12. Thus, there are about 800 rows in each range. In the first setting, our method adds 8 dummies (rows) to the response of each range query. That is, it corresponds to 1% of total volumes.

Table IV shows our results from Experiments III and IV. In both experiments, 6 out of 10 databases (60%) were successfully reconstructed, and the error rate in the reconstructed databases was 9%-15%. They are comparable to results, 100% and 0.7%, in previous experiments in Table III. It is reminded that the success criterion for reconstruction is that all 12 candidate values is recovered. 60% of recovery, therefore, is far from the success of an attack. In order to investigate the impact of dummy data further, we add 2% of dummy data out of total volumes in the second setting. Table V shows its results. In both experiments, no database was reconstructed at all. This is mainly attributed to the fact that the database construction attack primarily relies on the volume size of query responses. It is so sensitive to the size that small inclusion of dummy can even weaken its success rate.

TABLE IV. RESULTS (SUCCESS RATE AND ERROR RATE) FROM EXPERIMENTS III AND IV (1% OF DUMMY)

|  | Exp. III | Exp. IV |
|---|---|---|
| Success rate [%] | 60% | 60% |
| Error rate [%] | 10-14% | 9-15% |

TABLE V. RESULTS (SUCCESS RATE AND ERROR RATE) FROM EXPERIMENTS III AND IV (2% OF DUMMY)

|  | Exp. III | Exp. IV |
|---|---|---|
| Success rate [%] | 0% | 0% |
| Error rate [%] | - | - |

## VII. CONCLUSION AND DISCUSSION

This paper investigated the impact of side-channels on open-source database engines. We triggered a side-channel attack on a cache shared by victim VMs and a spy VM using SQLite to obtain approximate, noisy volumes of the database. Two algorithms that extended a clique finding algorithm were introduced in order to perform a database reconstruction attack. This paper also introduced a mitigation method that added additional dummy data to results of range queries. Experiments were conducted with a database of 10,000 records and with 12 ranges for queries. Results showed that the database reconstruction attack could recover almost 100% volumes of the database with maximum error rate of 0.7%. With 1% of additional dummy data, however, only 60% of database were recovered with up to 15% of error rate. When adding 2% of dummy data, no database was constructed at all; the database construction attack was completely failed.

As a future work, it would be interesting to investigate the impact of the volume of dummy data further. Given the number of records (10,000) used in our experiment, the size of the volume for each range query is about 800. 1% of additional data represents 8 records only, which does not seem to be a problem. But, as the size of the database increases, this volume also increases. This will naturally increase the processing time of query requests and use a lot of memory. It is necessary to find solutions to defend against attacks without performance degradation in large scale database settings. It would be also interested to examine our models on a scenario where victim VMs and a spy VM do not share a library with a more generic form of cache side-channel attack [6].

# An Approach for Classification of Diseases on Leaves

Quy Thanh Lu
Information Technology Department
FPT University
Can Tho, Viet Nam

*Abstract*—In recent years, significant advancements have been made in the realm of plant disease classification, with a particular focus on leveraging the capabilities of deep learning techniques. This study delves into the utilization of renowned Convolutional Neural Network (CNN) models, including EfficientNetB5, MobileNet, ResNet50, InceptionV3, and VGG16, for the purpose of plant disease classification. The core methodology involves employing transfer learning, wherein these established CNN models are employed as a foundation and subsequently fine-tuned using a publicly accessible plant disease dataset. The study also compared the results with some deep learning models and with state-of-the-art. Among the tested CNNs, EfficientNetB5 has shown the best performance. EfficientNetB5 has outperformed another model and obtained 99.2% classification accuracy.

*Keywords*—*Classification of diseases on leaves; transfer learning; fine-tuning; image classification; deep learning*

## I. INTRODUCTION

Plant diseases are a pervasive and complex aspect of agriculture and horticulture, exerting significant impacts on global food production and ecosystem health. Plant diseases can manifest in various ways, from visible symptoms like wilting, discoloration, and lesions to more subtle signs of stunted growth and reduced yield. The management of plant diseases necessitates a multifaceted approach, combining practices such as crop rotation, the use of disease-resistant cultivars, proper sanitation, and judicious application of pesticides. As the world grapples with the challenge of feeding a growing population, understanding and mitigating plant diseases is of paramount importance to ensure sustainable agricultural systems and safeguard global food security [1].

Hence, numerous studies in this field have been conducted, deploying various methods such as classical machine learning models and state-of-the-art deep learning techniques [2] [3] [4] [5]. Authors have also employed data preprocessing methods to enhance model accuracy. Besides, there have been studies focusing on feature extraction using traditional techniques like SURF [6], HOG [7], etc.

In this study, we used a CNN [8] model, including EfficientNetB5, MobileNet, ResNet50, InceptionV3, and VGG16, to classify plant diseases within an existing dataset. Additionally, the study compared the results with other deep learning models and state-of-the-art methods. The obtained results were highly satisfactory, achieving an accuracy and F1-score of 99.2% and 99.22%, respectively.

This article is divided into five sections. The first section is the introduction. In the subsequent Section II, we present related works. Moving forward, Section III is the proposed methodology. The experimental procedures and outcomes are discussed in Section IV. Lastly, the conclusion wraps up the article.

## II. RELATED WORKS

Numerous research have been conducted in recent years to address the issue of plant disease. Researchers are continuously finding new, creative ways to increase their accuracy.

In the article [9], the author proposed a deep learning-based method for tomato disease detection that utilizes the Conditional Generative Adversarial Network (C-GAN) to generate synthetic images of tomato plant leaves. Then, a DenseNet121 model is trained on synthetic and real images using transfer learning to classify the tomato leaves images into ten categories of diseases. The results obtained accuracy of 99.51%, 98.65%, and 97.11% for tomato leaf image classification into five classes, 7 classes, and 10 classes, respectively.

In [10], a comprehensive four-step procedure is presented for enhancing the accuracy of plant disease detection and classification in images. The process commences with pre-processing, employing a Wiener filter to mitigate background noise. Disease spots are subsequently identified using the hue histogram in the HIS model, followed by precise segmentation through the K-means algorithm and highest hue value calculation in the HSV color model. Afterward, seventeen color and texture features are extracted from the disease-affected regions and input into a forward-propagation deep neural network (FPDNN) classifier. To improve results, the Bayesian regularization back propagation algorithm is applied. Impressively, the FPDNN was subjected to testing with varying hidden layers, achieving its peak accuracy of 97.18% with 19 hidden layers. This underscores the effectiveness of this methodology in accurate plant disease identification and classification.

In [11], the authors concentrated their efforts on crafting an integrated model for the precise detection of tomato diseases through the utilization of image data. To achieve this, they rigorously assessed the performance of seven distinct neural network architectures, including renowned ones like VGG16, ResNet50, and various EfficientNet variants, all fine-tuned through transfer learning methodologies. After a thorough evaluation, the most proficient models were selected, and a weighted average ensemble technique was applied to amalgamate them. This amalgamation resulted in the proposal of a final model boasting an impressive accuracy rate of 98.1%.

This study [12], the identified diseases were categorized into three distinct groups: bacterial, viral, and fungal infections. The research delved into a thorough exploration of these aspects and employed a range of machine learning (ML) and deep learning (DL) techniques. The ML methods employed in the study encompassed SVM, KNN, RF (Random Forest), and LR (Logistic Regression), while the DL approach featured the use of Convolutional Neural Networks (CNN) for disease prediction in plants. Among the machine learning classifiers, the RF (Random Forest) yielded the highest accuracy, achieving an impressive rate of 97.12%. However, the CNN classifier, representing the deep learning model, outshone them all with an even higher accuracy of 98.43%.

In the study [13] conducted by Nagamani H S and Sarojadevi H, the focus was directed towards the detection and classification of diseases that impact tomato leaves, employing a range of machine learning techniques. This comprehensive investigation encompassed the utilization of FuzzySVM, Convolutional Neural Network (CNN), and Region-based Convolutional Neural Network (R-CNN) models. The researchers executed an array of sophisticated image processing and feature extraction methodologies to enhance the predictive capabilities of their models. Remarkably, their findings unveiled that the R-CNN model emerged as the standout performer, achieving an impressive accuracy rate of 96.735% in the classification of various disease types afflicting tomato plants.

In research [14] of Nishant Garg and colleagues , the model was meticulously trained on a substantial dataset consisting of 8,000 images across the relevant classes and rigorously tested on a separate test set comprising 2,000 images. The hybrid methodology employed a fusion of Convolutional Neural Network (CNN) for effective feature extraction from input data and a finely tuned Support Vector Machine (SVM) classifier for precise classification. This synergistic combination proved to be highly effective, achieving an impressive accuracy rate of 92.6%. The authors, in [15], used a Convolutional Neural Network (CNN), specifically the VGG model, to detect Multi-Crops Leaf Disease (MCLD) by classifying diseased and healthy crop leaves. They achieved impressive results with an accuracy of 98.40% for grapes and 95.71% for tomatoes.

In their research paper [16], the authors conducted a comprehensive assessment of deep learning techniques, leveraging pre-trained CNN models within the PyTorch framework for the classification of tomato plant diseases. They evaluated various models, such as EfficientNetB0, ResNext-50-32x4d, and MobileNet-V2, with ResNext-50-32x4d emerging as the top performer, achieving an impressive accuracy rate of 90.14%. In the paper cited as [17], the authors introduce a novel approach for classifying seven distinct types of tomato diseases employing Deep Learning models. Their models were trained on an extensive dataset comprising 10,448 images, and the results were striking. The trained models exhibited remarkable accuracy, with the highest testing precision achieving an impressive 95.71%.

This article [18] used deep learning for crop disease detection. They employed a Convolutional Neural Network (CNN) with two convolutional and two pooling layers in the model. The results are quite promising, as the proposed CNN model outperformed well-known pre-trained models like InceptionV3, ResNet 152, and VGG19. The CNN achieved an impressive 98% training accuracy and maintained a strong 88.17% testing accuracy. This paper [19] focuses on the identification of tomato plant diseases, utilizing a transfer learning approach with the EfficientNetB3 model. The dataset comprises 11 distinct types of leaves and is sourced from an online database. The EfficientNetB3 model undergoes 15 training iterations with a batch size of 32, employing two optimizers, Adamax and Adam. Notably, the use of the Adam optimizer resulted in an accuracy of 94%.

In this research [20], a prediction model for Tomato Early Blight Disease (TEBD) was developed using image-based data. The TEBD dataset was improved through various image processing techniques such as Background Removal, Augmentation, Resizing, Noise Removal, and Segmentation. Subsequently, a Convolutional Neural Network (CNN) was employed to train the model on the enhanced dataset. The model's performance was exceptional, achieving a remarkable mean accuracy of 98.10%, demonstrating its capacity to accurately predict TEBD with a batch size of 64 and 15 training epochs.

In the study described in [21], the researchers employed established CNN architectures like AlexNet, ResNet50, and VGG16 for feature extraction. Subsequently, they applied the minimum redundancy maximum relevance feature selection algorithm to refine these features for optimal performance. These selected features were then combined through concatenation. To classify the concatenated features, the researchers utilized well-known machine learning classification algorithms. Remarkably, their proposed approach achieved outstanding results, boasting an impressive accuracy of 98.3% for tomato leaf disease detection and 96.3% for the Taiwan dataset.

In this study [22], an innovative approach was introduced by fusing two pre-trained models, namely EfficientNetB3 and MobileNet, collectively referred to as the EffiMob-Net model, for highly precise tomato leaf disease detection. The researchers conducted thorough hyperparameter tuning to meticulously select the ideal settings for constructing the most suitable model. The performance of this hybrid model was rigorously assessed, focusing on accuracy metrics specifically chosen for disease detection. Impressively, the proposed EffiMob-Net model achieved an exceptional success rate of 99.92%. In reference [23], the research leveraged pre-trained CNN models, namely Inception V3 and Inception ResNet V2, to effectively classify images of tomato leaves as healthy or unhealthy. Remarkably, their approach yielded outstanding results, boasting a remarkable accuracy rate of 99.22%. Additionally, they managed to keep the loss to an impressively low 0.03. This achievement was made possible through strategic use of dropout rates, with 50% for one model and 15% for the other.

In [24], authors employed a dataset comprising tomato leaves, encompassing six distinct disease types along with a class for healthy tomato leaves. This dataset, consisting of 6,594 tomato leaf images, was sourced from Plant Village. In addtional, approach of study, utilizing the ResNet-50 model, delivered a remarkable outcome, achieving a substantial accuracy rate of 96.35% when tested on a balanced dataset split, with 50% used for training and the remaining 50% for testing. In this study [25], Sanjeela Sagar and Jaswinder Singh conducted an experimental and comparative analysis of

tomato leaf disease classification, employing both traditional machine learning algorithms such as random forest (RF), support vector machines (SVM), and naïve bayes (NB), as well as a deep learning convolutional neural network (CNN) algorithm. Notably, our findings revealed that the CNN, specifically when integrated with a pre-trained Inception v3 model, outperformed traditional methods. This advanced approach achieved an impressive accuracy rate of over 95%.

In [26], Irene Sultana and her team have introduced a substantial dataset consisting of 14,529 tomato leaf images encompassing ten distinct infections. In their study, they harnessed the power of deep learning by employing InceptionV3 and ResNet-50 as the learning algorithms, capitalizing on transfer learning techniques for classifier training. Their innovative deep learning model delivered commendable outcomes, achieving an accuracy rate of 85.52% for InceptionV3 and an even more impressive 95.41% for ResNet-50. In this research paper [27], authors focus on the crucial task of cassava plant disease detection, recognizing that deep learning models surpass traditional machine learning methods, as observed in prior research. In additional, Prashant Giridhar Shambharkar and Saurabh Sharma employ the EfficientNet-B0 architecture in conjunction with k-fold cross-validation to develop a highly effective disease detection model. EfficientNet's reputation for superior classification, speed, and scalability across various dimensions makes it an ideal choice. Result attains an impressive 96.68% accuracy when evaluated on a collect Kaggle dataset.

The common challenge for researchers is the difficulty in increase accuracy to classification of plant diseases on leaves. Therefore, in this study, we have conducted several experiments on several Machine Learning models (including pre-trained Deep Learning models) to validate their better performance in the scenario.

## III. BACKGROUND

### A. Image Classification

One of the most pivotal and burgeoning research domains in contemporary times is image classification, particularly within the realm of medical imaging analysis. Image classification, also referred to as image categorization, plays a critical role in determining the presence of diseases by generating a classification output based on input images. Its primary objective is to assign a specific label to an image, which proves instrumental in various applications.

Image classification extends its relevance to numerous real-world sectors and industries, encompassing environmental studies, agriculture, remote sensing, urban planning, surveillance systems, geographic mapping, disaster management, and item identification. This versatile and transformative technology not only aids in medical diagnoses but also finds widespread utility in addressing a multitude of challenges and opportunities across diverse fields.

### B. Convolutional Neural Network (CNN)

Convolutional Neural Networks (CNNs) stand as a cornerstone in the domain of deep learning, particularly in the realm of image analysis and recognition [8]. CNNs leverage a distinctive mathematical technique known as convolution,

which involves performing an operation on two functions to derive a third function, illustrating the transformation of one function by the other. In CNN architecture, convolution plays a pivotal role in extracting hierarchical features from input images, enabling the network to progressively discern complex patterns. CNNs are composed of multiple layers of artificial neurons, which function as mathematical units responsible for aggregating input information and generating activation values, closely mirroring the information processing capabilities of human neurons, as they assimilate sensory inputs and produce corresponding responses. This structural and functional alignment with biological neural systems contributes to CNNs' extraordinary efficacy in tackling intricate image-based tasks and solidifies their status as a cornerstone technology in modern deep learning.

Kernel convolution [8] serves as a foundational element not only in Convolutional Neural Networks (CNNs) but also in various Computer Vision methodologies. This technique involves the application of a small matrix, referred to as the kernel or filter, to modify an image based on the filter's values. In the context of the mathematical representation, the input image is symbolized as $g$ and the kernel is represented as $p$. The process can be expressed using the following formula, which is instrumental in generating subsequent feature map values. The indices for the rows and columns of the resulting matrix are typically denoted as $a$ and $b$, respectively, as indicated in equation (Eq. 1). This fundamental operation forms the basis for extracting important visual information and features from images, underpinning a wide range of computer vision applications.

$$G[a,b] = (g*p)[a,b] = \sum_i \sum_j p[i,j]g[a-i,b-j] \quad (1)$$

Within the Convolutional Neural Network (CNN) architecture, the first layer is the convolutional layer, tasked with the process of disentangling diverse features from the input images. In this layer, a $NxN$ sized filter is employed in tandem with the input image to execute the convolution operation. The forward propagation through this layer unfolds in two phases. Initially, the first step is to determine the intermediate value $X$, which is produced when the input data from the previous layer is convolutioned with the $Y$ tensor (which contains filters), and then bias $d$ is added. The next involves using our intermediate value as the input for a non-linear activation function (our activation is denoted by $h$). For the fans of matrix equations, the subsequent formulas, encapsulated as Eq. (2) and (3).

$$X^{[l]} = Y^{[l]}.C^{[l-1]} + d^{[l]} \quad (2)$$

$$C^{[l]} = h^{[l]}(X^{[l]}) \quad (3)$$

### C. ResNet50 Model

ResNet [28] represents a distinctive variant of a convolutional neural network (CNN) that was first presented in the research paper titled "Deep Residual Learning for Image Recognition" in 2015. This concept is introduced by He Kaiming, Zhang Xiangyu, Ren Shaoqing, and Sun Jian. ResNet-50 is a convolutional neural network that is 50 layers deep, including

48 convolutional layers, one MaxPool layer, and one average pool layer. Residual neural networks are a type of artificial neural network (ANN) that constructs networks by assembling residual blocks [29].

### D. MobileNet Model

MobileNet [30] is a simple but efficient and not very computationally intensive convolutional neural networks for mobile vision applications. MobileNet is widely used in many real-world applications which includes object detection, fine-grained classifications, face attributes, and localization. In this lecture, I will explain you the overview of MobileNet and how exactly it becomes the most efficient and lightweight neural network. MobileNet uses depthwise separable convolutions. It significantly reduces the number of parameters when compared to the network with regular convolutions with the same depth in the nets. This results in lightweight deep neural networks.

### E. VGG16 Model

VGG16 [31] is a convolutional neural network model proposed by K. Simonyan and A. Zisserman from the University of Oxford in the paper "Very Deep Convolutional Networks for Large-Scale Image Recognition" [32]. The model achieves 92.7% top-5 test accuracy in ImageNet, which is a dataset of over 14 million images belonging to 1000 classes. It was one of the famous model submitted to ILSVRC-2014. It makes the improvement over AlexNet by replacing large kernel-sized filters (11 and 5 in the first and second convolutional layer, respectively) with multiple 3×3 kernel-sized filters one after another. VGG16 was trained for weeks and was using NVIDIA Titan Black GPU's.

### F. InceptionV3 Model

InceptionV3 [33] is an image recognition model that has been shown to attain greater than 78.1% accuracy on the ImageNet dataset. The model is the culmination of many ideas developed by multiple researchers over the years. It has a total of 42 layers and a lower error rate than its predecessors. Additional, it is introduced on the original paper: "Rethinking the Inception Architecture for Computer Vision" by Szegedy, et. al. [34].

### G. EfficientNetB5 Model

EfficientNetB5 [35] is part of a family of eight DCNN models called EfficientNet, introduced by Google AI [36]. The eight models of EfficientNet range from B0 to B7 where the largest is B7. EfficientNets showed higher accuracy and better efficiency in comparison to existing CNNs. The EfficientNet architectures are based on a scaling approach that uses a compound coefficient to consistently scale the three dimensions (resolution, depth, and width). This results in higher performance and greater accuracy of the models.

### IV. PROPOSED ARCHITECTURE

Fig. 1 shows our proposed approach. The goal of this process is to increase the amount of data large enough for deep learning models to bring high efficiency to the model. Then, the data will be divided into three parts: training set,

validating set and testing set. Next, pretrain models with the ImageNet dataset are used without the output layer. We reuse all the trained weights from the ImageNet dataset. After input layer, we create an additional layer called AugmentedLayer, this layer is responsible for enhancing data from the input dataset with different techniques such as: flip, rotation, zoom and contract. After that, we proceed to add layers in turn: Dense with 256 hidden units, followed by activation layer with ReLu, Batch Normalization layer, dropout layer with value 0.3, dense layer and final is output layer.

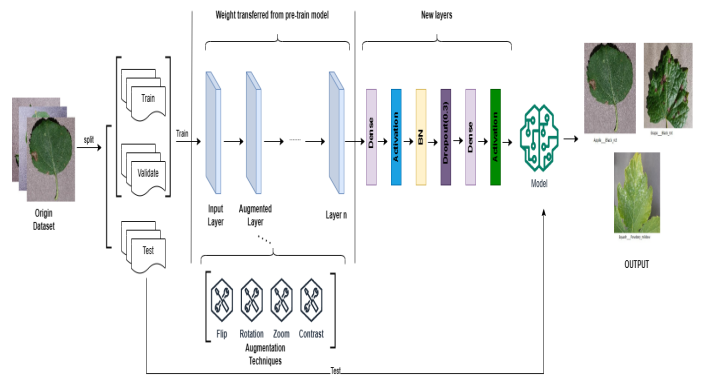

Fig. 1. Our proposed architecture.

The details of the input and output of each layer and the number of parameters of the proposed architecture are shown in Table I.

TABLE I. SUMMARY OF PROPOSED MODELS

| Layer (type) | Output Shape | Param # |
|---|---|---|
| inputLayer (InputLayer) | [(None, 224, 224, 3)] | 0 |
| AugmentationLayer (Sequential) | (None, 224, 224, 3) | 0 |
| efficientnetb5 (Functional) | (None, 2048) | 28513527 |
| dense_3 (Dense) | (None, 256) | 524544 |
| activation_1 (Activation) | (None, 256) | 0 |
| batch_normalization_1 (BatchNormalization) | (None, 256) | 1024 |
| dropout_1 (Dropout) | (None, 256) | 0 |
| dense_4 (Dense) | (None, 38) | 9766 |
| activationLayer (Activation) | (None, 38) | 0 |
| ... | | |
| Trainable params: 534,822 | | |
| Non-trainable params: 28,514,039 | | |

### V. EXPERIMENTS

### A. Dataset and Experimental Environment

The dataset [37] used contained 87,867 images of fruits and vegetables belonging to 38 different categories. The pre-split data consists of three sets: training, validation and testing. The training set includes 70,295 images. The validation set has 15,814 images. The test set contains 1,758 images. Each photo will contain a plant-diseases of leaves. Fig. 2 shows the distribution of data of the training set.

In this experimental, we train the data with the proposed model. The experiment was performed on a computer with the following configuration: Core i5 12400F, 32GB RAM, and Geforce RTX 3060 12VRAM graphics card.
Fig. 2. Data distribution.

Fig. 3. Accuracy and loss during training.

### B. Experiment 1: Evaluation of the Proposed Model

In this experiment, we performed on the hyperparameter set with the specified values as follows: batch_size=32, epoch=15, learning_rate=0.00001, and optimizer=Adam. The Table II compares the results between some deep learning models based on our approach. In which, (1) is train loss, (2) is train accuracy, (3) is validation loss, (4) is validation accuracy, (5) is test loss, (6) is test accuracy and final is F1-Score.

TABLE II. COMPARISON BETWEEN THE PROPOSED MODEL AND SOME OTHER MODELS

| Models | (1) | (2) | (3) | (4) | (5) | (6) | (7) |
|---|---|---|---|---|---|---|---|
| **EfficientNetB5** | **0.22** | **0.92** | **0.14** | **0.95** | **0.02** | **0.992** | **0.992** |
| InceptionV3 | 1.70 | 0.50 | 1.92 | 0.45 | 1.35 | 0.587 | 0.585 |
| MobileNet | 0.65 | 0.79 | 0.67 | 0.78 | 0.57 | 0.82 | 0.82 |
| ResNet50 | 0.06 | 0.97 | 0.10 | 0.96 | 0.03 | 0.9898 | 0.9898 |
| VGG16 | 0.24 | 0.91 | 0.21 | 0.92 | 0.06 | 0.9829 | 0.9829 |

From the comparison table above, we can see that the fine-tune EfficientNetB5 model achieves a performance of 99.2 with both accuracy and F1 measure. Fig. 3 shows the accuracy and loss in training data of it.

And the confusion matrix of the fine-tune EfficientNetB5 model is shown in Fig. 4.

### C. Experiment 2: Compare the Results with Some other Deep Learning Models and State-of-the-Art

In Experiment 2, to have a basis for evaluating the effectiveness of the proposed approach, we also compare the results of the proposed model (*fine-tuned EfficientNetB5 model with highest accuracy in Experiment 1*) with the state-of-the-arts. The results are shown in the Table III.

From the results in Table II and Table III, we can see that our approach is quite simple but achieves high effectiveness in the applied classification problem. With a large amount of image data (87,867 images) combined with augmented layer,

Fig. 4. Confusion matrix of fine-tuned efficientNetB5 model.

this study demonstrates superiority over most other models. However, in some cases, it is not as effective as [22] and [23].

## VI. CONCLUSION

The problem of plant disease classification based on images plays a significant role in real-life scenarios, particularly in contributing to addressing issues related to the quality and quantity of agricultural produce. The results of research on leaf

TABLE III. COMPARISON WITH STATE-OF-THE-ARTS

disease classification also aid in more accurate identification of various diseases affecting plants. In the realm of plant disease classification, numerous studies have explored various methodologies, including classical machine learning models, deep learning models, transfer learning, and fine-tuning techniques. However, the results have not yet been obtained really high such as: the number of plant disease leaves in the data set is small or the accuracy achieved is not high. Because of that, this study has proposed an approach through building a CNN model that is relatively simple but helps bring about high accuracy. The study tested on a data set of 38 classes of plant disease leaves. The results are very satisfactory with the accuracy and F1-Score of 99.2% and 99.22%, respectively. In the future, we will build new models or combine from many different models to further improve the accuracy of this problem.

# Transformer-based End-to-End Object Detection in Aerial Images

Nguyen D. Vo, Nguyen Le, Giang Ngo, Du Doan, Do Le, Khang Nguyen*
University of Information Technology, Ho Chi Minh City, Vietnam
Vietnam National University, Ho Chi Minh City, Vietnam

*Abstract*—Transformer models have achieved significant milestones in the field of Artificial Intelligence in recent years, primarily focusing on text processing and natural language processing. However, the application of these models in the domain of image processing, particularly on aerial images data, is actively research. This study concentrates on the experimental evaluation of Transformer-based models such as DETR, DAB-DETR, and DINO on the challenging Visdrone dataset, which is also essential for aerial image data processing. The experimental results indicate that Transformer-based models exhibit substantial potential, especially in object detection on aerial image data. Nevertheless, their application is not without challenges, including low resolution, dense object occurrences, and environmental noise. This work provides an initial glimpse into both the capabilities and limitations of Transformer-based approaches within this domain, with the aim of stimulating further development and optimization for practical applications, including traffic monitoring, environmental protection, and various other domains.

*Keywords*—*Object detection; aerial images; end-to-end; transformer-based; DETR; DAB-DETR; DINO*

## I. Introduction

One of the foundational tasks in the computer vision field is untangling the Object Detection problem. The purpose of this task is to predict the location and classify various objects in an image, thereby fostering an enhanced understanding of visual content. This serves as a critical cornerstone for numerous computer vision applications and various practical technology domains, including healthcare, security, transportation, education, etc. In recent years, the emergence of unmanned aerial vehicles (UAVs, drones, and flycams) has resulted in a surge of aerial data, presenting abundance of advantageous opportunities that conventional sources cannot provide, such as diverse perspectives and panoramic views (Fig. 1). Successfully tackling this task holds significant potential for enhancing and broadening intelligent applications like security monitoring or smart transportation. Hence, object recognition in aerial image data is a subject of paramount importance and a vigorously researched area. However, this task presents a myriad of challenges, including but not limited to small object dimensions, high object densities, and low image resolutions [1], [2].

Research on object detection in recent years can be categorized into three major divisions: two-stage methods, known for their high accuracy, with Faster R-CNN [3] serving as a representative example; one-stage methods, with YOLO [4] algorithm as a prominent representative, known for its fast

inference time; and end-to-end methods. End-to-end methods have gained popularity within the research community in recent years due to their simplicity, efficiency, ease of integration, utilization of global information, and time and cost savings during setup and training phases (see Fig. 2). For these reasons, conducting research on end-to-end methods for object detection is essential to enhance performance and facilitate their integration into real-world applications in the field of computer vision [5].

An abundance of end-to-end methods have been proposed to address object detection, including several Transformer-based end-to-end models, such as DETR [6], DAB-DETR [7], and DINO [8]. These methods are evaluated on general objects across standard datasets, such as Pascal VOC [9] and MS-COCO [10]. Each method has its own strengths and weaknesses. In contrast, there is still a limitation in evaluation of these methods in the aerial data domain. Exploring and analyzing the advantages and disadvantages of end-to-end methods promises to provide valuable information for future research.

Therefore, this study focuses on surveying and analyzing three representative end-to-end models, namely DETR [6], DAB-DETR [7], and DINO [8]. Experiments are conducted on standard aerial image datasets VisDrone2019 [11]. Challenges in the aerial image data domain will be highlighted and discussed, along with potential approaches to address the difficulties encountered by these models.

The remaining part of the paper is organized as follows: In Section II, we present related research. Three Transformer-based end-to-end object detection methods, including DETR, DAB-DETR, and DINO, will be described in Section III. The detailed experimental results of the Transformer-based end-to-end method on the VisDrone dataset are reported and discussed in Section IV, along with provided evaluations. Finally, Section V will conclude this paper and suggest directions for future research.

## II. Related Works

Object detection represents a foundational task within the field of computer vision, requiring the precise classification and localization of objects of interest within both images and video content.This task holds an essential position in a variety of practical applications, ranging from traditional utilizations like image annotation to modern applications such as autonomous vehicles, robots, surveillance systems, and augmented reality [12]. Over the past decade, object detection methods based on deep learning have garnered significant

*Corresponding author
Fig. 1. Images acquired from ground-level vantage points (below) and those obtained from aerial perspectives (above) provide a comparison in terms of perspective and scope. Aerial images (above) offer a wide field of view, encompassing diverse angles and densely distributed small objects. Ground-captured images (below) showcase finer details and focus on more distinct objects.

attention due to the rapid advancements in deep learning techniques [13]. However, there are still a substantial number of challenges, including balancing accuracy and efficiency, handling multi-scale objects, and developing lightweight models.

Traditional object detection methods have primarily relied on convolutional neural networks (CNNs), including Faster R-CNN [3], SSD [14], and YOLO [4]. Some YOLO-based methods, including PH-YOLOv5 [15], AVS-YOLO [16], YOLOv7-Drone [17], and so on, have been specifically developed for object detection in aerial images. Leveraging the considerable success of Transformer in natural language processing (NLP), researchers have been striving to apply Transformer architectures to computer vision tasks. As a result, an extensive number of vision models based on Transformer have emerged in recent years, achieving comparable or even superior performance compared to CNN-based variants.

Transformer architecture [18], which were initially proposed as a self-attention mechanism for machine translation tasks, have increasingly gained attention in object detection, especially in the last three years. High-performance models such as DETR [6], DAB-DETR [7], DINO [8], and many others have been proposed. Currently, Transformer-based models have become a novel approach to object detection, making systematic analysis and evaluation of these models essential for future research.

In recent years, unmanned aerial vehicles (UAVs) have been steadily developing, becoming more affordable, capable of longer flights, and highly maneuverable. Researchers leverage these advantages to employ drones in supporting various daily activities, including rapid delivery services, security surveillance, traffic monitoring, border patrols, and even military use. This has led to the generation of a vast number of images and videos, posing new challenges for object detection. While an abundance of object detection methods have been proposed and have achieved high effectiveness on common datasets like Pascal VOC [9] and MS-COCO [10], they often yield inferior results when tested on non-standard datasets, particularly in the aerial domain. This underscores the need for object detection algorithms and models capable of handling diverse object sizes, densities and viewing angles, as well as adapting to noisy images and low-resolution data resulting from remote sensing. Evaluating Transformer-based methods in the aerial domain is important, as it can provide valuable insights into the challenges of this unique data domain.

## III. METHODOLOGY

### A. DETR [6]

In two-stage object detection models, bounding boxes are estimated based on proposals using Region of Interest (RoI), while one-stage detector rely on anchors. Research has shown that the model's performance is significantly influenced by how initial predictions are generated. In mid-2020, Nicolas Carion and Francisco Massa along with other colleagues introduced a completely new approach to the object detection problem. The DETR model (Fig. 3) considers object detection as a set-based matching problem, performs detection and classification in an end-to-end pipeline harnessing the Transformer architecturea distinct paradigm when juxtaposed with one-stage modelsfor comprehensive image processing. DETR also does not generate RoIs or other intermediate steps (e.g., anchor boxes) as in two-stage models.

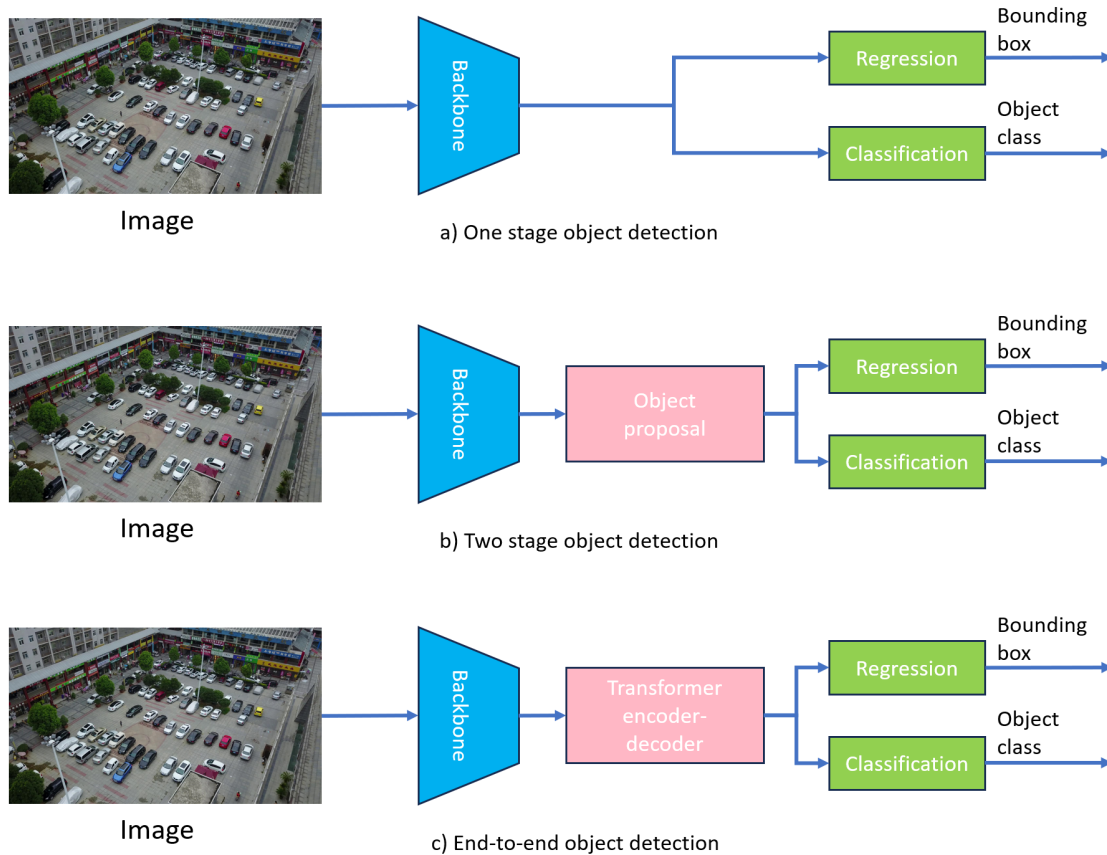
Two key factors that contribute to DETR's direct object detection capability are a loss function called bipartite matching loss, which ensures a unique match between predictions and ground truth; a network architecture capable of predicting sets of objects and modeling the relationships between them (Fig. 3). DETR is renowned for its revolutionary architecture that reduces the complexity of object detection while achieving strong performance in various scenarios.


Fig. 2. The framework of the three common object detection methods. Figure a) represents a one-stage object detection model. Figure b) represents a two-stage object detection model. Figure c) represents an end-to-end object detection model.[6]

In contrast, DETR has several limitations, including slow training convergence time compared to other object detection models like Faster R-CNN and subpar performance when detecting small-sized objects. The underlying reason of these problems can be attributed to the absence of components in the Transformer architecture while processing a set of object features. Initially, the attention modules assign random weights to all pixels in the object feature set. A considerable number of epochs is necessary during the training process to allow the attention weights to be learned, focusing on important and sparse pixels [19].

### B. DAB-DETR [7]

The DAB-DETR introduces a new query formulation, which is applied within the DETR (Detection Transformer) model, aiming to enhance the understanding of the role of queries in DETR. This new query formulation directly utilizes the coordinates of bounding boxes as queries during the decoding process of the Transformer and dynamically updates them across model layers. This approach has led to significant improvements in the similarity between queries and bounding box features, simultaneously solving the slow convergence issue during DETR training. By using bounding box coordinates as queries, the authors have been able to integrate explicit location information into the querying process and adjust attention maps' positions based on the width and height information of each bounding box.

This representation allows the deployment of queries in DETR as a soft Region of Interest (ROI) aggregation and layer-wise classification stacking process. Specifically, the DAB-DETR method utilizes 4D anchor box coordinates (x, y, w, h) as queries in DETR, as shown in Fig. 4, and updates them across layers. With the information about the size of each anchor box (w, h), Gaussian positional constraints can be adapted to better fit objects of different scales. Additionally, shaping queries as anchor boxes allows for using the center position (x, y) of anchor boxes for feature extraction, increasing the similarity between queries and features and eliminating the slow convergence issue during training. This provides a simpler implementation and a deeper understanding of the role of queries in DETR.

### C. DINO [8]

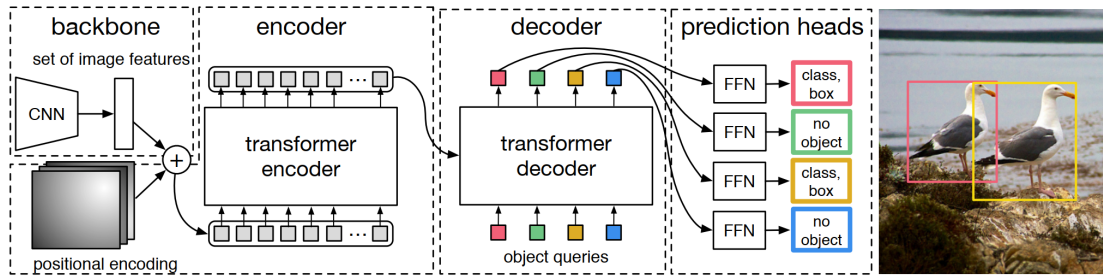
Research directions stemming from DETR are increasingly receiving attention and continuously evolving. The weaknesses of DETR have been addressed and improved continuously. However, most of the improvements have been focused on individual modules and have not resulted in a significant breakthrough. DINO synthesizes prior advancements and introduces superior methods, which have led to a significant leap forward for end-to-end approaches. DINO is a model similar to DETR, with an end-to-end architecture comprising a backbone, a multi-layer Transformer encoder, a multi-layer Transformer decoder, and multiple prediction heads. The overall pipeline is


Fig. 3. The architecture of DETR consists of three main components: a CNN network serving as the backbone to extract image features, a Transformer encoder-decoder architecture, and a feed-forward network (FFN) to generate the final predictions [6].

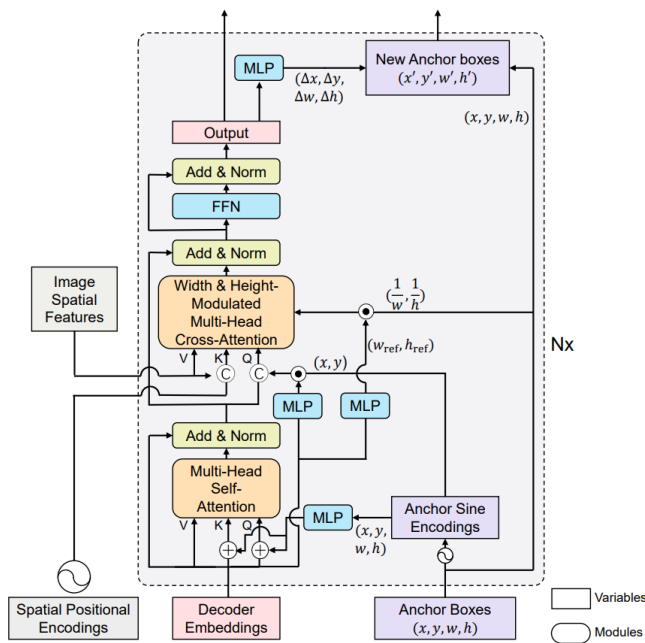

Fig. 4. DAB-DETR directly uses dynamically updated anchor boxes to provide both a reference query point (x, y) and a reference anchor size (w, h) to improve the cross-attention computation [7].

depicted in Fig. 5.

In this approach, multi-level features are extracted from input images using backbones like ResNet or Swin Transformer. These features, along with positional embeddings, are then processed through a Transformer encoder. A unique query selection strategy is introduced to initialize anchors as position queries for the decoder, while content queries are left for learning. The model utilizes these initialized anchors and learnable content-based queries in conjunction with a deformable attention mechanism to merge features from encoder outputs and update queries at each layer and stage. The ultimate output is generated from adjusted anchor boxes, and classification results are predicted using fine-tuned content features.

Just like DN-DETR, this model incorporates a denoising branch (DN) to carry out noise reduction during training. Beyond the conventional DN technique, a novel noise-contrastive reduction training method is introduced, taking into account challenging negative samples. To maximize the utilization of

information from the modified boxes in later stages, which aids in optimizing neighboring stage parameters, a unique "look forward twice" technique is introduced to facilitate the gradient propagation between adjacent layers.

## IV. RESULTS AND DISCUSSION

### A. Dataset

In this work, the VisDrone-DET (object detection in images) dataset [11] is utilized. This dataset comprises images collected through drones in various real-world scenarios, using different types of drones, across multiple locations (14 cities in China spanning thousands of kilometers), and under various weather and lighting conditions. VisDrone-DET contains a total of 8,629 images, with 6,471 for training, 1,610 for test-dev, and 548 for validation (Table I). The dataset also includes over 350,000 bounding boxes for labeled objects across 12 classes: *ignored regions, pedestrian, people, bicycle, car, van, truck, tricycle, awning-tricycle, bus, motor*, and *others*. Excluding the 2 classes, *ignored regions* and *others*, the study delves into the remaining 10 object classes. Some images of the dataset are shown in the Fig. 6

### B. Experimental Configuration

Experiments were carried out on Detrex Toolbox [20], Ubuntu 20.04.1 LTS operating system (Linux 5.8.0-53-generic x86-64), Python version 3.8.17, CUDA 11.3, PyTorch 2.0.1, and 2 NVIDIA GeForce RTX 2080 Ti GPUs. Pretrained models are employed for both the training and evaluation processes of three methods: DETR, DAB-DETR, and DINO, all utilizing the R50 backbone. The Average Precision (AP) metric introduced in MS-COCO [10] is used in the object detection process.

### C. Discussion

After training the DETR model with a ResNet-50 backbone, the best mAP result obtained was 7.64%. This data reveals that DETR struggles with objects of small or very small sizes. Table II has been presented, showcasing the AP results for each class of interest. Upon analysis, the classes *bus* (19.29%) and *car* (21.70%) achieved the highest scores. Overall, individual class scores remain limited, displaying significant variation. In comparison to other models in this study, DETR's performance on the VisDrone dataset remains notably low.
Fig. 5. Illustration of the DINO framework. The main improvements mainly focus on the Transformer encoder and Transformer decoder. The top-K encoder features in the last layer are selected to initialize query positions for the Transformer decoder, while content queries are retained as learnable parameters. The decoder also includes a DeNoising Contrastive component with both positive and negative samples [8].

Fig. 6. Some sample images from the VisDrone dataset [11].

TABLE I. STATISTICAL INFORMATION ABOUT THE VISDRONE2019 DATASET

| Class/ Subset | Ignore | Pedestrian | People | Bicycle | Car | Van | Truck | Tricycle | Awning-tricycle | Bus | Motor | Others |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Train | 8,813 | 79,337 | 27,059 | 10,480 | 144,867 | 24,956 | 12,875 | 4,812 | 3,246 | 5,926 | 29,647 | 1,532 |
| Validation | 1,378 | 8,844 | 5,125 | 1,287 | 14,064 | 1,975 | 750 | 1,045 | 532 | 251 | 4,886 | 32 |
| Test-dev | 2,180 | 21,006 | 6,376 | 1,302 | 28,074 | 5,771 | 2,659 | 530 | 599 | 2,940 | 5,845 | 265 |
| Total | 12,371 | 109,187 | 38,560 | 13,069 | 187,005 | 32,702 | 16,284 | 6,387 | 4,377 | 9,117 | 40,378 | 1,829 |

Upon examining the AP scores for each class in DAB-DETR, it is evident that the classes *car* and *bus* attained the highest scores at 36.40 and 34.86 AP points, respectively. Interestingly, the *car* class has the highest number of labels in the training dataset, with 144,867 labels, whereas the *bus* class has significantly fewer labels, specifically 5,926 labels. However, the AP score for the *bus* class is nearly on par with that of the *car* class.

Two other classes, *van* and *truck*, also achieved relatively good AP scores, with 22.31 and 20.81 AP points, respectively. The remaining classes, including *motor, bicycle, tricycle, awning-tricycle, people* and *pedestrian*, all had AP scores less than half of those for the *car, bus, van,* and *truck* classes.

*Bicycle* and *people* had the lowest AP scores, with only 5.36 and 4.35, respectively.

According to the results presented in Table II, a prominent observation arises, demonstrating DINO's distinction as the top-performing object detector, boasting an mAP score of 24.83%. This achievement can be partly attributed to DINO's notable performance in discerning object categories characterized by resemblances, for instance, *pedestrian* and *people*, with respective scores of 15.60 and 9.38, as well as *tricycle* and *awning-tricycle*, exhibiting scores of 17.25 and 16.76, which appear relatively subdued compared to other object classes. However, it is worth noting that DINO still exhibits relatively weaker performance when compared to other popular methods,

TABLE II. THE EVALUATION RESULTS OF THE DETR, DAB-DETR, AND DINO METHODS ON THE VISDRONE DATASET USING THE AP METRIC

| Class / Method | Pedestrian | People | Bicycle | Car | Van | Truck | Tricycle | Awning-tricycle | Bus | Motor | mAP (%) |
|---|---|---|---|---|---|---|---|---|---|---|---|
| DETR | 2.41 | 1.23 | 1.01 | 21.70 | 10.13 | 8.92 | 2.71 | 1.32 | 19.29 | 2.57 | 7.64 |
| DAB-DETR | 7.88 | 4.35 | 5.36 | 36.40 | 22.31 | 20.81 | 10.01 | 7.04 | 34.86 | 9.26 | 16.56 |
| DINO | 15.60 | 9.38 | 9.98 | 47.71 | 31.14 | 30.56 | 17.25 | 16.76 | 45.05 | 17.57 | 24.83 |

d. DINO

Fig. 7. Visualizing the results of the three object detection methods in challenging scenarios with occlusion and truncation.

such as YOLOv4 and YOLOv5 [1].

When using three models namely DETR, DAB-DETR, and DINO for inference on challenging images from the VisDrone dataset, each model yielded different results. Specifically, in Fig. 7, which shows a scenario with multiple small-sized, densely packed, and heavily occluded cars, the DETR model exhibited issues with multiple occlusion bounding boxes, imprecise positioning and sizing. On the other hand, the DAB-DETR and DINO models showed fewer instances of occlusion bounding boxes compared to DETR. While some objects were only detected when using a specific model, however, all three models failed to detect a partially obscured car in the distant corner.

Fig. 8 is captured in a more challenging scenario characterized by low lighting conditions, blurred and out-of-focus elements, and a higher density of both smaller and larger objects. The DETR model, while still experiencing bounding box overlap, managed to detect more objects in this context. Both DAB-DETR and DINO yielded relatively similar results,

particularly in detecting small pedestrian objects. DAB-DETR outperformed the other two models by detecting a bus object in the center of the image, which remained undetected by the other two methods. Due to the significant number of missed object detections, all three models have not yet achieved satisfactory results when confronted with blurred images, small objects, and high object density.

In Fig. 9, where the object density is not too high but the scene is considerably darker, causing objects to appear more blurred, the DETR model managed to detect most objects in the image, although a few objects were mislabeled, and there was an instance of bounding box overlap. DAB-DETR and DINO, on the other hand, detected fewer objects but provided more accurate results.

From the three examples above, it is evident that the DETR model excels in detecting more objects when images are dark and blurred. However, it faces challenges with a significant number of overlapping bounding boxes, and its accuracy in terms of bounding box size and position is not very high.

a. Ground truth

b. DETR
c. DAB-DETR

d. DINO

Fig. 8. Visualizing the results of the three methods for dark, blurry, and densely populated image scenarios.

This often results in mislabeling of objects. Conversely, the DAB-DETR and DINO models exhibit higher accuracy and stability. However, they are less effective when operating on dark, blurred, or fuzzy images.

## V. CONCLUSION

To offer a fresh perspective on the task of object detection in aerial image domains, we conducted experiments using three novel end-to-end object detection methods based on the Transformer architecture. These methods include DETR, DAB-DETR, and DINO, and they were evaluated on the well-known VisdroneDET2019 dataset. When using mAP as the evaluation metric, we observed that these end-to-end Transformer-based models achieved promising performance. While DETR was a pioneering method in tackling end-to-end object detection, it achieved a modest mAP score of 7.64. In contrast, DAB-DETR achieved a higher mAP score of 16.56 by employing the Dynamic Anchor Boxes technique. Specifically, the model achieving the highest mAP score among the three experimental methods is DINO, with an AP of 24.83. This is attributed to the application of several advanced techniques compared to DETR and DAB-DETR, such as Contrastive denoising training, Mixed query selection, and "Look forward twice". This is a stable and promising result for the object detection task using the end-to-end Transformer-based approach. This paper represents a crucial milestone for us to undertake more effective improvements in future research.

*Abstract*—Image captioning is an advanced NLP task that has various practical applications. To meet the requirement of visual information understanding and textual information generation, the encoder-decoder framework has been widely adopted by image captioning models. In this context, the encoder is responsible for transforming an image into vector representation, and the decoder acts as a text generator for yielding an image caption. It is obvious and intuitive that the decoder is crucial for the entire image captioning model. However, there is a lack of comprehensive studies in which the impact of various aspects of the decoder on the image captioning is investigated. To advance the understanding of the impacts of text generation techniques employed by the decoder, we conduct an extensive empirical analysis of three types of language models, two types of decoding strategies and two types of training methods, based on four state-of-the-art image captioning models. Our experimental results demonstrate that the language model affects the performance of image captioning models, while different language models may benefit different image captioning models. In addition, it is also revealed that among the decoding and training strategies under investigation, the beam search, AOA mechanism and the reinforcement learning based training method can generally improve the performance of image captioning models. Moreover, the results also show that the combinational usage of these strategies always outperforms the use of single strategy for the task of image captioning.

*Keywords*—*Image captioning; encoder-decoder; text generation techniques*

## I. Introduction

Image captioning aims to provide accurate and textual descriptions for a given image. It is a challenging task integrating visual as well as textual understanding, and it involves technologies from both computer vision and natural language processing. Automatic image captioning has found practical applications in various domains, including social media [1], remote sensing [2], robotics [3], and medical image report generation [4].

Automatic image captioning has been receiving much attention in recent years, and a variety of approaches and strategies have been proposed and studied [5]. Although deep learning models have made significant progress in image captioning, describing images correctly remains a challenge. Image captioning models need to understand image content, object recognition, and object relationships while capturing the interaction between images and language to generate natural language descriptions.

Inspired by the advances in neural machine translation, most state-of-the-art image captioning models follow the encoder-decoder pipeline , which consists of an encoder and a decoder. Specifically, an encoder is used to transform an image into vector representations, and a decoder is used for translating the information from the encoder into natural sentences, yielding a relevant caption. In the literature, different encoders, decoders, and varying strategies supporting the encoding or decoding process have been investigated [5], [6].

As one of the core elements of image captioning, the decoder that acts as a text generator has attracted lots of research focuses. At first, various different language models have been employed as the decoder. Under the encoder-decoder framework, a mainstream image captioning model is CNN-RNN [7], where convolutional networks (CNN) are employed as the encoder for feature learning, followed by recurrent neural networks (RNN) act as a decoder for caption generation. Apart from that, various different models have been proposed and developed, including CNN-Long Short-Term Memory (LSTM) [8], CNN-Gated Recurrent Unit (GRU) [9], and CNN-Transformer [10]. On the other hand, different decoding strategies have been proposed and studied. Firstly, beam search has been widely adopted by RNN-based decoders for improving the quality of the output caption [11]. Secondly, to enhance the attention-based decoder, the attention on attention (AOA) strategy [12] has been proposed to extend the conventional attention mechanism. Last but not least, in order to enhance the decoder's capability of learning to predict the words appearing in the caption, various training strategies have been explored, including cross-entropy loss and reinforcement learning.

Naturally, different image captioning approaches employing varying strategies or mechanisms may have varying capabilities of generating captions. As can be seen from Fig. 1, for the same given input image, four different image captioning approaches provide four different captions, which are of varying quality as revealed by the evaluation metrics. In other words, different image captioning approaches may exhibit different captioning performance. However, due to the complexity of the image captioning models, the difference in performance may originate from the encoder, the decoder, or the relevant strategies. Recent studies have comprehensively analyzed the effect of different encoders on the model performance from an empirical perspective [13]–[18]. For the decoder part, its impacts on the image captioning performance have also been revealed and studied [19]–[22]. Nevertheless, there is still a lack of detailed and comprehensive investigations

---
*Corresponding authors.
Fig. 1. For a given image, different image captioning approaches may yield varying captions.

of the impacts referring to various aspects of the decoder (including the language model, the decoding strategy, and training strategy).

To gain additional insights into the encoder-decoder based image captioning models, in this study, we conduct an extensive empirical study with the goal of comprehensively investigating the impacts of decoding related techniques on the performance of image captioning. We compared the impact of CNN-based, GRU-based, and LSTM-based decoders on image captioning models. In addition, we investigated the impacts of two types of decoding strategies, the search strategy (namely, the greedy search and the beam search) and the AOA mechanism.

We also analyzed the impacts of training methods on the performance of image captioning models and compared the impacts of two training methods, the Cross-Entropy Loss, and the reinforcement learning-based method. Furthermore, we investigated the impact of the combinational usage of these strategies.

We conducted experiments on the MSCOCO dataset [23], which is a widely-used dataset for the task of image captioning. We employed four state-of-the-art image captioning models as the basic models and further constructed a series of model variants from them by modifying the decoding parts of these basic models. To evaluate the performance of these image captioning models, we adopted six evaluation metrics, including BLUE1 [24], BLEU4 [24], METEOR [25], ROUGE [26], CIDEr [27] and SPICE [28]. Overall, our experimental results confirm the impacts of the language models, the decoding strategies, and the training strategies on the performance of image captioning models. More specifically, it is revealed that different language models may benefit different image captioning models, and the beam search, AOA mechanism, and the reinforcement learning based training method can generally improve the performance of image captioning models. In addition, it is also found that the combinational usage of various strategies can positively affect the captioning performance.

The contributions of this study are summarized as below.

- We conduct extensive experiments to empirically analyze the impacts of the decoder involving various text generation techniques on the performance of the image captioning models. Our study considers the impacts of

language models, decoding strategies, training strategies, and the combinational usage of decoding and training strategies, and accordingly evaluates the performance of 68 image captioning models (including 4 basic models and 64 model variants with varying usage of the language model, decoding strategy and training strategy).

- We highlight some practical findings. Our findings suggests that the performance of an image captioning model can be properly enhanced by configuring it with suitable language model as well as appropriate decoding and training strategies. This also provides a reference for further improving the performance of image captioning models.

The rest of the paper is structured as follows. Section II provides an in-depth discussion of previous research work We introduce some preliminary knowledge, including the commonly used language models, the decoding and training strategies for image captioning models, in Section III. In Section IV, we present our experimental design, including the research questions, the basic image captioning models employed in the experiments, the datasets and the evaluation metrics. Section V reports and discusses our experimental results to answer each of our research questions. Section VI concludes with a summary of this study and proposes directions for future research.

## II. RELATED WORK

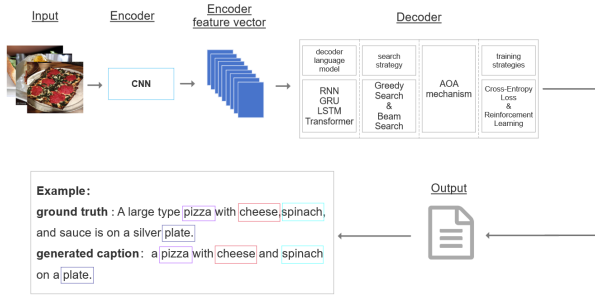
***Image caption :*** Image captioning [29], [30], [31], [12] achieves significant improvements over the neural encoder-decoder framework [6]. The Show-Tell model [30] uses convolutional neural networks (CNNs) [32] to encode images into fixed-length vectors, and a Long short-term memory (LSTM) [33] as a decoder to sequentially generate words. To capture fine-grained visual details, attention-to-image captioning models [29], [31], [12] have been proposed to dynamically pin words together with relevant image parts during generation. To reduce exposure bias in sequence training, Rennie et al. [34] use reinforcement learning to optimize non-differentiable metrics. In order to further improve the accuracy, transformer models [10], [35] were proposed, allowing the model to effectively capture the relationship between different positions in the input sequence.


Fig. 2. Encoder-Decoder based image captioning.

***Empirical study :*** The factors that affect the image caption model are roughly divided into two parts: encoder and decoder. In order to study the impact of encoders on image caption models, people began to use different CNN encoders, such as Inception-V3, VGG, Resnet, Densenet, etc., for empirical research. Among them, [13], [14], [16] used ordinary LSTM as the decoder, [17] used MSprop as the optimizer on this basis, and [18] changed the decoder part from LSTM to GRU. In order to ensure the comprehensiveness of the experiment, [15], [36] also used LSTM and a combination of LSTM and visual attention mechanisms as decoders.

The research on the decoder part mainly focuses on the decoder architecture, search strategy and visual attention mechanism. Among them, [37] mainly focused on the impact of search strategies. [20] considered the influence of one-way and two-way LSTM decoders and search strategies. [19] selected the injection model and conducted experiments using different search strategies. [21] and [22] mainly focued on the impact of visual attention mechanism on the model. In addition, [22] takes into account the Transformer model.

While other papers have analyzed only one aspect of the attention mechanism, or two types of decoder architectures, we have built on this foundation by experimenting with RNNs, GRUs, LSTMs, and Transformers using different types of strategies as well as combinations of strategies, in order to have a more comprehensive analysis of decoder language models.

## III. PRELIMINARIES

This section briefly introduces the commonly used language models, as well as the strategies that are applicable to text generators, in the context of encoder-decoder based image captioning.

### A. Decoder Language Models

As shown in Fig. 2, the decoder of an image captioning model is responsible for translating the vector representation resulting from the encoder into a natural language caption. In the context of image captioning, the generation of captions can be formulated as a sequence to sequence learning task. Several language models have been employed to accomplish this task, including RNN, LSTM, GRU, and Transformer.

RNN [38] is used to process sequential data, but it does not handle long sequences and long-distance dependencies well due to vanishing or exploding gradient problems.

LSTM [33] is an improved RNN that effectively solves the gradient problem by introducing a gating mechanism, making it good at capturing long-term dependencies and achieving good results in tasks such as text generation and machine translation.

GRU [39] is an improved version of RNN. It uses a gating mechanism, has a simple structure and fewer parameters, and shows good performance in multiple sequence generation tasks, similar to LSTM.

Transformer [40] is a neural network based on a self-attention mechanism. It has global context modeling and parallel computing capabilities. It can comprehensively consider image features and subtitle sequences to generate accurate and coherent image subtitles.

### B. Decoding Strategies

Apart from the language model, the decoder can be equipped with various different strategies. In this study, we mainly focus on the search strategy and the strategies relating to the attention mechanism.

*1) Search Strategy:* Greedy search and beam search are two search strategies for generating sequences that are commonly used in the task of image captioning.

Greedy search is a sequence generation method that selects the currently optimal option each time without considering the global optimal solution. It is usually computationally efficient but may sacrifice final performance.

Beam search is a sequence generation method that considers multiple alternative outputs and selects the set of alternative outputs with the highest probability score to improve the quality of the generated results, often used in natural language processing and machine translation tasks.

*2) Attention on attention mechanism:* For encoder-decoder framework based image captioning, the attention mechanism is commonly applied for guiding the decoding process. The Attention on Attention (AOA) approach aims at extending the traditional attention mechanism applied to image captioning tasks.

The AOA approach consists of two main parts: the first part is the global attention module, which is used to compute global attention weights between image features and context vectors; the second part is the local attention module, which is used to compute local attention weights based on the global attention weights.

### C. Training Strategies

The training process aims to prepare the captioning model for learning to predict the probabilities of words that will appear in the caption. Two types of commonly adopted training strategies are Cross-Entropy Loss and reinforcement learning.

*1) Cross-entropy loss:* Traditional image captioning models are usually trained using maximum likelihood estimation (MLE) to optimize model parameters by minimizing cross-entropy loss. However, this method cannot directly measure subtitle quality and can easily lead to inaccurate or repeated subtitles.

*2) Reinforcement learning:* Training image captioning models using reinforcement learning has led to significant improvements. A typical method is self-criticism sequence training [34], which treats the generated subtitles as a sequence of actions, the quality is evaluated with the CIDEr-D metric, and the metric is maximized through reinforcement learning.

## IV. EXPERIMENTAL DESIGN

This section presents our research questions, basic image captioning models, datasets, and evaluation metrics.

### A. Research Questions

We plan to investigate the following four research questions.

- **RQ1:** What is the impact of the language models on the performance of image captioning models?

- **RQ2:** How do different decoding strategies affect the performance of image captioning?
  RQ2.1: How does beam search compare to greedy search for the task of image captioning?
  RQ2.2: What is the impact of using the AOA mechanism with the language model on the performance of image captioning?

- **RQ3:** How do different training strategies used for the decoder impact the performance of image captioning?

- **RQ4:** What is the impact of the combinational usage of various strategies of the decoder on the performance of image captioning?

### B. Basic Image Captioning Models

In this study, we employed four state-of-the-art image captioning models as the basic models, based on which we constructed various model variants (the details are elaborated in Section V). The information of these models is summarized in Table I, and further described below.

**FC** [34]: The FC model utilizes a deep CNN model ResNet101 to encode the input picture, and then a linear map is used for embedding. The model uses an LSTM-based decoder.

**Att2in2** [34] : The Att2in2 model uses ResNet101 as an encoder and LSTM as a decoder. Particularly, it is an image captioning model involving the attention mechanism. The model is an improved version of the subtitle attention model [31].

**Up-Down** [29] : The up-Down model encoder part uses Faster R-CNN ResNet101, which is a classical target detection model, and local features from an image, and the decoder part employs a two-layer LSTM architecture (Top-Down Attention LSTM and Language LSTM), which utilizes both bottom-up and top-down attentional mechanisms, in order to generate natural language descriptions that match the content of the image.

**Transformer** [40] : The Transformer model uses Faster R-CNN ResNet101 as the encoder and employs a Transformer as the decoder. The Transformer decoder is an integral part of the Transformer model and is used to convert the input

sequence generated by the encoder into a target sequence. It gradually generates target sequences through the self-attention mechanism and encoder-decoder attention mechanism.

As shown in Table I , the encoders of the above four models are either Faster R-CNN Resnet101 [41] or ResNet101 [32]. We further detail these two models as below.

**ResNet101** [32]: ResNet101 is a CNN model having 101 layers. It is a variant of a Residual Network, and it introduces residual connections to solve the problem of gradient disappearance and gradient explosion in deep network training. Compared with traditional shallow networks, it can learn image features at a deeper level, thereby extracting more complex and advanced feature expressions.

**Faster R-CNN ResNet101** [41]: Faster R-CNN ResNet101 combines the Faster R-CNN object detection algorithm and the ResNet101 feature extractor. As a feature extractor, ResNet101 can efficiently extract features from images. Faster R-CNN ResNet101 combines the efficiency of the target detection algorithm and the deep feature learning ability of ResNet101, making the model perform well in target detection tasks.

### C. Dataset

Our experiments are conducted on the MSCOCO dataset [23], which is a popular benchmark for image captioning tasks, containing 123,287 images, each with 5 captions, for a total of 615,935 captions. We use the "Karpathy" data split [42], with 5,000 images for validation, 5,000 for testing, and the rest for training.

To preprocess the captions, we generated a vocabulary of 10,369 unique words by converting sentences to lowercase and removing words that appeared less than five times.

## V. EXPERIMENTAL RESULTS

This section analyzes and reports our experimental results. Specifically, for each RQ, we discuss the motivation, present the approach, and finally report the results.

### A. RQ1: Impact of Language Models on the Task of Image Captioning

**Motivation:** For an encoder-decoder based image captioning model, the language model constitutes the key part of the decoder, and thus it is crucial to the overall performance of image captioning. Prior studies have proposed various language models for supporting the decoding stage of image captioning [5]. Yet, there is still a lack of empirical evidence revealing the extent of the impact, and it is also unclear how different language models affect the performance of image captioning models. Therefore, in this RQ, we investigated image captioning models with varying language models, in order to reveal the impact of language models on the performance of image captioning models.

**Approach:** First, we utilized the three baseline models employing an RNN-based language model (namely, FC, Att2in2, and Up-Down) by following their original configurations in the prior studies [12]. Secondly, we constructed six model variants from the three baseline models by modifying the decoder part. That is, for each model, two variants were constructed by

TABLE I. BASIC INFORMATION OF THE SELECTED MODEL

| Model | Encoder | Decoder | Search Strategy | Attention |
|---|---|---|---|---|
| FC | ResNet101 | LSTM | Greedy | |
| Att2in2 | ResNet101 | LSTM | Greedy | ✓ |
| Up-Down | Faster R-CNN ResNet101 | Attention LSTM +Language LSTM | Greedy | ✓ |
| Transformer | Faster R-CNN ResNet101 | Self-Attention mechanism+feed-forward neural network | Greedy | ✓ |

replacing its default language model LSTM with an RNN and a GRU, respectively. For the sake of simplicity, we utilized $M \diamondsuit L$ to denote a model $M$ supported with the specific language model $L$. For example, FC$\diamondsuit$RNN represents one variant of model FC where the default language model LSTM is replaced with an RNN. Thirdly, for each of the models obtained in the previous steps, we further constructed a variant for each of them by modifying its encoder model (i.e. from ResNet101 to Fast RCNN ResNet101, or vice versa). Finally, we evaluated these 18 models (including three baseline models and 15 model variants) and collected evaluation results on a series of evaluation metrics.

*Results:* Tables II and III, respectively report the evaluation results of nine models employing the same encoder model. Based on these results, we make the following observations.

1) *The use of different language models leads to varying performance of the image captioning model.* As shown in Table II, for each of the models, the use of RNN, GRU, or LSTM as the decoder model yields different values for each of the six evaluation metrics. For example, the BLEU1 values for the three models, that is, FC$\diamondsuit$RNN, FC$\diamondsuit$GRU, and the original FC model are 73.70, 73.71, and 74.06, respectively. Table III consistently reveals this point.

2) *The language model affects different image captioning models in different ways.* At first, it is observed that the language model may have opposite impacts on different image captioning models. Consider the FC and Att2in2 models as an example. According to Table II, compared to the use of RNN, the use of GRU positively contributes to the BLEU1 value of FC (the BLEU1 values of FC$\diamondsuit$RNN and FC$\diamondsuit$GRU are 73.70 and 73.71), while it negatively affects the BLEU1 value of Att2in2 (the BLEU1 values of Att2in2$\diamondsuit$RNN and Att2in2$\diamondsuit$GRU are 75.56 and 75.11). On the other hand, the degrees of the impacts of the language models may also be different when they are applied to different image captioning models. As can be observed from Table III, FC$\diamondsuit$GRU outperforms FC$\diamondsuit$RNN in terms of the CIDEr metric, exhibiting a discrepancy of 1.65 (97.72 vs. 96.07). Nevertheless, although Att2in2$\diamondsuit$GRU also outperforms Att2in2$\diamondsuit$RNN in terms of the CIDEr metric, the discrepancy in the performance is relatively tiny (0.14).

3) *The best language model for different image captioning models may be different.* Among the three language models under investigation (that is, RNN, GRU, and LSTM), they are beneficial to different image captioning models. For the models employing the faster R-CNN ResNet101 as the encoder, the best language model for the FC model is LSTM; while the Up-Down model exhibits the best performance with the GRU as the language model (as observed from Table II). Quite differently, for the models employing ResNet101 as the encoder, the FC model performs best with GRU, the Att2in2

model achieves the best performance with LSTM, while the Up-Down model performs best with RNN (as observed from Table III).

> **RQ1** : For the encoder-decoder based image captioning models, employing different language models as the decoder always leads to varying captioning performance. Nevertheless, the impact of the language models on different image captioning models may vary, and accordingly, the good language models may also be different from the perspective of different image captioning models.

### B. RQ2: Impact of Different Decoding Strategies on Image Captioning Models

*Motivation:* At present, the endoer-decoder based image captioning models have been extended and enhanced via a variety of decoding strategies [5]. Although these decoding strategies have been demonstrated to be able to positively contribute to captioning performance, they have not been comprehensively investigated on the same set of image captioning models and datasets. To fill this gap, in this RQ, we empirically studied the impacts of two types of decoding strategies, the search strategy and the AOA mechanism.

*Approach:* We first focus on the search strategies adopted by the decoder of the image captioning model. To this end, we conducted experiments on 20 models, including the 18 models constructed for RQ1, the basic Transformer model and its variant employing the RestNet101 instead of the Faster R-CNN ResNet101 as the encoder. It is noted that all of these 20 models adopt the greedy search (as reported in Table I). Based on these, we further constructed 20 model variants from them by replacing the greedy search with beam search. In particular, the latter set of models is configured with various beam sizes (in this study, we adopted four beam sizes, 2, 3, 4, and 5). As a result, there are 20 groups of models, each of which consists of two models sharing the same technical details except for the search strategy. We evaluated all of these models on the dataset and compared the performances of models within individual groups.

To study the impacts of the AOA mechanisms, the three base models, Att2in2, Up-Down, and Transformer, and their variants are utilized. The FC model and its variants are excluded because they do not employ the attention mechanism and thus the AOA mechanism is not applicable. For each of the models, we constructed a variant for it by additionally applying the AOA mechanism, and then conducted a comparison analysis of their performance.

*Results:* Fig. 3 reports the performance comparison results of image captioning models using or not using the beam search strategy. Particularly, Fig. 3 (a)-(f) reports the results for the ten

groups of models employing the faster R-CNN ResNet101 as the encoder, where each subfigure focuses on the comparison of performance with respect to one of the evaluation metrics. Accordingly, the comparison results relating to the other ten groups of models that using the ResNet101 as the encoder are reported in 3 (g)-(l). Fig. 4 further reports the performance comparison results on seven groups of models applying or not applying the AOA mechanism. Based on these results, we have the following observations:

1) ***The use of different decoding strategies affects the performance of image captioning models.*** It can be observed from Fig. 3 that using greedy search or beam search leads to varying captioning performance of the relevant models. Similarly, Fig. 4 also shows that every image captioning model under investigation exhibits different performance with and without using the AoA mechanism.

2) ***Compared to greedy search, the use of beam search generally improves the captioning performance.*** Firstly, it can be observed from Fig. 3 that most of the models achieve better performance by using beam search. This indicates that the use of beam search is beneficial to image captioning models. On the other hand, it can also be found that the optimal beam size of the beam search for different models varies. Nevertheless, for the majority of models, the best performance is reached with a beam size of 2.

3) ***The application of the AoA mechanism benefits most of the image captioning models under investigation.*** Fig. 4 shows that after additional applying the AoA mechanism on the target image captioning models, the captioning performance has been improved in most cases (that is, for most of the models with respect to the majority of evaluation metrics). Although there are some models for which the application of the AoA mechanism leads to a decrease in captioning performance (i.e., the Up-Down model employing the encoder of faster R-CNN ResNet101), the extent of the decrease is relatively smaller than the extent of the increases resulted from

using the AoA mechanism.

> **RQ2** : For encoder-decoder based image captioning models, the application of decoding strategies affects the captioning performance.Specifically, the use of beam search always outperforms the use of greedy search, and most models exhibit the best performance with the beam search configured with a beam size of 2. Moreover, the application of the AoA mechanism is beneficial to most of the image captioning models under investigation.

*C. RQ3: Impact of the Training Strategies on Image Captioning Models*

***Motivation:*** Currently, encoder-decoder based image captioning models have emerged with various training methods. However, no prior study has focused on revealing the effect of training methods applied on the decoder part. Hence, in this RQ, we empirically studied two training approaches (Cross-Entropy Loss and Reinforcement Learning) and their impacts on captioning performance.

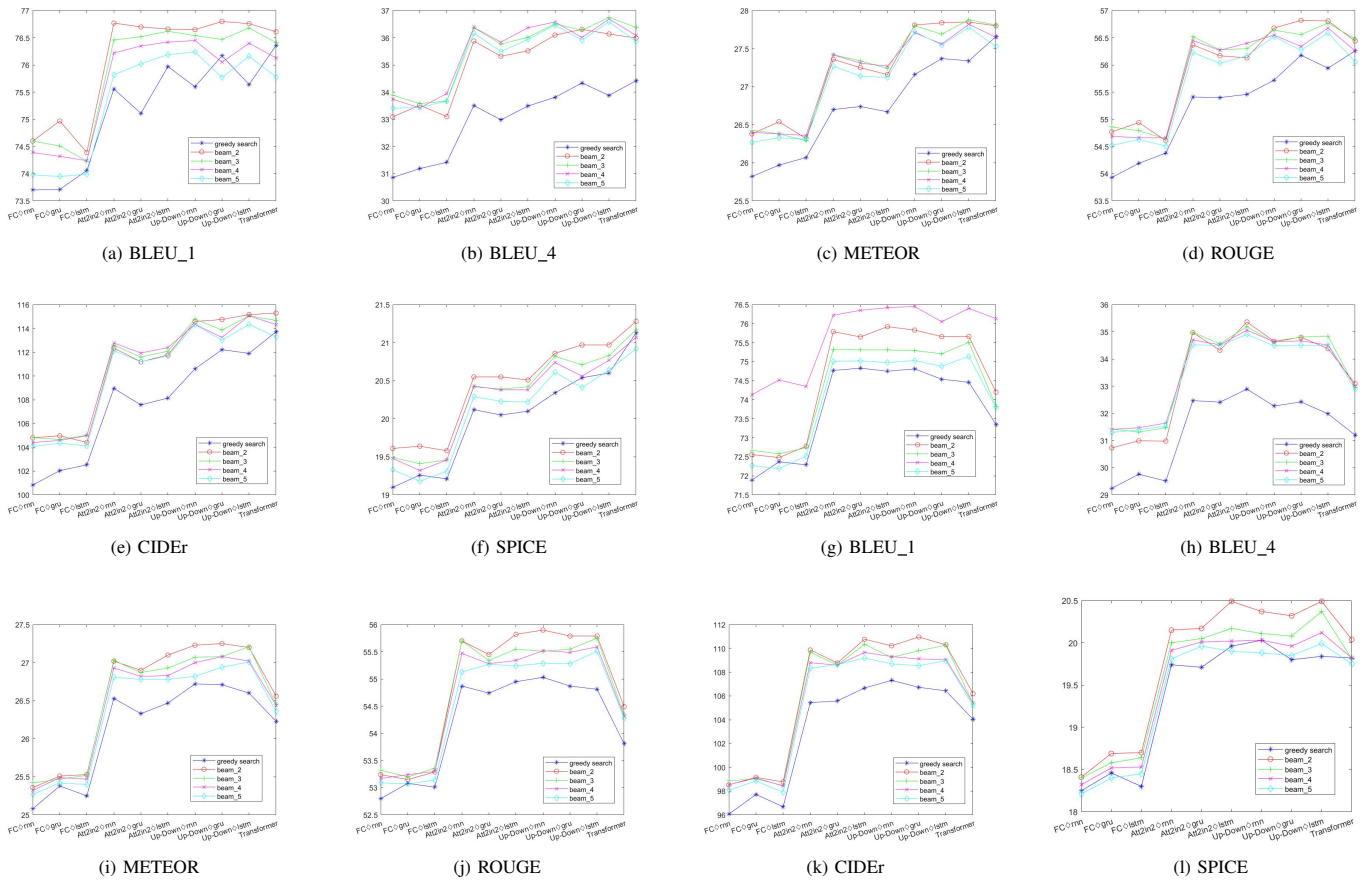
***Approach:*** In the experiments, we reused the 20 image captioning models, including the FC, Att2in2, and Up-Down models employing the RNN, GRU, and LSTM in the decoder part as well as the Transformer model, and also their relevant variants using a different CNN (faster R-CNN ResNet101 or ResNet101) as the encoder. Noted that all of these models are trained by following their default method, namely, the cross-entropy loss method. Based on each of these models, we further constructed a model variant by training its decoder via a reinforcement learning based method, the self-critical sequence training method. These result in 20 groups of model, where each group consists of a model and its variant involving a decoder trained via reinforcement learning. We evaluated these newly constructed model variants and further conducted a comparison analysis with individual groups.


Fig. 3. Comparison of models employing the greedy search with those employing the beam search. For the latter, various beam sizes (2, 3, 4 and 5) have been investigated. A total number of 20 groups of models are studied, including ten groups of models using Faster R-CNN ResNet101 ((a) - (f)) and another ten groups of models using ResNet101 ((g) - (l)).

**Results:** Tables IV and V, respectively report the evaluation results of ten newly constructed models employing the same encoder model. For each newly constructed model (where the decoder is trained via reinforcement learning), we further compared its performance with the relevant model that trained via the cross-entropy loss method (as reported in Tables II and III). Accordingly, Tables IV and V further report the improvements made by applying the reinforcement learning based training method (the improvement is indicated by the ↑). Based on these results, we make the following observations:

1) ***Reinforcement learning is an effective training method for supporting the task of image captioning.*** Both Table IV and Table V reveal that training the decoder by the self-critical sequence training method leads performance improvement for all of the target models. For example, after applying the self-critical sequence training method, FC◇RNN exhibits 4.02 improvement in terms of the BLEU1 metric, while the improvement is 12.24 with respect to the CIDEr metic (as shown in the first row of Table IV).

2) ***The performance improvements made by reinforcement learning are different for different image captioning models.*** According to Table IV, the performance improvements obtained via self-critical sequence training range from 0.59 to 14.16. Similarly, as shown in Table V, the highest increase

in performance is 12.92, and the lowest increase is 0.46. Furthermore, it can be observed that the application of the reinforcement learning based training method leads to varying performance improvement for every of the target models.

---

**RQ3** : For encoder-decoder based image captioning models, training the decoder with reinforcement learning will improve the model performance. Nevertheless, the degree of the improvements is different for different image captioning models.

---

*D. Impact of the Combinational Usage of Decoding Strategies on the Performance of Image Captioning Models*

**Motivation:** We have previously investigated the effect of every single strategy or mechanism on the performance of image captioning models. With the observation that these strategies and mechanisms can be applied to an image captioning model together, in this RQ, we further studied the effect of the application of various combinations of these strategies.

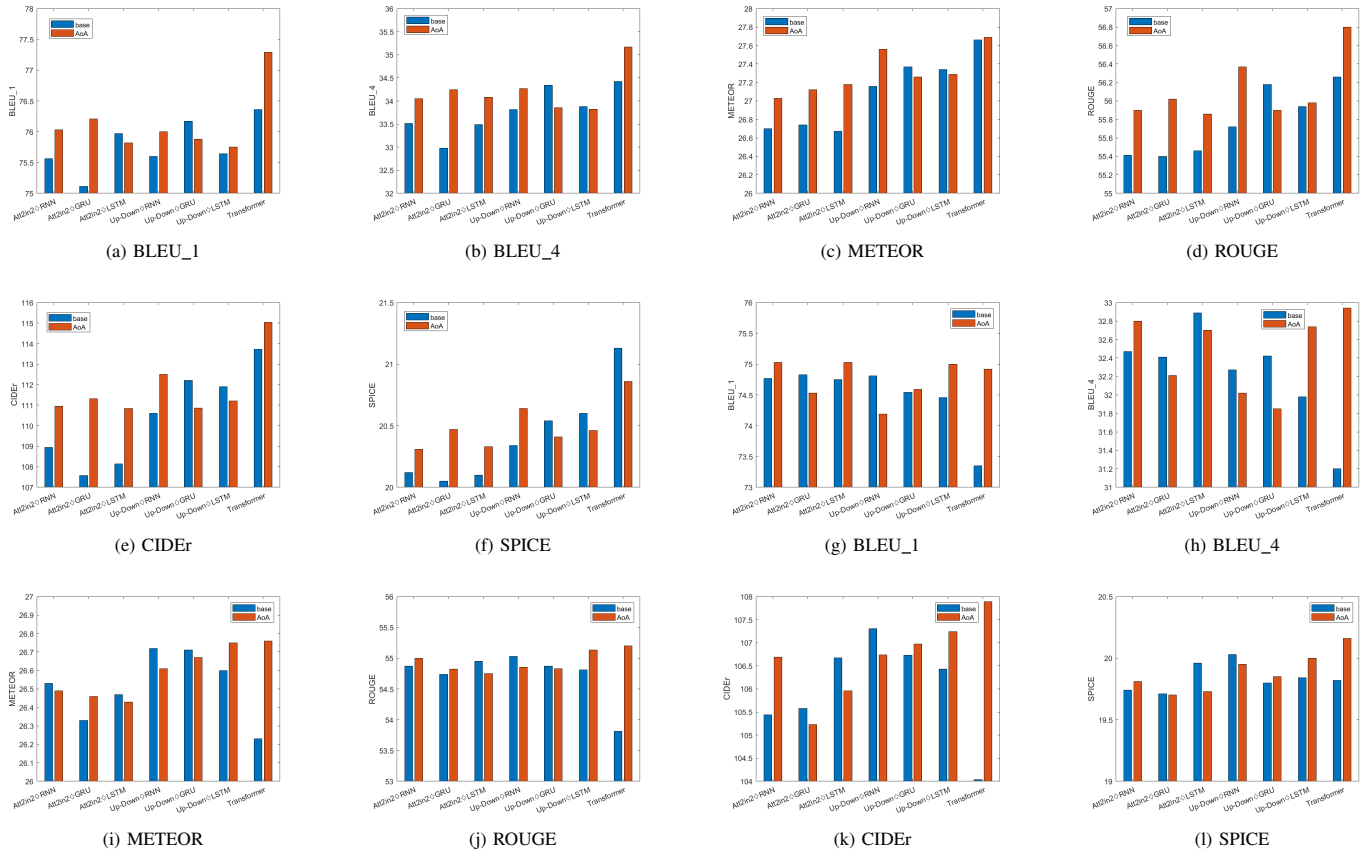
**Approach:** We utilized the four baseline models employing the faster R-CNN ResNet101 encoder as the basic model. We further considered the combination of the three strategies or methods, that is, the search strategy, the AoA mechanism, and the training method. We use $P_{xyz}$ to denote the application


Fig. 4. Comparison of the 14 groups of models, including seven groups of models using Faster R-CNN ResNet101 ((a) - (f)) and another seven groups of models using ResNet101 ((g) - (l)). In each group, one model does not using AoA (denoted as *base*), while the other one applies AoA (denoted by AoA).

of one combination of these three strategies, where $x = 1$, $y = 1$, and $z = 1$ respectively represent the use of the beam search, AoA mechanism, and the self-critical sequence training methods. For example, $P_{110}$ denotes that the beam search and

AoA mechanism are applied together, while $P_{011}$ represents that the AoA mechanism and the self-critical sequence training method are applied together.

We further applied various combinations of different strategies on every basic model to construct some model variants. For the FC model, since it does not support the attention mechanism, only $P_{101}$ (that is, beam search and the self-critical sequence training) is applicable. Accordingly, one model variant was constructed from the FC model. For the other three basic models, four different combinations of these strategies are applicable (namely, $P_{101}$, $P_{110}$, $P_{011}$, and $P_{111}$), and thus four model variants were constructed from each of them. At last, these model variants were evaluated on the dataset.

*Results:* Table VI reports the evaluation results of 13 model variants employing some combination of the strategies or methods applied on the decoder part. Noted that for each model variant, its relevant models employing one of these strategies have already been evaluated and investigated in the previous RQs, we thus compare it with the one exhibiting the best performance in order to report the performance improvement achieved via the application of combined strategies (the performance improvement is shown in Table VI). Based on these results, we make the following observations:

*1) The combination of various strategies helps to improve the performance of image captioning models in most cases.* Table VI shows that the captioning performance is improved in most cases (i.e., most of the evaluated metrics for most models) after using the combination strategy on the target image captioning models. Although the application of the combination strategy to some models leads to a decrease in their captioning performance (e.g., the Att2in2 model with the usage of the beam search and self-critical sequence training method), the decrease is relatively small.

*2) Different combinations of methods have different effects on the performance enhancement.* As can be seen from the Table VI, the model performance improvement is different for different models using the same combination of strategies, and the model performance improvement is also different for the same model using different combinations of strategies. Nevertheless, it is observed that for the three models to which variuos combinations of strategies have been applied, they exhibit the best performance with $P_{111}$. That is, by applying the beam search, the AoA mechanism, and the reinforcement learning based training method together, these models perform better than those equipped with only parts of these strategies.

---

**RQ4** : For encoder-decoder based image captioning models, applying various strategies to the decoder is helpful for improving the overall captioning performance. For the image captioning models under investigation, they exhibit the best performance with the use of the beam search, AoA mechanism and the reinforcement learning based training method.

---

## VI. Conclusion

In this work, we focus on the impact of various aspects of the decoder on image captioning. In order to understand the impact of the text generation technique employed by the decoder on the results, we have conducted an extensive empirical analysis involving three different language models, two different decoding strategies, and two different training methods. The results of the research and analysis show that different language models have different impacts on the performance of the generated subtitles. Meanwhile, the use of two different decoding strategies as well as the training method of reinforcement learning helps to improve the model performance. In addition, it was found that using a combination of these strategies is usually better than using only a single strategy in image subtitle generation tasks. Future research directions can consider expanding our research to more complex datasets, especially exploring in cross-cultural environments. In addition, further research on how to integrate other machine learning technologies, such as transfer learning, to further improve model performance is also an important direction. The development of these future works will help expand our research and have a broader impact.

*Abstract*—The advances in genome sequencing and metabolic engineering have allowed the reengineering of the cellular function of an organism. Furthermore, given the abundance of omics data, data collection has increased considerably, thus shifting the perspective of molecular biology. Therefore, researchers have recently used artificial intelligence and machine learning tools to simulate and improve the reconstruction and analysis by identifying meaningful features from the large multi-omics dataset. This review paper summarizes research on the hybrid of constraint-based models and machine learning algorithms in optimizing valuable metabolites. The research articles published between 2020 and 2023 on machine learning and constraint-based modeling have been collected, synthesized, and analyzed. The articles are obtained from the Web of Science and Scopus databases using the keywords: "Machine learning", "flux balance analysis", and "metabolic engineering". At the end of the search, this review contained 13 records. This review paper aims to provide current trends and approaches in *in silico* metabolic engineering while providing research directions by highlighting the research gaps. In addition, we have discussed the methodology for integrating machine learning and constraint-based modeling approaches.

*Keywords—Flux balance analysis; genome-scale metabolic model; machine learning; metabolic engineering*

## I. INTRODUCTION

Microorganisms have been used in industrial sectors such as food processing, chemical manufacturing, pharmaceuticals, fermentation, and others. Advances in genome sequencing have resulted in several innovations that allow researchers to gain in-depth knowledge and information about an organism. One of these advancements is metabolic engineering, which reengineers the cellular function of an organism. In the 1990s, metabolic engineering was introduced to describe recombinant DNA technology for optimizing microbial activity [1]. Metabolic engineering aims to optimize the synthesis of desired metabolites by directing the metabolic flow and the fluxes toward the desired metabolites. The designs are categorized into two types: [1] targeting metabolic network components, such as gene/reaction knockout/knock-in, and [2]

enhancing the metabolic network by altering it using network reconstruction tools or incorporating new non-native pathways into the host.

Over the previous few decades, there has been a noticeable breakthrough, such as incorporating adenosylcobinamide phosphate biosynthesis from *Rhadobacter capsulatus* into the *E.coli* strain, which improves the vitamin $B_{12}$ to 307 $\mu g/g$ [2]. In another case, the yeast was engineered to improve the production of rubusoside and rebaudiosides, leading to 1368.6 $mg/L$ and 132.7 $mg/L$, respectively [3]. Although metabolic pathway optimization technologies have shown promise, an incomplete understanding of the connection between target cell phenotype and genotype impedes their further development. This results in the prevalent utilization of conventional trial-and-error methodologies and indirectly remains tedious, costly, and time-consuming.

Therefore, constraint-based modeling (CBM) approaches have been used to analyze organisms by providing significant phenotypic knowledge based on genotypic perturbations. CBM approaches, which include Flux Balance Analysis (FBA) and its variants (Minimization of Metabolic Adjustment, MoMA; Regulatory on/off minimization, ROOM; and Flux Variability Analysis, FVA), are used to reveal metabolic phenotypes by analyzing the optimality of an organism [4], [5]. However, a significant challenge in CBM is that the desired flux is not limited to a single solution due to biological network redundancy and complex genome-scale metabolic model (GSMM), thus permitting alternate optimum solutions. Furthermore, due to the intricacy and interdependence of components in the metabolic network, selecting appropriate and optimal reactions/genes for knockout is difficult, laborious, and time-consuming [6]. Hence, previous research has combined meta-heuristic optimization algorithms such as genetic algorithm (GA), differential search algorithms (DSA), flower pollination algorithm (FA), and others [7], [8], [9], [10].

With the recent advancement of high-throughput technology and the overwhelming amount of omics data, data collection has increased considerably, thus shifting the perspective

on molecular biology [11]. Although big data in biology enables data-driven science to comprehend complex biological systems and events, interpreting data is still complicated. Therefore, machine learning (ML) has been applied to deal with biological omics data for various applications such as prediction, classification, and discovery. The involvement of ML in the data shows a great potential to reveal hidden and detailed information in the data.

It has proven successful in diabetes disease prediction, optical character recognition, face identification, and others [12], [13], [14], [15]. ML is a set of algorithms to improve prediction accuracy by learning and analyzing the patterns from large experimental datasets. Recently, ML has been applied to increase the accuracy of the genotype-phenotype relationship by analyzing the integrated metabolic networks with regulatory or signaling networks. Furthermore, ML requires fewer parameters than other statistical or computation approaches, thus making them useful for various tasks, including predicting the impact of genetic perturbations, reconstructing phylogenetic trees, and others [16], [17].

This paper aims to review how ML techniques are applied in metabolic engineering, specifically to optimize the production of desired metabolites. The paper is organized as follows: Section II introduces the definition of metabolic engineering. Section III provides a brief on constraint-based modeling. Section IV discusses machine learning in metabolic engineering. Then, applications of machine learning in metabolic engineering have been described in Section V. After that results and discussion are provided in Section VI. In the last, the conclusion is given in Section VII.

## II. Metabolic Engineering

Each component in biological systems plays a vital role in biological processes and interacts with each other. Therefore, it is crucial to analyze the systems as a whole. The organism's function can be divided into three major biochemical pathways: gene regulatory, signal transduction, and metabolic networks. Gene regulatory involves a set of genes, proteins, and their regulatory mechanisms that determine the expression of the gene. Signal transduction networks communicate between and within cells by mediating, detecting, amplifying, and integrating various external and internal stimuli to govern and coordinate cellular activities. Meanwhile, the metabolic network is a series of biochemical reactions involving the transformation and modification of substrates into different products in which the enzymes act as catalysis agents. The metabolic network is essential in assessing a cell's biochemical and physiological properties. This research is mainly concerned with metabolic networks.

Advancements in genome sequencing have brought about many developments that allow biological researchers to have more profound knowledge and information about an organism. One of the developments is the establishment of metabolic engineering (ME), which allows the researchers to probe in detail the organizations of an organism, including the reactions, pathways, metabolites, and genes, and exploit the organisms for strain optimization. Metabolic engineering aims to optimize the metabolism of organisms by exploiting and manipulating their metabolic capabilities through modeling and, thus, generates economically and industrially viable organisms through

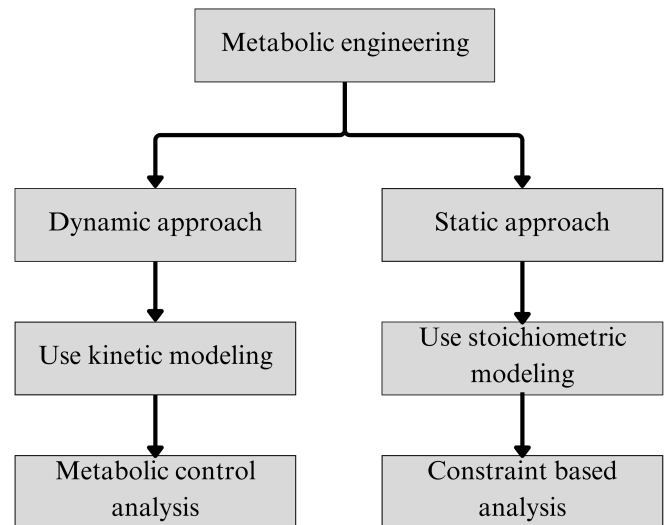

Fig. 1. Approaches in metabolic engineering.

optimization and predictive tools. In order to achieve this objective, it is necessary to adapt current metabolic engineering approaches by incorporating automated simulation techniques instead of relying on previous in vivo or in vitro investigations.

In order to exploit and manipulate the metabolic capabilities of an organism, the metabolic pathways within the cell need to be modeled. A model is a simplified system representation that allows the user to understand, predict, and control the system [18]. An organism can be modeled based on a dynamic or static approach. In ME, the metabolism of the target organism was represented in the mathematical model. Thus, the network's precise respective pathway or reactions that need to be manipulated and optimized can be identified. Various computational modeling approaches and algorithms have been developed and applied to aid the researchers [19]. Different approaches have been developed depending on the representations, as shown in Fig. 1.

The approaches in metabolic engineering can be divided into two, which are the dynamic approach and the static approach. Each approach varies in terms of metabolism representation, whereby the dynamic approach uses kinetic modelling and static approach uses a stoichiometric matrix to represent the metabolic network [20]. Furthermore, the difference between these two approaches is the model used. The dynamic approach uses a kinetic model, and the static approach uses a stoichiometric model or a metabolic network. Both of these models consist of different information and representations. The dynamic approach describes the changes in metabolite concentrations over time, while the static approach does not [21]. Table I defines the difference between the kinetic and the stoichiometric models.

In stoichiometric models, the biochemical reactions in the metabolic network are represented as a set of stoichiometric equations, whereby the elements of different metabolites in the metabolic network are denoted as stoichiometric coefficients in the stoichiometric matrix. Consequently, the intracellular metabolic fluxes can be determined at the steady state using the

TABLE I. DIFFERENCES BETWEEN THE KINETIC AND STOICHIOMETRIC MODELS

| Characteristics | Kinetic model | | Stoichiometric model |
|---|---|---|---|
| Definition | Describes changes in metabolite concentrations over time. | | Assumes the system is at steady-state conditions, where the concentrations of the metabolites are constant over time. |
| What information resides in the model? | 1)  Metabolites concentrations<br>2)  Kinetic parameters | | Stoichiometric information of all specified reactions and genes |
| How do they represent the model? | Ordinary differential equations (ODE) | | Linear equation |
| Size of the metabolic network for applicability | Small-scale metabolic network | | Large-scale metabolic network |
| How do they work? | It uses kinetic rate laws obtained from biochemical and mechanistic information. | | Imposes constraints and objective functions |
| Drawback | 1)  Requires many parameters<br>2)  Sometimes leads to uncertainty in the model prediction<br>3)  Not fully utilized in ME | | 1)  Lead to underdetermine system; the number of equations is larger than the number of variables<br>2)  Generate many possible solutions<br>3)  Solutions might not be unique |
| Time-consuming | High | | Low |
| Computational extensive | High | | Low |
| Accuracy | High | | Low |

mass balance constraints. However, stoichiometric models are often underdetermined and eventually lead to many possible non-unique solutions. Thus, the models require additional constraints to narrow the range of possible phenotypic solutions. These constraints may include physicochemical, biological, mass conservation, and thermodynamics. Stoichiometric models have been used to enumerate the fluxes in a metabolic network by employing an objective function. The main application of stoichiometric models is on metabolic networks, specifically in metabolic engineering strategies [7], [8], [22], [23].

Fig. 2. Unconstrained (a) and Constrained (b) Solution space.

## III. CONSTRAINT-BASED MODELING

The constraint-based method (CBM) is an approach to investigating the optimality of an organism by predicting and describing the metabolic phenotypes [24]. In CBM, constraints are applied to the systems, thus creating feasible flux distribution space. Different types of constraints can be categorized into physicochemical, topo-biological, environmental, and regulatory [25], [26]. These constraints can be expressed as equality or inequality constraints, as shown below, and have been reviewed by [26]. The equation that describes the incoming and outgoing fluxes accumulation for each metabolite in the metabolic network is described in 1.

$$\frac{d\mathbf{x}}{dt} = \mathbf{S} \times \mathbf{v} \qquad (1)$$

where $\mathbf{S}$ is the stoichiometric matrix of size $m \times n$ ($m$ is the number of metabolites and $n$ is the number of reactions), $\mathbf{X}$ is the $m$ concentration vector, and $v$ is the n flux vector. Each metabolite's production rate must equal the consumption rate

at the steady state. Therefore, the above equation is simplified to Eq. (2).

$$\mathbf{S} \times \mathbf{v} = \mathbf{0} \qquad (2)$$

The imposition of constraints will further reduce the number of allowable flux distributions and constraints taken upon the form in Eq. (3).

$$\alpha_i \leq v_i \leq \beta_i \qquad (3)$$

where $i$ is the length of $m$ reactions, $\alpha_i$ and $\beta_i$ are the lower and upper limits for the $i$ reaction, respectively. The values for $\alpha_i$ and $\beta_i$ are determined based on reactions' reversibility or irreversibility and measured uptake rates. These constraints may restrict specific phenotypes from existing in the solution space. Fig. 2 illustrates the differences between unconstrained and constrained solution space of feasible steady-state flux distributions.

As shown in Fig. 2, unconstrained steady-state solution space is underdetermined due to the ratio of reactions typically exceeding the number of metabolites. Eq. (1) provides a hyperplane that defines the allowable flux distributions. Considering different constraints, the solution space is limited to specific desired phenotypes. Therefore, CBM aims to describe and predict the desired phenotypes of an organism by describing the metabolic networks of an organism using the stoichiometric framework and a series of constraints. Despite the imposition of constraints and steady-state assumption, the solutions generated are not limited to a single solution. Instead, the solutions generated are limited to the desired phenotypes.

In order to solve the underdetermined system, the problem of measuring internal fluxes is solved using an optimization problem [28]. Thus, an objective function is defined, as illustrated in Fig. 3. Generally, an objective function is a biological assumption that an organism can be achieved. Then, linear optimization is used to find the solution that optimizes the desired objective function. Examples of objective functions include minimizing ATP production and nutrient uptake and maximizing growth rate. The most common objective function is growth rate since organisms maximize their growth after evolutionary pressures [29]. Referring to the above equations, Eq. 1 to 3, the objective function for maximizing the growth rate is mathematically represented by Eq. 4.

$$\max Z = v_{biomass} \qquad (4)$$

Generally, there are four CBM approaches - flux balance analysis (FBA), flux variability analysis (FVA), minimization of metabolic adjustment (MoMA), and regulatory on/off minimization (ROOM). Table II portrays the characteristics of the four CBM approaches and the applications that have been carried out.

As shown in Table II, FBA is a classical CBM method and has become one of the most common approaches researchers use [7], [8], [25], [30], [31]. Despite FBA's non-uniqueness due to the exclusion of regulatory and kinetic parameters, FBA excels in handling vast data within metabolic networks compared to other approaches, such as predicting higher steady states for

biological objectives such as growth rate and production rate. Moreover, despite the incompleteness of metabolic network models, FBA can still determine the organism's steady-state fluxes.

FVA employs linear programming to identify multiple biologically optimal solutions with the same objective value. These solutions are non-unique due to the metabolic network's ability to achieve the same objective value through different equivalent pathways, often represented by recessive phenotypes. Unlike FBA, which examines the distribution of flux within pathways, FVA focuses on determining the feasible ranges of minimum and maximum fluxes for each reaction. Meanwhile, MoMA employs quadratic programming to minimize the Euclidean distance on flux space between the wild-type and mutant, while ROOM predicts the post-genetic perturbation steady state of metabolic networks. In contrast to MoMA, ROOM identifies flux distributions that yield high-rate solutions while minimizing flux deviations between wild-type and mutant and preserving the linearity of fluxes based on experimental measurements [10], [32]. Additionally, ROOM can discover shorter alternative pathways for rerouting fluxes after genetic perturbations, employing mixed integer linear programming (MILP) to meet the same constraints as FBA.

## IV. Machine Learning in Metabolic Engineering

*In silico* metabolic engineering comprises computer simulations that predict and analyze an organism's metabolic network to improve the organism's cellular activities [8]. The improvement involves manipulating metabolic, signal, or regulatory networks. One approach to investigating the effects of genetic changes on metabolite synthesis is in silico reaction knockout modeling. The organism's behavior can be predicted through constraint-based modeling (CBM) methods by analyzing the effects of phenotypic and genotypic perturbations on the organisms.

High-throughput technologies such as gene sequencing, protein purification/quantification, mass spectrometry, and others have enabled a new era of biological information in which the amount of biological data has significantly expanded over

Fig. 3. The conceptual basis of CBM [27].

TABLE II. SUMMARY OF CONSTRAINT-BASED MODELING APPROACHES

| Characteristics | FBA | FVA | MoMA | ROOM |
|---|---|---|---|---|
| Purpose | Measure the optimal flux value | Measure the ranges of each flux | Compare the steady-state fluxes between mutant and wild-type | Minimize the number of significant flux changes between mutant and wild-type |
| Optimization model | Linear programming | Linear programming | Quadratic programming | Mixed-integer LP |
| Able to predict the lethality of genes? | Yes | No | No | Yes |
| Computational time | Short | Long | Long | Long |
| Size of model | Large | Large | Small | Large |
| Predicted solutions | Multiple optimal solutions | Assess the robustness of flux distribution | Transient metabolic states | The predicted solutions are nearer to the experimental data |

time. The various omics biological datasets, ranging from genomic to metabolomic and fluxomic, can provide direct insight into an organism's phenotype. An alternative approach is therefore needed to analyze and process large amounts of information quickly. Machine Learning (ML) has been increasingly used in metabolic engineering to replace human metabolic engineers [33], [34], [35]. Given its success in pattern recognition, model prediction, and others [36], [37], [38], [39], [40].

Machine learning (ML) is used to generate trial-and-error inferences and improve the predictions from data without a predefined set of rules. ML has been massively used in data analysis and typically allows applications to develop intelligently by understanding patterns in big data [1]. There are two types of ML based on data: labeled and unlabeled (Fig. 4). For the labeled data, algorithms learn from labeled training data to help predict the outcomes of unlabeled data. Meanwhile, unlabeled data use unsupervised learning to seek patterns and clusters in an unlabeled dataset. Examples of supervised learning algorithms include decision trees [41], support vector machines [42], and regression [43], whereas Principal Component Analysis (PCA) [44], [45] and K-means clustering [46] are unsupervised learning algorithms. Another ML type is reinforcement learning, in which the algorithm interacts with experience and learns to maximize the desired goal using experience, data, and trial-and-error interactions. Reinforcement learning does not need labeled input/output but focuses on balancing exploration and exploitation.

ML has recently played a significant role in biological research [16], [39]. These algorithms focus on model performance by training highly heterogeneous data. It is undoubtedly an opportunity to integrate ML algorithms with CBM models in various biological data sets such as gene expression, metabolites, phenotypes, and others [4], [47]. The application of ML in metabolic engineering will provide several benefits. First, ML can be used in various *in silico* metabolic engineering stages, from analyzing the metabolic flux data to designing optimal metabolic pathways. Second, the full integration of omics data, including genomic, transcriptomic, proteomic, and

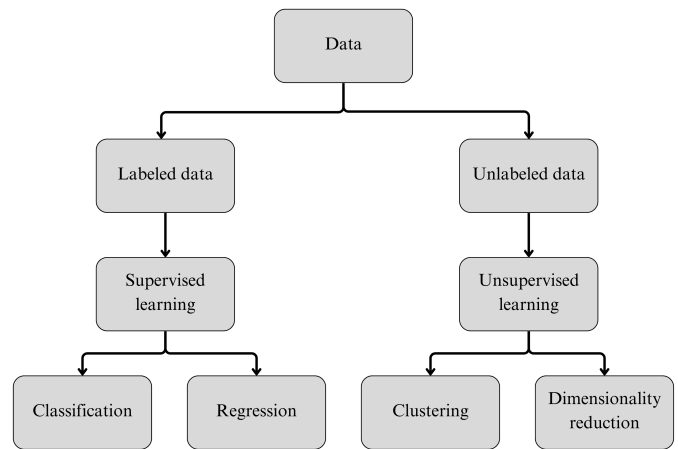

Fig. 4. Machine learning categories.

metabolomic data, is crucial for predicting the metabolic pathway as it provides valuable insight into biological networks [48]. Furthermore, via gene expression analysis using ML, the key regulators of a metabolic pathway can be identified based on the genetic perturbations on cellular metabolism.

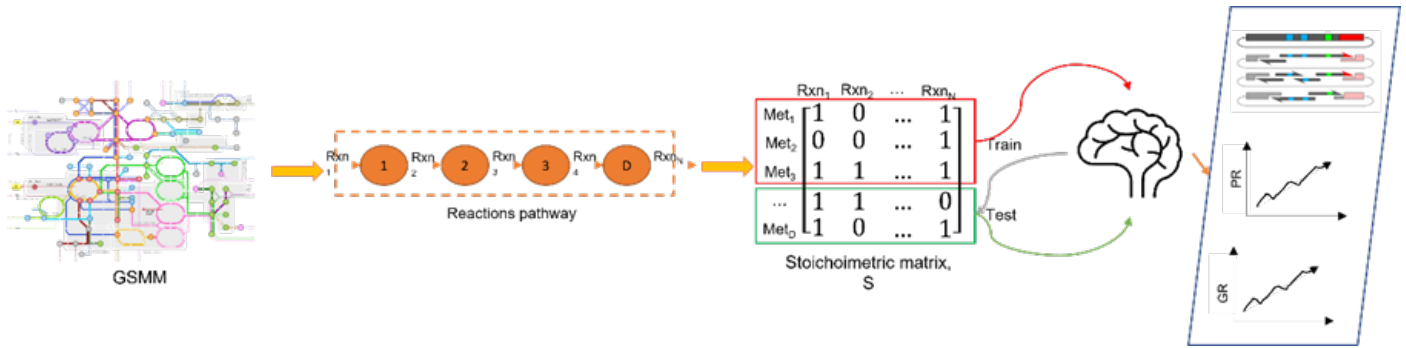
Therefore, by merging machine learning with other computational tools in metabolic engineering, researchers may optimize cellular metabolism for enhanced production of biofuels, chemicals, and other essential molecules in a quick, cost-effective, and sustainable way. As shown in Fig. 5, the reactions and metabolites from GSMM are extracted and represented in a stoichiometric matrix. These datasets comprise instances (reactions and metabolites involved in the specific pathway). The coefficient in the stoichiometric matrix represents the knockout (coefficient one) and non-knockout reactions (coefficient zero) involved in that pathway. In this case, different combinations of knockout reactions are obtained. The training data, then, is used to train the chosen ML algorithms and predict the response of the test dataset. The responses


Fig. 5. Overview of the standard workflow of ML in ME.

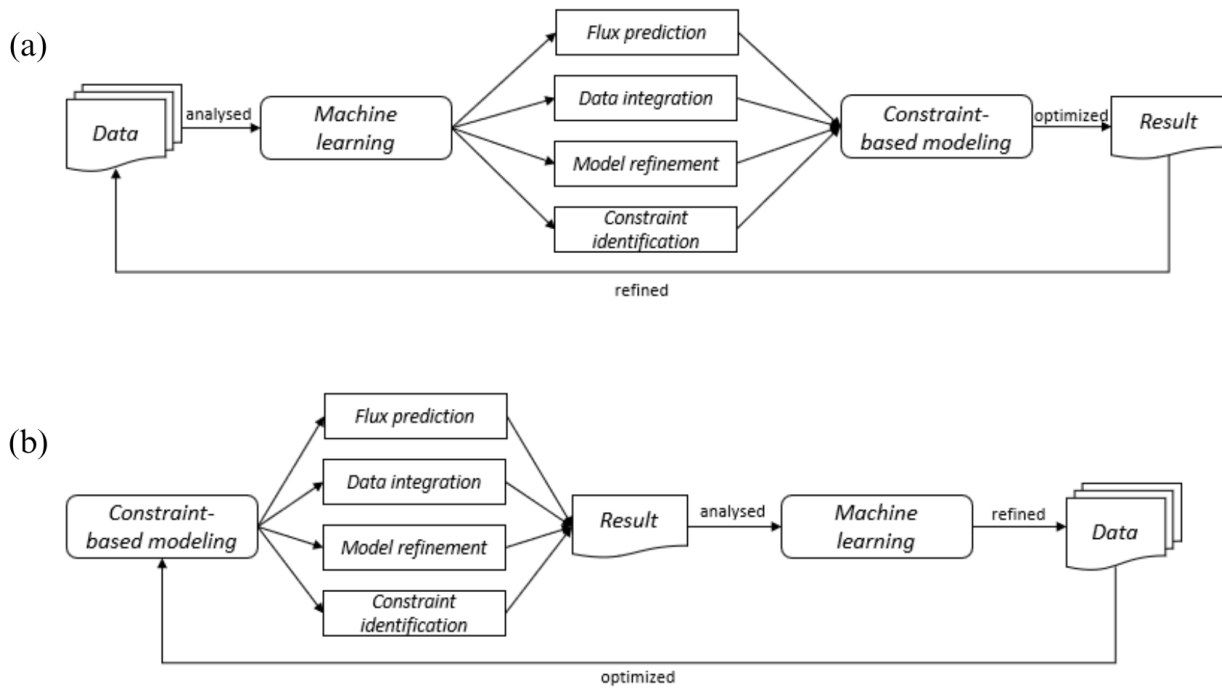

Fig. 6. Integration of machine learning and constraint-based modeling. (a) Refers to the ML as input to CBM, while (b) is CBM as input to ML).

include growth rate, product rate of desired metabolites, and different mutants with different combinations of knockout reactions.

According to [24], [49], the merging of ML and CBM can occur in three approaches. The first approach involves the inclusion of ML after CBM generates fluxomic data by predicting the growth conditions, cellular ML productivity, nutrient consumption, gene essentiality, or biomass concentration. The second approach uses a multi-omics data simplification process before entering the CBM process. The results of fluxomic data from CBM are then combined with the initial multi-omics data for the prediction process using a specific ML algorithm. The last approach uses ML on multi-omics data to get fluxomic data. This paper deduces that merging CBM with ML can occur in two ways, namely, ML as input to the CBM and CBM as input to the ML.

In the prior case, machine learning methods can improve metabolic models' accuracy and predictive power by predicting and refining metabolic models. The metabolic fluxes from omics data predicted using ML algorithms are input constraints for the metabolic model. Furthermore, ML can assist in identifying essential features (genes or reactions) for improving specific metabolite production. Considering that the metabolic model is complex, identifying crucial genes or reactions is essential while maintaining the viability of a cell. Meanwhile, in the post case, CBM can provide features, labels, and model selection to machine learning. Constraint-based approaches have been used to model the GSMM for simulating the phenotypic behavior after genotype perturbations. With the inclusion of machine learning methods, the selected features

from CBM can be used to train ML models for predicting the pathway activity, thus optimizing the metabolic model. Fig. 6 illustrates the integration of machine learning and constraint-based modeling approaches.

## V. Application of Machine Learning in Metabolic Engineering

An unprecedented amount of information has now been used to seek biological mechanisms at the molecular level. The recent advancement of high-throughput technologies has significantly boosted data collecting and fundamentally altered how people view molecular biology [50]. However, predicting bioproduction titers from microbial hosts has been challenging due to complicated interactions between regulatory networks, signaling, and metabolic networks [50]. There are several ways to carry out experiments concerning metabolic engineering. Machine learning, which has undoubtedly led to significant improvements in recent research and is expected to surge shortly, is a critical tool for analyzing, understanding, and exploiting omic data.

A novel approach for predicting yeast metabolome using machine learning based on quantitative proteomic data of kinase knockouts was presented by [51]. The results showed that the ML algorithm accurately predicts the metabolome with complex genetic modification. However, the study assumes that protein expression levels are proportional to changes in metabolic flux. Nevertheless, when post-transcriptional or post-translational modifications occur, the protein expression levels may differ and not proportionate to the changes in metabolic flux. Additionally, the dataset used is relatively small. Thus, expanding the dataset to include a broader range of genetic perturbations and experimental conditions could improve the generalizability of the ML models.

In another research, the integration of knowledge mining, genome-scale modeling, and ML for predicting the bioproduction of *Yarrowia lipolytica* has been proposed [50]. The proposed framework integrates different data, including genomics, metabolomics, and literature, to construct a knowledge-based and optimal GSMM. Then, ML algorithms are applied to predict bioproduction yields based on gene expression data and environmental conditions. They have successfully outperformed the traditional methods. However, the complexity of GSMM and lack of comprehensive knowledge may hinder accurate predictions. Thus, further development and validation are crucial to enhance its applicability and reliability.

Furthermore, [52] have proposed multi-omics data to analyze and characterize key molecular pathways and features essential for yeast growth based on different environmental conditions. The pipeline incorporates biological knowledge in the machine learning model to improve predictions. The proposed pipeline outperforms traditional ML methods and gives insight into the underlying biological mechanisms regulating cell growth. However, the pipeline has several limitations that need to be addressed. For instance, the pipeline relies on the quality and completeness of data sources, which may vary and be limited across different organisms.

A machine learning framework to assess microbial factories' performance was proposed by [1], which thos microbial are microorganisms that can produce various valuable compounds. Like [50], [52], the researchers proposed the integration of different data, including genomics, transcriptomics, metabolomics, and fermentation data. This integration framework is used to model the relationship between genetic and environmental factors and the production of target compounds. The proposed framework uses feature selection, regression, and classification algorithms to predict yields, identify genetic targets for strain engineering, and optimize the conditions. Although the proposed framework successfully demonstrated promising results, however, the framework relies on the availability of data sources. Furthermore, the complexity of metabolic networks and the lack of kinetic transcriptional or genomics data may affect the accuracy of prediction and strain engineering.

In addition, Tachibana and his colleagues prepared a study on Green Fluorescent Protein (GFP) extracted from engineered Escherichia coli. They conducted using Deep Neural Network (DNN) [53]. Before being assessed by machine learning to assign the GFP intensities into a reasonable range for analysis with the DNN technique, the GFP intensities were scaled down by five orders of magnitude. All machine learning methods utilized data from the yeast extract for double-validation calculations. The remaining data were divided into learning and test datasets for random cross-validation. DNNs were built using tanh activations and four hidden layers (200, 100, 50, and 20 units). The average Mean Squared Error (MSE), determined from the rearranged matrices for each variable, was used to measure representative importance in their study. Their research discovered that DNN showed high coefficients of determination and low MSE values.

Different ML algorithms, including random forest, support vector machine, and neural networks have been evaluated by [54], to assess their accuracy in predicting the phenotypic traits of three organisms: yeast, rice, and wheat. The study also investigates the impact of different feature selection methods and data preprocessing techniques on predictive performance. Based on the research, the authors found that combinations of ML algorithms and feature selection methods can achieve high accuracy in predicting phenotypic traits based on genetic data. In another domain, elastic net logistic regression has been proposed to determine the functional and structural brain alterations in female schizophrenia patients [55]. The study combines functional magnetic resonance imaging and diffusion tensor imaging to identify brain regions associated with the disease. The elastic net logistic regression selects relevant features and builds a predictive model. The study found that the model improves the accuracy of classifying the patients.

The developed framework or pipeline proposed by previous researchers demonstrates that machine learning can achieve high accuracy in predicting phenotypic traits based on genotypic perturbations. Moreover, multi-omics data integration has allowed ML algorithms to improve the accuracy of strain engineering in selecting the optimal genetic perturbations. However, there are some limitations and challenges that need to be addressed. Firstly, transcriptomic and genetic data availability is only limited to specific organisms. Thus, predicting and simulating genetic perturbations for less researched organisms is challenging. In addition, the complexity of metabolic networks, thus the complexity of integrated networks, may hinder the predictive capabilities and strain engineering. Therefore,

further development and validation, including biological validation, is needed to enhance ML's interpretability, robustness, and applicability in predicting phenotype changes.

Shimizu and Toya in 2021 experimented with evaluating the cellular performances of 13C- metabolic flux analysis using artificial gene deletion [56]. It is essential to understand the physiology of the metabolism in practical bioprocesses to evaluate the efficiency of the desired model. They stated that the quantitative imaging of microbial cells for metabolic engineering is enabled by metabolic flux analysis (MFA). The nonlinear least squares approach is used to compute metabolic fluxes. A mathematical model that includes carbon atom transfers and molecular mass balancing is provided. Based on the solution space, it is possible to calculate the best trajectory for a given growth and output rate. For the growth phase, the individual growth rate is kept at its highest level and shifted to the critical value, which produces the highest specific production rate.

### A. Combination of Unsupervised and Supervised Techniques

Moreover, many articles have reviewed the recent advances in model-assisted metabolic engineering, which aims to design and optimize the metabolic pathways of organisms to improve the production of desired metabolites [39], [57], [58]. Mainly, the review articles discussed the use of ML to assist in predicting the effects of genetic perturbations for integrated multi-omics data. Previously, metaheuristics optimization algorithms, such as Genetic Algorithm (GA), Differential Search Algorithm (DSA), flower pollination algorithm, Bee Algorithm, Particle Swarm Optimization (PSO), and others, have been used to improve the design of strain. The improved production of desired metabolites has proved the success of metaheuristic algorithms. However, with multi-omics data integration, the strain design becomes more challenging. Thus, using ML approaches is highly needed to enhance the accuracy of model predictions.

### B. Unsupervised Techniques

Unsupervised techniques identify patterns based on predetermined mathematical criteria (such as the number of clusters or variance independence). Large-scale biological datasets have been analyzed using both learning techniques, which have also been combined with FBA. For the unsupervised technique, Sahu et al. developed the "Split Lipids into Measurable Entities reactions" (SLIMEr) approach to model the lipids in genome-scale metabolic models in yeast [59]. SLIMEr later divides lipid components into acyl chain distributions and lipid classes using a mathematical framework, imposing limitations on both [59]. Subsequently, Sahu and his colleagues also established a framework to examine growth-related mechanisms of several S. cerevisiae strains by combining FBA with Multimodal Artificial Neural Networks [59]. The study was to use mechanistic knowledge to integrate data-driven ML techniques to overcome their "black-box" restriction in flux distributions. The framework was evaluated using 1,484 strains of *S. cerevisiae* with single gene knockouts. Growth rates were designated as constraints in pFBA. The study shows that Multimodal Artificial Neural Networks and FBA can train and predict the individual gene expression data for analyzing the flux distributions.

Jalili et al. (2021) performed cancer-specific metabolic signatures using Random forest classification with PCA and FBA [60]. For each cancer model, flux distributions were computed using FBA. After that, using PCA and Random Forests techniques, FBA-based characteristics were generated. PCA generates the variation of flux distributions in cancer models representing the response variables. Random Forests then employed these response variables to categorize crucial fluxes (which showed the impacted sub-cellular systems). Based on their study, the authors discovered that the pentose phosphate route, extracellular transport, mitochondrial transporters, fatty acid production, and other metabolic characteristics are the factors that distinguish between normal and abnormal cell metabolisms for the cancer model.

Meanwhile, unsupervised ML mainly creates clusterings or representations of the unlabeled dataset to reduce the dimensional complexity of data. Principal Component Analysis (PCA) and K-means clustering are examples of unsupervised ML. In ME, unsupervised ML techniques can be implemented to identify the appropriate and non-appropriate reactions involved in producing desired metabolites. Moreover, unsupervised clustering techniques have been used to distinguish different cell types, such as healthy and non-healthy, cancer and non-cancer markers, and stressed and non-stressed. Fig. 7 below illustrates the unsupervised methods in ME.

In another study, Barbosa and the team researched the effects of production factors such as sugar, nitrogen level, and fermentation temperature on wine quality in non-*Saccharomyces* yeasts [61]. The Exploratory Data Analysis (EDA) activity was enhanced by employing unsupervised machine learning on the entire experimental data set. Latent variable techniques, such as Principal Component Analysis, were used to investigate the responses of multivariate structure. Using agglomerative hierarchical clustering (AHC), 18 responses of natural groups were found. Consequently, the forward stepwise variable selection method is used to determine the input variables for the regression model. The study successfully found direct patterns between different production factors, signifying positive and negative correlations.

They stated that the correlation distance was used to identify clusters or groups of functionally related fermentation metabolites [61]. It was anticipated that the first principal component for the cluster-specific PCA models would explain the majority of the overall variability in the cluster due to highly correlated variables generating clusters. Upon completing PCA, supervised ML was also applied. They used a forward stepwise variable selection method to determine which input variables (experimental factors and their higher-order terms) should be included in the regression model. The stepwise selection technique involved picking and incorporating components one at a time. When there are no variables whose inclusion or exclusion from the model would result in a change in the model's explanatory power that is statistically significant, the method finally ends.

For unsupervised ML, they found that clear patterns of linked variables can be seen in the loading plots, such as those that cluster together or lie in the other direction, signifying positive and negative correlations, respectively, as in Fig. 8. This exploratory PCA analysis supports the necessity to investigate the modular structure of the answers in more detail
Fig. 7. Unsupervised ML in ME.

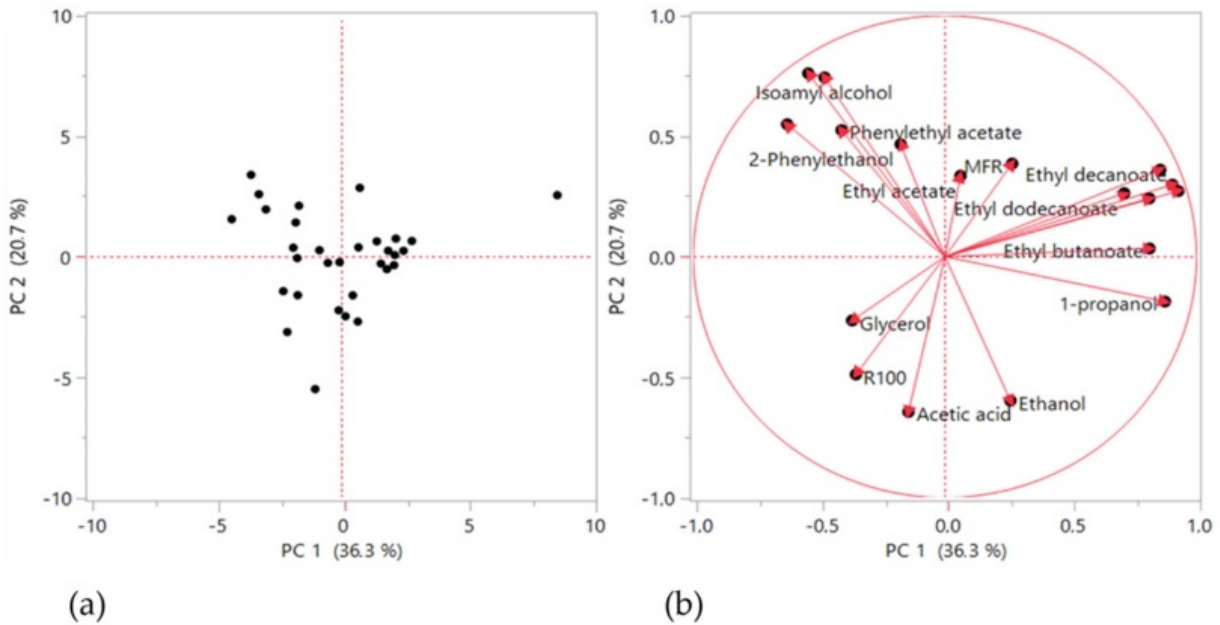

Fig. 8. Result using PCA. a) Scores plot, b) Loading plot [61].

and to identify the linked responses' natural building blocks. In order to uncover the natural blocks or clusters of variables, they implemented an agglomerative hierarchical variable-clustering approach (AHC). As a result, the variables are closer to each other, thus reducing the agglomeration distances [61]. For supervised ML, the considerable changes seen in the exploratory analysis section are confirmed by the modeling results utilizing main effects, second-order interactions, and quadratic terms, indicating the critical influence of the parameters on the fermentation process.

## VI. RESULT AND DISCUSSION

The first activity of this review is collecting the references. We first searched the Scopus and Web of Science databases with the keywords "Machine learning", "Flux balance analysis", and "Metabolic engineering" to find relevant literature in recent years. Then, we filtered for references related to the integration between ML and CBM from the results obtained.

After searching the keywords "Machine learning", "Flux balance analysis", and "Metabolic engineering", 223 research studies were extracted through automatic search from Scopus and Web of Science databases. Of the majority of these 223 studies, 32 were duplicate studies and review papers and thus were eliminated from the list. Based on the title, abstracts, and keywords, the remaining 191 research studies were examined, and 90 studies were excluded. Next, the remaining 101 studies were further selected, in which papers published from 2020 to 2023 were selected and left with 13 studies.

Then, the selected relevant references are synthesized. Table III illustrates the synthesis results of 13 relevant studies in the sources. In the table, 17 machine learning approaches are integrated into constraint-based modeling, namely, binary classifier, random forest, PCA, SVM, KNN, Decision tree, gradient tree boosting, DNN, CNN, t-SNE, ensemble learning, kMeans, lasso, multiview neural network, regularized logistic regression, ANN, and reinforcement learning. Out of those 13 studies, only two use the kinetic model, whereas most use the stoichiometric model. Since the stoichiometric model does

TABLE III. SUMMARY OF SELECTED RELEVANT STUDIES

| ID | Title | Year | Model | CBM | ML | Purpose | Strategy | Ref. |
|---|---|---|---|---|---|---|---|---|
| S1 | Prediction of gene essentiality using machine learning and genome-scale metabolic models | 2022 | S | FBA | Binary classifier | Improves the identification of the essential genes | 1 | [31] |
| S2 | Identifying metabolic shifts in Crohn's disease using' omics-driven contextualized computational metabolic network models | 2023 | S | FBA | Random forest | Identify biomarkers for Crohn's disease | 1 | [62] |
| S3 | Genome-scale modeling of Chinese hamster ovary cells by hybrid semi-parametric flux balance analysis | 2022 | S | FBA | PCA | Integrate parametric and non-parametric constraints for reducing the search space and improve the prediction of FBA | 2 | [29] |
| S4 | Computational Framework for Machine-Learning-Enabled C-13 Fluxomics | 2022 | S | MFA | SVM, KNN, decision tree, random forest, gradient tree boosting, DNN | Predict the flux ratio based on solvability and feature screening | 2 | [63] |
| S5 | Machine learning-guided evaluation of extraction and simulation methods for cancer patient-specific metabolic models | 2022 | S | FBA | CNN, t-SNE | Identify the biological features based on cancer patient-specific GEMs | 1 | [64] |
| S6 | Integrated knowledge mining, genome-scale modeling, and machine learning for predicting Yarrowia lipolytica bioproduction | 2021 | S | FBA | Ensemble learning | Reconstruct Yarrowia lipolytica GSM to improve organic acids' productions. | 2 | [50] |
| S7 | Integration of machine learning and genome-scale metabolic modeling identifies multi-omics biomarkers for radiation resistance | 2021 | S | FBA | Ensemble learning | Identify biomarkers that are associated with radiation resistance | 1 | [65] |
| S8 | In silico Design for Systems-Based Metabolic Engineering for the Bioconversion of Valuable Compounds From Industrial By-Products | 2021 | S | FBA | Random forest | Improve the production of glycerol by integrating transcriptomics data with metabolic network | 1 | [39] |
| S9 | A Hybrid Flux Balance Analysis and Machine Learning Pipeline Elucidates Metabolic Adaptation in Cyanobacteria | 2020 | S | rFBA | PCA, kMeans, Lasso | Identify the key cross-omics features | 1 | [66] |
| S10 | A mechanism-aware and multiomic machine-learning pipeline characterizes yeast cell growth | 2020 | S | pFBA | Multiview neural network | Improve the prediction of phenotypic traits of interest. | 1 | [52] |
| S11 | A biochemically-interpretable machine learning classifier for microbial GWAS | 2020 | S | popFVA | PCA, regularized logistic regression | Estimate the functional effects of genetic-associated alleles | 1 | [67] |
| S12 | A Machine Learning Approach for Efficient Selection of Enzyme Concentrations and Its Application for Flux Optimization | 2020 | K | FBA | PCA, ANN | Select the optimized enzyme concentration for optimal yield | 1 | [68] |
| S13 | Strain design optimization using reinforcement learning | 2022 | K | FBA | Reinforcement learning | Improve production of L-tryptophan | 1 | [69] |

Note : S represents the stoichiometric model; K represents the kinetic model; 1 represents CBM as input to ML; 2 represents ML as input to CBM.

not require intracellular experimental parameters, which are hardly known, stoichiometric models are more favorable for biologists to exploit the detailed capabilities of cell metabolism and [70] outperform kinetic model when the dataset used has large networks [71]. Though kinetic models provide detailed quantitative descriptions of the processes involved in the systems, thus revealing a system's actual dynamic biological behavior, the kinetic model is only limited to the small-scale and newly curated metabolic network [25].

Meanwhile, flux balance analysis (FBA) is the most widely used model assessment method because FBA uses linear programming that is easier to apply than MoMA and ROOM, which use quadratic programming and mixed-integer linear programming. Moreover, although the solutions provided by FBA are non-unique as it does not consider regulatory and signal data, the existing metabolic networks are still incomplete [23]. Regardless of these imperfections, FBA can determine the steady-state fluxes of organisms and predict the optimal long-term evolved state of the cells. In contrast, MoMA and ROOM predict the immediate initial outcome of genetic manipulations. However, cells will evolve from a minimized flux distribution state to an FBA solution [4]. In other words, genetic manipulations will first lead to flux distribution predicted by MoMA and ROOM, eventually converging to a solution predicted by FBA.

TABLE IV. SUMMARY OF MODEL, ADVANTAGE, AND DISADVANTAGES OF MACHINE LEARNING BASED ON THE RELEVANT STUDIES

| ID | Dataset | Result | Disadvantage |
|---|---|---|---|
| S1 | GEMs of Escherichia coli | The proposed approach showed that will-type FBA solutions contain enough information to predict essentiality, without perturbation such as reaction or gene knockout. | There is no a standar strategy on machine learning utilized for essentiality prediction generally. |
| S2 | RISK cohort data, gene expression data for all mucosal terminal ileal biopsies. | A framework that is a potential to identify pathways of clinical relevance in Crohn's disease, discover of novel diagnostic biomarkers, and therapeutic targets. | There is the discrepancy in the generated metabolic models of Crohn's disease in both RISK-derived tissue and enteroids. |
| S3 | GEMs of Chinese hamster ovary (CHO) cells | The proposed hybrid FBA by involving the mechanistic and non-parametric constraints can efficiently reduce the solution space and improve the prediction result of FBA. | Need the experimental fluxes datasets with the guaranteed high accuracy. |
| S4 | 13 C fluxomics | The proposed approach is reliable for fluxomics method readily and applicable to high-throughput metabolic phenotyping. | Computationally expensive especially in the large-scale metabolic network. |
| S5 | Cancer patient-specific GEMs | The results show that tINIT and GIMME has the high performance, but FBA and pFBA has poor performance in cancer metabolism. | Computationally expensive especially in the large GEMs. |
| S6 | GEMs of Yarrowia Lipolytica | This study succeed in integrating knowledge mining, feature extraction, GEMs, and ML for predicting chemical titers in Yarrowia lipolytica. | This model can not capture biosynthesis bottlenecks, consequently, the predictability for low-performance strains is not optimal. |
| S7 | Transcriptomic and genomic datasets | GEMs from patient tumors generated from transcriptomic and genomic datasets. The proposed approach, namely integrating ML and the generated GEMs, can identify prognostic metabolite biomarkers and predict radiosensitivity for individual patients. | Need to collect a larger datasets with the guaranteed high quality. |
| S8 | GEMs of Escherichia coli and transcriptomics data | The proposed method, namely the combination of transcriptome, GEMs, and machine learning can improve the production rate of glycerol. | It does not involve other parameters that influence metabolic processes, such as enzyme, transcriptional regulation, and signaling. |
| S9 | GEMs of Synechococcus sp. PCC 7002, transcriptomics | The proposed approach, namely model-generated flux data, are potential for predicting the growth rates. | Depends on Important information such as the specific metabolite uptake constraints and the nutrient uptake rates that are difficult to obtain directly. |

TABLE IV. SUMMARY OF MODEL, ADVANTAGE, AND DISADVANTAGES OF MACHINE LEARNING BASED ON THE RELEVANT STUDIES–CONTINUED

| ID | Dataset | Result | Disadvantage |
|---|---|---|---|
| S10 | Model of Saccharomyces cerevisiae | The proposed framework, namely, a multimodal learning framework, is capable for undestanding and manipulating complex phenotypes and increasing the prediction accuracy. | It does not involve other parameters that influence metabolic processes, such as enzyme, transcriptional regulation, and signaling. |
| S11 | Dataset of drug-tested Mycrobacterium tuberculosis strains | The proposed approach, namely metabolic allele classifier (MACs), can predict antimicrobial resistance (AMR) phenotypes with accuracy on par with mechanism-agnostic ML. | Not suitable for microbial genome-wide association studies. |
| S12 | The input data of 121 balances of four enzymes in the upper part of glycolysis | The ANN algorithms usedto select the enzyme concentration for the upper part of glycolysis | The ANN algorithms that was used to select the enzyme concentration for the upper part of glycolysis could select the optimum enzyme concentrations, improve flux up to 63%, and decrease a cost up to 25%. |
| S13 | GEMs of Escherichia coli, k-ecoli457 and Saccharomyces cerevisiae | The proposed method, namely MARL, could optimize the L-tryptophan production in S. cerevisiae and specific metabolite in the k-ecoli457. MARL could also be used to optimize metabolic gene expression levels. | Its application is still restricted to the particular target enzymes. |

As for integrating machine learning with constraint-based models, most those relevant studies employed the first strategy in which biological insights from CBM are used as input to ML. Given the intricacy of biological data and certain biological phenomena or systems that cannot be comprehensively described and examined mechanistically. In the table, there are 10 studies utilized the first strategy to integrate ML into CBM. The task of ML in those studies are to identify, improve, estimate, and select. In identifying, ML have been applied to identify the essential genes [31], biomarker [65], [62], the biological features [64], and the key cross-omics features [66]. Then, the application of ML in the improving process are to improve the production of glycerol [39], the prediction of phenotypic [69], and the production of L-tryptophan [69]. At the rest, ML was applied in estimating the functional effect of genetic-associated aleles and selecting the optimized enzyme concentration for optimal yield.

Nevertheless, some research studies employ a second strategy in which ML analyzes multi-omics data for CBM model reconstruction. In this strategy, ML have useful in the reducing, predicting, and reconstructing processes. In reducing, PCA has been implemented by integrating parametric and nonparametric constraints for reducing the search space in order to improve the prediction of FBA [29]. Then, several machine learning approaches have been utilized in the predicting process to get the optimal flux ratio based on solvability and feature screening [63]. Meanwhile, for reconstructing, Ensemble learning has been applied to reconstruct GSMMs of Yarrowia lipolytica in order to improve organic acids' productions [50], where the reconstruction of GSMM involves multiple steps, including annotation, gap filling, and refinement.

Table IV provides results, dataset used, and disadvantages of the relevant studies from Table III. Based on the synthesis and analysis results obtained from the relevant studies, there are several potentials of ML to contribute in *in silico* metabolic engineering. Integrating ML in traditional algorithms, such as flux balance analysis, can improve the production of the desired metabolites and even promise to guide strain optimization based on hybrid models, namely, the mechanistic and data-driven models. Moreover, ML has given positive influences on the prediction results by involving several experimental data such as fluxomic, transcriptomic, metabolomic, and proteomic in the process of constraint-based modeling. Also, it has been shown that ML can construct GSM, predict the essential genes, reduce the dimensionality of cross-omics features, and study the pattern of omic data. Based on those potentials, ML needs to be considered in metabolic engineering processes using CBM.

## VII. CONCLUSION

The advancements in biology, bioinformatics, and computational tools have led to the development of efficient software for modifying organisms for industrial use. Furthermore, the successful reconstruction models of complex biological systems by integrating data from various molecular levels have yielded valuable insights into organisms, thus offering accurate insights into cell activities during organism perturbations. However, this integration can complicate the identification of near-optimal reaction knockouts due to complex biological networks. Therefore, machine learning (ML) and constraint-based modeling (CBM) are employed to facilitate and enhance prediction accuracy.

This review introduced different structure models for representing organisms' systems. Due to the traditional approaches that are costly and irreversible, constraint-based methods have been introduced to overfit the production of valuable metabolites. Though it provides near-optimal solutions, integrating

diverse omics data holds substantial promise in predicting the future state of computational biology systems. Over the coming decade, there will be a growing need for machine learning methods that can be effectively utilized and tailored for these large datasets. Therefore, machine learning methods were integrated into CBM methods to improve the reconstruction of GSMM and the prediction accuracy of genetic perturbations.

We also reviewed several algorithms and applications developed and their different strategies and approaches used in metabolic engineering. As mentioned before, the integration of ML and CBM can happen in two ways. The first way is to apply ML to the integrated biological networks in which ML will identify the essential and meaningful features using the classification technique (supervised ML). This step minimizes the solution space and reconstructs a reduced integrated network for modeling in CBM. The second way is to analyze simulation modeling results from CBM (unsupervised ML).

In conclusion, ML is a superior technique for identifying meaningful features and patterns, which can help reconstruct integrated biological networks that represent the true nature of a cell, thus improving the predictive capabilities of identifying near-optimal reactions knockout for optimizing the production rate of valuable metabolites and growth rates of mutants for industrial purposes.

# Wrapper-based Modified Binary Particle Swarm Optimization for Dimensionality Reduction in Big Gene Expression Data Analytics

Hend S. Salem, Mohamed A. Mead, Ghada S. El-Taweel
Department of Computer Sciences, Suez Canal University, Ismailia, Egypt

*Abstract*—Gene expression data has emerged as a crucial aspect of big data in genomics. The advent of high-throughput technologies such as microarrays and next-generation sequencing has enabled the generation of extensive gene expression data. These datasets are characterized by their complexity, fast data generation, diversity, and high dimensionality. Analyzing high dimensional gene expression data offers both challenges and opportunities. Computational intelligence and deep learning techniques have been employed to extract meaningful information from these enormous datasets. However, the challenges related to preprocessing, reducing dimensionality, and normalization continue to exist. This study explored the effectiveness of the Wrapper-based Modified Particle Swarm Optimization (WMBPSO) algorithm in reducing dimensionality of big gene expression data for Alzheimer's disease (AD) prediction, using the GSE33000 dataset. The reduced dataset was then used as input to a CNN-LSTM model for prediction. The WMBPSO method identified 4303 genes out of a total of 39280 genes as being relevant for AD. These genes were selected based on their discriminatory power and potential contribution to the classification task, achieving an accuracy score of 0.98. The performance of the CNN-LSTM model is evaluated using these selected genes, and the results were highly promising. The results of our analysis are 0.968 for mean cross-validation accuracy, 0.995 for AUC, and 0.967 for recall, precision, and F1 score. Importantly, our approach outperforms conventional feature selection methods and alternative machine and deep learning algorithms. By addressing the critical challenge of dimensionality reduction in gene expression data, our study contributes to advancing the field of AD prediction and underscores the potential for improved diagnosis and patient care.

*Keywords*—*Alzheimer disease; big gene expression; binary particle swarm optimization; deep learning; dimensionality reduction*

## I. INTRODUCTION

In the rapidly evolving landscape of genomics and bioinformatics, the emergence of gene expression data as a prime example of big data presents both opportunities and formidable challenges. Big data, characterized by its immense size and complexity, demands innovative approaches for efficient processing and analysis [1]. Gene expression data, in particular, involves measuring the activity levels of thousands of genes across various biological samples or conditions. This surge in data generation has been fueled by advances in high-throughput technologies, such as microarrays and next-generation sequencing, ushering in an era of information abundance [2]. The following are some key aspects of gene expression data as big data:

- Volume: gene expression data is typically charac-

terized by its sheer volume. Experiments can yield thousands to millions of data points, each representing the expression level of a specific gene in each sample. These large datasets require substantial storage and computational power to manage and analyze effectively [3].

- Variety: gene expression data comes in various formats, such as raw intensity values from microarrays or read counts from RNA sequencing experiments. Additionally, it often includes associated metadata, such as sample annotations, experimental conditions, and clinical information. The integration and analysis of these diverse data types add complexity to the big data challenge [4].

- Velocity: the generation of gene expression data can be incredibly fast due to high-throughput technologies. With the ability to generate a massive amount of data in a short time, there is a need to find new ways to process and analyze the data rapidly [5].

- Complexity: analyzing gene expression data involves complex statistical and computational techniques to identify differentially expressed genes, perform clustering and classification, and infer gene regulatory networks. The complexity of these analyses increases with the size of the dataset [6].

- High dimensionality: each gene expression dataset typically consists of multiple samples (e.g., individuals, cells, or tissues) and thousands of genes. As a result, the data becomes high-dimensional, making it challenging to analyze and interpret effectively [7].

- Diversity of data sources: gene expression data is collected from diverse sources, including different tissues, organs, cell types, and experimental conditions. Integrating data from multiple sources adds complexity to the analysis and requires sophisticated data processing techniques [8].

While these characteristics offer tremendous insights into biological processes, they also present formidable analytical challenges. In light of these challenges, our study sets out to address two pivotal research questions that drive the core of our investigation.

Research Question 1: How can we effectively tackle the inherent complexity and high dimensionality of big gene expression data, specifically in the context of Alzheimer's Disease (AD) prediction?

As gene expression data exhibit substantial volume, diverse formats, rapid generation, inherent complexity, high dimensionality, and diverse data sources, it becomes paramount to devise innovative approaches to streamline the analysis process.

Research Question 1: How can we harness the power of Particle Swarm Optimization (PSO) to enhance deep learning models for gene selection, thereby improving AD prediction?

To overcome the challenges posed by high-dimensional gene expression data, we seek to integrate PSO into the feature selection process of deep learning models. This integration aims to harness PSO's optimization capabilities to select the most relevant genes, ultimately enhancing the performance of AD prediction models.

Alzheimer's Disease (AD) prediction stands out as a compelling application of gene expression data analysis. AD is a complex neurodegenerative disorder marked by progressive cognitive decline and memory loss [9]. Early and precise AD prediction is pivotal for timely interventions and personalized treatment strategies, with gene expression datasets serving as invaluable resources for identifying potential biomarkers and elucidating the underlying molecular mechanisms. Leveraging deep learning models and Particle Swarm Optimization (PSO) holds great promise in enhancing AD prediction accuracy and selecting the most relevant genes associated with the disease [9].

Deep learning models, such as convolutional neural networks (CNNs) and recurrent neural networks (RNNs), have revolutionized diverse fields by excelling in complex tasks like image recognition, natural language processing, and speech synthesis [10] [11]. Their capacity to automatically extract intricate hierarchical representations from data makes them particularly well-suited for gene expression data analysis in AD prediction tasks [12]. However, the effectiveness of deep learning models hinges on the availability of high-quality features that encapsulate pertinent information from the input data.

Feature selection plays a pivotal role in identifying and extracting the most informative features, thereby mitigating computational complexity and enhancing model interpretability [13].

Nonetheless, gene expression datasets often grapple with high dimensionality, encompassing a multitude of genes that may not all be pertinent for AD prediction [14]. Feature selection methods aim to tackle this challenge by combining the merits of filter and wrapper approaches. Filter methods gauge genes based on their statistical relevance to AD, utilizing metrics such as correlation or mutual information. In contrast, wrapper methods assess gene subsets using specific prediction algorithms.

Among these feature selection techniques, PSO has gained traction as an optimization algorithm for identifying the optimal gene subset [15]. Inspired by social behavior, PSO simulates the collective movement of particles within a search space, with each particle representing a potential solution guided by its own best position and the swarm's best position [16].

PSO has demonstrated effectiveness in solving optimization problems, including gene selection for AD prediction, through efficient exploration of the search space and convergence toward promising solutions.

This study's primary objective is to combine the strengths of deep learning models and PSO-based feature selection to enhance feature selection efficiency and deep learning model performance. By integrating PSO into the feature selection process of deep learning models, these hybrid approaches aim to overcome the limitations of traditional feature selection techniques and unlock the full potential of deep learning architectures. The utilization of PSO for feature selection involves two main stages: initialization and iterative optimization [17]. In the initialization stage, the PSO algorithm initializes a population of particles, each representing a potential feature subset. These particles traverse the search space, evaluating their fitness based on a fitness function that quantifies feature subset quality. The iterative optimization phase entails updating particle positions and velocities based on their own best positions and the best position discovered by the swarm, continuing until a termination criterion is met [18].

The integration of deep learning models with PSO-based feature selection offers several advantages. Firstly, it reduces input data dimensionality, crucial for managing large-scale datasets and mitigating overfitting risk. Secondly, it enhances model interpretability by selecting a subset of features most relevant to the target task. Lastly, it augments deep learning models' generalization capability by focusing on discriminative features, potentially leading to superior overall performance.

Having outlined these research questions, our study provides comprehensive answers and innovative solutions. We introduce a gene selection method based on a wrapper-based binary PSO (WBPSO) for dimensionality reduction. This method identifies the optimal subset of genes relevant to AD. Additionally, we propose a hybrid convolutional neural network (CNN) and long short-term memory (LSTM) deep learning model for precise AD prediction. Our study investigates the effectiveness of this approach in improving gene selection efficiency and deep learning model performance across various tasks. Comprehensive experiments conducted on benchmark gene expression datasets allow us to compare our method with other gene selection techniques and validate its superiority.

The remainder of this paper is organized as follows: Section II offers an examination of previous research concerning feature selection techniques and their integration with machine and deep learning models for Alzheimer's Disease (AD) prediction. Section III outlines the materials and methods employed in our proposed approach. Section IV delves into the experimental setup and presents an analysis of the results obtained from our experiments. Section V provides the limitations of the study and some future directions. Lastly, in Section VI, we wrap up the paper by summarizing our discoveries, highlighting the most important findings, and specifying our contribution.

## II. Literature Review

This section provides an overview of various investigations concerning feature selection techniques and the prediction of Alzheimer's disease (AD) using machine and deep learning approaches with gene expression data. Each study is summarized and evaluated for its contributions and limitations.

Martinez et al. [19] introduced a methodology to identify AD-associated genes using decision trees, quantitative association rules, and hierarchical clustering. While this approach effectively detected genes with significant expression changes, its scalability was limited for large-scale datasets.

In their work, Park et al. [20] proposed a deep learning model for AD prediction by integrating gene expression and DNA methylation data. Although their model showed improved accuracy compared to traditional machine learning methods, it faced limitations, including a small sample size, potential overfitting, and a lack of benchmarking with logistic regression or other deep learning algorithms.

Sharma et al. [21] employed random forest and regularized regression models (specifically LASSO) to analyze microarray datasets across four brain regions. This approach aimed to identify genetic biomarkers for AD prediction, achieving high accuracy. However, it faced challenges in handling high-dimensional data and potential overfitting.

Chen et al. [22] highlighted the significance of differential network analysis to uncover AD-related genes using the JDINAC machine learning method. This method successfully identified differential networks associated with AD pathology, contributing to a better understanding of the disease.

Patel et al. [23] focused on differentiating individuals with AD from others using gene expression biomarkers in blood samples. While their XGBoost classification models achieved success, there was a need to improve sensitivity and establish a more specific blood signature for AD.

Bogdanovic et al. [24] emphasized proper experimental design and preprocessing techniques to analyze a large dataset. Their approach, based on XGBoost, achieved competitive performance and offered interpretability, highlighting the importance of explainable machine learning in AD diagnosis.

In [25], an autoencoder (AE) was employed to integrate DNA methylation and gene expression data for AD prediction. The approach demonstrated improved accuracy, addressing the challenges of high-dimensional, low-sample size datasets.

Mahendran et al. [26] developed a gene selection pipeline for AD, combining mRmR, WPSO, and Autoencoder methods. They used Bayesian Optimization to tune hyperparameters and achieved promising results.

Lee et al. [27] utilized three publicly available datasets to investigate AD-related genes and develop classifiers. Their approach demonstrated predictive performance, even across different datasets.

Kamal et al. [28] employed machine learning techniques to classify AD using both image and gene expression data. The CNN achieved high accuracy for image data, while SVC demonstrated accuracy for gene expression data, with the aid of LIME for interpretability.

Maj et al. [29] combined deep learning and machine learning techniques to analyze gene expression data in AD. Their study highlighted the potential of recurrent neural networks (RNNs) in modeling gene expression data, although limitations included sample size and sex-specific considerations.

Kim et al. [30] used the SpliceAI framework, based on a variant of convolutional neural networks (CNNs) called the residual CNN model, to predict Alzheimer's disease (AD)-specific nucleotide alteration sites in pre-messenger RNA (mRNA) sequences. They identified 14 splicing sites in the PLCG1 gene with single-nucleotide variants (SNVs) occurring at the same position in both humans and the AD mouse model cortex. The study's limitation lies in investigating only one gene and lacking comparison with existing models. Future studies should consider analyzing more genes and incorporating high-quality gene expression data for a comprehensive evaluation of model performance.

The work in [31], a deep learning model based on Wasserstein Generative Adversarial Networks (GANs) with a gradient penalty term was utilized to predict the virtual disease/molecular progression of Alzheimer's disease (AD) using gene expression data from a mouse AD model. The latent space interpolation of GANs was leveraged to describe pathological pathway cascades in AD progression. However, the study had limitations, including a small number of differentially expressed genes (DEGs) used for training data and a small sample size of gene expression profiles, which hindered drawing conclusive results. Additionally, the proposed model was not compared to existing models to demonstrate its performance, and future studies should consider incorporating more genes and high-quality augmentation data.

Xie et al. [32] introduced MLP-SAE, a deep learning regression model for predicting gene expression based on genetic variation. The model outperformed other methods, highlighting the potential of deep learning in genomics data analysis.

Alhenawi et al. [33] conducted a systematic review of feature selection methods for microarray data analysis, highlighting the prevalence of hybrid feature selection methods as a promising research direction.

The existing methods, while contributing significantly to AD prediction using gene expression data, face limitations ranging from scalability to interpretability. These limitations have created a notable research gap, particularly concerning high dimensionality and feature selection accuracy

In this paper, we introduce a novel gene selection method based on a wrapper-based binary Particle Swarm Optimization (PSO) algorithm (WBPSO). Our approach is designed to overcome the limitations of existing feature selection techniques by efficiently selecting informative genes for AD prediction. Furthermore, we extend our approach by integrating the selected genes into a hybrid convolutional neural network (CNN) and long short-term memory (LSTM) deep learning model. This integration aims to enhance model interpretability and significantly reduce dimensionality, potentially improving overall AD prediction performance.

Table I provides a summary of some recent research investigating the prediction of Alzheimer's disease (AD) through

the analysis of gene expression data, utilizing various gene selection (GS) techniques and machine and deep learning (ML) models.

## III. MATERIALS AND METHODS

This section presents the proposed method, a comprehensive account of the dataset employed, the preprocessing steps applied to the microarray dataset, and the techniques employed for gene selection and AD prediction. As illustrated in Fig. 1, the overall approach consists of four main components: Preprocessing, Gene Selection, AD Prediction, Performance Evaluation. Utilizing this framework enables the opportunity to create a powerful AD prediction system that merges deep learning models with wrapper-based feature selection method that is inspired by nature. This system leverages big gene expression dataset to produce precise and dependable predictions, ensuring accuracy and reliability. The following sections provide a comprehensive explanation of each individual component in the proposed approach.

Fig. 1. The overall dimensionality reduction and AD prediction approach.

### A. Dataset

The dataset utilized in this study was obtained from the National Center for Biotechnology Information-Gene Expression Omnibus (NCBI-GEO) database [42]. Specifically, the dataset corresponds to the access number GSE33000. It comprises four DNA microarray data profiles, representing multiple tissues in the human brain. These profiles were collected from three distinct brain regions of AD patients: prefrontal cortex (PFC), visual cortex (VC), and cerebellum (CR). However, the focus of the GSE33000 dataset is exclusively on the PFC. In total, the dataset consists of 624 demented and non-demented control cases, each characterized by 39,280 genes.

### B. Preprocessing

To prevent training bias, it is crucial to normalize the input data within a specific range when training models using large channel values. The GSE33000 dataset is preprocessed by the following:

1) Filling the missing values (NaN) by using the mean Let $G$ is the set of genes and $C$ is the set of cases

that have value, and $C'$ is the complementary set of cases that are missing (denoted as NaN or NULL) For each case $ci$ : If the value of case $c_i$ in gene $g_j$ is missing, then its value is filled using the available values by the following formula:

$$m_{c_i,g_j} = \frac{\sum_{c_i \in C_{g_j}} v_{c_i,g_j}}{|C_{g_j}|} \tag{1}$$

where $m_{c_i,g_j}$ represents the missing value of case $i$ in gene $j$.

2) Scaling and Normalization: In this step we used the StandardScaler. In this scaler, the mean is subtracted from each sample and then scaled to have a unit variance. The data is re-scaled in a way that ensures it has a mean of 0 and a standard deviation of 1. The standard score $z$ of a sample $x$ is calculated using the formula:

$$z = (x - u)/s \tag{2}$$

Where $u$ represents the mean and $s$ denotes the standard deviation.

### C. Wrapper-based Modified Binary Particle Swarm Optimization(WMBPSO)

To address research question 1, which focuses on the utilization of Particle Swarm Optimization (PSO) for gene selection, we employ the Wrapper-based Modified Binary Particle Swarm Optimization (WMBPSO) algorithm. The Particle Swarm Optimization (PSO) algorithm is a metaheuristic optimization technique inspired by the social behavior of bird flocking or fish schooling in a search space. For gene selection, the PSO algorithm seeks to find the optimal set of genes that will maximize the performance of the deep learning model. In order to do this, the PSO algorithm assigns each gene a weight, and then iteratively updates these weights based on the fitness of the current solution. Binary Particle Swarm Optimization (BPSO) is a variant of PSO that is specifically designed for binary optimization problems. The Wrapper-based Modified Binary Particle Swarm Optimization (WMBPSO) algorithm includes some modifications compared to the base BPSO algorithm. Fig. 2 depicts the flowchart of the WMBPSO, and the following are the key modifications:

TABLE I. SUMMARY OF SOME RECENT RESEARCH INVESTIGATING THE PREDICTION OF AD THROUGH THE ANALYSIS OF GENE EXPRESSION DATA, UTILIZING VARIOUS GS TECHNIQUES AND MACHINE AND DEEP LEARNING MODELS

| Study | Dataset | GS Method | Model | Performance |
|---|---|---|---|---|
| [20] | GSE33000 GSE44770 GSE80970 | DMP DEG | DNN | Acc = 82.3% |

| [40] | GSE5281 | t-test | SVM | AUC=0.894 |

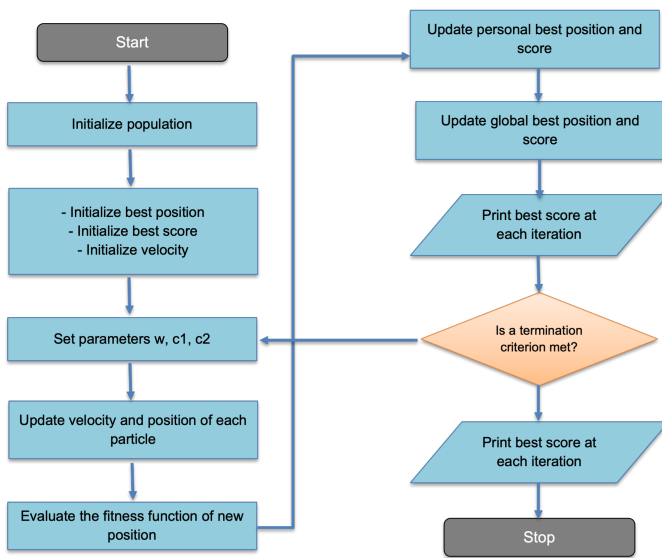

Fig. 2. WMBPSO flowchart.

1) Initialize the population: Each particle represents a subset of genes to be selected.
Let $X = [x_1, x_2, ..., x_n]$ be the binary feature vector

for a particle, where $n$ is the total number of features. The value of each feature $x_i$ is either 0 (not selected) or 1 (selected).

2) Evaluate the fitness: Train a CNN-LSTM model using the selected subset of features (genes). Evaluate the fitness of each particle based on the performance metrics (accuracy, F1, AUC, recall, precision) achieved by the model on the AD prediction task.

3) Update the velocity of each particle using Eq. 3:

$$v(t + 1) = w * v(t) + c_1 * r_1 * (pbest - x(t)) \\ + c_2 * r_2 * (gbest - x(t)) \quad (3)$$

Here, $v(t)$ represents the current velocity, $w$ is the inertia weight, $c_1$ and $c_2$ are acceleration coefficients, $r_1$ and $r_1$ are random numbers, $pbest$ represents the personal best position (best subset of genes) for the particle, and $gbest$ represents the global best position (best subset of genes) among all particles.

4) Update the position of each particle by rounding the sigmoid output of the velocity using the equation:

$$x(t + 1) = \text{round}\left(\frac{1}{1 + \exp(-v(t + 1))}\right) \quad (4)$$

5) Apply boundary conditions to ensure that the positions of particles (gene subsets) stay within the valid

range of feature selections.

6) Evaluate the fitness of each particle based on the performance of the CNN-LSTM model using the updated feature subset. Update the personal best position (*pbest*) and fitness for each particle if its fitness improves. Update the global best position (*gbest*) and fitness if any particle achieves a better fitness than the current global best.

### D. Hybrid Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM)

To answer research question 2, which revolves around enhance deep learning models for gene selection, thereby improving AD prediction, we incorporate the architectures of Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) along with WMBPSO for AD prediction into our model. The CNN-LSTM model combines the CNN and LSTM architectures to process both spatial and temporal information in the gene dataset.

*1) Convolutional Neural Network (CNN):* A Convolutional Neural Network (CNN) is a powerful deep learning technique that has found extensive use in various applications, including image classification, object detection, speech recognition, computer vision, video analysis, and bioinformatics [43]. Unlike traditional neural networks, CNNs are characterized by their deep architecture, incorporating multiple layers [44]. These networks utilize weights, biases, and nonlinear activation functions to process input data effectively. At its core, a CNN consists of convolutional layers, pooling layers, and fully connected layers, forming a comprehensive architecture for feature extraction and classification tasks [45]. Fig. 3 portrays the basic structure of CNN network.

Fig. 3. Basic structure of CNN model.

The CNN's core operation is convolution, which employs convolution kernels to perform convolutions on the inputs. It differs from fully connected structures by leveraging information from adjacent areas of the data matrix. Sparse connections and weight sharing significantly reduce the parameter matrix size. The pooling layer creates feature maps through averaging or taking the maximum value, compressing features and mitigating overfitting. CNN allows for constructing multi-layer convolution and pooling operations [46]. Deeper layers extract more abstract features. These abstract features are then merged using a fully connected layer. Finally, classification and regression problems can be addressed using softmax or sigmoid activation functions. In our case, we utilize one-dimensional convolution in CNN to effectively extract spatial features from gene expression data. The convolution layer operates as a filter and subsequently undergoes activation through a non-linear activation function, as described in Eq. 5:

$$a_{i,j} = f\left(\sum_{m=1}^{M}\sum_{n=1}^{N} w_{m,n} \cdot x_{i+m,j+n} + b\right) \quad (5)$$

where $a_i, j$ is the activation, $f$ denotes a non-linear function, $w_m, n$ represents the m×n matrix of convolution kernel weight, $x_{i+m,j+n}$ refers to the activation of the upper neurons and connected to the neuron $(i,j)$, and $b$ represents the bias value. In this study, the convolutional layers utilize rectified linear units (ReLU) for computing the feature maps. The non-linear function associated with ReLU is defined in Eq. 6:

$$\sigma(x) = \max(0, x) \quad (6)$$

Where $x$ is the input value and 0 is a threshold. The ReLU activation function takes an input $x$ and computes the output as follows: If $x$ is greater than or equal to 0, the function returns $x$. If $x$ is negative, the function returns 0. In essence, the ReLU activation function linearly activates the positive part of the input, while any negative input is turned off (outputting 0).

*2) Long Short-Term Memory (LSTM):* An LSTM network belongs to the class of recurrent neural networks (RNNs) and offers significant advantages over traditional RNNs, allowing for faster learning and addressing issues such as vanishing and exploding gradients [46]. By incorporating memory blocks and employing a cell state, an LSTM network can effectively store and retrieve long-term information. This is achieved through the utilization of input, forget, and output gates, which enable the network to retain relevant past data and connect it with the present inputs. As a result, LSTM networks are capable of solving complex tasks that were challenging for earlier RNN architectures, making them a valuable tool in various applications [43]. The cell state is the main component of LSTM, which involves three essential processes. The initial step entails deciding the type and quantity of information to be eliminated from the cell state, accomplished through the forget gate. Subsequently, the input gate determines the new information to be incorporated into the cell state. Lastly, the output gate determines the specific information to be outputted.

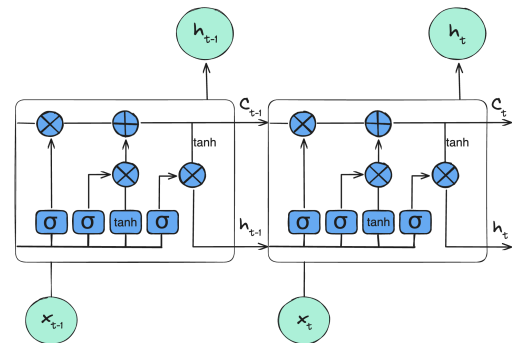

Fig. 4. Typical design of LSTM model.

The LSTM model enhances the original short-term memory unit, represented by $h_t$, by introducing a memory unit $C_t$

to preserve long-term memory or the cell state. In Fig. 4, we observe that an LSTM unit receives three inputs at each time step: the current input $x_t$, the previous state $C_{t-1}$, and the previous output $h_{t-1}$. Notably, both $x_t$ and $h_{t-1}$ are simultaneously utilized as inputs for three gates. The LSTM network follows a specific update process, which can be summarized in Eq. 7:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \tag{7}$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \tag{8}$$

$$\tilde{C}_t = \tanh(W_c \cdot [h_{t-1}, x_t] + b_c) \tag{9}$$

$$C_t = f_t \times C_{t-1} + i_t \times \tilde{C}_t \tag{10}$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \tag{11}$$

$$h_t = o_t \times \tanh(C_t) \tag{12}$$

where, $W_f$, $W_i$, $W_c$, $W_o$ represent the coefficient matrices, $b_f$, $b_i$, $b_c$, $b_o$ are the matrices of bias, $\sigma$ is a sigmoid activation function, $f_t$ denotes the forget gate, which regulates the amount of previous memory to be discarded. In contrast, the input gate denoted as $i_t$ determines the amount of new memory $\tilde{C}_t$ to be stored in long-term memory.

### E. Performance Evaluation

In this research, we assessed the performance of our approach using the test dataset. We employed five metrics to evaluate the predictive capability: Accuracy, Recall, Precision, F1 score, and AUC. These metrics quantify the number of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN), and the following are the details of each metric.

- Accuracy: is a metric that quantifies the ratio of correct predictions $(TP + TN + FP + FN)$ made by the predictor or classifier to the total number of data points $(TP + TN)$ in a dataset. The accuracy metric is calculated using Eq. 13 as follows:

$$Accuracy = \frac{TP + TN}{TP + FN + TN + FP} \tag{13}$$

- Recall (also known as sensitivity): measures the ability of a model to correctly identify positive instances out of all the actual positive instances. It quantifies the proportion of true positives that are correctly predicted. The recall metric is calculated by using Eq. 14 as follows:

$$Recall = \frac{TP}{TP + FN} \tag{14}$$

- Precision (also known as positive predictive value): measures the proportion of true positives out of all the instances that the model predicted as positive. It

focuses on the accuracy of the positive predictions.The precision metric is calculated by using Eq. 15:

$$Precision = \frac{TP}{TP + FP} \tag{15}$$

- F1 score: is a metric that combines precision and recall into a single value. It provides a balanced measure of a model's performance by taking into account both false positives and false negatives. The F1 score is calculated by using Eq. 16:

$$F1 = 2 \cdot \frac{precision \cdot recall}{precision + recall} \tag{16}$$

- AUC: stands for Area Under the Curve provides a single scalar value that summarizes the overall performance of a binary classification model in terms of its ability to rank and discriminate between positive and negative instances. Once the Receiver Operating Characteristic (ROC) curve is created by plotting the true positive rate (TPR), which is synonymous with sensitivity or recall, on the y-axis, and the false positive rate (FPR), calculated as (1 - specificity), on the x-axis , the AUC is computed as the area under this curve.

## IV. RESULTS AND DISCUSSION

For the experimental work, the code was executed using Python version 3.8.10. The libraries employed were Keras, Tensorflow, and Scikit-learn. The experimental setup included an Intel® CoreTM i5-8250U CPU @ 1.60 GHz, 8 GB of main memory, and a 64-bit OS running Ubuntu 20.04.1 LTS. In this study, the performance of WMBPSO algorithm was investigated for dimensionality reduction of big gene expression data in the context of AD prediction. The reduced dataset was then used as input for a CNN-LSTM model for prediction.

### A. Dimensionality Reduction using WMBPSO

The WMBPSO gene selection technique identified a total of 4303 genes as being relevant for AD prediction, achieving an accuracy score of 0.98. These genes were selected based on their discriminatory power and potential contribution to the classification task. This dimensionality reduction significantly improved model performance. The dimensionality reduction achieved through WMBPSO has profound implications. It not only improved AD prediction accuracy but also streamlined the feature set, making it more interpretable.

### B. Comparative Analysis of Gene Selection Methods

We conducted a comparative analysis of the WMBPSO-based approach with three commonly used methods for gene selection: the lasso-based approach, the ANOVA method, and a hybrid ANOVA-lasso-PSO method. The performance of the lasso approach compared to WMBPSO-CNN-LSTM is depicted in Fig. 5. The lasso approach achieved an accuracy of 0.920 and an AUC of 0.915. The F1 score, recall, and precision for the lasso approach were 0.929, 0.961, and 0.90, respectively. Fig. 6 reports the scores of ANOVA method, it achieved an accuracy of 0.89 and an AUC of 0.88, which are lower than those obtained by the WMBPSO approach.
Fig. 5. Comparison of the proposed WMBPSO with lasso method.

Fig. 7. Comparison of the proposed WMBPSO with hybrid anova-lasso-WMBPSO method.

Fig. 6. Comparison of the proposed WMBPSO with anova method.

F1, recall, and precision scores were 0.90, 0.93, and 0.87, respectively.

Fig. 7 describes the performance of the hybrid ANOVA-LASSO-PSO method. This method achieved an accuracy of 0.84 and an AUC of 0.84. Also, the method obtained the value 0.83 for F1 score, recall, and precision. The comparison between the WMBPSO-based approach and the other gene selection methods highlights the effectiveness of the WMBPSO approach and showed competitive performance with a strong AUC score.

## C. AD Prediction with WMBPSO-CNN-LSTM

The CNN-LSTM model, trained with the selected genes, yielded highly promising results. The performance of the CNN-LSTM model is evaluated using these selected genes, and the results were highly promising. The results of our analysis are presented in Fig. 8. To train the CNN-LSTM model for AD prediction, we utilized a cross-validation approach with k = 5 folds to further assess the robustness of

the model. The model was trained over 10 epochs, with a batch size of 32. The mean cross-validation (CV) accuracy, calculated over multiple iterations, was found to be 0.968. This value indicates a consistently high level of accuracy across different folds of the dataset, reinforcing the reliability of the proposed model. Moreover, the area under the curve (AUC) was used to evaluate the model's performance in terms of its ability to discriminate between AD and non-AD cases. The AUC value obtained was 0.9958, suggesting a high level of discrimination power. Additional performance metrics were computed, the recall value was 0.9677; this indicates that the model effectively identified a high percentage of AD cases. Similarly, the precision value was also 0.9677. This indicates that the model made a high percentage of correct positive predictions. Also, the F1 score was found to be 0.9677. This value indicates a balanced trade-off between precision and recall, demonstrating the model's ability to achieve both high precision and high recall simultaneously.

Fig. 8. Performance metrics of the proposed WMBPSO-CNN-LSTM approach.

To evaluate the superiority of the CNN-LSTM model

in combination with the WMBPSO-based gene selection method, we conducted a performance comparison between the WMBPSO-CNN-LSTM model and two other deep learning models, WMBPSO-RNN and WMBPSO-CNN, which also utilized the WMBPSO algorithm for gene selection. For the CNN model, as shown in Fig. 10, the results obtained were 0.94, 0.93, 0.95, 0.93, and 0.94 for mean cross-validation accuracy, AUC, recall, precision, and F1 score, respectively. Fig. 9 portrays the performance of WMBPSO-RNN. The results obtained were 0.84, 0.89, 0.84, 0.85, and 0.85 for mean cross-validation accuracy, AUC, recall, precision, and F1 score, respectively. The comparison among the three models

Fig. 10. Comparison of the proposed WMBPSO-CNN-LSTM model with CNN model.

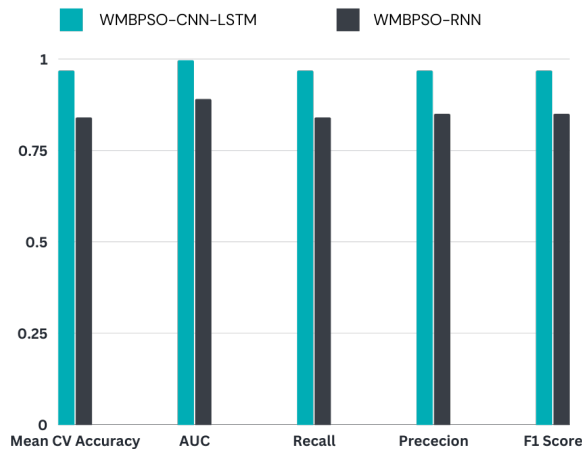

Fig. 9. Comparison of the proposed WMBPSO-CNN-LSTM model with RNN model.

TABLE II. PERFORMANCE EVALUATION VALUES OF DIFFERENT MACHINE LEARNING MODELS COMPARED TO THE PROPOSED WMBPSO-CNN-LSTM

| Model | Recall | Precision | F1 Score | Accuracy |
|---|---|---|---|---|
| Logistic Regression | 0.97 | 0.91 | 0.94 | 0.93 |
| Boosted Random Forest | 0.83 | 0.86 | 0.84 | 0.83 |
| Decision Tree | 0.82 | 0.79 | 0.80 | 0.78 |
| SVM | 0.95 | 0.93 | 0.94 | 0.93 |
| KNN | 0.80 | 0.87 | 0.83 | 0.82 |
| MLP | 0.66 | 0.97 | 0.79 | 0.80 |
| Guassian NB | 0.72 | 0.80 | 0.76 | 0.74 |
| ANN | 0.97 | 0.86 | 0.91 | 0.90 |
| **WMBPSO-CNN-LSTM** | **0.97** | **0.97** | **0.97** | **0.97** |

Further comparisons with various machine learning methods are presented in Table II.

The remarkable performance of the CNN-LSTM model highlights its effectiveness in handling the reduced dataset. This suggests that by effectively managing dimensionality, we can harness the full potential of deep learning models. In conclusion, according to the findings of this study, the WMBPSO-CNN-LSTM model demonstrated superior performance compared to the WMBPSO-CNN, WMBPSO-RNN, as well as other machine learning models and prevalent feature selection techniques in reducing dimensionality and predicting Alzheimer's Disease using big gene expression data. The WMBPSO-CNN-LSTM model exhibited outstanding AUC, higher accuracy, F1 score, recall, and precision. These results underscore its superior ability to capture relevant features and patterns related to big gene expression data.

*D. Implications and Suggestions*

Our findings carry significant implications for AD prediction and gene expression analysis:

- The dimensionality reduction techniques employed in this study have the potential to revolutionize AD prediction, making it more interpretable and precise.

highlights the superior performance of the WMBPSO-CNN-LSTM model in AD prediction using gene expression data. It achieved higher accuracy, AUC, F1 score, and recall compared to both the WMBPSO-CNN and WMBPSO-RNN models. The precision values were comparable between the WMBPSO-CNN-LSTM and WMBPSO-CNN models, indicating similar abilities to identify positive cases accurately. However, the WMBPSO-RNN model exhibited lower performance across all metrics, suggesting it may be less effective in capturing the complex relationships present in the gene expression data for AD prediction.

- The combination of WMBPSO and CNN-LSTM demonstrates the power of integrating feature selection with deep learning for complex biological data analysis.

- Future research should explore applications of these techniques in other disease prediction tasks and investigate novel approaches for feature selection and deep learning integration.

## V. LIMITATIONS AND FUTURE WORK

While our study has yielded promising results, it is essential to acknowledge its limitations and outline potential avenues for future research.

### A. Limitations

- Data Size: The study utilized a single gene expression dataset. Future work could explore the integration of multiple datasets to enhance the robustness and generalizability of the model.

- Generalization: Although our model exhibited exceptional performance on the specific dataset, further validation on diverse datasets and populations is necessary to establish its broader applicability.

- Feature Interpretation: While dimensionality reduction improved model performance, interpreting the biological significance of selected genes remains a challenge. Future research should focus on developing methods for gene function interpretation.

### B. Future Work

Several potential avenues of future research can be summed up as following: 1) Integrate biological constraints, such as gene pathway information or known gene-disease associations, to guide the gene selection process and ensure that the selected gene groups are biologically meaningful. 2) Group-based Velocity Update of the WMBPSO; modify the velocity update process to consider interactions between feature groups. The velocity update not only involves individual features but also considers the collective behavior of gene groups in the swarm. 3) Expanding the dataset by including additional samples from diverse populations and incorporating longitudinal data to enhance the generalizability and robustness of the WMBPSO-CNN-LSTM model. 4) Integration of Multi-Omics data such as DNA methylation, microRNA expression, or proteomics data, in combination with gene expression data, could provide a chance to validate the behavior of WMBPSO-CNN-LSSTM algorithm on such large-scale combined datasets. 5) Further validation of the WMBPSO-CNN-LSTM model on independent datasets to assess its performance and generalizability in real-world scenarios. 6) Advanced Deep Learning Architectures: Investigating state-of-the-art deep learning architectures and techniques, such as Transformers and attention mechanisms, may further enhance AD prediction accuracy.

## VI. CONCLUSION

In this study, we aimed to leverage the WMBPSO algorithm for dimensionality reduction in big gene expression

data. The accuracy score achieved by the WMBPSO algorithm in selecting genes was 0.98, indicating a significantly high level of accuracy. The objective was to develop an accurate AD prediction model using the WMBPSO algorithm in conjunction with a CNN-LSTM deep learning architecture. Through our investigations, we compared the performance of the WMBPSO-CNN-LSTM model with other deep learning and machine learning methods. Also, the performance of WMBPSO was compared with other common feature selection methods. The results obtained demonstrate the effectiveness of the WMBPSO algorithm for dimensionality reduction in big gene expression data. The WMBPSO-CNN-LSTM model achieved outstanding performance in AD prediction, as indicated by the high mean cross-validation accuracy (0.968), AUC (0.9958), F1 score (0.9677), recall (0.967), and precision (0.967). These metrics validate the potential of the WMBPSO algorithm for effectively selecting informative genes and improving the classification accuracy of the AD prediction model. Comparative analyses were conducted with other deep learning models, including WMBPSO-RNN and WMBPSO-CNN, as well as traditional feature selection methods such as ANOVA, lasso, and hybrid approach. The results indicated that the WMBPSO-CNN-LSTM model outperformed these approaches in terms of accuracy, AUC, F1 score, recall, and precision. In conclusion, our study has made significant strides in addressing the challenges of Alzheimer's Disease (AD) prediction using gene expression data. We have demonstrated that effective dimensionality reduction with the WMBPSO algorithm, coupled with the power of CNN-LSTM, can yield highly accurate predictions. Our research contributes by:

- Introducing an innovative approach to gene selection using WMBPSO, which outperforms traditional methods.

- Highlighting the potential of combining feature selection and deep learning for AD prediction.

- Offering valuable insights into the management of high-dimensional biological data.

While there are limitations to our study, such as dataset size and generalization, the future holds promising prospects for improving AD prediction, advancing gene function interpretation, and ultimately aiding in early diagnosis and intervention. Our work underscores the importance of interdisciplinary research at the intersection of bioinformatics and machine learning, paving the way for more precise and reliable disease prediction models in the era of precision medicine.

# Development of YOLO-based Model for Fall Detection in IoT Smart Home Applications

Pengcheng Gao[*]

School of Cyber Security, Gansu University of Political Science and Law, Lanzhou 730070, Gansu, China

*Abstract*—In smart home applications, effective fall detection is a critical concern to minimize the occurrence of falls leading to injuries, especially for the assistance of elderly individuals. Various methods have been proposed, including both vision-based and non-vision-based approaches. Among these, vision-based approaches have garnered significant attention from researchers due to their practicality and applicability. However, existing vision-based methods face challenges such as low accuracy rates and high computational costs, which still need further exploration to enhance fall detection effectiveness. This study aims to develop a vision-based fall detection system tailored for smart home care applications. The objective of this study is to develop an accurate and lightweight fall detection method that is applicable in IoT platforms. A You Only Look Once (YOLO) based network is trained and tested to identify human falls accurately. The experimental results demonstrate that the developed YOLO-based technique shows promising outcomes for human fall detection and holds potential for integration in the Internet of Things (IoT) enabled smart home applications.

*Keywords—Smart home; IoT; elderly care; computer vision; deep learning; YOLO*

## I. INTRODUCTION

In recent years, the rapid progress in Information and Communication Technology (ICT) has brought about significant changes in people's lives thanks to groundbreaking innovations. This has led to the rise of intelligent environments, cities, and societies [1]. By leveraging cutting-edge technologies like Artificial Intelligence (AI) and the Internet of Things (IoT), we have the potential to greatly improve our quality of life. These advanced solutions empower us to monitor our surroundings and make well-informed decisions to achieve desired outcomes. Among these advancements, smart homes play a crucial role as the cornerstone of smart living. They are poised to be instrumental in the development of smart cities and societies since homes serve as the fundamental building blocks for both urban areas and social structures.

Presently, several socioeconomic factors are contributing to a significant decline in fertility rates and an increase in life expectancy [2]. As a result, a growing number of elderly individuals are striving to maintain their independence and stay in their own homes. To address this, an automated home-based solution that reduces the burden on healthcare services and provides valuable insights into fall risk becomes an appealing alternative [3]. Furthermore, with the global increase in the elderly population, healthcare considerations for seniors are becoming increasingly critical. For this reason, human motion

capture technologies are essential for elderly individuals living alone, as they can help tackle these challenges. By observing their posture, it becomes possible to monitor the health of elders, and if high-risk postures such as falling are detected, timely warnings can be sent [4], [5].

Compared to traditional Machine Learning (ML) algorithms, deep learning significantly simplifies the process of feature selection by automatically extracting abstract features through multiple hidden layers [6]. The effectiveness of deep learning in unsupervised learning and reinforcement learning has been proven, leading to a surge in the development of deep learning-based Human Activity Recognition (HAR) frameworks [5]. In particular, Convolutional Neural Networks (CNN), inspired by the hierarchical processing in the human visual cortex, have achieved remarkable success in image categorization in recent times [7]. CNN-based methods can automatically learn distinctive features from training data, making them highly efficient for feature extraction and classification tasks [8], [9].

Two general categories can be made for CNN-based identification tasks. The first category consists of two-stage detection algorithms that divide the phases of target detection into finding and identifying them. Conventional approaches, such as Region-Convolutional Neural Networks (R-CNN), have flaws and fall short of real-time performance requirements. Faster R-CNN and Faster R-CNN have been introduced, although they are still insufficient for real-time applications [10]. The second group uses a single-stage detection method that combines the positioning of the target with its identification.

This study addresses the research problem of devising a precise and resource-efficient fall detection method suitable for IoT platforms. The research questions include the design of such a method, the effectiveness of utilizing the YOLO5 network due to its memory-efficient and speedy detection characteristics, and the steps required for dataset curation to train and test the YOLO model in recognizing fallen postures for improved fall detection. The research objectives encompass creating an optimized fall detection solution for IoT environments, assessing the YOLO5 network's suitability for this purpose, and developing and preparing a dataset for robust fall posture recognition within the YOLO framework.

The main contributions of this study are as follows:

*1) Developing* a vision-based approach for fall detection with feasibility and applicability considerations.

*2) A* Yolo-based network implementation and model generation for human fall posture identification.

*3) Fall* dataset generation using image collection from various internet resources and annotation and augmentation process.

The rest of this paper is consisted as: Section II reviews the related works. Section III discuss about the research methodology. Section IV presents the results and discussion. Finally, this paper concludes in Section V.

## II. RELATED WORKS

Ajerla et al.'s [11] developed a fall detection framework based on an LSTM network that took advantage of edge computing tools like laptops, reducing the requirement to upload raw data to the cloud for real-time fall event prediction. The system used the open-source Apache Flink streaming engine to process the three-axis accelerometer raw data. A part of the MobiAct dataset, which is openly accessible, was used for training and testing. To get the best results, the system advised putting sensors at the waist—the suggested framework successfully anticipated fall occurrences using real-time fall data with an amazing accuracy of 95.8%. The use of various sensors and data streams led to improved performance.

Queralta et al. [12] proposed a fall detection system for health monitoring facilities using low-power wide-area network (LPWAN) technologies with Edge computing and Fog computing, as well as a compression technique for data transfer, lowering system latency. To recognize falls from the received data, LSTM and RNN networks were developed on the edge computer. These edge gateways were used to transmit real-time alerts and notifications while unprocessed data was transferred to the cloud for online processing. With this strategy, the operation was possible even in places with poor network access and increased battery life.

By suggesting an approach based on video analysis, Wang et al. [13] attempted to increase fall detection accuracy and speed in complex contexts. The introduction of the YOLOv3 network model as the detection algorithm was the main contribution. In order to train and test the network model on a GPU server, they constructed their dataset for human fall detection using the Pascal VOC data set format. According to experimental data, the method is more reliable and efficient than traditional fall detection algorithms, achieving a mAP of 0.83 and an AP down at 0.97.

In study [14], an approach to detecting human falls based on the Fast Pose Estimation technique was presented. The method classified data from picture frames using TD-CNN-LSTM and 1D-CNN models, demonstrating excellent accuracy. The suggested technique proved to be a valuable addition to reliable human fall detection, suitable for implementation in edge devices due to its minimal computational and memory requirements. They enhanced the URFD dataset for training by applying rotation, brightness adjustments, horizontal flipping, and gamma correction.

## III. RESEARCH METHODOLOGY

This section presents the research methodology. Firstly, the background of the YOLO method is discussed. Secondly, the preparation of the dataset is presented. Thirdly, the implementation environment using Google Colab is explained, and lastly, the training and testing procedure is presented for fall detection.

### A. Background of YOLO

YOLO (You Only Look Once) was a pretrained object detector designed to recognize common objects like tables, chairs, cars, phones, and more [15]. A newer version of the YOLO algorithm, called YOLOv5, has been proposed with enhancements over YOLOv3. YOLOv5 achieves greater precision and smaller model size, leading to significantly faster detection speed compared to its predecessor. Despite its potential, the YOLOv5 technique has not yet been widely applied in fall detection [16]. Therefore, this paper aims to improve the YOLOv5 model for detecting senior fall behavior.

The YOLOv5 is one of the most prominent models in the one-stage detection series, avoiding the recomputation of candidate areas utilized in the two-stage series. It boasts excellent recognition accuracy and quick inference. The YOLOv5 architecture comprises four primary model structures: YOLOv5l, YOLOv5x, YOLOv5m, and YOLOv5s, each offering progressively fewer complex networks. Additionally, a YOLOv5n model was later developed with only 1.9 MB parameters, the same depth as YOLOv5s but with half the network width, making it suitable for deployment on mobile devices.

As depicted in Fig. 1 [16], the YOLOv5 baseline architecture consists of three main components: the backbone, neck, and head. Fig. 1(a) to Fig. 1(d) illustrates the composition of modules related to the baseline architecture. One of the Backbone structures is a Convolutional Neural Network (CNN), which combines various fine-grained images to form image features.

The architecture utilizes the conv module for 2D convolution, regularization, and activation. The c3 module aids in feature extraction, reducing the model size and enhancing inference speed. The up-sample and concat modules handle feature map sampling and combination. The spatial pyramid pooling (SPP) module expands the network's perceptual area. The Neck structure improves information flow with feature pyramid network (FPN) and path aggregation networks (PAN). Adaptive pooling connects features for optimal data utilization. Overall, these components optimize the model's accuracy and efficiency.

### B. Dataset Preparation

The dataset for fall detection was compiled from diverse sources, including Google Images, to create a custom dataset. This dataset consists of images categorized into three labels: "Fall Detected," "Walking," and "Sitting ". The initial dataset involves 485 images. To prepare the dataset with mode diversity, image augmentation is performed. After augmentation, total dataset involves 1455 images. The labels directory also has two subdirectories, namely "train", "val." and "test". Within these directories, text files are provided,

containing labels corresponding to specific images. Fig. 2 displays some examples from our dataset.

The dataset for fall detection may not be large by industry standards, but it's essential to consider its specific context and the chosen model's complexity. As our experimental results indicated, it is sufficient for a well-designed model. Additionally, the dataset is diverse and representative of real-world scenarios, that it helps the model generalize effectively.

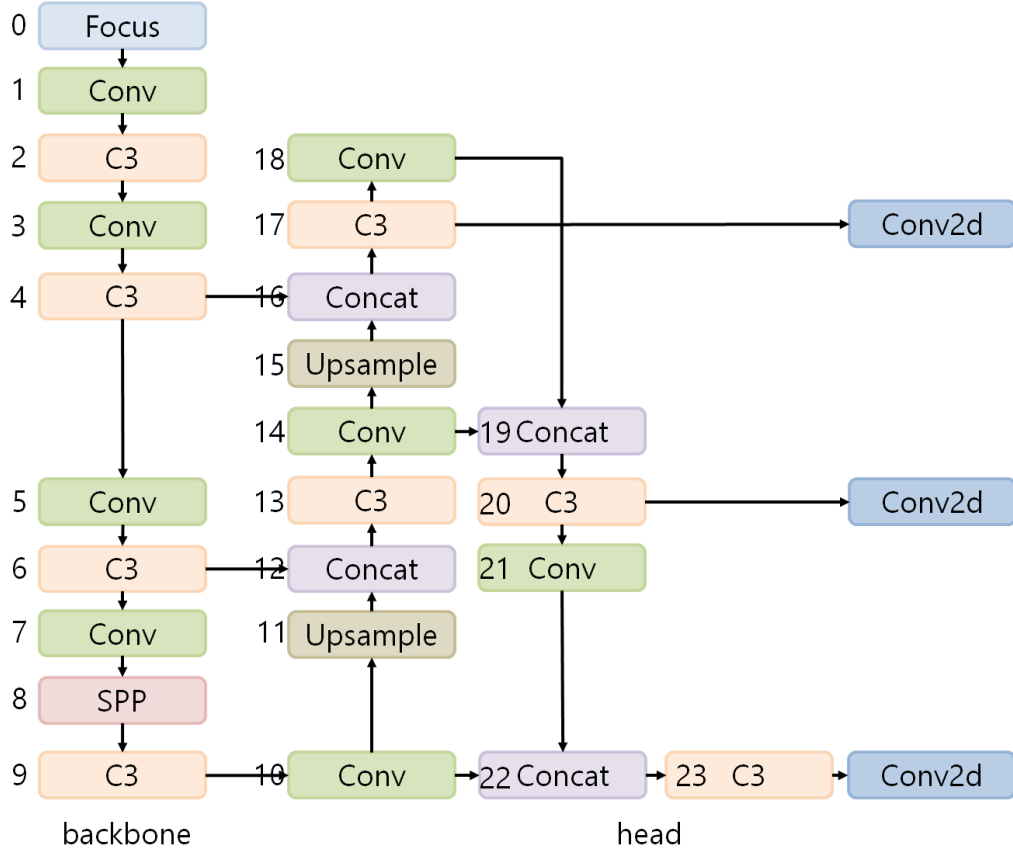

Fig. 1. The architecture of the YOLOv5 network.

Fig. 2. Sample images from the dataset.

## C. Training and Testing

When training an object detector, one common approach is to start with a preexisting model that has already been trained on large and diverse datasets. These pretrained models have learned to recognize various objects from the data they were initially trained on. Although the pretrained weights may not include specific objects relevant to the current experiment, they still capture valuable general features and patterns that can be beneficial for the new task.

This process of using a pretrained model as a starting point and fine-tuning its weights for a specific task is called transfer learning. By leveraging transfer learning, we can save time and computational resources, as the pretrained model has already learned to detect common objects effectively. The model acts as a feature extractor that can be fine-tuned to recognize the specific objects we need in our experiment.

In this case, a pretrained model containing weights trained on the COCO dataset is used as the starting point for the object detection task. COCO is a large and diverse dataset that includes a wide range of objects from various categories. Using a model pretrained on COCO, our network can benefit from the learned features, leading to faster convergence during training.

With transfer learning, we can achieve good results with fewer training data. In this experiment, the total dataset consists of 1455 images. To split the dataset for training, validation and testing, 70% of the images are used for training the model, and the remaining 20% are used for validating, and 10 % for testing for performance evaluation of the model.

In summary, transfer learning is a powerful technique that allows us to leverage existing knowledge from pretrained models to boost the performance of our object detection task. Utilizing a pretrained model and carefully selecting the appropriate amount of data for training and validation, we can efficiently train an accurate and effective object detector for our specific needs.

## IV. RESULTS AND ANALYSIS

In this section, we discuss the experiment's details, then show the training results using pretraining weights and compare the three models of YOLOv5.

### A. Experimental Results

At this stage, we show a series of the model's stress measurement results and achieved high accuracy. Fig. 3 illustrates the results of the prediction fall in the dataset.

Fig. 3. Prediction results of fall detection.

### B. Model Evaluation

The first version of our model was trained for the training set. The results of it are shown in Fig. 4. Label 0 is for falling, label 1 for walking and label 2 for sitting. As experimental results are shown in Fig. 4, this model achieved relatively accurate results.
Fig. 4. Labels in the training process.

Various performance metrics are computed to evaluate the fall detection model. These metrics typically include precision, recall, and F1 score. We calculated the precision rate and recall rate. The results of the evaluation metrics of the trained model are shown in Fig. 5. Precision measures the accuracy of fall predictions, recall measures the model's ability to detect all falls, and the F1 score combines precision and recall into a single value. An analysis of the model's errors is performed to gain insights into its performance. This involves examining false positive and false negative predictions [18]. False positives are instances where the model incorrectly identifies a non-fall instance as a fall, while false negatives are cases where the model fails to detect an actual fall. Analyzing these errors helps identify areas for improvement in the model and dataset. Fig. 5 to Fig. 7 illustrates the performance metrics.

Fig. 5. Result of precision metric.

As shown in Fig. 5, a precision curve graph for a generated YOLOv5 model fall detection system with fall, walking, and sitting classes shows the relationship between the confidence rate and the precision rate. The X-axis represents the confidence rate, which indicates the level of confidence the model has in its predictions. In contrast, the Y-axis represents the precision rate, which measures the accuracy of the fall detection system. To obtain accurate results based on the obtained precision confidence from the generated YOLOv5 model, the following steps are typically followed:

Prediction and Confidence Threshold: The YOLOv5 model is applied to the test dataset, and for each detected object, the model assigns a confidence score or probability indicating its confidence in the prediction. The confidence score represents the model's belief that the object belongs to a particular class, such as falling, walking, or sitting. To generate the precision curve graph, different confidence thresholds are set to analyze the trade-off between precision and recall.

Precision Calculation: For each confidence threshold, the model's predictions are compared against the ground truth labels. True positive (TP) refers to the correct detection of a fall instance, false positive (FP) represents a non-fall instance being incorrectly identified as a fall, and false negative (FN) indicates a missed detection of a fall. The precision is then calculated using the formula: Precision = TP / (TP + FP) [17,18]. By examining the precision curve graph, one can identify the confidence threshold that provides the desired precision rate for fall detection. It allows for fine-tuning the system based on the specific requirements, striking a balance between accurate fall detection and minimizing false positives.

As depicted in Figure 5, the achieved precision rate of 0.93 for the YOLOv5 model in detecting fall, walking, and sitting classes is highly indicative of its effectiveness. A precision rate of 0.93 implies that 93% of the predicted positive cases were indeed true positives, minimizing false positives. This high precision indicates the model's ability to accurately classify these activities, reducing the likelihood of misclassification.

Fig. 6. Result of recall metric.

Fig. 6 illustrates the recall curve. A recall curve graph for a generated YOLOv5 model fall detection system with fall, walking, and sitting classes shows the relationship between the confidence rate and the recall rate. The X-axis represents the confidence rate, which indicates the level of confidence the model has in its predictions, while the Y-axis represents the recall rate, which measures the ability of the fall detection system to correctly identify all instances of falls.

For recall calculation, the model's predictions are compared against the ground truth labels for each confidence threshold. True positive (TP) refers to the correct detection of a fall instance, false positive (FP) represents a non-fall instance being incorrectly identified as a fall, and false negative (FN) indicates a missed detection of a fall. The recall is then calculated using the formula: Recall = TP / (TP + FN) [19,20].

Moreover, for recall curve plotting, as the confidence threshold is varied, the recall rate is calculated at each point. These recall values are plotted against the corresponding confidence thresholds on the graph. The resulting recall curve shows how the recall rate changes as the confidence rate increases. A higher recall rate indicates that the fall detection system is more effective in correctly identifying all fall instances. The recall curve graph allows us to analyze the relationship between recall and confidence thresholds. Based on the desired trade-off between recall and precision, an optimal confidence threshold can be selected. If maximizing the number of detected falls is the priority, a lower confidence threshold can be chosen, which may result in higher recall but potentially more false positive predictions. By examining the recall curve graph, one can identify the confidence threshold that provides the desired recall rate for fall detection.

As depicted in Fig. 6, the overall recall rate is 0.93 for the YOLOv5 model in detecting fall, walking, and sitting classes. I show that the model successfully captured 93% of all actual positive cases, demonstrating its ability to detect these classes with a high level of sensitivity.
Fig. 7.   Result of precision-recall curve.

As shown in Fig. 7, the precision-recall curve graph for a generated YOLOv5 model fall detection system with fall, walking, and sitting classes shows the relationship between the confidence rate and the precision-recall rate. The graph provides a visual representation of how precision and recall change as the confidence threshold varies. Precision measures the accuracy of fall predictions, while recall measures the ability to detect all fall instances. By examining the curve, the optimal confidence threshold can be determined based on the desired balance between precision and recall.

The precision-recall curve graph helps in evaluating the performance of the fall detection system and selecting the appropriate confidence threshold. A higher precision indicates more accurate fall predictions, while a higher recall indicates a greater ability to detect all fall instances. The graph allows for the analysis of the trade-off between precision and recall, enabling the system to be fine-tuned to meet specific requirements. By selecting the optimal confidence threshold based on the precision-recall curve, the generated YOLOv5 model can achieve accurate results in detecting falls while minimizing false positives and false negatives.

Finally, as illustrated in Fig. 7, the overall precision-recall rate of 0.93 for the YOLOv5 model in detecting fall, walking, and sitting classes. This metric signifies a balanced performance in terms of precision (the ability to correctly classify positive cases) and recall (the ability to capture all actual positive cases). This obtained score demonstrates the model strikes a favorable balance between minimizing false positives and successfully identifying true positives.

## V.   CONCLUSION

In IoT smart home applications, detecting human fall detection is a difficult problem. The high complexity, poor accuracy, and time constraints of human fall detection in smart home applications is the focus of this work. The aim of this study is to develop an accurate and lightweight fall detection method that is applicable in IoT platforms. It developed a vision-based fall detection system that can recognize human fallen posture for use in smart home applications. The developed method involves training and testing a YOLO network to identify the postures in the prepared dataset. Based on the YOLO5 algorithm, which offers a high accuracy rate and satisfactory speed in posture identification, this Yolo-based technique was developed. One limitation of this study is the reliance on a relatively small dataset, which may limit the diversity and representation of fall-related scenarios. A larger and more diverse dataset could provide a more comprehensive understanding of fall detection in various real-world situations, potentially enhancing the model's generalizability and robustness to different environmental and contextual factors. Future work in this area could involve the expansion of the dataset to include a wider variety of fall-related scenarios, encompassing different environments, age groups, and diverse physical conditions. This would help improve the model's ability to handle a more extensive range of fall detection challenges. Other potential directions for future study include improving the accuracy and performance of the system by exploring alternative deep learning models or refining the existing technique. Another direction is to focus on the real-time implementation and deployment of the system in real-world smart home environments, considering factors such as scalability, reliability, and integration with IoT technologies. These advancements would contribute to the effective utilization of the system in IoT-based smart home applications.

*Abstract*—With the expanding utilization of cyber-physical structures and communication networks, cyberattacks have become a serious threat in various networks, including the Internet of Things (IoT) sensors. The state estimation algorithms play an important role in defining the present operational scenario of the IoT sensors. The attack of the false data injection (FDI) is the earnest menace for these estimation strategies (adopted by the operators of the IoT sensor) with the injection of the wicked data into the earned mensuration. The real-time recognition of this group of attacks increases the network resilience while it ensures secure network operation. This paper presents a new method for real-time FDI attack detection that uses a state prediction method basis on deep learning along with a new officiousness identification approach with the use of the matrix of the error covariance. The architecture of the presented method, along with its optimal group of meta-parameters, shows a real-time, scalable, effective state prediction method along with a minimal error border. The earned results display that the proposed method performs better than some recent literature about the prediction of the remaining useful life (RUL) with the use of the C-MAPSS dataset. In the following, two types of attacks of the false data injection are modeled, and then, their effectiveness is evaluated by using the proposed method. The earned results show that the attacks of the FDI, even on the low number of the sensors of the IoT, can severely disrupt the prediction of the RUL in all instances. In addition, our proposed model outperforms the FDI attack in terms of accuracy and flexibility.

*Keywords—Cyberattacks; false data injection (FDI) attacks; internet of things (IoT); deep learning*

## I. INTRODUCTION

The current developments and the rapid growth of the Internet of Things sensors have increased the possibility of predictive maintenance. This capability is a method for the prevention of asset damage by the generation of data analysis and the template identification for the prediction of the subjects before which they occur. Using these PdM techniques leads to an $20\% - 25\%$ increment in productivity, a 35%−45% decrease in downtime and the 25%−20% decrease in maintenance cost [1]. Due to this good feature, the equipped PdM solutions with machine learning and IoT sensors are transforming the transportation, oil, gas, aerospace, automotive, national defense and construction industries. For example, recently, the algorithms of deep learning have displayed massive achievement in these applications [2]. However, unfortunately, the sensors of the IoT and the algorithms of deep learning widely are delicate to cyberattacks

[3]. This bad feature is a considerable menace to the overall system of the PdM. Due to the provided reportage by Malwarebytes, the cyber menace versus the factories/occupations has enhanced to over 200% in the prior year [4].

In particular, recognizing covert attacks like the false data injection (FDI) attack [5] in the PdM system is quite challenging due to the unique nature of this attack type. The attack of the false data injection (FDI) [5] is in such a way that an attacker secretly compromises the measurements of the sensors of IoT. This is done by the method that the measurements of the manipulated sensor bypass the original detection method of the "defective data" by the sensors. Then they propagate into the output of the sensor. The attack of FDI can be fulfilled by completing the communication network of the sensors, the physical sensors and the processing applications of the data. These types of attacks in the system of PdM may not even display their effect. But, in lieu, the attack propagates aboard the sensor to the machine learning part of the system of PdM. Next, it tricks the system with the prediction of the possession defeat and or the interval of the delayed maintenance. It may evince a considerable cost with the creation of an unplanned defeat and or human life loss on the applications of the safety-critical [6], [7], [8]. In the past, the attacks of the FDI have made the very incidents of the known catastrophic. The most important example is the Northeast blackout in the United States in 2003 and the attack on the Ukrainian power grid. These attacks have influenced more than 230,000 people. They have been without power for multiple hours. A vast investigation has been done about the identification and reduction of the attacks of FDI in the field of cyber-physical systems [9], [10], [11]. The current users of this type of system for aircraft engine maintenance are Honeywell, Rolls-Royce, Pratt & Whitney, US Air Force and General Electronics [6], [12], [13].

The proposed solutions for sensor attack detection, which are provided so far in the field of the system of cyber-physical and IoT, are not enough for the solution of this subject because utmost of the existing method travail from the scalability subjects and the resource overhead when they deployed individually on thousands of the sensors. Many IoT sensors have limited power and limited resources. This paper presents a real-time attendance recognition method for these attacks in earned mensuration by applying the models of deep learning for the precise state prediction along with an impressive abnormal identification approach in the predicted

states with the use of the matrix of the error covariance. When the change rate of the eigenvalues of the error covariance matrix exceeds a predefined threshold, then the network operator indicates the presence of the attack of FDI on a collection of the accessible mensuration. This shows an effective deployment of the scalable 920D. Therefore, our article contributions are as the below:

- By effectively adjusting the presented deep learning-based method parameters, a collection of the indices of the minimum error have been obtained. An encyclopedic compersion between two non-uniform deep learning-based methods and a conventional ML-based method, such as the SVM and an actuarial prediction method, such as the integrated moving average of the autoregressive, is carried out in this work.

- By incorporating the noise into the existing mensuration, the presented deep learning-based method provides flexible action with minimal changes on the indices of the error.

- The presented abnormal recognition scheme shows a robust, real-time and excellent FDI attack recognition approach with the tracking of the change rate of the eigenvalues of the matrix of the error covariance.

- Since our presented method does not require the major modification of the standard BDD, therefore, it represents a cost-impressive method.

The continuation of this paper is as the below: In Section II, the related works is presented. In Section III of the paper, the proposed algorithm details are presented. Then, Section IV presents the earned results from the designed experiments. Eventually, Section V presents the potential conclusions and future perspectives.

## II. RELATED WORKS

The available studies on the data injection attacks on smart networks are listed in [27] to [35]. The work in [29] introduces an analysis of the economic effects of data injection on electricity markets in the smart power grid. In this reference, it is assumed that an attacker participates in the virtual transactions of the electricity market with complete information that he has from the network and it designs his attack strategy based on the manipulation of the electricity price in order to maximize the profitability and by observing all the limitations of the attack. In [30], the operation of the data injection attack in the electricity market environment is considered for a connected micro-grid to the power system. This attack can affect the optimal outputs of micro-grid energy management, such as the total cost of production. The research in [31] suggests the monetization of malicious data attack on electric energy production markets and the necessary strategy to maximize the revenue. The study in [32] proposes LR as a type of FDIA that the load distribution attack can affect the operation of the smart grid by attacking the economic load distribution bound by the security constraints (SCED). To solve this problem, [33] has introduced the problem of the distributed resilient economic load distribution

under cyber-attacks. With the aim of directly controlling local marginal prices (LMPs) in real time through FDIA, [34], a control theory based on a method is presented to analyze the effect of attack implements pricing stability.

In [35] and [36], a zero-sum game is formulated between an attacker and a defender, in which the attacker changes the estimated throughput of the lines to manipulate the prices. According to this game theory, a two-level optimization problem is formed. In [37] and [38], the economic effect of the structured information attacks as a generalized type of FDIA in electricity markets by using the virtual bidding activities is studied. The structured information of smart grids is used to exploit the system for management. The network is very vital in a safe way, but this information can be manipulated by a cyber-attacker by changing the on/off state of the power switches. In addition to these, recently in [39], an attack strategy has been proposed in which a cyber-attacker can effectively change LMPs by manipulating some vital parameters of the model and achieve the financial gain. Also, an FDIA can be well matched with a coordinated physical attack and actually create a coordinated physical-cyber-attack (CCPA), which has a more destructive effect on the normal operation of the smart network.

In [40], the coordinated attack includes connecting the physical shortening of the transmission lines, after infiltrating the communication network with the cyber protection layers. The research in [41] has designed a CCPA with the aim of maximizing disruption in the day-ahead (DA) and real-time electricity markets. The study in [42], an attack of a CCPA based on AC state estimation proposes to disrupt the operation of the electricity market by manipulating the nodal prices. All the above related studies are based on the hypothesis that the cyber attacker has complete knowledge about the target smart grid information, which includes the network topology, the branch parameters, etc. In fact, in any given smart grid, the network information is vast and highly secure and vital. Moreover, information is dynamic; because the network topology can be reconfigured in both normal and event situations. Therefore, in practice, it is very difficult for a limited attacker to access the complete information of the network. In several recent works based on [33] to [35], this aggressive challenge in FDIA design has been addressed to some extent according to different tools, techniques and requirements.

In study [43], the attacker has formulated a secret profitable attack without prior knowledge of network topology and only through phasor observations by using the linear independent component analysis. In study [44], the attacker designs an online attack strategy against the real-time electricity market based only on real-time information received from measuring devices and without the need for the network topology information. A profitable data injection attack on electricity markets by limited attackers with incomplete network information is studied in [45]. In this reference, the uncertainties associated with random network information, a model and a possible framework for designing an undetectable and profitable attack are presented. One of the problems in this reference is the need for past data to properly

estimate the probability distribution functions of the parameters.

## III. PROPOSED SCHEME FOR THE FDI ATTACK DETECTION

In this section, the presented method for detecting the attacks of false data injection is detailed. For this purpose, first, a brief explanation of these types of attacks and how the definition of them are provided. In the following, the proposed scheme is expressed.

### A. Definition of FDI Attack

At first, it should be stated that the only purpose of the attack of the FDI is the bypassing of the remaining test in the centers of control with the attenuation of the climacteric vulnerabilities of the sensors and RTUs. This progressive cyberattack scheme in various networks (such as the Internet of Things) leads to the change of a group of the state estimations from a group of the obtained mensuration. A vector expansion approach of the indiscoverable covert attack for the nonlinear algorithm of the state prediction is presented, which shows:

$$a_1 = h(\hat{x}_{a_1}) - h(\hat{x}) \tag{1}$$

$$\hat{x}_{a_1} = \hat{x} + c' \tag{2}$$

$$z_{a_1} = z + a_1 \tag{3}$$

where, $a_1 \in R^m$ represents the vector of the injected attack to the obtained collection of the mensuration $z$ for the presentation of a group of the corrupt mensuration $z_{a_1} \in R^m$. Therefore, it creates a set of the false estimation states $\hat{x}_{a_1} \in R^n$. The statistical remaining test, which is performed by the BDD in the above conditions, can be seen as follows:

$$r_{a_1} = ||z_{a_1} - h(\hat{x}_{a_1})||_2 = ||z + a_1 - h(\hat{x}_{a_1}) + h(\hat{x}) - h(\hat{x})||_2 = ||z - h(\hat{x})||_2 = r \tag{4}$$

From the above equations, it can be seen which vector of the extended attack can bypass as successfully the remaining test. Therefore, it leads to climacteric operational scenarios.

The existing operators in the center of the control adopt the algorithms of the state prediction for the definition of the climacteric network actions, such as the load prediction, the load distribution of the economy, and so on [14]. The mensuration in the SCADA is broadcasted via BDDs to meet the integrity and the quality of the mensuration. Then the bad information removes according to the noise in the networks of communication, the meter malfunction, and so on. In most of the unfavorable papers [15], [16], [17], a method of the nonlinear state prediction is presented, that is shown as follows:

$$z = h(x) + e_1 \tag{5}$$

where, $z \in R^m$ represents the available measurements which are obtained from the BDDs. Also, $x \in R^n$ represents the set of operational states while $e_1 \in R^m$ displays the vector of the error for the prediction method. Furthermore, $h()$ represents the nonlinear function that draws a collection of the obtained mensuration by the network operational states. For the estimation of a collection of the operational states with the use of the method of the nonlinear state prediction as displayed in Eq. (5), a flattish start method is adopted, as is displayed in Eq. (6):

$$x[0] = [0\ 0\ \dots\ 1\ 1]^T \tag{6}$$

With the use of the flattish start method, an iterative Gauss-Newton approach is performed for the determination of a set of estimated states. In it, the matrix of Jacobian $J \in R^{m \times n}$ is reformulated in each epoch. The exiting BDD in the EMS module on the SCADA performs the remaining test of the actuarial that is shown below:

$$r = ||z - h(\hat{x})||_2 \le \tau \tag{7}$$

where $\tau$ depends on the degrees of freedom $(m - n)$ throughout the specified system, since the obtained mensuration has enough redundancy on them, the mensuration, which shows the remaining higher than $\tau$, successfully scraped as the worst possible information.

### B. Proposed Scheme

The accurate and impressive performance of the analysis based on the regression has been demonstrated by the methods of deep learning. This data-driven prediction approach has shown the onomastic error in forecasting [18], [19], [20]. The current article considers MAE, MSE and RMSE for the performance parameters that are defined below:

$$RMSE = \sqrt{\sum_{a''=1}^{b''} \frac{(f''_{a''} - s''_{a''})^2}{b''}} \tag{8}$$

$$MSE = \sum_{a''=1}^{b''} \frac{(f''_{a''} - s''_{a''})^2}{b''} \tag{9}$$

$$MAE = \sum_{a''=1}^{b''} \frac{|f''_{a''} - s''_{a''}|}{b''} \tag{10}$$

The estimated operational states with $f$, is denoted and the actual operational states with $s$ is denoted. The bald number of the instances for the estimation is $b''$. With the effective optimization of the meta-parameter, the presented neural network by the scenario of the network steady-state effectively can estimate the predicted states by the lowest value for the performance parameters. In the current article, a strong nonlinear structure of the LSTM is proposed.

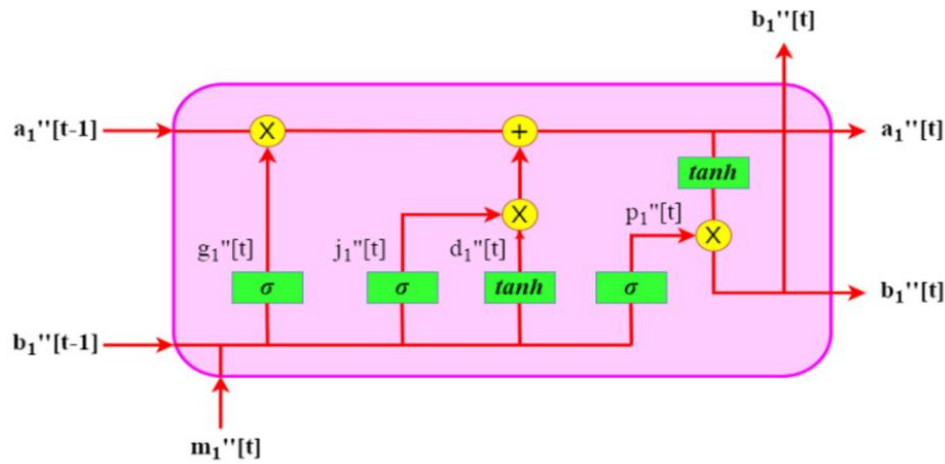
The LSTM model is a particular architecture from the RNN that helps with the learning of the patterns of the complex temporal, which are provided in the dataset of the training. This particular type of RNN is able to the nature maintaining of the data at a given step of the time. Thus, the LSTM provides the possibility to read, retain, and remove the data from the memory cells by setting three distinct controllable gates, which is named the gate of the forget $g''_1(t)$, the gate of the input $j''_1(t)$ also, the gate of the output $p''_1(t)$. Fig. 1 shows the structure with the single cell for a module of LSTM. Also, the model of the presented LSTM is displayed in Fig. 2.


Fig. 1. Single-cell structure from an LSTM cell.

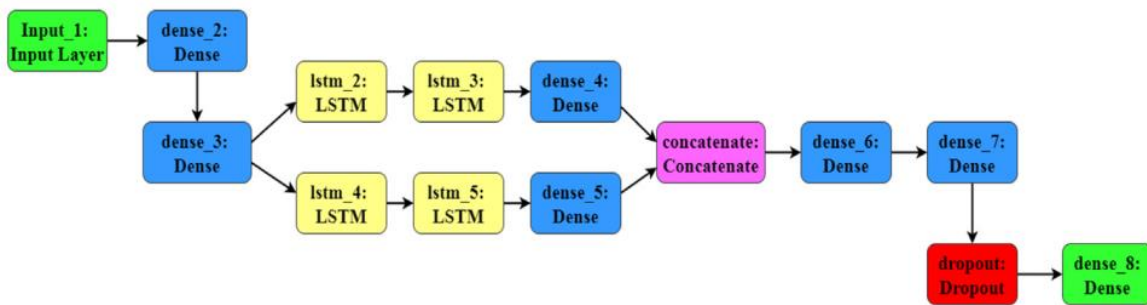

Fig. 2. The proposed LSTM model.

The admission or the rejection of the information in the form of the binary (0 or 1), which is related to the current state of the cells, depends on the gate $g''_1(t)$. The forget gate is defined by Eq. (11). On the modules of LSTM, the activation function of *sigmoid* is used. $j''_1(t)$ represents the gate of the input from the module of LSTM, which is displayed in Eq. (13). For the updation of the state of the current cell, generally, a decision of the binary by means of the gate of the input is taken. For the module of LSTM, the updated cell state is denoted with $a''_1(t)$ also, the novel contributor is $d''_1(t)$. As shown in Eq. (15), the accumulated data is discharged to the next neurons. The weights with $w''_{1(.)}$ is denoted. Also, the outputs are denoted with $b''_1(t)$, the inputs are denoted with $m''_1(t)$ and finally, the biases are denoted with $b''_{1(.)}$. These cases are shown in Eq. (11) to Eq. (16). The concatenation operation is indicated by $[.,.]$.

$$g''_1(t) = sig(w''_{1_{g''_1}}[b''_1(t-1).m''_1(t)] + b''_{1_{g''_1}}) \quad (11)$$

$$a''_1(t) = [g''_1(t) \times a''_1(t-1)] + [j''_1(t) \times d''_1(t)] \quad (12)$$

$$j''_1(t) = sig\left(w''_{1_{j''_1}}[b''_1(t-1).m''_1(t)] + b''_{1_{j''_1}}\right) \quad (13)$$

$$d''_1(t) = \tanh\left(w''_{1_{d''_1}}[b''_1(t-1).m''_1(t)] + b''_{1_{d''_1}}\right) \quad (14)$$

$$p''_1(t) = sig\left(w''_{1_{p''_1}}[b''_1(t-1).m''_1(t)] + b''_{1_{p''_1}}\right) \quad (15)$$

$$b''_1(t) = p''_1(t) \times \tanh(a''_1(t)) \quad (16)$$

Fig. 2 displays which the model of the presented LSTM has *eight* layers hidden along with one layer of the output and one layer of the input. It can be viewed that in the second layer of the hidden, the model is divided into the layers of the sub-hidden. These layers of the sub-hidden combine the structures of LSTM by the neural networks of the dense for improvement of the efficiency of the state prediction. These models of the nonlinear are found by the layers of the sub-hidden for the representation of a superior approach for the prediction. Finally, all layers of the sub-hidden are compromised in a common layer which is called the layer of the concatenation. Two layers of the dense are placed in place of the layer of the concatenation, and then the layer of the output is placed. The drop-out regularization is effectively adopted for the avoidance of the model over-inflating. The proposed nonlinear method is fed with the activation function of *ReLU* to each layer which is expressed by Eq. (17).

$$y''_{1_{i'_1}} = ReLU(w''_{1_{i'_1}} k'_{1_{i'_1}} + b'''_{1_{i'_1}}) \quad (17)$$

For layer $i'_1$, the set of predicted features is equal to $y''_{1_{i'_1}}$ and the input features are equal to $k'_{1_{i'_1}}$. Other parameters of a specific layer consist of bias $b'''_{1_{i'_1}}$ and weight $w''_{1_{i'_1}}$. The output of the layer of LSTM from the presented nonlinear method is directly entered into the next layer of the dense that this layer has the activation function of *ReLU*. The layer of the

output of this nonlinear method includes an activation function of *ReLU* according to Eq. (17). The proposed model is trained in 500 iterations and using the optimizer of *Adam*. The initial rate for the learning of the proposed method is equal to 0.001.

By effectively training the model, a superior policy can be demonstrated for the estimation of states by the indices of the minimum error. The scheme of the real-time FDI attack recognition, which is the basis of the matrix of the error covariance, is presented in Fig. 3. The algorithm of the presented anomaly detection performs the vector of the

developed error according to the predicted operational states and predicted operational states in the SCADA.

$$e(t) = \hat{x}_{for}(t) - \hat{x}_{test}(t) \qquad (18)$$

$\hat{x}_{for}(t) \in R^n$ represents the predicted set from the estimated states, which is obtained by the benchmark of the scalable nonlinear neural network and $\hat{x}_{test}(t) \in R^n$ represents the predicted states of the step of the time $t$, which are recovered with the use of the algorithm of the state prediction. Also, $e(t) \in R^n$ represents the error vector.

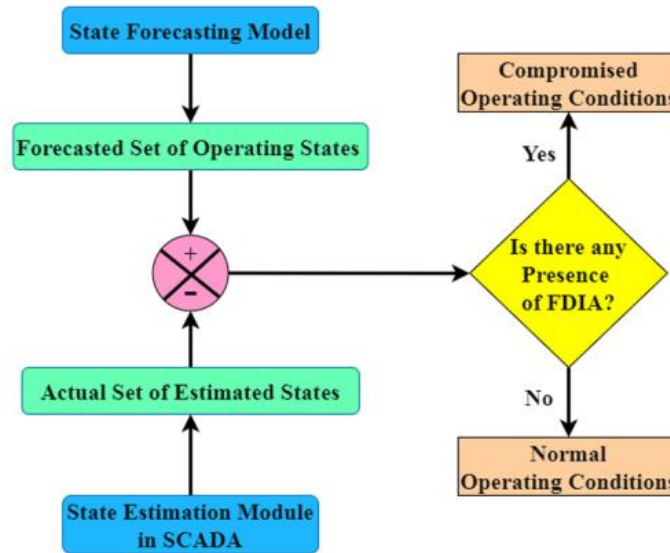

Fig. 3. The proposed method for the detection of the attack of FDI.

The main purpose of the method of anomaly recognition is the identification of the eigenvalues change rate of the matrix of the error covariance, which is displayed as follows:

$$\frac{d\mu}{dt} = x_1^T(t)\frac{dE(t)}{dt}x_1(t) \qquad (19)$$

$$\frac{dE}{dt} \approx \frac{E(t) - E(t - \delta t)}{\delta t} \qquad (20)$$

$x_1(t) \in R^n$ represents the eigenvector for the matrix of the error covariance $E(t) \in R^{n \times n}$ which is generated pending the time of the current sampling $t$. Since $E(t)$ and $E^T(t)$ are the matrices of the symmetric positive definite covariance. Therefore, these matrices have the same eigenvalues and the same eigenvectors. The change rate of the eigenvalues among two intervals of the consecutive time $t$ and $(t - \delta t)$ can be shown by Eq. (19) and Eq. (20), respectively. The proposed detection scheme for the FDI attack that performs the change rate of eigenvalues is described as follows:

$$\varepsilon = \begin{cases} 1 & \frac{d\mu}{dt} > RMSE + \delta_1 \\ 0 & otherwise \end{cases} \qquad (21)$$

where $\varepsilon$ displays the criterion of the recognition that is adjusted with 1. Thus, if the change rate of eigenvalues in a specific time $t$ exceeds a particular threshold, as is displayed in Eq. (21), it shows the presence of the FDI attack inside the obtained measurements. $\delta_1$ displays a numerical constant with a very small positive value which belongs to the operator

knowledge. This parameter inherently is insignificant because the model of the nonlinear state prediction shows better accuracy for prediction.

## IV. EVALUATION RESULTS OF THE PROPOSED METHOD

In this section, the results of the evaluation of the presented method are examined. First, the used dataset is described. In the following, the results of the proposed deep learning method for the prediction of RUL are evaluated. Then, the continuous and temporary signatures from the FDI attack are provided, and then the attack's impact on the prediction of RUL is stated. The Python programming language has been used for the implementation of these tests. The presented method is implemented on a computer which has a Core (TM) i7 CPU, 3.0 GHz Intel(R) and 8G RAM.

### A. Used Dataset

For the performance evaluation of the presented method, the dataset of the NASA C-MAPSS turbofan engine destruction simulation is used. The used dataset consists of 21 data of the sensor by the number of the conditions of the operational and the conditions of the different error. On the used dataset, four subsets (FD001-04) are defined. Each subset includes the data from the training and the data from the test. The data of the test is reached to the data of the defeat from the multiple engines with the same group. In the data of the test, each row is a cycle of time that is defined as one hour of working. A cycle of time has 26 columns which column 1

displays the ID of the engine and column 2 displays the number of cycles of the current operation. Columns 3 to column 5 display the three settings of the operational and also, the columns 6 to column 26 display the 21 values of the sensor. The data of the time series is only terminated when it encounters an error. The data of the test consist of only the information for some cycles of the time because our purpose is the estimation of the cycles of the time of the remaining operational before the occurrence of a defect.

### B. Results of the Proposed Method of RUL Prediction

For the confirmation of the proper efficiency of the presented algorithm, which is the basis of the LSTM, this method has been evaluated on the dataset of C-MAPSS. For the performance evaluation of predictors, RMSE, MSE and MAE are used. These metrics are widely used as the criteria of evaluation in the studies of the evaluation of the model. The results are related to the network, which this network has 100 nodes in the layers hidden from the first layer. In addition, it has 100 nodes in the layers hidden from the second layer and 100 nodes in the layers hidden from the third layer.

Furthermore, the length of its sequence is equal to 80. Table I shows the meta-parameters of the proposed LSTM model (inspired by [21]). Fig. 4 shows the performance results of the presented method. Also, Table II shows the results of the error evaluation for the presented method and the similar presented methods in [22], [23] and [24].

TABLE I.    THE HYPER-PARAMETERS SETTINGS OF THE PRESENTED LSTM MODEL

| Model | Hidden Neuron | Dro-pout | Batch Size | Epochs | Activation Function |
|---|---|---|---|---|---|
| LSTM | 100 | 0.2 | 200 | 100 | ReLU |

Fig. 4.   The comparison results of the prediction of RUL by the proposed scheme and the actual RUL value.

TABLE II.    THE COMPARISON RESULTS BETWEEN THE PRESENTED METHOD AND THE SIMILAR METHODS

| Model | RMSE | MSE | MAE |
|---|---|---|---|
| Proposed LSTM | 6.948 | 3.241 | 132.894 |
| Proposed in [22] | 7.422 | 5.022 | 145.488 |
| Proposed in [23] | 9.711 | 8.925 | 150.961 |
| Proposed in [24] | 13.324 | 10.052 | 166.922 |

It is evident from Fig. 4 and Table II that the proposed algorithm with a sequence length equal to 80 has the lowest amount of error. This means that the presented method is very precise about the prediction of RUL on the used dataset. It should be noted that the displayed results in Table II state that the prediction method basis on LSTM does much better than the presented works on [22], [23] and [24]. In the next stage, the attack of FDI in the proposed LSTM-based method is modeled for the evaluation of their resilience against the attack of FDI.

### C. Modeling Two FDI Attack Scenarios and the Impact Examination of these Attacks in RUL Prediction

The average engine degradation point $N_{avg}^d$, for the FD001 dataset, is taken to be 130 [25]. It is assumed that the system of the monitoring dispatches 20 cycles of the time ($N_b$) from the data to the side of the ground. The dataset of the training and the dataset of the test have 21 data of the sensor. The attack of FDI is performed in 21 sensors. However, for the creation of the realistic attack, the FDI attack only in *three* sensors ($T24$, $P30$ and $T50$) is performed. The details of 21 sensors are provided in [26]. On the first FDI attack scenario,

i.e. the scenario of the continuous, the attacker has begun the attacks since $N_{avg}^d$ (that is equal to 130-time cycles) and the duration of the attacks is up to the engine life's end. In the second scenario of an FDI attack, i.e. scenario temporary, the attacker has begun the attacks since $N_{avg}^d$ (that is equal to 130 cycles of time). The duration of these attacks is 20 hours. With respect to the attack begins, since 130 cycles of the time, only the engines with data greater than 130 cycles are considered. In the FD001 dataset, the number of these engines is equal to 37. The resulting dataset is re-appraised with the use of the proposed LSTM-based model. The obtained values for RMSE, MSE and MAE are respectively equal to 20.651, 10.236 and 159.415.

To model the FDI attack on the sensors, a null vector is added to the main vector that changes the output of the sensor with a so little border equal to 0.01% to 0.05% for a random

FDI attack and equal to 0.02% for a biased FDI attack. Here, the random FDI attack means that the added noise to the output of the sensor has a span equal to 0.01% to 0.05%. At the same time, the biased FDI attack adds a fixed noise value to the output of the sensor. Fig. 5 displays a collation of the signal of the output of the main FDI attack and the signal of the output of the biased FDI attack from the second sensor for the engine with an ID equal to 3. On the continuous attack of FDI, the output of the sensor from 130 cycles of time up to the engine life end is attacked. In the case of a biased attack of FDI for a period of the temporary, similar to Fig. 6, the duration of the attack only is 20 cycles of the time (130 cycles of the time to 150 cycles of the time). Be careful; on the limited attack, the attacker has restricted accessibility to the sensors. Similar to Fig. 5 and Fig. 6, the attack signature is very analogous to the main signal. Its detection makes it hard even with the common defense mechanisms.

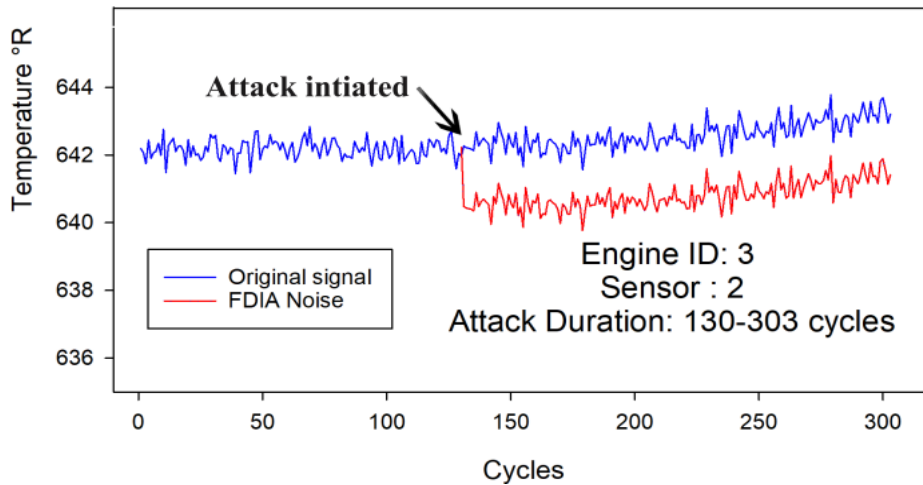

Fig. 5.   The continuous FDI attack signature.

Fig. 6.   The temporary FDI attack signature.

Now, the effect of the scenarios of the attack of FDI on the proposed LSTM-based method is investigated. To demonstrate the effect of attack of the attack of FDI on the system of monitoring, an attack by the mentioned scenario is ran. The FDI attack in three sensors ($T24$, $P30$ and $T50$) is

performed instead of the attack in all 21 sensors of the dataset. In the scenario of the continuous FDI attack, the attacker makes the attacks from 130 cycles of time until the end of the engine life. It is clear from Fig. 7 that the proposed LSTM-based method is greatly affected by the continuous attack of

FDI. About the fortuitous FDI attack and the biased FDI attack, the random FDI attack has shown a significant impact on the proposed LSTM-based model. Table III shows the relevant results.

In the scenario of the temporary FDI attack, the attacker makes the attacks between 130 cycles of time and 150 cycles of time. It is clear from Fig. 8 that the proposed LSTM-based method is greatly affected by the temporary attack of FDI. Table IV shows the relevant results. With the comparison between the continuous FDI attack and the temporary FDI attack, it can be seen that the error of a continuous attack of FDI is almost twice the error of a temporary attack of FDI. Hence, continuous FDI attacks are stronger than temporary FDI attacks.

*D. Discussion*

In this work, the proposed method is evaluated on the dataset of C-MAPSS, and the obtained results show the great prospects for deep learning in PdM. It is also observed that sequence length and network architecture are very important in accurately predicting RUL. The proposed work shows that the proposed method is several times better than recent works that use deep learning on the dataset of C-MAPSS. The analysis of the impact of an FDI attack on aircraft sensors in the dataset of CMAPSS provides interesting insights. It is observed that the CNN-based model is strongly affected by random and biased FDI. In the case of temporary FDI, the random and biased RMSE of CNN is several times higher than

the true RMSE, and in the case of continuous, the random and biased RMSE is several times higher than the true RMSE. Also, it is observed that the CNN-based model is more flexible in both random and biased cases in compared to other models. In the case of temporary attack, the random and biased RMSE is several times higher than the true RMSE, which makes it disastrous for the PdM system. This may lead to delays in timely maintenance of the aircraft engine and ultimately lead to engine failure in some cases.

Note, the FDI attack signature is very close to the original sensor output, which makes it more difficult to detect by common defense mechanisms in the engine health monitoring system. A piecewise prediction approach is used in visualizing the impact of attacks on sensors, which clearly shows that the PdM system is susceptible to sensor attacks. The CNN-based prediction results show that special measures should be taken when designing and by using PdM systems because they are very sensitive to FDI. Such an analysis can serve as empirical guidance for the development of subsequent data-driven PdM systems. All these obtained results show that DL-based PdM systems have good prospects for aircraft maintenance; however, they are highly susceptible to sensor attacks. Hence, it is necessary to explore suitable detection techniques to identify such stealth attacks and special care should be taken when building IoT sensors for DL/AI applications. For this reason, when designing a PdM system, the designer should also consider the flexibility of the DL algorithm instead of emphasizing the accuracy of the algorithm.

TABLE III.    THE RELEVANT RESULTS TO THE SCENARIO OF THE CONTINUOUS ATTACK OF FDI

| Model | RMSE | MSE | MAE |
|---|---|---|---|
| Model Under Random FDI Attack | 50.325 | 25.614 | 1036.234 |
| Model Under Biased FDI Attack | 37.512 | 19.512 | 797.328 |

Fig. 7.   The relevant results to the RUL prediction in the scenario of the continuous attack of FDI.

TABLE IV.    THE RELEVANT RESULTS TO THE TEMPORARY FDI ATTACK SCENARIO

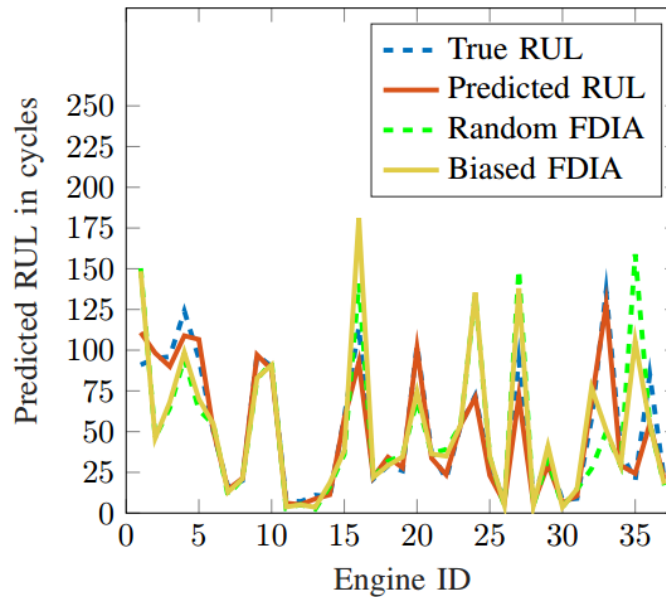
| Model | RMSE | MSE | MAE |
|---|---|---|---|
| Model Under Random FDI Attack | 27.651 | 14.351 | 548.678 |
| Model Under Biased FDI Attack | 19.547 | 10.985 | 410.365 |


Fig. 8. The relevant results to the RUL prediction in the temporary FDI attack scenario.

## V. CONCLUSIONS AND SUGGESTIONS

With the expansion of the use of cyber-physical structures and communication networks, cyberattacks have become a serious threat in various networks, including the sensors of the Internet of Things. These attacks create the so assailable conditions. Therefore, the main consideration of this current paper is the detection in real-time of the done FDI attack on the Internet of Things, which is related to the estimated RUL prediction. The robust and nonlinear structure of the LSTM shows a better view of the RUL prediction compared to similar methods. The method of the presented nonlinear LSTM is successfully implemented in real-time because the efficiency of its computational (the time of the test and the time of the training) is on the scope of the microseconds. In the future, the method of the presented detection can be performed by the scenarios of the contingency of the smart networks and by a more intransigent constraint on the criterion of detection, which ultimately results in a stronger feasibility of the FDI attack detection. Also, an end-to-end method can be developed for the recognition and reduction of attacks on the sensor in a system of network health monitoring.

# Automated Fruit Grading in Precise Agriculture using You Only Look Once Algorithm

Weiwei Zhang

Henan Polytechnic Institute, Nanyang Henan 473000, China

*Abstract*—In the realm of precision agriculture, the automated grading of fruits stands as a critical endeavor, serving to maintain consistent quality assessment and streamline the sorting process. Traditional methods based on computer vision and deep learning techniques have both been explored extensively in the context of fruit grading, with the latter gaining prominence due to its superior performance. However, the existing research landscape in the domain of deep learning-based fruit grading confronts a compelling challenge: striking a balance between accuracy and computational cost. This challenge has been consistently noted through an extensive analysis of prior studies. In response, this study introduces an innovative approach built upon the YOLOv5 algorithm. This methodology encompasses the creation of a bespoke dataset and the division of data into training, validation, and testing sets, facilitating the training of a robust and computationally efficient model. The findings of the experiments and the subsequent performance evaluation underscore the effectiveness of the proposed method. This approach yields significant improvements in both accuracy and computational efficiency, thus addressing the ongoing challenge in deep learning-based fruit grading. Therefore, this study contributes valuable insights into the field of automated fruit grading, offering a promising solution to the trade-off between accuracy and computational cost while demonstrating the practical viability of the YOLOv5-based approach.

*Keywords—Precise agriculture; automated fruit grading; deep learning; computer vision; Yolov5*

## I. INTRODUCTION

In recent years, the field of precise agriculture has gained significant attention due to its potential to revolutionize traditional farming practices by incorporating advanced technologies for improved crop management [1, 2]. One crucial aspect of precise agriculture is automated fruit grading, which plays a vital role in ensuring consistent quality assessment and efficient sorting of fruits [2, 3]. Automated fruit grading systems leverage computer vision and machine learning techniques to analyze fruit characteristics and assign appropriate grades, reducing the reliance on manual labor and improving productivity.

The integration of video-based technologies has emerged as a promising approach for object detection, tracking and specifically for automated fruit grading [4-6]. Video-based systems capture a continuous stream of fruit images, allowing for more comprehensive analysis and enabling real-time grading and sorting [7-9]. These technologies have shown great potential in enhancing the accuracy and efficiency of fruit grading systems, leading to improved productivity and quality control [10].

Despite the advancements in video-based technologies, there are still challenges that need to be addressed in the field of automated fruit grading [11, 12]. Existing methods often rely on traditional image processing techniques and rule-based algorithms, which may not fully capture the complex features and variations present in fruits [4]. This limitation has led to a growing interest in deep learning-based methods, particularly convolutional neural networks (CNNs) [13-15], which have demonstrated remarkable capabilities in image analysis tasks. Deep learning approaches offer the potential for more accurate and robust fruit grading systems capable of handling diverse fruit types and variations.

Previous studies have shown the effectiveness of deep learning-based methods in automated fruit grading. These methods have been successful in capturing fine-grained features and patterns, leading to improved accuracy rates compared to traditional approaches [11, 16]. However, existing research primarily focuses on high computational costs and may not address the requirements of low computational resources, which are often present in practical agricultural settings [17]. This research gap presents an opportunity to develop lightweight deep-learning models that can balance computational efficiency with high accuracy rates.

This paper aims to address the aforementioned research gap by proposing a lightweight deep-learning approach based on YOLO (You Only Look Once) algorithms for automated fruit grading in precise agriculture. This study leverages a custom dataset of fruit images and employ a training, validation, and testing process to generate a robust and efficient model. The research contributions include identifying the research gap in low computational cost and high accuracy rate requirements, proposing a lightweight deep learning-based method to address the limitation, and conducting comprehensive experimental and performance evaluations to validate the effectiveness of the proposed approach.

The main research contributions of this study are as follows:

### A. Identification of Research Gap

The paper identifies the research gap in the field of automated fruit grading regarding the requirements of low computational cost and high accuracy rates. By recognizing this gap, the paper aims to address the limitations of existing methods and propose a solution that satisfies these specific requirements.

## B. *Proposal of a Lightweight Deep Learning Approach*

The paper proposes a lightweight deep learning-based method for automated fruit grading using YOLO algorithms. This approach takes into consideration the need for computational efficiency while maintaining high accuracy rates. By leveraging YOLO algorithms, the proposed method aims to achieve real-time fruit grading with optimal resource utilization.

## C. *Comprehensive Experimental and Performance Evaluations*

The paper conducts thorough experimental and performance evaluations to validate the effectiveness of the proposed approach. By utilizing a custom dataset of fruit images and employing a rigorous training, validation, and testing process, the paper demonstrates the robustness and efficiency of the generated model. These evaluations provide empirical evidence of the accuracy and effectiveness of the proposed method in addressing the identified research gap.

The reminding of this paper is as follows, related works review in Section II. Methodology discusses in Section III. Section IV presents results and discussion. Finally, the paper concludes in Section V.

## II. RELATE WORKS

The paper in [18] developed the classification and grading of Okra-ladies fingers using deep learning techniques. The research challenge addressed in the paper is to develop an efficient and accurate system for automated classification and grading of Okra-ladies' fingers based on their quality attributes. The proposed approach utilizes deep learning models, specifically convolutional neural networks (CNNs), to analyze the visual features of Okra-ladies finger images. The CNN model is trained on a large dataset of labeled Okra-ladies finger images to learn the patterns and characteristics associated with different quality grades. Experimental results demonstrate the effectiveness of the deep learning-based approach in accurately classifying and grading Okra-ladies' fingers. The system's performance is evaluated using metrics such as accuracy, precision, and recall, showing promising results in achieving reliable quality assessment in an automated manner. The proposed system offers potential applications in the food industry, facilitating efficient sorting and quality control processes for Okra-ladies finger production.

Ismail and Malik [19] presented a real-time visual inspection system for grading fruits using computer vision and deep learning techniques. The research challenge addressed in the paper is to develop an efficient and accurate system that can automatically grade fruits based on their quality attributes. The proposed system leverages computer vision algorithms and deep learning models to analyze fruit images and classify them into grades or categories in real-time. By combining advanced image processing techniques with deep learning, the system achieves high accuracy and enables fast and automated fruit grading, providing an effective solution for quality control in the fruit industry.

Patil et al. [20] presented a grading and sorting technique for dragon fruits using machine learning algorithms. The research challenge addressed in the paper is to develop a reliable and efficient system that can automatically grade and sort dragon fruits based on their quality attributes. The proposed technique utilizes machine learning algorithms, including decision trees and support vector machines, to analyze the visual features of dragon fruit images and classify them into different grades. The system is trained on a dataset of labeled dragon fruit images to learn the patterns and characteristics associated with each grade. Experimental results demonstrate the effectiveness of the machine learning-based approach in accurately grading and sorting dragon fruits. The proposed technique offers a practical solution for the fruit industry, enabling automated and consistent quality assessment for dragon fruit production.

Chakraborty et al. [21] focused on developing an optimally designed real-time automatic citrus fruit grading-sorting machine by leveraging a computer vision-based adaptive deep learning model. The research challenge addressed in the paper is to create a machine that can accurately grade and sort citrus fruits in real-time. The proposed system utilizes computer vision techniques and adaptive deep learning models to analyze fruit images and classify them according to quality attributes such as size, color, and shape. By combining these advanced technologies, the machine achieves high accuracy and efficiency in citrus fruit grading and sorting, offering a practical solution for the citrus industry's quality control and productivity enhancement.

## III. METHODOLOGY

To propose a YOLOv5-based model for automated fruit grading and sorting using a custom dataset of 544 images, the details of the methodology discuss as follows:

### A. *Data Pre-processing*

In the data pre-processing step, the first task is to split the dataset of fruit images into three distinct sets: training, validation, and testing. This split is done using the specified ratios of 70%, 20%, and 10% for training, validation, and testing sets, respectively. By dividing the dataset in this manner, it is ensured that the model is trained on a substantial portion of the data while retaining separate sets for evaluation.

Next, it is crucial to shuffle the dataset randomly. This randomization ensures that the fruit images are distributed across the different sets in a diverse manner. By avoiding any specific order or patterns in the dataset, it reduced the risk of introducing biases into the model during training and evaluation.

Furthermore, various pre-processing steps are applied to the fruit images. Firstly, the images are resized to a consistent size to meet the requirements of the YOLOv5 model, typically around 416x416 pixels. This standardization facilitates efficient processing and consistent results. Additionally, pixel values are normalized to a common scale, often within the range of [0, 1]. Normalization aids in improving the convergence and stability of the training process.

Lastly, bounding boxes need to be annotated around the fruits in the images. These annotations provide the necessary training labels for the YOLOv5 model to learn object

detection. By defining the precise locations of the fruits within the images, the model can be trained to accurately detect and classify the fruits during the subsequent training phase.

### B. Model Architecture

The YOLOv5 model represents an advanced object detection approach built on a convolutional neural network (CNN) architecture. This model has demonstrated outstanding performance in real-time object detection tasks, making it an excellent choice for automated fruit grading and sorting. To begin implementing YOLOv5 for our project, we need to access the official YOLOv5 repository hosted on GitHub. By navigating to the repository at https://github.com/ultralytics/yolov5, it can clone the entire codebase to our local development environment. This step is essential as it provides all the necessary files, scripts, and resources needed for training and utilizing the YOLOv5 model. Fig. 1 illustrates the YOLOv5 model architecture [22].

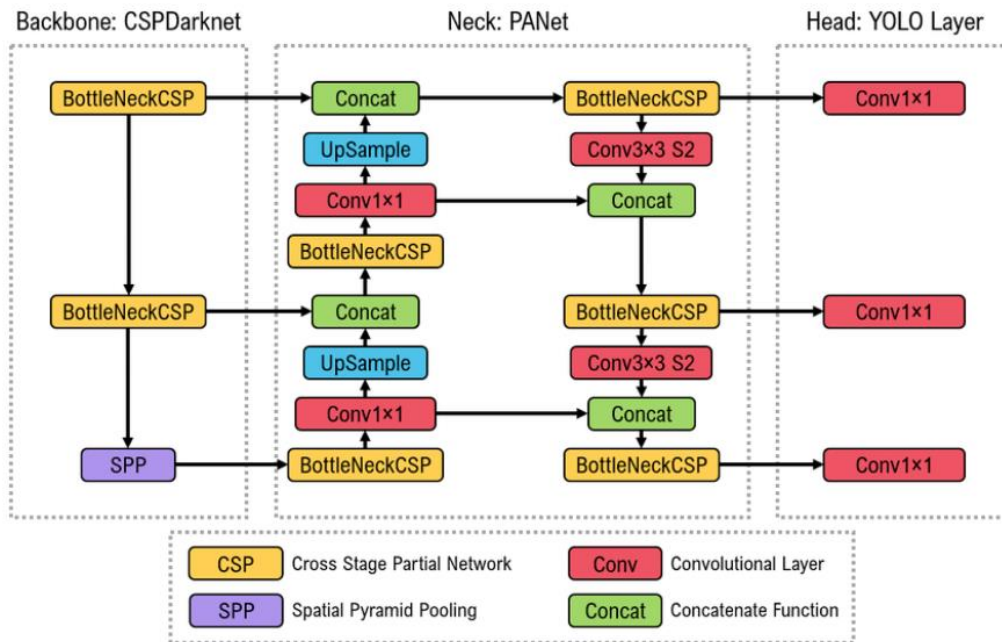

Fig. 1. The YOLOv5 model architecture [22].

With the YOLOv5 repository successfully cloned to the local environment, it is possible to proceed to tailor the model to our specific fruit grading and sorting task. One critical aspect of customization involves modifying the YOLOv5 configuration file. This file allows us to configure various aspects of the model, accommodating our dataset's unique characteristics and requirements. Among the customizable parameters are the number of classes to be detected and sorted, which would be the different fruit types or grades in this context. Additionally, it can adjust settings such as the input image size, the architecture of the underlying neural network, and training hyperparameters.

Customizing the YOLOv5 configuration file ensures that the model is designed to recognize the specific fruit types and grading categories present in our dataset accurately. Fine-tuning these parameters allows the YOLOv5 model to be tailored precisely to our use case, maximizing its performance and enhancing the accuracy of the fruit grading and sorting process. By configuring the model in this manner, it enables to identify and classify fruits based on their unique characteristics, providing us with a powerful tool for automating the grading and sorting tasks with efficiency and precision.

In the implementation process for training a YOLOv5 model for fruit grading, the first step involves partitioning the dataset into a training set, which constitutes 70% of the total data, containing images and their corresponding annotated bounding boxes. Next, the YOLOv5 model is configured by utilizing a modified configuration file specifying parameters such as the number of classes, input image size, and network architecture, and the training data is pre-processed, including resizing images, normalizing pixel values, and incorporating annotated bounding boxes. The model is initialized with random weights before training commences. To facilitate training for object detection, an appropriate loss function, like YOLOv5 Loss or GIoU Loss, is selected to quantify the disparity between predicted bounding boxes and ground truth annotations. An optimizer, such as SGD or Adam, is used to update the model's weights based on the computed loss. During training iterations, data is fed to the model in batches with batch size selection depending on available computational resources, typically ranging from 8 to 32. The number of training epochs is chosen for convergence and desired model performance. The forward pass predicts bounding box coordinates, objectness scores, and class probabilities, while the backward pass calculates the loss and uses backpropagation to adjust the model's parameters for minimizing discrepancies. The training process is closely monitored by tracking metrics like loss and accuracy, which can be visualized using tools like TensorBoard, allowing for analysis and fine-tuning of the

model's training process to ensure accurate fruit grading based on the learned criteria.

*C. Model Training*

During the training process for fruit grading and sorting using the YOLOv5 model, several key steps are involved. Here's an explanation of each step:

*1) Training set usage:* The training set, which accounts for 70% of the total dataset, is utilized to train the YOLOv5 model. This set consists of images and their corresponding annotated bounding boxes.

*2) Training setup*: The YOLOv5 model is configured by incorporating the modified configuration file and the pre-processed training data. The configuration file contains parameters such as the number of classes, input image size, and network architecture. The pre-processed training data includes resized images, normalized pixel values, and annotated bounding boxes.

*3) Model initialization*: Before training begins, the YOLOv5 model is initialized with random weights. These initial weights serve as a starting point for the training process.

*4) Loss function and optimizer*: To train the YOLOv5 model for object detection, a suitable loss function is chosen. YOLOv5-specific loss functions like YOLOv5 Loss or GIoU Loss are commonly used. The loss function quantifies the discrepancy between predicted bounding boxes and the ground truth annotations. An optimizer, such as SGD or Adam, is employed to update the model's weights based on the computed loss.

*5) Batch size and epochs*: The training process involves feeding the training data to the YOLOv5 model in batches. The batch size determines the number of images processed before weight updates occur. Depending on available computational resources, typical batch sizes range from 8 to 32. The number of training epochs specifies how many iterations are performed over the entire training dataset. This value is chosen based on convergence and desired model performance.

*6) Forward and backward pass*: The training data is passed through the YOLOv5 model in batches during each training iteration. The model predicts bounding box coordinates, objectness scores, and class probabilities. The loss between the predicted values and the ground truth annotations is calculated. This loss is then used to update the model's weights through backpropagation, which adjusts the parameters to minimize the discrepancy between predictions and ground truth.

*7) Training monitoring*: The training process is monitored to assess the model's progress and performance. Metrics such as loss and accuracy are tracked to evaluate the model's convergence and generalization. Tools like TensorBoard can be utilized to visualize the training metrics and observe any trends or patterns over time. Logging the metrics at regular intervals allows for analysis and fine-tuning of the training process.

By following these steps, the YOLOv5 model is trained using the provided dataset, enabling it to learn to detect and classify fruits based on their grading criteria accurately.

*D. Model Validation*

During the validation process for the generated YOLOv5 model used in fruit grading and sorting, the following steps are involved:

*1) Validation set usage:* The 20% validation set is utilized to evaluate the performance of the trained YOLOv5 model. This set consists of images from the dataset that were not used during training.

*2) Model evaluation:* The trained YOLOv5 model is applied to the validation images, and predictions are made for the bounding box coordinates, objectness scores, and class probabilities. These predicted values are then compared with the ground truth annotations provided in the validation set.

*3) Calculation of evaluation metrics:* To assess the accuracy and generalization capabilities of the YOLOv5 model, evaluation metrics such as mean average precision (mAP) are calculated. The mAP measures the precision and recall of the detected objects across various confidence thresholds. Higher mAP scores indicate better detection accuracy.

*4) Hyperparameter tuning:* Based on the results obtained from the validation process, adjustments can be made to fine-tune hyperparameters or modify the training settings to improve the model's performance. This may involve changing parameters such as the learning rate, optimizer, and batch size or adjusting the number of training epochs.

The validation process helps in evaluating how well the YOLOv5 model generalizes to unseen data and provides insights into its overall performance. By assessing metrics like mAP, we can gauge the model's ability to detect and classify fruits for grading and sorting purposes accurately. Fine-tuning the hyperparameters based on validation results allows us to optimize the model's performance further and ensure its effectiveness in real-world scenarios.

## IV. RESULTS AND DISCUSSION

This section presents experimental results, performance evaluation of the YOLOv5 algorithm, performance result of training and performance result of validation.

*A. Experimental Results*

The generated YOLOv5 model for fruit grading has achieved accurate results, demonstrating its proficiency in accurately detecting, localizing, and classifying fruits. The model's architecture, optimized loss functions, and training process have contributed to its accuracy, as validated by metrics such as mean average precision (mAP). With the ability to precisely locate fruit bounding boxes and assign correct class or grade labels, the YOLOv5 model proves its effectiveness for automated fruit grading and sorting systems, offering a reliable and consistent quality assessment. Fig. 2 demonstrates some samples of our experimental results.

Fig. 2.   Sample of experimental results.

*B. Performance Evaluation of YOLOv5 Algorithm*

The graph comparing the mAP (mean average precision) of YOLO base models, such as YOLOv5, YOLOv6, YOLOv7, and YOLOv8, with the number of parameters plotted on the X-axis, reveals that YOLOv5 stands out as a smaller and more compact model compared to the others. Despite its smaller size, YOLOv5 still maintains competitive performance regarding mAP. Fig. 3 demonstrates the performance evaluation of the YOLOv5 algorithm in terms of the number of parameters.

As shown in Fig. 3, the fact that YOLOv5 has lower parameters while achieving comparable mAP scores indicates that it is designed to be a fast, accurate, and efficient model. The reduced parameter count means that YOLOv5 requires less computational resources, making it more lightweight and easier to deploy on various devices and platforms.

The design of YOLOv5 focuses on striking a balance between speed and accuracy, making it an excellent choice for a wide range of object detection applications. Its smaller size allows for faster inference times, enabling real-time or near-real-time object detection. The model's accuracy, as indicated by its competitive mAP scores, ensures reliable and precise object detection results.

Moreover, Fig. 4 illustrates the performance result of the YOLOv5 model in terms of latency. The model is designed to be fast and easy to use and implement, making it accessible to both researchers and practitioners. Its simplicity and effectiveness make YOLOv5 a popular choice for object detection tasks in various domains, including fruit grading and sorting.

Therefore, the YOLOv5 model's smaller size, lower parameter count, competitive mAP scores, and user-friendly design make it a fast, accurate, and easy-to-use option for a wide range of object detection applications. Its efficient performance and ease of deployment make it particularly suitable for tasks where real-time or near-real-time object detection is required, such as fruit grading and sorting.
Fig. 3.    Performance Evaluation of  the YOLOv5 Algorithm in terms of the number of parameters  [23].

Fig. 4.    Performance result of the YOLOv5 model in terms of latency [23].

*C.  Performance Result of Training*

When training a YOLOv5 model for fruit grading, several graphs can be generated to monitor the training progress and assess the model's accuracy. The most commonly analyzed graphs include the train/box_loss, train/obj_loss, and train/cls_loss graphs. Fig. 5 shows the performance result of training.

As shown in Fig. 5, train/box_loss Graph: This graph represents the box loss over the course of training. The box loss measures the discrepancy between the predicted bounding box coordinates and the ground truth annotations. A lower box loss indicates that the model is accurately predicting the positions and sizes of the fruit bounding boxes. As the training progresses, we aim to see a decreasing trend in the box loss graph, which signifies that the model is improving its ability to locate the fruits precisely.
Fig. 5.   Performance result of training.

Train/obj_loss Graph: The obj_loss graph depicts the objectness loss throughout the training process. The objectness loss quantifies the difference between the predicted objectness scores (indicating the presence of an object) and the ground truth labels. As the model learns, it should minimize the obj_loss, indicating that it becomes more accurate in determining the presence or absence of fruits in the images. A decreasing obj_loss graph suggests that the model is becoming more proficient in identifying fruits accurately.

Train/cls_loss Graph: The cls_loss graph illustrates the classification loss during training. This loss measures the discrepancy between the predicted class probabilities and the ground truth labels. Fruit grading involves assigning the correct class or grade to each fruit. By monitoring the cls_loss graph, we can ensure that the model is learning to classify the fruits accurately. A decreasing cls_loss graph indicates that the model is improving its ability to assign the correct class probabilities to different fruit types or grades.

Achieving accuracy in training using these graphs involves monitoring their trends and making necessary adjustments. If the box_loss, obj_loss, or cls_loss values are not decreasing or stabilizing over time, it may indicate that the model needs further optimization. Possible steps to enhance accuracy include adjusting the learning rate, modifying the loss function, increasing the training dataset size, or fine-tuning the model architecture.

By closely monitoring these graphs and iteratively improving the model based on the insights gained from them, we can train a YOLOv5 model that accurately detects, localizes, and classifies fruits for grading purposes. The aim is to achieve decreasing losses over time, indicating the model's increasing accuracy and proficiency in fruit grading tasks.

### D. Performance Result of Validation

The validation graphs, including val/box_loss, val/obj_loss, and val/cls_loss, play a crucial role in achieving an accurate YOLOv5 model for fruit grading. These graphs provide valuable insights into the model's performance on unseen validation data and guide us in improving its accuracy. By analyzing these graphs, we can assess the model's ability to accurately localize fruits, determine their presence or absence, and classify them correctly. Fig. 6 displays the performance result of validation.

Fig. 6.   Performance result of validation.

As shown in Fig. 6, the val/box_loss graph helps us evaluate how well the model is localizing fruits by measuring the discrepancy between predicted bounding box coordinates and ground truth annotations. A decreasing trend in the val/box_loss graph indicates that the model is improving its accuracy in fruit localization.

The val/obj_loss graph allows us to assess the model's ability to detect fruits by comparing predicted objectness scores with ground truth labels. A decreasing trend in the val/obj_loss graph indicates that the model is becoming more accurate in determining the presence or absence of fruits in the validation images.

The val/cls_loss graph helps us evaluate the model's fruit grading performance by measuring the discrepancy between predicted class probabilities and ground truth labels. A decreasing trend in the val/cls_loss graph indicates that the model is improving its accuracy in assigning the correct class or grade to each fruit.

By monitoring these validation graphs and making necessary adjustments based on their trends, we can refine the YOLOv5 model for fruit grading, leading to enhanced accuracy in fruit localization, object detection, and classification. These insights help us optimize the model's performance and ensure its effectiveness in real-world fruit grading and sorting applications.

## V. CONCLUSION

This paper presents a novel solution to bridge the research gap in automated fruit grading in precise agriculture. This approach focuses on proposing a lightweight deep learning method utilizing YOLO (You Only Look Once) algorithms. To train a robust and efficient model, we utilize a custom dataset consisting of fruit images and conduct a rigorous training, validation, and testing process. The contributions lie in identifying the need for low computational cost and high accuracy rate requirements, introducing a lightweight deep learning-based method to overcome these limitations, and conducting extensive experimental and performance evaluations to validate the efficacy of the approach. Directions for future work can be considered to improve the computational efficiency of the automated fruit grading system. This can involve exploring techniques such as model compression, quantization, or optimization algorithms to reduce the computational cost without compromising accuracy. Investigating hardware acceleration techniques, such as utilizing specialized processors or GPUs, can also be explored to speed up the inference process.

Moreover, integrating multi-modal data sources, such as incorporating spectral or hyperspectral imaging, can provide additional valuable information for fruit grading. Future research can focus on developing fusion models that combine visual data with other modalities to enhance the accuracy and robustness of the fruit grading system. This can potentially improve the system's ability to handle various fruit types, different lighting conditions, and other environmental factors, leading to more precise and reliable grading results.

Business School, Jiangxi Institute of Fashion Technology, Nanchang, 330201, China[5]

*Abstract*—As the growth of immersive 3D animation, its application in ink element animation is constantly updating and advancing. However, the current immersive 3D ink element animation production also has the problem of lack of innovation and repeated development, so the research innovatively designs and develops the image stitching method for immersive 3D ink element animation production. The method is designed through stereo matching algorithm and scale-invariant feature transform algorithm, and the stereo matching algorithm is optimized with the weighted median filtering method based on the guide map. In addition, the study also designs the specific implementation of this method from different functional modules. The experimental results show that on four different datasets, the error percentages of the optimized stereo matching algorithm in non-occluded areas are 0.3885%, 0.4743%, 1.6848%, and 1.34%, respectively. The error percentages of all areas are 0.8316%, 0.8253%, 4.3235%, and 4.1760%, respectively. The research and design of image stitching methods can be applied in other fields and has good practical significance.

*Keywords*—*Immersive; 3D; ink element animation; image stitching; stereo matching algorithm*

## I. INTRODUCTION

As the advancement of immersive 3D animation, it has gradually become a popular form of artistic expression in animation [1]. Immersive 3D animation technology is developed on the basis of computer vision technology and image technology, and can complete its own construction through fixed steps [2]. Stereoscopic 3D animation can generate highly realistic 3D animation images by simulating the human visual system. With the development of 3D technology, the design and application of ink element animation (IEA) in 3D animation are also constantly deepening [3-4]. However, at present, the quality of immersive 3D ink element animation production enterprises is uneven, and the content produced by most enterprises is also very superficial. And this also leads to a lack of deeper thinking and spirit in the current immersive 3D ink element animation, a lack of innovation, and the problem of repeated development [5]. The current solution to the problem of missing content is to transform the existing classic 3D ink element animation into immersive 3D ink element animation, which requires the use of image stitching algorithms [6]. At present, research on image stitching algorithms mainly focuses on the stitching of monocular images, with less involvement in the stitching of

binocular images. Due to the visual differences between left and right eye images, it is not appropriate to directly use monocular image stitching to process binocular images, which can affect consumers' viewing experience [7]. Based on these issues, the study innovatively designed and developed an image stitching method for immersive 3D ink element animation production, starting from the horizontal parallax dependence of stereoscopic perception. The method was designed using stereo matching algorithms and scale invariant feature conversion algorithms, and the specific implementation of the method was designed from different functional modules. The research aims to design image stitching methods for immersive 3D ink element animation production through stereo matching algorithms and scale invariant feature transformation algorithms, solve the problem of disparity, maintain the three-dimensional sense of animation, and improve the viewing experience of consumers. There are two innovative points in the research, one is the combination of stereo matching algorithm and scale invariant feature transformation algorithm, and the other is the use of weighted median filtering method to improve the stereo matching algorithm. The research is divided into four parts. The first part is a literature review, mainly involving the literature review of image stitching methods for immersive 3D ink element animation production. The second part is the specific design of image stitching methods, including image stitching algorithm design, image stitching architecture design, and functional model implementation design. The third part is the analysis of the results of the image stitching method, mainly including the performance verification of the algorithm designed by the research institute and the overall effect analysis of the image stitching method. The fourth part is the conclusion of the study, mainly summarizing and elaborating on the results of the image stitching method designed by the research institute.

## II. RELATED WORKS

With the growth of immersive 3D animation technology, its own application fields are constantly expanding, and research on IS methods for immersive 3D IEA production is gradually enriching. To explore the animation of virtual medical systems, researchers such as Li designed a virtual medical system based on reality technology and 3D animation modeling. The experimental findings denoted that the calculated results under the implicit method did not increase

with the increase of the difference, and had good stability when obtaining larger values [8]. Sandoub and other experts proposed a low light level image enhancement algorithm based on fusion to avoid halo artifacts and color distortion issues when enhancing images. This algorithm estimated the illumination of low light images through the maximum color channel, and used thinning methods to improve the sharpness of the initial enhanced image. The research outcomes indicated that the proposed method was significantly superior to existing methods and reduced the issues of halo artifacts and color distortion [9]. Hosseinzadeh and other scholars proposed a new method for image centralization and pose estimation to study the creation of stitched images inside pipelines. This method would inspect and concentrate the captured video, and then generated a stitching image of the interior of the pipeline. The research findings expressed that this method had good results in IS inside pipelines [10]. Damghani and other researchers proposed an adaptive method to reduce the distortion caused by embedding information in the transformation space. This method was based on the interaction between the changes made when embedding the algorithm. The research results indicated that this method was more efficient than the most advanced methods in the field [11]. Ro and other experts put forward an in situ analysis method of mineralogy based on handheld microscope to conduct in situ analysis of mineralogy. This method solved the small observation range of microscopes through IS. The experimental outcomes denoted that this method was very effective in real-time mineralogy analysis [12].

Chen and other scholars proposed a method to convert 3D motion graphics to stereoscopic display to realize the use of stereoscopic video on mobile platforms. This method was mainly developed on the basis of animation software and output synthetic images that match the stereoscopic display. The research findings expressed that compared to traditional methods, this method had better results and faster speed in image generation [13]. Nie and other researchers proposed an IS learning framework to avoid the issue of unavailability of traditional IS methods. The framework estimated the homography through the multi-scale depth homography model, and learned the deformation rules of IS through the edge preserving deformation module. The experimental outcomes expressed that the framework had good generalization ability and was significantly superior to existing methods [14]. Dai and other experts proposed an end-to-end deep learning framework to solve the problem of artifacts when creating Panorama. This framework considered the synthesis stage in IS as a problem of image mixing and used perceptual edges to guide the network. The experimental results indicated that the framework could generate useful results in less time and had good performance [15]. Zhao and other scholars proposed an IS method based on depth homography estimation to solve the low IS accuracy. This method involved resolution and feature maps and a loss function for stitching. The experimental findings expressed that this method had good performance in quantitative evaluation and visual stitching effects [16]. Luo and other researchers proposed an IS method with constraint on the position relationship between feature points and lines to eliminate parallax. This method reduced the computation of feature matching by quickly detecting overlapping areas, and

guided mesh deformation through local mesh models [17].

In summary, there is currently a wealth of research on IS methods for immersive 3D IEA production both domestically and internationally, and the methods used are also diverse. However, these studies also have certain problems, such as the lack of innovation in immersive 3D animation content, and repeated development in one direction. Therefore, the research innovatively proposes an IS method for immersive 3D IEA, constructs the method through SM algorithm and SIFT algorithm, and designs the specific implementation of the method.

## III. CONSTRUCTION OF IMAGE SPLICING METHOD AND DESIGN OF FUNCTIONAL MODEL IMPLEMENTATION METHOD FOR 2D IEA PRODUCTION

To construct an IS method for immersive 3D IEA, SM algorithm and SIFT algorithm are applied in the design of its functional modules. In addition, to better utilize the role of SM algorithms, a weighted median filtering method based on directional maps is used to optimize it. To design the specific implementation of the IS method functional module, the development language, library functions, and specific implementation steps of the module are studied and explained.

### A. Design of IS Methods for Immersive 3D IEA Production

3D animation is a form of animation that includes computer graphics technology and is not limited by time and space conditions. 3D IEA is mainly produced through computer 3D software, which involves model building and light and shadow settings [18-19]. The production of 3D IEA should be based on its own spatial construction characteristics to achieve spatial transformation. The spatial construction characteristics of 3D IEA are shown in Fig. 1.

Fig. 1.    The spatial construction characteristics of 3D IEA.

As shown in Fig. 1, the spatial construction characteristics of 3D IEA mainly include four points, namely stereo sense, spatiotemporal sense, motion sense, and extensibility. The stitching of immersive 3D IEA is mainly divided into seven steps. The first step is to input the image, the second step is to preprocess the data, and the third step is to register the image. The fourth step is to establish the transformation model, the fifth step is to carry out unified coordinate transformation, the sixth step is to fuse the images, and the seventh step is to obtain panoramic images. Among them, image registration and fusion are the core steps. SM algorithms can be divided into global and local SM algorithms, while the Semi Global Matching (SGM) algorithm belongs to the global algorithm [20]. The pixel level cost and smoothing constraints of the SGM algorithm are shown in Eq. (1).

$$E(D) = \sum_p \left( C(p, D_p) + \sum_{q \in N_p} P_1 T\left(\left|D_p - D_q\right| = 1\right) + \sum_{q \in N_p} P_2 T\left(\left|D_p - D_q\right| > 1\right) \right) \quad (1)$$

In Eq. (1), $D$ denotes the disparity variable; $q$ and $p$ express pixels; $P_1$ means the penalty factor; $P_2$ indicates the constant penalty factor with larger values; $C$ represents the matching cost of pixels; $Np$ refers to adjacent pixels of pixel $p$; $T$ denotes the judgment value. The calculation of $P_2$ is shown in Eq. (2).

$$P_2 = \frac{P_2}{\left| I_{bp} - I_{bq} \right|} \tag{2}$$

In Eq. (2), $I_b$ indicates the reference map. When performing cost aggregation, the SGM global energy function is shown in Eq. (3).

$$E(D) = \sum_p C(p, D_p) + \sum_{q \in Np} P_1 T \left[ \left| D_p - D_q \right| = 1 \right] + \sum_{q \in Np} P_2 T \left[ \left| D_p - D_q \right| > 1 \right] \tag{3}$$

The sum of matching costs for pixels in disparity $D$ is achieved through term $\sum C(p, D_p)$. The SGM algorithm can avoid the approximate solution of equation conversion and solve one-dimensional problems in eight directions, as shown in Eq. (4).

$$L_r(p, d) = C(p, d) + \min(L_r(p - r, d)),$$
$$L_r(p - r, d - 1) + P_1$$
$$L_r(p - r, d + 1) + P_1$$
$$\min(L_r(p - r, i) + P_2) - \min L_r(p - r, d + 1) k \tag{4}$$

In Eq. (4), $r$ stands for a direction pointing towards the current pixel $p$; $d$ expresses the value of parallax; $i$ and $k$ represent the pixel grayscale value.

### B. IS Architecture Design for Immersive 3D IEA Production

There are three common ways to make 3D animated films, of which the first involves computer graphics technology. The second type will use parallel cameras for production, and the third type will use relevant algorithms and software [21]. To make the immersive 3D IEA better, the research uses a method that combines computer graphics technology and live shooting technology. The overall architecture of the IS system for immersive 3D IEA production is shown in Fig. 2.

As shown in Fig. 2, the IS system for immersive 3D IEA production is mainly divided into three modules, namely the 3D image source on-demand acquisition module, the ensuring parallax comfortable stitching module, and the display module. The on-demand acquisition module for stereoscopic image sources involves calculating the viewing comfort range, determining the optimal shooting position, and promoting the development of animation plots. The module for ensuring comfortable disparity stitching mainly involves depth IS, image SM, weighted median filtering, and stitching. The display module mainly includes parallax optimized line chart and panoramic effect display. When obtaining stereoscopic image sources on demand, the positioning of virtual stereoscopic cameras is mainly achieved based on the input needs of the viewer. In addition, the manipulation of scene nodes can be completed through Maya software. After the generation of stereo images, stereo perception correspondence is required, and the corresponding of stereo perception is shown in Fig. 3.

Fig. 2. The overall architecture of IS system.

Fig. 3. The corresponding process of stereoscopic perception.

As shown in Fig. 3, the corresponding process of stereo perception is divided into three main parts: virtual space, binocular stereo display, and real space. Virtual space includes animated scenes and cameras, binocular stereo display involves stereo image pairs and viewing screens, and real space mainly includes human eye perception of stereo effects. Immersive 3D IS uses the SIFT (SIFT) algorithm, which can observe and analyze local features in images and videos. The SIFT algorithm is mainly divided into four steps. The first step is to detect the extreme values in the scale space, the second step is to locate the key points, the third step is to determine the method, and the fourth step is to describe the key points. To provide better IS functionality, the study used random sample consistency (RANSAC) algorithm and fast library for approximate nearest neighbors (FLANN) algorithm based on tree structure to optimize the SIFT algorithm. The optimization of disparity post-processing in SM algorithms is mainly achieved through the weighted median filtering (WMF) method based on directional maps [22]. This method is mainly divided into three steps. The first step is left and right consistency detection, the second step is filling in the disparity value of singular points, and the third step is smoothing the disparity value of singular points. When the matching information is insufficient, the expression of left and right consistency detection is shown in Eq. (5).

$$D_L(x,y) = D_R(x - D_L(x,y), y) \tag{5}$$

In Eq. (5), $D_L$ denotes the left disparity map of the left eye image pair; $D_R$ means the right disparity map of the right eye image pair; $(x,y)$ expresses the coordinates of the interest points based on the left eye image. When the disparity value of the point in the left eye image exceeds the boundary in the right eye image, the expression of left and right consistency detection is shown in Eq. (6).

$$x - D_L(x,y) \geq 0 \tag{6}$$

To preserve the high-frequency edges of the image, the WMF method is optimized. The weight calculation involved in optimization is shown in Eq. (7).

$$W_{\partial,j}^{bf} = \frac{1}{K_\partial} e^{\left(\frac{|\partial - j|^2}{\sigma_s^2}\right)} e^{\left(\frac{|I_\partial - I_j|^2}{\sigma_c^2}\right)} \tag{7}$$

In Eq. (7), $\partial$ and $j$ denote the coordinates of two points in the guidance map; $\sigma_c$ and $\sigma_s$ indicate constants; $K_\partial$ is used to control the weight size; $bf$ means the balance calculation value when the feature is $f$. The stereo display Comfort zone is $[D_{min}, D_{max}]$, and its calculation is shown in Eq. (8).

$$\begin{cases} D_{min}(v_d) = \frac{p_d}{2} \cot(\arctan \frac{p_d}{2v_d} + \frac{|\delta\theta|}{2}) \\ D_{max}(v_d) = \frac{p_d}{2} \cot(\arctan \frac{p_d}{2v_d} - \frac{|\delta\theta|}{2}) \end{cases} \tag{8}$$

In Eq. (8), $p_d$ means the distance between the binocular pupils; $v_d$ denotes the distance from the viewer to the screen; $\delta\theta$ expresses the difference between the convergence angle and the adjustment angle. The calculation of parallax at a certain point in the scene is shown in Eq. (9).

$$d = I_s \cdot f \left(\frac{1}{Z_p} - \frac{1}{D}\right) \tag{9}$$

In Eq. (9), $I_s$ expresses the distance between the axes of the cameras; $f$ means the focal length of the stereoscopic camera; $Z_p$ refers to the distance from the zero parallax plane to the camera plane. The mapping relationship between the depth of the scene and the disparity at a certain point in the scene is shown in Eq. (10).

$$p(D) = I_s \cdot \left(1 - \frac{Z_P}{D}\right) \tag{10}$$

By substituting Eq. (8) into Eq. (10), the mapping relationship between parallax and viewing distance can be established, as shown in Eq. (11).

$$\begin{cases} p_{min}(v_d) = p_d \cdot \left(1 - \frac{2v_d}{p_d \cot\left(\tan^{-1}\frac{p_d}{2v_d} + \frac{|\delta\theta|}{2}\right)}\right) \\ p_{max}(v_d) = p_d \cdot \left(1 - \frac{2v_d}{p_d \cot\left(\tan^{-1}\frac{p_d}{2v_d} - \frac{|\delta\theta|}{2}\right)}\right) \end{cases} \tag{11}$$

If $P_P$ is the parallax of a point in virtual space, its expression derived from the off axis model is shown in Eq. (12).

$$P_P = \left(1 - \frac{zp}{Z}\right) S \tag{12}$$

In Eq. (12), $zp$ means zero parallax; $S$ stands for the distance between the left and right eye cameras; $Z$ refers to the distance between the points in the scene and the stereo camera. If the perspective of the central camera is $\alpha$, the width of the projection plane is shown in Eq. (13).

$$W_p = 2 * zp * \tan \frac{\alpha}{2} \tag{13}$$

In Eq. (13), $W_p$ is the virtual unit of length. The expression of parallax in real space is shown in equation (14).

$$P_r = \frac{W_r}{W_P} P_p$$
(14)

At this point, if the pixel spacing is $P_p$, the final disparity is shown in Eq. (15).

$$P = P_r * b$$
(15)

### C. Design of Functional Model Implementation Methods for Immersive 3D IEA Production

To implement the functional modules of the IS method in detail, the study presents 3D IEA scenes on the basis of Maya software. During the preparation phase, the development language and library functions are set up. The Maya MEL language, which is the built-in scripting language of Maya software, is selected for development language research. The image library research selects OpenCV image library, which is powerful and has a modular structure. The functions of OpenCV can be divided into various types based on different purposes, such as video processing and graphical user interface functions. The implementation of IS method for immersive 3D IEA production is shown in Fig. 4.

In Fig. 4, the first step of the implementation of the IS method is to generate 3D image pairs, and the second step is to stitching Panorama. The third step is to generate the trget and reference Panoramas on the basis of Panorama staitching, and the fourth step is to calculate the panorama parallax. The fifth step is to optimize the seam of the current Panorama by combining the calculated panorama parallax map and the comfortable parallax range. The realization of the system function can be divided into five functional modules, namely, stereo image pair on-demand acquisition module, immersive 3D IS module, comfort zone calculation module, SM module and seam disparity optimization module. The implementation of different modules is shown in Fig. 5.

As shown in Fig. 5, the implementation of the on-demand acquisition module for stereo images mainly involves determining the position of virtual stereo cameras, which involves two methods. One is to customize the camera position by professionals, and the other is to use MEL scripting language. In addition, the rendering part is also implemented using MEL scripts. The immersive 3D IS module can achieve the acquisition of data such as the coordinates of the seam and the panoramic images of the left and right eyes through Panorama stitching of depth image pairs. In addition, the RANSAC algorithm is introduced into the findHomegraph function and used to solve the homography matrix of the image matrix. The comfort zone calculation module is mainly realized by calculating the user's viewing distance, pupil distance and other data, and the final output of the module is the range value of the comfort zone. The SM module calculates the disparity map of panoramic stereo images through the optimized SGM algorithm. The flowchart of disparity optimization at the seam is shown in Fig. 6.

In Fig. 6, the first step in optimizing the disparity at the seam is to input data into the panoramic disparity map, which mainly includes the comfortable disparity range, seam coordinate positioning, and viewing distance. The second step is to input the left Panorama into the panorama parallax map, and the panorama parallax map will return to the right Panorama based on the input data. The third step is to output the panoramic disparity map data and optimize the disparity at the seam.

## IV.    RESULT ANALYSIS OF IS METHODS FOR IMMERSIVE 3D IEA PRODUCTION

To analyze the results of the IS method for immersive 3D IEA production, the functional module performance and overall performance of the IS method were studied. Among them, the performance analysis of functional modules was mainly achieved by comparing F1 values and image generation error rates under different datasets. The overall performance of IS methods was mainly analyzed through runtime and rendering effects.

### A. *Functional Module Performance Analysis of IS Methods for 3D IEA Production*

The performance testing and analysis of SM models were mainly achieved through algorithm comparison, and the selected comparison algorithms include the sum of squared differences (SSD) algorithm and the sum of absolute differences (SAD) algorithm. Four standards Middlebury stereo image datasets were selected, namely the Tsukuba, Venus, Teddy and Cones6 datasets. The comparison indicators included F1 value and error rate of image generation. The comparison of F1 values between different algorithms is shown in Fig. 7.

From Fig. 7 (a), on the Tsukuba dataset, the max, mini and average F1 value of the SGM algorithm were 0.996, 0.982 and 0.9904, respectively. The max, mini and average F1 value of the SSD algorithm were 0.885, 0.871 and 0.8794, respectively. The max, mini and average F1 value of the SAD algorithm were 0.874, 0.86 and 0.8684, respectively. From Fig. 7 (b), on

the Venus dataset, the max, mini and average F1 value of the SGM algorithm were 0.996, 0.981 and 0.9902, respectively. The max, mini and average F1 value of the SSD algorithm were 0.895, 0.88 and 0.8892. The max, mini and average F1 value of the SAD algorithm were 0.891, 0.876 and 0.8852. The performance of SGM algorithm was significantly better than the other two algorithms. To analyze the performance of the optimized SGM algorithm, the study selected SGM algorithms optimized using other filtering methods for comparison, including box filtering (Box), guided filtering (Guided), and bilateral filtering (BF). The comparison of matching error percentages for different SGM algorithms under the Tsukuba and Venus datasets is shown in Fig. 8.

From Fig. 8 (a), on the Tsukuba dataset, the error percentage of the SGM, SGM+Box, SGM+Box, SGM+BF and SGM+WMF algorithms in non-occluded areas were 3.3862%, 3.2254%, 3.0173%, 2.1268% and 0.3885%, respectively. On the Venus dataset, the error percentage of non-occluded areas in the five algorithms were 0.7217%, 0.7356%, 0.2329%, 0.5478% and 0.4743%, respectively. As shown in Fig. 8 (b), the error percentage of all regions of the five algorithms on the Tsukuba dataset were 5.9688%, 4.2336%, 3.7276%, 3.2244% and 0.8316%, respectively. On the Venus dataset, the error percentages for all regions of the five algorithms were 0.9946%, 0.8234%, 0.4562%, 0.6602%, and 0.8253%, respectively. The comparison of matching error percentages for different SGM algorithms under the Teddy and Cones6 datasets is shown in Fig. 9.

From Fig. 9 (a), on the Teddy dataset, the error percentage of non-occluded areas in the SGM, SGM+Box, SGM+Guided, SGM+BF and SGM+WMF algorithms were 2.1155%, 1.9232%, 3.2346%, 1.8020% and 1.6848%, respectively. On the Cones6 dataset, the error percentages for all regions of the five algorithms were 1.9993%, 1.6732%, 2.3449%, 1.3467%, and 1.34%, respectively. From Fig. 9 (b), on the Teddy dataset, the error percentage of all regions of the five algorithms were 5.0838%, 5.1033%, 4.8143%, 4.9133% and 4.3235%, respectively. On the Cones6 dataset, the error percentages for all regions of the five algorithms were 5.9187%, 5.8999%, 5.2333%, 4.6776%, and 4.1760%, respectively.

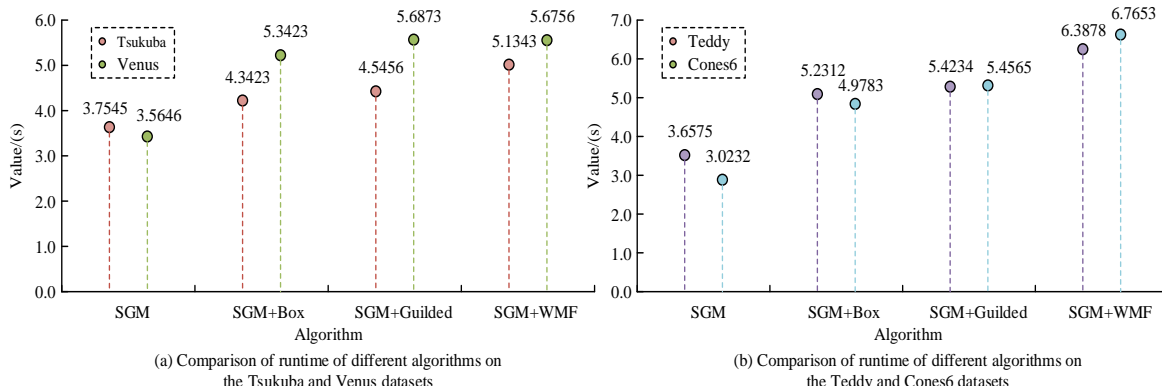
## B. Overall Effect Analysis of IS Methods for 3D IEA Production

To analyze the overall effect of IS methods for 3D IEA production; the running time of different SGM algorithms was compared. The image rendering results of the 3D IEA production IS method was mainly evaluated by observer scoring. In addition, the overall performance of the IS method was analyzed through the smoothness and restoration of the image. The comparison of the runtime of different SGM algorithms on different datasets is shown in Fig. 10.

From Fig. 10 (a), on the Tsukuba and Venus datasets, the


running time of the SGM, SGM+Box, SGM+Guided and SGM+WMF algorithms were 3.7446s and 3.5657s, 4.3434s and 5.3434s, 4.5467s and 5.6884s, 5.1354s and 5.6767s, respectively. From Fig. 10 (b), on the Teddy and Cones6 datasets, the running time of the SGM, SGM+Box, SGM+Guided and SGM+WMF algorithms were 3.6586s and 3.0243s, 5.2323s and 4.9794s, 5.4245s and 5.4576s, 6.3889s and 6.7664s, respectively. In summary, although the SGM+WMF algorithm had no significant advantage in runtime, it had no impact on the overall performance of the method. The image rendering results of the 3D IEA production IS methods are shown in Fig. 11.

(a) Comparison of runtime of different algorithms on the Tsukuba and Venus datasets

(b) Comparison of runtime of different algorithms on the Teddy and Cones6 datasets

Fig. 11. Image rendering results for different animations.

(a) Smoothness comparison of 5 consecutive frames of animation

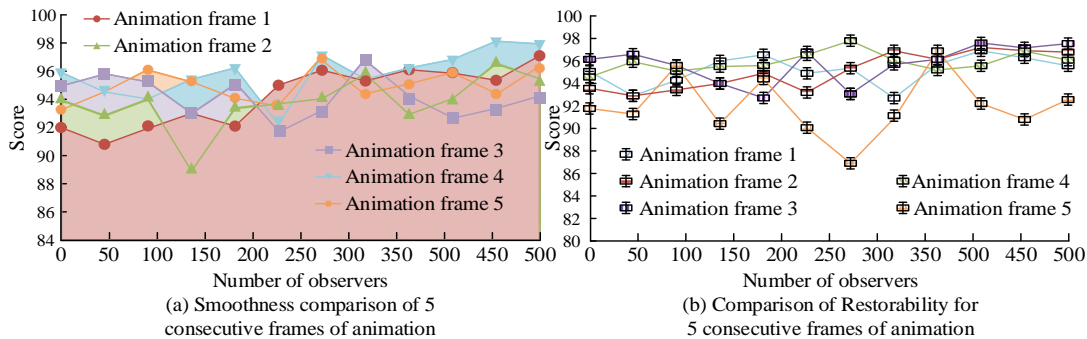
(b) Comparison of Restorability for 5 consecutive frames of animation


Fig. 12. Image smoothness and restoration.

From Fig. 11 (a), in the first ink painting animation, the max and mini rendering score of the first frame image were 98.5 and 81.3, respectively. The max and mini rendering scores for the second frame were 98.9 and 88.7, respectively. The max and mini rendering scores for the third frame were 99.5 and 97.3, respectively. The max and mini score for the fourth frame image rendering were 99.3 and 97.3, respectively. The max and mini score for the fifth frame image rendering were 99.2 and 96.5, respectively. From Fig. 11 (b), in the second IEA, the max and mini rendering score of the first frame image were 99.1 and 81.7, respectively. The max and mini rendering scores for the second frame were 99.6 and 90.1, respectively. The max and mini rendering scores for the third frame were 98.7 and 87.5, respectively. The max and mini score for the fourth frame image rendering were 99.1 and 98.1, respectively. The max and mini score for the fifth frame image rendering were 99.4 and 95.5, respectively. The image smoothness and restoration results of the 3D IEA production IS method are shown in Fig. 12.

From Fig. 12 (a), the max and mini smoothness scores of the first frame image were 96.3 and 91.2 respectively. The max and mini smoothness scores of the second frame image were 97.1 and 89.5 respectively. The max and mini smoothness scores of the third frame image were 97.2 and 92.1 respectively, while the max and mini smoothness scores of the fourth frame image were 98.4 and 94.3 respectively. The max and mini smoothness score of the fifth frame image were 97.3, and 94.5 respectively. As shown in Fig. 12 (b), the max and mini smoothness scores of the first frame image were 97.4 and 93.2 respectively. The max and mini smoothness scores of the second frame image were 97.7 and 93.5 respectively. The max and mini smoothness scores of the third

frame image were 98.1 and 94.5 respectively, while the max and mini smoothness scores of the fourth frame image were 98.3 and 95.4 respectively. The max and mini smoothness score of the fifth frame image were 97.4 and 87.4 respectively.

## V. DISCUSSION

In response to the lack of content in current immersive 3D ink element animations, it is necessary to use image stitching algorithms to transform existing classic 3D ink element animations into immersive 3D ink element animations. At present, image stitching algorithms mainly focus on the stitching of monocular images, which is difficult to directly apply to the stitching of binocular images. Therefore, starting from the horizontal parallax dependence of stereoscopic perception, the research innovatively designed and developed an image stitching method for immersive 3D ink element animation production. The method was designed using stereo matching algorithms and scale invariant feature transformation algorithms, and optimized using a weighted median filtering method based on directional maps. In addition, the study also designed the specific implementation of this method from different functional modules. The analysis of the research results mainly focuses on two aspects: one is the performance verification of the algorithm used in the study, and the other is the overall effect analysis of the image stitching method. On the Tsukuba dataset, the average F1 value of the SGM algorithm is 0.9904, while the average F1 values of the SSD and SAD algorithms compared are 0.8794 and 0.8684, respectively. On the Venus dataset, the average F1 values of the three algorithms are 0.9902, 0.8892, and 0.8852, respectively. It can be seen that on different datasets, the average comprehensive evaluation value F1 of the SGM

algorithm is better than the other two comparative algorithms, indicating that the performance of the SGM algorithm is better. In the overall effect analysis of the image stitching method, the maximum rendering scores of the first ink wash animation for five consecutive frames were 98.5, 98.9, 99.5, 99.3, and 99.2, respectively. The maximum rendering scores of the second ink wash animation for five consecutive frames are 99.1, 99.6, 98.7, 99.1, and 99.4, respectively. It can be seen that the image stitching method designed by the research institute has good image rendering effects.

## VI. CONCLUSION

To avoid the lack of innovation and repeated development problems existing in the current immersive 3D IEA production, an IS method was innovatively designed and developed. The method was constructed through SM algorithm and SIFT algorithm. The experimental findings showed that on four different datasets, the error percentages of the optimized SM algorithm in non-occluded areas were 0.3885%, 0.4743%, 1.6848%, and 1.34%, respectively. The error percentages of all areas were 0.8316%, 0.8253%, 4.3235%, and 4.1760%, respectively. The optimized SM algorithm had a smaller matching error rate. On four different datasets, the running time of the SGM+WMF algorithm was 5.1354s, 5.6767s, 6.3889s, and 6.7664s, respectively. The average values of image rendering scores were 90.88, 94.22, 98.6, 98.38, and 98.1, respectively. The average image smoothness values were 94.4, 93.2, 94.52, 96.62, and 95.7, respectively, while the average restoration values were 95.18, 95.36, 96.64, 96.56, and 93.36, respectively. Although research and development have been conducted on IS a method for immersive 3D IEA production, there are still certain shortcomings, such as the further improvement of SM algorithms, which can be improved in future research.

*Abstract*—With the advancement of virtual broadcasting technology, the use of artificial intelligence animated characters in virtual scenes is becoming increasingly widespread. However, there are still a series of challenges and limitations to make the behavior of animated characters more natural, intelligent, and diverse. Therefore, this study proposes a behavior tree based animation character behavior modeling and a short-term memory action recognition method combining human geometric features. The research results indicate that when the behavior modeling model faces different obstacles, the successful avoidance rate is over 80%, and the avoidance reaction time is 0.41s-0.65s. The accuracy and loss function values of the action recognition method gradually converge to 1 and 0 with the quantity of iterations grows. For the recognition of seven types of actions, the accuracy of raising the left hand, raising the right hand, waving the left hand, and waving the right hand reaches 100%, and the recall rate of raising the right hand is 100%. The majority of action types have F-value scores above 0.9. Relative to the recurrent neural network model, the accuracy of the double-layer long-term and short-term memory model is 95.8%, which is significantly better than the former's 86.3%, showing better recognition performance. In summary, modeling and identifying the behavior of artificial intelligence animated characters can make the characters in virtual broadcasting more intelligent, natural, and realistic, thereby improving the viewing experience of virtual broadcasting, which has important practical value and research significance. This has significant practical and research value, providing insightful references for related fields.

*Keywords—Virtual broadcasting; animated characters; behavioral modeling; action recognition; behavior tree; long and short-term memory*

## I. INTRODUCTION

Virtual broadcasting technology is a cutting-edge interdisciplinary field in the fields of computer graphics and artificial intelligence, playing an important role in media such as movies, television programs, and games [1]. Through the integration of virtual broadcasting technology and artificial intelligence (AI) animated characters, viewers can experience a fully immersive audio-visual encounter [2]. However, there are still challenges to achieving more natural, intelligent, and diverse behavioral representations of animated characters [3]. Traditional virtual animation character behavior modeling relies on rule design and manual programming, which limits the ability to flexibly respond to complex environments. Action recognition methods are often limited to specific action categories and are difficult in scenarios with high real-time requirements. Therefore, this study proposes a behavior tree based animation character behavior modeling and a Long

Short Term Memory (LSTM) action recognition method that combines human geometric features. This study aims to improve the behavior and recognition abilities of AI-animated characters in virtual broadcasting, allowing them to display more natural and intelligent actions in intricate scenarios and interact with users in real-time.

Section I of the study introduces relevant technologies and methods, including existing research results on behavior modeling and action recognition, as well as research on behavior trees and LSTM. Section II provides a detailed explanation of related works. Section III is the establishment of an AI animation character behavior model, experiment and evaluation of animation character behavior model and action recognition is detailed in Section IV. Section V and Section VI delves into comparison and conclusion respectively.

## II. RELATED WORK

Behavioral modeling (BM) refers to the process of establishing and describing the behavior of individuals or systems, which has numerous applications in various fields, including AI, computer graphics, virtual reality, game development, robotics technology, etc. As the boost of computer technology and AI, significant progress and development have been made in the field of behavior modeling. Colledanchise et al. presented a method that combines automatic planners and machine learning to automatically generate a behavior tree strategy for the application requirements of industrial robots in unpredictable environments. This approach offers a practical solution for enabling robots to operate autonomously in complex environments and has significant theoretical and practical implications [4]. Kumar proposed a deep learning (DL) classifier method on the ground of children's emotions to predict children's behavior, addressing the problems in establishing a behavioral model for predicting children's current emotional activities. This provides theoretical guidance for predicting children's emotional behavior [5].

Action recognition refers to the recognition and classification of human or objects actions through technologies such as computer vision and machine learning. At present, action recognition technology has made significant progress and has been widely applied in multiple fields. Song et al. addressed the issues of complex and overly parameterized state-of-the-art models, as well as inefficient training and inference, by embedding separable convolutional layers into early fusion multi input branch networks to construct efficient graph convolutional network baselines. It is used for skeleton action recognition, effectively improving

accuracy, reducing model parameters and training costs [6]. Gharaee introduced a novel approach to recognizing human actions by employing a self-organizing mapping system. The objective was to address the problem of identifying the start and end times of online unsegmented actions for automated recognition purposes. This method can effectively extract and cluster features of action sequences, thereby achieving accurate recognition and segmentation of actions [7].

Behavior tree is a graphical tool used to model complex behaviors, commonly used in game development and virtual character control. LSTM is a special type of recurrent neural network designed to process sequential data, such as time series or text. Junaidi A et al. presented the utilization of behavior tree algorithm to effectively manage and control the diverse behaviors of NPCs for the type of side scrolling game, to enhance the fun and realism of the game. This accomplishment led to a more precise management and control of behavior, resulting in an enhanced player experience and game quality [8]. Shen et al. proposed a framework that combines bidirectional short-term memory networks and data sorting for real-time prediction of the diameter of shotcrete columns in soft soil, providing more accurate and reliable predictions for shotcrete processing in soft soil, and further improving the design of shotcrete columns [9]. Priyadarshini et al. proposed a combined model of short-term and short-term memory, CNN, and grid search to address the increase in user generated content on the Internet and the challenge of understanding emotions and emotions involved. This model helps to better understand user attitudes, viewpoints, and emotions, providing important basis for decision-making and analysis in various application scenarios [10].

In summary, scholars have conducted in-depth research on behavior modeling and action recognition. However, in many research results, the traditional virtual animation character model is not flexible and lacks real-time performance in action recognition, which needs further research. Therefore, this study proposes an animation character behavior modeling on the ground of behavior trees and an LSTM action recognition method combining human geometric features. This provides an innovative way to improve the behavior performance and action recognition ability of AI-animated characters in virtual broadcasting.

## III. ESTABLISHMENT OF AI ANIMATION CHARACTER BEHAVIOR MODEL AND ACTION RECOGNITION METHOD

As an execution method for planning models, behavior trees are widely used to construct complex AI character behaviors, enabling virtual actors to exhibit more natural, intelligent, and diverse behavior. The LSTM action recognition method involves combining geometric features of the human body with the LSTM neural network in deep learning to achieve precise recognition of actions.

### A. Establishment of AI Animation Character Behavior Model Based on Behavior Tree

AI animated characters require complex behavior and diverse decision-making in virtual broadcasting. Traditional modeling techniques, such as finite state machines, have

limitations in representation [11]. To overcome its shortcomings, this study adopts behavior tree modeling. The behavior tree has a parallel mechanism that supports hierarchical structure and node combination, making the behavior logic easier to understand. Its modular design reduces post maintenance costs, dynamically adjusts role behavior, and improves flexibility and scalability [12]. Visual perception possesses an essential influence on modeling the behavior of animated characters, simulating the visual cone of the real human eye, and setting appropriate field of view angles and ranges. The human eye's maximum visual range is $60^{\circ}$, with a comfort range limited to $30^{\circ}$. Only objects located within the visual cone can be perceived [13]. The human eye is more sensitive to dynamic objects, which allows for easier detection of their movements and changes. The visual perception model of animated characters is shown in Fig. 1.

(a)Visual stereogram      (b)Plane decomposition graph
Fig. 1. Visual perception model of animated characters.

In Fig. 1, assuming that a point on the observed object is P. O represents the eye of the animated character, which is the starting point of the line of sight. R represents the angle of view. D represents the field of view distance. If the distance between OPs is less than d and the angle between OP and the Z-axis is less than half of the field of view angle R, it is assumed that the observed object is within the field of view of the animated character. In a virtual environment, animated characters need to further determine whether there is an occlusion relationship. Point occlusion method is used for line of sight detection in this study. Assuming that the world coordinate of point O is $(x_0, y_0, z_0)$ and point P is $(x_p, y_p, z_p)$, OP is represented as shown in Eq. (1) [14].

$$\begin{cases} x = x_0 + m(x_p - x_0) \\ y = y_0 + m(y_p - y_0), 0 \le m \le 1 \\ z = z_0 + m(z_p - z_0) \end{cases} \quad (1)$$

In Eq. (1), $m$ is to be solved. Assuming that there is a rectangular object between O and P as an obstruction, it projects it onto the XY plane to obtain a rectangular projection. It sets the coordinates of the four vertices as $(x_i, y_i, z_i), i = \{1, 2, 3, 4\}$, and the equations for each edge are shown in Eq. (2).

$$\frac{x - x_i}{x_{i+1} + x_i} = \frac{y - y_i}{y_i + y_i}, i = \{1, 2, 3, 4\} \quad (2)$$

It brings Eq. (2) into Eq. (1) and solve for the value of $m$. If $m$ has no solution, then OP has no intersection with the projection rectangle, indicating that the observed object is not obstructed. If $m$ has a solution, then the obtained value is taken into Eq. (1) to calculate the value of $z$. If the value of $z$ is greater than the Z coordinate value corresponding to the highest point of the obstruction, it indicates that the observed object is not obstructed. Otherwise, it is obstructed. In addition to the visual model, an auditory model should also be established. The auditory perception model of the animated character is shown in Fig. 2.

In Fig. 2, in a virtual environment, to simulate real auditory perception, the auditory range of the animated character is limited by a spherical area. Only sound located within the spherical area can be heard by the animated character [15]. It sets the auditory threshold $V_0$, assuming that the sound intensity is $V$ and the distance between the animated character and the object is $d$. Only in the case of $V/d > V_0$ an animated character hear sound and make decisions about it. On the contrary, it exceeds the auditory perception range of the animated character, and the animated character will not be able to perceive the sound. In virtual broadcasting, AI-animated characters are modeled through perception to construct their next behavior, which corresponds to the child nodes of the behavior tree, namely the animated character behavior nodes. To achieve complete action recognition and control, this study combines the perception model and behavior model into a whole, forming an animation character control behavior tree, as shown in Fig. 3.

Fig. 3 shows that in virtual broadcasting, the behavior tree of animated characters is composed of a parent node as the root node, connecting the selection node, the order node of different branches, and the standby behavior node. The standby behavior node maintains the initial behavior of the animated character. The decoration node lies beneath the order node and is accountable for continuous visual and auditory perception. Once the environmental information within the perception range of the animated character changes, the sequential logic nodes and decoration nodes come into play, interrupt standby behavior, and execute the corresponding behavior under the sequential nodes. Through this structure, animated characters make intelligent behavioral decisions on the ground of environmental changes, resulting in more realistic performance in virtual broadcasting.

### B. LSTM Action Recognition Method Combining Human Geometric Features

AI-animated characters in virtual broadcasting require action recognition ability to make corresponding action responses on the ground of user input or environmental changes. This study adopts the LSTM action recognition method that combines human geometric features [16]. AI characters obtain user action data through sensors, such as geometric features such as posture and joint position, as input. After processing by the LSTM neural network, they learn the temporal evolution patterns of action sequences and extract relevant features. Three different geometric structures of human bone point features, including 3D position difference, 3D angle difference, and bone vector angle feature, are proposed and normalized, and fused as input for the action recognition network model. The framework of the LSTM action recognition method combining human geometric features is shown in Fig. 4 [17].

Fig. 4 shows that the LSTM action recognition method is suitable for processing custom datasets containing sequences of human bone data points, and can effectively process data with temporal features. The method first extracts geometric features and normalizes human bone data points to ensure consistent data scales [18]. Then, the fused features are input into the LSTM network model to capture the dependencies and temporal correlations of action sequences. Next, the custom dataset trains the LSTM network to optimize model parameters and accurately recognize various human movements [19]. Finally, the probability distribution output by the LSTM network is converted into action classification results through the Softmax function, achieving accurate recognition and classification of human actions.

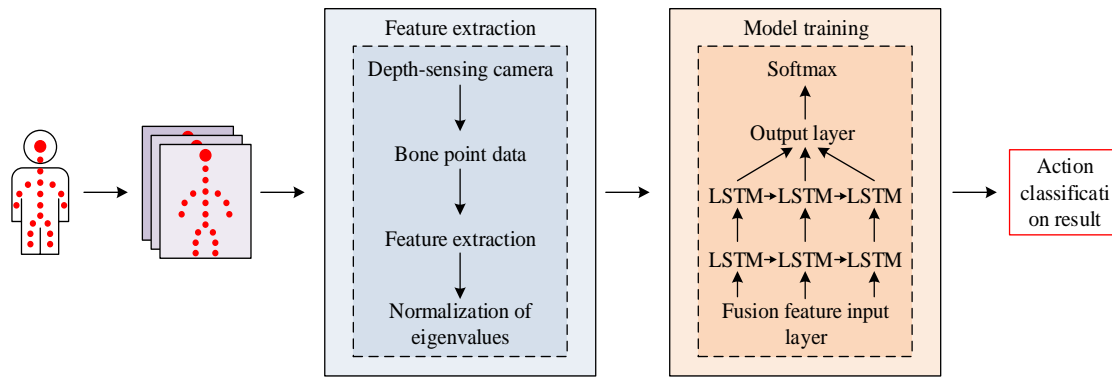
Fig. 3. The animation character controls the behavior tree.


Fig. 4.   LSTM action recognition method framework combining human body geometric features.

Recurrent Neural Network (RNN) is commonly used to process serialized data, which exhibit temporal properties and cyclic transitivity. Recurrent neural networks are widely used to handle serialization problems because they can have a "memory" function that links the information of the entire network together. The expression of output layer (OLA) $h^{(t)}$ in the two-layer RNN structure is shown in Eq. (3).

$$h^{(t)} = f\left(h^{(t-1)}, x^t\right) \tag{3}$$

In Eq. (3), $x^t$ is the input of the current time (CTI) model. $f$ represents the model function, also known as the activation function. The RNN sequence length is independent of $f$ and is suitable for handling long sequence problems in different time dimensions. During network transmission, the output $h_t$ of RNN nodes at each time point is shown in Eq. (4).

$$h_t = \varphi\left(W_{xh} \cdot x_t + W_{hh} \cdot h_{t-1} + b\right) \tag{4}$$

In Eq. (4) $\varphi$ represents the activation function. $W_{xh}$ and $W_{hh}$ represent the weight matrix (WMA) in the input and output of the network nodes at the CTI, and the WMA of the hidden layer meanwhile. $b$ serves as the bias parameter. RNN transfers the output at the current moment (CMO) to the OLA and the hidden transmission at the next moment. Recursive transmission has defects, and the network gradient gradually decreases with the increase of sequence length, resulting in slower iterative updates and the issue of gradient disappearance or explosion. LSTM solves the above problems and improves the efficiency and stability of the network by adding "memory" units to the hidden layer and selectively "forgetting" long-term sequences. RNN is a standard recursive neural network, while LSTM has added three gate level control units that control the flow of information, including input gate (IGA) $i$, forgetting gate (FGA) $f$, and output gate (OGA) $o$, and has built-in hidden layer memory cell $C_t$ [20]. The FGA $f$ is utilized for controlling the degree to which information from the previous moment is retained in the current memory cell. The formula for calculating FGA $f$ at time $t$ is shown in Eq. (5).

$$f_t = \sigma\left(W_f \cdot \left[h_{t-1}, x_t\right] + b_f\right) \tag{5}$$

In Eq. (5), $W_f$ is the WMA of the FGA. $h_{t-1}$ is the hidden state of the previous moment. $x_t$ is the input at the CTI. $b_f$ is the bias parameter of the FGA. $\sigma$ serves as an S-type activation function, used to map the calculation results to the range [0,1], representing the output value of the FGA. The calculation formula for IGA $i$ is shown in Eq. (6).

$$i_t = \sigma\left(W_i \cdot \left[h_{t-1}, x_t\right] + b_i\right) \tag{6}$$

In Eq. (6), $W_i$ is the WMA of the IGA. $b_i$ is the bias parameter of the IGA. The IGA controls the degree to which the input information at the CMO updates the memory cells. The calculation formula for OGA $o$ is shown in Eq. (7).

$$o_t = \sigma\left(W_o \cdot \left[h_{t-1}, x_t\right] + b_o\right) \tag{7}$$

In Eq. (7), $W_o$ is the WMA of the OGA. $b_o$ is the bias parameter of the OGA. The OGA controls the degree to which information in memory cells is output at the CMO. The calculation of candidate memory cell $C_t^{'}$ is shown in Eq. (8).

$$C_t^{'} = \tanh\left(W_c \cdot \left[h_{t-1}, x_t\right] + b_c\right) \tag{8}$$

In Eq. (8), $W_c$ is the WMA of the input and the previous hidden state. $b_c$ is the bias parameter for candidate cells. $\tanh$ is a hyperbolic function, and the candidate memory cell is a temporary memory cell calculated at each time step to store new input information. The calculation of updated memory cells is shown in Eq. (9).

$$C_t = f_t \cdot C_{t-1} + i_t \cdot C_t^{'} \tag{9}$$

In Eq. (9), $C_{t-1}$ serves as the memory cell of the previous moment. Updating memory cells is achieved through the weighted sum of FGAs, IGAs, and candidate memory cells. The output of memory cells is shown in Eq. (10).

$$h_t = o_t \cdot \tanh\left(C_t\right) \tag{10}$$

In Eq. (10), $h_t$ represents the hidden state of LSTM at the

CTI $_t$ , which is also the output of memory cells. To better capture temporal features and improve recognition accuracy, a two-layer LSTM network model is introduced to increase network depth [21]. Fig. 5 showcases the relevant structure.

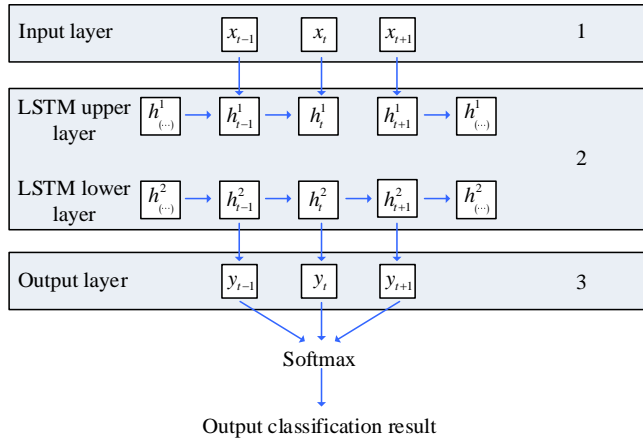

Fig. 5.  Two-layer LSTM network model.

Fig. 5 shows that in a two-layer LSTM network model, two LSTM models are set at the same level, with the upper layer (ULA) being the input layer (ILA), and the ULA LSTM model is as the input sequence. The lower layer is the OLA, and the lower layer LSTM model is used as the output model. The forward formula of the double-layer (DLA) LSTM network model is shown in Eq. (11).

$$\begin{cases} i_{l,t} = \delta\left(W_{xi}x_t + U_{hli}h_{l,t-1} + U_{h(l-1)i}h_{l-1,t} + V_{ci}c_{l,t-i} + b_i\right) \\ f_{l,t} = \delta\left(W_{xf}x_t + U_{hlf}h_{l,t-1} + U_{h(l-1)f}h_{l-1,t} + V_{cf}c_{l,t-i} + b_j\right) \\ o_{l,t} = \delta\left(W_{xo}x_t + U_{hlo}h_{l,t-1} + U_{h(l-1)o}h_{l-1,t} + V_{co}c_{l,t-i} + b_o\right) \\ C_{l,t} = f_t \cdot C_{t-1} + i_{l,t} \cdot \tanh\left(W_{xc}x_t + U_{ltc}h_{l,t-1} + U_{h(l-1)c}h_{l-1,t} + b_c\right) \\ h_{l,t} = o_{l,t} \cdot \tanh\left(C_{l,t}\right) \end{cases} \quad (11)$$

In Eq. (11), $h_{l,t-1}$ and $h_{l-1,t}$ respectively represent the hidden states of the ULA LSTM model and the lower layer LSTM model. $x_t$ is the ILA. $U_{hl}$ and $U_{h(l-1)}$ represent the weight matrices of the ULA LSTM model and the lower layer LSTM model, respectively. $b$ represents the offset parameter. All variables are classified as IGA $i$ , FGA $f$ , or OGA $o$ on the ground of $i$、$f$、$o$ in the table below. At moment $t$ , the output $y_t$ of the DLA model is shown in Eq. (12).

$$y_t = U_{hlt}h_{l,t} + b_y t \quad (12)$$

In Eq. (12), $U_{hlt}$ represents the WMA. $h_{l,t}$ serves as the hidden state of the lower layer LSTM at time $t$ . $b_y$ represents the offset parameter. The Softmax function is showcased in Eq. (13).

$$\xi_i = \frac{e^{Z^i}}{\displaystyle\sum_{J=1}^{n} e^{Z^j}} \quad (13)$$

In Eq. (13), $Z^i$ represents the $i$ -th action sequence. $J$ serves as the quantity of the action type. $n$ serves as a total of $n$ actions identified. When updating network parameters, the study adopts a cross entropy loss function, as shown in Eq. (14).

$$E\left(y_t, y_t'\right) = -y_t \log y_t' = -\sum_{t=1}^{n} y_t \log y_t' \quad (14)$$

In Eq. (14), $y_t$ represents the label of the actual action. $y_t'$ represents the label that identifies the action. The training process iteratively updates the network, leading to a gradual decrease in the loss function's value. After each update, the gradient values overlay, as demonstrated in Eq. (15).

$$\frac{\partial E}{\partial w} = \sum_{t=1}^{n} \frac{\partial E}{\partial w} \quad (15)$$

In Eq. (15), $E$ represents a loss function. $w$ represents the weight parameter in the network. Through continuous iterative updates and gradient stacking, the DLA LSTM model can gradually optimize during training and adapt to features of the data to improve recognition of temporal features with increased accuracy.

## IV. EXPERIMENTAL ANALYSIS OF AI ANIMATION CHARACTER BEHAVIOR MODELING AND ACTION RECOGNITION

To explore the effectiveness and superiority of the behavior tree based animation character behavior modeling and the LSTM action recognition method combined with human geometric features; the study started with simulation experiments and tested the collision avoidance and sound source capture indicators of the behavior modeling. Meanwhile, it conducted testing experiments on the LSTM action recognition method and compared it with the RNN model.

### A. Behavior Modeling Experiment Simulation Based on Behavior Tree

The objective of the experiment is to test the effectiveness of animation character behavior modeling on the ground of behavior trees in handling obstacles to prevent collisions and capture sound sources. Specifically, this study aims to evaluate the effectiveness of the system in avoiding collision objects and ensuring the safe movement of the modeled object in the environment. It also aims to determine whether the testing system can accurately detect and locate sound sources, thus simulating the modeled object's perception and positioning ability towards sound. The relevant situation of development environment is shown in Table I.

Table I shows that the experimental computer is configured with an AMD Ryzen 5 3600X 6-Core processor,

32GB DDR5 6000MHz memory, and is equipped with an NVIDIA GeForce RTX 3070 high-performance graphics card. This configuration meets the development requirements of the experiment and enables real-time behavior modeling and simulation in complex scenarios. Unity 3D is utilized as the game engine, supporting the development of 2D and 3D games, virtual and augmented reality applications, simulators, and animations. BM adopts the free software DAZ Studio, which provides rich functionality for creating high-quality digital characters, scenes, and animations. To achieve complex AI behavior, it uses the professional behavior tree plugin Behavior Designer. Its evaluation system performance uses collision avoidance and sound source capture metrics. The collision avoidance indicator evaluates the system's contact with collision objects in different scenarios, calculates the successful avoidance ratio and average avoidance time. The experimental results are shown in Fig. 6.

Fig. 6 shows that the successful avoidance rate is above 80% when encountering different obstacles. Among them, when facing obstacle 5, the avoidance rate at position 3 reaches 96%, which means that in most cases, the system can effectively perceive the obstacle and make timely avoidance decisions, thereby successfully avoiding collisions. The reaction time for taking avoidance actions when facing obstacles is within 0.41s-0.65s, indicating that the system has relatively fast response ability in collision avoidance. The system rapidly detects the presence of obstacles and makes appropriate decisions to evade them. The sound source capture indicator uses a virtual sound source to simulate the sound in the environment, and records the system's perception and positioning of the sound source position. It evaluates the sound source capture accuracy of the system by comparing the error between the predicted position and the actual position. The experimental outcomes are showcased in Table II.

Table II shows that the percentage of capture error for different sound sources ranges from 1.40% to 1.88%, with an average error of approximately 1.56% for sound source capture. For the given experimental data, it was observed that the percentage of error between the actual position and the predicted position is not fixed under different obstacles, but fluctuates slightly. As the distance increases, the error also increases. Overall, the predicted results (PRE) captured by the sound source are all near the actual sound source location, with small errors and within an acceptable range. This suggests that the system excels at capturing sound sources with high levels of precision and accuracy.

## B. Experimental Analysis of LSTM Action Recognition Method

The experiment used the UCF101 dataset, created by a team of researchers at the University of Central Florida, and a custom dataset, which included 101 different categories of movements and more than 13,000 video clips covering movements of a variety of daily life and sports. The latter was gathered utilizing a half-body camera and comprised of 12 crucial bone points and seven fundamental movements from a total of 10 participants. The cross-validation numbers are 1-10, the training set contains 634 action sequences, and the test set contains 618 action sequences. The collected 3D position difference feature is an 11-dimensional vector, the 3D Angle difference feature is a 12-dimensional one, and the bone vector Angle feature is an 8-dimensional one. To reduce the risk of overfitting, 0.1 random inactivation is added to the hidden unit of the network. The study first conducted fusion comparative experiments on three different features: 3D position difference feature, 3D angle difference feature, and bone vector angle feature. It records three different features: 3D position difference feature, 3D angle difference feature, and bone vector angle feature, which are A, B, and C. The fusion feature of A and B is D, and the fusion feature of the three features is E. The recognition rate results obtained from the experiments are shown in Table III.

TABLE III.    MODEL RECOGNITION RATE WITH FEATURE FUSION

| Input feature vector | Maximum recognition rate (%) | Minimum recognition rate (%) | Average recognition rate (%) |
|---|---|---|---|
| A | 78.12 | 72.48 | 75.23 |
| B | 72.54 | 51.89 | 65.65 |
| C | 86.39 | 67.73 | 76.45 |
| D | 89.45 | 76.28 | 84.32 |
| E | 98.23 | 92.46 | 95.03 |

Table III shows that the recognition rate for A is fairly consistent, ranging from a high of 78.12% to a low of 72.48%. The difference between the highest and lowest recognition rates of B is significant, making it the most unstable of the five features. Meanwhile, the average recognition rate is only

65.65%, which is also the lowest. The performance of C and D is average, but D, which combines the two features, has a marked enhancement relative to C. For E, the fusion of three features resulted in a maximum recognition rate of 98.23%, a minimum recognition rate of 92.46%, and an average recognition rate of 95.03%, indicating a significant improvement. Therefore, E was utilized as the input for the double-layer LSTM network model to obtain the accuracy change curve and loss function value (LFV) change curve, as shown in Fig. 7.

In Fig. 7, the accuracy curve shows that the accuracy gradually converges to 1 with an increase in iterations, suggesting perfect classification performance for the training data. The LFV in the LFV change curve gradually converges to 0 with the quantity of iterations grows, indicating that the error between the PRE of the model and the actual labels is effectively reduced during the training. This research uses IDLE for stationary and WALK for walking. RUN stands for running. LHU means raising the left hand. RHU stands for raising the right hand. WLH means waving to the left. WRH means waving to the right. The study evaluated and identified seven actions and obtained their accuracy, recall, and F1 score (F1 Score) results, as shown in Fig. 8.

Fig. 8 shows that the accuracy of LHU, RHU, WLH, and WRH actions is 100%, indicating that the model has no errors in the recognition and prediction of these four actions. The recall rate of action type RHU is also 100%, indicating that the model has excellent capture ability for this action and has not missed any real positive examples. The F1 Score of most action types is above 0.9, indicating that the model performs well on multiple indicators and has good classification performance. The recognition rate of action types WALK and RUN is relatively low because they belong to repetitive dynamic feature sequences. Furthermore, during the capture process, only the upper body mode was employed, thus neglecting bone points such as the knees and ankles, which offer improved distinguishing features between these movements. For demonstrating the superiority of the DLA LSTM model, comparative experiments were conducted with the RNN model. The results are shown in Fig. 9.

(a) The relationship between accuracy and the number of iterations

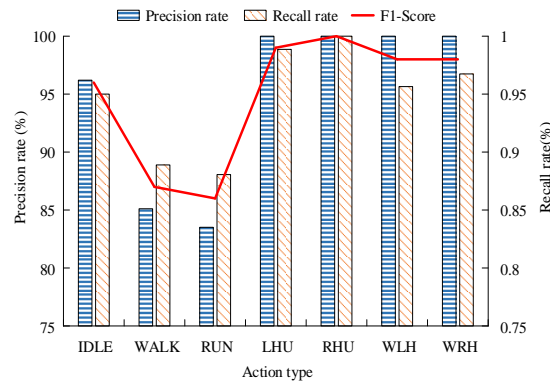
(b) The relationship between Loss function value and the number of iterations
Fig. 7.    Accuracy curve and LFV curve of two-layer LSTM network model.


Fig. 8.    Model recognition result.

(a) Two-layer LSTM model confusion matrix

(b) RNN model confusion matrix

(c) Comparison of F1-Score of two models

Fig. 9.    Comparison of experimental results between two-layer LSTM model and RNN model.

Fig. 9 shows that the RNN model lacks a "rgetting unit" resulting in a significant increase in misclassification of actions during the recognition process compared to the DLA LSTM model. The diagonal elements of the confusion matrix represent the recall rate of the current model, which is the probability of accurately predicting actions. When comparing the F1 Score values of the DLA LSTM model and the RNN model, it is evident that the LSTM model outperforms the RNN model in all seven classification actions. After calculation, the accuracy of the DLA LSTM model is 95.8%, and the accuracy of the RNN model is 86.3%, indicating that the DLA LSTM model has better recognition performance.

## V.    COMPARISON

The conclusions of study [22] were compared with the conclusions of the research, in which study [22] mentioned the application of transformer-based deep neural networks to human action recognition, and the overall success rate reached 94.96% for six kinds of actions. The accuracy rate of the two-layer LSTM model proposed in this research was 95.8%, surpassing that of the aforementioned [22] method, thus demonstrating the superiority of this study.

## VI. CONCLUSION

In response to the limitations in traditional virtual animation character behavior modeling and action recognition methods, this study proposes a behavior tree based animation character behavior modeling and an LSTM action recognition method combining human geometric features, and verifies the performance and effectiveness of both methods. The research results indicate that when the behavior modeling model faces different obstacles, the proportion of successful avoidance is over 80%, and the avoidance response time is within 0.41s-0.65 seconds, indicating that the system can effectively perceive obstacles and make avoidance decisions in a timely manner. The accuracy and LFVs of the LSTM action recognition method gradually converge to 1 and 0 as the number of iterations increases. This indicates the model's ability to perform perfect classification on the training data and effectively reduce the error between the PRE and real labels during the training process. Meanwhile, the LSTM action recognition method achieves 100% accuracy in identifying seven types of actions, including LHU, RHU, WLH, and WRH. The RHU achieved a recall rate of 100%, and most action types received an F1 Score higher than 0.9. In the comparative experiment between the DLA LSTM model and the RNN model, the accuracy of the DLA LSTM model was 95.8%, and the accuracy of the RNN model was 86.3%, demonstrating that the DLA LSTM model has better recognition performance. Overall, the behavior modeling and action recognition methods studied and designed have high effectiveness and certain advantages, providing an effective solution for AI animation character behavior modeling and action recognition in virtual broadcasting. However, this study used upper body mode for behavior capture, ignoring bone points such as knees and ankles that are more likely to distinguish between the "walking" and "running" categories, and further discussion is needed.

*Abstract*---A bidirectional phonetizer, morphologizer, and diacritizer pipeline (FSPMD) for modern standard Arabic (MSA) that integrated pronunciation, concatenative and templatic morphology, and diacritization were developed. Grammar and segmental phonology rules were applied in the forward direction to ensure the order of the proper rules, which were supplemented with special backward direction rules. The FSPMD comprises bidirectional finite-state transducers (FSTs) consisting of an ordered composition of FSTs, unordered parallel FSTs, unioned FSTs, and for validity, finite-state acceptors. The FSPMD has unique, innovative features and can be used as an integrated pipeline or standalone phonetizer (FSAP), morphologizer (FSAM), or diacritizer (FSAD). As the system is bidirectional, it can be used in forward (generation, synthesis) and backward (analysis, decomposition) directions and can be integrated into systems such as automatic speech recognition (ASR) and language learning tools. The FSPMD is rule-based and avoids stem listings for morphology or pronunciation dictionaries, which makes it scalable and generalizable to similar languages. The FSPMD models authentic rules, including fine granularity and nuances, such as rewrite and morphophonemic rules, subcategory identification and utilization, such as irregular verbs. FSAP performance regarding text from the Tashkeela corpus and Wikipedia demonstrated that the pronunciation system can accurately pronounce all text and words, with the only errors related to foreign words and misspellings, which were out of the system's scope. FSAM and FSAD coverage and accuracy were evaluated using the Tashkeela corpus and a gold standard derived from its intersection with the UD_PADT treebank. The coverage of extraction of root and properties from words is 82%. Accuracy results are roots computed from a word (92%), words generated from a root (100%), non-root properties (97%), and diacritization (84%). FSAM non-root results matched and/or surpassed those from MADAMIRA; however, root result comparisons were not conducted because of the concatenative nature of publicly available morphologizers.

*Keywords---Computational linguistics; phonology; morphology; modern standard Arabic; diacritization; text-to-speech; language learning tools*

## I. Introduction

Natural language processing technologies, such as automatic speech recognition (ASR) systems, rely on pronunciation dictionaries that provide word listings and corresponding phone pronunciations for both training and recognition. In the ASR training phase, an orthographic text passage is transformed into its phonetic transcription (pronunciation), which comprises a sequence of phonemes or phones. In the recognition phase, the phonetic transcription is transformed into its associated word sequence orthographic text (1).

Because effective ASR requires a large dictionary that lists the words and their pronunciation, the system perplexity increases, and the accuracy declines. One possibility to reduce the size for languages that have deep orthography and highly irregular mapping, such as English, French, and Danish, is to list the affix and stem pronunciations rather than the words; however, this requires a concatenative morphologizer (prefix, stem, and suffix). At the other end of the spectrum, languages that have shallow orthography (phonetic languages) and a one-to-one correspondence between the letters and phonemes, such as Finnish and Turkish, only require a very simple dictionary of letters and the associated phonemes. Because middle-spectrum languages, such as Russian, German, and Spanish, have complex correspondences between the letters and pronunciation, they are not amenable to rules [1] (2).

However, other languages in the middle spectrum, such as Arabic and Hebrew, do have rules-based pronunciation, which means that rule-based transducers between the words and their phonemic transcriptions could resolve the need for large pronunciation dictionaries. If a transducer is bidirectional, it could be used for both the ASR training and recognition phases. In the backward direction, in which a phonetic sequence is mapped to an orthographic text, a word acceptor based on morphemes is needed to avoid invalid words, the use of which could avoid large word lists that would require an integrated phonetizer and morphologizer. While building a more efficient, accurate ASR could be a valid motivation for designing a bidirectional rule-based pronunciation transducer (phonetizer), such automata would be useful in its own right as it could be applied to other domains, such as text-to-speech synthesis, that require the identification of both suprasegmental features and segmental phonology. In addition to designing and constructing a bidirectional rule-based phonologizer that maps the relationships between orthographic text and its phonetic transcription, this study also developed a bidirectional concatenative (prefixes, stems, suffixes) and templatic (roots, patterns) morphologizer that generates words from morphemes and decomposes words into morphemes. Templatic morphology is another major feature not present in languages such as English.

Besides being important in its own right in multiple technologies, there are two main reasons a morphologizer is required in phonetizers: as an acceptor to filter out invalid words without the need for a large word list and as a phonological morphology-based rules regulator to determine whether a word is a noun or a verb to reduce pronunciation ambiguity.

In languages such as Arabic and Hebrew, the written script

---

is either undiacritized or diacritized. As phonetizers and morphologizers generally require diacritized text, a diacritizer is also needed to complete the pipeline. In the system developed in this study, the diacritizer is independent of the phonetizer and morphologizer; however, it uses the same constructs as the morphologizer.

The links between morphology, phonology, morphology, and diacritics result in an integrated system. Therefore, this study proposes a method and structure that can exploit the innate grammar of a language. While Arabic is used as the demonstration language in this study, the proposed method can be equally applied to other such languages. Semitic languages, such as Arabic and Hebrew, have form-based morphology and rules-based pronunciation and are usually undiacritically written (3).

An integrated bidirectional finite-state (FSPMD) system was designed and constructed that incorporates a phonetizer (FSAP), a morphologizer (FSAM) that can work with both diacritized and undiacritized text, and a diacritizer (FSAD). The various linguistic and segmental phonological rules were fully incorporated and finite-state transducers (FST) were solely employed to build the system; therefore, it was not necessary to include the additional features found in other systems, such as two-level finite states and flags.

In the forward direction, the FSAP transforms a diacritized passage into its corresponding pronunciation; FSAM generates words from the patterns, roots, prefixes, and suffixes; and FSAD inserts diacritics into undiacritized words. In the backward direction, the FSAP produces a text passage for a sequence of phones; FSAM decomposes the words into their prefixes, patterns, roots, suffixes, and linguistic features, such as gender and part of speech; and FSAD strips the diacritics from diacritized words. The FSAM can also work as an acceptor for morphologically valid words

The FSPMD, therefore, connects phonetic transcriptions and diacritization to morphology to create a tight system that among other constraints, limits words corresponding to a pronunciation when there is an absence of listings. The FSPMD's bidirectional pipeline synthesizes words from affixes, patterns, and roots, computes the pronunciation from texts based on segmental phonological units, and diacritizes words, and in the opposite direction, analyzes a word into its morphemes, transforms pronunciation into text, and undiacritizes words.

This study excluded end-of-word diacritics as these are governed by syntactic rules that are unable to be formulated as regular expressions that can be realized as finite-state transducers (FSTs), that is, they require higher-order formal language, such as context-sensitive grammar. Particular attention was paid to authentic grammar rules and many details and nuances were incorporated, such as the effects of text marks in phonology and the inclusion of rewritten rules for the morphological orthography.

The remainder of this paper is organized as follows. Section II details the problem and the integrated architecture, Section III presents the phonetizer, Section IV presents the morphologizer, and Section V presents the diacritizer. Appendix A presents the phonetizer and morphologizer literature reviews. Appendix B presents additional phonetizer and morphologizer evaluation results. Transliterations of Arabic to Roman letters were not used to reduce confusion. Supplementary material 1 is a compendium for Arabic orthography, phonetics, and morphology and provides details not necessary to understand the main paper. Supplementary material 2 gives the finite-state automata and their earlier usages in linguistics and phonology and a related literature survey.

## II. PROBLEM FORMULATION AND INTEGRATED ARCHITECTURE

An orthographic text is a sequence of characters that make up words and marks such as tabs, text beginnings, and commas. An Arabic word comprises a sequence of graphemes that include alphabetic and non-alphabetic letters and diacritics. In addition to syntax, which governs the end-of-word diacritics, diacritized text has all the diacritics mandated by the associated spelling and morphological rules; however, undiacritized texts only have Shaddah and sometimes Tanween and Sukoon as diacritics. Because syntactic processing may not be realized by FSTs, in this study, the undiacritized Arabic texts also included end-ofword diacritics. A phonetic transcription (pronunciation) is a sequence of phones consisting of phonemes and fermatas that represent pauses of various durations and continuation. These graphemes, marks, phonemes, and fermatas are described in Supplementary material I along with the mappings between the marks and fermatas. If there is more than one realization based on the context, the phonetic transcriptions may also contain an allophone variation of a phoneme.

Phonetically transcribing an orthographic text produces phonemes and fermatas that depend on both graphemes and marks, that is, the transformation of phonetic transcription to orthographic text depends on both phonemes and fermatas, which is why the fermata plays a more important transformation role in Arabic than in other languages.

The proposed system has various FSTs to transform the input sequences into output sequences. The transducer also acts as an acceptor, which produces a FALSE notification if the input is not valid according to the transducer rules. As the forward direction FST was designed to utilize linguistic grammar rules, depending on the particular FST, the forward direction could be either generation/synthesis or analysis/decomposition. Bidirectional FSTs were employed to enable generation as well as analysis using analysis rules. This was made possible by the method used to construct the FSTs, which incorporated some unidirectional limiting rules exceptions and some additional rules for the opposite direction only. The rules were written as regular expressions, which were then transformed into non-probabilistic FSTs using the open-source Foma compiler (4).

The FSAP mapped between the diacritized texts and the phonetic transcriptions, with the forward direction producing the pronunciation from the diacritized orthographic texts, which was represented by International Pronunciation Association (IPA) and fermata symbols. Because the phonetizer can realize segmental rules, it did not embody phonological suprasegmentals, such as syllables, stress, or intonation. The FSAD mapped between the diacritized words and the corresponding undiacritized words, with the forward direction generating diacritized words from an undiacritized word. The FSAM mapped between the words and associated morphemes (pattern, root, prefix, suffix), with the backward direction generating words

from the morphemes. While these FSTs were constructed from multiple FST components, as described in the various sections, each can also be used as a standalone system.

The three FSTs were integrated into a pipeline structure to compute the phonetic transcriptions for the undiacritized (or diacritized) texts or to decompose an undiacritized word into its morphemes. The integrated pipeline system's (Fig. 1) forward and backward direction functions are detailed in the following.

Fig. 1. Bidirectional integrated system mapping between the orthographic undiacritized text and the phonetic transcription (pronunciation). M refers to morphemes (prefix, root, suffix, and pattern), N refers to nouns, and V refers to verbs, as these affect the pronunciation.

In the forward direction, the system takes four steps to produce a phonetic transcription of an undiacritized text: (1) the diacritizer maps a given sequence of undiacritized words into diacritized words; (2) the morphologizer extracts the morphemes (prefix, root, suffix, pattern) and morphological properties (noun or verb) of each word in the sequence; (3) the system then concatenates the morphologizer and diacritizer results to produce a sequence of diacritized words and the associated morphological properties; and (4) finally, the concatenation sequence is input into the phonetizer, which produces the phone sequences.

In the backward direction, the pipeline system takes three steps to produce the undiacritized and diacritized orthographic

texts to be input into the phonetic transcription: (1) the phonetizer used in the reverse direction produces multiple diacritized word sequences from the phone sequence; (2) the morphologizer, which is used as an acceptor, filters out the morphologically incorrect diacritized word sequences and produces a set of valid diacritized texts; and (3) finally, the diacritizer used in the reverse direction undiacritizes the diacritized word sequences to produce an undiacritized text.

### III. Phonetic Transducer (FSAP)

The phonetic transducer was constructed using a combination of an ordered composition of FSTs and unordered parallel FSTs, with the finite-state automata (FSAs) being the acceptors to define the grapheme, marker, phoneme, and fermata subsets. The unordered FSTs embodied non-contextual rules and the ordered FSTs realized the contextual grammar, which required a thorough and precise ordering of the rules to ensure precise results.

In contrast to the current approaches outlined in Appendix A, FSTs rather than procedural methods were utilized, which avoided the need for a two-level FST that makes multiple transformations in favor of a single level; syllabic structures to compensate for shortcomings in the realization of the rule; the incorporation of context-dependent rules in a specified order, which is generally ignored; and the realization of all MSA rules, including those related to text markers, which can significantly effect phonetization.

Geminated consonants and long vowels were also considered phonemes in their own right. Previous studies(5) have tended to consider gemination by doubling a singleton consonant or mapping it into its singleton version, which has been shown to be phonetically inaccurate, as demonstrated by geminated plosives that have a single voice onset time and release. Similarly, long vowels have previously been dealt with by doubling the short version; however, the spectral characteristics of long vowels are noticeably different from their short vowel counterparts(5).

Rather than applying simplifications to these rules, special attention was paid to the precise complex rules regarding Wasl (ب ف ك و) and Illah (ا و ي) characters, including those in the Sukoon (ـْ) context. Rules regarding the noun versus verb factors in the pronunciation of diacritized words were also considered as diacritized words still have some pronunciation ambiguity in Alif Wasl (ا).

The following subsections present the contextual and non-contextual orthography: phoneme mappings and contextual phonemes; allophone rules and backward phonemes; and orthography results. The section ends with the phonetic transducer evaluations.

### A. Orthography: Phoneme Mappings

The orthographic and phonetic representation mappings were divided into non-contextual and contextual rules. The first two subsections present the non-contextual diacritics; vowel and character and phoneme mappings; and the latter three sections present the contextual letters; the phoneme mappings and pronunciation rules governed by a word's part of speech, such as noun or verb. The markings affecting the way the letter/diacritic is pronounced are also detailed in the following rules.

*1) Diacritics: vowels mappings:* A Harakat (ﹷ) grapheme can be mapped to its corresponding short vowel (/a/, /u/, and /i/) in all contexts; however, it is not pronounced (/•/) when it precedes its corresponding 'vowel characters' (ي), (و), (ى' ا). A Tanween (ﹸ) grapheme only diacritizes the end of words and generally maps to its corresponding vowel when followed by /n/ (/a/ / n/, /u/ /n/, /i/ /n/); however, Tanween is not pronounced (/•/) if it diacritizes a word that ends the sentence.

*2) Non-contextual characters: phoneme mapping:* The diacritic ﹽ (shaddah) causes a gemination in the sound of the preceding letter it diacritizes, and ﹿ maps to a zero duration pause /Φ/. The Hamza set (ؤ ئ إ أ ء) is pronounced as /ʔ/, and the other mappings are as follows: ('ː /aː/), (آ: /ʔaː/), (ب: /b/), (ت: /t/), (ث: /θ/), (ج: /dʒ/), (ح: /ħ/), (خ: /χ/), (د: /d/), (ذ: /ð/), (ر: /r/), (ز: /z/), (س: /s/), (ش: /ʃ/), (ص: /sˤ/), (ض: /dˤ/), (ط: / tˤ /), (ظ: /ðˤ/), (ع: /ʕ/), (غ: /ʁ/), (ف: /f/), (ق: /q/), (ك: /k/), (م: /m/), (ن: /n/), (ه: /h/).

*3) Contextual letters: phoneme mapping:* The context determines the pronunciation for (ل، ا، ي، و، ى، ة). The rules are presented from the simplest to the most complex for the Wasl letters (ك ل ت ب و), the Alef Wasl (ا), the definite article (ال), and the other rules. The following are the contextual mappings for the letters and letter combinations.

The letter ة is always at the end of a word followed by a Haraka and maps to /t/ or /h/. ة : /t/ if it is in a word in the middle/start of a sentence and not followed by ﹿ; ة : /h/ if followed by ﹿ or in a word that ends a sentence. The letter ى always ends a word and maps to /aː/ or /a/; ى maps to /a/ if it ends in a word that precedes a word that starts with ا, and ى, and /aː/ if it is in a word that ends a sentence or precedes a word that doesn't start with ا.

The letter و maps to /w/, /wː/ or /uː/. و : /w/ if followed by a diacritic other than ﹿ and preceded by ﹿ; و : /wː/ if followed by ﹿ and preceded by ﹿ ;, and و: /uː/ if preceded by ﹿ. The letter ي maps to /j/, /jː/, or /iː/. ي : /j/ if preceded by ﹿ or ﹿ and followed by a diacritic other than ﹿ ; ي : /jː/ if preceded by ﹿ or ﹿ and followed by a diacritic other than ﹿ; and ي: /iː/ if preceded by ﹿ.

The letter ا maps to /ʔ/ or is not pronounced /•/. ا: /ʔ/ if it starts a word and is followed by a Harakah; اː, and /•/ if it is preceded by a Wasl letter (ك ل ت ب و). The combination ﹷـ maps to /a/ if it ends a word, and maps to /aː/ if it is between letters.

The letter ل maps to /l/ or /ɛ/ (not pronounced) when it is part of the definite article (ال); otherwise, it is pronounced /l/. The letter combination ال (the definite article) maps to /ʔal/, /ʔa•/, /•l/, or /•/ (not pronounced), ال: /ʔal/ if it is followed by a Lunar letter; ال: /ʔa•/ if it is followed by a Solar letter, ال: /•l/ if it is preceded by a Wasl letter, and ال: /•/ if it is preceded by a Wasl letter and followed by a Solar letter. The pronunciation of ا and ال at the beginning of a word also depends on whether the word is a verb or a noun, as detailed in Subsection III-A4.

*4) Noun and verb rules pertaining to Alif Wasl:* When it occurs at the start of the word without diacritization and as part of the spelling, the pronunciation of Alif Wasl (ا) is ambiguous and requires knowledge of the word's part of speech, particularly whether it is a noun or verb. Specifically, the situations are as follows: (1) ا: /ʔa/ if ا is part of ال at the beginning of a verb and not a noun, that is, it is not treated like ال the definite article; for example, الْعَب : /ʔalʕab/ and الْجُمْ : /ʔaldʒum/; (2) ا : /ʔu/ if ا is at the beginning of a verb in which the third letter is diacritized with ﹹ ; for example, اكْتُبْ : /ʔuktub/; (3) ا: /ʔi/ if ا is at the beginning of a noun and not part of the definite article (ال); for example, امْرُؤٌ : /ʔimruʔ/, اسم : /ʔism/, and ابْن : /ʔibn/.

### B. Contextual Phoneme: Allophone Mappings

Multiple phoneme to allophone mappings exist and have several variations, two of the most prominent of which are described here. The first is pharyngealization, which produces a pharyngeal counterpart (if it exists) of a phoneme followed by a pharyngeal phoneme. The second is homorganic nasal place assimilation, which changes a nasal phoneme. For example, the alveolar nasal /n/ is pronounced as the bilabial nasal /m/ if it is followed by the voiced bilabial /b/ or the bilabial nasal /m/. Table I gives some examples of these rule occurrences.

### C. Phonetic Transcription to Orthographic Text

The previous subsections presented the bidirectional mappings formulated in the forward direction. As mentioned, the FST's bidirectional nature allows the system to map from phonetic transcription to orthographic text. Some mappings, however, need to be explicitly expressed in the backward direction only. Table II provides a few examples generated by the phonetizer.

The rules that lead to the deletion of characters can interfere with the rules and cause an infinite loop, that is, no results. This can be resolved by including a special symbol to indicate deletion and by not applying the deletion in the reverse direction. Because some of the outputs in this direction were not valid words due to the deletions that occur in pronunciation and the lack of word lists, the produced words were input into the morphologizer in the analysis direction to treat the lack of analysis as a rejection.

### D. FSAP Evaluation

In the absence of a pronunciation corpus with a sufficient number of examples to gain a numeric accuracy and recall evaluation, fully diacritized pronunciation examples, which were independently verified by a linguist, were produced to test the FSAP's scope and accuracy, with the performances being assessed based on: 1) individual words and small sentences with the associated pronunciation to test the specific context and check the inclusion and accuracy of all rules; 2) passages from Tashkeela(6) to test the ability to deal with multiple contexts at a time and to handle unknown words; and 3) examples from Wikipedia [2] [3] with the associated transcription to assess the validity of the system. The evaluation of the examples demonstrated that the pronunciation system was able to accurately pronounce all text and words, with the only errors being foreign words and misspellings, such as a missing Mad character, which was out of the system scope.

---

[2]https://en.wikipedia.org/wiki/Varieties_of_Arabic
[3]https://en.wikipedia.org/wiki/Arabic_phonology

TABLE I. SAMPLE ALLOPHONIC CHANGES IN MODERN STANDARD ARABIC

| Word | Gloss | Phonemic | Allophonic | Change |
|---|---|---|---|---|
| استصلح | consider useful | /ʔis.tasˤ.la. ħa/ | [ʔisˤ.tasˤ.la.ħa] | pharyngealization |
| فرعون | Pharaoh | /fir.ʕawn/ | [ firˤ.ʕawn ] | pharyngealization |
| انبعث | regain one's strength and vividness | /ʔin.ba.ʕa.θa/ | [ʔim.ba.ʕa.θa] | Homorganic nasal place assimilation |
| من بعد | after | /min baʕ.di/ | [mim‿baʕ.di] | Homorganic nasal place assimilation |

TABLE II. PHONETIC TO ORTHOGRAPHIC TRANSFORMATION: Φ: ZERO DURATION PAUSE, μ: SHORT DURATION PAUSE (SUCH AS THE BREATH TAKEN BETWEEN EACH WORD), ω: MEDIUM DURATION PAUSE, α: LONG DURATION PAUSE, ‿: CONTINUATION, •: NOT PRONOUNCED

| Phonetic | Orthographic | Phonetic | Orthographic | Phonetic | Orthographic |
|---|---|---|---|---|---|
| /ma‿ • smik/ | مَا اسمِك | /ʔat:amarΦ/ | التَّمَر | /bim • aː/ | بِمَا |
| /ʔinbaʕaθa/ | انبَعَثَ<br>انبَعَثَ | /bariː?/ | بَرِيء<br>بَرِيء | /masʕuːlin/ | مَسؤُولٍ |
| /min μ baʕdi/ | مِن بَعدٍ | /bima/ | بِمَ | /ʔum:i/ | أمِّ |
| /bimaː/ | بِما | /wa • stasˤlaħa/ | وَاستَصلَحَ<br>وَاستَصلَحَ | /katabaː/ | كَتَبَا |

*1) Evaluation of the words and phrases:* A rich listing of valid diacritized words and phrases was produced to test the edge cases. The following words were a test bed for Harakat: vowels and non-contextual graphemes; phonemes and contextual graphemes; phonemes; and words may have multiple pronunciations. Words and short sentences were then chosen that contained characters that had varied context pronunciation, specifically, the definite article (ال), Harakat (ـَ ـِ ـُ), Tanween (ـً ـٍ ـٌ), ta' marbutah (ة), alif (ا), lam (ل), waw (و), and ya (ي). Table XII gives the comprehensive evaluation of the phonotizer to ensure that all edge cases were tested. A comparison of the system outputs with the IPA transcription by a language specialist revealed the transducer's accuracy and coverage. Notice that phonotizer output symbols, such as zero duration pauses and deletions, were not present in the transcription. Table III presents the system output of various inputs and is a subset of Table XII in Appendix B.

*2) Tashkeela corpus evaluation:* Table XIII in the evaluation appendix details the system results for a random sample of sentences from Tashkeela corpus that are fully diacritized MSA texts taken from various internet sources, such as Al Jazeera and al-kalema.org. Numbers, foreign words, misspellings, partially diacritized text, and colloquial dialects were out of the system scope.

The phonetizer output was compared with the output from a native Arabic speaker trained in reading IPA and MSA, who provided an IPA transcription of the texts as this was not provided in the Tashkeela corpus. Table XIII indicates that the proposed system performed accurately on a large variety of texts.

Differences between the proposed system's output and the expected transcription were due to missing diacritization, the lack of Mad character in a word, and loan words that had a lack of diacritization and sometimes irregular pronunciation. Detailed explanations for these specific differences are shown in Table XIII in Appendix B.

*3) Wikipedia sentence evaluation:* Table XIV in Appendix B compares the phonetizer output and the IPA transcription for the selected Wikipedia examples [4] [5]. These examples were used because there were no corpora available that contained both orthographic texts with phonetic transcriptions. As can be seen, no deviations were found between the two.

## IV. MORPHOLOGICAL TRANSDUCER (FSAM)

A morphological FST was designed that generates/synthesizes words in the forward direction from morphemes and in the backward direction, decomposes a word into its morphemes. The morphologizer concatenates morphemes that are prefixes, stems, or suffixes and also works on a templatic level when morphemes are interdigitized patterns and roots that make a stem and are meaning-bearing units. Interdigitation refers to the insertion of root components into the corresponding placeholders in the pattern.

In contrast to the existing approaches outlined in Appendix A, the proposed morphologizer is both concatenative and templatic, with the FST used instead of tabulation for the con-

Fig. 2. Arabic word morpheme breakdown. A word is a concatenation of a prefix, stem, and suffix (concatenative). A stem is a meaning-bearing unit that can be further decomposed into its root and pattern (templatic). The root gives the core meaning and the pattern provides the part of speech (POS, category) and other linguistic properties, such as number, tense, and gender. This image uses the Buckwalter transliteration scheme (www.qamus.org/transliteration.htm).

catenative rules. The proposed FST has a single level rather than two levels, into which patterns and roots are input. The morphologizer has a distinct rewrite rules layer to interdigitate the patterns and roots and concatenate the affixes and stems.

Fig. 3 illustrates the proposed FST's inputs and outputs using the word example fasamiEahaA (so he heard her), which was decomposed to the prefix fa (so), the stem samiEa (he heard), and the suffix haA (her), and the stem was further analyzed to the root s m E (to hear) and the pattern faEila (he did). The forward direction FST analysis produced the morphemes and the linguistic features, such as gender, and in the backward direction, generated a word.

The FST works as an acceptor, a synthesizer, and an analyzer and uses the same architecture for both diacritized and undiacritized words. The diacritized version has diacritized morphemes and the undiacritized version has undiacritized morphemes. The morphemes and allowable combinations were derived from multiple linguistic sources (7; 8; 9).

State-of-the-art concatenative morphological formalism comprises three components: lexical automaton, morphotactic rules, and rewrite rules. FSAs are constructed to represent prefixes, stems, and suffixes, which are concatenated with markers based on morphotactic rules that specify valid combinations to separate them into lexical forms, that is, the morphotactic (governing the morphemic combinations, which are meaning-bearing units) and orthographic (spelling) rules are programmed into the FST. The orthographic changes that need to be made to the lexical form to yield the surface form (word) that incorporates contextual mapping are coded using rewrite rules in the FST.

The automaton utilizes morphotactic MSA grammatical rules that govern the allowable affixes and stem concatenations, and the Arabic grammar licit templatic morphological pattern and root combinations, which ensures that there are no invalid words. The proposed architecture incorporates roots and a wide variety of patterns, thereby generating a rich set of valid forms and an average of around 28 analyses per undiacritic word, which compares favorably to the table-based unidirectional universal machines in leading morphologizers that only provide a single analysis and do not have any root-based generation capabilities.

FSAM can be used as a forward direction generator and as a backward direction analyzer for both diacritic and undiacritic words. Therefore, finite-state machines (FSM's) benefits are its unified architecture, its bidirectionality, and its ability to hard wire patterns, which allows for the synthesis, analysis, and diacritization of words without the need for a lookup table.

The generator input is a root that can be either a pattern, an affix, or "print lower-words," and the output is all licit root, pattern, and affix combinations. A word that cannot be decomposed into a pattern and root is a fixed word, such as Washington, which is represented by the root being recognized as a fixed word without affixes and with the pattern being the identity.

The analyzer input is a word and the output is valid alternative morpheme decompositions (prefix, root, and suffix), patterns, parts-of-speech (category), and morphosyntactic features such as number and gender.

FSAM is a composite of three main automata layers, as

analyzer

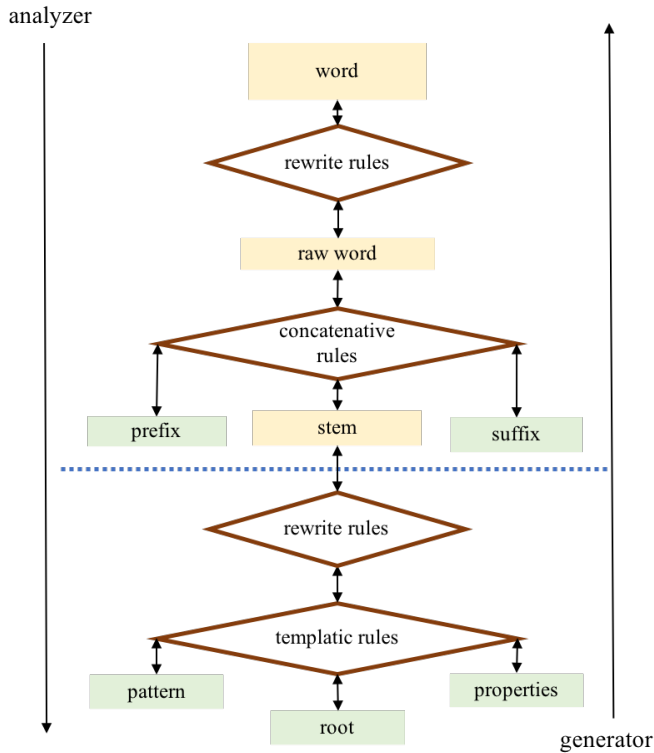

Fig. 3. Architecture for the bidirectional Finite-State Machine based morphological system. The top portion is the rule-based concatenative morphologizer and the bottom portion is the rule-based templatic morphologizer that produces the root, morphological pattern, and properties, such as the category (PoS) and the morphophonemic features. All of these are optional inputs in the generation (synthesis) direction.

shown in Fig. 3: (1) a templatic rule-based automaton that generates the pattern and root combinations into a word; (2) a concatenative rule-based automaton that generates prefix-stem-suffix combinations into a word; and (3) a rewrite rule transducer that applies orthographic and morphophonemic rules to the raw words.

### A. Stem Vocabulary Coverage

Stem vocabulary is synthesized in the transducer using a "print lower-words" command, from which a full list of stems is produced, all of which are valid words. The focus is on the stems (base words) rather than the words because of the large vocabulary that arises from additional prefix and suffix combinations. Table VI of Appendix B shows the related statistics.

When the undiacritized stem vocabulary was compared to the undiacritized words in the Tashkeela corpus, an overlap of 88,784 stems was found between the generated FSAM stems and the Tashkeela words, which contrasted favorably (six times more) with the 14,951 stem overlaps between MADAMIRA and the Tashkeela corpus.

### B. Expanding Coverage

Based on the compiled morpheme, the morphological automata strictly enforce the allowable prefixes, suffixes, and roots that can combine with a morphological pattern. As morpheme

combinations occur, they need to be added to the system sets. To allow for this expansion, a morphological automata version is constructed in which the restrictions on the roots, prefixes, and suffixes that combine with a pattern are removed but the precisely known hardwired patterns are retained.

An example of a pattern is فَعَلَ ('has done'), which could have the restricted sets وَ, فَ as roots ء ك ل, د ر س, ف ه م as prefixes, and هَا as suffixes. Therefore, if the word كَتَبَ is input into the proposed system, which does not have the root ك ت ب in the sets related to the فَعَلَ pattern, it can be analyzed using the open system and then added to the closed system, which only allows valid words to be analyzed, to improve the coverage.

If a trilateral pattern is allowed to correspond to any three-letter root, there is an unrestricted subsystem that allows valid words to be analyzed and the list of roots in the restricted system to be expanded. However, as this subsystem also admits many invalid words, it can only be used by a language specialist to expand the morpheme list.

### C. Evaluation

Different data sets and sources were employed to evaluate the various system parts. As detailed in Appendix B, to ensure there were no invalid or dialectal words that ignored the OOV and punctuation, a gold standard treebank was developed from the intersection of the PADT UD treebank[6] and the Tashkeela[7] corpus to test the morphologizer generation and analysis (synthesis) tasks for both the undiacritic and diacritic words.

The FSAM and FSAD results were compared to the leading Arabic morphologizer, MADAMIRA, which is a concatenative morphological analyzer that uses a Penn Arabic treebank as part of its training set and overlaps with the UD PADT. MADAMIRA(10) is a combination of the MADA (Morphological Analysis and Disambiguation of Arabic), which was built based on the SAMA (Standard Arabic Morphological Analyzer) and AMIRA (a morphological system for colloquial Egyptian Arabic). Different from MADAMIRA, FSAM and FSAD's rule-based system conducts an MSA templatic morphological analysis that yields a root and pattern, generation, and diacritization.

*1) Synthesizer evaluation:* FSAM synthesizes words in two ways: 1) it inputs the prefix-root-suffix to the system and outputs all words resulting from the many pattern and root combinations; and, 2) it issues a "print lower-words" command to the transducer to synthesize all stems that are valid pattern and root combinations or all words that are valid pattern, root, prefix, and suffix combinations. FSAM synthesizes the word vocabulary corresponding to the gold standard by inputting the root, prefix, and suffix combinations, which are decompositions of the gold standard words in the treebank. Consequently, the vocabulary is larger than the gold standard because of the additional patterns applicable to the prefix-root-suffix combinations. Table IX in the appendix illustrates the tremendous effect that the patterns have.

To evaluate the root generation ability, the root provided by the gold standard and the prefix and suffix provided by the gold standard word segmentation were used to generate possible

[7]https://sourceforge.net/projects/tashkeela/

Table IV. FSAM-generated Words from the Gold Standard Roots. The 'generated' Column Shows the Percentage of Roots the Model Generated from the Words; for example, Root لك is not Considered a Root in Arabic, and Therefore, no Words were Yielded. The 'correct' Column is the Percentage of FSAM-generated Words that Matched the Gold Standard.

### Generated/Synthesized Words from Roots

| UNDIAC | generated | correct |
|---|---|---|
| verb | 94.96 | 100 |
| tool word | 90.71 | 100 |
| noun | 91.71 | 100 |
| proper name | 91.28 | 100 |
| noun+verb | 92.48 | 100 |
| all | 91.89 | 100 |

words from the prefix, root, pattern, and suffix combinations. Table IV shows that 100% accuracy and 92% coverage were achieved when generating words from the root and its prefix and suffix.

*2) Analyzer evaluation using the gold standard:* The analyzer input is a word and the FSAM output is the root, pattern, category, or other linguistic information, such as number, gender, case, definiteness, and aspect. As the MADAMIRA output does not include the root or pattern, MADAMIRA was run in analysis-only mode.

A full analyzer evaluation should only be conducted against a gold standard reference. The Tashkeela corpus, however, is only a collection of morphologically valid Arabic words, whereas the gold standard treebank has root, category, and other linguistic information. For the undiacritized evaluation, all treebank words were input into the analyzer and matched against the analysis. The gold standard no OOV treebank was then used to evaluate the systems. Both systems had around 99% accuracy when computing gender, definiteness, person, case, aspect, and voice; however, the FSAM performed well for mood (99.7% vs 93%) and number (97.8% vs 90.5%) and was able to determine the root correctly about 92% of the time. Appendix B provides more details on the FSAM evaluation.

The advantage of the proposed system is that it can extract the word roots and patterns, that is, it can provide a shallow analysis of a word based on the pattern without needing to refer to a table of stems and their properties. Both systems' properties could produce the category, case, gender, mood, definiteness, number, person, voice, and aspect.

*3) Analyzer coverage evaluation:* The model coverage was evaluated by computing the percentage of analyzed words using a large corpus (Tashkeela). The FSAM analyzed 81.83% of the undiacritized words in the Tashkeela corpus and analyzed 82.24% of the undiacritized words in MADAMIRA (in analyses-only mode and no backoff). The backoff mode in MADAMIRA was not used because it admits invalid words.

The reduced coverage was largely because of the invalid words in the corpus. Invalid words are words that are misspelled, not words in the Arabic language, or a concatenation of words. Examples of words that could not be analyzed by both systems and were deemed invalid were شرنبلالي, السنبوسك , فوشيكوس, and words that were not separated by

whitespace and were considered to be one word (the dash (-) indicates where the words should be separated), such as : عباس-الفواحش,بالليل-والإباحة ,المصلين-والوجه,العدو-عليكم, الشعثاء-في, السدي-وخرج, الأواه-الذي, المسلمين-حال, وغيرها-وإني, مالك-والشافعي, المساجد-إلا, فأخبرني-محمد, يعني-البينات, عصير-والوجه, قوله-وهذا, سفيان-أن, أول-احتباسها

## V. Diacritic Transducer (FSAD)

As illustrated in Fig. 5, the system's diacritizer was developed using diacritized fixed words, the prefix and suffix listing for the simple diacritizer, and the diacritized MSA patterns for the pattern-based diacritizer. The simple diacritizer was used for the fixed words and affixes because they did not follow any pattern.

The diacritizer was designed in the forward direction, in which diacritics were inserted. The FST for the fixed words and affixes is a table that maps between the diacritized and undiacritized versions. The model used for the pattern-based words was an insertion FST that inserted diacritics into an undiacritic pattern to create the diacritic counter parts; for example, [8] $\Omega\Gamma\Lambda \rightleftharpoons \Omega a\Gamma a\Lambda a, \Omega a\Gamma{\sim}a\Lambda a, \Omega a\Gamma i\Lambda a, \Omega u\Gamma i\Lambda a$, where $\Omega$, $\Gamma$, and $\Lambda$ were placeholders for the root.

Fig. 4. Architecture for the finite-state machine-based diacritizer. The downward (forward) direction outputs diacritized words from an input undiacritized word. The segmenter decomposes the word into its prefix-stem-suffix. The pattern-based diacritizer inserts the diacritics into an undiacritized pattern to produce corresponding diacritized patterns; for example, فعل ⇌ فِعِل, فُعِل, فَعَل. To diacritize the stem using the pattern diacritizer, the stem is matched with the corresponding undiacritized pattern to produce the diacritic stem. The simple diacritizer inserts the diacritics directly into the undiacritized affix.

The segmenter decomposes a word into its prefix-stem-suffix components for which the stem could be a pattern-based word or a fixed word. After the word components are diacritized, they are then concatenated to form the diacritic word. The system diacritizer is illustrated in Fig. 4. A sample input and output(s) to this system is ودرسها ⇌ وَدَرَسَهَا, وَدَرَّسَهَا.

The diacritizer was evaluated by selecting all undiacritized words in the gold standard treebank, passing them into the diacritizer, and checking the output against the diacritized word contained in Vform. The diacritizer output was evaluated according to standard Arabic spelling rules. Note that the gold

---

[8]Please note we are using Buckwalter transliteration when not using Arabic script: http://www.qamus.org/transliteration.htm

standard meets these standards with some exceptions that are only apparent upon visual inspection.

TABLE V. DIACRITIZATION ACCURACY FOR THE TREEBANK. THE PATTERN-BASED MODEL HAD SIGNIFICANTLY HIGHER ACCURACY

| Word | FSAD | MADAMIRA |
|------|------|----------|
| verb | 85.91 | 80.99 |
| proper name | 82.46 | 50.78 |
| noun | 83.67 | 53.49 |
| noun+verb | 84.01 | 58.76 |
| toolword | 83.34 | 53.43 |
| all | **83.65** | 58.59 |

The evaluation in Table V indicates that the FSAD performed better than the MADAMIRA for the full diacritization (84% vs 59%) because the FSAD does not learn the diacritization from the corpus but deduces it based on the patterns that exist in the Arabic language, whereas MADAMIRA trains its model on corpora and, therefore, has a more partial diacritization.

Because the gold standard has spelling inconsistencies between the diacritized and undiacritized words, the performance was reduced, as shown in Table V. The following examples had the following (inconsistencies), which could have had a significant effect on the evaluation.

- Using ى instead of ي (e.g., مدنى ⇐ مَدَنِـيٌّ , فى ⇐ فِـي ,
  (أَلفِـيَ ⇐ ألفى, حَوَالَـي ⇐ حوالـى)

- Using ا instead of آ (e.g., اب ⇐ آبَ, الاستانة ⇐ الآسِتانَةِ,
  (آخَرُ ⇐ اخر)

- Using ا instead of إ (e.g., الى ⇐ إلَى, اطلاق ⇐ إطلاقِ,
  (إشَارَةِ ⇐ اشارة)

## VI. CONCLUSION

This study designed and constructed a bidirectional integrated phonetizer, morphologizer, and diacritizer system (FSPMD), the coverage of which could be increased by adding foreign words and special morpheme roots with the associated rules in the appropriate order. The FSPMD structure could be mimicked to build morpho-phonological systems for rule-based languages, such as Hebrew and Aramaic. The system could also be used in many language technologies, such as speech recognition, information retrieval, and spelling and grammar checkers, without the need to incorporate large tabulations that increase system complexity, out-of-vocabulary words, and perplexity. The system could also be used to construct a semantic analyzer and word translator and as part of a suprasegmental phonologizer that applies syllables, stress, and intonation rules, which would make it useful for text-to-speech technologies. On the text side, the syntactic parser has greater scope than most FSMs, which means it can deal with long-distance rules beyond formal languages, such as context-sensitive grammar or tree adjoining grammar.

## Appendix A
## Related Work

### A. Arabic Morphologizers

The most significant morphological analyzers are those that utilize finite-state transducer formalism, such as Xerox(11), the morphological analyzer and generator for the Arabic dialects (MAGEAD)(12; 13) , and the Arabic Computer Lexicon (AraComLex)(14), and those that utilize a tabular approach, such as Darweesh(15), the Buckwalter Morphological Analyzer for Arabic (BAMA)(16), the Standard Arabic Morphological Analyzer (SAMA)(17), ElixirFM(18), a high-level implementation of functional Arabic morphology, Morphological Analysis and Disambiguation of Arabic (MADA)(19), and MADAMIRA(10).

The Xerox Arabic morphologizers, which are bidirectional morphologizers that take diacritized or undiacritized words as the input and compute the prefix, pattern, root, and suffix, were based on a finite-state transducer (FST) and utilize grammar rules rather than listing the stems. For example, Beesley's(11) Xerox finite-state morphological analyzer, which was built on finite-state transducer advancements to handle morphology and uses Xerox finite-state language modeling tools, is rule-based and has a large coverage. Because the Xerox finite-state morphological analyzer adopts a root-and-pattern approach, it can generate all possible morphological features for each word; 4,930 roots and 400 patterns that generate 90,000 stems; can also reconstruct the vowel marks, and provides an English glossary for each word. The Xerox finite-state morphological analyzer was based on the ALPNET developed earlier by Beesley and Buckwalter, which was founded on PC-KIMMO. This tool was constructed as two-level morphology by Antworth and Karttunen(20; 21).

The MAGEAD morphologizer system, which extended Kiraz's(22) work using AT&T's finite-state machine toolkit(23), decomposes an isolated diacritized word into prefix, pattern, root, and suffix and generates words from input morphemes, that is, it is a bidirectional morphologizer. MAGEAD also provides linguistic features, such as word class, in a hierarchical form; however, it is currently restricted to verbs. MAGEAD, which is based on a multitape finite-state transducer similar to the Xerox-based work of Beesley and Kiraz, has morphophonemic and orthographic rewrite rules that extend Kiraz's analysis by introducing a fifth tier: Tier 1: pattern and affixational morphemes; Tier 2: root; Tier 3: vocalism; Tier 4: phonological representation; and Tier 5: orthographic representation. In the generation direction, tiers 1 through 3 are always the input tiers, Tier 4 is first, an output tier and then, a subsequent input tier, and Tier 5 is always an output tier.

The AraComLex is an open-source data-driven Arabic morphologizer that utilizes a bidirectional FST and uses the lemma as its base form. As a lemma is a marked form of a word without affixes and is not inflected, it has shorter lexicons than stem-based methods and can benefit from generalized rules rather than listings. For Arabic, this is typically the perfective, 3rd person singular verbs or the singular indefinite form for nouns and adjectives. Other inflected forms are derived from the lemma using alteration rules, which is different from the root-based Xerox morphologizer and the stem-based BAMA/SAMA morphologizers.

Darwish's(15) tabular method is a morphological analyzer that uses automatically-derived rules and statistics from the "Build-Model" module in the morphologizer. This module takes a list of word-root pairs as the input, which allows it to extract a list of prefixes, suffixes, and stem templates. The probability of each item's occurrence in these lists is then used to generate the statistical rules. The Darwish Morphologizer has been found to have an 84% success rate(15). Its "Detect-Root" module extracts all possible roots for an input word by generating a prefix, suffix, and stem, removing the prefix and suffix from the stem, and matching the stem against the templates, with the resultant template (along with the stem) being used to determine the root.

The BAMA was first developed by Buckwalter and has since had three versions; BAMA[9] versions 1.0 and 2.0(16); and SAMA[10] 3.1.; all of which are available as source codes from LDC. The input and output are in transliterated Roman letters and the program is written in Perl.

SAMA's input is isolated words, that is, sentence context is not considered in the disambiguation. The input word may be either diacritized on undiacritized, with the output being all possible prefix, stem, and suffix combinations, that is, it is a stemmer rather than a deep morphologizer. As SAMA is non-bidirectional, words may not be generated from the prefix, stem, and suffix inputs. In addition to stemming, the BAMA/SAMA also provides a part of speech tag. Rather than incorporating grammatical rules, BAMA/SAMA uses manually entered lexicons and morphotactic rules as its tables, which makes it difficult to generalize and requires significant manual effort to scale. In addition to the tables that specify the allowable prefix, suffix, and stem set combinations, the lexicons also include prefix, suffix, and stem sets. BAMA 1.0 has 299 prefixes,

---

[9] https://catalog.ldc.upenn.edu/LDC2002L49, https://catalog.ldc.upenn.edu/LDC2004L02

[10] https://catalog.ldc.upenn.edu/LDC2010L01

618 suffixes, and 82158 stems, 1648 prefix-stem combinations, 1285 stem-suffix combinations, and 598 prefix-suffix combinations. SAMA 3.1 has 1328 prefixes, 945 suffixes, 79318 stems, 40654 stem categories, 2497 prefix-stem combinations, 1632 stem-suffix combinations, and 1180 prefix-suffix combinations. A simple Perl program uses these to segment a word into all possible prefix-stem-suffix set combinations. Although the BAMA/SAMA uses reasonably sized tables, it is quite efficient and compact.

ElixirFM uses SAMA resources and Haskell's functional morphology library to incorporate the interface between morphology and syntax and determine the morphophonemic patterns to identify the roots and templates for the SAMA lexical items. MADA (Morphological Analysis and Disambiguation for Arabic) uses Support Vector Machines to compute nineteen features; five for spelling variations and fourteen for morphological features, such as number, gender, case, and mood. MADAMIRA is a concatenative morphological analyzer that uses the Penn Arabic treebank as part of its training set. MADAMIRA (10) is a combination of the MADA, which was based on SAMA, and AMIRA (24), a morphological system for colloquial Egyptian Arabic).

### B. Arabic Phonetizers

Classical Arabic literature provides a rich set of pronunciation rules for classical Arabic(25). Recent publications provide pronunciation rules for modern Arabic that were extracted from traditional sources(26; 27). However, some rules that should be included have been excluded, others that should have been excluded because they relate to spelling have been incorporated, and the effect of text markers has been ignored, all of which have significant consequences on phonetization, which means that the pronunciation produced using these rules can have many errors.

In recent publications, gemination has been handled by doubling a singleton consonant or mapping into its singleton version, which is phonetically inaccurate as demonstrated by geminated plosives that have a single voice onset time and release. Similarly, a long vowel is dealt with by doubling its short version, whereas the spectral characteristics of a long vowel are noticeably different from its short vowel counterpart(**author?**) (5). Also, the rules related to Wasl characters (ب ف ك و) are ignored, even though they frequently occur. Four additional forms for (ء) (أ إ ؤ ئ), (آ), end of sentence vowels, mapping (ا) at the beginning of a sentence into a glottal stop, and the pronunciation of (ة) as /h/ at the end of the sentence are also not considered.(26) ignored short vowels at the end of a sentence by removing them and (آ), and(27) did not incorporate situations that require the mapping of (آ).

(28) used a rule-based two-level finite-state automata to develop an orthographic to allophonic mapping, with the first level being grapheme to grapheme changes such as deletion and duplication, and the second level being grapheme to phoneme changes. The allophonic changes are then applied to the phoneme level to produce an allophonic transcription and evaluate the system output on the diacritized words from the Penn Arabic treebank(29). While some of the problems in previous publications were resolved, duplication rather than gemination is employed and Sokoon is excluded from the rules when it uses

syllable structure to determine the pronunciation of waw, ya', and Alif Wasl. In addition, ta' marbutah is deleted rather than pronouncing it as /h/ at the end of an utterance.

APPENDIX B
FSPMD (SYSTEM) EVALUATION

</center>

### A. Reference Corpus for Evaluation

Tashkeela(6), PADT_UD treebank, and MADAMIRA(10) were used to evaluate and compare the performance of the developed morphology generator, analyzer, and diacritizer. Tashkeela, Wikipedia , and modern standard Arabic orthography to phoneme transcriptions as well as specific examples that highlighted edge cases were used to fully test the orthography to phoneme transcription system.

As FSAM performs generation, analysis, and diacritization tasks that cover both undiacritic and diacritic words, a corpus of diacritized Arabic was needed to evaluate the proposed system. Tashkeela is one of the few available corpora that satisfied our requirements as it is a collection of diacritized passages in Classical and modern standard Arabic. Further, as our system is a deep morphologizer that works at pattern and root levels, the PADT_UD treebank, which was built on the Prague Arabic Treebank (Hajic et al. 2004), was the only resource available for a granular generation and analysis evaluation because alternatives such as the Penn Arabic treebank (Maamouri et al. 2004) lack root information. The PADT_UD is the Universal Dependencies Prague Arabic Treebank of modern standard and colloquial Arabic that contains undiacritized words, with the analysis consisting of the root, the Vform (the diacritized word), gender, number, case, definite, voice, and others. The FSAM was compared with the MADAMIRA (in analysis-only mode), which is a concatenative morphologizer (a morphologizer that gives the features of the words such as number, gender, person, etc. but does not give the composition of the word in terms of its pattern and root) rather than a templatic morphologizer, which partially makes up for the absence of patterns and roots by utilizing the SAMA stem categories to provide some granular analysis.

*1) Fully diacritized text and corpus and treebank vocabulary:* The diacritized texts in the Tashkeela corpus were utilized to manually test the ability of our orthography to phonemic systems and to test the correctness of our model, IPA was used to transcribe the MSA fully diacritized sentences from Wikipedia.

The undiacritized and diacritized word vocabulary was computed in Tashkeela and PADT_UD. Table VI conveys the word statistics after the punctuation was removed.

*2) Gold sandard :* A gold standard was generated from the PADT_UD treebank as a reference for the evaluation of the analysis and generation capabilities. A gold standard must be free from punctuation, abbreviations (e.g., كم "km"), foreign words (e.g., واشنطن "Washington"), affixes (e.g., ال), and single-character graphemes (ت); which are not considered words in the Arabic language.

To eliminate words that were colloquial rather than modern standard Arabic, PADT_UD was intersected with Tashkeela, followed by the serial removal of affixes, single-character graphemes (letters), foreign words, and abbreviations. Table VI also details the statistics for the intersection between

TABLE VI. LEFT: DIACRITIZED VOCABULARY AND THE RESULTING UNDIACRITIZED WORDS IN EACH RESOURCE IGNORING PUNCTUATION. THE PADT_UD DIACRITIZED WORDS ARE THOSE LISTED AS VFORM (VOCALIZED FORM) IN ITS ANALYSIS OF UNDIACRITIZED WORDS. RIGHT: GOLD STANDARD TREEBANK IS THE INTERSECTION OF TASHKEELA AND THE PADT_UD FOLLOWED BY THE REMOVAL OF ISOLATED AFFIXES, LETTERS, FOREIGN WORDS, ABBREVIATIONS, AND ENTRIES WITH NO ANALYSIS (OOV)

| References Vocabulary | | | | | |
| --- | --- | --- | --- | --- | --- |
| | undiacritized | diacritized | | undiacritized | diacritized |
| Tashkeela | 481,611 | 982,922 | Intersection | 16,760 | 27,097 |
| PADT UD | 23,175 | 33,597 | Gold Standard | 16,469 | 26,772 |
| | | | Gold Standard - no OOV | 15,035 | 24,080 |

PADT_UD, Tashkeela, and the gold standard, which is the intersection that excludes affixes, foreign words (determined by Foreign = Yes in the PADT_UD analyses), and abbreviations (determined by Abbr = Yes in the PADT_UD analyses).

*3) Category correspondence:* There is a mismatch in groupings and terminologies between our system, PADT_UD, and MADAMIRA. As the proposed system is based on Arabic language constructs, it uses intrinsic categories; verb, noun, tool word, and proper name. The verbs and nouns are further classified as regular and irregular. In contrast, PADT_UD labels words according to the standard part-of-speech classification scheme in English, and MADAMIRA labels words according to stem classes in the underlying SAMA corpus.

TABLE VII. PADT_UD LABEL CORRESPONDENCE TO THE NOUN, VERB, TOOL WORD, AND PROPER NAME CATEGORIES, AND THE DIACRITIZED (DIAC) AND UNDIACRITIZED (UNDIAC) STATISTICS FOR EACH LABEL

| LABEL | CATEGORY | DIAC | UNDIAC |
| --- | --- | --- | --- |
| NOUN | noun proper name tool word | 14,405 | 8,424 |
| X | proper name tool word noun | 2,693 | 2,679 |
| VERB | verb | 4,603 | 3,551 |
| PART | tool word | 19 | 21 |
| CCONJ | tool word proper name | 83 | 49 |
| AUX | | 99 | 90 |
| PRON | tool word | 12 | 34 |
| ADV | tool word | 22 | 25 |
| DET | tool word | 34 | 37 |
| PROPN | proper name | 29 | 28 |
| ADJ | noun proper name | 5199 | 3587 |
| INTJ | noun tool word | 3 | 3 |
| ADP | tool word proper name noun | 94 | 105 |

A label can map onto more than one category. For instance, a noun in PADT_UD may be a noun, proper name, or tool word as it contains words such as ميراث (inheritance) "noun," دولار (dollar) "proper name," and كل (all) "tool word." Therefore, a word that is analyzed as a noun in PADT_UD and analyzed as a tool word in the proposed model is marked as a tool word and a match occurs.

Table VII details the correspondence between the

TABLE VIII. MADAMIRA LABEL CORRESPONDENCE TO THE NOUN, VERB, TOOL WORD, AND PROPER NAME CATEGORIES

| LABEL | CATEGORY | LABEL | CATEGORY | LABEL | CATEGORY |
| --- | --- | --- | --- | --- | --- |
| abbrev | proper name | noun quant | noun | part interrog | tool word |
| noun prop | proper name | noun num | noun | part neg | tool word |
| verb | verb | noun | noun | part restrict | tool word |
| verb pseudo | verb | adj | noun | part verb | tool word |
| adv | noun | adj comp | noun | part voc | tool word |
| adv interrog | noun | adj num | noun | prep | tool word |
| adv rel | noun | part | tool word | pron | tool word |
| conj | noun | part det | tool word | pron dem | tool word |
| conj sub | noun | part focus | tool word | pron interrog | tool word |
| interj | noun | part fut | tool word | pron rel | tool word |

PADT_UD labels and the categories in the proposed system. Table VIII details the MADAMIRA label correspondence to the various categories: noun, verb, tool word, and proper name.

### B. FSAM analysis evaluation

Table XI compares the MADAMIRA's and FSAM's verb and noun analyses. Because of the overlap between Penn Arabic treebank, which is used as the MADAMIRA training corpus, and UD_PADT, the basis of our gold standard, MADAMIRA analyzed around 100% of the gold standard verbs and nouns, whereas FSAM analyzed around 84% of verbs and nouns.

MADAMIRA categorized the word correctly 100% of the time and FSAM categorized it correctly 97% of the time. Both systems had similar performances at around 99% accuracy when computing gender (99.5% vs 99.4%), definitiveness (99.3% vs 98.0%), person (98.2% vs 99.9%), case (99.4% vs 99.8%), aspect (99% vs 99.9%), and voice (99.8% vs 97.9%). FSAM performed better for mood (99.7% vs 93%) and number (97.8% vs 90.5%), and found the root with approximately 92% correctness.

### C. FSAP (Phonetic Transducer) Evaluation

The full range of examples to test FSAP are provided in Tables XII, XIII and XIV. In addition to the IPA non-phonemes of continuation (⌣), medium duration pause (|), and long duration pause (‖), we used zero duration pause, short duration pause, and not pronounced to more comprehensively reflect the morphophonetic relationships. These are the only expected differences between the Expected IPA and Output.

Table XII tests FSAP in all context dependent pronunciation environments, and as can be observed from the table, the system performs with 100% accuracy in those examples. Table XIII uses diacritized text from the Tashkeela corpus(6) to evaluate the system on diverse examples. Both tables XII and XIII don't have the expected IPA transcription as part of the corpus, so we used a language expert to transcribe the sentences into IPA to get the expected output.

TABLE IX. FSAM-GENERATED STEM VOCABULARY FOR EACH SUB-CATEGORY AND CATEGORY (TOP), AND MADAMIRA TABULATED STEM VOCABULARY (BOTTOM). *UNK MEANS THAT THE REFERENCE HAS NO STEM CATEGORIZATION. NO COUNTERPART IN MADAMIRA UNLESS THEIR REFERENCE - SAMA (HAS A LISTING OF STEMS) - IS DIRECTLY UTILIZED. NOUN, VERB, TOOL WORD, AND PROPER NAME CATEGORIES ARE BASED ON THE LABEL CORRESPONDENCE IN THE MADAMIRA REFERENCE TABLE SHOWN IN TABLE VIII. NOTE THAT A STEM HAS MULTIPLE LABELS IN THE REFERENCE

| Stem Vocabulary | | | | | |
|---|---|---|---|---|---|
| FSAM | undiacritized | diacritized | MADAMIRA | undiacritized | diacritized |
| regular verb | 579,522 | 1,882,047 | verb | 4,269 | 4,843 |
| irregular verb | 98,668 | 282,611 | noun | 11,950 | 12,763 |
| regular noun | 716,177 | 2,192,815 | toolword | 32 | 37 |
| irregular noun | 157,322 | 405,834 | proper name | 544 | 556 |
| toolword | 238 | 261 | UNK* | 8,849 | 11,897 |
| proper name | 7,681 | 8,352 | | | |
| TOTAL | 1,196,895 | 4,018,302 | TOTAL | 24,055 | 29,685 |

TABLE X. OVERLAP COUNT BETWEEN THE SYNTHESIZED UNDIACRITIZED STEMS AND THE GOLD STANDARD STEMS. THE INTERSECTION IS BETWEEN THE GOLD STANDARD AND SYNTHESIZED STEMS. MISSING IS THE SET GOLD STANDARD STEMS, THAT IS, THE SYNTHESIZED STEMS. AS THERE IS NO REFERENCE TO MADAMIRA FOR THE GENERATION OF STEMS FROM ROOTS, THE OVERLAP OF STEMS WAS CHECKED FROM THE UNDERLYING LISTING FOR THE GOLD STANDARD STEMS (8,536 STEMS)

| Generated Stem Overlap with the Gold Standard Stems | | |
|---|---|---|
| UNDIAC | FSAM | MADAMIRA |
| Intersection | 6,622 | 5,146 |
| Missing | 1,914 | 3,390 |
| Total | 8,536 | 8,536 |

TABLE XI. ANALYSIS ACCURACY FOR THE UNDIACRITIZED WORDS FOR THE GOLD STANDARD TREEBANK. ON THE LEFT IS FSAM (F) AND ON THE RIGHT IS MADAMIRA (M). TO PRODUCE ROOTS, THE MODEL OUTPERFORMED IN MOOD, NUMBER, AND VOICE PROPERTIES. MADAMIRA HAD ALMOST FULL COVERAGE OF THE GOLD REFERENCE BECAUSE OF THE OVERLAP BETWEEN THE TRAINING DATA AND THE REFERENCE

| Analysis Performance FSAM (F) vs MADAMIRA (M) | | | | | | |
|---|---|---|---|---|---|---|
| UNDIAC | verb | | noun | | noun+verb | |
| | F | M | F | M | F | M |
| analyzed | 94.9 | 99.9 | 83.4 | 99.8 | 83.8 | **99.8** |
| category | 99.0 | 99.9 | 96.8 | 100 | 97.0 | 100 |
| root | 94.0 | NA | 91.8 | NA | **92.3** | NA |
| case | - | - | 99.4 | 99.8 | 99.4 | 99.8 |
| gender | 99.4 | 100 | 99.6 | 98.9 | 99.5 | 99.4 |
| mood | 99.7 | 92.2 | - | - | **99.7** | 92.2 |
| definite | - | - | 99.3 | 98.0 | 99.3 | 98.0 |
| number | 99.3 | 100 | 97.4 | 88.0 | **97.8** | 90.3 |
| person | 98.2 | 99.9 | - | - | 98.2 | 99.9 |
| voice | 99.8 | 97.7 | - | - | 99.8 | 97.7 |
| aspect | 99.0 | 99.9 | - | - | 99.0 | 99.9 |

Table XIV tests the system on peer reviewed examples from Wikipedia [11] which contains the diacritized text and the corresponding expected IPA transcription.

Supplement 1: Arabic Orthography, Phonology, and Morphology
Compendium

*Abstract*—Concise and specific information on modern standard Arabic (MSA), which can also be used as a standalone MSA reference, is given as a background to the main text and covers topics, such as textual marks and fermatas that significantly affect the phonetic transcription of text transformations that are not normally discussed in other texts in English. Minimal consonant pairs, geminates, and vowels to indicate phonemic contrasts are also given. To avoid confusion, the original Arabic symbols were retained rather than using Roman transliteration. Other than minimal pairs, the compendium was compiled from various Arabic references (7; 30).

## A   Orthography

Modern Standard Arabic (MSA) is written cursively from right to left, with the letter shapes changing according to the position. MSA has forty-six characters; twenty-eight alphabet letters, ten non-alphabet letters, and eight diacritics; and ligatures (لا,لأ,لأ,لإ), which are letter combinations used when writing but are not counted as characters because they are only graphical representations. Tables XV and XVI show the MSA script alphabet and non-alphabet letters and the diacritics. Table XVI presents the alphabet letter shapes based on their position in a word, an example word containing the alphabet letter, its IPA transcription using segmental phonology, and the word meaning.

Table XVI introduces the ten non-alphabet letters, four (أ, إ, ئ, ؤ) of which are part of the five-member "Hamza sisters," and the fifth being the alphabet letter (ء). Five of the non-alphabet letters (ا, ى, ة, آ, ٱ) produce complexities as they map to one or more sounds based on their position in the word and the surrounding words; this is discussed in more detail in later sections. Kasheeda (ـ) is used for graphical justification and elongation and has no underlying pronunciation. The letter mad (٘) is part of MSA but is non-existent on computer keyboards and, therefore, is missing in modern texts and needs to be added to the thirteen words that contain it before any processing.

Table XVII lists the diacritics, which may not be at the start of a word, and divides the diacritics into three categories: Harakah (◌َ, ◌ِ, ◌ُ), Tanween (◌ً, ◌ٍ, ◌ٌ), and other (Shaddah ◌ّ; Sukoon ◌ْ). A Harakah character is pronounced as a short vowel, a Tanween character is pronounced as a combination of a short vowel and /n/ and can only occur at the end of a word, Sukoon (◌ْ) is a zero-length pause, and as Shaddah (◌ّ) indicates the gemination of the sound it follows, it cannot be preceded by a diacritic.

Diacritics cannot be consecutive, except for Shaddah (◌ّ), which is generally followed by Harakah and sometimes by Tanween or Sukoon. Other rules restrict a sequence of characters; for example, إ can only be followed by a kasra, أ is only followed by Sukoon, dhamma, or fatha, ؤ may not be followed by kasra, shaddah, and ya' and can only be preceded by dhama, ئ cannot be followed by a shaddah and is only preceded by kasra, and ء cannot start a word.

Five MSA letter groupings are related to pronunciation: Hamza, Wasl, Solar, and Lunar. The Hamza set {ئ ؤ ء إ أ} are pronounced as glottal stops, and the Wasl symbols {ك ل ت ب و} are characters that affect the pronunciation of ا; for example, if

any of the Wasl symbols precede ا when ا is at the start of the word, then ا is not pronounced.

The Solar set {ت ث د ذ ر ز س ش ص ض ط ظ ن ل} and the Lunar set {ب ج ح خ ع غ ف ق ك م ه و ي ء إ أ} are grouped because the Solar and Lunar letters affect the pronunciation of ل in a very specific character environment (when it is part of the definite article in Arabic: ال); for example, when a Solar letter follows ل, then ل is not pronounced, but when a Lunar letter follows ل, it is pronounced.

It is also important to describe the text markings as they not only correspond to "sounds" but also regulate the contextual pronunciation of the consonants as detailed in the rules presented in the main manuscript. Table XV details the marks and their corresponding fermatas.

TABLE XV. Marks and their Corresponding Pauses and Continuations

| Description | Mark | Mark symbol | Fermata | IPA symbol | System symbol |
|---|---|---|---|---|---|
| | | End of File, eof, | | | |
| Between paragraphs, sentences | Start of File tab, new line | sof \t, \n | Long duration pause | ‖ or (…) | α |
| Between phrases | . ! ; | !;.? | Medium duration pause | | or (.) | ω |

## B   Segmental Phonology

MSA is a Semitic language with 55 consonants and six vowels. In addition to labio-dental and velar sounds, MSA is rich in glottal, uvular, and pharyngeal sounds such as /ʕ/, and has regular and velarized or pharyngealized pairs, such as /d/

and /dˤ/. The geminated counterparts of the phonemes are also MSA phonemes.

MSA has eight plosives; one bilabial /b/, four alveolars /t/, /d/, /tˤ/, /dˤ/, one velar /k/, one uvular /q/, and one glottal /ʔ/); two nasals; bilabial /m/ and alveolar /n/; one alveolar trill; /r/; thirteen fricatives; one labiodental /f/, three dental /θ/, /ð/, /ðˤ/, three alveolars /s/, /z/, /sˤ/, one postalveolar /ʃ/, two uvular /χ/, /ʁ/, two pharyngeal /ħ/, /ʕ/, and one glottal /h/; two approximants; one bilabial /w/ and one palatal /j/; one postalveolar affricate; /d͡ʒ/; and an alveolar lateral approximant; /l/. MSA has only six long and short vowels: /aː/, /iː/, /uː/, /a/, /i/, /u/. Table XIX shows the consonant chart, with the consonants based on voicing, pharyngealization, place of articulation, and manner of articulation. Table XX enumerates the geminated consonantal phonemes with examples. Table XVIII presents the vowel chart. Minimal pairs that validate the phonemes are in Appendix A.

Phonemes are also grouped based on the pronunciation of their related character: coronals; dental, alveolar, and postalveolar, with /θ/, /ð/, /ðˤ/, /r/, /n/, /t/, /d/, /tˤ/, /dˤ/, /s/, /z/, /sˤ/, /l/, /ʃ/, /d͡ʒ/ being the phonemes the Solar letters map to; and non-coronals; bilabial, labiodental, palatal, velar, uvular, pharyngeal, and glottal, with /b/, /m/, /w/, /f/, /j/, /k/, /q/, /χ/, /ʁ/, /ħ/, /ʕ/, /ʔ/, /h/ being the phonemes Lunar letters map to. Hamzah sisters map to the glottal stop, Harakah map to short vowels, Tanween maps to a short vowel followed by /n/ depending on the context, and Shaddah causes gemination.

TABLE XVIII. VOWEL CHART: UPPER LEFT IS NORMAL UNROUNDED, UPPER RIGHT IS NORMAL ROUNDED, LOWER LEFT IS LENGTHENED AND UNROUNDED, AND THE LOWER RIGHT IS LENGTHENED AND ROUNDED

|  | Front | Central | Back |
|---|---|---|---|
| Close (high) | i<br>iː |  | u<br>uː |
| Mid |  |  |  |
| Open (low) | a<br>aː |  |  |

TABLE XIX. CONSONANT CHART : THE SYMBOL ON THE TOP RIGHT IS NORMAL VOICED, THE SYMBOL ON THE TOP LEFT IS NORMAL UNVOICED, THE SYMBOL ON THE BOTTOM RIGHT IS PHARYNGEALIZED VOICED, AND THE SYMBOL ON THE BOTTOM LEFT IS PHARYNGEALIZED UNVOICED

|  | Bilabial | Labio-dental | Dental | Alveolar | Post-alveolar | Palatal | Velar | Uvular | Pharyngeal | Glottal |
|---|---|---|---|---|---|---|---|---|---|---|

| Lateral Approximant |  |  |  | l |  |  |  |  |  |  |

## C   MORPHOLOGY

Morphology deals with the internal structure of words. More specifically, it dictates the composition of a word from smaller meaningful units called morphemes. There are two approaches to morphology; form-based and functional. Form-based morphology considers the form of the units making up a word, their interactions, and how they relate to the word's overall form. Functional morphology is about the function of the units inside

TABLE XX. MSA GEMINATED PHONEMES. ALL CONSONANTS EXCEPT FOR THE GLOTTAL STOP. THE EXAMPLES BELOW SHOW WORDS WITH GEMINATED CONSONANTS

| Phone | Word | IPA | Gloss | Phone | Word | IPA | Gloss |
|---|---|---|---|---|---|---|---|
| [bː] | تبًا | /tabːan/ | perish! | [tˤː] | الطبيب | /ʔtˤːabiːb/ | the doctor |
| [tː] | التل | /ʔtːal/ | the hill | [ðˤː] | الظل | /ʔðˤːil/ | the shadow |
| [θː] | الثلاثاء | /ʔθːulaːθaːʔ/ | Tuesday | [ʕː] | لعّب | /laʕːaba/ | he played with |
| [d͡ʒː] | أجّل | /ʔd͡ʒːala/ | delayed | [ʁː] | صغر | /sauʁːara/ | he made smaller |
| [hː] | وحّد | /wahːda/ | united | [fː] | أفّ | /ʔufːin/ | expressing impatience/contempt |
| [χː] | أخّر | /ʔaχːara/ | delayed | [qː] | وقّت | /waqːata/ | he timed |
| [dː] | الدّمار | /ʔdːamaːr/ | the destruction | [kː] | أكّل | /ʔkːala/ | he fed |
| [ðː] | الذّنب | /ʔðːanb/ | the sin | [lː] | اللمس | /ʔlːams/ | the touch |
| [rː] | الرّز | /ʔrːuz/ | the rice | [mː] | نمّام | /namːam/ | he who spreads scandals |
| [zː] | الزّوج | /ʔzːawd͡ʒ/ | the husband | [nː] | النّمر | /ʔnːimr/ | the tiger |
| [sː] | السّماء | /ʔsːamaːʔ/ | the sky | [hː] | وهّم | /wahːam/ | puzzled somebody |
| [ʃː] | الشّمس | /ʔʃːams/ | the sun | [wː] | توّاب | /tawːab/ | repentant |
| [sˤː] | الصّباح | /ʔsˤːabaːh/ | the morning | [jː] | جيّد | /d͡ʒajːit/ | good |
| [dˤː] | الضّفدع | /ʔdˤːufdaʕ/ | the frog |  |  |  |  |

Fig. 5. Arabic word morpheme breakdown. A word is a concatenation of a prefix, stem, and suffix (concatenative). A stem is a meaning-bearing unit that can be further decomposed into its root and pattern (templatic). The root gives the core meaning and the pattern provides the part of speech (POS, category) and other linguistic properties, such as number, tense, and gender. This image uses the Buckwalter transliteration scheme (www.qamus.org/transliteration.htm).

a word and how they affect its overall syntactic and semantic behavior.

Fig. 5 illustrates the structure of Arabic words. Arabic utilizes form-based morphology and has concatenative and templatic morphemes (smallest units in a word). Concatenative morphology is centered on stems and affixes (prefixes, suffixed, circumfixes), and the morphemes are generally concatenated in a sequence to produce a surface form (word). Morphological grammar that constructs stems from the interdigitation (interleaving) of the root and pattern is called templative morphology. In Arabic, morphological form and function are independent although most templatic processes are derivational and most concatenative processes are inflectional. Derivational functional morphology is concerned with creating new words from other words, and in inflectional morphology, the meaning and part of speech remain the same (31).

The two broad morpheme classes in concatenative morphology are stems and affixes. Stems are the core meaning-bearing units, and affixes are added before and after stems to alter the meaning and function. An affix may be a prefix (concatenated before the stem), a suffix (concatenated after the stem), or a circumfix, with parts added before and after a stem. The stem can be templatic (derived) or non-templatic (fixed). Templatic stems are stems that can be formed using templatic morphemes, whereas non-templatic word stems are not derivable from templatic morphemes and tend to be of foreign origin or names.

### Appendix A
#### A. Minimal Pairs/near-minimal Pairs (Evidence for the MSA Phonemic Inventory)

The sounds of Modern Standard Arabic (MSA) could be classified as phonemes or allophones. In order to differentiate between phonemes and allophones, a list of minimal or near-minimal pairs have been found for all the phonemes in MSA. Two things to note include: (1) The diacritics convey the vowel sounds, which is why the correct diacritics are important to correctly phonetically transcribe orthography. (2) There are MSA characters that convey the vowel sounds.

Table XXI lists the minimal / near minimal pairs for non-geminated consonants. Table XXII lists the minimal / near minimal pairs for geminated consonants that are compared to the non-geminated version of the consonant. Table XXIII list the minimal / near minimal pairs for the short and long vowels, and Table XXIV conveys that the long and short vowels are contrastive.

TABLE XXI. Minimal Consonant Pairs

| Contrastive Phones | | Shared Property | Minimal Pair / Near-Minimal Pair | | |
|---|---|---|---|---|---|
| Phone 1 | Phone 2 | | Word | IPA | Gloss |
| /t/ | /d/ | alveolar stops | دُب | [dub] | bear |
| | | | تُب | [tub] | repent |
| /s/ | /sˤ/ | voiceless alveolar fricatives | سُورَة | [surah] | chapter of the Qur'an |
| | | | صُورَة | [sˤurah] | picture |
| /l/ | /r/ | liquids | لَان | [la:n] | relent, soften |
| | | | رَان | [ra:n] | seize; overcome; prevail |
| /ʕ/ | /ħ/ | pharyngeal fricatives | غُلِب | [ʕulːib] | was boxed |
| | | | حُلِب | [ħulːib] | was milked |
| /q/ | /k/ | unvoiced plosives | قَلْب | [qalb] | heart |
| | | | كَلْب | [kalb] | dog |
| /m/ | /n/ | voiced nasals | مَال | [mala] | swayed |
| | | | نَال | [nala] | gained |
| /ʃ/ | /d͡ʒ/ | postalveolar | أشمل | [ʔaʃmal] | more general |
| | | | أجمل | [ʔad͡ʒmal] | more beautiful |
| /ð/ | /ðˤ/ | voiced dental fricatives | ذَلك | [ðalik] | that 'male' |
| | | | ظَالِم | [ðˤalim] | unjust/ oppressive |
| /z/ | /s/ | alveolar fricatives | زَاهِر | [za:hir] | blooming |
| | | | سَاهِر | [sa:hir] | up late into the night |
| /q/ | /χ/ | voiceless uvular fricatives | قَدَم | [qadam] | leg |
| | | | خَدَم | [χadam] | servants |
| /ʃ/ | /f/ | voiceless fricatives | شَعَل | [ʃaqala] | lit |
| | | | فَعَل | [faqala] | 'he' did |
| /ʁ/ | /ʕ/ | voiced fricatives | غالي | [ʁa:liː] | expensive |
| | | | عالي | [ʕa:liː] | high |
| /b/ | /m/ | voiced bilabials | بَال | [ba:la] | urinated |
| | | | مَال | [ma:la] | tilted |
| /ʔ/ | /h/ | unvoiced glottals | مُؤْمِن | [muʔmin] | faithful |
| | | | مَهْمِل | [muhmil] | careless |
| /θ/ | /ð/ | dental fricatives | ثَمَر | [θamar] | fruit |
| | | | ذَهَب | [ðahab] | gold |
| /j/ | /w/ | voiced approximants | بَيْت | [bajt] | house |
| | | | مَوْت | [mawt] | death |
| /t/ | /tˤ/ | voiceless alveolar plosives | تَبِيت | [tabiːt] | she sleeps over |
| | | | طَبِيب | [tˤabiːb] | doctor |
| /d/ | /dˤ/ | voiced alveolar plosives | دَمَار | [dama:r] | destruction |
| | | | ضَمِير | [dˤamiːr] | conscience |

TABLE XXII. Geminated Characters are Language Phonemes and Contrast the Nongeminated Phonemes

| Phoneme | Word (geminated) | IPA | Gloss | Word (un-geminated) | IPA | Gloss |
|---|---|---|---|---|---|---|
| b | حبّ | /habːa/ | had loved | حب | /hab/ | a seed |
| t | التلّ | /ʔatːal/ | the hill | تل | /tal/ | hill |
| θ | الثّلاثاء | /aθːulaːθaːʔ/ | Tuesday | تمر | /θamar/ | fruit |
| d͡ʒ | أجّل | /ʔadʒːala/ | delayed | أجل | /ʔadʒal/ | time |
| h | وحّد | /wahːda/ | had united | وحد | /wahada/ | united |
| χ | أخّر | /ʔaχːara/ | delayed | آخر | /ʔaχar/ | other |
| d | الدّمار | /ʔadːamaːr/ | the distruction | دمار | /damaːr/ | distruction |
| ð | الذّنب | /ʔaðːanb/ | the sin | ذنب | /ðanb/ | sin |
| r | الرّز | /ʔarːuz/ | the rice | رز | /ruz/ | rice |
| z | الزّوج | /ʔzːawdʒ/ | the husband | زوج | /zawdʒ/ | husband |
| s | السّماء | /ʔasːamaːʔ/ | the sky | سماء | /samaːʔ/ | sky |
| ʃ | الشّمس | /ʔaʃːams/ | the sun | شمس | /ʃams/ | sun |
| sˤ | الضّباح | /ʔasˤːabah/ | the morning | صباح | /sˤabaːh/ | morning |
| dˤ | الضّفدع | /ʔadˤːufdaʕ/ | the frog | ضفدع | /dˤufdaʕ/ | frog |
| tˤ | الطّبيب | /ʔatˤːabiːb/ | the doctor | طبيب | /tˤabiːb/ | doctor |
| ðˤ | الظّل | /ʔaðˤːil/ | the shadow | ظل | /ðˤil/ | shadow |
| ʕ | لعّب | /laʕːaba/ | played with | لعب | /laʕab/ | played |
| ʁ | صغّر | /saʁːara/ | made smaller | صغر | /saʁar/ | became smaller |
| f | أفّ | /ʔufːin/ | expressing impatience or contempt | لف | /luf/ | wrap (command) |
| q | وقّت | /waqːata/ | timed | وقت | /waqt/ | time |
| k | أكّل | /ʔakːala/ | fed | أكل | /ʔakala/ | ate |
| l | اللّمس | /ʔlːams/ | the touch | لمس | /lams/ | touch |
| m | نمّام | /namːaːm/ | person who spreads scandals | سمع | /samaʕ/ | heard |
| n | النّمر | /ʔanːimr/ | the tiger | نمر | /nimr/ | tiger |
| h | وهّم | /wahːam/ | puzzled somebody | وهم | /wahm/ | assumed |
| w | توّاب | /tawːab/ | repentant; remorseful; regretful | مواد | /mawaːd/ | material |
| j | أيّد | /ʔajːad/ | supported | يد | /jad/ | hand |

TABLE XXIII. Minimal Vowel Pairs

| Contrastive Phones | | Shared Property | Minimal Pair / Near-Minimal Pair | | |
|---|---|---|---|---|---|
| Phone 1 | Phone 2 | | Word | IPA | Gloss |
| /i:/ | /u:/ | vowel - high | فُول | [fu:l] | type of Levantine bean dish |
| | | | فِيل | [fi:l] | elephant |
| /i/ | /a/ | vowel - front | أُمَّك | [ʔum:ak] | your mother - 'to male' |
| | | | أُمِّك | [ʔum:ik] | your mother - 'to female' |
| /i:/ | /a:/ | vowel - front - long | قِيل | [qi:l] | it was said |
| | | | قَال | [qa:l] | he said |
| /i:/ | /u/ | vowel - high | قِيل | [qi:l] | it was said |

TABLE XXIV. Minimal Pairs to Show that Long and Short Vowels are Contrastive

| Contrastive Phones | | Minimal Pair / Near-Minimal Pair | | |
|---|---|---|---|---|
| Phone 1 | Phone 2 | Word | IPA | Gloss |
| /i:/ | /i/ | فيل | /fi:l/ | elephant |
| | | فلم | /film/ | movie |
| /a:/ | /a/ | بادر | /ba:dara/ | took initiative |
| | | بدر | /badr/ | full moon |
| /u:/ | /u/ | ثوم | /θu:m/ | garlic |
| | | ثمّ | /θum:a/ | then |

Supplement 2: Finite-state Machines for Linguistics

### A  AUTOMATA HIERARCHY AND POWER

In comparison to other automata, finite-state machines (FSMs) have the least computing power beyond finite languages and can process regular expressions. More powerful complex automata and languages are push-down automata for context-free languages; embedded push-down automata for mildly context-sensitive (linear indexed) language; nested stack automata for indexed language; linear bounded automata for context-sensitive language; always halting Turing automata for recursive language; and the Turing machine for recursively enumerable language (all formal languages). Fig. 6 illustrates the hierarchy of formal languages (32).

Fig. 6. Formal languages and associated automata; https://www.cs.rochester.edu.

### B  DEVELOPMENT FSM AND COMPILATION TOOLS

Finite-State Machines (FSMs) are either finite-state automata (FSA), which are acceptors of strings constructed to define sets of characters, or finite-state transducers (FSTs), which convert an input string into an output string using contextual or non-contextual replacement, insertion, or deletion. FSAs and FSTs are written using regular expressions and are closed under operations such as concatenation and union. FST is bidirectional and hence input and output can be inverted for the same FST.

The author in (33) constructed cascaded FSTs, with an FST mapping one character at a time between input and output. (34) developed an FST in which the rules were executed in parallel and obligatory or optional single-character mapping rules were allowed. This approach was implemented in various systems such as KIMMO and PC-KIMMO (35; 21; 20).

Bear introduced a unification-based grammar for morphotactic parsing and used diacritics coded in lexical entries to allow the rules to apply to a subset of the lexicon (36; 37). This formalism was adapted by various implementations, which allowed a rule to map between equal-sized input and output string subsequences rather than single characters (38; 39; 40; 41; 42).

Ruessink's formalism allows unequal size sequences and explicit contexts; however, this results in some invalid combina-

tions (43). Pullman and Hepple extended Ruessink's formalism by adding rule features; however, their proposal had problems with the interpretation of obligatory rules. Carter suggested that Pullman and Hepple's formalism was impractical for specifying the mappings between unequal-length sequences (44). Grimley-Evans, Kiraz, and Pulma redefined the obligatory rules in Ruessink's formalism (45).

Algorithms exist for the compilation of rules written as regular expressions into automata (33). Computationally, parsers and compilers for regular expressions are O(n), where n is the length of the input string. Widely available FST compiler tools include Lex, Flex, xfst from Xerox, HFST, Foma, and OpenFST. Foma (4) is an open-source library for unweighted FSTs that has an interface similar to the proprietary XFST from Xerox. OpenFST is suitable for dealing with weighted transducers and has been considered a better tool than the FSM Library of AT&T. In addition, more powerful automata are available in the Natural Language Toolkit (46).

### C  FST FOR COMPUTATIONAL LINGUISTICS

A finite-state transducer (FST) can model most phonological rules, possibly with exceptions related to some stress and tone rules (47), which has been independently verified by (33) (21; 48). Many finite-state models are also available for phonology (49). Cascade and other extensions of finite-state technology are also available (50).

An important FST class is a two-level finite-state formalism that allows the mapping rules between input and output strings to be implemented with finite-state transducers. The same automaton can be used for analysis (decomposition) and synthesis (generation), thereby providing bidirectionality. The two-level formalism and its generalization to multi-levels are used for the phonological analyzer and the concatenative and templatic morphology analyzer.

### D  MULTI-LEVEL FINITE-STATE FORMALISM

(51) described a root-and-pattern morphology FST. (35) proposed a two-level system for language morphology. (52) proposed a framework in which each of the autosegmental tiers was assigned a tape in a multitape finite-state machine, with an additional tape for the surface form. Kay's approach followed the CV model and used four-tape automata, which was an extension of the traditional FST. (52) also proposed a framework for handling templatic morphology in which each templatic morpheme was assigned a tape in a multitape finite-state machine and an additional tape for the surface form.

The two-level formalism has been extended to multiple levels, as illustrated in Fig. 7, in which the templatic morphemes are roots, patterns, and vocalisms. The vocalism morpheme specifies the short vowels to use with a pattern; in contrast, traditional accounts of Arabic morphology collapse the vocalism into the pattern.

The advancement to templatize morphology was achieved by having multiple inputs (tapes) to the FSTs based on linguistic abstractions of Semitic nonlinear morphology. However, such constructs handle only a subset of Arabic words, such as verbs, nouns, or broken plurals.
Fig. 7. Three-level FST where the pattern, root, and vocalism are the input tapes.

McCarthy's CV-based model was presented for Arabic morphology under an autosegmental phonology framework to handle verbs (51; 53). A stem is represented by three tiers: the root, vocalism, and a CV pattern. Associations are made based on well-formed conditions, association conventions, and additional rules. The Moraic model uses a different vocabulary to represent the pattern morph based on the noun prosody (54), while the Affixational model derives several templates using affixation under prosodic circumscription for verbs (55).

Infixation and reduplication are handled within the standard two-level morphology using diacritics (20). Kay's approach followed the CV model using a four-tape automaton, which was an extension of the traditional FST (52). (56) used a lexical component that takes the intersection of rules and pattern expressions and produces verbal stems, with the stems being the input for a standard two-level system. (56) also presented a system for handling Akkadian root-and-pattern morphology by adding an additional lexicon component to Koskenniemi's two-level morphology (34). Beesley's intersection approach is probably the largest system for Arabic morphology (57; 39; 58). Beesley later compiled all combinations into a transducer (59).

### E  CONCATENATIVE MORPHOLOGICAL FORMALISM

The state-of-the-art concatenative morphological formalism consists of three components: lexical automata, morphotactic rules, and rewrite rules (60). Finite-state automata are constructed to represent prefixes, stems, and suffixes. The prefix, stem, and suffix are concatenated with markers separating them to form a lexical form based on morphotactic rules that specify valid combinations. Orthographic changes that need to be made to the lexical form to yield the surface form (word) are coded using rewrite rules incorporating contextual mappings and are implemented using an FST.

Morphotactic rules can be implemented in an FST with continuation classes using filters (34; 20; 21). Continuation classes are, however, inappropriate for handling separated dependencies, interdigitation, infixation, and reduplication, and, therefore, flag diacritics are used to address the separated dependencies, discontinuous dependencies, and long-distance dependencies within the FST framework. However, as using FSTs

can be awkward, context-free grammar (with feature unification if necessary) is used to address the complex dependencies (36; 39; 40; 41; 42; 49).

### F  TEMPLATIC MORPHOLOGICAL FORMALISM

(61) embedded pattern and vocalism morphs in the surface expression of the rules, (62) extended the two-level model by adding a third abstract level for inflection patterns, and Kiraz (1994) developed a two-level formalism based on Kay's approach that could handle CV, Moraic, and Affixational models. The first large-scale Arabic morphology implementation within finite-state method constraints, which was conducted by (39), included a 'detouring' mechanism to access multiple lexica, which was the forerunner to other studies by (63). (33) constructed cascading FSTs, in which an FST mapped one character at a time between the input and output. Subsequent advancements in this approach can be found in (63), (50), and (16). Cascade and other extensions of finite-state technology are also available (16). (64) extended Kay's approach and implemented a multi-tape system for MSA.

### G  PHONOLOGY FORMALISM

(65) modeled autosegmental phonology using FSTs, in which the autosegmental phonology was coded as linear strings, (49) used a one-level phonological approach to code autosegmental representations as a triangular prism, and (66) used multilinear coding that was processed using state labeled finite automata, which were shown to be more powerful than FSTs.

# Applications of Artificial Intelligence for Information Diffusion Prediction: Regression-based Key Features Models

Majed Algarni*, Mohamed Maher Ben Ismail

King Saud University, College of Computer and Information Sciences
Department of Computer Science, Saudi Arabia

*Abstract*—Information diffusion prediction is essential in marketing, advertising, and public health. Public health officials may avoid disease outbreaks, and businesses can optimize marketing campaigns and target audiences. Information diffusion prediction helps identify influential nodes in social networks, enabling targeted interventions to spread positive messages or counter misinformation. Organizations can make informed decisions and improve society by analyzing information propagation patterns. This research study investigates the prediction of information diffusion on social media platforms using a diverse set of features and advanced machine learning and deep learning models. We explore the impact of network structure, early retweet dynamics, and tweet content on social media, provided by the publicly available dataset Weibo, a social network like Twitter. By applying the training of the models on set of features separately, we observed different performances. The Random Forest model using all features achieved an R-squared of 76.690%. The Random Forest (RF) model focusing on the following network structure achieved an R-squared of 90.773%. The RF model analyzing the retweeting network structure achieved an R-squared of 98.161%.

*Keywords—Information diffusion; social media data; machine learning; deep learning*

## I. INTRODUCTION

In our current digital age, the number of Internet users has increased, which has been accompanied by an increase in the number of users of social media. This was reflected significantly in the speed of exchanging and sharing information through social media platforms. Information is divided by its nature into useful and harmful, directly affecting society in economic, political and commercial terms [1]. The dissemination of this information can be studied and predicted in terms of and is affected by many variables, such as the timing of the publication [2], as well as the content of the publication, and the characteristics of the participating users [3,4]. A comprehensive understanding of the dynamics of information spread on social media platforms can provide valuable insights in various domains, including marketing, disaster management, and community detection. The dissemination of information via social media is a multifaceted process that relies not only on the substance of the communicated content but also on the method of transmission. The comprehension of the mechanisms by which information is conveyed through these networks is progressively imperative due to the escalating migration of various aspects of our

existence to online platforms. The spread of information through social media sites like Twitter and Facebook has greatly impacted. The study of how information spreads on these platforms is complex and constantly changing, which is why it's attracted so much attention from researchers. By understanding how information spreads, we can predict how popular information will become, maximize the influence spread, and monitor how cascades develop. On Twitter, users can "retweet" or share a tweet with their followers, which helps information spread even faster. The Popularity of a tweet is measured by its content and how many times it's been retweeted. By understanding how information spreads on social media, platforms can better monitor and guide the spread of information in different scenarios like online advertising, viral marketing, and fake news detection. Several approaches to predicting information diffusion exist but machine learning and deep learning techniques [5, 6] have recently shown much promise.

In this study, the authors proposed Machine learning and deep learning models to improve our forecasts using a publicly available dataset provided by authors in [7]. This dataset was collected from Weibo, a social network like Twitter. The authors applied the models to features such as following network structure, retweeting network structure, early-stage popularity dynamics, and tweet content. Our study offers significant contributions to the domain of predicting information diffusion on social media platforms.

*1) Comprehensive examination:* Our study delves into the dissemination of information on social media platforms through the utilization of an extensive array of features and sophisticated machine learning and deep learning models.

*2) An examination of essential factors for comprehension:* In this study, we investigate the influence of network structure, early retweet dynamics, and tweet content on information diffusion. Through our analysis, we aim to gain valuable insights into the underlying factors that contribute to information propagation.

*3) Model performance:* The models trained using distinct sets of features in order to evaluate their performance. The RF model based on all features demonstrated an R-squared value of 76.690%, whereas the model that specifically targeted the indicated network structure exhibited an R-squared value of 90.773%. The RF model utilized for analyzing the retweeting

*Corresponding Author.

network structure exhibited a high R-squared value of 98.161%.

*4) Real-world applications:* It refers to the practical utilization of knowledge, theories, and concepts in various fields. These applications involve The results of our study have the potential to assist the organizations in enhancing their decision-making processes, contribute to societal improvement by facilitating comprehension of information diffusion, and enable the identification of influential individuals within social networks for the purpose of implementing targeted interventions. The aforementioned findings carry significant ramifications for the fields of marketing, advertising, and public health. The remains sections of this research article are as follows: a comprehensive review of related work in Section II, followed by the methodology in Section III. Section IV delves into evaluation metrics. Experimental results, discussion, and conclusion in Section V, Section VI and Section VII respectively.

## II. RELATED WORK

### A. Background of the Information Diffusion

Sharing content on social media platforms like Twitter and Facebook spreads information. Social media is about sharing content. Businesses, advertisers, and marketers should address this important issue. They may effectively communicate with their target audience, strategically advertise their products and services, and remain competitive. Social media is crucial for marketing. Companies can grow their market and build client relationships [8]. Commercial organizations can improve their business strategies, increasing their expertise in efficiently spreading their message and news, and leverage social media platforms to amplify their brand by researching information dissemination that helps promote their products and services further in this section. In information diffusion, there are three main elements Sender, Receiver, and Medium, as shown in Fig. 1. The sender, whether an individual or a group, initiates the dispersion process. They are the ones who are in charge of spreading the information that needs to be spread. The receiver, or group of receivers, denotes the individuals who have received the information that has been spread. The process of dispersion generally has a wider scope of influence, as evidenced by the fact that the number of receivers usually be more than the number of senders. The medium is the way information about diffusion travels from sender to receiver. There are many communication channels for information spreading such as TV, newspapers, and social media platforms like Twitter. Additionally, personal connections play a dynamic role in communication. Furthermore, factors such as airborne diseases can also impact the way information is disseminated. Understanding diffusion is crucial process. It shows us how information spreads and changes behavior in a system. Researchers can study the sender-receiver relationship and the medium used. This helps them learn about diffusion and find ways to manage and control it.

### B. Literature Review

Twitter has become a powerful tool for spreading information. People can share information with followers and beyond through retweets, posts, and hashtags. Various research studies have observed what makes people retweet and how information spreads on these networks. Factors can include the tweet's content, the source of the information, emotional appeal, timing, and social influence. Researchers found Twitter as a way to study diffusion patterns and how different factors affect information spread. But knowing how information spreads efficiently on Twitter is still a challenge. Machine learning and deep learning techniques are being used to analyse and predict diffusion patterns on Twitter. These techniques can find hidden patterns in large datasets. They can help us understand what drives information to spread.

The Research domain of information diffusion on Twitter has a variety of approaches. Study conducted by authors [9] aimed to determine the characteristics that predict the level of engagement a tweet receives. The findings suggest that tweets with positive sentiment and positive arousal receive more retweets and favourites, although the effect size is small. Predicting information diffusion has been another focal point of research. A study by authors in [10] suggest that modelled tweet popularity as the number of retweets and developed machine learning models predict the same, achieving an accuracy of up to 60% and an F1 score of 67%. Another researcher proposed approach to predict information diffusion based on user-based, time-based, and content-based features, resulting in a model that improves the F-measure by about 5% compared to the state-of-the-art Masud et al. Authors in [5] in their study Twitter hate speech based-on topics. The researchers analyze a massive collection of tweets, retweets, user activity logs, and follower networks. They also collect online news stories. The authors provide feature-rich methods for predicting hashtag-related hate speech. The best model scored 0.65 macro F1. RETINA, a neural network for Twitter retweet prediction, is also presented. This design has a macro F1-score of 0.85. Their study sheds light on how Twitter users start hate speech and spread it through retweets. Authors in study [11], introduce an approach for predicting the spread of information prompted by a Twitter user's tweet. They leverage six user features, like number of followers and tweet frequency, along with 80 linguistic and psychological aspects provided by the Linguistic Inquiry and Word Count (LIWC) software. Their approach comprises a module that formulates regular basic tweet propagation patterns and a classifier that anticipates the tweet pattern associated with a specific user tweet. The study uses Tree-Shaped Tweet Cascades for the dataset, achieving significant accuracy in predictions, notably an F-measure of 0.89 with the JRIP model.

Fig. 1. Demonstrating the information diffusion process on social media.

The propagation on Twitter is the current problem, with a particular emphasis on influence and prediction. The authors of [3] examine Twitter's information diffusion model, which sees the spread of information on the platform as a problem with several variables over time. It focuses on tweet quantity, emotional tone, and influence. Time series clustering reveals Twitter information transmission patterns. The study clusters hashtags with similar patterns using time series clustering methods. This study forecasts three-dimensional parameters using Autoregressive Integrated Moving Average and LSTM linear and non-linear time series models. LSTM models attained an accuracy of 80%.

Previous studies have directed their attention towards more granular facets of information dissemination on the Twitter platform. The study proposed an information diffusion model that conceptualized information diffusion as a problem of multivariate time series analysis. This model specifically addressed the variables of tweet volume, tweet sentiment, and tweet influence [12]. In their study, the authors introduced an algorithm named SentiDiff, which integrates textual data and sentiment diffusion patterns to effectively forecast sentiment polarities conveyed in Twitter messages. The algorithm that has been suggested demonstrates improvements in PR-AUC, ranging from 5.09% to 8.38% for classification tasks, in comparison to existing sentiment analysis algorithms that rely on textual information [12, 13].

Other approaches are based on the anticipated graph information diffusion node activations; the Topological Recurrent Neural Network (Topo-LSTM) was introduced in [14]. Diffusion topologies are used to characterize the cascade structure. This DAG model depicts the cascade. The Topo-LSTM is a diffusion-prediction-specific LSTM architecture. A MAP increases from 20.1% to 56.6%. The researchers found that using dynamic directed acyclic graphs (DAGs) with the innovative data model and Topo-LSTM architecture improves diffusion structure representation.

Authors in [15] presented a model that predicts how information flows on Twitter. The model learns the probability of influence between users. It considers both time-based and structural aspects of influence spread. The effectiveness of the suggested models is examined on two datasets, Darwin and MelCup17. The TDD-CP model achieved a balanced precision of 94.64% and a recall of 95.9% on the Darwin dataset. The MelCup17 dataset achieved a balanced precision of 95.13% and a recall of 98.2Authors in the study [16] developed a Twitter information spread model. To improve predictions, the model has used custom-weighted word characteristics. A Custom Weighted Word Embedding is proposed to measure content diffusion via retweets. Twitter postings are used to extract lexical units, build a matrix with word sequences, and apply specific weights based on the sentence's presence index. Long Short-Term Memory (LSTM) and Convolutional Neural Networks (CNN) are used to predict information dissemination and improve accuracy and training time. The CWWE framework improves the deep learning framework model accuracy, according to experiments. The researchers collected 230,000 tweets from over 45,000 users over six months. Model accuracy increased from 53% to 80%. The authors in [32] introduced the LARM (Lifetime Aware Regression Model), a

ground-breaking method for tackling the problem of online content popularity long-term prediction in dynamic YouTube networks. One way that LARM sets itself apart is by considering content longevity as a significant aspect, which helps to mitigate the drawbacks that come with a large amount of historical data and inappropriate model assumptions. The model exhibits flexibility to different observation intervals and is fitted using a forecast lifetime metric that is derived from early-accessible variables. The varied lives of video content are accommodated by specialized regression models. Based on two YouTube datasets, the experimental findings demonstrated the significant advantage of LARM, with prediction error reductions of up to 20% and 18%, respectively.

Despite the considerable body of research that has been conducted on the phenomenon of information diffusion on the social media platform Twitter, there remains a notable gap in the existing literature that necessitates further investigation and exploration. The authors in [34] explored the intricacies of information dissemination on social media, focusing on the Sina microblog controversy around the L group Double 11 fraudulent advertising incidents. Using a strong data analytics methodology that combines time series regression and data mining, the study reveals the key variables influencing the dissemination of information. User activity, emotional shifts, and media attention have been recognized as important drivers, with sentiment polarity and reposting being critical factors in various dissemination phases.

The area of utilizing the number of retweets and retweeted counts, in combination with advanced machine learning techniques, is currently lacking in comprehensive exploration. The comprehension and anticipation of diverse aspects of information diffusion, encompassing the factors that impact the dissemination of information and the dynamics of diffusion patterns, constitute significant areas of scholarly inquiry that merit consideration. This study addresses the identified research gap by proposing using machine learning and deep learning models. Through utilizing these models, significant insights can be obtained regarding the intricacies of information dissemination on the social media platform Twitter. This research endeavor aims to augment our comprehension of the mechanisms through which information propagates on social media platforms. This pursuit aims to establish a basis for enhanced prediction and awareness of the intricate dynamics of disseminating information.

## III. METHODOLOGY

This study proposed a methodology for predicting information diffusion in social media based on retweets and retweeted counts. Deep learning and machine learning techniques are used to predict information dissemination. The methodology involves data preparation and training models on large-scale social media datasets. The choice of the features and the proposed framework used in our study was a carefully considered process aimed at comprehensively understanding social media information diffusion. The elected features, such as Following Network Structure (FNet), Retweeting Network Structure (RNet), and Early Popularity (early), were strategically picked to capture dissimilar dimensions of the

diffusion phenomenon. The proposed framework of the information diffusion prediction is demonstrated in Fig. 2.

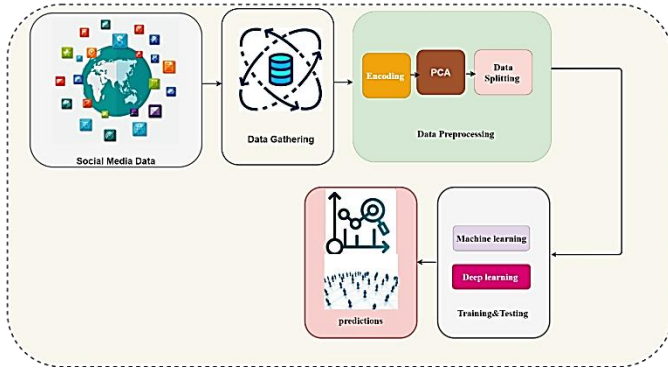

Fig. 2. The proposed framework for information diffusion prediction.

### A. Data Source

Sina Weibo is a popular social network site like Twitter. We used a large dataset from Sina Weibo [7] for our research. The dataset provides by DataCastle. It has 30,010 original tweets. Each tweet has its own ID. The ID has information like the user's ID, the time the tweet was posted, and the tweet's content. The tweets were posted between January 1, 2015 and May 20, 2016. This dataset was developed by authors in [7]. It is publicly available online. The dataset is large, so we can study how information spreads on Weibo. We can learn more about predicting information cascade scales based on analyzing set of features.

### B. Feature Extraction

The dataset developers categorized data features into four groups: following network structure, retweeting network structure, early-stage popularity dynamics, and tweet content. We aim to capture various aspects of information diffusion dynamics by extracting and incorporating these features.

*1) Following network structure:* The following network structure plays a crucial role in information diffusion. The constructs a network (G_F) based on the relationships among users who follow each other. Five network structural features are derived from measuring user influence in this network, including out_degree_F, in_degree_F, all_degree_F, bi_degree_F, and pagerank_F, as described in Table I [7].

*2) Retweeting network structure:* Retweeting is a key mechanism for information diffusion. The builds a retweeting network (G_R) using retweet data from the first 60 minutes. Similar to the following network, by extracts five network structural features to quantify user influence in the retweeting network: out_degree_R, in_degree_R, all_degree_R, bi_degree_R, and pagerank_R, as described in Table I [7].

*3) Early retweet dynamics:* The early-stage retweet time series contains valuable temporal information. We construct four types of temporal features to capture trends and fluctuations in cascade sizes over time. These features include cascade (cumulative cascade sizes in one minute intervals), burstiness (measuring the burst of popularity), stability

(assessing the stability of Popularity), and release_time (hour of original tweet release), as described in Table I [7].

*4) Tweet content:* The initial tweets' content also plays a role in how the information spreads. To get feature vectors out of the tweet content, the dataset developers [18] used the word frequency-inverse document frequency algorithm. In addition, they get topic distributions using the latent Dirichlet allocation (LDA) topic model. Contentgory (themes category), wordlength (text length), URL presence, hashtag presence, photo presence, and mention presence are the six features retrieved from tweet content, as described in Table I [7].

TABLE I. ILLUSTRATES THE FOUR CATEGORIES OF FEATURES USED IN THE PREDICTION OF CASCADES

| Features | Description | Representation |
|---|---|---|
| Following Network Structure (FNet) | The count of individuals who are following the user who made the post. | out_degree_F [7,17,18,19,,20]. |
| | The count of individuals whom the posting user follows. | in_degree_ [7,17,18,19,,20]. |
| | The count of individuals who either follow or are followed by the posting user. | all_degree_F [7]. |
| Following Network Structure (FNet) | The count of individuals who both follow and are followed by the posting user. | bi_degree_F [7] |
| | PageRank centrality in $G_F$ | pagerank_F [7] |
| Retweeting Network Structure (RNet) | The count of individuals who retweet the tweets of the posting user | out_degree_R [7] |
| | The count of individuals who have been retweeted by the posting user | in_degree_R [7] |
| | The count of individuals who either retweet or are retweeted by the posting user | all_degree_R |
| | The count of individuals who both retweet and are retweeted by the posting user | bi_degree_R |
| | PageRank centrality in $G_R$ | pagerank_R [33] |
| Early Popularity (early) | the sizes of cascades during the observation period, divided into intervals of 1 minute | cascade |
| | The measure of how quickly and intensely popularity increases in the early period | burstiness |
| | The measure of how consistent and stable the popularity remains in the early period | stability |
| | The timestamp indicating when the original tweet was posted | Release_time |

### C. Data Pre-processing

A rule-based methodology has been employed to label the dataset to encode the variable 'all_degree2', which signifies the number of retweets and retweeted counts. This study aimed to minimize the level of variability in the chosen variable and enhance the ease of analyzing diffusion patterns. The encoding procedure entailed the categorization of values into three distinct groups: 'low diffusion' (set as '10'), 'medium diffusion' (set as '20'), and 'high diffusion' (set as '30'). The encoding scheme offers a distinct representation of the levels of diffusion linked to the number of retweets and retweeted counts.

Assigning discrete levels to the variable 'all_degree2' enhances comprehensibility and facilitates the analysis of diffusion patterns in the dataset. Fig. 3 represents the retweet counts in the dataset.

Fig. 3. Representing of the dataset retweet count analysis.

Fig. 4 provides a visual representation of the encoded values, thereby offering valuable insights into the distribution patterns of diffusion levels. This methodology streamlines the inspection of information propagation dynamics and deepens our comprehension of the dataset samples.

Fig. 4. Show the distribution of the dataset classes.

### D. Data Normalization

In this study, the standard scalar is used on features for predicting information spread on social media. It makes the features have a similar scale values. This helps some machine learning algorithms that are sensitive to the scale of input data. This step makes all features contribute equally to the prediction task at hand. No feature dominates the learning process because of its original scale. The standard scaler calculates the mean and standard deviation of each feature. Then it transforms the values based on these statistics. The scaled features have a mean of zero and a standard deviation of one [21]. Using the standard scaler on this study's features enhances the model's comparability and interpretability. This leads to more accurate predictions and analysis.

### E. Dimensionality Reduction

The Principal Component Analysis (PCA) uses to remove unimportant elements from high-dimensional data to ease interpretation. Dimensionality reduction shortens data analysis and interpretation without sacrificing essential features. A PCA finds the dataset's most variable eigenvectors. PCA selects the most significant eigenvectors while retaining the most variation by reducing data dimensionality. The PCA projects data onto eigenvectors for visualization task. This helps identify data patterns and simplifies multidimensional data. It facilitates complex data, focuses on critical issues, and aids interpretation [22].

### F. Data Split

In research, it is common practice to split the data into training and testing sets, usually using 80:20 ratios. The training set is used to train the model, while the testing set is used to evaluate the model's performance on test data. This split allows researchers to assess how well their models generalize to new, unseen data and make reliable results based on their research findings.

### G. Prediction Models

This subsection details of machine learning and deep learning model architecture to analyze and model information diffusion patterns in social media networks.

*1) Machine learning models:* Machine Learning is a subfield within the realm of artificial intelligence that facilitates the acquisition of knowledge and improvement of systems through experience, thereby enhancing their performance without the need for explicit programming [23]. Regression is a widely employed machine learning methodology that aims to forecast continuous outcomes by utilizing statistical techniques to establish the association between independent and dependent variables.

*a) Linear regression model:* Linear Regression (LR) is a Statistical analysis method. This analysis considers several independent factors and one dependent variable and the relations between them [24]. The LR technique can help one understand how social media spreads information. In study of RL analysis for information dissemination, dependent variable is information dispersion or an analogous indicator like retweets or post spread. Independent variables include content features, network design, and other external factors that may affect content transmission. Fitting a linear regression model to the data estimates the coefficients for each independent variable. They control the variable. This model assumes a linear relationship between characteristics and diffusion strength. Linear regression helps us understand how features affect diffusion levels. Positive coefficients mean an increase in the feature leads to an increase in diffusion. Negative coefficients mean the opposite. The intercept shows the baseline diffusion when all features are zero, giving us insight into the content's inherent diffusion capacity.

*b) Random forest regressor model:* The Random Forest Regressor (RFR), a machine learning technique, is well-suited for modelling information diffusion. It predicts information dissemination by averaging the results of several decision trees. This prediction aggregation reduces variance, improving the model's test set generalization [25]. The RFR model can handle diverse, noisy data because it resists outliers. This is one of the RFR main advantages. It can also discover non-linear data linkages, which helps it produce accurate forecasts

even in challenging settings. It distributes errors evenly across classes to handle unbalanced datasets. The RFR also helps assess the model's numerous variables' relative importance. It assigns significance scores to qualities, indicating their relevance to the prediction task. This knowledge can help researchers comprehend information spread factors.

*2) Deep learning models:* CNNs and RNNs can be used to model how information spreads through social networks and communication channels. CNNs can identify important elements or patterns that spread information by extracting relevant textual or visual input features. The ANN, BiLSTM [26], and GRUs models can sequential data well for temporal information diffusion analysis. These architectures can identify critical diffusion nodes and anticipate future spread by capturing relationships and patterns in interaction or event sequences. Deep learning approaches can help to predict, analyse, and intervene in information diffusion by revealing its mechanisms and dynamics.

*a) The ANN Model:* In this study, ANN Regression has been proposed for information diffusion prediction in online social media. This sequential regression neural network model architecture consists of the input, output and hidden layers [27]. The input data passed to two hidden layers with 64 units with rectified linear unit (ReLU) activation function. Those layers can capture non-linear relationships and complex patterns present in the data. The model's output is a single unit for predicting the continuous variables related to information diffusion. The model Parameter describes in Table II.

TABLE II. THE ANN USED PARAMETERS

| Parameter | Dilates |
|---|---|
| Input Shape | (4, 1) |
| Input Dimensions | Input shape |
| Hidden Layers | 2 |
| Output Units | 1 |
| Optimizer | Adam |
| Epochs | 100 |

The mean squared error (MSE) has been used to measure the average squared difference between predicted and actual values. The Adam optimizer dynamically adjusts the learning rate based on the gradients' first and second moments to update the model's weights. MSE and MAE are used to evaluate model performance. These metrics reveal the model's accuracy and precision, helping researchers assess its ability to predict information diffusion patterns in online social media.

*b) CNN-BiLSTM Model:* This paper introduces a neural network model designed to predict information diffusion on online social media platforms. The model was constructed utilizing the Keras library and incorporates a range of components designed to effectively capture complex patterns and dynamics associated with information propagation. The architecture has proposed adheres to a sequential structure, wherein each component has been meticulously considered. The initial stage involves utilizing one-dimensional

convolutional layer (Conv1D) comprising ten filters and a kernel size of 3. The function of this particular layer is to detect and analyze localized patterns and connections within the given input data. This process aids in identifying and extracting significant features associated with the diffusion of information. To avoid the overfitting issue, a dropout layer is incorporated into the model architecture, wherein a random selection of 20% of the input units are dropped or deactivated during the training process. The utilization of this regularization technique facilitates the process of generalization and diminishes dependence on particular features, thereby enhancing the resilience of diffusion predictions. Subsequently, a bidirectional Long Short-Term Memory (LSTM) layer [26], consisting of 10 units, is incorporated. Long Short-Term Memory (LSTM) networks demonstrate exceptional performance in modeling sequential data and effectively capturing temporal dependencies. The model's bidirectional characteristic enables it to consider both preceding and subsequent time steps, thereby facilitating a holistic comprehension of diffusion dynamics.

Two dense layers follow the LSTM layer. The first dense layer consists of 10 units with the rectified linear unit (ReLU) activation function, enabling the extraction of higher-level features. The second dense layer, with a single unit, generates the final diffusion predictions. To prepare the output for the dense layer, a flatten layer is added, reshaping the preceding layer's output into a one-dimensional vector. The model Parameter describes in the Table III. The evaluation metrics, such as MSE and mean absolute error (MAE), were used to assess the model's performance in accurately predicting the diffusion patterns.

TABLE III. SUMMARIZING OF THE CNN-BILSTM PARAMETERS

| Parameter | Dilates |
|---|---|
| Input Shape | (4, 1) |
| Convolutional Layer | Filters: 10, Kernel Size: 3 |
| Padding | Same |
| Activation Function | ReLU |
| Dropout Rate | 0.2 |
| Bidirectional LSTM Layer | Units: 10, Dropout: 0.3, Recurrent Dropout: 0.3 |
| Dense Layer 1 | Units: 10, Activation Function: ReLU |
| Flatten Layer | - |
| Dense Layer 2 | Units: 1 |
| Loss Function | Mean Squared Error (MSE) |

*c) CNN-GRU Model:* In this study, the CNN-GRU deep learning model architecture uses to predict information diffusion in social media platforms. We define a sequential model to build linear information diffusion. The model consists of one-dimensional convolutional layer employs 10 filters and a kernel size of 3, while utilising the Rectified Linear Unit (ReLU) activation function. This layer is responsible for extracting pertinent features and patterns from the input data to comprehend the information diffusion processes. During training, the dropout layer is employed to randomly deactivate 20% of the input units to mitigate the

overfitting risk. Regularization techniques enhance generalization capabilities of prediction models by reducing feature dependence, thereby increasing their robustness. A Gated Recurrent Unit (GRU) layer follows, consisting of 10 units. This recurrent layer captures temporal dependencies in sequential data, allowing the model to capture the dynamics of information diffusion over time. The model architecture also includes two dense layers. The first dense layer has 10 units with the ReLU activation function, extracting higher-level features. The second dense layer, with a single unit and no activation function, generates the final predictions. The evaluation metrics, such as MSE and mean absolute error (MAE), were used to assess the model's performance in accurately predicting the diffusion patterns. Table IV provides the summarization of the CNN-GRU used parameters.

TABLE IV.    THE CNN-GRU MODEL PARAMETERS

| Parameter | Dilates |
|---|---|
| Input shape | (4,1) |
| Conv1D | Filters: 10, Kernel Size: 3, Padding: 'same' |
| Activation | ReLU |
| Dropout | Rate: 0.2 |
| GRU | Units: 10, Dropout: 0.3, Recurrent Dropout: 0.3 |
| Dense | Units: 10, Activation: ReLU |
| Flatten | - |
| Dense | Units: 1 |
| Optimizer | Adam |

## IV.    EVALUATION METRICS

In this study, the researchers used various fundamental measurement metrics to evaluation the models' performance, including Mean Squared Error (MSE), Mean Absolute Error (MAE), R-squared (R2), and Root Mean Squared Error (RMSE). These metrics function as significant indicators of the accuracy and predictive capabilities of the models, allowing for a precise evaluation and comparison of their performance.

### A. Mean Squared Error (MSE)

The Regression analysis uses MSE to evaluate prediction models. The MSE method calculates the averages of the squared deviations between predicted and actual values. Squaring large deviations makes the MSE more sensitive to outliers [28]. The RF model performs best with a low MSE. The following formula can calculate the MSE [28].

$$MSE = \frac{1}{n}\sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \qquad (1)$$

### B. Root Mean Squared Error (RMSE)

The Root Mean Squared Error (RMSE) is a commonly employed evaluation metric especially for regression analysis. It calculates the square root of the mean of the squared differences between the predicted and actual values [31]. Root Mean Square Error (RMSE) is a statistical metric that quantifies the typical magnitude of errors and indicates the standard deviation of the residuals. This technique proves to be highly advantageous in scenarios where substantial errors notably influence the model's overall performance. Smaller root mean square error (RMSE) values indicate enhanced

model accuracy and a stronger alignment with the observed data. The following formula can calculate the RMSE [31].

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n} (\hat{y}_i - y_i)^2} \qquad (2)$$

### C. Mean Absolute Error (MAE)

Mean Absolute Error (MAE) is an alternate evaluation metric frequently used in regression analysis. It calculates the average absolute discrepancy between forecasted and actual values in a dataset. This discrepancy evaluates the accuracy of forecasts. Unlike Mean Squared Error (MSE), which squares errors before averaging, MAE doesn't square errors [29]. This makes it less influenced by outliers or extreme values. It provides an indication of the average error magnitude in predictions. Smaller MAE values signify improved model performance, similar to MSE. A value of zero denotes perfect correspondence between forecasted and actual values. MAE is particularly helpful where the focus is on absolute error magnitude rather than squared discrepancies. This is because MAE considers absolute error magnitude. Eq. (3), calculates the MAE metric [29].

$$MAE = \frac{1}{n}\sum_{i=1}^{n} |y_i - \hat{y}_i| \qquad (3)$$

### D. R-squared (R2)

R-squared, or coefficient of determination, is a statistical measure assessing the goodness-of-fit of a regression model. It represents the proportion of variance in dependent variables explained by the model's independent variables [30]. The R-squared value ranges from 0 to 1. 1 indicates a perfect fit where the model presents all variability in data. 0 indicates model doesn't show any variability. R-squared can be interpreted as the percentage of variance in dependent variables accounted for by independent variables in the model. Eq. (4) calculates the R-squared [30].

$$R^2 = 1 - \frac{SS_{res}}{SS_{tot}} \qquad (4)$$

## V.    EXPERIMENTAL RESULTS AND DISCUSSION

In this section, we present the experimental results of our study, conducted on a laptop equipped with an 8th generation Intel Core i7 processor, 16GB of RAM, and an NVIDIA GeForce GTX GPU with 8GB. We evaluated the performance of our models using three metrics: Mean Squared Error (MSE), Mean Absolute Error (MAE), and R-squared.

### A. Models Performance Based on All Feature

The RF model has the best performance among these for modelling information diffusion on social media using All Features, as described in Table V. Based on R-squared value, a statistical measure representing a proportion of variance for dependent variables explained by independent variables in the regression model, the RandomForest model appears best performing. It has the highest R-squared value of 0.767, explaining approximately 76.7% of the variance in the dependent variable. Moreover, for MSE and MAE measures of prediction error, the RF model has the lowest scores on the test set. This signifies the smallest prediction errors among models. Therefore, based on provided metrics (R-squared, MSE, and

MAE), the RF model models is provided the best results among used models.

### B. Models Performance Based on Early Retweet Dynamics Features

The ANN model has the best performance for modelling information diffusion on social media using early retweet dynamics features. Based on the R-squared value described in Table VI, the highest R-squared value was achieved by the ANN model, which indicates that it explains approximately 24.30% of the variance in the dependent variable. It is essential to consider that this value is relatively low, which indicates that there is only a limited amount of goodness of fit to the data. Every model could be improved by performing additional tuning or using additional or different features.

TABLE V. RESULTS OF INFORMATION DIFFUSION BASED ON ALL FEATURES

| Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|
| Linear Regression | 46.364 | 6.811 | 5.864 | 33.995 |
| CNN-BiLSTM | 29.610 | 5.440 | 4.482 | 57.846 |
| CNN-GRU | 24.400 | 4.939 | 3.953 | 65.264 |
| ANN | 18.679 | 4.323 | 3.237 | 68.021 |
| RF | 16.374 | 4.048 | 2.599 | 76.690 |

TABLE VI. RESULTS OF INFORMATION DIFFUSION BASED ON EARLY RETWEET DYNAMICS FEATURES

| Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|
| Linear Regression | 53.459 | 7.314 | 5.932 | 8.48 |
| CNN-BiLSTM | 43.708 | 6.609 | 5.740 | 18.32 |
| Random Forest | 46.608 | 6.826 | 5.729 | 20.21 |
| CNN-GRU | 44.626 | 6.678 | 5.810 | 23.60 |
| ANN | 44.212 | 6.645 | 5.776 | 24.309 |

### C. Models Performance Based on Following Network Structure Features

The Random Forest model has the best performance among these for modelling information diffusion on social media using the Following network structure features. Based on R-squared value, Random Forest model is the best performing among these for models, as described in Table VII. It has highest R-squared value of 0.907, explaining approximately 90.7% of the variance in dependent variable. RandomForest model also has lowest MSE and MAE values on the test set, implying smallest prediction errors among models.

### D. Models Performance Based on Retweeting Network Structure

Based on R-squared value, Linear Regression model is best performing among these for modelling information diffusion on social media using retweeting network structure features, as described in Table VIII. It has highest R-squared value of 0.982, explaining approximately 98.2% of the variance in dependent variable.

Although RF model has slightly higher MSE and MAE values on test set compared to Linear Regression, its R-squared value is also very close, making it a strong competitor.

### E. Models Performance Based on Tweet Content Features

The ANN model achieved a higher level of effectiveness in representing the spread of information on social media platforms using tweet content features, as evidenced by the R-squared value. The R-squared of the ANN model is 0.055, suggesting that it explains approximately 5.5% of the variability observed in the dependent variable. Nevertheless, it is crucial to acknowledge that all models exhibit low or negative R-squared values that suggests inadequate alignment with the observed data. Table IX below summarizes the results using Tweet content features.

TABLE VII. RESULTS OF INFORMATION DIFFUSION BASED ON THE FOLLOWING NETWORK STRUCTURE FEATURES

| Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|
| Linear Regression | 46.669 | 6.836 | 5.155 | 20.1 |
| CNN-GRU | 25.957 | 5.095 | 4.086 | 55.6 |
| CNN-BiLSTM | 22.762 | 4.767 | 3.970 | 57.5 |
| ANN | 20.031 | 4.475 | 3.549 | 65.7 |
| RF | 5.389 | 2.322 | 0.999 | 90.8 |

TABLE VIII. THE RESULTS OF INFORMATION DIFFUSION BASED ON RETWEETING NETWORK STRUCTURE

| Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|
| CNN-BiLSTM | 5.846 | 2.416 | 1.392 | 80.1 |
| CNN-GRU | 11.601 | 3.405 | 2.280 | 80.1 |
| ANN | 5.253 | 2.293 | 1.486 | 91.0 |
| Linear Regression | 1.097 | 1.048 | 0.237 | 98.1 |
| Random Forest | 1.074 | 1.036 | 0.233 | 98.2 |

TABLE IX. THE RESULTS OF INFORMATION DIFFUSION BASED ON TWEET CONTENT FEATURES

| Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|
| Linear Regression | 68.593 | 8.289 | 6.708 | -0.174 |
| Random Forest | 68.548 | 8.284 | 6.707 | -0.174 |
| CNN-BiLSTM | 56.095 | 7.491 | 6.289 | 0.040 |
| CNN-GRU | 55.754 | 7.468 | 6.329 | 0.045 |
| ANN | 54.834 | 7.404 | 6.257 | 6.124 |

## V. DISCUSSION

Our findings have significant implications for predicting the spread of information through social media. The models were evaluated based on their ability to capture the intricacies of the information diffusion process. Their performance was measured using various feature sets such as all features, early retweet dynamics, Following network structure, Retweeting network structure and Tweet content. The RF model performance is higher than other models. The model's MSE was 16.374, RMSE was 4.049, MAE was 2.599, and R-squared was 76.690. This result indicates that more accurate predictions of the extent of information dispersion can be achieved by including a wide variety of features. The RF model reduces variation and improves generalization performance by averaging predictions from multiple decision trees.

We also explored how tweet content features play a role in prediction. The ANN model was run on these features, and the results showed that the MSE, RMSE, MAE, and $R^2$ values were as follows: 44.212, 6.645, 5.776, and 24.309, respectively. The model performance was not good when we concentrated most of our attention on early retweet dynamics. Consequently, it would appears that the dynamics of early-stage popularity may not be adequate to accurately predict the extent of information cascades, even though they do play a part in the process of information dissemination.

The impact of network structural features on prediction performance was then examined. The MSE, RMSE, MAE, and R-squared for a RF model trained on the following network architecture were 5.389, 2.321, 0.999, and 90.773, respectively. This shows how the extent of information cascades heavily depends on the level of user influence in the subsequent network. Similar success was seen with a RF model that was trained using variables extracted from the retweeting network; this model achieved an excellent MSE of 1.074, RMSE of 1.036, MAE of 0.233, and an astounding R-squared of 98.161. These findings underline the significance of taking into account the topology of the retweeting network when estimating the rate of information diffusion in a Twitter stream.

Finally, we investigated the significance of tweet content features in the context of prediction. The ANN model, which was exclusively trained using the content of tweets, demonstrated performance metrics including a mean squared error (MSE) of 54.834 , root mean squared error (RMSE) of 7.404, mean absolute error (MAE) of 6.257, and a relatively low R-squared value of 6.124. This implies that the sole consideration of tweet content may not be adequate in accurately predicting the sizes of cascades. Including network structure and the dynamics of early-stage popularity appears essential to understand the intricacies of information diffusion comprehensively.

This study emphasizes the significance of considering various factors in predicting the scale of information diffusion on social media. The optimal predictive performance is achieved by considering a combination of network structure features, early-stage popularity dynamics, and tweet content. The RF models' efficacy in capturing network structure's impact has been demonstrated. In contrast, the ANN model offers valuable insights into the significance of early-stage popularity dynamics.

Subsequent investigations may priorities examining supplementary attributes and integrating more sophisticated machine learning and deep learning methodologies to enhance the precision of predicting information dissemination on social media platforms. Fig. 5 shows the regression plots for the best models performance for information diffusion.

(a) The RF regression performance using all features.

(b) The RF regression performance using following network structure features.

(c) The RF regression performance using Retweeting network structure.

(d) The ANN regression performance using Early retweet dynamics.

(e) The ANN regression performance using Tweet content features.

Fig. 5.   Shows the combination of various regression models performance plots for predicting information diffusion.

Table X summaries the best results obtained from our experimental work carried out in this study.

TABLE X.   PRESENTING THE BEST RESULTS OF OVERALL

| Features Used | Best Model | MSE | RMSE | MAE | R-squared (%) |
|---|---|---|---|---|---|
| All features | Random Forest | 16.374 | 4.049 | 2.599 | 76.690 |
| Early retweet dynamics | ANN | 44.212 | 6.645 | 5.776 | 24.309 |
| Following network structure | Random Forest | 5.389 | 2.321 | 0.999 | 90.8 |
| Retweeting network structure | Random Forest | 1.074 | 1.036 | 0.233 | 98.2 |
| Tweet content | ANN | 54.834 | 7.404 | 6.257 | 6.124 |

As shown in above cited X table, the best results gained for information diffusion on social media by the ANN and RF models. The results emphases on important findings  with various characteristics that perform differently in terms of models, and some features have better predictive ability and accuracy when it comes to comprehending the dynamics of information dissemination on social media platforms. The R-squared values provide information about how well the models represent the diffusion process's variability. These results advance our knowledge of information distribution inside social media networks in a more complex way.

Fig. 6 presents the visualization of the best results for the proposed models.

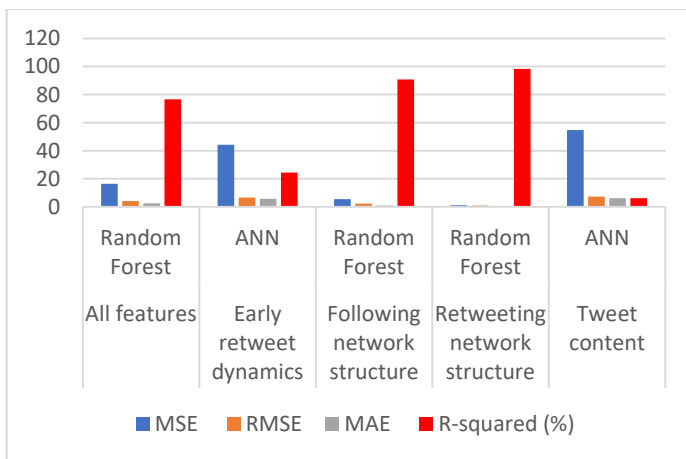

Fig. 6.   Graphical representation shows the best models performance and results.

In our research study, we compared how well our models predicts the spread of information based on retweets and retweet counts versus another study that used XGBoost modeling. We aim methodically to evaluate our model's performance with exist ones. We observed the root mean squared error (RMSE) - a standard way of measuring how closely regression models predict values. We investigated the RMSE for different features, like, all features, early retweet dynamics, Following network, Retweeting network, Tweet content. Authors in study [7]  used XGBoost model, which had RMSE ranging from 134 to 237 for the different features. Our models using RF and neural networks performed much better,

with RMSE from 1.036 to 7.404 as described in Table XI. These results demonstrate our models predict information diffusion from retweets and retweet counts far more accurately than the XGBoost models in the other study. Our models matched the real dynamics of information spreading much closer, as shown by the lower RMSE values.

TABLE XI.   A COMPARISON BETWEEN THE RESULTS OF OUR APPROACH WITH EXISTING ONES

| Features | Result from Study [7] (XGBoost ) | Our  Study (RF / ANN) |
|---|---|---|
| All features | 196 | 4.049 |
| Early retweet dynamics | 237 | 6.645 |
| Following network | 151 | 2.321 |
| Retweeting network | 134 | 1.036 |
| Tweet content | 205 | 7.404 |

## VI.   CONCLUSION

This study predicted social media information diffusion based on the number of retweets and retweets counts. The deep learning and machine learning models were trained on Weibo, a social network platform similar to Twitter. Those models used various features such as all features, early retweet dynamics, following network structure, Retweeting network structure, and Tweet content. The best result was achieved by RF 98.161 using Retweeting network structure features. The results of our study provide insights into mechanisms of information dissemination on social media platforms and provide guidance for predicting potential influence of forthcoming news events. Optimal predictive performance is attained by considering interplay of network structure, early popularity dynamics, and features inherent to tweet content .Accurate information diffusion prediction helps businesses improve their marketing strategies, public health officials respond to disease outbreaks, and identify social network influencers. The present study has potential to establish a fundamental basis for future investigations integrating cutting-edge machine learning and deep learning techniques to explore supplementary variables and other social media features that can enhance precision of predictions of information diffusion on online platforms. Enhancements in capacity to forecast extent of information dissemination hold significant potential for various domains, including advertising, crisis management, and examination of online social dynamics.
