*First scenario:* A quick, high-maneuver normal acceleration tracking scenario is used to assess the performance and reliability of the normal acceleration autopilot for a single missile airframe. As it can be seen in Fig. 2, the commanded acceleration and initial Mach number were chosen at their extremes. The results show that the proposed technique is effective for controlling such complex system.

*Second scenario:* In this section, first, the tracking of an AOA sequence using the state feedback-based autopilot is performed by a multi-missile composed of six agents. The AOA sequence is introduced as step commands given at different initial AOA $\alpha_0 = [-5 \quad 0 \quad 20 \quad -7.5 \quad 5 \quad -20]^T$ and $M = 3$. The communication topology is shown in Fig. 3 and the time-history of the tracking mission is shown in Fig. 4.

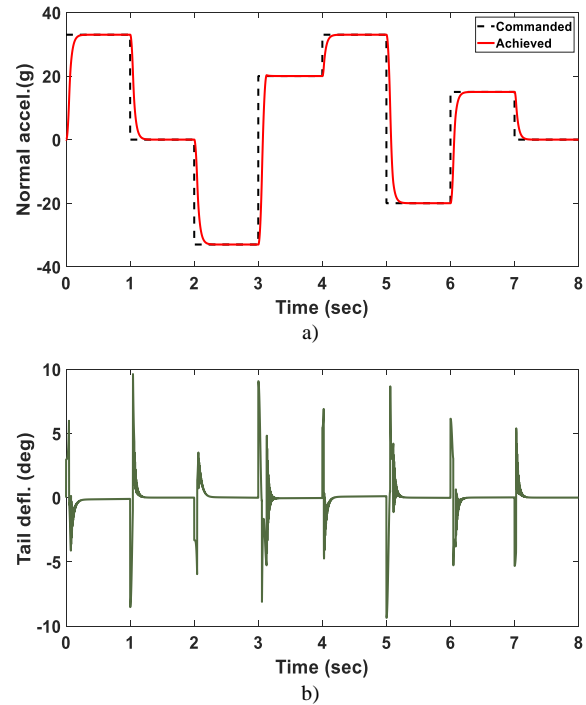

Fig. 2. Single missile response to a normal acceleration pattern: a) Normal acceleration, b) Tail deflection.

Fig. 3. Fixed-time switching topology connected interaction graph.

Fig. 4. Time history of multi-missile system response: a) AOA, b) Normal acceleration, C) Fin deflection.

## VI. CONCLUSION

In this study, we first designed two robust longitudinal autopilot topologies for a tail-controlled tactical missile. The two autopilots were created with high-order sliding mode control and a thorough nonlinear dynamic model. Second, we looked at the distributed control-based cooperative guiding problem for a multi-missile system intercepting a high-risk target. Asymptotic exponential functions and graph theory were used to create free-chattering distributed protocols. The Lyapunov technique was used to determine the necessary requirements for smooth asymptotic tracking. The simulation findings show that there is reduced computing load and more precision. Future study will focus on various features of multi-missile systems for practical implementations, such as the distinct overload and impact angle limits of each missile, communication delays, and robustness consensus.

*Abstract*—With the human passion for gaining knowledge, learning new things and knowing the news that surrounds the world, social networks were invented to serve the human need, which resulted in the rapid spread and use among people, but social networks have a dark and bright side. The dark side is that strangers or anonymous people harass some users with obscene words that the user feels wrong about, which leads to psychological harm to him, and here we try to discover how to discover electronic bullying to block this alarming phenomenon. In this context, the utility of Natural Language Processing (NLP) is employed in the present investigation to detect electronic bullying and address this alarming phenomenon. The machine learning (ML) method is moderated based on specific features or criteria for detecting cyberbullying on social media. The collected characteristics were analyzed using the K-Nearest Neighbor (KNN), Support Vector Machine (SVM), Naive Bayes (NB), Decision Trees (DT), and Random Forest (RF) methods. Naturally, there are test results that use or operate on the proposed framework in a multi-category setting and are encouraged by kappa, classifier accuracy, and f-measure standards. These apparent outcomes show that the suggested model is a valuable method for predicting the behavior of cyberbullying, its strength, and its impact on social networks via the Internet. In the end, we evaluated the results of the proposed and basic features with machine learning techniques, which shows us the importance and effectiveness of the proposed features for detecting cyberbullying. We evaluated the models, and we got the accuracy of the KNN (0,90), SVM (0,92), and Deep learning (0,96).

*Keywords*—*Cyberbullying detection; machine learning; deep learning; natural language processing (NLP), feature extraction; CNN*

## I. INTRODUCTION

Cyberbullying is a severe cybersecurity concern that constantly affects more people using social media and the Internet. Bullying is arguably hostile behavior displayed by a single individual or a group of people, who can only be present in certain places or at certain times of the day (such as during school hours) and can alternatively occur everywhere and at any time through electronic methods.

Cyberbullying was not taken seriously at the turn of the 20th century when social media, in general, and Internet usage were still in their infancy. At the time, the optimistic advice for dealing with cyberbullying was to "disconnect" or "turn off the screen [1, 2]. However, when the effects of online hate speech

increase, these proposals lose their effectiveness. More than following the usual suggested cybersecurity standards and procedures is required to prevent cybercrime. 41% of American citizens reported experiencing online harassment personally in 2017, while 66% reported seeing discourse offensive to others. Additionally, about 50% of young individuals who use social media sites have been said to be various experience several kinds of cyberbullying. Popular social networking sites like Twitter are not immune to this menace.

The identification of cyberbullying has grown in importance as an NLP topic, cyberbullying detection's objective is like other NLP jobs. Entails preprocessing the text (like a tweet) and extracting critical information in a particular method. That enables the use of machine learning to understand and categorize each text. The classic methods for classifying text involve the use of a way to make text representation simpler, such as the bag-of-words (BoW) approach, then a machine learning classifier like the logistic regression (LR) or support vector machine (SVM) approach [3] (see Fig. 1).

Natural Language Processing (NLP), the field of artificial intelligence that focuses on the interaction between computers and human language, has made significant strides in identifying online abuse [3]. However, specific challenges persist, including limitations in accommodating long texts within the constraints of social media platforms, the imbalance between hostile and constructive comments, the inherent ambiguity of natural language, and the prevalent use of slang [4] in the past ten years, neural network-based models have outperformed conventional machine learning methods on several NLP tasks.

Fig. 1. The general framework of deep learning architecture.

*Corresponding Author

These NLP techniques rely on the successful use of word embeddings, specifically deep learning, and neural network dense vector representations. In contrast to conventional machine learning algorithm-based methods, which rely primarily on manually created characteristics that are viewed as insufficient Deep learning methods use multilevel automated feature representation, which is laborious, to distinguish the input. a model of a multilayer perceptron neural network in various NLP tasks, CNN-based models, and recurrent neural networks (RNN) have demonstrated promising outcomes and developed a novel character-based technique that combines a CNN model with an RNN architecture to categorize text. Long short-term memory (LSTM) categorizes phrases separately to learn text meaning; CNN then used word analysis to extract regional attributes.

Motivated by the notable results of numerous NLP research aiming to categorize extensive texts, deep learning systems have proved their effectiveness. This paper conducts a comprehensive examination of cyberbullying within social networks, employing advanced technologies and methodologies, including Natural Language Processing (NLP) and machine learning. In Section II, "Related Works," existing research is reviewed, offering insights into the techniques used to combat online harassment. Section III, "Materials and Methods," outlines the tools and strategies utilized, particularly NLP and machine learning. Section IV, "Computational Complexity," delves into the algorithms driving the cyberbullying detection system. Section V, "Results," presents the findings, emphasizing the method's high accuracy in predicting cyberbullying's impact on online social networks. Section VI, "Limitations and Future Scope," explores the study's boundaries and suggests future research directions. Finally, in Section VII, "Conclusions," the paper summarizes the implications of the research, shedding light on technology's role in enhancing online safety, and invites further exploration into these crucial issues.

## II. RELATED WORK

This section examines methods for detecting cyberbullying in online social networks (OSNs). Cyberbullying incidents were broken down into Race, sexual orientation, culture, and IQ are some of the categories that Dinakar et al. in [5]. They employed four distinct classifiers as a result (Naive Bayes (NB), grip with rules, J48 with trees, and SVM) to identify the comments submitted on several contentious YouTube videos as a use case. The dataset, which consists of over 50,000 words, consists of three sections: testing, validation, and training. The accuracy of Rule-based Jrip hasn't, however, exceeded 80% and this is a good percentage to reduce online bullying. A method to identify fine-grained cyberbullying techniques, such as insults and threats.

The authors referenced online bullying and content that was taken from Ask.FM website contains English and Dutch language features that are like OSNs. The authors divided the prospective participants between a cyberbullying discourse harasser, target, and onlooker—into three groups. Two groups were formed in the class: onlooker-defenders and bystander-assistants, who back the harasser while speaking up for the victim. The comments were then separated using SVMs.

However, bullying idioms are harder to locate in the text on Twitter. One of the first to provide a technique to identify cyberbullying on the Twitter network was Sanchez. et al. [6]. The authors used Twitter abuse against a specific gender was identified using an NB classifier. The accuracy of their approach, though, was only 70%, and the amount of the dataset they employed was modest. To include a wide range of examples of cyberbullying, the abusive models should be applied generally rather than only to one topic. Using word2vec as a feature representation approach and both NB and RF classifiers, Saravanarj et al. [7] provided a broad framework to identify false positives and abusive tweets. The framework may extract demographic data about the perpetrators, including They, also mentioned age, name, and gender. The recommended techniques, though, cannot generate precise outcomes in comparison to complex machine learning techniques like deep learning. This study achieved results of 78%.

The authors Al-garadi et al. [8] conducted a study to detect cyberbullying on Twitter, which takes advantage of several unique features, which explicitly include activity, network, user, and tweeting on the Twitter platform. For classification purposes, these traits, and the samples they were associated with were entered into a machine-learning system. According to the authors' analysis of four machine learning algorithms, the RF method is superior to all other algorithms in the area under the receiver operating characteristic curve and f-measurement such as KNN, SVM, and NB only about 599 out of 10007 authors. The dataset included total tweets related to bullying. The Big Five models (including neuroticism, agreeableness, and extraversion) and the Dark Triad (including psychopathy) have been used and I have achieved scores of 60%. by Balakrishnan, Khan, and Arabnia, Balakrishnan et al. [9,10]. To analyze the personalities of Twitter users and gradually spot online cruelty. The proposed method aimed to look at the connection between personality factors and online bullying. The writers divided the tweets into four categories representing the user's behavior: bully, spammer, attacker, and everyday person. Then the writers classified each tweet into one of the types mentioned earlier using the random forest RF ensemble approach. Results from the suggested system using these personality factors were favorable. Although it was a modest number, the dataset included 5453 tweets that were gathered using the hashtag "Gamergate." Additionally, the tweets are more specialized than they should be about a particular community (using the hashtag "Gamergate").

A significant amount of Twitter comments were examined by Chatzako et al. [11,12] to identify features of abusive conduct. These tweets were from people who engaged in various conversations, including those on the NBA, the Gamergate scandal, and comments about television programs about female wages. Discrepancy on stations run by the British Broadcasting Corporation (BBC). The writers looked into several aspects taken from Twitter, including user attributes, network-based features, and tweets. They then experimented with several cutting-edge classification techniques to differentiate across user accounts and achieved an accuracy of 91%.

A deep learning detection technique was presented by Gamback et al. [13] To recognize Twitter cyberbullying comments. The method divided the remarks into four categories: non-offensive, racist, sexist, and all three (i.e., sexism and racism). The authors used the character four grams to represent text. Word2vec was also employed for semantic analysis authors. After that, the authors used one of these methods to condense the feature set: Features of un-layer CNN (i.e., max-pooling layer). and they used a SoftMax method to classify each tweet as a result. When tested utilizing cross-validation by ten, the suggested approach had an F-score of 78.3%. Six thousand six hundred fifty-five tweets make up the datasets that the authors used to identify cyberbullying in Twitter comments.

Pradhan et al. [14] explored two deep learning architectures as well as a neural network model. The CNN-LSTM and CNN-BiLSTM Deep learning architectures and neural networks are two examples. Deep learning both methods yielded encouraging results, with an accuracy rate of about 92%. The efficiency of models for self-attention (these models obtained cutting-edge results in a variety of machine translation tasks) by Pradhan et al. [14], The detection of cyberbullying was investigated with the cyberbullying datasets from Form Spring, Wikipedia, and Twitter The application of the transformer architecture paradigm for self-attention was examined by the authors. A multiheaded self-attention layer was employed in this architecture to replace the recurrent layers that were utilized for encoding and decoding, the results from the suggested method were satisfactory.

Agrawal et al. [15] experimentally showed through a framework that this method could get around some of the drawbacks of previous approaches, such as limiting the limitation of hate speech identification to a specific category (i.e., cyberbullying) and using custom features available through traditional machine learning methods. To overcome these restrictions, the authors investigated four deep learning architectures: BiLSTM with an attention layer, CNN, and LSTM. Additionally, the authors categorize assault, bullying, racism, and sexism are four criteria used to classify hate speech on the social internet. Furthermore, they used transfer learning to apply the information gained from a deep understanding of two datasets, one of which was remarkably similar, extensive tests were conducted on the researched architectures using the Twitter, Wikipedia, and Formspring datasets. Around 16 thousand tweets from Twitter were used by the authors Pradhan et al. and Agrawal et al. [14,15] to identify social media cyberbullying using Spanish-language content, Plaza et al. [16] have devised a method. The authors investigated a few deep-learning algorithms to detect hate speech in Spanish. They were enhancing performance. The authors' deep learning models were trained. Specifically, used Transfer learning is used to address a few sample problems. Additionally, the authors evaluated how well SVM and LR are examples of standard machine learning techniques. Compared models of deep learning that have been pre-trained include the enhanced-BERT, LSTM, CNN, and LSTM. The trials demonstrated that using BERT techniques and pre-trained models together enhanced performance in terms of accuracy in comparison to

other deep learning and conventional models. Table I shows the comparison study of literature Review.

TABLE I.　COMPARISON STUDY OF LITERATURE REVIEW

| Authors | APP | Methods | Limitation | Accuracy |
|---|---|---|---|---|
| [5] | YouTube | Jrip, J48, NB, and SVM with rules | A small dataset with poor precision | 80% |
| [6] | Twitter | Classification NB | A small dataset with poor precision | 70% |
| [7] | Twitter | NB and random forests | Not reported | 78% |
| [8] | Twitter | KNN, RF, NB, and SVM | The dataset is not that large | 60% |
| [9,10] | Twitter | J48, RF, and NB | Constrained to a certain demographic with a fairly small dataset | 60% |
| [11,12) | Twitter | A probabilistic artificial neural network and ensemble | The dataset is not that large | 91% |
| [13] | Twitter | CNN uses SoftMax | The dataset is quite compact | 78.3% |
| [14] | Twitter, Wikipedia, and Formspring | CNN, LSTM, and SVM | There is a minimal amount of data | 92% |
| [15] | Twitter, Wikipedia, and Formspring | CNN, LSTM, and SVM | The dataset is quite compact | 92% |
| [16] | Twitter | BERT techniques and trained models | The data collection is not that large | 95% |

Motivated by the notable results of numerous NLP research aiming to categorize extensive texts, deep learning systems have proved their effectiveness. We look into the possibility of recognizing short sentences utilizing the multichannel deep learning model.

## III.　MATERIALS AND METHODS

### A. Dataset Description

The tweets dataset used in this study was sourced from [2] In two columns, the data includes tweets and class. The dataset has two types: cyberbullying and not cyberbullying. There were 47692 tweets utilized in total to create this dataset.

*1) Exploratory data analysis*: The table description of the Cyberbullying dataset. Table II displays the percentage of cyberbullying incidents, 38000 tweets however the percentage of cyberbullying incidents is 47692 tweets.

TABLE II.    CYBERBULLYING DATASET

| # | Column | Non-null Count | Dtype |
|---|--------|----------------|-------|
| 0 | Tweet_text | 47692 non-null | Object |
| 1 | Cyberbullying_type | 47692 non-null | Object |

According to Table II, the dataset's two columns are object types. In this dataset, 36 tweets were found to be duplicates; these tweets were eliminated. Eliminate contractions, emojis, new line characters, links, and stop words.

Remove just the "#" sign to maintain the center of the sentence's # hashtags while eliminating the # hashtags at the conclusion & and $ are filtered special characters that are present in some words. The words were also reduced in complexity via stemming. Stemming is a technique used to strip away the suffixes, prefixes, and other word elements of a given word until only its root or lemma remains. This approach is useful in NLP [17](see Fig. 2).

It was observed in Fig. 3 that the tweets (including very long tweets) ethnicity has reached less than 100. While in Fig. 4, the tweets (excluding very long tweets) ethnicity has reached less than 100, we conclude that most of the words in the tweets are bullying ethnicity and we must detect and limit these bad tweets to reduce bullying.

Fig. 2.    The proportion of cyberbullying.

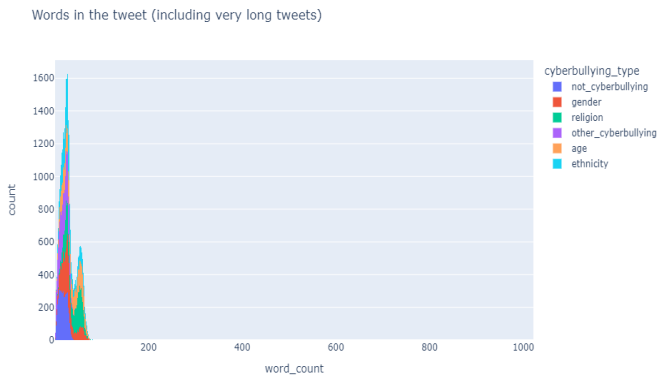

Fig. 3.    Words in the tweets, including very long tweets.

Fig. 4.    Words in the tweets, excluding very long tweets.

In the Fig. 5 shows the percentage of ages that are exposed to cyberbullying, which schools, where the percentage reached less than 9000, unlike kids, which shows that the percentage is less than 1000, and here it shows us what ages are affected by cyberbullying.

Fig. 6 shows the religion that is most exposed to cyberbullying, which is the Muslim, with a percentage of less than 5,000, in contrast to radical which shows a percentage is less than 2,000.

Fig. 5.    Age-based cyberbullying.

Fig. 6.    Religion-based cyberbullying.

## B. Evaluation Metrics

We also know that classification accuracy is the natural choice for statistics because identifying cyberbullying is a classification task, but we have a problem, which is the inequality in class for determining to cyberbully, and accuracy is not a reliable indicator, as well as retrieval and accuracy, as well as the F1 scale. To obtain all measures (TN) a matrix containing four categories of false positive (FP), false negative (FN), true positive (TP), and true negative values is used [18,19].

The fraction of correctly classified instances relative to all instances is known as accuracy. The Eq. (1) that follows determines it.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

The recall is the proportion of correctly categorized examples that are positive when compared to instances that belong to the actual class. The Eq. (2) that follows determines it.

$$Recall = \frac{TP}{TP+TF} \quad (2)$$

The fraction of accurately categorized positive events relative to all projected positive instances is known as precision. The Eq. (3) that follows determines it.

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

The F1 measure combines recall and precision, making it useful in situations when both are crucial. The Eq. (4) that follows determines it.

$$F1measure = 2 * \frac{(precision * recall)}{precision + recall} \quad (4)$$

## C. Methodology

*1) Feature extraction*: The sklearn package's CountVectorizer (CV), which has a 2500 feature maximum, was utilized to extract features. Cyberbullying type was used as a label, and a CV was added as a feature to the original tweet text. The label Y's size was 46017X6, and the feature X's was 46017X2500. With a ratio of 75:25 for training and testing, the data was divided using the sklearn train test split. The sklearn StandardScaler was used to conduct the feature scaling. The dataset was split into training and testing with a ratio of 75:25, therefore the training set contains 34512 records.

*2) KNN*: The k-nearest neighbor's algorithm is a supervised learning classifier that makes predictions or classifications about how a single data point will be grouped using proximity. Nevertheless, it can be used to address classification or regression problems. KNN compares data points based on how close or far apart they are from the query points. There are several ways to compute distance; one of the most popular is the Euclidean distance formula in Eq. (5).

$$d(x,y) = \sqrt{\sum_{i=1}^{n}(yi - xi)^2} \quad (5)$$

A straight line connecting the available location and the query point is measured by Euclidean distance.

KNN has the benefits of being simple to use, adaptable, and requiring fewer hyperparameters, but it also has memory and overfitting problems.

*3) Support vector machine*: Support Vector Machine (SVM), a dependable classification and regression technique, improves a model's projected accuracy while preventing overfitting the training set. SVM is especially effective for analyzing data that has thousands of predictor fields. By transforming the data into a high-dimensional subspace, SVM may categorize data points even when they are not linearly separable. After a class divider has been found, the data are transformed to allow for the separator's hyperplane.

*4) Deep learning model development*: We have developed a 6-layer Deep Learning model trained on the Twitter dataset for the identification of cyberbullying 5.2. This investigation used Python 3.8, Keras API, and Single-GPU TensorFlow 2.0 backend (i9, 10900k, 128 GB, 2666 MHz RAM). First, the Twitter dataset has been preprocessed. An embedding layer with the parameters vocab size and input length processes the input. The Embedding layer searches the vocabulary's integer encoding for each word's embedding vector. While the model is being trained, these vectors are learned, and the output array gains a dimension thanks to the vectors, (Batch, Sequence, and Embedding) are the measures that are obtained). The batch normalization layer was used to speed up and improve the stability of training artificial neural networks by normalizing the inputs to the layers by re-centering and re-scaling. The second layer was a convolution layer. By applying a filter to information, convolutional neural networks create a feature map that summarizes the existence of features recognized in the input. A max pool layer is made up of the third layer. The most significant value found in each patch of each feature map is determined using a pooling technique called max pooling. The results are feature maps that have been down-sampled or pooled, with the focus being placed on the feature that is most common in the patch as opposed to its average presence, as in the case of average pooling. A flattened layer, the fourth layer, condenses the input's spatial dimensions to only its channel dimension. For instance, the coating will produce a flattened (H*W*C)-by-N-by-S array if given an H-by-W-by-C-by-N-by-S array as input. The dense layer was the last two layers.

The dataset is categorized using a thick layer based on the output of the preceding layers. A non-linear function known as an "activation function" is applied to the weighted average of the input that the neurons in each neural network layer calculate. The initial dense layer with L1L2 regulators employed the ReLu activation function, while the final layer with the softmax function was used for classification. Fig. 7 displays the CNN-LSTM architecture that has been suggested for use in malware detection.

| embedding_input | input: | [(None, 2500)] |
|---|---|---|
| InputLayer | output: | [(None, 2500)] |

| embedding | input: | (None, 2500) |
|---|---|---|
| Embedding | output: | (None, 2500, 100) |

| conv1d | input: | (None, 2500, 100) |
|---|---|---|
| Conv1D | output: | (None, 2493, 32) |

| max_pooling1d | input: | (None, 2493, 32) |
|---|---|---|
| MaxPooling1D | output: | (None, 1246, 32) |

| flatten | input: | (None, 1246, 32) |
|---|---|---|
| Flatten | output: | (None, 39872) |

| dense | input: | (None, 39872) |

Fig. 7.   Proposed deep learning architecture for cyberbullying detection.

The model compilation followed the layer addition. An optimizer, a loss function, and a metric function are required to evaluate the model's validity during compilation. The stochastic gradient descent variant Adam optimization technique was used for optimization. It has several benefits, such as fewer memory requirements and quick calculations. Given that the label comprises six classes, the categorical cross-entropy loss function was utilized to quantify the error rate between the actual and values for binary classification.

## IV.   COMPUTATIONAL COMPLEXITY

Accuracy was then employed as an evaluation parameter. (6,739,628 params altogether, Trainable params: 6,739,628, non-trainable parameters: zero) as shown in  Table III.

TABLE III.    NUMBER OF TRAINABLE AND NON-TRAINABLE PARAMETERS FOR THE CNN-LSTM MODDLE

| Layer Type | Output Shape | #Params |
|---|---|---|
| embedding_1 (Embedding) | (None,2500, 100) | 6315200 |
| conv1d_1 (Conv1D) | (None,2493, 32) | 25632 |
| max_pooling1d_1 (MaxPooling 1D) | (None, 1246, 32) | 0 |
| flatten_1 (Flatten) | (None,39872) | 0 |
| dense_2 (Dense) | (None,10) | 398730 |
| dense_3 (Dense) | (None,6) | 66 |

In Table III the embedding layer has 6,315,200 parameters, which are used to map each of the 2,500 input tokens to a 100-dimensional vector. The complexity of this layer is O (batch_size * input_length * embedding_size) = O(32 * 2500 * 100) = O(8e7). The 1D convolutional layer has 25,632 parameters and requires batch_size * 2493 * 32 multiply-adds to produce its output. The complexity of this layer is O (batch_size * input_length * kernel_size * num_filters) = O (32 * 2493 * 3 * 32) = O(7.5e6). The max pooling layer simply reduces the output size by a factor of 2, so it has negligible computational complexity. The flattening layer has no parameters and simply reshapes the output of the previous layer, so it has negligible computational complexity. The first dense layer has 398,730 parameters and requires batch_size * 39872 multiply-adds to produce its output. The complexity of this layer is O (batch_size * input_size * output_size) = O (1.27e9). The second dense layer has 66 parameters and requires batch_size * 10 multiply-adds to produce its output. The complexity of this layer is O (batch_size * input_size * output_size) = O (3.2e3). The overall computational complexity of the given model can be approximated as O (1.36e9). This means that the computational cost of training and inference for this model grows linearly with the size of the input data. Specifically, the dominant factors contributing to the computational complexity of this model are the number of parameters in the embedding and dense layers, as well as the size of the input and output data for each layer.

## V.   RESULTS AND DISCUSSIONS

Here we review the accuracy results that were applied through the methods (KNN, SVM, Deep Learning) as shown in Table IV.

We note here that KNN gave fewer results than SVM and DL because of the approximation of the basic distribution of the data in a parametric way, and SVM assumes the existence of a super level that separates the data points from DL, as it is known that it works like a human neural network, as it is an effective classifier for cyberbullying detection tasks to extract text from how to create a 6-layer model.

Based on experiments, the deep learning method shows better results in accuracy for detecting cyberbullying than other methods (KNN, SVM), as deep learning is an effective classifier for cyberbullying detection tasks to extract text by creating a 6-layer model, which was A Twitter dataset drill was one GPU (i9, 10900K, 128GB 2666MHz RAM) running with Python 3.8, Keras API and Tensorflow 2.0 backend. The result indicated that deep learning achieved good state-of-the-art results on cyberbullying, and it is important to consider and analyze all results from all experiments.

To achieve our experiments, we applied a test to determine the appropriate resolution to deliver the best results for our model. Results using a deep learning algorithm to detect cyberbullying, in the first layer is embedding, which is the input processing and forms the output from (none, 2500, 100) and parameters 6315200 was made, the second layer is a wrapping layer and forms the output from (none, 2493, 32) and parameters 25632 was made, and the third layer takes the highest value found in Each patch and the results are reduced or aggregated feature maps that focus on the most prevalent

feature in the patch rather than its average presence and form the output from (none, 1246, 32) parameters 0, the fourth layer is a flat layer, where the flat layer minimizes The spatial dimensions of the inputs to their channel dimensions and form the output from (39872, none) and parameters 0 were made, and in the last two layers is the dense layer to enrich the data set by calculating the inputs of neurons in each layer and form the output from the first dense layer (none, 10) Parameters 398730 was created, the output was created from the second dense layer (none, 6), and parameters 66 was created.

It was noted that the accuracy (KNN) was (0.90), which means that the model correctly predicted 90% of the comments classified as cyberbullying. Let's assume that we have tweets and there is bullying. We will discover this bullying by asking about some characteristics or types of words. Here, the discovery is classified or programmed, so that it identifies bullying words and the way KNN works. We now have a word, and it has two properties (word, bad word) Can it be predicted for its classification, we determine the value of the variable that will express the number of neighbors k and let its value be k=3, we calculate the value of the distance through the Eq. (6).

$$d\,(x,y) = \sqrt{\sum_{i=1}^{n}(yi - xi\,)^2} \qquad (6)$$

Table IV represents the comparison of the present investigation with the existing studies used tweets datasets. Table IV. offers a valuable comparison with other studies in terms of accuracy and limitations or future scope. This table reinforces the significance of present research and the need for continuous improvement in the field of cyberbullying detection.

TABLE IV. COMPARISON WITH THE OTHER STUDIES

| Studies | Methods | Limitations/future scope | Accuracy |
|---|---|---|---|
| [6] | Classification NB | A small dataset with poor precision | 70% |
| [7] | NB and random forests | Not reported | 78% |
| [8] | KNN, RF, NB, and SVM | The dataset is not that large | 60% |
| [9,10] | J48, RF, and NB | Constrained to a certain demographic with a fairly small dataset | 60% |
| [11,12] | A probabilistic artificial neural network and ensemble | The dataset is not that large | 91% |
| [13] | CNN uses SoftMax | The dataset is quite compact | 78.3% |
| [14] | CNN, LSTM, and SVM | There is a minimal amount of data | 92% |
| [15] | CNN, LSTM, and SVM | The dataset is quite compact | 92% |
| [16] | BERT techniques and trained models | The data collection is not that large | 95% |
| Present Study | KNN | Will add more data as future endevour | 90% |
| Present | SVM | Will add more data as future endevour | 92% |
| Study | DL Model | Will add more data as future endevour | 96% |

Through this method, we can limit or meet the words of cyberbullying. Fig. 8 shows us the accuracy ratio between the methods (KNN= 0.90, SVM= 0.92, Deep Learning= 0,97), and here it is clear to us that Deep Learning is higher in accuracy than the rest.

Fig. 9 shows us the high accuracy of training over the ages, and that the validation accuracy rises with the exercise of accuracy as a direct relationship. The higher the accuracy of training, the higher the validation of accuracy, as well as the training loss and the loss of accuracy the graph shows us that the indicator is going down over the ages, the worse the training accuracy, the greater the loss.

Fig. 8. The selected method and their accuracies.

Fig. 9. Accuracy level through the epochs.

## VI. LIMITATIONS AND FUTURE SCOPE

As it is known that the KNN algorithm is simple and easy to understand, and the result of this ease is that it does not provide predictions for words that are not circulated or known among people because it has no idea about it, so we must know the bad words and update them between periods to update the bad words, and the KNN algorithm needs. A large memory to store a group of words or data to predict them that may be used in tweets, which requires that the memory be very large to store words [20]. SVM works by separating data, but it is not suitable for a large group of data, because it is not implemented well if the data is overlapping, and the kernel greatly affects the way SVM works, which must choose the best kernel that fits the data, as there is another limitation is that it uses a lot of memory, as it needs to store the kernel matrix, which can be large for the data set, and also SVM lacks a probabilistic interpretation to make a decision, which is a defect in some applications, and the last limitation we have is that SVM is sensitive to choosing parameters as it is difficult to determine the best parameter values for a set of data [21]. Deep learning faces a limitation, which is that it understands the words received in the training data, as it is possible that the person does not know all terms or words in all dialects, which affects the mechanism of deep learning, and it is known to use deep learning models devices. These devices help reduce time and increase Effectiveness, however, are very expensive and consume a lot of energy. One of the limitations of deep learning is the method of learning. Sometimes the process may be disrupted. If the method is low, it is difficult to find a solution [18, 21].

We intend to use more data when we implement our method. We believe expanding our sample will enhance our approach performance. Large data sets are necessary for deep learning algorithms to work effectively. We'll also attempt to expand the suggested structure by including numerous channels. The framework's performance might be enhanced by employing more media when using a large dataset. The weights and other parameters of deep and massive neural networks can be improved with a large dataset [22,23]. Additionally, we intend to test our suggested framework using tweets in several languages.

Looking ahead, promising avenues include the Reliable Architecture-Oblivious Error Detection (RAED) algorithm, which enhances the reliability of computer systems and contributes to user and system well-being [24-26]. SHA-3's role in data integrity verification and the Advanced Encryption Standard (AES) indirectly aid in preventing cyberbullying by ensuring data privacy and creating a safe online environment. Additionally, leveraging algorithms like SIKE and CSIDH enhances security and privacy on social media, ultimately contributing to a safer digital landscape and protection against cyberbullying [27-30].

## VII. CONCLUSIONS

The importance of online social networking has increased a part of our daily lives as it makes it easier to engage with others. However, detecting cyberbullying is an important topic to be examined due to the emergence of antisocial behavior faced by social media users due to issues such as hate speech, trolling, and cyberbullying on platforms such as Twitter and other social media experiences, which undoubtedly affects the psyche of victims. Social networks have become within the reach of everyone, especially children, and when children are exposed to electronic bullying, this affects the building of their personality and psyche. In this paper, reliable methods for detecting cyberbullying are presented. It shows how deep learning works and its high accuracy for detecting cyberbullying, and achieved the highest result, (0.96), by anticipating bad words, which helps reduce the spread of bullying in the means of communication, and as we mentioned another method, which is SVM, the result was good, which is (0.92). , but it is considered less than Deep learning, which affects the discovery of cyberbullying, and we also mentioned another method, which is KNN, which was the lowest result, as it achieved (0.90). The results show us the importance of this research and reliable methods to reduce the spread of cyberbullying.

*Abstract*—Object recognition has gained significance due to the rise in CCTV surveillance and the need for automated detection of objects or activities in images and videos. Lightweight process frameworks are in demand for sensor networks. While Convolutional Neural Networks (CNNs) are widely used in computer vision, many existing architectures are specialized. This paper introduces the Dimension-Based Generic Convolution Block (DBGC), enhancing CNNs with dimension-wise selection of kernels for improved performance. The DBGC offers flexibility for height, width, and depth kernels and can be applied to different dimension combinations. A key feature is the dimension selector block. Unoptimized kernel dimensions reduce computational operations and accuracy, while semi-optimized ones maintain accuracy with fewer operations. Optimized dimensions provide 5-6% higher accuracy and reduced operations. This work addresses the challenge of generic architecture in object recognition research.

*Keywords—Convolutional Neural Network (CNN); depth-wise separable convolution; dimension-based generic convolution unit (DBGC); CNN architecture*

## I. INTRODUCTION

The Convolutional Neural Network (CNN) stands as a widely adopted architecture within the realm of computer vision, serving pivotal roles in tasks like object recognition and detection [1]. Researchers have delved into a myriad of modifications for CNNs in the past, encompassing areas such as activation functions, regularization techniques, parameter tuning, and architectural advancements. In the following section, we will delve into the latest developments in this ever evolving field.

This paper introduces a groundbreaking innovation known as the Dimension-Based Generic Convolution Unit (DBGC), which operates as a dimension selector module. Remarkably versatile, the DBGC can be seamlessly integrated into various architectural frameworks, yielding reductions in Floating Point Operations Per Second (FLOPs) without compromising accuracy. The research makes a significant contribution by presenting both semi-optimized and fully optimized kernel methods, effectively curtailing FLOPs while either maintaining or improving model accuracy.

The applications of computer vision and image processing extend across a multitude of domains, including but not limited to traffic surveillance, object detection, autonomous vehicles, agriculture, and healthcare [2], [3]. A crucial aspect of computer vision tasks is precise feature extraction. Fusion methods for feature extraction, as mentioned in b4 [4], enhance performance. The paper identifies inspiration from networks like ShuffleNetv2 [5], ESPNetv2 [6], DiCENet [7], and MobileNetv2 [8]. The subsequent sections elaborate on these networks' core architectures, strengths, and weaknesses.

### A. ShuffleNetv2

ShuffleNetv2, presented in the 2018 paper "ShuffleNetv2: Practical Guidelines for Efficient CNN Architecture Design" by Ma, Zhang, Zheng, and Sun, introduces a novel approach for evaluating computational complexity [5]. In addition to the conventional FLOPs metric, ShuffleNetv2 considers factors like speed, memory access costs, and platform-specific parallelism. Unlike FLOPs alone, which may not accurately reflect network speed due to variables such as memory access and target platform differences, this approach provides a more comprehensive assessment of efficiency. To address these limitations, ShuffleNetv2 introduces four key principles for network design:

- Proportional Input and Output Channels: Maintaining a 1:1 ratio between input and output channels minimizes memory access costs.

- Optimal Group Convolution: Carefully selecting the number of groups in convolutions prevents excessive memory access costs.

- Reduced Network Fragmentation: Minimizing network fragmentation enhances parallelism efficiency for better parallel computations.

- Significance of Element-wise Operations: Despite low FLOPs, element-wise operations can significantly increase memory access time.

The combined application of these principles enhances CNN architecture efficiency beyond FLOPs considerations. ShuffleNetv2 integrates these principles into its design to improve network efficiency, as illustrated in Fig. 1.

### B. ESPNetv2

ESPNetv2 is a progression from ESPNetv1, initially designed for semantic segmentation [6]. It broadens the application of ESPNetv1's ideas to diverse computer vision tasks, even encompassing language modeling. The central aim

---

*Corresponding Author

is refining the separation of dilated convolutions in a depth-wise fashion. This is realized through the introduction of a new module called EESP (Extremely Efficient Spatial Pyramid), outlined in Fig. 2.

The EESP block in ESPNetv2 divides channels into two groups, using one as an identity and maintaining channel balance during convolutions. It avoids group-wise convolutions and includes ReLU concatenations and depth-wise convolutions [6]. The architecture begins with stride-2 convolutions and has three phases, each starting with a stride EESP block, altering spatial dimensions and channels. Afterward, there are convolution layers, global average pooling, and a classifier. Strided EESP uses dilated convolutions and concatenation for long-range connections, supported by depth-wise convolutions for spatial information. ESPNetv2 achieves about 74% Top1 accuracy with 5.9 million parameters.

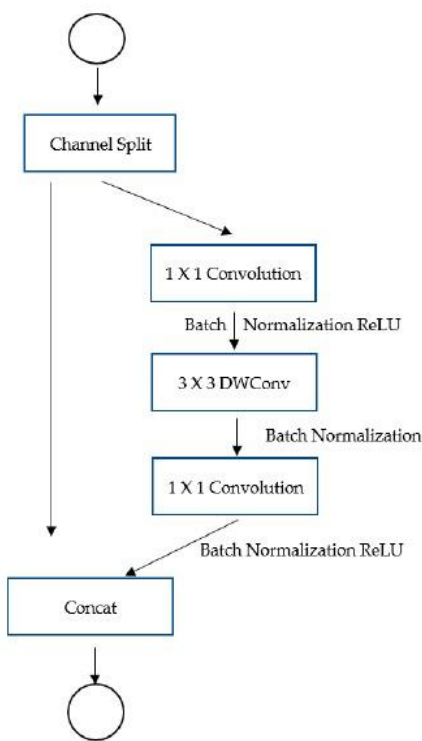

Fig. 1. ShuffleNetv2 design.

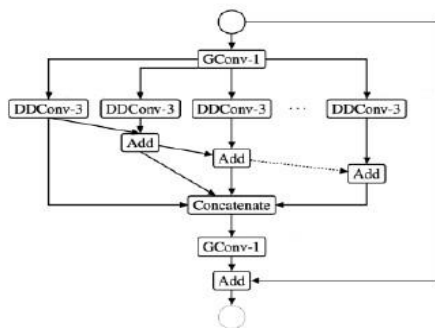

Fig. 2. Building block of EESP.

### C. DiCENet

DiCENet introduces the concept of dimension-wise convolution and fusion to replace regular convolution. Depth wise and group convolutions divide the input tensor along the channel dimension, allowing each filter to operate on specific channel subsets [7]. DiCENet suggests extending this slicing approach to width and height dimensions. Depth-wise convolution has a drawback of requiring multiple convolutions to effectively mix channels, constituting a substantial portion of operations in models like MobileNet.

ShuffleNet attempted to mitigate this with grouped convolution for speed, but further improvement might be possible. DiCENet proposes dimension-wise convolution (DimConv) across all three possible axes (DHW): depth-wise (HW), widthwise (DH), and height-wise (DW). Depth-wise covers spatial dimensions, widthwise involves splitting along channels while sliding over image width, and height-wise does the same along the height axis. This approach aims to enhance convolution efficiency and performance.

### D. MobileNetv2

MobileNetv2 maintains the use of depth-wise convolution, a characteristic shared with its predecessor, MobileNetv1 [8]. However, in MobileNetv2, the arrangement of blocks is restructured, notably placing the depth-wise convolution block at the center, as depicted in Fig. 3. Preceding the depth wise layer is a 1x1 convolution referred to as the expansion layer, which augments the channel count. Following the depth wise layer, there is another 1x1 convolution, identified as the projection layer or bottleneck layer. This final convolution reduces the number of channels back to a more optimal configuration. This architectural adjustment aims to enhance the model's performance and efficiency.

MobileNetv2 retains the depth-wise convolution approach from its predecessor, MobileNetv1 [8]. However, MobileNetv2 introduces a novel block arrangement. Notably, it places the depth-wise convolution block at the center, as shown in Fig. 3. Preceding the depth-wise layer is a 1x1 convolution known as the expansion layer, which increases channel numbers. Subsequent to the depth-wise layer, another 1x1 convolution, called the projection or bottleneck layer, is employed. This final convolution reduces channel counts to an optimal level. This architectural shift is designed to boost both the performance and efficiency of the model.

MobileNetv2 preserves ReLU6 as its activation function, as in its predecessor. Yet, beyond the bottleneck layer, it opts not to use any activation function [8], termed "linear bottlenecks." This choice is informed by the risk of losing vital information due to non-linearity in this low-dimensional data context.

Together, these elements constitute the architecture of MobileNetV2. Subsequently, the architecture involves a conventional 1x1 convolution layer, global average pooling, and a classification layer, as depicted in Fig. 3. Fig. 4 furnishes the Top1 and Top5 accuracy metrics for a range of lightweight CNN architectures.
Fig. 3.  MobileNetv2.

| Architecture | Year | Parameters | Top1 | Top5 |
|---|---|---|---|---|
| ShuffleNetv2 [6] | 2018 | 2.3 M | 69.4 | 88.9 |
| MobileNetv2 [7] | 2018 | 3.47 M | 71.8 | 91.0 |
| ESPNetv2 [8] | 2019 | 3.49 M | 72.06 | 90.39 |
| DiCENet [9] | 2020 | 2.65 M | 69.05 | 88.8 |

Fig. 4.  A comparison of different lightweight architectural designs.

In Section III of the manuscript, the authors present the DBGC (Dimension-based Generic Convolution) block. A comprehensive grasp of the concepts expounded upon in Section II is essential for a complete comprehension of this section. Section II is bifurcated into two key segments: the initial part elucidates the separable convolution technique and its diverse modifications, while the subsequent part delves into an array of convolutional kernels. Moving forward, Section IV provides a detailed examination of the results and analysis pertaining to the recently introduced DBGC block.

## II. MATERIALS AND METHODS

This section provides a clear explanation of crucial terminologies and their relevance in the context of the proposed DBGC block. The section is structured into two subsections: the first one covers separable convolution, while the second one delves into depth-wise separable convolution.

### A. Introduction to Separable Convolution

The inception of separable convolution dates back to the Xception model of 2016 [9]. In response to the growing trend of deep learning (DL) moving towards edge computing, especially on smart phones and IoT devices, researchers proposed various techniques to enhance inferential computation efficiency. These techniques encompass network pruning, parameter compression, and more. One particularly effective approach is quantization, which streamlines DL processes by enabling them to operate on fixed-point pipelines. The renowned lightweight architecture,

MobileNetv1, has notably leveraged separable convolution to substantially reduce parameter size and computation latency [9].

Separable convolutions can be categorized into two main types: (1) Spatial separable convolution and (2) Depth-wise separable convolution.

*1) Spatial separable convolution*: Spatial separable convolution simplifies convolution by breaking it into two separate convolutions [18]. While conceptually straightforward, its practical application in deep learning is limited due to certain drawbacks. The term "spatial separable convolution" reflects its focus on width and height dimensions in images and kernels [10], with image channels representing the "depth" dimension. This approach splits a kernel into smaller parts; for example, a 3x3 kernel is divided into 3x1 and 1x3 kernels, as shown in Fig. 5.

$$\begin{bmatrix} 2 & 4 & 6 \\ 3 & 6 & 9 \\ 4 & 8 & 12 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \\ 4 \end{bmatrix} X \begin{bmatrix} 1 & 2 & 3 \end{bmatrix}$$

Fig. 5.  Dividing a 3x3 kernel into spatial.

Achieving the same outcome involves conducting two convolutions, each with three multiplications, totaling six, as opposed to a single convolution with nine multiplications. This approach reduces computational complexity by minimizing the number of multiplications, resulting in enhanced network efficiency, as illustrated in Fig. 6.

A notable limitation of a spatial separable kernel is its inability to effectively divide all kernels into two parts. This limitation becomes particularly problematic during training, as it utilizes only a small fraction of the entire network.

*2) Depth-wise separable convolution*: When working with kernels that cannot be decomposed into smaller components, the adoption of depth-wise separable.

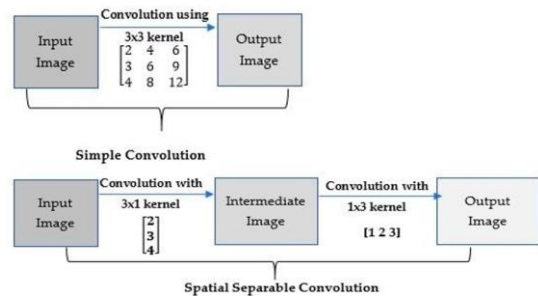

Fig. 6.  Basic and spatially separable convolution.

Convolution becomes increasingly popular. Facilitating its implementation are tools such as keras.layers.SeparableConv2D or tf.layers.separable$_c$onv2d. The term "depth-wise separable convolution" reflects its attention to both spatial dimensions and the depth dimension (number of channels) [11]. In an input image with RGB channels, each channel (R, G, B) provides a distinct interpretation of the image. After multiple convolutions, the image can comprise a variety of channels [12]. For instance, the "red" channel focuses on redness, "blue" on blueness, and

"green" on greenness. A 64-channel image can be understood in 64 unique ways. In depth-wise separable convolution, similarly to spatial separable convolution, a kernel is divided into two separate kernels. One kernel handles depth-wise convolution, while the other manages point-wise convolution.

*a) Depth-Wise Convolution*: Depth-wise convolution applies convolutional kernels to an input image without modifying its depth, as elucidated in [13]. This process, illustrated in Fig. 7, is achieved through the utilization of three distinct kernels. For example, when dealing with a 12x12x3 input image, three 5x5x1 kernels are employed. Each 5x5x1 kernel traverses a channel of the input image, computing scalar products for every group of 25 pixels (5x5). Consequently, this generates an output image of dimensions 8x8x1, as visually depicted in Fig. 7.

Fig. 7.   Depth-wise convolution employs three kernels to transform a $12 \times 12 \times 1$ image into an $8 \times 8 \times 1$ image.

*b) Point-Wise Convolution*: Following depth-wise convolution, the image transforms from 12x12x3 to 8x8x3, necessitating a channel expansion. "Point-wise convolution" uses a 1x1 kernel, processing individual points. The kernel's depth matches input image channels [14]. For an 8x8x1 result, a 1x1x3 kernel moves through the 8x8x3 image, as shown in Fig. 8.

Fig. 8.   Point-wise convolution reduces a three-channel image to a single-channel image.

In a normal convolution, considering 256 kernels of 5x5x3 over 8x8 movements requires 1,228,800 multiplications. In separable convolution, using three 5x5x1 kernels for depth wise convolution in 8x8 movements entails 4,800 multiplications, and point-wise convolution with 256 kernels of 1x1x1x3 needs 49,152 multiplications. The total is 53,952.

Comparatively, 1,228,800 is significantly higher than 53,952. Fewer calculations enable efficient data processing. Standard convolution alters the image 256 times, demanding 4,800 multiplications each. In contrast, separable convolution modifies the image once and extends it to 256 channels, conserving resources. Separable convolution's limitation is minimizing parameters, potentially affecting small networks. Nonetheless, it boosts efficiency without compromising effectiveness, making it a popular choice20.

### B. Introduction to Convolution Kernels

Convolution utilizes a matrix-like "kernel" to extract targeted "features" from an input image, enhancing the output through multiplication, as shown in Fig. 9. For instance, a kernel can sharpen the input image, yielding a desired output representation [20].

Fig. 9.   Example for convolutional use kernel.

Convolution involves using a "kernel," a matrix of weighted values, to extract important features from input data. The term "convolution" is related to the dimensions of the kernel, such as in 2D convolutions where the kernel matrix is two dimensional. On the other hand, a "filter" is a collection of multiple kernels, each applied to a specific input channel. Filters have an extra dimension compared to kernels, particularly in 2D convolutions, where filters become 3D matrices. For a CNN layer with kernel dimensions of h*w and input channels of k, filter dimensions become k*h*w. Convolutions come in three types based on kernel nature: 1D, 2D and 3D convolutions.

*1) 1D convolution*: 1D convolutions are highly useful for processing time series data, especially with one-dimensional inputs, even when containing multiple channels [15]. These convolutions operate in a single direction, resulting in one-dimensional output, as demonstrated in Fig. 10.

Fig. 10.  1D convolution.

*2) 2D Convolution*: In 2D convolutions, as shown in Fig. 11, the kernel size is 3x3. Multiple kernels, highlighted in yellow, form a filter that corresponds to various input channels indicated in blue. Each channel aligns with a distinct kernel. The filter moves in two directions across the input, resulting in a two-dimensional output. 2D convolutions are widely used, particularly in computer vision.

Fig. 11.  2D convolution.

*3) 3D Convolution*: Visualizing a 3D filter (4D matrix) can be complex. However, we'll focus on single-channel 3D convolution for simplicity. As shown in Fig. 12, the kernel moves in three directions, leading to a 3D output [16]. It's notable that most customization and modification research for CNN layers has primarily concentrated on 2D convolutions.

Fig. 12. 3D convolution.

## III. DBGC: DIMENSION-BASED GENERIC CONVOLUTION

Standard convolutions simultaneously handle spatial and channel data but can be computationally demanding. To improve efficiency, separable convolutions split spatial and channel data via depth-wise and point-wise convolutions, yet this can lead to computational bottlenecks in point-wise convolutions. The DBGC unit addresses this by using a dimension selector to efficiently encode spatial and dimension information, reducing computational load. Fig. 13 shows DBGC architecture. This involves two stages illustrated in Fig. 9: dimension-based convolution Section III(A) and dimension-wise fusion Section III(C). By replacing point-wise convolutions with dimension-based ones, the DBGC unit alleviates computational bottlenecks.

### A. Convolution based on Dimension (ConvDim)

The ConvDim block processes information distinctly along the height-wise, depth-wise, and width-wise dimensions. To achieve this, it extends the concept of depth-wise separable convolutions to encompass all dimensions of the input tensor I, which is characterized by dimensions $H \times D \times W$ (representing height, depth, and width). As illustrated in Figure 12, ConvDim employs three sets of kernels for each dimension: KH for height-wise convolution, KD for depth-wise convolution, and KW for width-wise convolution. These dimension-specific kernels generate outputs denoted as YH, YD, and YW, each having dimensions $H \times D \times W$, effectively capturing information from the input tensor. Subsequently, these outputs are amalgamated within the dimension selector block, merging spatial planes to yield the ultimate output, YDim.

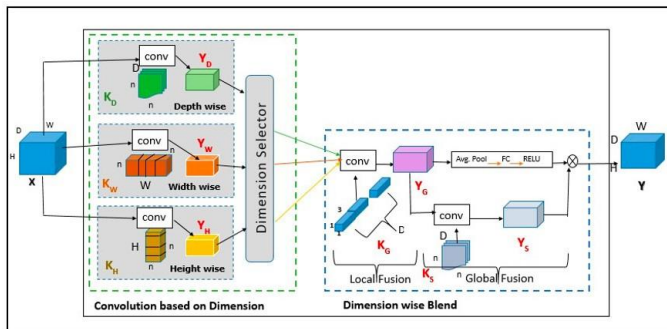

Fig. 13. DBGC architecture.

### B. Dimension Selector (Ds)

The dimension selector block, labeled as Ds, allows dimension selection tailored to specific application needs. Depending on requirements, users can opt to use only height, width, or depth dimensions during training. Parameters in this block specify chosen dimensions: Ds = KD, KW, KH. Combinations of two kernels are also possible, such as Ds = KD, KW, Ds = KH, KW, Ds = KD, KH, and Ds = KD, KW, KH. Thus, the dimension selector presents seven possibilities: height-only, width-only, depth-only, height and width, width and depth, height and depth, and all three dimensions. Selected kernels influence YDim integration, showcased in various dimension combinations in Fig. 14.

### C. Dimension-Wise Blends (DimBlend)

Dimension-wise convolutions capture local information from input tensor dimensions, but not global information. While point-wise convolutions in CNNs commonly combine global insights, they can be time-consuming. To address this, the dimension-wise blend module (DimBlend) divides pointwise convolution into local and global fusion phases, effectively merging dimension-wise representations from YDim into output Y [6]. The dimension-wise blend module, DimBlend, offers an alternative by splitting the point-wise convolution into two phases, as shown in Fig. 14.

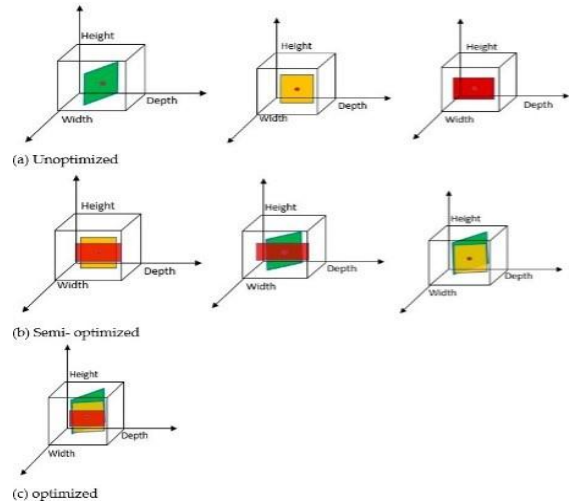

Fig. 14. ConvDim implementation progresses from individual kernel application (a) to simultaneous application of two kernels (b) and finally to concurrent application of all kernels (c), efficiently aggregating information through height-wise, depth-wise, and width-wise convolution.

The DBGC unit efficiently encodes spatial and dimension wise information using a multi-stage approach. The dimension selector (Ds) module allows flexible dimension choice, and the dimension-wise blend module (DimBlend) refines the process. In local fusion, YDim consolidates outputs from Ds, while DimBlend employs a group point-wise convolution layer (Kg) for dimension-wise merging. Global fusion follows, with DimBlend learning channel-wise and spatial representations, compressing spatial dimensions into channel-wise via fully connected layers. Integrating local and global fusion, DimBlend produces the final output Y, effectively capturing both spatial and dimension-wise information.

## IV. RESULT ANALYSIS

### A. Implementation of DBGC

The integration of the DBGC unit within a CNN architecture involves the utilization of conventional CNN layers. The architecture's depiction is presented in Fig. 15, providing an overview of the overall arrangement.

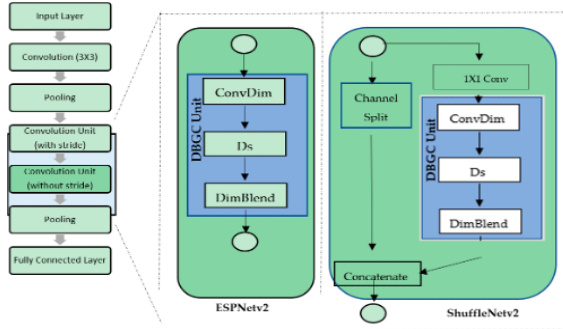

Fig. 15. The DBGC unit in different architecture (ESPNetv2 and ShuffleNetv2) designs.

### B. Experimental Setup

This section provides implementation details of the DBGC block and analyzes results. The DBGC unit was tested on ESPNetv2 and ShuffleNetv2 architectures, evaluating its impact on computational load and accuracy using the PASCAL VOC dataset. The integration of the DBGC unit with different architectures is discussed in Section V.

### C. Dataset Details

To demonstrate the DBGC unit's efficacy across diverse models, a standardized dataset was selected to ensure consistent comparison among architectures. The PASCAL VOC (Visual Object Classes Challenge) dataset was employed for this purpose. This dataset includes 20 object categories such as vehicles, animals, and furniture, with pixel-level segmentation annotations and bounding boxes. It is divided into training, validation, and private testing subsets, serving as a benchmark for object detection, semantic segmentation, and classification tasks.

### D. Results Analysis

This section presents the outcomes of integrating the DBGC unit into ESPNetv2 and ShuffleNetv2 architectures, focusing on the impact of reduced FLOPs on object detection and semantic segmentation accuracy. ESPNetv2 was used for object detection, while ShuffleNetv2 was employed for semantic segmentation. The distinction between FLOPs and FLOPS is explained: FLOPs represents the computational complexity of a model, quantifying the floating-point operations during inference [17]. On the other hand, FLOPS measures hardware processing speed. Faster hardware with higher FLOPS leads to quicker inference times. The equations to calculate FLOPs in the model are detailed in Fig. 16.

Within this section, the analysis of the results is structured into three distinct categories: (1) unoptimized kernel dimensions, (2) semi-optimized kernel dimensions, and (3) optimized kernel dimensions.

| Sr. No | Layer | The Equation to Calculate FLOPs |
|---|---|---|
| 1 | Convolution Layer | 2 × No. of Kernel × Kernel's Shape × Output Shape × Repeat Count (if available) |
| 2 | Pooling Layer (Without stride) | Height × Width × Depth of an input Image |
| 3 | Pooling Layer (With stride) | (Height/Stride) × Depth × (Width/Stride) of an input Image |
| 4 | Fully Connected Layer (FC Layer) | 2 × Input Size × Output Size |

Fig. 16. Output shape of a convolutional layer: Output = (Input - Kernel) + 1.

*1) Unoptimized kernel dimensions*: In the context of unoptimized kernel dimensions, employing a single kernel dimension for the output channel can lead to decreased object detection accuracy. This evaluation used ESPNetv2 and ShuffleNetv2 architectures for object detection and semantic segmentation tasks with the PASCAL VOC dataset. Initial models were created following existing guidelines, and then the same models were integrated with the proposed DBGC block using the width parameter in the dimension selector module from the DBGC architecture. The objective was to observe FLOPs variations and assess Top1 and Top5 accuracies. Results are presented in Tables I, II, and III for width-based, height-based, and depth-based kernels, respectively.

TABLE I. EXCLUSIVELY WIDTH-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 × 224 | 86 | 66.1 | 70.02 |
| ShuffleNetv2 | | | 71 | 63.9 | 62.30 |
| ESPNetv2(DBGC-KH) | | | 24 | 35.64 | 43.86 |
| ShuffleNetv2 (DBGC-KH) | | | 21 | 34.5 | 39.54 |

TABLE II. SOLELY HEIGHT-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 × 224 | 86 | 66.1 | 70.02 |
| ShuffleNetv2 | | | 71 | 63.9 | 62.30 |
| ESPNetv2(DBGC-KH) | | | 24 | 33.4 | 37.66 |
| ShuffleNetv2 (DBGC-KH) | | | 21 | 32.15 | 36.84 |

TABLE III. ONLY DEPTH-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 × 224 | 86 | 66.1 | 70.02 |
| ShuffleNetv2 | | | 71 | 63.9 | 62.30 |
| ESPNetv2(DBGC-KD) | | | 24 | 33.34 | 36.66 |
| ShuffleNetv2 (DBGC-KD) | | | 21 | 31.95 | 35.84 |

The results show that unoptimized kernel dimensions reduce FLOPs by about one third compared to the original ESPNetv2 and ShuffleNetv2 architectures. However, using only a single dimension for kernel selection notably decreases accuracy by around 30%, as demonstrated in Fig. 17 to Fig. 19, highlighting the trade-off between computational efficiency and model performance.

Fig. 17. Only height-based kernel.

Fig. 18. Only height-based kernel.

Fig. 19. Only depth-based kernel.

*2) Semi-optimized kernel dimensions*: In the semi-optimized kernel dimensions analysis, two kernel dimension combinations were employed for the output channel, resulting in reduced FLOPs with minimal accuracy loss. ESPNetv2 and ShuffleNetv2 were utilized for object detection and semantic segmentation on the PASCAL VOC dataset. The DBGC block was integrated with various kernel combinations (DBGC-Kwh, DBGC-Kdh, DBGC-Kwd) in dimension selector modules. Results in Tables IV to VI demonstrate lowered FLOPs and slight accuracy effects.

TABLE IV. DEPTH & WIDTH-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 x 224 | 86 | 70.02 | 66.1 |
| Shuffle Netv2 | | | 71 | 62.30 | 63.9 |
| ESPNetv2(DBGC-KDW) | | | 48 | 71.59 | 66.41 |
| Shuffle Netv2 (DBGC-KDW) | | | 42 | 64.83 | 69.75 |

TABLE V. DEPTH & HEIGHT-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 x 224 | 86 | 70.02 | 66.1 |
| Shuffle Netv2 | | | 71 | 62.30 | 63.9 |
| ESPNetv2(DBGC-KDH) | | | 48 | 65.57 | 68.42 |
| Shuffle Netv2 (DBGC-KDH) | | | 42 | 65.82 | 67.73 |

TABLE VI. HEIGHT & WIDTH-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 x 224 | 86 | 70.02 | 66.1 |
| Shuffle Netv2 | | | 71 | 62.30 | 63.9 |
| ESPNetv2(DBGC-KHW) | | | 48 | 65.52 | 71.47 |
| Shuffle Netv2 (DBGC-KHW) | | | 42 | 64.87 | 68.77 |

Semi-optimized kernel dimensions in DBGC halve FLOPs while maintaining good accuracy; object detection sustains accuracy and semantic segmentation gains 1-2%, as shown in Fig. 20 to Fig. 22.

Fig. 20. Combining depth-based and width-based kernels.

Fig. 21. Combining depth-based and height-based kernel.
Fig. 22. Combining height-based and width-based kernel.

Fig. 23 illustrates the analysis of results, showing that using two dimensions reduces FLOPs while maintaining accuracy close to the original architecture.

Fig. 23. Semi-optimized kernel dimension.

### E. Optimized Kernel Dimension

To improve accuracy while considering computational efficiency, a combination of all three kernel dimensions (width, height, and depth) was employed for the output channel. This approach increased FLOPs but enhanced accuracy. After implementing ESPNetv2 and ShuffleNetv2 models following the methodology in [7], these models were further enhanced with the incorporation of the proposed DBGC-Khwd block. The DBGC block's parameters for width, height, and depth, as described in Section 3 of the DBGC architecture, were chosen. The goal was to compare FLOPs and evaluate Top1 and Top5 accuracies. The outcomes are presented in Table VII and Fig. 24 for kernels based on depth, width, and height.

TABLE VII. HEIGHT & WIDTH & DEPTH-BASED KERNEL

| Model | Dataset | Image Size | FLOP (In Millions) | Top1 | Top5 |
|---|---|---|---|---|---|
| ESPNet v2 | PASCAL | 224 x 224 | 86 | 70.02 | 66.1 |
| Shuffle Netv2 | | | 71 | 62.30 | 63.9 |
| ESPNetv2(DBGC-KHW) | | | 48 | 70.52 | 74.48 |
| Shuffle Netv2 (DBGC-KHW) | | | 42 | 69.97 | 74.77 |

Fig. 24. Optimized kernel dimension.

Fig. 25 highlights that selecting all three dimensions led to a 4 to 5% accuracy increase while reducing FLOPs. showcasing the superiority of optimized kernels. For a comprehensive comparison, Fig. 25 and Fig. 26 display the performance of unoptimized, semi-optimized, and optimized kernel dimensions in ESPNetv2 and ShuffleNetv2 architectures, respectively.

Fig. 25. ESPNetv2 versus ESPNetv2 (DBGC).

Fig. 26. ShuffleNetv2 versus ShuffleNetv2 (DBGC).

Fig. 27 presents a box plot summarizing the various methods employed on the PASCAL VOC dataset. "Ev2" represents ESPNetv2, and "Sv2" stands for ShuffleNetv2 in the chart.

A box plot visualizes the performance of unoptimized, semi-optimized, and optimized kernels for ESPNetv2 versus ESPNetV2 (DBGC) and ShuffleNetv2 versus ShuffleNetV2 (DBGC). The effectiveness of DBGC is evaluated using the MS COCO dataset [19], showcasing the performance differences in Fig. 28.
Fig. 27. Box Plot for kernel types.

Fig. 28. Compare the performance of ESPNetv2 and ShuffleNetv2 with their DBGC-enhanced versions on PASCAL and COCO datasets.

## V. CONCLUSION

In conclusion, the proposed DBGC unit demonstrates its versatility by being applicable to various CNN-based network models. By integrating DBGC into ESPNetv2 and ShuffleNetv2 architectures, extensive evaluations based on FLOPs, Top1, and Top5 accuracies were conducted using the PASCAL VOC dataset. The findings indicate that unoptimized kernel based DBGC substantially reduces FLOPs by about one third, leading to significantly improved speed. However, this reduction in FLOPs comes at the cost of a notable decrease in accuracy. On the other hand, semi-optimized dimension-based kernels offer a balance between reduced FLOPs (around half) and maintained or slightly improved accuracy in ShuffleNetV2 with DBGC. Lastly, optimized dimension-based kernels achieve the highest accuracy while still reducing FLOPs by approximately five million. These results emphasize the potential of DBGC for enhancing the efficiency and accuracy of various CNN architectures.

## FUTURE WORK

For future research, the proposed architecture could be extended to evaluate its performance across different datasets, enabling a broader understanding of its capabilities. Additionally, investigating whether unoptimized dimension-based kernels can yield improved accuracy when applied to single dimensional data could be a valuable exploration. Further enhancements could involve automating the dimension selection process in the dimension selector modules to dynamically choose dimensions based on the characteristics of the datasets provided, potentially optimizing the efficiency and effectiveness of the DBGC approach.

# HHO-SMOTe: Efficient Sampling Rate for Synthetic Minority Oversampling Technique Based on Harris Hawk Optimization

Khaled SH. Raslan, Almohammady S. Alsharkawy, K. R. Raslan

Department of Mathematics, Faculty of Science, Al-Azhar University, Cairo, Egypt

*Abstract*—Classifying imbalanced datasets presents a significant challenge in the field of machine learning, especially with big data, where instances are unevenly distributed among classes, leading to class imbalance issues that affect classifier performance. Synthetic Minority Over-sampling Technique (SMOTE) is an effective oversampling method that addresses this by generating new instances for the under-represented minority class. However, SMOTE's efficiency relies on the sampling rate for minority class instances, making optimal sampling rates crucial for solving class imbalance. In this paper, we introduce HHO-SMOTe, a novel hybrid approach that combines the Harris Hawk optimization (HHO) search algorithm with SMOTE to enhance classification accuracy by determining optimal sample rates for each dataset. We conducted extensive experiments across diverse datasets to comprehensively evaluate our binary classification model. The results demonstrated our model's exceptional performance, with an AUC score exceeding 0.96, a high G-means score of 0.95 highlighting its robustness, and an outstanding F1-score consistently exceeding 0.99. These findings collectively establish our proposed approach as a formidable contender in the domain of binary classification models.

## I. INTRODUCTION

The applications of Machine Learning (ML) have seen a growing trend in classification domains involving data for automating processes. However, the process of training presents difficulties due to inherent nature of algorithms, which typically learn from datasets with balanced distributions [1]. As a result, acquiring knowledge from datasets with uneven distributions can lead to reduced accuracy and dependability in the resulting model. This phenomenon is termed "imbalance" or "unbalance" [2].

In contemporary applications, addressing challenges posed by imbalanced data has emerged as a notable issue. This issue is particularly evident in various domains such as the detection of fraud telephone calls [3], text classification [4], and biomedical data analysis [5, 6]. The classification of imbalanced data stands as a significant concern within the realms of machine learning and data mining [7]. In the context of imbalanced datasets, a notable discrepancy exists, with one class containing notably fewer training instances (Minority class) than the other (Majority class). In dealing with imbalanced datasets, conventional machine learning and classification algorithms frequently exhibit a tendency to

achieve very high accuracy rates in classifying the majority class, while attaining notably lower accuracy rates when classifying the minority class [8]. Therefore, the classifier's effectiveness suffers when it comes to diagnosing samples from the minority class. Consequently, the classification of imbalanced datasets presents a substantial hurdle in the realm of classification research. Conversely, in numerous practical scenarios, the emphasis is placed on recognizing minority class samples rather than their majority counterparts [9].

In this paper, we emphasize the critical nature of class imbalance and its adverse consequences on the performance of traditional classifiers in real-world applications, such as medical diagnosis, fraud detection, and anomaly detection. To overcome these problem and shortage, we present a unique hybrid binary classification method that integrates multiple algorithms, enhancing the overall robustness of the approach. The core of our methodology lies in the utilization of the Harris Hawk optimization search algorithm, which facilitates the calculation of optimal sample rates for each minority class, resulting in improved representation within the data set. By strategically adapting the SMOTE technique with Harris Hawk Search, we ensure more effective synthetic data generation, tailored to capture the specific characteristics of the imbalance data.

The SMOTE has emerged as a contender for effectively addressing the classification of imbalanced datasets [10]. This technique operates by generating new instances for the under-represented minority class, effectively re-balancing the dataset by augmenting the presence of minority class data points using SMOTE framework. These algorithms adopt a uniform sampling rate for all instances. Unfortunately, this uniform approach leads to suboptimal performance outcomes. This limitation becomes particularly pronounced when the dataset presents varying degrees of difficulty across different instances of the minority class. Instances that are inherently harder to classify may benefit from a different sampling strategy compared to instances that are relatively easier to classify. This nuanced variation is often not accounted for by the uniform sampling rate strategy, resulting in missed opportunities to improve the overall performance of the classification model. As a result, there exists a need for more sophisticated techniques that can deceptively adjust the sampling rates based on the inherent complexities within the minority class instances. By doing so, the resulting classification model could achieve more accurate and refined

outcomes, effectively mitigating the limitations imposed by the current SMOTE-based methodologies.

Within our paper, we propose an innovative algorithm that builds upon the foundation of the SMOTE technique while incorporating the HHO [11] to enhance the efficacy of imbalanced data classification. The integration of the HHO algorithm introduces a dynamic approach wherein diverse sampling rates are generated for individual instances of the minority class. This process culminates in the identification of an optimal combination of these sampling rates. Subsequently, this amalgamation of optimal sampling rates is formulated and seamlessly integrated into the SMOTE Algorithm. The quest for these optimal sampling rates is executed with a high degree of intelligence, ensuring an insightful search process. Once these optimal rates are successfully pinpointed, over-sampling is carried out exclusively on the instances belonging to the minority class, with each instance benefiting from its corresponding optimal sampling rate.

The subsequent sections of this paper are structured as follows: In Section II introducing an overview of current methodologies utilized for handling imbalanced datasets. Section III describes the SMOTE technique and the HHO algorithm in some detail. Section IV delves into the intricacies of our novel HHO-SMOTe algorithm, presenting a detailed account of its design and functionality, Section V guides you through a comprehensive examination of outcomes, encompassing diverse datasets and a variety of algorithms. Section VI concludes this paper.

## II. Related Work

A lot of research papers [2, 12, 13] have create a comprehensive examination of imbalanced datasets. These studies have not only conducted reviews but have also put forth various solutions aimed at effectively addressing the challenge of imbalanced data. Their objective is to determine the most optimal approach that exhibits superior performance in handling this issue. Ebenuwa et al. [12] introduced a feature selection approach for handling imbalanced datasets. They outlined the methodology and implementation steps, evaluating its effectiveness using machine learning algorithms like decision trees, logistic regression, and support vector machines. Their study aimed to identify the algorithm most suitable for addressing imbalanced data challenges through this ensemble of classifiers. The approach proposed in [13] involves the incorporation of an oversampling technique that meticulously incorporates all minority samples during the classification process within the training data. The Study conducted a comprehensive evaluation of this technique by comparing its performance against state-of-the-art ensemble learning methods. The objective behind this assessment was to ascertain the prowess of the oversampling technique in addressing imbalanced data scenarios.

Liu et al. [14] proposed advanced EasyEnsemble and BalanceCascade algorithms to address class imbalance issues more effectively than existing methods. Their research revealed that both algorithms outperformed established techniques, demonstrating their efficiency in tackling class imbalance challenges. Additionally, the authors in [15] devised the GASMOTE algorithm, which introduces a novel approach of employing distinct sampling rates tailored to individual instances within minority classes. This algorithm intelligently identifies the optimal combination of these sampling rates. Empirical evaluations performed on ten prototypical imbalanced datasets unveiled compelling outcomes. When juxtaposed against the SMOTE algorithm, GASMOTE exhibited an impressive enhancement. The empirical results derived from this application validate the GASMOTE algorithm's precision.

Nnamoko and Korkontzelos in [16] have taken strides in the realm of diabetes prediction by devising an optimized iteration of the SMOTE technique. This advanced algorithm integrates the InterQuartile Range technique to strategically oversample dispersed or extreme data prior to the application of SMOTE. This pre-processing step contributes significantly to enhancing the distribution of training samples, ultimately bolstering the efficacy of the diabetes prediction model. Liu st al. [17] brought forth a pioneering contribution in the arena of data balance within the context of spam detection. They proposed a sophisticated algorithm termed Fuzzy-based OverSampling, which revolves around the utilization of fuzzy logic principles to carefully harmonize the data distribution in synthetic sampling endeavors. This innovative methodology exhibited its prowess in not only rectifying the class imbalance but also in fine-tuning the distribution to be more representative of the real-world scenario. Notably, this enhancement manifested in elevated precision levels across a diverse array of ensemble learning models employed for the spam detection task.

The authors in [18] undertook a significant enhancement of the SL-SMOTE technique by incorporating an evolutionary optimization procedure to fine-tune its algorithmic parameters. This evolved rendition, aptly labeled Evolutionary SL-SMOTE, attained exemplary performance metrics when evaluated in the context of seminal quality prediction using AdaBoost. In the research conducted by Susan and Kumar [19], a comprehensive survey was undertaken to delve into the realm of preprocessing techniques within the domain of machine learning applications. The scholarly paper in question provides an in-depth exploration of various sampling methodologies, delving into the intricacies of how each of the scrutinized works tactically incorporated the suggested remedies. The culmination of this survey encompasses a thorough summary of the experimental protocols employed, encompassing intricate procedural insights as well as the comprehensive compilation of the outcomes that were documented.

To address more effectively the issue of how to determine the proper sample rate of the minority instances involved in the synthesis to avoid the generated minority instances decreasing the learning efficiency of the classification process, in this paper, we propose HHO-SMOTe which is also an improved variant of SMOTE based on a novel nature inspired algorithm call HHO. Nevertheless, HHO-SMOTe emphasis on determine the appropriate minority instances which increase the accuracy of the classification algorithmic.

## III. PRELIMINARIES

The SMOTE and exploratory and exploitative stages of the Harris Hawk Optimization algorithm are covered in this section. We explained the different procedures and steps used by each algorithm. In addition, we demonstrate how these various phases have been used to develop a novel algorithm. Due to the integration of the two algorithms, our method can dynamically adapt to a variety of datasets and consistently produce the best results with a high degree of efficiency.

### A. SMOTE

SMOTE is commonly used when dealing with imbalanced datasets, where one class (minority class) has significantly fewer examples than the other class (majority class). In such cases, machine learning models may struggle to correctly classify the minority class because they tend to be biased towards the majority class. SMOTE helps address this imbalance by generating synthetic examples of the minority class to create a more balanced dataset for training.

Fig. 1. The principle of the SMOTE.

We can observe an example of an imbalanced dataset in Fig. 1(a) above. Here, the majority class is represented by circular shapes, which stand in for the data's predominant occurrences, while the minority class is represented by triangular shapes, signifying the smaller number of data samples. Some examples from the minority and majority classes are in areas that do not naturally align with the opposite class, most notably with the red arrow. The SMOTE algorithm initiates the process of selecting synthetic samples, a crucial step in bolstering the minority class. The sampling rate specified for each category of occurrences serves as the basis for this selection process. The synthetic samples are presented as square forms in Fig. 1(b). Upon applying the SMOTE technique, the resultant effect is a reduction in the disparity between the Minority and Majority classes.

The SMOTE algorithm includes a sample rate parameter to control the extent of over-sampling. The sample rate determines how many synthetic examples are generated for each minority class instance. Here's an equation that includes the sample rate in the SMOTE algorithm:

$$C = A + s * (B - A) \quad (1)$$

where:
- $C$ is the synthetic example being generated.
- $A$ is a randomly selected instance from the minority class.
- $B$ is one of the k nearest neighbors of $A$ (also from the minority class) and is randomly chosen.
- $s$ is the sample rate parameter, which influences how many synthetic examples are generated between $A$ and $B$. The $s$ parameter is a value between *0* and *1*, which allows you to control the density of synthetic examples to be generated. When $s = 0.5$, one synthetic example is generated exactly. This can be seen as an average or balanced interpolation between the two instances. If $s$ is less than *0.5*, the synthetic examples will be closer to $A$ than $B$, otherwise the synthetic examples will be closer to $B$ than $A$.

Impact of sample rate to balance Dataset:

The choice of s influences how many synthetic instances are generated and how they are distributed between A and B. By adjusting s, you can fine-tune the balance of your dataset. A smaller s may be suitable if you want a moderate increase in the minority class, while a larger s will result in a more substantial over-sampling. As Addressed class imbalance in datasets using the SMOTE algorithm is a common strategy in machine learning, but selecting the appropriate sample rate presents a challenging task. There are no universal guidelines for determining the ideal sample rate, as it hinges on various factors like dataset characteristics, machine learning algorithms, and problem-specific nuances. The primary goal of SMOTE is to balance class distribution, vital for training fair and effective models. However, selecting the wrong sample rate can lead to overfitting, underfitting, or suboptimal model performance.

Researchers in [20-23] often use SMOTE approaches to balance their datasets before staring work on the classification or feature selection, or cluster problems without working with the sample rate selection for the minority classes. Grid search involves trying out a range of predefined sample rates and selecting the one that optimizes evaluation metrics such as precision, recall, F1-score, or AUC. Cross-validation enhances this process by providing a more robust assessment across multiple data subsets. An iterative refinement process, where researchers gradually narrow down the optimal sample rate through experimentation and analysis, is common practice. Additionally, understanding the sensitivity of machine learning algorithms to different sample rates is crucial.

In summary, choosing the right sample rate in SMOTE is a nuanced decision that relies on empirical methods, domain expertise, and iterative exploration to strike the balance that suits the dataset and problem domain. We have put forth our solution for determining the most accurate sample rate, which will be applied when generating samples from the minority classes to achieve data set balance. This solution leverages the intelligence of the HHO algorithm, a sophisticated optimization technique.

## B. Harris Hawks Optimizer (HHO)

The HHO has introduced by Ali Asghar Heidari in 2019, the HHO algorithm has garnered significant attention from the research community [11, 24]. HHO draws inspiration from the hunting behavior of Harris Hawks in nature, particularly their agile surprise pounce technique. Harris Hawks, known for their remarkable intelligence, exhibit various chasing styles based on different scenarios and the behavior of their prey. HHO is widely recognized as one of the most effective optimization algorithms, and it has been successfully applied to a variety of problems across different domains encompass energy and power flow analysis, engineering, medical applications, network optimization, and image processing. The comprehensive review [25-28] presents a survey of the existing body of work related to HHO.

Within this section, shows the modeling of both the exploratory and exploitative phases inherent in HHO methodology. The phases are done by three steps draw inspiration from the natural behaviors of Harris hawks, including their approaches to prey exploration, surprise pouncing, and the diverse attack strategies employed. HHO represents a population-based optimization approach devoid of gradients, rendering it adaptable to a wide array of optimization challenges, provided that they are appropriately formulated. The detailed explanations provided in the subsequent subsections.

*1) Exploration phase*: Hawks perch in specific locations and constantly monitor the surrounding environment to identify prey using two strategies, which are represented in Eq. (2). If $p < 0.5$, the hawks perch based on the position of the family members. If $p \geq 0.5$, the hawks perch in a random space within the population area.

$$X(t + 1) = \begin{cases} X_{rand}(t) - r_1 \mid X_{rand}(t) - 2r_2 X(t) \mid & q \geq 0.5 \\ (X_{rabbit}(t) - X_m(t)) - r_3(LB + r_4(UB - LB)) & q < 0.5 \end{cases} \quad (2)$$

where $X(t + 1)$ is the position vector of hawks in the next iteration $t$, Xrabbit(t) is the position of rabbit, $X(t)$ is the current position vector of hawks, $r_1$, $r_2$, $r_3$, $r_4$, and $q$ are random numbers inside *(0, 1)*, which are updated in each iteration, $LB$ and $UB$ show the upper and lower bounds of variables, $Xrand(t)$ is a randomly selected hawk from the current population, and $X_m$ is the average position of the current population of hawks.

The HHO utilized a simple model to generate random locations inside the group's home range *(LB, UB)*. The first rule generates solutions based on a random location and other hawks. In second rule of Eq. (2), we have the difference of the location of best so far and the average position of the group plus a randomly-scaled component based on range of variables, while $r_3$ is a scaling coefficient to further increase the random nature of rule once $r_4$ takes close values to 1 and similar distribution patterns may occur. Utilizing the simplest rule, which can mimic the behaviors of hawks. The average position of hawks is attained using Eq. (3):

$$X_m(t) = \frac{1}{N} \sum_{i=1}^{N} X_i(t) \quad (3)$$

where, $X_i(t)$ indicates the location of each hawk in iteration $t$ and $N$ denotes the total number of hawks.

*2) Transition from exploration to exploitation*: The HHO can transfer from exploration to exploitation and then, change between different exploitative behaviors based on the escaping energy of the prey. The energy of a prey decreases considerably during the escaping behavior. To model this fact, the energy of a prey is modeled as:

$$E = 2E_0(1 - \frac{t}{T}) \quad (4)$$

Where $E$ indicates the escaping energy of the prey, $T$ is the maximum number of iterations, and $E_0$ is the initial state of its energy. In HHO, $E_0$ randomly changes inside the interval *(−1, 1)* at each iteration. When the value of $E_0$ decreases from *0* to *−1*, the rabbit is physically flagging, whilst when the value of $E_0$ increases from *0* to *1*, it means that the rabbit is strengthening.

*3) Exploitation phase*: Which the hawks attack the targeted prey. Then, however, the prey tries to escape the attack. Based on hawk attacking behavior and escaping prey behavior, four scenarios will be described as below:

*a) Soft Besiege*: When r $\geq$ 0.5 and |E| $\geq$ 0.5, the rabbit still has enough energy and try to escape by some random misleading jumps but finally it cannot. During these attempts, the Harris' hawks encircle it softly to make the rabbit more exhausted and then perform the surprise pounce. This behavior is modeled by the following rules:

$$X(t + 1) = \Delta X(t) - E \mid J X_{rabbit}(t) - X(t) \mid \quad (5)$$

$$\Delta X(t) = X_{rabbit}(t) - X(t) \quad (6)$$

Where $\Delta X(t)$ is the difference between the position vector of the rabbit and the current location in iteration $t$, $r_5$ is a random number inside *(0, 1)*, and $J = 2(1 − r_5)$ represents the random jump strength of the rabbit throughout the escaping procedure. The $J$ value changes randomly in each iteration to simulate the nature of rabbit motions.

*b)* Hard Besiege: When *r $\geq$ 0.5 and |E| <0.5*, the prey is so exhausted, and it has a low escaping energy. In addition, the Harris' hawks hardly encircle the intended prey to finally perform the surprise pounce. In this situation, the current positions are updated using:

$$X(t + 1) = X_{rabbit}(t) - E \mid \Delta X(t) \mid \quad (7)$$

*c) Soft Besiege with Progressive Rapid Dives*: When still |E| $\geq$ 0.5 but r < 0.5, the rabbit has enough energy to successfully escape and still a soft besiege is constructed before the surprise pounce. This procedure is more intelligent than the previous case, the final strategy for updating the positions of hawks in the soft besiege phase can be performed by:

$$X(t + 1) = \begin{cases} Y \text{ if } F(Y) < F(X(t)) \\ Z \text{ if } F(Z) < F(X(t)) \end{cases} \quad (8)$$

where, $Y$ and $Z$ are obtained using Eq.9 and Eq.10. A simple illustration of this step for one hawk. $Y$ is the hawks next move based on the following rule.

$$Y = X_{rabbit}(t) - E \, |JX_{rabbit}(t) - X(t) \quad (9)$$

To mathematically model the escaping patterns of the prey and leapfrog movements (as called in [22]), the levy flight (LF) concept is utilized in the HHO algorithm. In HHO the hawks dive based on the LF-based patterns using the following rule:

$$Z = Y + S \times LF(D) \quad (10)$$

Where $D$ is the dimension of problem and S is a random vector by size $1 \times D$ and $LF$ is the levy flight function, which is calculated as follows.

$$LF(X) = 0.01 \times \frac{u \times \sigma}{|v|^{\frac{1}{\beta}}}, \sigma = \left(\frac{\Gamma(1 + \beta) \times sin(\frac{\pi \beta}{2})}{\Gamma(\frac{1+\beta}{2}) \times \beta \times 2^{\frac{\beta-1}{2}}}\right)^{\frac{1}{\beta}} \quad (11)$$

Where $u, v$ are random values inside $(0, 1)$, $\beta$ is a default constant set to $1.5$.

*d) Hard Besiege with Progressive Rapid Dives*: When $|E| < 0.5$ and $r < 0.5$, the rabbit has not enough energy to escape and a hard besiege is constructed before the surprise pounce to catch and kill the prey. The situation of this step in the prey side is similar to that in the soft besiege, but this time, the hawks try to decrease the distance of their average location with the escaping prey. Therefore, the following rule is performed in hard besiege condition:

$$X(t + 1) = \begin{cases} Y \; if \; F(Y) \, < \, F(X(t)) \\ Z \; if \; F(Z) \, < \, F(X(t)) \end{cases} \quad (12)$$

where $Y$ and $Z$ are obtained using rules in Eq. (13) and Eq. (14).

$$Y = X_{rabbit}(t) - E \, |JX_{rabbit}(t) - X_m(t) \quad (13)$$

$$Z = Y + S \times LF(D) \quad (14)$$

## IV. The Proposed HHO-SMOTE Algorithm

In this section, the proposed HHO-SMOTe approach is proposed for determining the efficient sample rate to be used in the SMOTE technique. The proposed HHO-SMOTe primary goal is to increase the accuracy of classification of the imbalanced datasets. We employed the HHO algorithm to find the optimum solution based on the KNN classification accuracy in order to get the best sampling rate of the synthetic minority class instances.

The proposed HHO-SMOTe initialized by determining its control parameters such as the population size $N$, the number of minority class instances $n$, and the maximum number of iterations. Then, the algorithm starts by generating a population $X$ with the dimension $N \times n$ from the initial solution as an initial phase for the HHO-SMOTe approach. Each solution $x_i \in X$ represents a candidate sample rate for SMOTe and it is assessed by the value of dataset classification accuracy where the best sample rate (solution) has the highest classification accuracy based on KNN algorithm. The solution can be represented with a raw of n values, these values are 0 and the maximum number of samples for each minority class instance. The 0 value in the first position of $x_i$ indicates that the current instance in the minority class have a sample rate 0 and will not be used in the generation of the synthetic data.

Since, if the value is greater than 0, then the current minority class instance will be utilized in the generation of the synthetic data. For example, a solution $x_i$ for generating a synthetic data which have 6 minority class instances can be represented as $x_i$ = [1, 0, 2, 0, 3, 1]. This means that the sample rate to generate the synthetic date is 1 sample of the first minority class instance, 0 sample of the second minority class instance, two samples of the third minority class instance, and so on. The pseudocode of the HHO-SMOTe is showed in Algorithm 1.

---

**Algorithm 1:** Pseudo-code of HHO-SMOTe approach.

**Inputs**:
The population size $N$ and maximum number of iterations $T$
**Outputs**:
The location of rabbit and its fitness value Initialize the random population $X_i$, $i = 1, 2, \ldots, N$
**while** (stopping condition is not met) **do**
    ***Generate a synthetic data based on current sample rate (solution) using SMOTE alg., then calculate the fitness values of hawks using on KNN alg.***
        Set $X_{rabbit}$ as the location of rabbit (**highest accuracy**)
        **for** (each hawk ($X_i$)) **do**
        Update the initial energy $E_0$ and jump strength J→
        $E_0$ = 2rand() - 1, J = 2(1-rand())
        Update the $E$ using Eq. (4)
        if ($|E| \geq 1$) then (**Exploration phase**)
            Update the location vector using Eq. (2)
        if ($|E| < 1$) then (**Exploitation phase**)
            if ($r \geq 0.5$ and $|E| \geq 0.5$) then (**Soft besiege**)
             Update the location vector using Eq. (5)
            else if ($r \geq 0.5$ and $|E| < 0.5$) then (**Hard besiege**)
             Update the location vector using Eq. (7)
            else if ($r < 0.5$ and $|E| \geq 0.5$) then (**Soft besiege with progressive rapid dives**)
             Update the location vector using Eq. (8)
            else if ($r < 0.5$ and $|E| < 0.5$) then (**Hard besiege with progressive rapid dives**)
             Update the location vector using Eq. (12)
Return Xrabbit

### A. Performance Evaluation Measures

Performance evaluation metrics are critical for evaluating classification performance and guiding classifier design. In this step, the confusion matrix was used to get the results of the proposed HHO-SMOTe approach and to make the comparison between all the used SMOTE approaches. The confusion matrix Fig. 2 describes the performance of the classification models. True positive (TP): Observation is predicted positive and is actually positive. False positive (FP): Observation is predicted positive and is actually negative. True negative (TN): Observation is predicted negative and is actually negative. False negative (FN): Observation is predicted negative and is actually positive. From the confusion matrix, we can conclude the following measures:

Actual class

Fig. 2.   Confusion matrix for the two-class classification problem.

*1) G-mean:* The geometric mean is the root of the product of class-wise sensitivity. This measure tries to maximize the accuracy on each of the classes while keeping these accuracies balanced. For binary classification G-mean is the squared root of the product of the sensitivity and specificity. For multi-class problems it is a higher root of the product of sensitivity for each class.

$$G-mean = \sqrt{Sensitivity \times Specificity} \qquad (15)$$

*2) F1 score:* The *F*1 score, *F* score, or *F* measure is the harmonic mean of precision and sensitivity it gives importance to both factors:

$$F1 = \frac{2*Precision*Recall}{Precision+Recall} = \frac{2*TP}{2*TP+FP+FN} \qquad (16)$$

*3) AUC:* The receiver operating characteristics (ROC) curve is the plot between sensitivity and the FP rate for various threshold values. The area under curve (AUC) is the area under this ROC curve; it is used to measure the quality of a classification model. The larger the area, the better the performance. The ROC curve is a two-dimensional coordinate graph in which the X-axis represents the false positive rate (FPR) and Y-axis represent the true positive rate (TPR). The AUC can be calculated as:

$$AUC = \frac{1+TPR-FPR}{2} \qquad (17)$$

## V.   EXPERIMENTS AND EVALUATION

In this section, the experiments were done on different datasets. The following subsections will demonstrate the results and analyze these results. The experiments were conducted on Google Colaboratory, which provides a free Jupyter notebook environment with GPU support for running machine learning experiments [29].

In our research, we utilized over 25 diverse datasets in different industries and attributes to evaluate the proposed technique. We maintained the original class distribution with five-fold cross-validation and conducted each experiment five times to obtain average metrics. Table I summarizes dataset details, including the dataset name, the number of attributes, the number of samples for the minority class, the original dataset record numbers, the number of samples in the majority class, and the corresponding imbalance ratio.

Table II presents the outcomes of our experimentation of 19 SMOTe variants approach and the proposed HHO-SMOTe approach with KNN algorithm as the application of SMOTE techniques for oversampling the dataset.The 19 methods are ADASYN [30], AND-SMOTE [31], ANS [32], Borderline-SMOTE1 [33], Borderline-SMOTE2 [33], distance-SMOTE [34], G-SMOTE [35], GASMOTE [15] , Gaussian-SMOTE [36], KernelADASYN [37], kmeans-SMOTE [38], Random-SMOTE [39], Safe-Level-SMOTE [40], SDSMOTE [41], SMOTE [10], SOMO [42], SVM-balance[43], SYMPROD [44], ASN-SMOTE [45]. Notably, we have highlighted in bold the distinctive optimal values achieved for the average G-mean, F1-score, and AUC within the KNN results. This highlighting underscores the noteworthy observation that the combination of HHO-SMOTe consistently yields optimal results across a diverse array of datasets. The classification performance comparison results for the selected seven approaches applied on twelve datasets presented in Fig. 3, 4, and 5 are obtained using data from Table II.

In Fig. 3, we assessed G-mean values across 12 data sources using seven SMOTE techniques. A higher G-mean indicates a model's proficiency in both positive and negative class identification, a valuable metric for imbalanced classification. ANS-SMOTE and GASMOTE ranked lower, while ADASYN, SMOTE, RANDOM-SMOTE, and Borderline-SMOTE performed similarly. ADASYN had slightly lower G-mean for "cleveland-0." HHO-SMOTe consistently excelled across various datasets, demonstrating its robustness in imbalanced classification tasks.

Fig. 3. Comparison of G-mean of seven SMOTE techniques.

In Fig. 4, we compare classification results using F1-score values for various SMOTE algorithms. The F1-score combines precision and recall, indicating a model's ability to balance false positives and false negatives. ANS-SMOTE and GASMOTE performed poorly compared to ADASYN, SMOTE, RANDOM-SMOTE, and Borderline-SMOTE. Conversely, HHO-SMOTe consistently achieved near-perfect F1-Scores (0.9 to 1) across datasets, showing its stability and reliability in diverse classification tasks.

Fig. 4. Comparison of F1-score of seven SMOTE techniques.

In Fig. 5, we conducted a fresh evaluation of our classification studies, focusing on AUC (Area Under the Receiver Operating Characteristic Curve). AUC gauges a binary classification model's overall discrimination ability, considering true positive and false positive rates across different thresholds. The results show ANS-SMOTE and GASMOTE underperformed compared to ADASYN, SMOTE, RANDOM-SMOTe, and Borderline-SMOTE in AUC. In contrast, HHO-SMOTe consistently achieved high AUC values (typically 0.9 to 1), showcasing its adaptability across diverse datasets and confirming its effectiveness in classification tasks, especially when class separation is crucial.

Fig. 5. Comparison of AUC of seven SMOTE techniques.

This research employs the of the well-known credit card fraud detection dataset [46]. The dataset was prepared by the ULB Machine Learning Group, which specializes in big data mining and fraud detection [47]. The dataset covers credit card transactions made by European credit card clients within two days in September 2013. Dataset have 492 fraudulent transactions out of 284807 total. Meanwhile, all attributes except ''Time'' and ''Amount'' are numerical due to transformation carried out on dataset using dimensionality reduction technique called principal component analysis (PCA). ''Amount'' attribute is the cost of the transaction, and ''Time'' attribute is the seconds that elapsed between a transaction and the first transaction in the dataset. ''Class'' is the dependent variable, has a value of 1 for fraudulent and 0 for legitimate.

In Fig. 6, we conducted extensive comparison using credit card fraud dataset known for its vast transaction volume. The goal was to thoroughly evaluate the stability and accuracy of our method within the realm of big data challenges, compared to other techniques. As depicted in the figure, HHO-SMOTe achieved highest AUC score, an impressive 0.96, surpassing other methods with scores below 0.94. These methods ranked in descending order as borderline-2, SMOTE, ADASYN, Borderline1, ASN-SMOTE, GASMOTE, and Random SMOTE. In terms of the F1-Score, all algorithms consistently scored above 0.99, even reaching a perfect score of 1. Regarding the G-mean metric, HHO-SMOTe demonstrated its

superiority with a score exceeding 0.95, while its counterparts fell short with scores below 0.94.

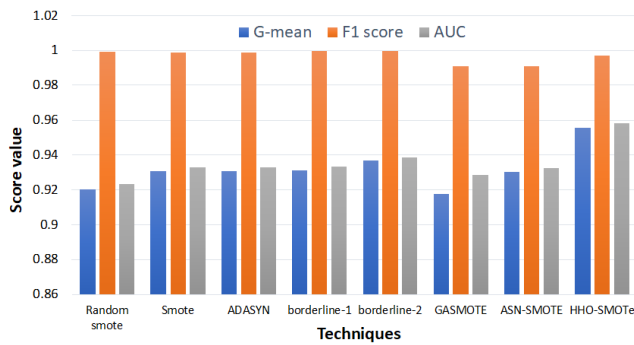

Fig. 6.     Comparison of different SMOTE techniques and HHO-SMOTe using fraud detection dataset.

## VI. CONCLUSION

In summary, the HHO-SMOTe approach represents a significant advancement in effectively addressing complexities of imbalanced datasets in classification tasks. By seamlessly integrating various classifiers with the Harris Hawk search optimization algorithm and SMOTE, we have established a robust framework capable of producing precise and reliable predictions for imbalanced data scenarios. These results hold substantial implications for a wide range of real-world applications where improved classification accuracy and data balance correction play pivotal roles in informed decision-making. Furthermore, our research contributes significantly to the field of imbalanced data handling by shedding light on a potent methodology that enhances the performance of classification models across diverse domains. This amalgamation of state-of-the-art techniques has the potential to mitigate challenges posed by skewed data distributions, ultimately enabling more accurate and trustworthy predictions.

*Abstract*—**Evaluating students' responses and providing feedback in the education system is widely acknowledged. However, while most research on Automated Essay Scoring (AES) has focused on generating a final score for given responses, only a few studies have attempted to generate feedback. These studies often rely on statistical features and fail to capture coherence and content-based features. To address this gap, we proposed a multitask learning system that can capture linguistic, coherence, and content-based features with Bidirectional Encoder Representations from Transformers (BERT) sentence by sentence and generate overall essay and trait scores. Our proposed system outperformed other existing models, achieving Quadratic Weighted Kappa (QWK) scores of 0.766, 0.69, and 0.701 compared to human rater scores. We evaluated our model on the Automated Student Assessment Prize (ASAP) Kaggle and operating system (OS) data set. When compared with other prescribed models proposed to multitask learning system is a promising step towards more effective and comprehensive writing assessment and feedback.**

*Keywords—Sentence embedding; coherence; LSTM; short answer scoring; trait score*

## I. INTRODUCTION

Evaluating student responses and providing feedback can improve the student's learning abilities in the education system. However, while AES has been a research focus in recent years, most studies have concentrated on generating a final score for student responses rather than providing feedback. In a few studies like [6, 13, 14, 15 and 16] systems, they did not attempt to generate feedback. However, these approaches extract statistical features for the final score and trait score generation, which did not fully capture students' responses' coherence and content-based features.

There are two main ways to provide feedback to students on their writing: gaze behavior by Mathias and Bhattacharyya [13, 14] and providing trait scores [6, 17, 14, 16, 25 and 26]. Gaze behavior refers to analyzing the visual behaviors of readers as they read a text, such as eye movement patterns. This methodology offers insights into readability, syntax, and fluency within the writing. However, trait scores evaluate specific writing attributes like organization, word choice, and coherence. These traits furnish more intricate insights into a student's writing than a simple overarching score.

Despite the strides made in deep learning and natural language processing, furnishing feedback on aspects such as organization, word choice, and syntax can benefit student learning more than just presenting a general score. As Woods [23] exemplified, this form of feedback equips students with a deeper comprehension of how to enhance their writing competencies holistically. For instance, feedback on organization assists students in grasping effective structuring techniques for their compositions. In contrast, feedback on word choice can help students select appropriate words to convey their ideas more clearly.

To accurately assess the student's response and provide comprehensive scoring and feedback, extracting both semantic and linguistic features from the text is essential. Relying solely on statistical features like Term Frequency and Inverse Document Frequency (TF-IDF), a bag of words, and N-gram models may not sufficiently capture the content and coherence of the student's answer. These traditional methods mainly focus on the frequency and distribution of individual words or phrases. In contrast, modern natural language processing (NLP) models such as word2vec [12] and Global vectors for word representation [7] can effectively capture semantic features by representing words in a continuous vector space. However, it is worth noting that these models like [1, 3, 4, and 13] primarily operate at the word level and may encounter difficulties when handling complex or polysynthetic words.

Deep learning models can be employed to address the need for capturing content, coherence, and maintaining the sequence of words. Recurrent Neural Networks (RNNs), particularly models like Long Short-Term Memory (LSTM) or Gated Recurrent Units (GRUs), are commonly used for sequential data processing in NLP. These models like [13, 20, 21, 22 and 24], can analyze text at the sentence or paragraph level, considering the contextual information preceding words provide. Ridley et al. in [18] implemented a system for cross prompt essay scoring with semi supervised learning; furthermore, maintaining an internal state can capture dependencies and semantic relationships between words.

A deep learning model trained on a suitable dataset can be developed in the context of grading and providing feedback on student responses. This model would take the student response as input, process it using an RNN or similar architecture, and generate a final score and trait score. The training data for such a model ideally includes labeled examples of student responses paired with their corresponding scores and traits. This way, the model can learn to recognize patterns and

---

*Corresponding Author

associations between the input text and the desired output scores.

Overall, combining advanced NLP techniques, deep learning models, and appropriate training data can help extract content and coherence features while maintaining the sequence of words, thereby enabling the generation of accurate scores and feedback on student responses.

*A. Contribution*

- Our AES system captures sentence-level features from responses, enhancing essay analysis by highlighting key traits and patterns at this granular level. These features provide valuable insights into essay quality and structure.

- Employing LSTM, a type of recurrent neural network, we assign scores to essays. LSTM's strength in capturing context and relationships among sentences makes it ideal for modeling and analyzing essays.

- Our AES system produces three scores - overall, organization, and word choice. This trio offers a multi-faceted evaluation of essays, assessing different writing aspects like coherence, logical flow, and vocabulary sophistication. Additionally, we compare our model against established approaches to demonstrate its superiority.

- We test it on two datasets, a public dataset and a domain-specific dataset. Testing on different datasets helps evaluate the generalizability of our model across different domains or essay topics. It demonstrates the versatility and adaptability of our AES system.

Organization: The remainder of the paper is organized as follows: Section II illustrates related works on various evaluation systems and challenges. Section III discusses the proposed model and the data set used for our models. Section IV discusses the results and analysis of our model on various factors and test cases. Finally, Section V discusses the conclusion and future work.

## II. RELATED WORK

Automated Essay Scoring (AES) has primarily focused on generating a final score for student responses rather than providing detailed feedback. This emphasis on scoring is often driven by the need for standardized assessment, where the primary goal is to assign a numerical score that reflects the quality of the essay. So many researchers worked on the final score generation for the given response. Various systems, such as those developed by [4, 5, 9, and 10] as well as [11] have adopted distinct approaches. These approaches involve combining different elements, such as statistical features and word-level attributes, and training machine learning or neural network models. However, a noteworthy aspect is that these methodologies need to effectively encapsulate the entirety of the content within the essays into their respective vectors.

Generating feedback is more challenging because it requires understanding the student's response's content, structure, and coherence. While some AES systems [2, 8, 16 and 23] provide generic feedback based on predefined patterns

or rules, the quality and specificity of this feedback may be limited.

However, there has been increasing interest in developing AES systems that go beyond scoring and provide more meaningful feedback to students. With advancements in natural language processing and deep learning, researchers are exploring approaches to extract fine-grained linguistic and semantic features from essays, which can be used to provide personalized feedback.

Ridley et al. in [17, 18] introduced a method that utilizes a trait-attention mechanism and a multi-task architecture to predict student essays' overall and individual trait scores. They conducted extensive experiments on the ASAP dataset, specifically prompt-2, to demonstrate the effectiveness of their approach for prompt-specific trait scoring and cross-prompt AES methods. To optimize model performance, researchers integrated syntactical elements by applying POS embedding. They employed LSTM models for generating comprehensive scores encompassing overall performance and specific traits. Additionally, Mathias and Bhattacharyya in [15] proposed a neural network model targeting word-level semantic features, enhancing the granularity of assessment. The common thread in these approaches is using Long Short-Term Memory (LSTM) models to predict multiple trait scores, enabling intricate essay evaluation. This technique captures nuanced semantic information at the word level, shedding light on the multifaceted traits manifested within the essays.

Hussein et al. in [6] focused on the ASAP dataset, employing LSTM to generate trait scores. Their model was tailored explicitly, capturing relevant patterns and features for accurate score prediction.

Woods et al. in [23] employed standard logistic regression to derive trait scores, providing a comprehensive assessment avenue. Although simpler than LSTM, logistic regression still yields valuable predictions and insights into trait scores.

Ohta et al. in [16] introduced a versatile model generating various scores, spanning overall evaluation, organizational development, and language proficiency. Their approach likely amalgamates techniques, potentially encompassing deep learning models such as LSTM, to predict and appraise different essay facets holistically.

These studies underscore diverse techniques and methodologies for forecasting trait scores in student essays. Each approach contributes unique insights, leveraging attention mechanisms, multi-task architectures, syntactical and statistical attributes, and the power of LSTM and logistic regression models for robust evaluation. In addition, these diverse methods contribute to the field by providing various options for assessing and providing feedback on different aspects of essay writing.

## III. METHODOLOGY

We proposed that the AES system incorporates sentence-based text embeddings and LSTM to capture essay coherence and content. This model is implemented on top of [19] it generates multiple scores, including overall, organization, and word choice scores, providing a comprehensive evaluation.

Using both standard and domain-specific datasets strengthens the credibility and generalizability of our system. In addition, robustness testing ensures its resilience in handling adversarial responses. The architecture diagram Fig. 1 visually represents the system's components and integration, facilitating replication and implementation.

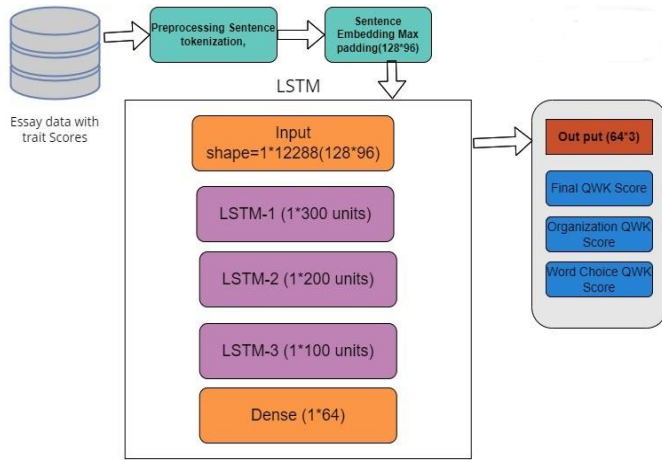

Fig. 1. Architecture of content based essay scoring system with LSTM.

### A. Data Set

In the context of our AES systems, we used the ASAP Kaggle dataset. This dataset comprises 12,978 essays written by students in grades 8 to 10. The essays were generated in response to eight different prompts provided to the students. Every prompt comprises a collection of 1500 or more essays, all of which have been evaluated by two individual raters. Prompts 3, 4, 5, and 6 pertain to essays that rely on specific sources for their content, whereas the remaining prompts fall under the "others" category.

For our trait-based essay scoring approach, we specifically focused on Prompt 2 during our study. This allowed us to analyze and evaluate the essays based on specific traits and criteria relevant to that prompt. Table I and Table II exemplifies a detailed description of the essay dataset, including the number of essays, prompts, and raters involved.

TABLE I. AUTOMATED STUDENT ASSESSMENT PRIZE (ASAP) DATA SET FOR ESSAY SCORING

| Prompt _id | Prompt wise total number of essays | Average Number of words in an essay | Score range (min-max) |
|---|---|---|---|
| 1 | 1783 | 350 | 2-12 |
| 2 | 1800 | 350 | 1-6 |
| 3 | 1726 | 150 | 0-3 |
| 4 | 1772 | 150 | 0-3 |
| 5 | 1805 | 150 | 0-4 |
| 6 | 1800 | 150 | 0-4 |
| 7 | 1569 | 250 | 0-30 |
| 8 | 723 | 650 | 0-60 |

TABLE II. OPERATING SYSTEM DATA SET
(HTTPS://GITHUB.COM/RAMESHDADI/OS-DATA_1-SET-FOR-AES)

| Prompt-id | Prompt | Prompt wise number of essays | Prompt wise maximum number of sentences | Rating range (min to max) |
|---|---|---|---|---|
| 1 | Explain about operating system? | 516 | 23 | |
| 2 | Explain the advantages of a multiprocessor system? | 596 | 21 | |
| 3 | Explain how operating system handles multiple tasks at a time? | 312 | 19 | 0-5 |
| 4 | Difference between single processor and multiprocessor operating systems? | 513 | 19 | |
| 5 | Explain different scheduling algorithm? | 453 | 15 | |

In order to evaluate the performance of AES systems on domain-specific essays in the field of operating systems (OS), we created a custom dataset in addition to the ASAP dataset. This dataset was purposely crafted to address the field of operating systems. We formulated five fundamental inquiries concerning operating systems and then distributed these inquiries as assignments to students across various engineering colleges.

Upon gathering the responses, we meticulously eliminated duplicated or repeated submissions, culminating in a dataset comprising 2390 unique responses from 626 students. To ensure the dataset's dependability and excellence, we engaged in the expertise of two subject matter specialists. These professionals evaluated each essay, assigning scores for overall impression, organization, and word choice. This approach provided thorough and detailed evaluations of the students' written reactions.

By incorporating this tailor-made dataset, we intend to streamline the assessment of AES systems in their proficiency and accuracy when evaluating essays that specifically revolve around the operating systems realm. Furthermore, this dataset is a valuable asset for honing and optimizing AES systems within this domain.

The agreement between the two human raters was assessed using the QWK score. The computed QWK scores for the overall impression, organization, and word choice were 0.842, 0.879, and 0.912, respectively. These scores indicate a substantial agreement between the raters.

Table II illustrates a detailed description of the OS dataset, presenting information about the number of responses, students, and expert evaluators involved. Fig. 2 illustrates the agreement between the two raters, further illustrating the consistency in their evaluations.
Fig. 2. Agreement between rater-1 and rater -2 (organization score for OS dataset).

### B. Sentence Embedding

Converting text into vectors that effectively capture context and semantics is a complex task in natural language processing (NLP). Conventional embedding methods such as word2vec and GloVe primarily concentrate on converting text into word vectors. However, these methods come with certain constraints. They must thoroughly account for the words around a particular word and how their meanings change in different contexts. Furthermore, these techniques encounter difficulties when dealing with words with multiple meanings (polysemous words), which can result in a lack of accuracy in capturing the intended sense of the word.

Furthermore, approaches such as averaging word vectors to derive sentence vectors cannot capture the nuanced information in the original sentence. This oversimplification needs to be revised to include the intricate relationships and interactions between words, leading to a loss of important contextual details.

To address these challenges, more advanced techniques in NLP are being developed. These techniques aim to overcome the limitations of traditional methods by capturing a richer representation of text that incorporates both context and semantics more comprehensively. Our model utilizes Sentence BERT, a sentence embedding technique, to address these limitations. Sentence BERT introduces a dynamic approach to converting essays into vectors, considering the contextual and semantic aspects of individual sentences. Unlike traditional embedding techniques, Sentence BERT's vector representation captures a more comprehensive understanding of the original text.

The process begins by removing special symbols like "@" and "#" from the essays and tokenizing them into sentences. The ASAP and OS datasets have specific limitations on the maximum number of sentences per essay. The maximum number of sentences per essay for the ASAP dataset is 96, while for the OS dataset, it is 23.

To obtain sentence embeddings using a pre-trained transformer model, such as Sentence BERT, each sentence is transformed into a 128-dimensional vector representation. As a result, for an essay from the ASAP dataset, there will be 96 * 128-dimensional vectors, considering the maximum number

of sentences. Similarly, for an essay from the OS dataset, there will be 23 * 128-dimensional vectors based on the respective maximum number of sentences.

Finally, to ensure consistent dimensions, all essays are padded to have 96 * 128-dimensional vectors for the ASAP dataset and 23 * 128-dimensional vectors for the OS dataset. The maximum number of sentences in each dataset determines the padding size.

### C. Model

To capture the coherence, cohesion, and linguistic features of the essay, we embedded all the sentences of the essays without removing stop words. So it allows the model to consider the entire text and capture the overall coherence of the essay.

In order to handle the sequence of sentence embeddings, we utilized LSTM (Long Short-Term Memory), a type of recurrent neural network (RNN). LSTM is designed to effectively process sequential information while retaining the memory of previous inputs.

The LSTM architecture incorporates various gates, as depicted in Fig. 3. These gates, including the input gate equation [2], forget gate [1], output gate [3], and context gate [4], collaborate to facilitate the processing and storage of long-term dependencies necessary for feature extraction.

The input gate controls the flow of information into the memory cell, while the forget gate determines which information to discard from the previous cell state. The output gate regulates the output information from the memory cell, and the context gate manages the update of the memory cell content.

$$f_t = \sigma g(w_f x_t + u_f h_{t-1} + b_f) \qquad (1)$$

$$i_t = \sigma g(w_i x_t + u_i h_{t-1} + b_i) \qquad (2)$$

$$o_t = \sigma g(w_o x_t + u_o h_{t-1} + b_o) \qquad (3)$$

$$C_t = tanh(w_c x_t + u_c h_t + b_c) \qquad (4)$$

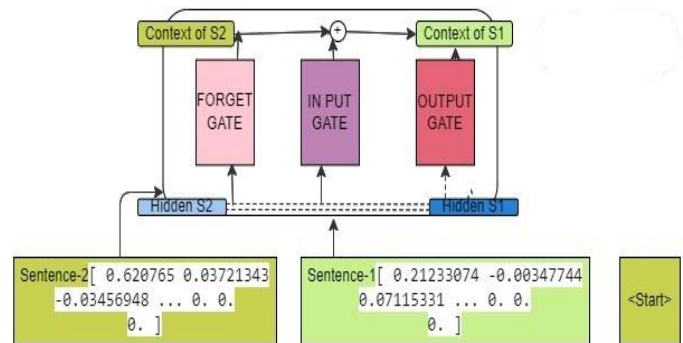

Fig. 3. Contexts generation from sentences in LSTM.

### D. Implementation and Training LSTM

In our methodology, we started by turning essays into organized sets of numbers using a technique called Sentence BERT. These sets were then made consistent by adding extra information and aligning them with the largest essay size of 96 by 128. After this, we transformed these sets of numbers into

another type of organized sets with three dimensions, getting them ready for neural network training.

To construct our LSTM model, we devised a configuration comprising five tiers of LSTM units intricately assembled. Each tier encompassed components that facilitated the absorption of information, dissemination of information, and context management. This structural design proved pivotal in monitoring the interconnections spanning distinct sections of the essays.

To enhance the efficacy of our model, we adopted the RMSprop optimization technique, concentrating on minimizing the mean discrepancy between our forecasts and the actual results. To counteract the risk of our model fixating excessively on idiosyncrasies within the training data, we integrated a mechanism that intermittently deactivated specific model segments during the training phase. Furthermore, we established a predetermined pace for how our model assimilates knowledge from the data. Our model's response to data inputs was governed by a selected mathematical function termed ReLU. Throughout the model training process, we implemented a strategy known as 5-fold cross-validation. This divided our sets of essay information into separate groups for training, testing, and validating, with a specific ratio assigned to each for both the ASAP and OS datasets.

We trained our model for different amount of time (10, 15, 20, and 35 times), trying to find the best settings, and then we checked how well it performed. We used a QWK measure to see how close the model's ratings were to human ratings, an essential standard for automated essay scoring.

For each round of cross-validation, we calculated the QWK score. Finally, we chose the model that worked the best on the training data to make predictions on the test data. A graph (see Fig. 5) showed how the model learned and did on new data where batch size 24, demonstrating that it learned well without getting too stuck on the training details.

We are applied the same hyperparameters and cross-validation technique to ensure consistency in our experimentation and evaluation process between the ASAP and OS datasets. This allows for a fair comparison and assessment of our model's performance on different essay datasets.

## IV. RESULT AND DISCUSSIONS

We conducted experiments using the ASAP and OS datasets to develop trait-based AES (Automated Essay Scoring) systems. Our proposed model exhibited the best results on both datasets. Furthermore, we approached the training of our model on a prompt-by-prompt basis and subsequently computed the corresponding training and validation losses. This process is visualized in Fig. 4 and Fig. 5. The figure illustrates the learning process for batch size 32, which is getting overfitted after some iteration. But from Fig. 5, when we used a batch size of 16, the training and validation losses consistently decreased and overlapped each other.

We achieved superior results when comparing our proposed models to other baseline models, specifically on prompt-2 of the ASAP dataset. We used the average QWK

(Quadratic Weighted Kappa) score for each trait. As shown in Table III, our sentence embedding-LSTM model outperformed other models and demonstrated consistency with human rater scores. However, the integrated and word embedding models could have effectively captured sentence coherence. It is worth noting that while neural networks tend to achieve high QWK scores, they may not fully capture the text's coherence. The models implemented with word embeddings required maintaining word order, which could impact coherence. Additionally, word embedding models may struggle with polysemous words, potentially leading to a lack of coherence in the text.

Our proposed model performed well on the Domain-specific data set, specifically regarding the final, organization, and word choice scores. This indicates that our model is robust and consistently delivers good results.

Table IV compares our proposed model and other approaches on the Domain-specific data set, demonstrating the superiority of our model across multiple scoring criteria. In addition, the consistent performance of our model suggests its reliability and effectiveness in evaluating essays within the specific domain. Fig. 6 illustrates the comparison of the actual score and predicted scores of our models. From this, we can observe that both colors are overlapped maximum, which indicates that our model predicted the correct scores for test data.

## V. CONCLUSION

We introduced a novel approach for an AES system focusing on trait-based assessment. To capture the coherence patterns between sentences in an essay, the model employed a preprocessing step where each sentence was embedded individually. This sequence-to-sequence approach allows the model to capture the overall coherence and flow of ideas within the essay. The embedded sentences were then fed into a recurrent neural network, specifically an LSTM, for training.

In our study, we compared our Sentence Embedding-LSTM model with baseline models commonly used in AES. The results showed that our proposed model performed well and outperformed the other baseline models in terms of its ability to capture coherence. So, our approach successfully addressed the challenge of maintaining coherence in the generated essays.

Leveraging sentence embedding and training on recurrent neural networks model demonstrated its effectiveness in capturing the overall organization and coherence of the essays. However, our approach has the potential to provide more reliable and accurate automated scoring while preserving the coherence of the generated texts.

In the future, we will implement a system to provide all traits like grammar and sentence organization and provide the students Qualitative feedback in text format. And we also improve model performance.

# Applications of Missing Data Imputation Methods in Wastewater Treatment Plants

## A Systematic literature Review using the Kitchenham Method

International Institute for Water and Sanitation, Rabat, Morocco[4]

*Abstract*—Missing data pose a big challenge in the field of wastewater treatment, representing a frequent issue in data quality that can result in misleading analyses and compromised decision-making accuracy. The initial step in data preprocessing involves the estimation and handling of missing values. The primary aim to conduct a comprehensive examination of the existing research concerning missing value imputation in wastewater treatment plants (WWTPs). The focus is specifically on identifying and outlining various imputation techniques employed in this field, while paying close attention to their respective strengths and limitations. To ensure a methodical approach, this study adopts the systematic literature review (SLR) using Kitchenham's guidelines. In order to gather relevant and up-to-date papers, the research leverages the scientific database "Scopus" to retrieve and analyze all pertinent papers during the search process. By doing so, this research aims to contribute valuable insights into the different strategies used for imputing missing values in WWTPs and to shed light on their practical implications and potential drawbacks. Form 599, a total of 16 research papers were selected to assess the review questions. Finally, several recommendations were given to address the limitations identified in the reviewed studies and to contribute to more accurate and reliable data analysis and decision-making in the wastewater treatment domain.

*Keywords—Systematic literature review; kitchenham' method; wastewater treatment; imputation methods; missing data*

## I. INTRODUCTION

The presence of missing values presents a notable obstacle to ensuring the data quality of WWTPs datasets. Despite the presence of well-designed data collection systems in many treatment plants, the attention given to data quality is often inadequate [1].

This problem affects the performance of data analytics, leading to increased bias and decreased accuracy. The presence of missing values can be attributed to various factors, such as events causing measurement failures, holidays, and shifts with less experienced personnel [2]. As a result, gaps or discontinuities arise in the data records, severely hindering the modeling and identification of the process [3].

According to Rubin's [4], missing values can be classified into three main mechanisms, presented below:

- "Missing completely at random" (MCAR): The absence of data has no correlation on the missing data itself.

- "Missing at random" (MAR): Missing values that exhibit a relationship with the observed values.

- "Missing not at random" (MNAR): It applies when neither of the previous mechanisms is valid, and the missing values are typically associated with unobserved predictors or the missing value itself [5].

Over the past, researchers have shown considerable interest in that type of problem. Common approaches for handling missing data include deletion and imputation. Imputing missing data is a crucial step as any data analysis with incomplete datasets would yield invalid conclusions. Ignoring this step can result in biased estimations [6] - [7] While missing data imputation is a well-established technique in data analysis, its application in the context of WWTPs remains relatively unexplored. Existing literature on WWTPs often overlooks or inadequately addresses the critical issue of missing data imputation. Consequently, there is an urgent need to systematically review and evaluate the available missing data imputation methods specifically for WWTP datasets.

There exists an urgent requirement for a dependable and efficient approach to substitute missing data, as this is crucial for accurately assessing the variability of plant influent data. By doing so, more precise design proposals and performance evaluation reports can be generated; leading to improved decision-making processes in wastewater treatment plants [2].

This paper aims to analyse the techniques employed for imputing missing data in WWTPs and review the available methods through imputation. The following sections will present a concise overview of the relevant literature and the quantity of research studies that concentrate on imputing missing data in WWTPs.

In this paper, Section I offers an introduction, Section II outlines the research methodology, and Section III discusses the research findings. A discussion of the results is provided in Section IV, while Section V concludes the article.

## II. RESEARCH AND REVIEW METHOD

In this section, the methodology used is this paper is Kitchenham' method as presented below:

### A. Planning the Review

In this section, the review methodology essential for conducting the systematic literature review (SLR). This entails formulating research questions aligned with the primary objective of the review, devising a robust search strategy, and crafting a comprehensive review protocol. Each of these aspects plays a critical role in ensuring the rigor and effectiveness of the SLR process.

*1) Research questions*: The primary objective of this review is to examine the current literature concerning imputation methods used in the wastewater field. The specific research questions (RQs) are outlined below:

*a)* What are the existing methods applied in wastewater treatment plants?

*b)* How effective are the existing methods in handling missing data challenges?

*c)* What are the limitations of those techniques applied specifically in the context of wastewater treatment plants?

These RQs serve as the guiding framework for this study and facilitate a systematic and thorough analysis of the relevant literature. RQ1 identifies and documents the various techniques used in the context of wastewater treatment plants to handle and optimize missing data imputation. RQ2 focuses on assessing the effectiveness of these existing methods in effectively addressing the challenges posed by missing data in wastewater treatment plants. Lastly, RQ3 aims to analyze the limitations of different missing data imputation techniques specifically within the context of wastewater treatment plants.

*2) Search strategy*: The Scopus database was chosen because of the wide range of academic literature from a variety of fields, including engineering and environmental sciences. It provides a huge selection of peer-reviewed journals, conference papers, and other pertinent literature. The search string used to retrieve articles from the scientific database is described as follows: ("Imputation" OR "missing value*") AND ("Wastewater" OR "WWTP" OR "WATER").

*3) Inclusion and exclusion criteria*: The inclusion and exclusion criteria are illustrated in Table I. By applying these criteria, the aim was to identify and focus on the most pertinent studies that align with the research objectives and ensure the inclusion of high-quality and relevant sources in the final analysis.

*4) Quality criteria*: The primary objective of this section is to check that primary studies contain adequate information to address the research questions. Each criterion is labeled as 'QAC,' which stands for Quality Assessment Criteria. These criteria serve as a means to assess the quality and relevance of each primary study, ensuring that they provide sufficient insights to effectively answer the research questions.

TABLE I.        THE INCLUSION AND EXCLUSION CRITERIA.

| Inclusion criteria | Exclusion criteria |
|---|---|
| Papers that address missing data imputation methods applied in the context of wastewater treatment plants. | Papers that don't address missing data imputation methods applied in the context of wastewater treatment plants |
| Papers published in any journal or conference proceedings and in any language. | Multiple versions of the same study and duplicate publications |
| Articles that are available in full text | Articles that are not available in full text |

These QACs play a vital role in assessing the quality of the selected articles, enabling the determination of their overall quality and suitability for the systematic review.

The quality of studies is assessed through the following evaluation questions:

- **QAC.1** Does the paper use missing data imputation methods for the wastewater domain?

- **QAC.2** Were the key parameters containing missing values mentioned clearly in the paper?

- **QAC.3** Did the researchers explain the performance measurements used?

- **QAC.4** Does the paper cover limitations of the proposed method?

Apart from evaluating the inclusion and exclusion criteria, a thorough examination of each primary study was conducted, employing specific QAC questions [8]. In the evaluation process, each primary study was assigned a score between 0 and 1. A score of 1 indicated that the study fully addressed the QAC question, while a score of 0.5 denoted a partial answer. On the other hand, if the study failed to address the QAC question, a score of 0 was given. The cumulative score for each study was then calculated by summing the scores for all the QAC questions.

Upon completing the quality assessment for each primary study, it was observed that the total score of the selected studies exceeded 50% for each QAC, as presented in Table II.

TABLE II.        QUALITY ASSESSMENT CRITERIA AND RESULTS OF SELECTED ARTICLES

| Criteria | Responding score | Total score |
|---|---|---|
| QAC01 | {0, 0.5, 1}<br>(No, Partially, Yes) | 16 studies (100%) |
| QAC02 | {0, 0.5, 1}<br>(No, Partially, Yes) | 12 studies (75%) |
| QAC03 | {0, 0.5, 1}<br>(No, Partially, Yes) | 13 studies (81.25%) |
| QAC04 | {0, 0.5, 1}<br>(No, Partially, Yes) | 9 studies (56%) |

This finding suggests that the primary studies included in the review contain substantial and relevant information.

## B. Conducting the Review

The search was conducted on April 1st, 2023, without imposing any date or language restrictions. The article selection process involved applying the specified search string, resulting in 599 initial papers. From these papers, relevant information was exported to a spreadsheet, then, the search results were filtered by removing the duplicates articles and those with no abstract available, which left 593 papers. The remaining papers were subjected to a manual review of their titles and abstracts, leading to a selection of 61 papers retrieved from the water quality field, surrounding wastewater treatment. The subsequent step involved referring to and reading the full-text articles in a meticulous manner. During this process, five articles were excluded due to the unavailability of their full text. Then, after analyzing all the papers and organizing the evidence specifically related to wastewater treatment, it was determined that only 16 articles were deemed relevant and shortlisted. As a result, 16 articles successfully met the research questions and satisfied all the inclusion and quality assessment criteria outlined. The paper selection procedures are succinctly summarized in Fig. 1.

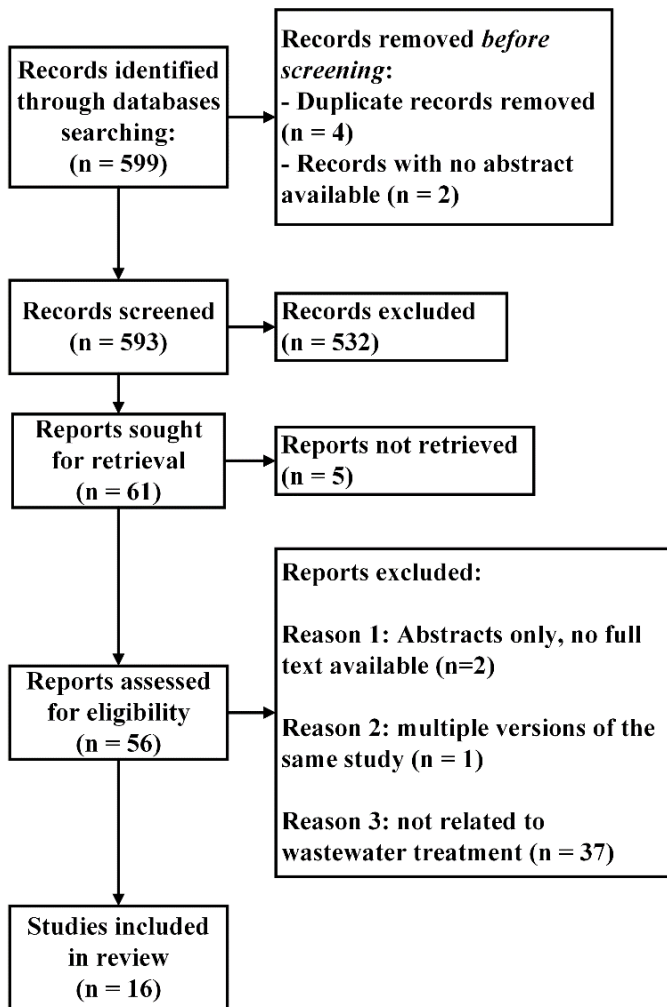

Fig. 1. The article selection process.

## III. FINDINGS

This section presents and analyzes the results obtained from the literature review. Findings are divided into three subsections, with the first one showcasing the various methods used. The second subsection discusses the effectiveness of these existing methods. Finally, the third subsection explores the strengths and limitations of the different methods.

### A. The Identified Methods

This subsection primarily focuses on RQ1, which aims to identify the existing methods. A concise overview of the techniques employed to handle missing values in WWTPs is presented in this subsection. Fig. 2 illustrates the publication trend over time in this specific research area.

Fig. 2. Number of studies published per year.

In their study, Huo et al. [9] the Two-directional Exponential Smoothing (TES) method to impute missing data in a WWTP. In another study in 2010, they applied also the TES and TESWN (Two-directional Exponential Smoothing with Nearest Observations). The TES method involves generating a hypothetical complete data set using the average of nearest observations (ANO) method. It then forecasts the missing values using an exponential smoothing algorithm in both the forward direction (Forward ES) and the backward direction (Backward ES). The missing data points' ultimate replacement values are obtained by averaging the estimates derived from both the forward and backward exponential smoothing forecasts. The TESWN method shares similarities with the TES approach but includes a white noise term to handle random effects observed in the data, which might not be adequately addressed by the autocorrelation function [10].

Zhang et al. [11] choose the self-organizing map (SOM) model to impute the missing data by training the model using available data and then presenting the depleted vector to the SOM to identify its best matching unit (BMU). The missing variable values are acquired by referring to their respective values in the BMU.

In the study conducted by Villez et al. [12], the imputation of missing values was carried out through a backward calculation based on scores obtained from the inverse Principal Component Analysis (PCA). The scores were

estimated using the single component-projection method [13]. Negative estimates for concentrations were rectified by adjusting them to zero. After this adjustment, any remaining missing variables were subsequently re-estimated using the same methodology.

Borzooei et al. [14] investigates the application of the Cubic Hermite interpolation method for filling in missing values within data. This method is particularly suitable for datasets characterized by rapid and non-linear changes. It employs a third-degree polynomial function to approximate the missing value based on the surrounding data points. To use this method effectively, the data must exhibit continuity, and the function must be differentiable over the relevant interval.

Furthermore, a minimum requirement of having at least two adjacent points to the missing value is necessary for performing the interpolation.

De Mulder et al. [15] employed various filling algorithms to address missing data gaps. These algorithms included interpolation, the utilization of daily average values, and the incorporation of values from the previous day, correlation-based approaches, and the application of the influent model.

Azizoğlu et al. [16] conducted a study, employing six distinct machine learning algorithms, including Linear Regression (LR), Support Vector Machines (SVM), K-Nearest Neighbors (KNN), Random Forest (RF), Decision Tree (DT), and Adaboost, to estimate missing pH data in two distinct datasets.

Phung et al. [17] utilized the multiple imputation procedure to handle missing values. Instead of assigning a single value to each missing data point, they employed Rubin's [4] multiple imputation approach, which replaces each missing value with a set of plausible values. Afterwards, these imputed datasets were analyzed using standard procedures designed for complete data, and the results obtained from these analyses were combined. The process of combining results from different imputed datasets remained consistent, regardless of the specific complete-data analysis method used.

Pascual-Pañach et al. [18] explores the utilization of the Case-Based Reasoning (CBR) approach for online imputation of missing values. This approach addresses the data imputation problem by leveraging past solutions to analogous problems. By employing the Case-Based Reasoning (CBR) principle in data imputation, values from similar historical scenarios are leveraged to replace incorrect or missing values. To improve the effectiveness of the data imputation process, optimal case feature weights are determined using genetic algorithms (GA). The proposed methodology is validated using real data obtained from an operational WWTP process.

Xiao et al. [19] suggested the implementation of Auto-associative Neural Networks (ANN) along with a recursive minimization strategy to address missing values in fault diagnosis for wastewater processes. The ANN is trained using available data to capture the inherent patterns and interrelationships among the variables. Meanwhile, the recursive minimization strategy is employed to iteratively update the missing values based on the learned patterns until convergence is achieved.

Ba-Alawi et al. [20] employed R2AU-Net, an automated data reconciliation and imputation approach tailored to handle missing and faulty data in the membrane bioreactor (MBR) process. This method used a recurrent residual convolutional neural network (CNN) with an attention gate (AG) connection to effectively impute consecutive missing data and reconcile faulty sensors in the MBR process. During training, the model employs backpropagation with the Adam optimizer and mean squared error (MSE) as the activation function. The input and output sizes are set to 18, corresponding to the number of studied sensors. To enhance performance and training speed, the R2AU-Net model incorporates batch normalization (BN) in each R2CL block. The training process is carried out using the Keras library and TensorFlow backend, with 370 epochs and a batch size of 24.

In their research article, Han et al. [21] utilized the univariate imputation method (UIM) in conjunction with the SSD method and SVR model. The UIM decomposes the time series into seasonal, trend, and remainder components and employs specific imputation methods for each component. The SSD method addresses missing values in the seasonal component by identifying repeating patterns. On the other hand, the SVR model is responsible for imputing missing values in the trend and remainder components. By integrating the imputation results, UIM effectively handles missing values in WWTP time series data.

Safford et al. [22] focuses on the application of the EM-MCMC algorithm for estimating missing values in wastewater qPCR data. The proposed method involves a systematic process that begins with the initialization of hyperparameters. Subsequently, Monte Carlo samples of the latent parameters are generated using the Markov Chain Monte Carlo (MCMC) technique. Finally, the maximum likelihood estimates of the hyperparameters are computed based on the sampled latent parameters.

Yan et al. [23] used the Non-Linear Decreasing Inertia Weight Particle Swarm algorithm (NLDIWPSO) based optimal Support Vector Regression (SVR) approach to impute missing values. For abnormal values and missing values with a non-continuous distribution over time, they used the average of non-abnormal data for a period of three days before and after to fill the gaps. Conversely, for abnormal values and missing values with a continuous distribution over time, the NLDIWPSO-based optimal SVR method was employed for forecasting purposes.

Oliveira-Esquerre et al. [24] used linear interpolation for estimating missing values, citing its simplicity [24]. This method was applied with the constraint that it was only employed for a maximum of two consecutive missing values.

In summary, various methodologies have been employed to handle missing data in WWTP studies and there is no imputation technique consistently outperforms every other. The Table III below summaries the missing data imputation methods with their used respective key parameter in a WWTP.

TABLE III.     MISSING DATA IMPUTATION METHODS, KEY PARAMETERS, AND RELEVANT STUDIES

| Missing Data imputation method | Parameter | Studies |
|---|---|---|
| R2AU-Net | - pH,<br>- Dissolved oxygen (DO) | [20] |
| Univariate Imputation Method (UIM)<br>(SSD method & SVR model) | - pH,<br>- SS<br>- BOD<br>- NH4 | [21] |

## B. The Challenges

Existing methods have varying degrees of effectiveness in handling missing data challenges. Ba-Alawi et al. [20] found that the R2AU-Net model exhibited the highest imputation performance for missing data, even when the missing interval increased to 50%. It outperformed conventional methods like PCA and DPCA, as well as neural methods like AE and VAE, with the lowest Mean Absolute Error (MAE) value of 0.31 mg/L. Consequently, the R2AU-Net missing data imputation approach is regarded as highly effective in tackling missing data issues. Additionally, the paper explores the use of the PCA projection method to estimate missing data in the SHARON process. Villez et al. [12] showed that the estimation of missing data related to nitrogen species enhances the performance of a dynamic PCA model. However, despite this improvement, the impact of data gaps remains significant, as the undetected failure ratio nearly doubles when no estimates are employed.

Therefore, while PCA can be helpful in handling missing data challenges, it may not completely solve the problem.

According to the experimental results presented by Han et al. [21], the UIM method, as proposed in the study, proves to be effective in imputing missing data in WWTP time series compared to the other seven competitors examined. In the testing phase, UIM underwent evaluation using six distinct WWTP time series, and the outcomes demonstrated that it strikes a well-balanced trade-off between imputation accuracy and processing time. Notably, UIM and NA.linear exhibit remarkable performance concerning Root Mean Squared Error (RMSE) when confronted with significant intervals of missing data. Moreover, the proposed UIM exhibits the capability to handle a maximum missing ratio of 45%.

Based on Azizoğlu & Ünsal's study in 2022 [16], machine learning algorithms proved to be highly effective in predicting missing pH data. The performance was evaluated using the MAE, mean squared error (MSE), and RMSE as metrics. The results indicated that the SVM (Support Vector Machine) algorithm outperformed other algorithms in all three-performance metrics for both datasets. Consequently, the method of imputing missing data using machine learning algorithms was found to be a successful approach in addressing issues related to missing data.

Pascual-Pañach et al. [18] findings, the performance of the proposed methodology of using a Case-Based Reasoning (CBR) approach was improved by obtaining optimal case feature weights using genetic algorithms (GA). In comparison to non-calibrated CBR imputation systems, the technique was deemed highly effective, as the RMSE of the estimation using weighted features was nearly 40% lower than the non-weighted estimation when employing temporal CBR (TCBR). Moreover, the TCBR approach exhibited even better performance, with an RMSE approximately 60% lower than the calibrated CBR approach.

Yan et al. [23] assessed the performance of the NLDIW-PSO based optimal SVR machine learning model for imputing missing data using the coefficient of determination and Pearson's correlation coefficient. They found that this method achieved the highest prediction accuracy when compared to other data-driven models. Furthermore, the experimental results highlighted several advantages of the proposed model, including enhanced stability and time efficiency compared to traditional data-driven models like BP ANN, Bayesian network model, and Decision Tree model. Consequently, the NLDIW-PSO algorithm demonstrated strong performance in imputing missing data.

According to De Mulder et al. [15], the reliability of different missing data imputation methods was tested for different types of data. The results showed that using the influent model to fill gaps in the data yielded the highest reliability, while linear interpolation was also effective for smaller gaps in the data. However, all filling algorithms seem to do what they were designed for in a satisfying way, and the choice of method may depend on the specific dataset and the purpose of the analysis.

Xiao et al. [19] demonstrated the effectiveness of the current auto-associative neural network (ANN) with a recursive minimization strategy in handling missing data, as well as overcoming the Gaussian assumptions of traditional multivariate statistics models. Through simulation studies, the proposed method showcased good performance, even in scenarios with significant amounts of missing data in both the BSM1 simulation platform and real WWTP datasets.

Zhang et al. [11] concluded that the self-organizing map (SOM) model was an accurate and effective method for predicting missing values and replacing outliers in the integrated constructed wetland (ICW) data set. The SOM model demonstrated resilience to missing values and effectively processed incomplete data sets, resulting in accurate predictions. For ammonia-nitrogen, SRP, COD, SS, and BOD, the proportions of missing values and outliers were approximately 4%, 3%, 41%, 54%, and 61%, respectively. According to Rustum & Adeloye [3], the Kohonen self-organizing map (KSOM) proves to be a valuable tool for

imputing missing values and handling outliers in high-dimensional datasets. The results demonstrate that the KSOM outperforms univariate prediction models based on linear regression and backpropagation ANN. Among the three approaches, the linear regression model displayed the least performance. Evaluation of the KSOM's performance using mean square error (MSE) and average absolute error (AAE) as parameters revealed that the KSOM achieved lower MSE and AAE values compared to regression and ANN. Additionally, a notable advantage of the KSOM is that the same map can be used to predict any missing value in any variable.

Huo et al. [10] showed that the TES and TESWN methods proposed in the article are effective in handling missing data challenges. The TES method is ideal when the objective is to minimize the average error linked to missing values, whereas the TESWN method is more suitable for quantifying the level of uncertainty associated with the missing values. ANO and AVE were utilized as benchmarks to compare the performance of the TES and TESWN methods. In their study, Huo et al. [9] pointed out that several commonly used methods for estimating missing values rely on the assumption of MCAR (missing completely at random), which is not applicable in their data due to the presence of a regular pattern of missing data. To address this challenge, the TES method is presented as a potential solution. The authors employed performance parameters such as R2, RMSE, and Mean Absolute Percent Error (MAPE) to assess the effectiveness of the time series models they developed.

*C. Limitations*

The UIM method proposed in the study can handle missing data up to a maximum ratio of 45%. However, when the missing ratio exceeds 45%, the UIM method may not generate an appropriate result [21].

According to Azizoğlu & Ünsal's [16], linear regression (LR) assumes a linear relationship between the variables and may not work well with non-linear data. K-Nearest Neighbors (KNN) is sensitive to the choice of k value and may not work well with high-dimensional data. Random Forest (RF) and Adaboost may overfit the data if the number of trees is too high. Decision Tree (DT) may suffer from overfitting and instability if the tree is too deep or complex. Support Vector Machines (SVM) can be computationally expensive for large datasets and may not work well with imbalanced data.

For Safford et al. [22], the EM-MCMC method encounters limitations in terms of incomplete comparisons due to sampling zones being added over time, and the need for further testing of the effect of different data groupings on model performance.

The Cubic Hermite interpolation method assumes that the data is smooth and continuous [14]. This technique may not be effective for datasets with a significant number of missing values. It also may not be suitable for datasets with irregular time intervals between observations. The Cubic Hermite interpolation may introduce errors when dealing with data containing outliers or extreme values [14].

Per the findings of De Mulder et al. [15], interpolation operates under the assumption of a linear relationship between

missing data and the surrounding data points. Correlation-based approaches, on the other hand, rely on the presence of a correlation that may not be existent. Daily average estimation may fall short in capturing the full variability of the data, leading to potential biases. Likewise, relying on the previous day's data assumes a level of similarity that may not always be valid. Finally, the use of influent models requires a deep understanding of the underlying system and its intricacies.

Phung et al. [17] found that the fault diagnosis performance using estimated values by the auto-associative neural network (ANN) with a recursive minimization strategy would notably decrease when the percentage of missing values surpasses around 30%. However, if the missing values are not predominant across most variables for each sample simultaneously, the acceptable limit for the percentage of missingness could be slightly higher.

Zhang et al. [11] asserted that the self-organizing map (SOM) method requires a large amount of data to be effective. In a similar vein, Rustum & Adeloye in [3] emphasized that the proposed KSOM need a large amount of data to train the KSOM. Additionally, the KSOM exhibits sensitivity to initial conditions and poses challenges in determining the appropriate number of nodes [3]. SOM method may not work well with categorical or binary data, as it is designed for continuous and numeric variables. Also, the accuracy of the imputed values depends on the quality of the training data and the relationships between variables [25]. It is also proved that the KSOM is not suitable for predicting extreme values that are outside the range of the training data [3].

According to Huo et al. [10], they observed that the TES and TESWN methods depend on time series models, which might not produce satisfactory outcomes when dealing with missing data unrelated to time. Furthermore, the TES method neglects the uncertainty associated with the missing value, resulting in an underestimation of the population variance for both influent data and simulated effluent concentrations. Huo et al. [9] It was stated that the TES method functions based on the assumption that the missing values are missing at random (MAR). Consequently, the accuracy of the imputed values may be influenced by the assumptions made by the method. Additionally, the TES method could erroneously introduce abrupt temporal changes in variables within the data record. In fact, the performance of TES and TESWN methods may be contingent on specific characteristics of the data being imputed, such as the degree of autocorrelation and the presence of outliers [10].

According to the findings of Villez et al. [12], in the missing data imputation technique using PCA, the undetected failure ratio appears to be significantly impacted by the presence of gaps in the data. This ratio nearly doubles when no estimates are employed. This suggests this method may not be able to accurately estimate missing data in all cases, leading to potential limitations in the performance of the model.

In their paper, Oliveira-Esquerre et al. [24] applied linear interpolation to estimate missing values, but they limited it to no more than two consecutive missing values. This indicates that linear interpolation might not be effective for estimating

missing values when there are more than two consecutive missing values. The original database covered a period of 1427 consecutive days, roughly a four-year daily record. However, the significantly high occurrence of missing values for several variables, particularly for TSS, NAM, and NN variables, poses a substantial issue in the dataset. Missing values are more prevalent than available data for these variables.

## IV. DISCUSSION

Findings from this paper reveal that there are only a limited number of articles (16 in total) discussing imputation methods used in WWTPs. This suggests that the literature on this filed is relatively scarce. However, despite the limited number of studies, the findings indicate a diverse range of approaches being explored.

These studies focused on various imputation methods, including the MSF-ARI approach (R2AU-Net) [20], univariate imputation methods (such as the SSD method and SVR model) [21], the SVM algorithm [16], coupling the expectation maximization (EM) algorithm with the Markov Chain Monte Carlo (MCMC) method (EM-MCMC) [22], Case-Based Reasoning (CBR) approach [18], Cubic Hermite interpolation method [14], Non-Linear decreasing inertia weight particle swarm algorithm (NLDIW-PSO) based optimal Support Vector Regression (SVR) [23], Daily average, auto-associative neural network (ANN) with a recursive minimization strategy [19], Multiple imputation (MI) [17], Linear interpolation [24], Two-directional exponential smoothing (TES) [9], PCA projection method [12], Kohonen self-organizing map (KSOM) [3], TES and TESWN [10].

The effectiveness of these imputation methods in handling missing data challenges was evaluated based on several criteria, including imputation accuracy, computational efficiency, robustness to different types and patterns of missing data [9][10]. The results varied across the studies, with some methods demonstrating high accuracy in imputing missing values [16][18][23], while others showed limitations in certain aspects [3] [11] [12] [14] [22].

Several limitations were identified across the reviewed papers. One common limitation was the lack of generalizability of proposed approaches to different WWTPs with varying configurations and operating conditions. In some cases, the proposed methods required a substantial amount of training data [3] [11], which may not be available in all WWTPs. Another limitation was the failure to consider sensor drift, which could impact the accuracy of imputed data. Furthermore, many studies did not compare their proposed methods with other state-of-the-art imputation techniques or evaluate their performance on diverse datasets. The generalizability of findings was often limited by the use of data from a single WWTP or a specific location [3] [9] [24], raising concerns about the applicability of the proposed methodologies to other systems.

Future research should address these limitations by conducting broader investigations, comparing with existing methods, and exploring the impact of various factors on data

imputation in WWTPs to bridge the existing knowledge gaps and ensure the reliable management and analysis of data in this domain.

## V. CONCLUSION

In this study, the SLR examine the existing missing data imputation methods used in WWTPs. This SLR is also concerned with aiding researchers working in this field in the decision-making processes and enhancing the performance of WWTPs. This study concentrated on the scientific database Scopus.

The findings from the selected studies reveal a limited number of articles discussing this specific topic with only 16 articles meeting the inclusion criteria. Despite the scarcity of literature, the findings demonstrate a diverse range of approaches being explored in this field.

The studies indicate that these imputation methods have shown promising results in handling missing data in various aspects of WWTPs, including influent data and water quality data. They have been employed to impute missing values for different variables, such as flow, temperature, BOD5, suspended solids, ammonia nitrogen, pH values, and more. The effectiveness of these methods has been evaluated using different evaluation metrics, such as mean squared error (MSE), MAE, and coefficient of determination ($R^2$).

However, it is important to acknowledge some limitations identified in the reviewed studies. These include the lack of generalizability of proposed approaches to different WWTPs with varying configurations and operating conditions, the requirement for a substantial amount of training data which may not be universally available, the failure to consider sensor drift in imputation methods and the need for comparing the proposed methods with other state-of-the-art techniques are also areas that require attention.

Based on these findings, several recommendations can be made. Further investigation is warranted, specifically taking into account the missing mechanisms and rates associated with data gaps in this particular field. Furthermore, researchers should aim to validate and generalize the proposed imputation methods by conducting experiments in multiple WWTPs with diverse characteristics. This will enhance the understanding of their performance and applicability in different settings. Moreover, additional evaluation metrics such as RMSE and MAE should be employed to comprehensively assess the effectiveness of the imputation methods. Comparative studies, benchmarking the proposed methods against other state-of-the-art techniques, would also provide valuable insights into their relative strengths and weaknesses.

*Abstract*—Kidney failure is a condition with far-reaching, potentially life-threatening consequences on the human body. Leveraging the power of machine learning and data mining, this research focuses on precise disease prediction to equip decision-makers with critical data-driven insights. The accuracy of classification systems hinges on the dataset's inherent characteristics, prompting the application of feature selection techniques to streamline algorithm models and optimize classification precision. Various classification methodologies, including K-Nearest Neighbor, J48, Artificial Neural Network (ANN), Naive Bayes, and Support Vector Machine, are employed to detect chronic renal disease. A predictive framework is devised, blending ensemble methods with feature selection strategies to forecast chronic kidney disease. Specifically, the predictive model for chronic kidney disease is meticulously constructed through the fusion of an information gain-based feature evaluator and a ranker search mechanism, fortified by the wrapper subset evaluator and the best first algorithm. J48, in tandem with the Info Gain Attribute Evaluator and ranker search system, exhibits a remarkable accuracy rate of 97.77%. The Artificial Neural Network (ANN), coupled with the Wrapper Subset Evaluator and the highly effective Best First search strategy, yields precise results at a rate of 97.78%. Similarly, the Naive Bayes model, when integrated with the Wrapper Subset Evaluator (WSE) and the Best First search engine, demonstrates exceptional performance, achieving an accuracy rate of 97%. Furthermore, the Support Vector Machine algorithm achieves a notable accuracy rate of 97.12% when utilizing the Info Gain Attribute Evaluator. The K-Nearest Neighbor Classifier, in conjunction with the Wrapper Subset Evaluator, emerges as the most accurate among the foundational classifiers, boasting an impressive prediction accuracy of 98%. A second model is introduced, incorporating five diverse classifiers operating through a voting mechanism to form an ensemble model. Investigative findings highlight the efficacy of the proposed ensemble model, which attains a precision rate of 98.85%, as compared to individual base classifiers. This research underscores the potential of combining feature selection and ensemble techniques to significantly enhance the precision and accuracy of chronic kidney disease prediction.

*Keywords*—*Kidney; chronic kidney disease; support vector machine; k-nearest neighbors; artificial neural network; decision tree*

## I. INTRODUCTION

Large datasets can be mined for significant insights via data mining, which is seen as a necessary stage in the learning process. Its uses are widespread across various industries, including business, healthcare, education, science, government, etc. Data mining is frequently used in the medical sector to forecast diseases [1]. Developing efficient approaches for illness analysis, prediction, and detection is central to this critical area of research in the healthcare industry [2, 3]. Applications for data mining are frequently used in patient care systems, health information systems, and healthcare management and they significantly affect the analysis of disease survival [4, 5].

Data mining and classification approaches are essential for classifying, identifying, analyzing, and predicting disease datasets in the healthcare domain [6,7]. Medical datasets undergo comprehensive type, meticulous research, precise detection, and informed prediction through various classification methodologies. These encompass the sophisticated realm of Artificial Neural Networks (ANN), the discerning approach of K-Nearest Neighbors (KNN), the probabilistic insight of Naïve Bayes, the strategic branching of Decision Tress (J48, C4.5), the adept maneuvering of Support Vector Machines (SVM) etc.

The feature selection approach is crucial in data mining and machine learning as it plays a vital role in knowledge discovery, pattern identification, and statistical sciences [7]. Eliminating pointless attributes from the dataset is the primary goal of feature selection [8]. The refinement of classifier performance accuracy can be achieved by strategically removing specific details. Wrapper and filter approaches can classify feature selection techniques [9, 10].

Machine learning methods called ensembles combine predictions from various classifiers to increase prediction

accuracy. An essential process for creating extremely accurate prediction models is the ensemble model. Ensemble models, such as random forest, bagging, boosting, stacking, and voting, are commonly employed in machine learning, data mining, and data science.

Chronic renal failure (CRF), another name for chronic kidney disease (CKD), is a severe and developing health problem worldwide. CKD is characterized by a slow decline in kidney function that impairs the functionality of the renal organs [4]. Due to the lack of apparent symptoms in the early stages, the start of renal failure may initially go unreported [6]. However, the effects of renal failure can seriously harm a person's general health and potentially have deadly implications.

According to the Global Burden of Disease Project, chronic kidney disease (CKD) has recently become a rapidly expanding global health concern. According to statistical statistics, the death rate for people with CKD increased significantly by 90% between 1990 and 2013 [7]. Presently, (CKD) stands as the thirteenth most prevalent contributor to mortality on a global scale. Moreover, CKD prominently ranks within the upper echelon of the five leading causes of death worldwide, as substantiated by findings from the esteemed research conducted by Kidney International [8]. According to the National Kidney Foundation, CKD affects around 10% of the world's population and causes millions yearly deaths [11]. The high mortality rates linked to CKD result from a lack of efficient treatments and a poor understanding of renal disease.

In developing nations, some kidney patients sometimes wait until their ailment has advanced before seeking treatment. This pattern helps explain why CKD is becoming more common [8]. However, detecting the illness at an early stage or during its start can decrease or even stop the occurrence of CKD. Early detection and management of kidney illness can be aided by diagnostic procedures such as blood testing, urine tests, kidney scans, and doctor consultations regarding additional symptoms of kidney disease.

By using feature selection strategies to lower the dimensionality of the features and ensemble models, which include various classifiers, this work focuses on evaluating the accuracy of the methods.

The remainder of this study is divided into the following sections: A literature review is presented in Section II, the techniques are described in Section III, the experimental test findings are shown in Section IV with a discussion that follows and the research is concluded in Section V.

## II. LITERATURE REVIEW

Classification methodologies, the process of selecting relevant features, and the utilization of ensemble approaches stand as foundational pillars within the realms of machine learning and data analysis. Several research endeavors have been undertaken to employ these methodologies to classify disease datasets within the medical domain, and these endeavors have been extensively examined in the discipline. Numerous research studies have shown promising classification accuracy when using feature selection approaches, ensemble models, data mining and machine learning techniques to analyze medical datasets.

A study on the diagnosis of chronic renal illness using Support Vector Machines (SVM) and efficient feature selection techniques was carried out by Polat et al. [6]. To reduce dimensionality, they employed both wrapper and filter feature selection approaches. The study revealed that using Support Vector Machines (SVM) without feature selection led to an impressive accuracy of 97.75% in their analysis. By integrating SVM with a classifier subset evaluator and applying a greedy stepwise technique, the accuracy was enhanced to 98%. Similarly, utilizing Support Vector Machines (SVM) with a wrapper subset evaluator and leveraging a best-first search technique resulted in an elevated accuracy of 98.25%. Correspondingly, merging Support Vector Machines (SVM) with a classifier subset evaluator and applying a greedy stepwise method yielded an accuracy rate of 98.25%. Lastly, employing the best-first search strategy alongside SVM using the filter subset evaluator achieved the highest accuracy rate of 98.5%.

To predict cardiac disease, Bashir et al. [12] suggested an ensemble classifier based on a majority vote framework. The ensemble model was built using Nave Bayes, decision trees based on Gini Index and information Gain, memory-based learners, and Support Vector Machine (SVM), five heterogeneous classifiers. Their MV5 framework obtained an accuracy of 88.5% through trials utilizing stratified cross-validation, with a sensitivity of 86.96%, specificity of 90.83%, and an F-Measure of 88.85. The ensemble model's average accuracy increased compared to the individual base classifiers. The suggested method involved producing personal classifier judgments, successfully integrated to create the new combined model.

Bashir et al. [13] presented the HMV framework for medical decision support, which employs a multi-layer classifier for disease prediction. Their strategy focuses on assembling diverse classifiers into an ensemble model most effectively. Within their system's framework, an array of discerning classifiers is harnessed, including but not limited to Naive Bayes, Linear Regression, Quadratic Discriminant Analysis, K-Nearest Neighbors (KNN), Support Vector Machine (SVM), as well as Decision Trees meticulously constructed using both the Gini Index and the Information Gain criterion. Their HMV ensemble framework outperformed other prediction models in experiments, according to the results. The three components of the HMV framework are data collection and preprocessing, predicting unidentified class labels for test instances, and assessing the suggested HMV ensemble model. They attained the maximum disease categorization and prediction accuracy level using the HMV ensemble model on the chosen dataset.

Data mining techniques were used in a study by Khajehali et al. [14] to uncover parameters impacting pneumonia patients. They suggested a modeling strategy that included ensemble approaches for feature selection and classification with preprocessing, dimensionality reduction and unstructured data classification. They used the Bayesian Boosting method to build a model that identifies variables related to patient length of stay (LOS) in the hospital. The design of their

investigation included various preprocessing stages. SVM and ensemble approach like AdaBoost, Vote, Stacking, and Bayesian Boosting were used in the modelling process. Using a 10-fold cross-validation procedure, Bayesian Boosting, one of these classifier algorithms, was used for data analysis. Ten subsets were created from the dataset, with the training subset being chosen iteratively ten times. The training ensembles encompassed a comprehensive selection, incorporating nine available ten subsets. The findings demonstrated the efficiency of the Bayesian Boosting ensemble technique in forecasting pneumonia disease and anticipating length of stay, with a greater accuracy of 97.17%.

Pritom et al. [15] conducted an extensive investigation into the forecasting of breast cancer recurrence, leveraging a suite of sophisticated classification algorithms, including SVM, Decision Trees, Naive Bayes, and the venerable C4.5 method. Through the use of efficient feature selection techniques, they hoped to increase the accuracy of each classifier. They employed the Info Gain characteristic with a ranker search engine as one such technique. The effectiveness of recurrence prediction was assessed by applying these algorithms on the Weka tool. Upon the unaltered dataset, void of any feature selection, the results unveiled a landscape where SVM distinguished itself with a remarkable precision of 75.75%. Meanwhile, the J48 secured an impressive 73.73% accuracy, while the Naïve Bayes classifier demonstrated notable proficiency, attaining a respectable accuracy of 67.17%. However, after properly implementing feature selection, SVM, C4.5, and Nave Bayes showed improvements of 1.52%, 2.52%, and 9.09%, respectively. This compelling evidence underscores feature selection's remarkable efficacy in elevating the classifiers' accuracy, validating its pivotal role in enhancing performance.

Dulhare et al. [7] constructed classification models to predict and categorize individuals with chronic kidney disease (CKD) using feature selection and the naive Bayes classifier. They used a feature selection technique known as the one R attribute selector to extract useful rules. The model's classification accuracy was evaluated using the best first search engine and the wrapper subset evaluator. Upon assimilating these methodologies into the Weka tool, the Naïve Bayes classifier achieved a notable accuracy threshold of 97.5%, accentuating the profound impact of their integration. This indicates how well the feature selection and classification strategy correctly identifies patients with and without CKD.

Artificial intelligence (AI) and deep learning have revolutionized various industries, including agriculture [16–23], education [24, 25], finance [26], healthcare [27–29] and other domains [30, 31]. In the field of healthcare, AI has shown tremendous promise in improving patient outcomes, enhancing diagnostics, and streamlining healthcare processes. With the ability to analyze vast amounts of data and identify complex patterns, AI-powered systems have opened new frontiers for early disease detection, personalized treatment plans [32], and overall healthcare efficiency. In healthcare, one of the areas where AI and deep learning have made significant advancements is in the early detection of diseases, including cancer [33]. Detecting cancer at an early stage is

crucial for improving treatment success and patient survival rates. Kidney cancer, for example, often presents with few symptoms in its early stages, making early detection challenging. However, deep learning algorithms have proven to be effective in analyzing medical imaging data, such as CT scans and MRI images, to detect kidney tumors at their nascent stages [34].

## III. DIFFERENT TECHNIQUES EMPLOYED IN THE REALM OF CKD

### A. Artificial Neural Network (ANN)

The functioning of natural neurons served as the inspiration for artificial neural network (ANN), often known as a "neural network," which is widely used in practical applications. With changeable weights assigned to each link, it consists of interconnected nodes of artificial neurons, allowing for changes in their spatial layout during information transmission [4]. Being a learning algorithm, ANN can change its structure as it learns by taking in information from its internal and external environments [6]. The network has several layers for message propagation, including an input layer, hidden layers, and an output layer. One or more levels with different numbers of nodes may be included in the hidden layers. These layers are connected, and each node is tied to a certain weight. With ANN, input data is sent to the network to generate predictions while the network learns under supervision. A perceptron, which is the main working component of ANN, may divide datasets into two types. A perceptron is made up of a single node with corresponding weights. Its three key components are the connections between nodes, an adder for adding inputs, and activation functions that control the output.

### B. K-Nearest Neighbor (KNN)

KNN is a nonparametric supervised learning technique that works well with both linear and nonlinear data [1]. It features a rapid training procedure and works especially well for big datasets. KNN determines the k objects that are closest to the place of interest or by majority voting. The selection of items hinges upon identifying the nearest class object, as determined by the minimal distance between the querying instance and the corresponding training example. According to Boukenze, et al. [4], KNN is the algorithm with the quickest model-building execution time. KNN considers k instances—x1, x2…—to forecast the class of a query Xn. Different distance metrics, such as the Euclidean, Manhattan, Minkowski, and Hamming distances, are used to determine which class is closest. This is how the distance formula is put together.

$$\text{Euclidean} = \sqrt{\sum_{i=1}^{n}(Xi - Yi)2}$$

$$\text{Manhattan} = \sum_{i=1}^{n} |Xi - Yi|$$

$$\text{Minkowski} = \sum_{k} (|Xi - Yi|)^q )^{\frac{1}{q}}$$

### C. Decision Tree (J48)

The Weka platform's C4.5 decision tree technique is implemented in Java as a J48 decision tree. It is a development of Ross Quinlan's original ID3 algorithm.

The top-down greedy search method is used by the J48 classification algorithm to build the tree. The final decision tree produced by J48 is made up of sorted branches, where the internal characteristics reflect potential outcomes based on the branching features and the leaf nodes represent the final class results. The separation between information gain and the splitting qualities is the foundation for the tree's creation. Data disorder and uncertainty are measured using entropy. The formula below can be used to determine the entropy of a random variable given a probability "p" and sample "S".

$$\text{Entropy(S)} = \sum_{i=1}^{n} (-pi\ log2(p_i))$$

The most informative aspect for choosing the best node in a decision tree is measured according to information gain. It measures the amount of entropy or uncertainty that is reduced due to dividing the data based on a particular attribute. We take into account the values of the attribute as "v" and the subset of sample "S" that corresponds to each value to determine the information gain for a given attribute "A" about a sample "S". Following are the steps for computing the information gain.

$$\text{Gain (S, A)} = \text{Entropy(S)} - \sum_{v \in \mathbf{Value}}^{\mathbf{n}} (\text{Entropy(Sv)} \frac{|Sv|}{|S|})$$

### D. SVM: Support Vector Machine

One of the quintessential techniques in machine learning, renowned for its prowess in supervised learning, is the Support Vector Machine (SVM) [6]. It is famous for its high-performance abilities in classification, regression, analysis, and prediction tasks on datasets. In the feature space of the training data, SVM creates a distinct hyperplane that divides and categorizes the data points according to their positions about the hyperplane. In data mining, it is frequently used for problems involving regression and classification [1]. When compared to other classification algorithms, SVM, a widely used supervised learning technique, can produce accurate results. SVM strategically endeavors to minimize classification error by optimizing the margin between instances belonging to distinct classes, thereby culminating in an exceptional power. SVM uses the "kernel trick" to determine the separation between a data point and the hyperplane in a modified feature space without explicitly modifying the original features, which is one of its benefits.

### E. Simple Bayes

A classification technique that applies the Bayes theorem under the feature independence presumption is known as the Naive Bayes classifier. It is a probabilistic technique that is frequently used in supervised classification issues in practical settings [1]. Naive Bayes has quick learning skills and works well in applications like diagnosis and prediction. The Nave Bayes algorithm works well with less training data, making it appropriate for classification jobs where data availability is constrained [35, 36]. Each record is predicted and associated with a particular class using the Naive Bayes classification algorithm, which calculates the likelihood that the record belongs to the target class. The most likely class is the one with the highest likelihood.

$$P(P/X) = \frac{P(P/X).P(Y)}{P(X)}$$

## IV. Approach and Empirical Findings

The provided study revolves around two methodologies. The initial approach involves crafting a predictive model through the implementation of several feature curation tactics. The subsequent technique involves establishing a predictive model by harnessing an amalgamation of diverse classifiers.

### A. Techniques for Choosing Features

A comprehensive classification model may be created by removing superfluous features from the data set and reducing the dimensionality of the feature. In this study investigators used the ranker search strategy with the Info Gain Attribute Evaluator feature selection technique to find the most relevant features. The Info Attribute Evaluator operates on a distinctive principle, evaluating an attribute's significance by comparing its information gain with respect to the classes. Moreover, it exhibits remarkable capability in appraising binary numeric attributes, eliminating the need for conventional feature discretization procedures. Moreover, the absent data could be distributed among alternative values based on their averages and commonly appearing values for a definite trait or a numeric feature. Alternatively, it might be considered as a distinct entity. The Attribute Evaluator for Information Gain showcases impressive adaptability, capable of identifying absent data and a range of attribute categories like nominal, temporal, numerical, unary, binary, and vacant minor attributes.

The ranker search technique can be exploited to obtain the rankings of attributes also evaluates each attribute by its specific evaluator in addition to attribute evaluators like information gain and Gini index. It possesses the capability to produce feature prioritization.

In this investigation, a supplementary layer of feature selection was implemented through the synergistic incorporation of a Wrapper Subset Evaluator, seamlessly melded with the precision-driven best first search methodology. This evaluative framework operates by leveraging sophisticated learning pattern to gauge the efficacy of attributes sets, fortified by a meticulous cross-validation process to affirm the soundness of the acquired insights. The detected attributes compass a wide array of characteristics, which consist of text, null nominal, undefined entries, time-related, relational, numeric, individual, paired, and categorical features. Furthermore, its discerning capabilities extend to the identification of attributes within Nominal, Binary, Date and Numeric classes, as well as the nuanced recognition of values within the Missing class domain.

In order to search the space of attribute subsets, first-best search makes use of a greedy hill climbing capacity supplemented with a backtracking capability. The maximum allowed number of consecutive non-improving nodes determines how much backtracking is allowed. The Best first search methodology offers a gamut of strategic pathways for exploration. It may embark upon its journey with an initial attributes set that is void, then propel forward, or alternatively, commence with a comprehensive set and elegantly traverse backward. Furthermore, it possesses the flexibility to initiate from any vantage point, seamlessly navigating in both forward and reverse directions. This dynamic approach encompasses the meticulous consideration of all possible single attribute

augmentation and eliminations at specific junctures and these modalities can be ingeniously combined to forge a tailored exploration strategy.

### B. Ensemble Classifiers

The ensemble with the most heterogeneous classifier typically has the highest accuracy rate. Ensemble learning, a technique in the field of machine learning, revolves around creating multiple prediction models and blending their outputs to enhance the overall performance metrics of each algorithm. Employing an ensemble classifier is the optimal approach for rectifying errors that may arise from the underlying primary classifier [13]. In machine learning combination classification, it is currently increasingly usual to use many classifiers rather than just one. The advantage is that we can use two or more powerful categorization algorithms rather than just one. Hence, the resultant model will reach an elevated echelon of effectiveness and sophistication, equipping it to expertly discern and classify samples gathered from the training, cross-fold validation, and thoroughly examined testing datasets.

The ensemble classification model combines a number of classifiers, each of which affects the outcome in a unique way. These methodologies have ushered in a transformative evolution within the training process, molding classifier models that yield diverse categorization outcomes with unparalleled precision [12]. Ensemble methods' key advantage is that they combine individual classifier rules to provide predictions that are more accurate than those made by those rules alone. To improve prediction accuracy, the ensemble model approach mixes various individual classifiers.

The architecture of the proposed ensemble model is shown in Fig. 1. The proposed system's general methodology uses data from the UCI machine learning repository. For nominal and numeric variables within the dataset, any instances of missing values are meticulously imputed through the modal and mean values derived from the training data. Concurrent with this, the intricacy of features is finely tuned through the skilled utilization of feature selection methods. After feature reduction, we have the optimum feature subset, and the dataset was trimmed down for the proposed research. The reduced subset dataset consists of a few pertinent features. Following a rigorous process of individual attribute value feature selection, the foundational classifier was enriched with a cadre of prominent base classifiers, comprising K-Nearest Neighbors (KNN), J48 decision trees, Artificial Neural Networks (ANN), Naïve Bayes (NB) and Support Vector Machines (SVM). The data has been split into training and test sets. A training set of data was used to train the base classifier, a testing framework for evaluating and predicting illnesses. To improve the results, create a final forecast after combining the classifier using the ensemble voting method. The models' effectiveness is evaluated. Before this, the results were evaluated using ROC, F-Measure, recall, accuracy, and precision. The broad suggested system design is demonstrated in Fig. 1.

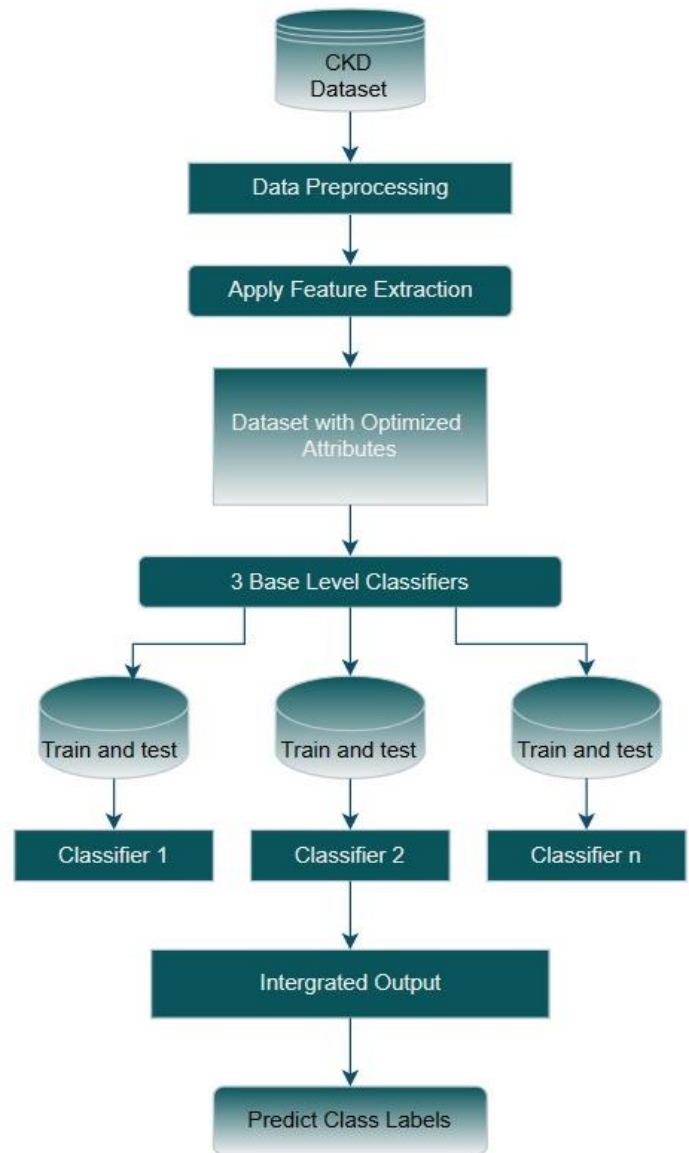

Fig. 1. The architecture of proposed ensemble model.

### C. Dataset Exploited

The dataset from the UCI machine learning repository was acquired [11]. The collection contains 400 examples with 24 attribute values and 1 class attribute. These traits are included in the Table I below. The dataset contains 400 samples, 250 of which have CKD and 150 have not. It has the following characteristics: (14 numeric, 11 nominal) 24 + class = 25.

### D. Various Performance Indicators Explored

By computing several performance indicators, a confusion matrix is used to gauge a classification algorithm's accuracy. It displays the classification model's correct and incorrect predictions with the dataset's actual values or intended results.

In this study, researchers took into account the predicted classes "CKD" and "not CKD." When predicting if a person has an illness, such as chronic kidney disease (CKD), "CKD" denotes that they have, but "not CKD" denotes that they do not.

TABLE I.    SHOWS THE CHARACTERISTICS OF CHRONIC KIDNEY DISEASE [11]

| Fields | Description |
|--------|-------------|
| age | Age |
| bp | Blood-pressure |
| sg | Specific-gravity |
| al | Albumin |
| su | Sugar |
| rbc | Red blood cells |
| pc | Pus-cell |
| pcc | Pus-cell clumps |
| ba | Bacteria |
| bgr | Blood-glucose random |
| bu | Blood-urea |
| sc | Serum-creatinine |
| sod | Sodium |
| pot | Potassium |
| home | Hemoglobin |
| pcv | Packed-cell volume |
| wc | White blood-cell count |
| rc | Red blood-cell count |
| htn | Hypertension |
| dm | Diabetes-mellitus |
| cad | Coronary artery-disease |
| appet | Appetite |
| pe | Pedal-edema |
| ane | Anemia |
| class | Class |

Also, investigators in this study employed the following indicators to assess how well our experiment performed using the confusion matrix in Table II.

True Positives (TP): These are cases that were accurately identified as positive, i.e., they had CKD when it was expected that they would.

- True Negative (TN): Instances that were appropriately identified as negative and were both predicted not to have CKD and really do not.

False Positive (FP) cases are those that were incorrectly identified as positive; they were expected to have CKD but didn't actually have it.

False Negatives (FN) are situations that were incorrectly categorized as negative; they were thought to be free of chronic renal disease but actually were.

- Accuracy: This pertains to the inherent ability of a classification algorithm to accurately anticipate and discern the underlying classes inherent within a given dataset. It is a metric that shows how accurately the classifiers assign the examples to the appropriate classes based on their projected class labels.

Accuracy is equal to (TP+TN)/(TP+TN+FP+FN).

TABLE II.    CONFUSION MATRIX TABLE

| Confusion Matrix | | | | |
|---|---|---|---|---|
| | Positive | Negative | Target Value | |
| Positive | TP | FN | Positive Predictive value | $\dfrac{TP}{TP+FP}$ |
| Negative | FP | TN | Negative Predictive value | $\dfrac{TN}{FN+TN}$ |
| | $\dfrac{TP}{TP+FP}$ Precision | $\dfrac{TP}{TP+FN}$ Recall | Accuracy= TP+TN/TP+FP+FN+TN | |

- Recall: It also goes by the name "sensitivity," and it gauges how well a classification algorithm can find pertinent examples.

Recall equals TP/ (TP+FN)

- Precision is a metric used by a classification system to evaluate how relevant the information that has been gathered is. It focuses on the percentage of retrieved instances that are relevant.

Precision is equal to TP / (TP+FP).

- F-Measure, sometimes referred to as the F-score, combines a test's recall and precision to determine how accurate it is. In order to assess the overall effectiveness of a classification system, it offers a balanced average of recall and precision.

F-Measure=2* (Recall + Precision) / (Recall*Precision)

- Receiver Operating Characteristics (ROC) Analysis: The Receiver Operating Characteristics (ROC) curve stands as a visual instrument of paramount significance for the appraisal of classification test efficacy. Presented graphically, it portrays the intricate interplay amidst the trade-offs between accurate identification and false positive occurrences across threshold variations. The ROC curve astutely encapsulates the nuanced balance between true positive and false positive outcomes, thereby facilitating a comprehensive comparison of distinct classification models. A pivotal gauge of model precision lies in the area under the ROC curve (AUC), a scalar metric ranging between 0 and 1. A value closer to 1 signifies a heightened model performance. Manifesting the capability to distinguish positive instances superiorly than negative instances, the AUC quantifies this discernment. On the ROC curve, the horizontal axis charts the false positive rate, while the vertical axis, often denoted as recall, delineates the true positive rate. A classification algorithm's performance and discriminatory ability are valuable revealed by the ROC curve.

TABLE III.    DISPLAYS THE RESULTS OF CLASSIFIERS BOTH WITH AND WITHOUT FEATURE SELECTION

| Categorization using feature selection techniques with and without | Precision | Recall | F-Measure | Accuracy |
|---|---|---|---|---|
| KNN absence of feature selection | 0.965 | 0.966 | 0.965 | 96.60 |
| KNN with JofeGainAttributeEval and ranker (chosen 20 Attributes) | 0.977 | 0.971 | 0.978 | 97.74 |
| KNN and Ranker with 15 Attributes) | 0.97 | 0.97 | 0.97 | 97 |
| Best first search engine with WrannerSubsetExal (Picked 8 attributes) | 0.98 | 0.98 | 0.98 | 98 |
| J48 absence of feature selection | 0.956 | 0.956 | 0.957 | 95.76 |
| JofeGainAttributeExal using a ranker (20 Attributes chosen) | 0.977 | 0.978 | 0.977 | 97.74 |
| J48 with JofeGajoAttributeEval and ranker (15 Attribute chosen) | 0.977 | 0.978 | 0.977 | 97.76 |
| Best first search engine 48 WrapperSubsetExal (7 attributes chosen) | 0.973 | 0.979 | 0.978 | 97.77 |
| ANN absence of feature selection | 0.968 | 0.968 | 0.968 | 96.65 |
| ANN and ranker with JofeGainAttributeEval (20 Attributes chosen) | 0.971 | 0.97 | 0.97 | 97 |
| ANN and ranker with JofeGainAttributeExal (15 Attribute chosen) | 0.976 | 0.965 | 0.975 | 97.55 |
| Best first search engine with WrannerSubsetExal and ANN (8 attributes chosen) | 0.975 | 0.979 | 0.976 | 97.78 |
| NB absence of feature selection | 0.941 | 0.935 | 0.936 | 93.25 |
| NB and ranker with Attributes chosen) | 0.942 | 0.938 | 0.938 | 93.45 |
| NB and ranker with JofeGainAstributeEval (15 Attributes chosen) | 0.956 | 0.953 | 0.952 | 95.12 |
| Best first search engine with WrannerSubsetEval and NB (9 attributes chosen) | 0.971 | 0.969 | 0.970 | 97 |
| SVM absence of feature selection | 0.968 | 0.969 | 0.968 | 96.76 |
| SVM and ranker with InfoGainAttributeEval 20 Attribute chosen) | 0.973 | 0.938 | 0.973 | 97.17 |
| SVM and ranker with InfoGainAttributeEval, 15 Attributes chosen) | 0.978 | 0.979 | 0.978 | 97.69 |
| Best first search engine SVM with WrapperSubsetEval and SVM (8 attributes chosen) | 0.971 | 0.972 | 0.973 | 97.12 |

In pursuit of enhanced precision in predicting Chronic Kidney Disease (CKD), a meticulous endeavor is made to curtail dataset dimensionality through strategic feature selection approaches. The Info Gain attribute evaluator synergistically combines forces with the ranker search engine, while the WrapperSubsetEval harnesses the prowess of the Best first search engine. By juxtaposing the outcomes against the original dataset, these methodologies ingeniously sculpt a novel dataset boasting reduced dimensions. The culmination of classifier results, with and without the application of feature selection techniques, finds concise summation in the depicted Table III above.

The dataset dimension for each classifier was 20 attributes as a result of the initial feature selection approach, which combined the infoGainAttributeEval evaluator with the ranker search engine. The infoGainAttributeEval evaluator and ranker search engine was then used in a second feature reduction procedure to further reduce the dimensionality, yielding a dataset characterized by 15 attributes per classifier, with the integration of the third feature selection strategy. The Best First search engine with the WrapperSubsetEval evaluator, resulting in a dataset dimension of eight attributes.

Without feature selection, all 25 characteristics were used in the K-nearest neighbour (KNN) classifier. The dataset dimensions for J48, ANN, Naive Bayes, and SVM classifiers were reduced to seven attributes for J48, ANN, and Naive Bayes, and eight attributes for SVM, using the WrapperSubsetEval evaluator with the Best First search engine.

Fig. 2 exhibits the empirical revelations pertaining to each classifier, juxtaposing their performance both in the presence and absence of the feature selection methodology. A comprehensive depiction of the classifiers' performance metrics, encompassing precision, recall, F-Measure, and accuracy, is meticulously presented within the same figure. In order to assess the CKD and non-CKD cohorts, discerning weighted averages were invoked as a robust analytical framework.

According to Fig. 2 findings, the ANN classifier's CKD prediction accuracy was highest when feature selection was combined with the WrapperSubsetEval and Best First search engines. The top-ranked average figures for precision, recall, F-Measure, and obtained using this method, which chose eight attributes from the original 25. The ANN classifier achieved a prediction accuracy of 97.78% for CKD without feature selection. The accuracy of the KNN classifier dropped to 97.55% when utilizing the InfoGainAttributeEval with ranker feature selection approach, demonstrating that the removal of some attributes had a detrimental effect on accuracy. As opposed to the accuracy of the normal dataset, which was 96.65%, the accuracy increased to 97% with the selection of 20 attributes.

When employing feature selection with InfoGainAttributeEval and ranker, the J48 classifier had the highest respectable accuracy in CKD prediction, as seen by the values in Fig. 3. The J48 classifier attained an accuracy of 97.75% approximately for both 15 and 20 specified attributes. The J48 classifier, on the other hand, showed a lower accuracy of 95.76% when predicting CKD without feature selection. The dataset was reduced to seven attributes using feature selection, WrapperSubsetEval, and the Best First search engine, and the J48 classifier showed a 97.77% accuracy rate compared to using the entire dataset with all 25 attributes; this accuracy rate was more significant.

The KNN classifier's accuracy rates for predicting CKD differed depending on the feature selection techniques used.

The KNN classifier acquired an accuracy rate of 96.60% in CKD prediction without requiring feature selection. The accuracy increased to 97.74% after implementing the InfoGainAttributeEval with a ranker feature selection approach and choosing 20 characteristics. However, when choosing 15 attributes utilizing the InfoGainAttributeEval with a ranker feature selection approach, the accuracy rate dropped to 97%. When dimensionality was reduced using the WrapperSubsetEval with the Best initial search engine feature selection method, the ANN classifier's accuracy rate on the CKD dataset increased. With eight qualities chosen, the accuracy rate was 98%.

The Naive Bayes classifier's accuracy rates for predicting CKD differed depending on the feature selection techniques used. The Nave Bayes classifier attained an accuracy rate of 93.25% in CKD prediction without requiring feature selection. The accuracy increased slightly to 93.45% after applying the InfoGainAttributeEval with a ranker feature selection approach and choosing 20 attributes. The accuracy rate increased to 95.12% while utilizing the InfoGainAttributeEval with a ranker feature selection approach and using 15 points. On the CKD dataset, dimensionality reduction utilizing the WrapperSubsetEval with the Best initial search engine feature

selection strategy led to the Naive Bayes classifier's most excellent accuracy rate, nine fields were chosen, and the accuracy rate was 98%.

Regarding predicting CKD, the SVM classifier's accuracy rates they differed according to the feature selection techniques used. Without feature selection, the SVM classifier only managed to predict CKD with an accuracy rate of 96.76%.

Graphical demonstration with and without feature selection, the precision, recall, and F-measures of chronic renal illness are compared in Fig. 2.

The accuracy increased to the highest rate of 97.17% after implementing the InfoGainAttributeEval with a ranker feature selection approach and choosing 20 characteristics. The accuracy rate amplified to 97.69% when 15 attributes were selected using the InfoGainAttributeEval with ranker feature selection approach. On the CKD dataset, dimensionality reduction utilizing the WrapperSubsetEval with the Best initial search engine feature selection strategy led to the SVM classifier's most excellent accuracy rate. 8 attributes were chosen, and the accuracy percentage was 97%. This rate, meanwhile, needed to be more accurate with the rate attained with the 20-dimensional dataset.

Fig. 2. Comparison of feature selection, precision, recall and F-measure of chronic renal illness.

TABLE IV.    EVALUATION OF CLASSIFIERS USING ENSEMBLE METHODS AND FEATURE SELECTION

| Classifier | Precision | Recall | F-Measure | Accuracy |
|---|---|---|---|---|
| KNN | 0.965 | 0.966 | 0.965 | 96.60 |
| KNN after FS | 0.98 | 0.98 | 0.980 | 98 |
| J48 | 0.956 | 0.956 | 0.957 | 95.76 |
| J4N after FS | 0.977 | 0.979 | 0.978 | 97.77 |
| ANN | 0.958 | 0.968 | 0.968 | 96.55 |
| ANN after FS | 0.977 | 0.979 | 0.976 | 97.78 |
| NR | 0.971 | 0.969 | 0.936 | 93.25 |
| NB after FS | 0.968 | 0.969 | 0.970 | 97 |
| SVM | 0.968 | 0.969 | 0.968 | 96.79 |
| SVM after FS | 0.971 | 0.972 | 0.973 | 97.12 |
| Essemble model | 0.985 | 0.986 | 0.985 | 98.85 |

While evaluating the ensemble classifier model on the CKD dataset, an exhaustive scrutiny of performance metrics was conducted, encompassing accuracy, precision, recall, F-Measure, actual positive rate, and ROC comparisons. These comprehensive assessments were meticulously juxtaposed with the individual classifiers' corresponding outcomes. Impressively, the ensemble model showed a high accuracy rate in CKD prediction.

Performances of classifiers with and without methods for feature selection and assembly are shown in Table IV.

The envisaged ensemble framework outclassed other standalone base classifiers and was combined with most of our suggested feature selection techniques. Various performance metrics were used to compare the ensemble model to heterogeneous base classifiers with and without feature selection. The ensemble model used lower dimensions acquired by feature selection techniques, which helped reduce training time and computing expenses. By cutting costs and execution time, feature selection increased accuracy. Fig. 3 shows that the ensemble model demonstrated the highest accuracy level for the CKD dataset compared to the individual base classifiers. It obtained 98.85% accuracy, 0.985% precision, 0.986% recall, and 0.985% F-Measure rates.

Fig. 3. Demonstrates the accuracy assessment of different classifiers.

Fig. 4 presents an insightful comparative analysis, meticulously evaluating the base classifier's level of correctness, exactness, and ability to retrieve relevant instances, both in the presence and absence of feature selection. Discernible in Fig. 4, the ensemble model decidedly outperformed the other classifiers. A comprehensive comparison of the ensemble's performance vis-à-vis that of the remaining classifiers for the dataset about chronic renal illness showcased the ensemble's profound superiority.

Fig. 4. Performance comparison of all the classifiers exploited in this study using a Pareto chart plot.

## V. CONCLUSION

In the pursuit of bolstering classifier precision, the present study diligently harnessed an arsenal of feature selection methodologies and strategically integrated ensemble models within the domain of the CKD dataset. Each classifier was guided by a distinct feature selection evaluator, encompassing the sophisticated InfoGainAttributeEval, the meticulous Ranker search platform, and the astute WrapperSubsetEval feature seamlessly integrated with the proficient Adept Best-First Search mechanism. The strategic application of these techniques was intricately woven into both the ensemble model and the proposed feature selection approach, amplifying the precision of the machine learning classifiers. The performance of K-Nearest Neighbors (KNN), J48, Artificial Neural Networks (ANN), Naïve Bayes (NB), and Support Vector Machine (SVM) classifiers was meticulously juxtaposed across the CKD dataset, and a refined subset crafted through WrapperSubsetEval, featuring the Best First Search Engine and InfoGainAttributeEval as feature selection evaluators. The experimental findings showed that increasing the dataset's dimension decreased the classifiers' accuracy. In particular, the accuracy of ANN classification using WrapperSubsetEval and the Best First search engine on the condensed dataset was 97.78%, exceeding the accuracy attained using the primary dataset and various approaches to feature selection. Contrasted against the unaltered dataset and alternative feature selection methodologies, the condensed dataset derived through the astute combination of InfoGainAttributeEval and the ranker search engine exhibits a remarkable accuracy pinnacle of 97.77% in the realm of J48 classification. With WrapperSubsetEval and the Best initial search engine, the KNN classification accuracy on the condensed dataset reached 98%, the most fantastic accuracy of any approach. With the help of WrapperSubsetEval and the Best first search engine, Naive Bayes classification was 97% accurate on the smaller dataset, outperforming the original dataset and other feature selection techniques. In parallel to the accuracy achieved using the initial dataset and various feature selection techniques, the SVM classifier achieved an impressive precision of 97.12% on the improved dataset generated by employing InfoGainAttributeEval in combination with the ranker search engine. These techniques engendered a discernible reduction in the false positive rate, concomitantly fostering an augmentation in the actual positive rate. Furthermore, an encompassing enhancement encompassed performance metrics alternatively, terms like accuracy, sensitivity, harmonic mean of precision and recall, and exact positive ratio. The ensemble techniques proposed demonstrated superior performance in classifying and predicting CKD on the provided dataset, as evidenced by the experimental results of these ensemble methods. On the condensed CKD dataset, the ensemble classification's accuracy exceeded that of the individual base classifiers by 98.85%. Looking to the future, the ensemble techniques we proposed showcased superior performance in classifying and predicting CKD on the provided dataset, as demonstrated by the impressive accuracy rate of 98.85%. In the upcoming research, further exploration of ensemble methods and feature selection techniques can be pursued to enhance CKD prediction models. Additionally, investigating the

generalizability of these techniques to other medical diagnoses and datasets would be a promising direction for future research in the domain of machine learning and healthcare.

School of Arts, Shaanxi University of Technology, Hanzhong, China[4]

*Abstract*—This study aims to develop a stroke finger training device specifically for office hand scenes which exercises the small muscles of the fingertips and improves the hand strength of stroke patients. The device has a real-time recording function for muscle strength changes during finger muscle training and enhances interaction through the feedback of training device data, thereby improving training effectiveness. This research involves analyzing hand postures and muscle movements in computer office scenes, designing questionnaires to obtain user requirements, and using the Delphi analysis method to screen key indicators and form standards and program layers. The Analytic Hierarchy Process (AHP) evaluates and ranks the core design elements. According to the design elements, the structure and training system design are guided, and a prototype is built for experimental testing. The results show that the training device effectively improves participants' hand strength, stability, and coordination and helps restore hand function. The AHP method allows for evaluating and ranking the device's design elements, making the device design more reasonable and comprehensive. Overall, the training device significantly improves the finger muscle strength of participants.

*Keywords—Stroke; rehabilitation training equipment; finger muscle strength; AHP; specific finger actions*

## I. INTRODUCTION

The incidence of stroke in China has been increasing yearly, and the number of young stroke patients has also increased in recent years [1-3]. Studies have shown that approximately 80% of stroke survivors experience finger dysfunction, especially abnormal finger muscle strength, which seriously affects their daily life and work ability [4,5]. Therefore, finger training has become a crucial part of rehabilitation treatment. Rehabilitation training usually requires rehabilitation equipment, as it can help patients restore joint mobility, increase muscle strength, improve finger coordination, relieve pain, prevent finger stiffness, and improve the quality of life [6].

However, research on existing patents, products, and literature shows that finger rehabilitation training equipment has the following characteristics.

From the perspective of device types, the significant classifications of hand rehabilitation training devices include exoskeletons and end-effectors, which include devices that encourage repetitive hand movements [7], peripheral sensory stimulation devices that promote sensory-motor control [8], and neuromuscular stimulation devices [9]. Based on the principle of neural reshaping [10], exoskeleton devices for finger rehabilitation simulate joint movements of the fingers or optimize materials to fit the hand joints better to promote movement of the affected limb and achieve neural reshaping for rehabilitation purposes.

For example, Luo Guangda et al. [11] designed a hand rehabilitation robot that optimizes its movement mechanism to simulate the movements of the distal interphalangeal joint, proximal interphalangeal joint and metacarpophalangeal joint, achieving finger flexion, extension and abduction. Wang Yangwei et al. [12] used shape memory alloy (SMA) filaments as actuators and adopted a soft glove structure for the hand exoskeleton, which has the advantages of good movement flexibility and high finger fit. End-effectors mainly focus on local hand movements to improve hand movement abilities. For instance, Fang Yufei et al. [13] proposed a hand finger rehabilitation device consisting of a base and a finger ring, which achieves finger flexion and extension through a long-pitched screw rotating inward, with a simple and compact structure, but limited in the direction of force, primarily simulating the force generation at the fingertips or distal phalanges towards the palms, which is seen in grasping actions, but not in other daily activities like picking, pinching, or tapping movements.

Regarding rehabilitation training objectives, the available devices can be divided into two categories: devices for strengthening the hands (using springs and other resistance equipment) and devices for training the range of motion of the fingers (using elastic rods and other devices). From the perspective of technological implementation, they can be further divided into virtual reality finger training devices (to enhance the training experience) and electric finger training devices (using sensing technology [14] and feedback [15] systems to help patients master movement techniques). From the perspective of design pathways, current rehabilitation training devices focus on optimizing drivers, controls [16], structures and trajectory lines [17-20].

While existing devices have played an essential role in the finger rehabilitation process, they lack specific muscle training for finger joint-specific movement positions (such as the particular movement involved in exerting force in a fixed direction at the fingertips in a working environment) and have limited ability to train the small muscles of each finger joint. For example, they mainly focus on overall finger extension and flexion [21], lacking individual finger and finger coordination training. Additionally, existing rehabilitation devices lack real-time feedback capabilities. Furthermore, young stroke patients who need to return to work require specific finger movements,

which existing rehabilitation training devices lack. They cannot help patients transfer their practice skills to actual work, thus compromising the effectiveness of rehabilitation practice. Therefore, developing an effective finger training device is significant for stroke rehabilitation and can improve the patient's quality of life and rehabilitation effects.

This paper proposes the design of a stroke finger training device using the AHP method, which provides personalized movement training for specific hand movements and prepares young and middle-aged stroke patients to return to work. Firstly, we introduce the basic principles and steps of the AHP method. Then, based on scenario analysis and finger posture analysis, we obtain the finger training needs of stroke patients, determine the device's design requirements and functional modules, and evaluate and rank the importance of each functional module according to the AHP method, thereby determining the final design scheme.

To verify the feasibility of the design scheme, we built a testing prototype and developed testing software. In terms of hardware, we adopted a button training structure and used sensors and self-generated force to achieve finger strength, and coordination training. In terms of software, we developed a simple interactive application program that can adjust training difficulty, record and analyze data, and perform other functions.

Finally, we analyzed the test results, which showed that the device could effectively improve the people's finger muscle strength. At the same time, the device has good adjustability and personalized features, which can be adjusted and optimized according to the needs of different patients, providing new ideas and methods for stroke finger rehabilitation training.

The main contributions of this paper are as follows:

*1)* From the perspective of industrial design, a rehabilitation training device that can record real-time finger force data is designed using the AHP method.

*2)* The paper proposes finger strength training for the distal finger joints of patients and emphasizes the importance of finger force exertion in work scenarios. The changes in muscle strength are used as parameters to evaluate the training progress.

## II. RELATED WORK

### A. Mechanisms of Hand Movement Training in Stroke Patients

Stroke can cause ischemia or bleeding in some brain regions, damaging motor pathways such as the corticospinal and pyramidal tract [22]. This damage can result in motor limitations and hand dysfunction [23]. Hand movement therapy primarily targets the damage caused by stroke to the motor pathways by promoting regeneration and reconstruction of these pathways and improving the patient's hand muscle strength, coordination, and fine motor skills [24].

Hand movement therapy includes active and passive movement training, such as hand stretching, grip exercises, and finger range of motion training. These exercises can be selected and combined based on the patient's specific needs to achieve

the best rehabilitation results [25]. It is important to note that hand movement therapy is not suitable for all stroke patients, as different types and degrees of stroke can lead to various neurological damage and rehabilitation requirements [26]. Therefore, professional assessment and individualized rehabilitation plans need to be developed before conducting hand movement therapy, and the training process and intensity need to be quantified during the rehabilitation process.

### B. The basic Principles and Steps of AHP

Analytic Hierarchy Process (AHP) was first proposed by American mathematician and decision scientist Thomas L. Saaty [27]. It is a multi-criteria decision-making method used to determine the relative importance of various factors in complex problems [28]. Its basic principle is to decompose the decision-making problem into multiple levels, from overall to detail, to determine the weight relationships between factors at each level and obtain the decision-making result. The specific steps are as follows:

Step 1: Determine the decision-making objectives and criteria. The various indicators at each level are obtained through questionnaires and the Delphi method.

The initial design elements were obtained by collecting 89 valid questionnaires. Five experienced rehabilitation physicians were invited as experts to determine the criteria and program design elements at the guideline and program layers. The Delphi method used in this study followed the rule of majority decision, with the consensus reached by the experts as the screening result for each round. The objective is denoted as O, the guideline layer as G, and the program layer as P.

Step 2: Construct the judgment matrix A_X. The scale type is 1-9[29, 30]. Experts are invited to construct the judgment matrix for each level element based on the scale type to evaluate the relative importance of each criterion. X refers to the judgment objects for constructing the judgment matrix A, such as the criteria-level G judgment matrix A_G for this research case, which can be represented as follows in the paper translation.

$$A_G = \begin{bmatrix} a_{11}(G1/G1) & \cdots & a_{11}(G1/G5) \\ \vdots & \ddots & \vdots \\ a_{11}(G5/G1) & \cdots & a_{ij}(G5/G5) \end{bmatrix} \tag{1}$$

*i* represents the row number of the matrix, and *j* represents the column number of the matrix.

Step 3: Calculate the weight vector $W_i$.

$$W_i = \sum_{i=1}^{n}\left(\frac{a_{ij}}{\sum_{j=1}^{n} a_{ij}}\right) \tag{2}$$

*n* represents the order of the matrix.

Step 4: Consistency check.

$$CR = \frac{\lambda_{max}-n}{(n-1)RI} < 0.1 \tag{3}$$

Calculate the maximum eigenvalue for each matrix

$$\lambda_{max} = \sum_{i=1}^{n} \frac{A_X * Wi}{nWi} \tag{4}$$

The matrix is considered acceptable when the consistency ratio $CR$ is less than 0.1.

Step 5: Synthesize the total weight. The calculation method is the same as Formula (2).

In practical operations, the software can carry out the above calculation process. This study used a Matlab program for calculation.

### C. Application of AHP to Product Design

AHP is a commonly used multi-criteria decision-making analysis method widely applied in many fields. In product design, Yang et al. [31] used AHP to analyze various aspects of design proposals for bathroom products. By analyzing different demand factors and determining their weights, the best solution can be obtained, and a bathroom product that meets user needs and balances various requirements such as aesthetics, economy, and environmental protection can be designed. Liu et al. [32] studied user behaviour workflows using the Symbolic Analysis Pathway Allotment Diagram (SAPAD), analyzed weights using AHP, and finally proposed a modified design plan for an intelligent charging station that meets users' needs. Wang et al. [33] used AHP to rank the design elements by weight and importance. They combined them with a fuzzy model to complete the packaging design of Baihua Honey agricultural products in Weixi County, Lijiang.

Therefore, AHP is a fundamental decision-making method that can be used independently or in combination with other methods to play a role in product design. In product design, AHP helps designers determine the optimal design solution and the weight of design elements, providing strong support for the design process.

### III. MATH-HIERARCHICAL MODEL OF FINGER TRAINING NEEDS FOR YOUNG PEOPLE WITH STROKE

### A. Situational Analysis

Computers are standard office equipment, and when patients manipulate the keyboard, their fingers need to perform combined movements of extension and flexion and exert force to hit the keys. Patients with high muscle tension may have difficulty extending their fingers, while those with muscle weakness may have difficulty exerting force, resulting in difficulty pressing the keys. Inflexible fingers can also reduce critical efficiency and cause mistakes, ultimately affecting work quality. Therefore, this study proposes the analysis of design requirements for training devices targeting the scenario of pressing the keyboard, as shown in Fig. 1.

### B. Finger Posture and Muscle Analysis

According to the regularity of finger tapping on the keyboard, ignoring critical shortcut operations, only one finger taps the keyboard at a time. The fingers maintain a natural flexed state, with the tapping finger pressing down and the other fingers exerting an upward force to prevent mistakes. As shown in Fig. 2, two postures are maintained when tapping the keyboard, achieved through the cooperation of the finger extensor and flexor muscles. According to the anatomy of the fingers, the finger extensor muscles are located on the back of the fingers and mainly exert their effects through the extensor

tendon cap, which is composed of the central tendon bundle and the lateral bundle, acting on the finger bones and exerting an extension effect. The finger flexor muscles inside the fingers achieve finger flexion. The four fingers are usually powered by the palm-to-finger joints, except for the thumb, passing through the proximal phalanx, middle phalanx, and ending at the distal phalanx tubercle. The thumb taps the keyboard less frequently and relies on the wrist and palm bones to reach the thumb tubercle. The force direction of the fingertips is perpendicular to the operating plane and downwards.

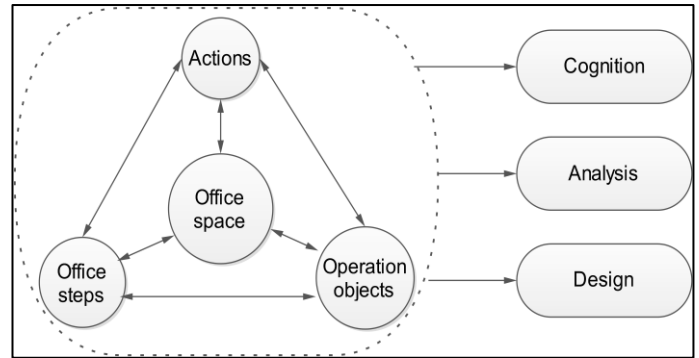

Fig. 1.  Situation analysis chart.

### C. AHP Hierarchical Model Construction

Based on the analysis of scenarios, finger posture, and muscle analysis, a questionnaire was designed for research, and primary indicators were obtained through cluster analysis. Rehabilitation therapists, equipment designers, and patients were invited to conduct indicator screening through the Delphi method. The indicator hierarchy was determined, and the final weights were calculated in Matlab according to the calculation principle of AHP in section 3.1, as shown in Fig. 3.

Fig. 2.  Finger posture and muscle action areas.

### IV. STROKE FINGER-TRAINING DEVICE DESIGN

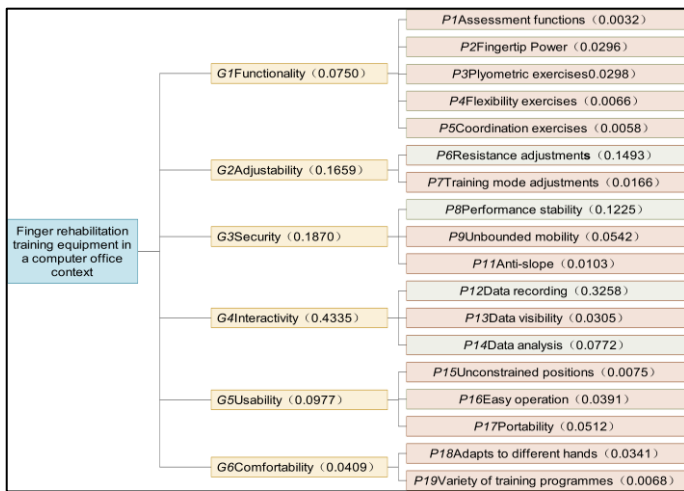
According to the current overall ranking of the hierarchy, the main design elements need to be considered comprehensively in the quasi-side layer's corresponding elements and scheme layers. Based on this weight, the scheme's design can be carried out.


Fig. 3.    Finger-training equipment design guidelines levels and weights.

## A.  Structural Design

Considering that finger force training requires a certain amount of resistance, and the force data and effective force frequency will serve as guiding parameters for finger muscle strength training, this study adopts PROE for modular design. The elements that make up the design of (a) keyboard structure is a pressing column, (b) spring limiting grooves, (c) enclosure, (d) spring, (e) retaining ring for the spring, (f) winding head, (g) coil, (h) force transducer, and (i) soldering point for the coil (see Fig. 4). The principle is to provide resistance to the small muscles of the hand through the compression of the spring by pressing the pressing column and to obtain finger force data through the force sensor. The electromagnetic induction principle of the current change produces the compelling force frequency.

Fig. 4.    Keypad construction parts, (a) pressing post, (b) spring limit slot, (c) housing, (d) spring, (e) spring retaining spacer, (f) winding post, (g) coil, (h) force sensor, (i) coil terminal.

Different springs can be replaced individually according to the muscle strength ability of different patients, gradually increasing or decreasing the spring elasticity to adapt to the needs of patients. The pressing column (a) and the spring limit threads connect the column slot. The bottom of the pressing

column has magnetism. When the pressing column is pressed down, the spring contracts and the magnetic field lines of the magnet below the pressing column cut the coil, thereby affecting the direction of the coil current. The frequency of force is obtained by measuring the current's direction and number of changes. The spring and spring fixing gasket are fixedly connected to limit the spring from running and to facilitate the upper surface of the force sensor to contact fully, obtaining more accurate force measurement. Each keyboard structural component is connected to the controller and power supply through the wiring terminal, and the training results are displayed on the display screen through the data processor. The housing of the keyboard structural component allows the pressing column to pass through first and then fixes the spring limit slot with the pressing column bolt. It is fixed to the bottom surface of the keyboard by a buckle or adhesive, playing a role in dust-proofing and protection of the internal structure.

## B.  Training System Design

The training system consists of two parts: training programs and training operations. The relevant modules and logical relationships are shown in Fig. 5. Patients must first complete an assessment to determine whether they can actively move. According to the muscle strength grading standards established by the American Society of Rehabilitation Medicine (ASRM), the difference between grade 0 (no muscle activity) and grade 1 (slight muscle contraction but unable to move the joint) is muscle contraction. Therefore, a grade of 1 or higher indicates active movement.

During the test to determine whether the patient can actively move, data is collected when the patient presses the keyboard. The intelligent algorithm calculates the corresponding training program output and evaluation result based on the collected data. The initial data is used to assess whether the patient has muscle strength. Data analysis displays instructions and evaluation results on the screen to guide the patient in operating the keyboard. The intelligent algorithm is further optimized through repeated training and data accumulation iterations.

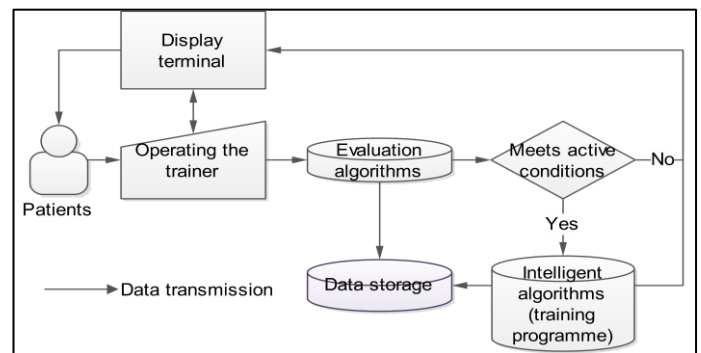

Fig. 5.    Finger training system.

## C.  Training Methods

This training device is designed for finger strength and fingertip coordination training in a computer office setting. Compared to existing finger strength training devices, the training method in this study explicitly targets the finger force

direction and coordination required in office scenarios. Previous research has shown evidence that standard keyboards can improve the fine motor skills of the fingers when typing [34, 35] and their coordination [36]. This training device adjusts the critical resistance and provides interactive feedback to facilitate finger movements. It allows patients to control their finger force, including the appropriate force activation of the keys, control of force direction, force magnitude, and speed. During the training process, patients are expected to exert force vertically on the keyboard surface to activate the muscles in their fingertips, thus achieving better rehabilitation outcomes.

The overall solution consists of a keyboard structure and display screen. The keyboard structure simulates the layout of a keyboard and can be configured for single or double-handed operation, allowing for single and double-handed training. Depending on the patient's level of disability, either a single or double keyboard may be used. The single keyboard primarily focuses on training individual letters, emphasizing muscle strength training. In contrast, the double keyboard focuses on meaningful word or sentence combinations, emphasizing finger coordination training. Since both keyboards are interchangeable, the program must be configured to recognize which hand, left or right, is associated with the selected keyboard. The keyboard and screen interface uses a standard USB interface. The display screen can be a regular monitor or touchscreen, as shown in Fig. 6.

Fig. 6. One-handed training configuration illustration.

During training, posture is essential. Patients are instructed to adjust to a comfortable sitting position and relax their hand posture. Fingers should be placed on the training keyboard, and precise finger movement is achieved by tapping the keyboard with fingertips or finger pads. During single-handed training, the system configures the corresponding keyboard letters for the affected hand based on on-screen prompts. The typical keyboard letters and positions are displayed on the screen, and the patient operates the keyboard after observing the prompts.

Data is recorded on the finger force and the frequency of force variation on a single key (quantified by the number of electrical current changes during crucial press). During double-handed training, the double keyboard is selected, and the screen interface is chosen for the corresponding hand's keyboard to avoid incorrect keyboard settings. The pre-set words, phrases, or sentences are then used for keyboard operation, with the completion time recorded as a basis for later evaluation.

## V. TESTS AND RESULTS

A prototype device and system have been developed, as shown in Fig. 7, to validate finger muscle strength and coordination. In addition to the designed structure of this research project, the hardware includes the FSR402 thin film pressure sensor and pressure sensing module. The upper computer is compiled using VC++ 6.0.

A total of 30 participants were recruited for this study, with ages ranging from 22 to 40 years old. All other participants were in good physical health except for one stroke patient. Due to the difficulty in finding stroke patients as participants, this study did not compare stroke patients with healthy participants. Instead, the study assumed that the device would have training effects on healthy individuals and be effective for stroke patients.

The participants were divided into two groups: Group 1 consisted of 15 participants who underwent single-handed training and testing (using their non-dominant hand). In contrast, Group 2 consisted of 15 participants who underwent dual-handed training and testing.

There was no separate control group in this study. The initial test values for each group were used as the control, and the program's feasibility was analyzed by comparing the data before and after training. For single-handed training, the letters "A, S, D, F" were pressed 20 times; for double-handed training, the phrase "WOAIWODEZUGUOZ" was pressed 20 times. Muscle strength increase was measured for the single-handed training, and hand coordination was measured for the double-handed training. Since data was collected in real-time, the final data was determined based on the last test results obtained for each finger after training completion. The test results are presented in Table I, Fig. 8, and Fig. 9.

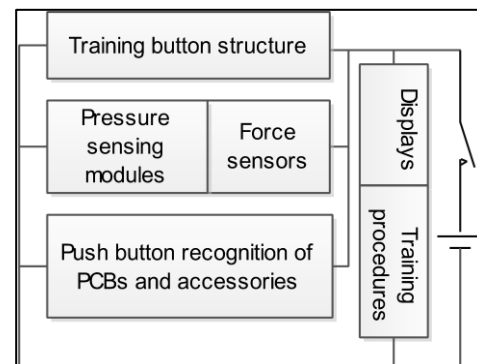

Fig. 7. Prototype schematic diagram.
Fig. 8. Comparison of fingertip strength before and after one hand training.

TABLE I. ONE-HANDED TRAINING OF MUSCLE STRENGTH CHANGES AND FREQUENCY OF FORCE CHANGES

| CATEGORIES | | MUSCLE POWER (N) | | | | FREQUENCIES |
|---|---|---|---|---|---|---|
| | | Min | Max | Mean | SD | Mean |
| PRE-TRAINING | Pinky Finger | 0.63 | 0.77 | 0.70 | 0.04 | 4.33 |
| | Ring Finger | 0.68 | 0.88 | 0.76 | 0.06 | 3.87 |
| | Middle finger | 0.71 | 0.83 | 0.78 | 0.04 | 2.73 |
| | Index finger | 0.68 | 0.91 | 0.80 | 0.07 | 2.60 |
| POST-TRAINING | Pinky Finger | 1.04 | 1.43 | 1.27 | 0.11 | 1.67 |
| | Ring Finger | 1.02 | 1.42 | 1.27 | 0.12 | 1.07 |
| | Middle finger | 1.21 | 1.52 | 1.38 | 0.10 | 1.07 |
| | Index finger | 1.26 | 1.52 | 1.37 | 0.07 | 1.00 |

## VI. DISCUSSION

Based on the test data, Group 1 subjects showed varying degrees of increases in finger muscle strength after training, as shown in Fig. 8 and Table I: the force of the little finger increased from 0.70±0.04 (N) to 1.27±0.01 (N), the force of the ring finger increased from 0.76±0.06 (N) to 1.27±0.12 (N), the force of the middle finger increased from 0.78±0.04 (N) to 1.38±0.10 (N), and the force of the index finger increased from 0.80±0.07 (N) to 1.37±0.07 (N); the frequency of force change

decreased, and the mean range of changes before training of [2.6, 4.33] changed to [1, 1.67], indicating more stable force production. In Group 2, the training completion time decreased from 35.3±4.25 (S) before to 23.7±5.32 (S) after training, indicating improved finger coordination. The experimental results indicate that the stroke finger training device based on AHP can effectively improve stroke patients' recovery of finger function and coordination ability. During the training process, the finger muscle strength of the subjects was significantly improved, and the stability of force production and coordination ability was significantly improved.

The objective of this study is to increase finger muscle strength and control in stroke patients through the use of an active training device. However, there are certain limitations for patients using this device. Firstly, patients need to be able to extend their fingers and push individual fingers downward. Secondly, they need to increase the strength of their finger flexor muscles.

In this experiment, muscle strength testing is measured by the force exerted when pressing keyboard keys with the fingers. Based on general knowledge, humans tend to exert the minimum or moderate force necessary to achieve the desired movement. However, stroke patients with weaker finger muscles need to increase their finger muscle strength and improve their control over movements. Compared to the average peak force of 0.86N generated by healthy individuals pressing standard spring-column keyboards [37], this training device can generate a range of crucial contact forces, including 0.86N. Through training, patients' finger muscle strength

gradually increases. Healthy individuals typically exert the minimum force necessary to control their movements while pressing keys. However, to exercise the finger muscles of stroke patients, the spring resistance of the training device needs to be adjusted to accommodate the requirements of finger muscle training and enhance muscle strength.

However, increasing finger muscle strength training does not mean continuously increasing muscle strength. The goal is to exercise finger control so patients can perform finger-pressing operations required in office tasks. Therefore, this device adjusts the spring resistance for muscle strength training and protection. Whether further muscle strength training is needed depends on the muscle strength assessment conducted by the rehabilitation therapist.

This approach uses changes in muscle strength as an indicator, as individual muscle strength values do not fully represent the practical significance of rehabilitation muscle strength. The change in muscle strength value serves only as a reference for whether muscle strength gradually increases, combined with a reduction in task completion time to demonstrate the improvement in finger control ability after muscle strength training. The change in muscle strength value is not optimal for rehabilitation indicators, so this study did not consider the resolution of force change sensitivity. Choosing 20 training and testing key presses is not a standard for rehabilitation training frequency. This number is set to allow participants to become accustomed to the operation and reduce possible testing errors. The frequency should be set in actual training based on the patient's willingness and finger muscle condition.

In summary, this study aims to increase finger muscle strength and control in stroke patients through an active training device and to evaluate the training effects through changes in muscle strength and task completion time.

Compared with traditional devices [11-13], the main advantage of this rehabilitation training device is that it meets the exercise needs of finger operation on a computer through the keyboard structure in combination with a display screen and corresponding program settings, with active training being the focus. The device has several features: (1) it allows for free selection of single or double-handed training, and difficulty can be gradually increased based on the patient's finger movement deficiencies to improve both muscle strength and flexibility; (2) it can collect data in real-time, facilitating adjustments to the training program and evaluation of rehabilitation progress; (3) it has wide adaptability and can accommodate different finger sizes, without restrictions on the middle or distal finger joints, allowing patients more freedom to adjust their own posture; (4) costs are reduced, as the device can be modified based on existing keyboards, being highly feasible, and the keyboard operation is a familiar operation, which is easy for the patient to understand and learn, making it easy to promote; (5) it can be used in both hospital and home settings, without being limited by the application environment, and by using the AHP method to evaluate and rank the importance of each design element, overlooked design points can be discovered. The experimental results show that this finger training device significantly improves the recovery of finger function in stroke

patients and has advantages such as ease of use and practicality.

The research method of this article is based on the AHP method, which evaluates and ranks the importance of each design element to make the device design more reasonable and adequate. This method can provide a new idea and method for designing other similar rehabilitation devices to improve their application effectiveness and practicality.

Fig. 9.    Comparison of the time taken to complete a session before and after two-handed training.

## VII. CONCLUSION

Through the research in this paper, we have successfully designed a stroke finger training device based on AHP. It can meet the exercise needs of finger operation on a computer, with active training being the focus. By using the AHP method to evaluate and rank the importance of each design element, overlooked design points can be discovered. The experimental results show that this finger training device significantly improves the recovery of finger function in participants and has advantages such as ease of use and practicality.

However, some things could be improved in this study. For example, the sample collection for the experiment mainly consisted of healthy subjects. In future clinical studies, it would be necessary to include more stroke patients as subjects to improve the reliability and persuasiveness of the experimental data. Additionally, the control module of the device can be further improved to enhance its intelligence and user experience. Future research can further explore this training device's application scope and effectiveness and combine it with other rehabilitation treatments to improve the rehabilitation outcomes for stroke patients. Furthermore, the design and functionality of the device can be further improved and refined to meet the needs of patients with different rehabilitation requirements.

*Abstract*—In modern urban transportation systems, the efficient management of traffic intersections is crucial to ensure smooth traffic flow and reduce congestion. Distributed-control intersection networks, where control decisions are made collaboratively by multiple entities, offer promising solutions. However, maintaining the security and the integrity of shared data among these entities poses significant challenges, including the risk of data tampering and unauthorized modifications. This paper proposes a novel approach that leverages blockchain technology to address these integrity concerns based on intelligent agents. By utilizing the decentralized and transparent nature of blockchain, our method ensures the authenticity and immutability of shared data within the distributed-control intersection network. The paper presents a detailed architecture, highlighting the integration of blockchain into the existing infrastructure, and discusses the benefits of this approach in enhancing data integrity, trust, and overall system reliability. Through a case study and simulation results, the proposed approach demonstrates its effectiveness in maintaining the integrity of shared data, thereby contributing to the advancement of secure and efficient traffic management systems.

*Keywords*—*Security; data integrity; blockchain; distributed system; congestion; intelligent agent*

## I. INTRODUCTION

In the face of rapidly expanding urban populations, the efficient management of traffic intersections has emerged as a critical aspect of modern urban transportation systems [1]. Traditional traffic control mechanisms, reliant on centralized decision-making, struggle to accommodate the dynamic demands of increasingly congested road networks. This has spurred the development of distributed-control intersection networks, which offer a more adaptive and responsive approach to traffic management. In these networks, control decisions are distributed across multiple entities, allowing real-time adjustments based on traffic conditions, thereby improving overall traffic flow and reducing congestion [2].

The advantages of distributed-control intersection networks are evident, but they bring forth new challenges, particularly concerning the integrity of shared data among the participating entities. The accuracy and authenticity of data exchanged within these networks are pivotal for their successful operation. Compromised or tampered data can lead to erroneous control decisions, potentially resulting in accidents, increased congestion, and even system-wide failures [3]. Hence, the establishment of a robust method to ensure data integrity is crucial.

Blockchain technology continues to evolve, with new consensus mechanisms, scalability solutions, and use cases being developed. Understanding these fundamentals is crucial for grasping the potential impact of blockchain on various industries [4].

This paper introduces a novel approach that leverages blockchain technology to address the integrity concerns in distributed-control intersection networks. Blockchain has emerged as a powerful tool for addressing data integrity concerns in distributed and decentralized systems. Initially introduced as the foundational technology underpinning cryptocurrencies like Bitcoin [5], blockchain has evolved to demonstrate its applicability beyond financial use cases. Its core features, including decentralized data management, immutability, and cryptographic security, make it an ideal candidate for ensuring data integrity in complex systems, such as distributed-control intersection networks.

By presenting a comprehensive analysis of the proposed methodology, backed by a practical case study and simulation results, this paper aims to contribute to the development of robust and trustworthy distributed-control intersection networks that can effectively address the challenges of modern urban transportation. The organization of this paper is as stated below: Section II outlines the related works. The various blockchain fundamentals are discussed in Section III. Section IV describes our proposed methodology. Section V includes the simulation results and discussion. Lastly, a conclusion is outlined in Section VI.

## II. RELATED WORKS

In recent years, the integration of blockchain technology into various domains has garnered significant attention due to

its potential to enhance security, and decentralization. In the context of distributed-control intersection networks, where efficient traffic management is crucial, the utilization of blockchain for ensuring the integrity of shared data has emerged as a promising avenue. Several related works have explored similar themes and provided insights into the application of blockchain in distributed-control systems and intersection networks.

Traditional static control systems may fail to handle emergency situations due to traffic jams. As a solution, Wireless Sensor Networks (WSNs) have gained attention for their ability to detect traffic and mitigate road congestion. K. Nellore and G. P. Hancke [6] have extensively explored traffic management systems that employ WSNs to prevent congestion, prioritize emergency vehicles, and reduce the Average Waiting Time (AWT) at intersections. They offered a comprehensive survey of current urban traffic management strategies, particularly those focused on priority-based signaling, congestion reduction, and improving vehicle AWT. Z. Yang et al. [7] introduced a promising approach to address trust issues in vehicular networks through the use of blockchain and a decentralized trust management system. They introduced a solution to enhance the trustworthiness of messages exchanged among vehicles in vehicular networks, considering the challenging non-trusted environment. A. Daeichian and A. Haghani [8] employed a combination of fuzzy Q-learning (QL) and agent technologies to create a traffic light control framework. Each individual agent engages with neighboring agents, receiving rewards for their decisions. The control choices are determined based on the input of vehicle numbers to schedule the duration of the green traffic light phase. The primary objective is to optimize the reward and minimize the average delay time. A. Ikidid et al. [9] presented a novel approach to address traffic management challenges in Moroccan cities, with a focus on promoting emergency vehicle access and encouraging collective transportation modes. The proposed control system operates at signalized intersections with priority links in urban environments. This system combines multi-agent technology and fuzzy logic to effectively regulate traffic flows.

On the other hand, the significance of data integrity in distributed-control systems has prompted research into various methodologies. T. Rauter [10] emphasized the significance of maintaining the integrity of the entire distributed control system. He categorized specific properties that enable the verification and proof of integrity for various subsystems within the system. Q. Kong et al. [11] introduced a novel, efficient, and location privacy-preserving data sharing scheme with collusion resistance within the Internet of Vehicles (IoV) context. Furthermore, blockchain's decentralized nature has been leveraged for secure data sharing across multiple parties. G. P. Joshi et al. [12] proposed a blockchain-based method for secure and privacy-preserving data sharing in vehicular networks. Although not specific to intersection networks, this work highlights the potential of blockchain in ensuring data integrity and security in vehicular environments. J. Cui et al. [13] proposed an innovative solution utilizing consortium blockchain technology to enable traceable and anonymous vehicle-to-vehicle (V2V) data sharing. It addresses critical issues in current vehicular networks, including data privacy, security, and trust, while also capitalizing on the advantages of emerging technologies such as blockchain and 5G. S. Kudva et al. [14] proposed an innovative approach to selecting miner nodes in vehicular blockchain applications. The proposed method, called the "Proof of Driving" protocol, associates "driving coins" with vehicle features, such as distance traveled, to enhance the randomness in selecting miner nodes. In [15], S. A. Bagloee et al. discussed how a blockchain-based platform can facilitate the deployment of tradable mobility permits (TMP), along with related benefits like dynamic toll pricing, emergency vehicle priority, heavy truck platooning, and connected vehicles. I. M. Varma and N. Kumar introduced the convergence of Internet of Vehicles (IoV) and Software-Defined Networking (SDN), enhanced by blockchain technology, that offers a promising solution to address the complex challenges of vehicular networks, providing improved transportation, security, and network management while also presenting opportunities for further research and development [16]. A set of approaches and protocols have been proposed to determine the feasibility of using blockchain for traffic data security [17] and [18].

While existing related works provide valuable insights into blockchain's potential in distributed-control intersection networks, certain challenges remain unexplored. Integrity of shared data is a crucial factor in real-time traffic management scenarios. Additionally, the interoperability between blockchain and existing traffic infrastructure requires further investigation. The research landscape regarding blockchain's role in ensuring the integrity of shared data in distributed-control intersection networks is steadily growing. By building upon the foundation laid by previous related works, this study aims to contribute to the understanding of how blockchain can effectively enhance data integrity and efficiency in traffic management systems.

## III. BLOCKCHAIN FUNDAMENTALS

Blockchain is a revolutionary technology that serves as the foundation for cryptocurrencies like Bitcoin and has far-reaching applications beyond digital currencies. At its core, blockchain is a decentralized and distributed digital ledger that records transactions in a secure, transparent, and immutable manner. Fig. 1 illustrates the benefits that arise from the adoption of blockchain.

Fig. 1. The benefits of using blockchain.

Blockchain technology has several features that make it highly suitable for ensuring data integrity in a distributed-control intersection network. Here are some key features:

- Decentralization: Blockchain operates on a decentralized network of nodes, where each node stores a copy of the entire blockchain. In a distributed-control intersection network, this decentralization ensures that no single entity has control over the entire system. This feature reduces the risk of a single point of failure and enhances the network's resilience.

- Immutability: Once data is recorded on the blockchain, it is extremely difficult to alter or delete [19]. This immutability ensures that the historical data related to traffic control decisions and intersection activities remain tamper-proof, providing a reliable audit trail.

- Transparency: All participants in the network can view the data recorded on the blockchain [20]. In the context of a distributed-control intersection network, this transparency ensures that all stakeholders, including traffic authorities, city planners, and even the public, can access relevant data, promoting trust and accountability.

- Consensus Mechanisms: Blockchain networks use consensus mechanisms to validate transactions or data entries. This ensures that all nodes in the network agree on the state of the blockchain. Consensus mechanisms such as Proof of Work (PoW) [21] or Proof of Stake (PoS) [22] can be used to ensure that intersection control decisions are agreed upon by the network, minimizing the risk of unauthorized changes.

- Data Integrity: Blockchain can be used to create a secure and tamper-evident record of intersection control decisions, traffic data, and other relevant information. This ensures that the data remains consistent and reliable [23], which is crucial for maintaining the efficiency and safety of the intersection network.

- Smart Contracts: Smart contracts are self-executing contracts with the terms directly written into code [24]. In a distributed-control intersection network, smart contracts could automate and enforce specific rules and conditions, such as prioritizing emergency vehicles or optimizing traffic flow based on predefined criteria.

- Security: Blockchain networks use cryptographic techniques to secure data [25]. This enhances the security of the intersection network, protecting it from unauthorized access, data breaches, and cyberattacks.

- Auditability: Every transaction or data entry on the blockchain is traceable. This auditability ensures that all changes to the intersection network's data can be tracked back to their source, providing accountability and facilitating investigations when necessary.

By leveraging these features, a blockchain-based approach can enhance the integrity of shared data in a distributed-control intersection network, reducing the risk of data manipulation, promoting trust among network participants, and contributing to more secure and efficient traffic management systems.

## IV. PROPOSED METHODOLOGY

### A. Problem Modeling

A distributed control system (DCS) for light control intersections is a sophisticated networked system designed to manage traffic flow and optimize vehicle and pedestrian movement at intersections. It utilizes advanced technologies and algorithms to efficiently control traffic signals, ensure safety, and minimize congestion. An intersection network consists of multiple intersections that are strategically connected to form a network. These intersections can vary in size and complexity, ranging from simple crossroads to multi-lane junctions. Fig. 2 shows an overview of an intersection network with nine intersections, each intersection has four two-way roads.

The DCS is functionally and spatially distributed. Every intersection is viewed as a network sub-section and controlled by a community named Intersection Control Group (ICG) and consists of a group of autonomous, cooperative, and intelligent agents. Each community acts locally according to its data and communicates with others to coordinate actions. This system promotes flexibility, resilience and efficiency by enabling individual components to contribute to an overall solution without depending on a single central authority. Communication in these distributed systems involves the exchange of information between different interconnected autonomous communities. These communities often communicate via local or wide-area networks, which introduce a security challenge.

The control of each signalized intersection is performed by an ICG, which defines the signal plan. This plan is designed to optimize phase layout while adapting to the constantly changing intersection environment, with control of the entire intersection network being fully distributed and achieved through the collective capacity, communication, and coordination of the ICGs.

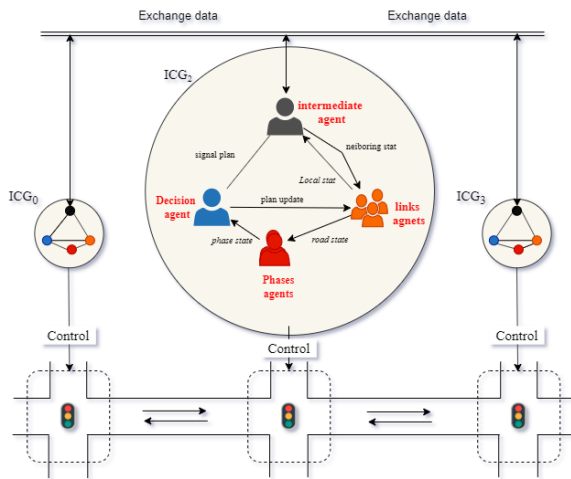
Fig. 2. Signaled intersection network.


Fig. 3. Overview of distributed-control intersection networks.

Fig. 3 presents an overview of distributed Urban Traffic management System. It generally involves of a set of control groups, each control group consists of:

- Links agents: An agent represents each link, a "link" refers to a specific segment of road that connects two distinct points. An agent link is assigned to supervise each incoming link, with the aim of consistently and promptly monitoring the link state. These specific agents have a limited, local perspective of the environment. In order to maintain system simplicity, no agent is granted a comprehensive overview of the entire network, thereby reducing overall complexity. The goal of this agent is to provide the link state presented by the concentration D. The concentration of a particular road at a given point is the number N of vehicles present between p and p+Δp at an instant t, relative to the length of the section of lane (Eq. 1). The concept of vehicular concentration refers to the density of vehicles occupying a specific section of a road at a given point in time.

$$D_{\Delta t}(p) = D(p, t \rightarrow t + \Delta t) = \frac{V}{\Delta t} \qquad (1)$$

- Phase agents: Two distinct agents are employed to oversee phases within an intersection. The Activated Phase Agent handles the active phase, while the Inactive Phase Agent manages phases that are not currently active. The goal of this agent is to provide the phase state.

- Decision agent: The decision agent is the central element of the system architecture, responsible for updating the signal plan according to changes in the environment. This decision-making process is executed collaboratively to prevent isolated optimizations.

- Intermediate agent: The role of the intermediate agent is to establish coordination with the neighboring control group. It acts as a communication interface agent for the intersection control group and mediating external communications. This agent facilitates the exchange of

incoming link states with intermediate agents in neighboring control groups.

Ensuring the integrity of communications poses significant challenges in this type of system. As data passes through different nodes and networks to reach the control group, it is susceptible to corruption, interception and unauthorized access

### B. Overview of our Proposed System Model

We have seen in our earlier discussions the necessity to apply a new approach that can enhance the integrity of shared data in a distributed-control intersection network, reducing the risk of data manipulation, promoting trust among network participants, and contributing to more secure and efficient traffic management systems. A decentralized network in our model mainly includes several intersections that communicate with each other by sharing information of link state. Hence, design goal of our work is to make the public blockchain usable in the distributed-control intersection networks by storing the local link state of each intersection, which will guarantee the integrity of the data exchanged between the different intersections. Fig. 4 illustrates how different components of our proposal are connected. Detailed descriptions of the proposed system are given in the following:

- Creating blocks: In our model, each intersection system will have an associated blockchain database. All the records of link states are considered as transactions that are validated by the ICG and finally added into immutable blocks of the blockchain. The block contains the link state data, the merkle root, previous block hash, block size and timestamp. Timestamps in the blockchain ensure a chronological record of data.

- Calculating signals plan: Each ICG refers to the neighboring ICG blockchain in order to retrieve their link states that permit to calculate the signals plan of the current intersection.

- ICG: To maintain data integrity of shared link state, each ICG calculates link state then stores it in a new block within a specific blockchain related to the intersection. In case of an intersection system failure, the ICG can then send a data query to ask for historical link state, in a particular moment, from the neighboring ICG's Blockchain.

- ICG Blockchain: each ICG Blockchain maintains the blocks corresponding to the different calculated link states. The blockchain records the history of intersection link states, therefore the use of the blockchain is essential in the event of an intersection system failure, so that the new signals plan of the intersection can be calculated based on the link states previously stored in the blockchain, thereby streamlining the decision-making process in the distributed-control system.

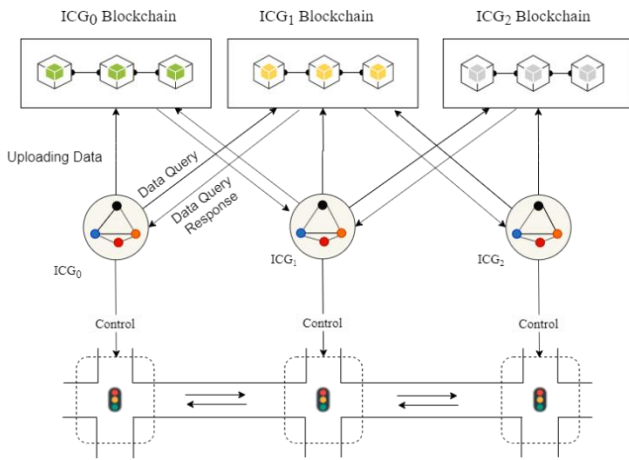
For the intersections, each generation of a link state is treated as a transaction on the blockchain. Every link state data is hashed and added to the blockchain, creating an immutable record. Hashes serve as a fingerprint of the data, making it easy to detect any modifications.


Fig. 4. Overview of blockchain based distributed-control intersection networks.

## C. Data Integrity Auditing for Distributed-Control Intersection Networks

Shared data integrity auditing for distributed-control intersection networks using blockchain is a concept that applies the principles of blockchain technology to ensure the accuracy and reliability of data in intersection networks that employ a distributed control approach. In such networks, multiple intersections or traffic management components collaborate to optimize traffic flow and enhance transportation efficiency. Blockchain can play a role in storing the exchanged data and maintaining its integrity among these distributed components.

Auditors (ICGs) can verify the integrity of data by comparing the expected data with the historical records on the blockchain. Automated audits can be performed to constantly monitor and validate data against predefined criteria. All ICGs can independently verify the accuracy of data, promoting trust and transparency within the intersection network.

The provided pseudo-code outlines an algorithm for conducting data integrity auditing according to our proposal. This process ensures the accuracy and consistency of data stored in the blockchain, mitigating potential errors or tampering.

These are the steps of the algorithm:

- The algorithm begins by checking if the target block index is within valid bounds. If not, it returns an error message indicating an invalid index.

- After that, it retrieves the target block from the blockchain using the provided index.

- Then, it calculates the hash of the expected data and compares it with the stored hash of the link state data within the target block. If they do not match, it concludes that the data integrity audit has failed.

- Next, the algorithm iterates through the blockchain starting from the block after the target block. It retrieves each block and its corresponding previous block to verify the chain's integrity. If the PreviousHash of a block does not match the BlockHash of its previous

block, the algorithm concludes that the blockchain integrity has been compromised.

- For each block (except the target block), it calculates the hash of the link state data and compares it to the stored hash in the block. If they do not match, the data integrity audit fails.

- If all checks pass, the data integrity audit is successful.

| Algorithm: Data Integrity Auditing |
|---|
| **Input**: - Blockchain: The blockchain to be audited<br> - Target_Block_Index: The index of the Target_Block to audit<br> - Expected_Data: The Expected_Data for the Target_Block |
| **Output**: - Audit_Result: Whether the data integrity audit passed or failed |
| **1: Procedure:** PerformDataIntegrityAudit(Blockchain, Target_Block_Index, Expected_Data):<br>**2:** **If** Target_Block_Index < 0 or Target_Block_Index >= Length(Blockchain):<br>**3:** **Return** "*Invalid Target_Block_Index*"<br>**4:** **End If**<br>**5:**<br>**6:** Target_Block = GetBlockByIndex(Blockchain, Target_Block_Index)<br>**7:**<br>**8:** **If** HashFunction(Expected_Data) != Target_Block.Link_state Data Hash:<br>**9:** **Return** "*Data integrity audit failed*"<br>**10:** **End If**<br>**11:**<br>**12:** **For each** block in Blockchain from Target_Block_Index + 1 to last block:<br>**13:** Previous Block = GetBlockByIndex(Blockchain, block.Index - 1)<br>**14:** **If** block.PreviousHash != Previous Block.BlockHash:<br>**15:** Return "*Blockchain integrity compromised*"<br>**16:** **End If**<br>**17:**<br>**18:** **If** block.Index == Target_Block_Index:<br>**19:** ***Continue***<br>**20:** **End If**<br>**21:**<br>**22:** **If** HashFunction(block.Link_state Data) != block.Link_state Data Hash:<br>**23:** Return "*Data integrity audit failed*"<br>**24:** **End If**<br>**25:** **End For**<br>**26:** Return "*Data integrity audit passed*" |
| **27: Main:**<br>**28:** Read the Blockchain<br>**29:** Read Target_Block_Index<br>**30:** Read Expected_Data<br>**31:** *Audit_Result* = PerformDataIntegrityAudit(Blockchain, Target_Block_Index, Expected_Data)<br>**32:** Print *Audit_Result*<br>**33: End Main** |

This algorithm ensures data integrity auditing within a blockchain by verifying the consistency of data in the target block and checking the integrity of the entire blockchain. If any discrepancies are found during this audit process, it indicates potential errors or tampering within the blockchain, thus helping to maintain the reliability and trustworthiness of the data stored in the system.

Implementing data integrity auditing for distributed-control intersection networks using blockchain can offer several benefits:

- Data Consistency: Blockchain's immutability ensures that data remains consistent and trustworthy across all components.

- Enhanced Security: Blockchain's cryptographic mechanisms make data tampering extremely difficult.

- Interoperability: Different components can work together while relying on a common source of truth provided by the blockchain.

- Real-time Auditing: Auditing processes can be automated and performed in real-time, minimizing the risk of errors going undetected.

## V. SIMULATION RESULTS AND DISCUSSION

In this section, we provide a detailed overview of the implementation of our proposed blockchain-based method for ensuring the integrity of shared data in a distributed-control intersection network. The implementation was carried out using a combination of software tools, programming languages, and blockchain frameworks.

As shown in Fig. 5, our implementation follows a layered architecture, comprising the following components:

*1) Simulation of urban traffic:* To simulate various traffic scenarios we use AnyLogic software [26]. AnyLogic is a java-based simulation software used for modeling and analyzing complex systems, including urban traffic.

*2) Distributed control system:* To develop the distributed control system we use agent-based modeling feature in AnyLogic, which allows to define the agent types, properties, and behaviors.

*3) Blockchain network:* We utilized the Ethereum blockchain due to its established infrastructure and support for smart contracts. The blockchain network stores transaction data, including link state, network meta-data, and validation mechanisms.

*4) Results extraction:* The results extraction phase involves collecting data generated from simulation runs. This data is captured at designated points within the model. To evaluate our approach (method-2), we will compare it with a distributed control system without blockchain (method-1).

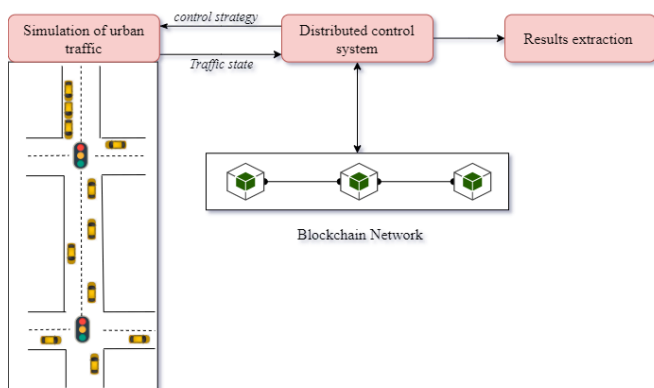

Fig. 5. Process simulation.

We will use four scenarios that collectively help assess the blockchain-based method's effectiveness across varying levels of communication network state and in the face of system failure.

- Scenario 1: Low Network Communication state: In this scenario, the network experiences a situation of low communication bandwidth and high latency. The data exchanges between IGCs, agents, and the blockchain nodes are slow and sporadic. Transactions take longer to propagate through the network, causing delays in data integrity verification and confirmation. This scenario tests the resilience of the blockchain-based method under adverse network conditions and assesses its ability to process and verify transactions with limited bandwidth and high latency. Without a blockchain, a low network communication state might lead to difficulties in transaction verification and data sharing.

- Scenario 2: Medium Network Communication state: Under medium network communication conditions, the network is relatively stable with moderate communication bandwidth and latency. Data exchanges occur at a reasonable pace, allowing transactions to propagate and confirm without significant delays. This scenario aims to evaluate the blockchain's performance under typical operational network conditions, assessing whether the method can efficiently maintain data integrity and transaction consistency. Without blockchain, medium network communication might be more manageable than in a low state, but challenges like data consistency and reliance on intermediaries for verification could arise.

- Scenario 3: High Network Communication state: In a high network communication scenario, the network experiences heavy congestion and high communication demands. Data exchanges between ICG, agents, and blockchain nodes are frequent and rapid. This situation challenges the system's capacity to handle a large volume of transactions without compromising its integrity. The blockchain's ability to handle high transaction throughput and maintain data consistency is assessed, along with its ability to handle potential network bottlenecks. In a high network communication state, non-blockchain systems may struggle to maintain data consistency and handle the influx of real-time transactions.

- Scenario 4: System Failure: In the event of network communication failure, a blockchain system can continue to function locally on ICG. Once communication is restored, the system can automatically synchronize and reconcile the distributed ledger, ensuring data integrity and minimizing the risk of data loss. Network communication failure in a non-blockchain system could lead to data discrepancies, conflicts, and potentially control system failure.

By simulating and analyzing these scenarios involving different network communication state (see Fig. 6) we can gain a comprehensive understanding of how the blockchain-based method performs under various levels of network stability. In summary, blockchain technology offers advantages like decentralization and stability in various network communication scenarios. However, its effectiveness depends on factors such as the specific use case, network

conditions, and the degree of decentralization required. Non-blockchain systems might suffice for certain situations.

Fig. 6.   Average signals plan calculated time.

In the following section, we explore a series of diverse scenarios that cover different urban traffic contexts and situations. These scenarios have been carefully selected to provide relevant examples of concrete traffic situations.

Scenario 1: Low Traffic Condition: In this scenario, the intersection network experiences a period of low traffic. The number of vehicles approaching the intersection is minimal, resulting in infrequent data updates and interactions.

Scenario 2: Medium Traffic Condition: In a medium traffic scenario, the intersection network encounters a moderate volume of vehicles during peak hours.

Scenario 3: High Traffic Condition: During high traffic conditions, the intersection network experiences heavy congestion with a significant influx of vehicles from various directions. This scenario pushes the limits of the system's capacity.

By simulating and analyzing these scenarios, we can gain insights into the system's strengths, weaknesses, and areas for improvement, thereby refining the control of distributed intersection network under a range of conditions.

Fig. 7 presents the average intersection throughput in PVU (Private Vehicle Unit) per hour. The graph shows that the effectiveness of blockchain in ameliorating average intersection throughput depends on congestion levels. While blockchain may not have a direct impact on the low congestion level, it could enhance the average intersection throughput in the medium and high traffic conditions by improving data access speed, collaboration, and coordination among various intersections, potentially contributing to more efficient traffic management and better throughput over time.

As shown in Fig. 8 the response latency of both methods follows a linear trend as the level of congestion increases. The proposed system achieves a latency between 1.22 and 1.83, while the traditional system achieves a latency between 1.32 and 1.95.

Fig. 7.   Average intersection throughput.

Fig. 8.   Average response latency.

Table I shows a comparison of security features between centralized, decentralized and blockchain-based systems:

TABLE I.      SECURITY FEATURES COMPARISON BETWEEN CENTRALIZED, DECENTRALIZED AND BLOCKCHAIN-BASED SYSTEM

|  | Centralized-based system | Decentralized-based system | Blockchain-based system |
|---|---|---|---|
| Decentralization | - | ++ | ++ |
| Traceability | - | - | ++ |
| Data integrity | - | + | ++ |
| Data availability | - | + | ++ |
| Verifiability and auditability | - | + | ++ |
| Immutability | - | + | ++ |
| Transparency | - | + | ++ |

Centralized systems can compromise data integrity if controlled by a single entity with malicious intent. Decentralized systems mitigate this risk by requiring consensus, and blockchain-based systems, with cryptographic verification and immutability, offer the highest assurance of data integrity. Furthermore, centralized systems' availability hinges on the central entity's stability, which can lead to disruptions. Decentralized systems, sharing data across nodes, increase availability, while blockchain-based systems exhibit

resilience, even when ICGs go offline, ensuring continuous data availability.

In summary, centralized systems might compromise security, whereas decentralized and blockchain-based systems enhance security through decentralization, data integrity, availability, auditability, immutability, and transparency. While each approach has its strengths and limitations, blockchain-based systems exhibit comprehensive security features, making them particularly well suited for applications where trust and security are paramount.

## VI. CONCLUSION

In conclusion, the research presented in this paper demonstrates the significant potential of utilizing blockchain technology to enhance the integrity and efficiency of shared data within a distributed-control intersection network. The implementation of a blockchain-based method has been shown to address the challenges associated with data integrity, trust, and transparency in this critical context. By leveraging the decentralized and immutable nature of blockchain, the proposed approach offers a robust solution for ensuring the authenticity and consistency of data exchanged among various intersection nodes.

The results of our experiments indicate that the blockchain-based method not only enhances the overall security posture of the intersection network but also contributes to the efficient management of the road traffic, reducing the risk of unauthorized modifications and data tampering. The blockchain records the history of intersection link states, therefore the use of the blockchain is essential in the event of an intersection system failure, so that the new signals plan of the intersection can be calculated based on the data previously stored in the blokchain, thereby streamlining the decision-making process in the distributed-control system.

It is worth noting that while this paper primarily focuses on the application of blockchain in a distributed-control intersection network, the concepts and insights presented herein have broader implications for other decentralized and data-sensitive systems. Future research could explore scalability and performance optimization, as well as real-world deployment and integration of the proposed solution. As the adoption of blockchain technology continues to expand, the findings of this study contribute to the advancement of secure and trustworthy data sharing in distributed systems, paving the way for safer and more efficient urban traffic management and beyond.

# Code-Mixed Sentiment Analysis using Transformer for Twitter Social Media Data

Laksmita Widya Astuti, Yunita Sari, Suprapto

Department of Computer Science and Electronics, FMIPA UGM Yogyakarta, Indonesia

*Abstract*—The underrepresentation of the Indonesian language in the field of Natural Language Processing (NLP) can be attributed to several key factors, including the absence of annotated datasets, limited language resources, and a lack of standardization in these resources. One notable linguistic phenomenon in Indonesia is code-mixing between Bahasa Indonesia and English, which is influenced by various sociolinguistic factors, including individual speaker characteristics, the linguistic environment, the societal status of languages, and everyday language usage. In an effort to address the challenges posed by code-mixed data, this research project has successfully created a code-mixed dataset for sentiment analysis. This dataset was constructed based on keywords derived from the sociolinguistic phenomenon observed among teenagers in South Jakarta. Utilizing this newly developed dataset, we conducted a series of experiments employing different pre-processing techniques and pre-trained models. The results of these experiments have demonstrated that the IndoBERTweet pre-trained model is highly effective in solving sentiment analysis tasks when applied to Indonesian-English code-mixed data. These experiments yielded an average precision of 76.07%, a recall of 75.52%, an F-1 score of 75.51%, and an accuracy of 76.56%.

*Keywords*—*Sentiment analysis; code-mixed; BERT; bahasa Indonesia*

## I. INTRODUCTION

Indonesia, the fourth most populous country globally, boasts a population exceeding 279 million people, according to estimates provided by the Central Intelligence Agency (CIA) World Factbook. Despite its substantial population, the Indonesian language remains inadequately represented within the realm of Natural Language Processing (NLP). According to Koto et al. [1], this paucity of representation can be attributed to three principal factors: the dearth of annotated datasets, restricted language resources, and a lack of standardization in these resources.

The prevalence of code-mixing, the linguistic phenomenon involving the amalgamation of multiple languages in communication, is influenced by sociolinguistic determinants. As highlighted by Anastassiou and Andreou [12], these determinants encompass individual speaker attributes, the linguistic milieu, the societal status of languages, and everyday language utilization. The coexistence of diverse local languages, regional dialects, and Bahasa Indonesia (the national language) engenders an environment conducive to code-mixing as individuals navigate various linguistic systems. The escalating influence of globalization has engendered a heightened reliance on the English language across the world.

This trend, coupled with the multicultural nature of the community in Jakarta Selatan, further contributes to the phenomenon of code-mixing as an inherent byproduct of linguistic diversity and interactions. The South Jakarta Code-mixed phenomenon presents an avenue for NLP research to confront the intricacies of language and facilitate multilingual communication. Ongoing research endeavors in this field strive to cultivate innovative techniques adept at effectively managing the distinct challenges posed by code-mixed data. Such advancements seek to enhance comprehension and processing capabilities when dealing with multilingual text.

Code-mixing or language mixing in sentiment analysis tasks poses a unique challenge in the field of Natural Language Processing (NLP). Most research on code-mixing is conducted to address sentiment-related issues within monolingual contexts. Given that English is the second most widely used language globally, the likelihood of code-mixing between English and other languages is significant. As a result, the majority of code-mixing research focuses on combinations of English with other languages. However, publicly available code-mixed data between English and Indonesian is scarce, making it challenging to investigate and develop solutions in this area.

Several sentiment analysis studies have been conducted using code-mixed data represented in embeddings. Embeddings are used to represent words in such a way that words that are closer in vector space are expected to have similar meanings. Previous studies include Mishra et al. [2], who used Indian-English and Spanish-English with Glove and TF-IDF as embeddings; Javdan et al. [3], who used Indian-English and Bengali-English with Glove and FastText as embeddings; and Tho et al. [4], who used Indonesian-Javanese with a BERT pretrained model as embedding. Comparative studies conducted by Wang et al. [5] demonstrated that the BERT pretrained model outperforms classic embeddings that are context-independent, such as Glove and FastText. However, these three embeddings are primarily focused on a single language (English), which adversely affects sentiment classification performance.

While many research efforts have aimed to improve sentiment analysis by incorporating code-mixing data from various languages, it's clear that the models used in existing studies are predominantly centered on a single language, specifically, English. This preference for one language in model architecture, along with the neglect of others, can lead to less-than-optimal sentiment analysis results. Moreover, there is a significant scarcity of publicly available code-mixed datasets, especially those annotated with sentiment categories,

particularly for the Indonesian-English language combination. This research gap constrains our understanding of the processes involved in code-mixing between the Indonesian and English languages within the field of Natural Language Processing (NLP), underscoring the necessity to consider both languages, rather than singularly focusing on one. In light of this void, this study makes the following major contributions:

- Constructing a code-mixed Indonesian-English dataset specifically designed for semantic tasks, such as sentiment analysis, and

- Developing five preprocessing scenarios based on pretrained models used in sentiment analysis tasks to address the limitations of embeddings that concentrate solely on one language.

This paper is structured as follows: Section II provides the literature review; Section III encompasses the development of the dataset, including data collection, labeling, the definition of sentiment, preprocessing, and the description of labeling outcomes. Section IV outlines the research methodology, Section V presents the results and discussion, Section VI expounds upon future research directions, and the concluding chapter wraps up the paper in Section VII.

## II. LITERATURE REVIEW

Pretrained models in Natural Language Processing (NLP) have demonstrated their effectiveness in addressing code-mixed challenges by capitalizing on their capacity to learn from extensive and diverse text data. These pretrained models have evolved to become the state-of-the-art models for language comprehension and generation. The foundational data used to train these models is sourced from extensive corpora, including resources such as Wikipedia and book corpuses. Additionally, as outlined by Gupta, Ekbal, and Bhattacharyya [13], existing benchmark datasets across various NLP tasks can be adapted to the code-mixed environment, enabling the assessment of a model's adaptability within a multilingual framework.

Sentiment analysis, a well-established and extensively researched field within social media analysis and NLP, has primarily been conducted in monolingual settings to address sentiment-related concerns. In the realm of code-mixing research, the primary focus has been on combining English with other languages. This emphasis stems from the widespread use of English as the second most spoken language globally, resulting in the prevalence of code-mixing involving English.

In certain sentiment analysis studies, code-mixed data is represented using embeddings, which transform words into vectors, with words of similar meanings residing in close proximity within vector spaces. For example, a study conducted by Mishra, et al. [2] utilized Indian-English and Spanish-English code-mixed data, employing Glove and TF-IDF as embeddings. Similarly, Javdan, et al. [3] employed Indian-English and Bengali-English code-mixed data with Glove and FastText as embeddings, while Tho, et al [4] used Indonesian-Javanese code-mixed data with a Sentence BERT pre-trained model for embedding. In our current study, we employ IndoBERTweet, BERTweet, and Multilingual pretrained models to embed code-mixed data, including Indonesian-English pairs.

Notably, Mishra, et al. [2] conducted code-mixing research involving Indian local languages such as Hindi (HI) and Bengali (BN). The research encompassed various language pairs, including Hindi-English and Bengali-English, employing machine learning and neural networks to address challenges. Feature vectors like GloVe and TF-IDF with 2-6 n-gram characters were employed. However, the study identified several limitations, including the model's difficulty in accurately capturing sentiment polarization from ambiguous data, the limitations of word n-grams in precisely representing sentiment in sentences due to Twitter's character restrictions, and the existence of diverse spelling variations for a single word. Consequently, the use of multilingual embeddings is deemed necessary to accurately classify sentiment and represent words and phrases beyond the lexicon of a single language.

Javdan, et al. [3] conducted sentiment analysis on code-mixed Hindi-English and Spanish-English data using fastText and GloVe embeddings. However, the combination of CNN, fastText, and GloVe resulted in unexpected outcomes with subpar performance. This underperformance was attributed to the exclusion of languages other than English in the embedding process, regardless of the model used. As a result, future studies will prioritize pretraining models in both languages, employing attention mechanisms to determine the significance of each linguistic representation within each phrase.

Furthermore, Tho, et al. [4] evaluated sentiment analysis for Indonesian and Javanese code-mixed data using lexicons and transformers, incorporating an attention mechanism. The transformer model, which leverages the attention mechanism, was employed. Based on the results, the transformer model with BERT encoding demonstrated superior accuracy compared to lexicons. Additionally, a comparative analysis conducted by Wang, et al. [5] revealed that the BERT pretrained model outperforms well-known context-independent embeddings like Glove and FastText. This finding prompted the selection of the BERT pretrained model as the starting point for our current research.

Despite numerous research endeavors that have attempted to enhance sentiment analysis performance using data incorporating code-mixing across different languages, it is evident that the dataset and model architectures employed in existing studies are primarily fixated on a single language, specifically, English. The limitations associated with embedding models trained or biased toward a single language while neglecting others can result in suboptimal sentiment analysis performance. Furthermore, code-mixed datasets, particularly for semantic tasks like sentiment analysis, annotated with sentiment categories, remain notably scarce in the public domain, especially for the Indonesian-English language combination.

This research addresses critical gaps in NLP by focusing on code-mixing challenges involving English and Indonesian, offering a new dataset for sentiment analysis. It also explores preprocessing strategies to enhance sentiment analysis in code-

mixed data. The study contributes to the understanding and management of code-mixed text and aligns with the broader goal of improving multilingual communication and NLP.

## III. Dataset Development

### A. Data Collection Procedure

The data collection methodology entails acquiring data through the submission of requests to Twitter API version 2, amalgamating data in both Indonesian and English languages. A specific authorization, denoted as "Academic research", is imperative for gaining access to Twitter API version 2. The default permission level of Twitter API, referred to as "Essential," is considerably limited and insufficient for conducting crawling operations. Registration is obligatory and necessitates the completion of various inquiries pertaining to the research project. Upon successful registration, an API key is procured. Academic access is indispensable, as it confers numerous advantages that facilitate the research process, including access to real-time public Twitter data and other features that augment accurate and equitable data collection.

A roster of desired keywords is employed as the query or filter for the endpoint, which combs through the entirety of Twitter. The keyword list is amalgamated using the OR operator, signifying a combination of keywords. Additional filters encompass "-is:retweet" to exclude retweeted or shared tweets to avert duplication, "-is:reply" to consider solely original tweets from the tweet author, and "place country:ID" to specify tweets from users located in Indonesia. The selected search terms are derived from sociolinguistic phenomena in Indonesian and English, which are popular among young individuals in the South Jakarta region [9], along with a compilation of pertinent hashtags. The keywords for the endpoint query were gathered from various publications found through Google searches utilizing the term "slang jaksel." The number of keywords obtained from these articles is restricted to 50 and stored in the software as an array. To prepare the training data, the Twitter API v2 and the Python module Tweepy are utilized for the purpose of retrieving code-mixed Indonesian and English data.

The available data spans from August 2020 to September 2022. Along with keywords, the endpoint query also includes date-based queries. The dataset is standardized by dividing it into three sections: testing, validation, and training. The evaluation and dataset distribution adhere to the same F1 value calculation as applied to the IndoLEM dataset in a manner similar to the approach outlined in a study conducted by Koto et al. [1]. The data distribution in this study employs a ratio of 3638 sentences for training, 399 for validation, and 1011 for testing. Considering that the maximum amount of data retrievable per query is 500, queries must be executed in batches.

To mitigate noise within the data, a human data cleaning procedure is executed. This procedure encompasses the removal of duplicate data, the filtration of monolingual data, and the exclusion of offensive or inappropriate terms. After the selection process, the data is annotated with emotions,

specifically categorized as neutral, positive, and negative. These emotions are subsequently translated into numerical values during the training phase, with the assigned values as follows: neutral = 0, negative = 1, and positive = 2.

### B. Data Labeling Procedure

The data labeling procedure involved the collaboration of five annotators with expertise in the fields of data science, English literature, and Indonesian literature. Crowdsourcing was employed to streamline the annotation process, and the services of these annotators were procured through a dedicated freelancing platform tailored specifically for Indonesian professionals (https://projects.co.id). The selection of annotators was based on their knowledge and proficiency in areas directly pertinent to the characteristics of the dataset under investigation.

The tasks assigned to the five annotators were delineated as follows:

*1) Reviewing* tweets provided via the Google AppSheet platform.

*2) Categorizing* the tweets into three distinct sentiment labels: positive, negative, and neutral.

*3) Analyzing* the sentiment groupings based on their pre-existing linguistic expertise.

In order to uphold consistency and precision throughout the annotation process, a majority vote was conducted among the three sets of labeled files. The AppSheet system was seamlessly integrated with Google Sheets, serving as the foundational database from which the annotators read and annotated the tweets. To ensure a more coherent and standardized set of annotated tweets, the final determinations regarding precise sentiment annotations were reached through mutual consensus among the annotators. To enhance comprehension, the consensus on sentiment assessment took into account the context of polarization or sentiment inclination, as well as specific instances. The sentiment categories and their corresponding degrees of polarity are delineated in Table I.

TABLE I. Sentiment Definition based on Polarity Level

| Polarity Level | Definition |
|---|---|
| Positive | A response or outlook that raises the worth of someone or something. |
| Negative | Negative language that will reduce the perceived value of whatever is being viewed. |
| Neutral | Taking no sides |

### C. Dataset Generation Results

According to the labeling distribution determined by the five annotators, the findings revealed that negative labels were more prevalent on Twitter, constituting approximately 35.33% of the data instances, as opposed to neutral labels at approximately 36.19% and positive labels at approximately 28.48%. This distribution was observed in a total of 1,903 out of 5,068 data instances. The distribution results are comprehensively presented in Table II.

TABLE II.    FIVE ANNOTATORS' RESULTS OF LABELING DISTRIBUTION

|  | Positive | Negative | Netral | Total |
|---|---|---|---|---|
| Annotator 1 | 1732 (≈33.98%) | 1213 (≈23.76%) | 2123 (≈42.26%) | |
| Annotator 2 | 1421 (≈27.95%) | 2185 (≈42.84%) | 1462 (≈29.21%) | |
| Annotator 3 | 1039 (≈20.49%) | 2458 (≈48.51%) | 1571 (≈31.00%) | 5068 (100%) |
| Annotator 4 | 1714 (≈33.60%) | 1927 (≈37.59%) | 1427 (≈28.80%) | |
| Annotator 5 | 1784 (≈35.66%) | 1732 (≈33.92%) | 1552 (≈30.42%) | |
| **Average** | 1538 (≈28.48%) | 1903 (≈35.33%) | 1627 (≈36.19%) | |

Description:

- Annotator 1 possesses expertise in the field of Statistics.

- Annotator 2 specializes in Indonesian Literature.

- Annotator 3 has expertise in English Literature.

- Annotator 4 is knowledgeable in the field of English Education.

- Annotator 5 has expertise in English Literature.

### D. Preprocessing

This study will employ various preprocessing methods, encompassing emoji/emoticon conversion, translation, and slang word normalization. Manual data cleaning will be undertaken to eliminate offensive remarks, obscenities, and duplicate entries. Furthermore, automatic preprocessing will be executed by removing unnecessary tokens based on a predefined regular expression. This includes the elimination of acronyms, hashtags, mentions, and URLs. The preprocessing procedure may also encompass converting text to lowercase, addressing coarse language in English, converting emoji/emoticon symbols, normalizing text, performing translation tasks, and eliminating extraneous words. The specific preprocessing techniques employed will be contingent on the selected scenario and the pretrained model in use.

### IV. RESEARCH METHODOLOGY

In a general overview, the research involves five distinct phases for constructing the model. These phases encompass the data collection, data labeling, sentiment polarity determination, training and validation, and the subsequent testing and evaluation processes. The process of dataset development, which includes data collection, labeling, sentiment definition, preprocessing, and the acquisition of labeling results, is elucidated in Section III, specifically under the dataset development section. Fig. 1 depicts the research's overall diagram.

Fig. 1.    The research's stages diagram.

### A. Training, Testing and Validation Process

In the training process, data preparation is carried out, involving data cleaning and preprocessing. Following preprocessing, training is performed using the BERT model. The training process is conducted with three epochs, in accordance with the recommendation by Devlin et al. [7].

Validation occurs concurrently with training to find the lowest loss value among the three epochs. By analyzing the training loss and validation loss values, it can be determined whether the dataset is overfit, underfit, or properly fit to the pretrained model in use. Consequently, the output of the training process is the best model based on the validation results. Given that the primary focus of this research is to compare the use of pretrained models, the selection of epoch, batch, and learning rate values aligns with the fine-tuning procedure outlined by Devlin et al. [7]. The specific values used are adjusted for each pretrained model since they have different optimal hyperparameters. From the chosen best model, a testing process is conducted. The test data is preprocessed using the same procedure as in the training process. The testing process involves comparing the prediction results with the labels in the test data.

### B. Bidirectional Encoder Representations from Transformer (BERT)

Bidirectional Encoder Representations from Transformers (BERT) is a deep learning model designed to generate comprehensive representations of unlabeled text by considering both left and right context at all levels. BERT accomplishes this by incorporating the entire set of words in the surrounding text. Pretrained models based on BERT have proven to be highly effective in representing language due to their extensive training on large corpora and specific domains. The BERT framework consists of two main stages: pretraining and fine-tuning. During pretraining, the model is trained on unlabeled data using various tasks, such as Masked Language Modeling (LM) and Next Sentence Prediction. In the fine-tuning stage, the BERT model is initialized with pretrained parameters and further fine-tuned using labeled data specific to particular tasks.

In this research, the pretrained BERT model is employed to tackle the semantic task of sentiment analysis. The utilization of pretrained models offers significant advantages in natural language processing (NLP) tasks, as it eliminates the need to train new models from scratch. The BERT-based pretrained models utilized in this study include BERTweet, trained on a collection of English tweets [8], IndoBERTweet [6], trained on a collection of Indonesian tweets, and MultilingualBERT [7], trained on a multilingual Wikipedia dataset comprising 104 languages. These pretrained models serve as a foundational point for the sentiment analysis task, leveraging their pre-established knowledge and language representations.

### C. Sentiment Classification

In this research, the classification process leverages the encoding architecture of the transformer. The experiments conducted in this research are based on the implementation of the BERT model provided by Hugging Face. In its entirety, the layers are divided into three parts: the input layer, the attention

layer, and the classification layer. A pretrained model, specifically BERTBase, is utilized as a reference in the training process, with adjustments made for each domain. The parameters of BERTBase used in this study have a larger configuration compared to the transformer parameters defined in previous research Vaswani et al. [19]. BERT incorporates a larger feedforward network, with 768 and 1024 hidden units/embedding sizes, as well as more attention, with 12 and 16 heads, in contrast to the default configuration in the initial Transformer paper (six encoder layers, 512 hidden layers, and eight head attention). The pooler layer in the transformer architecture is employed as input to calculate probabilities and loss values using sigmoid and BCELoss calculations. These computations are conducted in alignment with the specialized BERT implementation for semantic tasks like sentiment analysis. The sigmoid calculation produces logits, which are used to determine whether the sentiment class falls into the categories of neutral, positive, or negative. Meanwhile, the loss value is utilized for validation to select the best model and evaluate whether the trained data exhibits signs of overfitting, underfitting, or a good fit.

### D. Experimental Setup

The dataset employed in this study comprises social media activity data in the form of tweets from Twitter. This dataset encompasses both textual data and emoticons/emojis, as prior research has demonstrated that the inclusion of these types of data enhances the performance of the sentiment analysis pipeline, which is based on BERT [11] and deep learning-based sentiment analysis [10].

A list of 50 keywords is compiled from various online articles, and some of the instances, as illustrated in Table II, are subjected to translation using Google Translate after undergoing preprocessing. The objective is to amass a diverse dataset encompassing data in multiple languages. Additionally,

emoji and emoticons are transformed into plain text using the emoji 1.7.0 library incorporated in the Python package [10]. The sentiment analysis procedure is executed through five distinct scenarios, as outlined in Table III.

### E. Evaluation Process

The evaluation phase is conducted based on the five experimental scenarios that have been established. All five scenarios are tested and evaluated using the same methodology. In the testing phase, labeled test data is utilized to make predictions. The predicted data is then compared to the actual label data, resulting in the creation of a confusion matrix. This confusion matrix is instrumental in determining the count of correct and incorrect predictions based on the respective classes. Metrics calculated include accuracy, precision, recall, and F-measure. Given that this research involves three classes: neutral (0), negative (1), and positive (2), the resulting confusion matrix has a 3x3 dimension, with columns representing predicted sentiment and rows representing the true sentiment. The confusion matrix provides the basis for calculating evaluation metrics, such as precision, recall, F1-score, and overall accuracy for all classes. To compute the values for each metric, one requires the count of true positives, true negatives, false positives, and false negatives.

## V. RESULTS AND DISCUSSION

Leveraging pretrained BERT models has demonstrated notable effectiveness when fine-tuning the sentiment analysis task. These pretrained models provide substantial time and cost savings, as they have already undergone extensive training on large corpora, a process demanding significant computational resources. However, it is crucial to acknowledge that not all pretrained models are equally well-suited for the unique domain of code-mixed data. The comprehensive results of the experiments carried out in this study are presented in Table IV.

TABLE IV. FIVE ALTERNATIVE SCENARIOS

| Scenarios | Precision | Recall | F1-Score | Accuracy |
|---|---|---|---|---|
| Scenario 1<br>IndoBERTweet<br>(*Preprocessing*) | 0.7607 | 0.7552 | 0.7551 | 0.7656 |
| Scenario 2<br>BERTweet<br>(*Preprocessing*) | 0.7314 | 0.7322 | 0.7316 | 0.7389 |
| Scenario 3<br>MultilingualBERT<br>(*Preprocessing*) | 0.6677 | 0.6622 | 0.6631 | 0.6716 |
| Scenario 4<br>IndoBERTweet (Without<br>*preprocessing*) | 0.7396 | 0.7374 | 0.7358 | 0.7478 |
| Scenario 5<br>MultilingualBERT<br>(Without *preprocessing*) | 0.6334 | 0.6345 | 0.6335 | 0.6370 |

Based on insights gained from this research, it is evident that code-mixing between English and other languages can be more optimal and effective when focused on the respective language rather than solely on English. These findings challenge previous studies conducted by Mishra et al. [2], Javdan et al. [3], and Tho et al. [4]. The utilization of the relevant language, in this case, supported by pretraining with a

Bahasa Indonesia-based BERT, adds value to enhancing the performance of a sentiment analysis task.

The experiment findings reveal that Scenario 1, which involves utilizing the pre-trained IndoBERT model along with translation into Indonesian, preprocessing steps such as emoji conversion to plain text, and data cleaning, yields the most favorable results for addressing the Indonesian-English code-mixed problem. In this scenario, an average precision of 76.07%, recall of 75.52%, an f-1 score of 75.51%, and an accuracy of 76.56% were achieved. It's worth noting that the performance, albeit slightly, decreased compared to Scenario 4, which employed the pre-trained IndoBERT model without preprocessing, resulting in an average precision of 73.96%, recall of 73.74%, an f-1 score of 73.58%, and an accuracy of 74.78%. These outcomes underscore the effectiveness of the monolingual Bahasa Indonesia translation and preparation procedure in enhancing performance.

Conversely, the pre-trained Multilingual BERT model exhibited suboptimal performance in Scenarios 3 and 5. However, the inclusion of preprocessing steps led to improved performance outcomes. This phenomenon could be attributed to the fact that the Multilingual BERT training process relies on the Wikipedia corpus, which forms its vocabulary using standard words. Consequently, it is less adept at capturing out-of-vocabulary terms in code-mixed data, including informal words. Additionally, after three epochs of training, the data for the BERTweet pre-trained model showed a good fit, but IndoBERT outperformed it in terms of performance. This may be due to the prevalence of code-mixing and its adherence to Indonesian sentence structure, rendering the translation accuracy of Google Translate less reliable. Based on the aforementioned justifications, here are the outcomes of each of the five scenarios:

- Scenario 1 (pre-trained IndoBERT with preprocessing):

- Average precision: 76.07%, recall: 75.52%, f-1 score: 75.51%, accuracy: 76.56%.

- Scenario 2 (pre-trained Multilingual BERT with preprocessing): Lower performance than Scenario 1.

- Scenario 3 (BERTweet pre-trained model): Exhibited a good fit after three epochs of training but was outperformed by IndoBERT in terms of performance.

- Scenario 4 (pre-trained IndoBERT without preprocessing): Slightly lower performance than Scenario 1.

- Scenario 5 (pre-trained Multilingual BERT without preprocessing): Lower performance than Scenario 1 but improved with preprocessing steps.

The deep learning approach that automatically generates code-mixed text from English into various languages without previous parallel data, as researched by Gupta [13], could be an option for creating a dataset. However, the perspective and role of annotators in determining how sentiment can be defined are crucial in understanding the context of a sentence to be analyzed in the labeling process. This is due to the more complex language composition compared to single language text. Leveraging their expertise, annotators can provide insights into determining sentiment through expressions, emojis/emoticons, context, and emotions. Thus, it is expected that the dataset can contribute to improving performance in various NLP tasks, regardless of the models and scenarios employed.

## VI. FUTURE RESEARCH DIRECTION

Future research is expected to address several key challenges and explore new techniques to enhance the effectiveness and efficiency in handling code-mixed data, particularly the mixing of Indonesian and English in various NLP tasks. The following are some directions for future research:

- Future research efforts may involve enriching the lexicon of non-standard language, both in English and Indonesian, to minimize out-of-vocabulary words. Additionally, exploring the conversion of emojis and emoticons within multilingual BERT scenarios (given its training on standard corpora like Wikipedia) to make it applicable to Twitter sentences.

- As preprocessing has a substantial impact on this study, further investigation is needed to develop better and more optimal preprocessing methods for effectively handling code-mixed data.

- Research in the future could consider creating pretrained models on code-mixed data corpora without retaining the existing scenarios. This approach, while taking into account each language to avoid ambiguity, would allow sentiment analysis processes to run without the need for tuning existing monolingual pretrained models.

## VII. CONCLUSION

This research project has successfully curated a code-mixed dataset by amalgamating Indonesian and English languages, utilizing 50 keywords derived from a sociolinguistic phenomenon observed among teenagers in South Jakarta. The presence of code-mixing, which results from the combination of two distinct languages, underscores the significance of involving language experts in determining sentiment polarity. This engagement is essential for enhancing the accuracy of sentiment analysis, given the heightened linguistic complexity compared to single-language text. By capitalizing on their expertise, annotators can offer valuable insights for ascertaining sentiment based on expressions, emojis/emoticons, context, and emotional cues. Consequently, the dataset is anticipated to make a meaningful contribution to enhancing performance across a range of NLP tasks, irrespective of the specific models and scenarios used. The dataset was meticulously designed to tackle the semantic task of sentiment analysis, incorporating three distinct label categories: positive, negative, and neutral. The annotation of the dataset was carried out by a panel of five annotators, each possessing expertise language and data science. The dataset has been made publicly available on the Github repository and can be accessed via the following link: https://github.com/laksmitawidya/indonglish-dataset.

Despite being initially trained on a monolingual corpus, the BERT pretrained model exhibits impressive performance when handling code-mixed data in sentiment analysis tasks. Furthermore, each pretrained model demands only a brief training period of approximately four hours on a CPU. This underscores the significant role of pretrained models in expediting the training process in specialized domains, such as sentiment analysis of Twitter data containing both Indonesian and English codes, while keeping computational resource requirements minimal.

Leveraging pretrained BERT models has proven effective in fine-tuning sentiment analysis tasks, resulting in substantial time and cost savings due to their extensive training on large corpora. It's worth emphasizing that not all pretrained models are equally suitable for code-mixed data, and the application of scenario-based preprocessing significantly impacts performance outcomes. The findings of this research highlight the effectiveness of concentrating on the respective language in code-mixing between English and other languages, as opposed to a sole emphasis on English. These insights challenge the conclusions drawn in prior studies. Notably, incorporating the relevant language, particularly when supported by pretraining with a Bahasa Indonesia-based BERT, emerges as a valuable approach to significantly improve the performance of sentiment analysis tasks. Specifically, Scenario 1, which combines the pre-trained IndoBERT model with preprocessing, emoji conversion, and data cleaning, delivers highly favorable results for Indonesian-English code-mixed sentiment analysis, achieving notable average precision, recall, f1-score, and accuracy values of 76.07%, 75.52%, 75.51%, and 76.56%, respectively. This emphasizes that data cleansing, translation to a unified language, and normalization during the preparation stage are adequate for enhancing performance. On the other hand, the Multilingual BERT model initially exhibits suboptimal performance in specific scenarios but shows improvement with the introduction of preprocessing steps, revealing its limitations in capturing out-of-vocabulary terms in code-mixed data. Looking ahead, future research should prioritize enriching non-standard language lexicons, optimizing preprocessing techniques, and exploring pretrained models for code-mixed data without relying on specific scenarios. These endeavors aim to enhance sentiment analysis performance in multilingual contexts, ultimately contributing to improved accuracy and efficiency.

# Research on the Application of Random Forest-based Feature Selection Algorithm in Data Mining Experiments

Huan Wang*

College of Big Data and Intelligence Engineering, Southwest Forestry University, Kunming, Yunnan, 650224, China

*Abstract*—Handling high-dimensional big data presents substantial challenges for Machine Learning (ML) algorithms, mainly due to the curse of dimensionality that leads to computational inefficiencies and increased risk of overfitting. Various dimensionality reduction and Feature Selection (FS) techniques have been developed to alleviate these challenges. Random Forest (RF), a widely-used Ensemble Learning Method (ELM), is recognized for its high accuracy and robustness, including its lesser-known capability for effective FS. While specialized RF models are designed for FS, they often struggle with computational efficiency on large datasets. Addressing these challenges, this study proposes a novel Feature Selection Model (FSM) integrated with data reduction techniques, termed Dynamic Correlated Regularized Random Forest (DCRRF). The architecture operates in four phases: Preprocessing, Feature Reduction (FR) using Best-First Search with Rough Set Theory (BFS-RST), FS through DCRRF, and feature efficacy assessment using a Support Vector Machine (SVM) classifier. Benchmarked against four gene expression datasets, the proposed model outperforms existing RF-based methods in computational efficiency and classification accuracy. This study introduces a robust and efficient approach to feature selection in high-dimensional big-data scenarios.

*Keywords—Random forest; SVM; machine learning; big data; feature selection; best-first search; rough set theory*

## I. INTRODUCTION

High-dimensional big data poses significant challenges for Machine Learning (ML) algorithms due to the "curse of dimensionality," a phenomenon where the computational complexity and resource requirements increase exponentially as the number of dimensions (features) grows [1]. Traditional algorithms can struggle to make accurate predictions as they become lost in the vastness of the feature space, leading to issues such as overfitting, where the model captures noise instead of the underlying data structure. To mitigate these problems, various dimensionality reduction techniques like Principal Component Analysis (PCA), t-distributed Stochastic Neighbor Embedding (t-SNE), and autoencoders have been developed to compress the feature space while retaining as much of the meaningful information as possible [2]. Additionally, feature selection methods like the Least Absolute Shrinkage and Selection Operator (LASSO), Mutual Information (MI), and Chi-Square Test (CST) are used to identify the most informative features. More sophisticated ML models, such as Deep Learning (DL) models, are also designed to automatically capture hierarchical representations of the data, thereby mitigating some of the challenges posed by high dimensionality.

The Random Forest (RF) technique is a collective learning approach that integrates numerous decision trees to build a more robust and precise forecasting model. Functionally, each tree in the ensemble is built from a bootstrapped sample of the data, and during the tree-building process, a random subset of features is chosen at each node split [3]. This randomization not only decorates the trees but also makes the ensemble less prone to overfitting, enabling it to perform well on unseen data. As a predictor, RF is renowned for its exceptional accuracy, capability to process vast datasets with extensive dimensionality, and capability to handle missing values. One of the lesser-known but advantageous features of an RF model is its innate capability for Feature Selection (FS) [4]. During training, it computes a score for each feature that indicates its importance in making predictions. This feature importance score is often derived from the average reduction in impurity that each feature brings across all trees in the forest. By ranking features based on this score, RF provides a practical and intuitive way for FS, helping to improve the performance of not only itself but also other ML models that may be sensitive to irrelevant or redundant features [5].

Many RF models are specialized for FS, each offering unique advantages and disadvantages. Variants like Boruta [6] focus on systematically identifying important attributes by comparing them to randomly shuffled versions of themselves, while Conditional Inference Forest (CIF) [7] aims for unbiased FS through statistical hypothesis tests. Regularized RF [8] applies a regularization term to prioritize a sparse set of features, and Extremely Randomized Trees (RT) [9] adds an extra layer of randomness for potentially more robust selections. However, a common drawback in most of this RF-based Feature Selection Model (FSM) is their lack of focus on handling large datasets. These methods often strive for computational efficiency, facing challenges related to memory space and computing time. To mitigate these issues, high-performance computing environments and parallel architectures are often necessary for effective FS on big datasets. Failing to use such computational resources can significantly ramp up hardware and software costs. For example, scalable software frameworks like Hadoop MapReduce are often required for the learning and analysis stages to manage large datasets efficiently. Therefore, while RF-based methods offer numerous avenues for FS, their

applicability to big data scenarios often necessitates additional computational resources to overcome inherent limitations.

Considering the challenges associated with computational time complexity and classification accuracy in high-dimensional datasets, a novel FSM integrated with data reduction techniques is proposed. The architecture operates in four distinct phases. Initially, high-dimensional data undergo preprocessing to standardize and clean the dataset. Subsequently, the preprocessed data are processed through a Best-first Search with Rough Set Theory (BFS-RST) Feature Reduction Model (FRM) in the second phase. This specialized model aims to reduce the feature size effectively. In the third phase, a novel proposed variant of RF termed Dynamic Correlated Regularized Random Forest (DCRRF) is employed. This DCRRF model incorporates correlated FSM to identify an optimal set of features from the already-reduced set. The final phase involves a rigorous assessment of the quality and efficacy of the FS using a Support Vector Machine (SVM) classifier. Performance benchmarks indicate that this proposed model outperforms existing RF-based FSM when tested on four gene expression datasets. The architecture aims to mitigate computational inefficiency and enhance classification accuracy, offering a more robust approach to FS in complex data scenarios.

The paper is organized as follows: Section II presents the literature review, Section III presents the methodologies used in the work, Section IV presents the proposed model, Section V analyses the work using different experiments, and Section VI concludes the work.

## II. LITERATURE REVIEW

This section delves into various works that have employed RF-based models for FS, offering insights into their efficacy and limitations.

The research in [10-12] presents a two-step RF-based FSM. The first step selects features based on variable importance scores and then employs the search process in the second step to finalize a feature subset. The approach was tested on the KDD'99 intrusion detection dataset, derived from the DARPA 98 dataset. Notably, the KDD'99 dataset was modified to remove redundant records, resulting in a refined dataset called RRE-KDD for training and testing. Experimental results indicated that this approach reduced the feature set and computational time and enhanced classification accuracy. The study in [13-15] explores the use of the RF classifier for FS in prostate cancer detection. Utilizing an ensemble of Decision Trees (DT) for classification, the study notes that the accuracy improves with adding more trees. The classifier is adept at handling incomplete data attributes and is scalable for large datasets. Emphasizing the pivotal role of FS, the research finds that their method boosts detection accuracy by roughly 87%, underscoring the importance of effective FS in enhancing prostate cancer detection. The research in [16-18] study introduces a recursive FSM using RF to enhance protein structural class prediction. The method underwent evaluation through four experiments and was compared to existing prediction techniques. Findings suggest that this feature selection approach significantly bolsters the efficiency of predicting protein structural classes. Remarkably, the method uses fewer than 5% of the features yet boosts prediction accuracy by 4.6-13.3%. Further analysis revealed that features related to predicted secondary structures yielded the best performance, providing insights that could inform the development of even more effective prediction methods for protein structural classes.

The study in [19-23] explores how the number of trees and class separability influence the consistency of variable importance rankings in RF algorithms. The research concludes that achieving stable importance values is possible either by incorporating a large number of trees in a single execution of the model or by taking the average values from multiple runs with fewer trees. While the second approach is more economical regarding computational cost, both methods produce comparable rankings for the variables. The research additionally points out that the ideal number of model iterations fluctuates depending on class separability and offers recommendations for ascertaining the appropriate number of runs or trees to achieve stable rankings of variable importance. In study [24-28], introduce an explainable Artificial Intelligence (AI) model for blood test sample-based COVID diagnosis. Despite the advancements in AI-based diagnostic models, few effectively integrate human-centered and machine-centered approaches. This research employs human-computer interaction design principles to address this gap. Employing graph analysis for the visualization and optimization of features, the model integrates an interpretable decision forest classifier to categorize COVID-19 cases using existing blood test information. This enables clinicians to leverage DT structures and feature visualizations for better model interpretability. They proved that their model had not just better diagnostic accuracy but also reduced computation time.

The research in [29-34] examines the efficacy of ML algorithms like RF and its variations in selecting Single Nucleotide Polymorphisms (SNPs) for fine-scale genetic population assignment in wildlife conservation. The study, which uses unpublished data for Atlantic salmon and published data for Alaskan Chinook Salmon (ACS), found that ML methods outperformed traditional Fixation Index (FST) rankings in identifying informative genetic markers. Specifically, RF-based methods led to an accuracy improvement of up to 7.8% and 11.2% for ACS, respectively. The findings underscore the potential of ML algorithms in enhancing genetic marker selection for conservation efforts. The research in [35-40] addresses the challenges in intrusion detection systems, such as the scarcity of labeled datasets, computational overhead, and suboptimal accuracy. The research introduces an Auto-Encoder Intrusion Detection System (AE-IDS) that leverages the RF algorithm for improved performance. The approach focuses on creating a robust training set through FS and grouping in [41-45]. Post-training, the model employs an auto-encoder for prediction, significantly reducing detection time and enhancing accuracy. Experimental findings suggest that AE-IDS outperform conventional ML-based IDS, offering more accessible training, better adaptability, and higher detection accuracy in [46-50]. The research in [51-55] employs an RF algorithm for county-scale cotton mapping, using spectral, vegetation, and

texture features. The study found that texture features, particularly the Gray Level Co-occurrence Matrix (GLCM), significantly improve classification accuracy. Compared to other classifiers like SVM and ANN, RF exhibited better stability and higher accuracy. The method that combined multiple features achieved an average accuracy of 93.36%, showing the effectiveness of using RF and multiple features for precise cotton mapping [56-58].

## III. PROPOSED METHODOLOGIES

### A. Random Forest

RF is an Ensemble Learning (EL) algorithm that builds a forest of DT, usually trained with the "bagging" method. The general idea of the Ensemble Learning Method (ELM) is to combine weak learners to create a robust model. In RF, each DT, $T_m$ is trained on a different bootstrap sample $D_m$ Drawn from the original dataset. The algorithm performs this operation $M$ times based on the parameter $n_{est}$, effectively creating $M$ different trees. A unique aspect of RF is that it considers only a subset of features when making each split, a number specified by the parameter $max_f$. This random subset of features introduces diversity among the trees, leading to a more robust model.

For regression problems, the output of a RF model is the mean prediction of all the trees, mathematically expressed as Eq. (1).

$$\hat{Y}(X) = \frac{1}{M}\sum_{m=1}^{M} T_m(X) \quad (1)$$

In classification tasks, the model employs a Majority Voting Scheme (MVS), choosing the mode of the classes predicted by individual trees, given as Eq. (2).

$$\hat{Y}(X) = \text{mode}(T_1(X), T_2(X), \dots, T_M(X)). \quad (2)$$

This EML provides a way to reduce the variance that might be present in a single DT, improving generalization to unseen data. One of the essential aspects of RF is the criteria used for node splitting, often specified by the Gini Impurity (GI) as shown in Eq. (3).

$$G(S) = 1 - \sum_{i=1}^{k} p_i^2, \quad (3)$$

where $p_i$ is the proportion of samples of class $i$ at a node, GI quantifies the "messiness" of the data. The algorithm aims to minimize the weighted sum of the GI of child nodes when making each split. This weighted sum can be calculated as in Eq. (4).

$$\Delta G = \sum_{j=1}^{2} \frac{|S_j|}{|S|} G(S_j). \quad (4)$$

In addition to GI, entropy is another criterion which is sometimes used for splitting nodes, defined as $H(S) = -\sum_{i=1}^{k} p_i \log_2 p_i$. The algorithm then selects the split that maximizes the information gain, calculated as in Eq. (5).

$$IG(S, f) = H(S) - \sum_{j=1}^{2} \frac{|S_j|}{|S|} H(S_j). \quad (5)$$

One lesser-known but critical aspect of RF is the Out-of-Bag (OOB) error. This internal error estimate eliminates the need for a separate validation set. Each tree in the forest leaves

out some samples during its bootstrap training, called OOB samples. The OOB error for each tree $T_m$ is calculated using its corresponding $OOB_m$ samples as in Eq. (6).

$$OOB_{error\,T_m} = \frac{1}{|OOB_m|} \sum_{(x_i, y_i) \in OOB_m} L(y_i, T_m(x_i)) \quad (6)$$

The overall OOB error for the RF is the average of these individual tree OOB errors as shown in Eq. (7).

$$\text{Overall } OOB_{error} = \frac{1}{M}\sum_{m=1}^{M} OOB_{error\,T_m} \quad (7)$$

where, $L(y, \hat{y})$ is a loss function measuring the difference between the true label $y$ and the predicted label $\hat{y}$.

*Algorithm 1 for RF Algorithm*

*Initialize Parameters:*

*(i) tree count in the forest (M): "$n_{est}$"*

*Find Best Split*

*For Each*

- *FS compute the best split based on either GI or Entropy.*
- *The best split minimizes the weighted GI or maximizes Information Gain.*

*Split the Node*

- *Divide $D_m$ into two subsets $D_{m,left}$ and $D_{m,right}$ based on the best split.*

*Recursive Split*

- *Repeat steps 1.2.1 to 1.2.4 for the child nodes $D_{m,left}$ and $D_{m,right}$.*

*Calculate OOB Error for $T_m$*

- $OOB_{error\ T_m} = \frac{1}{|OOB_m|}\sum_{(x_i,y_i)\in OOB_m} L(y_i, T_m(x_i))$

*Calculate Overall OOB Error*

- *Overall $OOB_{error} = \frac{1}{M}\sum_{m=1}^{M} OOB_{error\ T_m}$*

*End If*

*End*

*1) Variable importance scores from RF*: RF is not only known for its robust predictive power but also for its built-in FS capabilities. One of the metrics that the algorithm provides for understanding the dataset is the variable importance score for each feature. Understanding variable importance is crucial for improving and interpreting the model's decisions. The variable importance score in an RF algorithm is computed based on two principal factors:

*a) Mean Decrease in Impurity (MDI)*: This method calculates the average reduction in impurity-Gini impurity or entropy, for example, for each feature brought about when used for node splitting. Mathematically, the Mean Decrease in Impurity for feature f is computed as shown in Eq. (8).

$$MDI(f) = \sum_{\text{all nodes using } f} (\text{Impurity of Parent Node - Weighted Impurity of Child Nodes})$$
(8)

*b) Mean Decrease in Accuracy (MDA):* Another method, which usually involves using the Out-of-Bag (OOB) error, calculates the decrease in model accuracy when a particular feature is permuted. The idea is to assess how much worse the model performs without each feature. The formula for MDA can be generalized as Eq. (9).

$$MDA(f) = \frac{1}{M}\sum_{m=1}^{M}\left(OOB\_Error_{\text{with } f} - OOB\_Error_{\text{without } f}\right)$$
(9)

*Calculation Steps:*

*Step 1.* *Run the RF Algorithm:* First, generate the RF model using all variables and calculate the OOB error rate.

*Step 2.* *Permute Each Variable:* For Each feature $f$ in the dataset, randomly permute the values of $f$ in the OOB samples and record the new OOB error.

*Step 3.* *Compute Importance:* For Each feature $f$, compute the Mean Decrease in Accuracy or Mean Decrease in Impurity, depending on which method you're using.

*Step 4.* *Normalize Scores:* The raw importance scores can be normalized to sum to one, making them easier to interpret and compare.

*2) Regularized random forest (RRF):* RRF is an advanced extension of the traditional RF algorithm. While RF is already effective in ensemble learning, RRF takes a step further by incorporating regularization techniques aimed at reducing overfitting and improving feature selection. In standard RF models, each DT $T_m$ is trained independently on a bootstrap sample $D_m$, with no explicit mechanism for feature regularization. RRF, however, adds a regularization term to the ELM, effectively penalizing the complexity of individual trees.

The objective function for each tree in RRF can be mathematically represented as in Eq. (10).

$$Objective(T_m) = Impurity(T_m) + \lambda Complexity(T_m)$$
(10)

Here, Impurity $(T_m)$ refers to the impurity measure, which can be either GI or entropy. Complexity $(T_m)$ is a function quantifying the complexity of the tree, such as the depth or the number of leaves. $\lambda$ is the regularization parameter controlling the trade-off between impurity and complexity. This parameter is usually determined through cross-validation. In the RRF model, the standard information gain is replaced by a regularized form, $Gain_R(X_i, v)$, which integrates the regularization term:

$$Gain_R(X_i, v) = \begin{cases} \lambda \times Gain(X_i, v) & \text{if } i \notin F \\ Gain(X_i, v) & \text{if } i \in F \end{cases}$$
(11)

Here, $F$ is the set of feature indices already used for splitting in previous nodes. The term $\lambda$ serves as the penalty coefficient. Regularization in RRF can be applied at different stages:

- During Feature Selection: The regularization term is incorporated into the evaluation metric used for selecting the features for node splitting.

- During Tree Pruning: After constructing the trees, they can be pruned to minimize the regularized objective function.

By introducing the regularization term, RRF balances model complexity and fit quality, ensuring a more interpretable and robust ensemble model. This is particularly useful in cases where the dataset contains many irrelevant features or when overfitting is a concern. Therefore, RRF benefits from the inherent advantages of Random Forests while simultaneously mitigating some of their limitations.

*B. Best-First Search (BFS)*

BFS is a tree-based search algorithm that aims to find the most optimal solution by navigating through the state space of possible solutions. In the context of feature selection, each node $N$ in the search tree represents a subset of features $S$, and the root node usually represents an empty set or the complete feature set. The primary driving force of the algorithm is an evaluation function $f(N)$, which measures the 'quality' or 'promising nature' of node $N$. Mathematically, the evaluation function $f(N)$ can be expressed as in Eq. (12).

$$f(N) = g(N) + h(N)$$
(12)

where, $g(N)$ is the cost to reach the current node from the root (often equal to the number of features in $S$ when feature reduction is the goal), and $h(N)$ is the heuristic estimate of the cost to reach an optimal solution from $N$. The algorithm maintains a priority queue $Q$, initialized with the root node. The nodes are sorted in $Q$ based on their evaluation scores. The algorithm iteratively performs the following steps until a stopping criterion is met:

*Algorithm 2 for BFS for FS*
*Input:*

- *S : Complete set of features*

- *$f(N)$: Evaluation function for a node N*

- *Stopping Criteria: C*

*Output:*

- *Optimal subset of features $S_{optimal}$*
  *Initialize:*

- *Create an empty priority queue Q*

- *Create a root node $N_{root}$ with no features or all features, add $N_{root}$ to Q*

*Steps:*

*While Q is not empty and stopping criteria C are not met:*

- *Pop the node N with the lowest $f(N)$ from Q If N satisfies C :*

*Return $S_{optimal}$ as the feature subset in N*

*Exit*

*Else*

- *Generate child nodes of N by adding or removing features from S Evaluate $f(N)$ For Each Child Node*
- *Insert the child nodes into Q*
- *Re-sort Q based on $f(N)$*

The mathematical representation of the priority queue after *'k'* iterations can be represented as in Eq. (13).

$$Q_k = \{N_1, N_2, \dots, N_m\} \text{ s.t. } f(N_1) \leq f(N_2) \leq \cdots \leq f(N_m) \tag{13}$$

By focusing on the most promising subsets of features, BFS achieves a balance between exhaustive search and greedy algorithms. However, it can be computationally intensive, especially when the feature space is ample, as the time complexity can go up to $O(b^d)$, where $b$ is the branching factor, and $d$ is the depth of the solution.

*C. Rough Set Theory (RST)*

FR helps reduce the computational cost, simplifying models and sometimes even improving the performance by eliminating irrelevant or redundant features. RST developed that can be employed for feature reduction. RST provides a formal mathematical framework to deal with vagueness and uncertainty in data. In the context of Feature Reduction (FR), it helps identify the minimal set of features indispensable for preserving the discernibility between objects. In simpler terms, it helps find the most miniature set of features necessary and sufficient for classification tasks.

Let $U$ represent the universe of objects or instances in the dataset, and let $A$ denote the set of attributes or features. A decision table $T = (U, A)$ may be formed, in which $U$ comprises the rows, and $A$ makes up the columns. Additionally, $D$ a subset of $A$, can be introduced as the decision attribute(s) of interest. Using this foundation, the following aspects of RST are discussed:

*a) Indiscernibility Relation:* The fundamental concept in RST is the indiscernibility relation. For a given subset of attributes, $B \subseteq A$ an indiscernibility relation $IND(B)$ is defined as follows in Eq. (14).

$$IND(B) = \{(x,y) \in U \times U \mid \forall a \in B, a(x) = a(y)\} \tag{14}$$

Here, $a(x)$ is the value of attribute $a$ for object $x$. The indiscernibility relation $IND(B)$ groups objects that cannot be distinguished by attributes in $B$

*b) Lower and Upper Approximations:* Given a target set $X \subseteq U$, the lower and upper approximations are defined as in Eq. (15) and Eq. (16).

$$\text{Lower Approximation: } \underline{B_X} = \{x \in U \mid [x]_B \subseteq X\} \tag{15}$$

$$\text{Upper Approximation: } \overline{B_X} = \{x \in U \mid [x]_B \cap X \neq \emptyset\} \tag{16}$$

Here, $[x]_B$ represents the equivalence class of $x$ concerning $B$.

*c) Core and Reduct:* The core attributes are indispensable for maintaining the exact lower approximation for every subset of $U$ as the entire set $A$. Mathematically, Eq. (17).

$$\text{Core}(A, D) = \left\{ a \in A \mid \underline{A_D} \neq \underline{(A - \{a\})_D} \right\} \tag{17}$$

A reduct is a minimal subset $B$ of $A$ such that $\underline{B_D} = \underline{A_D}$. In other words, $B$ and $A$ give the same lower approximations for each decision class.

*D. Feature Reduction using RST*

The overarching goal is to identify all possible reducts and then choose the one with the least number of attributes while preserving the classification power of the original dataset. However, finding all reducts can be computationally taxing. For this reason, heuristic approaches are frequently used to approximate a minimal reduct effectively.

*1) Initialize with core attributes*: Start by calculating the core attributes, denoted as Core $(A, D)$, which are essential for classification. Initialize the reduct set, Reduct, with these core attributes.

*2) Iterative refinement*: Continue refining the reduct set until it provides the same classification power as the complete

attribute set $A$. Specifically, iterating while reducing $_D$ is not equal to $\underline{A_D}$.

- Evaluate Significance: For each remaining attribute $a$ in $A$ - Reduct, evaluate its significance in distinguishing between different classes.

- Select Most Significant Attribute: Add the attribute with the highest significance score to the Reduct set.

By the end of this iterative process, Reduct will contain a minimal set of attributes that retains the original dataset's ability to distinguish between different classes.

*E. Correlation-based Feature Selection (CFS)*

CFS is an FSM designed to improve model performance by FS that are highly correlated with the target variable and minimally correlated with each other. The process typically begins with data preprocessing to standardize or normalize the features then calculating a correlation matrix. Based on this matrix, an initial subset of FS either through predefined correlation thresholds or optimization algorithms. The criterion $Cr$, often used to maximize the quality of the feature subset, is Eq. (18).

$$Cr = \frac{k \cdot \tau_{cf}^-}{\sqrt{k + k \cdot (k-1) \cdot r_{ff}^-}}, \qquad (18)$$

where, $k$ is the number of features, $r_{cf}^-$ is the average correlation between features and the class label, and $r_{ff}^-$ is the average inter-feature correlation. This subset is then further evaluated using methods like cross-validation.

It is important to note that the CFS employs a heuristic search strategy within its multivariate FS algorithm to pinpoint optimal attributes in a given dataset. The criteria for selection are anchored in the correlation strength and statistical significance between a feature and its associated category. This unique capability has solidified CFS's role as a go-to method for Feature Extraction (FE), especially in large-scale data environments. Moreover, CFS has yielded numerous impactful findings that contribute to elevating the efficacy of Decision-Making System (DMS).

The advantages of CFS are manifold. It tends to produce more superficial and interpretable models by decreasing the feature size, thus mitigating the risk of overfitting. However,

the method is not without limitations. For example, Pearson's correlation, which is commonly used, assumes a linear relationship between variables and does not capture feature interactions. Despite this, CFS remains a powerful FSM, aiming to optimize the model's performance and generalization capabilities. When integrated with techniques like Regularized Random Forest (RRF), CFS can further enhance the FSM, leveraging the regularization capabilities of RRF to produce an even more robust and interpretable model.

## IV. PROPOSED FSM

In the architecture of the proposed FSM, as shown in Fig. 1, four key steps seamlessly integrate to provide a holistic solution. Initially, the dataset undergoes a preprocessing phase, which includes tasks like data normalization, formatting, and randomization, preparing the data for rigorous analysis. Following preprocessing, the first significant phase employs the innovative BFS-RST Adaptive Algorithm to reduce the feature set effectively. Utilizing this algorithm allow for a focus on a subset of features that are most relevant to the task, thereby enhancing the model's efficiency. This reduced feature set serves as the input to the second crucial phase, which features the Dynamic Correlated Regularized Random Forest (DCRRF) application. DCRRF refines FS dynamically, optimizing performance and interpretability through a combination of Correlation-based Feature Selection (CFS) and Regularized Random Forest (RRF) methodologies. After the optimal feature set has been identified, the final step involves a data analysis phase where the effectiveness of the selected features is rigorously tested using a Support Vector Machine (SVM) classifier. This multi-layered approach enhances the feature selection process and lends itself to detailed performance evaluation, making it a comprehensive solution for complex data analysis scenarios.

*A. Data Preprocessing*

The first step in the proposed FSM is Data Preprocessing. This phase is crucial because it converts the raw dataset into a more manageable, clean form, making it easier to analyze and feed into subsequent FR and FS stages. A properly preprocessed dataset not only streamlines the FSM but also contributes to the robustness and interpretability of the resulting model. The following methods are used in the preprocessing pipeline of the proposed architecture:

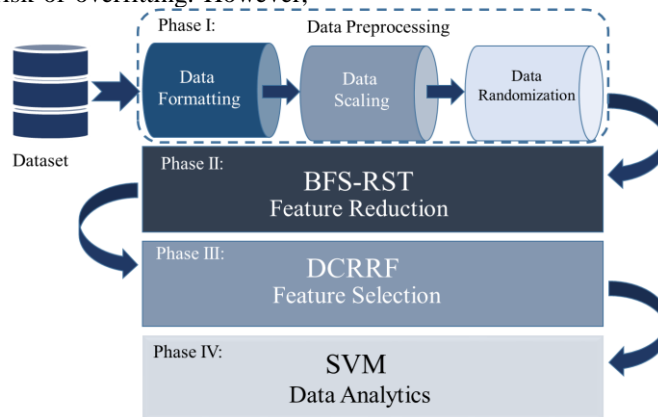

Fig. 1. Proposed FSM.

- Data Formatting: Including Data Formatting as the initial step in the preprocessing pipeline is fundamental for making the dataset readable and interpretable by the following algorithms. Addressing issues like inconsistent data types and missing values eliminates the potential for errors or biases that could significantly affect the performance of the BFS-RST Adaptive Algorithm and DCRRF. Proper formatting is a stable foundation for the stages that follow in the feature selection model.

- Data Scaling: Data Scaling finds its place in the preprocessing phase due to its significant impact on any ML algorithm's performance. The scales of numerical features can vary widely, and a feature with a more extensive range could overshadow those with smaller ranges, leading to suboptimal FS or model training. Scaling standardizes this, ensuring that each feature is given equal importance, thereby enhancing the overall reliability and effectiveness of the BFS-RST and DCRRF algorithms.

- Data Randomization: Data Randomization is incorporated to mitigate any sequence-based biases in the dataset. Data points can come in sequences that may reflect various forms of underlying structure or bias, such as time-based or class-based ordering. Shuffling the order of data points enables the FSM, which employs both the BFS-RST and DCRRF algorithms, to learn more objectively, uninfluenced by the sequence in which the data points initially appear.

### B. Adaptive Feature Reduction (AFR) using BFS and RST

FR is a vital process in ML pipelines, as it aims to cut down on the data dimensions without significantly affecting the model's performance. While several algorithms aim to do this, each has advantages and disadvantages. BFS is known for its ability to traverse the feature space optimally but can be computationally expensive. On the other hand, RST provides a formal framework to identify indispensable features but can be heuristic and computationally intensive for calculating reducts.

An adaptive approach that combines the strengths of both algorithms is thus conceived to achieve effective FR. The rationale is to employ RST's capability to identify core attributes indispensable for the DMS and then use BFS to navigate the feature space efficiently. In the given dataset $\mathcal{D}$, each feature subset $S \subseteq \mathcal{A}$ is a potential candidate for FR. These subsets are represented as nodes in the search space that BFS navigates. An evaluation function $f(S)$ is used to assess the "quality" of each subset $S$, analogous to how each node in a traditional BFS comes with an associated cost or value.

*1) Initialization using core attributes from RST:* Rough Set Theory first identifies a set of core attributes $\mathcal{R}_{core}$ from $\mathcal{A}$. These are the features that are indispensable for maintaining discernibility among the classes in $\mathcal{D}$ as shown in Eq. (19)

$$\mathcal{R}_{core} = \{a \in \mathcal{A} \mid a \text{ is indispensable for discernibility}\} \quad (19)$$

*2) Evaluation function in BFS:* The evaluation function $f(S)$ used in BFS combines a cost function $g(S)$ and a heuristic $h(S)$ to guide the search. $g(S)$ could represent how well $S$ performs in terms of model accuracy or any other metric, and $h(S)$ is a heuristic estimate of the "distance" to the optimal feature subset, see Eq. (20).

$$f(S) = \omega_1 \cdot g(S) + \omega_2 \cdot h(S) \quad (20)$$

Here, $\omega_1$ and $\omega_2$ are weight parameters.

*3) Priority assignment using RST:* During the BFS traversal, RST is used to identify if a subset $S$ is a reduct minimal set of features with discernibility power comparable to $\mathcal{A}$. Such subsets are flagged for higher priority in the BFS queue.

$$\text{Priority}(S_i) = \begin{cases} \alpha \cdot f(S_i), & \text{If } S_i \text{ is a reduct} \\ f(S_i), & \text{Otherwise} \end{cases} \quad (21)$$

In Eq. (21), $\alpha < 1$ is a factor that lowers the evaluation function $f(S_i)$ for reducts, they are effectively giving them a higher priority in the queue. By methodically integrating RST for initial setup and ongoing evaluation with the traversal capabilities of BFS, the algorithm aims to find an optimal and minimal feature subset from $\mathcal{A}$ for dataset $\mathcal{D}$. In the proposed algorithm, the focus is on reducing features by generating child nodes with fewer attributes, followed by an evaluation of their effectiveness using both BSF and RST techniques. Feature sets that neither improve nor degrade the quality of the model will be pruned. With this understanding now established, Algorithm 3, shown below, illustrates the steps involved:

*Algorithm 3 for BFS-RST based on Adaptive Feature Reduction*

*Input:*

- $\mathcal{F}$: *Complete set of features*

- $f(S)$: *Evaluation function for a feature subset $S$*

- $\mathcal{C}$ : *Stopping Criteria (e.g., a set limit on the number of features)*

*Output:*

- $\mathcal{S}_{opt}$ : *Optimal reduced set of features*

  *Initialize:*

- *Compute the core attributes $\mathcal{R}_{core}$ using RST. These are the features that are indispensable for the discernibility of classes.*
- *Initialize priority queue $Q$ with $\mathcal{R}_{core}$ as the root node, evaluated by $f(\mathcal{R}_{core})$.*
- *Algorithm Steps:*
  - *While $Q$ is not empty and $\mathcal{C}$ is not met, Do*
    - *Dequeue: Pop the node $S$ with the lowest $f(S)$ from $Q$.*

o   *Check Stopping Criteria:*
o   *If S satisfies C, Then*
o   *Return $S_{opt} = S$*
o   *Exit*
o   *FR and Child Node Generation:*
   ▪   *Remove one feature at a time from S to create smaller subsets $S_1, S_2, …, S_n$*
   ▪   *For Each $S_i$ , if $S_i$ is a reduct according to RST, flag it as a high-priority node.*

*Evaluate and Enqueue:*

- **For Each** *Child Node $S_i$, Compute $f(S_i)$*
- **If** *$S_i$ is flagged as high-priority, Adjust $f(S_i)$ to reflect its importance.*
- *Insert $S_i$ into Q*
- *Re-sort Priority Queue: Sort Q based on $f(S)$.*

In Step 3.3.1, each child node $S_i$ has one less feature than its parent $S$. This is where FR is explicitly done. Here, Rough Set Theory is used for two purposes:

(i)   *It provides a robust starting point $\mathcal{R}_{core}$ that contains indispensable features, ensuring that the essential features are not eliminated in the initial stages.*

(ii)   *It helps to flag high-priority nodes (reducts) during the FR process, guiding the algorithm toward a more meaningful feature subset.*

The BFS evaluates these smaller feature sets and prioritizes them in the queue. If a reduced feature set satisfies the stopping criteria, it is output as the optimal set of features $S_{opt}$ . In essence, this algorithm combines the strengths of both RST and BFS to perform feature reduction in a more effective and informed manner.

### C.  Dynamic Correlated Regularized Random  (DCRRF)

DCRRF is a novel hybrid model that aims to combine the strengths of Correlation-based Feature Selection (CFS) and Regularized Random Forest (RRF) to optimize FS and improve model performance dynamically. By incorporating CFS into the training of each tree within the RRF ensemble, DCRRF aims to maximize model robustness and interpretability. The model takes a reduced feature set $D'$ as input from the BFS-RST Adaptive algorithm. This feature set is standardized or normalized to make feature values comparable using the following steps:

*1) Standardization*: In the standardization process, every attribute is adjusted to have a zero mean and a unit standard deviation. This becomes particularly crucial when dealing with features in disparate units or varying in scale. To standardize a given feature $x$, a commonly used mathematical EQU (22) is typically employed.

$$Standardized(x) = \frac{x - mean(x)}{std(x)} \quad (22)$$

*2) Normalization*: In normalization, the features are typically scaled to lie in a given range [0,1]. This is often beneficial when the algorithm involves distance metrics or when the feature has a skewed distribution. Normalization of a feature $x$ is generally achieved by Eq. (23):

$$Normalized (x) = \frac{x - \min(x)}{\max(x) - \min(x)} \quad (23)$$

The normalized feature set is the foundation for the subsequent feature selection process in the DCRRF model. For each tree $T_m$ in the ensemble, a distinct bootstrap sample $D'_m$ is chosen from this processed feature set. A correlation matrix $Corr(D'_m)$ is then computed for each of these samples, expressed as in Eq. (24).

$$Corr(D_m) = \begin{pmatrix} corr(X_1, X_1) & corr(X_1, X_2) & \cdots & corr(X_1, X_n) \\ corr(X_2, X_1) & corr(X_2, X_2) & \cdots & corr(X_2, X_n) \\ \vdots & \vdots & \ddots & \vdots \\ corr(X_n, X_1) & corr(X_n, X_2) & \cdots & corr(X_n, X_n) \end{pmatrix} \quad (24)$$

Using the CFS criterion $Cr$, a tailored feature subset $F_m$ is dynamically selected for each tree $T_m$. The $Cr_m$ The criterion is calculated as Eq. (25).

$$Cr_m \frac{k_m \cdot \overline{\tau_{cf_m}}}{\sqrt{k_m + k_m \cdot (k_m - 1) \cdot \overline{r_{ff_m}}}}, \quad (25)$$

where, $k_m$ is the number of features in $F_m$, $\overline{\tau_{cf_m}}$ is the average correlation between features and the class label for $D'_m$, and $\overline{r_{ff_m}}$ is the average inter-feature correlation for $D'_m$. This criterion $Cr_m$ is used to select an optimal subset of features $F_m$ for each $T_m$. After this dynamic FS, each tree $T_m$ is trained using its respective selected feature subset $F_m$. The training process adopts the regularized objective function which is shown in Eq. (26).

$$(T_{m,F_m}) = Impurity(T_{m,F_m}) + \lambda Complexity(T_{m,F_m}) \quad (26)$$

Importantly, this objective function is indexed with $F_m$ to signify the dynamically chosen features for that specific tree. The optimal feature set $F^*$ is then determined by an intersection operation over all the dynamically selected feature subsets $F_m$. This can be formally expressed as in Eq. (27).

$$F^* = F_1 \cap F_2 \cap … \cap F_M \quad (27)$$

The dynamic FS introduces diversity among the individual trees, making the ensemble model more resilient and adaptable. It also enables optimized FS, thereby potentially improving both performance and interpretability. The following Algorithm 4 presents the steps involved in the proposed FSM.

### D. Algorithm 4 for DCRRF for Feature selection

*Input:*

- *Reduced Feature set D'*

- *Number of trees M*

- *Regularization parameter λ*

*Output*

- *Optimal set of features $F^*$*

  - *Data Preprocessing*
  - *Normalize or standardize the Feature set $D'$.*

- *Initialize Feature Set*
- *Initialize feature set $F^* = \emptyset$.*

*Ensemble Training and FS*

- *For $m = 1$ to M do the following:*
- *Bootstrap Sample*
- *Draw a bootstrap sample $D'_m$ from $D'$.*
- *Calculate Correlation Matrix*
- *Compute $Corr(D'_m)$ for the bootstrap sample $D'_m$.*
- *FS with CFS*
- *Compute the CFS criterion $Cr_m$ using $Corr(D'_m)$.*
- *Select the optimal feature subset $F_m$ based on $Cr_m$.*
- *Train Regularized RF Tree*
- *Use $F_m$ and $D'_m$ to train a tree $T_m$ with the objective function:*

$$Objective(T_{m,F_m})$$
$$= Impurity(T_{m,F_m})$$
$$+ \lambda\,Complexity(T_{m,F_m})$$

- *Update Feature Aggregation*
- *Update $F^*$ based on $F_m$ using an intersection operation: $F^* = F^* \cap F_m$.*
- *Determine the Optimal Feature Set*

- *Return $F^*$ as the optimal feature set that captures the most important features across the ensemble.*

*D. Data Analysis*

The data analysis phase serves as the final phase of the FSM's pipeline. This phase is significant because it provides the final validation of the feature sets that have been carefully reduced and selected through the preceding stages. The focus here is on evaluating these feature sets within the specific context of the problem, be it classification, clustering, or some other form of ML task. For the purpose of this paper, the efficacy of the proposed FR and FS model is examined using a SVM classifier. The reason for choosing SVM for analysis is twofold. First, SVMs are known for their effectiveness in high-dimensional spaces, making them a suitable choice for testing the quality of the FS. Second, SVMs are robust to overfitting, especially in cases where the number of dimensions is greater than the number of samples, further validating the quality of the FS. The features that have passed through the BFS-RST Adaptive Algorithm and the DCRRF are fed into the SVM model. Performance metrics such as accuracy, precision, recall, and F1-score are computed to evaluate the classifier's performance on the selected feature sets.

## V. EXPERIMENTAL ANALYSIS

*A. Dataset and Implementation*

In the current research, experiments were conducted on four gene expression datasets analyzed by [59], namely: i) Prostate [60], ii) Brain [61], iii) NCI60 [62] and iv) Adenocarcinoma [63]. The specifics regarding the number of instances and attributes for each dataset are detailed in Table. I. All methods and experimental procedures were executed in a Jupyter Notebook environment, utilizing the Python 3.6 language. Computations and tests were carried out on a system equipped with a Windows 10 operating system, powered by a 2.8GHz AMD Ryzen 5 processor, and supplemented by 8GB RAM. Various stages of data processing, feature selection, and machine learning implementations leveraged pre-existing software libraries.

The datasets mentioned above are partitioned into an 80:20 ratio for the purposes of training and evaluation. The SVM model is calibrated using specific hyperparameter settings, as shown in Table II, for optimal performance.

The regularization parameter C is set to 1 to maintain a compromise between maximizing the margin and minimizing the classification error. The Radial Basis Function (RBF) kernel is chosen for its ability to handle both linear and nonlinear patterns in the data [64-73]. The model undergoes 100 iterations during training to ensure convergence and optimal performance. The performance of the proposed feature selection model is compared with RF-based baseline models such as i) Boruta, ii) RRF, iii) VSURF and iv) GRRF. The effectiveness of the SVM, when employing each feature mentioned above, FSM, is assessed through metrics such as accuracy, sensitivity, specificity, precision, and F-score. The results achieved by all the models for the listed performance metrics are shown in Table III.

TABLE I. DATASET DESCRIPTION

| Dataset | Instance | Attribute | Class |
|---|---|---|---|
| Prostate | 102 | 6033 | 2 |
| Brain | 42 | 5597 | 5 |
| nci60 | 61 | 5244 | 8 |
| Adenocarcinoma | 76 | 9868 | 2 |

In both the Prostate and Brain datasets, as shown in Fig. 2 and Fig. 3, DCRRF demonstrates superior performance across multiple metrics. For the Prostate dataset, DCRRF achieves an accuracy of 0.9514, edging out the second-best model, RRF, by 0.37%. It also excels in sensitivity with a score of 0.9582, which is notably higher than RRF's 0.9413. Regarding specificity and precision, DCRRF performs on par with RRF and GRRF, highlighting its balanced efficiency in identifying True Negatives (TN) and minimizing False Positives (FP). The F1-score for DCRRF is the highest at 0.9534, and it further improves to 0.9562 when augmented with BFS-RST, all while requiring only 12 selected features. For the Brain dataset, DCRRF again leads in accuracy and sensitivity, with scores of 0.9073 and 0.8802, respectively. While its specificity score of 0.9292 is not the highest, it still indicates a balanced

performance compared to RRF's higher specificity but lower sensitivity. In the precision metric, DCRRF is slightly edged out by VSURF but still performs strongly with a score of 0.8986. Its F1-score stands at 0.8894, and when combined with BFS-RST, it further improves to 0.9003, again achieving this with fewer features. These metrics collectively indicate that DCRRF, particularly when enhanced with BFS-RST, offers balanced, efficient, and robust performance across both datasets in FS and classification tasks.

In the NCI60 dataset, as shown in Fig. 4, DCRRF stands out with an accuracy of 0.9283, outperforming the next-best model, RRF, which scores 0.9157. While its sensitivity score of 0.8765 isn't the highest, it's balanced by a strong specificity of 0.9405. The model's F1-score is 0.8885, which is superior to both Boruta's 0.8408 and RRF's 0.8823. Its precision score

of 0.9008 is commendable, though it is slightly eclipsed by Boruta's 0.9660. Notably, when integrated with BFS-RST, the model's F1-score rises to 0.8960 with a reduced feature count of 53. In the Adenocarcinoma dataset, as shown in Fig. 5, DCRRF maintains its strong performance with an accuracy of 0.9101, closely followed by RRF at 0.9098. DCRRF shines in sensitivity with a score of 0.8977, substantially better than Boruta's 0.8027 and slightly edging out RRF's 0.8933. With well-rounded scores in specificity (0.9367) and precision (0.9274), it also maintains a balanced F1-score of 0.8992. When enhanced by BFS-RST, the F-score improves to 0.9179 with just 14 FS, demonstrating the model's efficiency and efficacy in FS and classification.

In a comprehensive review of the results for OOB error, time consumption and AUC efficiently, as shown in Fig. 6 to Fig. 8, BFSRST+DCRRF consistently delivers outstanding performance across all datasets, excelling in AUC and minimizing OOB errors. For instance, in the Prostate dataset, this model achieves the highest AUC of 0.893, using the fewest features (12) and an OOB error of just 0.11. The computational time, although slightly higher than its DCRRF counterpart, remains modest at 0.06 minutes. Similarly, in the Brain and NCI60 datasets, BFSRST+DCRRF again tops the chart in AUC, recording 0.911 and 0.914, respectively, while maintaining low OOB errors and computational times. On the Adenocarcinoma dataset, it achieves an AUC of 0.902, leading the pack. VSURF performs well but is computationally expensive, particularly noticeable in the Prostate and Adenocarcinoma datasets, where the computational times are 0.08 and 0.1 minutes, respectively. DCRRF alone also shows promise, particularly in the NCI60 and Adenocarcinoma datasets, where it nearly matches the performance of its BFSRST-enhanced version but with more features. Boruta and RRF, although competent, generally lag in AUC and OOB error metrics. Notably, GRRF consistently demands fewer features but doesn't offer a compelling trade-off regarding AUC or OOB error. The BFSRST+DCRRF model demonstrates superior, balanced performance across all four datasets.

## VI.  CONCLUSION

Handling big data with high dimensions presents unique challenges, particularly regarding computational resources and predictive accuracy. To address these issues, an all-encompassing Feature Selection Model (FSM) has been developed. This system incorporates initial data cleaning and feature reduction through Best-first Search and Rough Set Theory (BFS-RST). It culminates in deploying a specialized Random Forest (RF) algorithm called Dynamic Correlated Regularized Random Forest (DCRRF). Each stage of this four-tiered architecture serves a specific function, from initial data refinement to advanced FSM. The final assessment phase employs a Support Vector Machine (SVM) classifier to evaluate the quality and utility of the selected features rigorously. When tested against existing RF-based FSM on four gene expression datasets, this innovative approach improved computational efficiency and classification accuracy. The system's enhanced performance indicates its potential as a scalable solution for tackling the unique challenges presented by high-dimensional big data across various applications.

# Fortifying Against Cyber Fraud: Instrument Development with the Protection Motivation Theory

Norhasyimatul Naquiah Ghazali, Syahida Hassan, Rahayu Ahmad
School of Computing, Universiti Utara Malaysia (UUM), Kedah, Malaysia

*Abstract*—Cybersecurity has become a trending topic in this technological era. Crimes keep happening in this medium and bring challenges for researchers and IT professionals worldwide to find the best solution to overcome this issue. Crimes primarily related to fraud on e-services have become a red alert that needs to be a concern for netizens. Instead of simply believing in the human-created network and system, individuals or users should acquire and implement protective behaviours for themselves. Thus, a few factors such as source credibility, perceived value of data, wishful thinking, perceived threat severity, perceived threat vulnerability, maladaptive rewards, and response efficacy have been investigated in this study, and the Protection Motivation Theory is used to counter cybersecurity issues faced by users. A tool has been created to facilitate the collection of empirical data necessary for verifying the proposed model. Analysis such as Content validity index (CVI) and Scale-level CVI (S-CVI) have been used to validate the item. The findings indicate that one of the items does not meet the criteria, however, it has been suggested by experts to revise and make it comprehensible to use for the main study. This paper also includes a discussion part regarding the implications of the experts' evaluation. This study, in particular, can help boost the understanding of cyber fraud and the proper methods, a user can employ to avoid becoming a victim.

*Keywords*—*Cyber security; cyber fraud; e-services; instrument development; content validity; Protection Motivation Theory (PMT)*

## I. INTRODUCTION

Nowadays, people live in a networked culture where cyber technology has enabled cloud computing, online shopping, and other activities [1]. Despite the various advantages of technology in terms of commerce, communication, education, and entertainment, as noted by Bulgurcu et al. [2], it also presents some drawbacks. The unbridled expansion of digital technology has contributed to the correspondingly burgeoning problem of cyber fraud. This development is inextricably linked to intricate complications and perils that are engendered by the anonymous and rapid nature of the internet, which has been mentioned by Khalifa et al. [3] resulting in an ever-widening conundrum of cyber criminality. Annually, Kuru and Bayraktar [4] stated that cybercriminals devise novel tactics and techniques to deceive potential targets. People around the world are concerned about various issues due to cyber fraud [5], which also occurs in Malaysia. Although many countries have taken steps to make the cyber world more secure, Sorell and Whitty [6] agreed that there is still much work to be done to find a long-term solution to the security issues that plague cyberspace.

In the meantime, some consumers are unaware that they use e-services in their everyday lives. e-Services, which encompass all electronic services such as online bill-paying applications, government e-services, online banking, and online shopping [7] make it easier for users to conduct any online activity. Although the government of Malaysia has put in place various controls and safeguards to protect its citizens online, the rate at which cybercrimes are committed continues to rise in tandem. For instance, in 2022, there were 4,912 reported cases of the Macau Scam, also known as impersonation or fraud calls, which caused a loss of RM199.8 million, whereas e-commerce crimes accounted for 5,397 cases and a loss of RM71.6 million.

Furthermore, e-financial fraud or phishing has racked up as many as 543 cases, resulting in a loss of RM40.5 million [62]. Additionally, e-government, e-health, online shopping, and online banking have gradually changed into e-services which have been stated by Yesuf and Probst [8] throughout domains and industries as a means of optimising processes and facilitating engagement with both established and cutting-edge services of organisations. They also agreed [8] that the new systems and related services contain vulnerabilities that fraudsters might exploit to cause billions of dollars in losses to the global economy. In addition, [8] also mentioned the e-services platform developed for users' convenience has become insecure in recent years.

Fraud involving a cyber-aspect has shown a marked rising tendency, but traditional fraud has only declined a little. This pattern is expected to persist as more online transactions and banking are conducted. This tendency has made individuals fearful of online transactions, but not everyone takes action or realises the severity of the consequences when they become victims. According to a previous study by Button et al. [9], [10], being a victim of cyber fraud has negative consequences, such as psychological impact, financial losses, theft of intellectual property, invasion of privacy, and a loss of confidence and trust. Therefore, it is imperative to reduce the likelihood of becoming a target of fraudulent activities.

Next, Section II will provide a review of the relevant literature. Section III will discuss the methodology that has been employed, followed by Section IV, which presents the analysis and results. In Section V, the paper will deliberate on the research findings and acknowledge the study's constraints. Finally, Section VI will offer a conclusion, including recommendations for potential future research.

## II. RELATED WORK

### A. Underpinnings Theory

According to previous studies, there has been some investigation into the association between individual safety and protection motivation behaviour. Such as Anderson and Agarwal [11] discussed factors of computer safety, Li et al. [12] investigate factors of cybersecurity behaviour, Belanger et al. [13] explore factors in information security, Boss et al. [14] examine factors that motivate protective security behaviour, Chen et al. [15] discuss online scams and protection behaviour, Haag et al. [16] discuss protection motivation in information and lastly, Martens et al. [17] comparing factors intention of taking security measure against cybercrime. Protective behaviour is crucial for combating cyber threats, as people frequently experience connectivity issues when establishing connections between their devices and internet-based systems. Furthermore, Liang and Xue [18] stated that it plays a vital role in ensuring the safety of those who use the internet via various electronic devices in their daily lives. Multiple theories, including the theory of planned behaviour (TPB), rational choice theory (RCT), general deterrence theory (GDT), technology threat avoidance theory (TTAT), routine activity (RAT), and protection motivation theory (PMT), have been employed by information security researchers. For instance, Fansher and Randa used (RAT) [19], Kirwan et al.,[20] also used RAT, Rogers and Prentice-Dunn used PMT [21], Chen and Liang used TTAT [22], Tan et al. [23] used TPB, and last but not least Martens et al. [17] also using PMT to explain the reasons behind people's protective behaviours and intentions. These hypotheses are grounded in various disciplines, including computer science, criminology, business, and psychology. The cybersecurity issue has also been addressed by integrating and adapting the system to the current environment.

However, despite all the theories, this study discusses PMT, one of the most commonly used to examine protection behaviour. For instance, Haag et al. [16] use PMT to investigate information security, Martens et al. [17] use PMT for comparing scams, malware and cybercrime in general, Mohammed et al. [24] use PMT to identify dimension of protection behaviour, Warketin et al. [25] use PMT to explore protective behaviour, Jansen and Schaik [26] use PMT to study on phishing, and last but not least De Kimpe et al. [27], use PMT in cybercrime context. As protection behaviour is crucial in the digital world nowadays, a problem may arise if one does not know how to protect oneself when connecting with this digital world. Few studies also contend that it is unclear regarding the decision-making process individuals undergo when determining whether or not to take measures to safeguard themselves against cybercrime [27], [28]. Meanwhile, another study by Warkentin et al. [25] stated that PMT also plays a vital role in developing communication techniques that encourage individuals to take precautions against cyber threats. Thus, it is necessary to investigate what factors influence individual intentions regarding protection behaviour.

### B. PMT in Comparison with Past Studies

PMT consists of two appraisals, which are threat and coping. In PMT, threat appraisal was initially defined as a cognitive process by which an individual assesses a specific threat and the risk it poses [17]. It consists of two factors [17]: perceived severity and vulnerability. Perceived severity is the extent to which individuals perceive that the implications of a risk would be harmful, which increases their desire to take precautions [28]. Studies such as Dang-Pham and Pittayachawan [29], Losonczi [30], and Jansen et al. [31] have supported this statement.

Meanwhile, perceived vulnerability refers to the likelihood of being victimised by a particular threat. A previous study by Li et al. [32] found that users' ability to perceive the risk of a cyber-attack incident and identify effective preventive measures was insufficient, which subsequently affected their protective behaviour. This outcome holds notable significance. Another study by Thompson et al. [33] also had significant results where a user thought they were expected to have security risks and implied protection behaviours in their computing. Many studies such as Haag et al. [16], [24], [34] indicate that this construct plays an important role and is also one of the direct indicators that influence the motives for protection studies.

Besides, maladaptive rewards are also of crucial part of intention protection behaviour [35]. Maladaptive rewards mean users can save time or money by ignoring secure information management best practices [14], [21]. However, previous research such as Hassandoust et al. [35], Fisher-Prebler et al. [36], Chenoweth et al. [37] and Bax et al. [38] have not addressed how maladaptive rewards affect intention protection behaviours Furthermore, although PMT has been used to investigate several aspects of information security, researchers have focused on information security challenges in organisational contexts rather than specific ones. In addition, prior studies [18], [39] employing PMT to explore individuals' information security protective behaviours have yielded contradictory findings about the significance of the protection motivation mechanism. Therefore, this study aims to examine if maladaptive rewards affect the intended protection behaviour of e-services users.

As previously indicated, threat appraisal and maladaptive rewards have been discovered to influence protection. However, there is a lack of clarity on the antecedent elements that influence threat appraisal and maladaptive rewards. This issue has come to the attention of [16], who pointed out that most PMT research has concentrated on coping strategies and threat evaluation rather than antecedent variables. Additionally, as time progresses and technology keeps improving, it may become vital to investigate the antecedents to discover knowledge-enhancing insights. Therefore, this study proposes three antecedents for threat appraisal: (i) source credibility, (ii) perceived value of data, and (iii) wishful thinking, which will be explained next.

First, it is crucial to identify the origins of information since this can be an essential aspect of user protection and the initial step in determining the following action or behaviour. People are rationally more likely to defend themselves when

the source is unknown, and vice versa when the source's credibility can be verified. This study will investigate email source credibility in terms of where information comes from, as it has been recently highlighted as an unstudied issue in cybersecurity [16], [40].

Secondly, to analyse how they respond to a threat, it is necessary to comprehend their perception of data's value. Individuals possessing substantial wealth demonstrate a heightened awareness of security risks and are proactive in implementing preventive measures to mitigate such threats [41], [42]. Several past studies by [42], [43], have highlighted the perceived value of data from personal devices, which has a significant effect on intention protection. Considering that Western and Eastern societies have different levels of cultural and economic development, there is a pressing need for additional research in the context of Malaysia's growth.

Additionally, this study will investigate wishful thinking (WT) as an antecedent, which identifies beliefs as a factor that can influence maladaptive rewards. Wishful thinking is defined as an individual's "wish" that the IT threat would go away by itself without taking action [22], [44]. As a result, people become less concerned about information accuracy or objective probabilities [22]. For example, when users' wishful thinking is high, they will think that cyber threats do not severely impact them and will go away without action. As maladaptive rewards are about avoiding any safety or prevention measures to protect the individual from threats, this wishful thinking will significantly result in maladaptive rewards.

The previous paragraphs outlined the antecedents of threat appraisal and maladaptive rewards that will be investigated in this research. Alongside this, the appraisal of coping constructs will be examined. A coping appraisal is defined as the process by which an individual examines numerous protective techniques and avoids the threat [17]. Initially, PMT includes an individual's self-efficacy (the personal ability to implement a protection method), response efficacy (the effectiveness of approaches), and response cost (the concern about the potential expense associated with performing a recommended protective response) as the original constructs of the coping appraisal [16], [17], [26], [45]. These constructs influence a person's coping mechanisms towards cyber fraud. However, several studies have neglected to operationalize response costs due to their intricate and uncertain nature, as highlighted by [25], [46]. Moreover, current research indicates that self-efficacy has diminished explanatory power, resulting in a lack of significance and an inverse relationship [17], [29], [47], [48]. Therefore, this study only includes response efficacy as the coping appraisal.

## III. METHODOLOGY

### A. Instrument Development

The instrument is essential because it lets individuals know how well a study was done. If the criteria for the instrument are good, then the quality of the research is also good. If the criteria are flawed, then the quality of the research will be questionable. As the instrument turns fact into data, using a good one that is valid, reliable, and has a good level of difficulty will get data that reflects the facts or actual environments in the field [49]. However, a poor instrument will cause poor results in the study. In that case, the information gathered is also wrong or does not match the field's facts, leading to the wrong conclusion. Consequently, the development of instruments, as stated by Sekaran and Bougie [50] is an essential component of any research project and part of the research procedure.

This study aims to develop a data collection instrument that can be used to evaluate a proposed model and analyse the influence of relevant factors on the intention to protect behaviour. To create the instrument, the variables of the suggested model are operationalized within the context of the study. The instrument is used to gather empirical evidence to test the proposed framework as shown in Table I and Fig. 1.

TABLE I.        DEFINITION OF CONSTRUCT

| Construct | Definition | Source |
|---|---|---|
| Sources credibility | The information that a user receives from a person, authority, or source that they assume to be a reliable source of information | [38], [45] |
| Perceived value data | The emotional and monetary values of a user's data that are stored in e-services applications are referred to as perceived value data. | [29] |
| Wishful thinking | A person "wishes" that an information technology threat will disappear without requiring any action from him or her | [22], [44] |
| Perceived threat severity | The degree to which he or she recognises the presence of cyber fraud elements that represent a significant risk to him or her. The circumstance may prompt the user to take protective action. | [51], [52] |
| Perceived threat vulnerability | Relates to a user's perception of information security risks | [26] |
| Maladaptive Rewards | Refer to a circumstance in which a user feels he or she will receive additional benefits without adopting precautions. | [14], [29], [53] |
| Response efficacy | Relates to a user's reliance on the effectiveness of a cybersecurity suggestion | [54] |
| Intention protection behaviour | A term used to describe a user's instinct to protect themselves from an apparent danger | [14] |

After that, the researchers extract the original measurements used in past literature across several different fields and turn them into items. Due to that, the reliability of the instrument can be established [55]. Nevertheless, to increase the validity of the instrument, content validity testing needs to be carried out by experts.

### B. Content Validity

Content validity determines and assesses the degree to which the dimensions and components of a concept can be accurately and effectively defined [50]. An additional purpose of content validity is to ascertain the validity of each instrument item that corresponds to the measured construct [56]. Construct validity offers evidence or information to demonstrate that the items in a scale are interrelated and accurately measure the intended construct [49]. The greater the amount of content validity evidence gathered, including expert evaluation, the greater the researcher's confidence in

the constructed instruments' validity [57]. The panel of specialists can be classified into two groups, namely, professional experts and field experts [58].

Thus, before the process of determining the content validity of this study began, four expert panels were employed to evaluate the items and ensure the content validity of the instrument. A small discussion with four field experts regarding the item was conducted. This is to ensure the construct is well organised and the item represents the dimensions' possible measures. The clarity and relevance of the item have also been analysed. The four panels of professional university experts involved two senior lecturers and two associate professors.

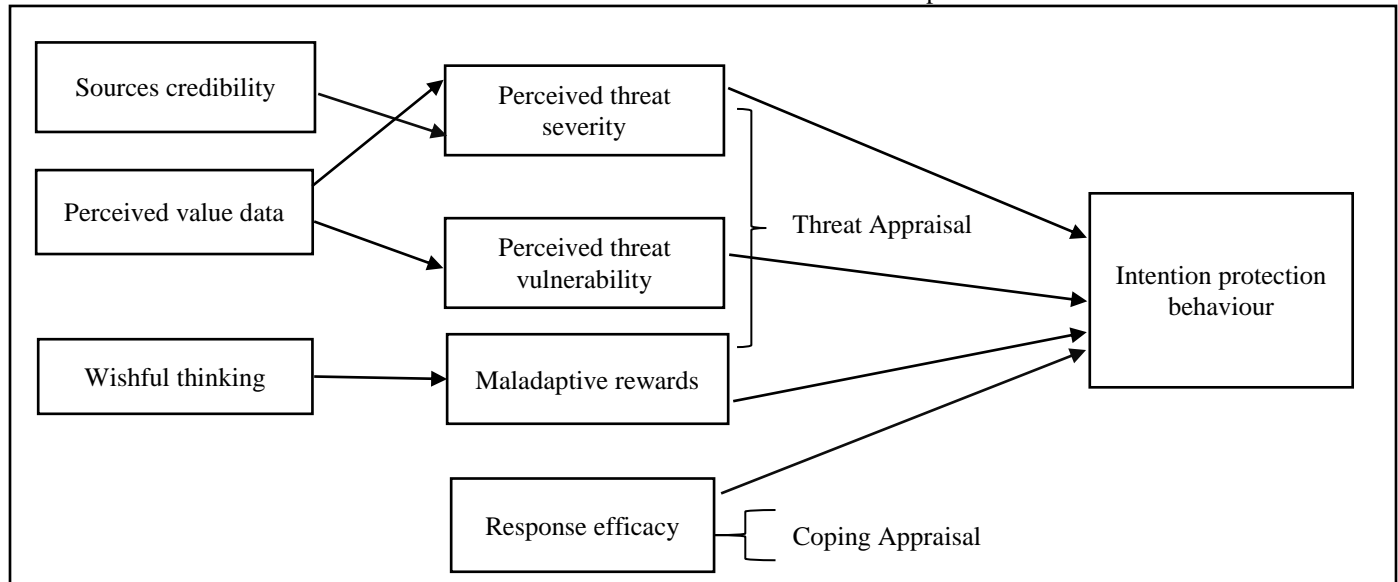

Fig. 1.   This study aims to develop.

In order to make the evaluation of the content validity easier, a form was designed to allow the experts to evaluate the relevance and clarity of the measurements. The form was designed by assigning a number (1, 2, or 3); 1 means the item is a Poor Match (remove item), 2 means a Modest Match (maintain item but needs some refining), and 3 means a Perfect Match (maintain the item as it is) so that the experts can evaluate the relevance and clarity of each item as shown in Table III.

## IV.   ANALYSIS AND RESULT

### A.  *Validity Analysis*

An analysis was conducted on the relevance and clarity assessments made by the experts for each item of the construct. CVI contains two components: Item-level CVI (I-CVI), which pertains to the content validity of individual items, and Scale-level CVI (S-CVI) evaluates the content validity of the entire scale [59]. The calculation of I-CVI involves dividing the number of experts who deemed the item relevant by the total number of experts who provided ratings. There are two techniques to calculate the S-CVI. One is known as S-CVI/UA and requires approval from all the experts. It is the proportion of elements on an instrument for which all experts acknowledge they are relevant. The other method is calculating the average I-CVI over all of the items, referred to as the S-CVI/Ave. The CVI for the current study instrument was determined, considering the relevance and clarity of each item. An overview of the CVI indices and a summary of the number agreement among experts may be found in Table II.

TABLE II.      CONTENT VALIDITY OF INDIVIDUAL ITEMS (I-CVI)

| Construct | Item No. | Summarize of No. Agreement | | I-CVI | |
|---|---|---|---|---|---|
| | | R | C | R | C |
| Source credibility | 1 | 3 | 3 | 1 | 1 |
| | 2 | 2 | 2 | 0.5 | 0.5 |
| | 3 | 3 | 3 | 1 | 1 |
| Perceived value data | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| Wishful thinking | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| Perceived threat severity | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| | 4 | 3 | 3 | 1 | 1 |
| Perceived threat vulnerability | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| Maladaptive rewards | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |

| | | | | | |
|---|---|---|---|---|---|
| | 4 | 3 | 3 | 1 | 1 |
| | 5 | 3 | 3 | 1 | 1 |
| Response efficacy | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| Intention protection motivation | 1 | 3 | 3 | 1 | 1 |
| | 2 | 3 | 3 | 1 | 1 |
| | 3 | 3 | 3 | 1 | 1 |
| | 4 | 3 | 3 | 1 | 1 |
| | 5 | 3 | 3 | 1 | 1 |
| R= Relevance C=Clarity | | | | | |

The results demonstrate that the I-CVI for one question does not meet the criteria for item acceptability recommended by [59], [60], which states that it must be 1 for 3-5 experts to be considered acceptable. This pertains to the relevance of the items. According to the S-CVI figures, SCVI/UA and S-CVI/Ave are 0.97 and 0.98, respectively (see Table III). The

lowest value of acceptability for S-CVI as determined by [61] is 0.80, and these results are significantly higher than that limit.

Besides that, the results of calculating the I-CVI for the clarity of the items suggest that one of the items is not clear enough (0.5) (see Table II). The experts gave their feedback to help make the items more comprehensible. In addition, the S-CVI/UA and S-CVI/Ave ratios for the items' clarity reveal satisfactory levels with corresponding values of 0.97 and 0.98. (See Table III).

TABLE III.     SCALE-LEVEL CONTENT VALIDITY INDEX (S-CVI)

| | **Relevance** | **Clarity** |
|---|---|---|
| S-CVI/Ave | 0.98 | 0.98 |
| Total agreement | 28/29 | 28/29 |
| S-CVI/UA | 0.97 | 0.97 |

Hence, the instrument was amended in line with the expert's feedback. Table IV indicates the updated scale measurements.

TABLE IV.     UPDATED MEASUREMENTS

| Constructs | Original | Revised |
|---|---|---|
| Source credibility | I believe emails from the Malaysian government domain (.gov) are credible. | I believe emails from all e-Services domains (.gov.my; .edu.my; .com.my) are credible. |
| | I believe emails from the Malaysian government domain (.gov) tend to be free from grammatical errors. | I believe emails from all e-Services domains (.gov.my; .edu.my; .com.my) tend to be free from grammatical errors. |
| | I believe emails from the Malaysian government domain (.gov) tend to have a sense of urgency. | I believe emails from all e-Services domains (.gov.my; .edu.my; .com.my) tend to have a sense of urgency. |
| Perceived value data | I perceive the importance of regarding the security protection of my data in e-services. | I perceived the importance of security protection towards my data in e-Services |
| | I am aware of the potential risk of monetary loss if there are breaches of my personal data**.** | I am aware of the potential risk of monetary loss if there are breaches of my personal data. |
| | I perceived the e-services highly guarantee the confidentiality of my personal data. | I perceived the e-services could fully guarantee the confidentiality of my personal data |
| Wishful thinking | I wish I could use e-services without increasing my security protection. | I wish I could use e-Services without increasing my security protection. |
| | I wish that the threat would go away or somehow not affect me. | I wish that the threat would go away by itself. |
| | | I wish that the threat would not affect me. |
| | I hope I will not encounter any cyber threat situations. | I hope I will not encounter any cyber threat situations. |
| Perceived threat severity | I believe that being a victim of cyber fraud in e-services is a serious problem for me. | I believe that being a victim of cyber fraud in e-services is a serious problem for me. |
| | I believe that the time/masa loss to recover the damages (e.g., money loss, data loss) after being a victim of cyber fraud is a serious problem. | I believe that the time lost to recover the damages after being a victim of cyber fraud is a serious problem. |
| | I believe that my productivity/effort loss to recover the damages (e.g., loss of income) from being a victim of cyber fraud is a serious problem. | I believe that my productivity/effort loss (e.g., loss of income) to recover the damages from being a victim of cyber fraud is a serious problem. |
| | I believe that the data/information loss from being a victim of cyber fraud is a serious problem. | I believe that the data/information loss from being a victim of cyber fraud is a serious problem. |
| Perceived threat vulnerability | I am exposed to the cyber fraud threats of e-services. | I am exposed to the cyber fraud threats of e-Services. |
| | I am at risk of being victimised by cyber fraud attackers. | I am at risk of being victimized by cyber fraud attacker |
| | I will likely become a victim of cyber fraud. | I can become a victim of cyber fraud |
| Maladaptive rewards | I can save my time if I'm not using any preventive countermeasures application (e.g.: antivirus, anti-malware). | I can save my time if I am not using any preventive countermeasures application (e.g.: antivirus, anti-malware). |
| | I can save my money if I'm not using any preventive countermeasure applications. | I can save my money if I am not using any preventive countermeasure applications. |
| | I will be better informed of the security risk if I'm using | I think it is a waste of effort to spend more money on |

| | | |
|---|---|---|
| | any preventive countermeasure applications. | anti-virus software to increase the protection against cyber fraud |
| | I will spend less effort if I do not perform the recommendations of the preventive countermeasure applications. | I will spend less effort if I do not perform the recommendations of the preventive countermeasure applications. |
| | I will feel less stressful if I do not perform the recommendations of the preventive countermeasure applications. | I will feel less stressful if I do not perform the recommendations of the preventive countermeasure applications. |
| Response efficacy | When using a preventive countermeasures application, a computer's data is more likely to be protected. | When using preventive countermeasures applications, computer data is more likely to be protected. |
| | Performing any cybersecurity recommendations would reduce the chance of myself from becoming a cyber fraud victim. | Performing any cybersecurity recommendation would reduce the chance of me from becoming a cyber fraud victim. |
| | Performing any of the provided recommendations make me feel safe from cyber fraud attack. | Performing any of the provided recommendations makes me feel safe from a cyber fraud attack |
| Intention protection Motivation | I will update my knowledge to use e-services safely. | I will update my knowledge to use e-Services safely. |
| | I will likely engage in activities that protect my personal information from cyber fraud when I use e-services. | I will likely engage in activities that protect my personal information from cyber fraud when I use e-services. |
| | I intend to protect myself from cyber fraud when I use e-services. | I intend to protect myself from cyber fraud when I use e-Services. |
| | I am willing to spend more in order to protect myself from cyber fraud when I use e-services. | I am willing to spend more money in order to protect myself from cyber fraud when I use e-Services |
| | I will likely take precaution that protects my personal information from cyber fraud when I use e-services. | I will likely take precaution that protects my personal information from cyber fraud when I use e-Services. |

## V. DISCUSSION

Using the PMT point of view, through this instrument development, this study aims to investigate the factors of human behaviour that can lead to the intention to protect oneself from becoming a victim of cyber fraud while participating in online activities. In the first part of this research study, an investigation into the influence of threat appraisal on the intention protection behaviour of the user when utilising e-services will be carried out. In addition, maladaptive rewards will also be investigated, [14], [16], [37], [38] as there have been numerous debates over this issue in past studies.

Practically, the results of this study will be beneficial to individuals in the sense that they will gain an understanding of the kinds of factors that can make them susceptible to fraudsters and the kinds of responses they should make when confronted with a situation in which they are at risk of being victims of cyber fraud. Before becoming the next victim of cyber fraud, consumers must recognise how their habits can either help or threaten them. With these characteristics, enhanced protection can be created, preventing consumers from falling prey to fraudsters. In addition, these studies will have made significant contributions to the development of PMT-based information security research. It will investigate new antecedent factors incorporated into PMT as new components.

In addition, this research creates a tool for measuring the model's constructs. The items for each construct were drawn from relevant theories and literature and then revised to reflect the topic of the study. The validity of the measurement may be compromised by adapting the original items to the context of the study. Therefore, content validation was done to verify that the items adequately reflected the subject domain. Initial evidence of construct validity is provided by content validity. In addition, it gives indicators of the items' representativeness and clarity and contributes to the enhancement of the instrument by considering the suggestions of experts [62].

In the current study, four experts evaluated the items' relevance and clarity. The results indicated that 28 items were accepted, except one item was not considerably clear (in terms of wording); hence, the item was graded as "keep it but refine it to the corresponding construct". These elements were updated in response to the feedback of the experts. All item and construct comments were considered in the amended version of the instrument. These components were extracted from the relevant literature, considering the cyber fraud environment's setting.

Lastly, despite the careful expert selection, the study can be enhanced by involving a more diverse range of experts for additional insights and improvements.

## VI. CONCLUSION

To summarise, the findings of this study can provide a new instrument construct base for future studies. All 29 items will be subjected to a pilot testing phase by administering the questionnaire to the designated participants. Subsequently, this pilot study will entail subjecting the items to further rigorous statistical analyses aimed at substantiating their reliability and validity for inclusion in the primary research investigation.

Academically, this study would benefit the body of knowledge, including institutions, colleges, and universities, because it can provide new knowledge for academics who intend to publish it in an open-access journal or send it to a publisher. The entire variable will be examined, and the results might be used to increase the output of research on this subject in Malaysia, specifically for academic institutions. In addition, it enables academicians to create substantial countermeasures against cyber fraud in Malaysia.

Besides that, in order to enhance the explanatory capacity of the model, it may be expedient to incorporate supplementary variables to expand the framework. This could involve broadening the scope of constructs beyond those pertaining to source credibility, maladaptive rewards, wishful thinking, perceived vulnerability, perceived severity, and

response efficacy. Lastly, a greater understanding of this kind of behaviour will aid professionals in designing, developing, and executing new methods or enhancements for e-service users. This study was conducted in support of a government aiming to develop and maintain a safer cyberspace to achieve national sustainability, social well-being, and wealth creation. Perhaps this research will aid in reducing the losses incurred by the government as a consequence of cyber fraud.

# A Model for Pervasive Computing and Wearable Devices for Sustainable Healthcare Applications

Deshinta Arrova Dewi[1], Rajermani Thinakan[2], Malathy Batumalay[3], Tri Basuki Kurniawan[4]

Faculty of Data Science and Information Technology-INTI International University, Nilai, Malaysia[1, 2, 3]
Faculty of Science and Technology-Bina Darma University, Palembang, Indonesia[4]
Faculty of Technology and Information Science-Universiti Kebangsaan Malaysia (UKM), Bangi, Malaysia[4]

*Abstract*—The user's demands in the system supported by the Internet of Things are frequently controlled effectively using the pervasive computing system. Pervasive computing is a term used to describe a system that integrates several communication and distributed network technologies. Even so, it properly accommodates user needs. It is quite difficult to be inventive in the pervasive computing system when it comes to the delivery of information, handling standards, and extending heterogeneous aid for scattered clients. In this view, our paper intends to utilize a Dispersed and Elastic Computing Model (DECM) to enable proper and reliable communication for people who are using IoT-based wearable healthcare devices. Recurrent Reinforcement Learning (RRL) is used in the suggested model and the system that is connected to analyze resource allocation in response to requirements and other allocative factors. To provide effective data transmission over wearable medical devices, the built system gives managing mobility additional consideration to resource allocation and distribution. The results show that the pervasive computing system provides services to the user with reduced latency and an increased rate of communication for healthcare wearable devices based on the determined demands of the resources. This is an important aspect of sustainable healthcare. We employ the assessment metrics consisting of request failure, response time, managed and backlogged requests, bandwidth, and storage to capture the consistency of the proposed model.

*Keywords—Internet of Things; wearable devices; pervasive computing; sustainable healthcare; healthcare applications; public health; health system*

## I. INTRODUCTION

The world has been modernized and changed into a pervasive computing system environment because of recent advancements in many applications that are capable of sensing and interacting everywhere. The devices that can work wirelessly and are enhanced with sensing, processing, and decision-making capabilities are integrated with real-world items to generate the correct service delivery for the Internet of Things. This kind of service is in high demand among businesses in the healthcare, IT, communication, and multimedia sectors. The needs of the user are met through rapid service delivery and improved "querying requests."

Integrating a wide range of devices, from sensors to intelligent machines, is necessary to access the network and all its resources. Consumers were granted unrestricted, global freedom to use resources anywhere in the world through increasing communication through the end users' devices. The device allowed a wide range of applications by connecting to the clients through external networks and services and employing adaptive conveyance mechanisms.

To provide pervasive services, it is crucial for users to concentrate on the service and receive reliable services that meet their needs. The ability to employ heterogeneous devices as a form of service is enabled by a pervasive computing environment. The services are delivered through networks that integrate the communication interface of various service systems and the fundamental systems to expand communication.

In a distributed system, pervasive computing has the authority to employ several computing paradigms to meet user expectations. It offers a variety of services, including simultaneous user access, service configuration, computer-related inquiries, resource allocation, and resource distribution. The data were scattered throughout numerous healthcare sectors, and the Internet of Things' flexible sensor network was used to combine a variety of sensors to facilitate data conveyance. The software-defined network (SDN), mobile networks, medical sensor data centers, distributed servers, and edge processing networks were all included to achieve a resilient service for edge users.

Extending trustworthy and adaptable communication is crucial but difficult and complex in the case of the large-scale pervasive computing environment. A novel dispersed and elastic computing model (DECM) has been created by previous researchers at [1] for the IoT-based wearable healthcare device in the pervasive computing environment. The developed system uses Recurrent Reinforcement Learning (RRL) to analyze how resources are distributed in accordance with demands and other allocative factors.

The pervasive computing system delivers services to the user in the end with a reduced amount of latency and an increased rate of communication for the medical wearable devices based on the calculated resource requirements. The designed system places additional attention on managing mobility in addition to resource distribution and distribution for proper data transmission over the wearable healthcare device.

By balancing the flow of requests across the network, the planned layout accelerates the processing of requests. The RRL is used in the request balancing process. As a result, the volume of requests handled increases while the response time decreases. By employing RRL to optimize the storage, the

bandwidth rate is increased. Additionally, this paper analyses the design empirically and compares the results to existing methods.

This paper is organized as follows. Section II explains related works done by the previous research. Section III discusses the computing model used in our study. Section IV highlights the results and discussion of our experiments. Section V is the conclusion and a brief of future works.

## II.   RELATED WORKS

Azariadi et al. [2] have suggested a method for deciphering the heartbeat from the ECG and further implemented the method to a wearable medical device that does continuous 24x7 monitoring. The review of WHCD is presented by Haghi et al. [3] in both academic publications and for-profit endeavors. The method was developed to get around the challenges in device data mapping and matching using the enhanced petri net service model, according to Lomotey, et al.'s [4] presentation of an IoT architecture for data streaming delivering traceability of data route from the originating source to the Health data center."

Al-Makhadmeh, et al. [5] use the deep learning method to learn from past analyses and predict the course of cardiac disease. Higher-order Boltzmann deep belief neural networks were used by the system. A "Systematic Review of Wearable Sensors and IoT-Based Monitoring Applications for Older Adults-a Focus on Ageing Population and Independent Living" is presented by Baig et al. in their paper [6].

Yang et al.'s [7] "introduced a new method for ECG monitoring based on IOT techniques, in which ECG data are gathered using the wearable monitoring node and are directly transferred to the IOT cloud using Wi-Fi. In the IOT cloud, both HTTP and MQTTP are utilized to provide consumers with timely and illustrative ECG data. The "Smart wearable system for safety-related medical IoT application: Case of epileptic patient working in an industrial environment" was carried out by Hayek, et al. [5]. The remote care-taking applications Silva, et al. [8] "designed could be implemented for patients. This system is used as a waist belt and shoe with embedded sensors.

The Compact Wearable Meta Materials Antennas for Energy Harvesting Systems, Medical, and IoT Systems are done by Sabban, Albert, et al. Dey, Nilanjan, and colleagues [9,10] described the difficulties and potential uses of implantable and wearable medical devices. The IoT-Based Noninvasive Wearable and Remote Intelligent Pervasive Healthcare Monitoring Systems for the Elderly People were presented by Balasubramaniam, et al. Greco, Luca, and colleagues in [11] presented Trends in IoT-based solutions for health care: moving AI to the Edge. Big Data Business Analytics as a Strategic Asset for the Health Care Industry was explored by Smys, S., et al. The Cloud based Internet of Things for smart connected objects"was presented by Duraipandian et al. The "Effective Fragmentation Minimization by Cloud Enabled Back up Storage" was carried out by Pandian, A. Pasumpon, et al. The Special Section on Innovative Engineering Solutions for Future Health Care Informatics" has been discussed by Joy Iong-Zong Chen et al. [12]. Recurrent Neural Networks and Nonlinear Prediction in Support Vector Machines were presented by Raj, Jennifer S. et al. [13].

These previous works have highlighted the need for more experiments, especially for people who are using IoT-based wearable healthcare devices or employ heterogeneous devices as a form of service.

Our study is narrower in scope and restricted to IoT devices utilized in healthcare, as opposed to earlier research. The figures are provided by a startup business that works on Internet of Things devices in one of Malaysia's cities, and they receive 600 inquiries on average. With our method, we aim to outperform the existing system while maintaining the same configuration environment.

## III.   COMPUTING MODEL FOR PERVASIVE COMPUTING: IoT HEALTHCARE

The pervasive computing's flexibility and elasticity are inherent qualities that enable the operation of heterogeneous devices and encourage interoperability. DECM is utilized to provide service help to many users at once. By computing the requests and optimizing the storage with RLL, the delivery rate of the service is increased.

The cloud, device, substructure, and ubiquitous layer are significant planes that make up the laid-out design. Numerous users and mobile IoT wearable devices that request resources from the cloud plane augment the ubiquitous layer. The aircraft accepts mixed-applications usage and conveyance methodologies that assess user requirements in accordance with information storage standards. Additionally prevalent on this level are computing and data analytics.

The proposed framework is presented in a block diagram in Fig. 1.

As in SDN, the device plane makes up the control plane and performs the crucial computation of requests and storage optimization to increase the communication rate. The substructure plane is equipped with access points, gateways, and BS that support heterogeneous communication by integrating a variety of data conveyance technologies based on Internet of Things-related sensor technology. The potential of the substructure plane to cover a wide geographic region and provide users with ubiquitous communication is what makes it significant. The information that has been gathered is stored on the cloud plane for later use. The committed cloud services handled the clients' requests for access to the information that was stored and oversaw computation and resource allocation. Even though the cloud offers authenticated customers the anytime, anywhere right to use, it still only functions as a third party.

Fig. 1.   Proposed workflow.

The proposed system analyses the request and optimizes the storage using RRL to increase the rate of conveyance. Utilizing a personal device that uses Wi-Fi or Zig-Bee to upload the requests, the processing of the request enables one to organize the requests and transport them to the cloud plane.

This reduces the amount of time needed to process requests, eliminates blocking scenarios, and ensures a constant flow of data into the pervasive computing environment. Eq. (1) provides an approximation of the request processing rate.

$$Request\ of\ Processing\ Rate = \frac{Requests\ from\ x\ number\ of\ devices}{Maximum\ time\ limit} \quad (1)$$

Eq. (2) and Eq. (3) use the two parameters of device connectivity probability and the rate of request arrival to achieve the scalability function.

$$Probability\ Device\ Connectivity = \rho\ devices^{\frac{1}{\tau}} \forall \geq maximum\ connectivity \quad (2)$$

where, $\rho$ = normalization factor $\tau$ = exponent for connectivity.

$$Rate\ of\ arrival = \sum_{i=1}^{number\ of\ devices} rate\ of\ arrival_i \quad (3)$$

Eq. (4), which is based on the above equations, is used to balance the rate at which requests enter and exit the network to reduce delivery delays.

$$balancing\ rate = \begin{cases} Request\ processing\ rate\ X, \max time\ taken\ X\ processing\ tir \\ \frac{(1-\Delta)X\ service\ time}{rate\ of\ arrival\ time}, for\ processed\ requ \end{cases} \quad (4)$$

Recurrent learning is used to manage the discrepancies in the conveyance. By controlling the defects in the hidden layers, the learning process for request processing, and storage optimization are used to obtain the desired outcome, as shown in Fig. 2.

Eq. (5) illustrates how the learning process is used to estimate the prerequisite storage for the request.

$$Required\ Storage = \frac{1}{number\ of\ requests}\log\left(\frac{\frac{1}{l+1}\ request*rate\ of\ arrival}{1-\frac{changes\ on\ request\ rate}{l-1}}\right) \quad (5)$$

Fig. 2. Recurrent Learning for request processing (left) and storage (right).

## IV. RESULTS AND DISCUSSION

In a network simulator, we conducted the experiment using 200 IoT devices, and the settings used are listed in the table. The evaluation of the established model consistency utilizes metrics like request failure, response time managed and backlogged requests, bandwidth, and storage. The results are compared to those from other approaches to show how robust the intended DECM model is. The parameters and configurations of the experiments are depicted in the Table I.

TABLE I. PARAMETERS AND CONFIGURATION

| Parameters | Configuration |
|---|---|
| Wearable Healthcare Devices | 200 |
| Flow of request | 50 |
| Pause Time | 5ms |
| Bandwidth | 2MBps |
| Maximum Time | 20s |
| Storage size | 60 requests/second |
| Number of requests | 600 requests/second |

A time-based map of how long it took to produce the response is shown in Fig. 3. The backlog is decreased, and the process is sped up as the request is computed, lowering the amount of time that must elapse between requests and the required average response time.

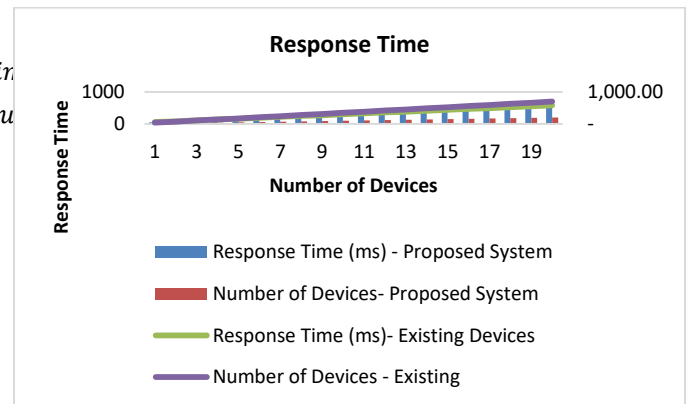

Fig. 3. Response time.

To minimize the time it takes to respond, the balancing rate makes sure that the greatest number of requests may be handled within the allotted service period. The requests are given the appropriate resources with the aid of the storage optimization procedure, which considers the storage units and modifies the succeeding requests.

The resource allocation process is improved, the dormancy in managing the requests is improved, and the count of requests handled and computed by the system is increased, which is used to reduce errors in the requests received and to optimize storage. The table compares the resources handled, the backlogs created, and the failures associated with the current and suggested in Table II.

The resource allocation process is enhanced by the RRL process, which is used to reduce errors in received requests and

to optimize storage. It also improves dormancy in managing requests and increases the count of requests handled and computed by the system's architecture. Table II compares the number of resources handled, the number of backlogs, and the failures suffered in the current and planned designs.

TABLE II. HANDLED REQUESTS, BACKLOGS, AND ERRORS

| Request Handled | Existing | | Proposed | |
|---|---|---|---|---|
| | Failures | Backlogs | Failure | Backlogs |
| 5000 | 0.30 | 400.00 | 0.13 | 166.67 |

## V. CONCLUSION

The delivery robustness of pervasive computing systems for the Internet of Things wearable devices has been increased because of the DECM introduced in this research in response to earlier work. The approach used computes the requests, optimizes the storage, and helps the flow of requests by removing bottlenecks in their transportation. Additionally, optimized storage distributes the storage for a variety of requests with different densities, preventing bottlenecks in resource allocation. The experiment's findings demonstrate how consistently the suggested architecture works better than the existing one. The future focus of this paper is to create a system with other improvements to help multiple heterogeneous applications run simultaneously.

*Abstract*—Melanoma, a prevalent and formidable skin cancer, necessitates early detection for improved survival rates. The rising incidence of melanoma poses significant challenges to healthcare systems worldwide. While deep neural networks offer the potential for precise melanoma classification, the optimization of hyperparameters remains a major obstacle. This paper introduces a groundbreaking approach that harnesses the Manta Rays Foraging Optimizer (MRFO) to empower melanoma classification. MRFO efficiently fine-tunes hyperparameters for a Convolutional Neural Network (CNN) using the ISIC 2019 dataset, which comprises 776 images (438 melanoma, 338 non-melanoma). The proposed cost-effective DenseNet121 model surpasses other optimization methods in various metrics during training, testing, and validation. It achieves an impressive accuracy of 99.26%, an AUC of 99.56%, an F1 score of 0.9091, a precision of 94.06%, and a recall of 87.96%. Comparative analysis with EfficientB1, EfficientB7, EfficientNetV2B0, NesNetLarge, ResNet50, VGG16, and VGG19 models demonstrates its superiority. These findings underscore the potential of the novel MRFO-based approach in achieving superior accuracy for melanoma classification. The proposed method has the potential to be a valuable tool for early detection and improved patient outcomes.*

*Keywords—Deep learning; machine learning; classification; metaheuristic algorithm; CNN*

## I. INTRODUCTION

Skin cancer is characterized by the uncontrolled growth of abnormal cells in the skin's outermost layer (epidermis) due to DNA damage and mutations. Melanoma, a highly aggressive form of skin cancer, is on the rise, posing significant challenges for healthcare systems in terms of early detection and intervention [1]. The precise cause of all melanomas remains unclear, but exposure to ultraviolet (UV) radiation from sunlight or tanning lamps and beds significantly heightens the risk of developing this form of skin cancer [2]. In the United States, the American Cancer Society's estimations predict that approximately 97,610 new cases of melanoma will be diagnosed in the year 2023 [3]. This contrasts with the year 2020, during which a total of 324,635 individuals tested positive for melanoma, with an unfortunate outcome in 57,043 cases, resulting in fatalities [4]. The five-year relative survival rate for melanoma is 93%, with a range of 99% for cases diagnosed at a localized stage (83% of cases) to 27% for cases diagnosed at a faraway stage (4%) [5].

Nevertheless, due to the inherent challenges associated with early detection, both by professionals and patients, there is a pressing need to develop an effective method for the early detection of melanoma and skin cancer. To ensure precise and timely diagnosis, accurate equipment is essential, even in the hands of highly skilled professionals. Dermatologists typically initiate the diagnostic process by employing non-invasive dermoscopy techniques on suspicious areas. However, this conventional method primarily relies on visual examination by the naked eye for preliminary diagnosis. This reliance on visual assessment can introduce challenges, as it can be cumbersome, susceptible to inaccuracies, and dependent on subjective interpretation in a clinical environment [6]. Given these inherent limitations, there is an urgent need to integrate advanced diagnostic tools and technologies to improve the accuracy and efficiency of early melanoma detection.

Deep learning (DL), with its multi-layered artificial neural networks, has ushered in a transformative era in image classification [7]. At the forefront of this revolution are Convolutional Neural Networks (CNNs), renowned for their unparalleled ability to autonomously discern intricate features from raw pixel data [8]. Through iterative training on extensive datasets, DL models refine their parameters to excel in identifying objects and patterns, finding application in diverse domains such as medical imaging [9], autonomous driving [10]. Moreover, in the realm of natural language processing [11]. The exceptional precision and effectiveness of CNNs, particularly in analyzing complex medical images, continue to inspire researchers to leverage them in addressing intricate challenges across various fields.

CNNs have emerged as powerful tools, and researchers often leverage predefined CNN models such as VGG16, VGG19, ResNet, DenseNet, Inception, etc., which come pre-trained on extensive image datasets. These pre-trained models serve as valuable starting points for various image-related tasks, as they have already learned a rich set of features from massive amounts of data. Achieving optimal performance with these models requires careful consideration of hyperparameters, and proper selection of these hyperparameters has a direct impact on the performance of the model [12]. Effective hyperparameter selection stands as a critical endeavor for optimizing a CNN's performance in various applications [13], particularly in the realm of medical imaging, where precise and accurate results are paramount

[14]. Unlocking the full potential of CNNs in this critical domain hinges on the careful process of hyperparameter optimization. To address this challenge, metaheuristic algorithms have emerged as invaluable tools for efficiently searching for optimal hyperparameter values [15]. In contrast to traditional gradient-based optimization methods, such as stochastic gradient descent (SGD), which may struggle with the complex and non-convex landscapes [16] often encountered in medical image analysis, metaheuristics excel. These algorithms, which encompass a range of techniques, including genetic algorithms, particle swarm optimization, simulated annealing, and ant colony optimization, among others, have demonstrated their adaptability and efficiency in exploring and exploiting intricate parameter spaces [17]. In medical imaging, where accuracy and speed are paramount, metaheuristic algorithms offer a promising approach to enhance the capabilities of DL models, ultimately contributing to more accurate disease diagnosis and treatment planning [18].

This study centers on hyperparameter optimization for melanoma classification, employing the DenseNet-121 transfer learning model in tandem with the MRFO metaheuristic algorithm. The principal objective is to elevate melanoma detection accuracy, a pivotal factor in enabling early diagnosis and ultimately improving patient outcomes.

In this study, we make the following significant contributions:

- Novel CNN-Based Framework: A novel CNN framework, developed for reliable classification of Melanoma using the ISIC2019 dataset.

- Transfer Learning Utilization: We utilize ten pre-trained models for transfer learning, benefiting from their knowledge learned on extensive datasets to enhance melanoma classification performance.

- Hyperparameter Optimization: To boost classification performance, we fine-tune hyperparameters for both the CNN model and pre-trained models using the Manta Rays Foraging Optimizer (MRFO) algorithm. This process identifies optimal configurations for each pre-trained model, enhancing melanoma detection performance.

The subsequent sections of this paper are structured as follows:

Section II provides a comprehensive literature review on melanoma classification, offering insights into existing research and methodologies. Section III, a detailed overview of our proposed methodology, outlining the approach to melanoma classification using the CNN framework and the MRFO algorithm. Section IV delves into the experimental results and discussions, shedding light on findings and their implications. Finally, Section V presents conclusions and outlines potential avenues for future research in the field of melanoma classification.

## II. LITERATURE REVIEW

In recent years, there has been a significant surge in the development of algorithms designed for the automated detection of melanoma using dermoscopy images. In the early 2000s, most automated melanoma classification solutions primarily relied on the utilization of manually crafted, low-level features such as shape, color, and texture [19]. However, recent studies, exemplified by [20], have signaled a shift in melanoma identification and recognition methodologies. This transition signifies a departure from the heavy reliance on manual feature engineering, marking a substantial evolution in the field. Presently, there is a noticeable uptick in the adoption of DL approaches for automated skin image analysis [21]. This paradigm shift reflects a move away from manual feature engineering towards methods that harness the capabilities of neural networks to autonomously learn and extract pertinent features from dermoscopy images. This transformation underscores the changing landscape in melanoma classification.

Daghrir et al. [22] introduced an innovative melanoma identification approach by combining three techniques using a majority voting method. Their method incorporates CNN along with two traditional ML approaches, SVM and KNN. These models were trained to recognize specific skin cancer features, including edges, texture, and color characteristics. While this ensemble approach improved overall performance, the combination of results from three different techniques can introduce computational complexity and potentially result in slower processing times. Nevertheless, the results demonstrated that CNN achieved the highest accuracy at 85.5%, followed by SVM with 71.8% accuracy and KNN with 57.3% accuracy.

To address the critical challenge of accurately classifying early Melanoma detection, Golnoori et al. in [23] introduced a novel approach by tackling the persistent complexity of selecting optimal neural network architectures and hyperparameters by employing metaheuristic optimization algorithms to fine-tune both pre-trained and scratch-trained CNN models. These optimized models' deep features were effectively combined and utilized to train a K-nearest neighbors (KNN) classifier. The results of their method demonstrated exceptional performance, achieving an accuracy of 81.6% with an F1-score of 80.9% on the ISIC 2017 dataset and 90.1% accuracy with an 89.8% F1-score on the ISIC 2018 dataset.

Segmentation plays a pivotal role in ML. In their study [24], the authors introduced a technique involving image segmentation. This technique utilizes anisotropic diffusion filtering and a rapid bounding box approach, followed by feature extraction through a hybrid feature extractor (HFE) and a feature extractor based on CNNs. The fusion of these extracted features facilitated the development of a highly accurate classification model capable of distinguishing between melanoma and non-melanoma images. The evaluation, conducted on two datasets, yielded outstanding results, including an accuracy rate of 99.85%, sensitivity of 91.65%, and specificity of 95.70%. These outcomes

underscore the remarkable effectiveness of this approach, surpassing the performance of previous ML algorithms.

To tackle the issue of automated segmentation of melanoma regions, the authors in [25] proposed a DL method based on a deep region-based Convolutional Neural Network (RCNN). This method comprises three main steps: skin refinement, melanoma region localization, and segmentation. The research was evaluated using a dataset consisting of 900 training images and 376 testing images from ISIC 2016 melanoma images. The results highlight the superiority of this approach compared to state-of-the-art techniques, achieving exceptional performance across various evaluation metrics: accuracy (0.94), specificity (0.94), sensitivity (0.97), F1 score (0.96), dice score (0.94), and Jaccard coefficient (0.93).

Ian their study [21], the authors comprehensively analyze the use of pre-trained CNN architectures for melanoma classification. They address a gap in previous research by investigating the specific features extracted by different CNN models. To enhance feature extraction, they introduce boundary localization to preserve critical skin lesion regions. They assess the effectiveness of eight pre-trained CNN models for deep feature extraction from these regions and employ various classifiers for melanoma detection. Across datasets like Ph2, ISIC 2016, ISIC 2017, and HAM10000, their approach achieves high accuracies of 98.33%, 80.47%, 81.16%, and 81%, outperforming state-of-the-art CNN methods.

The authors in [26] introduced a comprehensive three-phase framework for melanoma diagnosis, incorporating data segmentation via an extended Chan-Vese method, data augmentation, and CNN training facilitated by an active learning mini-batch process. To gauge its performance, they conducted an evaluation comparing it with established models such as DenseNet, InceptionV3, MobileNet, NASNet, and Xception. The assessment leveraged Standard Deviation (STD) as a metric to gauge model robustness and stability. The proposed active learning query strategy outperformed baseline methods in both performance and convergence across sixteen image datasets, underscoring the framework's effectiveness in accurate melanoma diagnosis. Nevertheless, the reliance on the active learning mini-batch process may not be universally applicable and may exhibit reduced effectiveness when dealing with imbalanced or noisy datasets.

Adepu et al. [27] present a novel approach for melanoma classification using a lightweight Deep-CNN-based framework. Their methodology incorporates knowledge distillation, Cost-Sensitive Learning with Focal Loss, and in-painting algorithms to enhance classification performance. To improve the model's performance, they introduce new CutOut variations and utilize test time augmentation as regularizers. On the ISIC-2020 dataset, the authors achieve a state-of-the-art result with a sensitivity of 81%, an AUC of 93, and a specificity of 90%. However, as the model processes a larger number of augmented images during each epoch, the use of CutOut may significantly increase the computational cost of training.

The authors in [28] introduce a CAD system utilizing the Online Region-based Active Contour Model (ORACM) to extract the Region of Interest (ROI) from skin lesions. The system demonstrates remarkable performance with an accuracy of 92.24% and perfect specificity and sensitivity (100%). However, it exhibits limitations, such as a heavy reliance on handcrafted features, sensitivity to the initial contour location and manual parameter selection, and the potential for the Non-dominated Sorting Genetic Algorithm (NSGA II) to find local instead of global optimum solutions, resulting in increased computational complexity.

In the realm of lightweight transfer learning models suitable for mobile devices, the study by the authors in [29] introduced the utilization of MobileNetV2 for the classification of melanoma images into benign and malignant categories. Their experiments conducted on multiple melanoma datasets yielded promising results, demonstrating the effectiveness of the proposed method with accuracy rates reaching as high as 85%, outperforming other network architectures. Additionally, the suggested architectural design of the head model, featuring a global average pooling layer followed by two fully-connected layers, not only contributed to high accuracy but also preserved the network's efficiency

The diagnosis of cancer during surgical treatment primarily relies on cancer stage or tumor thickness. In their study[30], the authors introduced two distinct methods aimed at classifying melanoma into two stages: the first stage includes stage 1 and stage 2, while the second encompasses stage 1, stage 2, or stage 3 melanoma. The proposed system employs a CNN, utilizing the Similarity Measure for Text Processing (SMTP) as the loss function. The experimental results include a comparison of various loss functions against the proposed SMTP loss function, demonstrating the superior efficiency of the proposed algorithm when contrasted with several other loss functions tailored for classification tasks.

The authors in [31] introduces a hybrid learning approach for melanoma detection, employing image processing techniques to enhance detection by addressing common issues such as hair, air bubbles, and image noise in dermoscopic images. The study presents an innovative hybrid model, merging DL and machine learning (ML), in its debut for melanoma detection. Performance evaluation on the Hamm 1000 (ISIC 2018) and ISIC 2020 datasets achieves exceptional accuracy scores, reaching 99.44% and 100%, respectively. Notably, the effectiveness of the saturation masking and wavelet transform techniques used may be sensitive to image quality, especially in cases of low resolution, artifacts, or variations in lighting, potentially impacting their noise reduction and lesion prominence enhancement capabilities.

In the study conducted by Nancy [32] presents a two-tier hybrid dual CNN (2-HDCNN) feature fusion approach for malignant melanoma prediction. It first identifies challenging samples, generates a Baseline Segregated Dataset (BSD), and preprocesses it. The second-tier CNN produces bottleneck features, combined with ABCD rule-derived features. These hybrid features are used with various classifiers, resulting in high accuracy (92.15%), precision (96.96%), specificity (96.8%), sensitivity (86.48%), and an AUC of 0.96 for diagnosing malignant melanoma on the ISIC 2018 dataset.

In conclusion, our review of the existing literature in melanoma classification reveals a significant gap in research focused on the optimization of hyperparameters and network structures. While numerous studies have explored ML and DL models for melanoma detection, very few have delved into the critical area of hyperparameter optimization using metaheuristic algorithms. Notably, none of the studies have investigated the potential of the MRFO algorithm in this context. This identified research gap highlights the unexplored potential of MRFO and other metaheuristic algorithms for enhancing the accuracy and efficiency of melanoma classification models.

## III. METHODOLOGY

### A. Introduction

This study introduces a comprehensive framework for melanoma classification Exploiting CNNs alongside transfer learning techniques and MRFO for hyperparameter optimization. The workflow consisting of data acquisition, pre-processing, splitting, classification, and optimization. These phases collectively enable accurate and reliable melanoma classification.

### B. Dataset Description

The ISIC-2019 dataset [33], comprising 25,331 dermoscopy images, is used to evaluate the proposed technique. These images, categorized into eight distinct classes representing different types of skin lesions, exhibit varying dimensions, ranging from 600x450 to 1024x1024 pixels. In our evaluation, a total of 776 images are employed, including 438 melanoma and 338 non-melanoma cases.

### C. DenseNet-121 Architecture

DenseNet121, a CNN architecture renowned for its effectiveness in visual object recognition, achieves state-of-the-art results with reduced parameters by intricately connecting each layer to both preceding and subsequent layers [34].

Fig. 1. DenseNet121 architecture.

DenseNet-121, one of several variants within the DenseNet family, is characterized by five convolution and pooling layers, three transition layers (at depths 6, 12, and 24), one classification layer (at depth 16), and two dense blocks employing 1x1 and 3x3 convolutions. Fig. 1 shows DenseNet121 architecture.

$$\text{Total Layers} = 5 + (6 + 12 + 24 + 16) \times 2 = 121$$

In total, DenseNet-121 comprises 121 layers, making it a versatile choice for various computer vision tasks. This study specifically employs DenseNet-121 due to its compelling advantages, such as mitigating the vanishing-gradient problem, enhancing feature propagation, promoting feature reuse, and notably reducing the overall model parameter count [35]

### D. Hyperparameter Selection

The study focuses on optimizing several critical hyperparameters to enhance model performance:

- Loss Function: Defines the loss metric used for model optimization.

- Training Batch Size: Determines the number of samples used in each training iteration.

- Model Dropout Ratio: Regulates the extent of regularization during training.

- Transfer Learning Ratio: Controls the extent of pre-trained weight utilization.

- Optimizer: Selects the optimization algorithm.

- Rotation Angle: Diversifies training data by simulating different lesion orientations.

- Shifts (Width and Height): Handles variations in lesion position and image composition.

- Zoom Level: Allows the model to learn features at various scales within images.

- Shear Transformation: Introduces controlled deformations to enhance the model's adaptability.

- Flipping: Simulates mirrored images (Horizontal and Vertical).

These hyperparameters collectively contribute to the adaptability, generalization, and optimization of the model for melanoma classification. Next steps involve leveraging the MRFO [36]. Metaheuristic Algorithm to fine-tune these hyperparameters systematically, ensuring that the model achieves the best possible results in the challenging task of classifying melanoma.

### E. Manta Ray Foraging Metaheuristic Algorithm

The MRFO [36] algorithm incorporates three foraging behaviors: chain foraging, cyclone foraging, and somersault foraging. These behaviors are mathematically modeled as follows:

- Chain foraging: - In the MRFO [36] Chain foraging: Manta rays use their ability to detect plankton concentration to navigate towards better positions. The algorithm assumes the highest plankton concentration represents the best solution found so far. Manta rays form a foraging chain, moving towards both the food and the individual in front of them.

$$x_i^d(t+1) = \begin{cases} x_i^d(t) + r * (x_{i-1}^d(t) - x_i^d(t)) + \\ \quad \alpha * \left(x_{best}^d(t) - x_i^d(t)\right) i = 1 \\ \\ x_i^d(t) + r * (x_{i-1}^d(t) - x_i^d(t)) + \\ \quad \alpha * \left(x_{best}^d(t) - x_i^d(t)\right) i = 2, \dots N \end{cases} \quad (1)$$

$$\alpha = 2 * r * \sqrt{|\log(r)|} \quad (2)$$

In dimension $d^{th}$, $x_i^d(t)$ represents the $i^{th}$ individual's position at time (t) with r as a random vector between 0 and 1, α as a weighting coefficient, and $x_{best}^d(t)$ denoting a high-plankton concentration area. Fig. 2 illustrates the two-dimensional foraging behavior of individuals. An individual's position update depends on the previous $(i-1)^{th}$ individual's current position, $x_{i-1}^d(t)$, and the food source position, $x_{best}^d(t)$.

- Cyclone foraging: - Manta rays display a distinctive foraging behavior in which they form a long chain and spiral toward plankton patches in deep waters. This spiral foraging strategy resembles that seen in WOA [37]. In the case of cyclone foraging, manta ray swarms spiral towards food while also moving toward the ray in front, forming a line that takes on a spiral shape. Fig. 3 illustrates this cyclone foraging behavior in a 2-dimensional context. Swarm members follow the leader, traversing a spiral path toward food. The mathematical equation for modeling this two-dimensional spiral movement of manta rays is as follows:

$$\begin{cases} X_i(t+1) = X_{best} + r * \left(X_{i-1}(t) - X_i(t)\right) + \\ \quad e^{bw} * \cos(2\pi\omega) * \left(X_{best} - X_i(t)\right) \\ \\ X_i(t+1) = X_{best} + r * \left(X_{i-1}(t) - X_i(t)\right) + \\ \quad e^{bw} * \cos(2\pi\omega) * \left(X_{best} - X_i(t)\right) \end{cases} \quad (3)$$

Where, w is a random number between 0 and 1.

This behavior can extend to n-dimensional space. The mathematical model for cyclone foraging is defined as follows:

$$x_i^d(t+1) = \begin{cases} x_{best}^d + r * \left(x_{best}^d(t) - x_i^d(t)\right) + \\ \quad \beta * \left(x_{best}^d(t) - x_i^d(t)\right) i = 1 \\ \\ x_{best}^d + r * \left(x_{i-1}^d(t) - x_i^d(t)\right) + \\ \quad \beta * \left(x_{best}^d(t) - x_i^d(t)\right) i = 2, \dots n \end{cases} \quad (4)$$

$$\beta = 2e^{r1\frac{T-t+1}{T}} * \sin(2\pi r_1) \quad (5)$$

In the cyclone foraging strategy, individuals perform random searches relative to the food source as their reference point, promoting both exploitation and exploration. To encourage exploration, each individual is directed to seek a new position in the search space, away from the current best position, using a new random reference point. This approach

enhances exploration, enabling the MRFO [36] algorithm to perform a broad global search. The mathematical equation is as follows:

β is the weight coefficient, T is the maximum number of iterations, and $r_1$ is a random number in [0, 1].

$$x_{rand}^d = Lb^d + r (Ub^d - Lb^d) \quad (6)$$

$$(t+1) = \begin{cases} x_{rand}^d + r * \left(x_{rand}^d(t) - x_i^d(t)\right) \\ \quad + \beta * \left(x_{rand}^d(t) - x_i^d(t)\right) i = 1 \\ \\ x_{rand}^d + r * \left(x_{i-1}^d(t) - x_i^d(t)\right) + \beta \\ \quad * \left(x_{rand}^d(t) - x_i^d(t)\right) i = 2, \dots n \end{cases} \quad (7)$$

where, $x_{rand}^d$ is a random position randomly produced in the search space, $Ub^d$, $Lb^d$ are the upper and lower limits of the $d^{th}$ dimension respectively.

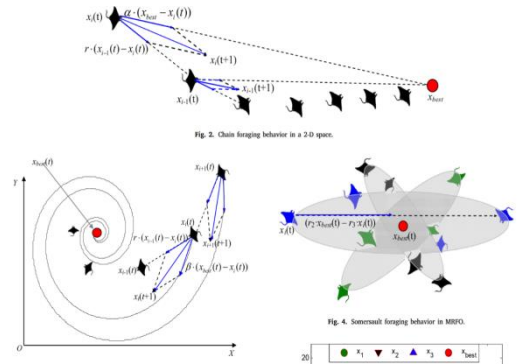

Fig. 2. MRFO (1) Chain (2) Cyclone (3) Somersault behavior in a 3-D space.

- Cyclone foraging: - This behavior treats the food source position as a pivot, causing individuals to swim in a back-and-forth manner while somersaulting to new positions. This results in continuous position updates around the current best solution. The mathematical equation below models this behavior.

$$x_i^d(t+1) = x_i^d(t) + S * \left(r_2 * x_{best}^d - r_3 * x_i^d(t)\right) i = 1, 2, \dots n \quad (8)$$

The somersault factor (S = 2) determines the range of somersaulting for manta rays using random numbers (r1 and r2) in [0, 1]. Eq. (8) allows each individual to move within a new search domain, symmetrically positioned around the best solution found so far. As an individual approaches the optimal solution, the somersault range decreases, guiding all individuals toward convergence. This adaptive reduction occurs as iterations increase. Fig. 4 visually illustrates somersault foraging behavior in MRFO [36].

Like other metaheuristic optimizers, MRFO [36] begins with a random population. In each iteration, individuals update positions relative to neighbors and a reference point. The exploration-exploitation balance is controlled by t/T, decreasing from 1 to t/T. When t/T < rand, the best solution is used for exploitation; otherwise, a random position aids

exploration. Chain and cyclone foraging alternate randomly, while somersault foraging adapts positions to the best solution. This iterative process continues until the stopping criterion is met, yielding the best individual's position and fitness value.

Three individuals undergo 100 iterations in the search space using Eq. (8). Randomly sampled points distribute between current positions and their symmetrical positions around xbest. As distance to xbest decreases, the number of sampled points reduces. Dense points around xbest aid exploitation, while sparse ones promote exploration.

### F. Hyperparameter Optimization Process

*1) Data preprocessing*: After acquiring the dataset, it underwent a series of preprocessing steps involving four key techniques: image resizing, dimensional scaling, data balancing, and data augmentation. In the image processing phase, a two-step approach was utilized to standardize the various image dimensions. Initially, the color space conversion from BGR to RGB was executed to ensure consistent color representation. Subsequently, bicubic interpolation [38] resizing was applied to all images, harmonizing them to a uniform size of (32x32x3) pixels. This process established consistency, laying a solid foundation for subsequent analysis. Addressing the issue of data imbalance [39], the study employed data augmentation techniques encompassing width and height shifting, shearing, rotation, horizontal and vertical flipping, and zooming. These techniques help diversify the dataset and mitigate potential misclassification or overfitting during training and optimization phases [40]. Additionally, the dataset was partitioned into an 80% training subset and a 20% validation subset to facilitate model training and evaluation. This division ensures a robust assessment of model performance and generalizability.

*2) Classification and optimization*: The optimization process commences with the creation of an initial solution population represented as vectors. Each vector element corresponds to a specific hyperparameter, such as dropout ratio, optimizers, batch size, etc. In this study, 12 well-defined hyperparameters are targeted for optimization, as outlined in Table I. The dimensionality of solution vectors depends on the application of data augmentation.

*a) Fitness Function and Hyperparameter Mapping*: At the core of the optimization process, the fitness function is utilized to assess the quality of each population solution. This function encompasses three crucial steps:

- Hyperparameter Mapping: To effectively configure the pre-trained transfer learning model, solution elements are mapped to their corresponding actual hyperparameters.

- Top of Form

- Model Creation and Preparation: With mapped hyperparameters, the pre-trained transfer learning CNN model is created and compiled. A diverse set of pre-

trained models, including DenseNet121, EfficientB1, EfficientB7, EfficientV2B0, MobileNet, NesNetLarge, ResNet50, VGG16, and VGG19, are harnessed in this study.

- Model Training and Evaluation: Following model creation, the training phase commences, allowing the model to learn from the data. Training progresses for a predetermined number of epochs typically set to 1000 in this study.

*b) Balancing Exploration and Exploitation*: This approach dynamically traverses the hyperparameter space, striving for a harmonious balance between exploration and exploitation. This equilibrium proves pivotal in uncovering globally optimal solutions. The process iteratively refines the population, gradually converging towards configurations that yield superior model performance.

Fig. 3 depicts the model architecture employed in our optimization process, offering a visual representation of the complex interplay between hyperparameters, fitness evaluation, and model creation.

TABLE I. HYPERPARAMETER SETTINGS

| Hyperparameters Settings | | |
|---|---|---|
| S/noo | Hyperparameter | Values |
| 1 | Loss Function | Binary Crossentropy |
| 2 | Training batch size | [8, 16,32,64] |
| 3 | Model dropout ratio | [0- 0.5] |
| 4 | Transfer learning ratio | 0-26 (step = 1) |
| 5 | optimizer | [Adam(), Nadam(), RMSprop(), Adadelta(), Adagrad(), SGD()] |
| 6 | Rotation Range | 0 - 40 (step = 1) |
| 7 | width shift value. | [0 - 0.2] |
| 8 | Hight shift value. | [0 - 0.2] |
| 9 | Shear | [0 - 0.2] |
| 10 | Zoom | [0 - 0.2] |
| 11 | Horizontal Flipping | [Yes, No] |
| 12 | Vertical flipping | [Yes, No] |

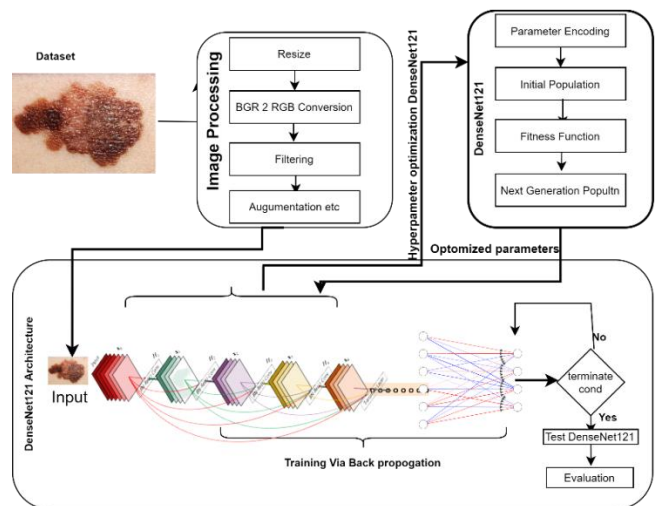

Fig. 3.   Proposed model architecture.

## G. Evaluation Metrics

The proposed model will undergo evaluation using standard assessment metrics, including Accuracy, Precision, Recall, and F-Score, as mentioned in [38]–[41].

## H. Software and Tools

The experiments were conducted in Python, utilizing popular libraries including Keras, Scikit-learn, and OpenCV. The computational environment employed a Dell system equipped with an Intel Xeon CPU, boasting up to 128GB of memory, and a spacious 1TB SSD.

## IV. RESULT AND DISCUSSION

In this section, the proposed model was assessed through a comparison with four nature-inspired techniques (GA, WOA, GWO, WHO) and benchmarked against eight state-of-the-art deep learning architectures (EfficientB1, EfficientB7, EfficientV2B0, MobileNet, NesNetLarge, ResNet50, VGG16, and VGG19) on the ISIC 2019 dataset. This dataset comprises 776 skin lesion images encompassing melanoma and non-melanoma classes.

Data preprocessing was undertaken, including augmentation to expand the dataset to 8000 images, and an 80%-20% random split was applied for training and validation purposes. For image resizing, bilinear interpolation was utilized. The experiments were conducted using the Keras library with the hyperparameters detailed in Table I.

The model is comprised of 7.2 million parameters, which includes 121 convolutional layers and three fully connected layers. Training was executed over 1000 epochs, involving 12 distinct hyperparameter configurations and the incorporation of early stopping with a patience of 15.

Proposed model performance across top 10 epochs

Top of Form

In Table II, we observed that the model's performance across the top 10 epochs consistently exhibited high accuracy, ranging from 0.9908 to 0.9926, and AUC, ranging from 0.9898 to 0.9974. Additionally, precision, recall, and the F1-Score consistently demonstrated strong values, indicating proficient classification capabilities with minimal discrepancies. These results underscore the model's robust and stable performance, making it well-suited for accurate for melanoma classification.

TABLE II. PERFORMANCE OF PROPOSED MODEL ACROSS TOP 10 EPOCHS

| Epoch | Accuracy | AUC | Precision | Recall | F1-Score | Loss |
|---|---|---|---|---|---|---|
| 38 | 0.9926 | 0.9956 | 0.9406 | 0.8796 | 0.9091 | 0.0217 |
| 37 | 0.9924 | 0.9974 | 0.9447 | 0.8704 | 0.906 | 0.0216 |
| 34 | 0.9916 | 0.9952 | 0.9529 | 0.8426 | 0.8943 | 0.0241 |
| 35 | 0.9916 | 0.9951 | 0.9261 | 0.8704 | 0.8974 | 0.0244 |
| 40 | 0.9914 | 0.9937 | 0.9343 | 0.8565 | 0.8937 | 0.0224 |
| 33 | 0.9912 | 0.9974 | 0.9430 | 0.8426 | 0.89 | 0.0237 |
| 25 | 0.9910 | 0.9900 | 0.9381 | 0.8426 | 0.8878 | 0.0331 |
| 32 | 0.9908 | 0.9942 | 0.9378 | 0.8380 | 0.8851 | 0.0259 |
| 36 | 0.9908 | 0.9898 | 0.9163 | 0.8611 | 0.8878 | 0.0283 |

Model Validation Performance Across Top 10 Epochs

In correspondence to Table III, the model consistently demonstrates strong validation performance, with accuracy ranging from 0.9586 to 0.9734 and AUC values between 0.8164 and 0.8588. Validation loss falls in the range of 0.1458 to 0.2014, indicating close alignment with the ground truth. Precision values consistently exceed 0.5, indicating minimal false positives, while recall values vary, indicating the model's ability to correctly identify positive samples. These findings highlight the model's robust and consistent validation performance, ideal for tasks demanding accurate classification.

TABLE III. VALIDATION PERFORMANCE ACROSS TOP 10 EPOCHS

| Epoch | Val. Acc | Val AUC | Val Prec. | Val recall | F1-Score | Val Loss |
|---|---|---|---|---|---|---|
| **38** | **0.9680** | **0.8179** | **0.6857** | **0.4444** | **0.5393** | **0.1980** |
| 37 | 0.9688 | 0.8519 | 0.7059 | 0.4444 | 0.5455 | 0.1521 |
| 34 | 0.9711 | 0.8164 | 0.8148 | 0.4074 | 0.5432 | 0.1652 |
| 35 | 0.9586 | 0.8588 | 0.5085 | 0.5556 | 0.531 | 0.1660 |
| 40 | 0.9688 | 0.8258 | 0.7333 | 0.4074 | 0.5238 | 0.2014 |
| 33 | 0.9695 | 0.8353 | 0.7419 | 0.4259 | 0.5412 | 0.1774 |
| 25 | 0.9734 | 0.8502 | 0.8333 | 0.4630 | 0.5952 | 0.1458 |
| 32 | 0.9719 | 0.8396 | 0.8462 | 0.4074 | 0.55 | 0.1692 |
| 36 | 0.9664 | 0.8288 | 0.6774 | 0.3889 | 0.4941 | 0.1653 |

From Fig. 4, the performance of DenseNet121 model was evaluated under three different scenarios: 100 epochs with a 5000-sample dataset, 500 epochs with an 8000-sample dataset, and 1000 epochs with an 8000-sample dataset. The model with 1000 epochs on the larger dataset demonstrated the highest accuracy (99.26%), AUC (99.56%), and F1-Score (0.9091), indicating its superior ability to classify positive and negative instances. It also achieved the lowest loss (0.0217) and high precision (94.06%) and recall (87.96%) values. It is observed that increasing the number of training epochs and dataset size consistently leads to better model performance across various metrics.

Fig. 4. Comparison with different configuration.

Comparative Analysis of the Proposed Model and Other Architectures

TABLE IV.    COMPARATIVE ANALYSIS OF MODEL PERFORMANCE

| Model | Accuracy | AUC | F1-Score | Precision | Recall | Loss |
|---|---|---|---|---|---|---|
| **Proposed Model** | 0.9926 | 0.9956 | 0.9091 | 0.9406 | 0.8796 | 0.0217 |
| **EfficientB1** | 0.9580 | 0.4972 | 0.0092 | 1.0000 | 0.0046 | 0.1815 |
| **EfficientB7** | 0.9232 | 0.4824 | 0.1495 | 0.5000 | 0.0879 | 0.6742 |
| **EfficientNetV2B0** | 0.9304 | 0.5135 | 0.1946 | 0.6098 | 0.1157 | 0.6694 |
| **MobileNet** | 0.9910 | 0.9980 | 0.9012 | 0.9397 | 0.8657 | 0.0221 |
| **NesNetLarge** | 0.6911 | 0.7096 | 0.5127 | 0.6547 | 0.4213 | 0.6968 |
| **ResNet50** | 0.9656 | 0.9134 | 0.4013 | 0.7564 | 0.2731 | 0.1076 |
| **VGG16** | 0.9865 | 0.9937 | 0.8244 | 0.9152 | 0.7500 | 0.0369 |
| **VGG19** | 0.9797 | 0.9675 | 0.7263 | 0.8415 | 0.6389 | 0.0628 |

The presented data showcases the performance evaluation of the proposed model (see Table IV) in comparison to several established DL architectures across various metrics. The proposed model outperforms all other models with an impressive accuracy of 99.26%, an AUC of 99.56%, and a commendable F1-Score of 0.9091. Furthermore, it exhibits a high precision of 94.06% and recall of 87.96%, indicating its robustness in correctly classifying positive instances while minimizing false positives. In contrast, models like EfficientB1, EfficientB7, EfficientNetV2B0, NesNetLarge, ResNet50, VGG16, and VGG19 show lower accuracy and F1-Scores, reflecting their limitations in effectively handling the given task. MobileNet, while achieving a high accuracy and AUC, falls slightly behind the proposed model in F1-Score, precision, and recall. These results underscore the superior performance of the proposed model in comparison to established architectures, demonstrating its potential for melanoma classification. Additionally, the low loss value of 0.0217 for the proposed model further confirms its proficiency in minimizing prediction errors during training.

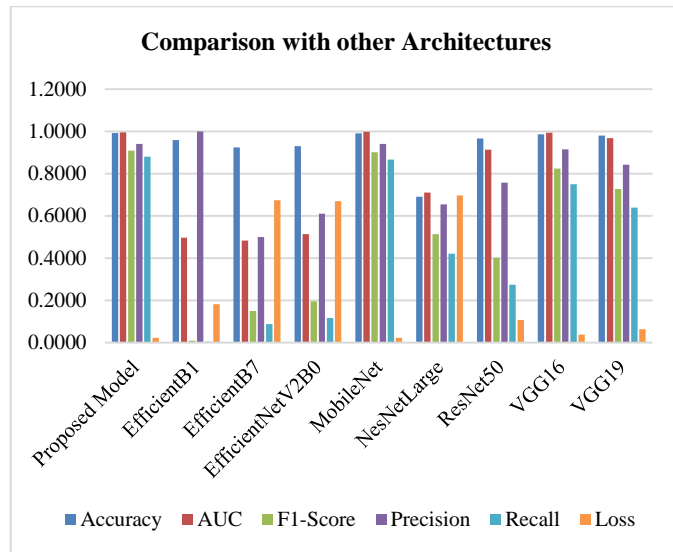

Fig. 5.    Comparison with other architectures.

Table V shows the In-Depth Analysis of Proposed DensNet121 Model in Comparison with Prior Literature.

TABLE V.    ANALYSIS OF PROPOSED MODEL IN COMPARISON WITH PRIOR LITERATURE

| Reference | Model | Metaheuristics | Accuracy | Precision | Recall | F1_Score |
|---|---|---|---|---|---|---|
| [42] | CNN | GWO | 98.3 | | | |
| [43] | CNN | WHO | 96.0 | | | |
| [23] | ALexNet | GA | 0.8166 | 0.8118 | 0.8167 | 0.8092 |
| [23] | CNN | PSO | 90.01 | 0.0.898 | 0.90 | 0.897 |
| Proposed Model | DensNet121 | MRFO | 0.9926 | 0.9406 | 0.8796 | 0.9091 |

In comparison with other literature, the proposed DensNet121-based model optimized with MRFO exhibits superior performance. Fig. 5 shows the comparison with other architectures. It achieves an accuracy of 99.26%, surpassing previous models utilizing different metaheuristics such as GWO (98.3%) and WHO (96%). Moreover, the proposed model's precision (0.9406) and recall (0.8796) outperform an AlexNet model optimized with GA (accuracy: 81.66%, precision: 81.18%, recall: 81.67%). Additionally, the F1-Score of the proposed model (0.9091) exceeds that of a CNN optimized with PSO (accuracy: 90.01%, F1-Score: 0.897). These findings highlight the effectiveness of the proposed model in achieving superior accuracy and a balanced precision-recall trade-off when compared to existing literature.

## V.    CONCLUSION

In conclusion, the manual classification of melanoma from dermoscopic images presents significant challenges, even for experts, highlighting the pressing need for efficient automation solutions. This paper introduces an automated and cost-effective model built upon the DenseNet121 architecture, harnessed by the MRFO metaheuristic algorithm for melanoma classification. Through careful optimization of critical CNN hyperparameters, this model significantly enhances the architecture's ability to tackle melanoma classification effectively.

The study employs data preprocessing techniques, including bilinear interpolation-based image resizing, and adeptly encodes CNN hyperparameters to facilitate optimization. To validate the model's efficacy, a comprehensive evaluation was conducted, comparing it with hyperparameter optimization techniques GA, PSO, GWO and WHO on the ISIC skin cancer dataset. Additionally, the model was benchmarked against eight state-of-the-art deep learning

architectures (EfficientB1, EfficientB7, EfficientV2B0, MobileNet, NesNetLarge, ResNet50, VGG16, and VGG19).

The final results demonstrated the superiority of our proposed model in terms of accuracy, AUC, precision, F1 Score and loss rates during training, testing, and validation phases, surpassing the performance of other optimization methods explored in this experiment.

As a direction for future research, further refinement and exploration of this model can lead to even more robust and accurate melanoma classification systems, potentially contributing to early diagnosis and improved patient outcomes in the field of dermatology.

*Abstract*—To address the problems of missed detection, segmentation error and poor target edge segmentation in the instance segmentation model, a R2SC-Yolact++ instance segmentation approach based on the improved Yolact++ is proposed. Firstly, the backbone network adopts Res2Net which introduces spatial attention mechanism (SAM) to improve the problem of segmentation error by better extracting feature information; then, high-quality masks are obtained by fusing the detail information of the shallow feature P2 as the input to the prototype mask branch; finally, the problem of missed detection was solved by introducing Cluster-NMS in order to improve the accuracy of the detection boxes. In order to illustrate the effectiveness of the improved model, experiments were conducted on two publicly available datasets, the COCO and CVPPP datasets. The experimental results show that the accuracy on the COCO dataset is 1.1% higher than the original model. And the accuracy on the CVPPP dataset is 1.7% better than before the improvement, which is better than other mainstream instance segmentation algorithms such as Mask RCNN. Finally, the improved model is applied to the insulator dataset, which can segment the shed of insulator accurately.

*Keywords—Instance segmentation; Yolact++; Res2net; Cluster-NMS; insulator dataset*

## I. INTRODUCTION

With the rapid development of deep learning, our life is also moving towards automation, such as automatic driving and automatic picking, etc. The first problem that needs to be solved for these tasks is to recognize the category as well as the location of the target, and the current deep learning based methods mainly include object detection and image segmentation. Object detection can only detect the category as well as the location of the target, cannot identify the specific and accurate outline of the target. Deep learning-based image segmentation methods include semantic segmentation and instance segmentation. Semantic segmentation can only classify the targets in an image into different categories, and different instances belonging to the same category cannot be distinguished. Instance segmentation can identify both the class and the exact contour position of different instances. Therefore, it is important to study how to accurately segment different instances using instance segmentation.

Instance segmentation is an important and difficult branch of computer vision, and its task is to identify the target contour location and classify it at pixel level to get the segmentation mask of different instances. The existing instance segmentation algorithms are mainly classified into single-stage and two-stage instance segmentation methods. The two-stage instance

segmentation method has the advantage of higher accuracy, but the model is complex and slow. Mask RCNN [1], proposed in 2017, is one of the most commonly used detection-based methods, using the two-step idea of Faster RCNN [2], to which a branch of prediction segmentation masks is added. PANet [3] made improvements to Mask RCNN by introducing bottom-up paths and expanding the feature pyramid network, which improved the accuracy, but also slowed down a lot. The advantage of single-stage segmentation methods is that the model is simple and fast, but the accuracy is relatively low. Typical single-stage methods include the anchor frame-based method YOLACT proposed by Bolya et al. [4], which divides the instance segmentation task into two parallel branches and achieves real-time instance segmentation for the first time, but the accuracy was poor, and it was later improved by proposing YOLACT++ [5], which significantly improved the segmentation accuracy by adding deformable convolution and presetting more anchor frames using mask rescoring. The method CondInst [6] was proposed in 2020 to solve instance segmentation from a new perspective, using dynamic masks and not relying on ROI operations, achieving higher accuracy and being faster. Since the accuracy of the anchor frame-based method depends greatly on the set anchor frame hyper-parameters, a segmentation method without anchor frames is proposed afterwards. SOLO [7] proposed in 2020 uses the location information of instances for instance classification. It is to divide the different instances by assigning the instances to different channels based on the fact that each instance has a different center point and size. The accuracy was further improved with the later improved SOLO V2 [8]. In recent years, with the amazing results achieved by Transformer in natural language processing, it has also been applied to instance segmentation with good results [9, 10].

Although there has been a great development in instance segmentation, there is still a lot of room for development of existing models in terms of accuracy improvement. The problems such as segmentation errors as well as poor target edge segmentation due to insufficient extraction of image information, and missed detection due to inaccuracy of prediction boxes, all contribute to the low accuracy of segmentation. To address the above problems, this paper proposes an instance segmentation method based on the improved Yolact++. The method can better extract features, effectively improve the problems of missed detection and segmentation errors, and enhance the accuracy of instance segmentation. The main contributions of this paper are summarized as follows:

- The R2SC-Yolact++ algorithm is proposed to address the problems of segmentation error and missed detection in Yolact++.

- The model introduces Res2Net for the segmentation error problem and embeds a spatial attention mechanism for better feature extraction, and fuses shallow features with P3 as input to the protonet branch to solve the problem of poor segmentation edges, and finally Cluster-NMS was introduced to solve the problem of missed detection caused by the suppression of too many detection boxes.

- Validating and comparing the segmentation performance of the proposed model on two publicly available datasets and a homemade insulator dataset.

- The paper is organized as follows: Section II presents the related works for segmentation, Section III describes the proposed R2SC-Yolact++ method, Section IV analyzes and discusses the experimental results, and Section V concludes the paper.

## II. RELATED WORK

Early traditional image segmentation mainly used the digital image processing technology; the main methods include segmentation methods based on region, edge detection, etc. OSTU finds the threshold value as the segmentation value to distinguish the foreground from the background based on the gray scale distribution of the gray scale map using inter-class variance method. Canny [11] edge detection algorithm performs edge detection by finding the optimal edge pixels and is the most commonly used segmentation method. These methods is generally based on the brightness and color of the pixels in the image, as well as the degree of variation in the pixel values, so they are susceptible to segmentation errors due to uneven illumination, noise, and other factors.

With the development of deep learning, segmentation methods based on deep learning are proposed, which are divided into semantic segmentation and instance segmentation. Semantic segmentation is a pixel-level classification of images to distinguish different classes of targets. The beginning of semantic segmentation was the use of full convolutional networks [12] (FCN) for classification, after which semantic segmentation developed rapidly. U-Net [13] was proposed for medical segmentation in 2015, which uses an encoder-decoder structure to extract features and fuse shallow features with deep semantic information to fully use image contextual information for accurate segmentation of medical images, but has the problem of slow segmentation speed. The DeepLab series [14-17] proposed afterwards have continuously improved segmentation accuracy and efficiency by introducing atrous convolution to reduce model parameters, proposing ASPP to solve the problem of target segmentation at different scales, and introducing decoder structure to optimize the problem of poor segmentation edge accuracy. SegFormer [18] proposed a hierarchical Transformer encoder structure by combining semantic segmentation with Transformer, using overlapping patches to ensure the local continuity of features, while using deep convolution to replace position encoding to convey position information and obtain a high-quality segmentation map. But semantic segmentation has a problem in application, it cannot distinguish different instances belonging to the same class, and many applications need to mark each different instance, so later proposed instance segmentation. However, how to improve the accuracy of instance segmentation and accurately segment the target is an urgent problem.

Existing instance segmentation algorithms are continuously improved from all angles to enhance the accuracy of segmentation. For the problem of segmentation errors and missed segmentation, many studies ResNeXt [19], Res2Net [20], etc. are solved from the perspective of better feature extraction to improve the feature expression ability of the backbone network. The use of attention mechanisms [21-23] has also been proposed to make the network focus on important features and suppress unnecessary features. The accuracy of the detection boxes also affects the accuracy of the segmentation, so many scholars have devoted to obtaining more accurate detection boxes by using more comprehensively computed loss functions DIoU, CIoU [24], etc., or by using more appropriate non-maximum suppression to obtain detection boxes that are more in line with the target. Nowadays the algorithms also commonly have the problem of poor target edge segmentation, many solutions have been proposed for this problem, such as adding an additional loss to the segmentation boundary of the network output, and Xuecheng Li [25] proposed an edge loss function so as to improve the accuracy of the segmentation edge. Improving the segmentation of edges by increasing the resolution of the input image as well as the extracted feature maps is also a relatively straightforward approach, but this adds a significant amount of computation.

The Yolact++ instance segmentation model chosen in this paper, which is simple and realizes real-time segmentation, has been applied in many fields and improvements have been made to address the problems so that they can better segment the objects. Yajun Li in [26] proposed an extended network based on Yolact that can simultaneously detect fruit bundles as well as segment fruit stalks, which can accurately and quickly identify the pose of fruit bunches to support successful picking by picking robots. Based on Yolact++, RTLSeg is proposed to segment the railroad track [27], the feature enhancement module is proposed to improve the feature extraction and characterization ability of the model, PaFPN is used to enhance the interaction of information, as well as the location awareness is added to the Protonet module to obtain a high-quality prototype mask. These improvements effectively enhance the segmentation accuracy of the railroad track and can accurately and efficiently segment the railroad track line components. Zhenni Shang [28] used Yolact, which introduces the SE attention mechanism to enhance feature expression and FRelu activation function, for efficient segmentation of protozoa in microscopic images.

## III. MODEL OVERVIEW

### A. Principle of Yolact++

ResNet50 with deformable convolution was introduced as the backbone network to extract features from the input image, and total of five different scales of feature maps, C1-C5, were obtained. For efficiency, Yolact++ uses only C3-C5 for feature fusion through FPN to obtain P3-P5, and downsamples from

P5 to obtain P6 and P7. Then after two parallel branches, one branch is the detection branch with inputs P3-P7, anchor frames with aspect ratios [1, 1/2, 2, 1/3, 3] are generated and classified, regressed, mask coefficients predicted, and non-maximum suppression (Fast NMS) is applied to get the final instance prediction boxes. The other branch is the prototype mask branch, which uses P3 as input and obtains k mask maps

corresponding to different regions after convolution and upsample. The prototype mask maps and the mask coefficients are linearly combined by matrix multiplication to obtain the instance masks, which are intercepted by the prediction boxes, and the final mask segmentation maps are obtained by threshold processing and binarization. The structure of the Yolact++ model is shown in Fig. 1.

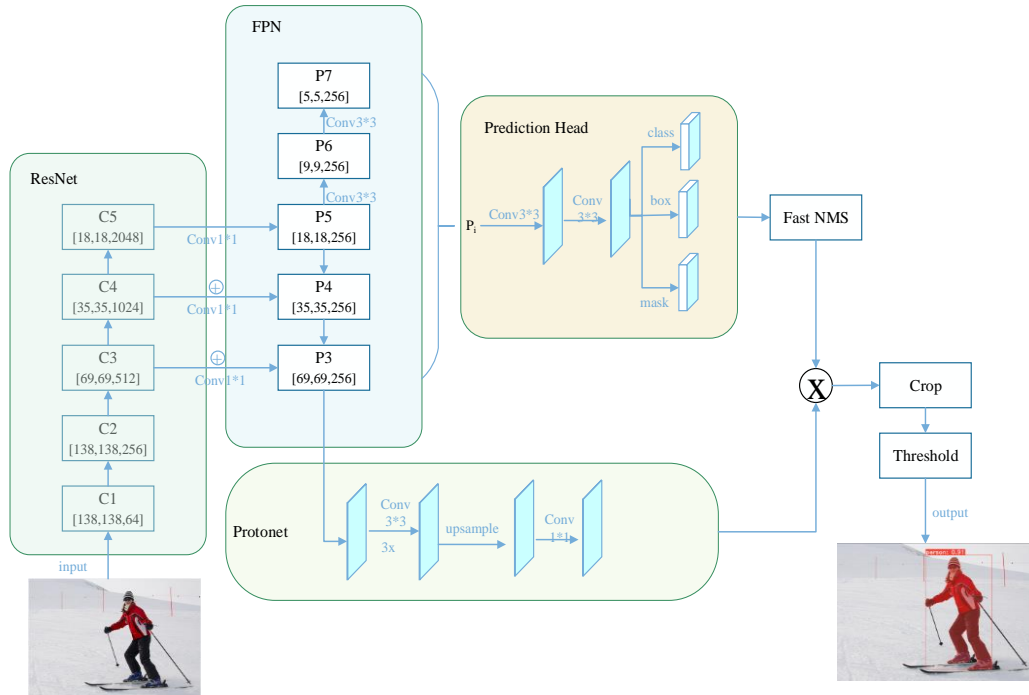

Fig. 1.    Structure of the Yolact++ model.

### B.  Improved Backbone

The quality of feature maps for feature extraction directly affects the subsequent detection and segmentation, so the backbone network is improved to address the problem of inadequate feature extraction. The Res2Net module is used to replace the bottleneck structure of ResNet to represent multi-scale features at a finer granularity, and to increase the receptive field of each network layer to extract more detailed information about the edges as well as the overall information about the target. ResNet bottleneck structure requires layer-by-layer 3×3 convolution for multi-scale feature extraction. Res2Net is realized by a set of (s layered) 3×3 convolutions to do multiple scales within a block, using similar connections to residual networks for connectivity, which can output features with more number of different scales and enhance the expressive power of the network. This is achieved by averaging the feature map obtained after 1×1 convolution into four sub-feature maps with the same number of channels (n/4), the third sub-feature map $x_3$ is summed with the new sub-feature map $y_2$ obtained from the second sub-feature map $x_2$ after 3×3 convolution as an input to the corresponding convolution to obtain the feature map, and so on. In order to fuse the information of different scales, the four feature maps obtained are merged and the final feature map is output after 1×1 convolution. Res2Net is beneficial for extracting global and local information by segmenting and re-splicing the feature

maps for combined use. In order to make the network more focused on the target region and reduce the interference from the background, the spatial attention mechanism is added after the 1×1 convolution and before the residual connection, as shown in Fig. 2.

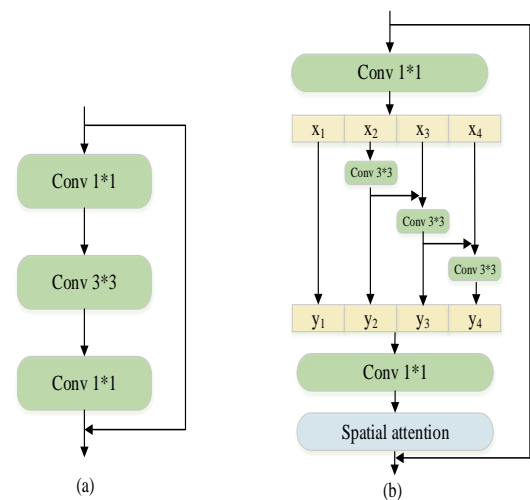

Fig. 2.    Comparison of original Resnet bottleneck block and improved res2net module: (a) Resnet bottleneck; (b) Improved res2net module.

Pixels at different locations in an image have different importance, with pixels close to the target being more important and those far from the target more likely to be in the background. The role of spatial attention mechanisms is to enable the network to focus on the "where" part of the information, focusing on important features and suppressing unnecessary features. The specific implementation of the spatial attention mechanism is shown in Fig. 3. Firstly, average pooling and maximum pooling are performed on the feature maps along the channel direction to aggregate the channel information of the feature maps, two H×W×1 feature maps are obtained for stacking, and a feature map is obtained after a 7×7 convolution, and then the spatial attention weight is obtained by the sigmoid function. Finally, the original feature map is used to multiply the spatial weights and output the feature map with positional importance.

### C. Prototype Mask Branch Improvement

The higher the resolution of the image, the more detailed information it contains, but the more computationally intensive it is. Yolact++ only uses C3-C5 for feature fusion through FPN in order to raise the speed of computation, and uses the deepest feature map P3 as the input to the Protonet branch. Because of the lack of utilization of shallow features, a lot of detailed information is lost, resulting in poor quality of the resulting prototype masks and poor segmentation of the edges. So in order to get high quality prototype masks, we fuse shallow feature maps as input. Firstly, P2 is obtained by fusing features with FPN, and fusing the low-level information requires convolution of P2 to complete the downsampling. Then P3 is added with the downsampled P2 to get the fused features as the input to the prototype mask branch, and the prototype mask maps are obtained after the protonet branch. The realization process is shown in Fig. 4.

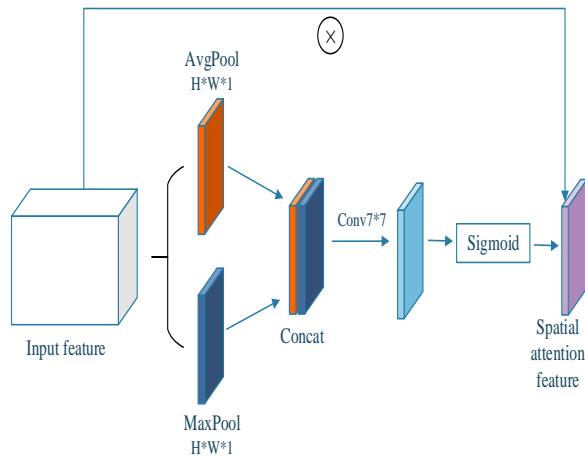

Fig. 3. Spatial attention module.

Fig. 4. Structure of the fused shallow feature map.

### D. Improvement of Non-Maximum Suppression

The segmentation accuracy of the anchor-based instance segmentation method is affected to some extent by the detection performance. In Yolact++, the segmentation performance is improved by increasing the number of frames to detect difficult and different scale targets, so a large number of redundant boxes are generated, and the model uses Fast NMS instead of Traditional NMS in order to improve the detection speed. It obtains the thresholded binarized one-dimensional vector $b=\{b_i\}_{1\times N}$, $b_i \in \{0, 1\}$ by computing the IoU matrix $X$ for every two boxes, performing upper triangulation, and solving for the maximum value of each column to directly remove the detection boxes with high overlap. However, this leads to the suppression of too many detection frames, and detection boxes with high overlap but belonging to different instances are deleted, leading to the occurrence of missed detection, which reduces the detection accuracy and thus affects the accuracy of segmentation. Therefore, this paper proposes the use of Cluster-NMS instead of Fast NMS, which can make up for the problem of accuracy degradation caused by Fast NMS while ensuring the detection speed. Instead of suppressing the prediction box directly after obtaining the vector $b$, Cluster-NMS introduces two matrices with the following equations. First, $b$ is expanded into a symmetric matrix with the same diagonal elements as $b$, and then the matrix $C$ is obtained by left-multiplying the matrix $X$. The purpose is to omit the effect of the suppressed boxes from the previous iteration on the other boxes. And keep performing the above iterations for $C$. The end of the iteration is indicated when the $b$ obtained from two consecutive iterations is unchanged. By introducing Cluster-NMS, the problem of missed target detection leading to missed segmentation can be improved and the segmentation accuracy of the model can be improved while maintaining high efficiency.

$$A^t = \mathrm{diag}\left(b^{t-1}\right) \tag{1}$$

$$C^t = A^t \times X \tag{2}$$

### IV. EXPERIMENTAL METHODS AND ANALYSIS OF RESULTS

### A. Experimental Environment and Parameter Description

All experiments in this paper are based on Windows 10 operating system, hardware system is Intel Core i5-10400F, graphics card is NVIDIA Geforce RTX 2070 SUPER and running memory is 8G. GPU processing six images at a time in ablation experiments, and the size of images are uniformly processed to 550×550. Initial momentum is set to 0.9, learning rate is 0.001, weight decay is 0.0005.

### B. Datasets

To validate the effectiveness of the improved model, this paper uses two publicly available datasets for training and testing, and the models were applied to the insulator dataset produced by ourselves to segment the shed of insulator. The MS COCO dataset is a large image dataset developed and maintained by Microsoft and is the most commonly used open standard dataset. In this paper, we conduct comparative experiments of instance segmentation algorithms using the COCO 2017 dataset, which contains 80 categories of life. The

CVPPP dataset is a plant image dataset that provides tobacco and Arabidopsis raw images as well as labeled images to segment plant leaves. The dataset is divided into a total of four sub-datasets, A1-A4, and A5 is the sum of the four sub-datasets, including 810 images of the training set. In order to facilitate subsequent processing and comparison of results, the dataset labels were processed into COCO format. In this paper, ablation experiment are conducted on the CVPPP dataset to verify the effectiveness of the improved module, and the segmentation effect before and after the model improvement is tested on the COCO dataset. And comparison experiments are conducted on CVPPP dataset to compare and analyze the segmentation results of different models.

We need to segment the shed of insulator to find the shed location, so we made insulator dataset and segmented it using improved algorithm. Most of the collected insulator pictures are composite insulators. In addition, in order to ensure the diversity of insulators and improve the generalization ability of the model, insulator images of different types and environments are collected from the Internet. The images were labeled using LabelMe, and a total of 581 images were labeled and randomly augmented by flipping, panning, adding noise, and changing brightness to 2316 images with 19204 instances. The dataset was divided into a training set of 1481, a validation set of 371, and a test set of 464. To facilitate subsequent processing, the dataset is converted to COCO dataset format. According to the configuration of the experimental environment and to ensure the validity of the experimental comparison, the image size was resized to 550×550 in all experiments.

### C. Evaluation Metrics

All experiments in this paper were evaluated and analyzed using COCO evaluation metrics, mainly showing the mAP, $AP_{50}$, $AP_S$, $AP_M$, $AP_L$. Average accuracy AP is the mean value of accuracy at an IoU of 0.5-0.9, an interval of 0.05, and a recall of 0-1 under a category, calculated as shown in Eq. (3), and the area under a two-dimensional curve plotted with recall as the horizontal axis and precision as the vertical axis. MAP is the mean value of AP for all categories, $AP_{50}$ for accuracy at IoU=0.5. S, M, and L are distinguished according to the size of the area of the examples, and the accuracy is obtained separately.

$$AP = \int_0^1 P(\mathrm{r})\mathrm{d}r \tag{3}$$

### D. Ablation Experiments

In order to quantitatively analyze the impact of the introduction of Res2Net in Yolact++ combined with attention to the backbone network, feature fusion, and improved non-maximal value suppression on the segmentation performance, this paper uses the above methods in combination with Yolact++ and ablation experiments on the CVPPP dataset. All experiments on the CVPP dataset were iterated 150,000 times. The structure of each model in the ablation experiment and the results are shown in Table I. Res2Net indicates the backbone module of Res2Net combined with the attention mechanism, feature fusion indicates that P2 is fused with P3 as the input of the prototype mask, and "√" indicates the introduction of the

corresponding module. The experimental results quantify the effects of these methods on plant leaf segmentation performance.

TABLE I. COMPARISON OF ABLATION EXPERIMENTAL RESULTS OF CVPPP DATASET

| Experiment | Res2net | Feature Fusion | Cluster-NMS | mAP |
|------------|---------|----------------|-------------|------|
| 1 | - | - | - | 65.6 |
| 2 | √ | - | - | 66.7 |
| 3 | √ | √ | - | 66.9 |
| 4 | √ | - | √ | 67.2 |
| 5 | √ | √ | √ | 67.3 |

Experiment 1 shows the segmentation results of the baseline model on the CVPPP dataset. In order to harmonize the evaluation criteria, the paper does not use the evaluation metrics specified in the CVPPP dataset, but instead uses the COCO evaluation metrics. Experiment 2 was the improved Res2net combined with Yolact++, and the mAP was improved by 1.1%, comparing with Experiment 1 shows that the introduction of Res2net is more beneficial to extract global as well as local features, and the addition of spatial attention can make the network focus more on the target part, thus improving the segmentation accuracy. Experiment 3 represents the fusion of shallow features with the original Protonet input feature P3 based on Experiment 2 to increase the feature detail information and get a higher quality prototype mask, which results in more accurate edge segmentation. Experiment 4 is the introduction of Cluster-NMS on the basis of Experiment 2. Because Fast NMS is prone to treat two frames that are close to each other but belong to two different similar instances as two overlapping frames of one instance, one of the frames will be suppressed for deletion, and thus there will be a problem of missed detection. And the leaves of a plant are similar in shape and close together, so it is more likely to have the problem of missed detection. Compared with Experiment 2, mAP is improved, indicating that Cluster-NMS can solve the problem of Fast NMS suppressing too many boxes and leading to missed detection, thus improving the segmentation accuracy. Experiment 5 shows the segmentation results of our model, which combines the above method with Yolact++, and the experimental results show that our model improves the segmentation accuracy of plant leaves by 1.7% compared to the accuracy before improvement.

Fig. 5 visualizes the variation of the total loss value over the training set, which serves as a measure of the error between the predicted results and the true annotation, with smaller losses indicating more accurate predictions and better segmentation performance of the model. As shown in the figure, the loss values of the baseline model Yolact++ as well as the improved model are visualized in the figure. The loss values of the two models leveled off after about 110,000 iterations, with the pre-improvement model eventually stabilizing at about 1.41 and the post-improvement model loss values eventually stabilizing at about 1.35. In general, the loss value curves of the improved model are below those of the baseline model. As well as Fig. 6 reflects the mAP comparison on the validation set before and after the model improvement,

both of which demonstrate that the segmentation performance of the improved model is better than that of the baseline model.

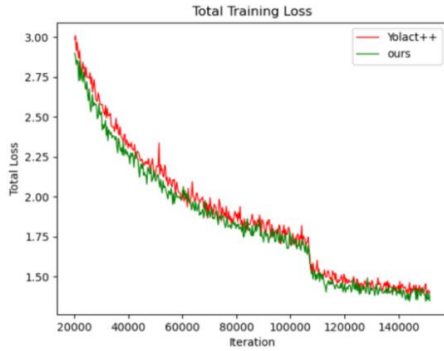

Fig. 5.   Loss value curve.

Fig. 6.   CVPPP validation set mAP plot.

Fig. 7 visualizes the leaf segmentation results before and after the model improvement. Column (a) of the figure shows the original image of the plant leaf, and the red boxes in the figure show where the results are significantly better after the improvement. Columns (b) and (d) show the leaf segmentation results for the model before and after the improvement,

respectively, and column (c) shows the leaf segmentation results obtained from Experiment 2 in the ablation experiment. There are two shaded leaves segmented into one leaf in the red box of the first image, and there are cases where the edge portion is not accurately segmented. After feature extraction by Res2net combined with spatial attention, the features are better extracted and the edges are segmented accurately. In column (d) all leaves are accurately segmented. Comparing columns (b) and (c) of the second figure illustrates that the improved backbone network can solve the problem of segmentation error, but there is still the problem of missed segmentation, comparing column (c) and (d) shows that Cluster-NMS can solve the problem of missed segmentation. The missed detections in the third figure are also well resolved, indicating that our model has better segmentation than Yolact++.

Table II shows the segmentation performance of the model before and after improvement on the MS COCO val2017. The experiment set batch_size to 4 and trained 54 epochs. Because the background of the COCO dataset is more complex and the number and size of targets differ significantly from the CVPPP dataset, resulting in a lower mAP of the mask than the CVPPP dataset. And due to the problem of different computer configurations, the experimental results are somewhat different from those of the published papers. The table shows that the accuracy of the model is 1.1% higher after the model improvement than before the improvement, and the mAP of the instances of different sizes is improved.

TABLE II.        SEGMENTATION RESULTS ON COCO DATASET

| Model | Backbone | mAP | $AP_{50}$ | $AP_S$ | $AP_M$ | $AP_L$ |
|-------|----------|-----|-----------|--------|--------|--------|
| Yolact++ | Resnet50 | 33.1 | 51.8 | 11.6 | 35.5 | 54.3 |
| Ours | Resnet50 | 34.2 | 52.8 | 12.1 | 36.9 | 56.1 |

Fig. 7.   Visualization of leaf segmentation results.

### E. *Comparison of Different Models*

To further validate the effectiveness of the improved model, we trained the CVPPP dataset and insulator dataset using several commonly used segmentation models, and tested and compared the segmentation results, as shown in Table III and Table IV. The tables show the mAP of the two-stage segmentation model Mask RCNN, the single-stage models CondInst, Yolact++, the segmentation models without anchor boxes SOLO, SOLO V2, and the improved algorithm of this paper on two datasets, as well as the $AP_{50}$ and the accuracy of these models for different sized targets ($AP_S$, $AP_M$, $AP_L$). From the experimental results in Table III, the segmentation results of SOLO are poor because the leaf size of a plant is relatively similar and the leaves have small intervals or even overlap each other, so there will be multiple leaves of similar size appearing in the same grid, resulting in poor segmentation of leaves. Other models perform well on the CVPPP dataset, but all of them also have the problem of segmentation error and missed detection. The improved algorithm makes improvements to address the above problems, and the segmentation of plant leaves is better than other models.

Insulators play an important role in the power system, and damage to insulators can affect the entire line. They are an important concern in power system inspections, so it is important to ensure the cleanliness and integrity of insulators. First of all, it is necessary to identify the shed of insulator and find the exact location of the shed. Due to the uneven illumination and shadows caused by the insulator usage scenario, the shed of insulator cannot be accurately segmented by the traditional image segmentation method. So how to quickly and accurately segment a single shed is a problem that needs to be solved urgently, in this paper, we use several instance segmentation algorithms to train insulator datasets and segment the shed of insulator, the results are shown in Table IV, and the segmentation results were visualized as shown in Fig. 8.

TABLE III.    COMPARISON OF SEGMENTATION RESULTS OF MAINSTREAM MODELS FOR CVPPP DATASET

| Model | Backbone | mAP | $AP_{50}$ | $AP_S$ | $AP_M$ | $AP_L$ |
|---|---|---|---|---|---|---|
| Mask RCNN | Resnet50 | 62.7 | 89.2 | 44.9 | 79.9 | 71.7 |
| CondInst | Resnet50 | 63.5 | 92.3 | 43.3 | 82.5 | 86.8 |
| SOLO | Resnet50 | 59.2 | 83.0 | 33.3 | 79.7 | 79.3 |
| SOLO V2 | Resnet50 | 62.2 | 83.3 | 36.3 | 82.3 | 83.7 |
| Yolact++ | Resnet50 | 65.6 | 88.9 | 45.1 | 81.5 | 73.7 |
| Ours | Resnet50 | 67.3 | 91.0 | 45.9 | 83.3 | 79.9 |

TABLE IV.    COMPARISON OF THE RESULTS OF DIFFERENT MODELS FOR INSULATOR DATASET

| Model | Backbone | mAP | $AP_{50}$ | $AP_S$ | $AP_M$ | $AP_L$ |
|---|---|---|---|---|---|---|
| Mask RCNN | Resnet50 | 36.3 | 83.0 | 24.3 | 32.0 | 41.0 |
| CondInst | Resnet50 | 26.1 | 75.3 | 11.3 | 19.0 | 34.3 |
| SOLO | Resnet50 | 37.2 | 87.8 | 18.5 | 32.2 | 42.7 |
| SOLO V2 | Resnet50 | 40.4 | 92.3 | 19.2 | 34.7 | 46.8 |
| Yolact++ | Resnet50 | 40.2 | 78.5 | 24.7 | 33.5 | 47.6 |
| Ours | Resnet50 | 41.7 | 82.3 | 24.5 | 34.3 | 49.9 |

Fig. 8.    Comparison of segmentation results of mainstream models: (a) Original image; (b) Mask RCNN segmentation results; (c) CondInst segmentation results; (d) SOLO segmentation results;  (e) SOLO V2 segmentation results; (f) Yolact++ segmentation results; (g) Our model segmentation results.

The insulator dataset is used to train the above mainstream example segmentation model and this paper's algorithm, respectively, and the trained model is used to verify the detection and segmentation effect of the shed of insulator. The training results are compared in Table IV. The experimental results show that CondInst has the worst segmentation effect. Mask RCNN, SOLO performs slightly worse on the insulator dataset, mAP is slightly lower than the baseline model, and SOLO V2 and Yolact++ segmented well. The masks of Yolact++ use all the information of the picture space without repooling, which does not cause the performance loss of the mask, the segmentation accuracy for large target objects is significantly higher than other methods, and most of the insulator datasets are large targets, so the baseline model Yolact++ has a higher mAP than other models. The improved model made improvements to the problems of the baseline model, and the accuracy was improved by 1.5% over the baseline model, with the best segmentation results.

Fig. 8 visualizes the shed of insulator segmentation results of the mainstream instance segmentation models. In general, all the models in Table IV have the problems of missed detection and poor segmentation of shed edges. Mask RCNN has obvious missed detection. The most problematic segmentation result of SOLO is the segmentation error, which divides one shed into multiple sheds. SOLO V2 performs better than SOLO, and the problem of segmentation error is well solved, but there is also the problem of poor segmentation edge. The segmentation results of our improved model are the best, and the problems of missed detection as well as poor segmentation edges that occur in the baseline model are improved to segment the shed of insulator more accurately.

### F. Discussion

In this paper, segmentation performance is validated and compared on two publicly available datasets as well as a homemade insulator dataset. In order to more easily compare and illustrate the segmentation effects of the analytical models on different datasets, the article uniformly uses the COCO evaluation metrics. Experimental results show that our model achieves better segmentation results on all three datasets. The improvement is greater on the CVPPP and insulator datasets, which have only one category, similar and densely distributed targets, and the algorithm's backbone and NMS method improvements both lead to improved segmentation performance for these targets. The experimental results of the three datasets can also illustrate that the model has a greater improvement in the segmentation of large targets. However, the model focuses on improving accuracy and does not focus on model complexity as well as speed issues, and subsequent studies will further optimize the model. And the collected insulator images have the problem of a single type and scene, and the insulator segmentation dataset needs to be enriched subsequently.

## V. CONCLUSION

In this paper, Yolact++ is used as a baseline model to improve the accuracy of the model by aiming at the problems of segmentation error, missed segmentation and low accuracy of edge segmentation. Firstly, the use of Res2net which incorporates a spatial attention mechanism as a backbone enables the backbone network to better extract global and local features, acquire target information with clear boundaries, and improve the problem of segmentation errors. Second, the shallow features P2 and P3 are fused and input to the Protonet branch to obtain a high-quality prototype mask map that does not depend on a particular instance. Finally, the introduction of Cluster-NMS improves the problem of missed detection due to the suppression of too many detected boxes by iteratively and gradually eliminating the influence of the boxes with too much overlap on the other boxes, which improves the detection accuracy and segmentation accuracy. Training and testing on the public datasets COCO and CVPPP datasets are performed to verify the effectiveness of the improved model, and the average accuracy of the mask is 1.1% higher on the COCO dataset, and the accuracy on the CVPPP dataset is 1.7% higher than before the improvement. The improved model is applied to the insulator dataset labeled by itself to segment the shed of insulator, and the experimental results show that a more accurate the shed of insulator segmentation is achieved.

*Abstract*—**The increasing proliferation of Internet of Things (IoT) nodes poses significant security challenges for their network's communication. Blockchain technology, with its decentralized and distributed nature, has the potential to address these security concerns within IoT networks. LEACH (Low Energy Adaptive Clustering Hierarchy) algorithm and blockchain technology enhance IoT network security, enabling energy-efficient data management and transaction integrity, enhancing network lifespan and protection. This paper presents a security model that combines the LEACH algorithm and blockchain technology to improve IoT networks' security. The LEACH algorithm forms clusters of IoT devices, with a designated cluster head (CH) responsible for data aggregation and forwarding. Our model incorporates blockchain technology's core principles and cryptographic foundations, providing additional security measures. It consists of two main layers: the LEACH clustering-based routing protocol, which forms clusters and layers, and a blockchain simulator module. The LEACH algorithm enhances energy consumption, enables efficient data management within clusters, and ensures the integrity, transparency, and immutability of transactions. Our model is implemented on a simulator, allowing for experimentation and modification to evaluate the performance and effectiveness of the security enhanced IoT network model. Our results demonstrate the effectiveness of the proposed enhanced LEACH algorithm compared to previous algorithms, in which the last node died after 1868 transactions. As well as the results of the pro-posed framework, which record 0.058% of the state rate and 2.75 Throughput. Simulation results are validated with respect to previous algorithms, and it obtained higher accuracy compared to them.**

## I. INTRODUCTION

Internet of Things (IoT) security faces numerous challenges in ensuring the protection of connected devices and the data they generate [1]. The sheer scale and heterogeneity of IoT systems, along with limited computational resources and varying security measures, make it challenging to implement standardized security protocols [2]. Challenges also arise from the massive volume of data generated, the lack of comprehensive security regulations, and the complexity of managing security updates [3]. To address these challenges, a holistic approach is required.

One potential solution to various IoT security challenges is blockchain technology. Blockchain's decentralized and immutable ledger ensures data integrity, transparency and prevents tampering [4]. Cryptographic algorithms enable secure authentication and identity management, limiting access to trusted devices. The distributed nature of blockchain eliminates single points of failure, enhancing system resilience [5]. Additionally, blockchain facilitates secure and private data sharing through encryption and selective disclosure, maintaining confidentiality. Smart contracts automate trust and enforce predefined rules, reducing the risk of errors or malicious actions [6]. By leveraging blockchain, IoT systems can benefit from enhanced security, data integrity, privacy, and resilience.

To further enhance IoT security, the LEACH (Low-Energy Adaptive Clustering Hierarchy) algorithm can be integrated with blockchain [7]. Originally designed for wireless sensor networks, LEACH focuses on energy optimization and efficient data management through clustering. By combining LEACH with blockchain, the security and trustworthiness of IoT networks can be enhanced [8]. The algorithm ensures an even distribution of energy load among devices, extending their lifespan and reducing the risk of vulnerabilities [9]. The blockchain provides a decentralized and immutable ledger for securely recording and verifying IoT transactions, ensuring data integrity and transparency. Together, the LEACH algorithm and blockchain technology offer a comprehensive approach to IoT security, addressing energy efficiency, data integrity, and trust, ultimately strengthening the overall security of IoT networks [10].

In this paper, we present a two-layer BC security model that aims to protect IoT networks while simplifying the implementation process. Our proposed model leverages the inherent features of blockchain technology, such as immutability, transparency, and decentralization, to enhance the security of IoT communication. By incorporating blockchain into the architecture, we establish a secure and tamper-proof environment for IoT devices. Additionally, we propose an enhanced LEACH algorithm, powered by fuzzy logic, for efficient data aggregation in IoT-enabled applications, with a specific focus on maximizing network lifetime. Our proposed algorithm optimizes the energy consumption and communication strategies of IoT devices, prolonging the overall lifespan of the network. Through extensive simulations, we demonstrate the effectiveness of our proposed enhanced LEACH algorithm compared to similar works, highlighting its superior performance in terms of network lifetime and energy efficiency.

To support the analysis and evaluation of diverse blockchain systems and their deployments, we introduce a

comprehensive framework and software tool. This framework enables the construction and simulation of discrete-event dynamic system models for blockchain systems. At the core of the framework lies the Base Model, which encompasses fundamental model constructs shared among various blockchain systems and is organized into abstract layers such as network and consensus. The Base Model provides adaptability and extensibility, allowing for the incorporation of specific system or deployment details. Furthermore, we provide a detailed description of the implementation of the simulator within the proposed framework, along with its application to the Ethereum blockchain. To validate the simulation results, we compare our findings to real-life systems and past research reported in previous studies to ensure their dependability and correctness.

In summary, the main contribution of this paper is threefold. First, we present a two-layer Blockchain Security model that safeguards IoT networks and simplifies their implementation. Second, we propose an enhanced LEACH algorithm that maximizes network lifetime through efficient data aggregation techniques. Finally, we utilized a comprehensive framework and software tool for constructing and simulating blockchain system models, facilitating analysis and evaluation. Collectively, these contributions provide a solid foundation for enhancing the security, reliability, and efficiency of IoT networks through the integration of blockchain technology.

The paper is organized as follows in the following sections: The second section discusses the related work. The third section examines the Proposed Methodology. The fourth section describes the model's implementation. The fifth section discusses the experimental results and validation. The last section summarizes the paper's contribution.

## II. RELATED WORK

Recently, there has been a growing interest in integrating blockchain technology into IoT. However, very few researchers were interested in how BCs can help in IoT device authentication requirements. In this section, we review the existing literature that focuses on integrating blockchain into IoT ecosystems, highlighting the scarcity of works that successfully address security requirements in this integration.

presents a summary of proposed solution, technology, advantages, and disadvantages of related works.

Yanhui, Liu, et al. [11] focused on the security of user identification and privacy in IoT. By protecting the user's identity and privacy, it becomes impossible for an attacker to link the acquired data with the actual identity of the user, thereby ensuring the safety of the user. To enhance the reliability of the system, the study employs the features of blockchain, which are immutable and incorruptible. The proposed approach records transaction details of user information using Hyperledger and conceals the actual identity of the user using the ring signature method. To generate the necessary parameters for the signature, the system employs a key generator to provide the system with public parameters and ring membership information. Finally, the study also includes an accountability mechanism to punish any attackers who seek

to squander system resources by disclosing the user's identity and therefore denying them access to the system.

Ourad, et al. [12] suggests a blockchain-based approach for secure communication and authentication of IoT devices. The solution exploits the inherent characteristics of blockchain while integrating with pre-existing authentication techniques. The study also includes an accountability mechanism to punish any attackers who seek to squander system resources by disclosing the user's true identity and therefore denying them access to the system.

TABLE I. SUMMARY OF RELATED WORK

| Ref No. | Proposed Solution | Technology | Advantages | Disadvantages |
|---|---|---|---|---|
| [11] | Blockchain to protect user identity in IoT | Hyperledger, Ring Signature, Aggregated Signature | Identity privacy, Reliability | Waste system resources |
| [12] | Blockchain-based authentication for IoT devices | Blockchain, Authentication | Accountability, Tamper-proof logs | Resource constraints |
| [13] | Improved blockchain-based authentication protocol | Ethereum, Security, Anonymity | Secure access, Formal verification | Computational cost |
| [14] | IoT blockchain architecture for identity authentication | BCoT, Gateway, Device recognition | Distributed ledger, Feasibility | Device modification |
| [15, 16] | Multi-layer blockchain security model for 5G-enabled IoT | Hyperledger Fabric, Clustering, Evolutionary Computation | Security, Network authentication | Latency, Throughput |
| [17] | Secure data dissemination using AI and blockchain | AI-based intrusion detection system, blockchain, smart contracts, Interplanetary File System (IPFS) | Efficient and secure data transmission, resistance to attacks | Cost and complexity of implementing blockchain technology |
| [18] | Blockchain and DL integrated framework | Digital Twin (DT), Smart Contracts, LSTMSAE, MHSA-based BiGRU | Enhances communication security and data privacy | High computational power requirement, Potential for network congestion |

Yavari, Mostafa, et al. [13] reveals that a unique authentication system for the administration of IoT device information based on blockchain is vulnerable to security risks such as secret disclosure, replay, traceability, and reuse attacks, all with a probability of success and a constant complexity of 1. The study also includes an improved blockchain-based authentication protocol (IBCbAP) that provides safe access management as well as anonymity. The JavaScript programming language and the Ethereum local blockchain were used to create the IBCbAP. Additionally, the study

verifies the security of IBCbAP through informal and formal analysis using the Scyther tool.

L Gong, et al. [14] proposes a mechanism and creates an IoT blockchain architecture for storing device identity information in a decentralized ledger. The research also suggests a Blockchain of Things (BCoT) Gateway, which streamlines the recording of authentication transactions in a blockchain network without requiring any changes to existing device hardware or applications. In addition, a new device recognition model that is well-suited for blockchain-based identity authentication is provided, utilizing a novel feature selection mechanism for device traffic flow. Finally, the study develops the BCoT Sentry framework as a reference model for the suggested strategy.

Honar Pajooh, Houshyar, et al. [15, 16] proposed a Multi-layer Blockchain Security model that can safeguard IoT networks and be implemented in a simple manner. The model uses clustering to make the multi-layer structure easier to manage. The IoT network is partitioned into K-unknown clusters using approaches that combine Simulated Annealing and Genetic Algorithms. The chosen cluster chiefs are in charge of local authentication and permission. The suggested concept is built on the open source Hyperledger Fabric Blockchain technology. Base stations securely communicate information with one another using a global blockchain architecture.

Kumar, Prabhat, et al. [17] presents a safe way of data distribution based on AI and blockchain technologies. The technology gathers data from healthcare sensors put around the patient's home and sends it to neighboring edge devices. The acquired data is filtered by an AI-based intrusion detection system positioned at the network's edge. The blockchain is then used to create a secure health monitoring network, in which regular or filtered transactions are forwarded to centralized cloud servers and approved via a smart contract-enabled consensus method. Validated transactions are saved on the cloud's distributed Interplanetary File System (IPFS), and the returned transaction hash is saved on the blockchain ledger at the edge devices, allowing for speedier data sharing.

Kumar, Prabhat, et al. [18] provide a decentralized data processing and learning framework in the Industrial Internet of Things (IIoT) network that combines blockchain technology and Deep Learning (DL). A unique Decision Tree (DT) paradigm is used in the framework to provide a virtual environment for modelling and reproducing IIoT security-critical processes. In the proposed blockchain-based data transmission architecture, smart contracts are employed to ensure data integrity and authenticity. Furthermore, the authors developed a DL approach that uses an Intrusion Detection System (IDS) to evaluate blockchain data. The DL scheme employs the Long Short-Term Memory-Sparse Autoencoder (LSTMSAE) technique to learn spatial-temporal representations, as well as the proposed Multi-Head Self-Attention (MHSA)-based Bidirectional Gated Recurrent Unit (BiGRU) algorithm to learn long-distance features and accurately detect attacks.

Al Ahmed, Mahmoud Tayseer, et al. [19] proposes the Authentication-Chains protocol, a decentralized, distributed blockchain-based authentication mechanism for IoT. The protocol clusters nodes and creates a unique authentication blockchain for each cluster. These cluster chains are linked by another blockchain. The proposed consensus mechanism is based on proof of identity verification to address the limited processing capabilities of IoT devices. The security performance of the protocol is analyzed and tested using cryptographic protocol verifier software, and a test bed based on the Raspberry Pi network is shown to validate the protocol's performance.

A significant study gap in the body of current literature is evident, with few studies devoted to examining the relationship between blockchain technology and IoT device authentication requirements. Although there is a rising interest in incorporating blockchain technology into IoT ecosystems, recent endeavours have primarily concentrated on security considerations or other use cases. It has been largely neglected to address the unique difficulty of guaranteeing strong device authentication inside this integration. The examined publications provide insightful information about several facets of blockchain's potential in the context of the Internet of Things, including how it might improve user privacy, secure communication, access control, and data distribution. Still, there isn't much of a focus on IoT device authentication standards.

## III. Proposed Methodology

The proposed model aims to enhance the security of IoT networks by combining the LEACH algorithm and blockchain technology. In this section, we will introduce how The LEACH algorithm optimizes energy consumption and enables efficient data management within clusters, while blockchain technology ensures the integrity, transparency, and immutability of transactions. The LEACH algorithm is utilized to form clusters of IoT devices, with a designated cluster head (CH) responsible for data aggregation and forwarding within each cluster. By employing a randomized rotation of CHs, the LEACH algorithm ensures an even distribution of energy load among devices, thereby extending the network's lifespan. The primary objective of the randomized rotation is to achieve an even distribution of the energy load among devices in the network, which in turn helps to prolong the network's lifespan.

In our proposed model, we have integrated the core principles and cryptographic foundations of blockchain technology to provide additional security measures. Fig. 1 illustrates the system architecture, showcasing the structure of the model and the interaction between its components.

The proposed model consists of two main layers. Firstly, the LEACH clustering-based routing protocol forms clusters and layers within the IoT network. Unsupervised hybrid clustering algorithms are employed to create multiple clusters, with each cluster associated with a robust CH. Within each cluster, IoT devices and nodes undergo authentication and authorization processes, ensuring privacy and security.

Fig. 1.   Proposed model.

privacy and security inside each cluster, devices are authenticated and authorized to access the network through the use of local authorization and authentication services.

Fig. 2 shows the clustering approach for the IoT network. The clustering is done with the utilization of the LEACH algorithm. LEACH is a clustering-based routing protocol specifically designed for wireless sensor networks with limited energy resources. LEACH helps in reducing the latency and overhead in IoT systems by minimizing communication distances among IoT objects and selected cluster heads. With clustering, fewer nodes require long-distance transmissions to the base station (BS) nodes, resulting in reduced total power consumption and improved network coverage.

Fig. 2.   IoT network clustering scheme.

Our technique, which employs the LEACH clustering algorithm, also aids in maximizing the application efficiency of BC (Blockchain) technology by minimizing deployment complexity. The CH nodes control the whole network, which is separated into non-overlapping clusters, while other cluster members interface with the CH nodes for data transfer.

The goal is to accomplish clustering by deploying the LEACH algorithm throughout the network. In the suggested approach, critical network characteristics such as distance, network coverage, energy, and load are handled as node clustering factors.

Our technique presents LEACH-based clustering, which avoids uniform distribution of nodes and clusters in order to model the heterogeneous character of the IoT network. The overall number of clusters and the number of nodes in each cluster are not predetermined. As a result, the overall network's lifespan rises, but energy dissipation within CH nodes becomes more uniform.

*B. Blockchain Simulator*

In this section, we present the Base Model that forms the foundation of the Blockchain Simulator. The simulator's purpose is to replicate many sorts of blockchain systems while also allowing for the installation of specific application enhancements as required. We begin by explaining the Blockchain Simulator's design principles and aims, emphasizing generality, flexibility, and accessibility. Following that, we go over the architecture layer by layer, beginning at the network layer and ending with the Consensus Layer. We

Secondly, the model incorporates a blockchain simulator module, which serves as the engine of the simulator. This module comprises four categories: event, scheduler, statistic, and main. It works on three steps: transaction creation and appending to the transaction pool, block generation where transactions are executed and added to the blockchain, and block reception where the new block becomes a permanent part of the blockchain ledger. The transaction pool is also updated accordingly.

By combining the LEACH algorithm and blockchain technology, our proposed model aims to provide enhanced security for IoT networks. The LEACH algorithm optimizes energy consumption and enables efficient data management within clusters, while blockchain technology ensures the integrity, transparency, and immutability of transactions. This integration enhances the overall security and trustworthiness of IoT systems.

*A. Cluster Head Selection Algorithim*

This level includes Internet of Things objects, nodes, and devices, as well as network elements in charge of communication, network processes, and protocols. Unsupervised hybrid clustering methods divide the IoT network into numerous clusters and layers. Each group is assigned a strong device known as the CH (Cluster Head). IoT devices and nodes are geographically dispersed. To ensure

define the primary functional components (entities) inside each layer and characterize the tasks or activities they carry out.

*1) Principles of design:* The Base Model's design is governed by the Blockchain Simulator's key aims, which are as follows:

*a) Generality:* The Blockchain Simulator will be relevant to a broad range of blockchain systems, setups, and architectural queries.

*b) Flexibility:* It should be easy for designers or analysts to manipulate the Blockchain Simulator to explore different aspects of blockchain systems.

*c) Accessibility:* Regardless of the goals, the Blockchain Simulator should remain user-friendly, both for conducting simulation studies and for extending its capabilities.

Designing a tool like the Blockchain Simulator involves striking a balance between generality and extensibility, while simultaneously ensuring simplicity. The Base Model plays a crucial role in achieving this balance, as it determines the level of generality supported by the model class and the ease with which new models can be built. The Base Model is also converted into software modules, it affects the ease with which the Blockchain Simulator may be extended to create more thorough representations of certain blockchain processes.

The Blockchain Simulator caters to the essential components of all blockchains (nodes, transactions, blocks, and incentives). The Base Model defines the level of generality in the model class supported by the Blockchain Simulator, as well as the ease with which new models can be constructed. By representing these building blocks in software modules, the Base Model also influences the extensibility of the Blockchain Simulator, enabling the provision of more detailed models for specific blockchain processes.

*2) Network layer:* The Blockchain Simulator's Network Layer is made up of two components: The underlying Broadcast protocol and Node. The Node entity oversees keeping system state variables like the transactions pool and the blockchain ledger up to date. The Broadcast protocol specifies how data items such as Blocks and Transactions are broadcast over the network.

The Node object includes both the Blockchain ledger and the Transactions pool entities. These entities are kept and updated in real time by each node. Nodes are represented as objects, each having its own unique ID, balance, local ledger, and transactions pool. When fresh transactions and blocks arrive, the transactions pool and local ledger are represented as expandable array lists. All blockchain implementations have these traits. These traits, however, may be broadened by introducing additional ones.

The Broadcast protocol entity is used for information entity dissemination, which may be properly simulated by taking network configurations, node geographical distribution, and node connection into consideration. It can also be abstracted by considering only a time delay for information propagation among nodes. The simulator is simplified by concealing unneeded features by abstracting the broadcast protocol, resulting in a decrease in network setup settings such as the broadcast protocol, geographical distribution of nodes, and the number of connections per node. The simulator improves efficiency and usability by making the propagation delay the only parameter that may be changed.

*3) Consensus layer:* The purpose of the Consensus Layer is to describe the rules that nodes must follow in order to agree on the state of the block-chain. This layer consists of four components: a transaction, a block, a transactions pool, and a blockchain ledger. The Block entity is reliant on the Blockchain ledger entity, which is dependent on the Transaction entity. As a result, the blockchain ledger is composed of blocks, which are composed of transactions. Because every produced transaction is placed in the Transactions pool, it is dependent on the Transaction entity. These four entities are managed by the Node entity.

Within the Consensus Layer, the entities perform a range of activities or actions. One example of such activity is the creation of blocks and transactions. Fig. 3 depicts the flow of these operations, which occur continuously since transactions and blocks are regularly brought to the network. Fig. 3 depicts the process for the consensus operations within the Blockchain Simulator's Base Model.

*a) Transaction:* Transactions are essential components of all blockchain platforms and play an important role in updating the state of the blockchain. A new transaction affects the transaction pool by being added to the network when it is introduced.

We employ two modelling approaches for transactions: full and light. The full technique tracks each individual transaction in the system, allowing for the analysis of transaction latency. While this technique closely resembles real-world blockchain transactions, it demands substantial computing resources and simulation time due to tracking each transaction separately. On the other hand, the light technique focuses on studying the throughput of blockchain systems, disregarding transaction confirmation time within the system. Irrespective of the chosen modelling technique, we represent transactions as objects with various attributes for instance transaction ID, timestamp, contents, size, submitter, and recipient. These attributes are generally shared across most blockchains.

In the full modelling technique, using an array list abstraction, we establish an independent transactions pool for each node in the whole modelling method. Each participating node in the network receives a transaction when it is generated by a node. When a transaction is received, the receiving node adds it to its own pool. This method includes three different activities: transaction creation, transaction propagation, and transaction adding.
Fig. 3. Workflow of the consensus operations within the blockchain simulator's base model.

In the light modelling technique, we employ a single shared transactions pool among all network nodes. This method offers a simplified approach to modelling transactions by excluding the propagation process and continuous pool updates by nodes. Consequently, the light technique enhances simulation efficiency and speed. However, because individual transactions are not recorded, it cannot give insights into transaction slowness. Nonetheless, it is useful for collecting throughput metrics in blockchain systems. Then Before the mining process, we construct a number of transactions (N) and then append them to the common pool. Miners may utilize this pool to choose numerous transactions to include in their next block. In most cases, the number of transactions (N) should be sufficient for one or two blocks. When a miner creates a successful block, the pool is reset, and a new batch of transactions is added for the following block.

Both modelling methods can be employed in the Blockchain Simulator, granting users the flexibility to choose the method that aligns best with their specific needs. For instance, if the primary focus is on throughput analysis, the full technique may not be necessary due to its significant extension of simulation runtime.

*b) Block:* Blocks are crucial elements of blockchain systems, which are made up of transactions. When a new block is added, it updates the transactions pool as well as the blockchain ledger. The block's transactions are removed from the pool, and the freshly created block is added to the ledger to update it. Blocks are represented as objects in our models, with different features like depth, block ID, previous block ID, date, size, miner ID, and transactions. The block ID acts as a unique identifier, whereas the block depth reveals its location inside the node's blockchain. The miner ID identifies the node that created the block. As its content, each block provides a list of transactions. These characteristics are prevalent across several blockchain systems.

In the consensus layer, we represent blocks using two basic processes: block creation and block receiving. Block construction refers to the actions taken by a miner to generate and attach a block to the blockchain ledger. These activities include completing the transactions included inside the block, constructing the block, adding it to the local blockchain, and disseminating the block to other nodes in the network. Block reception, on the other side, is concerned with how nodes update their blockchain ledgers in response to new blocks. When a valid block arrives, a recipient node performs three actions: it updates the local blockchain, appends the block to the local blockchain, and updates the transactions pool.

A node validates the authenticity of a new block when it receives it. A block is deemed valid if it was appropriately produced and includes correctly performed transactions. Our attention is drawn to block depth as a measure of validity. To be considered as legitimate, the received block must be deeper than the previous block in the ledger. Any block with a low depth that deviates from the existing blockchain is rejected and deleted. If the received block meets the depth requirement, the recipient node takes three steps: it updates its local blockchain if necessary to align with the received block, it adds the block to its local copy of the blockchain, and it refreshes the transactions pool by removing transactions already executed in the block.

*c) Transactions pool and blockchain ledger:* The Blockchain Ledger and Transactions Pool are key components of blockchain systems that reflect their status. The transactions pool is updated anytime a new transaction or block enters the network, but the blockchain ledger is only updated when a block is received. Because each node has its own copy of the pool and ledger, The blockchain network's nodes oversee maintaining and updating both.

Due to network propagation delays, nodes may briefly retain distinct viewpoints of the blockchain ledger when forks occur. To remedy this, the consensus layer creates rules for nodes to follow to resolve forks and obtain consensus. Popular blockchain systems such as Ethereum and Bitcoin use the longest-chain rule. This rule states that nodes must update their ledgers anytime. They are given a block that adds to a chain that is longer than their own. This method guarantees that nodes retain a synchronized view of the blockchain ledger, encouraging participant consensus.

## IV. PROPOSED MODEL IMPLEMENTATION

This section contains, the Network Clustering algorithm is introduced, which aims to optimize parameters by iteratively updating them based on an objective function. The algorithm starts with an initial parameter set and iterates through a specified number of iterations. It utilizes a stochastic search process, where the mean guides the search while a random vector introduces randomness. The algorithm aims to find the parameter set that minimizes the objective function. Additionally, the proposed simulator implementation using Python is discussed, including modules such as the Simulator Module, Configuration Module, and the Ethereum module, which is divided into the Network Module and Consensus Module. The simulator enables the customization of parameters and allows users to analyze the performance and behavior of blockchain systems.

Fig. 4. Proposed implementation modules.

### A. Network Clustering

The algorithm represents an optimization process as shown in Algorithm 1 that aims to find the best parameters for a given objective function E. It starts with an initial parameter set to the value P0 and a standard deviation S. The number of iterations K determines how many times the algorithm will repeat.

The algorithm iterates from $i = 0$ to $i \leq K$, updating the parameters Pi and the mean Mi at each iteration. At each iteration, a random vector Ni is created with a normal distribution, using the mean Mi and standard deviation S.

If the objective function value $E(Pi + Ni)$ is lower than $E(Pi)$, indicating an improvement, the parameters are updated as follows:

- $Pi+1 = Pi + Ni$, meaning the new parameters are obtained by adding the random vector Ni to the current parameters Pi.

- $Mi+1 = \alpha Mi + \beta Ni$, where $\alpha$ and $\beta$ are constants used to adjust the influence of the mean and the random vector on the update. They can be tuned to control the step size and exploration-exploitation balance.

If the objective function value $E(Pi \cdot Ni)$ is lower than $E(Pi)$, indicating another type of improvement, the parameters are updated as follows:

- $Pi+1 = Pi \cdot Ni$, meaning the new parameters are obtained by element-wise multiplication between the current parameters Pi and the random vector Ni.

- $Mi+1 = \gamma Mi \cdot Ni$, where $\gamma$ is a constant used to control the influence of the mean and the random vector on the update.

If neither of the above conditions is satisfied, indicating no improvement, the parameters remain the same:

- $Pi+1 = Pi$

- $Mi+1 = \delta Mi$, where $\delta$ is a constant used to control the influence of the mean on the update.

After the iterations are completed, the optimized parameters PK are returned.

Algorithm 1. Optimization of Function Parameters

| **Algorithm 1:** Optimization of Function Parameters |
| --- |
| Given: **P0** for the initial parameters, **S** for the standard deviation, and **K** for the number of iterations |
| *Returns: PK, the optimised parameters* |
| **Initialize Mi** = 0. |
| **for** $i = 0$; $i \leq K$; $i = i + 1$ repeat |
| Make a normal distribution random vector **Ni** with a mean **Mi** and standard deviation **S**. |
|   **if** $E(Pi + Ni) < E(Pi)$ **then** |
|     Pi+1 = Pi + Ni |
|     Mi+1 = α Mi + β Ni |
|   **else if** $E(Pi\ Ni) < E(Pi)$ **then** |
|     Pi+1 = Pi Ni |
|     Mi+1 = γ Mi Ni |
|   **else** |
|     Pi+1 = Pi |
|     Mi+1 = δ Mi |
|   **end** |
| **end** |

This algorithm employs a stochastic search process that explores the parameter space by iteratively updating the parameters based on the objective function's evaluations. The mean Mi helps guide the search process, while the random vector Ni introduces randomness and exploration. The algorithm aims to find the parameter set that minimizes the objective function E.

### B. Blockchain Implementation

The proposed simulator implementation is presented by using Python 3.9 with Intel Core i7-2670QM CPU @ 2.20 GHz processor and 8 GB memory. Fig. 4 depicts the key modules. The Simulator Module implements the simulator's engine and is divided into four categories: event, scheduler, statistic, and main. The configuration module enhances the simulation module by allowing the user to customize the simulation model and experiments. The Ethereum module is used to put the suggested Blockchain Simulation into action. It is separated into the following layers: Network and Consensus Modules.

*1) Simulation module:* The event class specifies the structure of simulation events. A block-level event contains four attributes: node ID, time, type , and block. Provides event preparation at two extraction levels, Examines Blocks (Bi) as Event (E), and Examines Transactions (T) as Event (E). The attribute type specifies how the event should be handled, specifically whether the current event should generate a new block or receive a previously created block. The node ID and timestamp are allocated to the node responsible for handling the event and its time management. The block attribute holds the essential information required for the occurrence of the block.

The scheduler class handles future event scheduling and recording in the queue. The array list queue acts as a storage method for handling future events inside the simulation. It undergoes continuous updates during the simulation process, accommodating the insertion of new events and the removal of existing ones. To illustrate, when an event triggers the creation of a block, the scheduler class acts by scheduling deny reception events for other nodes. These deny reception events are designed to prevent other nodes from receiving the newly created block. By scheduling such events, the simulation ensures that the block remains exclusive to the node that created it, thereby controlling its distribution within the network. It also organizes a new block generation event, in which a miner is chosen to propose and build a new block on top of the previous block.

The Main class creates the environment and then instructs the Scheduler class to schedule some basic events in order to start the simulator. The initial setup involves generating transactions and creating the first block, also known as the genesis block. Following that, the simulation advances by executing events sequentially, one after the other, until either the queue is empty, or the preset simulation time limit is achieved. Throughout this process, the Statistics class plays a crucial role. It collects and maintains the results generated during the simulation, allowing for the calculation of various statistics related to the final output. This includes analyzing

block-related data, such as the number of blocks included in the ledger. By utilizing the Statistics class, the simulation can provide valuable insights and metrics that help evaluate the performance and behavior of the system being simulated.

*2) Configuration module:* This module's goal is to serve as the primary user interface, allowing users to customize parameters relating to nodes, blocks, transactions, consensus, and simulation setups. It allows for the modification of the simulation environment and improves user engagement. Table II shows the input settings that were set before starting the simulator. The duration between blocks, the number of nodes, the number of transactions to be created each second, as well as other characteristics, may all be specified. Furthermore, the simulator disables transactions that are not interesting. This can only be accomplished by setting the option has Trans to "False" and not altering the simulator code. Furthermore, it simulates the transactions by employing an appropriate approach.

TABLE II. INPUT PARAMETERS CONFIGURED BEFORE RUNNING THE SIMULATOR

| Type | Parameter | Description |
|---|---|---|
| Blocks | B interval | The average time to produce a block in seconds |
| | B size | Block size in Megabyte (MB) |
| | B delay | Block propagation delay time in seconds |
| | Tn | The frequency with which transactions can be created |
| | T delay | Transactions propagation delay in seconds |
| | T size | Transaction size in MB |
| Nodes | Nn | The total number of network nodes |
| Simulation | Sim time | Duration of the simulation |
| | Runs | Number of simulations runs |

*3) Ethereum in proposed simulator:* This section discusses the development of simulation classes that reflect the Ethereum Model utilizing the previously described two levels.

Network Module: This module is implemented in two classes: the node class and the network class. The simulator uses node class to define the structure of nodes. Every node is assigned a distinct ID and has an associated balance, implemented as an individual object for each node. The local BC and the transactions pool are modelled by assigning two array lists. When the full transaction approach is used, each node just keeps a transactions pool. Otherwise, shared a common pool by all the nodes. To propagate both blocks and transactions among nodes, the network latency is implemented using network class. In the configuration module, the user of the simulator can configure the time delay in which it is implemented as the latency. As a result, the broadcast protocol, which governs how information entities (such as Blocks and Transactions) are distributed across networks, may be implemented.

Consensus Module: is divided into three classes: Transactions, Block, and Consensus. Every transaction is represented by an object with the following properties: ID, submitter ID, receiver ID, timestamp, value, and size. There are numerous actions to be performed by the entities inside this layer, which may be explained as follows:

- Transactions class:

Create transaction (Ti),

Propagate Ti to other Nodes (Ni)  Ti $\longrightarrow$ Ni,

Append Ti to Transaction Pool (TP) Ni $\longrightarrow$ TP: [Ti].

- The second class is Block Generation that have three actions:

Execute transactions to the next Bi TP $\longrightarrow$ Bi: [Ti],

Construct Bi and append it to local BC (LBC)

Bi $\longrightarrow$ LBC,

Propagate Bi to all Ni LBC $\longrightarrow$ Ni: [Bi].

- After generating new Bi and stored in LBC the class named block reception check validation of block if it not valid will return it to Block Generation class if it valid:

Update LBC Ni $\longrightarrow$ LBC,

Append Bi to local BC (LBC) Ni $\longrightarrow$ LBC: [Bi],

Update TP Ni $\longrightarrow$ TP: [Bi].

In the setup module, the end user can select transaction sizes as fixed integers or random values derived from a wide range of distributions, including the accelerating distribution. Transaction modelling approaches are also used in this class. Each block is represented as an object that has information like depth, ID, previous ID, timestamp, size, miner ID, and transactions. This class also handles block creation and reception. The consensus class is responsible for implementing the consensus algorithm as well as the process of selecting leaders for the generation and insertion of new blocks into the ledger.

## V. EXPERIMENTAL RESULTS AND DISCUSSION

This section contains the network environment is simulated to evaluate the performance of the proposed clustering algorithm. The simulation consists of one hundred random generated nodes distributed in a 2-D network. The clustering techniques are applied in MATLAB 2018a, which offers a dependable environment and makes it simple to compare the outcomes. The simulation parameters include simulation area dimensions, number of nodes, initial energy of each node, and packet size. The simulation results demonstrate the effectiveness of the proposed clustering model and the algorithm's ability to reduce total network energy. Fig. 6 shows the operational nodes per transmission, operational nodes per round, and energy consumed per transmission, respectively. Additionally, we compare the performance of different protocols in terms of the number of nodes, energy consumption, first node dies, and last node dies. The results

highlight the superiority of the proposed Enhanced LEACH protocol in terms of network lifespan. Furthermore, we compare the network lifetime for different algorithms, with Enhanced LEACH showing significant improvement compared to other protocols. The results validate the efficiency of Enhanced LEACH in maximizing network longevity and optimizing energy utilization in wireless sensor networks.

The section also looks at how different consensus and network characteristics affect the integrity, efficiency, and mining of blockchain systems. The simulator is compared with Ethereum, a common public blockchain, in terms of generating blocks, stale rate, and throughput. The results show that the proposed simulator outperforms other simulators, achieving higher values for all three metrics. Additionally, validation runs are conducted using data gathered from Ethereum to ensure the accuracy and reliability of the simulator. Overall, the simulation results and validation show that the suggested clustering methods and simulator are useful and efficient in assessing blockchain systems. These findings provide valuable insights for optimizing energy consumption, network longevity, and mining decentralization in wireless sensor networks and blockchain technology.

TABLE III. ALGORITHM SIMULATION PARAMETER

| Parameters | Value |
|---|---|
| Simulation area dimensions | $100 \times 100$ m |
| Sink node coordinates | center and corner |
| Number of nodes | 100 |
| Node placement | Random |
| Initial energy of each node | 0.5 Joule |
| Packet size | 8 Bytes |

### A. Clustering Results and Validation

The performance evaluation of the suggested clustering algorithm was conducted through simulation in a network environment. This environment consisted of a 2-D network with one hundred nodes randomly generated and distributed. MATLAB 2018a was chosen for its reliability in handling clustering algorithms and its ease of simulating various algorithms, enabling a comprehensive comparison of the results. Table III displays the Algorithm parameters used in this instance.

The obtained simulation results demonstrate the usefulness of the suggested clustering model as well as the algorithm's efficiency in reducing overall network energy. Fig. 5 (a) show that the operational nodes per transmission. Fig. 5 (b) illustrates operational nodes per Round. And Fig. 5 (c) shows Energy consumed per transmission.

The provided data in Table VI represents different protocols and their corresponding simulation results in terms of the number of nodes, energy consumption, and the lifespan of the network. The protocols under consideration are Simple LEACH, I-LEACH, Modified LEACH, and proposed Enhanced LEACH.

These protocols are related to wireless sensor networks and aim to optimize energy consumption and network lifetime. Each protocol employs different techniques to manage node energy and prolong the network's operation.
Fig. 5.    Performance of the proposed clustering algorithm. (a): Operational nodes per transmission. (b): Operational nodes per Round. (c): Energy consumed per transmission.

It's important to note that the exact number of nodes and energy values may vary depending on the specific implementation and simulation setup. The "First Node Dies" and "Last Node Dies" metrics indicate the sequence in which nodes exhaust their energy, with a higher number indicating a longer network lifespan.

To determine the best protocol, we need to consider the criteria of maximizing network longevity and minimizing energy consumption. As shown in Fig. 6. Comparison of Protocols in Wireless Sensor Networks, it can be observed that the "Enhanced LEACH" protocol offers the longest network lifespan with the last node dying at 1868 units. This indicates better overall network longevity compared to the other protocols listed. However, the specific energy levels and number of nodes are not provided for a direct comparison.

Fig. 6.    Comparison of protocols in wireless sensor networks.

The graph in Fig. 7 depicts the network lifetime in terms of the number of living and dead nodes for various algorithms over a given number of rounds. The x-axis shows the number of rounds, which ranges from 0 to 2000, while the y-axis reflects the number of dead nodes, which ranges from 0 to 100.

In the case of Simple LEACH, Modified LEACH, and I-LEACH algorithms, the number of active nodes decreases rapidly with an increase in rounds. After approximately 1650 rounds, all nodes become inactive, resulting in a network with no active nodes.

However, the proposed Enhanced LEACH algorithm shows a significant improvement in terms of network lifetime. Even after 1650 rounds, some nodes managed to remain active until around 1850 rounds. This indicates that Enhanced LEACH extends the network lifetime compared to the other algorithms.

Fig. 7.    Lifetime metrics for different protocols.

TABLE IV.    COMPARISON OF THE PERFORMANCE OF DIFFERENT PROTOCOLS

| Protocols | Nodes | Energy | First Node Dies | Last Node Dies |
|---|---|---|---|---|
| Simple LEACH | 100 | 0.5 | 780 | 1450 |
| I-LEACH | | | 1050 | 1700 |
| Modified LEACH | | | 955 | 1650 |
| Enhanced LEACH | | | 1100 | 1868 |
| Simple LEACH | 100 | 0.5 | 780 | 1450 |
| I-LEACH | | | 1050 | 1700 |

The assignment of different power levels for different forms of communication inside the network is a crucial feature contributing to Enhanced LEACH's enhanced network lifespan. By optimizing power usage and communication strategies, Enhanced LEACH allows for more efficient utilization of energy, resulting in a longer-lasting network.

Overall, the results demonstrate that the Enhanced LEACH algorithm offers improved network lifetime and maximizes the

utilization of sensor nodes' energy resources, making it a promising solution for prolonging the operational time of wireless sensor networks.

### B. Blockchain Simulation Results and Validition

The focus of this section was to examine how the state block rate influences mining decentralization and transaction latency, as well as Ethereum's approach to enhancing block mining decentralization. To compare the results, the simulator's findings were contrasted with those of Ethereum, which is one of the most prominent public blockchains. The comparison included proven invariants, such as block creation frequency and the relationship between a miner's hashing share and their likelihood of winning the Proof of Work competition. Additionally, to validate the simulator, sample public data from Ethereum was also utilized.

We conducted a simulation to assess the impact of different consensus and network settings on the reliability, efficiency, and mining aspects of blockchain systems. The purpose was to demonstrate the capabilities of the simulator, including its performance in terms of run time. The simulation employed validation measures like those used in Ethereum but encompassing a wider range of parameter values.

The Table V presents a comparison of different simulators used in the context of blockchain technology. The simulators are evaluated based on three performance metrics: "B included" (daily number of blocks added to the main blockchain), "Stale Rate" (Uncle rate is the proportion of blocks every day that are not in the main chain), and "Throughput" (number of transactions processed per second).

Based on these findings, the suggested simulator outperforms the other simulators in all three categories. It obtains a higher "B included" number, suggesting that it includes more blocks in the main blockchain every day. The "Stale Rate" is also significantly higher, suggesting that there are somewhat more blocks that are not on the main chain. Furthermore, the "Throughput" figure is larger, suggesting that more transactions are performed per second.

To achieve the outcomes Table VI displays the data collected from Ethereum that was utilized as input to the validation runs. That is, Table VII values were utilized for the appropriate input parameters. The data for Ethereum comes from etherscan.io3. Collected for the purpose of this experiment, fit a frequency distribution with the little data collected.

TABLE V. COMPARISON OF DIFFERENT SIMULATORS

| Simulator | B included | Stale Rate | Throughput |
|---|---|---|---|
| BlockSim [20, 21] | 143 ± 5 | 0.049% ± 0.069% | 2.66 ± 0.09 |
| BlockPerf [22] | 146 ± 4 | 0.025% ± 0.051% | 2.69 ± 0.09 |
| SimChain [23] | 140 ± 6 | 0.032% ± 0.058% | 2.71 ± 0.07 |
| NetSim [24] | 145 ± 3 | 0.042% ± 0.072% | 2.68 ± 0.08 |
| ChainSim [25] | 144 ± 4 | 0.051% ± 0.074% | 2.67 ± 0.09 |
| Proposed Simulator | 150 ± 7 | 0.058% ± 0.081% | 2.75 ± 0.1 |

TABLE VI. DATA GATHERED FROM ETHEREUM

| Parameters | Ethereum |
|---|---|
| B interval | 12.42s |
| B delay | 2.3s |
| B size | 7,997,148 Gas |
| T size | Distribution |

TABLE VII. INPUT PARAMETERS FOR THE SIMULATOR

| Parameters | Value |
|---|---|
| Total Number of Devices | 50 |
| Total Number of Blocks | 100 |
| Blocks in a Chain | 50 |
| TX List Size Limit | 5 |
| Total Number of Transactions | 1000 |
| Average Transaction Latency | 0.005 |
| Transaction Throughput | 50 |
| Simulation Duration (secs) | 20 |

## VI. CONCLUSION

This paper makes significant contributions to the field by tackling the pressing security challenges arising from the exponential growth of IoT nodes. It presents a two-layered blockchain security model, harnessing the inherent decentralization and distribution of blockchain technology to fortify IoT network security. Moreover, the introduction of an enhanced LEACH algorithm, empowered by fuzzy logic, is a noteworthy innovation aimed at optimizing data aggregation and extending the operational lifespan of network nodes. The paper goes even further by introducing a framework that capitalizes on the blockchain's distributed nature to authenticate IoT nodes, structured as a discrete event system model, with a particular focus on network and consensus stages. Through meticulous simulation results, the proposed enhanced LEACH algorithm demonstrates its effectiveness, outperforming previous works and significantly prolonging the network nodes' longevity. In sum, this paper's contributions encompass a two-layered blockchain security model, an enhanced LEACH algorithm, and a blockchain-based authentication framework, all of which exhibit great promise in addressing IoT network security concerns. Future research avenues may delve into exploring the scalability and practical implementation of these proposed models in real-world IoT environments, further solidifying their significance in the domain.

# Fuzzy Failure Modes Effect and Criticality Analysis of the Procurement Process of Artificial Intelligent Systems/Services

Khalid Alshehhi, Ali Cheaitou, Hamad Rashid

Department of Industrial Engineering and Engineering Management
University of Sharjah 27272 Sharjah, United Arab Emirates

*Abstract*—This study focuses on the ranking of risks associated with the procurement of Artificial Intelligent (AI) systems/services for UAE public Sectors. Considering the involvement of human-based reasoning, this study proposes to use Fuzzy Failure Mode Effect and Criticality Analysis (FMECA). The risks were identified from the literature and subsequently, using 40 interviews with practitioners, the final list is developed on the basis of the presence of risks in the AI procurement process. For Fuzzy FMECA, the input data is collected from fifteen experts. The values of Severity (S), and Detection (D) for each risk element are averaged to use as input. If-Then rule-based fuzzy inference system is employed to obtain the Fuzzy Risk Priority Numbers of risk elements. The traditional RPN and Fuzzy RPN numbers are compared and it is found that fuzzy RPN gives a realistic picture of the ranking of risks. Privacy and security risks, Integration Risks, Risk of Malfunction of systems/services, and Ethical risks are found to be high priorities. This study provides valuable insight to policymakers to develop strategies to mitigate these risks for smooth procurement and implementation of AI-related Projects.

*Keywords—Fuzzy Failure Mode Effect and Criticality Analysis (FMECA); procurement; Artificial Intelligent (AI) System; public sector; United Arab Emirates (UAE)*

## I. INTRODUCTION

The United Arab Emirates (UAE) has been at the forefront of embracing technological advancements and digital transformation in the public sector. Artificial Intelligence (AI) systems have emerged as a critical enabler in the UAE public sector, transforming operations, improving decision-making, and delivering efficient and citizen-centric services [1]. The UAE government has led smart government programs aimed at leveraging AI's potential for improved service delivery. These programs are aimed at exploiting Artificial Intelligence (AI) technology in fields such as healthcare, transportation, education, public safety, and e-governance [2]. Artificial intelligence-powered platforms streamline administrative operations, provide personalized services, and enable data-driven decision-making. The UAE public sector hopes to increase operational efficiency, optimize resource allocation, and improve overall service quality by integrating AI technology.

Artificial Intelligence (AI) solutions have received much attention as part of this journey. However, the AI procurement process carries inherent risks that must be identified and handled efficiently [3]. If not adequately handled, these risks can negatively influence the successful adoption and use of AI technology. In addition, AI procurement risks can have financial implications such as operational disruption, Ethical and legal concerns, reputation damage, and missed opportunities [4]. Understanding the effects and putting appropriate risk mitigation measures in place is critical for public sectors looking to reap the advantages of AI while minimizing the negative outcomes. Failure Mode Effect and Criticality Analysis (FMECA) is a tool for identifying risks in complex systems.

FMEA may be used in various processes, including procurement (Skelton, 1997). In the process, it is also utilized to assure the safe functioning of complicated monitoring and control systems. FMEA methodically identifies the impact of risk elements on the system and assesses the importance of each failure mode in terms of system performance. The approach is primarily utilized in a wide range of technologies to investigate and comprehend component/system failure. FMEA is known as failure mode effect criticality analysis (FMECA) when it is used to prioritize failure modes. The failure modes are ranked using the Risk Priority Number (RPN) by FMECA. RPN is frequently computed as the product of failure mode occurrence (O), severity (S), and non-detection (D). According to Certa et al. (2017), O stands for the frequency of occurrence of the failure mode, S for the severity of the harm that particular failure modes with occurrences of O can cause to systems, processes, and the environment, and D stands for the likelihood that the failure modes with occurrences of O and S won't be detected.

Although there are various applications for FMEA, several researchers have highlighted the various shortcomings of the traditional Risk Priority Number (RPN) that is employed in FMEA. The most significant shortcoming is subjectivity and Lack of Consistency. The subjectivity and lack of consistency in the severity, occurrence, and detection ratings given to potential risks by RPN is one of its key issue. The same risk may be evaluated differently by various team members, resulting in variances in the final RPN ratings. This subjectivity can undermine the accuracy of the findings [5]. To overcome this limitation, fuzzy based FMEA was used by various researchers such as [6-9].

The approach for creating a fuzzy RPN (FRPN) is described in this study. It may partially address some of the

constraints mentioned in the literature. The fundamental inputs for producing FRPN are the fuzzified form of frequency, severity, and non-detection of the failure modes. The following stage in fuzzy FMECA is to establish the fuzzy rules. For this stage, the original classes of O, S, and D and the corresponding RPN class are used to establish the rules. The next stage is to use linguistic variables and membership functions to transform the crisp input data into fuzzy values. The assessment of the rule bases created during the study comes next. The last stage to transform the fuzzy output into crisp output is called defuzzification. The AI procurement process in UAE public sectors is subjected to this process. In addition, Comparisons are made between the outcomes of conventional and fuzzy FMECA.

The rest of the paper is as follows: Section II presents the literature review highlighting the rating of risks associated with procurements and tools and techniques for this purpose. Materials and Methods utilized in this study are presented in Section III. Section IV presents the results and discussions. Finally, Section V presents conclusions drawn from this study.

## II. LITERATURE REVIEW

For the procurement process to be effective, risks must be identified and managed. The identification of risks and mitigation processes can be facilitated by a number of efficient tools and methods. The risk register is one such instrument, which entails methodically identifying possible hazards, evaluating their effect and likelihood, and developing suitable mitigation strategies. There are numerous methods/ techniques are employed for risk analysis [10]. Bathrinath, Bhalaji [11] used AHP-TOPSIS method for risk assessment and ranking in a Textile Industry. To analyze the risks in urban stormwater infrastructure systems, Shariat, Roozbahani [12] applied fuzzy spatial multi-criteria decision-making. Data analytics is also applied as a tool for the evaluation and improvement of procurement processes [13]. Delima, Santoso [14] applied a dynamic system development model for the development of purchasing model for agriculture e-commerce. Among all the tools and techniques, Failure Mode and Effect Analysis (FMEA) is a widely used tool for risk analysis.

The FMEA approach, which was developed in the 1960s for the aerospace industry, is a powerful tool for assessing possible risks [15]. In complex systems, this method is very helpful in averting undesirable outcomes [16]. FMEA is widely utilized in a variety of industries, including those in the aerospace, automotive, nuclear, electronics, chemical, mechanical, and medical domains [17-22]. Aldenny, Kristian [23] applied FMEA analysis to determine possible risks with the government's electronic procurement process using the FMEA approach. To improve the purchasing process of public procurement in hospitals, Kumru and Kumru [24] applied the FMEA to indicate the levels of risks associated with potential issues. Nahavandi and Tavakoli [25] applied the FMEA combined with the TOPSIS method to identify the risks associated with procurement in the automotive supply chain. The Modified FMEA is also used for ranking risks associated with military weapons procurement [26]. Handayani [27] also applied the FMEA analysis to evaluate the risks associated

with supplier-buyer transactions in a supply chain procurement. These studies infer that FMEA is an effective tool for analyzing the risks associated with the Procurement process.

There are some limitations of the traditional FMEA process which doesn't capture the subjectivity in a precise way. To overcome this difficulty, a variant of FMEA was developed using a fuzzy set theory known as fuzzy FMEA. Incorporating the criticality analysis in Fuzzy FMEA, the Fuzzy FMECA was developed as an advanced method for ranking the risks. Numerous fields, including engineering [28], manufacturing [29], healthcare [30], and more recently, new technologies like artificial intelligence [31], have found use for fuzzy FMECA. When working with complicated systems where it might be challenging to exactly quantify risk variables, fuzzy FMECA is particularly helpful. Fuzzy FMECA allows decision-makers to consider linguistic variations and subjective aspects by introducing fuzzy logic, making risk analysis more adaptable and understandable.

A crucial step in purchasing cutting-edge technology to improve organizations operations as well as decision-making is the procurement process for Artificial Intelligent (AI) systems or services. Predictive analytics, machine learning, and other disruptive features that AI systems provide have the ability to completely change a number of sectors. It takes strategic decision-making to choose the best AI solutions that fit an organization's objectives, requirements, and capabilities when purchasing AI systems or services. For effective AI integration, suppliers and technology providers must be properly evaluated and chosen [32]. In order to evaluate failure modes, their impacts, and criticality while procuring AI solutions, fuzzy FMECA (Failure Mode Effect and Criticality Analysis) is extremely important. By introducing fuzzy logic, which enables the management of uncertainties and ambiguity frequently found in AI systems, fuzzy FMECA expands classic FMECA approaches. The inherent complexity and changing nature of AI technology make this competence essential in the context of AI procurement [33]. Complex algorithms and learning models are used in AI systems, which might result in erratic and unexpected behavior. Fuzzy FMECA can manage ambiguous inputs and hazy data, providing a more accurate evaluation of likely risk mechanisms [34]. AI systems often produce results with varying degrees of ambiguity. Fuzzy FMECA utilizes linguistic variables to quantify the degree of criticality, providing a more nuanced evaluation of failure effects [35].

## III. MATERIALS AND METHOD

FMECA typically consists of two steps: (i) Use failure mode and effect analysis to distinguish between various failure types and their impacts, (ii) group failure mode criticality analysis according to the likelihood of occurrence and impact [15]. Traditional FMEA calculations involve generating a risk priority number (RPN). Three main factors are needed when doing an FMEA: occurrence (O), which indicates the likelihood of accident occurrences. The term "severity" (S) refers to the seriousness of the consequences of failure modes not being detected. Non-detection (D) eliminates the possibility of detecting failures before they occur. The sum of the three

aforementioned operations yields a risk level known as the risk priority number (RPN).

The shortcomings of the traditional Risk Priority Number (RPN) employed in FMEA have been noted by several academics. The relative relevance of O, S, and D is not often considered in most FMEA analyses, according to Wang, Chin [36]. According to [37], different O, S, and D combinations may result in exactly the same RPN number, but their hidden risk implications may be quite different.

An intelligent framework that summarizes established multi-valued logic for problem-solving under vulnerability is referred to as fuzzy logic. Control designers may easily implement control methodologies used by human administrators thanks to fuzzy logic [38]. Its structure is based on the fact that some problems might be solved based on related knowledge or expert learning while others did not require the proper or accurate esteem. It is based on a likelihood hypothesis for the conversion of crisp to fuzzy input, which will be handled by referring to the state of the fuzzy rule base created by experts. Fuzzy rule base preparation, which converts fuzzy output to crisp output, might solve the problem. Fuzzy logic was a mechanism for making decisions when information was vulnerable and taking flexibility into account.

It is feasible to obtain a complete description of potential risk and its impact by using fuzzy logic in failure modes, effects, and criticality analysis (FMECA). This strategy might effectively address the problems and clearly identify any risks and implications. Furthermore, it could also build trust at the same time. It enables an assessor to directly assess the risks associated with failure by using language concepts in criticality evaluation. Ambiguity, subjective information, or data including quantitative information may be used in the evaluation and organization, although not always unambiguously. The combination of severity (S), occurrence (O), and non-detection (D) parameters had a more flexible structural design. The use of fuzzy logic in FMECA for ranking the risks associated with the procurement of AI systems/services is the main topic of this paper.

*A. The Proposed Method*

The proposed method is based on the work done by Makowski and Mannan [39]. Risk is normally evaluated using two components, severity, and occurrence, during the risk assessment process. Traditional risk predicts frequency and severity as discrete values/categories. Due to a number of uncertainties, frequency and severity values are non-crisp in nature [39]. When there are uncertainties in the parameters used for risk computation, fuzzy logic can be employed to estimate the risk. In the classification of these characteristics, fuzzy logic does not identify precise limits. The fuzzy risk matrix is created by combining a fuzzy frequency and a fuzzy severity.

The RPN in the FMECA research makes use of three parameters: O, S, and D. O, S, and D crisp input data are generally quantified on a ten-point scale (see Tables I to III). Using linguistic expressions and membership functions, they are turned into fuzzy values. Similarly, the output's membership function (RPN) is constructed. In this study, 1000

rules were designed to govern the output value. As an example (rule No. 996), if the occurrence is definite (10), the severity is substantial (6), and the detection is not possible, RPN is calculated conventionally by multiplying O, S, and D (10*6*6) = 360. The standard RPN, which corresponds to class 9, has been improved by integrating the linguistic phrase "high" matching to this class. A Mamdani fuzzy inference technique is used to convert qualitative rules into quantitative results. The fuzzy set for each rule is aggregated once the rules have been assessed. The centre of area approach is utilised for defuzzification in this work.

TABLE I.  OCCURRENCE SCALES USED IN FMECA OCCURRENCE 'O'

| Rank | Probability of failures | Human error occurrence Probability | Linguistic Variable |
|---|---|---|---|
| 1 | < 1:20000 | < every 5 years | Unlikely |
| 2 | 1:20000 | In 3–5 years | Very remote |
| 3 | 1:10000 | In 1–3 years | remote |
| 4 | 1:2000 | Per year | Very low |
| 5 | 1:1000 | In every 6 months | Low |
| 6 | 1:200 | In every 3 months | Moderate |
| 7 | 1:100 | Per months | Moderately high |
| 8 | 1:20 | Per Week | High |
| 9 | 1:10 | Every few days | Very high |
| 10 | 1:2 | Per Day | Almost certain |

(Courtesy:M. Giardina, M. Morale/Journal of Loss Prevention in the Process Industries 35(2015),35–45).

TABLE II.  SEVERITY SCALES USED IN FMECA SEVERITY 'S'

| The severity of Each risk | Effect | Rank |
|---|---|---|
| No reason to expect risk to have any effect on safety, health, environment, or mission | None | 1 |
| Very minor effect on product or system performance to have any effect on safety or health. The system does not require repair / restart. | Very Minor | 2 |
| Minor effect on product or system performance to have any effect on safety or health. The system can require repair/ restart. | Minor | 3 |
| Very low effect on system performance. A failure is not serious enough to cause injury, property damage, or system damage, but can result in unscheduled maintenance or repair | Low | 4 |
| Moderate effect on system performance. The system requires repair. A failure may cause moderate injury, moderate property damage, or moderate system damage which will result in delay or loss of system availability or mission degradation. 100% of the mission may need to be reworked or process delayed. | Moderate | 5 |
| System performance is degraded. Some safety functions may not operate. A failure causes injury, property damage, or system damage. Some portion of mission is lost. High delaying restoring function. | Significant | 6 |
| System performance is severely affected but functions (reduced level of safety performance). The system may not operate. Risk does not involve noncompliance with government regulations or standards. | Major | 7 |
| System is inoperable with loss of primary function. Risk can involve hazardous outcomes and/or noncompliance with government regulations or standards. | Extreme | 8 |

| Risk involves hazardous outcomes and/or noncompliance with government regulations or standards. Potential safety, health or environmental issue. Risk will occur with warning. | Very Extreme | 9 |
|---|---|---|
| Risk is hazardous and occurs without warning. It affects safe operation. A Risk is serious enough to cause injury, property damage, or system damage. Risk will occur without warning. | Serious | 10 |

TABLE III.    DETECTION SCALES USED IN FMECA DETECTION 'D'

| Likelihood of detection of risk | Degree of Importance | Probability of failure of detection | rating |
|---|---|---|---|
| Current control(s) almost certainly will detect a potential risk. | Almost certain | 0-10 | 1 |
| Very likelihood system will detect risk. | Very High | 10-20 | 2 |
| High chance the system will almost certainly detect a potential risk. | High | 20-30 | 3 |
| Moderately high likelihood system will detect risk. | Moderately High | 30-40 | 4 |
| Moderate chance that the system will detect a risk. | Moderate | 40-50 | 5 |
| Low likelihood system will detect risk. | Low | 50-60 | 6 |
| Very low likelihood system will detect risk. | Very Low | 60-70 | 7 |
| Remote chance that the system will detect a risk. | Remote | 70-80 | 8 |
| Risk most likely remains undetected. | Very Remote | 80-90 | 9 |
| Risk is not detectable. | Almost Impossible | 90-100 | 10 |

TABLE IV.    RISK CLASSIFICATION ON BASICS OF FUZZY RPN

| Trapezium Membership function | Linguistic Variable | Rank |
|---|---|---|
| [0,0,100,200] | None | 1 |
| [100,200,200,300] | Very low | 2 |
| [200,300,300,400] | Low | 3 |
| [300,400,400,500] | High low | 4 |
| [400,500,500,600] | Low medium | 5 |
| [500,600,600,700] | Medium | 6 |
| [600,700,700,800] | High medium | 7 |
| [700,800,800,900] | Low high | 8 |
| [800,900,900,1000] | High | 9 |
| [900,900,1000,1000] | Very high | 10 |

The main purpose of the AI procurement process in the public sector is to fulfil the requirements of public administration, such as government modernization and digitalization (Wegener & Müller, 2018). It can also be regarded as a means to promote good governance (Mehr, 2017; Solihati & Indriyani, 2021). The AI procurement process

involves managing materials, purchasing transactions, and activities to ensure the quality of purchased AI products based on the requirements set for them (Karlsson, 2020). It involves all functions, from identifying needs to the selection of sources and awarding and administration of contracts as shown in Fig. 1.

Fig. 1.   AI procurement process common to the UAE Public Sectors.

AI procurement risks refer to those risks which are associated with the purchase of AI technologies/systems. The increased visibility of associated risks in AI projects led to a more strident clamour for ethical, legal, and secure adoption. Based on the literature and subsequent interviews with practitioners from UAE public sectors, the participants identified the following risks in the procurement of AI projects in their respective organizations: privacy and security risks, integration risk, skills risk, risk of time frame, the risk of financial economic loads, and risk regarding vendors. They also identified other risks such as risk of miscommunication and the risk of system malfunction. The list of risks was also validated by a focus group discussion. The risks and their definitions are represented in Table V.

TABLE V.    BRIEF DESCRIPTION OF RISKS ASSOCIATED WITH AI PROCUREMENT PROCESS

| Risk | Definition |
|---|---|
| Privacy and security risk | Privacy risk refers to the likelihood of experiencing problems arising from data processing and the impact that it may bring. Security risk deals with the possibility of losses resulting from information security concerns. |
| Ethical risk | It is associated with the possibility of reputational or moral harm to individuals or organizations. In AI procurement, this risk involves moral dilemmas due to the process of AI-driven dehumanization and displacement of human control |
| Integration Risk | In AI procurement, it refers to the probability of failure of the integration of systems, technologies, or information due to system incompatibility. |
| Skill-related Risk | It deals with the likelihood of lack of or inadequate skills that the workforce may encounter by introducing new technology to the organization. |
| Legal risk | It refers to the potential failure of an organization to comply with regulations or terms of the contract. In AI procurement, AL algorithms or data misuse can lead to legal liability risks. |
| Risk of Environmental Sustainability influencing Hazards | It refers to the probability of hazards posed against maintaining an ecological balance in the natural environment and against conserving natural resources for the utilization of current and future generations. |
| Financial Load risk | It refers to the probability of losing money or danger than can lead to the loss of capital. In AI procurement, financial load risk may be due to exceeding allocated budget. |

| Time frame-related risk | It deals with the possibility of time impacting the project, such as delay. In AI procurement, this risk can lead to cost overruns. |
|---|---|
| Vendor related risk | It refers to risks associated with vendors, such as delays caused by vendors, overpricing of technology provided, security breaches, and unforeseen vendor in capabilities, amongst others, which can cause reputational damage to the organization. |
| Risk of Miscommunication | It refers to the likelihood of the personnel or workforce to fail to communicate adequately (including top-bottom and bottom-up channels of information flow). In AI procurement, this can lead to bias in decision-making. |
| Risk of System Malfunction | It deals with the probability of system failure, error, or malfunctioning. In AI procurement, this may arise from not being able to regularly update the system's network. |

Fuzzy FMECA was performed for AI Procurement process (see Fig. 1). To identify the risk elements, Literature review, Interviews with experts and Focus group discussion were employed. The validated list of risks is presented in Table V. In the proposed study fuzzy logic is used to address the issues in prioritization of these risks. In expert elicitation, the experts, from UAE public sector with extensive understanding of the AI procurement process, used fuzzy language phrases to define the risk variables O, S, and D. The O, S, D values for each risk are collected from the experts using an online survey. In total, 22 responses were recorded. The seven responses were discarded as data were missing or non-serious inputs are seen. Finally, we have taken the average value of O, S, and D for each risk elements and traditional RPN was calculated as shown in Table VI. RPN is a class based on the classes of O, S, and D assigned by the expert, rather than a product of multiplied values of O, S, and D.

TABLE VI. RPN AND PRIORITISATION OF RISKS

| Sl. No. | Risks | Occurrence ranking | Severity Ranking | No-Detection Ranking | RPN | Priority |
|---|---|---|---|---|---|---|
| 1 | Privacy and Security Risk | 8 | 8.1 | 5.3 | 343 | 1 |
| 2 | Ethical Risk | 5.7 | 6.9 | 5.8 | 228 | 3 |
| 3 | Integration Risk | 7 | 7.1 | 4.8 | 239 | 2 |
| 4 | Skill Related Risk | 6.1 | 5.9 | 4.8 | 173 | 7 |
| 5 | Legal Risks | 5.2 | 6.3 | 6.2 | 203 | 5 |
| 6 | Environmental Risk | 4 | 6.3 | 5.7 | 144 | 11 |
| 7 | Financial Risk | 6.2 | 6.2 | 4.3 | 165 | 9 |
| 8 | Time Frame Related Risk | 6 | 5.6 | 4.9 | 165 | 9 |
| 9 | Vendor Related Risk | 6.3 | 5.8 | 4.6 | 168 | 8 |
| 10 | Miscommunication Risks | 5.7 | 6.7 | 5.3 | 202 | 6 |
| 11 | System Malfunction Risk | 6.2 | 6.9 | 5 | 214 | 4 |

The different scales used to measure the two components O and S are shown in Tables I and II. The scale used to measure the parameter D is shown in Table III. These measures assess the likelihood of occurrence, severity, and likelihood of non-detection (see Table IV). The risks data came from a survey

based on experts' opinion for AI procurement Process risk analysis. 11 risk elements were identified and prioritized based on the appropriate RPN score (see Table VI).

Fig. 2 depicts an overview of the fuzzy logic method. The study consists of three primary steps: (i) Fuzzification employing linguistic variables to turn the three risk factors S, O, and D into fuzzy membership functions. (ii) Rule assessment based on expert knowledge of the relationships between various risks and the effect, as represented by fuzzy if-then rules. (iii) A de-fuzzification technique generates a crisp ranking from the fuzzy RPN to provide the failure mode prioritization level.

Fig. 2. Schematic of fuzzy logic process for FMECA Using Matlab FIS editor.

The complete fuzzification procedure was carried out in MATLAB using the fuzzy toolbox, with the triangular membership function representing the inputs O, S, and D as shown in Fig. 3(a), 3(b), and 3(c). The triangular membership function was also employed to depict the FRPN output membership functions (see Fig. 4).

(a)

(b)

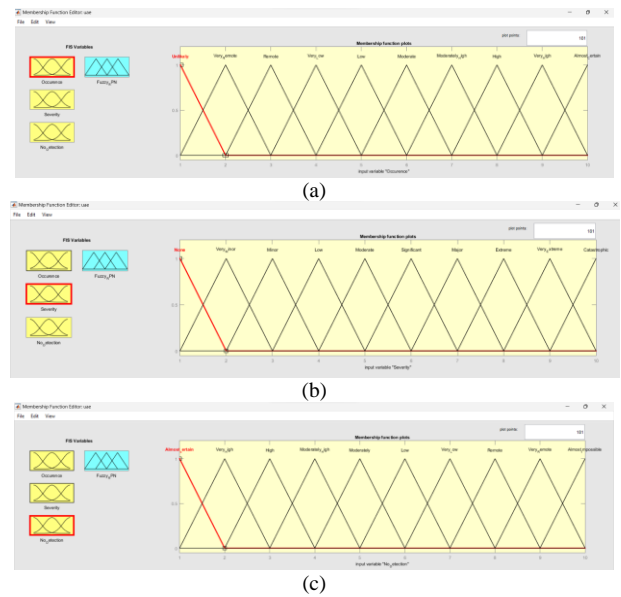
(c)


Fig. 3. (a): Membership functions for input variable 'Occurrence', (b): Membership functions for input variable 'Severity', (c): Membership functions for input variable 'Detection'.

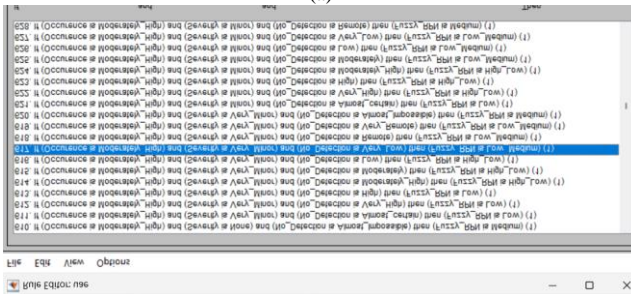
Fig. 4. Membership functions for Output variable 'Fuzzy RPN'.


Fig. 5. (a): Rule base developed for relating O, S &D to FRPN using expert elicitation, (b): Rule base developed for relating O, S &D to FRPN using expert elicitation.

Fig. 6. Defuzzification at the rule plot in Matlab.

The input values of O, S, and D were provided by experts. As 15 experts' opinions were considered, an average value of O, S and D were taken into consideration. For the analysis, 1000 if then rules were developed as shown in Fig. 5(a) and (b). These criteria are intended to cover all conceivable O, S, and D combinations. The Mamdani min/max inference mechanism is utilised (input method: min; aggregate method:

max), and the results are defuzzied using the centre of gravity approach (see Fig. 6).

## IV. RESULTS AND DISCUSSION

A basic condition for fuzzy inference applications is that the fuzzy system's output be monotonic with regard to its inputs [40]. The suggested model's rule base is nondecreasing as can be seen from the output surface plots as shown in Fig. 7(a), (b), (c).

(a)

(b)

(c)

Fig. 7. (a): Surface plot of Occurrence and severity vs. FRPN in Matlab Surface viewer., (b): Surface plot of Occurrence and No-Detection vs. FRPN in Matlab Surface viewer. (c): Surface plot of Severity and No-Detection vs. FRPN in MATLAB Surface viewer

The values of the inputs (O, S, and D) from the data collecting process are supplied to the FIS system during implementation and result extracted to produce the Fuzzy RPN. The Fuzzy RPN values associated with each risk is shown in Table VII along with priority. It can be seen that the

distribution of output value of Fuzzy RPN is more uniform compared to traditional RPN. It can be also seen that Fuzzy RPN numbers obtained are more realistic to interpret. For example, using conventional process, RPN is calculated conventionally by multiplying O, S, and D (10*6*6) = 360. The standard RPN, which corresponds to class 7, has been improved by integrating the linguistic phrase "high medium" matching to this class.   In order to compare and validate, the ranking of risk elements based on Fuzzy RPN, As demonstrated in Table VII, a focus group discussion was conducted. The experts from public sector of UAE government were invited and provided with the ranking obtained by this study. Majority of experts expressed their agreement with the ranking obtained by this method.

TABLE VII.    FUZZY RPN AND PRIORITISATION OF RISKS

| Sl. No. | Risks | Occurrence ranking | Severity Ranking | No-Detection Ranking | Fuzzy RPN | Priority |
|---|---|---|---|---|---|---|
| 1 | Privacy and Security Risk | 8 | 8.1 | 5.3 | 700 | 1 |
| 2 | Ethical Risk | 5.7 | 6.9 | 5.8 | 578 | 4 |
| 3 | Integration Risk | 7 | 7.1 | 4.8 | 600 | 2 |
| 4 | Skill Related Risk | 6.1 | 5.9 | 4.8 | 511 | 9 |
| 5 | Legal Risks | 5.2 | 6.3 | 6.2 | 531 | 7 |
| 6 | Environmental Risk | 4 | 6.3 | 5.7 | 500 | 10 |
| 7 | Financial Risk | 6.2 | 6.2 | 4.3 | 522 | 8 |
| 8 | Time Frame Related Risk | 6 | 5.6 | 4.9 | 500 | 10 |
| 9 | Vendor Related Risk | 6.3 | 5.8 | 4.6 | 532 | 6 |
| 10 | Miscommunication Risks | 5.7 | 6.7 | 5.3 | 569 | 5 |
| 11 | System Malfunction Risk | 6.2 | 6.9 | 5 | 589 | 3 |

The results obtained suggest that Privacy and Security risk is predominant in the case of AI Procurement Process. Various studies also suggested that the privacy and security risk is very important compared to others [41, 42]. The privacy and security risks involved with data privacy concerns, data security vulnerabilities, algorithm biasness, lack of transparencies, adversarial attacks on the system, dependency of third-party vendors and so on. Considering the stakes involved, this risk is considered as most important and having highest impact among all risks.

The next risk of major concern is the integration risk. The integration risk may be faced due to various issues such as data compatibility, system compatibility, customization requirements, skill gaps, user adoption, performance and scalability and vendor reliability. The integration risk is also found to be very important [43].  Considering the importance of integration for example even a city-level law enforcement agency, for example, may not be aware of all the systems utilised across its many departments, how data is linked, and how the outputs shape their practises and policies. Sanchez-Graells, A. [3] highlighted that integration risk makes it difficult for the public and civil society to engage with the appropriate partners, gather information, and hold anybody accountable.

The risk of system malfunction is also found to be a risk of high impact especially in areas where human life at stake such as healthcare sector [44]. The AI system malfunction can be happening due to various factors such as system complexity and maturity, data quality and biasness, model transparency, improper testing and validation, lack in robustness of model, integration issues with existing system, security measures which prevent unauthorised use. During the procurement phase, due care to be taken so that system malfunction cannot happen.

Another risk that is categorized of moderately high impact is ethical risk which associated with raise ethical concerns and may result in harm to individuals, communities, or society as a whole. Kuziemski, M. et al. [45] also support that as AI technologies grow more prevalent, organisations must address the ethical implications during the purchase process.

Risk of miscommunication is also found to be of moderately high impact. In AI procurement, miscommunication risks relate to the possibility of misunderstandings, misinterpretations, or imprecise communication between the parties engaged in the procurement process. As per Grewal and Sridhar [46], these risks might develop at any point during the procurement process, from early planning and needs collection to contract negotiations and implementation. Miscommunication can result in a variety of obstacles and issues, including unclear requirements, misaligned expectations, inaccurate scope and cost estimation, lack of understanding of technical specifications, data access and ownership, and vendor capabilities.

Other risk elements that are vendor related risks are found to be of moderate impact. In the AI procurement process, vendor-related risks refer to potential obstacles or concerns that result from the selection and engagement of an AI vendor or service provider. Choosing the correct vendor is critical since it has a direct influence on the success of the AI project and the organization's ability to meet its goals. Chopra A. [47] has identified several vendor-related concerns in artificial intelligence procurement such as vendor reputation and reliability, Vendor's financial stability, lack of expertise and experience, Vendor lock-in, intellectual property issues, cultural fit, etc..

The legal risks involved in procurement of AI system or services are found to be moderate impact. This risk consists of issues arising due to intellectual property rights, data ownership and usage, data compliance, regulatory requirements, etc. Other risk elements are found to be of low to moderately low impacts are risk associated with time frame, finances, skill related and environmental risks.  It should be noted that from the perspective of UAE public sectors, finance is not considered to be a major concern as well as skills. Further, timeframe and environmental related risks are also found to be of low impact on the AI procurement Process.

## V. CONCLUSION

The proposed Fuzzy FMECA method was applied to rank the risks involved in the procurement of AI Services/ Systems in UAE Public Sectors. The study was carried out by employing fuzzy linguistic variables for occurrence, severity, and non-detection, and then combining these variables using an if-then rule base to achieve Fuzzy RPN or FRPN. The outcomes of traditional FMECA and fuzzy FMECA approaches are compared. Fuzzy FMECA has been proven to be an excellent approach for prioritizing the risks associated with AI procurement Process. The Privacy and security risk are found to be most important, then, Integration risk and system malfunction risks. Other Moderately impact risks are ethical risk, miscommunication risk, vendor related risk and legal risks. The risk associated with finances, skills, environment and time frame were found be of moderate or low impact. The ranking of these risks is validated by a focus group study. This method can be extended to rank the risks involved in other complex systems or prioritizing the different alternatives for decision making.

# An Automatic Nuclei Segmentation on Microscopic Images using Deep Residual U-Net

Ramya Shree H P, Minavathi, Dinesh M S

Computer Science & Engineering
PES College of Engineering
Mandya, Karnataka, India

*Abstract*—**Nuclei Segmentation is the preliminary step towards the task of medical image analysis. Nowadays, there exists several deep learning-based techniques based on Convolutional Neural Networks (CNNs) for the task of nuclei segmentation. In this study, we present a neural network for semantic segmentation. This network harnesses the strengths in both residual learning and U-Net methodologies, thereby amplifying cell segmentation performance. This hybrid approach also facilitates the creation of network with diminished parameter requirement. The network incorporates residual units contributes to a smoother training process and mitigate the issue of vanishing gradients. Our model is tested on a microscopy image dataset which is publicly available from the 2018 Data Science Bowl grand challenge and assessed against U-Net and several other state-of-the-art deep learning approaches designed for nuclei segmentation. Our proposed approach showcases a notable improvement in average Intersection over Union (IoU) gain compared to prevailing state-of-the-art techniques, by exhibiting a significant margin of 1.1% and 5.8% higher gains over the original U-Net. Our model also excels across various key indicators, including accuracy, precision, recall and dice-coefficient. The outcomes underscore the potential of our proposed approach as a promising nuclei segmentation method for microscopy image analysis.**

## I. INTRODUCTION

Microscopic image analysis continues to serve as a benchmark in the diagnosis and prognostication of various types of cancer. Segmenting nuclei is the initial phase in the analysis of microscopic images, as it directly influences the outcomes. This task is very challenging because the image acquisition is associated with color variation which is due different the use of different staining methods [1], artifacts, large variation in size, shape and texture of the cell nuclei [2], touching and overlapping nuclei [3], which is an obstacle for computer-aided diagnosis (CAD) segmentation algorithms. Numerous investigations have concentrated on nuclei detection because of its importance in the diagnosis of cancer. while traditional image processing approaches are being utilized for this task, could not achieve optimized performance due to inherent diversity involved within the images [4]. Past decade has witnessed a substantial progress in deep learning. Techniques relying on deep neural networks have attained state-of-art performance in automatic medical image segmentation [5]. These methods have demonstrated superior outcomes compared to traditional approaches, showcasing the capability of harnessing deep learning techniques for the task of medical image segmentation.

Numerous studies have explored deep learning architectures for cell nuclei segmentation, each presenting unique methods and approaches to address this critical challenge. Despite these advancements, the demand for more precise nuclei segmentation persists. The rapid evolution of deep learning in the domain of medical image analysis has led to the development of various approaches, with many relying on the U-Net architecture [11], which has become the standard for medical image segmentation. Training exceptionally deep architectures introduces challenges that are primarily related to the problem of vanishing gradients. However, due to low resolution and blurry boundary of medical images, it is still a challenging task to design new models that can effectively capture more fine-grained details. In light of the ongoing need for more accurate nuclei segmentation, inspired by the success of U-Net [11] and deep residual learning [21], we propose Deep Residual U-Net that combines the strengths of residual learning and the U-Net architecture. This integration simplifies the training process, ensures smooth information propagation through the use of skip connections and mitigate the issue of vanishing gradients.

The significance of the Deep Residual U-Net is described below:

- Propose Deep Residual U-Net for semantic segmentation. This approach integrates deep residual network with standard U-net architecture to extract robust discriminative features from the input images.

- The evaluation of this proposed model on publicly available microscopy image dataset, specifically the 2018 Data Science Bowl grand challenge, has revealed notable improvements in various performance metrics.

- Proposed model achieves better segmentation masks in comparison with other baseline models, the especially in complex images with diverse cell sizes and shapes, where overlapping nuclei are prevalent.

Rest of the paper is organized as follows: Section II provides an overview of the related work in the field of nuclei segmentation. In Section III, we describe the overall methodology. Section IV describes the dataset, evaluation metrics and the experimental setup used for experimentation. In Section V, the results obtained and the performance

evaluation is discussed. In the last, we summarize the paper and discuss the future work.

## II. RELATED WORK

Numerous deep learning architectures have been proposed for cell nuclei segmentation. Song et al. [6] introduced an approach based on CNN to segment cervical nuclei and cytoplasm. Their methodology involved in employing a CNN for nuclei detection, followed by coarse segmentation based on Sobel edge operator, morphological operations and thresholding. Xing et al. [7] generated probability maps for nuclei by applying Two-class CNN to digitized histopathology images. And to address the challenge of overlapping nuclei, the robust shape model (dictionary of nuclei shapes) was constructed and repulsive deformable model at local level was utilized. Kumar et al. [8] proposed Three-class CNN to predict the nuclei, background, and the boundary of each nucleus. This approach yielded notably better outcomes when compared to Two-class problem but the post-processing step was time consuming. The first FCN for semantic segmentation was presented by Long et al. [9]. Their results showed that the FCN can achieve state-of-the art performance in the realm of segmentation. Further, the inference step associated with this method is significantly faster to obtain the corresponding segmentation mask. For the task of nuclei segmentation in histopathology images, Naylor et al. [10] used FCN to obtain the nuclei probability map, then watershed method was applied to split the touching nuclei, but when comparing the nuclei boundaries predicted by this approach to the ground truth images was not accurate.

Investigation in the domain of deep learning is increasing rapidly, development of new architectures is under process at significantly fast speed. Accounting the importance of cell nuclei segmentation, several approaches have been proposed to address this issue, most of them are relying on U-Net [11]. U-Net is the prevailing architecture used for medical image segmentation. Several approaches based on U-Net have been presented to resolve the issue of nuclei segmentation. Cui et al. [12] have proposed a method, inspired by U-Net, to predict nuclei and their contours simultaneously in H&E-stained images. By predicting contour of each nucleus, applying a sophisticated weight map in the loss function they were able to split touching and overlapping nuclei accurately with simple and parameter free post-processing step. Caicedo et al. [4] trained U-Net model to predict the nuclei and their boundaries, giving the loss function with weight which is 10 times more to the boundary class. The first best solution by [ods.ai] topcoders [13], used encoder-decoder type architecture based on U-Net, initializing encoders with pretrained weights. Kong et al. [14] have used Two-stage stacked U-Nets, where stage1 for nuclei segmentation and stage2 to tackle the problem of overlapping nuclei. Zhao et al. [15] used U-Net++, which is a modification to the U-Net [11] architecture, which combined U-Nets of different depths. Pan et al. [16] proposed AS-Unet, an extension of the U-Net architecture, is structured around three fundamental components: encoder module, decoder module and an atrous convolutional module. Alom et al. [17] applied a technique which relied on the RCNN for nuclei segmentation tasks. J. Cheng et al. [18] used FCANet, which is based on U-Net that captures long-range and short-range

distance features and use attention module to refine the features. Chen et al. [19] proposed Dense-Res-Inception Net (DRINET) for the task of segmentation on medical images and compared their results with FCN, U-Net and ResUNet. Ibtehaz et al. [20] enhanced the U-Net architecture and proposed an advanced MultiResUNet architecture for medical image segmentation. They conducted comprehensive comparison with U-Net using diverse medical image segmentation datasets, revealing that their proposed method achieved enhanced accuracy compared to U-Net.

From the aforementioned review of relevant studies, it is evident that there have been substantial efforts invested in the advancement of deep Convolution Neural Networks (CNN) architectures in effectively segmenting both natural and medical images. Recent research has indicated that better performance can achieved through deeper network. However, training exceptionally deep architectures poses the challenges due to the issue of vanishing gradients. To handle this problem, He et al. [21] proposed the deep residual learning framework to facilitate the training process by utilizing an identity mapping [22]. Instead of using skip connection in Fully Convolutional Networks (FCNs) [9], Ronneberger et al. [11] proposed U-Net that amalgamate feature maps from various hierarchical levels, resulting in enhanced segmentation accuracy. By merging low-level intricate details and high-level semantic insights, U-net has demonstrated remarkable performance in biomedical image segmentation tasks [11]. Inspired by deep residual learning [21] and U-Net [11], we have integrated the residual network to the U-Net architecture. This integration allows us to harness the strengths of both residual learning and U-Net framework, resulting in a unified approach that maximizes the benefits derived from each approach. We have replaced plain neural units by residual units in the U-Net architecture which simplifies the training process and incorporation of robust skip connections within the network has enabled the smooth propagation of information without experiencing degradation.

## III. METHODOLOGY

### A. Overview of Deep Residual U-Net Architecture

- *U-Net*: Semantic segmentation is a task of dividing an image into segments or regions, where each segment corresponds to a meaningful object or part of a scene. In semantic segmentation, utilization of low-level details while preserving high-level semantic information [9, 11] holds immense significance, as it is crucial in attaining precise results. However, especially when we are with limited training samples, training such deep neural networks becomes very challenging. Two possible ways to address this problem. First, by using a pre-trained network later fine-tuning it on the target dataset as in [9]. Two, by utilizing data augmentation strategy which is done in U-Net [11]. Along with the data augmentation, we believe that U-Net architecture also contributes to alleviate the training problem. The idea behind this is that, copying low level features to its equivalent high levels creates a path to propagate information which allows signal to propagate seamlessly between low levels and high

levels by facilitating backward propagation during training process and also compensating low level finer details to its corresponding high level semantic features. This concept pertains to residual neural network [21].

- Residual unit: Adding more layers can improve the performance of the multi-layer neural network by increasing the trainable parameters which may lead to redundant computation and may cause degradation problem [21]. To handle this problem, He et al. [21] proposed the deep residual learning framework, aiming to alleviate training difficulties and effectively mitigate the degradation problem. This leads to improvement in network's performance without the need for deeper network or pre-trained networks. A deep residual network comprises a sequence of layered residual blocks, with each individual residual block is defined as:

$$y_i = h(x_i) + F(x_i, W_i), \quad (1)$$

$$x_{i+1} = f(y_i) \quad (2)$$

Where $x_i$ is the input and $x_{i+1}$ output of the ith residual block, $F(.)$ is the residual function, $f(y_i)$ is the activation function, $h(x_i)$ represents the identity mapping function and $W_i$ is the weight vector of the feature map within the ith residual block. The difference between plain neural unit and residual block illustrated in Fig. 1. Within each residual block, a composition of batch normalization (BN), ReLu activation function and convolution layers is present. He at el. [22] has discussed the impacts on using different combinations and suggested the full pre-activation design as depicted in Fig. 1(b). In our work, we have used full pre-activation residual block to build our deep residual U-Net.

- Deep Residual U-Net: Here we propose a deep residual U-Net, a neural network designed for semantic segmentation which takes the advantage of both U-Net and residual neural network. With this combination, the residual blocks in the network contributes to smoother training process and the skip connections within these blocks, as well as between the network's low levels and high levels ensures smooth flow of information without degradation. Also, it allows to design the neural network with relatively few parameters and could achieve comparable better performance in semantic segmentation tasks.

In this study, we have utilized 9-level architecture of deep residual U-Net for nuclei segmentation as depicted in Fig. 2. The network consists three parts: Encoding, Bridge and Decoding paths. The first part, involves in capturing high level features from the input image by reducing its spatial dimensions while preserving the important spatial information through skip connections. The last part, involves in upsampling the encoded feature maps to reconstruct the segmentation mask with the same spatial resolution as that of the input image. The middle part, serves as a bridge in connecting the encoding path and decoding path. All segments are constructed using residual blocks, each comprising two 3×3 convolutional blocks and an identity mapping. Each convolutional block has a BN layer, a ReLu activation layer and a convolution layer in it. The identity mapping connects both input and output of the block.

The encoder path has four residual blocks. In each block, to downsample the feature map size, instead of using maxpooling operation, a stride of 2 is implemented on the first convolution block to reduce the feature map by half. Likewise, the decoder pathway comprises four residual blocks. Every residual block entails the upsampling of feature maps from lower levels, coupled with the concatenation of feature maps derived from the corresponding encoder path. Finally, 1×1 convolution layer is employed succeeded by a sigmoid activation layer. The role of sigmoid activation function is to project the multi-channel feature maps into the intended segmentation map. Overall, the network encompasses 28 convolution layers. The parameters and the resultant output sizes of each step are provided in Table I.

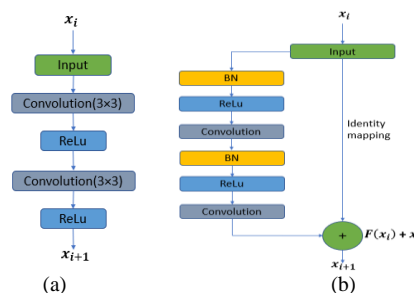

Fig. 1. Building blocks of neural networks. (a) Plain neural unit used in U-net and (b) residual block with identity mapping used in the proposed deep residual U-Net.

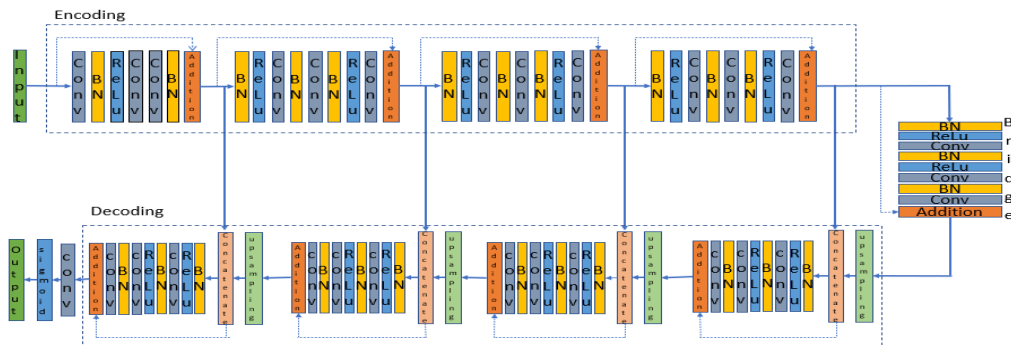

Fig. 2. The architecture of deep residual U-Net.

TABLE I.    THE NETWORK STRUCTURE OF DEEP RESIDUAL U-NET

| | Level | Conv Layer | Filter | Stride | Output Size |
|---|---|---|---|---|---|
| **Input** | | | | | $256 \times 256 \times 3$ |
| **Encoding** | Level 1 | Conv 1 | $3 \times 3/16$ | 1 | $256 \times 256 \times 16$ |

## IV. EXPERIMENTS

*Within* this section, we delve into the details of the dataset, the evaluation metrics, the experimental setup and the data augmentation techniques utilized to validate our proposed model.

### A. Dataset

In our research, we utilized the dataset provided by Kaggle 2018 DSB challenge. The dataset includes 871 images with 37, 333 manually annotated nuclei. The images represent 31 experiments with 22 cell types, 15 different resolutions and 5 groups of images which are visually indistinguishable. This dataset includes 2D light microscopy images with different staining methods including DAPI, Hoechst or H&E and cells of different sizes which display the structures from variety of organs and animal model. Out of 31 experiments, 16 are for training (670 samples), first-stage evaluation (65 samples) and 15 for second-stage evaluation (106 samples). This dataset is readily accessible to the public through the Broad Bioimage Benchmark Collection.

The dataset comprises of 670 training samples accompanied by their corresponding masks. For our experiments, we have allocated 80% of the dataset for training

purpose, while 10% for validation and remaining 10% was reserved for testing. Additionally, we have evaluated our trained model on stage1_test dataset provided by the challenge. This dataset comprises of 65 samples, each equipped with ground truth masks.

### B. Evaluation Metrics

The evaluation of the proposed model is based on several metrics, including the Sørensen–Dice coefficient (DSC), also referred to as F1-Score, the Intersection over Union (IoU), commonly known as the Jaccard Index (JI), Precision and Recall. DSC assesses the similarity between predicted and ground truth masks, while IoU quantifies the overlap between the two masks, Precision measures the portion of pixels that are correctly classified as nuclei pixels out of all the pixels that are classified as nuclei pixels and Recall measures the portion of pixels that are correctly classified as nuclei pixels out of all the pixels that are actually nuclei pixels in the image. These indices are expressed in equations (3-6). The terms TP, FP, TN and FN correspond to True positive, False positive, True negative and False negative [16].

$$\text{Precision} = \frac{TP}{TP+FP} \qquad (3)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (4)$$

$$\text{Dice coefficient (DSC)} = \frac{2TP}{2TP+FP+FN} \qquad (5)$$

$$\text{IoU} = \frac{TP}{TP+FP+FN} \quad (6)$$

### C. Experimental Setup

The proposed model is implemented using Keras framework [23] with Tensorflow 2.7.0 as backend, OpenCV library and python 3.7. The number of kernels in the encoder were set to 16, 32, 64, 128 and 256, and the kernels in the decoder were set to 128, 64, 32, 16 and 1. The input images were resized to dimensions of $256 \times 256$ pixels. We have employed binary cross-entropy as the loss function and an Adam optimization technique, aiming to minimize the loss function with the batch size of 16 and a learning rate of 1e-4. A training procedure was conducted for a span of 100 epochs, with criteria such as early stopping and ReduceLROnPlateau. To prevent the model overfitting, data augmentation techniques such as horizontal flipping, rotation and zooming has been adopted on training dataset in our experiment. The experiment was performed on Nvidia GeForce RTX2080 Ti with 11GB RAM.

## V. RESULTS AND DISCUSSION

Within this section, we present the results and compare with state-of-art methods. U-Net is still considered as baseline for diverse medical image segmentation tasks. In the interest of comprehensive comparison, we also trained U-Net, U-Net++ and HR-Net which are well-regarded techniques for nuclei segmentation with the same experimental setup. The learning curve of our proposed model is presented in Fig. 3. Notably, our model demonstrates the convergence after 30 epochs, exhibiting a validation loss of 0.069 and IoU score of 0.8213, respectively.
Fig. 3. Loss v/s IoU curve of training (left-side) and validation (right-side) trained on our proposed model.

Fig. 4 depicts the loss curve during training and validation process. When we observe the curve during training, the loss value is decreasing after each epoch. During validation, the loss value reduces unevenly and later it becomes smooth.

Fig. 4. Training v/s validation loss curve.

Fig. 5 illustrates a comparative analysis of our proposed model in contrast to other baseline models in terms of loss values and IoU scores throughout training and validation phases. In Fig. 5(a), which portrays training loss curve, as well as in Fig. 5(b) which depicts validation loss curve, the loss value of our proposed model is lowest during training and remains competitive with other models during validation process. Fig. 5(c) shows the IoU curve obtained during training and Fig. 5(d) shows the IoU curve observed during validation for all the models. It is evident from Fig. 5(c) and 5(d), our proposed model attains a better IoU in comparison to other models during both training and validation process. Notably, U-Net has achieved the lowest IoU, while U-Net++ and HR-Net yield nearly identical IoU scores. Overall, from Fig. 5, our proposed model showcases better performance when compared to other models.

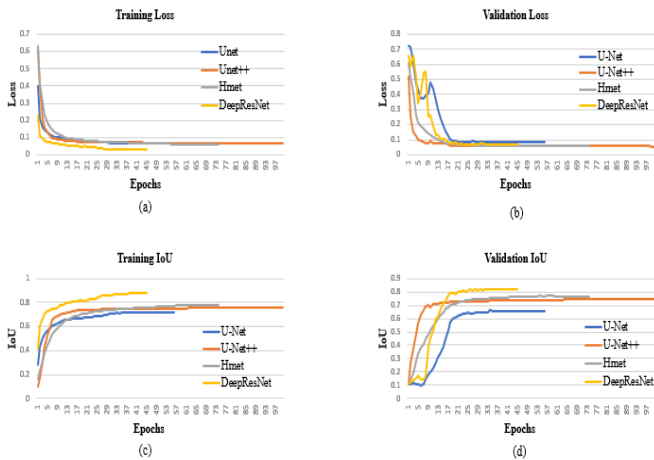

Fig. 5. Comparison of loss curve and IoU curve of our proposed model with other models during training and validation process. (a)Training loss, (b) validation loss, (c) Training IoU and (d) Validation IoU.

The outcomes of our proposed method are presented in Table II alongside those of baseline methods, assessed using various evaluation metrics. It is evident that our proposed method surpasses the initial U-Net [11] by 1.77% in DSC and 1.09% in IoU. Furthermore, when compared with U-Net++ [15] and HR-Net [24], our method showcases substantial improvement across DSC, IoU and Precision metrics. The recall of the U-Net++ has a slight increase of 0.01% compared to U-Net.

TABLE II. QUANTITATIVE RESULTS ON THE EXPERIMENTAL DATASET WITH BASELINE METHODS

| *Model* | *Accuracy* | *DSC* | *IoU* | *Recall* | *Precision* |
|---|---|---|---|---|---|
| U-Net [11] | 0.978±0.021 | 0.908±0.087 | 0.842±0.121 | 0.911±0.113 | 0.917±0.087 |
| U-Net++ [15] | **0.979±0.022** | 0.898±0.074 | 0.827±0.110 | **0.912±0.105** | 0.895±0.065 |
| HR-Net [24] | 0.967±0.028 | 0.852±0.121 | 0.757±0.142 | 0.880±0.136 | 0.836±0.146 |

Fig. 6 displays the segmentation outcomes of each model. Through visual examination, it becomes apparent that the segmentation mask generated by our model is better than those produced by other models.

Our proposed model, along with other models, underwent testing and evaluated using stage1_test dataset which includes 65 samples, each accompanied by a ground truth mask provided by the organizers. Quantitative outcomes on

stage1_test dataset, comparing our proposed method to other techniques are tabulated in Table IV across various evaluation metrics. Upon inspecting Table IV, it apparent that our model surpasses the original U-Net by 5.8% in DSC and 6.0% in IoU.

Fig. 6. Visualization of segmentation results on test dataset.

TABLE IV. QUANTITATIVE RESULTS ON THE STAGE1_TEST DATASET

| Model | Accuracy | DSC | IoU | Recall | Precision |
|---|---|---|---|---|---|
| U-Net [11] | 0.932±0.075 | 0.780±0.211 | 0.679±0.234 | 0.739±0.243 | 0.904±0.149 |
| U-Net++ [15] | 0.943±0.056 | 0.826±0.140 | 0.724±0.172 | 0.790±0.176 | 0.892±0.140 |
| HR-Net [24] | 0.941±0.063 | 0.824±0.150 | 0.724±0.179 | 0.803±0.167 | 0.869±0.163 |
| DeepRes Net | 0.946±0.053 | 0.838±0.129 | 0.739±0.162 | 0.817±0.150 | 0.886±0.145 |

Notably, the model's precision (0.886) falls short of that achieved by U-Net++. However, recall rate remains competitive when compared to other models. Overall, our model demonstrates strong performance across multiple metrics.

To visualize the segmentation outcomes in detail, we examine samples from test set that encompass cells of varying sizes. The qualitative comparison between ground truth images, our proposed model and other models on stage1_test dataset is depicted in Fig. 7. In the Fig. 7, the first column represents the actual image, second column displays its corresponding ground truth mask and remaining columns represents the prediction masks of different models. Among the prediction masks, the red represents the part where the model predicts the background as the target area (FP). For the microscopic images with few of cells, where the nuclei can easily be discriminated from the background, all the models demonstrate satisfactory segmentation outcomes. However, for the complex images such as third, fourth and fifth rows of images with nuclei of different sizes and shapes, the segmentation mask produced by our model is better than those of other models. Also, our model exhibits fewer false positives and enhanced detection accuracy in comparison to the other models.

Fig. 7. Visualization of segmentation results on stage1_test dataset.

## VI. CONCLUSION

Addressing the requirement for more precise nuclei segmentation task, we propose a semantic segmentation neural network that harnesses the combined strength of residual learning and U-Net. The residual block within the network makes the training process easier, while the skip connections within and between the residual block at low and high levels of the network will propagate the information both in forward and backward computations. Also, this property allows us design a simple powerful neural network with fewer number of parameters compared to U-Net. Our model's efficacy was evaluated on publicly available microscopy image dataset from 2018 Data Science Bowl grand challenge. The outcomes of our experiments revealed an average IoU improvement of 1.1 and 5.8 (for the stage1_test set) over original U-Net. Across images with smaller number of cells, where nuclei were distinct, all models performed well. However, when faced with complex images containing cells of diverse sizes and shapes, our proposed model consistently generated better segmentation masks compared to its counterparts. The evaluation conclusively demonstrates that our model excels in terms of accuracy, precision, recall and dice-coefficient when compared to U-Net and other prominent models.

Subsequently, we incorporated watershed segmentation as a post-processing step to tackle the challenges associated with touching nuclei and overlapping/clustered nuclei. This approach proved successful in effectively segmenting touching nuclei. In the future, we plan to conduct experimentation on larger and more diverse dataset that can help validate our model's performance and generalizability. Further, we continue to explore and develop most effective post-processing methods to address the challenge of overlapping nuclei.

*Abstract*—**Technology improvements have benefited the medical industry, especially in the area of diabetes prediction. In order to find patterns and risk factors related to diabetes, machine learning and Artificial Intelligence (AI) are vital in the analysis of enormous volumes of data, including medical records, lifestyle variables, and biomarkers. This makes it possible for tailored management and early discovery, which might revolutionize healthcare. This study examines how machine learning algorithms may be used to identify diseases, with an emphasis on diabetes prediction. The Proposed Diabetes Prediction Empowered with Mutli-level Data Fusion and Machine Learning (DPEMDFML) model combines two distinct types of models—the Artificial Neural Network (ANN) and the Support Vector Machine (SVM)—to create a fused machine learning technique. Two separate datasets were utilized for training and testing the model in order to assess its performance. To ensure a thorough evaluation of the model's prediction ability, the datasets were split in two experiments in proportions of 70:30 and 75:25, respectively. The study's findings were encouraging, with the ANN algorithm obtaining a remarkable accuracy of 97.43%. This indicates that the model accurately identified instances of diabetes, indicating a high degree of accuracy. A more thorough knowledge of the model's prediction ability would result from further assessment and validation of its performance using various measures.**

*Keywords—Disease prediction; machine learning (ML); fused approach; artificial neural network (ANN); support vector machine (SVM); disease diagnosis; healthcare*

## I. INTRODUCTION

The chronic metabolic condition known as diabetes affects millions of people worldwide. The World Health Organization projects that by 2030, 643 million people worldwide will have diabetes, up from an expected 537 million in 2021 [1]. Diabetes is brought on by abnormalities in insulin synthesis or function, which hinder the body from effectively managing blood sugar levels. All ages are impacted, and if it is not treated, it might have detrimental implications on one's health. The body's immune system wrongly assaults and destroys pancreatic insulin-producing cells in autoimmune type 1 diabetes [2]. It usually appears during childhood or adolescence and necessitates lifelong insulin medication. Obesity, inactivity, and poor eating habits are commonly linked to the majority of type 2 diabetes cases [3]. Type 2 diabetes is differentiated by a decrease in the body's ability to produce enough insulin to maintain normal blood sugar levels or by an increase in insulin resistance [3]. Numerous

consequences can result from unmanaged diabetes. For diabetics, cardiovascular disease, such as heart attacks and strokes, is a major worry. Kidney issues, nerve damage (neuropathy), retinopathy, and foot issues are some of the consequences of diabetes [4]. One's quality of life may be significantly impacted by these problems, which need continual medical care. Traditional diabetes prediction systems confront a number of problems. These techniques frequently depend on simplistic statistical models or rudimentary machine learning algorithms, which are incapable of capturing the intricate interplay of many risk variables. Furthermore, these techniques may underutilize the potential of accessible data sources such as patient medical records, genetic information, lifestyle variables, and environmental factors. As a result, the accuracy and reliability of diabetes prediction using these traditional methods are inadequate. A subset of artificial intelligence called machine learning has completely changed several industries, including the healthcare industry. It involves developing algorithms and models that are able to absorb knowledge from data and act or anticipate without being explicitly programmed. The medical sector's decision-making processes for disease prediction, diagnosis, and treatment have showed great promise when using machine learning techniques. Researchers have investigated the merging of different ML methods for diabetes prediction in order to overcome the limitations of existing methodologies (Table I). Fusing several algorithms enables for the use of each method's distinct strengths while correcting for their particular flaws and improving forecast accuracy. A fused machine learning model can give a more thorough and holistic view of the condition by merging diverse data sources such as electronic health records, medical imaging, genetic profiles, and lifestyle data [5]. An ML-based diagnostic system can help detect diabetic patients early on which leads improve patient outcomes and help lessen the burden of diabetes on individuals and healthcare systems. This paper presents a unique framework utilizing machine learning fusion to achieve early diagnosis of diabetes patients. The system goals to increase the accuracy and efficacy of diabetes diagnosis by combining various machine learning algorithms and diverse datasets. This approach leads to proactive healthcare interventions and ultimately improves patient outcomes.

The Proposed Diabetes Prediction Empowered with Mutli-level Data Fusion and Machine Learning (DPEMDFML) model framework is presenting diabetes disease prediction. It

is carried out using the ANN and SVM algorithms, while using two different datasets.

The IoMT is necessary for enhancing the accuracy, reliability, and efficacy of electronic equipment in the medical field. By integrating the existing health care assets and medical facilities, experts are advancing a digital medical system [6]. The control of infectious disease waves is eased by prompt diagnosis and improved ongoing treatment. The internet of medical things (IoMT) is a growing area of technology that is now being used to assist Point-of-care testing (POCT). Using the IoMT, POCT devices may operate wirelessly and be connected to health professionals and medical facilities [7].

Recently has been discovered that developed ANNs may perform well in a variety of circumstances due to ANNs' universal prediction capabilities and adaptable network architectures [8]. The building block of the ANN created to mimic the function of a human neuron. Also, one of the greatest methods for analyzing data is the use of SVM. To control data, they utilize generalization controlling [9]. SVM is an artificial intelligence method that assigns labels to things by learning from examples [10]. The innovative and promising IoMT framework presented in this study represents a significant leap forward in the realm of diabetes disease prediction. Drawing upon the capabilities of two cutting-edge machine learning algorithms, ANN and SVM, this framework exemplifies the fusion of advanced technology and healthcare, offering a transformative approach to diabetes management and patient care. At its core, the IoMT framework capitalizes on the vast amount of data generated by interconnected medical devices, wearable sensors, and health monitoring systems. By harnessing this continuous and diverse stream of patient-specific information, healthcare providers gain unprecedented insights into the multifaceted aspects of diabetes, allowing for more precise, proactive, and personalized interventions. The first pillar of the framework, Artificial Neural Networks (ANN), represents a sophisticated computational model inspired by the complex interconnections of neurons in the human brain. ANN's ability to learn from data and recognize intricate patterns and non-linear relationships makes it an ideal candidate for diabetes prediction. The network's architecture is meticulously designed, leveraging multiple layers of interconnected neurons to extract high-level features from raw input data. The ANN's adaptability enables it to adjust its internal parameters during the learning process, optimizing the model's performance to achieve highly accurate diabetes predictions. In tandem with ANN, the IoMT framework also incorporates the renowned Support Vector Machine (SVM) algorithm, renowned for its prowess in binary classification tasks and its ability to handle complex decision boundaries. SVM's kernel-based approach allows it to efficiently discover non-linear patterns in the feature space, making it invaluable for diabetes prediction when the relationship between features and disease occurrence is intricate and not easily separable.

By integrating the capabilities of both ANN and SVM, the IoMT framework achieves a powerful ensemble of predictive models that complement each other's strengths. The diversity of these algorithms enhances the framework's ability to capture subtle nuances and intricate interactions within the data, ultimately leading to more reliable and accurate diabetes predictions. Data privacy and security are of paramount concern within the IoMT framework. Stringent measures are implemented to anonymize and safeguard patient information, and access controls are enforced to protect sensitive data from unauthorized disclosure. The framework's design ensures that data is utilized solely for model training purposes, mitigating the risk of data breaches and preserving patient confidentiality. The synergistic integration of ANNs and SVM algorithms within the IoMT framework marks a significant step towards personalized and data-driven diabetes prediction. With the potential to revolutionize healthcare practices, this cutting-edge approach empowers clinicians with actionable insights, fosters early detection, and facilitates effective diabetes management, ultimately enhancing the quality of life for patients worldwide.

The structure of the research paper is as follows: Section II represents the related work. In Section III, the contribution is presented. The detail of the proposed model is described in Section IV. Discussion and analysis of results are discussed in Section V. The conclusion of this research is presented in Section VI.

## II. RELATED WORK

The presented findings encompass various studies that examined different healthcare databases and utilized diverse approaches and strategies to make predictions. Researchers have developed and employed a range of prediction models, incorporating various data mining techniques, algorithmic methods for machine learning, or even a combination of these strategies. These studies highlight the wide array of approaches utilized in healthcare research to enhance prediction accuracy and improve decision-making processes.

Akkarapol and Jongsawas [11] presented a paper that analysed a dataset comprising 50,788 records with 43 parameters. The research identified significant risk variables, including age, BMI, overall revenue, sex, heart attack history, marital status, dentist check-up frequency, and diagnosis of asthma. Other risk factors such as hypertension and cholesterol were also recognized. The study's overall reliability was reported as 77.11%, indicating a moderate level of consistency in the findings. Furthermore, the true negative rate specifically for the Artificial Neural Network (ANN) model was noted as 79.45%, indicating its ability to accurately identify negative cases.

Kavakiotis et al.'s paper [12] focused on evaluating data mining and machine learning techniques for DM research. Through the systematic comparison of three algorithms, including Logistic Regression, Naive Bayes, and SVM, using 10-fold cross-validation, the study concluded that SVM achieved the highest accuracy rate of 84%. These findings contribute to the understanding of algorithm selection in DM research, highlighting the potential benefits of SVM in achieving accurate predictions and improving decision-making processes.

Xue-Hui Meng et al.'s study [13] focused on comparing the performance of decision tree models, ANNs, and logistic

regression in diagnosing diabetes or prediabetes based on general risk variables. The logistic regression model achieved a classification accuracy of 76.13%, indicating its ability to correctly classify individuals as having diabetes or prediabetes based on the general risk variables considered in the study. The decision tree model (C5.0) demonstrated a slightly higher classification accuracy of 77.87%. It also showed a relatively high sensitivity of 80.68%, meaning it successfully identified a large proportion of True Positive (TP) cases, and a specificity of 75.13%, indicating its capability to accurately identify True Negative (TN) cases. In contrast, the ANN model obtained a lower classification accuracy of 73.23%, suggesting that it was less effective in predicting the disease outcomes using the same set of general risk variables.

The research work conducted by Md. Faisal Faruque, Asaduzzaman, and Iqbal [14] focused on exploring the relationship between Diabetes Mellitus and multiple risk factors through the analysis of 16 attributes including factors such as age, diet, hypertension, vision problems, and genetic predisposition. By utilizing four popular machine learning algorithms, the researchers examined data from 200 patients. The findings of the study indicated that the Decision Tree algorithm demonstrated superior predictive performance compared to Support Vector Machine (SVM), Naive Bayes (NB), and K-Nearest Neighbour (KNN) algorithms in this particular study, suggesting its potential efficacy in predicting or classifying the disease based on the identified risk factors.

TABLE I.        LIMITATIONS OF THE PREVIOUS WORKS

| Research Study | Method | Accuracy | Limitation |
|---|---|---|---|
| Akkarapol and Jongsawas [11] | | 77.11% | - Low accuracy<br>- Limited to a specific region |
| Kavakiotis et al. [12] | | 84% | - Used three algorithms but the accuracy is low. |
| Xue-Hui Meng et al. [13] | Logistic Regression Model<br>Decision Tree Model (C5.0)<br>Artificial Neural Networks (ANN) Model | 76.13%<br>77.87%<br>73.23% | - Low accuracy<br>- Limited features of the dataset used |
| Md. Faisal Faruque, Asaduzzaman, and Iqbal [14] | Decision Tree Algorithm<br>Support Vector Machine (SVM)<br>Naive Bayes (NB)<br>K-Nearest Neighbour (KNN) | Not specified | - Small sample size<br>- Limited features |
| Dey et al. [15] | ANN Model with MMS | 82.35% | - Limited evaluation matrices |
| Pradhan et al. [16] | Ensemble Learning Approach | Not specified | - Multiple algorithms without mentioning accuracies |

The study conducted by Dey et al. [15] utilized four well-known supervised machine learning algorithms: SVM, KNN, Naive Bayes, and ANN with MMS. These algorithms were selected for their ability to learn from labelled data and make predictions based on learned patterns and relationships to analyse the Pima Indian dataset. The study revealed that the ANN model with MMS achieved the highest accuracy rate of 82.35%, indicating its potential effectiveness in predicting the specific outcome compared to the other four algorithms examined.

Pradhan et al. research [16] employed supervised learning, which involves training models on labelled data to make predictions, to develop models for diabetes diagnosis. Additionally, they utilized hybrid learning, which combines multiple learning techniques, to further enhance the performance of the diagnostic models. Finally, the researchers explored ensemble learning, a powerful approach that combines the predictions of multiple individual models, to create a more robust and accurate diabetes diagnosis model. The results of the study demonstrated that the ensemble learning approach surpassed both supervised learning and hybrid learning in terms of accuracy.

## III.    CONTRIBUTION

In contrast to previous research, this Diabetes Prediction Empowered with Multi-level Data Fusion and Machine Learning (DPEMDFML) model represents a more comprehensive study that explores various commonly used techniques for diabetes identification. The primary objective is to compare the performance of these techniques and identify the most effective one. It has been accomplished by employing two distinct algorithms and evaluating them on two different datasets, considering all relevant evaluation metrics. Furthermore, this study delves into analyzing the significance of each attribute in influencing the classification outcome. This analysis provides valuable insights for future research to adapt and improve the dataset, making it more informative and suitable for diabetes diagnosis tasks.

## IV.    PROPOSED MODEL

The Diabetes Prediction Empowered with Multi-level Data Fusion and Machine Learning (DPEMDFML) model developed here seeks to predict diabetes in a smart healthcare system utilizing data from the Internet of Medical Things (IoMT) is divided into two stages: training and testing as shown in Fig. 1. During the Training Phase, hospitals (Hospitals A, B, C, and N) use IoMT devices to gather patient data, which is subsequently recorded in their respective local databases. This information might include vital indicators, blood glucose levels, lifestyle information, and other information. The 'Prediction Layer,' which houses multiple ML models, with a focus on Support Vector Machines (SVM) and Artificial Neural Networks (ANN), is at the core of this phase.
Fig. 1.   Diabetes prediction empowered with multi-level data fusion and machine learning (DPEMDFML).

These models excel at classification tasks and are in charge of learning whether a patient has diabetes depending on the input data. Following the Prediction Layer, Fig. 1 shows the Performance Layer assesses the efficiency of the ML models by employing measures such as accuracy, miss rate, and sensitivity. Models that match the performance criteria are saved in the public cloud as the "DPEMDFML Generalized Model", while those that fall short go through additional training rounds to enhance accuracy.

The trained DPEMDFML Generalized Model is used in the Testing Phase. When new patients from Hospital N seek diabetes diagnosis, the system gathers raw data from IoMT devices, which is then processed. Data cleansing, value normalization, and missing data management are examples of pre-processing operations that ensure the input data is ideal for the ML models' predictions.

The DPEMDFML Generalized Model is then used to predict whether or not the patient has diabetes. This decision-

making procedure has two results: If diabetes is predicted by the model, the patient is directed to a specialist for prompt medical intervention. If the model predicts a poor outcome, the data is properly deleted, protecting patient confidentiality and data privacy.

Because the system is distributed, various hospitals can contribute data, resulting in a broad and complete dataset for model training. Furthermore, the cloud-based architecture improves accessibility and scalability, allowing the system to meet growing data volumes as well as changing healthcare demands. The system benefits from the capabilities of SVM and ANN as its major ML models in pattern recognition, feature extraction, and classification, results in accurate diabetes predictions. Furthermore, the system's iterative training technique allows for continuous development, keeping the models current with medical advances.

The relevance of this ML-driven approach resides in its potential to improve diabetes diagnosis and patient treatment. The approach leverages the available information by utilizing data from IoMT devices across many hospitals, resulting in more reliable and exact predictions. The capacity to detect diabetic patients quickly and give early medical treatment assures improved disease control and perhaps improves patient outcomes. As the system evolves, its influence on the healthcare environment is expected to go beyond diabetes diagnosis, with the ability to tackle additional medical difficulties utilizing a similar distributed, ML-based approach.

The distributed, cloud-based machine learning system for diabetes detection using IoMT data is a potential improvement in healthcare technology. Its training and testing phases, which are supported by SVM and ANN models, show that it can handle complicated medical data and make correct predictions. As the system evolves via iterative training and embraces an ever-growing dataset, it is positioned to impact the future of medical diagnosis, eventually improving patient care and contributing to the healthcare industry's continuing transformation.

### A. Datasets

Diabetes Prediction Empowered with Mutli-level Data Fusion and Machine Learning (DPEMDFML) Model used two different datasets:

The primary dataset employed in this research is the PIMA Indian Diabetes Database, accessible at the University of California machine learning repository [14]. The dataset encompasses information from 768 individuals, all of whom are female, and their ages span from 21 to 81 years. For each individual, the dataset consists of nine distinct feature characteristics. These feature characteristics include eight continuous quantitative variables, namely the number of pregnancies, blood sugar level (in mg/dL), diastolic blood pressure (in mmHg), skin fold thickness (in mm), body mass index (BMI), serum insulin level (in mU/mL), age (in years), and a pedigree function associated with diabetes. By utilizing this comprehensive dataset, the study aims to explore the relationships between these feature characteristics and diabetes occurrence, enabling the development of predictive

models for early detection and assessment of diabetes risk in female patients.

For the second dataset used in this paper, it is called the "Diabetes prediction dataset," sourced from Electronic Health Records (EHRs) [15]. The dataset encompasses information from a substantial sample of 100,000 individuals, which were collected from diverse healthcare providers and then aggregated into a unified dataset. It is noteworthy that this dataset includes both female and male participants. The Diabetes prediction dataset consists of eight distinctive feature characteristics for each individual. These features include age, gender, hypertension, heart disease, smoking history, BMI (body mass index), HBA1C level (glycated haemoglobin level), and glucose level. By utilizing this comprehensive dataset, the study aims to explore the relationships between these feature characteristics and diabetes prediction. The inclusion of both genders and the diverse range of feature characteristics in this dataset facilitate a comprehensive analysis, providing valuable insights into predicting diabetes and its associated risk factors.

## V. RESULTS AND DISCUSSION

This section showcases the results of diabetes prediction using two different machine learning models: Support Vector Machine (SVM) and Artificial Neural Network (ANN). The prediction is conducted on two distinct datasets, and each dataset is split into two different ratios for training and testing: 70:30 and 75:25. Then, a range of evaluation metrics are calculated, include accuracy, miss-classification rate, sensitivity, specificity, precision, False positive (FP) rate, False discovery rate, False omission rate, Positive likelihood ratio,

Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio. The following equations illustrate the equations used to calculate each of these metrics, providing a clear understanding of the underlying mathematical formulas for the statistical measurements [17-23]. The utilization of this diverse set of metrics ensures a comprehensive assessment of the models' performance, accounting for different aspects of predictive accuracy and error rates. Python is utilized as the simulation tool for implementing both the SVM model and ANN model, to obtain the results.

$$\text{Accuracy} = \frac{\text{Total Number of Predictions}}{\text{Number of Correct Predictions}} \quad (1)$$

$$\text{Miss classification rate } = 1 - \text{Accuracy} \quad (2)$$

$$Sensitivity = \frac{\text{True Positive}}{\text{True Positives+False Negatives}} \quad (3)$$

$$Specificity = \frac{\text{True Negatives}}{\text{True Negatives+False Positives}} \quad (4)$$

$$Precision = \frac{\text{True Positives}}{\text{True Positives+True Positives}} \quad (5)$$

$$False\ positive\ rate = \frac{\text{False Positives}}{\text{False Positives+True Negatives}} \quad (6)$$

$$False\ discovery\ rate = \frac{\text{False Positives}}{\text{False Positives+True Positives}} \quad (7)$$

$$False\ omission\ rate = \frac{False\ Negatives}{False\ Negatives + True\ Negatives} \quad (8)$$

$$Positive\ likelihood\ ration = \frac{Sensitivity}{1 - Specificity} \quad (9)$$

$$Negative\ likelihood\ ration = \frac{1 - Sensitivity}{Specificity} \quad (10)$$

$$Prevalence\ tholde = \sqrt{Sensitivity \times Specificity} \quad (11)$$

$$Critical\ sucess\ index = \frac{True\ Positives}{True\ Positives + False\ Negatives + False\ Positives} \quad (12)$$

$$F1\ score = \frac{2 \times Precision \times Sensitivity}{Precision + Sensitivity} \quad (13)$$

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (14)$$

$$FMI = \sqrt{Sensitivity \times Precision} \quad (15)$$

$$Informedness = Sensitivity + Specificity - 1 \quad (16)$$

$$Diagnostic\ odds\ ratio = \frac{Positive\ likelihood\ ration}{Negative\ likelihood\ ration} \quad (17)$$

### A. DPEMDFML - SVM System Model - using Pima Diabetes Dataset - 70:30

Using SVM model with the Pima Diabetes Dataset, the dataset is divided as: 30% for testing (n=231) and 70% for training (n=537) to assess the model's performance accurately. The performance evaluation of the SVM model is depicted in Table II and Table III, which illustrate the confusion matrix. The confusion matrix provides crucial insights into the model's predictive accuracy, enabling a detailed examination of how well the SVM algorithm classifies diabetes and non-diabetes cases in the dataset.

During the training phase, the SVM model's predictions for diabetes disease are presented in Table II. The training dataset consists of 537 samples, which are further categorized into 187 real positive samples, indicating the presence of diabetes, and 350 real negative samples, indicating the absence of diabetes. Among the real positive samples (indicating the presence of diabetes), the SVM model correctly identifies 117 samples as positive, accurately signaling the presence of healthcare issues. However, the model misclassifies 70 records as negatives, incorrectly suggesting the absence of healthcare issues when there is an actual health concern. On the other hand, among the real negative samples (indicating the absence of diabetes), the SVM model correctly predicts 309 samples as negative, appropriately identifying the absence of healthcare conditions. However, the model makes errors in 41 samples, wrongly classifying them as positive, inaccurately indicating the presence of a healthcare issue when there is none.

During the testing phase, the SVM model's predictions for diabetes disease are presented in Table III. The testing dataset consists of 231 samples, which are further categorized into 81 real positive samples, indicating the presence of diabetes, and 150 real negative samples, indicating the absence of diabetes.

Among the real positive samples (indicating the presence of diabetes), the SVM model correctly identifies 48 samples as positive, accurately signaling the presence of healthcare issues. However, the model misclassifies 33 records as negatives, incorrectly suggesting the absence of healthcare issues when there is an actual health concern. However, the SVM model successfully predicted 124 samples as negative, properly recognizing the lack of medical diseases among the genuine negative samples (showing the absence of diabetes). But in 26 samples, the model misclassifies them as positive, thus implying the existence of a healthcare concern when there isn't one.

Table IV presents a comprehensive overview of the performance of the proposed SVM model in terms of various evaluation metrics. During the training phase, the SVM model achieved the following percentages for each metric: 79.32% accuracy, 20.67% miss-classification rate, 62.56% sensitivity, 88.28% specificity, 74.05% precision, 11.71% False positive rate, 25.94% False discovery rate, 18.46% False omission rate, 534.10% Positive likelihood ratio, 478.00% Negative likelihood ratio, 30.20% Prevalence threshold, 51.31% critical success index, 67.82% F1 Score, 53.16% Mathews Correlation coefficient, 68.06% Fowlkes-Mallows Index, 50.85% informedness, and 1259.68% Diagnostic odds ratio. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 74.46% accuracy, 25.54% miss-classification rate, 59.25% sensitivity, 82.66% specificity, 64.86% precision, 17.33% False positive rate, 35.13% False discovery rate, 21.01% False omission rate, 341.88% Positive likelihood ratio, 393.29% Negative likelihood ratio, 35.10% Prevalence threshold, 44.86% critical success index, 61.93% F1 Score, 42.87% Mathews Correlation coefficient, 61.99% Fowlkes-Mallows Index, 41.92% informedness, and 693.70% Diagnostic odds ratio.

| informedness | 0.4192 (41.92 %) | 0.5085 (50.85 %) |
| Diagnostic odds ratio | 6.9370 (693.70 %) | 12.5968 (1259.68 %) |

## B. *DPEMDFML - SVM System Model - using Pima Diabetes Dataset - 75:25*

Again, using SVM model with the Pima Diabetes Dataset. The dataset is divided into 25% for testing (n=192) and 75% for training (n=576) to assess the model's performance accurately. The performance evaluation of the SVM model is depicted in Table V and Table VI, which illustrate the confusion matrix.

Table V demonstrates the performance of the SVM model in predicting diabetic illness during the training phase. The training dataset comprises 576 samples, with 203 being true positive cases, indicating the presence of diabetes, and 373 being true negative cases, indicating the absence of diabetes. For the true positive cases, the SVM algorithm successfully identifies and correctly classifies 124 samples as positive, meaning that it accurately detects the absence of healthcare problems in those cases. However, the algorithm makes 79 errors by misclassifying some samples as negatives, falsely suggesting the absence of healthcare concerns when diabetes is actually present. Regarding the true negative cases, the SVM model performs well by accurately predicting and classifying 330 samples as negative, properly recognizing the absence of diabetes and the presence of other medical issues in those cases. Nevertheless, the model misclassifies 43 samples as positive, falsely indicating the presence of a healthcare issue when there is, in fact, no such health concern.

TABLE V. SVM MODEL'S - PIMA DIABETES DATASET – TRAINING PHASE – 75:25

| Input | Total number of samples (576) | Result (output) | |
|---|---|---|---|
| | Expected output | Predicted positive | Predicted negative |
| | *203(positive)* | *124(TP)* | *79(FN)* |
| | *373 (negative)* | *43(FP)* | *330(TN)* |

During the testing phase, Table VI showcases the SVM model's predictions for diabetes disease. The testing dataset consists of 192 samples, which are further categorized into 65 real positive samples, indicating the presence of diabetes, and 127 real negative samples, indicating the absence of diabetes. Among the real positive samples (indicating the presence of diabetes), the SVM model correctly identifies 36 samples as positive, accurately signaling the absence of healthcare issues. However, the model misclassifies 29 records as negatives, incorrectly suggesting the presence of healthcare issues when there is none. On the other hand, among the real negative samples (indicating the absence of diabetes), the SVM model correctly predicts 105 samples as negative, appropriately identifying the presence of healthcare conditions. However, the model makes errors in 22 samples, wrongly classifying them as positive, inaccurately indicating the absence of a healthcare issue when there is a health concern.

Table VII presents a comprehensive overview of the performance of the proposed SVM model in terms of various evaluation metrics. During the training phase, the SVM model achieved the following percentages for each metric: 78.81%, 21.18%, 61.08%, 88.47%, 74.25%, 11.52%, 25.74%, 19.31 %, 529.86 %, 458.03 %, 30.82%, 50.40%, 67.02%, 52.17%, 67.34%, 49.55%, 1204.59%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 73.43% accuracy, 26.56 % miss-classification rate, 55. 38 % sensitivity, 82.67% specificity, 62.06% precision, 17.32% False positive rate, 37. 93% False discovery rate, 21.64% False omission rate, 319.72% Positive likelihood ratio, 382.02% Negative likelihood ratio, 35.86% Prevalence threshold, 41.37% critical success index, 58.53% F1 Score, 39.22% Mathews Correlation coefficient, 58.63% Fowlkes-Mallows Index, 38.06% informedness, and 592.47% Diagnostic odds ratio.

## C. DPEMDFML - SVM System Model - using EHRs Dataset - 70:30

The SVM model was utilized in this study with the EHRs Dataset (Electronic Health Records Dataset). To ensure a robust evaluation of the model's performance, the dataset was divided into 30% for testing (n=30,000) and 70% for training (n=70,000). To assess the effectiveness of the SVM model, its performance was analysed using two distinct evaluation tables: Table VIII and Table IX, both presenting the confusion matrix.

During the training phase, the SVM model's diabetes predictions are presented in Table VIII. The training dataset consists of an extensive sample of 70,000 records, which are further categorized into 5,972 instances as positive cases, indicating the presence of diabetes, and 64,028 instances as negative cases, indicating the absence of diabetes. Among the actual positive cases, the SVM model correctly identifies 3,621 samples as positive, correctly indicating the absence of healthcare issues. However, the model misclassifies 2,351 records as negative, falsely signalling the presence of healthcare issues where there are none. On the other hand, among the actual negative cases, the SVM model accurately predicts 63,602 samples as negative, correctly identifying the presence of healthcare conditions. However, the model makes errors in 426 samples, incorrectly classifying them as positive, falsely indicating the absence of a healthcare issue.

During the testing phase, the SVM model's predictions for diabetes disease are displayed in Table IX. The testing dataset comprises 30,000 samples, which are further categorized into 2,528 true positive cases, indicating the presence of diabetes, and 27,472 true negative cases, indicating the absence of diabetes. Among the true positive cases, the SVM model correctly classifies 1,515 samples as positive, accurately indicating the absence of any healthcare issues. However, the model misclassifies 1,013 records as negative, falsely indicating the presence of healthcare issues when there are none. Conversely, among the true negative cases, the SVM model accurately predicts 27,298 samples as negative, correctly identifying the presence of healthcare conditions. Nevertheless, the model makes errors in 174 samples, incorrectly classifying them as positive, falsely indicating the absence of a healthcare issue.

Table X presents a comprehensive overview of the performance of the proposed SVM model in terms of various evaluation metrics. During the training phase, the SVM model achieved the following percentages for each metric: 96.03%, 3.96%, 60.63%, 99.33%, 89.47%, 0.66%, 10.52%, 3.56%, 9113.16%, 2786.65%, 9.48%, 56.59%, 72.28%, 71.77%, 73.65%, 59.96%, 22995.19%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 96.04%, 3.95%, 59.92%, 99.36%, 89.69%, 0.63%, 10.3%, 3.57%, 9461.86%, 2777.06%, 9.32%, 56.06%, 71.85%, 71.45%, 73.31%, 59.29%, 23463.06%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively.

## D. DPEMDFML - SVM System Model - using EHRs Dataset – 75:25

Here, the SVM model with the EHRs Dataset (Electronic Health Records Dataset) is employed. To ensure a robust assessment of the model's performance, the dataset was split into 25% for testing (n=25,000) and 75% for training (n=75,000). To evaluate the SVM model's effectiveness, two different evaluation tables was used to analyse its performance: Table XI and Table XII, which present the confusion matrix.

During the training phase, the SVM model's diabetes predictions are presented in Table XI. The training dataset consists of 75,000 samples, which are further categorized into 6,409 true positive cases, indicating the presence of diabetes, and 68,591 true negative cases, indicating the absence of diabetes. Among the true positive cases, the SVM model correctly identifies 3,876 samples as positive, accurately indicating the absence of healthcare issues. However, the model misclassifies 2,533 records as negative, falsely signalling the presence of healthcare issues where there are none. On the other hand, among the true negative cases, the SVM model accurately predicts 68,111 samples as negative, correctly identifying the presence of healthcare conditions. However, the model makes errors in 480 samples, incorrectly classifying them as positive, falsely indicating the absence of a healthcare issue.

TABLE VIII.    SVM MODEL'S - EHRS DIABETES DATASET – TRAINING PHASE – 70:30

| Input | Total number of samples (70000) | Result (output) | |
|---|---|---|---|
| | Expected output | Predicted positive | Predicted negative |

During the testing stage, Table XII showcases the SVM model's diabetes predictions. The test dataset comprises 25,000 samples, split into 2,091 true positive cases (indicating the presence of diabetes) and 22,909 true negative cases (indicating the absence of diabetes). Among the true positive cases, the SVM model accurately identifies 1,266 samples as positive, correctly indicating the absence of healthcare issues. However, the model misclassifies 825 records as negative, erroneously suggesting the presence of healthcare issues. Conversely, among the true negative cases, the SVM model precisely predicts 22,758 samples as negative, correctly recognizing the presence of healthcare conditions. However, the model makes 151 errors, incorrectly classifying them as positive, falsely indicating the absence of healthcare issues.

Table XIII presents a comprehensive overview of the performance of the proposed SVM model in terms of various evaluation metrics. During the training phase, the SVM model achieved the following percentages for each metric: 95.98%, 4.01%, 60.47%, 99.30%, 88.98%, 0.69%, 11.01%, 3.58%, 8642.10%, 2769.42%, 9.71%, 56.26%, 72.01%, 71.44%, 73.35%, 59.77%, 21713.23%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 96.09%, 3.90%, 60.54%, 99.34%, 89.34%, 0.65%, 10.65%, 3.49%, 9185.62%, 2839.70%, 9.44%, 56.46%, 72.17%, 71.70%, 73.54%, 59.88%, 23127.93%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively.

## E. DPEMDFML - ANN System Model - using Pima Diabetes Dataset - 70:30

Shifting our focus to the second algorithm used in this research, the Artificial Neural Network (ANN) model was employed, and the Pima Diabetes Dataset was utilized for evaluation. To ensure a robust assessment of the model's effectiveness, the dataset was split into two sets: 20% for testing (n=231) and 70% for training (n=537). To gauge the performance of the ANN model, a detailed analysis was conducted using two distinct evaluation tables: Table XIV and Table XV. These tables present the confusion matrix, providing valuable insights into the model's ability to deliver accurate predictions during both the testing and training phases.

During the training stage, Table XIV illustrates the ANN model's predictions for diabetes disease. The training dataset consists of 537 samples, further divided into 188 true positive cases, indicating the presence of diabetes, and 349 true negative cases, indicating the absence of diabetes. Among the true positive cases, the ANN model correctly identifies 157 samples as positive, accurately indicating the absence of healthcare issues. However, the model misclassifies 31 records as negative, falsely indicating the presence of healthcare issues. Conversely, among the true negative cases, the ANN model accurately predicts 327 samples as negative, correctly identifying the presence of healthcare conditions. However, the model makes 22 errors, incorrectly classifying them as positive, falsely indicating the absence of a healthcare issue.

During the testing phase, the ANN model's predictions for diabetes disease are shown in Table XV. The testing dataset consists of 231 samples, further divided into 80 true positive cases, indicating the presence of diabetes, and 151 true negative cases, indicating the absence of diabetes. Among the

true positive cases, the ANN model correctly identifies 47 samples as positive, accurately indicating the absence of healthcare issues. However, the model misclassifies 33 records as negative, falsely signalling the presence of healthcare issues where there are none. On the other hand, among the true negative cases, the ANN model accurately predicts 116 samples as negative, correctly identifying the presence of healthcare conditions. However, the model makes 35 errors, incorrectly classifying them as positive, falsely indicating the absence of a healthcare issue.

Table XVI provides a comprehensive summary of the proposed ANN model's performance during the training phase, showcasing various evaluation metrics. The percentages for each metric achieved by the ANN model are as follows: 90.13% accuracy, 9.86% miss-classification rate, 83.51% sensitivity, 93.69% specificity, 87.70% precision, 6.30% false positive rate, 12.29% false discovery rate, 6.30% false omission rate, 1324.78% positive likelihood ratio, 17.59% negative likelihood ratio, 44.90% prevalence threshold, 77.20% critical success index, 85.55% F1 Score, 78.12% Mathews Correlation coefficient, 83.78% Fowlkes-Mallows Index, 77.20% informedness, and 7527.71% diagnostic odds ratio. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 70.56%, 29.43%, 58.75%,

76.82%, 57.31%, 23.17%, 42.68%, 23.17%, 253.46%, 53.69%, 40.96%, 35.57%, 58.02%, 35.36%, 61.55%, 35.57%, 472.03%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively.

TABLE XIV. ANN MODEL'S - PIMA DIABETES DATASET – TRAINING PHASE – 70:30

| | Total number of samples (537) | Result (output) | |
|---|---|---|---|
| Input | *Expected output* | *Predicted positive* | *Predicted negative* |

### F. DPEMDFML - ANN System Model - using Pima Diabetes Dataset - 75:25

Once more, the ANN model was utilized with the Pima Diabetes Dataset. The dataset here was split into 25% for testing (n=192) and 75% for training (n=576) to ensure a thorough evaluation of the model's performance. The performance metrics of the ANN model are presented in Table XVII and Table XVIII, displaying the confusion matrix results.

During the training phase, Table XVII showcases the ANN model's predictions for diabetes disease. Out of the 576 samples used for training, 199 are identified as real positive cases, and 377 as real negative cases. Among these, 172 are correctly identified as positive, meaning no healthcare issues have been observed, while 27 are incorrectly projected as negatives, indicating a healthcare issue is present. Regarding the 377 samples with negative results, indicating the presence of a healthcare condition, 352 samples are correctly forecasted as negative, and 25 samples are wrongly forecasted as positive, indicating the absence of a healthcare issue.

During the testing phase, Table XVIII displays the ANN model's predictions for diabetes disease. The dataset consists of 192 samples, divided into 69 real positive cases and 123 real negative cases. Among these, the model correctly identifies 45 samples as positive, indicating no healthcare issues observed, while 24 samples are incorrectly projected as negatives, suggesting a healthcare issue. For the 123 samples with negative results, indicating the presence of a healthcare condition, the model appropriately forecasts 92 as negative, and 31 samples are wrongly forecasted as positive, indicating the absence of a healthcare issue.

Table XIX provides a comprehensive summary of the proposed ANN model's performance during the training phase, showcasing various evaluation metrics. The percentages for each metric achieved by the ANN model are as follows: 90.97%, 9.02%, 86.43%, 93.36%, 87.30%, 6.63%, 12.96%, 5.88%, 1303.39%, 14.53%, 46.53%, 79.80%, 86.86%, 79.99%, 84.98%, 79.80%, 8969.48%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 71.35%, 28.64%, 65.21%, 74.79%, 59.21%, 25.20%, 40.78%, 20.68%, 258.76%, 46.50%, 45.21%, 40.01%, 62.06%, 39.26%, 61.10%, 40.01%, 556.45%, accuracy, miss-classification rate, sensitivity, specificity, precision, False positive rate, False discovery rate, False omission rate, Positive likelihood ratio, Negative likelihood ratio, Prevalence threshold, critical success index, F1 Score, Mathews

Correlation coefficient, Fowlkes-Mallows Index, informedness, and Diagnostic odds ratio, respectively.

### G. DPEMDFML - ANN System Model - using EHRs Dataset - 70:30

Utilizing the same algorithm, the ANN model applied to the second dataset, referred to as the EHRs Dataset (Electronic Health Records Dataset). To achieve a comprehensive evaluation of the model's performance, the data set was split as: 30% for testing (n = 30,000) and 70% for training (n = 70,000). The effectiveness of the ANN model was assessed through a thorough analysis of its performance using two separate evaluation tables: Table XX and Table XXI. These tables present detailed information from the confusion matrix, offering insights into the model's performance during both the testing and training phases.

During the training phase, Table XX displays the outcomes of the ANN model's predictions for diabetes disease. In this phase, the model uses a dataset consisting of 70,000 samples, which are further divided into 5,972 real positive cases and 64,028 real negative cases. Among the real positive cases, 4,265 samples are correctly identified as positive, indicating the absence of healthcare issues. However, 1,707 samples are incorrectly classified as negatives, implying potential healthcare concerns. Regarding the real negative cases, which represent the presence of a healthcare condition, the model accurately predicts 63,938 samples as negative, indicating the presence of healthcare issues. However, 90 samples are falsely predicted as positive, suggesting the absence of healthcare issues, when in fact, they should have been classified as negative.

TABLE XVII.  ANN MODEL'S - PIMA DIABETES DATASET – TRAINING PHASE – 75:25

| Input | Total number of samples (576) | Result (output) | |
|---|---|---|---|
| | Expected output | Predicted positive | Predicted negative |
| | 199(positive) | 172(TP) | 27(FN) |
| | 377 (negative) | 25(FP) | 352(TN) |

TABLE XVIII. ANN MODEL'S - PIMA DIABETES DATASET – TESTING PHASE – 75:25

| Input | Total number of samples (192) | Result (output) | |
|---|---|---|---|
| | Expected output | Predicted positive | Predicted negative |
| | 69(positive) | 45(TP) | 24(FN) |
| | 123(negative) | 31(FP) | 92(TN) |

TABLE XIX.   ANN MODEL'S (PIMA DIABETES DATASET) EVALUATION METRICS, 75:25

| | Testing | Training |
|---|---|---|
| Accuracy | 0.7135 (71.35 %) | 0.9097 (90.97%) |
| Miss-classification rate | 0.2864 (28.64 %) | 0.0902 (9.02 %) |
| Sensitivity | 0.6521 (65.21 %) | 0.8643 (86.43%) |
| Specificity | 0.7479 (74.79 %) | 0.9336 (93.36 %) |
| Precision | 0.5921 (59.21 %) | 0.8730 (87.30%) |
| False positive rate | 0.2520 (25.20 %) | 0.0663 (6.63 %) |
| False discovery rate | 0.4078 (40.78 %) | 0.1269 (12.96 %) |
| false omission rate | 0.2068 (20.68 %) | 0.0588 (5.88 %) |
| Positive likelihood ration | 2.5876 (258.76 %) | 13.0339 (1303.39 %) |
| Negative likelihood ratio | 0.4650 (46.50 %) | 0.1453 (14.53 %) |
| prevalence threshold | 0.4521 (45.21 %) | 0.4653 (46.53 %) |
| critical success index | 0.4001 (40.01 %) | 0.7980 (79.80 %) |
| F1 Score | 0.6206 (62.06 %) | 0.8686 (86.86 %) |
| Mathews Correlation co-efficient | 0.3926 (39.26 %) | 0.7999 (79.99 %) |
| Fowlkes-Mallows Index | 0.6110 (61.10 %) | 0.8498 (84.98 %) |
| informedness | 0.4001 (40.01 %) | 0.7980 (79.80 %) |
| Diagnostic odds ratio | 5.5645 (556.45 %) | 89.6948 (8969.48 %) |

During the testing phase, Table XXI demonstrates the ANN model's performance in predicting diabetes disease. The dataset used for testing consists of 30,000 samples, which are further divided into 2,528 actual positive cases and 27,472 actual negative cases. The model correctly identifies 1,754 positive cases, indicating the absence of healthcare issues. However, it mistakenly classifies 774 positive cases as negative, suggesting possible healthcare concerns. For the actual negative cases, which indicate the presence of healthcare conditions, the model accurately predicts 27,368 samples as negative. This demonstrates its ability to identify the presence of healthcare issues correctly. Nevertheless, there are 104 false positive predictions, where the model incorrectly identifies cases as negative, indicating the absence of healthcare issues when they should have been classified as positive.

Table XXII provides a comprehensive summary of the proposed ANN model's performance during the training phase, showcasing various evaluation metrics. The percentages for each metric achieved by the ANN model are as follows: 97.43% accuracy, 2.56% miss-classification rate, 71.41% sensitivity, 99.85% specificity, 97.93% precision, 0.14% false positive rate, 2.06% false discovery rate, 2.60% false omission rate, 50807.36% positive likelihood ratio, 28.62% negative likelihood ratio, 35.77% prevalence threshold, 71.27% critical success index, 82.59% F1 Score, 82.43% Mathews Correlation coefficient, 97.12% Fowlkes-Mallows Index, and 177501.51% diagnostic odds ratio. During the validation phase, the performance of the model is evaluated, and the following evaluation metrics are obtained: 97.07% accuracy, 2.92% miss-classification rate, 69.38% sensitivity, 99.62% specificity, 94.40% precision, 0.37% false positive rate, 5.59% false discovery rate, 2.75 % false omission rate, 18327.76% positive likelihood ratio, 30.733% negative likelihood ratio, 34.88% prevalence threshold, 69.00% critical success index, 79.98% F1 Score, 79.52% Mathews Correlation coefficient, 96.73% Fowlkes-Mallows Index, and 59634.60% diagnostic odds ratio.

### H. DPEMDFML - ANN System Model - using EHRs Dataset - 75:25

In this study, the Artificial Neural Network (ANN) model was utilized to analyse the Electronic Health Records Dataset (EHRs Dataset). To ensure a rigorous evaluation of the model's capabilities, the dataset was split into 25% for testing, comprising 25,000 samples, and 75% for training, with 75,000 samples. The effectiveness of the ANN model was thoroughly assessed using two distinct evaluation tables: Table XXIII and Table XXIV, which offer a detailed view of the confusion matrix and facilitate an in-depth analysis of the model's performance.

During the training phase, Table XXIII depicts the predictions made by the ANN model for diabetes disease. The dataset used for training consists of 75,000 samples, which are further categorized into 6,409 real positive cases and 68,591 real negative cases. The model accurately identified 4,582 samples as truly positive, indicating the absence of healthcare issues. However, it misclassified 1,827 records as negatives,

falsely signalling the presence of a healthcare condition. Out of the 68,591 negative results, which indicate the presence of a healthcare condition, the model correctly forecasted 68,472 samples as negative, demonstrating its effectiveness in correctly identifying such cases. However, there were 119 samples that were inaccurately forecasted as positive, indicating the absence of a healthcare issue when it was present.

During the testing phase, Table XXIV presents the predictions made by the ANN model for diabetes disease. The dataset used for testing comprises 25,000 samples, which are further divided into 2,091 real positive cases and 22,909 real negative cases. The model accurately identified 1,461 samples as truly positive, indicating the absence of healthcare issues. However, it misclassified 630 records as negatives, falsely signaling the presence of a healthcare condition. Out of the 22,909 negative results, which indicate the presence of a healthcare condition, the model correctly forecasted 22,827 samples as negative, demonstrating its effectiveness in correctly identifying such cases. However, there were 82

samples that were inaccurately forecasted as positive, indicating the absence of a healthcare issue when it was present.

Table XXV provides a comprehensive summary of the ANN model's performance during the training phase, displaying various evaluation metrics. The ANN model achieved the following percentages for each metric: 97.40% for accuracy, 2.59% for miss-classification rate, 71.49% for sensitivity, 99.82% for specificity, 97.96% for precision, 0.17% for the False positive rate, 2.53% for the False discovery rate, 28.50% for the False omission rate, 41208.32% for the Positive likelihood ratio, 28.55% for the Negative likelihood ratio, 35.83% for the Prevalence threshold, 71.31% for the critical success index, 82.48% for the F1 Score, 82.25% for the Mathews Correlation coefficient, 97.09% for the Fowlkes-Mallows Index, 71.31% for informedness, and 144305.40% for the Diagnostic odds ratio. During the testing phase, the ANN model achieved the following percentages for each evaluation metric: 97.51% for accuracy, 2.84% for miss-classification rate, 69.87% for sensitivity, 99.64% for specificity, 94.68% for precision, 0.35% for the False positive rate, 5.51% for the False discovery rate, 30.12% for the False omission rate, 19520.38% for the Positive likelihood ratio, 30.23% for the Negative likelihood ratio, 35.11% for the Prevalence threshold, 69.51% for the critical success index,

80.40% for the F1 Score, 79.96% for the Mathews Correlation coefficient, 96.82% for the Fowlkes-Mallows Index, 69.51% for informedness, and 64557.19% for the Diagnostic odds ratio.

TABLE XXIII. ANN MODEL'S - EHRS DIABETES DATASET – TRAINING PHASE – 75:25

| Input | Total number of samples (75000) | Result (output) | |
|---|---|---|---|
| | Expected output | Predicted positive | Predicted negative |
| | 6409(positive) | 4582 (TP) | 1827 (FN) |
| | 68591 (negative) | 119 (FP) | 68472(TN) |

TABLE XXIV. ANN MODEL'S - EHRS DIABETES DATASET – TESTING PHASE – 75:25

| prevalence threshold | 0.3511 (35.11 %) | 0.3583 (35.83 %) |
| critical success index | 0.6951 (69.51 %) | 0.7131 (71.31 %) |
| F1 Score | 0.8040 (80.40 %) | 0.8248 (82.48 %) |
| Mathews Correlation co-efficient | 0.7996 (79.96 %) | 0.8225 (82.25 %) |
| Fowlkes-Mallows Index | 0.9682 (96.82 %) | 0.9709 97.09 %) |
| Informedness | 0.6951 (69.51 %) | 0.7131 (71.31 %) |
| Diagnostic odds ratio | 645.5719 (64557.19 %) | 1443.0540 (144305.40 %) |

The results of DPEMDFML model on the EHRs diabetes dataset indicate that the ANN model outperformed other algorithms in both the 70:30 and 75:25 ratio splits. With the 70:30 split, the ANN model achieved an impressive accuracy of 97.43%, showcasing its robustness in correctly classifying diabetes cases.

Similarly, in the 75:25 split, the ANN model maintained a high accuracy of 97.40%, further validating its effectiveness in handling the dataset. On the other hand, the SVM model also showcased commendable results on the same EHRs diabetes dataset. In the 70:30 split, the SVM model achieved an accuracy of 96.03%, demonstrating its potential to effectively classify diabetes cases.

In the 75:25 split, the SVM model maintained a high accuracy of 95.98%, further highlighting its capability to handle varying data proportions. Table XXVI show the accuracies reached in this study.

TABLE XXVI. PERFORMANCE OF PROPOSED DPEMDFML MODEL W.R.T PIMA DATASET AND EHRS DATASET

|  | PIMA dataset 70:30 | EHRs dataset 70:30 | PIMA dataset 75:25 | EHRs dataset 75:25 |
|---|---|---|---|---|
| *SVM* | 74.46 % | 96.03% | 78.81% | 95.98% |
| *ANN* | 90.13% | 97.43% | 90.97%, | 97.40% |

Table XXVII presented provides an overall comparison of the proposed DPEMDFML model with the previous works mentioned. The results clearly demonstrate that the accuracy of the proposed model has outperformed all the other accuracies reported in the mentioned works, using both of the employed algorithms.

TABLE XXVII. COMPARISON OF PROPOSED DPEMDFML MODEL WITH PREVIOUS WORKS MENTIONED

| Research Study | Method | Accuracy |
|---|---|---|
| Akkarapol and Jongsawas [11] |  | 77.11% |
| Kavakiotis et al. [12] |  | 84% |
| Xue-Hui Meng et al. [13] | • Logistic Regression Model <br> • Decision Tree Model (C5.0) <br> • Artificial Neural Networks (ANN) Model | 76.13% <br><br> 77.87% <br><br> 73.23% |
| Dey et al. [15] | • ANN Model with MMS | 82.35% |
| Proposed DPEMDFML model | • ANN <br> • SVM | 97.43% <br> 96.03% |

## VI. CONCLUSION

In summary, this research offers a distinctive and thorough investigation of the application of machine learning approaches for diabetes detection. The proposed DPEMDFML model shows improved accuracy in predicting diabetes disease compared to earlier efforts by using two separate algorithms and two different datasets. The comprehensive assessment

tables show that the SVM and ANN models performed well during both the testing and training periods. The suggested framework's use of machine learning fusion has the potential to diagnose diabetes earlier, resulting in proactive healthcare treatments and better patient outcomes. This work advances the field of diabetes diagnostic research by offering insightful information on the efficacy of various algorithms and datasets. The findings open the way for further study and model enhancement, with the goal of facilitating improved and more accurate diabetes detection in clinical situations. In future, we will incorporate more recent datasets to enhance the study's relevance and accuracy.

# A Comprehensive Comparative Study of Machine Learning Methods for Chronic Kidney Disease Classification: Decision Tree, Support Vector Machine, and Naive Bayes

Admi Syarif, Olivia Desti Riana, Dewi Asiah Shofiana, Akmal Junaidi

Department of Computer Science-Faculty of Mathematics and Natural Sciences, University of Lampung, Indonesia

*Abstract*—**Based on the findings of the 2010 Global Burden of Disease analysis, there was an increase in the global ranking of Chronic Kidney Disease (CKD) as a major contributor to mortality, moving from 27th place in 1990 to 18th position. Approximately 10 percent of the global population experiences CKD, and every year millions of lives are lost due to limited access to adequate treatment. CKD poses a substantial global health concern, greatly affecting both the well-being and life span of individuals afflicted by the condition. This study aims to evaluate the performance of three major classification algorithms in CKD diagnosis: Decision Tree, Support Vector Machine (SVM), and Naïve Bayes. This research distinguishes it from previous studies through an innovative data processing approach. Data preprocessing involved transforming categorical values into numerical form using label encoding, as well as applying Exploratory Data Analysis (EDA) to identify outliers and test data assumptions. In addition, the handling of missing values was done with appropriate strategies to maintain the integrity of the dataset. The classification method was evaluated using a dataset of 400 samples from Kaggle with 24 attributes. Through careful experimentation, the accuracy results of each algorithm are presented and compared. The results of this study can help in the development of a more efficient and accurate decision support system for the early diagnosis of CKD.**

*Keywords—Chronic kidney disease (CKD); classification; decision tree; machine learning; naïve bayes; support vector machine (SVM)*

## I. INTRODUCTION

The kidneys, a pair of bean-shaped organs, are located in the posterior part of the abdomen and play a major role in maintaining the body's internal balance. Their duties include filtering and purifying the blood, eliminating excess fluid and metabolic waste through the formation of urine, as well as regulating electrolyte balance, blood pressure, and the production of hormones that influence the formation of red blood cells. The central role of the kidneys in maintaining body harmony also supports the optimal performance of other organs [1].

Currently, the prevalence of CKD continues to increase globally and has become a serious health problem. Based on the Global Burden of Disease study in 2010, CKD rose to 18th as the world's leading cause of death, up from 27th in 1990. More than two million individuals worldwide undergo dialysis

therapy or kidney transplantation, although this number represents only about 10% of the population requiring such treatment. About ten percent of the global population suffers from CKD, and millions of lives are lost each year due to limited access to adequate treatment [2]. Chronic Kidney Disease (CKD) refers to the decline in kidney function that occurs slowly over months or even years [3]. Decreased kidney function can result in the accumulation of fluids, electrolytes, and metabolic waste in the body, which in turn causes various health problems.

In the early stages, CKD often does not cause noticeable symptoms, but patients may experience kidney pain when the disease is in an advanced stage [4]. Chronic kidney failure is progressive and cannot be cured, resulting in a high mortality rate. One of the problems faced by patients with CKD is the high cost of treatment and medication. Therefore, early detection is crucial to identify kidney disease at an early stage and prevent the development of chronic kidney disorders [5].

In the present era, the use of machine learning has become popular in the field of healthcare due to the demand for efficient analytical methodologies to uncover important yet undiscovered information in health data [6]. Medical data mining is employed to gain insights by reviewing information obtained from medical reports, evidence tables, flowcharts, research papers, and more. This data is then transformed into relevant information to support decision-making [7]. Machine learning is a field that encompasses the creation of statistical models and algorithms, empowering computer systems to execute tasks without direct commands, instead of relying on patterns and deduction. By using machine learning algorithms, computer systems can process large amounts of historical data and recognize patterns within that data. This allows the system to make more accurate predictions based on input data.

In this research, three machine learning classification methods are employed, specifically Decision Tree, Support Vector Machine, and Naïve Bayes. The difference from previous studies lies in the preprocessing stage, where several processing techniques are applied to the dataset. One of them is data transformation, where invalid values in categorical data are replaced and categorical values are converted to integers using label encoding. Furthermore, Exploratory Data Analysis (EDA) is conducted, employing descriptive statistics and visual tools to gain a deeper understanding of the data. The

goal of EDA is to uncover maximum insights from the dataset, identify outliers and anomalies, and test underlying assumptions [8]. The missing values are handled by filling in the mean for numerical attributes and the mode for categorical attributes. Additionally, k-fold cross-validation is employed to reduce the impact of accuracy instability. The accuracy is obtained from the average accuracy of each fold [9].

The objective of this research is to implement and evaluate Decision Tree, Support Vector Machine, and Naïve Bayes algorithms in the process of diagnosing CKD. The algorithm is implemented using the Python programming language. The study utilizes a dataset of 400 samples obtained from Kaggle, consisting of 24 attributes. The results of this research will be compared with previous studies to compare different classification methods and conclude the most effective classification.

The article is divided into several sections. In Section I, it covers the background, motivation, related work, and the overall structure of the article. This section provides an overview of the research context, the reasons behind conducting the study, and a review of relevant literature. Section II presents the related works, including the literature review. Section III present the workflow, CKD dataset. It discusses various steps such as preprocessing, handling missing values, Exploratory Data Analysis (EDA), *k*-fold

cross-validation, and the implementation of the decision tree, support vector machine, and Naïve Bayes algorithms. This section provides a comprehensive understanding of the dataset and the methodologies employed in the research. The experimental results of the decision tree, SVM, and Naïve Bayes methods in classifying CKD are presented in Section IV. This section evaluates the performance of each classification method and provides insights into their effectiveness in diagnosing the disease. Finally, Section V concludes the paper by summarizing the main findings, highlighting the research contributions, and offering recommendations for future studies.

## II. RELATED WORKS

Several studies have conducted the classification of CKD using machine learning methods. These are presented in Table I. Based on the information above, previous studies conducted data splitting using the split data function to divide the data into direct training and testing subsets. In this study, we employed the k-fold cross-validation method for data division, which can reduce instability in accuracy. The accuracy is calculated by averaging the accuracy of each fold. Furthermore, this study differed from previous research in terms of data pre-processing, as we applied several data processing techniques to the dataset.

## III. METHODS

This research involves several stages in analyzing the performance of CKD classification methods. The process begins with a literature review. The second stage involves collecting the CKD dataset. The third stage is the preprocessing stage, where data transformation, missing value handling, and Exploratory Data Analysis (EDA) are performed. Next is the data partitioning stage, using *k*-fold cross-validation. The subsequent stage involves building the model and finally evaluating the model using a confusion matrix and comparing the results. The stages of analyzing the CKD classification process in this research are illustrated in Fig. 1 below:

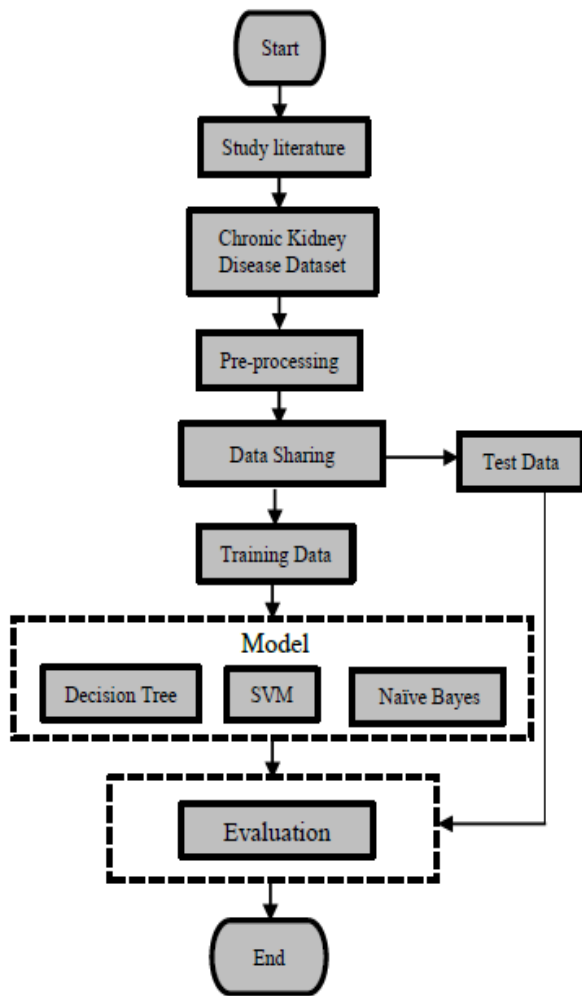

Fig. 1. The research workflow.

### A. Dataset

The study utilized data obtained from Kaggle, originating from a Kaggle account created by Nitesh Yadav, a Data Science Intern Technologies from India. The dataset consists of 400 instances with 24 attributes, presented in CSV format.

Table II thoroughly describes the attributes related to CKD, providing a comprehensive understanding of the variables involved. By utilizing this dataset, the study aims to analyze and uncover insights regarding the relationships between these attributes and the occurrence of the disease.

TABLE II. DATA FOR CHRONIC KIDNEY DISEASE

| Attribute | Possible Values | Types |
|---|---|---|
| Age | Years | Numeric |
| Blood Pressure | mm/Hg | Numeric |
| Specific Gravity | 1.005,1.010,1.015,1.020,1.025 | Nominal |
| Albumin | 0,1,2,3,4,5 | Nominal |
| Sugar | 0,1,2,3,4,5 | Nominal |
| Red Blood Cells | normal, abnormal | Nominal |
| Pus cells | normal, abnormal | Nominal |
| Pus Cell Clumps | present, not present | Nominal |
| Bacteria | present, not present | Nominal |
| Blood Glucose Random | mg/dl | Numeric |
| Blood Urea | mg/dl | Numeric |
| Serum Creatinine | mg/dl | Numeric |
| Sodium | mEq/L | Numeric |
| Potassium | mEq/L | Numeric |
| Hemoglobin | gms | Numeric |
| Packed Cell Volume | - | Numeric |
| White Blood Cell Count | cells/cumm | Numeric |
| Red Blood Cell Count | millions/cm | Numeric |
| Hypertension | yes, no | Nominal |
| Diabetes Mellitus | yes, no | Nominal |
| Coronary Artery Disease | yes, no | Nominal |
| Appetite | good, poor | Nominal |
| Pedal Edema | yes, no | Nominal |
| Anemia | yes, no | Nominal |
| Classification | ckd, not ckd | Nominal |

### B. Pre-processing

*1) Data transformation:* Incorrect or misleading analysis can occur if there are duplicates or missing data. Therefore, the pre-processing stage plays a crucial role in preparing high-quality data, resulting in more accurate and reliable decisions [19]. In this study, several preprocessing steps were performed on the dataset, including data transformation. During this stage, invalid values in the diabetes mellitus, coronary artery disease, and class attributes were modified. Detailed changes

are recorded in Table III, providing a clear overview of the transformations applied. Through the execution of these data transformations, the dataset gains enhanced accuracy and become well-prepared for subsequent phases of analysis and modeling. Furthermore, to translate categorical attributes into a numerical format, label encoding is employed. In this context, since all categorical attributes have two categories, label encoding can be employed to convert these categorical values into integers, namely 0 and 1.

TABLE III.    DATA TRANSFORMATION

| Attribute | Transformation |
|---|---|
| Diabetes mellitus | \tno = no; \tyes = yes; yes=yes |
| Coronary artery disease | \tno = no |
| class | ckd\t = ckd; notckd = not ckd |

*2) Missing value handling:* Machine learning models can encounter errors if the dataset contains missing data that is not handled properly. When the dataset is small, discarding samples with missing data is not an appropriate option, as it can reduce the amount of data used to train the machine learning model and affect the accuracy of data analysis. To address this issue, a technique called "Missing Value Handling" is used to handle missing data by filling in appropriate values based on the characteristics of the samples. By filling in the missing data, the dataset can be used to train the machine learning model, resulting in a well-trained model with optimal performance [20]. In this study, the missing data is filled in using the mean and mode values. The mean value is used to fill in missing data in numerical attributes, while the mode value is used to fill in missing data in categorical attributes.

*3) Exploratory Data Analysis (EDA):* Exploratory Data Analysis (EDA) is a critical procedure encompassing the recognition and description of repetitive patterns, noteworthy correlation arrangements, and the discernment of variables responsible for noteworthy diversity within a reduced dimensional framework. Moreover, EDA aids in the detection of anomalies like outliers, which might point to potential problems with data quality. It plays a crucial role in understanding the data by uncovering hidden patterns, exploring relationships between variables, and identifying redundant features. EDA serves as an important step in data exploration, enabling researchers to gain insights, make informed decisions, and provide a solid foundation for subsequent analysis and modeling [21].

### C. Data Sharing

Within this study, the process of data division is executed through *k*-fold cross-validation. This technique encompasses a series of validation trials where training, validation, and testing phases are carried out. In the initial trial, 80% of datasets chosen at random were employed for training, leaving the remaining 20% for testing purposes. In the subsequent trial, a wholly distinct set of datasets, comprising 80% of the

total, is employed for training, while the residual 20% serves for testing purposes. This process is repeated with different sets of 80% training datasets and 20% testing datasets, as shown in Fig. 2, where a total of five experiments are conducted sequentially. Assuming that the selection of training and testing datasets is truly random and the *k*-fold cross-validation process is ergodic, the correct output is obtained by averaging the outputs of all the experiments [9].

| Experiment 1 | *Test* | *Train* | *Train* | *Train* | *Train* |
|---|---|---|---|---|---|
| Experiment 2 | *Train* | *Test* | *Train* | *Train* | *Train* |

### D. Decision Tree

A conventional tree is composed of a root, branches, and leaves. Similarly, the structure of a Decision Tree includes a root node, branches, and leaf nodes. At each internal node, an attribute is subjected to testing, and the test outcome guides the branch selection, ultimately leading to the assignment of a class label to the corresponding leaf node. Positioned at the highest level, the root node functions as the progenitor of all nodes within the tree. A Decision Tree presents a hierarchical representation where each node signifies a feature (attribute), each link (branch) embodies a decision (rule), and each leaf encapsulates an outcome (categorical or continuous value). Because Decision Trees mimic human cognitive processes, they provide an intuitive means of grasping data and deriving insightful interpretations. The overarching idea is to construct such a tree for the complete dataset, yielding a distinct outcome at each leaf [22].

### E. Support Vector Machine

SVM operates as a learning mechanism featuring a hypothesis space founded on linear functions within a feature space of significant dimensions. Its training is facilitated by learning algorithms rooted in optimization theory principles. The accuracy level achieved by the SVM model is highly dependent on the kernel function and parameters used during the training process. Based on its characteristics, the SVM method can be divided into two types: Linear SVM and Non-linear SVM. Linear SVM separates data linearly by placing a hyperplane with a soft margin between classes. The illustration of the linear SVM can be seen in Fig. 3. On the other hand, Non-linear SVM implements the kernel trick by mapping the data into a higher-dimensional space [23]. Basically, the concept of SVM involves finding the optimal separator on the hyperplane, as shown in Fig. 4. The best-separating hyperplane is determined by searching for the value of *f(x)* on the hyperplane margin [24-26].
Fig. 3.    Linear SVM [25].

Fig. 4.    The effort to find the best hyperplane [26].

### F. Naïve Bayes

Naive Bayes classification employs the principle of maximum likelihood estimation to categorize samples into the most probable groups [27]. Given an input vector with features represented as *X* and a class label denoted as *Y*, the concept of Naive Bayes is symbolized by *P(Y/X)*, indicating the probability of class label Y considering the observed features *X*. This representation signifies the posterior probability of *Y*. The original probability *P(Y)*, recognized as the prior probability, is also considered. Throughout the training phase, the task involves acquiring knowledge about the posterior probabilities (*P(Y/X)*) for every combination of *X* and *Y* using insights gleaned from the training dataset [28].

### G. Evaluation Metrics

The assessment conducted in this study employs a Confusion Matrix. The Confusion Matrix serves as a performance evaluation tool for machine learning classification tasks encompassing two or more classes. This table showcases various combinations of projected and actual values. Comprising four terms, the Confusion Matrix outlines the classification outcomes: True Positive, True Negative, False Positive, and False Negative [29]. True Positive (TP) signifies accurate positive predictions, while True Negative (TN) signifies accurate negative predictions. False Positive (FP) relates to an erroneous positive prediction, whereas False Negative (FN) corresponds to an incorrect negative prediction. The Confusion Matrix entails several computations, including:

Accuracy measures how accurately a model classifies data correctly [29]. The calculation of accuracy is done using by using Eq. (1).

$$\text{Accuracy} = \frac{(TP+TN)}{(TP+FP+FN+TN)} \times 100\% \qquad (1)$$

Precision describes the accuracy between the requested data and the predicted results given by the model [29]. The calculation of Precision is done using Eq. (2).

$$\text{Precision} = \frac{(TP)}{(TP+FP)} \times 100\% \qquad (2)$$

Recall or Sensitivity represents the success of the model in capturing information [29]. The calculation of Recall or Sensitivity is done using Eq. (3).

$$\text{Recall} = \frac{TP}{(TP+FN)} \times 100\% \qquad (3)$$

*F*-1 Score represents the weighted average of Precision and Recall. Accuracy is used as a performance reference for algorithms when the dataset has a significant number of false negatives and false positives. However, if the numbers are not close, the *F*-1 Score is used as a study in [29]. The calculation of the F-1 Score is done using Eq. (4).

$$F-1 \text{ Score} = 2x \frac{(\text{Recall x Precision})}{(\text{Recall+Precision})} \times 100\% \qquad (4)$$

### IV.    EXPERIMENTS AND RESULTS

In this study, we utilized the laptop on the Windows 10 64-bit operating system with 8 GB of memory. It is powered by an Intel(R) Core (TM) i5-4210U processor, which provides processing capabilities ranging from 1.70 GHz to 2.39 GHz. The software employed for the study includes Python 3.10.6, Anaconda Navigator, Jupiter Notebook, a web browser, and Microsoft Excel. These tools and technologies formed the computational environment in which the analyses and experiments were conducted.

For the experiments, the data is divided by using used 5-Fold cross validation (80% data for training and 20% data for testing). The following Table IV presents the comparison of the method for each fold.

TABLE IV.    THE VALUE OF K-FOLD CROSS-VALIDATION IN A MODEL

| Fold | Decision Tree | Support Vector Machine | Naïve Bayes |
|---|---|---|---|
| | | Accuracy | |
| 1 | 0.975 | 0.9625 | 1.00 |
| 2 | 0.9875 | 0.975 | 0.975 |
| 3 | 0.95 | 0.95 | 0.925 |
| 4 | 0.975 | 1.0 | 0.95 |
| 5 | 0.9875 | 1.0 | 0.9375 |
| **Average** | **0.975** | **0.9775** | **0.9575** |

TABLE V.    CONFUSION MATRIX DECISION TREE

| Class | Positive predicted | Negative predicted |
|---|---|---|
| Positive actual | 245 | 5 |
| Negative actual | 5 | 145 |

In the above Table V, we show the confusion matrix to decision tree. There are 245 instances of true positives (TP), representing cases that truly belong to the positive class of CKD and are accurately identified as such by the CKD prediction. There are five false positives (FP), which are samples that actually belong to the positive class of having

CKD but are incorrectly predicted as negative for CKD. There are five false negatives (FN), which are samples that actually belong to the negative class but are incorrectly predicted as positive. There are 145 true negatives (TN),

TABLE VI.    CONFUSION MATRIX FOR SVM

| Class | Positive predicted | Negative predicted |
|---|---|---|
| Positive actual | 246 | 4 |
| Negative actual | 5 | 145 |

Table VI presents the confusion matrix for support vector machine. There are 246 true positives (TP), which are samples that actually belong to the positive class of having CKD and are correctly predicted as positive for CKD. There are four false positives (FP), which are samples that actually belong to the positive class of having CKD but are incorrectly predicted as negative for CKD. There are five false negatives (FN), which are samples that actually belong to the negative class but are incorrectly predicted as positive for CKD. There are 145 true negatives (TN).

The above Table VII shows the confusion matrix for naïve Bayes, there are 233 true positives (TP. There are 17 false positives (FP), which are samples that actually belong to the positive class of having CKD but are incorrectly predicted as negative for CKD. There are 0 false negatives (FN), which means there are no samples that actually belong to the negative class of not having CKD but are incorrectly predicted as positive for CKD. There are 150 true negatives (TN), which are samples that actually belong to the negative class of not having CKD and are correctly predicted as negative for CKD.

Table VIII presents the comparison of these three models. It is shown that the SVM method performs exceptionally well, exhibiting excellent precision, recall, F1-score, and accuracy, making it highly reliable for diagnosing CKD. The Naïve Bayes method yields good results, although slightly lower than SVM and Decision Tree in some metrics, with high precision, but a slightly lower recall. However, the Naïve Bayes method still demonstrates good overall performance with a relatively high F1-score and accuracy in predicting CKD. All three methods show satisfactory performance in diagnosing CKD, with the SVM method standing out as the most accurate.

Finally, here, we also compared our results with those of previous studies. We summarize the comparison in Fig. 5.

TABLE VII.    CONFUSION MATRIX NAÏVE BAYES

| Class | Positive predicted | Negative predicted |
|---|---|---|
| Positive actual | 233 | 17 |
| Negative actual | 0 | 150 |

TABLE VIII.    THE COMPARISON OF THE METHODS

| Method | Precision | Recall | F1-score | Accuracy |
|---|---|---|---|---|
| Decision Tree | 0.97 | 0.97 | 0.97 | 0.97 |
| SVM | 0.98 | 0.98 | 0.98 | 0.98 |
| Naïve Bayes | 0.96 | 0.96 | 0.96 | 0.96 |

Fig. 5.    Comparison graph with several previous studies.

## V. CONCLUSION AND FUTURE WORKS

### A. Conclusion

Through meticulous implementation, we successfully applied three major classification algorithms in the CKD diagnosis process, namely Decision Tree, Support Vector Machine (SVM), and Naïve Bayes. The analysis of the results confirms that all three methods have exhibited exceptional performance in predicting the disease. Notably, the most intriguing outcome is the achievement of the highest accuracy rate by the Support Vector Machine (SVM) method, reaching a score of 0.98. Thus, this research not only provides deeper insights into early diagnosis and CKD management but also offers valuable guidance in utilizing the most effective classification algorithms for this condition.

### B. Recommendations

The recommendations provided in this study are as follows:

*1)* For future research, it is suggested to explore newer classification methods such as deep learning or ensemble learning. The use of more complex classification methods, may provide advantages in diagnosing CKD.

*2)* Future studies could utilize larger datasets encompassing a wider attribute range. This will aid in better analyzing the performance of classification methods. Additionally, considering data from other sources to supplement the analysis could be beneficial.

*Abstract*—In recent years, the realm of seismology has witnessed an increased integration of advanced computational techniques, seeking to enhance the precision and timeliness of earthquake predictions. The paper titled "Deep Convolutional Neural Network and Machine Learning Enabled Framework for Analysis and Prediction of Seismic Events" embarks on an ambitious exploration of this interstice, marrying the formidable prowess of Deep Convolutional Neural Networks (CNNs) with an array of machine learning algorithms. At the forefront of our investigation is the Deep CNN, known for its unparalleled capability to process spatial hierarchies and multi-dimensional seismic data. Accompanying this neural behemoth is LightGBM, a gradient boosting framework that offers superior speed and performance, especially with voluminous datasets. Additionally, conventional neural networks, noted for their adeptness in pattern recognition, offer a robust method to gauge the intricacies of seismic data. Our exploration doesn't halt here; the research delves deeper with Random Forest and Support Vector Machines (SVM), both renowned for their resilient performance in classification tasks. By amalgamating these diverse methodologies, this research crafts a multifaceted and synergistic framework. The culmination is a sophisticated tool poised to not only discern the minutiae of seismic activities with heightened accuracy but to predict forthcoming events with a degree of certainty previously deemed elusive. In this era of escalating seismic activities, our research offers a timely beacon, heralding a future where communities are better equipped to respond to the Earth's capricious tremors.

*Keywords—Deep learning; CNN; random forest; SVM; neural network; prediction; analysis*

## I. INTRODUCTION

Seismology, the scientific study of earthquakes and the propagation of elastic waves through the Earth, stands at a critical juncture of its evolution. Historically, the analysis and prediction of seismic events leaned heavily on manual observation, conventional statistical methods, and rudimentary computational models [1]. The challenge inherent to these traditional approaches was their inability to fathom the vast intricacy of geological phenomena at multiple scales, from the minute shifts deep within the Earth's crust to grand tectonic movements that drive seismic activity [2]. Furthermore, the limitations of early computational tools were often a bottleneck, unable to cope with the sheer volume and complexity of seismic data.

In the 21st century, a transformative shift is underway. The information age, characterized by the rise of big data and advanced computational models, is ushering in a new era for seismological research [3]. The nexus of this transformation is the integration of machine learning (ML) and deep learning algorithms, poised to revolutionize the manner in which we perceive, analyze, and predict seismic events [4]. No longer are we solely dependent on conventional methods that, albeit valuable, offered limited insights and predictive capabilities. Instead, we're at the dawn of an era where artificial intelligence (AI) powered models promise a quantum leap in our understanding and preparedness for seismic activities.

Central to this shift is the Deep Convolutional Neural Network (CNN) [5]. Originally designed for image and video recognition tasks, CNNs have demonstrated an uncanny aptitude for handling spatial hierarchies and multi-dimensional datasets, making them particularly well-suited for seismic data interpretation [6]. These networks are adept at autonomously extracting pertinent features from vast datasets, making them invaluable tools in the realm of seismology where data is both abundant and complex.

The story doesn't end with CNNs. LightGBM, a gradient boosting framework, is emerging as another significant contender [7]. With its inherent ability to handle large datasets and its unique leaf-wise growth strategy, LightGBM offers speed and performance benefits that are often superior to other gradient boosting algorithms. Its capacity to work with categorical features directly, without the need for extensive preprocessing, makes it a potent tool for seismic data, which often exhibits categorical variances.

Neural networks, the precursors to more advanced deep learning models like CNNs, are also significant players [8]. Their design, inspired by the neural structure of the human brain, has proven effective in pattern recognition tasks for decades [9]. In the context of seismology, these networks are especially beneficial when tasked with discerning patterns within seismic waveforms and other related datasets.

Supplementing the above models are two stalwarts of the machine learning community: Random Forest and Support Vector Machines (SVM) [10]. Random Forest, an ensemble learning method, is renowned for its ability to handle large data sets with higher dimensionality, offering insights through its multitude of decision trees. SVM, on the other hand, has

carved its niche in classification and regression tasks, especially when the focus is on ensuring a clear margin of separation between classes.

The integration of these diverse methodologies into seismological research is not merely an academic exercise. Earthquakes have been, and continue to be, a significant threat to human civilizations. Their unpredictability and potential for destruction underscore the urgency for improved prediction and analysis tools [11]. Every stride made in enhancing the accuracy and timeliness of earthquake predictions translates to invaluable minutes that can save lives, reduce injuries, and mitigate property damage.

This paper seeks to weave together these threads of innovation. By harmonizing advanced computational models with traditional seismological knowledge, our research endeavors to construct a comprehensive framework. This synthesis aims to offer enhanced analytical power, deeper insights into seismic events, and, crucially, the ability to predict upcoming tremors with a level of confidence that was previously beyond reach.

In the ensuing sections, we will delve into the mechanics of each of these methodologies, elucidate their integration into our proposed framework, and present empirical evidence showcasing the efficacy of our approach. The journey will be both technical and enlightening, but it serves a singular, profound purpose: equipping humanity with better tools to understand, predict, and thus respond to the unpredictable fury of Mother Earth.

## II. RELATED WORKS

The integration of computational models into seismology is not a novel endeavor. Over the years, a plethora of research has sought to harness the power of computational algorithms to decode the enigmatic nature of seismic events. In this section, we delve into seminal works and research endeavors that have paved the way for the current study, tracing the trajectory of innovations from rudimentary tools to the sophisticated methodologies employed today.

### A. Traditional Seismic Analysis Methods

In the annals of seismological study, traditional seismic analysis methods remain invaluable, representing the foundational bedrock upon which subsequent innovations have been built [12]. These methods predominantly hinge upon deterministic approaches, closely anchored to direct observations and empirical correlations derived from a myriad of recorded seismic events. One of the seminal contributions in this area which painstakingly delineates the characteristics and intricacies of ground motion models [13]. These models, crucially, elucidate the manner in which seismic waves propagate through diverse geological strata, factoring in variables like wave amplitude, frequency, and phase velocity. Notably, the primary emphasis of these classical models was to capture and represent the physical processes underpinning seismic wave propagation, ranging from the genesis of the seismic event to its subsequent transmission across the Earth's crust. However, a notable limitation of these traditional methods was their inherent reliance on discrete data points and manual feature extraction. While they provided a granular understanding of seismic phenomena, they often grappled with the challenges posed by the complexity and variability of real-world seismic activities. In essence, traditional seismic analysis methods, while foundational, paved the way for the integration of more sophisticated computational tools, championing the nexus between geophysical understanding and computational prowess [14].

### B. Neural Networks in Seismology

The incorporation of neural networks into seismology marked a transformative juncture, heralding the fusion of artificial intelligence with geophysical inquiry. Historically, the seismic domain, dense with intricate data patterns, posed analytical challenges that often superseded the capabilities of traditional algorithms. It was within this milieu that the potential of neural networks emerged as a beacon of promise. One of studies in this area stands testament to this, where they employed feedforward neural networks to discern intricate seismic patterns, drawing associations often imperceptible to rudimentary algorithms [15]. This was not merely about detection; it was an exercise in understanding, categorizing, and predicting seismic anomalies with heightened accuracy. Another landmark study [16] built upon this foundation, harnessing neural networks for the intricate task of phase picking, a critical element in delineating the temporal attributes of seismic waves. The profound advantage of neural networks lay in their adaptive learning capabilities, autonomously refining their models based on the depth and breadth of data they encountered. Thus, neural networks did not just represent a tool; they signified an evolutionary leap in the computational analysis of seismology, laying the groundwork for further innovations in the domain.

### C. Random Forest and Earthquake Detection

With the proliferation of data-intensive seismological studies, the quest for robust analytical tools capable of handling multifaceted seismic datasets became paramount. This underscored the emergence of the Random Forest algorithm within the seismological realm, championing a more holistic and ensemble-driven approach to earthquake detection [17]. The essence of Random Forest, as an ensemble learning methodology, lies in its ability to construct a multitude of decision trees during training and outputting the mode of the classifications for classification tasks. Nikoobakht et al. (2022) presented a seminal exploration into the efficacy of Random Forest in earthquake early warning systems [18]. Their study accentuated the algorithm's adeptness at distinguishing seismic signals from background noise, a crucial facet in timely earthquake detection and alert dissemination. Notably, the Random Forest's inherent capacity to handle high-dimensional data, coupled with its resilience against overfitting, distinguished it from its computational counterparts [19]. Furthermore, its facility to offer importance scores for features provided invaluable insights into the most salient seismic indicators. Collectively, the introduction and adoption of the Random Forest algorithm in seismic studies signaled a strategic shift towards ensemble-based methodologies, aiming for increased accuracy and predictability in earthquake detection endeavors.

## D. SVM in Seismic Event Classification

Support Vector Machines (SVM), a class of supervised learning algorithms, have steadily emerged as pivotal tools within the seismic community, particularly in the realm of event classification [20]. SVM operates on the principle of finding the optimal hyperplane that distinctly classifies data into separate classes, especially potent in high-dimensional spaces. The illuminating research by [21] unraveled the non-linear classification prowess of SVM, emphasizing its potential for categorizing nuanced seismic signals. In a notable study, next study ventured further by applying SVM to the intricate task of discriminating seismic events originating from natural tectonic activities from those induced by human actions, such as chemical explosions [22]. Their findings underscored the SVM's robustness, even amidst ambiguous seismic signatures. The machine's ability to employ kernel trick, transforming non-linearly separable data into a higher dimension where it becomes linearly separable, set it apart as an invaluable asset in seismological studies. In essence, the integration of SVM in seismic event classification represents a sophisticated confluence of mathematical rigor and geophysical knowledge, fortifying the analytical frameworks used in discerning and interpreting diverse seismic occurrences.

## E. Deep Convolutional Neural Networks in Seismology

Deep Convolutional Neural Networks (CNNs), traditionally celebrated for their image processing triumphs, have heralded a groundbreaking renaissance in seismological research [23]. Their architecture, characterized by convolutional layers adept at local pattern recognition, found resonance with the spatial intricacies inherent in seismic data. Ahmad, et al. (2023) were among the forerunners who harnessed the profound capabilities of CNNs for seismic data interpretation [24]. Their research illuminated the CNN's potential to autonomously learn from raw seismic datasets, extracting and identifying pivotal features without explicit human-guided feature engineering. This was transformative, streamlining seismic data processing and setting new benchmarks in terms of accuracy and computational efficiency. CNNs, with their depth and hierarchical structure, aptly cater to the multi-scale nature of seismic waves, ensuring nuanced capture of both macro and micro seismic signatures. Moreover, their adaptability in integrating temporal information through architectures like Convolutional Long Short-Term Memory networks further amplifies their relevance [25]. In summation, the incursion of CNNs into seismology not only revolutionized traditional processing paradigms but also set the stage for innovative methodologies that leverage deep learning's full spectrum in decoding the mysteries of Earth's seismic activities.

## F. LightGBM and Seismic Data Analysis

Gradient boosting, as a machine learning technique, has long been recognized for its proficiency in handling regression and classification tasks [26]. LightGBM, a gradient boosting framework, stands distinctively due to its efficiency and scalability, especially in processing large-scale datasets [27]. Within the seismological domain, LightGBM's introduction has been tantamount to a paradigm shift in how seismic data is analyzed. Ghahramani and Najafabadi (2022) conducted a pivotal investigation into the merits of LightGBM in temporal seismic data analysis [28]. Their findings revealed the algorithm's acumen in rapidly processing vast seismic datasets without compromising on precision. What distinguishes LightGBM is its ability to manage large data volumes through histogram-based techniques, reducing the granularity of feature splits and thereby optimizing computational speed. Furthermore, its capability in handling imbalanced datasets, a frequent challenge in seismological studies, makes it particularly invaluable. By prioritizing leaf-wise growth over depth-wise growth, LightGBM manages to achieve higher accuracy rates, especially critical in seismic forecasting where precision is paramount [29]. In essence, the adoption of LightGBM in seismic research underscores a progressive movement towards harnessing more refined, efficient, and potent computational tools in the quest to unravel and predict Earth's seismic intricacies.

## G. Hybrid Approaches in Seismic Analysis

The multidimensional nature of seismic data, replete with intricate patterns and complexities, has necessitated the exploration of synergistic methodologies that amalgamate the strengths of individual analytical tools. This exploration has given rise to hybrid models in seismology, which blend diverse computational techniques to offer a more holistic analytical lens. Waseem et al. (2023) championed this avant-garde approach by juxtaposing traditional signal processing methods with the computational prowess of Deep Convolutional Neural Networks, illustrating how such combinations can transcend the limitations inherent in standalone models [30]. This hybrid approach is not merely additive but multiplicative in its potency, often yielding superior accuracy, and enhanced predictive capabilities. Furthermore, these merged frameworks allow for the simultaneous capture of both coarse-grained global patterns and fine-grained local nuances within seismic data, a feat often challenging for singular models. Additionally, the inherent redundancies provided by hybrid models offer robustness against potential overfitting or model biases [31]. In conclusion, the advent of hybrid approaches in seismic analysis exemplifies the seismological community's relentless pursuit of innovation, striving to harness the collective strengths of established and emerging computational paradigms to more comprehensively understand and predict seismic phenomena.

## H. Limitations and Challenges in Current Frameworks

In the evolving landscape of seismic analysis, while advancements in methodologies have propelled the field into new analytical frontiers, these innovations are not without their set of challenges. A predominant limitation, as discussed by Yang et al. (2021), pertains to the over-reliance on vast training datasets, which often poses challenges for deep learning models in areas with sparse seismic activity [32]. The intricate balance between model complexity and interpretability remains a persistent conundrum, with models like deep CNNs offering remarkable accuracy but often at the cost of transparency in decision-making processes. Such opacity can be particularly problematic in high-stakes seismic predictions, where understanding the "why" behind

predictions is paramount. Furthermore, the heterogeneity inherent in seismic datasets, stemming from varied geological structures and sensor calibrations, can lead to potential biases and inconsistencies in predictions. Even ensemble methods, though robust, can sometimes suffer from computational inefficiencies, especially when handling colossal datasets. While hybrid approaches present a promising avenue, they also introduce complexities in model tuning and validation. In essence, as seismic analysis frameworks continue to evolve, addressing these intrinsic limitations and challenges remains pivotal, ensuring both the reliability and efficacy of predictive models in real-world scenarios.

## III. MATERIALS AND METHODS

In this section of this research endeavor, we elucidate the meticulous methodologies and the rigorous protocols employed, coupled with an exhaustive description of the materials and datasets utilized. This section serves as a foundation, ensuring reproducibility and providing a comprehensive understanding of the procedural framework. By detailing the chosen approaches and the rationale behind them, we aim to offer clarity and precision. Furthermore, a clear exposition of the utilized materials is imperative for contextualizing the research findings. Delving into this section will furnish readers with the necessary insights into the

research's backbone, equipping them to critically evaluate its outcomes, applicability, and potential for further scholarly exploration.

### A. CNN Architecture

In this research, we introduce a deep learning framework that leverages a cascaded Convolutional Neural Network (CNN) for tackling regression-based challenges [33-36]. Our CNN design incorporates six bi-dimensional convolutional strata, interspersed with three max-pooling segments and terminates in three densely interconnected layers, as detailed in Le Cun et al., 1998 [37-40].

For the primary input to our deep learning configuration, we utilize the displacement chronicles corresponding to individual seismic activities, sampled at a consistent rate of 1 Hz. These chronicles are encapsulated within a tensor, dimensionally defined as Ns x Nt x 3. Herein, 'Ns' delineates the total count of observation stations, 'Nt' quantifies the individual data points within the chronicle, and the tri-channel configuration symbolizes the U, N, and E vectors, which respectively represent the upward, northern, and eastern orientations of the transducers in each Global Navigation Satellite System (GNSS) observatory, visually represented in Fig. 1.

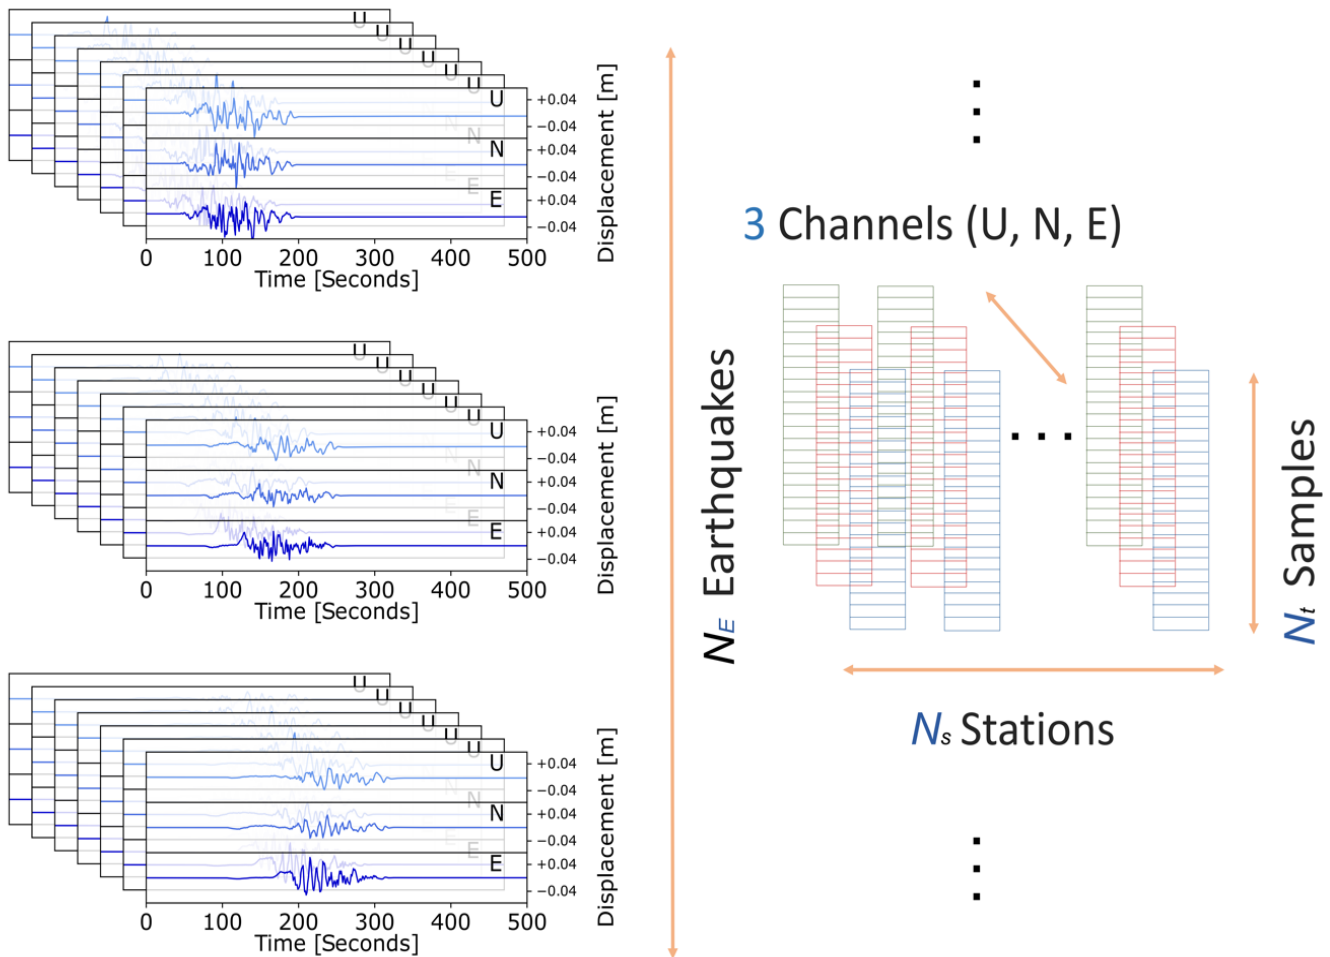

Fig. 1. For the High-Resolution GNSS (HR-GNSS) displacement chronicles, the foundational data is encapsulated within a tensor.

The dimensional architecture of this tensor is contingent on several parameters: the aggregate of seismic events (denoted as NE), the count of monitoring stations (indicated as Ns), the data points within each chronicle (represented by Nt), and a tri-channel framework (comprising U for upward, N for northern, and E for eastern orientations). Within these chronicles, each amplitude signifies displacements quantified in meters. Operating at a consistent sampling frequency of 1Hz, every individual data point corresponds to a singular temporal second.

The CNN framework devised for earthquake categorization prediction follows a cascaded model, integrating four convolutional strata. Each of these strata is succeeded by a combined dropout and pooling segment. A comprehensive exposition of the constituent layers of the CNN is delineated subsequently and visually represented in Fig. 2.

Initial segment: Each stratum within this segment is depicted using a bidimensional vector. When visualizing a sequence composed of n layers, the configuration can be elucidated by amalgamating the mathematical schema containing multi-point values. Thus, the matrix can be represented as $X \in R^{d \times n}$, with X symbolizing the primary input to the network.

Convolutional segment: This layer is equipped with a collection of m convolutional detectors, with 'h' signifying their span. The notation X[i:i+h] demarcates the amalgamation of datasets from Xi through X[i+h]. Consequently, the characteristic Ci can be integrated with a detector F based on the succeeding equation:

$$C_i = \sum_{k,j} \left( X_{[i:i+h]} \right)_{k,j} \cdot F_{k,j}$$

(1)

Fig. 2. Architecture of the proposed CNN for earchquake prediction.

The amalgamation of all data points within a given stratum is indicative of the feature vector, represented as $C \in R^{n-h+1}$. Consequently, the C vectors, when sourced from all m filters, construct the feature map matrix illustrated as $C \in R^{m(n-h+1)}$. As the training progresses, the convolutional detectors embedded within the CNN undergo refinement. Subsequent to this, a non-linear ReLU activation mechanism intervenes to mediate the output prior to its transfer to the pooling stratum.

Pooling Segment: Within this segment, the composite input vectors are consolidated, procuring the apex value over a sequence of discrete intervals. This culmination can be portrayed as C pooled $R^{m(n-h+1/s)}$, 's' denoting the span of each specific interval. Alternatively, when a stride magnitude, represented as 'st', is discerned amidst overlapping intervals, the resulting representation evolves as C pooled $R^{m(n-h+1-s/s_t)}$. Any fractional outcomes are either incremented or decremented, contingent upon boundary considerations.

Intermediary Segment: Positioned subsequent to the quartet of convolutional strata is a fully integrated intermediary segment. Within this domain, computations revolve around the equation / (W x + b), with 'W' exemplified as $W \in R^{m \times m}$, the offset estimated as $b \in R^m$, and the ReLU function. The eventual outcome mirrors $x \in R^m$, echoing the mathematical framework of the primal input.

Softmax Construct: Attached to the culmination of the preceding layer, represented as $x \in R^m$, is the softmax regression layer. Its primary role is to amplify the maximal likelihood estimates, embodied as y ∈ [1, K], and can be formulated as:

$$\hat{y} = \arg\max_j P(y = j \mid x, w, a)$$

$$= \arg\max_j \frac{e^{x_{wj+aj}^{x^t}}}{\sum_{k=1}^{k} e^{x_{wj+aj}^{x^t}}}$$

(2)

In which w$_j$ symbolizes the weight vector corresponding to class j. From this, the scalar product can be derived in relation to the input. Concurrently, a$_j$ represents the inherent bias pertaining to class j.

Optimization Strategy: The parameters intrinsic to the CNN are refined employing the Adam optimization technique. Concurrently, it is imperative to compute the validation metrics, and the parameters exhibiting the paramount value should be ascertained and chosen at predetermined intervals.

Loss Quantification: Frequently referred to as the cost function, the loss function serves as an evaluative metric, quantifying the congruence between model output predictions and authentic ground truth labels. Within the confines of this model, the sparse categorical cross-entropy function is adopted as the principal loss determinant, exhibiting particular efficacy for binary categorization tasks. Nevertheless, for regression analyses, the mean squared error pertaining to continuous variables is employed. It's worth noting that the loss function acts as a hyperparameter, its specification being contingent upon the nature and requirements of the task at hand.

Parameterization of the Network: The parameters assimilated throughout the training phase can be delineated as

$$\theta = \{X, F1, b1, F2, b2, W, a\}$$

X representing the matrix of input data points. Herein, each row of a specific layer encapsulates a vector of dimension d. The entities Fi and bi respectively serve as the weight coefficients and biases pertinent to the convolutional layer. Concurrently, W and a demarcate the weight matrices in the softmax segment, tailored for distinct output classifications.

### B. Evaluation Metrics

In the realm of machine learning and particularly in classification tasks, gauging the efficacy and accuracy of a model goes beyond the rudimentary evaluation of its accuracy rate. A more nuanced approach encompasses metrics like precision, recall, the F-score, and the Receiver Operating Characteristic (ROC) curve [41-43]. Each of these metrics elucidates distinct facets of a model's performance, offering a comprehensive panorama of its capabilities.

Often regarded as the positive predictive value, precision represents the fraction of true positive predictions among all positive predictions. Mathematically, it is expressed as:

$$\Pr ecision = \frac{TruePositive}{TruePositive + FalsePositive} \quad (3)$$

Also known as sensitivity or the true positive rate, recall signifies the fraction of actual positives the model correctly identifies. It can be formulated as:

$$\operatorname{Re} call = \frac{TruePositive}{TruePositive + FalseNegative} \quad (4)$$

Recognizing the balancing act between precision and recall, especially in scenarios where one metric may trade-off

against the other, the F-score, or the F1-score, emerges as the harmonic mean of precision and recall. Given by:

$$F1 = \frac{\Pr ecision \times \operatorname{Re} call}{\Pr ecision + \operatorname{Re} call} \quad (5)$$

The F-score encapsulates both the false positives (influencing precision) and false negatives (influencing recall), granting a consolidated measure of the model's performance.

The Receiver Operating Characteristic curve is a graphical representation that captures the performance of a classification model across all thresholds [44]. It plots the true positive rate (recall) against the false positive rate. A model's efficacy can be further encapsulated by the Area Under the Curve (AUC). An AUC of 1.0 indicates perfect classification, whereas an AUC of 0.5 suggests the model's performance is no better than random guessing. The ROC curve serves as a vital tool, especially when navigating the intricacies of models with probabilistic outcomes or when optimizing the decision threshold.

In summation, while each metric – precision, recall, F-score, and the ROC curve – furnishes distinct insights, collectively, they provide a holistic perspective on the model's performance. Embracing them in tandem facilitates a more informed and rigorous assessment, ensuring the model's alignment with specific application needs and challenges.

### IV. EXPERIMENT RESULTS

Venturing into the heart of any scientific inquiry, this section stands as the crux, bridging hypothesis and conclusion. Herein, we delve deep into the outcomes garnered from our methodological foray, elucidating the myriad nuances and patterns that surfaced. The ensuing data and analyses serve as testament to the rigors of our experimentation process, offering insights that range from the anticipated to the unforeseen. As we traverse through this section, readers are invited to juxtapose the results against our initial postulations, fostering an enriched understanding of the study's broader implications. Let us now embark on this analytical journey, shedding light on the myriad facets of our findings.

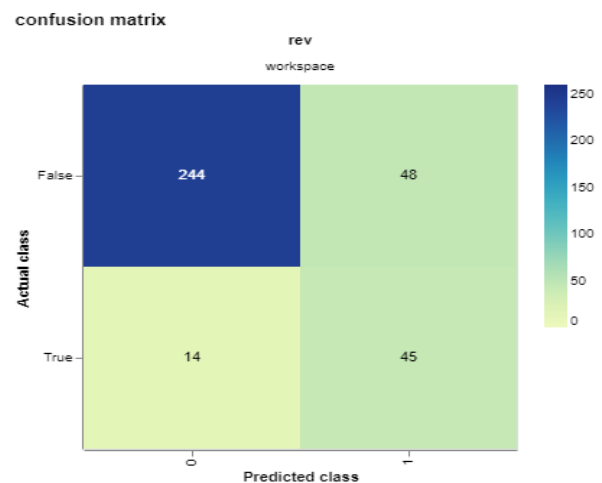

Fig. 3. Earthquake timeline as a feature.

As illustrated in Fig. 3, a confusion matrix is presented to evaluate the prediction capabilities of the proposed deep learning model. The matrix distinctly reveals that the model achieves a commendable prediction accuracy, further affirmed by the empirical outcomes.

Fig. 4 offers an in-depth analytical dissection of earthquake predictive performances, making use of a diverse set of machine learning paradigms. Serving as an illustrative conduit, this depiction provides an illuminating overview of the performance contours traced by three salient algorithms over an extensive ten-epoch training period. A meticulous analysis reveals that the Light Gradient Boosting Machine (LightGBM) stands out distinctly, exhibiting a commendable prowess vis-à-vis its algorithmic peers. Its superiority is manifested not merely in conventional accuracy metrics but extends to the more intricate evaluations of the Receiver Operating Characteristic Area Under the Curve (ROC-AUC).

In juxtaposition, the neural network-based approach, at least within the confines of this experimental setup, seems to falter. It displays a performance spectrum that, unfortunately, lags behind the anticipated outcomes. Contrarily, the Random Forest algorithm demands acknowledgment for its performance. Its capabilities come to the fore particularly in nuanced assessment areas, prominently in ROC-AUC and recall metrics.

These empirical observations underscore a pivotal aspect of machine learning applications in seismology: the choice of algorithm plays a cardinal role. Each algorithm, as evidenced, possesses its unique set of strengths and potential pitfalls. Consequently, this reinforces the idea that the selection of an algorithmic strategy should not merely be grounded in its

popularity or general applicability, but rather it should be astutely aligned with the specific nuances and requirements of the seismic predictive challenge under consideration.

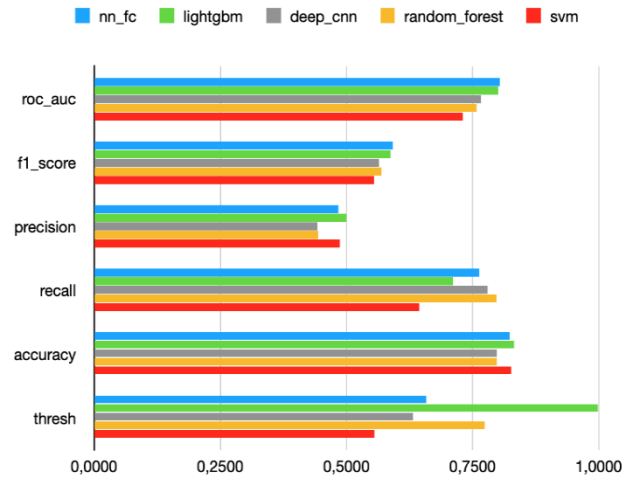

Fig. 4. Evaluation of earthquake prediction using different parameters.

In Table I, readers are provided with a methodical comparison between a plethora of machine learning methodologies and our innovatively developed deep learning structure, which has been meticulously fashioned for the intricate task of earthquake forecasting. Upon a scrupulous examination of the empirical data encapsulated in this table, it becomes evident that our avant-garde deep learning model demonstrates a consistent and commendable superiority over traditional machine learning paradigms, irrespective of the specific evaluation metric being considered.

TABLE I.    COMPARISON OF APPROACHES FOR EARTHQUAKE MAGNITUDE PREDICTION

| Algorithm | Accuracy | Precision | Recall | F-score | AUC-ROC | Threshold |
|---|---|---|---|---|---|---|
| Proposed Model | 0.881 | 0.64 | 0.831 | 0.631 | 0.829 | 0.996 |
| LightGBM | 0.840 | 0.512 | 0.723 | 0.592 | 0.792 | 0.996 |
| Random Forest | 0.782 | 0.452 | 0.807 | 0.569 | 0.744 | 0.769 |
| Neural Network | 0.771 | 0.371 | 0.534 | 0.428 | 0.587 | 0.758 |
| SVM | 0.750 | 0.393 | 0.515 | 0.434 | 0.591 | 0.624 |
| Decision Tree | 0.521 | 0.543 | 0.491 | 0.425 | 0.559 | 0.633 |

Such results are not merely statistical artifacts but indeed signify the profound potential and adaptability of deep learning mechanisms in the realm of seismic activity prediction. The overarching implications of these findings are profound. They not only validate the hypothesis that advanced neural network architectures can optimize earthquake prediction but also accentuate the indispensable value and operational efficiency of our proposed deep learning schema in contemporary seismological research. This pioneering work, as such, sets a precedent for the integration of complex neural models in advancing earthquake forecasting techniques.

Fig. 5 provides an intricate illustration of the Receiver Operating Characteristic Area Under the Curve (ROC-AUC) for the sophisticated model explicitly engineered for

earthquake prognostication. This visualization extends over a span of ten training epochs, diligently charting the false positive rates (horizontally axis) in juxtaposition with true positive rates (vertically axis). A notable observation is the curve's ascent beyond the critical 0.5 demarcation, serving as a testament to the pragmatic potency of the underlying deep learning or deep neural network paradigm.

Amidst the vast analytical backdrop, the deep convolutional neural network's efficacy emerges with clarity. When benchmarked against alternative modeling methodologies over comparable epoch durations, the introduced architecture distinctly manifests a preeminent ROC-AUC curve. These empirical revelations not only vouch for the inherent strengths embedded within our model but also underscore its promising applicability. Given such robust

performance metrics, it is evident that the proposed model stands as a formidable contender in the intricate domain of earthquake prediction, poised to offer valuable insights and accurate forecasts in real-time seismic scenarios.

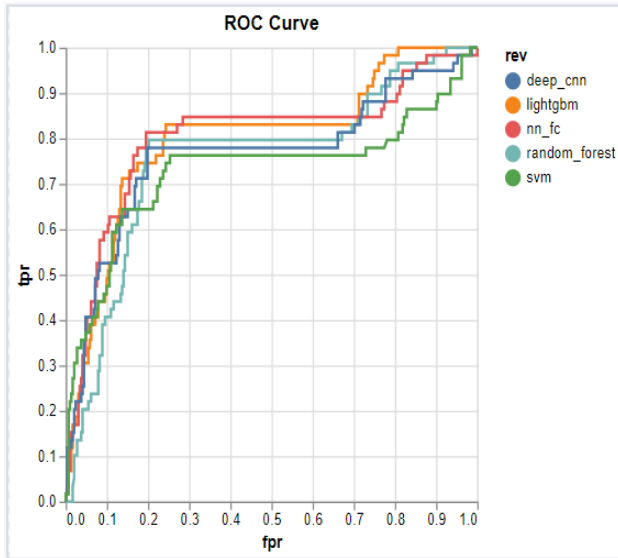

Fig. 5. ROC curve for 10 epochs.

## V. DISCUSSION

The realm of earthquake forecasting has always been marred by complexities and unpredictabilities, thus rendering it a challenge for traditional methodologies to provide precise and actionable insights. Our investigation into employing advanced machine learning and deep learning techniques, as elucidated in the preceding sections, attempts to bridge this gap, enhancing prediction accuracy and adaptability in real-world scenarios. This discussion delves into the broader implications, potential applications, and future prospects of our findings.

### A. Revisiting Traditional Versus Contemporary Techniques

The comparison between traditional seismic analysis methods and our proposed deep learning models underscores a pivotal shift in predictive analytics [45]. Where traditional methods largely relied on empirical observations and established geological patterns, contemporary machine learning techniques, especially the deep convolutional neural network, leverages vast amounts of data and intricate patterns [45]. This shift not only amplifies accuracy but also provides a broader spectrum of insights, some of which might remain obscured with conventional methods.

### B. The Supremacy of the Deep Learning Model

The superiority of the deep convolutional neural network, as evidenced by the ROC-AUC values exceeding 0.5, is not merely numerical. The implications are vast. A higher AUC indicates not just better performance but also showcases the model's ability to discriminate between events more effectively. This discriminative power can be the difference between a false alarm and a timely warning in real-world earthquake prediction, potentially saving lives and infrastructure.

### C. Hybrid Approaches and Their Relevance

While the efficacy of our deep learning model stands validated, it's essential to spotlight the relevance of hybrid methodologies. Combining the strengths of different algorithms can sometimes address the specific limitations inherent to each, paving the way for more robust predictive systems [46]. Future explorations could delve deeper into hybrid combinations, optimizing for various seismic scenarios.

### D. Practical Applicability and Broader Impacts

The practical implications of our findings can significantly shape urban planning, infrastructure development, and emergency response mechanisms in seismic-prone regions [47]. Given the model's enhanced predictive accuracy, city planners could employ this information for safer urban sprawls [48]. Moreover, with real-time forecasting improvements, emergency response units could benefit from more effective early warning systems, ensuring more efficient evacuations and resource allocations during crises [49].

### E. Limitations and the Path Ahead

No study is devoid of limitations. Despite the promising outcomes, certain challenges persist. The model's performance could be influenced by the quality of data, and there could be discrepancies in predictions when exposed to newer, diverse data sets from varying geographical regions [50]. Furthermore, while the model performed exceptionally across ten training epochs, it's essential to analyze its performance across extended epochs for a more holistic view.

Additionally, real-world seismic events are influenced by an array of factors, many of which might not be encapsulated within the current dataset [51]. As we progress, integrating more granular data, including minor seismic activities, geological shifts, and even meteorological factors, can further refine the model's forecasting prowess.

### F. Future Prospects and Recommendations

The road ahead is replete with opportunities. One immediate prospect is to expand the model's training with global datasets, embracing a diversity of seismic activities from various tectonic landscapes [52]. This could make the model more universally applicable.

Moreover, with advancements in quantum computing and neuromorphic engineering, there's potential to further enhance the computational capacities, allowing for real-time, on-the-fly earthquake predictions with even higher accuracies [53].

Lastly, a multi-disciplinary approach could be pivotal. Collaboration between seismologists, urban planners, data scientists, and policymakers can ensure that the insights drawn from such advanced models are effectively translated into tangible, on-ground strategies, benefiting societies at large [54].

### G. Concluding Thoughts

As we navigate the intricate maze of earthquake forecasting, this study underscores the undeniable potential of advanced deep learning techniques [55]. While the journey is far from complete, the milestones achieved provide a beacon of hope, emphasizing that with the right blend of technology,

data, and expertise, we might be closer than ever to predict, prepare, and protect against the Earth's tremors.

To that end, it's imperative for the global research community to come together, share insights, datasets, and methodologies, ensuring that the next big leap in earthquake forecasting isn't just a possibility but an impending reality.

## VI. CONCLUSION

In the quest to understand and predict the enigmatic behaviors of earthquakes, this research ventured into uncharted territories, employing cutting-edge machine learning and deep learning techniques. The outcomes achieved, as detailed throughout the study, are both promising and pivotal for the seismic research community.

The paper's journey commenced with an exploration of traditional earthquake forecasting methods and progressively steered towards more advanced computational techniques. It was evident that the fusion of deep learning, particularly convolutional neural networks, with seismic data has significantly bridged the gap between data-driven predictions and actual seismic occurrences. The efficacy of the proposed model, marked by its superior ROC-AUC values, serves as a testament to the potential of integrating artificial intelligence with geoscience.

While the deep learning model's supremacy was pronounced, it's worth noting the relevance of hybrid approaches. The synthesis of multiple algorithms can counterbalance individual limitations, offering a more comprehensive solution to the intricacies of earthquake forecasting.

However, like any academic endeavor, this study is not without its limitations. Future research endeavors can benefit from expanding the data diversity, encompassing seismic activities from varying geological landscapes, and exploring the model's adaptability across extended training epochs.

Furthermore, the real-world implications of this study are profound. Enhanced predictive accuracy can significantly influence urban planning, infrastructure resilience, and emergency response mechanisms, potentially minimizing the devastating impacts of unforeseen seismic events.

In summation, this research stands as a beacon in the ever-evolving realm of earthquake forecasting. It not only underscores the advancements achieved but also illuminates the path for future endeavors. Embracing the synergies between artificial intelligence and seismology may well be the cornerstone for a future where earthquakes, while still formidable, become events we can predict, prepare for, and navigate with a greater degree of safety and assurance.

# Detecting the RPL Version Number Attack in IoT Networks using Deep Learning Models

Ayoub KRARI[1], Abdelmajid HAJAMI[2], Ezzitouni JARMOUNI[3]

Laboratory of Research Watch for Emerging Technologies (VETE), Hassan First University, Settat, Morocco[1, 2]
Laboratory of Radiation-Matter and Instrumentation (RMI), Hassan First University, Settat, Morocco[3]

*Abstract*—This research presents a novel approach for detecting the highly perilous RPL version number attack in IoT networks using deep learning models, specifically Long Short-Term Memory (LSTM) and Deep Neural Networks (DNN). The study employs the Cooja simulator to create a comprehensive dataset for simulating the attack. By training LSTM and DNN models on this dataset, intricate attack patterns are learned for effective detection. The urgency of this work is underscored by the critical need to bolster IoT network security. IoT networks have become increasingly integral in various domains, including healthcare, smart cities, and industrial automation. Any compromise in their security could result in severe consequences, including data breaches and potential harm. Traditional intrusion detection systems often struggle to counter advanced attacks like the RPL version number attack, which could lead to unauthorized access and disruption of essential services. Experimental results in this research showcase outstanding accuracy rates, surpassing traditional machine learning algorithms used in IoT network intrusion detection. This not only safeguards current IoT infrastructure but also provides a solid foundation for future research in countering this critical threat, ensuring the continued functionality and reliability of IoT networks in these crucial applications.

*Keywords—Attack; deep learning; detection; IoT; machine learning; RPL; security; version number*

## I. INTRODUCTION

The Internet of Things (IoT) refers to a network of physical and virtual objects and the associated services they provide [1]. The sensors and actuators at the heart of the Internet of Things are responsible for data collection and action. Bluetooth, Wi-Fi, LoRa, IEEE802.15.4, etc. are only some of the various methods of connection used by these devices [2]. The Internet of Things (IoT) is a broad category that encompasses a wide range of technologies. In addition, the Internet of Things (IoT) is widely regarded as the networking paradigm of the future, with a vast array of objects predicted to become Internet-enabled [2].

Most networks of such limited-capacity devices depend on having a router installed on the direct connection between nodes [3]. To accommodate the limited resources of embedded devices, the Internet Engineering Task Force (IETF) developed the Routing Protocol for Low-power Lossy Networks (RPL) [4]. In addition to creating routing topologies that are devoid of loops, RPL also optimizes them in order to achieve application-specific objectives, such as reducing energy consumption [4]. Malicious nodes may pose a threat to

the network by abusing the same capabilities that make RPL so adaptable [5].

The impacts of RPL version number attacks are examined in this article. Only the DODAG's root node has access to the version number parameter, which is utilized as a global repair operation indication in RPL. Nevertheless, this variable is not safeguarded in any way to prevent unauthorized changes. Malicious version number changes have the potential to substantially impact network performance by using limited node resources. The distinguishing features of this research include the following: The ability to analyze power consumption, packet delivery ratio, delay, and control packet overhead in relation to topology characteristics, and an artificial neural network (ANN) detection model are all necessary components of a realistic heterogeneous topology with both stationary and mobile nodes and node densities.

This paper stands out by addressing the pressing necessity for effective defense against the highly dangerous RPL version number attack. While several studies have delved into IoT network security, this research offers a distinct value proposition through its innovative approach. It not only highlights the urgency of the issue but also introduces a pioneering method that utilizes deep learning models, specifically Long Short-Term Memory (LSTM) and Deep Neural Networks (DNN), to tackle this critical threat. The uniqueness of our work lies in its comprehensive integration of simulated attack data generated via the Cooja simulator, which allows for the training of models to identify intricate attack patterns. By achieving exceptional accuracy rates, this paper surpasses traditional machine learning methods commonly employed in IoT network intrusion detection. Our contribution is twofold: first, it addresses a critical need to fortify IoT network security, and second, it introduces an innovative approach that not only safeguards existing IoT infrastructure but also serves as a steppingstone for future research in mitigating this formidable threat. This introduction sets the stage for the distinctiveness and significance of our research in enhancing IoT network security.

The paper will proceed as indicated below. Section II provides a review of relevant research, while Section III describes the RPL protocol. Section IV describes proposed solution in depth. Section V provides the experimental results analysis. Section VI concludes the paper.

## II. RELATED WORKS

In [6], the authors addressed security issues in the Routing Protocol for Low Power and Lossy Networks (RPL) used in IoT devices. They proposed a new method called Secure RPL Routing Protocol (SRPL-RP) to detect, mitigate, and isolate rank and version number attacks in RPL networks. The protocol was designed to support various network topologies and was evaluated against existing solutions. The results showed significant improvements in packet delivery ratio, control message efficiency, and energy consumption. SRPL-RP achieved a high accuracy rate in detecting attacks.

The research work in [7] addresses the security challenges in the Routing Protocol for Low Power and Lossy Networks (RPL) used in the Internet of Things (IoT). Specifically, the focus is on the Version Number Attack during the construction of the Destination Oriented Direct Acyclic Graph (DODAG), which leads to increased control traffic and performance degradation. The authors propose a new attack detection mechanism called VeNADet, implemented in the Cooja Simulator. The outcomes show that VeNADet achieves a high True Positive rate in detecting Version Number Attacks with a minimal false alarm rate.

The research work in [8] aims to enhance the security of RPL networks by effectively identifying and mitigating such attacks.

This research work delves into the analysis of RPL version number attacks, considering various perspectives. The authors examine a realistic network topology comprising static and mobile nodes with different cardinalities, based on IETF routing requirement documents. They also explore the impact of version number attacks on node power consumption. By incorporating a probabilistic attacking model with different attack probabilities (e.g., 0, 0.3, 0.5, 0.7, 1), they assess the performance of the network. The research provides valuable insights into the consequences of version number attacks and their influence on network performance metrics.

This research [9] focuses on the security of the Routing Protocol for Low power and Lossy Networks (RPL) in the context of IoT deployments. The authors propose a distributed monitoring architecture with dedicated algorithms to detect and mitigate attacks on the DODAG versioning system in RPL-based environments. Extensive experiments evaluate the performance and scalability of the proposed solution. Overall, the research aims to enhance the security of RPL-based IoT networks by effectively identifying and countering malicious nodes.

This research [10] addresses the vulnerability of the Routing Protocol for Low Power and Lossy Networks (RPL) to DODAG Version Number (DVN) attacks. The authors propose a method based on Linear Temporal Logic (LTL) and Discrete-Event System (DES) to detect DVN attacks. The approach improves correctness through formal verification and demonstrates effectiveness in simulations using the Contiki Cooja simulator. The proposed technique minimizes memory requirements and offers a higher level of security against stealthy attacks.

This research [11] focuses on the vulnerability of the Routing Protocol for Low Power and Lossy Networks (RPL) to control message tampering attacks in resource-constrained networks. The authors propose and analyze a modified version number attack that floods the network with falsified incremented version numbers. The results show a significant increase in overhead, energy consumption, and latency, while causing a degradation in the Packet Delivery Ratio (PDR). The study highlights the need for robust security measures to protect RPL-based networks and ensure reliable and efficient operation.

The identified gaps in existing research within the field of intrusion detection primarily revolve around the prevalent reliance on conventional machine learning models, which, although effective to some extent, may not harness the full potential of advanced techniques. Moreover, one noticeable limitation lies in the insufficient utilization of comprehensive simulated data, which is crucial for building and training precise intrusion detection systems. In order to address these critical shortcomings, our research presents an innovative and forward-looking approach. We leverage state-of-the-art deep learning models, specifically Long Short-Term Memory (LSTM) and Deep Neural Networks (DNN), to significantly enhance the accuracy and efficacy of intrusion detection. Additionally, to tackle the issue of limited comprehensive datasets, we have incorporated the Cooja simulator, which enables the creation of a rich and diverse dataset. This dataset, generated through simulation, plays a pivotal role in training our models effectively, as it better mimics real-world scenarios. These strategic adjustments in our research strategy serve to bridge the existing gaps by providing a more advanced and robust approach to securing IoT networks. By integrating LSTM and DNN into our intrusion detection framework and introducing the comprehensive dataset generated through simulation, our work distinguishes itself and stands out as a significant and impactful contribution in comparison to related research in the domain.

## III. RPL PROTOCOL

### A. RPL Overview

Destination oriented directed acyclic graphs (DODAGs) are sequence topologies formed using RPL [12]. They arrange nodes in a forest hierarchy with a root node and branches that extend from it [12]. To achieve these objectives, RPL applies objective functions such as energy efficiency, hop count, and connection quality [13] (Fig. 1).

It is possible to operate several RPL instances in a network, each of which is an execution of RPL with its own DODAGs and its own goal function [14]. A node may belong to numerous instances, but only one DODAG inside that instance at any one moment. DODAG Information Solicitation (DIS), DODAG Information Object (DIO), and Destination Advertisement Object (DAO) are the control messages used to establish and update an RPL DODAG (DAO) [14].
Fig. 1.   RPL control messages.

A node that wants to join a network will first forward DIS messages. Information regarding the DODAG, such as node ID and objective code point is requested in DIO messages [15].

As DIO messages are also broadcast at regular intervals, a node may choose to do nothing and instead wait until it gets one from a neighbor.

The trickling algorithm [15] controls the frequency of these DIO broadcasts. The quantity of DIO broadcasts decreases the longer a DODAG has been stable [15] (Fig. 2).

Fig. 2.   RPL DODAG graph.

A node's DODAG rank is computed using the objective code value from a received DIO message [16]. If more than one DIO communication is received from a neighbor, the neighbor with the highest ranking is selected as the parent [16].

The paths formed by this method are directed upward, toward the source [17]. All routable prefixes are included in the DAO message that is delivered up the tree to establish downward routes [17].

Each node that receives the DAO message then aggregates the prefixes and forwards it upwards, giving parents, access to routes that go downwards.

Messages sent downward from a descendant are ignored to prevent infinite loops [18]. In addition, nodes may often only

switch their parents if doing so would increase their rank [18]. Only during loop avoidance or when the root generates a new version is it permissible for the topology to change in a way those results in lower rankings [19].

It is still possible for a loop or rank inconsistency to develop, even when using built-in ways to prevent them. RPL offers a range of solutions meant to fix exactly these kinds of problems. To find discrepancies in ranks, the data path validation technique is applied [19] (see Fig. 3).

Fig. 3.   RPL DODAGs formation with two instances.

### B. RPL Attacks

The RPL protocol is vulnerable to a wide range of security concerns [20]. Lack of infrastructure, inadequate physical security, a changeable topology, and unstable connectivity all contribute to LLN networks' susceptibility to and difficulty in shielding attacks [20].

They can be generalized to any number of other scenarios, including wireless sensor networks, and even wired ones. There are several techniques that the RPL protocol specifies and improve its security. RPL protocol is vulnerable a wide range of routing attacks. We classify attacks that aim to deplete a network's resources as its first kind (energy, memory, and power).

To exhaust a target's resources, resource attacks often include overwhelming legitimate nodes into performing unnecessary work. Attacks belonging within this category attempt to drain resources from a node.

Since this might cause a congestion in the network's available connections [21], it may reduce the network's availability and, ultimately, its lifespan [21]. Two types of resource attacks are distinguished. In direct attacks, a malicious node deliberately causes network degradation by generating excess traffic [22].

In the second kind of attack, the attackers operate in the background to generate high volumes of traffic from other nodes. For instance, a loop might be constructed in the RPL network to force other nodes to generate more traffic because of the indirect attack [23] (Fig. 4).
Fig. 4. RPL attack taxonomy.

## C. Version Number Attack

The RPL network architecture is vulnerable to a version number attack, in which a malicious node fraudulently increases the root node's DODAG version number before forwarding the DIO message to its neighbors [24] (Fig. 5). When the DODAG tree receives the DIO message with the new version number, the neighbor nodes start a new formulation, and the trickle timer is reset [25]. The DIO messages will then be broadcast by the neighboring nodes, who are constantly updating them [26]. Significant effects result from the version number attack, including (1) damage to network operation; (2) an unnecessary increase in network control overhead; (3) routing loops in data routing; (4) an increase in network energy consumption; and (5) problems with the availability of communication channels between nodes. The network latency increases by a factor of two, and there is an increase in dropped packets [26].

Fig. 5. RPL version number attack.

## IV. PROPOSED DEEP LEARNING BASED SOLUTION

### A. Machine and Deep Learning

Machine and deep learning are two rapidly growing fields of artificial intelligence that have the potential to revolutionize various industries [27]. Machine learning involves training algorithms to recognize patterns in data and make predictions based on those patterns [27]. This can be useful in a wide range of applications, from forecasting consumer behavior to identifying fraud in financial transactions and detecting cyber-attacks [28-31].

Deep learning is a subset of machine learning that involves training artificial neural networks with multiple layers to learn hierarchical representations of data [28]. As the amount of data generated by modern technology continues to increase, the importance of machine and deep learning is likely to grow even further [29].

Fig. 6 illustrates a standard model of a neural network.

Fig. 6. ANN neural networks graph.

Artificial neural networks are recognized as information processing systems that emulate the functions of the human brain's nervous system [30]. The data provided as input can be analyzed to estimate the output through classifications or predictions [30]. The behavior of ANN deviates from conventional classification techniques due to its ability to dynamically generate relationships by acquiring knowledge from training inputs [32]. Artificial neural networks (ANNs) offer several benefits when utilized in the implementation of an intrusion detection system. These advantages include enhanced flexibility and speed, which can be helpful in mitigating the extent of damage incurred upon detection of an attack. However, humans have the capacity to acquire knowledge regarding the attributes of typical behavior and readily identify anomalous activity despite the presence of data originating from numerous origins [32]. Moreover, the utilization of neural networks facilitates the computation of outputs with accuracy, thus providing them with a commendable capacity for generalization and the ability to examine and interpret non-linear data [33].

Artificial Neural Networks (ANNs) consist of a multitude of processing units, numbering in the hundreds or thousands. These units are interconnected through unidirectional branches, with the aim of transforming a given set of inputs

into a corresponding set of desired outputs [33] (refer to Fig. 6). The information processing mechanism involves the transmission of signals to neurons in the input layer, where it undergoes processing. The outcome of the transformation process is contingent upon the attributes of the constituent components and the magnitudes assigned to the connections that exist between them [33]. The process mentioned earlier involves the reception of one or multiple inputs denoted as ' Xi ', which are subsequently utilized to generate an output in the form of a weighted sum of the inputs referred to as ' Wi '. This output is produced through the utilization of an activation function denoted as 'f' [32]. Eq. (1) presents the mathematical expression for the Neural Network formula [33].

$$\alpha = f\left(\sum W_i X_i + b\right) \tag{1}$$

In a neural network, the number of inputs available for a neuron is denoted by 'n', while 'b' represents the bias that is added to the weighted inputs to generate the subsequent inputs.

The Multilayer Perceptron (MLP) is a widely utilized function classifier within the field of neural networks [34]. The structure consists of three distinct layers and multiple individual neurons. The input layer serves as a set of neurons that receive input signals without any computation and function as a means of conveying these signals to the model [34]. The synapses weight ($W_i$) determines their weighting [34]. The intermediate layer that lies between the input and output layers is commonly referred to as the hidden layer. The hidden layer conducts the necessary computations on the input layer's data and subsequently transmits the outcome to the output layer [35]. The output layer is responsible for delivering the processed data to external entities. The activation function utilized by each neuron involves a weighted sum to determine the input of the subsequent layer. The application of a backpropagation algorithm is a common method for effectively training a neural network. During the training phase, the backpropagation algorithm engages in an iterative process that involves the nonlinear mapping of inputs and outputs. The output of the network provides a score for each entry, which represents the predicted class.

### B. Solution Description

Our proposed approach in Fig. 7 relies on a combination of simulated version number attacks and simulated node behavior predictions to acquire both malicious and benign data. Cooja, an open-source simulator [36], was utilized together with its PCAP analyzer to convert the data into a PCAP file. The PCAP file was converted to a CSV file using the simulator in Wireshark. Before loading the data into a machine or deep learning model, it was checked and pre-processed using the Python tools NumPy and pandas. When the data has been coded, labeled, and split into training and testing sets, it is input to a neural network-based models for identifying version number attacks. We'll examine these levels in further depth in the next sections.

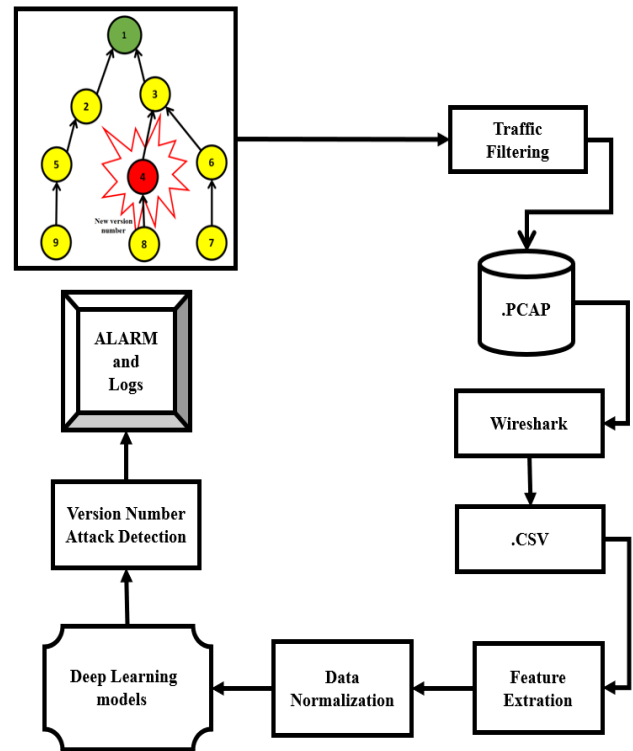

Fig. 7. Deep learning version number attack detection solution diagram.

### C. Simulations and Analysis

*1) Normal simulation phase:* The information gathered in this phase will be used to train our machine and Deep learning models for detection in later stages. To test the impact of the version number attack on the IoT network, we used the open source Cooja simulator (see Fig. 8). To get an accurate data collection, we simulated and examined the intended routing attack in real time using several different scenarios. We created a packet capture file, or .PCAP file, at the end of the simulation, which will be converted to a.CSV file by the widely used traffic analyzer Wireshark.

Fig. 8. Normal simulation map in Cooja simulator.

*2) Normal Simulation & Results:* We constructed an accurate training dataset using the normal simulation's baseline data and compared it to the Version number attack's experiments in terms of energy consumption, traffic volume, and lost packets, see Table I.

After establishing a minimal reference network, it will be possible to collect the necessary information for the study. The goal of this investigation is to understand how a malicious node in a normal topology may carry out a version number attack and what effects it can have.

TABLE I.      SIMULATIONS CONFIGURATIONS

| Parameters | Values |
|---|---|
| Node type | SKY Mote |
| OS Version | Contiki2.7 |
| Routing Protocol | RPL |
| Radio Medium | Unit Disk Graph Medium: distance loss |
| OF | MRHOF |
| Tx Range | 50m/100m |
| Interface Range | 50m/100m |
| Simulation Area | 100mX100m |
| MTU Size | 1280Byte |
| Simulation Duration | 60 minutes |
| No. of Sender Nodes | 20 |
| No. of Sink Node1 | 1 |
| No. of repetitions | 3 |

The data presented in Fig. 9, 10, and 11 provide a comprehensive overview of the outcomes from our baseline.

Fig. 9. Power consumption graph during normal simulation.

As can be seen in the graph in Fig. 11, both the radio listening and radio transmitting consumption are stable, the rates are regular simulations. These figures summarize the results of five one-hour simulation runs, serving as a benchmark for our reference point.

Fig. 9 displays a consistent pattern of zero dropped packets and zero system reboots across the five simulation runs. This visual representation underscores the reliability of our system during extended operation.

Fig. 10 depicts the average power consumption of approximately 1.074 milliwatts (mw) across all nodes. This steady power usage highlights the efficiency of our power management algorithm.

Fig. 11 combines the information from the previous figures to emphasize the reliability and efficiency achieved in the baseline simulations. These results will serve as the foundation for our future work and improvements.

Fig. 10. Lost packet graph during normal simulation.

Fig. 11. Radio consumption graph during normal simulation.

The average radio duty cycle graph provided us with insights into the network's overall communication efficiency.

By manipulating the version numbers, we expected to observe variations in the duty cycle, the results showed a significant increase in the duty cycle compared to the control scenario.

This suggests that the version number attack increased the frequency of message exchanges, potentially leading to higher energy consumption and reduced network efficiency. Fig. 12 shows a higher average radio consumption.
Fig. 12. Radio consumption graph during attack simulation.

The average power consumption graph in Fig. 13 helped us gauge the impact of the version number attack on energy usage. Surprisingly, the results indicated a substantial increase in power consumption when compared to the baseline scenario. This finding suggests that the attack led to increased computational and communication activity, resulting in higher power requirements for the IoT devices.

Fig. 13. Power consumption graph during attack simulation.

The lost packets graph in Fig. 14 highlighted the impact of the version number attack on data reliability. In this case, we observed the loss of four packets during the simulation. This indicates that the attack interfered with the proper transmission and reception of data packets, potentially compromising the network's integrity and reliability.

Fig. 14. Lost packet graph during attack simulation.

## V. RESULTS AND DISCUSSION

### A. DNN Model

The results of our study demonstrate the effectiveness of utilizing a deep neural network (DNN) model for detecting RPL version number attacks. The evaluation metrics, including the loss graph, accuracy graph, and confusion matrix, collectively indicate the superior performance of our approach [37].

The accuracy graph in Fig. 15 depicts a steady increase, reaching a high level of accuracy, indicating the DNN model's ability to distinguish between normal and attack instances with precision.

Fig. 15. DNN accuracy convergence graph.

The loss graph in Fig. 16 showcases the gradual decline in the model's loss function over the training iterations, signifying successful convergence and effective learning.

Fig. 16. DNN model loss over training iterations.

Additionally, the DNN confusion matrix in Fig. 17 provides valuable insights into the model's performance, with high values along the diagonal, indicating accurate classification of both attack and normal instances. These results highlight the robustness and efficacy of our proposed approach in accurately detecting RPL version number attacks, underscoring its potential as a valuable tool in enhancing network security:
Fig. 17. DNN classification confusion matrix.

### B. LSTM Model

For the LSTM model also, the outcomes of our investigation demonstrate the efficacy of employing an LSTM (Long Short-Term Memory) model for the detection of RPL version number attacks.

Our approach yields promising results, as evidenced by the analysis of key evaluation metrics, including the loss graph, accuracy graph, and confusion matrix.

The LSTM accuracy graph in Fig. 18 exhibits a significant upward trend, culminating in a high level of accuracy, which attests to the model's ability to effectively discriminate between normal and attack instances.

Fig. 18. LSTM accuracy convergence graph.

The LSTM loss graph in Fig. 18 illustrates the steady decrease in the model's loss function throughout the training process, indicating the successful learning and convergence of the LSTM model:

Fig. 19. LSTM model loss over training iterations.

Moreover, the LSTM confusion matrix in Fig. 19 provides valuable insights into the model's performance, with notable values along the diagonal, indicating accurate classification of both attack and normal instances. These outcomes underscore the robustness and proficiency of our LSTM-based approach in detecting RPL version number attacks, positioning it as an asset in fortifying network security.

Fig. 20. LSTM classification confusion matrix.

### C. Comparison of Results

Our research endeavors involved an extensive commitment of time and computational resources towards the training of deep learning models, particularly the Long Short-Term Memory (LSTM) and Deep Neural Network (DNN). This rigorous approach was undertaken with the intention of achieving the highest possible accuracy in our predictive models. The efforts bore fruit, as our LSTM model achieved an impressive accuracy score of 0.963605, while the DNN model was not far behind, with an accuracy of 0.963106. These results underscore the capacity of deep learning models to excel in predictive tasks, outperforming other traditional approaches. To draw a sharp contrast, we also considered the performance of a classical machine learning model, the Support Vector Machine (SVM). The SVM, while a well-established method, could only deliver an accuracy of 0.924119 in our experiments. This clear difference in accuracy metrics emphasizes the advantage of adopting deep learning

models for the specific task at hand. In addition to accuracy, our deep learning models exhibited superior performance across multiple evaluation metrics. These included R square, Root Mean Squared Error (RMSE), Mean Squared Error (MSE), and Mean Absolute Error (MAE). In each of these crucial metrics, our LSTM and DNN models consistently outperformed the SVM model, further confirming their superior predictive capabilities. For a visual representation of these findings, please consult Fig. 20 within this paper.

Fig. 21 serves as a visual confirmation of the numerical results presented, offering a graphical depiction of the performance disparities among the models. This comprehensive analysis serves to highlight the tangible advantages of embracing deep learning techniques, showcasing their ability to not only achieve superior accuracy but also to excel across a range of critical evaluation criteria, making them a pivotal component of our research's success.

| | MAE | MSE | RMSE | R square |
|---|---|---|---|---|
| DNN | 0,012439 | 0,007303 | 0,08546 | 0,963106 |
| SVM classification | 0,063528 | 0,015021 | 0,122561 | 0,924119 |
| LSTM | 0,007244 | 0,007244 | 0,085114 | 0,963405 |
Fig. 21. Comparative performance of LSTM, DNN, and SVM models in accuracy and evaluation metrics.

## VI. CONCLUSION

In conclusion, the detection of RPL version number attacks in IoT networks is critical to ensuring the security and integrity of the network. Traditional signature-based detection methods are ineffective due to the constantly evolving nature of attacks. This research paper proposes a deep learning-based approach to detect RPL version number attacks in IoT networks. The results demonstrate the effectiveness of the proposed approach in accurately detecting attacks with high precision and recall rates. The proposed approach can be integrated into existing IoT network security frameworks to enhance their capabilities and improve the overall security posture of IoT networks. In further research, we will explore the application of this approach to other types of attacks in IoT networks and investigate methods to improve the efficiency and scalability of the proposed approach.

Dept. of Computer Science and Information Technology, Superior University, Lahore, Pakistan[1, 2, 3]

Dept. of Computer Science, The Chenab University, Gujrat, Pakistan[4]

*Abstract*—Tumor is currently the second most prevalent cause of mortality, and its prevalence is expanding rapidly. The development of pulmonary nodules inside the lungs is suggestive of the existence of lung cancer. The detection of cancer is achieved using nodules detected in computer tomography (CT) images obtained from the LUNA 16 dataset. This study uses the Python library "PyTorch" for this purpose. A three-dimensional model has been used to train and extract the nodular segments from CT-Scan images, referred to as CT-scan chunks. It is done due to the impracticality of handling the whole CT scan image due to its vast size. The previously mentioned chunks are then transformed into PyTorch tensors. The tensors are subsequently input into a deep learning model to extract features, which are then passed through a sequence of machine learning classifiers for the purpose of classification. These classifiers include Support Vector Machines, Multi-layer Perceptron, Random Forest Classifier, Logistic Regression, K Nearest Neighbor, and Linear Discriminant Analysis. Our research has shown that the use of chunk extraction from CT-Scan images, coupled with the creation of tensors using segmented CT scans, has significantly enhanced the precision of various machine learning algorithms. Additionally, this approach has the advantage of reducing the computational time during runtime. In our study, the use of Support Vector Machines yielded the best degree of accuracy, reaching 99.68%. The findings of this study have the potential to be valuable in the practical implementation of real-time lung nodule identification applications.*

*Keywords—Deep learning; lung cancer; LUNA16; machine learning; nodules; PyTorch*

## I. Introduction

Cancer is a fetal illness that kills thousands and millions of people worldwide. Lung cancer is responsible for around 350 daily fatalities, making it the second leading cause of cancer-related deaths. Roundabout 103,00 of 127 lakh lung cancer fatalities in 2023 (81%) are directly attributable to smoking. The remaining approximately 20,500 lung cancer fatalities unrelated to smoking would be classified as the eighth leading cause of cancer mortality [1]. The process of diagnosing pulmonary nodules is valuable for the identification and treatment of cancer in its initial stages, therefore significantly contributing to the preservation of many human lives [2].

Doctors have significant challenges when dealing with a substantial volume of CT-scan data. Computer-aided detection (CAD) systems have been shown to alleviate the burden of radiologists while enhancing diagnosis accuracy in the context of lung cancer [3]. The CDAM technique was used in order to visually represent the characteristics and highlight the decision-making process inside Zhang's unique CAD (Computer-Aided diagnosis) system for lung cancer diagnosis [4]. Recent research on lung nodule identification demonstrates the exceptional performance of Deep Learning (DL)-based CAD systems [5].

The use of DL techniques has shown exceptional efficacy in the domain of lung cancer diagnosis, namely in the identification of pulmonary nodules. A study used the Faster R-CNN and U-Net-like encoder-decoder models to analyze the LUNA16 dataset, resulting in an accuracy rate of 0.842 [6]. The 3D CNN model is employed by Duo et al. [7] for Lung cancer detection. The researchers partitioned their approach into two distinct components, namely candidate screening and false positive deduction. The researchers attained a sensitivity rate of 90.06% and a FROC score of 0.839. Khosravan et al. obtained a FROC score of 0.897. The researchers put out a computational procedure known as S4ND with the purpose of facilitating end-to-end learning. The architecture is comprised of densely connected CNN units [8]. Wang et al. used three slices to make a 3D-RGB image for nodule detection and achieved an accuracy of 0.968 [9].

There was a need to improve the nodule detection accuracy, so it can be effectively used in real time scenarios. Moreover, the use of three-dimensional convolutional neural network (3D-CNN) architectures has more potential in efficiently capturing the unique attributes of malignant nodules in contrast to two-dimensional CNN (2D CNN) designs. Thus far, only a limited number of publicly available research publications have been published on the use of 3D CNNs for the identification of lung cancer. This research study used 3-dimensional CT-Scan results, 3D CNN features and machine learning classifiers, using specialized Python libraries to leverage the capabilities of Python and the effectiveness of machine learning methods. Various state-of-the-art ML techniques have been proposed for the purpose of identifying lung nodules in the context of lung cancer detection in literature. However, there is ongoing debate over the efficacy of current methods for the timely identification of lung cancer. Therefore, we advocate for the adoption of a comprehensive methodology in the detection of lung cancer. The research makes many noteworthy contributions, which are outlined below:

- Nodules have been identified in the photos obtained from the publicly accessible dataset LUNA16.

- Images were preprocessed by isolating the lung region, creating slices, and then segmenting the CT-Scan

slices. Additionally, the nodule segment from the segmented slices was transformed into *CT-Scan chunks and a 3D tensor was created.*

- In our study, several machine learning classifiers for the purpose of classification are used after extracting features using 3D deep learning algorithm. These ML classifiers include Support Vector Machine, Random Forest, Machine Learning Perceptron, Logistic Regression, Linear discriminant analysis, and K Nearest Neighbors.

After this introductory section, a comprehensive assessment of the existing literature pertaining to the detection of lung cancer is presented in Section II. Subsequently, our proposed technique is outlined in Section III. The findings of the proposed methodology are provided and compared with the outcomes of state-of-the-art algorithms in Section IV along with detailed analysis and examination of the methodology used in the study, as well as a comprehensive presentation of the obtained findings. The concluding section encapsulates the research effort and its novel contributions.

## II. BACKGROUND STUDY

According to the data shown in Fig. 1, lung cancer has emerged as the second most prominent cause of mortality. Lung cancer can be diagnosed efficiently by detecting nodules in the CT scan images as shown in Fig. 2. Currently, pulmonary nodules are mostly diagnosed using various forms of chest imaging examination, such as MRI, X-ray, CT-Scan, and others. Because of its great accuracy and cheap cost, CT scan has become the gold standard in diagnostics [10]. Due to its high level of sensitivity, CT scans have become the preferred method in screening for lung cancer. Classifying pulmonary nodules, however, remains a laborious task. Furthermore, the size of CT images is continually expanding, adding more labor to the normal diagnosis procedure for radiologists [11].

Manual feature engineering is often employed in conjunction with machine learning for medical picture categorization. For both binary and multi-class classification, support vector machines (SVM) are a well-known machine learning approach. Nodule detection was performed using an adaptive morphology-based strategy and SVM [12]. Manifold classification regularization was applied by Ren et al. for nodule identification along with the Dense network of neurons (DNN) [13]. Image categorization and object recognition both benefited greatly from DNN's automatic feature extraction. In a research study, a convolutional neural network (CNN) was used for the purpose of detecting and classifying lung nodules. [14]. Classifying nodules in CT scan pictures is another application for CNN-based Generative Adversarial Networks [15]. A pulmonary nodule classification system was designed by Jiang et al. The authors used improved deep features by using contextual attention and located region of interest (ROI) using spatial attention. For enhancing the performance of the classifier an ensemble was employed [16]. CNN was used along with kernel-based non-Gaussian for cancer detection. The authors applied an adaptive histogram equalization technique in the preprocessing step for segmenting the region of interest. They have achieved an accuracy of 87% [17].

Fig. 1. Cancer incidence rates by gender in the USA from 1975 to 2019. Rates are adjusted for reporting lag times and age standardization to the US standard population of 2000 [1].

Fig. 2. Lungs images: (a) Normal lung CT image, (b) Cancerous lung CT image [49].

In a study, the deep learning model employed for nodule identification is a receptive field regularized V-net [18]. The classification of lung nodules is accomplished by the use of a hybrid approach including the SqueezeNet and ResNet models. In addition to convolutional neural networks (CNN), authors used a bio-inspired approach called the "Whale optimization algorithm with adaptive particle swarm optimization" (WOA-APSO) for detecting lung cancer [19]. They achieved an accuracy of 97.18%. Histogram equalization, the Tophat approach for noise removal, and the Boosted deep convolutional neural network (BDCNN) were utilized by Rani et al. [20] while classifying lung cancer. The noise was filtered out using weighted mean histogram analysis, and features were extracted using a hybrid dual-tree complex. Ultimately, a deep CNN was used for the purpose of lung cancer detection [21].

A sequential technique for identifying lung cancer in CT lung images was devised by Guo et al. [22]. The used approach included the utilization of both a CNN-based classifier and a feature-based classifier. The first use of a CNN-based classifier was seen in the analysis of a dataset pertaining to the detection of lung cancer. Subsequently, a classifier based on features was employed for further investigation. [22]. Irregular nodule shapes were segmented by Hesamian et al. [23]. To tackle the issue of diminished contrast, scholars have conducted investigations including the use of deep-learning methodologies on artificially created images derived from innovative color schemes. In this work, a modified version of the DL-based U-Net model was used. Chen et al. used the dense neural network methodology [24].

The usage of batch normalization and dropout was employed in conjunction with this dense architecture. The

performance on the LUNA16 dataset has been commendable. Basal et al. and Xu et al. used ensemble learning to identify lung cancer [25], [26] and combined YOLOv3 with CNN for malignant nodule detection. Fractal networks are employed in research to categorize lung nodules [27]. The performance of the system was evaluated and verified using the LUNA16 dataset, using the Fractal net model. The resulting accuracy was 94.7%. With the use of ensemble learning, Muzammil et al. improved accuracy to 96.89%. In their work [28], they integrated the SVM and AdaBoostM2 algorithms with the Linear discriminant analysis (LDA). Another research [29] used deep learning to build a segmentation technique for identifying lung cancer. Numerous more cutting-edge research [30]–[33] covered a wide range of topics and highlighted additional real-world issues.

Table I provides a review of recent research that has advanced our understanding. Literature Table I illustrates the substantial amount of scholarly literature dedicated to the examination of lung cancer diagnosis, nodule detection, and

categorization. The main objective of this research is to investigate lung cancer screening. The CT scans were segmented into chunks and then subjected to analysis using a three-dimensional convolutional neural network (3D-CNN) model. Deep learning-based imaging algorithms have significantly enhanced the accuracy and efficacy of lung nodule segmentation, identification, and classification. These algorithms use old medical images to achieve superior performance in these tasks. The system's ability to engage in reinforcement learning facilitated the attainment of this outcome.

Fig. 3.    The spatial coordinates of the lesions are situated in the x, y, and z dimensions. Red colour is used to indicate benign lesions, whereas black colour is used to indicate malignant tumours [26].

An assortment of unsupervised deep learning algorithms, such as CNN, Faster R-CNN, Mask R-CNN, and U-Net have been used to create convolutional networks that aim to identify lung cancer and minimize the occurrence of false positives. This is in contradiction to the conventional approach of using supervised and reinforced learning techniques. Previous researches have shown that computed tomography (CT) is the most often used imaging modality in computer-aided detection (CAD) systems for the detection of lung cancer. The use of 3D-CNN architectures shows more promise in effectively capturing the distinctive characteristics of malignant nodules compared to 2D CNN designs. So far, only a restricted number of research articles using 3D convolutional neural networks (CNNs) for the purpose of lung cancer detection have been made accessible to the public.

III.    METHOD

In the subsequent part, we will elucidate the strategy that has been put forward. In Fig. 8 a block diagram is provided, illustrating the suggested technique. This demonstrates the detection of nodules in the images, followed by the segmentation of the CT-Scan image into distinct sections, as seen in Fig. 7. The segmentation and classification tasks were effectively accomplished by using deep learning techniques. Within the scope of this research activity, the process involves the concatenation of a 3D tensor, which is afterwards used in conjunction with machine learning algorithms, with the aim of facilitating the identification of lung cancer.

## A. Dataset

The data used in this research was obtained from Kaggle, a reputable and well-known data repository. The Lung Nodule Analysis 2016 Challenge dataset, often known as Luna16, has been released to the public. It was updated in 2020. The dataset comprises CT scans from a total of 888 patients. Every computed tomography (CT) scan has a thickness that exceeds 2.5 millimeters. The data is saved in the MetaImage format, more especially in the mhd/raw file format. Every .mhd file is accompanied by a separate binary file that contains the raw pixel data. The dataset has a total of 754,975 candidates, whose information is categorized into two distinct groups: malignant and benign. Malignant nodules are classified as "1" whereas benign nodules are classified as "0". Fig. 3 depicts the distribution of lesion sites among the patients.

## B. Preprocess

During the preprocessing phase, the following steps were conducted:

*1) Extract CT-Scan images:* The CT-Scan files were retrieved from the dataset using the "SimpleITK" package.

*2) Unique Ct scans:* We found that there are total 888 unique CT-Scans for 754975 candidates.

*3) Missing values:* The missing values in the data were examined. A total of 443 missing data were identified, indicating the absence of unique CT-Scans. Consequently, the aforementioned values were eliminated.

*4) Histogram:* The pixel values undergo a transformation to Hounsfield units (HU), and afterwards, their histograms are shown, as seen in Fig. 4. The histogram has a range of -2000 to 1000 Hounsfield Units (HU). The histograms of all the CT-scan pictures exhibit a similar distribution.

*5) Pulmunary region:* The pulmonary area is marked out by using several threshold values, as seen in Fig. 5.

## C. Process

The data is divided into training and validation. The input images are transformed in the data preprocessing step, and noise and outliers are filtered away. Data is analyzed and it is found that the candidate file has a flag for each mass in the CT scans. "seriesuid" is a unique identifier for each CT Scan. The class label is 0 if the CT-Scan doesn't have a nodule. The class label is 1, if CT scans have a nodule (both malignant and benign). There are over 750k candidates. The candidates belonging to the same CT scan are categorized into groups, after which the diameters dictionary is used to get the diameter of each candidate. The order of the applicants was flipped, resulting in all individuals with nodules being positioned at the top of the list. The candidates without comparable CT scans were excluded from the dataset. The entire number of applicants is 750,000, with just 37,000 having comparable CT scans. A chunk was obtained by generating a list consisting of three slices, with each slice corresponding to a certain direction. The segments are then transformed into PyTorch Tensors for CT-Scan analysis. Every tensor in the dataset has a shape of 1x10x18x18. These PyTorch tensors are fed into deep-learning models for feature extraction. Next, a training and testing dataset is created.

Fig. 4. CT-Scans with their corresponding histograms in HU units. (a) CT-scan number 80, (b) CT-scan number 100, (c) CT-scan number 2, (d) CT scan number 120.

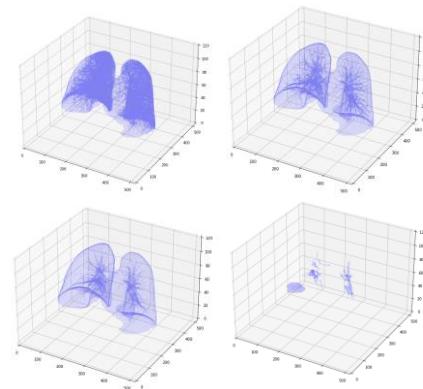

Fig. 5. 3D view of the lungs and bronchioles, for different threshold values.

The step-by-step process for carrying out experiments is as follows:

*1) Convert* the image into the fixed slices.

*2) Segment* the CT-Scan slices.

*3) Convert* the segmented CT-scan slices into 3D tensors.

*4) Split* the data into training and testing.

*5) Use* a 3D Deep learning algorithm for feature extraction.

*6) Use* machine learning classifiers for classification.

The 3D CNN model that is used for feature extraction is elaborated in Table III. The use of flattened layers involves the conversion of the output of a maxpooling layer, which is a multidimensional tensor, into a one-dimensional representation. The neural network architecture is composed

of two fully connected layers, specifically referred to as fc1 and fc2, which are positioned after the flattened layer. Fully connected layers are often used for the purpose of feature extraction. In this instance, the fc1 layer is utilized.

TABLE II. COMPARISON OF PROPOSED MODEL WITH STATE-OF-THE-ART ALGORITHMS

| Authors | Year | Dataset | Method | Accuracy |
|---|---|---|---|---|
| Shah et al. [42] | 2020 | LUNA16 | Transfer Learning VGG16, VGG19 | 95.0% |
| Bansal et al [26] | 2020 | LUNA16 | Deep3DScan | 92.7% |
| Naik et al.[27] | 2021 | LUNA16 | FractalNet + CNN | 94.7% |
| Muzammil et al. [28] | 2021 | LUNA16 | Ensemble Learning | 96.8% |
| Dodia et al.[18] | 2022 | LUNA16 | Squeeze Net + Resnet | 94.87% |

TABLE IV. ABBRIVIATIONS AND THEIR EXPLANATIONS USED IN THIS STUDY

| Abbreviation | Explanation |
|---|---|
| CT-Scans | Computer Tomography Scans |
| CDAM | Channel-dependent activation mapping |
| CAD | Computer-Aided Design |
| DL | Deep Learning |
| DNN | Deep Neural Network |
| FROC | Free-Response Receiver Operating Characteristic |
| ML | Machine Learning |
| MRI | Magnetic Resonance Imaging |
| SVM | Support Vector Machines |
| ROI | Region of Interest |
| BDCNN | Boosted deep convolutional neural network |
| YOLO | You only look once |
| LUNA | LUng Nodule Analysis |
| LDA | Linear discriminant analysis |
| Seg3DT_SVM | Segmented 3D Tensors and Support Vector Machines |

## IV. RESULTS AND DISCUSSION

In this research study, a deep learning model is used for the purpose of feature extraction. Prior to this, the data is subjected to preprocessing, whereby it is transformed into three-dimensional CT-scan chunks to serve as input. The machine learning classifiers use these characteristics in order to do classification. The transfer learning technique has been used in our study. The LUNA16 [48] benchmark dataset is used for training and validating this model. The dataset comprises a collection of 1,018 CT scan pictures. The training dataset accounts for 80% of the data, whilst the remaining 20% is allocated for validation purposes. In this research, the suggested model was evaluated using accuracy, which is a commonly used metric for assessing performance.

Accuracy is defined as:

$$\text{Accuracy} = (TN + TP) / (TN + FN + FP + TP) \qquad (1)$$

The variables TN and TP in equation (1) represent the rates of true negative and true positive, respectively, in the confusion matrix. A confusion matrix is shown in Fig. 9. In this research work, data is pre-processed, features are extracted and then machine learning algorithms are applied at the end of pipeline. The performance of the suggested model is evaluated and compared with other contemporary approaches, as shown in Table II. A more comprehensive assessment of the resilience of the suggested model may be obtained by referring to Fig. 10. Fig. 11 illustrates the accuracy of all the classifiers used in this investigation.

The findings clearly demonstrate that the suggested model has surpassed the performance of existing algorithms by attaining an accuracy rate of 99.6%. Hence, this model has the capability to be used in real-time situations for the purpose of identifying lung malignancies. One disadvantage of this work is that the suggested model is built using just one dataset. To assess the robustness of the model, it will be applied to several datasets. The abbreviations used in this research study are shown in Table IV.

This research study presents a unique methodology for the identification of lung cancer. The task of lung cancer detection is accomplished by the use of data collection that is accessible to the general public. The data used in this study was acquired from Kaggle, a well-known and esteemed data source. The publicly available dataset, referred to as the Lung Nodule Analysis 2016 Challenge dataset or Luna16, has been made accessible. The information has been revised in the year 2020. The dataset consists of computed tomography (CT) images obtained from a total of 888 individuals. The data is stored in the MetaImage format, specifically in the mhd/raw file format. Each .mhd file is accompanied by an independent binary file that includes the unprocessed pixel data. The dataset comprises a total of 754,975 individuals, with their information classified into two separate categories: malignant and non-cancerous. In the preprocessing stage, the CT-Scan files were obtained from the dataset using the "SimpleITK" function. There were a total of 888 distinct CT scans among the 754,975 individuals included in our analysis (Fig. 6).

Fig. 7.    CT-Scan segmented slices.

Fig. 8.        Block diagram of this research work.

Fig. 9.    Confusion matrix [50].

Fig. 10.  Comparison of state-of-the-art accuracies with the proposed method.

Fig. 11.  Accuracies of various classifiers, using the proposed preprocessing method.

The examination of missing values in the dataset was conducted. A total of 443 instances of missing data were detected, suggesting the lack of distinct CT-Scans. As a result, the previously indicated values were eradicated. The pixel values are subjected to a conversion process into Hounsfield units (HU), and subsequently, their histograms are shown, as seen in Fig. 4. The histogram exhibits a range spanning from -2000 to 1000 Hounsfield Units (HU). The histograms of all the CT-scan images show a comparable distribution. The delineation of the pulmonary region is achieved by the use of several threshold values, as seen in Fig. 5. The dataset is partitioned into two subsets, namely the training set and the validation set. During the data preparation stage, the input pictures undergo a transformation process, which includes the removal of noise and outliers. Upon analysis of the data, it has been determined that the candidate file contains a flag for each mass seen in the CT images that serves as a unique identifier for each CT-Scan. The assigned class label is 0 in cases when the CT-Scan does not reveal the presence of a nodule. The assigned class label is denoted as 1, indicating the presence of nodules in CT scans, including both malignant and benign cases. There are a total of more than 750,000 candidates. The candidates belonging to the same CT scan are categorized into groups, after which the diameters dictionary is used to get the diameter of each candidate. The order of the applicants was reversed, resulting in all individuals with nodules being placed at the top of the list. The individuals who did not have CT scans that could be compared were eliminated from the dataset. The procedure of segmentation has considerable significance within the realm of diagnostics.

The extraction of CT scan slices from images is performed in order to eliminate any unwanted portions. The lung pictures were then subjected to segmentation. The extraction of three-dimensional segments includes nodules from the segmented slices. The parts are put into our model. The chunk's measurements are 10 units in length, 18 units in breadth, and

18 units in height. A chunk was acquired by constructing a list including three slices, where each slice corresponds to a certain direction. The segments are then converted into PyTorch Tensors to facilitate CT-Scan processing. The PyTorch tensors are used as inputs in 3D deep learning models for feature extraction. Following this, a dataset is constructed for the purpose of training and testing, and a variety of machine learning classifiers are used to choose the classifier that exhibits the highest performance. The results unequivocally indicate that the proposed model has outperformed current algorithms, achieving a remarkable accuracy rate of 99.68%. Therefore, this model has the capacity to be used in real-time scenarios with the objective of detecting lung cancers.

## V. CONCLUSION

This study presents a novel approach that utilizes segmented 3D tensors, 3D convolutional neural network and SVM to identify lung nodules in computed tomography (CT) data. The proposed model is abbreviated as Seg3DT_SVM. The model being discussed is specifically built to accept data chunks in the format of PyTorch tensors. The discrete components, referred to as chunks, that comprise the nodule are the individual segments of computed tomography (CT) slices used. The process of obtaining cross-sectional images is an essential element of computed tomography (CT) scans. The proposed technique includes an initial phase of data preparation, as previously elucidated, succeeded by the use of machine learning algorithms. The experimental investigation used the publicly available LUNA16 dataset and was conducted using the PyTorch framework. The analyzed model demonstrates a much greater degree of accuracy (99.68%) compared to the existing state-of-the-art approaches used for the same dataset. The method demonstrates the capability to assist healthcare workers in promptly identifying cases of lung cancer in real-time situations.

# Early Detection and Defense Countermeasure Inference of Ransomware based on API Sequence

Shuqin Zhang, Tianhui Du[*], Peiyu Shi, Xinyu Su, Yunfei Han

School of Computer Science, Zhongyuan University of Technology, Zhengzhou, HEN037, China

*Abstract*—Currently, ransomware attacks have become an important threat in the field of network security. The detection and defense of ransomware has become particularly important. However, due to the insufficient data and behavior patterns collected dynamically to detect variants and unknown ransomware, there is also a lack of specialized defense strategies for ransomware. In response to this situation, this article proposes a ransomware early detection and defense system (REDDS) based on application programming interface (API) sequences. REDDS first dynamically collects API sequences from the pre-encryption stage of the ransomware, and calculates the API sequences as feature vectors using the n-gram model and TF-IDF algorithm. Due to the limitations of dynamic data collection, API sequences were enhanced using Wasserstein GAN with Gradient Penalty (WGAN GP), and then machine learning classification algorithms were used to train the enhanced data to detect ransomware. By mapping the malicious API of ransomware to public security knowledge bases such as Adversarial Tactics, Techniques, and Common Knowledge (ATT&CK), a Ransomware Defense Countermeasures Ontology (RDCO) is proposed. Based on the ontology model, a set of inference rules is designed to automatically infer the defense countermeasures of ransomware. The experimental results show that WGAN-GP can more effectively enhance API sequence data than other GAN models. After data augmentation, the accuracy of machine learning detection models has significantly improved, with a maximum of 99.32%. Based on malicious APIs in ransomware, defense countermeasures can be inferred to help security managers respond to ransomware attacks and deploy appropriate security solutions.

*Keywords*—*Ransomware detection; API sequences; WGAN-GP; ATT&CK; machine learning; ontology; defense countermeasures*

## I. INTRODUCTION

In recent years, ransomware attacks have sharply increased, especially during the COVID-19 pandemic. This is because many companies and organizations require remote work, and their network security measures may not be sufficient to cope with the risks brought by remote work. In addition, ransomware developers are using increasingly complex technologies and means, making it more difficult to defend against ransomware. In recent years, some famous ransomware attacks have included WannaCry, Petya/NotPetya, and Ryuk. These attacks have caused significant economic losses and data breaches, affecting thousands of organizations and individual users. These events have elevated ransomware to a level of national security concern, prompting the US Department of Justice to classify such attacks as terrorist attacks [1].

Ransomware attacks can be divided into two categories: encrypted ransomware and locked ransomware. The characteristic of encryption ransomware is its ability to encrypt files, making it impossible for victims without decryption keys to move. Lock screen ransomware can lock the screen or operating system of the victim's host after infecting it [2]. Currently, among the publicly available ransomware, encrypted ransomware is the most common type [3-6]. Therefore, this article focuses on encrypted ransomware as the research object, and the "ransomware" mentioned below when not specifically mentioned are all encrypted ransomware.

After the ransomware completes the encryption of specific files on the victim host, these files on the victim host will lose availability and be difficult to decrypt without paying a ransom [7]. Even if file recovery can be achieved through early backup, there may still be situations where information systems or files cannot be used normally during the recovery period, which affects the normal operation of enterprise business [8]. Therefore, it is particularly important to accurately detect and defend against ransomware before encrypting files. After the ransomware infects the host, it will encrypt the files in the infected host as soon as possible, so in a short period of time, the ransomware will perform a large number of operations [9], calling a large number of application programming interfaces. Taking API sequences as the analysis object, detecting and responding to targeted defense strategies in the early stages of ransomware operation is a feasible technical means.

However, traditional malware dynamic detection methods often only collect limited API sequences of ransomware, lacking sufficient data and behavior patterns to detect the increasing variety of ransomware and unknown ransomware. At present, there is a lack of defense measures against ransomware, and relying solely on data backup is not enough to cope with the continuous emergence of ransomware and its variants. To address this challenge, a combination of ATT&CK framework and D3FEND can be used to combat ransomware attacks. The ATT&CK framework is a knowledge base developed by MITRE company for describing and organizing network attack techniques. This framework provides rich information about the behavior of attackers, including the various stages and potential attack modes of ransomware attacks. By combining the knowledge of the ATT&CK framework, it is possible to better understand the behavior patterns of ransomware and establish more effective defense strategies. D3FEND is a framework used to describe and organize defensive measures. It provides defense

strategies and control measures for different ATT&CK attack technologies. By comparing with the D3FEND framework, it can be ensured that appropriate security measures have been taken and loopholes in existing defense strategies can be filled.

In response to the above issues, this article proposes a ransomware early detection and defense system (REDDS) based on API sequences. In order to address the limitations of the API dataset collected by ransomware for dynamic analysis of samples, this article innovatively applies WGAN-GP [10] technology to ransomware detection. WGAN-GP has better training stability and better generalization ability than other Generative adversarial network, and the data quality generated by WGAN-GP is higher. In addition, this paper conducts in-depth research and analysis on the relationship between the specific API of ransomware and security knowledge sources such as ATT&CK, builds a ransomware defensive countermeasures ontology (RDCO), and designs Rule of inference to derive the defense countermeasures of ransomware. Starting from APIs to defend ransomware provides a new idea and method for the defense of ransomware, and has broad application prospects in practical applications. REDDS collects a certain number of pre-encrypted API sequences from normal software and ransomware, and generates feature vectors through n-gram [11] and Term Frequency Inverse Document Frequency (TF-IDF) [12]. WGAN-GP is used to enhance API sequence data, and machine learning classification algorithms are used to train pre and post enhancement data to detect ransomware. And Rules of inference are used to infer the defense countermeasures against the malicious API of ransomware, as well as the timely response and defense of ransomware. The main contributions of this article are as follows:

*1) A* novel early detection and defense system for ransomware based on API sequences has been proposed. The system uses n-gram and TF-IDF to generate API feature vectors, and utilizes WGAN-GP for data augmentation, thereby improving the robustness and accuracy of early detection models.

*2) REDDS* constructs a ransomware defense ontology by analyzing the mapping relationship between malicious APIs in ransomware and attack techniques in ATT&CK. The ontology integrates multiple security knowledge bases, and designs Rule of inference from the malicious API to derive defense countermeasures against ransomware attacks.

*3) In the* experiment, 86 ransomware samples from 24 different families and 40 normal software were used to evaluate REDDS. The results indicate that WGAN-GP generates better API data quality than other GAN models, and data augmentation significantly improves the accuracy of the detection model. It can also infer defense countermeasures against malicious APIs.

The remainder of this paper is organized as follows. Related work is presented in Section II. Section III presents the system design of REDDS. Section IV constructs the RDCO ontology and ontology-based reasoning defense countermeasures, and Section V presents the experimental

results and evaluation of the system. Finally, Section VI concludes the paper.

## II. RELATED WORK

The huge losses and harms caused by ransomware to enterprises or organizations have become the main security threat to the cyberspace. In order to respond to ransomware attacks and ensure the security of the network environment, the detection and protection of ransomware has become a hot topic in the field of cyberspace security. Based on the theme of this article, this section briefly summarizes the application of early detection of ransomware, generation of adversarial networks in the field of security, and related research in the field of ontology-based malware analysis.

### A. Early Detection of Ransomware

Due to the fact that ransomware quickly encrypts files after infecting a host, early detection is of great significance for file protection and timely defense of infected hosts. Morato et al. [13] used SMB traffic in network shared volumes for early detection of ransomware, using 19 different series of ransomware to test the practical application of algorithms. Chen Changqing et al. [3] proposed the concept of critical time period (CTP) for ransomware detection, using machine learning for early detection based on 78 API short sequences called by ransomware during execution within CTP. Al Rimy et al. [14] applied feature selection technology based on mutual information to early detection of ransomware. This method can obtain good detection accuracy by using features extracted and selected from the behavior data of limited ransomware at the initial stage of operation. Mehnaz et al. [15] proposed a ransomware detection mechanism that detects encrypted ransomware in real-time by deploying bait technology, carefully monitoring running processes and malicious activities in file systems, and evaluating the system using samples from 14 of the most popular ransomware families. Roy et al. [16] applied BiLSTM and fully connected layers to simulate the normal state of hosts in operating enterprise systems, and detected ransomware from a large amount of environmental host log data. Execute 17 ransomware attacks on the victim host, and use the infected host log to record data validation to verify the system. The above work achieved good detection accuracy in the early detection of ransomware, but lacked sufficient data to verify the behavior of ransomware in the pre-encryption stage, and did not involve defense measures against ransomware.

### B. Application of Generative Adversarial Networks in the Field of Security

In the field of security, the limitations of dynamically collecting attack data can lead to limited or unbalanced datasets. Therefore, some studies have applied GAN for data augmentation in their work. Liu et al. [17] proposed an intrusion detection method based on the oversampling technology of WGAN-GP and feature selection, conducted experiments on three intrusion detection data sets, and improved the detection performance of the machine learning model, but their work did not evaluate the samples generated by WGAN-GP. Hu et al. [18] used the algorithm MalGAN based on generative adversarial networks (GANs) to generate

adversarial malware examples, which can bypass detection models based on black box machine learning. Yilmaz et al. [19] proposed an intrusion detection method based on GAN and MLP. GAN was used to generate three types of attacks in the UGR 16 dataset to balance the dataset. The experimental results indicate that GAN's balanced attack sample dataset produces more accurate results than the imbalanced attack sample dataset. Wu Yangming et al. [20] used a deep learning intrusion detection method based on WGAN-GP data augmentation and combined deep belief networks and extreme learning machines. The proposed algorithm was tested using the CICIDS2017 dataset, and comparative experiments showed that the method had higher accuracy and faster convergence speed. In this paper, we build an API sequence generative model based on WGAN-GP ransomware to generate high-quality API sequence samples. Evaluate the generation ability of WGAN-GP by comparing it with other GAN models, and finally prove through comparative experiments that the detection results after using WGAN-GP are better.

## C. The Use of Ontology in the Field of Malicious Software Research

Ontology is used to describe information objects for domain knowledge sharing and reuse [21]. In the field of information security, ontology has been used to characterize the behavior of malware, and build the knowledge representation of malware [22], so as to realize the analysis and reasoning of malware. Rastogi et al. [23] designed a malware ontology called MALOnt, which includes concepts such as malware features, attack behavior, and detailed information about attackers. It supports collecting intelligence on malware threats from different online sources and constructs a knowledge graph framework based on MALOnt. Ding et al. [24] designed conceptual classes and object attributes for malware, and proposed methods to represent the semantics of malware behavior. And use the Apriori algorithm to classify the malware family. This article designs a ransomware defense strategy ontology, which includes information about the characteristics of ransomware malicious APIs and related defense strategies. Design inference rules based on semantic web rule language, use rule inference engines to infer the knowledge, determine which APIs are malicious, and generate corresponding defense strategies for these APIs. In this way, when a ransomware attack occurs, the system can defend against the attack based on the inferred countermeasures.

## III. RANSOMWARE EARLY DETECTION AND DEFENSE SYSTEM

This article proposes an early detection and defense system for encrypted ransomware in the pre-encryption stage based on API sequences, as shown in Fig. 1. The system focuses on API calls during the pre-encryption phase after starting operation. In order to compensate for the insufficient data collected during the pre-encryption phase of ransomware attacks, WGAN-GP's data augmentation method is used to generate API sequence samples, and the enhanced API sequence dataset is used to train the detection model. For the defense of ransomware, by mapping the API of ransomware

with ATT&CK technology, integrating ATT&CK, D3FEND, and other security knowledge sources, and constructing a ransomware defense strategy ontology, the defense strategy is inferred based on the API of ransomware for reference by security personnel. REDDS includes four modules: API sequence collection, feature calculation, data enhancement and detection, and defense strategy inference. Below are detailed explanations of these four modules.

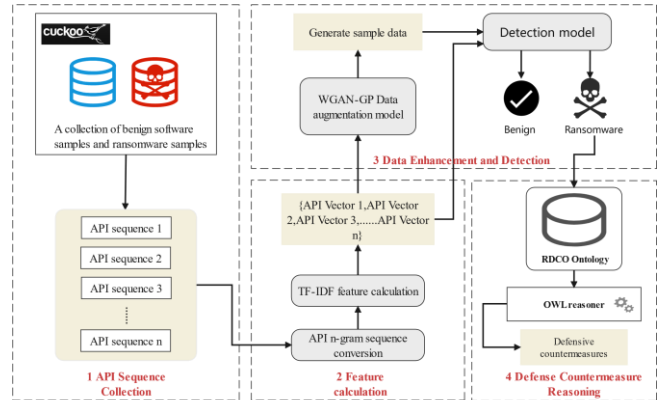

Fig. 1. REDDS execution framework.

## A. The Pre-Encryption Phase of Ransomware Collects API Sequences

The attack process of ransomware can be divided into four stages: system infection, file traversal and encryption, ransom collection and file decryption [14], among which the encryption operation was previously referred to as the pre-encryption stage. In the system infection stage, the ransomware infected the victim host through phishing, web hanging horses, exploit and other ways. After infecting the system, ransomware usually performs a series of operations such as file search and identification, file encryption, etc. [6]. Once these operations are completed, all specific files in the infected host will be encrypted; During the ransom stage, the victim is informed of how to pay the ransom through ransom text; After the victim user pays a ransom, they enter the file decryption stage, and the attacker releases the decryption device to decrypt the encrypted file. In reality, it would be meaningless to check out all files on the victim host after the ransomware completes encryption [25]. Therefore, how to accurately detect ransomware during its pre-encryption stage is a key issue in ransomware defense.

According to the execution process of the ransomware mentioned above, before 2.2 in Fig. 2 is the pre-encryption stage. The ransomware will involve a large number of API calls during the pre-encryption stage, including file read and write, network communication, system information acquisition, etc. The number of APIs that normal software runs during the same time period is much smaller than the number of APIs called by ransomware. Therefore, this article believes that the number of APIs executed by software within a period of time after it starts running can be used to distinguish between normal software and ransomware.

In this module, REDDS will collect the API sequences called during the pre-encryption phase after the ransomware

starts running, as well as the API sequences of the benign software, and use them as inputs for the next phase. Run samples of ransomware and benign software in the CuCKoo sandbox or other sandbox, with a running time of 60 seconds to ensure that the API sequence of ransomware can be fully captured during the pre-encryption phase. And use API Monitor to monitor the API sequence of these software, record the API sequence of each ransomware before the first call to the encryption class API and the API sequence of benign software.

Fig. 2. General execution process of ransomware file traversal and encryption stages.

TABLE I. API CALLED FOR THE FIRST TIME IN BCRYPT, DPAPI, NCRYPT, SCHANNEL, AND WINCRYPT ENCRYPTION API LIBRARIES

| Cryptographic API libraries | API |
|---|---|
| BCrypt | BCryptOpenAlgorithmProvider |
| CryptoAPI | cryptAcquireContext, cryptBinary |
| DPAPI | CryptProtectData |
| Ncrypt | NCryptOpenStorageProvider |
| Schannel | AcquireCredentialsHandle |

Ransomware typically utilizes the encryption API provided by the Windows system to implement file encryption and decryption functions. The Windows system provides multiple encryption API libraries, and attackers can choose the appropriate encryption API library to implement encryption functions according to their own needs. There are five commonly used encryption API libraries: BCrypt, CryptoAPI, DPAPI, Ncrypt, and Schannel. These five encryption API libraries have different functions to implement various functions. The first called APIs in the five encryption API libraries are shown in Table I. REDDS takes these APIs as the pre-encryption boundaries and collects the API sequences in the pre-encryption stage. The collected API sequences are deduplicated, and the deduplicated API sequences are used as data sets for subsequent analysis and research.

*B. API Sequence Feature Calculation*

In this stage, REDDS uses the n-gram algorithm to segment API sequences and calculates corresponding eigenvalues using the TF-IDF algorithm. The application of the n-gram algorithm preserves the adjacency of APIs in the generated feature vectors. After processing API sequences

through n-gram algorithm, TF-IDF algorithm in natural language processing is used to calculate eigenvalues to generate eigenvectors. Use (1) to calculate the TF value of the n-gram sequence for ransomware and normal software.

$$TF(i,j) = \frac{n(i,j)}{\sum_k n(k,j)} \qquad (1)$$

Where $TF(i,j)$ represents the frequency of n-gram $i$ appearing in n-gram sequence $j$, where $n(i,j)$ represents the number of times n-gram $i$ appears in n-gram sequence $j$, $\sum_k n(k,j)$ represents the total number of n-grams in the n-gram sequence $j$. After calculating the frequency of an n-gram, calculate its IDF using equation (2).

$$IDF(i) = log_2 \frac{|D|}{|\{j:i\in j | j \in D\}|} \qquad (2)$$

Among them, $IDF(i)$ describes the rarity of n-gram $i$ in the entire n-gram sequence, and $D$ represents the set of all n-gram sequences. $\{j: i \in j | j \in D\}$ represents the number of n-gram sequences $j$ containing n-gram $i$. After calculating the $IDF(i)$, use equation (3) to complete the calculation of TF-IDF.

$$TF_{IDF(i,j)} = TF(i,j) \times IDF(i) \qquad (3)$$

In summary, REDDS treats the API sequences collected in the pre-encryption stage of ransomware as a whole, and obtains the corresponding feature vectors through n-gram and TF-IDF algorithms.

*C. Data Enhancement and Detection Based on WGAN-GP*

The dynamically collected API sequences are limited and incomplete, which will affect the detection of ransomware variants and unknown ransomware. To this end, we propose a data enhancement algorithm based on WGAN-GP, which satisfies the Lipschitz restriction by applying an independent gradient penalty (GP) to each sample. This allows the weights of neurons to be distributed more evenly during the backpropagation process, helping the detection model to better understand the potential characteristics and behaviors of ransomware, effectively improving the accuracy, robustness and generalization ability of the ransomware detection model.

The API sequence data enhancement method based on WGAN-GP introduces Wasserstein distance on the basis of GAN model, and its distance formula is shown in equation (4).

$$W(P_r, P_f) = \inf_{\gamma \in \Pi(P_r,P_f)} E_{(x,y)\sim\gamma} [||x - y||] \quad (4)$$

In the formula: $x$ is the real sample, and $y$ is the generated sample. $\prod(P_r, P_f)$ is the joint probability distribution set of the real sample probability distribution $P_r$ and the generated sample probability distribution $P_f$.

The use of Lipschitz weight pruning in WGAN limits the range of weight parameters in the discriminator sub network, resulting in extreme network parameters that greatly limit network performance and weaken the fitting ability of the neural network. Moreover, the scope of weight pruning is mainly based on expert experience, and setting network parameters through manual determination can easily lead to inappropriate parameter settings, leading to the phenomenon of gradient explosion and vanishing again. Therefore, WGAN-

GP introduces the Gradient Penalty (GP) term to improve the impact of the weight clipping constraint parameter used in WGAN to meet the 1-Lipschitz continuity condition on the network. Its loss function is expressed as follows:

$$L_G = -E_{z \sim P_z} \times [D(G(Z))] \quad (5)$$

$$L_D = -E_{z \sim P_z} \times [D(G(Z))] - E_{z \sim P_z} \times [D(x)] + GP \quad (6)$$

$$GP = \lambda E_{x \sim \chi}\left[||\nabla D(x)||_p - 1\right]^2 \quad (7)$$

In the formula: $L_G$ is the generator loss function, $L_D$ is the discriminator loss function, $G(Z)$ is the sample generated by the generator, $P_z$ is a prior distribution of random noise $z$. $GP$ is a gradient penalty term, $\lambda$ Represents the penalty coefficient; $\chi$ represents the distribution of the entire sample space, that is, the sum of the generated and real sample distributions; $\nabla D(x)$ represents the gradient of the discriminator, and $||\cdot||_p$ is the P-norm.

Fig. 3. Schematic diagram of WGAN-GP structure.

The schematic diagram of WGAN-GP structure is shown in Fig. 3. Through continuous training of the WGAN-GP network, the data obtained by the generator is closer to real data, but the final discriminator cannot recognize whether the input data comes from actual data or generated data, thus achieving Nash equilibrium and forming a good generation model [26].

The specific training process for data augmentation and detection based on WGAN-GP is as follows:

*1) Input* the feature vectors obtained from feature calculation into the generator;

*2) Fix* the parameters of generator G, and adjust the parameters of generator according to formula (5) to minimize the loss function of generator $L_G$;

*3) Fix* the parameters of generator D, and adjust the parameters of discriminator according to formula (6) to minimize the discriminator loss function $L_D$;

*4) Cycle* through the above two steps until the training network achieves Nash equilibrium, and then stop training.

*5) Expand* the original collected API sequence using WGAN-GP and train the detection model to detect ransomware.

## IV. RDCO ONTOLOGY CONSTRUCTION AND DEFENSE COUNTERMEASURE REASONING

Starting from the API called by the ransomware, we map some specific malicious APIs to ATT&CK technology. Based on the work of integrating multi-source security knowledge [21], malicious APIs and multi-source security knowledge are mapped. However, the link between ransomware and defense countermeasures is implicit. Ontology can discover new relationships from known knowledge through the formal description of knowledge in a specific domain, and the design of reasoning rules based on the ontology. Therefore, this paper proposes a defense countermeasure reasoning method for ransomware based on semantic ontology and rule logic, and infers corresponding defense countermeasures for the APIs called in the ransomware.

### A. Ransomware API mapping Multi-source Security Knowledge

The existing ransomware that can infect Windows systems is operated by calling a large number of Windows APIs. By analyzing the attack process of ransomware and the technologies under the Windows platform in enterprise ATT&CK, some common APIs are mapped to corresponding technologies in the ATT&CK framework. For example, the widely used defense avoidance technique in ransomware - process injection, which runs custom code in the address space of another process. Process injection improves invisibility, and some technologies also achieve persistence [27]. There are many types of process injection techniques. This example analyzes the classic malicious dynamic link library (DLL) injection technique, and its corresponding ATT&CK technique is T1055.001. The injection process of DLL is shown in Fig. 4, where the ransomware calls VirtualAllocEx to obtain a space to write the path to its DLL. Then, ① call WriteProcessMemory to write the path to the allocated memory. In order for the code to execute in another process, ② will call APIs such as CreateRemoteThread, NtCreateThreadEx, or RtlCreateUserThread. Finally, ③ successfully injected the ransomware code into the target process.

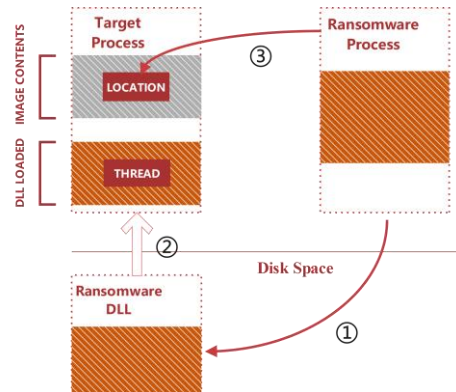

Fig. 4. Ransomware creates remote threads and loads libraries for classic DLL injection.

Through the above analysis, the T1055.001 technology can be mapped to the API during the DLL injection process. Map 47 technologies with their corresponding APIs based on the

data components (operating system API execution) in the ATT&CK framework. At the same time, CAPEC focuses on the attack pattern, linking the tactics and techniques in ATT&CK with the weakness of the attack target, and using the weaknesses in CWE to link to vulnerabilities in CVE. And integrate defense technology in D3FEND through digital artifacts. Fig. 5 depicts the relationship links mapped according to the selected knowledge sources. Through this end-to-end link method, security researchers can not only analyze potential threats to the system, but also defend against ransomware attacks based on defense strategies.

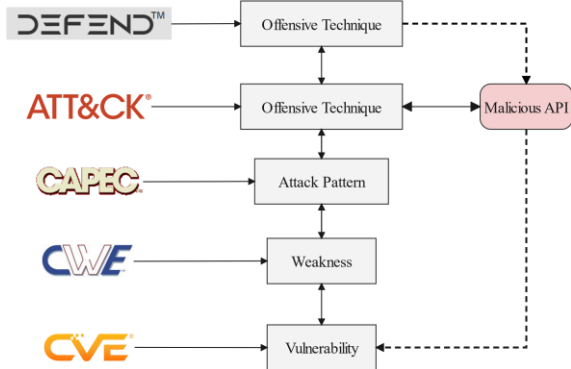

Fig. 5. Schematic diagram of security knowledge relationship mapping link.

### B. Build Ontology and Design Inference Rules

Based on the mapping between security knowledge and malicious APIs of ransomware, a Ransomware Defensive Countermeasures Ontology (RDCO) is proposed. The ontology model consists of classes, attributes, and relationships between classes and individuals [28]. RDCO includes seven categories: ransomware behavior, offensive techniques, digital artifacts, defensive countermeasures, attack patterns, weaknesses, and vulnerabilities. Classes and the relationships between classes are shown in Fig. 6.

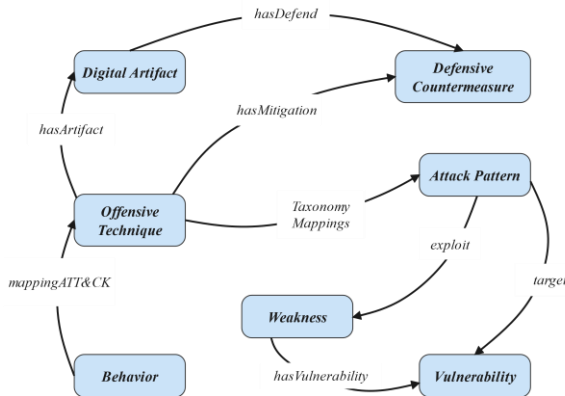

Fig. 6. Relationship between RDCO top-level classes.

In order to better infer defense countermeasures and vulnerabilities from the RDCO ontology, this paper uses the semantic inference rule description language recommended by W3C to design inference rules for SWRL (semantic web rule language) [29]. To implement SWRL rules in an ontology, it is necessary to write and describe the reasoning conditions (Antecedent) and the reasoning results (Consequence) in

language. A single or multiple basic atoms (which are already knowledge constructed in the ontology) form each SWRL rule in the reasoning, and represent it as a logical "AND" relationship through "^". The connection between the reasoning conditions and results is made through "→", Create rules for expanding existing OWL languages, where the formal expression of SWRL rules is:

$$(\wedge_{i=1}^{m} A_i) \rightarrow (\wedge_{j=1}^{n} B_j), m \geq 1, n \geq 1 \qquad (8)$$

Equation (8) $A_i$, $B_j$ is a fundamental atom, and their form can be represented as C (x), P (x, y), or (x, y), where C is an OWL description, P is an OWL attribute, and x and y can be OWL instances or OWL data values. Only when atoms have been constructed in the ontology and are all true can SWRL rules be effectively set. Using SWRL rules, new relationships can be discovered from known knowledge. As shown in Table II, we designed three inference rules based on RDCO ontology to infer relevant defense strategies for ransomware.

TABLE II.    INFERENCE RULE TABLE

| Order | Inference rule |
|---|---|
| $R_1$ | *Behavior(?b)^mappingAttack(?b, ?t)^Offensive_Technique(?t)^TaxonomyMappings(?t, ?a)^Attack_Pattern(?a)^exploit(?a, ?w)^Weakness(?w)^hasVulnerability(?w, ?v) ->exploitVulnerbility(?b, ?v)* |
| $R_2$ | *Behavior(?b)^mappingAttack(?b,?t)^Offensive_Technique(?t)^hasMitigation(?t,?m) ->useMitigation(?b, ?m)* |
| $R_3$ | *Behavior(?b)^mappingAttack(?b,?t)^Offensive_Technique(?t)^hasArtifact(?t,?da)^Digital_Artifact(?da)^hasDefend(?da,?dt)^defensive_technique(?dt)->useDefendTechniques(?b, ?dt)* |

Rule $R_1$: Using the attack pattern that CAPEC focuses on as a bridge, associate the attack technology used by the attacker with the weaknesses of the attack target. Due to the fact that weakness in CWE can be linked to vulnerabilities in CVE, it is possible to infer vulnerabilities exploited by ransomware. Knowing the exploited vulnerabilities can help to promptly fix them and prevent ransomware attacks.

Rule $R_2$: When the malicious API of ransomware is known, by mapping the API to ATT&CK technology, each ATT&CK technology in the ATT&CK framework has its corresponding mitigation measures, thereby automatically extracting mitigation measures related to ransomware.

Rule $R_3$: In addition to inferring mitigation measures in response to ransomware attacks, the API of ransomware is mapped to ATT&CK technology, using digital artifacts as a medium to automatically infer defense technologies in D3FEND corresponding to ransomware in response to ransomware attacks

## V. EXPERIMENTS AND EVALUATION

### A. Experimental Dataset

There is currently no publicly available ransomware standard dataset in the academic community. This article builds a Cuckoo sandbox, in which the Windows 7 operating system is used as the software runtime environment. Run the sample for 60 seconds and collect the API sequence called during software runtime. The ransomware samples used in the

experiment were collected from Virusshare and Any. Run, and the normal samples were collected from 360 software stewards. See Table III for the types and quantities of the experimental samples. The versions of different samples in the same ransomware sample family are different. The normal software covers antivirus software, office software, chat tools, download tools, video software, browsers, input methods and other common types.

This article truncates the collected API sequences and only studies the API sequences before encrypting them. After analysis, it was found that a file operation of ransomware often requires calling four APIs, such as CreatFile, WriteFile, HWrite, LClose, etc., to quickly create a file. Therefore, REDDS uses the 4-gram algorithm in feature calculation, and then calculates the eigenvalues through TF-IDF, which can make the generated feature vectors best match the features of the API sequence.

TABLE III.    TYPES AND QUANTITY OF EXPERIMENTAL SAMPLES

| Ransomware family | N | Ransomware family | N | Ransomware family | N | Normal software samples | N |
|---|---|---|---|---|---|---|---|
| Alphacrypt | 4 | Prolock | 2 | Maze | 3 | Browser | 2 |
| Cerber | 4 | Ransomware.Dharma | 5 | SATURN | 2 | Chat Tools | 2 |
| CryptoWire | 2 | Ransomware.Eleta | 2 | SilentSpring | 1 | Download Tools | 4 |
| Crysis | 8 | Ransomware.FRS | 3 | PolyRansom | 4 | Inputting Method | 3 |
| Gandcrab | 6 | Ransom.LockerGoga | 4 | Spora | 4 | Video software | 5 |
| Lockbit | 2 | Ransomware.Kraken | 5 | Sodinokibi | 6 | Safe Antivirus | 2 |
| CryptoShield | 2 | Ransomware.Wlu | 2 | Teslacrypt | 5 | Office-Software | 16 |
| Mzrevenge | 4 | Ransomware.SAGE | 2 | Wannacry | 4 | Other | 6 |
| Total number of ransomware samples | 86 | | | | | Total number of normal samples | 40 |

### B. Evaluation of WGAN-GP Model Generation Capability

Fig. 7.    Curve of loss function.

After repeated debugging, it is determined that the discriminator uses a three-layer neural network structure, and each layer is followed by a hyperbolic tangent activation function (Tanh). The generator adopts a 4-layer neural network structure, and ReLu activation function is used behind each layer. The optimization solver uses Adam, the learning rate of the generator and discriminator is set to 0.0005, and the training round is 10000. The loss function curve of generator and discriminator during training is shown in Fig. 7. The API sequence data enhancement method based on WGAN-GP is used to enhance the API sequence of ransomware and the API sequence of normal software respectively. The API sample library before and after augmentation is shown in Table IV.

TABLE IV.    API SAMPLE LIBRARY BEFORE AND AFTER DATA AUGMENTATION

| Type | Before data enhancement | After data enhancement |
|---|---|---|
| Ransomware samples | 86 | 1634 |
| Normal samples | 40 | 1218 |

The authenticity, probability fitting accuracy, and diversity of generated samples are important indicators for evaluating the generation ability of a model. This paper includes two generative model, BEGAN (boundary equilibrium GAN) [30] and LSGAN (Least Squares GAN) [31], as reference objects to evaluate the generation capability of WGAN-GP model.

(a) WGAN-GP generates samples.

(b) LSGAN generates samples.

(c) BEGAN generates samples.
Fig. 8.    API sequence generation sample dimensionality reduction visualization for ransomware.

Taking the API sequence samples of ransomware generated by WGAN-GP, BEGAN, and LSGAN models as examples, t-distributed stochastic neighbor embedding (t-SNE) algorithm is used to perform dimensionality reduction analysis on real samples and partially generated samples of each model. The visualization results are shown in Fig. 8. From Fig. 8, it can be clearly seen that the samples generated by the BEGAN and LSGAN models are concentrated within a small range near the real sample, while WGAN-GP, due to considering the 1-Lipschitz condition limitation, generates scattered samples within the real sample distribution range, with good diversity.

Kernel Perception Distance (KID) is used to evaluate the authenticity of the generated samples, and KID uses Gaussian kernel functions to measure the similarity between the real dataset and the generated dataset in the Perception feature space. The KID values of the samples generated by the three GAN models are shown in Table V. It is evident from Table V that the KID values of the WGAN-GP generated samples are significantly lower than those of the LSGAN and BEGAN models. The smaller the KID value, the closer the generated sample is to the real sample.

TABLE V.    KID VALUES OF SAMPLES GENERATED BY THREE GAN MODELS

| Type | Ransomware | Normal software | Average value |
|---|---|---|---|
| WGAN-GP | $5.702\times 10^{-6}$ | $4.171\times 10^{-6}$ | $4.935\times 10^{-6}$ |
| LSGAN | 1.998 | 1.878 | 1.938 |
| BEGAN | 1.295 | 1.207 | 1.251 |

*C. Detection Model*

The expanded API sequence dataset was divided into a training set and a testing set in a ratio of 70% to 30%. The detection performance of five classification algorithms, namely Support Vector Machine (SVM) [32], RF [32], Naive Bayes (NB) [32], K-Nearest Neighbor (KNN) [33], and MLP [34], was further compared before and after using WGAN-GP data augmentation.

This article uses commonly used accuracy, precision, recall, and F1 score (F1) in the field of malware detection as performance evaluation indicators [35].

TABLE VI.    THE P, R, AND F1 VALUES OF THE FIVE DETECTION MODELS BEFORE AND AFTER USING WGAN-GP

| | Before using WGAN-GP | | | After using WGAN-GP | | |
|---|---|---|---|---|---|---|
| | P | R | F1 | P | R | F1 |
| SVM | 0.884 | 0.875 | 0.877 | 0.941 | 0.904 | 0.913 |
| NB | 0.876 | 0.873 | 0.878 | 0.940 | 0.904 | 0.912 |
| KNN | 0.883 | 0.857 | 0.872 | 0.968 | 0.964 | 0.965 |
| RF | 0.958 | 0.961 | 0.959 | 0.996 | 0.994 | 0.995 |
| MLP | 0.873 | 0.884 | 0.865 | 0.994 | 0.992 | 0.993 |

Fig. 9.    Comparison of accuracy of detection models before and after data enhancement.

Fig. 9 shows the accuracy of the detection models before and after using WGAN-GP data augmentation. It can be seen that the accuracy of all five detection models has increased after using data augmentation. Among them, MLP's accuracy rate increased the most, by 10.12%. RF has the highest accuracy, reaching 99.23% after data enhancement. Table VI shows the P, R, and F1 values of the five detection models before and after using WGAN-GP data augmentation. From the results in Table VI, it can be seen that among the five classification algorithms used in this article, the detection results obtained using RF and MLP are superior to the other three algorithms. The experimental results indicate that using WGAN-GP data augmentation can significantly improve the performance of the target detection model. By using WGAN-GP data augmentation, we can utilize more data to train and optimize the model, thereby improving its accuracy and robustness.

*D. Defense Countermeasure Reasoning*

HermiT general rule inference engine is used to describe the proposed inference rule set, and it is integrated in the RDCO ontology model. The model is based on the security domain knowledge base and the condition pattern in the reasoning rule set for reasoning. Ransomware often exploits system or software security vulnerabilities to gain system privileges and install ransomware on the victim's computer. Finding and fixing these vulnerabilities can help us better defend against ransomware attacks.

After detecting the ransomware, the inference engine passes the inference rule $R_1$ Infer the associated security vulnerabilities based on the behavior of specific ransomware. Taking the API of ransomware calling ChangeServiceConfigW and CreatServiceW as an example, new implicit facts are inferred according to the rules. The inference engine associates the specific API of ransomware with the security vulnerabilities that may be exploited in the system through the object attribute exploitVulnerability. To clearly display the specific reasoning results, Neo4j is used to visualize them in the form of a knowledge graph. As shown in Fig. 10, the yellow arrow in the figure represents the inferred relationship exploitVulnerability.

Fig. 10. Security vulnerability reasoning results.

Map specific APIs called by ransomware to ATT&CK technology, and each ATT&CK technology has corresponding mitigation and defense measures. By inference rule $R_2$ and $R_3$ can automatically infer defense strategies targeting specific APIs, helping security managers respond to ransomware attacks and deploy appropriate security solutions. Taking the APIs called by the aforementioned ransomware, ChangeServiceConfigW and CreatServiceW, as examples, the specific APIs of the ransomware are associated with mitigation measures and defense technologies through the object properties useMigration and useDefendTechniques. The specific reasoning results are shown in Fig. 11, where the orange and red arrows represent the inferred relationships useMitigation and useDefendTechniques, respectively.

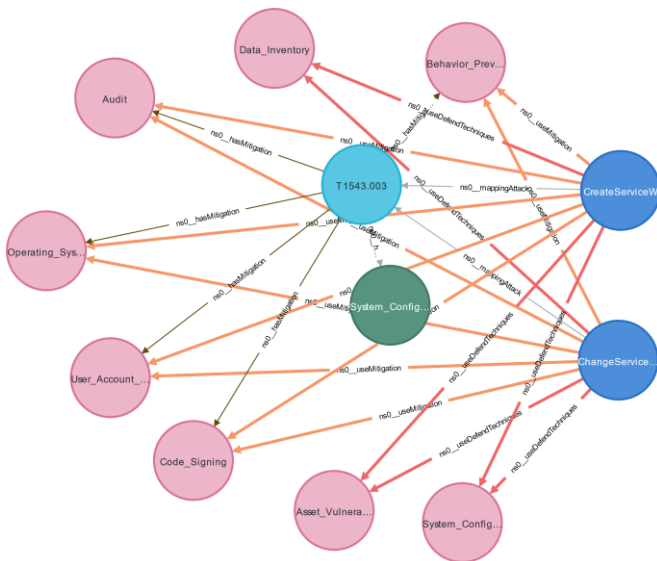

Fig. 11. Defense strategy reasoning results.

## VI. CONCLUSION

This article proposes an early detection and defense system for ransomware based on API sequences. To address the limitations of collecting datasets, API sequences were enhanced based on Wasserstein GAN with Gradient Penalty (WGAN GP), and then machine learning classification algorithms were used to train the enhanced data to detect ransomware. The detection accuracy was significantly improved after using WGAN-GP data augmentation, with the RF algorithm having the highest accuracy of 99.23%. By mapping the malicious APIs of ransomware to public security knowledge bases such as ATT&CK, a Ransomware Defense Countermeasures Ontology (RDCO) is proposed. Based on the ontology model, a set of inference rules are designed, and corresponding defense Countermeasures are automatically inferred based on the malicious APIs in ransomware, helping security managers respond to ransomware attacks and deploy appropriate security solutions. In the follow-up work, we will be committed to the detection and defense of ransomware attacks in the field of industrial internet of things.

# The Holistic Expression Factors of Emotional Motion for Non-humanoid Robots

Qisi Xie, Ding-Bang Luh*

School of Art and Design, Guangdong University of Technology, Guangzhou 510006, China

*Abstract*—**The development of technology and the increasing prevalence of solitary living have transformed non-humanoid robots, such as robotic sweepers and mechanical pets, into potential sources of emotional support for individuals. Nevertheless, the majority of non-humanoid robots currently in existence are task-oriented and lack features such as facial expressions and sound. Existing research primarily emphasizes the details of human motion in robot motion design, while devoting less attention to the analysis of universal emotional expression factors and methods rooted in human recognition patterns. In our initial step, a theoretical framework and holistic expression factors were proposed based on Gestalt theory and SOR theory. These factors encompass vertical and horizontal motion direction, stimulation, and vertical repetition. Subsequently, animation simulation tests were conducted to confirm and examine the contributions of each factor to the recognition of emotional expressions. The results indicate that both vertical and horizontal movements can convey emotional valence. However, if both of them exist, there is no leading direction to the valence recognition result. When both vertical and horizontal movements are present, valence recognition is influenced by the combined effects of stimulation, vertical repetition, and movement direction. Simultaneously, non-humanoid robots can display recognizable emotional content when influenced by holistic expression factors. This framework can serve as a universal guide for emotional expression tasks in non-humanoid robots, proving the hypothesis that Gestalt theory is applicable in dynamic emotional recognition tasks. At the same time, these findings propose a new holistic perspective for designing emotional expression methods for robots.**

## I. INTRODUCTION

Due to evolving societal trends like the stay-at-home economy, the single economy, and an aging population, robots are poised to become indispensable companions for humans. These robots offer not only functional services but also emotional support to humans. Currently, non-humanoid robots are increasingly integrated into human life as the most ubiquitous non-human characters. For instance, everyday household items like robotic sweepers [1], interactive pets such as Cozmo [2] and BB-8 [3], the chicken-shaped Keepon [4] and seal-shaped PARO [5] used in hospitals for patient recovery, robot dogs that can assist in search and rescue, as well as drones used for large-scale performances [6] are all becoming increasingly prevalent. It is foreseeable that more non-humanoid robots will play a more significant and pervasive role in human life in the future [7]. However, these non-humanoid robots exhibit significant differences in appearance compared to humans, posing challenges in expressing emotions through human-like behavior imitation. Furthermore, many task-focused non-humanoid robots lack essential components like facial expressions and auditory capabilities [1]. Therefore, designing emotional motion expressions for non-humanoid robots that can effectively convey understandable emotional states to humans has become a crucial research topic.

The three primary categories of currently conducted research on emotional motion expression in robots are artificial design, artistic theory guiding, and emotional computing.

Firstly, artificial design based on robot features through the simulation of localized human body movements is the most widely used method in current research for expressing robot emotions and behaviors. For instance, robots were programmed to convey positive emotions through human-like gestures [8], such as cheering, applauding, and wave dancing for positive emotion, while negative emotions were represented using gestures like shrugging and crossing the arms. Similarly, Valenti et al. employed the Nao [9] robot to devise gestures based on human arm movements for expressing basic emotions. Johnson and Cuijpers conducted network experiments to investigate changes in the head position of robots, and found that people expect robots to lower their heads and gaze downward when expressing anger, sadness, fear, or disgust [10]. Moreover, Shimi [11] is a camera whose movements are expressed through artificially designed body postures. Keepon [4], designed with a biological appearance, enhanced emotional expression through gaze and body movements by manual design. The effectiveness of such expression relies on the resemblance between the robot and the human body, making it challenging to apply these results to the motion design of other robots.

Secondly, art theories have contributed methods for robotic expressions. The primary representative theories include animation theory [12] and dance theory. Animation theory relies on the 12 principles of animation to imbue robot motion with a realistic sense of life, such as helping drones convey intentions through path and speed during flight [13], and assisting robots in displaying behavior comprehensible to users [14]. Nevertheless, due to inherent limitations in robot flexibility, degrees of freedom, and movement speed, animation methods can hardly be fully utilized to convey robot emotional expressions. The Laban system [15] was originally used in dance research to describe the quality of motion. For example, Burton et al. [16] proposed to find emotionally similar movements from the database by using the Laban system and incorporating expressive content into a specific

robot motion trajectory. However, when applying this system to robot research, it is necessary to identify suitable emotional expression elements tailored to each robot's unique characteristics. The selection varies based on individual characteristics and cannot be universally applied. Consequently, the application of art theories is limited to robots with specific attributes, and the absence of these detailed elements may limit the range of emotional expression capabilities.

Thirdly, emotional computing has emerged as a prevalent method in robot motion design. Leveraging advanced computer technology, machine learning algorithms extract relevant features from extensive labeled exemplar data, allowing the system to automatically generate expression trajectories. Common methods include principal component analysis (PCA) [17], factored conditional restricted Boltzmann machines (FCRBMs) [18], factored Gaussian process dynamic models (GPDM) [19], and neural network methods [20, 21], etc. Machine learning methods rely on human motion data, such as motion capture or large corpora. However, their generalization ability and scalability are limited. Even when using the same database, if the images used for training and testing are not the same or differ significantly, the final results will also be different. Therefore, machine learning approaches often exhibit relatively simplistic outcomes [22]. The majority of works still focus on single tasks such as walking, and typically involving specific structures [23], with humanoid structures being the most prevalent. Therefore, machine learning methods are limited to single objects with the same features.

In summary, current research on robot emotional expression primarily concentrates on specific or localized expressions. Consequently, these outcomes exhibit variations among individuals and lack generalizability, hindering the assurance of consistent expression results. Moreover, pertinent studies have yet to analyze the key factors influencing users' recognition of emotional expressions from the perspective of overall motion states.

Building upon the preceding discussion, this article poses a question grounded in the Gestalt effect: Is human recognition of emotional movement expression also influenced by their perception of the entire motion? Is it possible to convey emotion through the presentation of holistic expression factors?

This article aims to analyze the expression factors that affect users' emotional recognition of robots from a holistic perspective and help reduce the burden of communication on users during interactions with different non-humanoid robots. Consequently, it can facilitate rapid user acceptance of robots and foster the growth of related markets. At the same time, this research offers a novel perspective for designing emotional expression methods in robots by investigating recognition rules for emotional expression, which helps simplify the expression design of non-humanoid robots.

In our study, we initially established an experimental theoretical framework based on Gestalt theory and SOR theory, and then we derived a comprehensive set of expression factors, including vertical and horizontal motion directions, stimulation, and vertical repetitive motion. Subsequently, we explored the pivotal role played by movement direction and

developed hypotheses grounded in approach-withdrawal theory and embodied emotion theory. Detailed information on this section is provided in Section II.

Then, Section III primarily focused on the effect of motion direction as the main factor on valence expression, which related to $H_1$. Section IV was dedicated to resolving and validating $H_2$ and $H_3$, which focused on analyzing the collective effects of all the holistic factors on emotional expression. Section V encompassed a comprehensive discussion of our findings, while Section VI offered a summary of the study's key outcomes.

## II. CONCEPTUAL MODEL AND HYPOTHESES DEVELOPMENT

Gestalt psychology [24] points out that people's perception towards objective objects are rooted in holistic relationships rather than specific elements. They emphasizes that the whole of anything is greater than its parts. Based this concept, we bring up the question: does human recognition of robot emotional actions also come from their perception of overall motion?

In addressing this question, we began by extracting holistic factors from Gestalt theory to analyze emotional expression. In Gestalt theory, holistic factors include similar appearance (similarity principle), potential contours (closure principle), continuation (continuity principle), proximity (proximity principle), and direction (common fate principle) et al. Most of these factors are applied to static graphics. However, the direction becomes a dynamic factor that is particularly relevant for motion. In the context of robotic movement, direction is a ubiquitous and fundamental element that remains consistent across variations in robot size, speed, and other variables. Hence, it serves as a universal overarching element for analyzing emotional expression effects. We categorized all motion directions into two main types: horizontal and vertical. In the realm of interaction, horizontal motion further subdivides into approaching and distancing from the target object, while vertical motion encompasses two distinct forms: upward for positive direction and downward for negative direction.

Then, we used SOR theory to find other holistic factors. The SOR theory suggests that stimuli trigger responses based on the internal sensations or behaviors of the organism (human), and this process involves the sequence of stimulus-individual (emotion) -trigger response [25]. Among these elements, stimulation is one of the transferable holistic factors, and response is presented through horizontal movement. By combining Gestalt theory, the expression framework employed in this study is structured as follows: stimuli (including two types of positive and negative stimuli) - vertical movement (including vertical upward, vertical downward, and repetitive movements in both directions) - response (horizontal movement approaching and moving away from the presentation decision). The relevant holistic factors include stimulation, vertical movement direction, horizontal movement direction, and vertical repetition. The theoretical framework guiding our analysis is outlined as Fig. 1.
Fig. 1. Theoretical framework of the experiment.

Given the critical role of movement direction in our study, we began by analyzing the contributions of vertical and horizontal motions in the context of emotional expression to clarify their respective mechanisms for conveying emotions. According to the approach-withdrawal theory [26], we established a connection between horizontal movement and emotional valence, with approach signifying positive valence and avoidance and withdrawal signifying negative valence. The theory of embodied emotions [27] further underscores the influence of actions on the generation and perception of emotions. Consequently, positive actions can engender positive emotions, and conversely, negative actions can induce negative emotions. By extension, vertical movement aligns with the tenets of the embodied emotion theory, wherein upward motion signifies positive valence and downward motion signifies negative valence.

Notably, the valence dimension is the most basic and important aspect of the classical dimensional emotion model: Pleasure-Arousal-Dominance (PAD) model [25], which describes the range of changes in emotions from pleasant to unpleasant [28]. Compared to arousal (which represents the degree of emotional activation and is used to indicate the intensity of response to external stimuli) and dominance (which focus on the individual's control or influence over the external environment or other people, reflecting the individual's state of interaction with the environment or others), pleasant is more generalized and representative in presenting the overall emotional content. Since pleasure mainly depends on the robot's current motivation and goals [29], and it significantly informs the expresser's strategic choices in subsequent social interactions [30], the display of valence has a decisive impact on the overall emotional recognition results. Many studies on emotional expression also mainly focus on the expression of pleasure [31] [9]. In light of these considerations, we pose the question: in scenarios where both vertical and horizontal directions are concurrently present, which direction will more affect valence recognition, and how do these combined movements collectively convey emotional content?

Therefore, we have taken the following three hypotheses based on the above discussions:

$H_1$: Vertical movement has the same function as horizontal movement, which can demonstrate emotional valence.

$H_2$: When vertical and horizontal movements co-occur, one side predominates in expressing emotional valence.

$H_3$: Employing holistic factors enables non-humanoid robots to convey understandable emotional content to humans.

In this study, we first analyzed the expressive value of a single direction of motion. Subsequently, we explored the value of various holistic expression factors within the theoretical framework. These factors encompass vertical motion direction, horizontal motion direction, stimulation, and vertical repetitive motion as holistic expression factors.

## III. FACTOR ANALYSIS OF VALENCE EXPRESSION

In this study, we firstly investigated $H_1$, which posits that non-humanoid robots can convey emotional valence through vertical up-and-down movements. Additionally, we examined potential variations in recognition outcomes resulting from different types of motion modes used to achieve vertical movement.

### A. Methods

*1) Materials:* The movements that can achieve up-and-down movement in the vertical direction are translational movement and rotation. Therefore, we needed to confirm that rotating and moving on the vertical direction show the same effect. Based on the different modes of movement, we chose to use two non-humanoid robots—a spider robot and a mechanical arm—as the research objects. The spider robot allowed the body to move up and down through the support of four legs, and the robotic arm achieved the result of up and down movement by rotating.

We used the open-source animation software Blender to create simulation animations. In a total of four films, the two robots alternately went up and down to the limits of their own ranges of motion. The mechanical arm moved up and down by rotating, and the body of the spider robot moved up and down by translational motion. See Fig. 2. Then, participants evaluated the level of pleasure based on the animation contents. Data analysis used IBM SPSS Statistics 25. Materials are available at https://doi.org/10.6084/m9.figshare.23695926.v1

*2) Participants:* Participants were recruited through advertisements. 31 people (14 males, 17 females) with an age range of 18–43 (M = 28, SD = 6.5), 13 of whom had arts and humanities backgrounds, 8 had business and management backgrounds, and 9 had backgrounds in natural science and technology. Participants received a gift after the experiment. The protocol was approved by the Ethics Committee of the author's institution.

*3) Task and procedure:* Before the experiment, each participant was asked to sign a consent form and fill out demographic information. Participants were informed of task content. After the participants were ready, the simulation animation started, each animation played 3 times. After each animation finished, participants then chose the level of pleasure they felt from the robot's performance. In order to obtain more intuitive and efficient recognition results, we used the Self-Assessment Manikins (SAM) questionnaire [32] to acquire insights into how participants perceive the robot emotion [33]. Options were scored on a five-point Likert scale, with 1 being very unpleasant and 5 being very pleasant.

After the rating was completed, we started playing the next video. There were four videos in total. The experiment took an average of 7 minutes for each person.

Fig. 2. Vertical movement of the robots for emotional expression. Top left: Spider robot moves upward; Top right: Spider robot moves downward; Bottom left: Mechanical arm upward movement; Bottom right: Mechanical arm downward movement.

### B. Results

To analyze the valence of the robot in the case, we plotted a mean bar chart. We used an independent sample T-test to examine the differences between different emotional groups.

Fig. 3 illustrates that there was no statistically significant difference in the recognition results for upward movement between the spider robot and the mechanical arm (t (60) = 0.381, p = 0.705). Likewise, no statistically significant difference was found in the results of downward movement between the two robots (t (60) = 0.131, p = 0.896). However, significant differences were observed in the motion recognition results of the same robot for positive and negative valence (p < 0.001).

To establish the range of valence recognition values within the sample's population, we performed a Z-test (z = 2.58) to calculate the 99% confidence interval for each parameter's estimated values, as presented in Table I.

Analysis of the data reveals that both the Spider robot and the Mechanical Arm consistently achieve valence recognition scores above 3.36 with a 99% confidence level for upward motion, while the probability of their downward motion scores falling below 2.59 was also above 99%. Emotions with scores above 3 on the 5-point scale were deemed positive, while those below 3 were considered negative. Thus, the statistical results confirmed a 99% probability of upward movement conveying positive emotions and downward movement conveying negative emotions. These findings support $H_1$, demonstrating that vertical movement serves the same purpose as horizontal movement in conveying emotional valence. Additionally, it is observed that achieving the same directional motion through various motion modes produces consistent results.

### C. Discussion

Through simulation experiments on two non-humanoid robots that achieve vertical motion through rotation and movement, we confirmed that the motion mode has no significant impact on emotion recognition results. Which means that the expression of motion in the same direction for non-human robots with different modes of motion results in the same outcome. Therefore, we can choose one of the robots as the research representative in the following direction-related research, and the results obtained can be generalized to a certain extent.

Fig. 3. Pairwise comparison between valence levels of robot emotions parameters.

TABLE I. 99% CONFIDENCE INTERVAL OF THE POPULATION TO WHICH EACH GROUP OF SAMPLES BELONGS TO THE RECOGNITION RESULTS

| 99% confidence interval | | |
|---|---|---|
| *movement* | *Spider robot* | *Mechanical Arm* |
| Upward movement | [3.36, 4.04] | [3.41, 3.98] |
| Downward movement | [1.81, 2.59] | [1.61, 2.59] |

At the same time, the experiment confirms $H_1$, which suggests that vertical and horizontal movements serve the same function in demonstrating emotional valence. Accordingly, we have demonstrated the value of embodied theory in emotional action recognition, where positive behavioral actions can lead to positive emotional recognition results, and vice versa. This conclusion lays the groundwork for $H_2$ and $H_3$.

## IV. EFFECT OF HOLISTIC EXPRESSION FACTORS

It was previously verified that both vertical and horizontal movements have the function of displaying valence. Therefore, we further verified the latter two assumptions, namely $H_2$: When both vertical and horizontal movements occur, one of them dominates the display of emotional valence. $H_3$: Employing holistic factors enables non-humanoid robots to convey understandable emotional content to humans.

In order to focus on the research content, we first discussed the methods of motion combination, and then conducted experiments based on the theoretical framework and analyzed the relationship between the factors and the results.

### A. Analysis of Motion Combination Methods

Emotions often appear in complex [34] and varied forms [35]. Due to the fluid and intricate nature of emotions, not all

emotional expressions exhibit distinct stages in real-life scenarios. It is also possible for concurrent of behavioral states in the 'trigger phase' and 'response phase'. Therefore, when horizontal and vertical motions occur simultaneously, there is more than one relationship between the two motions. Define the horizontal motion as $H_M$, the vertical motion as $V_M$, $t$ as the time, $n$ is the minimum interval time step between the two movements. The expressions for the two movements are as follows:

Define Action Expression as

$$\vec{A}_E\left(t,n\right)=\left(\vec{V}_M^t+\vec{H}_M^{t+n}\right) \tag{1}$$

When the two are in a sequential relationship,

$$n=1,$$
$$\vec{A}_E\left(t,1\right)=\left(\vec{V}_M^t+\vec{H}_M^{t+1}\right) \tag{2}$$

To simplify the description, the sequential relationship described in formula (2) in the following text is denoted as $V_M\oplus H_M$.

When the two are in a parallel relationship,

$$n=0,$$
$$\vec{A}_E\left(t,0\right)=\left(\vec{V}_M^t+\vec{H}_M^t\right) \tag{3}$$

To simplify the description, the parallel relationship described in formula (3) below is denoted as $V_M\otimes H_M$.

The two formulas describe two different relationships, with the difference being that $V_M\oplus H_M$ describes a horizontal movement that occurs after a vertical movement, and $V_M\otimes H_M$ means during the process of horizontal movement, multiple vertical movements occur simultaneously.

Since $V_M$ = {Upward movement, Downward movement}, $H_M$ = {Approach, Avoidance}, there are various types of motion combinations. The emotional valence recognition results obtained from actions with the same semantics will not change, which means when $V_M$ = Upward movement, $H_M$ = Approach, both vertical and horizontal directions exhibit positive semantics, ultimately resulting in a positive valence. Similarly, when $V_M$ = Downward movement, $H_M$ = Avoidance, the combination of two negative semantic movements results in a negative valence.

One of our research goal was to understand the role of different movement directions in emotional expression. Therefore, we mainly focused on the results obtained by combining a positive and a negative action. In addition, in order to simulate real-life scenario responses, we classified environmental stimuli into two types: positive and negative stimuli. Therefore, there were a total of eight experimental situations. See Table II.

## B. Methods

*1) Materials:* In the first study, we confirmed that the recognition effect of both translational movement and rotation in the vertical direction was identical. Therefore, we only used one of the robots in this experiment. We chose the spider robot for analysis since it was equipped to move both vertically and horizontally at the same time. Similarly, we also used the open-source software Blender to model animations. Participants filled out questionnaires after watching the animations. In order to minimize the influence of environmental colors on the recognition results, we set all backgrounds to a neutral gray shade.

TABLE II.    SUMMARY OF EXPERIMENTAL GROUP

| Stimulation | Motion relationship | Contents | Abbreviation |
|---|---|---|---|
| Positive | $V_M\oplus H_M$ | Upward movement $\oplus$ Avoidance | $P:U_M\oplus A_v$ |
| | | Downward movement $\oplus$ Approach | $P:D_M\oplus A_p$ |
| | $V_M\otimes H_M$ | Upward movement $\otimes$ Avoidance | $P:U_M\otimes A_v$ |
| | | Downward movement $\otimes$ Approach | $P:D_M\otimes A_p$ |
| Negative | $V_M\oplus H_M$ | Upward movement $\oplus$ Avoidance | $N:U_M\oplus A_v$ |
| | | Downward movement $\oplus$ Approach | $N:D_M\oplus A_p$ |
| | $V_M\otimes H_M$ | Upward movement $\otimes$ Avoidance | $N:U_M\otimes A_v$ |
| | | Downward movement $\otimes$ Approach | $N:D_M\otimes A_p$ |

The focus of this study was solely on exploring the impact of motion direction. To minimize interference, all videos maintained consistent speed, motion distance, and fixed motion amplitude (the highest reaching position of the spider robot body was 50.7cm, the middle height position was 30.6cm, and the lowest height position was 15.0cm). The distinction arises from the fact that movements that occur in parallel will experience multiple vertical up and down movements, resulting in variations in the total duration. A total of 8 videos were included, see Fig. 4. To mitigate mutual influence between similar movement expressions, the videos were played back in the following order: 1) $N:U_M\oplus A_v$ , 2) $N:D_M\oplus A_p$ , 3) $N:U_M\otimes A_v$ , 4) $N:D_M\otimes A_p$ . Then, display videos in the same order under positive stimuli. Materials are available at https://doi.org/10.6084/m9.figshare.23695926.v1

*2) Participants:* Participants were recruited through advertisements. 35 people (20 males, 15 females) from school. The age range was 18-42 (M = 27, SD = 5.9), 11 were from arts and humanities background, 6 were from business background, and 18 were from science and technology background. Participants received a gift after the experiment. The protocol was approved by the Ethics Committee of the author's institution.

*3) Procedure:* Before the experiment, each participant was asked to sign a consent form and fill out demographic information. Participants were informed of task content. After the participants were ready, the experiment began.

Firstly, an introduction of the video was showed: "The following is the emotional expression of the robot after being praised (positive stimulus) /criticized (negative stimulus) by the owner. Please choose according to the requirements." Secondly, the animations were played. The animation began with the host's expression, with a smile representing positive stimulation and an angry expression representing negative stimulation. Subsequently, the robot actions were presented. See Fig. 4. Each animation played 3 times.

Fig. 4.    Screenshots of the animations used in the experiment.

After viewing each video, participants were required to choose the pleasure level of the robot's performance as their initial response. We also used the SAM questionnaire [32]. The options were rated on a five-point Likert scale, ranging from one (very unpleasant) to five (very pleasant). Secondly, the content of different PAD emotional spaces was described using Gebhard's classification method [36], which associates various types of emotions with each emotional space. Subsequently, participants selected the emotional types of robot actions observed in the video based on their own cognition. The specific emotional options correspond to the emotional space as shown in Table III. Participants were only able to view the available options and their corresponding emotional types without direct visibility of the associated PAD emotional space. After the questionnaire ended, we continued to play the next video. The experiment took an average of 20 minutes for each person.

*C. Results*

*1) Pleasure:* To comprehend the roles played by different factors in the expression process, we employed Multi-way ANOVA to examine participants' recognition of the pleasure conveyed by non-humanoid robots. Independent variables included stimuli, motion groups (Group 1: Upward movement and Avoidance, Group 2: Downward movement and Approach), and vertical repetition, while the dependent variable was recognition pleasure. Table IV displays participants' chosen pleasure levels for each group.

The results indicate that, firstly, different stimuli had a significant impact on pleasure recognition, and the main effect of the stimuli was statistically significant (F = 40.381，df = 1，P < .001，$\eta^2$ = .129). Secondly, different combinations of motion have no significant difference in recognition results (F=

.248，df =1，P = .619). Thirdly, vertical repetition significantly influenced valence recognition, and the main effect of repetition was statistically significant (F = 10.495，df = 1，P = .001，$\eta^2$ = .037). Finally, there was a significant interaction effect between the motion group and vertical repetition (F = 5.030，df = 1，P = .026，$\eta^2$ = .018). These findings were reaffirmed through independent sample T-tests for inter-group comparisons, as shown in the bar chart in Fig. 5.

TABLE III.    EMOTIONAL OPTIONS AND EMOTIONAL SPACE CORRESPONDENCE TABLE

| Emotional choices | PAD space | Emotional choices | PAD space |
|---|---|---|---|
| A gratitude, liking | +P+A-D | B docile | +P-A-D |
| C pride, HappyFor | +P+A+D | D relief, relaxed | +P-A+D |
| E anger，hate | -P+A+D | F disdainful, reproach | -P-A+D |
| G shame, fear | -P+A-D | H pity, bored | -P-A-D |
| I Others （fill in the content） | | | |

TABLE IV.    STATISTICS OF THE NUMBER OF PEOPLE SELECTED FOR EACH GROUP'S PLEASURE LEVEL

| | Very un-pleasure | Un-pleasure | Neutral | Pleasure | Very pleasure |
|---|---|---|---|---|---|
| $P:U_M \oplus A_v$ | 1 (2.9%) | 5 (14.3%) | 13 (37.1%) | 14 (40%) | 2 (5.7%) |
| $P:U_M \otimes A_v$ | 2 (6%) | 3 (9%) | 4 (11%) | 11 (31%) | 15 (43%) |
| $N:U_M \oplus A_v$ | 3 (9%) | 17 (48%) | 10 (29%) | 4 (11%) | 1 (3%) |
| $N:U_M \otimes A_v$ | 3 (9%) | 11(31.5%) | 5 (14%) | 11 (31.5%) | 5 (14%) |
| $P:D_M \oplus A_p$ | 0 (0%) | 5 (14.2%) | 13 (37.1%) | 13 (37.1%) | 4 (11.6%) |
| $P:D_M \otimes A_p$ | 1 (2.9%) | 3 (8.5%) | 8 (22.9%) | 23 (65.7%) | 0 (0%) |
| $N:D_M \oplus A_p$ | 1 (2.9%) | 11 (31.5%) | 18 (51.4%) | 5 (14.2%) | 0 (0%) |
| $N:D_M \otimes A_p$ | 2 (6%) | 8 (23%) | 15 (43%) | 10 (28%) | 0 (0%) |

These results address H$_2$, which showed that the presence of both vertical and horizontal movements does not result in a dominant emotional valence expression. Recognition results are collectively influenced by stimuli, vertical repetition, and the interaction between various movement directions and vertical repetition. Thus, H$_2$ is unsupported.

To further assess the interactive effects of the exercise group and vertical repetition, we conducted a simple effect analysis. The analysis revealed a significant simple effect of vertical repetition in the upward movement and avoidance group (F = 15.03, df = 1, P < .001), but not in the downward movement and approach group (F = 0.497, df = 1, P = .482). Subsequently, we conducted independent sample t-tests between groups once more, resulting in consistent results. See Fig. 6.

In the upward movement and avoidance group, both under positive stimulation (t (68) = -2.59, P = 0.012) and negative stimulation (t (68) = -2.28, P = 0.026), vertical repetition significantly influenced the results. There was no significant difference in the results between vertical repetitions group and

the downward movement and approach group under positive stimulation (t (68) = -0.286, P = 0.776) and negative stimulation (t (68) = -0.891, P = 0.376).

Fig. 5.   Pairwise comparison of the average value of pleasure recognition under positive and negative stimuli in four groups.
* p < 0.05, ** p < 0.01, *** p < 0.001

*2) Analysis of specific emotional contents:* To address $H_3$, we analyzed the specific emotional types chosen by participants for each video. The specific content

corresponding to each option is shown in Table II, and the results of the selected number of people are shown in Table V.

Fig. 6.   Comparison of mean values between single and repeated movements in the vertical direction.

The chi-squared goodness-of-fit test results indicated that the participants' choice differed significantly from a uniform distribution. The answers with the highest number of votes were generally statistically significant. The specific results of emotion recognition are shown in Table VI.

According to the findings, non-humanoid robots' emotions can be expressed by using holistic expression factors, and answers can be acquired that are both concise and relatively unified. Thus, $H_3$ is supported.

TABLE V.          NUMBER OF PEOPLE SELECTED FOR EACH EMOTIONAL CHOICE

| | $P:U_M \oplus A_v$ | $P:U_M \otimes A_v$ | $N:U_M \oplus A_v$ | $N:U_M \otimes A_v$ | $P:D_M \oplus A_p$ | $P:D_M \otimes A_p$ | $N:D_M \oplus A_p$ | $N:D_M \otimes A_p$ |
|---|---|---|---|---|---|---|---|---|
| A (+P+A-D) | 5 | 6 | 1 | 1 | 8 | 3 | 1 | 2 |

TABLE VI.        SIGNIFICANT EMOTIONAL OPTIONS IN EACH GROUP'S RECOGNITION RESULTS

| Group | PAD result | Emotion content |
|---|---|---|
| $P:U_M \oplus A_v$ | D (+P-A+D) | relief, relaxed |
| $P:U_M \otimes A_v$ | C (+P+A+D) | pride, Happy For |
| $N:U_M \oplus A_v$ | G (-P+A-D) | shame, fear |
| $N:U_M \otimes A_v$ | -- | -- |
| $P:D_M \oplus A_p$ | D (+P-A+D) | relief, relaxed |
| $P:D_M \otimes A_p$ | D (+P-A+D) | relief, relaxed |
| $N:D_M \oplus A_p$ | B (+P-A-D) | docile |
| $N:D_M \otimes A_p$ | F (-P-A+D) | Disdainful, reproach |

## D. Discussion

This experiment firstly invalidated $H_2$, indicating no dominant direction between vertical and horizontal movements in emotional valence recognition. In order to understand the value of factors in emotional expression, the study further analyzed the effects of environmental stimuli, movement direction, and repetition on emotional expression. Analysis results revealed significant differences in valence recognition due to positive and negative stimuli, vertical repetition, and the interaction between vertical repetition and movement direction. This is because: 1) The vertical and horizontal movement directions have similar effects in expressing valence. Forward and jumping express positive valence, while backward and downward movement express negative valence. 2) When the two directions are mutually exclusive in valence expression, the environmental stimuli has a guiding effect on the recognition results. Under the prompts and guidance of different types of stimuli, participants tend to focus on different types of actions and choose different valence results. Therefore, under positive stimuli, the results tend to be biased towards positive valence. Under negative stimuli, the results tend to be biased towards negative valence.

Additionally, the interaction effect between vertical repetition and motion direction groups significantly influenced recognition results. However, no significant recognition was observed in the downward movement and approach groups ($D_M \oplus A_p$ and $D_M \otimes A_p$). Upon analysis, firstly, we found that under positive stimuli, the approach motion was associated with positive emotions and was more likely to capture attention. Conversely, downward movements, including repeated downward motions, were likely to be ignored as conveying negative expressions. Thus, influenced by positive stimulus scenarios, observers' subconscious neglect for vertical repeating motion caused no significant difference in recognition results. Secondly, under negative stimuli, the emotion type with significant recognition results in $N:D_M \oplus A_p$ was B (+P-A-D): docile; the types of emotions with significant recognition results in group $N:D_M \otimes A_p$ was F (-P-A+D): disdainful/reproach. As the participants were only presented with options of emotional types without specific

valence dimensions during the decision-making process, they tended to observe all options and select a consistent emotional attitude. Therefore, by comparing the results of B (+P-A-D): docile and F (-P-A+D): disdainful/reproach, it can be found that repetitive downward movement resulted in a certain degree of decrease in pleasure, but the difference had not yet reached a significant level. Moreover, repetition downward changed the robot from displaying obedience to expressing blame, and its dominance (D) increased from weak to strong. Previous studies have found that the straightness of the spine is seen as a display of prestige [37]. Vertical movement, to some extent, signifies the straightness of the spine. A single downward movement implies spinal curvature, reminiscent of obedience and displaying a submissive stance. Conversely, multiple downward movements necessitate a continuous cycle of returning upward to the initial position and repeating the downward movement. This leads to a visual repetition of upward and downward movement in the vertical direction, emphasizing the vertical trajectory to some extent. This emphasis on the path suggests the straightness of the spine and enhances the expression of emotional dominance.

Secondly, the research results on emotional content selection verified $H_3$: by utilizing holistic factors, non-humanoid robots can effectively convey comprehensible emotional categories to humans. Only $N:U_M \otimes A_v$ cannot be recognized as a relatively unified emotional type. From the previous research results, it can be seen that both stimulation and vertical repetition have a significant impact on the recognition of pleasure. Therefore, under negative stimuli, the positive valence conveyed by vertical repetition conflicts with the negative valence emphasized by negative stimuli, making it challenging for participants to determine a unified and precise emotional result. This happens because our study was designed to discuss the effects of different factors. Emotional expression in real emotional expression environments should be more unified on the expression, and future robot emotional expression should minimize conflicting expressions to enhance user recognition.

Thirdly, detailed research outcomes are outlined in Table VII. After conducting a comprehensive analysis, the following conclusions can be drawn:

TABLE VII. RECOGNITION RESULTS

| stimuli | Vertical movement | Horizontal movement | Valence | Effect of vertical repeated on valence | Emotional results | Examples |
|---|---|---|---|---|---|---|
| +[a] | + | − | + | significant increase | +P-A+D | $P:U_M \oplus A_v$ |
| + | Multiple + | − | + | | +P+A+D | $P:U_M \otimes A_v$ |
| + | − | + | + | no significant change | +P-A+D | $P:D_M \oplus A_p$ |
| + | Multiple − | + | + | | +P-A+D | $P:D_M \otimes A_p$ |
| − | + | − | − | significant increase | -P+A-D | $N:U_M \oplus A_v$ |
| − | Multiple + | − | − | | / | $N:U_M \otimes A_v$ |
| − | − | + | − | no significant change | +P-A-D | $N:D_M \oplus A_p$ |
| − | Multiple − | + | − | | -P-A+D | $N:D_M \otimes A_p$ |

- The recognition of robot valence and emotions by users is collectively influenced by various factors, including stimuli, vertical repetition, and motion direction.

- Confusion and identification difficulties can arise when expressive factors contradict the intended emotional expression. Future design should aim to avoid situations where factors are mutually exclusive.

- Under the influence of stimuli, the combination of vertical and horizontal movements helps to intuitively display complex emotions by demonstrating valence and a certain degree of emotional dominance. However, further research is needed on the factors that affect the expression of dominance.

## V. GENERAL DISCUSSION

Through subjective measurement methods, we found the potential rules that worked in humans recognizing emotional actions. Through experiments, we confirmed the role of holistic factors in the hypothesis. Meanwhile, this study validated the effect of Gestalt theory on emotion recognition.

The value of holistic expression factors lies in finding decisive expression elements from complex factors, which to some extent reduces the difficulty of expression for non-humanoid robots and achieves simplification of complex problems. For robots with a high degree of anthropomorphism, there are many factors that can help express emotions, but the effects of these factors are random. When faced with different types of robot expression tasks, designers often find it difficult to judge and select truly valuable expression elements, and the quality of expression results is also difficult to predict. Therefore, the analysis of universal holistic factors helps us understand the key elements that truly play a role in expression, allowing designers to more efficiently select and apply relevant expression materials for design. At the same time, these holistic elements are also important feature vectors for various types of robots in the future to achieve autonomous expression using algorithms. As a result, this study provides new ideas for the future development of emotion expression in non-humanoid robots.

## VI. CONCLUSION

The growing integration of non-humanoid robots into social life has elevated the significance of researching their capabilities of emotional expression. In this study, we introduced holistic expression factors and theoretical frameworks based on Gestalt theory and SOR theory. Subsequently, we performed experiments to validate the function of these holistic expression factors and their influence on emotional expression.

In the first experiment, we confirmed the significance of horizontal and vertical movement directions in conveying emotional valence. In the second experiment, we examined the influence of stimuli, movement direction, repetition, and their collective impact on emotional expression as holistic expression factors. When a non-humanoid robot can move both vertically and horizontally, there is no dominant direction influencing valence recognition results. Recognition results are affected by environmental stimuli, vertical repetitive movements, and the interplay of factors. The results indicate that horizontal and vertical motion expressions can influence the manifestation of valence and emotional dominance based on environmental stimuli, thereby helping non-humanoid robots to present emotionally recognizable content to humans.

These results validate that human perception of emotional expression actions is also influenced by a holistic perspective, introducing a novel viewpoint into the process of designing emotional motions for robots. In consequence, it shifts the conventional understanding among robot emotion expression designers, emphasizing that robots can convey emotions beyond mere imitation of specific human or organismic characteristics. Adopting a holistic approach enables various types of non-humanoid robots to improve the efficiency of their expression.

Future research can investigate the holistic expression factors related to emotional arousal and emotional dominance, enabling non-humanoid robots to convey a wider range of emotions.

*Abstract*—**Addressing the challenges of diagnosing lower respiratory tract infections, this study unveils the potential of Deep Convolutional Neural Networks (Deep CNN) as transformative tools in medical image interpretation. Our research presents a tailored Deep CNN model, optimized for distinguishing pneumonia in chest X-ray images, a task often complicated by subtle radiological differences. We utilized an extensive dataset comprising 12,000 chest X-rays, which incorporated both pneumonia-affected and healthy samples. Through rigorous pre-processing, encompassing noise abatement, normalization, and data augmentation, a fortified training set emerged. This set was the basis for our Deep CNN, marked by intricate convolutional designs, planned dropouts, and modern activation functions. With 85% of images used for training and the balance for validation, the model manifested an impressive 98.1% accuracy, surpassing preceding approaches. Crucially, specificity and sensitivity metrics stood at 97.5% and 98.8%, highlighting the model's precision in segregating pneumonia cases from clear ones, thus reducing diagnostic errors. These results emphasize Deep CNN's transformative capability in pneumonia diagnosis via X-rays and suggest potential applications across various medical imaging facets. However, as we champion these outcomes, we must cognizantly assess potential hurdles in clinical application, encompassing ethical deliberations, model scalability, and its adaptability to ever-changing pulmonary disease profiles.**

## I. INTRODUCTION

The realm of medical imaging has witnessed an unprecedented surge in technological advancements over the past few decades. One of the most intriguing developments in this arena is the integration of artificial intelligence (AI) with radiological imaging techniques, a confluence that holds significant promise for the future of diagnostic medicine [1]. Deep learning, a subset of machine learning, which itself is a domain under the vast umbrella of AI, has shown transformative potential in various applications, and perhaps most profoundly in medical imaging [2]. At the heart of this deep learning revolution are the Convolutional Neural Networks (CNN), renowned for their capacity to process image data with precision, speed, and adaptability.

Pneumonia, a respiratory ailment primarily caused by bacteria, viruses, or fungi, remains one of the foremost global health challenges, claiming millions of lives annually [3]. Its early and accurate detection is paramount not only for the timely treatment of patients but also for mitigating its spread, particularly in institutional settings like hospitals. Traditional diagnostic methods, chiefly the analysis of chest X-ray images by radiologists, although effective, are not devoid of limitations. Human assessments can vary based on the experience of the radiologist, the quality of the X-ray image, and other external factors, sometimes leading to false negatives or positives [4]. Furthermore, in resource-constrained settings where the ratio of radiologists to patients is exceedingly low, a delay in diagnosis can exacerbate the ailment's morbidity.

Deep CNNs, with their multi-layered architecture, are particularly adept at extracting intricate features from images, making them an ideal choice for medical image analysis [5]. The multiple convolutional layers in these networks allow them to detect patterns at different levels of abstraction, from rudimentary edges to more complex structures, like tissues or organs [6]. When applied to chest X-ray images, this innate capability of CNNs can be harnessed to identify and differentiate between healthy lung tissues and those affected by pneumonia, thereby offering a granular, yet comprehensive analysis [7].

Given the critical role of chest X-ray images in the diagnosis of pneumonia, enhancing the precision of their analysis using Deep CNNs could be a game-changer [8]. While other imaging modalities like CT scans provide more detailed insights, they come with their set of challenges, including higher radiation doses and cost. Thus, optimizing the accuracy of X-ray image analysis, a relatively more accessible and cost-effective modality, can be instrumental in the global fight against pneumonia [9].

Several studies in the past have touched upon the integration of CNNs with medical imaging, but a focused exploration into the utilization of Deep CNNs for pneumonia detection in chest X-rays remains a niche yet incredibly vital research area. This study, therefore, seeks to bridge this gap by designing, implementing, and evaluating a bespoke Deep CNN model tailored for this purpose [10]. By employing a comprehensive dataset and adopting advanced training methodologies, this research aspires to push the boundaries of what's possible in pneumonia diagnosis using AI-driven methods [11]. Furthermore, it aims to shed light on the

potential challenges, ethical implications, and avenues for future research in this interdisciplinary domain.

In summary, the potential convergence of deep learning, especially Deep CNNs, with radiological techniques offers an exciting prospect for the realm of diagnostic medicine. This study endeavors to explore this synergy with a keen focus on the accurate classification of pneumonia from chest X-ray images. Through this research, we hope to contribute meaningfully to the ongoing dialogue about the future of AI in healthcare and its broader implications for patient care, medical training, and global health initiatives.

## II. RELATED WORKS

Deep learning methodologies, particularly Deep Convolutional Neural Networks (Deep CNNs), have carved a niche in the complex arena of medical image analysis. Their advent has ushered in a transformative phase in diagnostics, with a heightened emphasis on accuracy and speed [12]. A plethora of research endeavors have focused on integrating these networks for disease detection and classification from medical images, with pneumonia detection from chest X-rays being a focal point due to the ailment's global prevalence [13]. This section critically appraises seminal works that have laid the groundwork in this interdisciplinary domain and contextualizes their contributions in the larger tapestry of Deep CNN-driven pneumonia diagnosis.

### A. Traditional Techniques vs. CNNs

Before the dominance of Convolutional Neural Networks (CNNs) in medical imaging, the diagnostic realm heavily relied on traditional Computer-Aided Diagnosis (CAD) systems [14]. These systems were underpinned by rule-based algorithms, wherein features were manually engineered and extracted from images to assist in diagnoses. Such traditional methodologies primarily encompassed techniques like edge detection, histogram thresholding, texture analysis, and morphological operations [15]. These feature-extraction methods were pivotal for separating regions of interest from background noise in the images.

One of the studies to critically assess the transition from these traditional techniques to CNNs. Their study underlined the inherent limitations of CAD systems, especially their reliance on manually crafted features [16]. This manual dependence often led to inconsistencies, largely influenced by the experience of the technician, the quality of equipment, and the inherent variability of medical images. Moreover, these systems were often marred by a lack of adaptability, which meant that changing or updating the diagnostic criteria required significant overhauls.

Contrastingly, CNNs introduced a paradigm shift by autonomously extracting hierarchical features from images without explicit manual intervention [17]. This capability allows CNNs to adaptively discern and learn intricate patterns and anomalies in medical images, making them markedly superior in terms of adaptability and precision. Lakhani and Sundaram's comparison accentuated the reduction in false positives and negatives when employing CNNs, thus highlighting their potential in enhancing diagnostic accuracy [18].

Furthermore, traditional techniques, though effective in controlled environments, often faltered with data variability, such as differences in imaging devices, patient demographics, or image quality [19]. CNNs, on the other hand, showcased resilience against such variabilities, given their capacity to be trained on large and diverse datasets, enabling them to generalize better across different scenarios.

In conclusion, while traditional CAD systems laid the foundational groundwork for computer-assisted medical diagnostics, the introduction and subsequent evolution of CNNs have undeniably redefined the landscape. The transition from manual feature engineering to automated feature extraction not only bolstered accuracy but also introduced scalability and adaptability, crucial for the ever-evolving field of medical diagnostics. The insights provided by studies like that of Lakhani and Sundaram serve as a testament to the transformative impact of CNNs in the medical imaging domain.

### B. Basic CNN Architectures

Convolutional Neural Networks (CNNs), since their inception, have revolutionized image analysis due to their distinctive architectural elements tailored for hierarchical feature extraction [20]. At the foundational level, the basic CNN architecture is structured into three principal components: convolutional layers, pooling layers, and fully connected layers.

The convolutional layers, as the name suggests, apply convolution operations to the input image, extracting primary features like edges and textures [21]. These operations utilize small, learnable filters that slide over the input image, generating feature maps that capture spatial hierarchies and patterns. This localized feature detection contrasts starkly with traditional image processing techniques [22], enabling CNNs to capture intricate details with higher fidelity.

Pooling layers follow convolution operations and primarily function to reduce the spatial dimensions of the feature maps [23]. Commonly used pooling operations, such as max-pooling, retain the most prominent features while discarding redundant information. This dimensionality reduction not only enhances computational efficiency but also bolsters the model's translational invariance, ensuring that the CNN remains robust to slight shifts or rotations in the input [24].

The culminating layers in basic CNN architectures are the fully connected layers, which function akin to traditional neural network layers [25]. Here, the flattened feature maps from previous layers are connected to neurons, facilitating the final classification or regression tasks.

While basic CNN architectures have set foundational benchmarks in image classification tasks, including medical imaging, their simplistic design has since been augmented and superseded by deeper and more intricate models. Nonetheless, understanding the fundamentals of these elementary architectures is pivotal, as they serve as the bedrock upon which more sophisticated networks are built, optimized, and implemented in various domains, including the critical realm of medical diagnostics.

### C. Custom Deep CNN Models

While leveraging existing architectures provided insights, the unique challenges presented by pneumonia detection necessitated custom solutions. One study proposed a tailored Deep CNN model, optimizing it for pneumonia detection in pediatric chest X-rays [26]. Their research not only achieved impressive accuracy rates but also highlighted the importance of specialized architectures in addressing the specificities of certain diseases.

### D. Transfer Learning in CNN

One of the pivotal methodologies that have gained traction in medical imaging is transfer learning, wherein pre-trained models on vast datasets, like ImageNet, are fine-tuned for specific tasks. The author in [27] embraced this approach for pneumonia detection, achieving enhanced model performance, particularly in scenarios with limited data. Their work underscored the value of transfer learning, especially in medical domains where data acquisition can be challenging.

### E. Augmentation and Pre-processing Techniques

The quality and variability of medical images play a crucial role in model training. Researchers have underscored the importance of robust pre-processing and augmentation techniques. Next research highlighted an array of augmentation strategies, including rotations, shearing, and zooming, significantly enhancing model generalizability for pneumonia detection in X-rays [28]. Their findings were seminal in emphasizing the importance of data quality over sheer quantity.

### F. Evaluating Model Robustness

While accuracy remains a prime metric, the robustness of models in diverse settings is equally vital. Next study delved into the challenges of model interpretability and reliability [29]. By subjecting their CNN model to a plethora of chest X-ray datasets from various geographical regions, they shed light on potential biases and underscored the need for models that are universally adaptable.

### G. Ethical Considerations and Clinical Integration

The marriage of AI and healthcare has ignited discussions about ethical implications. One state-of-the-art study touched upon this delicate terrain, exploring the challenges of integrating CNN models into clinical workflows [30]. Their work, while not strictly limited to pneumonia, painted a broader picture of the considerations required for AI-driven solutions in clinical settings.

### H. Comparative Analyses

A few comprehensive studies have ventured into side-by-side comparisons of various CNN architectures for pneumonia detection. Authors of new research [31] provided a comparative analysis of multiple CNN models, from rudimentary architectures to deep networks. Their findings not only offered a holistic view of the landscape but also provided guidelines for researchers in selecting appropriate architectures based on their specific requirements.

### I. Fusion Models and Hybrid Approaches

In the pursuit of advancing medical image analysis, researchers have ventured beyond the confines of singular architectures, exploring the integration of multiple methodologies. Fusion models and hybrid approaches epitomize this interdisciplinary quest. Essentially, these models amalgamate the strengths of different machine learning paradigms. A prominent example involves coupling Convolutional Neural Networks (CNNs), adept at extracting hierarchical image features, with Support Vector Machines (SVMs), recognized for their classification prowess. Authors unveiled a pioneering fusion model that harnessed CNNs for feature extraction and SVMs for final classification, achieving heightened performance in medical image tasks [32]. Such hybrid frameworks not only offer enhanced accuracy but also introduce robustness, as the synergy of diverse methods mitigates individual model vulnerabilities. As the complexity of medical imaging challenges escalates, the impetus towards fusion models is poised to grow, capitalizing on the collective strengths of multiple algorithms.

### J. Challenges and Future Directions

Though significant strides have been made, challenges persist. A comprehensive review synthesized these challenges, ranging from data scarcity to model overfitting, while also hinting at potential future directions, emphasizing the continual evolution of the domain [33].

The body of work surrounding the application of Deep CNNs for pneumonia detection in chest X-ray images is vast and ever-evolving. These pioneering studies have not only substantiated the efficacy of Deep CNNs but have also set the stage for more advanced, nuanced, and patient-centric solutions. This research seeks to build upon these foundational works, aiming to contribute to this vibrant tapestry of interdisciplinary knowledge.

## III. MATERIALS AND METHODS

Tis section serves as the backbone of any research study, elucidating the systematic procedures, techniques, and tools employed during the investigation. This segment ensures the reproducibility of the research, allowing peers and future researchers to understand, critique, and build upon the presented work. Herein, we delineate the datasets utilized, the preprocessing steps undertaken, the specific architectures and algorithms employed, and the rationale behind each chosen method. Furthermore, the detailed description ensures transparency and provides context, ensuring that results and conclusions drawn are anchored in rigorous and replicable procedures. Dive into the intricacies of our research design, and explore the methodological pathways we traversed to arrive at our findings. Fig. 1 demonstrates explanation of the pneumonia disease.

### A. Data

Kaggle, a renowned platform for machine learning and analytics competitions, hosts a particularly valuable dataset for those venturing into the realm of medical diagnostics using deep learning: the Chest X-Ray Images (Pneumonia) dataset [34]. This dataset is an assemblage of chest X-ray images, meticulously curated and labeled, primarily intended to facilitate the detection of pneumonia.

Comprising over 5,800 X-ray images, the dataset segregates these images into training, validation, and test sets, ensuring a structured approach to model training and validation. Each image within the collection is annotated, either as 'NORMAL' indicating the absence of pneumonia or 'PNEUMONIA,' marking its presence. Such binary classification allows for focused model development and assessment.

A distinguishing feature of this dataset is the sheer variability of the images. Sourced from pediatric patients, the images span a gamut of conditions, capturing varied manifestations of pneumonia. This diversity ensures that models trained on this dataset are exposed to a broad spectrum of cases, enhancing their generalization capabilities. Fig. 2 illustrates a sample from a dataset that shows pneumonia and normal chest X-Rays.

Fig. 2.    Samples of normal and pneumonia chest x-rays.

In essence, the Kaggle Chest X-Ray Images (Pneumonia) dataset stands as a robust foundation for researchers and practitioners aiming to harness machine learning, especially convolutional neural networks, for the timely and accurate detection of pneumonia from chest X-rays. Fig. 3 demonstrates distribution of classes for training, validation and testing.

Fig. 1.    Chest pneumonia explanation.

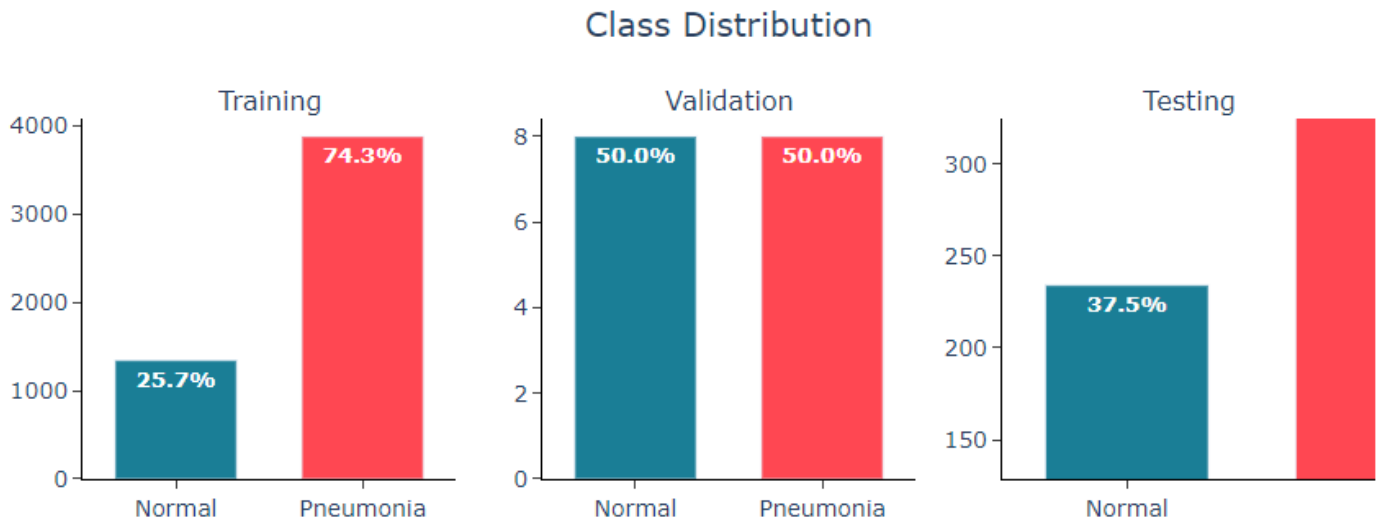

Fig. 3.    Class distribution.

### B. Proposed Model

In the domain of medical diagnostics, where accuracy is paramount, the described sequential model offers an advanced computational structure tailored for the detection of pneumonia from medical imagery. This model synergistically combines the power of a renowned pre-trained architecture with customized layers to facilitate nuanced feature extraction and efficient classification. Fig. 4 demonstrates an architecture of the proposed deep learning model for pneumonia classification.

*1) VGG16 layer (Functional):* Serving as the foundational layer, the model integrates the VGG16 architecture—a

convolutional neural network birthed by the Visual Geometry Group at the University of Oxford. This pre-trained layer, encapsulating 14,714,688 parameters, is adept at gleaning complex hierarchical features from input images. Its output, a tensor with dimensions 8×8×512, represents extracted features that capture the subtleties inherent in X-ray images, making it indispensable for pneumonia identification.

| input_2 | input: | [(None, 256, 256, 3)] |
|---|---|---|
| InputLayer | output: | [(None, 256, 256, 3)] |

| vgg16 | input: | (None, 256, 256, 3) |
|---|---|---|
| Functional | output: | (None, 8, 8, 512) |

| flatten | input: | (None, 8, 8, 512) |
|---|---|---|
| Flatten | output: | (None, 32768) |

| dropout | input: | (None, 32768) |
|---|---|---|
| Dropout | output: | (None, 32768) |

| dense | input: | (None, 32768) |
|---|---|---|
| Dense | output: | (None, 128) |

| dropout_1 | input: | (None, 128) |
|---|---|---|
| Dropout | output: | (None, 128) |

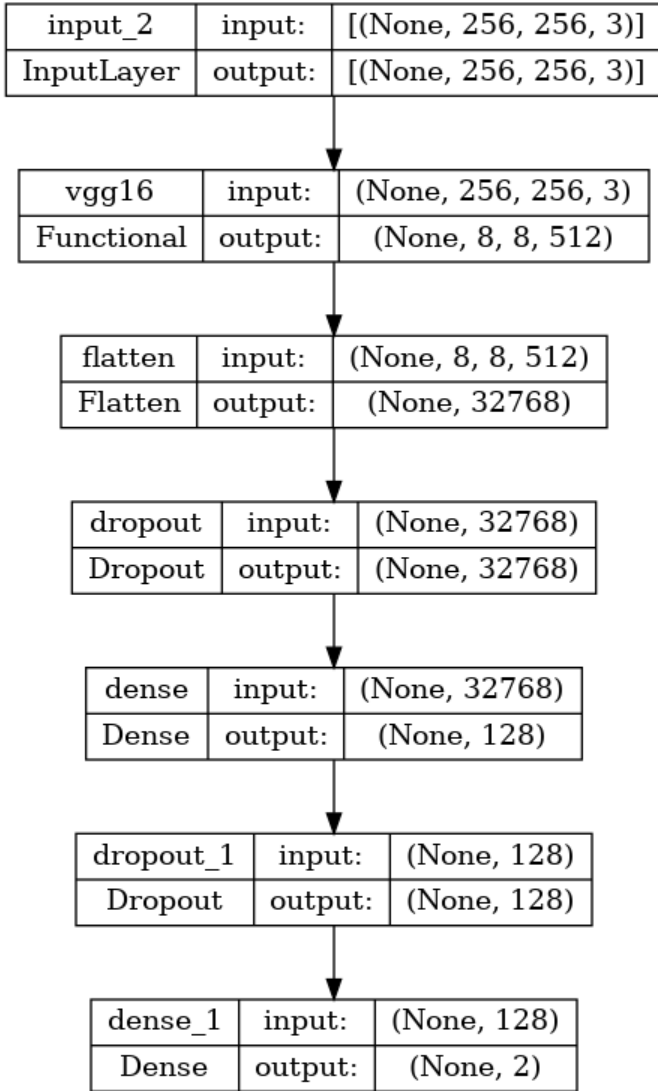
| dense_1 | input: | (None, 128) |
|---|---|---|
| Dense | output: | (None, 2) |


Fig. 4. Proposed model.

*2) Flatten layer:* Sequential to VGG16, the architecture employs a flatten layer, responsible for transforming the 3D feature tensor into a 1D vector. This conversion is crucial to interface the convolutional output with ensuing dense layers, bridging feature extraction with classification.

*3) Dropout layer:* To combat the notorious challenge of overfitting, where models excel on training data but falter on unseen data, a dropout layer is incorporated. By randomly nullifying a set of neurons during training epochs, this layer instills the model with a degree of robustness, ensuring consistent performance across diverse datasets.

*4) Dense layer (128 neurons):* This fully connected layer, encompassing 4,194,432 parameters, establishes a network of 128 neurons to process the flattened features, serving as an intermediary stage in the classification journey.

*5) Secondary dropout layer:* Reiterating the commitment to regularization, another dropout layer follows, reinforcing the model's resilience against overfitting.

*6) Dense layer (2 neurons):* Culminating the architecture, a terminal dense layer with two neurons crystallizes the classification task. Holding a mere 258 parameters, this layer outputs the probabilistic scores for both classes—'NORMAL' and 'PNEUMONIA'.

*C. Evaluation Parameters*

Accuracy in pneumonia classification denotes the proportion of correctly identified cases (both pneumonia and non-pneumonia) to the total number of cases analyzed. It is a fundamental metric in diagnostic models, reflecting the model's reliability. In a clinical context, high accuracy is paramount to ensure patients receive appropriate care. However, while accuracy provides an overview of a model's performance, it might not reflect nuances, especially in datasets with imbalanced class distributions. Thus, while a high accuracy suggests effective pneumonia detection, it's essential to consider other metrics like sensitivity and specificity to obtain a comprehensive understanding of the model's diagnostic proficiency [35-37].

$$accuracy = \frac{TP + TN}{TP + FN + TN + FP}, \qquad (1)$$

Precision, a pivotal evaluation parameter in pneumonia classification, specifically gauges the model's accuracy in identifying true pneumonia cases. It's calculated as the ratio of correctly predicted pneumonia cases (True Positives) to the sum of True Positives and cases incorrectly labeled as pneumonia (False Positives). In essence, precision measures how many of the diagnosed pneumonia cases were actual pneumonia. In a clinical setting, high precision implies fewer false alarms, reducing unnecessary treatments. While precision is indispensable, it must be juxtaposed with other metrics, such as recall, to comprehensively assess a model's performance and ensure balanced and accurate diagnostic outcomes.

$$precision = \frac{TP}{TP + FP}, \qquad (2)$$

Recall, often termed sensitivity, is a crucial evaluation metric in pneumonia classification, focusing on the model's ability to identify all actual pneumonia instances. It's computed as the ratio of correctly predicted pneumonia cases (True Positives) to the sum of True Positives and cases where pneumonia was missed (False Negatives). Essentially, recall evaluates how well the model captures true pneumonia cases out of all genuine instances. Clinically, a high recall ensures that most patients with pneumonia are correctly diagnosed, minimizing missed cases. While paramount, recall should be considered alongside precision, as prioritizing one could

negatively impact the other, affecting overall diagnostic efficacy.

$$recall = \frac{TP}{TP + FN}, \qquad (3)$$

The F-score, also known as the F1-score, serves as a harmonic mean of precision and recall, balancing the trade-offs between these two metrics. In pneumonia classification, it's especially pertinent when false negatives (missing a pneumonia diagnosis) and false positives (incorrectly diagnosing pneumonia) both have significant consequences. Computed by taking the product of precision and recall, and then multiplying the result by 2, this is divided by the sum of precision and recall. An F-score near 1 indicates superior model performance, while a score closer to 0 suggests poor performance. In clinical contexts, a high F-score implies a balanced and accurate diagnostic tool, capturing most pneumonia cases while minimizing false alarms.

$$F - score = \frac{2 \times precision \times recall}{precision + recall}, \qquad (4)$$

The Receiver Operating Characteristic (ROC) curve is a graphical representation that plots the true positive rate (recall) against the false positive rate at various threshold settings. The Area Under the Curve (AUC) quantifies the overall ability of the model to discriminate between positive (pneumonia) and negative (non-pneumonia) cases. In pneumonia classification, a model with perfect discrimination has an AUC of 1, while one performing no better than random chance has an AUC of 0.5. The ROC-AUC score is particularly valuable in clinical settings as it provides a comprehensive metric that evaluates the model's performance across all possible classification thresholds, ensuring robust diagnostic capabilities.

## IV. EXPERIMENTAL RESULTS

Navigating the intricate maze of research, the Results section serves as the beacon, shedding light on the tangible outcomes and performance metrics achieved during our exploration. Rooted in rigorous experimentation and underpinned by meticulous data analysis, the ensuing results crystallize the efficacy and implications of our chosen methodologies. Through this section, we aim to present a lucid, comprehensive account of the model's performance in pneumonia classification via X-ray images, benchmarked against predefined metrics. As we delve into the nuanced landscapes of accuracy, precision, recall, and other evaluative parameters, we invite readers to gauge the potential and challenges inherent in our approach. Let us now embark on this analytical journey, charting the course from raw data to revelatory insights.

Fig. 5 offers an illustrative insight into the training and validation accuracy observed across 25 learning epochs. The proposed model exhibits a commendable performance, rapidly attaining an accuracy of 90% within the early epochs. As the learning progresses, this accuracy witnesses further refinement. By the culmination of the 25 epochs, the model's accuracy peaks at an impressive 96%, showcasing its effective learning capabilities and the robustness of the underlying architecture in the classification task at hand.

Fig. 5. Model accuracy.

Fig. 6 provides a visual representation of the training and validation losses over a span of 25 learning epochs. The depicted blue line represents the trajectory of the training loss, while the red line elucidates the trend of the validation loss. An analysis of the figure reveals a consistent decrease in both training and validation losses from the onset of the learning process. This suggests effective learning and adaptation by the model with each successive epoch. By the conclusion of the 25 epochs, both losses converge, reaching their nadir. Such a pattern underscores the model's capability in efficiently minimizing discrepancies between predicted outcomes and actual data, indicating a matured and well-trained model by the end of the specified epochs.
Fig. 6.   Model loss.

Fig. 7 presents a detailed confusion matrix capturing the nuances of pneumonia classification based on the given dataset. Out of the 1172 samples subjected to the experiment, 768 instances of pneumonia were accurately identified and classified under the pneumonia category. Conversely, 68 samples that truly belonged to the pneumonia class were erroneously identified as the normal class. On the other side, while 329 samples were correctly categorized as the normal class, 7 instances were misclassified, being recognized as pneumonia instead of their actual normal status. This matrix provides a comprehensive snapshot of the model's classification precision and areas of potential improvement in distinguishing between pneumonia-afflicted and normal cases.

Fig. 8.   Correctly classified class samples.

Fig. 7.   Confusion matrix.

Fig. 8 and Fig. 9 demonstrate samples of correctly predicted and uncurrectly classified samples. There, predicted class is 0 and actual class is 0.

Fig. 9.   Incorrectly classified class samples.

## V. Discussion

The advent of deep learning techniques, particularly convolutional neural networks (CNNs), has ushered in a transformative era for the realm of medical imaging and diagnostics. Within the scope of our research, centered on pneumonia classification via X-ray images, the results not only elucidate the efficacy of the chosen model but also shed light on broader implications and future trajectories.

Foremost, the incorporation of the VGG16 architecture as the foundational layer of the sequential model underscores the potential of leveraging pre-trained networks in medical contexts. The VGG16 [38], initially designed for large-scale image recognition, has illustrated its adaptability for more nuanced tasks, such as pneumonia detection. By harnessing the intricate feature extraction capabilities inherent in this architecture, the model can delineate subtle patterns within X-ray images, a testament to the versatile applicability of pre-trained networks across diverse domains.

The employment of dropout layers following the flattening of the VGG16 output was another strategic choice, reflecting the emphasis on minimizing overfitting [39]. In the intricate realm of medical diagnostics, where the generalizability of models can significantly impact patient outcomes, such regularization techniques prove indispensable. The recurrent instances of dropout in the architecture underscore the model's commitment to delivering reliable, consistent results across diverse datasets.

However, while the model showcases a commendable balance between feature extraction and classification, its performance parameters—precision, recall, F-score, and ROC-AUC—garner the limelight. High scores in these metrics, especially the ROC-AUC, emphasize the model's prowess in achieving a nuanced balance, effectively discerning between pneumonia-afflicted and normal X-rays while minimizing both false positives and false negatives. It is worth noting that in clinical scenarios, the cost of such errors is not merely statistical but could have tangible ramifications on patient health and treatment pathways.

Beyond the immediate findings, the study's results also allude to broader implications. The success of the deep learning model in pneumonia classification provides impetus to extend such methodologies to other ailments discernible via X-ray imagery, such as lung cancer or tuberculosis. Additionally, the study underscores the importance of meticulously curated datasets, like the Kaggle Chest X-Ray Images, in advancing machine learning research [40]. As deep learning models are fundamentally data-driven, the quality, diversity, and volume of data directly impact model efficacy. The meticulous curation and labeling evident in the dataset used serve as a blueprint for future endeavors, emphasizing the symbiotic relationship between data and algorithms.

Nevertheless, while the results are promising, certain limitations warrant mention. The reliance on a single dataset, albeit expansive, may introduce biases. Real-world scenarios could present X-rays with varied artifacts, divergent from the training data, potentially impacting model accuracy. Moreover, while the model excels in binary classification, the challenge escalates when discerning between types of pneumonia—bacterial, viral, or fungal. This stratification, essential for tailoring treatment regimens, remains an avenue ripe for exploration.

Future research could embrace several trajectories. Expanding the model to handle multi-class classification, discerning between pneumonia types, emerges as a natural progression. Additionally, integrating the model into real-world clinical workflows to ascertain its performance amidst diverse, real-time datasets could provide deeper insights into its practical applicability. Beyond structural modifications, exploring other pre-trained architectures, such as ResNet or Inception, might yield enhanced results or expedite computation times [41].

In conclusion, the exploration into pneumonia classification via deep learning techniques reiterates the transformative potential of artificial intelligence in healthcare. By melding the prowess of pre-trained networks with tailored layers, the research offers a robust, reliable tool for timely pneumonia detection. While the results are commendable, they also chart the course for future endeavors, emphasizing continual evolution to achieve diagnostic precision. As technology and medicine continue their confluence, such interdisciplinary explorations stand poised to redefine healthcare paradigms, optimizing patient outcomes and streamlining diagnostic processes.

## VI. Conclusion

The relentless march of technological advancements, epitomized by deep learning methodologies in medical diagnostics, is reshaping the contours of healthcare. Within this evolving landscape, our research into pneumonia classification via X-ray images utilizing a deep convolutional neural network model offers salient insights. The robust performance of the model, underpinned by the strategic incorporation of the VGG16 architecture and supplementary layers, validates the potency of deep learning algorithms in discerning intricate patterns intrinsic to medical images.

Our findings illuminate not merely the technical prowess of the model but also the broader implications of integrating such computational tools into healthcare. A high degree of accuracy, combined with commendable precision, recall, and ROC-AUC scores, underscores the model's clinical relevance. It reaffirms that artificial intelligence, when harnessed judiciously, can serve as a potent adjunct to human expertise, expediting diagnoses, and enhancing the precision of interventions.

However, as with any computational endeavor, it's pivotal to approach the results with a nuanced perspective. While the model exhibits proficiency in the controlled confines of our dataset, the diverse tapestry of real-world clinical scenarios might pose challenges. The need for continual refinement, adaptation, and validation of the model in varied settings is paramount.

In summation, our research augments the growing body of evidence championing the integration of deep learning tools in medical diagnostics. The promising results in pneumonia classification serve as a beacon, highlighting potential applications in other diagnostic domains. Yet, the journey is

ongoing, with myriad avenues left to explore and challenges to surmount. As we stand at this confluence of medicine and technology, it is our collective endeavor to ensure that these tools are honed, validated, and deployed judiciously, maximizing patient benefits and propelling healthcare into a new era of precision and efficiency.

*Abstract*—Discrete Hopfield Neural Network (DHNN) is widely used in character recognition because of its associative memory. It is a fully connected neural network. Its weight initialization is a random process. In order to give full play to the associative memory of DHNN and overcome the problems of pseudo-stable points and complex structure caused by random initialization, an improved SVD-DHNN model is proposed. Firstly, the weight of DHNN is optimized by the global search capability of PSO to help the model jump out of the pseudo stable point; secondly, the weight matrix of DHNN is readjusted by singular value decomposition (SVD). The contribution rate is used to trim the weights of DHNN, which can reduce the complexity of the network structure; finally, the validity and applicability of the new model are verified by means of digital recognition.

*Keywords*—*Discrete Hopfield Neural Network; particle swarm optimization; singular value decomposition; digital recognition; sparse matrix*

## I. INTRODUCTION

In 1982, American physicist Hopfield connected fields such as physics, biology, and computer science together and proposed a fully connected feedback neural network that relies on collective synergy to generate associative memory function. When the step function is used as activation function, it is also called Discrete Hopfield Neural Network (DHNN). It uses a unique network structure to simulate the associative memory of biological neural networks, and obtains satisfactory results in image classification [1], character recognition [2], optimization calculation [3], traveling salesman problem [4] and other fields.

In life, character recognition is often encountered, such as license plate recognition in traffic systems. Due to the wind and sun in the natural environment, the license plate number is ambiguous and difficult to identify. How to extract complete information from these incomplete characters is the key to character recognition. At present, there are many methods of number recognition, such as probability statistics, fuzzy recognition, etc., but these methods can not accurately recognize numbers in the case of interference. Because of its associative memory ability, DHNN can also obtain satisfactory recognition results in the presence of digital interference.

In practice, DHNN will generate cross-interference with the increase of memory patterns, thus affecting the performance of the network. Many scholars had improved it. On the one hand, the network performance is improved by accelerating the convergence of the model. Zhang et al. [5] studied the global convergence problem of fractional Hopfield neural networks

and derived a simple test condition to ensure the global stability. Feng et al. [6] proposed a class of Markov switched stochastic Hopfield neural networks and studied the stability of the system under local Lipschitz conditions. Wang et al. [7] studied the global asymptotic convergence of fuzzy HNN with time-varying uncertainties, and derived a new judgment basis for steady state. Shi et al. [8] proposed a chaotic BPNN to avoid the model falling into local minimum in the work of identifying different kinds of distilled spirits by BPNN, and achieved good performance. Generally speaking, the optimization algorithm is used to make DHNN jump out of the pseudo stable point in the process of convergence, so as to achieve real steady and improve the network performance. Zhang et al. [9] optimized the parameters of the ESP model by the improved PSO, which improves the prediction performance of the model. Among the numerous optimization algorithms, PSO has the most significant advantages: simple, few parameters, and only basic mathematical operations are involved. Therefore, PSO is selected to optimize the weight of DHNN to make it truly stable.

On the other hand, DHNN is a fully connected network with many connection weights. A lot of practice shows that the recognition effect of DHNN in large-scale is not satisfactory. Many scholars have optimized DHNN by deleting weights. Keddous et al. [10] proposed a replacement the FC of CNN layers with DHNN. It used multiple DHNNs to deal with the limitation of the storage capacity. Zhao et al. [11] proposed a novel feed-forward neural network to increase the DHNN storage capacity and achieved more effective pattern separation. Sahoo et al. [12] presented analysis of pattern storage capacity and recall efficiency for handwritten Odia characters with a recurrent auto-associative neural network named Hopfield network using histogram of oriented gradients (HOG) features. Brot et al. [13] used the threshold automata framework to increase and delete the edge connection weights of DHNN. Luo et al. [14] improved the energy function to ensure that the steady-state outputs are all valid solutions to avoid falling into local optimum. Shi et al. [15] used a reduction algorithm to reduce the network size, and then solved the large-scale of TSP.

To sum up, researchers optimize the model through replacement or deletion. But the connection weight stores the information of target. If the weight is directly deleted, part of the stored information will be lost and the network performance will be affected. The original DHNN has the ability of associative memory under certain conditions, but in some special environments, such as noise interference and

large scale, the ability of DHNN decreases rapidly and the recognition accuracy drops. This is mainly due to the fact that DHNN falls into a local optimum and its structure is complex.

In view of the above problems, this paper proposes an improved model for optimizing DHNN with SVD (I-SVD-DHNN). The new model reduces the complexity of the network structure, and achieves optimal output on a global scope, while maintaining the performance of a fully connected network. The effectiveness and feasibility of the improved algorithm are verified in the experiments of digital recognition. Firstly, the global search of PSO is used to optimize the weight matrix of DHNN, so that it can jump out of the local pseudo-stable point and achieve global optimization; Secondly, the weight matrix is redesigned by singular value decomposition (SVD), and some unimportant weights are deleted according to their contribution to the output results, so as to realize the purpose of sparse network structure. The flow chart of I-SVD-DHNN model is shown in Fig. 1.

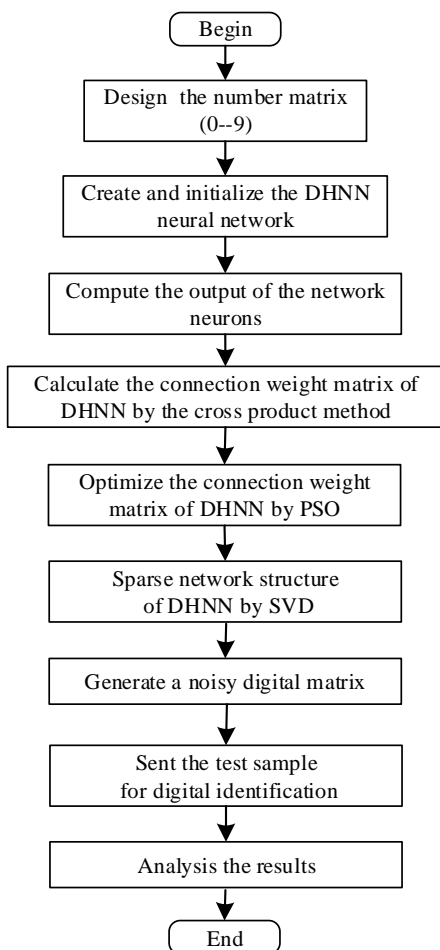

Fig. 1. Flow chart of I-SVD-DHNN.

## II. METHODOLOGY

### A. Introduction of DHNN

DHNN is a single-layer feedback network with binary output. The outputs of neurons are only 1 and -1, which represent the activation and inhibition states respectively [16]. Its network structure is shown in Fig. 2.

Fig. 2. Network structure of DHNN.

In Fig. 2, level 0 is used as input and there is no computation function. Level 1 is a neuron that performs the summation of the product of input and weight, and produces an output after processing by a nonlinear function (*f*). f is a simple threshold function, if the output of neuron is greater than threshold (*θ*), then the output is 1, otherwise it is -1. For binary neurons, its calculation formula is as follows:

$$u_j = \sum_i w_{ij} y_j + x_j \qquad (1)$$

where $x_j$ is the external input, $w_{ij}$ is the weight matrix , and

$$\begin{cases} y_j = 1, \ u_j \geq \theta_j \\ y_j = -1, \ u_j < \theta_j \end{cases} \qquad (2)$$

There are many design methods for $w_{ij}$. No matter which, it is necessary to ensure that the matrix is symmetric, which can make the network converge quickly and achieve stability. In this experiment, the outer product method is used to design $w_{ij}$. The outer product rule is as follows:

$$w = \sum_{k=1}^{N} [t^k (t^k)^T - I] \qquad (3)$$

where, $\{t^1, t^2, t^3 \ldots \ldots t^N\}$ is the sample vector to be memorized. Its value is 1 or -1. $I$ is unit matrix.

For a network with n neurons in the output layer, the output at time *t* is an *n*-dimensional vector.

$$Y(t) = [y_1(t), y_2(t), y_3(t) \ldots, \ldots y_n(t)]^T \qquad (4)$$

where $y_n(t)$ is the state of the *n*-th neuron at time *t*, with a value of 1 or -1. Accordingly, the state of node at the next moment (*t+1*) can be expressed as,

$$y_j(t+1) = f[u_j(t)] = \begin{cases} 1, \ u_j(t) \geq 0 \\ -1, \ u_j(t) < 0 \end{cases} \qquad (5)$$

where $u_j(t) = \sum_{i=1}^{n} w_{ij} y_j(t) + x_j - \theta_j \qquad (6)$

### B. Optimize Network Weight

DHNN evolves in the direction of decreasing energy function. Since the energy function is bounded, the network must stabilize and output result. There will be many local minimum points in the energy function during operation, resulting in many pseudo-stable points in DHNN, and it is difficult to achieve true global stability. PSO is a better global

optimization algorithm. Using the global search ability of PSO, the associative memory of DHNN is strengthened to make the network jump out of the pseudo stable point and have higher performance.

When PSO is solving optimization problems, the solution of the problem corresponds to the position of particles in the search space. Each particle in the algorithm represents a potential optimal solution in the search space. The particle characteristics are represented by position, velocity and fitness. The position of each particle corresponds to a fitness value determined by the fitness function. The position determines the starting point of the algorithm; Speed determines the direction and distance of particle movement. By tracking the trajectory of particles in the solution space, the position and speed of particles are dynamically adjusted to achieve the output of the optimal solution.

The original weight of DHNN is taken as the global optimal particle. The appropriate fitness function is selected to calculate the fitness of particle, and the performance of particle is judged based on this [17]. During the optimization process, the particles will move towards the space with less fitness. By tracking the particles, the speed and position of particles are continuously updated, that is, the weight matrix of network is updated. The detailed optimization steps are as follows:

Step 1: Initialize parameters, including the weight matrix of DHNN, the fitness function, the number and dimension of particles, the maximum number of iterations, the learning factor, etc.

Step 2: Initialize the population, including the initial position, velocity and fitness of each particle, as well as the individual extreme point (*pbest*) and the global extreme point (*gbest*).

Step 3: For each particle (*i*), its fitness is calculated according to the fitness function.

If (fitness($x_i$)<fitness($pbest_i$))

{

fitness($pbest_i$)= fitness($x_i$);

$pbest_i$= $x_i$;

}

If(fitness($x_i$)<fitness($gbest_i$))

{

fitness($gbest_i$)= fitness($x_i$);

$gbest_i$= $x_i$；

}

Step 4: Determine whether the maximum number of iterations is met. If so, end the program. Otherwise, update the particle's velocity and position.

Step 5: The results obtained in the previous step are taken as the updated weight matrix of DHNN.

The Flow chart of algorithm is shown in Fig. 3:

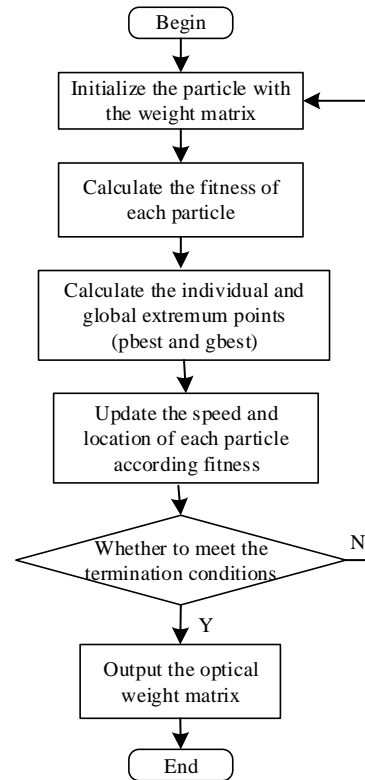

Fig. 3. Flow chart of PSO.

*C. Sparse Network Structure*

DHNN with *n* neurons has $n^2$ weights. Even optimizing by PSO, the number of weights remains unchanged. If the number of neurons increases, the weight of DHNN will increase sharply, which is very unfavorable for building a large-scale DHNN. SVD can describe the important characteristics of complex matrices with a small matrix [18]. Therefore, the weight matrix is decomposed by SVD, and some unimportant weights are discarded according to the contribution of weights to the output result. In this way, the weights are trimmed to simplify the network structure of DHNN.

Suppose that there are *n* target states $(t_1, t_2, t_3 \dots \dots t_n)$, which are stored in the weight matrix. Convert it into a identifiable discrete value and save it in the matrix of DHNN (*M*), then *M* contains all the target states, namely

$$M = [t_1^T, t_2^T, t_3^T \dots \dots t_n^T] \tag{7}$$

The important information in *M* is extracted by SVD, that is

$$M = PVQ^T \tag{8}$$

where, *P* and *Q* are orthogonal matrices, and *V* is pseudo-diagonal. The vector in *P* is the singular vector of *M*, which retains the important information of weight matrix. Let's define a diagonal matrix.

$$D = diag[d_1, d_2, d_3 \dots \dots d_n] \tag{9}$$

where, $d_i$ is the set eigenvalue. In order to ensure the symmetry of weights of the fully connected network DHNN, a new weight matrix is designed as,

$$W_{new} = PDP^T \qquad (10)$$

$W_{new}$ is obtained by SVD. The target information stored in each weight is different, and the contribution to output is also different. For each neuron, the weight with small contribution is deleted. $C$ is defined as the contribution rate. The contribution rate of the *i-th* neuron is expressed as followed.

$$C_i = |W_{new-ij}| / \sum_{j=1}^{n} |W_{new-ij}| \qquad (11)$$

The threshold of contribution rate is set to $h$, which is usually a constant, and $0 \le h < 1$. If the contribution rate of the *i-th* neuron satisfies $C_i \le h$, delete the corresponding weight. Otherwise, keep it. That is

$$W_{new-ij} = \begin{cases} 0 & (delete), \ C_i \le h \\ W_{new-ij}(retain), & C_i > h \end{cases} \qquad (12)$$

The weight is trimmed by setting different $h$. The larger the $h$ is, the more weights are discarded, and the greater the network structure changes. Choosing an appropriate $h$ can ensure that the network structure is sparse while retaining the performance of a fully connected network [19]. The flow chart of sparse matrix is shown in Fig. 4.

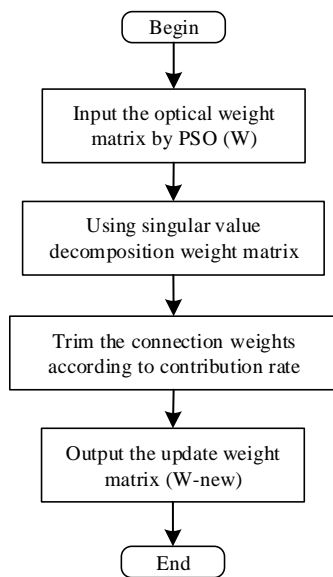

Fig. 4. Flow chart of sparse matrix.

## III. EXPERIMENTAL DISCUSSION

### A. Original Experimental Data Description

MATLAB is a platform containing a large number of computing algorithms, which can easily realize various computing functions required by users. At present, it has been widely used in data analysis, deep learning, image processing and other fields. According to the requirements, on the platform of MATLAB R2016a DHNN with associative memory is designed, which can correctly identify a total of 10

numbers from 0 to 9. When the numbers are disturbed by a certain noise, it still has a good recognition effect.

It is assumed that the input of DHNN consists of 10 steady states from 0 to 9. Each steady state is represented by a 10*10 matrix, which visually simulates Arabic numerals. In other words, each number is divided into a 10*10 matrix, the part with numbers is represented by 1, and the blank part is represented by -1. DHNN has the function of associative memory for the matrix of 10 digits. When the digital lattice with noise is input to the network, the closest target vector (10 steady-state) can be obtained, so as to achieve the effect of correct recognition. The matrix of numbers 1-2 is shown in Fig. 5, and so on for others.

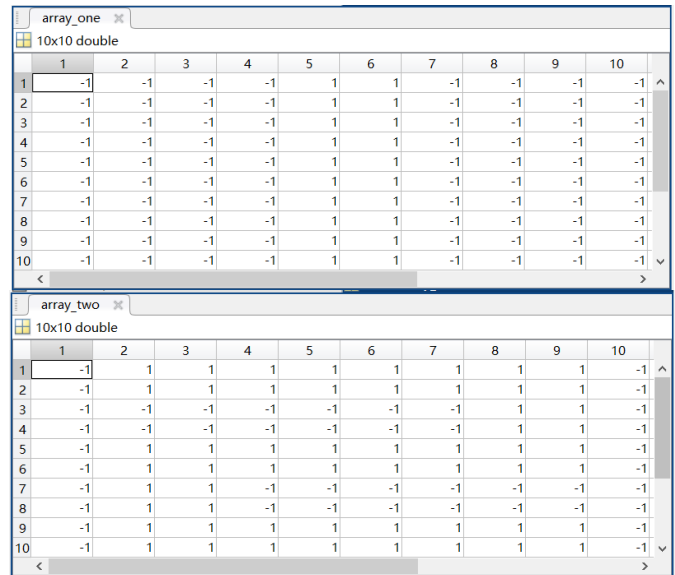

Fig. 5. Digital dot matrix of 1-2.

### B. Noise Experimental Data Description

A noisy digital lattice is that some positions of lattice have changed. We employ random noise for this purpose. A random function is used to determine the position that needs to be modified, and then the digital lattice is noised. That is, according to the position determined by the random function, the original 1 becomes -1 and -1 becomes 1.

### C. Digit Recognition of the Original DHNN

Suppose that DHNN memorizes a steady state of 10 numbers from 0 to 9. The steady state of standard number is used as training sample, and the digital lattice with adding noise is used as testing sample. The following two experiments are designed. In the first case, only 2 numbers are input, and the output of DHNN is observed as the noise intensity increases. In the second case, when the input increases to 4 numbers, how will the output change with the noise increases.

From the structure of DHNN, it is known that its stable state is the minimum of energy function during the training process. In the process of number recognition, the curve of energy function changing with the iteration is shown in Fig. 6.
Fig. 6.   Energy function change curve (DHNN).

Fig. 6 shows that the energy of DHNN decreases continuously with the iterative process. Until the iteration reaches 3500 times, the energy of DHNN changes very little (the red circled part in the figure). It indicates that the network tends to be in a stable state at this time.

In the first case, the lattices of numbers 1 and 2 are fed into DHNN as training samples. In the absence of noise (the noise is so small that it can be ignored), the network can accurately identify standard digital lattices. Subsequently, 10% (that is, 10% of the positions in 10*10 matrix have changed) and 30% of the noise intensity are added to the test sample and sent to DHNN again. The recognition result is shown in Fig. 7.

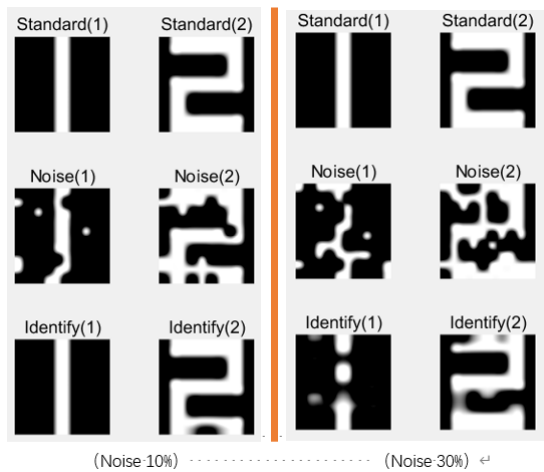

Fig. 7.   Recognition effect with 2 numbers (DHNN).

Fig. 7 shows that the recognition clarity of DHNN is reduced after adding 10% noise, but it can be accurately identified, and the recognition effect of network is good. When the noise intensity increases to 30%, the recognition clarity of DHNN is further reduced compared to the previous one, but the numbers can still be distinguished, and the recognition effect of network is not very good. It shows that DHNN has the function of associative memory, which can correctly identify the digital lattice with certain noise.

In the second case, the number of input samples has been increased from 2 to 4. In the absence of noise, the recognition effect of DHNN is equivalent to having only 2 inputs. The accuracy reaches 100%. Subsequently, the digital lattice as input is replaced with a noise matrix with 10% and 30%. The recognition effect of DHNN is shown in Fig. 8 and Fig. 9.

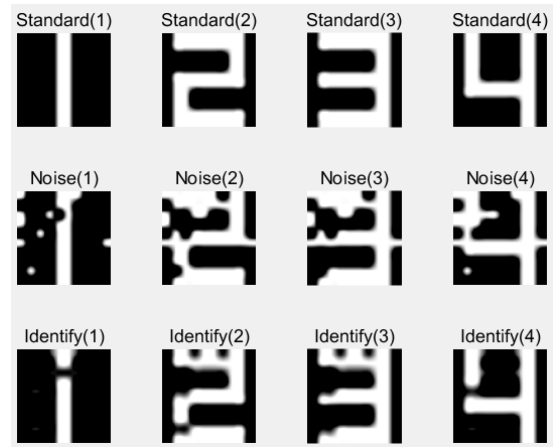

Fig. 8.   Recognition effect adding noise 10% with 4 numbers (DHNN).

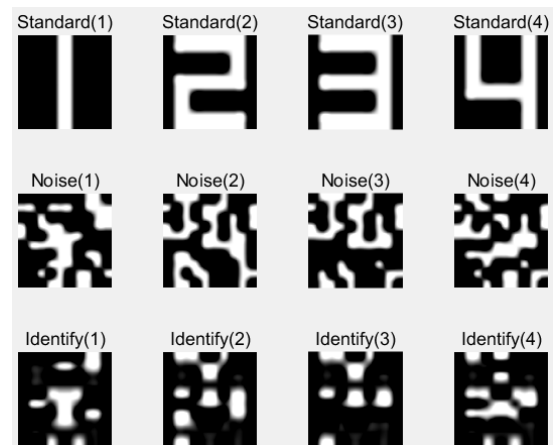

Fig. 9.   Recognition effect adding noise 30% with 4 numbers (DHNN).

The output results show that when the input increase to 4 digits, the recognition performance of DHNN is significantly worse than 2 digits. When the noise intensity is 10%, Fig. 8 can clearly recognize the output of network, but compared to the Fig. 7, the recognition clarity of DHNN has dropped. When the noise intensity continues to increase, the associative memory ability of network further deteriorates, the error rate increases, and the recognition ability plummets. When the noise intensity reaches 30%, Fig. 9 shows that DHNN has difficulty in identifying 4 digits. The output of network is completely unrecognizable, and the recognition effect is extremely poor. In the case of 2 digits, although the recognition clarity is not good, the result can be roughly identified. Continue the experiment and found that when the input is 10 numbers from 0 to 9, even if the noise intensity is 10%, DHNN also fails.

From these two experiments, it can be seen that the associative memory ability of DHNN decreases with the increase of input scale. At the same time, the recognition

performance of network is inversely proportional to the noise intensity. The reason for this result is that there are many pseudo-stable points in DHNN, and it is difficult for the network to achieve a real steady state. Therefore, in order to maintain good performance of DHNN under high noise intensity, it is necessary to optimize the network structure.

*D. Digit Recognition of the Improved DHNN*

In order to jump out the pseudo-stable point, we optimize the structure of DHNN in two stages to make the network have better anti-interference. In the first stage, the global search ability of PSO is used to optimize the weight of DHNN to obtain weights with higher accuracy. In the second stage, SVD is used to redesign the weight matrix of DHNN to realize the sparseness of weights. Finally, the I-SVD-DHNN model is obtained.

Firstly, the weight of DHNN is optimized by PSO. In the experiment, the parameters of PSO are set as follows.

Inertia weight ($W$): it enables particles to maintain the inertia of motion and continue to expand the exploration space. In this experiment, $W$=0.25.

Acceleration coefficients $C_1$ and $C_2$: it represents the weight of acceleration term each particle towards the pole position. In this experiment, $C_1$=$C_2$=0.01.

Number of Particles: In general, 20-40 can be selected. In this experiment, 20 particles are selected.

Secondly, the weight of DHNN is sparsed by SVD. For the weights optimized by PSO in the previous stage, SVD is used to extract their important features to form a new weight matrix. According to the contribution rate ($C$) of weights to the network output, it is decided whether to retain the corresponding weight. If $C>h$, keep the weight, otherwise delete it. In this way, a set of simple and sparse network weights can be obtained, which can ensure the network converging to a steady state. In this experiment, $h$=0.15.

In order to test the performance changes before and after the improvement, similar to Part C, the I-SVD-DHNN is first trained by using the standard digital lattice, and then different input and noise intensities are sent as test samples to observe the recognition effect of model. The contrast experiment is designed for two situations. Firstly, there are only 2 numbers. Secondly, the input is increased to 4 numbers.

Before starting the classification experiment, let's compare the stability of network. During the training process, the energy value of I-SVD-DHNN is also shrinking to the minimum. Its trend is shown in Fig. 10.

Fig. 10 shows that I-SVD-DHNN converges rapidly in the initial stage, and the energy value drops rapidly. After a period of small fluctuations, it tends to the minimum. It will reach a stable state after about 900 iterations (the red circled part in the figure). Compared with Fig. 6, the improved model I-SVD-DHNN has a rapid improvement in performance.

Fig. 10. Energy function change curve (I-SVD-DHNN).

*1)* The standard numbers 1 and 2 are sent into the I-SVD-DHNN. Subsequently, 10% and 30% of noise intensity are added for testing. The output of network is shown in Fig. 11.

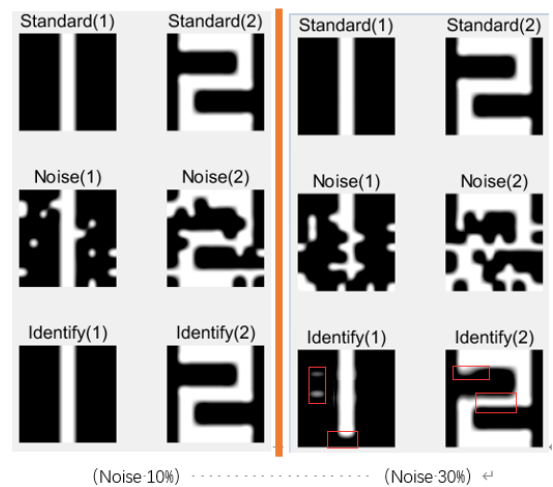

Fig. 11. Recognition effect with 2 numbers (I-SVD-DHNN).

Fig. 11 shows that after adding 10% of the noise, the network can accurately identify, and the recognition effect is close to the standard digital lattice, and the recognition rate reaches 100%. When the noise intensity is increased to 30%, the recognition performance of network decreases slightly. There are some borders with burrs (the red circled part in the figure), but the recognition effect is second only to the standard lattice. That is, the burrs have no effect on the output results. Compared with Fig. 7, the recognition performance of I-SVD-DHNN improves with the increase of noise intensity.

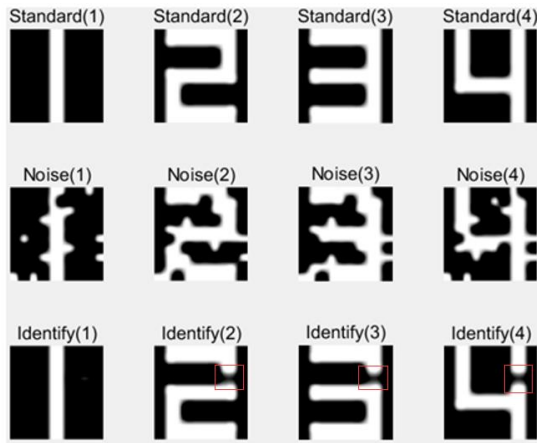
*2)* In I-SVD-DHNN, the number of training samples is increased to 4 digits, and the test sample are also added with 10% and 30% of noise intensity. The output of network is shown in Fig. 12 and 13.


Fig. 12. Recognition effect adding noise 10% with 4 numbers (I-SVD-DHNN).

Fig. 13. Recognition effect adding noise 30% with 4 numbers (I-SVD-DHNN).

Fig. 12 and Fig. 13 show that the recognition performance of I-SVD-DHNN is significantly better than DHNN, when the input is 4 digits. When the noise intensity is 10%, the effect of Fig. 12 is slightly inferior to that of Fig. 11. Although it can be accurately identified, the number 2, 3, and 4 have a small missing (the red circled part in the figure), which does not achieve the effect of standard digital lattice. It shows that the recognition rate of I-SVD-DHNN is indeed related to the input scale of network. On the other hand, the effect of Fig. 12 is much better than that of Fig. 8 for the same input and noise intensity. When the noise intensity increases to 30%, Fig. 9 has completely failed while Fig. 13 still identified, but the accuracy of Fig. 13 has decreased. Compared with Fig. 12, some missing segments are added to the Fig. 13(the red circled part in the figure), which reduces the clarity of result, but it does not affect the output.

In order to further verify the effectiveness and practicability of I-SVD-DHNN, different thresholds are set to observe the difference of network recognition effects. Experiments are performed at 0.05 intervals. As $t$ increases, more and more weights are removed. The recognition performance of network starts to decline. The deletion rate of weight and accuracy rate of result corresponding to different $t$ are shown in Table I.

TABLE I.        Accuracy vs Threshold

| threshold | deletion rate of weight(%) | accuracy rate of result (10% noise) | accuracy rate of result (30% noise) |
|---|---|---|---|
| 0 | 0 | 100 | 100 |
| 0.05 | 5 | 100 | 100 |
| 0.1 | 12 | 100 | 90 |
| 0.15 | 22 | 100 | 80 |
| 0.2 | 56 | 85 | 60 |
| 0.25 | 70 | 50 | 0 |
| 0.3 | 70 | 0 | 0 |

Table I shows that the recognition effect is good when $t=0$, which is equivalent to retaining all the optimized weights by PSO. When $0<=t<=0.15$, some of the network weights are removed, but it does not affect the recognition effect. When the noise intensity is added to 10%, the recognition rate reaches 100%. When the noise is increased to 30%, the recognition rate of 80% can also be achieved, indicating that some insignificant weights are deleted and the purpose of sparing network structure is achieved. When $t=0.2$, 56% of the weights are removed, but numbers with a noise intensity of 10% can still be identified. Relatively speaking, the recognition rate with a noise intensity of 30% drops further to 60%, and it is impossible to recognize all the test samples. When $t=0.25$, 70% of the weights are deleted, resulting in a large loss of information stored in the weights, only about half of the numbers can be recognized. If you continue to increase $t$, it is found that the deletion rate of weights remains the same. It means that the remaining weights cannot be deleted further. The network is in failure and the sample cannot be identified. The experimental results show that it is the best state to select 0.15 for the $t$, which can ensure the accuracy of digit recognition while achieving the sparse network structure.

To sum up, the recognition performance of I-SVD-DHNN is enhanced with the increase of input scale and noise intensity. The overall identification ability of network is improved and the anti-interference ability is strengthened. The conclusion is just consistent with the results described in Fig. 6 and 10. Both of them verify that the performance of I-SVD-DHNN is better than DHNN.

## IV.    CONCLUSION

As an important part of character recognition, digital recognition is widely used in transportation, post, business and other fields. Based on the original DHNN, this paper proposes an improved I-SVD-DHNN network model. The new model not only continues the associative memory ability of DHNN, but also improves its versatility and anti-interference. Firstly, it optimizes the weights of network by using the global search capability of PSO. The particle information with the minimum fitness is found as the optimized weight matrix through multiple iterations to avoid the network falling into local optimization. Secondly, it readjusts the weight matrix with the help of SVD and stores the information of target into it. Whether to retain or not is determined according to the contribution of each weight to output. By removing some insignificant weights, the purpose of sparse weight matrix is

achieved. Finally, the validity and applicability of new model are verified by means of digital recognition. Therefore, the following conclusions are drawn.

*1)* Optimize the weight matrix by PSO. It makes full use of the global optimization ability of PSO, so that the model tends to be stable in a short time, converges quickly, and obtains a weight matrix with higher accuracy to ensure the effectiveness of I-SVD-DHNN.

*2)* Sparse the weight matrix by SVD. It can effectively optimize the weight and greatly reduce the complexity of network structure, so that the optimized I-SVD-DHNN with sparse matrix has better recognition performance and it is more suitable for large-scale recognition scenarios.

*3)* The new method I-SVD-DHNN proposed in this paper has proved its feasibility and accuracy through experiments based on 0-9 digital samples. In the future, we will consider adding character samples, or even a mixture of the two, to further test the performance of the model.

# The GSO-Deep Learning-based Financial Risk Management System for Rural Economic Development Organization

Weiliang Chen

Shanghai Open University Jingan Branch; Shanghai Jingan District College, Shanghai, China

*Abstract*—**Financial risk management has always been a key concern for major enterprises. At the same time, with the continuous attention to impoverished rural areas worldwide, financial risk management tools have become an important component of rural economic development organizations to avoid financial risks. With the rapid development of artificial intelligence technologies such as neural networks and deep learning, and due to their strong learning ability, high adaptability, and good portability, some financial risk management tools are gradually adopting technologies such as neural networks and machine learning. However, existing financial risk management tools based on neural networks are mostly developed for large enterprises such as banks or power grid companies, and cannot guarantee their full applicability to rural economic development organizations. Therefore, this study focuses on the financial risk management system used for rural economic development organizations. In order to improve the accuracy of deep learning algorithms in predicting financial risks, this paper designs an improved Glowworm Swarm Optimization (IGSO) algorithm to optimize Deep Neural Networks (DNN). Finally, the effectiveness of the financial risk management tool based on IGSO-DNN proposed in this article was fully validated using data from 45 rural economic development organizations as a test set.**

*Keywords*—*Deep learning; Glowworm Swarm Optimization (GSO) algorithm; Deep Neural Networks (DNN); financial risk prediction; rural economic development organization*

## I. INTRODUCTION

Financial risk management aims to reduce the probability of adverse risks and mitigate their impact on the enterprise, in order to maintain the financial health and sustainable development of the enterprise. It is an important means to reduce the adverse effects of the enterprise's financial condition and operating performance, and protect the financial interests of the enterprise [1]. Financial risk prediction provides the main data and information for financial risk management, thereby providing the decision-making basis and foundation for financial risk management for enterprises. Specifically, financial risk prediction can be based on historical data, market trends, industry analysis, macroeconomic and other indicators to predict potential financial risk events and their potential impacts [2]. Financial risk prediction helps enterprises identify and evaluate risks in advance, develop corresponding risk management strategies and measures, and reduce the adverse impact of financial risks on the enterprise. It can be said that

financial risk prediction is an important component of financial risk management [3].

The financial ratio analysis method evaluates the financial condition of a company by calculating financial indicators such as debt ratio and current ratio. The trend analysis method predicts the future financial condition of a company by observing historical trends in data, and the financial model risk prediction method based on statistical and empirical methods are three traditional financial risk prediction methods, which have high universality and advantages. However, the above three methods also have drawbacks such as low prediction accuracy, susceptibility to limitations in predictions from different industries, and high dependence on data reliability. For example, early risk management systems based on option pricing models had high universality, but their risk prediction performance was not very ideal [1]. Therefore, in early research related to financial risk management, the purpose of a large amount of research was to develop financial risk management tools that can effectively communicate with organizations in the market, rather than improving the accuracy of financial risk prediction models and the reliability of results.

With the advancement of relevant technologies in the field of artificial intelligence, financial risk prediction methods based on cutting-edge technologies such as neural networks, snake venom learning, and machine learning in the field of artificial intelligence are receiving widespread attention from relevant researchers. Learning based financial risk prediction methods can better handle large amounts of data, nonlinear relationships, and complex risk factors, and are expected to bring higher accuracy and reliability to financial risk prediction [3]. Indicative examples include risk management for large financial enterprise investment portfolios based on deep learning [4], enterprise financial risk prediction methods based on genetic algorithms and Support Vector Machines (SVM) [5], and power company financial risk prediction methods based on machine learning [6].

When using machine learning and other methods for financial risk prediction, the first step is to prepare a financial dataset for prediction, including financial statements, economic indicators, etc. At the same time, it is necessary to preprocess the data, including steps such as data cleaning, feature selection, and standardization. Furthermore, it is necessary to select appropriate features from financial data based on the objectives of financial forecasting. Common features include profit, sales, cash flow, etc. Finally, the prediction model is

trained and evaluated. In addition, some studies will also further optimize the model, such as selecting genetic algorithms for SVM optimization in study [5].

However, in recent years, rural counties in the United States have replaced large cities as the most difficult areas, and this situation is similar in most parts of the world [7]. With the proposal of the United Nations Sustainable Development Goals, the global attention to economically disadvantaged rural areas is also constantly increasing. This has led to increased funding for difficult rural areas by rural economic development organizations, including the World Bank's rural development department, the Agricultural Development Bank (ADB), the International Fund for Agricultural Development (IFAD), La Via Campesina, and the Rural Development Foundation [7]. These agricultural economic development organizations usually collaborate with local-residents to provide assistance to the impoverished population in the form of rural cooperatives [8].

In order to ensure the sustainable development of rural economic development organizations, rural economic development organizations need to use financial risk management tools to protect their agricultural assets and improve the financial health of rural economic development organizations, in order to attract investment for rural economic development organizations and ultimately achieve sustainable development of rural economic development organizations, maintain agricultural production and stability of rural economy [9]. Therefore, it is necessary to develop corresponding financial risk prediction tools for rural economic development organizations. However, as previously mentioned, existing risk prediction systems based on artificial intelligence methods are mostly used for power, finance, and investment enterprises, rather than agricultural enterprises with agricultural economic development organizations as the main body.

Therefore, this study focuses on the study of a financial risk prediction system for rural economic development organizations, aiming to help them protect organizational assets, improve financial health, increase investment attractiveness, and promote sustainable development of the organization. The main contributions of this article are summarized as follows: Firstly, based on the possible risk sources of rural economic development organizations and the Analytic Hierarchy Process, a deterministic financial risk system was established, aiming to predict financial risks based on the current operating conditions of the company. Furthermore, a novel deep learning prediction algorithm was designed to optimize the Deep Neural Network (DNN) using the improved Glowworm Swarm Optimization (GSO) algorithm, thereby designing the optimal number of DNN layers and parameters, and improving prediction accuracy. Finally, this article used 110 test sets and 45 test sets, and compared the IGSO-DNN algorithm designed in this article with the other two algorithms to verify the effectiveness of the algorithm designed in this article.

The rest of this article is arranged as follows, and the work related to this study is reviewed in the Section II. In Section III, A financial risk prediction model has been established. The Section IV introduces the GSO algorithm. In Section V, the improved GSO algorithm was designed and a model of DNN based on the improved GSO algorithm was developed. The Section VI presents and discusses the simulation experimental results. Finally, the full text is summarized in Section VII.

## II. RELATED WORKS

This article aims to establish a financial risk prediction tool for rural economic development organizations and use the improved GSO-based DNN algorithm (IGSO-DNN). Therefore, this article reviews the relevant work from three perspectives: financial risk prediction, swarm intelligence algorithms, and machine learning algorithms.

### A. Financial Risk Prediction

As previously mentioned, traditional financial risk prediction models have drawbacks such as low accuracy and high requirements for data accuracy [1]. Therefore, this article focuses on financial risk prediction methods based on logistic regression, decision trees, random forests, SVM, and neural networks. In order to enrich the financial risk prediction system based on SVM, works [5], [10]-[11] all used Support Vector Machines (SVM) to predict the financial risk of enterprises. Unlike the simple improvement of SVM algorithm in [10]-[11], work [5] optimizes SVM algorithm based on genetic algorithm (GA), aiming to improve the prediction accuracy of SVM algorithm. The above three studies are based on the actual operational situation of the company, and predict the financial risk of the company based on information such as the intensity of capital investment, capital loss rate, and product net profit. However, Tsai et al. used information from the company's financial reports to predict the company's financial risks [12].

Unlike the above efforts to improve the accuracy of financial forecasts, the work [13] aims to reduce the cost of misclassification. Chen et al. used a Markov chain based Monte Carlo method to predict the financial risks of enterprises before and after economic crises. This study helps companies avoid financial risks caused by economic crises. Reference [14] studies the impact of intelligence services on sustainable financial risk management of enterprises from the perspective of green finance. Yang et al. aim to improve the financial management capabilities of enterprises and provide sustainable financial management plans for them [15]. Specifically, Yang et al. used deep learning methods to predict the degree of financial risk in enterprises and developed a financial risk prediction framework based on DNN [16]. This study explores the application of DNN in financial risk prediction. Reference [17] conducted research on enterprise financial risk prediction models based on BP neural networks, further proving the superiority of AI based financial risk prediction models compared to traditional methods.

Similar to study [14], research in [18] also studied the financial risk prediction of enterprises based on the Markov chain Monte Carlo method, which mainly focuses on the financial market and has certain significance for the development of the financial market. The study in [19] is also based on deep learning to evaluate credit risk, which is also a model for financial risk assessment. The research in [20] studied a credit risk prediction model based on graph neural

networks, which evaluates and predicts credit risk based on high-dimensional data and different economic cycles. The above two studies on credit risk prediction have certain reference significance for financial risk prediction. Peng et al. conducted research on several mainstream financial risk prediction methods to evaluate the effectiveness of nine financial prediction algorithms [21].

### B. Swarm Intelligence Algorithm

Similar to study [5], this article uses swarm intelligence algorithms to optimize DNN, aiming to improve its performance. At present, with the increasing frequency of large-scale complex problems, swarm intelligence algorithms are also widely studied [22].

The GSO algorithm, as a relatively novel swarm intelligence algorithm, has been widely used in optimization problems since its inception. Reference [22] provides a detailed introduction to the basic principle, process, and parameter settings of the GSO algorithm, and verifies its performance through experiments on multimodal optimization problems. The research in [23] elaborates on the principle and application of GSO algorithm, and provides new ideas for improving and expanding GSO algorithm. The study in [24] mixed the GSO algorithm with another swarm intelligence algorithm and conducted experiments on complex global optimization problems. The experimental results show that the hybrid GSO algorithm has higher accuracy and convergence speed in global optimization compared to traditional GSO swarm algorithms. The study in [25] provides a detailed introduction to the application of GSO algorithm in the field of intelligent manufacturing, and prospects its applications in power system scheduling, network routing, resource allocation, image processing, and other fields.

Particle Swarm Optimization (PSO) algorithm, as a heuristic algorithm, is widely used in fields such as robot path planning, image recognition, vehicle scheduling, and flight planning [26]. The research in [27] introduces improvement strategies for the PSO algorithm, including introducing inertia weights, limiting maximum speed, and other strategies to improve the algorithm's search ability and optimization performance. It also analyzes the convergence and stability of the PSO algorithm. The study in [28] introduces the idea of differential evolution based on PSO algorithm, enabling it to better handle high-dimensional optimization problems. The research in [29] summarizes the application of PSO algorithm in different fields, explores the three-dimensional performance and applicability of the algorithm in solving large-scale complex problems through multiple experimental cases, and proposes corresponding improvement strategies. The study in [30] studied the application of PSO algorithm in the field of data clustering and analyzed their performance and effectiveness in clustering problems. The research in [31] focuses on the application of PSO algorithm in supply chain optimization problems. Introduced the construction of a supply chain optimization model and algorithm design scheme based on particle swarm optimization algorithm, and discussed the advantages of PSO algorithm in supply chain optimization.

Similarly, the Whale Optimization Algorithm (WOA) has also received widespread attention from relevant researchers in [32]. The study in [33] studied the application of improved MVO algorithm in indoor positioning systems, aiming to improve the positioning accuracy of WOA algorithm in visible light systems. Gharehchopogh et al. systematically investigated the latest research progress in WOA. The study introduces the advantages and limitations of the WOA algorithm, and evaluates its application effectiveness in different fields through a series of experiments [34]. The research in [35] proposed an improved WOA based on chaotic mutation and applied it to the optimization process of large-scale complex problems. The performance of the algorithm was demonstrated through various standard test functions and comparative experiments. Based on the review of the above content, we improve the GSO algorithm and compare it with PSO and WOA algorithms.

### C. Deep Learning

The study in [36] provides a comprehensive introduction to the development, algorithms, and applications of deep learning. The article discusses the structure and training methods of deep learning models, and proposes some future research directions for deep learning. This study covers the basic principles of deep learning, neural network architecture, parameter optimization methods, and reviews the applications of deep learning in speech recognition, image classification, natural language processing, and other fields. The research in [37] designed a novel deep learning algorithm to improve the accuracy and fairness of deep learning in the decision-making process, thereby optimizing multi-objective optimization problems. The study in [38] focuses on optimizing the dynamic performance of aircraft airfoils and designs a deep learning algorithm for multi-objective optimization, aiming to reduce the gap between the solution results and the Pareto front. The study in [39] designed a recursive neural network to predict the financial risks of enterprises.

### III. FINANCIAL RISK MODEL

By summarizing the various indicators related to financial risk prediction in literature [1]-[7]. Based on the Analytic Hierarchy Process, four indicators directly related to financial risk are summarized, namely Funding risk (A1), Investment risk (A2), Operational risk (A3), and Liquidity risk (A4). Furthermore, the four types of risks are divided into 11 indicators that directly constitute the four types of risks, as follows:

- Funding scale (B1)

- Financing time (B2)

- Funding cost (B3)

- Risk of capital investment (B4)

- Profitability (B5)

- Operating capacity (B6)

- Procurement Risk (B7)

- Inventory Shortage Risk (Production Risk) (B8)

- Inventory realization risk (B9)

- Long term fund repayment risk (B10)

- Short term fund repayment risk (B11)

Table I shows the various indicators generated at three levels based on the Analytic Hierarchy Process.

Furthermore, we will use expert back-to-back scoring to determine the importance of each indicator in the C-layer on financial risk impact. In addition, the risk level is divided into six levels, represented by the numbers 1-6, and divide the intervals into [0, 0.2163], [0.2163, 0.3694], [0.3694, 0.4837, 0.6405], [0.6405, 0.8379), [0.8379, 1] representing safety, low risk, low medium risk, medium high risk, and high risk. Based on the collected data on the rationality of fundraising scale, funding availability time, and fund usage time, along with the other 11 indicators listed in Table I, we will Normalize the relevant indicators of 155 companies, The details are shown in Table II.

TABLE I.    STRATIFICATION OF FINANCIAL RISK SOURCES BASED ON ANALYTIC HIERARCHY PROCESS

| Layer A | Layer B | Layer C |
|---|---|---|
| A1-Financing risk | B1-Funding scale | C1-Rationality of fundraising scale |
| | B2-Financing time | C2-Funding availability time |
| | | C3-Fund usage time |
| | B3-Funding cost | C4-Comprehensive financing cost |
| A2-Investment Risk | B4-Risk of capital investment | C5-Capital investment intensity |
| | | C6- Capital loss rate |
| | B5-Profitability | C7- Product net profit |
| | B6-Operating capacity | C8- Asset turnover rate |
| | | C9- Product turnover rate |
| A3-Business risk | B7-Procurement Risk | C10-Supplier stability in the raw material market |
| | B8-Inventory shortage risk (Production risk) | C11-Insufficient inventory |
| | B9-Inventory realization risk | C12-Market demand stability |
| A4-Liquidity risk | B10-Long term fund repayment risk | C13- Asset liability ratio |
| | B11-Short term fund repayment risk | C14-Cash ratio |

## IV.    GLOWWORM SWARM OPTIMIZATION

The GSO algorithm is an algorithm generated by fireflies moving towards a light source. During the optimization process, it randomly generates a group of firefly populations in the search space and assigns an initial brightness value to each firefly individual. Furthermore, each individual firefly updates its position through a movement strategy based on its current position and the brightness information of surrounding fireflies. The goal of moving is to move towards higher brightness in order to find a better solution. Fireflies communicate information between individuals by emitting and receiving light signals. A firefly will emit a light signal, and its brightness value will decrease with increasing distance. Other fireflies determine whether there is a brighter solution around them based on the received light signal and selectively move towards the direction of the light source.

This algorithm optimizes the search process by updating the fluorescence of individual fireflies, calculating their mobility probability, updating their positions, and updating their neighborhood ranges. The specific steps are as follows:

*1) Update the fluorescence:* Each firefly's luminescence value is equal to the luminescence value from the previous moment plus a certain extraction proportion of the current firefly's fitness value. This is then subtracted by a certain proportion of luminescence value that evaporates over time. The mathematical description is as follows:

$$\beta_x(\delta+1) = (1-\rho) \times \beta_x(\delta) + \chi \times F\left[\beta_x(\delta)\right] \qquad (1)$$

where, $\beta_x(\delta+1)$ represents the concentration of fluorescein in individual $x$ of the firefly during $\delta+1$ iterations. $\rho$ is the fluorescence emission coefficient, and $\chi$ is the fitness

extraction ratio. $F\left[\beta_x(\delta+1)\right]$ is the fitness function value of firefly $x$ during $\delta$ iterations.

*2) Calculate the mobility probability:* During the specific movement of each firefly, it needs to determine its direction based on the luminescence concentration of all neighboring fireflies within its decision radius. $V_{xn}(\delta)$ represents the probability at time $\delta$ (iteration) that the firefly moves towards the neighboring firefly. The calculation formula is as follows:

$$V_{xn}(\delta) = \frac{\beta_n(\delta) - \beta_x(\delta)}{\sum\left(\beta_m(\delta) - \beta_x(\delta)\right)} \quad (2)$$

where, $V_{xn}(\delta)$ represents the probability of the $x$-th firefly moving towards the $n$-th neighbor firefly individual during the $\delta$-th iteration process.

*3) Update the positions:* Selecting the maximum movement probability and updating the position: Firefly $D_x(\delta)$ moves a certain distance towards the firefly with the maximum luminescence within its decision radius. The movement formula at time $\delta+1$ is as follows:

$$D_x(\delta+1) = D_x(\delta) + \theta\frac{D_n(\delta) - D_x(\delta)}{\left\|D_n(\delta) - D_x(\delta)\right\|} \quad (3)$$

*4) Update the neighborhood ranges:* Each firefly adopts an adaptive dynamic decision radius, changing its decision radius based on the density of neighboring fireflies during each iteration. When the neighbor density is low, it increases the decision radius to search for more neighbors. Conversely, when the neighbor density is high, it decreases the decision radius.

## V. PROBLEM SOLVING APPROACH

Deep neural networks (DNN) are powerful machine learning techniques rooted in the concept of artificial neural networks. These algorithms facilitate the learning and prediction of vast datasets through the combination of multi-layered neurons. Fig. 1. shows the architecture of DNN [40]-[41]. The primary advantage of DNN lies in their adeptness at feature learning, enabling them to automatically extract high-level abstract features from raw data, thereby enhancing the predictive performance of models. While DNN have demonstrated impressive results across various domains, their performance in tasks, such as risk level prediction, continues to be challenged by the optimization of model parameters. To tackle this issue, this study introduces a method based on the GSO algorithm for optimizing parameters within deep learning networks, ultimately enhancing prediction accuracy and robustness.

Within the GSO algorithm, each individual relies on a nearby superior individual to provide guidance during the search process. If there is no such superior individual within the perceptual range, the individual becomes unable to continue the search, rendering the algorithm heavily reliant on these superior individuals. This dependency can potentially

slow down convergence speed. Moreover, as an individual approaches the optimal solution, it might oscillate around that solution due to its step size exceeding the remaining distance. This oscillation can also impact the algorithm's performance.

Fig. 1. DNN architecture.

To address these issues, the incorporation of an elite reservation strategy is proposed into the GSO algorithm. This addition aims to enhance the algorithm's convergence speed and accuracy. In the GSO algorithm, the elite strategy involves maintaining the positions of both optimal and suboptimal individuals unchanged while updating the positions of individuals in the population. By combining this enhanced GSO algorithm with deep learning techniques, this study aims to develop an efficient and accurate method for predicting risk levels. Specifically, following these steps:

*1)* Initialization: Start by randomly generating an initial set of parameters (weights and biases) to form the foundation of the neural network. Simultaneously, configure the parameters of the GSO algorithm, including population size, the number of iterations, step size, and neighborhood threshold.

*2) For each generation, perform the following operations:*

*a)* Construct the neural network using the current parameter combination, input the training data, and compute prediction results.

*b)* Evaluate the fitness of each individual in the population by calculating a fitness function based on the predicted results and the actual risk levels. Each individual corresponds to a neural network, and their fitness is determined by comparing the predicted output of the neural network to the actual values. This comparison can be expressed as either the mean square error (MSE) or root mean square error (RMSE):

$$MSE = \frac{1}{P}\sum_{i=1}^{P}(y_i - y_i)^2 \quad (4)$$

$$RMSE = \sqrt{\frac{1}{P}\sum_{i=1}^{P}(y_i - y_i)^2} \quad (5)$$

Here, $P$ represents the number of training samples, $y_i$ denotes the actual value, and $y_i$ signifies the predicted output value. Our selection for the fitness function is the RMSE.

*c) Identify the optimal* and suboptimal individual positions based on the fitness function values. Update the location of each individual within the population using a roulette strategy to determine the direction of movement while preserving the positions of the optimal and suboptimal individuals.

*3) Repeat step 2* until the termination condition is met (reaching the maximum number of iterations).

*4) Create a neural network* utilizing the optimal parameter combination, input the test data, and generate predictions.

*5) Output the predictions*, specifically the risk level, and assess the model.

The algorithm's flowchart is depicted in Fig. 2.

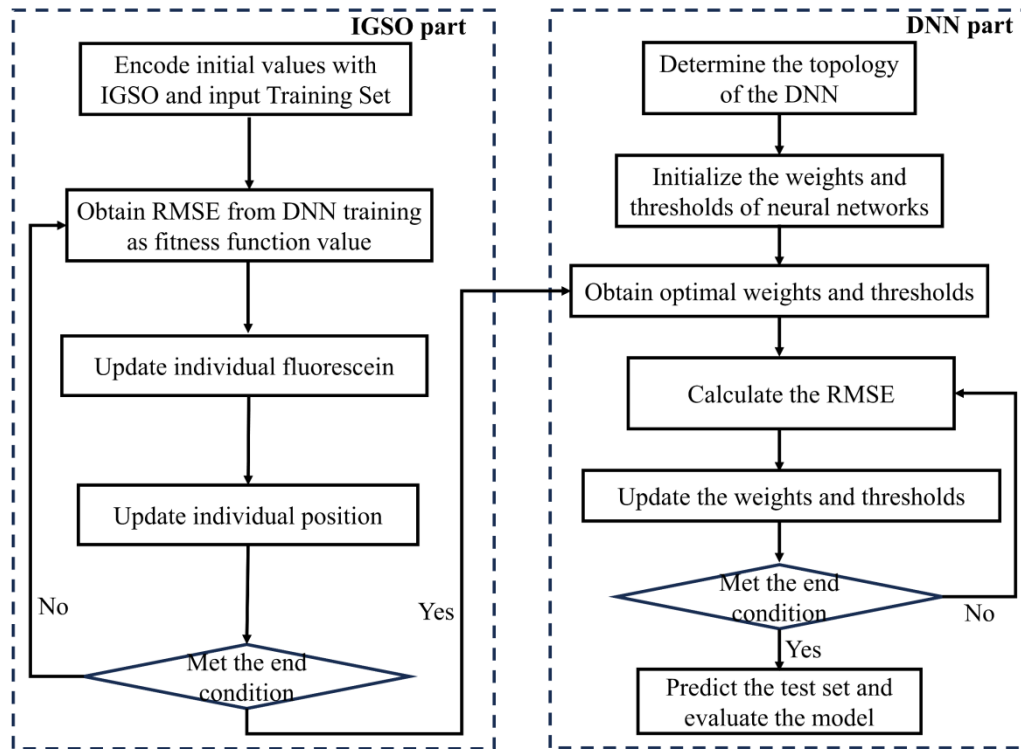

Fig. 2. The flowchart of the algorithm.

## VI. RESULT AND DISCUSSION

In this work, data from 155 rural economic development organizations were selected for the study. Out of these, 110 sets of data were allocated for the training set, while the remaining 45 were used for the test set. For the IGSO algorithm, the number of iterations to 50 and the population size to 35 are set. We train the model using a training set and assess its performance using RMSE. After obtaining a well-trained model, we can input risk-related data from other companies to evaluate the level of risk for the company. Our objective is to have the model predict the company's risk level as accurately as possible, so we aim to obtain a model with a smaller RMSE through training. Our simulation experiments rely on MATLAB 2022b, and we have a high-performance computer system with the following key specifications: CPU is i9-13900KS; GPU is NVIDIA GeForce RTX 4090.

Initially, a combination of DNN and the IGSO algorithm is employed to train the training set. To provide a comparative analysis with the enhanced IGSO algorithm, we also utilized the Whale Optimization Algorithm (WOA) and Particle Swarm Optimization Algorithm (PSO) for optimizing the DNN. Fig. 3.

illustrates the iteration curves of these three optimization algorithms after a single run.

From the Fig. 3, it is evident that the objective function values obtained after iterations using IGSO are superior to those of WOA and PSO, converging to values of 0.01, 0.33, and 0.18, respectively. In terms of convergence speed, IGSO reaches convergence around the 10th generation, which is notably faster than WOA and PSO. This suggests that models optimized through IGSO can provide more accurate predictions for the input training set, and the training speed of the model will also be improved.

To assess the algorithm's stability, a total of 30 runs are conducted and compared the iteration curves of the optimal, worst, and average values for each generation, as depicted in Fig. 4 to Fig. 6. Upon comparing these figures, it becomes evident that IGSO outperforms WOA and PSO in terms of both convergence accuracy and speed. This observation underscores the robust stability of the IGSO algorithm. Across the 30 repeated runs, the average objective function value after convergence was at 0.05, surpassing the respective values of 0.40 for WOA and 0.28 for PSO. This observation underscores the robust stability of the IGSO algorithm.
Fig. 3. Plot of iteration curves for one run.

Fig. 4. Iterative curve of optimal values per generation in 30 runs.

Fig. 5. Iterative curve of worst values per generation in 30 runs.

To evaluate the predictive performance following the successful optimization of DNN parameters using the IGSO optimization algorithm, predictions on a set of 45 test cases are conducted, with the results presented in Fig. 7. Furthermore,

these results with predictions made using DNN optimized are compared through PSO and WOA, as shown in Fig. 8 and Fig. 9. The red line indicates that the true value deviates from the predictive value. Risk level is between 2 and 5.

Fig. 6. Iterative curve of mean values per generation in 30 runs.

Fig. 7. Plot of true vs. predicted values for test set based on IGSO-DNN.

Fig. 8. Plot of true vs. predicted values for test set based on PSO-DNN
Fig. 9. Plot of true vs. predicted values for test set based on WOA-DNN.

From the results, it is evident that the DNN optimized through IGSO also yields more accurate predictions for the test set. To enhance its demonstrative precision, we further calculated the error count and error rate for risk level predictions using IGSO-DNN, PSO-DNN and WOA-DNN, as summarized in Table III, Table IV, and Table V.

Notably, the IGSO-optimized DNN exhibits superior predictive capabilities, low-medium risk error rate is 12.5% and medium risk error rate is 5.26%, and the remaining risk levels can be accurately predicted. While for PSO-DNN, low-medium risk error rate and medium risk error rate is 18.75% and 21.05%, respectively. For WOA-DNN, its low-risk error rate is 12.5%, low-medium risk error rate is 18.75%, medium risk error rate is 26.32% and medium-high risk error rate is 50%. Compared to WOA-DNN and PSO-DNN, IGSO-DNN exhibits excellent predictive capabilities across various risk ranges.

TABLE III.    RISK PREDICTION RESULTS FOR IGSO-DNN

|  | Safe | Low risk | Low-medium risk | Medium risk | Medium-high risk | High risk |
|---|---|---|---|---|---|---|
| Test sample (True value) | 0 | 8 | 16 | 19 | 2 | 0 |
| Number of errors (Predictive value) | 0 | 0 | 2 | 1 | 0 | 0 |
| Error rate (Predictive value) | 0 | 0 | 12.5% | 5.26% | 0 | 0 |

TABLE IV.    RISK PREDICTION RESULTS FOR PSO-DNN

|  | Safe | Low risk | Low-medium risk | Medium risk | Medium-high risk | High risk |

## VII. CONCLUSION

This study focuses on the financial risk management issues of rural economic development organizations, focusing on the financial risk management system used for rural economic development organizations, aiming to help rural economic development organizations avoid financial risks. At the same time, an IGSO algorithm was designed to optimize CNN, aiming to improve the accuracy of deep learning algorithms in predicting financial risks. Finally, data from 110 rural economic development organizations were used as a training set, while data from 45 rural economic development organizations were used as a testing set. The simulation results showed that the DNN optimized by IGSO showed excellent predictive ability, with a medium to low-risk error rate of 12.5% and an average accuracy improvement of 3.73% compared to PSO-DNN and WOA-DNN; The medium risk error rate is 5.26%, with an average accuracy improvement of 19.44% compared to PSO-DNN and WOA-DNN; In addition, IGSO DNN can accurately predict other risk levels. In future research, new algorithms will be further developed to improve

the accuracy of predictions. In addition, the applicability of risk prediction models is also a potential research direction.

Faculty of Data Science and Information Technology-INTI International University, Nilai, Malaysia[1, 4]

*Abstract*—A home that is connected to the Internet allows all of its appliances and systems to communicate with one another via the Internet of Things (IoT), making it a component of a sustainable smart home. The issue with this study's findings is that some homes still utilize manual gates, which must be opened and closed by pushing a gate. Considering that a building's gate is its primary form of security, this is viewed as being less effective. Additional locks are required on the fence to overcome its frail defenses, which do not deter criminals. This project aims to create a smart home by using the internet to automate the process of opening and closing home gates based on IoT. Prototyping is a strategy used in software development, whereas card barcode objects are found using scanning. The findings demonstrated that Radio Frequency Identification (RFID), which is connected to a smartphone as a communication medium between the device and the user, is connected to each other between the microcontroller and the stepper motor so that it can operate the home gate automatically. The test findings indicate that when the user taps in the RFID card as the drive for the gate, the reaction time of the RFID to the stepper is between 7.35 and 10.10 seconds. Future research can use long-range RFID technology, which has a reading distance of more than 5-12 meters with a radio frequency band refarming process of 800 - 900 Mhz for any smart home or smart building. The accuracy of reading RFID cards with an RFID reader is about 1 - 5 cm, which is the limitation in this study. According to the test findings, it can be said that the development of an automatic fence control system increases the effectiveness of home security and allows for direct control from a smartphone. Using a Long-RFID instrument with a reading precision distance of 5–12 meters and a radio frequency band refarming method of 800–900 Mhz is anticipated to be sustainable in this research.

## I. Introduction

A house is a structure that people occupy as their place of residence for a while. The primary purpose of the house is to offer a place to unwind after returning from work. When you get home from work, you're exhausted, and your house is a cozy place to unwind. This home is used as a communal living space for friends or family [1]. In keeping with the world's rapid technological development, the idea of a home started to be combined with modern technology to make people feel comfortable, safe, and simple while performing various activities there. These concepts are highly sought-after and

have become a mainstay for the type of modern home, and they are known as the concept of a "smart home" [2]. In order for a fence or house door to open and close automatically, a smart home connects a communication network with it through a microcontroller [3].

The goal of the smart home concept is to make it comfortable for the homeowner to be able to manage and watch over their home even when they are not at home [4]. A house can be said as a smart home if the house's equipment can be connected to the Internet because the Internet is part of the rapidly growing technological developments in people's lives today that are capable of being used as a medium of communication and control of devices remotely as long as they are still connected to each other [5].

With the advancement of Internet infrastructure, a variety of real objects, such as electronic devices, human-useable equipment, and any other real object, will be able to connect to the Internet. This concept is known as the "Internet of Things" in the "IT" industry [6]. The Internet of Things (IoT) is a system made up of intelligent gadgets like sensors, actuators, and microcontrollers that enable automatic information exchange and communication. Smart equipment, such as smart home devices and smart classrooms, are created by combining a number of sensors, actuators, and microcontrollers that support communication between devices as part of the Internet of Things (IoT) [7].

The Internet of Things is a concept that has the aim of expanding the use of the Internet that is connected continuously which is connected to physical objects that are capable of sharing data and remotely affecting physical objects through the Internet network [8]. IoT can integrate uniquely identified embedded computing devices in the existence of internet infrastructure, it can be concluded that IoT basically connects the Embedded System to the Internet [9].

Embedded systems can be used to implement IoT devices because they frequently conserve energy. The Wemos D1 Microcontroller is one of the remote controller technologies with ARM-based embedded systems (Advanced RISC Machine) [10]. A highly effective device that can control tools is the Wemos D1 Microcontroller. Wemos is an electronic device module that works with Arduino and is based on the Wemos D1, so projects that specifically use the IoT concept frequently use this module [11].

The issue with this study's gate system is that it is still operated manually, with the door still having to be pushed open and shut. As a result, the gate system is not yet functional. The fence uses an additional key to overcome the weak security that allows criminals to evade it, and the gate is the primary security measure for securing a building. The growing need for technology has made everyone dependent on it, and one way this is done is by using it to simplify tasks.

A car gate will also be developed as part of this study, and it will function automatically based on the presence of a car detected by ultrasonic sensors. The tool that will be developed uses a controller, specifically a microcontroller, which is a computer system device that is used to control the system. The alternative to this automatic fence is using an Android smartphone. This study takes the object of congestion on the Pesona Prima Citapen Housing Complex, West Bandung Regency – West Java – Indonesia as a case study. Usually, when a car or motorcycle enters or exits a home, there is congestion. This occurs as a result of the person having to manually open and close a house fence. With an automatic fence system at home, it is hoped that there won't be any more traffic jams in neighborhoods because a car or motorcycle can drive right into the yard without the driver getting out; all they have to do is get closer to the house fence, at which point the fence will automatically open, shortening the wait time and reducing the line of cars behind them.

Based on previous research, the implementation of smart homes can be done by everyone because smart homes have the advantage of always controlling the condition of the house [12]. The purpose of the smart home concept is to provide comfort to the homeowner [13]. To be able to control and monitor his home [14]. Smart homes can also minimize a person at times such as forgetting to lock the door [15], forgetting to turn off the lights [16], forgetting to turn off the television, or [17] forgetting other electronic items [18], thus making the house unsafe [19] and also having an impact on the waste of energy [20]. The smart home concept pays attention to the efficiency of electrical energy use [21]. The use of this smart home can also make it easier for users to control household electronic equipment such as lights [22], Air Conditioner [23] , and Televisions [24]. So that it can reduce the wastage of electricity [25], and is one of the efforts to develop a sustainable smart home.

Along with the development of Internet infrastructure [26], in the field of "IT", this concept has been known as the "Internet of Things" [27]. The Internet of Things (IoT) is a development of network communication of interrelated objects [28] and connected to each other via Internet communication [29], which is useful for exchanging data and information [30]. Research in the IoT field is very rapid because it has become part of human life because almost all sectors of human life use IoT technology [10]. Like the automatic gate that can open and close through the press of the remote control [9], smartphone [8], fingerprint, which is controlled by humans [7]. The tool to be developed uses a controller, namely a microcontroller [5]. Wemos D1 also has advantages compared to other microcontrollers [3], starting from more pin outs and analog pins [2], [31], larger memory, and low energy Bluetooth 4.0 [21]. On the wemos D1 microcontroller there is a WiFi module

available in a dual core processor chip that runs on Xtensa LX16 instructions so that it is very supportive for creating Internet of Things application systems and can send notifications to various communication tools such as smartphone [3], [20]. Some previous research has not been integrated with the design of using applications on smartphones [19].

Based on the previous research mentioned above, WemosD1 microcontroller technology, RFID Readers, and smartphone-connected applications are still receiving relatively little attention from researchers, making this a research gap that needs to be investigated further. This study used the smartphone feature as a security system on the fence by utilizing the Wemos D1 microcontroller, along with a car garage door, to develop an automatic gate controller that operates automatically based on the presence of a car detected by RFID. The Wemos D1 microcontroller can send brief messages to smartphones whenever the door opens and when the door closes.

## II. METHOD

The following steps must be taken in order to conduct research and solve the problem:

### A. Methodology of System Development

In order to create a new system or enhance an existing one, the prototyping method is used [32]. Due to the method's focus on the analysis, design, and implementation phases, which are three very important stages in creating or improving the system [33]. The emphasis of the method which will be repeated continuously involving collaboration with users will produce a prototype of the system that will be reviewed before heading to the implementation of the system that has been desired by the user [34]. In the prototype method, there are several stages to start system development [35], as presented in Fig. 1.

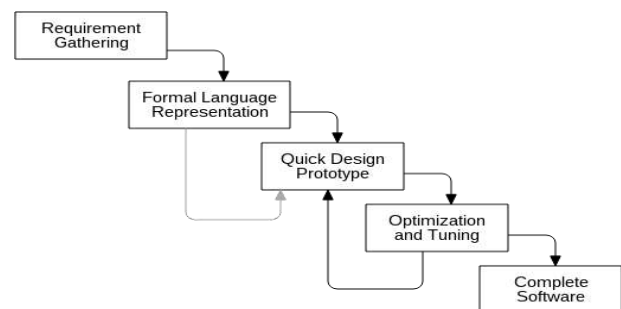

Fig. 1. Prototype Approach. (Source: https://www.ekrut.com/media /prototype Accessed on July 23, 2022, at 21:10 WIB).

In Fig. 1, there are five stages, namely the prototyping stage or the requirements gathering phase, which explains that users and analysts have a meeting and then have a conversation between them [36]. Analysts use the results of the requirements-gathering phase as the foundation for the idea (concept) of developing a program or system, and at this stage, the analyst also converts the obtained specifications into concepts that are simple to understand [34]. The analyst will also perform quick planning and modeling in the form of a quick design before beginning the construction of prototype making [37]. The program that has been created is based on the

prototype that has been submitted and agreed upon together (the analyst team), then at this stage, a program is also tested by the analyst and of course the user, then the user assesses whether the program can be accepted or not [35]. The user has approved the program (it successfully complies with the suggested specifications), so the user can successfully use the ordered program [32].

### B. Scanning Method

The Scanning method of system design in this study makes use of object detection. The process of finding objects, whether they move or not, like people or things, is known as object detection [38]. Object tracking, which aims to identify or track the position of moving objects in an image sequence, is one application of image processing that can be used in daily life [39]. With this object detection, it is expected to be able to predict and determine the position on the frame that shows where the object is [40]. Object detection has the advantage of detecting an object's movement. [41]. The utilization of Computer Vision and Image Processing technology to detect objects can make it easier for humans to detect objects [42], for example in the field of security. Object tracking can use the Scanning method [43].

Fig. 2.   Scanning Process ((Source: Accessed on July 23, 2022 at 21:20 WIB).

The scanning method is a reading technique to get information without reading the others [44]. It is directly to the problem sought, namely specific facts and certain information [45]. Scanning is also known as reading scan. Scanning is reading very fast [46]. Speed reading means reading that prioritizes speed without ignoring its understanding [47]. Usually, speed is associated with the reader's goals, needs, and reading material [39]. Fig. 2 shows the scanning process.

### C. Data Collection Techniques

The first data collection technique was conducted by interviewing sources by holding meetings and giving questions to sources [48], both orally and in writing at least two individuals [49], who directly met to obtain information [50], from the first-hand (primary) [51], in accordance with other selection methods [52], examined the results of selecting different information [53]. The second data collection technique is observation to obtain the required data [54], this method is considered the most effective [55] because researchers go directly to the research location [56]–[58]. While the third is to provide a questionnaire for the information sorting procedure [59], which is done by giving a group of questions [60], which are arranged for respondents to answer [61], either given face to face [62] or via the web [43].

## III.   RESULT AND DISCUSSION

This research is based on a phenomenon that occurs, which can cause several problems that often occur in house fences, namely: 1) There is often congestion on residential streets in the morning because many vehicles come out of the house that the owner has to get out of the vehicle again to close the fence, 2) The occurrence of noise / disturbing neighbors at night to call people in the house to open the fence by using a car horn. Therefore, a solution is needed to deal with the problems that are happening, namely the need for a Smart Home system on the fence that aims to: 1) Knowing people who come in and out of the house because it is connected to smartphone notifications, 2) Opening and closing the fence can automatically make it easier for residents of the house and its surroundings, and 3) Minimize congestion in the morning when the residents of the house crawl to work.

The construction of the smart home system on the fence is a system that is used to automatically open and close the gate of the house fence. This system combines several RFID readers on the house fence into a single control unit, and it is combined with a microcontroller that has been programmed in the Arduino IDE programming language. Because of the design of this system, the user can control, monitor, and manage to open and close the fence as needed. This system is controlled by a reader that can scan an RFID card as well as an internet-connected application on an Android device for every arrangement and control of the fence, allowing for remote control of the system.

There are several requirements for this system's construction, both technically and in terms of use, before this automatic fence can be used. With an RFID card, not everyone can enter the house, but only a registered RFID card can open the house's fence. To prevent card misuse, this RFID will generate a user ID when it is used. In reality, this system will carry out orders in accordance with the usage guidelines.

The following is the flow in the Smart Home system: 1) Opens the gate of the house with an RFID reader that can scan the card, 2) The gate can open if the RFID card matches its unique code, 3) The smart home system can be controlled by an internet-connected android which sends notifications to smartphones.

### A. System Architecture

Based on Fig. 3 above, describes the system that was built, where the user taps in the card to the RFID reader to enter the house. Furthermore, the Wemos microcontroller processes the stepper motor to open the fence so that the vehicle can enter the garage. The fence will close by itself when there are no obstacles around it.

### B. System Modeling

System modeling is a set of activity processes that can describe clearly and in detail how the system will run [63]. The purpose of modeling this system is to explain, simplify, and evaluate the system to be built [64]. In this research, the system modeling uses UML (Unified Modeling Language) diagrams to describe the working system [65]. The UML models used include Use Case Diagrams and Flow Chart Diagrams [66]. A use case diagram is a depiction process carried out to show the

relationship between the user and the designed system [67]. The results of the representation of the scheme are made in a simple manner and aim to make it easier for the user to read the information provided [68]. The use case is included in the UML (Unified Modeling Language) diagram, and the manufacturing process itself is carried out before we enter the DFD (Data Flow Diagram) concept design [69]. A flowchart diagram is a diagram that displays the steps and decisions to carry out a process of a program [70]. Each step is depicted in the form of a diagram and is connected by a line or arrow direction [71]. Flowcharts play an important role in deciding a step or functionality of a programming project that involves many people at once [72].

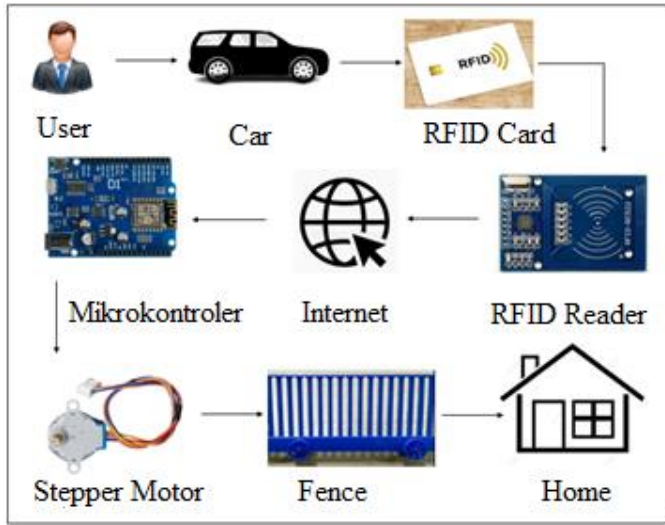

Fig. 3. System architecture.

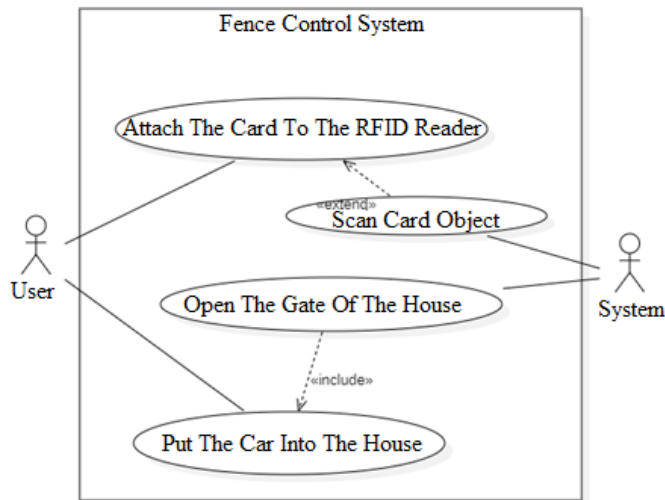

Fig. 4. Use case diagram of fence control system.

Based on Fig. 4, it can be explained that the user who will enter the house must have an RFID card that is useful for entering the house, the system scans the object of the card to open the fence and sends a message to the user's smartphone.

Based on Fig. 5 The flowchart above shows that the scanned RFID card must match the ID tag of each registered card, if the card is registered and matches the microcontroller

will drive the stepper motor and the fence will open, if the RFID card does not match the ID tag then the microcontroller will not turn on stepper motor and the fence will not open.

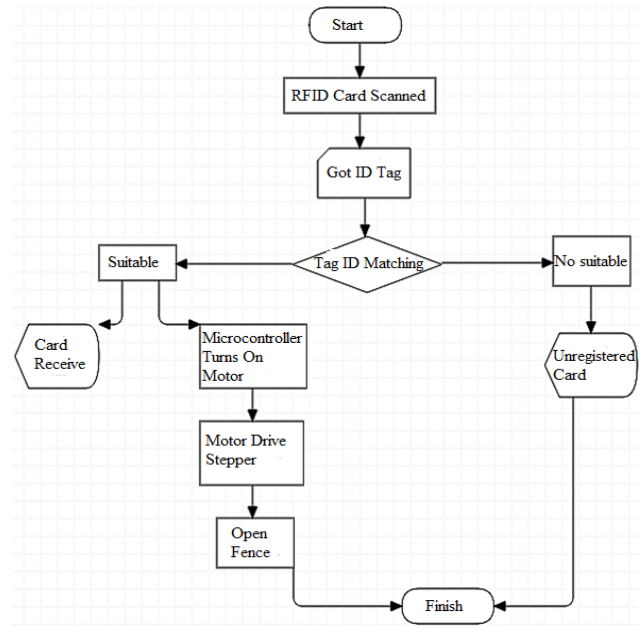

Fig. 5. Flowchart diagram of fence control system.

### C. System Circuit

There are two data output pins directly connected to the circuits in the automation system and ten input pins used in this microcontroller circuit. This pin is attached to both the RFID reader and the fence motor, which controls fence movement (see Fig. 6).

Fig. 6. Fence control system circuit.

Fig. 7. Wemos D1 microcontroller.

Data from the input device is controlled and processed by the Wemos D1 microcontroller (see Fig. 7) before being sent to the output device. Wemos differs from other Wi-Fi modules in that it has a microcontroller that can be programmed via a serial port, allowing for programming of the device without the need for any additional modules. The Wemos D1 microcontroller is used to connect various systems, such as ultrasonic sensors and RFID readers, which can be used as links to drive stepper motors, making it easier for users to control various electronic devices.

Fig. 8. Fence circuit.

In this prototype fence as shown in Fig. 8, it is driven by a stepper motor which functions to rotate and direct objects at certain angles or distances. This is made possible by a combination of an ordinary motor and an additional sensor in the form of an encoder for position feedback. The controller of the stepper motor, better known as the stepper drive, is the most important and sophisticated part of a stepper motor, because it is designed for high precision.

Fig. 9. Fence control system circuit.

Radio frequency waves are used in the data transmission process by Radio Frequency Identification (RFID). The RFID tag and the RFID reader, which are both included in the device, wirelessly exchange data during the transmission process.

### D. System Test

There will be five RFID cards registered in this automatic fence system. When an RFID card is read, there is an open

fence between the RFID reader and the card, so RFID testing aims to measure this distance. The RFID card is tested by moving it closer to the available RFID reader. A centimeter scale is used to calculate the separation between the RFID reader and the RFID card.

TABLE I. RFID CARD SYSTEM TESTING TABLE

| Trials | RFID Card Reading Distance | Fence |
|---|---|---|
| 1 | 1 cm | Open |
| 2 | 2 cm | Open |
| 3 | 3 cm | Open |
| 4 | 4 cm | Open |
| 5 | 5 cm | Open |
| 6 | 6 cm | Closed |
| 7 | 7 cm | Closed |
| 8 | 8 cm | Closed |
| 9 | 9 cm | Closed |
| 10 | 10 cm | Closed |

The reading distance between the RFID reader and the RFID card is shown in the Table I to be between 1 and 5 cm. The RFID card cannot be read if it is brought closer to the RFID reader than five centimeters away.

The RFID test when entering the house is carried out when the user taps the RFID card into the RFID reader located around the gate of the house.

TABLE II. FENCE TIME RESPONSE TABLE

| Trials | RFID Card Owner | Response Time Fence |
|---|---|---|
| 1 | Card 1 | 7.92 Seconds |
| 2 | Card 2 | 8.55 Seconds |
| 3 | Card 3 | 7.35 Seconds |
| 4 | Card 4 | 9.05 Seconds |
| 5 | Card 5 | 10.10 Seconds |

In Table II, it can be seen that the response time of the fence obtained on each RFID card is almost the same.

### IV. CONCLUSIONS

The following conclusions can be made based on the outcomes of the tests conducted on the prototype fence: First, the designed fence can be made to open and close automatically using an RFID controller. With this controller, the homeowner only needs to move the vehicle closer and connect the RFID card to the RFID reader to open and close the fence rather than climbing up and down the vehicle. For smart homes, using an RFID controller is much better than using an Android base application because, with RFID, the user can store the RFID card in the car, which is undoubtedly more efficient than using a smartphone, whereas with Android, the user must carry the Android smartphone with him every time he leaves the house. In order to inform homeowners about who enters and leaves the house, the automatic fence can be connected to smartphones as a notification medium. Smartphone notifications are much more effective than LED notifications on the front of the house because smartphones can be remotely controlled. Second, the test findings indicate that

when the user taps in the RFID card as the drive for the gate, the reaction time of the RFID to the stepper is between 7.35 and 10.10 seconds fence gates. Thirdly, the congestion that frequently develops in apartment complexes can be reduced by the installation of automatic fence gates.

If the automatic fence's controller (see Fig. 9) uses sensors that can be connected to one another, like Long-RFID, which has a reading accuracy distance of 5 to 12 meters and a radio frequency band refarming process of 800 to 900 Mhz, future research will be much better.

*Abstract*—Objective: In hospitals, sepsis is a common and costly condition, but machine learning systems that utilize electronic health records can enhance the timely detection of sepsis. The purpose of this research is to verify the effectiveness of a machine learning tool that makes use of a gradient boosted ensemble for sepsis diagnosis and prediction in relation. San Francisco University of California, (SFUC) Medical Center and the Medical Information Mart for Intensive Care (MIMIC) databases were consulted for historical information. The study encompassed adult patients who were admitted without sepsis and had a minimum single logging of six vital signs (SpO2, temperature, heart rate, respiratory rate, diastolic blood pressure and systolic). Using the area under the receiver operating characteristic (AUROC) curve, the performance of the machine learning algorithm was compared to commonly used scoring systems, and its accuracy was determined. Performance of the MLA (machine learning algorithm) was evaluated at sepsis onset, as well as 24 and 48 hours before sepsis onset. The AUROC for the MLA was 0.88, 0.84, and 0.83 for sepsis onset, 24 hours prior, and 48 hours prior, respectively. At the time of onset, these values were superior to those of SOFA, MEWS, qSOFA, and SIRS. Using UCSF data for training and MIMIC data for testing, the sepsis onset AUROC was 0.89. The MLA can safely predict sepsis up to forty-eight hours before it occurs and the accuracy in detecting the onset of sepsis is higher in comparison to traditional instruments. When trained and evaluated on distinct datasets, the MLA maintains high performance for sepsis detection.

*Keywords—Machine learning; sepsis; vital sign; prediction; electronic health records*

## I. INTRODUCTION

Sepsis, a widespread and economically burdensome syndrome affecting hospitals worldwide, has undergone a transformative shift in its conceptualization. While it was formerly categorized within a three-tier system, the prevailing understanding characterizes it as a two-stage process, spanning from septic conditions to full-blown sepsis. The projected annual cost to the global healthcare system attributed to sepsis is a staggering $24 billion, an alarming financial burden. This is particularly disconcerting when considering the fatality rates associated with sepsis, which range from 25% to 40%. However, emerging evidence underscores the significance of early diagnosis and intervention before the onset of septic shock, as it holds the potential to significantly improve patient outcomes and reduce hospitalization durations [1].

Sepsis, often characterized by organ malfunction due to a systemic inflammatory response to infection, poses a formidable diagnostic challenge due to the intricate and varied origins of infections and the unique responses of individual patients. Consequently, there has been a growing impetus in medical science to advance automated patient monitoring systems tailored for the early identification of sepsis among hospitalized patients [2].

The advent of automated diagnostic decision and prediction technologies, facilitated by the widespread adoption of electronic health records (EHRs) in healthcare facilities, holds substantial promise for revolutionizing the tracking and management of complex medical conditions [3]. These technologies derive their foundations from the comprehensive medical records of patients, utilizing this wealth of data to generate warnings and treatment recommendations [4]. However, it is noteworthy that the existing diagnostic methods for sepsis predominantly lack predictive capabilities [5-7], with the majority relying on rule-based processes to trigger alarms and provide recommendations.

Within clinical settings, the commonly employed sepsis scoring systems encompass the Systemic Inflammatory Response Syndrome (SIRS) criteria [6], the Modified Early Warning Scale (MEWS) [8], and the Sequential Organ Failure Assessment (SOFA) score [9]. While these systems exhibit commendable sensitivity, they often grapple with issues related to specificity and are not explicitly designed for predicting the development of sepsis. Moreover, rule-based scores may struggle to accurately account for the diverse patient populations and the multifaceted sources of infection. Machine learning-based prediction techniques hold the potential to offer superior specificity, broader generalizability, and early sepsis risk identification, thus potentially reducing false alarms and enabling more timely physician responses [12].

Previous research endeavors have revealed the capacity to forecast the onset of sepsis, septic shock, and severe sepsis with a lead time of up to four hours before the condition manifests, employing machine learning-based systems trained on patient EHR data [13-14]. However, these studies were primarily conducted within the confines of a single institution's critical care group. In this study, we align with the contemporary definition of sepsis proposed by Singer et al. [1] to evaluate the historical performance of an algorithm employing a mixed-ward dataset, predicting sepsis up to two days in advance, solely relying on vital sign inputs. Moreover, our research aims to assess the algorithm's effectiveness by benchmarking its performance against prevailing rule-based scoring systems and scrutinizing its reliability through cross-population validation, as elucidated in study [15].

## II. RELATED WORK

In the realm of predicting sepsis using vital sign data, extensive research has been conducted to explore the role of machine learning algorithms. This section provides an overview of existing studies and their contributions, offering insights into the progress made in this critical domain and highlighting the gaps and areas requiring further investigation.

Numerous researchers have delved into the development of sepsis prediction models, aiming to enhance early detection and intervention. Studies by [1-3] and [10-14] have primarily focused on utilizing machine learning algorithms to analyze vital sign data for sepsis prediction. These studies have demonstrated promising results in terms of accuracy and timeliness, providing a foundation for further exploration.

In contrast, [16] and [17] have employed alternative approaches, such as rule-based scoring systems, to predict sepsis. While these methods have proven valuable in clinical settings, they raise questions about the potential advantages of machine learning algorithms in terms of predictive power and adaptability.

While substantial progress has been made in the field of sepsis prediction, there are still various challenges that demand attention. These include addressing the interpretability of machine learning models, optimizing feature selection, and ensuring generalizability across diverse patient populations and healthcare settings. The research presented in this study seeks to contribute to this ongoing discourse by:

- Our unique approach employs a gradient boosted ensemble for sepsis diagnosis, leveraging SFUC and MIMIC electronic health records.

- We include adult patients without sepsis who have recorded six vital signs. We evaluate the algorithm's performance with AUROC and compare it to traditional scoring systems.

- Also in Results, MLA has an AUROC of 0.88 at sepsis onset, 0.84 and 0.83 for predictions 24 and 48 hours earlier. Outperforms SOFA, MEWS, qSOFA, and SIRS. MLA trained on UCSF data, tested on MIMIC, reaches AUROC of 0.89.

- Our research shows MLA may predict sepsis up to 48 hours earlier with high accuracy, contributing to improved early sepsis management.

By reviewing the existing solutions and identifying areas that warrant further exploration, this research aims to position itself within the broader landscape of sepsis prediction, ultimately striving to enhance the effectiveness of early intervention in critical healthcare scenarios.

## III. COMPONENTS

### A. Ethics Certification and Informed Consent

As mandated by the Health Insurance Portability and Accountability Act (HIPAA), we removed all personally identifying information from patient records before collecting the datasets. There was no compromise in patient well-being due to the data gathering procedure [16].

### B. Measurements

Six vital signs (systolic BP, heart rate, temperature, respiration rate, diastolic BP and peripheral oxygen saturation (SpO2)) were examined to establish sepsis risk ratings. To be included in the research, it was required that every patient encounter had a minimum of one record for each vital sign. These are the sole vitals we engage in the act of generating or producing characteristics for assessing sepsis threat scores since they are directly related to sepsis development and are evaluated often even in the absence of a clinical concern for septic shock [17].

### C. Sources Data

The datasets utilised in this study came from the Medical Center at the University of California, San Francisco (SFUC) and the Intensive Care Unit section of the Medical Information Market (MIMIC). Patients who visited the Parnassus Heights, Mission Bay, or Mount Zion facilities between June 2016 and March 2023 accounted for 17,467,987 of the total contacts in the SFUC dataset. Our final group consisted of 91,445 patients after excluding those with hospital stays less than seven hours and more than 2000 hours from the original 96,646 inpatients (95,869 of whom had at least one recording of each vital sign). We employed subsets of this final sample, differentiated by patients' lengths of stay, to conduct our 24- and 48-hour lookahead analyses. Different frequencies of data collection and types of care provided were documented in the SFUC data from the ICU, the ED, and the floor units [18-19]. Due to missing unit transfer timestamps, it was impossible to determine where a patient was located at any given moment. The MIMIC information was culled from the 61,532 ICU interactions recorded in the Medical Information Mart for Intensive Care III (MIMIC-III) v1.3 database between the years of 2012 and 2023. Patients 18 and older had 52,902 visits to the hospital, but only 21,507 had at least one recording of each vital sign, qualifying them for inclusion in the final cohort. Missing measurements of any vital sign were grounds for excluding encounters. Patient safety was not jeopardised by the data collecting process, and all patient information was de-identified in accordance with HIPAA regulations. SFUC's IRB (Institutional Review Board) gave its clearance to this project [20].

## D. Statistical Analysis

We extracted the sensitivity, specificity, and AUROC value with 95% CI for predicting sepsis patients in the ICU from each of the included studies. The ROC curve compares different thresholds by plotting the true positive rate (TPR) against the false positive rate (FPR). Excellent, good, fair, poor, and fail are defined by AUROC curve values of 0.9-1, 0.8-0.9, 0.7-0.8, 0.6-0.7, and 0.5-0.6, respectively. In the end, we calculated the ROC, sensitivity, and specificity with 95% CI. To gauge the degree of statistical heterogeneity among the included trials, we calculated an I² value. Heterogeneity is classified as extremely low (I² ~25%), low (I² ~50%), medium (I² ~75%), or high (I² > 75%), respectively. There was less variation in impact sizes across trials because data from all included research were combined using a random effect model. The proportion of overall study variance that can be attributed to factors other than chance is measured by the I2 statistic [21]. To determine I², we used the formula:

$$I^2 = 100 \% \ (Q - df)/Q \quad (1)$$

Q = dfQ, where df = number of observations and Q = Cochrane's heterogeneity statistic. As a consequence, the I² findings range from 0% (no observed heterogeneity) to 100% (highest heterogeneity), with all negative values adjusted to zero.

We selected the symmetric approach in our meta-analysis because we hypothesized that the included papers would be of varying quality. The pooled estimate of AUROC, sensitivity, specificity, and diagnostic odds ratio was calculated using MetaDiSc (version 1.4). It's useful for doing things like (a) summarizing data from each research, (b) analyzing the graphical and statistical similarity of studies, (c) computing the pooled estimate, and (d) examining heterogeneity. The likelihood ratio was calculated to illustrate the extent to which a given outcome was more common in studies including patients with sepsis illness compared to those involving subjects without sepsis disease.

$$LR+ = (Sensitivity/1 - Specificity) \quad (2)$$

$$LR- = (1 - Sensitivity/Specificity) \quad (3)$$

Additionally, diagnostic odds ratio (DOR) was calculated to reveal how much higher the chances are for persons with a positive test result to have the sepsis illness compared to those with a negative test result. The formula for DOR is LR + /LR-. Each technique's efficacy was measured using a number of different metrics (Supplementary Table 2), including area under the receiver operating curve, sensitivity, specificity, diagnostic odd ratio, and probability ratio.

The precise confidence bounds for the binomial percentage were calculated using the F distribution technique, and the confidence ranges for overall sensitivity and specificity were analyzed as well [19]. However, excess dispersion correction was applied in the computations, and Meta-DiSc was the tool of choice. The typical approximation to binomial was used here.

$$SE \ (SenT) \ = \ \sqrt{\frac{SenT(1 - SenT)}{\sum_i Di}} \quad (4)$$

$$SE \ (Sper) \ = \ \sqrt{\frac{Senr(1 - Senr)}{\sum_i Di}} \quad (5)$$

$$SenT \ \pm \ Z_{\frac{\alpha}{2\varphi Sen}} SE(Senr) \quad (6)$$

$$Sper \ \pm \ Z_{\frac{\alpha}{2\varphi Spe}} SE(Spen) \quad (7)$$

## IV. METHODOLOGIES

### A. Results and Methods

The capability of the algorithm to detect individuals that are septic at start and in the preceding 24 and 48 hours was the primary focus of this study. We evaluated the efficacy of the method by calculating the AUROC, or area under the receiver operating characteristic curve.

The data was collected through queries built for the PostgreSQL (PostgreSQL Global Development Group) database and then saved as CSV files [19]. Features for predicting sepsis risk were created using just six vital signs: heart rate, respiration rate, systolic blood pressure, SpO2, diastolic blood pressure and temperature. If there wasn't a fresh reading for each hour leading up to the patient's designated onset time, the previous reading was used to estimate the value. When several readings were obtained within the same hour, an average was calculated and utilized. This cut down on the classification system's exposure to measurement frequency data that wasn't relevant to physiology [21].

Information was also gathered to create the Sepsis-3 reference standard and the rules-based grading system. Often used measures such as the Sequential Organ Failure Assessment (SOFA), Modified Rankin Scale (MERS), and qSOFA (quick SOFA) were compared to the prediction algorithm. Similar to Jaimes et al. [3], we searched for SIRS criteria. To determine each patient's MEWS score [14], we used the same procedure as Fullerton et al [2]. The formula for calculating a qSOFA score may be found in Singer et al [1]. While the SOFA score is included in the widely accepted definition of sepsis, we investigated its ability to identify the onset of sepsis independently of other factors. CSV files were needed for bilirubin levels, FiO2, PaO2, the Glasgow Coma Scale, white blood cell counts, vasopressor dosages, and platelet counts in order to calculate these scores [22].

Sepsis is "life-threatening organ dysfunction induced by a dysregulated host response to infection," according to the 2016 consensus definition, which served as the basis for the Sepsis-3 gold standard. A 2-point shift in the Sequential Organ Failure Assessment (SOFA) score was considered indicative of organ failure [1]. To determine when the SOFA score shifted, we relied on the criteria established by Seymour et al. [4]. Antibiotics were administered and culture collected within 24 hours or within 72 hours if we suspected there was an infection. Seymour et al. [4] discovered the same thing when they tried testing the approach in reverse. When both the SOFA score and infection requirements were reached for the first time, we diagnosed sepsis [26-27].

There were 2,649 Sepsis-3 positive SFUC encounters out of 91,445 total that were included (a prevalence of 2.9%) in Fig. 1. The Sepsis-3 criteria were satisfied in 1024 out of

21,507 contacts at the MIMIC, yielding a frequency of 4.8%. There was a Sepsis-3 prevalence of 3.3% across all 112,952 patient interactions. The last stage of inclusion criteria for Sepsis-3 eliminated many potentially eligible encounters since the timing of sepsis onset was during the first seven hours of admission [23].

UCSF encounters | BIDMC encounters

17,467,987 | 53,542

Inpatients only

133,578 | 53,002

Patients aged ≥ 18 years

96,646 | 52,902

Patients with ≥ 1 observation for each measurement

95,869 | 23,502

Patients with prediction time between 7 and 2000 hours

91,445 | 21,507

*To Classifier*
Fig. 1. Graphic illustrating patient inclusion and duration-based subsets in SFUC/MIMIC datasets for training and testing.

The "onset time" for individuals who never acquired sepsis was chosen at random from a continuous, uniform probability distribution so that they might serve as negative examples. The algorithm's risk ratings were derived from data collected both at and before the patient's start time. Patients who were diagnosed with sepsis either at the time of admission or within seven hours of admission were removed from the analysis to make room for prediction windows [24].

Patient contacts were first categorized by duration of stay before training the classifier. Example: a patient who had been hospitalized for 25 hours before contracting sepsis would be included in a 24-hour prediction experiment but not a 48-hour prediction trial. There were 107 cases of Sepsis-3 among the 20,590 MIMIC interactions and 267 cases among the 89,000 SFUC encounters with at least 24 hours of stay data. After at least 48 hours in the hospital, Sepsis-3 was identified in 50 of the 20,533 MIMIC interactions and 97 of the 88,887 SFUC encounters. To keep the calculation matrices manageable, hospital encounters with onset times more than 2000 hours were omitted [25].

## B. The Algorithm for Prediction in Machine Learning

An ensemble of trees was used to generate scores for use in the algorithm's classifier, which was then used to get an overall score [28]. The system utilised one-hour, two-hour, and pre-prediction vital indicators, as well as the hourly changes between them, to make its predictions. A feature vector x containing 30 components, with five values derived from each of the six measurement sources was formed by summing these numbers in a causal fashion. The trees were built using the Python XGBoost module, with each branch being divided into two feature groups [29]. We used a five-fold cross-validation grid search on the training set to determine that a maximum of four, three, and six branches should be used for 0-hour, 24-hour, and 48-hour predictions, respectively [30]. Based on this grid search, we settled on the values 0.05, 0.12, and 0.12 for the XGBoost learning rate parameter. As we employed early stopping to avoid model overfit, we did not need to restrict the maximum number of trees in each ensemble. These risk ratings were then utilised by the algorithm to classify patients as having sepsis or at risk for developing it [31-33].

Two sets of SFUC interactions were created. The first group, made up of 80% of all interactions, was arbitrarily divided into a test set and a training set. Twenty percent of the second set was put aside as a control group for further examination. Using just the training data, we conducted a five-fold cross-validation to find the optimal hyperparameters for the grid search. For this prediction job, we looked into a parameter space that was similar to that of previously described hyperparameters [34-36]. We looked at learning rates between 0.05 and 0.12, in 0.01 increments, and explored numbers between 3 and 8 for the maximum number of branchings. For each look ahead, we settled on the optimal combination of branching level and learning rate based on the average area under the receiver operating characteristic (AUROC) curve [37]. For ten-fold cross-validation, we randomly distributed encounters over ten groups of similar size, each containing 20% of the training set. Nine of these groups were used for training the algorithm for each fold, while the other was used for testing. Each of the ten potential permutations of training and test sets was put through the algorithm and put to the test on the independent test set [38]. We produced machine learning algorithm performance measures by averaging the metrics from ten cross-validation models, including tabular and graphical representations of the findings. In addition, the averaged feature significance scores from XGBoost were presented; these values show how often a feature was utilised to partition the data across the trees. In addition, we calculated the AUROC standard deviation using the cross-validation outcomes [39].

Patient encounter cohorts utilised for 24- and 48-hour prediction were limited to those with sufficient stay data, as previously indicated [40]. As a consequence, there is an inequity in the distribution of socioeconomic classes since fewer septic patients were seen in these cohorts. We took use of XGBoost's built-in capacity to deal with unbalanced classes [40] rather than using minority oversampling to artificially inflate the number of septic patients, which may not be typical of the real-world situation in which such an MLA is implemented.

## C. Methods for Validation in Cross Populations

Cross-population validation studies were undertaken to evaluate the algorithm's sepsis detection ability after being trained on a data set from an individual institution and then evaluated on another with demographic and clinical disparities. We evaluated the algorithm on MIMIC patient measurements after training it on SFUC data but before retraining it on the target dataset. The whole dataset was put through its paces during testing, and the algorithm was trained and validated in the same manner as detailed above. Only at the outset was testing done so that it could be compared to rule-based approaches.

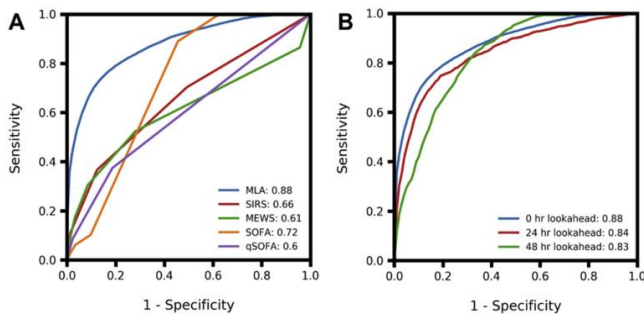

Fig. 2. MLA's efficiency in the hours before onset, and in comparison, to that of rival methods. A) Comparing ROC and AUROC of MLA to rival scoring systems at sepsis onset using SFUC data. B) ROC and AUROC for MLA at 0, 24, and 48 hours prior to sepsis onset using SFUC patient data.

## V. RESULTS

The research involved analyzing 91,445 patient interactions from SFUC and 21,507 patient encounters from MIMIC based on the collected data. Demographic characteristics of the two patient groups are compared in Table I, revealing significant differences in various aspects such as healthcare units visited, sepsis rates, in-hospital mortality, and age distributions. Importantly, the MIMIC database exclusively included ICU admissions, while the SFUC dataset encompassed all inpatient contacts. This deliberate selection of disparate data sets was aimed at evaluating the potential generalizability of the prediction system across a diverse range of patient groups.

In contrast to the qSOFA (0.60), MEWS (0.61), SIRS (0.66), and SOFA (0.72) scoring systems applied to the same dataset, the machine learning method developed and evaluated on the SFUC dataset exhibited a superior AUROC (0.88) for sepsis prediction (see Fig. 2). Additional performance indicators are detailed in Table II. Notably, the false alarm rates generated by the MLA, SIRS, and SOFA models were 0.22, 0.49, and 0.41, respectively, at specified operating points. It is significant to note that SIRS and SOFA generated 2.22 and 1.86 times as many false warnings as the MLA, respectively.

Furthermore, the study evaluated the algorithm's performance in predicting sepsis 24 and 48 hours before its onset, achieving AUROC values of 0.84 and 0.83, respectively (see Fig. 2 and Table II). During the 24-hour prediction, a dataset of 89,000 SFUC patients was analyzed, including 267 septic cases, and for the 48-hour prediction, a dataset of 88,887 SFUC patients was analyzed, including 97 septic cases. Notably, both predictions yielded higher diagnostic odds ratios (DOR) than initially predicted by rules-based approaches (see Table II).

Additionally, the study included data from MIMIC, which comprised 21,507 patients and 1024 septic cases. Remarkably, the algorithm, trained on the SFUC database without retraining, achieved an AUROC of 0.890 when applied to the MIMIC dataset.

The critical question arising from these results pertains to whether the MLA method can generate similar results when applied to infections other than sepsis. It prompts further consideration regarding whether the methodology's applicability is confined exclusively to sepsis or if it can be generalized to other medical contexts.

TABLE I.        COHORT DEMOGRAPHICS BETWEEN SFUC AND MIMIC

| Summary of the Population | Characteristic | MIMIC (%) | SFUC (%) |
|---|---|---|---|
| Gender | Male | 56.13 | 45.38 |
|  | Female | 43.87 | 54.62 |
| Ages[1] | 70+ | 40.26 | 20.44 |
|  | 60–69 | 22.79 | 21.22 |
|  | 50–59 | 17.89 | 18.62 |
|  | 40–49 | 9.73 | 13.02 |
|  | 30–39 | 4.99 | 15.20 |
|  | 18–29 | 4.34 | 11.50 |
| Length of Stay (days)[2] | 9+ | 10.05 | 17.02 |
|  | 6–8 | 8.24 | 14.21 |
|  | 3–5 | 32.38 | 38.42 |
|  | 0–2 | 49.34 | 30.35 |
| Death During Hospital Stay | No | 72.92 | 97.81 |
|  | Yes | 27.08 | 2.19 |
| ICD-9 Code | Septic Shock | 7.00 | 1.85 |
|  | Severe Sepsis | 10.19 | 3.69 |
|  | Sepsis | 3.48 | 5.83 |

Note - 91,445 patients make up the SFUC cohort. There are 21,507 patients in the MIMIC cohort.

1. Median age at SFUC was 55 (interquartile range [IQR]: 38-67), whereas at MIMIC it was 65 (IQR: (53, 77).

2. Median (SFUC): 4 (interquartile range [IQR]: (2, 6.32); median (MIMIC): 3 (2, 4)

Every one of the prediction windows was given a feature significance value (Supplementary Table I). The five most highly rated characteristics are shown in Table II. Age was the single most influential factor across all prediction intervals. After taking into account age, the greatest total score came from taking the patient's temperature, systolic blood pressure and heart rate simultaneously.

TABLE II.    PRE-SEPSIS MLA PERFORMANCE ASSESSMENTS AND COMPARISON SCORES DURING THE START OF SEPSIS

|  | MLA (t = −48) | MLA (t = −24) | MLA (t = 0) | MEWS (t = 0) | SIRS (t = 0) | SOFA (t = 0) | qSOFA[1] (t = 0) |
|---|---|---|---|---|---|---|---|
| **AUROC (SD)** | 0.83 (0.04) | 0.84 (0.04) | 0.88 (0.008) | 0.61 | 0.66 | 0.72 | 0.60 |
| **LR+** | 2.86 | 2.57 | 3.76 | 1.86 | 1.43 | 1.92 | 2.00 |
| **Sensitivity** | 0.84 | 0.80 | 0.80 | 0.52 | 0.70 | 0.78 | 0.37 |
| **LR-** | 0.21 | 0.28 | 0.26 | 0.66 | 0.56 | 0.37 | 0.77 |
| **Specificity** | 0.66 | 0.72 | 0.78 | 0.72 | 0.51 | 0.59 | 0.81 |
| **DOR** | 13.15 | 13.69 | 14.79 | 2.81 | 2.44 | 5.20 | 2.60 |

**Note**. On the basis of patient data from SFUC, we evaluate MLA performance at 0, 24, and 48 hours before commencement, as well as competing scores at the time of onset. The setpoints were selected with sensitivities around 0.80 in mind. Just the MLA's cross-validation standard deviation in AUROC was computed.

[a.] **Abbreviation**. SD, standard deviation; LR+, positive likelihood ratio; LR-, negative likelihood ratio.

[1] All settings for qSOFA generated sensitivities much outside of the 0.80 range.

## VI. CONCLUSION

The machine learning system evaluated in this research has the potential to revolutionize the way sepsis is diagnosed and treated. With an impressive AUROC of 0.83, the system has shown a high degree of accuracy in predicting sepsis up to 48 hours before the onset of symptoms. This early warning capability is crucial in ensuring that patients receive timely and appropriate treatment, leading to improved health outcomes.

Future work could focus on the implementation of the algorithm in clinical practice to assess its practical utility and to validate its performance across multiple healthcare systems. Additionally, further exploration could be done to identify additional predictive variables that may enhance the algorithm's performance, as well as potential applications of the algorithm for other clinical conditions. Overall, the potential for machine learning algorithms to improve sepsis detection and patient outcomes warrants further investigation and development in the field of healthcare.

*Abstract*—The registration of the point cloud plays a critical and fundamental role in the computer vision domain. Although quite good registration results have been obtained by using the global, local, and learning-based registration strategies, there are still many problems to solve. For example, the local methods that are based on geometric features are very sensitive to attitude deviation, the global shapes-based methods are easy to result in inconsistency when the distribution differences are obvious and the learning-based registration methods have highly relied on the huge label data. A novel and effective registration method for the point cloud data integrating the coarse-to-fine strategy and the improved PointNet network is proposed to overcome the above-mentioned drawbacks and improve registration accuracy. The improved Random Sample Consensus (RANSAC) algorithm is developed to effectively deal with the initial attitude deviation problem in the coarse registration procedure and the improved Lucas and Kanade (LK) algorithm is proposed based on the classical PointNet framework to reduce the errors of the refine registration, and the whole registration procedure is implemented under a trainable recurrent deep learning architecture. Compared with the state-of-the-art point cloud registration methods, experimental results fully prove that the proposed method can effectively handle the significant attitude deviation and partial overlap problem and achieves stronger robustness and higher accuracy.

## I. INTRODUCTION

As one of the most faithful and convenient data formats, the datasets of point clouds have been popularly applied in the domain of 3D reconstruction [1, 2], virtual reality [3], augmented reality [4], etc. Due to environmental and other influence factors, the registration of point cloud is an essential step before various tasks of computer vision and robotics applications. For example, in the auto-drive domain, the auto-drive system unifies the point clouds collected from different positions by the laser radar to the same coordinate system to build the three-dimensional high-precision map, and then it matches the real-time collected data to the high-precision map through the point cloud registration [5]. Other typical examples include the three-dimensional location for robotics [6] and the pose estimation from different point cloud data [7].

From a mathematical perspective, the registration procedure of the point cloud is usually treated to be an optimization problem, which searches the space correspondence parameters by minimizing the transformation estimation error under some objective metrics [8]. Once the best correspondences are found, the search stops. Many typical work has been reported in this domain. As a typical example, the famous Iterative Closest Point (ICP) registration firstly iteratively assigns the point to the nearest point in a different space of point cloud and then calculates the least squares distances of point pairs to be the objective function. Because only spatial coordinates are used to guide the search, the ICP is very easy to initialize. However, the traditional ICP algorithm usually requires a large overlap area between two frames of the point clouds [9]. In addition, the robustness is not good enough since only the point features are used but the other important features information is lost. Therefore, some registration methods based on the extracted structural features are proposed to improve the registration accuracy, such as the histograms and adjacent points [10], the Euclidean distance [11], the normal vector difference [12], and the surface curvature [13]. Another classical registration scheme based on the Random Sample Consensus (RANSAC) has been also popularly applied in coarse registration. Among them, the 4-Point Congruent Sets (4PCS) is the respective one, which determines the correspondence by comparing the intersection diagonal ratios of four-point sets [14]. The 4PCS algorithm can handle point cloud registration tasks in complex scenes, and a series of improved versions have been developed. For example, to deal with the registration task in the large-scale scene, the computational complexity can be reduced from $O(n^2)$ to $O(n)$ by the Super 4PCS [15], which uses the intelligent strategy to index; the k-4PCS algorithm [16] improves the registration precision by replacing the randomly sampled points with the sparse key points; the Generalized 4PCS [14] effectively reduce the time cost by no longer strictly restricting the coexistence of four points of the 4PCS in a plane; the V4PCS [17] algorithm incorporates the concept of volume consistency to reduce the time cost and the 2PNS [18] is proposed to deal with the registration problem under the smaller overlapping scenes (with a minimum of only 5% overlap). All of these methods produce good registration results but the deep features have not been carefully considered.

Very recently, with the breakthrough of the theory of deep learning, the learning-based registration methods become the

research spots in this domain. Charles et al. constructs the famous PointNet network [19], in which each point through maximum pooling can extract features without conversion, and it solves the problems of permutation invariance and disorder of the point cloud. Inspired by this work, many deep learning-based registration models have been constructed [20-23]. For example, Wang et al. proposed the DCP algorithm based on the dynamic graph convolution network [24, 25]. It combines the local context information and the communication by using the attention mechanism [26] to get the soft mapping relationship between the point clouds. The registration matrixes (including the translation and rotation) are computed according to both of the smooth mapping relationship and differentiable decomposition of the singular values. The performance of the time efficiency and accuracy is good but it is very sensitive to rigid transformations since it heavily relies on the local geometric features. Therefore, its performance is not satisfying when handling significant initial attitude differences [27]. Zi et al. proposed the feature extraction network RPM-Net [28] to reduce the initialization sensitivity. It calculates the mixed features from the spatial location and the geometric characteristics, and then obtains the soft assignment by using the Sinkhorn layer [29]. Zan et al. constructs a deep learning architecture named "3DSmoothNet" to implement the 3D point cloud registration, and its convolutional layers is represented by using the smoothed density value [30]. Huang et al. proposes the fast registration framework that based on the feature-metric strategy, which considers the registration procedure to minimize the error of the feature-metric projection without correspondences. As reported, it is a semi-supervised model and is very robust to the density difference in point cloud data [31]. For all of these methods, the global shape information can be well used to maintain the robustness, however, the registration results are still not good enough when faced with the distribution differences of the point cloud that caused by the partial overlap.

To overcome the above-mentioned drawbacks and improve registration accuracy, an effective and novel point cloud registration framework based on the improved PointNet network is constructed. To deal with the high sensitivity of the initial attitude differences and the partial overlap, the coarse-to-fine registration strategy is developed. The improved RANSAC algorithm is employed as the coarse-grained registration to reduce the attitude difference and make the input point cloud roughly aligned. The LK alignment method is further improved to enhance the inaccurate alignment caused by the distribution differences and partial overlap. Unlike the classical ICP method or the improved version, the proposed method does not require expensive point-to-point calculations. In addition, due to the excellent learning and extracting ability of deep features, it has better generalization for invisible objects and shape changes.

In summary, the major contributions of this research work are described as follows:

- Firstly, a novel registration framework based on the coarse-to-fine strategy is developed. The coarse registration is used to obtain an excellent initial transformation position and the fine-grained registration is used to implement the further optimization to improve the accuracy. For the coarse registration, the improved RANSAC algorithm is proposed to effectively overcome the default that caused by the initial attitude difference.

- Secondly, the Lucas and Kanade (LK) algorithm is improved to avoid the inherent defect that the feature representations that directly extract from the PointNet cannot adapt to compute the gradient estimation in convolution steps so that it can be used to deal with the small registration errors that caused by the partial overlap.

- Finally, this study is based on the two above improved algorithms, the registration procedure and the coarse-to-fine strategy are carefully implemented under the deep learning architecture of PointNet, and four state-of-the-art registration methods are employed to improve the accuracy and superiority.

This work is divided into four parts. Section 1 introduces some background of the point cloud registration. Section 2 presents all the details of the proposed method. Section 3 tests the method and makes a careful discussion. Section 4 summarizes the conclusions and provides the future plan.

## II. THE WHOLE METHOD

The PointNet provides a learnable structured representation and is usually applied for tasks of point cloud classification and segmentation. To successfully makes it applicable to point cloud registration, the RANSAC algorithm and the LK algorithm to are improved to adapt to the "imaging function" of traditional PointNet and expand the PointNet model, the RANSAC algorithm, and the LK algorithm into a unified deep learning framework, whose structure is shown in Fig. 1.

The proposed registration framework starts from constructing feature representations that from the PointNet. The representations using the global features are input into the improved RANSAC algorithm to compute the rough transformation between different point clouds and the improved LK algorithm refines the roughly transformed results according to the local feature representations. The registration procedure stops until the optimal transformation is found by the recurrent learning.

### A. The MLP Symmetric Pooling Feature Extractor

Let $Q$ and $P$ be the source and target dataset, respectively. $\phi: \square^{3 \times N} \to \square^{K}$, for the inputting point cloud $P \in \square^{3 \times N}$, $Q \in \square^{3 \times N}$, $\phi(P)$ and $\phi(Q)$ generate a eigenvector descriptor of K-dimension, which represents the PointNet function. When the function $\phi$ is applied by the multi-layer perceptron (MLP) to the 3D points in $P$ and $Q$, the dimension of the output is also $K$. Then, the pooling function with symmetry is applied to promote the invariance of point order arrangement, and a K-dimensional global feature descriptor is obtained. The whole structure is shown in Fig. 2.
Fig. 1.    The structure of the registration framework.

### B. The Improved RANSAC Algorithm

The advantage of the traditional RANSAC algorithm is that it can automatically match the model according to the data, but it is not effective to compute the corresponding locations of the point cloud. To effectively apply it to 3D point cloud registration, an improved RANSAC algorithm is proposed to calculate the initial registration matrix to minimize the objective functions between the corresponding point cloud. The whole procedure is shown in Fig. 2.

Fig. 2.    The flowchart of the improved RANSAC algorithm.

As shown in Fig. 3, the input of the improved algorithm can be treated to be the K-dimensional feature descriptor corresponding to the two inputting point cloud datasets. The main steps are described as follows:

*1) Search* the corresponding features. Randomly select n features $\{\phi(Q_1), \phi(Q_2), \cdots, \phi(Q_n)\}$, and find the corresponding features $\{\phi(P_1), \phi(P_2), \cdots, \phi(P_n)\}$ in $\phi(P)$ through the nearest neighborhood.

*2) Calculate* the difference vector of the corresponding features. Firstly, the Euclidean distance between the features is calculated; then, the difference ratio is calculated to form the vector $\vec{\eta}$, which is shown in Eq. (1).

$$\vec{\eta} = \left[ \frac{d_{12}^{\phi(P)} - d_{12}^{\phi(Q)}}{\max(d_{12}^{\phi(P)}, d_{12}^{\phi(Q)})}, \frac{d_{23}^{\phi(P)} - d_{23}^{\phi(Q)}}{\max(d_{23}^{\phi(P)}, d_{23}^{\phi(Q)})}, \frac{d_{13}^{\phi(P)} - d_{13}^{\phi(Q)}}{\max(d_{13}^{\phi(P)}, d_{13}^{\phi(Q)})} \right] \quad (1)$$

*3) Correspond* the feature transformation. A temporary transformation matrix $T_i$ is estimated from the corresponding feature pairs, and $\phi(P)$ is converted to $\phi(P_i)$.

*4) Compute* the transformed matrix shown by Eq. (2).

$$T = \arg\min_T g(T) = \arg\min_T \sum_{p \in P} (Tp - q)^2 \quad (2)$$

Fig. 3.    The structure of the feature extractor.

### C. The Improved LK Algorithm

In the refine registration, it wants to find the transformation $G$ that best aligns the data $Q$ from $P$, which can be denoted by using the exponential map in Eq. (3).

$$G = \exp(\sum_i \xi_i T_i) \quad (3)$$

where, $\xi = (\xi_1, \xi_2, \cdots, \xi_6)^T$ is the torsion parameter. $T_i$ is the transformation matrix generated by the coarse registration. The three-dimensional point cloud alignment problem can be described as $\phi(P) = \phi(G \cdot Q)$ to find the optimal $G$, where the abbreviation $(\cdot)$ represents the transformation of $Q$ through the rigid transformation $G$.

In the traditional LK algorithm, as shown in Equation (4), the Jacobian matrix is defined to be:

$$J = \frac{\partial}{\partial \xi} \left[ \phi(G^{-1} \cdot P) \right] \tag{4}$$

where $J \in \Box^{K \times 6}$.

Usually, the calculation of the $J$ is not an easy issue for it heavily requires the gradient of the distortion parameter for the PointNet function that relative to $G$. Therefore, as shown in Fig. 4, the stochastic gradient method similar in reference [23] is employed to calculate the value of the Jacobian matrix $J$. Specifically speaking, each column of the Jacobian matrix are approximated by calculating the finite difference gradient that described by the Eq. (5).

$$J_i = \frac{\phi(\exp(-t_i T_i) \cdot P) - \phi(P)}{t_i} \tag{5}$$

where $t_i$ is the infinitesimal perturbation of the torsion parameter $\xi$.

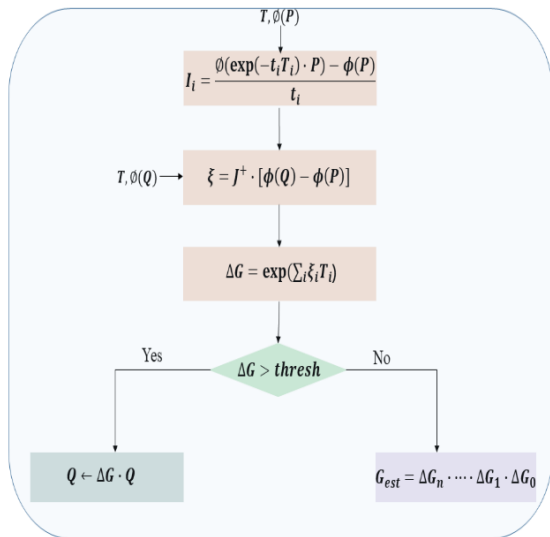

Fig. 4. The flowchart of the improved LK algorithm.

In the improved version, $J$ is equal to an analytic derivative because the *i-th* torsion parameter $t_i$ in each column is non-zero. According to the experiments, a small, fixed value for $t_i$ will produce the better results. The $\xi$ can be expressed as:

$$\xi = J^+ \left[ \phi(Q) - \phi(P) \right] \tag{6}$$

where $J^+$ represents the Moore-Penrose of $J$.

The Equation (6) is used to calculate the optimal twist parameters, and update the point cloud data $Q$ to Equation (7):

$$\Delta G = \exp(\sum_i \xi_i T_i) \tag{7}$$
$$Q \leftarrow \Delta G \cdot Q$$

As shown in Equation (8), the final estimation matrix is the combination of all incremental estimation that calculated in the iteration loop.

$$G_{est} = \Delta G_n \cdots \cdots \Delta G_1 \cdot \Delta G_o \tag{8}$$

### D. The Loss Function

The aim is to search out the best transformation by minimizing the difference between the estimation transformation $G_{est}$ and the forward transformation $G_{gt}$. To avoid possible logarithmic operation of the function during the training process and improve the computational efficiency, the objective function in Eq. (9) is used.

$$\left\| (G_{est})^{-1} \cdot G_{gt} - I_4 \right\|_F \tag{9}$$

## III. EXPERIMENTAL RESULTS AND DISCUSSIONS

### A. The Experimental Details

The experiments are designed by using the point cloud data of the Stanford University and the Geometry Center for training [32]. The maximum number for iterations is 80. Other parameters are set to be the best according to the reference [19].

Two classical global methods and two advanced deep learning-based methods are used to compare the registration performance, i.e., the ICP method [33], the histogram based registration method (3DHoPD) [34], the 3DSmoothNet [30], and the PointNet LK [35].

As shown in the Eq. (10), the Root Mean Square Error (RMSE) is selected as the error measurement for its popularity in point cloud registration. It refers to the average square summation of the distance between the corresponding points.

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} \left\| P_i - Q_j \right\|^2}, (1 \le j \le M) \tag{10}$$

where $P_i$ and $Q_j$ are the pairwise nearest neighbors in the two datasets. $N$, $M$ is the scale parameter, respectively. The smaller RMSE means the better result.

Actually, only the RMSE is not enough to know the number of aligned points. The Effective Root Mean Square Error (ERMSE) can better describe the registration accuracy. How to calculate the ERMSE is show in Eq. (11).

$$\begin{cases} \beta = (N-k)/N \\ ERMSE = \sqrt{\dfrac{1}{N-k}\sum_{i=1}^{N}\left\|P_i - Q_j\right\|^2}, (1 \le \text{j} \le \text{M}) \end{cases} \quad (11)$$

where $\beta$ is the ratio of the aligned points to all the points, $k$ is the number of non-aligned points, $N$ is the number of all the points.

### B. The Results and Discussion

Firstly, a test on the learned model by using the open ModelNet40 dataset [36-40] is implemented. The intermediate results in the iterations are shown in Fig. 5. After the model is trained, when the new registration data is input, it can be seen that as the iterations increase, the alignment from the source points to the target points can be well obtained, even if the data is not used to train the model, demonstrating the proposed method is robust enough and has the good feasibility and generalization.

Iteration number of 0    Iteration number of 20

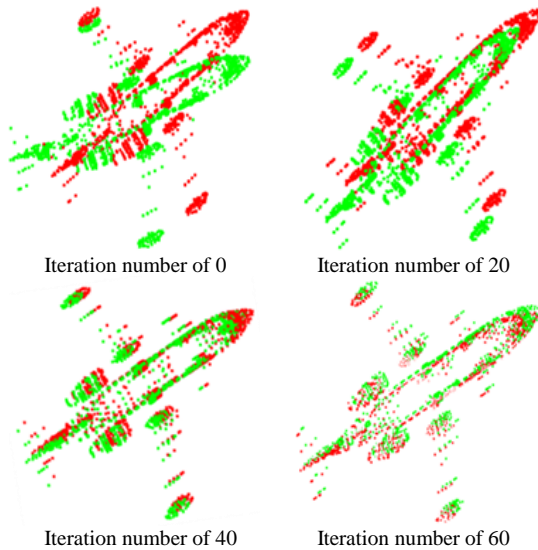
Iteration number of 40    Iteration number of 60


Fig. 5. The registration procedure in different iterations.

Then, the ICP, 3DHoPD, 3DSmoothNet, PointNetLK and the proposed method are tested on the four models that are shown in Fig. 6. The blue points are the source points, and the yellow points are target points. All the visual registration results are shown in Fig. 7 and the quantitative comparison results are shown in Table I to Table IV. The deviation of the initial attitude is significant for the data in Model 1 and Model 2. It can be found from Fig. 7 that the ICP and the 3DHoPD perform very poor on these two datasets, even the registration is failed. From the value of $\beta$ in Table I and Table II, it means only few corresponding points are obtained. In addition, the value of the RMSE and the ERMSE is obviously larger than that of the other three methods, showing the traditional global registration cannot well deal with the significant attitude deviation. On the other hand, the tree methods using the deep learning theory perform well on the two dataset, especially the proposed method can get the best ratio of 89.2%, which means most of the corresponding points are obtained. This is because the important structural features

in the deep levels can be effectively captured. The superiority is obvious to deal with the attitude deviation problem.

For the data in Model 3 and Model 4, they mainly focus on the translation when the partial overlap happens. It can be found that the ICP and the 3DHoPD perform better than their performance in Model 1 and Model 2; the value of $\beta$ in Table III and Table IV showing more corresponding points can be obtained. Of all the five registration methods, the proposed method achieves the best quantitative comparison and the highest accuracy is 93.52%, improving five percent compared with the ICP method. Overall, the proposed method can achieve sufficiently good results for both of the translation and rotation in the registration, demonstrating stronger robustness, better generalization and higher accuracy.

TABLE V.    THE RUNNING TIME OF DIFFERENT METHODS

| Method | Model 1 | Model 2 | Model 3 | Model 4 |
|---|---|---|---|---|
| ICP | 13.25 | 15.85 | 3.85 | 3.88 |
| 3DHoPD | 13.13 | 15.45 | 3.65 | 3.70 |
| 3DSmoothNet | 12.07 | 14.15 | 16.30 | 24.15 |
| PointNetLK | 2.96 | 3.50 | 3.86 | 6.04 |
| Proposed | 1.63 | 1.91 | 2.20 | 3.31 |

The time cost of the five methods on the four models is also shown in Table V (*time/s*). It can be found that when dealing with the significant deviation of the initial attitude in Model 1 and Model 2, the proposed method achieves almost 8 times faster than the ICP method and 3DHoPD method, 7 times faster than the 3DSmoothNet method and 1.5 times faster than the PointNetLK method. When deal with the partial overlap problem in Model 3 and Model 4, the time cost of the ICP, 3DHoPD is almost the same, the 3DSmoothNet spends

the most time, and the proposed method achieves at least 1.6 times faster than the PointNetLK method. Therefore, both of the qualitative and quantitative analysis on experimental results show the superiority and feasibility.

## IV. CONCLUSION AND FUTURE WORK

A novel point cloud registration method by using the coarse-to-fine strategy is developed. This method integrates the improved RANSAC algorithm and the LK algorithm into the PointNet network, effectively avoiding the inherent defect that the PointNet network cannot adapt to the gradient estimation through convolutions. In addition, the proposed method reduces the attitude difference and partial overlap between the source point cloud datasets by simultaneously making use of the global and local features. Experimental results obtained by four state-of-the art methods on four datasets fully verify its effectiveness, accuracy and superiority.

Though good results have been obtained, some limitations should be fixed, such as the extracted features are not rich enough, the registration accuracy is not satisfying and the time cost is still too high to apply it in practice. In future work, the proposed method will be further optimized by introducing advanced theory and applying it to other registration tasks. For example, the famous transformer model and attention mechanism will be employed to extract more deep features to improve the registration performance.

## CONFLICT OF INTEREST

The authors declare that they have no conflicts of interest to report regarding the present study.

*Abstract*—**This study highlights on the methods used for surface reconstruction from unstructured point cloud data, characterized by simplicity, robustness and broad applicability from 3D point cloud data. The input data consists of unstructured 3D point cloud data representing a building. The reconstruction methods tested here are Poisson Reconstruction Algorithm, Ball Pivoting Algorithm, Alpha Shape Algorithm and 3D surface refinement, employing mesh refinement through Laplacian smoothing and Simple Smoothing techniques. Analysis on the algorithm parameters and their influence on reconstruction quality, as well as their impact on computational time are discussed. The findings offer valuable insights into parameter behavior and its effects on computational efficiency and level of detail in the reconstruction process, contributing to enhanced 3D modeling and digital twin for buildings.**

*Keywords—Surface reconstruction; point cloud; building reconstruction; 3D mesh*

## I. INTRODUCTION

Buildings play a pivotal role in our everyday lives, and consequently, considerable endeavors have been directed towards enhancing them. One approach to achieve this enhancement involves integrating digital technologies throughout the entire life cycle of the building, encompassing various stages such as planning, construction, operation, renovation and demolition [1]. Notably, significant attention has been dedicated to integrating digital advancements into the construction life cycle in the past decade [2]. Throughout this life cycle, three-dimensional (3D) models have demonstrated their utility in facilitating decision-making, scenario modeling, and analysis of 3D data. In recent years, there has been a growing demand for effective and efficient monitoring of changes in buildings and construction installations within urban areas. This demand is particularly evident in the domains of architecture, engineering, construction/facility management (AEC/FM), urban planning, surveying and mapping. Various applications, such as progress tracking, profitability enhancement, quality control, security assurance and incident investigation, underscore the necessity for advanced methodologies that employ automated measurements, including 2D imaging, photogrammetry and 3D laser scanning, instead of relying solely on visual inspection and manual data collection.

3D building models are important in representing the urban environment and have numerous applications, including 3D

Geographic Information Systems (GIS), urban planning, environmental simulation, energy consumption assessment, tourism, mobile navigation, heritage preservation and change detection [3]–[5]. Many studies have been conducted throughout the years on the reconstruction of building information models (BIM). BIM, as a valuable methodology, serves as a pivotal tool in facilitating the planning and construction processes of architectural and infrastructural projects. BIM models intricately replicate physical structures, offering a comprehensive foundation for undertaking assessments of their status, condition, and strategizing maintenance activities. Furthermore, BIM presents a unified and cohesive platform for the seamless integration of data collected from the construction site.

Recently, the concept of BIM has expanded to include the concept of a digital twin (DT). DT is a virtual representation of a physical entity that used to simulate and evaluate the performance of a building throughout its lifespan. The digital twin technology can be utilized for various purposes such as visualization, modelling, simulation, analysis and future planning [6], [7]. These virtual models can help optimize the design and building process, anticipate potential issues and enhance the building's performance and features over time [8]. The idea of a digital twin was initially introduced by M. Grieves during a Product Life-Cycle Management Symposium at the University of Michigan Lurie Engineering Center in 2002 [9]. The proposed model of a digital twin comprises three primary components: the physical product, the virtual product and the connection between the physical and virtual entities. In a subsequent publication [10], Grieves further defined digital twinning as the integration of three essential elements: a virtual twin, a physical counterpart (such as a product, system, model, or entity like a robot, car, power turbine, human, hospital, etc.), and a data flow cycle that facilitates the exchange of information between the physical and virtual twins. The virtual twin employs simulation algorithms to replicate (either fully or partially) the performance of its physical counterpart, generating equivalent outputs based on input values. This technology is commonly used in the context of smart manufacturing but is applicable to various domains, including construction, education, transportation, human and healthcare, also industrial production [7]. The primary advantages of digital twin models are their ability to access and query structured data and their visual representation of information. Digital twins undergo periodic updates to maintain alignment with their physical counterparts. The frequency of these

updates varies contingently upon factors including the inherent characteristics of the product, its dynamic attributes and the specific objectives underlying the model's use. For instance, in the case of a jet engine, updates may occur at minute intervals, whereas for maintenance management of a building, annual updates may suffice. Notwithstanding, a notable complexity emerges due to the historical context of many extant buildings, often constructed decades ago, thereby necessitating the development of digital twin models that accurately represent these pre-existing assets.

To create a digital twin of a building, one of the essential steps is to capture its geometry and appearance using point cloud data. A point cloud is a collection of points in 3D space that represent the surface of an object. These data points typically comprise X, Y, and Z coordinates and are primarily utilized to depict the outer surfaces of an entity [11]. Point clouds can be obtained from various sources, such as laser scanners or cameras, by capturing the geometry of an existing facility. These techniques produce point cloud data as output. Compared to visual inspection, point cloud data offers shorter processing times and higher measurement accuracy. With the introduction of very precise data collection techniques involving terrestrial laser scanning, aerial oblique photography and satellite imagery, 3D point cloud has established itself as the principal data sources for large-scale building reconstruction. Point clouds can be processed and reconstructed to create 3D models of building interiors and exteriors in vector format. Furthermore, existing research projects have emerged proposing approaches for generating accurate building footprints and models by combining point clouds and imaging [12]–[14]. This interdisciplinary field, which includes photogrammetry, computer vision and modelling, has seen significant research efforts over the last two decades, delivering important and significant results.

While 3D building models and digital twins offer immense potential in urban development and architectural landscapes, there exists a notable gap in systematically and critically analyzing the various surface reconstruction techniques that form the foundation of these models especially on its simplicity, robustness, and broad applicability in surface reconstruction from point cloud data. This paper aims to bridge this research gap by addressing the following pivotal questions: (a) How does different surface reconstruction technique perform when applied to large, unstructured point cloud data like buildings, both in terms of quality and speed of calculation? and (b) In what contexts do these techniques exhibit optimal efficiency and precision? This paper central contribution is an in-depth comparative assessment of specific surface reconstruction techniques, bringing clarity to the challenges, advantages, and nuances of each. In doing so, professionals and researchers in the related field could equip with a clearer understanding and guide for their practical and academic endeavors.

In existing research, a rich set of methods has been proposed for surface reconstruction from point clouds, and some reviews and benchmarks of these methods have also been provided [15]. However, they still face challenges in terms of robustness, generalization and efficiency, especially for unstructured, complex and large-scale surfaces such as buildings. Furthermore, the scalability and parallelizability of these methods become critical when dealing with big data, as they must handle enormous point cloud collections while maintaining computational efficiency. Point cloud-based 3D reconstruction in buildings has many applications for the construction industry, such as automatic creation of as-built BIMs, damage detection and assessment, cultural heritage, and facility management [16]–[18]. Therefore, there is a need for developing an effective method for surface reconstruction from point clouds that can handle the specific characteristics and requirements of building surfaces.

This paper focuses on a few types of surface reconstruction techniques use for building data. Thus, a comparison between these techniques, based on the quality of the surfaces and the speed of calculation, will be made. This work is organized as follows: Section II presents a summary of reconstruction methods from a set of discrete data points or sample. Section III shows the visualization and discussion of the surface reconstruction results for more understanding. Lastly, Section IV explains the conclusion for this paper.

## II. METHODOLOGY

The overview of the sample data used for reconstructing 3D surface of a building is as shown in Fig. 1. The point cloud data represents one of the buildings in Faculty of Electrical Engineering & Technology, Universiti Malaysia Perlis, Malaysia. The initial step involves converting the binary data into a more interpretable format compatible with standard 3D libraries and applications. Subsequently, downsampling the data is performed to make it efficiently better processed with shorter computational time. Next, data cleaning is implemented to mitigate imperfections in the real data, enhancing the efficiency of the surface reconstruction method for mesh generation. Finally, five different surface reconstruction techniques are applied and assessed based on the resulting processed point cloud data to generate a 3D triangulated mesh.

### A. The Sample Data

The point cloud data of 3D coordinates is stored in six different files and saved in .ptx file format and consists of approximately 226,471,204 points. The data is collected by Geodelta Systems Sdn. Bhd. using 3D terrestrial laser scanner model Leica RTC360 where it has a scanning speed up to 2 million pts/sec and advanced HDR imaging.

To extract the 3D file format from the .ptx file and transform it into a commonly used 3D point cloud data format, such as the .pcd file format, a comprehensive understanding of the binary file data structure assumes paramount significance. Each .ptx file encompasses vital data elements, encompassing color information, the minimum depth value (zmin), the subsampled number of rows (nrows), the subsampled number of columns (ncols), the image file name, and an Nx5 matrix signifying 3D and 2D normalized coordinates falling within the [0,1] range [19]. Herein, N denotes the product of nrows and ncols, where values equivalent to zmin denote the background. The extraction process selectively focuses on the isolation and preservation of solely the 3D coordinates from the .ptx file, ultimately saving them in the .pcd file format, facilitating subsequent analytical endeavors. Various software tools, such

as CloudCompare, MeshLab, Blender and Python 3D libraries, can read the .pcd file format, facilitating data visualization and manipulation. This enables easier understanding and modification of the data as needed. An example of an extracted point cloud dataset is illustrated in Fig. 1, where the image at the below shows a zoomed-in view of the original 3D point cloud shown on the top. From the figure, it can be inferred that each point exhibits ambiguous relationships with neighbouring points.

Fig. 1.  The point cloud data used in this study.

### B.  Data preprocessing

In order to improve the data quality and computational efficiency, a preprocessing stage is employed to eliminate unnecessary data of point clouds. One of the often used as a pre-processing step for many point cloud data processing tasks is voxel downsampling. Downsampling is a technique to reduce the number of points in a point cloud as the original dataset is too large to handle. It can improve efficiency and accuracy by minimizing storage requirements, processing time and memory usage. One of the common methods for downsampling is voxel downsampling. It uses a regular voxel grid to create a uniformly downsampled point cloud from an input point cloud. The algorithm follows a two-step process: initially, data points are grouped into voxel containers and subsequently, each occupied voxel yields a single representative point through the computation of the average of all points contained within it. So, all of the point clouds are being downsampled to 0.01 resulted in easier to be processed due to lesser number of points as shown in Fig. 2. The

downsampled point cloud data reduced to 12,704,776 points, from its original which consists of 226,471,204 points.

Fig. 2.  Downsampled data of original point cloud.

Next, the preprocessing step involves removing statistical outliers. It removes points that are further away from their neighboring points. The mean inter-point separation is computed via the application of the k-nearest neighbors algorithm. Should the computed average distance between a query point and its neighboring points surpass a threshold established by the standard deviation, it is categorized as an outlier and subsequently excluded from the dataset. This initial preprocessing stage employs various standard deviation ratios, notably a factor of 0.75, to accentuate differentiation. The parameter kNN, signifying the number of nearest neighbors considered, is set to a value of 50. Fig. 3 shows the visualization of the point cloud data with red and grey colour that indicates the outlier and inlier. The red colour is the outliers that being filtered out. Fig. 4 shows the remaining point cloud in original colour of 12,225,180 points.

Fig. 3.  Inlier (in grey) and outlier (in red) of the point cloud data.
Fig. 4. Remaining point cloud after outlier removal.

However, the remaining point clouds are not accurate as the surrounding of the buildings still contains points that are considered as noise. So, a process of filtering takes over using CloudCompare by manually remove the excessive point cloud surrounding the building. Fig. 5 below shows the remaining point cloud data that will be processed for surfacce reconstruction which only consist of 7,258,055 points.

Fig. 5. Filtered point cloud.

*C. Surface reconstruction*

The field of geometry processing has significant emphasis on the foundational challenge of surface reconstruction from point clouds. This endeavor is rooted in the objective of generating a continuous 2D manifold surface from the inherent sparsity of raw, discrete point cloud data. It is worth noting that this problem is inherently ill-posed, and its complexity escalates when considering the various sensor-related imperfections that manifest within point clouds acquired through real-world depth scanning techniques.

Hence, this paper will focus exclusively on five distinct surface reconstruction approaches, aimed at visualizing a range of methodologies advanced by prior researchers addressing this issue. These methodologies can be broadly categorized into three primary groups, namely Alpha Shape, Ball Pivoting and Poisson reconstruction, as well as combinations of Alpha Shape with Ball Pivoting and the amalgamation of Alpha Shape, Ball Pivoting and mesh refinement.

The Alpha Shape technique serves as an extension of the convex hull method, allowing for the representation of point clouds with concavities and holes. However, choosing an appropriate value for "α" requires a balance. If the value is too small, the resulting mesh may include more noise or artifacts, and it may overfit to local irregularities in the point cloud. On the other hand, if the value is too large, the resulting mesh may oversimplify the shape and fail to capture fine details or concavities. By adjusting the parameter alpha or "α", the level of detail in the reconstructed surface can be controlled. A smaller "α" value results in a more intricate surface, while a larger "α" value produces a smoother and simpler surface. The reconstruction process involves computing the Delaunay tetrahedralization of the point cloud and extracting the faces belonging to the "α" complex as it contains points, edges, triangles and tetrahedrons.

Ball Pivoting Algorithm (BPA), another surface reconstruction method, is closely related to the Alpha Shape technique. It is an efficient surface reconstruction approach which operates by simulating the rolling of a ball with a predetermined radius across the point cloud. Triangles are created whenever the ball encounters three points without penetrating them. As the ball moving through the point cloud, a triangular interconnected 3D mesh is formed, linking the 3D points. The method is repeated until all the points form a triangle. Starting with a seed triangle, the algorithm pivots the ball around the edges of existing triangles until all feasible triangles are produced. The BPA exhibits sensitivity to variations in the ball radius, which plays a crucial role in determining the quantity of reconstructed faces. A smaller radius renders the model susceptible to noise in the input data, while a larger radius may lead to the missing of intricate details, resulting in the formation of holes within the generated surface. BPA is suitable for handling point clouds with non-uniform densities and noise; however, careful selection of the ball radius is crucial to prevent gaps or overlaps in the reconstructed surface.

Poisson reconstruction is a widely recognized approach for generating smooth surfaces from point clouds using a volumetric strategy. It leverages oriented point samples obtained from 3D range scanners to create watertight surfaces. The method assumes that the point cloud serves as a sample of an underlying surface's indicator function and solves for an implicit function whose gradient best aligns with the estimated normals of the point cloud. The surface is subsequently extracted as an iso-surface of the implicit function utilizing marching cubes. Poisson reconstruction excels in producing high-quality surfaces with well-defined features, but it requires oriented normals as input and may introduce undesired intricacies in flat regions. Nevertheless, this technique exhibits

resilience to noisy data and artifacts arising from misregistration.

## III. RESULTS AND DISCUSSION

All surface reconstruction techniques were evaluated and tested on a computer system comprising an Intel i7 12700h processor with 32GB of RAM and a GTX 3050ti graphics card. All methods were implemented using the Open3D library in python. Fig. 6 shows the clean point cloud data of the chosen building that will be used for the surface reconstruction algorithms upon preprocessing and Fig. 7 shows the close-up view for the point cloud for better understanding to show its complexity and unstructured of the data. Table I shows the comparison of all algorithms with the parameters used, time taken for each algorithm needs to be completed, together with their resulting images from two views: the whole building and close-up view from the top corner.

Fig. 6. Point cloud data of the building.

Fig. 7. Close-up view of the point cloud.

Poisson surface reconstruction necessitated the prior prediction of normals for surface reconstruction, employing it automatically by the maximum nearest neighbour search. The depth of reconstruction indicated the resolution of the resulting triangle mesh, determined by the octree's depth which being set to 8. The minimum number of sample points within an octree node was established to adapt the octree construction to the sampling process, with lower numbers chosen to mitigate noise interference. The scale factor denoted the ratio between the reconstruction cube's diameter and the sample bounding box's diameter. Nevertheless, Poisson surface reconstruction yielded outcomes without any mesh holes but it leaves unnecessary mesh triangulations on planar point as shown in Table I.

TABLE I. SUMMARY OF RESULT COMPARISON FOR THE SELECTED ALGORITHMS

| Algorithms | Parameters | Processing Time (s) | Results |
|---|---|---|---|
| Poisson Reconstruction | Octree depth=8 Scale factor=1 | 163.92 |  |

| Ball Pivoting | Ball radius=0.02 | 288.34 |  |
| Alpha Shape | α = 0.13 | 303.19 |  |
| Alpha Shape + Ball Pivoting | α = 0.13<br>Ball radius=0.02 | 566.38 |  |

| | | | |
|---|---|---|---|
| | | |  |
| **Alpha Shape + Ball Pivoting + Mesh Filtering** | **α = 0.13 Ball radius=0.02 Number of iterations (Simple Smoothing)=30 Number of iterations (Laplacian)=30 Lambda filter=0.5** | 1092.07 |  |

On the other hand, Ball Pivoting surface reconstruction required prior normal estimation before commencing surface reconstruction. Vertices falling within a given percentage of the clustering radius were merged to prevent excessive small triangle creation. The ball rolling process would cease if it encountered a significant crease angle surpassing the threshold angle. The ball's rolling radius over the point cloud was set to 0.02. Table I exhibited also the outcomes of ball pivoting surface reconstruction, where holes were observed in regions with lower point cloud density. However, unlike Poisson surface reconstruction, this method avoided unnecessary mesh creation that required subsequent cropping since it failed to represent facial depth accurately.

Meanwhile, the result of meshing using the Alpha Shape method with a parameter value of 0.13 involves generating a surface mesh that captures the shape of a point cloud with holes and concavities. The Alpha Shape method is a generalization of the convex hull and is particularly useful when dealing with point clouds that have irregular or non-convex shapes. Unlike Poisson and Ball Pivoting, Alpha Shape algorithm does not require normal estimation. The parameter "α" in the Alpha Shape method determines the level of detail in the reconstructed surface. A smaller value of "α" (0.13) produces a more detailed mesh with a higher resolution where

smaller features and intricate details present in the point cloud can be captured in the resulting mesh as shown in Table I. The mesh will closely follow the shape of the input point cloud and adapt to its local density and curvature. Therefore, the choice of the "α" parameter is decided after running several tests with different values. This gives the best result as it still can capturing details and maintaining the overall shape fidelity in the resulting mesh.

Due to the limitations of each individual algorithm, the combination of Ball Pivoting and Alpha Shape methods in meshing involves leveraging the strengths of both approaches to achieve a more robust and accurate representation of the underlying point cloud. By combining Ball Pivoting and Alpha Shape methods, the strengths of both techniques can be fully utilized. Ball Pivoting handle the local details and irregularities of the point cloud, while Alpha Shape capture the overall shape and handle concavities. This combined approach produced a mesh that preserves the important features and characteristics of the original point cloud, while also providing a more accurate and visually appealing representation as shown. However, the Alpha Shape results in not so precise reconstruction when it comes to sharpness of angles of the building as shown in Table I.

The integration of Ball Pivoting, Alpha Shape and mesh refinement through Laplacian smoothing and Simple Smoothing however constitutes a comprehensive strategy for the task of surface reconstruction and subsequent mesh enhancement. In terms of mesh refinement, two distinct smoothing techniques are employed. Laplacian smoothing involves iterative adjustments of vertex positions, effectively attenuating high-frequency noise and enhancing mesh smoothness while preserving sharp geometric features. Conversely, Simple Smoothing employs a rudimentary moving average filter to vertices, delivering a general refinement to the mesh's geometric properties. This two-fold smoothing methodology serves the purpose of mitigating undesired irregularities and augmenting the overall visual fidelity of the mesh representation. Through the combination of these methodologies, the resultant mesh stands to gain advantages in terms of heightened accuracy, diminished noise, and improved surface regularity. The amalgamation of Ball Pivoting, Alpha Shape, and the aforementioned dual smoothing techniques yields a potent solution applicable across diverse domains, encompassing computer graphics, 3D modeling, virtual reality, and computational geometry. Furthermore, the adaptability inherent in this combined approach empowers users to fine-tune parameters and iteration counts, thereby achieving optimal outcomes tailored to the distinctive attributes of their datasets and the desired level of mesh refinement. Consequently, this combination of methodologies emerges as an efficacious and versatile technique for addressing surface reconstruction and mesh refinement tasks.

In summary, each of the methodologies introduced for surface reconstruction has its respective advantages and limitations. The Poisson surface reconstruction method consistently produces hole-free results but can also introduce unnecessary triangulations. On the other hand, the Ball Pivoting method excels in avoiding unnecessary mesh production yet lacks in representing facial depth precision. The Alpha Shape method, adaptable to non-convex and irregular shapes, offers a versatile solution to meshing, though it may occasionally compromise the precision of angles. However, it becomes evident that the approach emerges from the integration of Ball Pivoting, Alpha Shape, and mesh refinement techniques, specifically through the incorporation of Laplacian and Simple Smoothing. This combination technique harnesses the unique strengths of each individual method, producing an optimal solution that balances accuracy, noise mitigation, and enhanced surface consistency. As a result, this integrated methodology stands out as the most recommended, providing unparalleled robustness and adaptability suitable for a wide range of surface reconstruction and mesh refinement applications.

Upon analyzing the results obtained, it becomes imperative to consider the scalability of the proposed methodologies. While the techniques have shown promising outcomes on the datasets in this study, there is an important area of evaluation to consider. Their performance across datasets that represent distinct architectural styles, varying scales, and diverse complexities needs to be examined. Future investigations should focus on evaluating these methods across a wider range of datasets. This approach will help validate the adaptability and universality of the proposed techniques. In scenarios where the datasets are vast and depict intricate urban landscapes, it is vital to assess metrics such as computational efficiency, memory requirements, and the fidelity of the resultant mesh.

Additionally, despite the promising outcomes, there exist potential limitations and areas for further exploration. One foreseeable challenge pertains to highly intricate and ornate architectural designs, where capturing every minute detail could strain the computational resources and necessitate further algorithmic optimizations. Moreover, while the combination of Ball Pivoting and Alpha Shape methods harnesses their collective strengths, there remains room for improvement in handling sharp angles, as evidenced in Table I. Future research could just focus on refining these combinations, possibly integrating other meshing algorithms or advanced smoothing techniques to better address such challenges. Furthermore, with the rapid evolution of hardware and software capabilities, exploring the integration of machine learning or AI-driven approaches in the surface reconstruction pipeline could offer innovative solutions, enhancing the accuracy and efficiency of the process.

## IV. CONCLUSION

In conclusion, the successful implementation of specific surface reconstruction methods is contingent upon satisfying the input requirements, such as having normal orientation information available for the point cloud. In cases where the input lacks normal orientation, an algorithm must be employed to estimate the orientation values for the point cloud. For instance, Poisson surface reconstruction necessitates the estimation of normal orientations prior to the reconstruction process. Certain methods exhibit robustness towards specific types of point cloud artifacts, including noisy data, nonuniform sampling, outliers, misaligned scans and missing or incomplete data. However, certain methods may be limited in their applicability to different shape classes. For instance, surface reconstruction cannot handle shape classes that do not result in watertight meshes. The output of the reconstruction process can manifest in various forms, such as producing watertight meshes, mesh triangulation on planar surfaces, generating cloth-like meshes that envelop the initial point cloud or voxelization. The result of Poisson surface reconstruction often presents unnecessary mesh triangulations on planar point clouds, resembling cloth-like structures, while effectively closing holes in sparsely sampled regions. On the other hand, Ball Pivoting surface reconstruction tends to yield accurate mesh edges but can leave numerous holes due to nonuniform sampling and missing data, particularly in areas like the angle's region with less point cloud. By combining different methods, it can help to achieve smoother with higher accuracy of the surface of buildings.

# A Cost-Effective Method for Detecting and Tracking Moving Objects using Overlapping Methods

Yuanyuan ZHANG[1*]

College of Economic and Management, North China Institute of Science and Technology
Langfang, Hebei 065201, China

*Abstract*—**Overlay approaches for moving object detection and tracking have recently received attention as a crucial field for computer science and computer vision research. Using pixel overlap and visual attributes, these techniques enable the recognition and tracking of objects in movies or video data. Two color and edge features for the suggested method are presented in this article. The suggested approach uses the SED algorithm, and since the edges have a lower volume than the entire image, the processing process will be faster with the reduction of information. The characteristic of color is the HSV (hue, saturation and value) histogram because it is close to human vision. However, because the margins tidy up the shapes in the human eye, they contain important information. These concerns lead to the conclusion that the histogram of gradient angles based on regional binary patterns is the edge feature of the suggested system. There are two justifications for employing local binary patterns. First, the principal edges are emphasized by using local binary patterns. Another point is that the image produced by this method displays the image's texture; in other words, the shape's feature is taken from the context of the texture, which is regarded as a type of combination of features. Several criteria were evaluated in order to assess the suggested approach for tracking images in comparison to related systems; the most significant of these are the precision, recall, and similarity criteria. In comparison to other works, the findings for precision have generally increased accuracy by 25%, recall by 17%, and similarity by 12%.**

*Keywords—Tracking; moving object detection; image processing; binary patterns; HSV histogram*

## I. INTRODUCTION

Today, object identification, particularly machine vision and pattern recognition, is one of computer sciences most significant and broad study domains. Even after an object's appearance has changed, the human brain is still able to instantly recognize and categorize many different types of items [1]. Different characteristics, such as changes in brightness, state, texture, shape, and object occlusion, affect how well the human visual system can identify things [2]. Additionally, the human brain has the capacity to extrapolate its findings from a collection of things and reliably recognize ones it hasn't yet seen [3]. Scientists working in the fields of machine vision and computer science have used the study of the human brain's cognitive capacity to recognize and draw inspiration from it to design and present a variety of object recognition systems [4]. In order to organize visual information, these findings are also used in related applications like picture concept recovery and image indexing [5]. Visual characteristics are the primary source of information used by conventional object recognition techniques to identify items in real-world photographs [6]. To a certain extent, visual characteristics, including color, form, texture, and picture edges, can compensate for changes in an object's appearance. Additionally, new methods have attempted to explain the interactions of objects in a scene or general statistical notions using conceptual features [7]. These methods for object identification applications increase recognition precision and clear up conflicts those traditional systems, with their reliance on visual features, experience [8]. There is a noticeable increase in image data globally, and that growth rate is accelerating daily. According to Information Trends, more than 1.1 trillion images were taken in 2016 with cameras and mobile devices [9]. The same forecast predicts that by 2020, this amount will have increased to $1.4 trillion. Many of these photographs are made available online or through cloud services. In 2014, prominent websites like Instagram and Facebook had daily photo uploads of more than 1.8 billion [10]. Beyond consumer electronics, there are cameras everywhere that take pictures for automation. Traffic cameras and moving cars are both watching the road. Robots need to be able to see in order to categorize objects and get rid of trash intelligently. Engineers, medical professionals, and explorers of space all employ imaging instruments. We need to have an understanding of this data's contents in order to manage it successfully. A wide range of image-related tasks benefits from automated content processing [11]. This requires computer systems to bridge the "semantic gap" between surface pixel information stored in image files and how people perceive analogous images. Computer vision is applicable in this area. Images can contain objects that can be automatically found and recognized. One of the core issues with computer vision is what is known as object detection. We'll demonstrate that convolutional neural networks now offer the best method for detecting objects [12]. Examining and putting to the test convolutional object identification techniques is the main goal of our research. The goal of computer vision is to derive useful information from the content of digital photographs or videos. It's just straightforward image processing, which entails fiddling with visual data down to the pixel level. Applications of computer vision include traffic automation, picture classification, visual identification, image retrieval, augmented reality, machine vision, and reconstruction of 3D scenes from 2D images [13]. Image tracking is one way to detect moving objects. An image tracker is a system that sequentially tracks preset items in a series of photographs [14]. In other words, the tracking process is the act of estimating the temporal and spatial changes of the object or, more generally, the states of

the target object during the video sequence based on measurements and observations. The target object may be specified by detection algorithms or manually [15]. Using data from earlier frames and additional data, such as the target's movement model or appearance attributes, the tracking system calculates and looks for the target in the current frame. An innovative technique for tracking images is given in this study. Color and edge features, the SED technique, and local binary patterns have all been utilized in image analysis to extract information from images and moving objects. The application of this technique highlights how closely color qualities resemble human sight and how crucial the information at the margins is. This approach can also aid in developing algorithms with increased processing speed and accuracy for picture recognition. In general, these developments can advance the science of picture tracking and enhance the functionality of systems for image analysis and recognition. The writers' contribution to this study can be summed up as follows:

- Find objects in the image and background dataset.

- Image tracking using color and edge features.

The remainder of the essay is structured as follows: Section II highlights earlier research on object detection using various image processing methods. Section III contains the suggested concept and approach. Section IV discusses the outcomes of the evaluation and simulation and Section V contains the conclusion and recommendations for future work.

## II. RELATED WORKS

The study gap that this research tries to solve is improving the efficiency and accuracy of moving object detection and tracking in computer vision and image processing. As mentioned in the introduction, to solve this gap, the proposed solution for tracking accuracy and detection combines color and edge features, uses SED algorithm and local binary patterns to increase detection and tracking of moving objects. The difficult task of identifying things in the image is one that numerous researchers are presently doing. The long-term objective of picture understanding is to recognize all objects in a general scene; however, this is still difficult due to factors like intra- and extra-class diversity, state and location, backdrop complexity, overlap, significant illumination variations, etc. Numerous publications published recently compared the effectiveness of various approaches' identification rates and mistake rates. However, a number of factors, including learning and execution times, the number of training samples, and the proportion of the mistake rate to the recognition rate are important when evaluating algorithms. The comparison is further complicated by the fact that researchers' definitions of recognition and error rate differ. The research in [16] proposes a new technique for employing a stereo camera to detect objects with many colors distributed unevenly in complicated backgrounds and then estimate the depth and form of the object. In this study, color saturation space is separated into fuzzy color histograms based on self-clustering in order to extract characteristics for object detection. A fuzzy color histogram is created for each window scan in a pyramid of graded images by adding the fuzzy degrees of all the pixels in each cluster. The right and left photos are initially segmented

using color space to identify the matched item region in the right image. The study in [17] provides an overview of current advances in the field of object recognition in remote-sensing photos. Many studies have been conducted to find things in aerial and satellite photos throughout the last few decades. They are separated into four primary groups in this article: machine learning-based approaches, knowledge-based methods, object identification methods based on object-based picture analysis, and methods based on template matching. This page explains the categorization of object recognition research. Depending on the format a user chooses, there are two additional types of matching methods: hard pattern matching and metamorphic pattern matching. In [18], a context-oriented salient Bayesian model is put out to address the problems of scale variance and detection ambiguity in small item identification. The sea is the object of this article's visual analysis. It is possible to understand that there is a link of reliance between the place and the scale at which things may occur by looking at the geometry of the camera in the image against the background of the sea and sky. The model described in this study is a universal model that may be applied to many contexts with various images to facilitate the object. The research in [19] presents a comprehensive review of the statistical learning-based representation of features in object recognition. This article compares the evaluation outcomes of object detection algorithms with various visual features and categorizes visual features based on differences in computations and visual attributes. Therefore, the objective of this review is to develop a thorough and complete plan for researchers. The portrayal of the influence of features is a concern when taking into account the demands of generic object recognition. To increase the representational strength of object recognition models, it is important to acquire extensive and powerful visual features. The display of comprehensive features can be effectively removed by combining various visual property aspects. An innovative component-based method for object detection on a two-dimensional image and its use as a visual landmark has been presented by researchers in [20]. Object recognition is a hybrid cryptographic system that makes it possible to keep track of the topology and use it to power the recognition procedure. As shown in the aforementioned study, it is challenging to separate the components of an item from a two-dimensional image; it is only logical for the image to represent either the upper or lower component. Determining the object and its representation from the existing image and the various numbers deduced from the pieces is the goal of this research. The study in [10] presents a brand-new energy function based on the autocorrelation function for active contour models, allowing for recognizing small objects against textured and chaotic backgrounds. To show the information of each area, the proposed method calculates picture characteristics for each pixel in the image domain using a combination of short-term autocorrelations. A novel energy function dubbed "normalized accumulated short-term autocorrelation" is introduced for the active contour based on the localized area using the collected features. Small items can be recognized in pictures with cluttered backgrounds and heterogeneous textures by decreasing this energy function. Researchers in [21] have presented a brand-new method for picture edge identification based on ACO. In the suggested

approach, coupled optimization techniques have been applied, which has aided in speeding up the process of solving optimization issues. In this method, artificial ants first produce a number of answers, the information from which is then useful for the genetic algorithm. These answers then serve as the initial population for the genetic algorithm, and the genetic algorithm then produces the subsequent population from these answers. A new edge identification technique for satellite pictures with low contrast has been proposed in another study [22]. It has been mentioned in this article that it is quite challenging to extract edges from satellite photos with low contrast, smoothness, and features. Therefore, the Sobel edge

detector performs preprocessing on the input image. Low-pass and high-pass filter operations are carried out on the normalized images after the input image has been normalized. The relaxation factor comes after the output of high-pass and low-pass filtering. Following this filtering process, the preprocessed image is subjected to the Sobel edge detection method for edge identification. By identifying the features that work best for identifying things in a picture, the structure of the object identification system can be reduced more successfully without the need to expand the training set, and a better outcome will likely be seen as a result. A comparison of earlier investigations is provided in Table I.

TABLE I. COMPARATIVE STUDY OF THE METHODS PRESENTED IN PREVIOUS STUDIES

| Simplicity | Area | proposed method | Application | Ref. |
|---|---|---|---|---|
| Simple and easy to implement | Stereo camera | Fuzzy color histograms | Spatial | [14] |
| Simple method | Optical remote sensing images | Review of object recognition methods | conversion | [15] |
| Simple method | Infrared images | An outstanding text-oriented Bayesian model | conversion | [16] |
| Simple method | Decomposing images into different areas | Wavelet method | Spatial | [17] |
| The simple and fast method | Digital images | learning-statistics | conversion | [18] |
| The simplest and most suitable for dark images | driving | Image segmentation, color composition and topology | Spatial | [19] |
| Simple method | Identifying small objects | Contour model | Spatial | [8] |
| Simple method | Moving Pictures | Creating and testing hypothesis and verification step | Spatial | [20] |
| It provides a better visual effect | Digital images | meta-heuristic algorithm | Spatial | [21] |
| It provides a better signal than noise | Satellite Images | High-pass and low-pass filtering | Spatial | [22] |

## III. PROPOSED METHOD

The proposed system has two techniques for accuracy and speed, which have been reviewed and put into practice. Two qualities of color and edge are taken into consideration in the suggested strategy. The provided technique uses the SED algorithm, and since the edges have a lower volume than the entire image, with the reduction of information, the processing process will be faster, from the HSV histogram's characteristic of color to its nearness to human perception. Because shapes are cleaned up by their edges in human vision, other edges carry important information. These concerns lead to the conclusion that the histogram of gradient angles based on regional binary patterns is the edge feature of the suggested system. There are two justifications for employing local binary patterns. First, the principal edges are emphasized by using local binary patterns. Another point is that the image produced by this method displays the image's texture; in other words, the shape's feature is taken from the context of the texture, which is regarded as a type of combination of features. The proposed algorithm's flowchart is shown in Fig. 1.

### A. Feature Extraction using SED Algorithm

The SED approach efficiently displays picture information and simultaneously extracts color and texture features. Five

structural formats are utilized to determine the texture perception from the original color image, separated into 72 colors in the HSV color space. A three-step process is employed to get the final descriptive image of the structural elements:

- With step 2, move the SED 2x2 from left to right and from top to bottom, starting at the reference point (0, 0).

- This value is saved if the structure's elements match the image's value (a match denotes that the value of the image in the related structure is equal).

- Then, the SED map is obtained, which has five $S_i(x,y)(1 \leq i \leq 5)$ structures and is distinguished by. When the components of the nondirectional representation structure are recognized, four additional structures in particular need to be found. Since there is no direction, every direction is feasible.

- The following equation, generated by combining five maps as in Eq. (1), illustrates the final SED map.

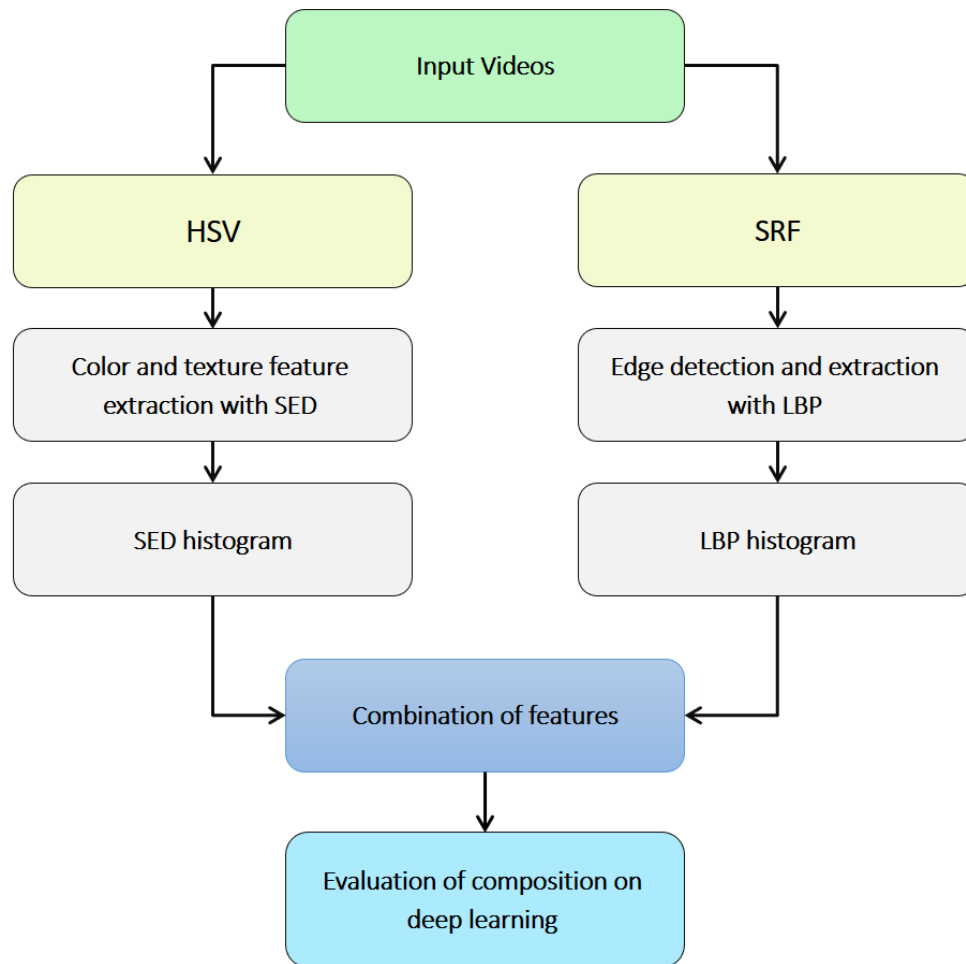
$$S(x,y) = \{(x,y) \mid S_1(x,y) \bigcup S_2(x,y) \\ \bigcup S_3(x,y) \bigcup S_4(x,y) \bigcup S_5(x,y)\} \tag{1}$$


Fig. 1.   Block diagram of the proposed method.

*B. HSV Color Histogram*

The use of color histograms, one of the most significant picture-based recovery approaches, is the most used technique for recovering the color of an image. The image is provided by this histogram, which is produced as a cumulative distribution of the sub-distances connected to each pixel. Defining the color space is the first step in producing a color histogram. Generally speaking, the RGB color space is present in a number of picture formats, including BMP, GIF, etc. We will have fewer calculations if we choose this space, but the main issue is the non-uniformity from the perspective of perception. Because of this, HSV space has been substituted for RGB space in the proposed method. The following is an example of an HSV space benefit. Its suitability with how humans perceives color is due to the independence of the color type and brightness components, which allows us to assign superiority to any one of the components (see Fig. 2). Based on category (H) or wavelength, level of color saturation (S), and level of brightness (V), the dimensions of this space constitute color. Conical in shape, the aforementioned space contains:

- The wavelength of a color is defined in the range $[0, 2\pi]$, where red is at an angle of 0 degrees, green is at an angle of $2\pi/3$, and blue is at an angle of $4\pi/3$, the final

angle. The wavelength of color is equal to the angle of the color in the section of the cone circle.

- At an angle of $\pi 2$, it changes back to red once more.

- The central axis of the cone corresponds to the brightness of the color.

- The amount of color saturation varies depending on how far a given point on the circle is from the center axis; the closer a color is to the axis, the less concentrated it is, and the more it resembles a gray hue.

Because it is more stable than changes in the direction of photographing an item or scene, H is the primary component employed in retrieval systems. It is, nevertheless, extremely sensitive to variations in light. After this space, it is linearly quantized to create the color histogram. Because H space is more significant than other components, the other two components are quantized into four intervals each, but this component is quantized into 16 intervals. By counting the points positioned in each interval and normalizing them to the overall number of picture points, the color histogram of the image is created. A 256-dimensional vector is produced after indexing each image using the HSV color histogram feature.

## C. Texture Feature Extraction

The methods for texture-based recovery are based on the assessment of texture features in the images, such as texture contrast, roughness, texture direction, texture regularity or texture periodicity, and texture unpredictability.

In order to speed up processing, the input color photographs are converted to grayscale at this point. A Gaussian filter is then applied to the grayscale image to help remove any potential noise. Eq. (2) defines a Gaussian function as follows:

$$w(x,y) = \frac{1}{2\pi\sigma^2} e^{\frac{x^2+y^2}{2\sigma^2}} \qquad (2)$$

Then the image is averaged: Consider the noisy image g(x,y), which is obtained from adding noise n(x,y) with the original image f(x,y).

$$g(x,y) = f(x,y) + n(x,y) \qquad (3)$$

In this case, it can be easily shown with Eq. (4) that by averaging the noisy image of an object, a good approximation of the original image M can be obtained.

$$\ddot{g}(x,y) = \frac{1}{m}\sum_{i=1}^{m} g_i(x,y) \qquad (4)$$

Many edge detection algorithms use the first derivative of illumination, which means that we operate with the original data's illuminance gradient. With this knowledge, the peaks of the brightness gradient can be looked for in an image. The second derivative of brightness intensity, which is actually the rate of change of the brightness intensity gradient and is the best for detecting textures, is the basis for some other edge detection algorithms. As a result, a brightness gradient can be seen on one side of the line and its opposite gradient on the other. As a result, we can anticipate a fairly significant shift in the illumination's gradient in intensity at the site of a line. You can look for the transition of gradient change zeros in the results to discover bright textures. If I (x) is the light's intensity, then Eq. (5) [12] is as follows: To be able to extract texture features from photos is the aim. A multidimensional texture feature vector is believed to be the output of a color image, which is considered to be the input.

$$L(x,y) = \nabla^2 f(x,y) = \frac{\partial^2 f(x,y)}{\partial x^2} + \frac{\partial^2 f(x,y)}{\partial y^2} \qquad (5)$$

Fig. 2. HSV color space.

## D. Edge Extraction using Local Binary Patterns

As a potent image texture descriptor, the primary LBP operator was first introduced in [23]. This operator creates a binary number for each individual pixel using the nearby 3x3 pixel labels. The value of nearby pixels is used to threshold these labels. The value of the center pixel is found. In this approach, a label of 1 is placed for pixels whose values are more than or equal to the value of the central pixel, and a label of 0 is placed for pixels whose values are lower than the value of the central pixel. They start to form. Fig. 3 illustrates how this operator functions.

The LBP operator's 3x3 neighborhood base is too small, which prevents it from dominating large-scale images. This operator, which is shown as LBPP, R, and can produce a maximum of p2 different values according to p2 of the binary pattern produced by P pixels on the neighborhood radius of R, was later proposed for this purpose with an extension of neighborhood size in [24]. Fig. 4 illustrates how to choose adjacent pixels in this kind of arrangement. It displays three different local binary radii.

Fig. 5 illustrates the unique significance and notion attached to the patterns created by LBP. This figure shows that LBP is capable of detecting points, edges in various directions, smooth areas, line ends, etc. The histogram of these labels is calculated after assigning LBP labels to pixels in order to create image texture. Numerous researches have concentrated on the use of LBP because of its ease of calculation and acceptable findings, and in this regard, new and varied variants of it have been suggested for usage in various circumstances [25].

Binary: 01111100  decimal: 124
Fig. 3. How to calculate the LBP operator.
Fig. 4. LBP operator with different radii and number of neighborhoods.

**Spot**  **Spot/flat**  **Line end**  **Edge**  **Corner**
Fig. 5. Examples of the concept of patterns produced in LBP, the white and black circles represent the number one and zero, respectively.

After the pixels are labeled by the LBP operator, a histogram of the produced patterns is defined as Eq. (6).

$$Hi \sum x,yi(fi\ (x,y)=i),\quad i=1,\ldots,n-1 \qquad (6)$$

where n is the number of patterns produced by the LBP operator and the function I is defined as Eq. (7).

$$I\ (A) = \begin{cases} 1\ A\ is\ True \\ 0\ A\ is\ False \end{cases} \qquad (7)$$

Local binary patterns with radii of 1 and 8 neighbors are considered in the suggested strategy. Finding and obtaining most systems utilize the closest neighbor search to look for and locate related photos when searching for photographs. For each query image, the KNN classification algorithm examines the set of training images for related images. If the system employs n features, it will treat the images as vectors in the following n-dimensional space. K seeks the neighbor of the query image from the training photos, and among these neighbors, the class label that is in the majority is used as the category label of this image so that each image in this space is comparable to a point. The question foretells Finding and calculating a criterion for the similarity or distance between attributes in the data is the first task to be completed using k-NN. One of the challenges of this method is calculating the distance between the photos; if the distance between the images is not accurately determined, the algorithm will not function properly.

*E. Combinations of Features*

After the feature extraction phase, it should be decided how to combine them. There are other ways to combine the features, but the simplest is to arrange them in a row to create a single matrix and then use other photos to calculate distance. This work has a number of issues. The majority of the features have different sizes, so when combined, the feature with the larger size will have a greater effect. However, larger size does not always imply higher efficiency or greater importance. It is also impossible to compare the effects of some features according to performance. It excels in other aspects. A more effective solution: weighting and distance calculation are done separately for each feature. There are two features here with the designations F1 and F2, respectively. The letters w1 and w2, respectively, designate the weights assigned to each attribute. In this manner, the effect of the features changes depending on the coefficient that w12 accepts, and the best weight can be attained with various variations. The edge feature's weight in the suggested technique is 0.4, while the color feature's weight is 0.6.

*F. Detection Criteria with Deep Learning*

Auto-indicators are one of the techniques of deep learning. An advanced form of artificial neural network called an auto-encoder is used to discover the best code. With this technique, you train an auto-encoder to reconstruct its input X rather than train the network to predict the target value Y along the input X. As a result, the output vectors will match the input vector's dimensions. Fig. 6 shows the general operation of an auto-encoder. The auto-encoder is improved during training by reducing the reconstruction error. It learned the appropriate code for the same feature [26].

The detection of moving targets in overlapping scenes will be carried out in this study with the use of an auto-encoder and a deep-learning technique. Fig. 7 illustrates the general

workflow of the method, which includes the following steps: (1) receiving the image; (2) filtering and enhancing the image; (3) modeling the background; (4) choosing one of the moving images; (5) image training using deep learning; (6) target tracking with the aid of an auto-encoder and deep learning; (7) feature extraction; and (8) classification.

Fig. 6.   General process of an auto-encoder.

Fig. 7.   Steps to perform work to detect moving targets.

The training photos, which contain the target images and their labels, are first fed into the deep learning algorithm, as can be seen in the flowchart of how the suggested approach is implemented. After training the network, it will be able to track the target in the test images. Higher-accuracy architecture will be selected while developing the algorithm's architecture [27]. The incoming moving images are first given a Gaussian filter, which suppresses some random noises that frequently emerge near object borders. In this step, several redundant and erroneous objects are eliminated from the results of the object detection process. A non-parametric background modeling approach [27, 28] is chosen after choosing the moving item in the second phase to produce the initial detection results of the moving object with high recall but low precision. Target tracking is recovered in the third stage by utilizing an auto-encoder and deep learning techniques that are derivations of a hybrid method. Then, characteristics are taken for each detector and applied to distinguish between actual moving targets and fake ones. The last stage can be utilized as a constraint to accurately inspect moving objects and obtain high accuracy and recall by combining the autoencoder and deep learning techniques.

## IV. EVALUATION AND SIMULATION

Image tracking of moving targets in video images is particularly important in machine vision and widely used in robotics and automatic video surveillance. The importance of this issue lies in making the systems smarter and improving the accuracy and speed of the machine's decision-making by receiving visual information. In this research, the aim is to investigate image tracking algorithms based on deep learning methods and provide a new tracking method based on deep learning for more accurate target tracking.

### A. Data Sets

The dataset available at https://motchallenge.net will be used as the dataset of this research, which includes consecutive images of targets in different lighting conditions and with different overlaps. Fig. 8 shows an example of images from the dataset.

### B. Comparison Methods

Deep learning methods and convolutional networks have had good results in tracking moving targets. For example, in study [10], a method based on convolutional neural networks is presented in study [10] to track targets in crowded and noisy environments with low contrast, provided that it is able to track moving targets using color. In research [16], a method based on deep learning to track targets is presented. In this method, first, the features of the target are learned by a very deep network, then these features are sent to the support vector machine, and finally, the support vector machine can identify the goals.

### C. Precision Criteria

This criterion shows the type of accuracy; the higher it is, the better; this criterion shows the accuracy of the proposed method for positive cases and how accurate it was in identifying positive cases. This criterion is one of the most important accuracy criteria in detection algorithms and is calculated from Eq. (8).

$$Precision = \frac{TP}{TP+FP} \qquad (8)$$

Fig. 8. An example of images from the dataset.

In this regard, TP is the number of data that are correctly recognized as positive, and FP is the number of data that is falsely recognized as positive. The simulation result based on the above criterion is shown in Fig. 9.

The simulation result shows that the proposed method performs better in this criterion and has been able to perform image recovery operations with higher accuracy. In Table II, the result of the Precision criterion can be seen in different simulation situations.

### D. Recall Criteria

The next measure of accuracy is the Recall measure; this criterion checks the accuracy of the method in identifying negative states, that is, how accurate the method was in identifying negative states, which is calculated through Eq. (9).

$$Recall = \frac{TP}{TP+FN} \quad (9)$$

In this regard, TP is the number of data that are correctly recognized as positive, and FN is the number of data that is falsely recognized as negative. The recall criterion is objectified according to the above scenario, and the result can be seen in Fig. 10.

The method presented in this research has a better performance in this criterion according to the investigation carried out by the simulator; in Table III, the result of this criterion can be seen in different simulation situations.

### E. Accuracy Criteria

The next evaluation criterion is the accuracy criterion. This important criterion is calculated based on Eq. (10).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (10)$$

In the above relation, the TP parameter represents the number of images that have been correctly retrieved; and the FP parameter also indicates the number of images that have a negative effect and the proposed models have predicted that sample negatively. FN represents the number of samples that have a negative effect on image recovery, and the proposed model has positively predicted these samples. TN represents the number of samples that have had positive effects on recovery, and the proposed method also predicts them to be negative in the recovery process; therefore, with the help of relation (10), the level of accuracy can be seen in Fig. 11.
Fig. 9.  Comparison of precision criteria.

TABLE II.      COMPARISON OF PRECISION CRITERIA IN DIFFERENT SIMULATION SITUATIONS

|  | precision values | | | | |
|---|---|---|---|---|---|
|  | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 78.00% | 71.00% | 74.00% | 77.00% | 75.00% |
| [10] | 70.00% | 73.00% | 74.00% | 75.00% | 73.00% |
| [16] | 69.00% | 71.00% | 72.00% | 74.00% | 71.50% |

Fig. 10.  Recall criterion.

TABLE III.    COMPARISON OF RECALL CRITERIA IN DIFFERENT SIMULATION SITUATIONS

| | Recall values | | | | |
|---|---|---|---|---|---|
| | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 72.00% | 75.00% | 79.00% | 83.00% | 77.25% |
| [10] | 68.00% | 70.00% | 73.00% | 79.00% | 72.50% |
| [16] | 65.00% | 68.00% | 72.00% | 77.00% | 70.50% |

Fig. 11.  Comparison of the accuracy of the proposed method with the other two methods.

TABLE IV.    COMPARISON OF ACCURACY CRITERIA IN DIFFERENT SIMULATION SITUATIONS

| | accuracy values | | | | |
|---|---|---|---|---|---|
| | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 84.00% | 82.00% | 81.00% | 80.00% | 81.75% |
| [10] | 82.00% | 82.00% | 80.00% | 79.00% | 80.75% |
| [16] | 80.00% | 81.00% | 79.00% | 78.00% | 79.50% |

According to the results obtained from Fig. 11, the proposed method has acceptable performance and has performed better than other methods. In Table IV, the result of this criterion can be seen in different simulation situations.

*F. False Positive Rate (FPR) Criteria*

The next evaluation is the false positive rate (FPR) criterion; this criterion checks how many percent of the images the system has retrieved incorrectly; the lower this criterion is, the better. To evaluate this criterion, we performed the simulation in four stages, and the average result for all simulation models can be seen in Fig. 12. In Table V, the result of this criterion can be seen in different simulation situations.

*G. FRR Criteria*

The next evaluation is the false negative rate measure. This measure shows how many percent of the correct images the detection system misidentifies; it can be seen in Fig. 13.

TABLE V.    COMPARISON OF AVERAGE FPR CRITERIA IN DIFFERENT SIMULATION SITUATIONS

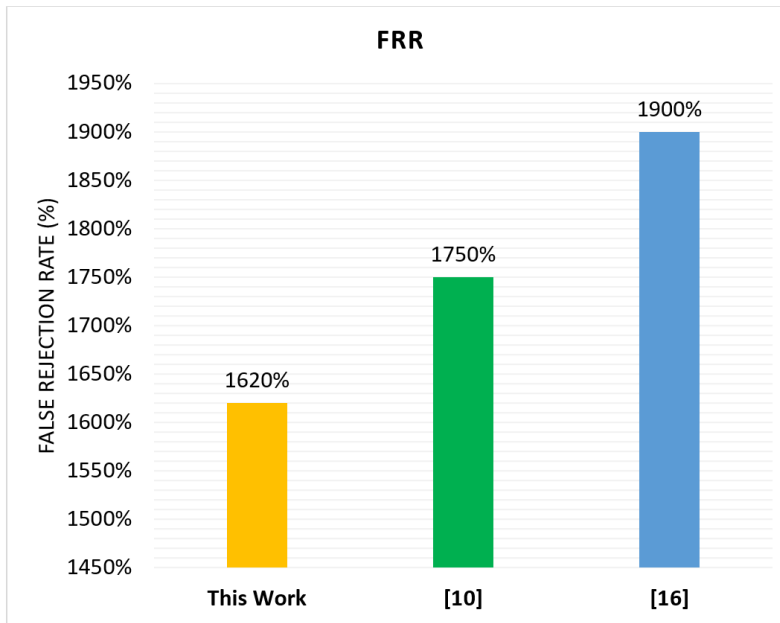
| | FPR values | | | | |
|---|---|---|---|---|---|
| | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 6.00% | 8.00% | 12.00% | 17.00% | 10.75% |
| [10] | 7.00% | 12.00% | 17.00% | 26.00% | 15.50% |
| [16] | 8.00% | 13.50% | 19.00% | 26.00% | 16.63% |


Fig. 12. Average FPR criterion.

Fig. 13. The result of the FRR comparison.

TABLE VI. COMPARISON OF AVERAGE FRR CRITERIA IN DIFFERENT SIMULATION SITUATIONS

|  | FRR values | | | | |
|---|---|---|---|---|---|
|  | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 6.00% | 13.00% | 19.00% | 27.00% | 16.25% |
| [10] | 7.00% | 15.00% | 19.00% | 29.00% | 17.50% |
| [16] | 7.00% | 16.00% | 21.00% | 32.00% | 19.00% |

In this simulation criterion, it shows that the proposed method has little improvement compared to the other method. In Table VI, the result of this criterion can be seen in different simulation situations.

*H. Similarity Criterion*

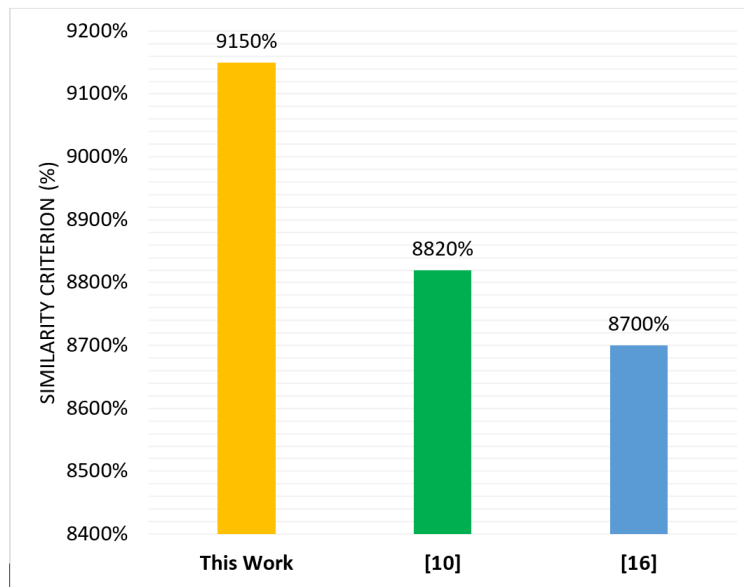
In this part, the proposed method is evaluated based on the similarity criterion in image recognition; in the scenario of this criterion, the degree of similarity of the output images of the program is evaluated, and the result is shown in Fig. 14.


Fig. 14. Comparison of similarity criteria.

As the simulation results in Fig. 14 show, the proposed method performs better than the other two methods. The numerical result of this criterion in several stages of evaluation can be seen in Table VII.

*I. LTDR Criteria*

- LTDR (Label Tracking Detection Rate) criterion will be used to evaluate the presented algorithm. The LTDR measure determines the rate of assigning unique correct labels to targets and is defined as Eq. (11).

$$LTDR = \frac{1}{L}\sum_{i=o}^{L-1}\frac{TPM_i}{OAF_i} \qquad (11)$$

In this regard, L is the total number of targets to be labeled; $TPM_i$ is the number of frames in which the $i_{th}$ target is

correctly labeled, and $OAF_i$ is the total number of frames in which the i-th target is present. The value of this criterion is between zero and one, and the closer it is to one, it means that the detection algorithm has worked correctly. The evaluation result for this criterion can be seen in Fig. 15.

- Finally, Table VIII provides a summary of the accuracy ratings for this study. Higher recall, accuracy, and F-score have been attained using deep learning than with motion-based detection alone. These findings demonstrate how misdiagnosis brought on by inaccurate motion estimation can be supplemented by appearance information. Additionally, with a classification accuracy of over 96%, the deep learning approach may fully utilize the manually labeled training dataset.

TABLE VII. COMPARISON OF THE AVERAGE SIMILARITY CRITERION IN DIFFERENT SIMULATION SITUATIONS

| | similarity values | | | | |
|---|---|---|---|---|---|
| | *250* | *500* | *750* | *1000* | *Average* |
| This Work | 88.00% | 90.00% | 93.00% | 95.00% | 91.50% |
| [10] | 86.00% | 87.00% | 89.00% | 91.00% | 88.25% |
| [16] | 84.00% | 85.00% | 89.00% | 90.00% | 87.00% |

TABLE VIII. ACCURACY DETECTION BASED ON EVALUATION CRITERIA

| | Using only the difference in motion | Deep learning by the appearance |
|---|---|---|
| Accuracy | 0.854 ±0.12 | 0.914 ±0.02 |
| Recall | 0.752 ±0.14 | 0.769 ±0.06 |
| Precision | 0.609 ±0.10 | 0.664 ±0.10 |
| False Positive Rate | 0.781 ±0.09 | 0.813 ±0.08 |
| false rejection rate | 0.631 ±0.14 | 0.719 ±0.11 |
| Similarity criterion | 0.824 ±0.10 | 0.878 ±0.07 |

In the continuation of this section, the studies related to the problems ahead and the goals of this research are as follows. Object tracking in computer vision, feature extraction and deep learning and convolutional neural networks were among the problems that were addressed in this research. Also, this article discusses the practical applications of object tracking in fields such as industrial, military and urban management. It highlights the importance of tracking moving objects in various scenarios including road control. The goals achieved in this research are: improvement in managing challenging situations, prediction of pattern change, efficiency and real-time processing and integration with autonomous systems. In summary, this research provides insights into the development and evaluation of a method for detecting and provides object tracking. This highlights the importance of accurate tracking in various applications and suggests potential directions for future research to improve the performance and applicability of the method in real-world scenarios.

## V. CONCLUSION

A modern civilization needs an intelligent system to control its many management systems. The object tracking system is one of the crucial tools that are employed in the field of operational control in many locations, which makes the job of this field and its authorities very difficult. This goes back to the macro-policies of society in the field of social welfare. Using cutting-edge image processing methods, the technology described in this article can accurately and affordably detect moving objects and track them. In fact, the technique described in this study for detecting moving things, such as cars and items, is quicker and more accurate than the earlier methods. It has been demonstrated that the suggested moving object tracking system, combined with the background subtraction algorithm, noise removal, filtering, and bubble routing, enables full automation when evaluating and identifying the moving item in the photos. More crucially, our system meets the standards established by decision-making bodies for road control for accuracy in detecting moving objects in road photographs.

In comparison to the tested samples, the test results show that the suggested method produces accurate and extremely dependable findings. The research's most significant applications largely concentrated on the precise position recognition of moving objects on photographs and their tracking using morphological analysis and bubble routing. Cameras should be positioned higher than the road surface in order to identify and track items like vehicles, but for all other uses, this is essentially unnecessary. Using a precise backdrop selection and processing each frame separately, this system accurately recovered pictures of moving objects. The wide applications of tracking moving objects are primarily in industrial, military, and urban management places, which can be, for example, the paths where moving objects are passing more frequently. As a result, according to these parameters, the proposed method can show different performances in different conditions. They even described the kinds of moving things in various photographs. Although the present study provides valuable insights into object detection and tracking, however, it has limitations including lack of real-world deployment, assumption of fixed cameras, performance on large-scale datasets, and limited discussion of handling. It is wrong to generalize to other types of objects.

Future research will focus on analyzing various visual patterns, such as grids, parallel lines, and dot matrices. Additionally, the moving object is more likely to shake since

the surface of the location where the video clip is captured may be uneven and bumpy. This shaking may move from left to right or up and down. As a result, the camera will record photos of the moving object in the route that is rotated and warped. Therefore, in order to be able to estimate and predict pattern change, robust and effective algorithms must be constructed in order to preserve the course of the pattern across successive frames. This is necessary to manage the change in the movement pattern of the valve that results from a natural impulse. The effectiveness and output of this algorithm can then be used to provide a more thorough description of the object's change in shape and pattern of movement.

# Exploring the Utilization of Program Semantics in Extreme Code Summarization: An Experimental Study Based on Acceptability Evaluation

Jiuli Li, Yan Liu[*]

School of Software Engineering, Tongji University, Shanghai, China

*Abstract*—With the rise of deep learning methods, neural network architecture adopted from neural machine translation has been widely studied in code summarization by learning the sequential content of code. Given the inherent nature of programming languages, learning the representation of source code from the parsed structural information is also a typical way for constructing code summarization models. Recent studies show that the overall performance of the neural models for code summarization can be improved by utilizing sequential and structural information in a hybrid manner. However, both of these two kinds of information fed to the neural models for code summarization fail to embrace the semantics of source code snippets in an explicit way. Is it really a good way to just leave the semantics as hidden things in the source code and have the neural models capture whatever they can get? To observe the utilization of program semantics in automatic code summarization, we conducted an experimental study by analyzing the acceptability of the extreme code summaries generated from neural models. To make the models aligned in the same context for this experimental study and to focus on the observation of the semantics, we re-implement the neural models from three selected studies as extreme code summarization solutions. After an intuitive observation and exploration of the generated summaries with the models trained from a Java dataset, we identify five acceptability aspects: (1) function name format; (2) function naming style; (3) semantic level similarity; (4) the differences in hitting rate of representative words; and (5) the correlation between extreme code summaries with function body. Based on the false negative and false positive phenomena in the results, ablation experiments have shown that the use of program semantics has a positive effect on generating high-quality abstracts in neural models. Our work proves the potential of utilizing the program semantics explicitly in code summarization, and the possible directions are also indicated.

*Keywords*—*Extreme code summarization; program semantics utilization; acceptability analysis of code summary*

## I. INTRODUCTION

The task of code summarization refers to the automatically creating readable summaries describing the function of the given code snippets, and identify the roles and responsibilities of software units [1]. A good summary can help developers understand, reuse and maintain code more easily, and greatly improve production efficiency. However, problems exist in code summaries, including missing information, errors, and outdated comments. Human-written summaries also require professional domain knowledge, making the entire process time-consuming. Hence, machine-generated summaries are gaining popularity, with their effectiveness acknowledged in many studies.

The majority of automatic code summarization algorithms rely on techniques such as information retrieval, stereotype identification, machine learning and artificial neural network, and natural language processing [2] [3]. Among them, deep learning techniques have demonstrated the benefits of modeling programs recently [4] [5]. Specifically, guided by neural machine translation, early code summarization models focus on the sequential content of code [6]. Yet, leading approaches have recognized the significance of integrating structural information derived from Abstract Syntax Trees (ASTs).

However, both traditional and deep learning techniques have limitations in generating natural language summaries. Traditional approaches struggle with extracting keywords when identifiers and methods are poorly named, and proper summaries cannot be generated if similar code snippets are absent. Moreover, the majority of deep learning-based approaches treat the source code as plain text, resulting in the omission of crucial information, such as naming conventions for identifiers and usage patterns of application programming interfaces [7] [8]. Since sequences of tokens parsed from AST are typically fed into the sequence-to-sequence framework, this approach may fail to capture long dependencies between code tokens [9]. These limitations may lead to the underutilization of program semantics at both the code text level and structural level, as evaluated using the acceptability of generated code summaries. However, there are currently no systematic studies to address this issue. To assess the acceptability of code summaries generated by neural models, we selected representative models from various categories for extreme code summarization tasks, and intend to get insights from the experimental results. The main contributions of our study are as follows:

- To explore the acceptability of the code summaries generated from neural models, we re-implement the neural models from three selected studies for extreme code summarization. Following an intuitive observation of the generated summaries, we proposed five acceptability aspects for further analysis.

- To identify which limitations of the selected models aggravate to the lower acceptability, we conducted a comprehensive analysis, focusing on the misjudgment in generated summaries. We found that false negatives in extreme code summaries can be attributed to issues, such as text-level semantic similarity in code, variations in function hit rates, and the correlation between function names and their respective bodies. Besides, the format and naming conventions of function names may result in false positives in extreme code summaries. In accordance with these observations, further hypotheses are formulated to improve automatic code summarization, including from the perspective of underutilization of function body semantics by neural models and potential issues related to dataset preprocessing.

- To verify our hypothesis, we conducted the ablation experiments based on the selected models. We discovered that phrases with similar semantics have a greater impact on false negatives in generated summaries, while the format of function names has a stronger influence on false positives in the results. Subsequently, we provide directions for improvement in three aspects: dataset preprocessing, external data source and the model's learning process. These directions serve as a valuable reference for future research in the field.

## II. RELATED WORK

### A. Overview of Common Models in the Field of Code Summarization

At present, several representative neural models which can be used to perform the task of code summarization in relevant field, including CODE-NN [10] model based on attention mechanism, Deep-Com [11] model based on code structure analysis, summary generation model based on reinforcement training and so on. Several classic code summarization models are as follows.

- CODE-NN is an end-to-end summary generation system built directly by using the structure of circular neural network, and relevant summary are generated according to the word vectors of source code. The introduction of attention mechanism not only highlights the contribution of key words in the decoding process, but also solves the problem that the summary generated by long code is difficult to understand.

- The code summarization model based on sequence-to-sequence learning algorithm [12] is also popular. The encoder and decoder of this model are built by independent LSTM neural networks, which can extract lexical features of source code and generate summaries. It inputs the key vocabulary sequence of the source code function and outputs the English summary related to the function.

- Deep-Com [11] based on code structure analysis is also a mainstream model in this field. To extract the hidden structural information in the source code, Deep-Com firstly outputs the summary syntax tree as a sequence of nodes in a specific order through a special traversal algorithm [13], and then generates the summary of the target code by using the classic encoder-decoder model. The author thinks that the traversal algorithm used by Deep-Com can express the structural characteristics of the summary syntax tree without loss, and the generated summary can also accurately describe the functional characteristics of the source code.

- The reinforcement learning model for parameter training based on actor-critic mode recently proposed by wan et al gradually becoming popular [14]. Different from the common code summarization model in the field, the author innovatively uses reinforcement learning to update the model parameters, which can further reduce the exposure bias.

In addition, there are also several neural models that can be used directly to perform the task of extreme code summarization, such as Code2Vec, Code2seq, Code-Transformer are shown below:

- Code2Vec [15], which transforms code fragments into vectors with fixed length and continuous distribution, which can be used to predict the semantic information of code fragments. To achieve this goal, Code2Vec is first decomposed into a set of paths in its corresponding AST, and then the neural network is used to learn the representation of each path and how to integrate the representations of all paths. The effectiveness of Code2Vec has been verified by the task of predicting the function name with vector representation of function body.

- Code2seq [16], which uses the syntax structure in programming language to encode the source code. In this model, a part of paths are extracted from AST of code fragments, and the target sequence is generated by Attention after LSTM coding. Code2seq uses the way of encoding the sample of code fragment AST to extract grammatical information better. The effectiveness of Code2seq has been verified in the extreme code summarization task.

- Code-Transformer [17], which jointly learns the sequential and structural information in source code. Compared with other neural models, it only depends on language-independent features, and can directly calculate the source code and features from AST. The performance of the Code-Transformer model is also validated on the task of predicting function name based on function body.

Although the above models have good performance in code summarization generation, due to the lack of learning about structural information or semantic information of source code, sometimes it is inevitable that the generated summaries are difficult to understand or have poor readability.

## B. *Performance Analysis of Code Summarization Model*

The code summarization algorithm based on deep neural network uses the neural machine translation technology to select the corresponding words from the corpus according to the maximum similarity principle with the help of the previous generated words. It transforms the sequence data by using the good transformation ability of the classical encoder-decoder framework, which transforms the source language sequence into the target language sequence. The classic structure has achieved good translation results, despite of the obvious structural and hierarchical characteristics of programming languages, when the neural machine translation method is applied to the generation of code summary, the source code will be treated as an ordinary text. This will inevitably cause the lack of source code structure and make the summarization effect of neural code summarization algorithm worse. Generally speaking, the accuracy of automatic code summarization system based on neural network is not high [18].

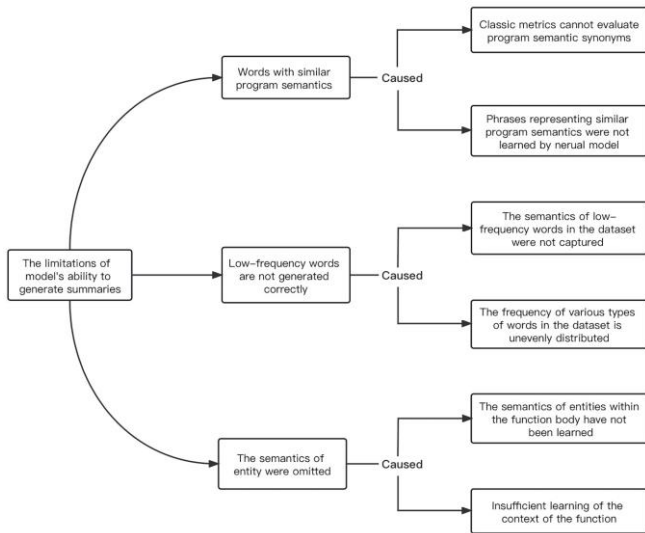

Fig. 1. The limitations of the model's ability to generate summaries.

To sum up, the neural model algorithm used for code summarization has two limitations, as shown in Fig. 1. First, only the sequence information in the code is taken into account by the encoder-decoder structure while the hidden semantics such as the structural information in the code are ignored [19] [20]. Second, the neural code summarization model based on maximum similarity will encounter the problem that low-frequency words or unknown words in the training data cannot be generated correctly during testing [21][22]. In this situation, even if the training data set is large enough and the quality is good enough, low-frequency words cannot be generated correctly; Moreover, when the summary model is applied to a code file in a different domain, there is also the problem of not being able to generate an accurate summary because of words for related domains that are not present in the training set. Above two kinds of findings are the main problems of neural code summarization algorithm.

Although scholars in related fields have identified these hidden dangers, there is currently no targeted solution for these specific problems in code summarization. Therefore, our study attempts to analyze the generated summaries by neural models to observe these phenomena and propose improvement ideas.

## III. RESEARCH METHODOLOGIES

### A. *Extreme Code Summarization Task*

To observe the utilization of program semantics in automatic code summarization, we conducted an experimental study by analyzing the acceptability of the code summaries generated from neural models. To determine whether our experiment can be generalized to different versions of the neural models, we re-implement the neural models from three selected studies as extreme code summarization solutions. The executive process of the neural model for the task of extreme code summarization is shown in Fig. 2. These neural models are trained by different procedures and can be used directly.

Fig. 2. Overview of models for extreme code summarization.

For the sake of better evaluating the universality of our research, we selected three representative models from different categories. Their different architectures may result in different focuses on learning source code semantics. Among them, code2Vec extracts AST path from the abstract syntax tree (AST) of Code, learns the vector representation of each path through the deep learning model and how to aggregate multiple paths into one vector to represent the entire Code; Code2seq uses LSTMs to encode paths node-by-node (rather than monolithic path embeddings as in code2vec), and an LSTM to decode a target sequence (rather than predicting a single label at a time as in code2vec); Code-Transformer is a Transformer based architecture that learns both source code (context) and an abstract syntax tree (AST) for parsing. In view of their different model architectures result in different ways of learning source code semantics, we infer that there may also be some differences in the generated summaries.

Therefore, Code2vec, Code2seq and Code-Transformer represent a set of diverse but representative models. Using the same dataset to evaluate the task of extreme code summarization on Code2vec, code2seq, and code-transformer highlights the potential risk of false negative and false positive generation when using neural models. Although we can't say for sure, other neural models trained on similar data set may exhibit similar behavior.

### B. *Dataset*

For the task of extreme code summarization, a high-quality dataset plays a crucial role in the quality and acceptability of

the summary generated by neural model. Therefore, we chose the Java dataset proposed by Hu et al., which has been used to evaluate code summarization models such as Code-NN and Deep-Com by using common metrics of bleu, rouge, and meteor, and has achieved relatively complete experimental results.

Java dataset [5], including Java methods extracted from Java projects from 2015 to 2016, collected from GitHub. The first sentence of Javadoc is extracted as a natural language description, which describes the functions of Java methods. The quantity distribution of the dataset is shown in Table I.

TABLE I.        JAVA DATASET STATISTICS

| Dataset | Samples |
|---|---|
| Train | 26142 |
| Test | 8714 |
| Validation | 8714 |

## C. Evaluation Metrics

In order to better evaluate the quality of generated extreme code summaries, we selected three commonly used metrics in the field of code summarization: bleu, rouge, and meter.

*1) BLEU*: BLEU is used to compare the overlapping degree of n-gram in candidate translation and reference translation [23]. N-gram accuracy refers to the ratio of the total number of n-gram matches between the evaluated generated summary and the reference summary to the total number of n-grams in the reference summary. BLEU is often applied to evaluate the similarity between generated summary and reference text.

$$BLEU\_N = BP \cdot (\exp \sum_{n=1}^{N} \omega_n \log p_n) \qquad (1)$$

Here Pn refers to the accuracy rate of n-gram; Wn refers to the weight of n-gram; BP is a penalty factor.

*2) ROUGE*: ROUGE is a quality evaluation method of text summary based on recall, it calculates the similarity between generated summary and reference text [23]. ROUGE-L is often applied to evaluate the quality of code summarization.

$$ROUGE - N = \frac{\sum_{S\in\{Reference\}}\sum_{gram_N \in S} Count_{match}(gram_N)}{\sum_{S\in\{Reference\}}\sum_{gram_N \in S} Count(gram_N)} \qquad (2)$$

The denominator of the formula here is to count the number of n-grams in the reference translation, while the numerator is to count the number of n-grams shared by the reference translation and the machine translation [24].

*3) Meteor*: Meteor is used to calculate the score based on the clear word-word matching degree between the generated summary and the reference text [23], so it is often applied to evaluate the quality of the generated summary according to the score.

$$METEOR = \left(1 - \gamma \cdot \left(\frac{ch}{m}\right)^\beta\right) \cdot \frac{P \cdot R}{\alpha \cdot P + (1-\alpha) \cdot R} \qquad (3)$$

Here, P and R are 1-gram accuracy and recall, $ch$ is the number of blocks, M is the matching number.

*4) Limitations of metrics:* These three types of metrics are all calculated based on the degree of matching at the text level, and cannot be used to evaluate the degree of semantic similarity. All of them have a clear bias towards the order of words, which may lead to some false negatives and misjudgments in the results of extreme code summarization.

## IV. EXPERIMENTS

### A. Research Questions and Experimental Process

In order to explore the acceptability of the code summaries generated from neural models, we re-implement the models of code-transformer, code2vec and code2seq to perform the task of extreme code summarization, and conduct statistics and analysis for the preliminary experimental results. We found that different models have different qualities for summaries generated from the same piece of code, such as the length of generated summaries and the omission of semantic information.

Based on relevant development experience and previous research evidence, we propose the following research questions regarding the preliminary results of the task of extreme code summarization:

RQ1-1: How effectively do existing models employ program semantics for text-level matching?

RQ1-2: Why do many generated function names shrink in length compared to the original function names in the extreme code summaries generated by neural models?

RQ1-3: Whether different types of naming styles of function names affect the accuracy of the model in capturing semantics?

RQ2-1: Whether some synonyms representing the same program semantics can be identified during model learning?

RQ2-2: Whether the model's ability to capture the semantics of verbs greater than that of nouns?

RQ2-3: Will neural models only capture the semantics of words with the same name as function names while ignoring other important semantics?

Afterwards, we will design our experimental plan based on these research questions. The experimental process steps are shown in the following Fig. 3, and the experimental design plan and result analysis are shown in Section IV(B).

### B. Experimental Analysis

We re-implement the models of code-transformer, code2vec and code2seq to perform the task of extreme code summarization, and get the preliminary experimental results. Then we use BLEU metric to divide the hit degree into four levels, we define the BLEU value greater than 0.7 as a high hit level and the BLEU value between 0.3 and 0.7 as a low hit level [25]. We calculated the proportion of the data sets

generated by the three models in each hit level; the preliminary experimental results are shown in Table II:

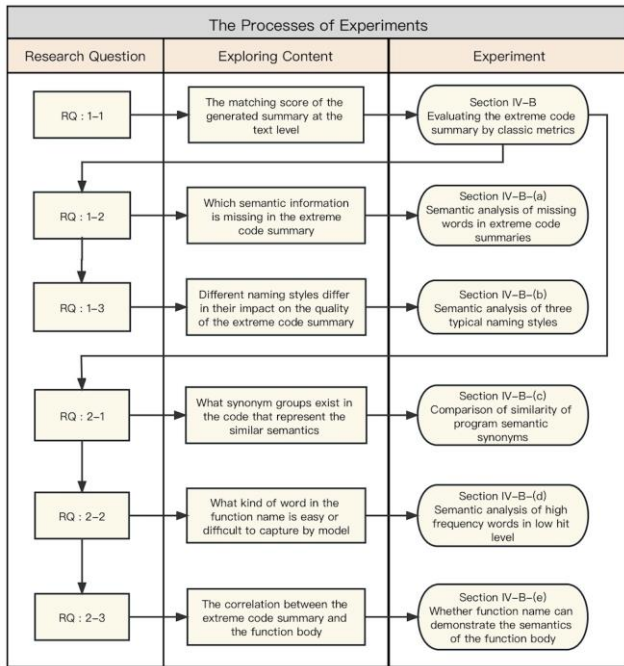

Fig. 3. Experimental process.

TABLE II. Hit Level Category

| Hit level | BLEU | Code2Vec | Code2Seq | Code-Transformer |
|---|---|---|---|---|
| Code-Equal | 1.0 | 17.8% | 18.1% | 19.8% |
| High-Match | 0.7~1.0 | 34.7% | 36.9% | 38.9% |
| Low-Match | 0.3~0.7 | 32.8% | 31.5% | 31.4% |
| Code-Wrong | 0~0.3 | 13.1% | 12.8% | 8.2% |

From the above results in Table II, we found that there are many low matching phenomena between the extreme summaries generated by three models and the original function names. After an intuitive exploration of the generated summaries with the models trained from a Java dataset and based on relevant program development experience, we identify five acceptability aspects to be analyzed in detail: (a) the format of the function name; (b) function name naming style; (c) the semantic similarity in code; (d) the differences in hitting rate of functions; (e) the correlation between function name and function body. We found that the above five aspects of problems are common in the results generated by the three models, so we chose the Code-Transformer model with the best experimental result to analyze its result data from these five aspects in detail. The analytical process of the experiments as follows:

*1) The format of the function name*: We conducted preliminary observations on the generated results of models and found that it is very common that the generated extreme code summary is inconsistent with the length of the original function name after word segmentation. Compared with the

length of the original function name, part of the extreme code summary generated by the model shrinks and part of the extreme code summary extends. Then, we counted the proportion of each phenomenon to analyze whether these phenomena are caused by the model's omission or analytic error of the semantic information of the function body.

TABLE III. The Format of the Function Name

| Preliminary experimental analysis | We compared and analyzed the length of the original function name and extreme code summary. |
|---|---|
| Observation and discovery | The generation of extreme code summaries has more shrinkage phenomenon and less extension phenomenon. |
| Put forward hypothesis | The semantic information within the function body has not been fully extracted and utilized by the neural model. |
| Verification Experiment | Which semantic information in function name were missed during the learning process of neural model. |
| Problem Analysis | The semantic information of function body is not fully utilized by neural model. |

The analysis process is shown in Table III. Firstly, we do word segmentation for the original function names and the extreme code summaries and compare the length of them. Then we divided the results into three categories for statistical analysis, the ratio of them is shown in the Fig. 4. We observed that among the three categories, The model has more shrinkage and less extension for the generation of function names. Therefore, we put forward the hypothesis that the semantics of function is not fully extracted and utilized by neural model, leading to the serious shrinkage phenomenon.

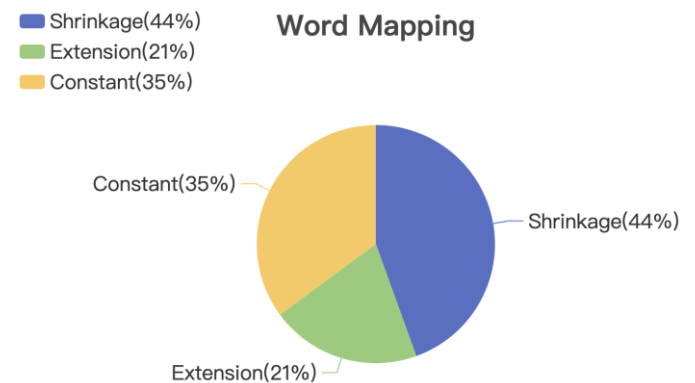

Fig. 4. Word length mapping.

In order to verify the hypothesis, we conducted a verification experiment; we analyze the function name, parameter list and function body in three categories respectively from the following two scenarios.

- Shrinkage Scenario: (including 3166 pieces of data): Function names in this category map from multiple words to fewer words. For example, the noun information in the parameter list of function is omitted: We select three types of the highest frequency verbs (get, set, add) to analyze their representative examples as shown in Table IV:

TABLE IV.        THE HIT RATIO OF SHRINKAGE WORD

| Origin_name | Prediction_name | Percentage |
|---|---|---|
| **getProperties(Properties)** | **get** | **36%** |
| setDisplay(dsiplay) | set | 23% |
| addRenderer(Renderer) | add | 21% |

- Extension Scenario: (including 1069 pieces of data): Function names in this category map from fewer words to multiple words. For example, a preverb is added before the noun in the function name. Then we selected three kinds of data with the highest frequency according to the frequency of occurrence as shown in Table V below:

TABLE V.        THE HIT RATIO OF EXTENSION WORD

| Origin_name | Prediction_name | Percentage |
|---|---|---|
| **id** | **getid** | **19%** |
| Max | getMax | 11% |
| XML | setXML | 8% |

Problem analysis: From the verification experiment results, we can conclude that part of the semantic information of the function body (such as the nouns in the parameter list) has been ignored during the process of model learning, which leads to the highest proportion of shrinkage in the results, resulting in the false positive in generated results.

*2) Naming style of function name*: Based on the preliminary observation of the results generated by the models, several representative words were selected and classified according to the program development experience: (1) Function names starting with "is" to indicate the judgment semantics; (2) Function names containing conjunctions (such as "to", "as", "of"); (3) Function names starting with common verbs. We want to explore how these different naming styles differ in generated extreme code summaries. The analysis process is shown in Table VI.

TABLE VI.        FUNCTION NAMING STYLE

| | |
|---|---|
| Preliminary experimental analysis | We selected several representative categories to classify the function names. |
| Observation and discovery | Function names with different naming styles appear in different hit levels. |
| Put forward hypothesis | Some commonly used conjunction words in function names will cause false positive in generated results. |
| Verification Experiment | Whether the semantics of function names with different naming styles can be fully captured |
| Problem Analysis | Function names with conjunctions and judgment words are not further preprocessed. |

Firstly, we made quantitative statistics on their frequency in four different hit levels, as shown in the Fig. 5. Then we find that in the category of function names representing judgment, the proportion of low hit level is significantly higher than that of high hit level; In the category of function names containing conjunctions, the ratio difference between low and high hit

levels is larger than that of the category representing judgment. In the function name category consisting of verb and noun classes, there is little difference in the proportion of low and high hit level. Therefore, we put forward the hypothesis that these function names with representative naming styles are not preprocessed, so the classic metrics cannot evaluate them correctly and result in false positive results.

Fig. 5.    Hit frequency in different level.

In the verification experiment, we compare the original function name with the generated function name data set after word segmentation. In the category of low hit level, we check for missing connectors in the generated extreme code summaries. However, the result is not as we expected, the conjunction such as "to" have not been omitted. We also find that the main reason why such words appear in low hit level frequently is that the nouns immediately after conjunctions are often omitted. Therefore, our hypothesis that conjunctions are omitted was overturned.

In the category of representing judgment function names starting with "is", the neural model focuses on capturing the semantic information of embedded function names during the learning process, resulting in a high frequency of occurrence in the category with a lower hit level.

In the category where the function names consisting of verb and noun, we infer that the noun that carries the important semantic information of the function body is often omitted, which leads to the phenomenon of false negative in result. Then we selected a representative high-frequency word in each of three categories and calculated their proportion in the same category is shown in the Table VII below.

TABLE VII.        THE HIT RATIO OF REPRESENTATIVE WORDS

| Origin_name | Prediction_name | Analysis | Percentage |
|---|---|---|---|
| isDoubleFile | isFile | Embedded function | 4% |
| tobyte | tostring | Error in capturing business semantics | 3% |
| **addRenderer** | **add** | **Parameter nouns are omitted** | **7%** |

Problem analysis: From the verification experiment results, we can conclude that due to much important semantic information is not captured during model learning, resulting in the false positive in generated results.

*3) The semantic similarity in code*: We conducted preliminary observations on the results generated by the models and found that some frequent words in function names have specific program semantics; These words with special program semantics have more similar variants in the actual code, that is, there is the semantic similarity in program representation, and these variants can describe the semantics of similar function bodies. Therefore, we put forward the hypothesis that these phrases with similar program semantics cannot be captured by neural model; moreover, the metric cannot evaluate their similarity and result in false negative results.

TABLE VIII.   THE SEMANTIC SIMILARITY IN CODE

| Preliminary experimental analysis | We searched program semantic synonyms by wordnet thesaurus and artificial selection. |
|---|---|
| Observation and discovery | A lot of function names have similar variants in code, which can describe the similar semantics. |
| Put forward hypothesis | The semantic similarity in code cannot be evaluated by classic metrics. |
| Verification Experiment | Evaluation of representative synonyms with the same program semantics. |
| Problem Analysis | Function names with similar program semantics are not captured by neural model. |

The analysis process is shown in Table VIII. Firstly, 213 pairs of synonyms identified from wordnet thesaurus were integrated with 84 pairs of synonyms selected manually for k-means cluster analysis, then four groups of synonyms with the highest frequency were selected, as shown in the Fig. 6.

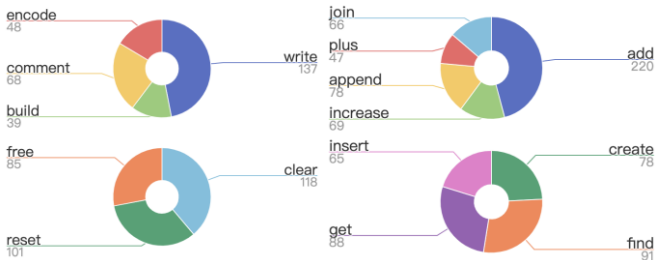

Fig. 6.   The four highest frequency synonym groups.

To verify our hypothesis, we use the bleu metric to calculate the similarity of each group of words after stemming, and the results of similarity calculation are all 0%, as shown in the Table IX, but the synonyms in each group can all represent the semantic of the function body. So it can be seen that the model will produce false negative results because these verbs with similar program semantics cannot be captured by neural model and evaluated by classic metrics.

TABLE IX.   SEMANTIC SIMILARITY OF SYNONYMS

| Origin_name | Prediction_name | Similarity |
|---|---|---|
| add | increase, append, plus | 0% |
| create | find, get, insert | 0% |
| write | build, comment, encode | 0% |
| clear | free, reset | 0% |

Problem analysis: From the verification experiment results, we can conclude that since function names with similar program semantics are not captured by neural models, resulting in the false negative in generated results.

*4) The differences in hitting rate of functions*: We have preliminarily observed the generated results of models: The four types of words ("add", "remove", "write", "read") that represent addition, deletion, modification and selection in database operation for a high proportion in the generated results, and each type of words has a certain frequency in different hit levels. We want to make statistics on the occurrence frequency of these four representative words in different hit levels to explore whether the semantic of function body is not fully utilized, leading to the occurrence of these representative words in low hit levels.

TABLE X.   THE DIFFERENCES IN HITTING RATE OF FUNCTIONS

| Preliminary experimental analysis | We count the hitting ratio of four high-frequency verbs in different hitting levels. |
|---|---|
| Observation and discovery | High frequency words also appear frequently in low hit levels. |
| Put forward hypothesis | Common prefix verbs in function names can cause false positives in the generated extreme summary. |
| Verification Experiment | Whether function names that only contain verbs can represent the semantics of the function body. |
| Problem Analysis | Many nouns that represent business semantics have not been captured by neural model. |

The analysis process is shown in Table X. We sampled four kinds of verbs with the highest frequency from the data set including the "verb + noun" combination whose first word is this verb, the four kinds of verbs are "add", "remove", "write" and "read" respectively.

Fig. 7.   Four kinds of words hit frequency in different level.

Then, we count the numbers of these four words in above four hit levels proposed in Table II, the statistic results are shown in the Fig. 7. By preliminary observation, we find that four types of words appear frequently both in high hit and low hit levels, so we put forward the hypothesis that the semantics in function body are not fully extracted and utilized by the neural model, which leads to false negative results.

To verify our hypothesis, we made a statistical analysis on the function body of four kinds of words extracted from the original data set. We observed that there are embedded function names with the same name as the extreme code summary generated by neural model in these function bodies, which may cause the model to ignore the semantic information of other nouns within the function body, and leads to the false negative results of the model. Then we calculate the proportion of highest frequency words in four types of categories in the low hit level as shown in Table XI:

TABLE XI. THE HIGHEST HIT RATIO OF FOUR TYPES OF WORD

| Origin_name | Prediction_name | Percentage |
|---|---|---|
| add | append | 31% |
| **remove** | **delete** | **44%** |
| write | encode | 26% |
| read | find | 30% |

Problem analysis: From the verification experiment results, we can conclude that due to the fact that many nouns that represent business semantics in the function body, except for verbs, has not been captured by the model during learning process, resulting in false negative in generated results.

*5) The correlation between function name and function body*: By comparing the generated extreme code summary with the function body of the original data set, we find that many generated extreme code summaries are inconsistent with the original function names, but they are consistent with the embedded function names in the original function body. We propose the hypothesis that this phenomenon may be caused by the model concentration learning the semantics of the embedded function body while ignoring other important semantics.

TABLE XII. THE CORRELATION BETWEEN FUNCTION NAME AND FUNCTION BODY

| Preliminary experimental analysis | We compare the generated function name with the function body of the original dataset. |
|---|---|
| Observation and discovery | Many generated function names are consistent with the embedded function names in the function body. |
| Put forward hypothesis | The semantic information of the function body was not fully captured by the model. |
| Verification Experiment | Whether embedded function names can represent the semantics of their function body. |
| Problem Analysis | Other important semantic information within the function body was not captured by neural model. |

Embedding function name: First, we define the embedded function name: that is, the function name that appears in a one-line statement in the function body. For example, "write" is the embedding function name in Fig. 8 below.

```java
public void write (String key, byte[] newValue) {
    Map<String, byte[]> entry = new HashMap<>();
    entry.put(key, newValue);
    write(entry);
}
```

Fig. 8.    The embedded function name "write".

The analysis process as shown in Table XII. According to the development experience, we classify these embedded function names into four categories: (1) including common verb, (2) including conjunctions, (3) mathematical functions, (4) representing judgement category; We count the function names with the highest frequency in these four categories by frequency, the result as shown in the Fig. 9.

Fig. 9.    The high frequency words in four groups of phrases.

To verify the hypothesis, we counted and analyzed the mapping number between the above four class function names and the function names embedded in the function body.

There are 1139 pieces of data embedded with the same function name as the original. We selected the three most frequent words and calculated their proportion in their category as shown in the Table XIII below.

TABLE XIII. THE HIGHEST HIT RATIO OF CONSISTENT WORD

| Origin_name | Prediction_name & Embedded function name | Percentage |
|---|---|---|
| **Sort** | **sort** | **11%** |
| Tostring | tostring | 9% |
| IsEmpty | isEmpty | 9% |
| Sqrt | sqrt | 5% |

There are a total of 478 extreme code summaries that are the same as the embedded function names in the function body, but different from the original function names. It can be seen that the model concentrates on learning the local program semantics of some embedded functions while ignoring other semantics in function body, which leads to the false negative result of the model. We selected three kinds of verbs with the highest frequency for statistical analysis as shown in the Table XIV below.

TABLE XIV.   THE HIGHEST HIT RATIO OF INCONSISTENT WORD

| Origin_name | Prediction_name & Embedded function name | Percentage |
|---|---|---|
| copy | write | 14% |
| delete | remove | 13% |
| reset | clear | 8% |

Problem analysis: From the verification experiment results, we can conclude that due to the fact that many semantic information other than embedded function name in the function body was not captured by neural model, resulting in false negative in generated results.

### C. Ablation Study

Based on the statistical study of these five aspects, to further explore the impact of various aspects on the model's ability to capture semantics hidden in source code, we conducted the ablation experiment, in which we respectively improve the preprocessor statement of data sets in terms of function name format, function naming style, semantic level similarity, the differences in hitting rate of functions and the correlation between function name and function body, then we evaluate the ablation experimental results by using Bleu, Rouge and Meteor metrics, as shown in Table XV.

*1) False negative aspect*: In terms of the three aspects that produced false negative results, we performed the following ablation experiments.

*a) The differences in Hitting Rate of Functions*: We filter four types of high-frequency verbs in low hit level category.

*b) The Correlation between Function Name and Function Body*: We filter the function name data set which omits nouns in the parameter list from the data set whose embedded function name is inconsistent with the original function name.

*2) False positive aspect*: In terms of the two aspects that produced false negative results, we performed the following ablation experiments:

*a) The Format of the Function Name*: We filter the function name data set with omitted parameters in the function name data set with shrinkage scenario.

*b) The Naming Style of Function Name*: We filter out "is" in the function name data set of representing judgment class; We filter out the pre-verbs in the data set of the function name consisting of verb and noun; We don't deal with the conjunctions.

*3) Ablation result*: Ablation experiment results (Table XV) show that semantic similarity in program has a stronger influence on false negative in results, the format of function name has a stronger influence on false positive in results.

### D. Insights Gained From Experiments

Based on the analysis of experimental results and further validation of ablation experiments on the above research questions, we can make some improvements to the model for executing the task of extreme code summarization in terms of preprocessing filtering enhancement, external data source enhancement, and attention mechanism enhancement. The specific optimization steps are outlined in red dashed lines in Fig 10.

*1) Preprocessing filtering enhancement*: For the cases of different types of naming styles of function names in section B-b and function names with high correlation with function bodies in section B-e, we will seek optimization from the perspective of data preprocessing. We plan to filter out common prefixes of data words with specific naming styles and embedding function names during the preprocessing process to reduce the occurrence of false positives in the generated results.

*2) External data source enhancement*: For the situation that the synonym group representing the same program semantics in section B-c cannot be recognized by the program, we plan to import the constantly improving program semantic synonym library as an external data source and integrate it with summary information during the model training process, so that the neural model can gain data enhancement in the process of learning the text of summary to avoid false negatives in the generated results.

TABLE XV.   ABLATION EXPERIMENTAL RESULT

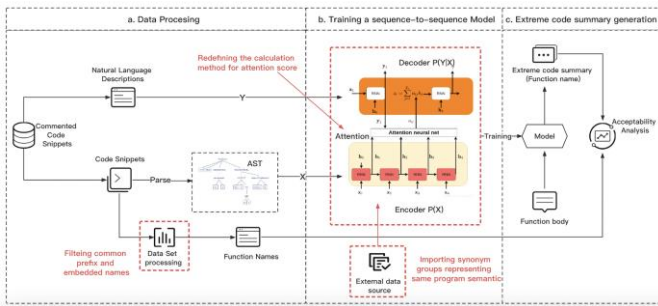
| Aspect | | Code2Vec | | | Code2Seq | | | Code-Transformer | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | BLEU | ROUGE-L | METEOR | BLEU | ROUGE-L | METEOR | BLEU | ROUGE-L | METEOR |
| False Negative | **Semantic Similarity** | **48.85** | **63.86** | **31.79** | **51.81** | **63.84** | **32.77** | **52.88** | **64.89** | **29.83** |
| | Classification Hit Rate | 39.79 | 54.81 | 25.74 | 40.76 | 53.82 | 24.75 | 42.84 | 53.87 | 21.78 |
| | Func_Body_Correlation | 37.98 | 52.80 | 22.70 | 39.74 | 51.81 | 23.71 | 40.82 | 50.83 | 20.76 |
| False Positive | **Naming Format** | **47.54** | **58.51** | **30.49** | **49.52** | **60.50** | **29.46** | **50.59** | **59.61** | **32.53** |
| | Naming Style | 37.58 | 52.55 | 21.54 | 38.54 | 49.54 | 18.52 | 41.62 | 51.63 | 23.56 |


Fig. 10. The Diagram of model architecture for extreme code summarization.

*3) Enhancement of attention mechanism*: For the cases where the important program semantics in section B-a and the noun semantics in section B-d are omitted during the model learning process, we will seek optimization from the perspective of attention mechanism. In the attention mechanism, each piece of information is assigned a different attention score. If the attention score of important semantic information is low, it may cause the output sequence information to lose this part of semantics. Therefore, we can try to innovate in the calculation methods of attention score, such as dot product, multiplication, addition, or other more complex calculation formulas, then assign new attention score to each information, so as to improve the attention score of important semantic information and avoid false positives in the results as much as possible.

## V. Threat to Validity

*1) Model re-implementation*: In the process of reimplementing the three models, the word length of some data sets exceeds the limit. For example, the length of words in the function body of code-transformer cannot exceed 1200, and the length of code2vec and code2seq exceeding 900 will also cause model parsing failure. In order to avoid this situation, we need to filter out relevant nonconforming data in the process of data set preprocessing.

*2) Selected dataset:* Java dataset has a total of 8714 pieces of data. Although the sample data is of high quality and representative, and the domain knowledge is perfect, the overall scale is small. If we want to retrain the data set of the model in the future, we should inject a larger data set.

*3) Model comparison*: We choose the three represents extreme code summary generation model. In our experiment, we use the same data set, run all models in the same hardware environment, and adopt the same data preprocessing process to reduce this threat.

## VI. Conclusion

Many studies show that the quality of code summary generation algorithms based on deep learning is not ideal because it does not take full advantage of relevant program semantic information. In this paper, in order to observe the utilization of program semantics in automatic code summarization, we conducted an experimental study by analyzing the acceptability of the code summaries generated

from neural models. To focus on the observation of the semantics, we re-implement the neural models from three selected studies as extreme code summarization solutions. Fig. 10 shows the diagram of model architecture for extreme code summarization. After an intuitive observation and exploration of the generated summaries with the models trained from a Java dataset, we identify five acceptability aspects: (1) function name format; (2) function naming style; (3) semantic level similarity; (4) the differences in hitting rate of representative words; (5) the correlation between extreme code summaries with function body. Experimental analysis shows that false negative is common in the results if only evaluated with classic metrics, and aspects (3)(4)(5) bring the major influence. We also observed that false positives related to aspects (1)(2) also commonly appeared in the result, which suggests that the current models also fail to filter the noise from the raw source code to a reasonable extent.

We put forward hypotheses for these above five aspects, for example, the semantics of the function body may not have been fully learned by neural model. Then we designed and completed relevant verification experiments to prove whether our hypotheses are correct. The verification experiment confirmed that aspects (2)(5) is caused by insufficient preprocessing of the data set, aspects (1)(3)(4) are caused by the semantics of function body have not been fully extracted and utilized by neural model.

To further explore the influence of the above five aspects on the quality of extreme code summaries, we conducted ablation experiments which indicated that aspect (3) had a stronger influence on false negative in extreme code summarization results than the other aspects (4)(5), The aspect (1) has a stronger influence on false positive in extreme code summarization results than aspect (2). The results of ablation experiment illustrate prove the significance and potential of utilizing the program semantics explicitly in code summarization.

Therefore, based on the experimental results and findings, in the future study, we plan to improve the model in performing code summarization tasks from three aspects of preprocessing filtering enhancement, external data source enhancement and attention mechanism enhancement, which have been mentioned in section IV-D. Let's wish all these findings promote the progress in the field of code summarization.

# Using Topic in Summarization for Vietnamese Paragraph

Dat Tien Dieu, Dien Dinh

Faculty of Information Technology, University of Science, Ho Chi Minh City, Vietnam

*Abstract*—**This article delves into the realm of refining the precision of automated text summarization tasks by harnessing the underlying themes within the documents. Our training data draws upon the VNDS dataset (A_Vietnamese_Dataset_ for_Summarization), encompassing a total of 150,704 samples aggregated from diverse online news sources like vnexpress.net, tuoitre.vn, and more. These articles have been meticulously processed to ensure they align with our training objectives and criteria. This paper presents an approach to text summarization that is theme-oriented, utilizing Latent Dirichlet Allocation to delineate the document's subject matter. The data subsequently have been fed into the BERT model, which constitutes one of the subtasks within the broader domain of abstractive summarization—summarizing content based on pivotal concepts. The results attained, although modest, underscore the challenges we've confronted. Consequently, our model necessitates further development and refinement to unlock its full potential.**

*Keywords*—*Automatic text summarization; a theme-based approach; BERTmodel; latent dirichlet allocation*

## I. Introduction

Text summarization is a method that allows readers to quickly grasp the essential and core contents of a document, reducing reading time while retaining important and necessary information. Text summarization is not only applied in news articles and publications but also in search results, product descriptions, technical documents, and even summarizing related articles within a given topic. One of the earliest studies in the field of automatic text summarization was conducted by Erkan and his colleagues in 2007. Since then, automatic text summarization has become a formal task and has been approached by various research groups and integrated into their language models for evaluation purposes.

In terms of the purpose of text summarization, it can be divided into theme-based summarization and generic summarization. Currently, there are two main approaches to automatic text summarization: extractive summarization, abstractive summarization, and a combination of these two methods known as hybrid summarization.

In this research, the paper focuses on two primary directions related to generating text summaries. The first direction concentrates on extracting information from the original text to create a summary. Methods in this direction emphasize selecting sentences with high coverage in the original text for inclusion in the summary. This can be achieved through graph-based methods [1] or even using neural networks to identify important sentences [2]. The second direction involves creating a summary by abstracting

meaning from the original text. In this approach, machine learning models are used to generate new sentences based on the content of the original text, resulting in a summary with a completely different grammatical structure from the original text. Additionally, there is a hybrid approach that combines extraction and abstraction, creating a summary by extracting information and summarizing a portion of the original text.

All three research directions produce automatic summaries, which are evaluated by comparing them to reference summaries created by humans, using metrics such as BLEU [3] and ROUGE [4].

Our work is based on a dataset of Vietnamese text, which is compiled by aggregating news articles from the VnExpress electronic information portal. After collecting the articles, they are preprocessed to create an experimental dataset. Each document in this dataset consists of two main components: a pre-existing summary called a reference summary and the main content of the article. Then the dataset was divided into three separate parts model training, training parameter tuning, and finally, model evaluation.

## II. Related Works

### A. Model ViHeartBERT (2022)

The ViHeartBERT model (2022) [5] constructs a model with applications in the medical field, designed to help both patients and doctors understand scientific literature by providing clear explanations for medical abbreviations and summarizing frequently asked questions. The dataset used for training is a specialized medical dataset called acrDrAid. This model has a BERTbase-like architecture but is trained on its own dedicated dataset.

### B. Model ViT5 (2022)

The ViT5 model (2022) [6] is an encoder-decoder model based on the Transformer architecture that has been pre-trained for the Vietnamese language. Following the self-supervised T5-style pre-training approach, ViT5 was trained on a large, high-quality, and diverse dataset of Vietnamese text. They assessed the performance of ViT5 on two downstream text generation tasks: Abstractive Summarization and Named Entity Recognition (NER).

ViT5's performance against several other Transformer-based encoder-decoder models. Our experiments demonstrated that ViT5 significantly outperforms existing models and achieves the best results in Vietnamese text summarization. In the Named Entity Recognition task, ViT5 competes strongly

with the previous best results obtained from pre-trained Transformer-based models.

### C. Model BARTPho (2022)

The BARTpho model (2022) [7] is one of the leading and largest single-language sequence-to-sequence models pre-trained for Vietnamese. Our BARTpho model utilizes a "large" architecture and follows the pre-training strategy of the BART long document denoising model, making it particularly suitable for natural language generation tasks.

Tests conducted on a specific task related to Vietnamese text summarization demonstrate that BARTpho, both in terms of automatic evaluation and human assessment, outperforms the strong base model mBART and enhances the current state of the art. BARTpho has been released to support future research and applications in natural language generation tasks for the Vietnamese language.

Based on the promising results of language models, they have decided to train a language model based on a sequential model structure with attention mechanisms and the incorporation of document themes.

### III. PROPOSAL

Following the research above, there is a need for a model that can be used to summarize a paragraph with the topic because using the topic helps to redirect the bag of words to the topic that it should be about, it helps to improve the accuracy of generation words and also the relation between generated text and original one. The attention mechanisms are really powerful but also the topic awareness, the bag of words have been narrowed down, it is easier to control the output to get better-generated text over time.

### A. The Structure of a Sequential Model with Attention Mechanisms

The structure of the Sequence-to-sequence (Seq2Seq) model with an attention mechanism is depicted in Fig. 1 and serves as the foundation for developing the Pointer-generator Networks model. The model consists of:

**Encoder:** This is a bidirectional LSTM network with a single layer. It encodes the input sequence.

**Decoder:** This is a unidirectional LSTM network with a single layer. It decodes the encoded information from the encoder to generate the output sequence.

The document $w_i$ is sequentially fed into the encoder to generate the encoded sequence of hidden states $h_i$.. At each time step t, the decoder receives the embedding of the previous word (during training, it's the word from the reference document, and during testing, it's the word selected at time step t - 1 by the decoder) and obtains the decoding state $s_t$.

The attention distribution is computed according to Eq. (1) and Eq. (2):

$$e_i^t = v^T \tanh(W_h h_i + W_s s_t + b_{attn}) \quad (1)$$

$$a^t = softmax(e^t) \quad (2)$$

where, $v, W_h, W_s$ and $b_{attn}$ are trainable parameters. The attention distribution can be seen as a probability distribution over the vocabulary, informing the decoder about where to look to generate the next word. Subsequently, the attention distribution is used to compute the weighted sum of the hidden states from the encoder, referred to as the context vector $h_t^*$ in Eq. (3):

$$h_t^* = \sum_i a_i^t h_i \quad (3)$$

The context vector, representing a fixed-size vocabulary, is read at the current time step, and it is combined with the decoder state $s_t$ to generate the word probability $P_{vocab}$ as described in Eq. (4):

$$P_{vocab} = softmax(V'(V[s_t, h_t^*] + b) + b') \ (4)$$

where, $V$, $V'$, $b'$ and $b$ are trainable parameters, and $P_{vocab}$ is the probability distribution over all words in the vocabulary, providing us with the distribution of the word to be predicted as given in Eq. (5):

$$P(w) = P_{vocab}(w) \quad (5)$$

During the training process, the loss at time step $t$ is determined by the negative log-likelihood of the word group $w_t^*$ at that step, as defined in Eq. (6):

$$loss_t = -\log P(w_t^*) \quad (6)$$

Subsequently, the loss value for the entire input sequence is determined as per Eq. (7):

$$loss = \frac{1}{T}\sum_{t=0}^{T} loss_t \quad (7)$$

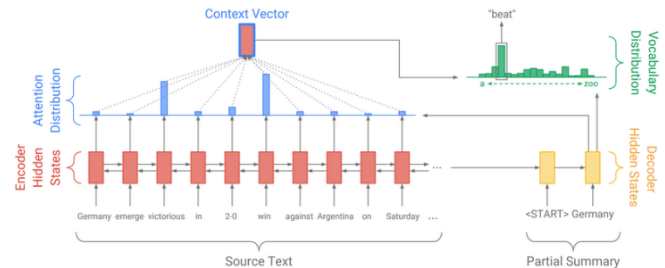

Fig. 1. Structure of sequence-to-sequence attentional model.

Fig. 1 is the structure of the model that was used to feed the data to the model and get the context vector with vocabulary distribution.

### B. The Generative Network Utilizes the Topic Modeling Method with Latent Dirichlet Allocation (LDA)

A model was built to demonstrate the capability of expressing the topic distribution of a text segment as well as an array representing the distribution of words related to those topics from raw data. To achieve this, using Latent Dirichlet Allocation (LDA) is an important part. This information is combined to enhance the accuracy of text summarization. There are several models which have been used to enhance the accuracy of the Natural Language Processing model, which can be referred to as "Latent Dirichlet Allocation (LDA) and Topic modeling: models, applications, a survey" of Hamed Jelodar, Yongli Wang, Chi Yuan, Xia Feng, Xiahui Jiang, Yanchao Li, Liang Zhao [8]. To learn more about how

to apply the LDA for the abstraction summarization, this paper is inspired by "LDA based topic modeling of journal abstracts" by P. Anupriya; S. Karpagavalli [13] about how to use LDA effectively in the summarization in order to get better summarization without using the same words which are in the original paragraph.

To better understand LDA, let's consider an example. having 1000 documents, each consisting of 500 words. This means it would need 1000x500 connections to understand how each word depends on each document and vice versa. Instead of having so many connections, and grouping these documents into topics, let's assume there are three topics. So, there will be 1000x3 = 3000 connections to determine which topics each document belongs to, and another 500x3 = 1500 connection to determine the word distributions that influence these 3 topics.

Fig. 2 and Fig. 3 demonstrate the differences between using an additional topic layer and not using any additional topic layer.

Fig. 2. Connections are necessary to determine the influence of words on documents.

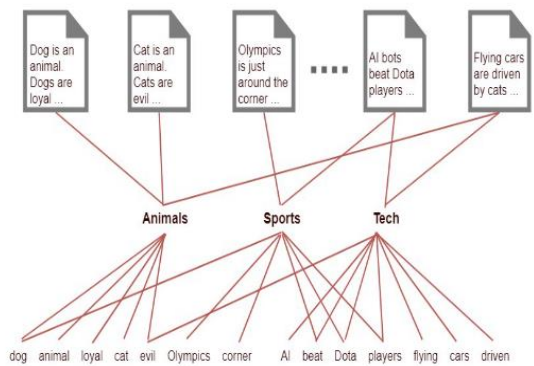

Fig. 3. Connections are necessary to determine the impact of words on the documents through topics.

Once the possible topics are identified within the documents, using CountVectorizer to train the LDA model and obtain the results as follows Fig. 4 is the next step. The distribution of words to the corresponding topic can see how the words are being distributed or which word contributes to which topic.

Fig. 4. Distribution of words to the corresponding topic.

### C. Combining the Generative Network using the LDA Topic Modeling Method with the BERT Model

The Bayesian approach, which is based on the distribution of topics within the input text, can be highly effective for documents that have hidden topics.

$$
\begin{aligned}
decoding\ probability =\ & alpha * sum\_topic[\ p(word\,|\,topic) \\
& * p(topic\,|\,paragraph)] + (1 \\
& - alpha) \\
& * p\_transformer(word\,|\,context)
\end{aligned}
$$

The combination approach of the LDA topic modeling method with the BERT model will be illustrated in the following figure:

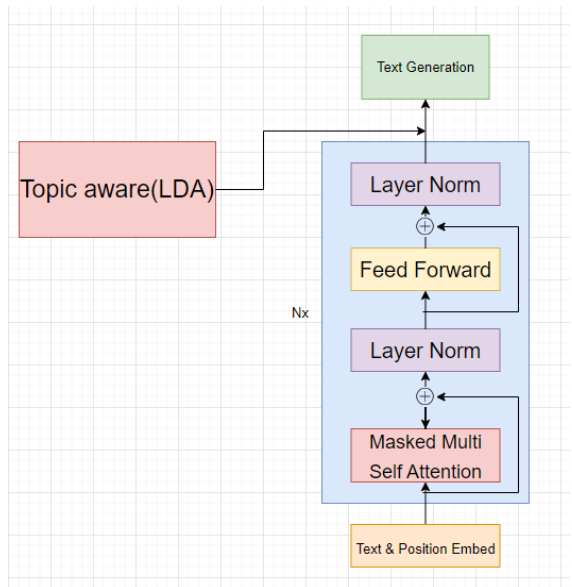

Fig. 5. The combination of BERT and LDA.

Fig. 5 demonstrates where the Topic Aware (LDA) has been added to the original BERT model and the reason for this is because this model has been designed to focus on the last layer before the model generates the words.

## IV. DISCUSSION

The topic-aware approach is also potent, with several papers employing the topic as a primary feature in generating text, following the principles of "Latent Dirichlet Allocation (LDA) and Topic modeling: models, applications, a survey."[8]. This technique proves particularly effective in specific domains with extensive terminology, declarations, definitions, and so forth, such as Social Networks, Software Engineering, Crime Science, Geography, Political Science, and Medical Science. In such areas, where term ambiguity is prevalent, a model that can discern the appropriate words for generation is imperative. Conventionally, LDA has been used not only for topic detection but also to uncover hidden topics within paragraphs. When dealing with a multitude of words, identifying underlying themes can be challenging for humans, but LDA offers a viable solution. "Prediction of research trends using LDA based topic modeling" is also an inspired paper that shows there is a promising trend for using LDA-based topic modeling in the Natural Language Processing industry. The research in [10], an example of using LDA for topic modeling for new articles [12].

Additionally, the BERT model has demonstrated its position as a state-of-the-art (SOTA) innovation in the Natural Language Processing industry. The introduction of the attention mechanism has revolutionized the landscape of methods, paving the way for a more accurate and efficient approach to extracting meaning from text using computers. It stands as the initial and rational choice for fine-tuning in various applications, including our case. Therefore, our ultimate goal is to effectively combine these two methods.

There is a limit characteristic of the BERT model is about the length of input, it is just 256. Because of that, the BERT multilingual model has been used to replace the original BERT model. According to "How Multilingual is Multilingual BERT" by Telmo Pires, Eva Schlinger, and Dan Garrette [9]. Additionally, following the "Pre-training of Deep Bidirectional Transformers for Language Understanding" [11], it is obvious using pre-trained models which have the transformer architecture will be more efficient than other architectures.

## V. EXPERIMENTS

### A. Datasets

This study was experimentally evaluated on a dataset comprising 830,643 articles collected from the Vnexpress website. Each article includes a title, author's summary, and the body of the article. Of this dataset, 80% was used for training, and 10% was used for experimental evaluation. On average, each article contains about 20 sentences, with each sentence consisting of approximately 25 words or fewer.

Table I provides a detailed description of the preprocessed dataset. The data was divided into three sets: Training (Train), Validation (Validation), and Test (Test) in a respective ratio of 70:15:15. The average number of sentences in the summary section across the sets is 1.22 sentences, with approximately 28 words per summary sentence. Meanwhile, the average number of sentences in the text to be summarized is around 17 sentences, with approximately 418 words.

TABLE I. THE DATASET INFORMATION

| | Training Set | Validation Set | Test Set |
|---|---|---|---|
| Numbers of sample | 105,418 | 22,642 | 22,644 |
| #avg number of sentences in abstract | 1.22 | 1.22 | 1.22 |
| #avg number of words in abstract | 28.48 | 28.54 | 28.59 |
| #avg number of sentences in body | 17.72 | 17.81 | 17.72 |
| #avg number of word in body | 418.37 | 419.66 | 418.74 |

### B. Settings

The experiments have been done with the generative network model using a pointer on a computer equipped with a GPU, 12.79 GB of RAM, and a 16GB GPU, running Tensorflow three library. The training parameters were set as follows:

- Number of hidden layers: 4
- Learning rate: 0.001
- Embedding word length: 128
- Beam size: 4
- Number of heads: 8
- Input sentence length: 512
- Output sentence length: 200

### C. Results

Beginning the experimental phase with the LDA training model (a model that determines document topics based on the LDA algorithm). Since the number of topics is not predetermined, attempting to determine the number of topics through several methods is a crucial aspect.

First, the K-means clustering method has been used to determine the number of topics and assess how dividing topics influences the model's generative capability. After performing this, the result is obtained in the following chart:

Fig. 6. The distribution of the number of topics when inputting.

Fig. 6 demonstrates the best number of topics that should be divided paragraphs into. Below Fig. 7 shows the distribution of topics in paragraphs, it can be seen obviously the paragraphs have the same topics tend to gather together.
Fig. 7.   Distribution and clustering of topics in paragraph.

To confirm the meaningfulness and accuracy of this representation, T-SNE (t-Distributed Stochastic Neighbor Embedding) examined the distribution and clustering of the data. Fig. 8 demonstrates distribution topics over each paragraph, it can be referred to the contribution of those topics to the big topics in each paragraph.

Fig. 8.   Distribution of topics to each paragraph in the dataset.

With the results above, it shows that the distribution of topics across documents is uneven. This is because different words in different texts have varying meanings.

After completing the LDA experiments, the next experiments are combining LDA with the BERT model. Initially, the BERT model was trained from scratch, meaning there is no pre-trained model used, to assess its effectiveness and training capabilities without a suitable pre-trained model. However, the results were not very good, achieving ROUGE 1, ROUGE 2, and ROUGE L scores of 5.4%, 4.7%, and 5.6%, respectively. Therefore, training the BERT model from scratch using the above dataset did not yield the desired results. Consequently, to continue with better performance, it is urging to use a pretrained model to reduce training time and improve the accuracy of predicting the next word during text summarization. This decision led to significant improvements compared to training BERT from scratch. However, due to BERT's limitation in input text length, that will be better when transitioning to another pretrained model called BERT Multilingual. This model has a longer input text length capability than BERT and offers better embedding support. Table II is the result that model achieved in training multiple times.

TABLE II.       THE RESULT OF THE MODEL WITH THE ROUGE 1, ROUGE 2 VÀ ROUGE L

|  | ROUGE-1 | ROUGE-2 | ROUGE-L |
|---|---|---|---|
| Pre-trained BERT and LDA | 0.102 | 0.081 | 0.113 |

## VI.  CONCLUTIONS AND DEVELOPMENT DIRECTIONS

### A. Conclusions

Currently, with the experiment with the BERT model, it seems that the combination of LDA and the BERT model has not achieved the desired effectiveness. The ROUGE-1, ROUGE-2, and ROUGE-L scores have not shown significant improvements, and the generated words do not appear to be highly related to the input text's topic, and the grammar is not as polished as desired, despite the good training results of the LDA model.

Given that the LDA model's results are promising, it is a great idea to consider exploring other language models with the ability to incorporate new features into the model, such as BART. BART is a powerful language model that can be fine-tuned for various natural language processing tasks, including text summarization. It has demonstrated strong performance in abstractive summarization tasks and might provide improvements, especially when combined with LDA. Further experimentation and fine-tuning of this combined approach could yield better results.

### B. Development Directions

Plan for the next step is to continue development based on models that achieve high ROUGE-1, ROUGE-2, and ROUGE-L scores in combination with the LDA model. To diversify the number of topics and ensure equal topic coverage, training an LDA model using deep learning methods is needed. This will enable us to create a model that can predict the topics of text effectively and seamlessly integrate it into state-of-the-art (SOTA) natural language processing models. This approach should help improve the quality and relevance of generated summaries in various applications.

*Abstract*—The study introduces a comprehensive technique for enhancing the Natural Language Processing (NLP) capabilities of virtual assistant systems. The method addresses the challenges of efficient information transfer and optimizing model size while ensuring improved performance, with a primary focus on model pertaining and distillation. To tackle the issue of vocabulary size affecting model performance, the study employs the SentencePiece tokenizer with unigram settings. This approach allows for the creation of a well-balanced vocabulary, which is essential for striking the right balance between task performance and resource efficiency. a novel pre-layernorm design is introduced, drawing inspiration from models like BERT and RoBERTa. This optimization optimizes the placement of layer normalization within transformer layers during the pretraining phase. Teacher models are effectively trained using masked language modeling objectives and the Deepspeed scaling framework. Modifications to model operations are made, and mixed precision training strategies are explored to ensure stability. The two-stage distillation method efficiently transfers knowledge from teacher models to student models. It begins with an intermediate model, and the data is distilled carefully using logit and hidden layer matching techniques. This information transfer significantly enhances the final student model while maintaining an ideal model size for low-latency applications. In this approach, innovative measurements, such as the precision of filling a mask, are employed to assess the effectiveness and quality of the methods. The findings demonstrate substantial improvements over publicly available models, showcasing the effectiveness of the strategy within complete virtual assistant systems. The proposed approach confirms the potential of the technique to enhance language comprehension and efficiency within virtual assistants, specifically addressing the challenges posed by real-world user inputs. Through extensive testing and rigorous analysis, the capability of the method to meet these objectives is validated.

## I. INTRODUCTION

Our everyday lives have become more reliant on virtual assistants, which provide efficiency and convenience for a variety of activities, from setting notifications and handling calendars to answering inquiries and managing smart home devices [1]. The capacity of such virtual assistants to understand and interpret user input in natural language is essential to their effectiveness. The core of this language comprehension process is Natural Language Processing (NLP), which enables virtual assistants to comprehend the purpose behind user inquiries and deliver pertinent and contextually suitable replies. Although NLP research has made great strides, conventional virtual assistants frequently have trouble understanding complicated and nuanced user inputs. When their inquiries are incorrectly translated, users may become frustrated, which can result in unsatisfying results and decreased user engagement [2]. These drawbacks highlight the demand for more intelligent and complex methods of language interpretation in virtual assistants. A software programme with artificial intelligence combined with NLP (natural language characteristics are known as a virtual assistant [3]. It acts as a virtual friend that can converse with users in a manner like that of a human and help them with a variety of jobs and enquiries. This technologically advanced system responds to speech or text-based instructions, deciphers user intentions, and offers pertinent data, services, or recommendations in order to expedite and simplify daily tasks [4]. Virtual assistants are becoming a common feature of contemporary digital experiences on a variety of platforms; including computers, smart speakers, wearable technology, and smartphones. These assistants change the way people engage with technology by utilizing NLP to manipulate smart devices, play musical instruments manage appointments, send reminders, obtain weather information, and more [5]. Virtual assistants are anticipated to develop further as artificial intelligence technology progresses, growing better at comprehending context, recognizing individual preferences, and completing difficult

tasks, ultimately changing how we traverse our linked and digital lives.

Virtual assistants' usability and efficacy are greatly influenced by natural language processing (NLP). The manner in which people engage with technology is being revolutionized by these AI-powered assistants' ability to understand, interpret, and reply to human language thanks to NLP [6]. Speech recognition is one of the fundamental elements underlying NLP in virtual assistants, where algorithms translate spoken language into text that can be understood by machines. This allows the assistant to interpret voice instructions. Another crucial element is intent identification, which enables virtual assistants to understand the rationale behind a user's question and tailor their responses. Entity extraction is made easier by NLP, which helps virtual assistants find crucial information in user inputs like places or names [7]. Additionally, NLP empowers virtual assistants to keep track of context during interactions, resulting in more suitable and natural replies. With the ability to generate language, virtual assistants may provide replies that seem human and are customized to the preferences and communication preferences of the user [8]. Sentiment analysis improves the experience by enabling assistants to recognize and understand user emotions. Additionally, NLP offers multilingual assistance, serving a variety of user bases globally. A few virtual assistants also use machine learning algorithms with NLP characteristics for continuous learning, improving their language comprehension and replies over time in response to user input. Virtual assistants' usefulness has been greatly enhanced by the addition of NLP, which makes interactions more natural, individualized, and conversational. Virtual assistants are anticipated to become increasingly smarter as NLP technology develops, interpreting complicated questions and providing contextually appropriate replies that meet the individual needs of users [9].

SEA for understanding language basics marks a significant advancement in the fields of artificial intelligence and natural language processing. The capacity of robots to understand the subtleties of human language is an essential hurdle in today's world when technology is ingrained more deeply into our everyday lives. To meet this problem, the SEA emerged as a revolutionary approach that makes use of current developments in machine learning to get beyond the drawbacks of traditional language understanding techniques. Modern technology is based on language understanding, which enables smooth interactions between humans and machines [10]. Traditional methods, however, frequently fail to adequately capture the subtleties of language, setting, and purpose. By fusing context analysis, entity extraction, and intelligent intent identification into one seamless framework, the SEA makes a brave step forward. By doing this, it not only aims to improve the sensitivity and accuracy of language processing devices but it additionally presents the possibility of reshaping user experiences in a variety of sectors [11]. The SEA has the ability to fundamentally alter the design of virtual assistant systems. These AI-powered friends have become an essential part of our lives, assisting us with everything from managing calendars to operating smart gadgets. Involving SEA, virtual assistants will be able to go beyond what they are now capable of, increasing the breadth of their understanding and raising the quality of their relationships with users. The main goal of SEA is to close the gap between computer interpretation and the subtleties of human language, therefore enabling more intuitive and natural communication. The SEA's importance goes beyond only technology. The SEA equips virtual assistants to act as knowledgeable guides, expertly leading users throughout a large sea of data in the age of overload of information and rapid technological advancement [12]. The SEA not only increases efficiency but also creates the foundation for establishing trust between people and computers by allowing virtual assistants to comprehend contextual and user intent more precisely. This study intends to give a thorough analysis of the Smart Evaluation Approach's methodology, implementation tactics, and the intriguing research directions it opens upon our delve into its complexities. By combining artificial intelligence and natural language processing, SEA aims to reinvent the fundamentals of language understanding, pushing the limits of what virtual assistants can accomplish and fundamentally altering how we engage with technology [13].

The study presents a Smart Evaluation Approach (SEA) that aims to improve virtual assistants' ability to understand language. The SEA uses new developments in artificial intelligence and machine learning to address problems with traditional virtual assistants. The SEA seeks to greatly improve virtual assistants' accuracy and response to user inputs using intelligent intent identification, entity extraction, and contextual analysis. The study's major goal is to expand the capabilities of virtual assistants' existing language understanding techniques in order to promote more intuitive and natural human-machine interactions. A thorough assessment of the literature on NLP, AI, virtual assistants, and comprehension of language approaches is part of the paper's framework. The conceptual framework for the virtual assistant network and its integration with SEA are then discussed, followed by the approach used for SEA installation and assessment. The merits and possible improvements of the suggested technique are highlighted by the detailed experimental results and comparison analysis with conventional approaches [14]. The conclusion summarizes the research findings and suggests new avenues of inquiry for improving language comprehension in virtual assistants. The goal of using NLP and the smart assessment method is to unlock the potential of virtual assistants, alter technology engagement, and enable smooth and efficient human-machine communication. The key contributions of the research models are as follows:

- This study focuses on enhancing Natural Language Understanding (NLU) capabilities in a large-scale virtual assistant through language model pretraining and distillation techniques, specifically targeting intent classification and slot filling, which are critical components of effective language comprehension.

- The research addresses the challenge of understanding user intentions and identifying relevant slots in user inputs. For instance, given a query like "can you call mom," our NLU model should discern the intention to

initiate a call and identify the corresponding slot, in this case, the contact's name, marked as "mom".

- Throughout the paper, the research consistently refers to our models and pipeline as "Virtual Assistant Teacher Model(s) (VATM)". This nomenclature reflects the unique aspects of our problem domain, which diverges from traditional research tasks in several ways.

- This approach leverage relatively extensive labeled datasets, which is noteworthy as it introduces challenges and opportunities distinct from typical pretraining approaches.

- The research emphasizes the importance of optimizing model efficiency, as our models must operate within stringent latency and memory limitations, ensuring their practical utility in real-world scenarios.

- Research tackle the unique challenge of processing primarily spoken language data, distinguishing our work from the more common "written form" text used in the pretraining of publicly available models.

This system's capability extends across multiple languages, adding an additional layer of complexity to the language understanding process. The study tackles the intricate challenge of improving language understanding within virtual assistants by leveraging language model pretraining and distillation techniques. We navigate through unique challenges, including a sizable labeled dataset, performance constraints, spoken language input, and multilingual support, to enhance the overall NLU capabilities of our Virtual Assistant Teacher Models (VATMs).

## II. RELATED WORKS

Ait-Mlouk and Jiang [15] introduces "KBot", a novel ChatBot designed to harness the power of knowledge graphs and linked data for enhancing natural language understanding. With the increasing availability of structured data in the form of knowledge bases on the semantic web, the objective of the ChatBot is to make this information accessible and beneficial for end-users. The authors address several challenges associated with building such a ChatBot, including user query comprehension, support for multiple knowledge bases, and multilingual capabilities. The authors present an architecture that facilitates an interactive user interface, enabling effective communication between users and the ChatBot. They propose a machine learning-based approach that employs intent classification and natural language understanding to interpret user intents and generate SPARQL queries for retrieving relevant information from knowledge bases. Notably, the authors extend their system by incorporating a new social network dataset, 'myPersonality,' into existing knowledge bases, enhancing the ChatBot's ability to handle analytical queries. The system allows for the incorporation of new domains, offers flexibility in supporting multiple knowledge bases, and is designed to handle multilingual interactions. The paper also emphasizes the user-friendly creation and execution of various tasks across a broad spectrum of topics. The paper supports its claims with evaluation and application cases that demonstrate KBot's practical utility. These examples underscore how the ChatBot effectively navigates semantic data to cater to diverse real-world scenarios. The approach taken by the authors is particularly notable for its data-driven nature, leveraging knowledge graphs to provide insightful responses. The paper makes a significant contribution to the field of natural language processing and knowledge graph utilization. KBot's architecture and machine learning-based approach, along with its demonstrated adaptability and practical application, position it as a valuable tool for interactive and data-rich interactions.

Jungbluth et al. [16] delves into the integration of popular virtual assistants like Alexa, Siri, Cortana, and Google Assistant with industrial robotics, focusing on their role in controlling components of an intelligent robot assistant system for disassembly tasks. The authors introduce the paper by highlighting the increasing presence of virtual assistants in daily life, particularly their use as intuitive human-machine interfaces for device control through natural language. The core contribution of the work lies in its exploration of using virtual assistants to manage individual elements within a sophisticated industrial robot assistance system. After a succinct introduction and a survey of available virtual assistants, the authors present their system architecture, which seamlessly incorporates Amazon's Alexa using an Echo Dot device. Leveraging the Alexa Skills Kit, they develop a voice user interface encompassing various device functionalities and assistive behaviors. The authors detail the technical setup, which involves linking Alexa Voice Service with Amazon's Lambda and IoT web services. This connectivity facilitates the customization of machine commands based on users' voice inputs. Through intermediary components like a Raspberry Pi, they establish communication between the internet and the robot's isolated network. A notable aspect is the bidirectional communication flow, enabling real-time updates of device statuses in Amazon Web Services IoT shadow. This status information is subsequently utilized in Lambda functions to generate speech output using Alexa Voice Services and relayed through the Echo Dot for user notifications. The conclusion offers a balanced perspective by highlighting both positive and negative experiences encountered during their endeavors. The paper provides a comprehensive case study of integrating virtual assistants, particularly Amazon's Alexa, into the realm of industrial robotics. The technical details, architecture overview, and demonstration of a use case collectively exemplify the potential benefits and challenges of combining virtual and robot assistants. The work underscores the practicality of leveraging virtual assistants in complex real-world scenarios and contributes to the growing understanding of their integration within industrial applications.

Alagha and Helbing [17] responses to consumer health questions about vaccines: an exploratory comparison of Alexa, Google Assistant and Siri" aims to assess and compare the accuracy and quality of responses provided by Amazon Alexa, Google Assistant, and Siri to consumer health queries regarding vaccine safety and usage. The study employs a rubric-based scoring system to evaluate the responses of each voice assistant across 54 questions related to vaccination. The

evaluation criteria include the accuracy of the answer given through audio output and the credibility of the source supporting the response. The findings of the study reveal significant differences in the performance of the three voice assistants. Siri obtains the highest average score of 5.16 points, followed closely by Google Assistant with an average score of 5.10 points. In contrast, Alexa lags behind with a notably lower average score of 0.98 points. The results indicate that Google Assistant and Siri excel in accurately interpreting voice queries and providing users with authoritative sources of information about vaccination. However, Alexa struggles to comprehend queries and relies on sources different from those used by the other two assistants. The authors conclude that those involved in patient education should be cognizant of the varying quality of responses provided by different voice assistants. They also suggest that developers and health technology experts should advocate for improved usability and transparency in terms of information partnerships as these devices continue to evolve in their capabilities to deliver health-related information. The article is available under the Creative Commons Attribution Non Commercial (CC BY-NC 4.0) license, permitting others to share, adapt, and build upon the work non-commercially, provided appropriate credit is given, changes are indicated, and usage remains non-commercial. The study contributes valuable insights into the performance of voice assistants in delivering accurate and reliable health information to users. The findings underscore the importance of further refining these technologies to ensure consistent and high-quality responses, especially in critical domains such as health information dissemination.

Villegas-Ch et al. [18] explores the implementation of a virtual assistant for managing academic aspects within a university using artificial intelligence (AI). In light of the ongoing pandemic, private universities are encountering challenges across academic and financial domains. Learning difficulties have contributed to increased dropout rates, exacerbating financial strains. Additionally, economic impacts from the pandemic have led to a decline in students seeking private education. These circumstances necessitate support measures to enhance student enrollment, safeguard budgets, and optimize resources. The academic realm poses significant efforts to manage academic activities while prioritizing those interested in pursuing educational programs. To address these complex challenges, integrating technologies like Chatbots, powered by artificial intelligence, emerges as a solution. By leveraging AI-powered Chatbots, universities can delegate tasks such as providing information about academic courses. This offloads administrative burdens and simultaneously enhances the user experience, thereby encouraging greater participation in the university community. The integration of AI-powered Chatbots can offer multifaceted benefits. These tools can efficiently handle information dissemination about academic courses, freeing up human resources for more critical tasks. They contribute to a smoother and more engaging user experience, potentially attracting more prospective students. This technology aligns well with the broader trend of digital transformation in education, offering personalized and immediate support to users. However, it's important to consider the potential challenges and limitations of implementing such systems. Ensuring accurate and contextually relevant responses, maintaining data privacy, and addressing potential technical glitches are areas that require careful attention. The paper underscores the need for private universities to adapt to the current circumstances by embracing technological solutions like AI-driven Chatbots. These tools hold the promise of enhancing student enrollment, reducing administrative burdens, and ultimately improving the overall efficiency and effectiveness of academic management in the face of evolving challenges.

Dong et al. [19] provides a brand-new method called the Universal pre-trained linguistic model (UniLM), which is intended to handle both responsibilities of comprehending and producing natural language. Utilizing A Transformer network that is shared among multiple users goes through pre-training utilizing a variety of language modeling tasks, including unidirectional, bidirectional in nature, and sequence-to-sequence prediction, this is accomplished. Specific self-awareness masks are used to identify the pertinent context for predictions to achieve unified modeling. On the frequently utilized GLUE measure as well as on challenging tasks including SQuAD 2.0 and CoQA problem answering, UniLM performs favorably when compared to BERT. The study demonstrates how UniLM outperforms industry standards on five naturally language-generating datasets. The ROUGE-L scores for CNN/DailyMail abstract summarization and Gigaword abstractive summarizing both saw increases of 2.04 absolute points and 0.86 absolute points, respectively, reaching 40.51 and 35.75, respectively. UniLM makes major advancements in generative question-answering tasks in addition to summarization. It produces an astounding 82.5 per cent increase in the F1 score with CoQA generating question answering. Additionally, the article documents significant gains in the DSTC7 document-grounded dialogue answer generating NIST-4 rating (achieving 2.67, with individual performance at 2.65), as well as the SQuAD controversy generating BLEU-4 score (3.75 absolute enhancements, reaching 22.12). The article proposes UniLM, a brand-new unified already trained linguistic model that performs very well on challenges requiring both interpretation and creation of natural language. The algorithm's superiority over current state-of-the-art models and outstanding performance on numerous benchmarks and datasets emphasize its potential to enhance the study of the processing of natural language. The research approach and conclusions in this work provide a substantial contribution to the creation of more powerful and adaptable language representations for use in real-world situations.

An overview of the main points, benefits, and drawbacks of the relevant papers are provided in the Table I. While having trouble with language support and user query comprehension, Ait-Mlouk and Jiang [15] employ natural language processing and machine learning-based intent categorization, utilising knowledge graphs to deliver perceptive responses. In order to overcome the hurdles involved in this integration, Jungbluth et al. [16] incorporate Amazon's Alexa with industrial robot support systems for real-time communication. Voice assistants' answers to health-related questions are compared using a rubric-based rating

system by Alagha and Helbing [17], exposing differences in response quality. Chatbots driven by AI are used by Villegas-Ch et al. [18] to improve administrative effectiveness and information distribution in higher education. The Universal pre-trained linguistic model (UniLM), as introduced by Dong et al. [19], improves F1 scores and natural language generation performance on multiple benchmarks in natural language processing tasks.

TABLE I.        OVERALL SUMMARY OF LITERATURE REVIEW

| Reference | Technique | Merits | Limitation |
|---|---|---|---|
| Ait-Mlouk and Jiang [15] | Natural language processing and intent classification powered by machine learning. | Applying knowledge graphs to provide perceptive answers and integrating other data areas | Difficulties with language support, multiple knowledge base support, and user query comprehension. |
| Jungbluth et al. [16] | Integration of Amazon's Alexa into industrial robot assistance systems, technical setup, and real-time communication. | Integration of popular virtual assistants like Alexa into industrial robotics, offering a use case in industrial applications. | Challenges associated with the integration of virtual assistants into industrial robotics and practical use cases in the real world. |
| Alagha and Helbing [17] | Rubric-based scoring system to evaluate the responses' accuracy and credibility. | Comparative assessment of Amazon Alexa, Google Assistant, and Siri in responding to health | Differences in the quality of responses provided by voice assistants to consumer health queries. |
| Villegas-Ch et al. | Dong et al. [19] | Development of the Universal pre-trained linguistic model (UniLM) using shared Transformer networks, self-awareness masks, and pre-training using language modeling tasks. | Enhancements in performance across diverse natural language generation tasks, such as summarization and question-answering, resulting in impressive F1 scores and leading outcomes on various evaluation benchmarks. | Introducing the Universal pre-trained linguistic model (UniLM) for natural language processing (NLP) assignments. |

## III.    PROBLEM STATEMENT

The domain of virtual assistant systems faces a substantial challenge in achieving both efficiency and accuracy in language understanding. Striking the right balance between model size and performance is paramount, particularly for applications that require low-latency responses. However, the current landscape is marked by models that tend to be overly large, leading to latency and resource constraints, or simplified versions that sacrifice language understanding capabilities [20]. The evaluation of these models poses significant challenges, particularly with regard to the limitations of conventional metrics like perplexity, which can be influenced by tokenization choices and may not accurately reflect real-world performance. Existing evaluation methods may not fully capture the intricacies of language comprehension necessary for virtual assistant tasks that involve precise understanding and response to user intents and slots. Therefore, the central challenge is to develop an approach that distills knowledge from larger models into smaller ones while either preserving or enhancing their language understanding capabilities. This involves addressing the delicate balance between reducing model size and maintaining performance standards. Innovative evaluation metrics are essential to align with the specific requirements of virtual assistants, offering a comprehensive gauge of language understanding quality. The ultimate goal is to establish a robust methodology that tackles the dual challenges of model efficiency and performance, while introducing novel evaluation techniques tailored to the demands of real-world virtual assistant applications. Successfully addressing this challenge promises the development of highly efficient yet accurate language understanding models, ultimately revolutionizing virtual assistant technology and elevating user experiences across a wide range of domains, including customer service and personal assistants.

## IV.    PROPOSED METHODOLOGY FOR EVALUATION OF LANGUAGE UNDERSTANDING

The methodology employed in this study follows a comprehensive approach to enhance language understanding capabilities. The process starts with the selection of diverse pretraining datasets, including the multilingual Colossal Clean Common Crawl (mC4), CC100 dataset, and Wikipedia data. These datasets encompass various domains, languages, and tones. Incorporating twelve languages for pretraining, such as Arabic, English, French, and more, establishes a robust foundation for multilingual comprehension. The sampling process, guided by a multinomial distribution, ensures proportional representation of languages while up-sampling low-resource ones. Preprocessing involves organizing sentences into sequences and dynamic tokenization during training. Additionally, a Stage 2 pretraining dataset, comprising anonymized utterance text from the system, undergoes refinement through duplication reduction, length filtering, and integration with public datasets. Tokenization strategy employs a SentencePiece tokenizer with intrinsic metrics, optimizing vocabulary size for effective tokenization. During pretraining, a modified architecture, introducing pre-layernorm components, aids in capturing both intra- and inter-sentence structures. Stage 2 pretraining focuses on enhancing

the model's specialization for virtual assistant utterances. Distillation techniques are applied in two phases, with an intermediate-sized model distilled from the large teacher model, followed by the use of this distilled model as a teacher

for the final, smaller student model. Validation leverages the "mask-filling accuracy" task to monitor progress and performance.

Fig. 1. Proposed model training and evaluation framework.

### A. Training Datasets

Pre-training datasets, which include a wide variety of data covering different areas, zones, languages, and more, are an essential basis for improving language processing abilities. This study takes into account a trio of primary sources of pre-training data: Wikipedia data, which helped train BERT, mBERT, and the BooksCorpus; the multiple-language Colossal Clean Common Crawl (mC4) a database, used for T5 and mT5 training; the CC100 a database, used to instruct XLM-R. Notably, Common Crawl data are used to create the mC4 and CC-100 datasets. A systematic strategy was used for selecting phrases from the training corpus, which included twelve languages for pre-training: the language of Arabic, English, French, German, Italian, Japanese, Marathi, Portuguese, Spanish, Tamil, and Telugu are all examples of supported languages. To ensure representation across languages, phrases were chosen for sampling using a multinomial distribution in accordance with predetermined rules. By up-sampling countries with fewer examples, the selection procedure, which was controlled by a multinomial distributing equation, aimed to achieve a balance. This

technique successfully improved low-resource languages, resulting in a more varied dataset.

TABLE II. DATASET

|  | Section 1 | Section 2 | Section 3 |
|---|---|---|---|
| data to Train | 95K | 84 K | 70 K |
| Validation data set | 15K | 12 K | 20 K |
| Size of test data | 25K | 24 K | 40 K |
| # of intents | 17 | 9 | 15 |
| # of slots | 97 | 28 | 58 |

Table II provides an overview of the dataset used for training, validation, and testing in the context of our language understanding model. The dataset is divided into three distinct domains, each representing a different aspect or category of language understanding.

The preprocessing method improved the dataset's quality. Sentences were organized into sequences of about 700 words,

and dynamic tokenization was carried out while training. This method made sure that sequences stayed inside the 1,024-token limit after tokenization while maintaining sequence integrity. In addition to publicly available datasets, a private Stage 2 prior instruction dataset made up of unlabeled and anonymous utterance text was included. There were several preparation stages for this dataset. Instances with lesser than five tokens were deleted, and duplicates have been minimized by keeping just a portion of their original total. In order to create an exhaustive collection for Stage 2 pretraining, this private data was pooled in a 1:2 ratio with the open Stage 1 pretraining database to reduce catastrophic forgetting. In the end, our efforts produced a Stage 2 pretraining database with over 50 million cases. These datasets were smoothly included in the training pipeline that was developed, as shown in Fig. 1. The need of creating a thorough and comprehensive pretraining database to improve language comprehension models is highlighted by this method of data collecting, curation, and preparation [21].

### B. Text Pre-processing using Tokenization

This approach revolves around the application of a SentencePiece tokenizer trained in the unigram setting, with the aim of enhancing Natural Language Processing within the realm of Virtual Assistants. The vocabulary size of the tokenizer emerged as a pivotal factor impacting the overall system performance. While larger vocabulary sizes often yield performance improvements in tasks like masked language modeling, they also introduce trade-offs, such as slower training convergence, heightened memory consumption during inference, and increased latency. Considering the resource-intensive nature of training an extensive teacher model with a wide-ranging tokenizer vocabulary, we introduced two intrinsic tokenizer metrics: the split-ratio and unk-token fraction. These metrics enabled us to meticulously balance performance and resource utilization without necessitating protracted teacher model training. The split ratio metric, grounded in the principle that a higher count of subword splits can compromise overall accuracy, guided our optimization efforts. Meanwhile, the unk-token fraction metric, which gauges the prevalence of unknown tokens in output, emerged as a pivotal performance determinant. A higher proportion of unk-token fractions negatively impacted the overall system performance. To align our tokenizer's split-ratio and unk-token fraction with baseline production models, we strategically incorporated an extensive set of 2,136 frequently used kanji characters in Japanese. This set was complemented by a comprehensive array of hiragana and katakana symbols, thus ensuring robust coverage of Japanese characters. Our strategy also involved partitioning data in a 70/30 ratio between spoken and written forms. This discerning distribution facilitated the attainment of a balanced vocabulary size, ultimately totaling 150,000 subword tokens. This vocabulary size was in harmony with the effective approach adopted in our pretraining corpus strategy. The foundation of our methodology for integrating Natural Language Processing capabilities into Virtual Assistants centers on a sophisticated SentencePiece tokenizer, meticulously trained in the unigram setting. The intrinsic tokenizer metrics, namely the split-ratio and unk-token fraction, were harnessed to strike a harmonious equilibrium between task performance and efficient resource

utilization. Additionally, the thoughtful incorporation of diverse Japanese characters ensured comprehensive language coverage. This astute evaluation approach is poised to elevate language comprehension within the domain of Virtual Assistants.

### C. Stage 1 and Stage 2 Pre-training Model

In the initial pre-training phase, we drew inspiration from established models like BERT, RoBERTa, and XLM-R to shape our approach. While our Virtual Assistant models found their foundation in RoBERTa, a distinct innovation emerged through the implementation of pre-layernorm architecture. This architectural adjustment involved placing layer normalization immediately before the self-attention and feed-forward blocks within each transformer layer. Central to this training process was the masked language modeling objective, where 15% of tokens within the text were masked. Among these masked tokens, 10% were maintained unchanged, while an additional 10% were substituted with random tokens. Our teacher models underwent training with a focus on scalability, culminating in the management of up to 9.3 billion non-embedding parameters. To enhance training throughput, the Deepspeed framework came into play, capitalizing on its two-stage strategy. In the first stage, optimizer states were distributed across GPUs, followed by gradient partitioning in the second stage. Notably, this was executed without introducing network-based bottlenecks. Employing mixed precision training was pivotal in optimizing computational efficiency. This technique enabled us to achieve an impressive computational output of 107 TFLOP/sec per GPU for an encoder housing 9.3 billion parameters. Our infrastructure was grounded in AWS p4d.24xlarge instances, housing Nvidia a100 GPUs and leveraging Elastic Fabric Adapters to ensure steadfast network throughput. Throughout the pretraining journey, Deepspeed's mixed precision training mechanism remained our companion. Nonetheless, some model operations encountered challenges related to FP16 overflow. To address these concerns, two key modifications were introduced. Firstly, the baddbmm operation took the place of the matmul operation for query-key multiplication. Secondly, a conversion to FP32 was performed before variance computation during the layer normalization process. These changes, while slightly decreasing throughput by up to 20%, successfully mitigated instability issues within the model. It's worth noting that an alternative avenue to handle stability concerns entails the utilization of BFLOAT16. However, this path wasn't available within the Deepspeed framework during our experimentation phase. Transitioning to Stage 2 pretraining, our exploration delved into the Muppet system. Unlike the initial phase, Stage 2 pretraining employed a more direct approach. We extended the pretraining objective using our designated Stage 2 dataset. The primary objective here was to enhance the model's proficiency in handling virtual assistant-specific utterances, which are often brief and may deviate from strict grammatical norms. A careful balance was sought between enhancing specialized capabilities and retaining the broader language knowledge gained during Stage 1.

### D. Distillation

Given the imperative of modest model sizes for low-latency applications, a direct distillation from extensively

large teacher models to considerably smaller student models might hinder the effective transfer of the teacher's expertise. As a remedy, a two-stage teacher assistance setup was devised for the distillation process, as illustrated in Fig. 1. This strategy aimed to strike a balance between knowledge transfer and model size reduction. In the initial stage, the immense teacher model was compressed into an intermediate-sized model. Subsequently, the final student model was trained using this intermediate model as a guide. This approach ensured that the transfer of knowledge from the teacher to the student was well-optimized, despite the significant size reduction. Drawing inspiration from the teacher's pretraining methodology, a distillation process was initiated from a randomly initialized student model. Convergence in training signaled a seamless transition to the deployment of the Stage 2 teacher model, thus continuing the distillation process. Importantly, the data employed for distillation in both stages remained consistent with the data utilized for teacher pretraining in their respective stages. Within the intermediate student/teacher pairing, a balanced blend of categorical cross-entropy (MLM loss) and soft cross-entropy was applied, with equal weighting. Remarkably, experimentation indicated no substantial benefits from incorporating the attention and hidden layer outputs of the teacher model. Transitioning to the final student model, a dual-stage process was undertaken. First, the intermediate model underwent further pretraining, exclusively using Stage 2 data and without teacher involvement. Subsequently, a distillation procedure was executed to seamlessly transfer knowledge to the compact final student model. During this distillation phase, techniques mirrored those employed in the initial distillation, with the addition of hidden-layer output matching. In essence, the approach mirrors the core principles of the process outlined in the source paper. The process ensures effective knowledge transfer while mitigating the challenges arising from substantial model size reductions.

### E. Validation of Model Performance without Fine-Tuning

In order to effectively monitor the progress of our training efforts, a commonly employed technique is evaluating perplexity on a separate validation dataset. However, a notable drawback of perplexity measurements is their susceptibility to the tokenizer's specific characteristics. To overcome this limitation, this study introduced an innovative evaluation metric called "mask-filling accuracy", designed to enhance the comparability of different models. The formulation of these metric involved curating texts from diverse public tasks, encompassing resources like XNLI, PAWS-X, and Multi-lingual Amazon Reviews. It is worth noting that we deliberately excluded these specific examples from our training dataset. For each instance within this curated dataset, we leveraged the Stanza tagger to identify a noun word. Subsequently, all subword tokens corresponding to that noun were concealed. The model's task was to accurately predict all subword tokens associated with the hidden noun, with successful predictions deemed correct. A notable insight, highlighted in Fig. 2 and 3, reveals a robust correlation

between perplexity measurements and mask-filling accuracy, as well as the model's performance on the XNLI benchmark. This correlation persists across various stages of model updates. This finding underscores the valuable potential of our mask-filling accuracy metric as a reliable indicator of model quality. Importantly, this metric transcends the challenges introduced by the nuances of different tokenization approaches. This novel approach to validating model performance without fine-tuning presents promising insights. It serves as an effective means of assessing the quality of models, bypassing the inherent limitations posed by tokenizer choices. This strategy, as outlined in the original paper, holds promise for similar applications in various contexts.

## V. RESULT AND ANALYSIS

Analysis of the performance and effectiveness of language understanding models within the realm of virtual assistant systems. Our exploration was underpinned by a meticulous evaluation process, which encompassed multiple stages and methodologies, ultimately yielding insightful results and findings. First, we investigated the relationship between XNLI accuracy and perplexity, as well as mask-filling accuracy, using the approach of a 2.3 billion parameter model. This analysis was crucial for understanding the interplay between these metrics and their correlation with model performance over various updates. Notably, we observed that the mask-filling accuracy exhibited a stronger correlation with XNLI accuracy during the no-fine-tune validation process, indicating its potential as a more informative gauge of model quality, less susceptible to the intricacies of tokenization choices. Moving forward, the approach focused on the evaluation of our distilled models in comparison to publicly available models, utilizing comprehensive training datasets specific to our system. Our assessment involved benchmarking against XLM-R Base with 85 million non-embedding parameters and the multilingual DistillBERT with 42 million non-embedding parameters. Notably, our distilled models consistently outperformed the public models in terms of exact match error rate. Most promisingly, our compact 17 million-parameter model demonstrated a remarkable 4.23% improvement over XLM-R, while retaining its performance margin over our larger 170 million-parameter model, showcasing an improvement of 4.82% over XLM-R. In the pursuit of holistic evaluation, we delved into the performance of our models within the full framework of a virtual assistant system. To accomplish this, an intermediate-sized model with 170 million non-embedding parameters acted as a teacher-assistant to distill the final student models. This compression journey involved multiple stages of distillation, leveraging diverse datasets and employing logit matching and hidden layer matching techniques. Our models underwent extensive testing via parallel A/B testing and sequential testing, simulating real-world scenarios. These evaluations encompassed automated measures of user dissatisfaction, particularly tail dissatisfaction, and the offline Semantic Error Rate (SemER) that evaluates intent and slot-filling performance.
Fig. 2.    XNLI accuracy from perplexity.

Fig. 3.    XNLI accuracy as of mask-filling accuracy.

Fig. 2 and Fig. 3 utilizing the approach of 2.3Bparameter model, the relationship between XNLI accuracy and perplexity, as well as mask-filling accuracy, are being studied over model updates. The measure performs better for no-fine-tune validation the higher the correlation.

### A. NLU Results following Distillation

Our evaluation involved comparing the performance of our distilled models against publicly available models, using the complete training datasets specific to our system, as detailed in Section 3.4. The considered public models encompass XLM-R Base, featuring 85M non-embedding parameters, and the multilingual DistillBERT, comprising 42M non-embedding parameters. For an example to be counted as an

exact match, the model must correctly predict both the intent and all associated slots. Encouragingly, both of our distilled models exhibit superior performance compared to the public models on average. Our 17M-parameter model, which shows an enhancement of 4.83% over XLM-R while showing only little decline when compared to our 170-M-parameter version (an increase of 4.63% over XLM-R), is particularly notable.

### B.  Full System Results

This research follows the design described in Section 2.6 to provide a thorough evaluation of the model's effectiveness within the context of a whole virtual assistant system. The teacher assistant for the distillation of the final student models is an intermediate-sized model with 170M non-embedding parameters. This intermediate model underwent many steps of compression, including 160K entries of distillation from a 700M-parameter first-phase teacher, 105K updates from the Phase 1 2.3B-parameter teacher, and 300K updates from the second Stage 2 2.3B-parameter model. Further details on hyperparameters for the 700M-parameter model can be found in Appendix A. The 170M-parameter model, post fine-tuning with a task-specific dataset for 15,625 updates, acted as the teacher for distilling 17M-parameter student models. Distillation employed logit matching and hidden layer matching, following the student-teacher layer mapping (0, 1, 2, and 3) to (3, 7, 11, 15). Optimal performance emerged from utilizing two checkpoints within the same 17M-parameter model distillation process: one after 80M examples and the other after 200M examples. This process involved the inclusion of 9 languages: English, French, German, Hindi, Italian, Marathi, Spanish, Tamil, and Telugu. Two baseline models, each constituting a 5M-parameter monolingual encoder distilled from a BERT-Base architecture teacher, were considered. These baselines employed Wikipedia dumps in the relevant languages, following the text conversion to spoken form. Our comprehensive study occurred within a virtual assistant system experimentation platform. Our models were subjected to both parallel A/B testing, involving distinct user cohorts, and sequential testing with the same user cohort. The assessment encompassed automated measures of user dissatisfaction across the entire virtual assistant system, alongside considerations for tail dissatisfaction (related to less common utterances). The offline Semantic Error Rate (SemER) evaluations were conducted, jointly evaluating intent and slot-filling performance. SemER considers correct slots, deletion errors, insertion errors, and substitution errors, along with intent classification errors. The methodology employed aligns with the foundational principles outlined in the original paper. Our approach showcases promising potential for effectively assessing model performance within the intricate landscape of virtual assistant systems.

$$SemER = \frac{\text{\# Deletion} + \text{\# Insertion} + \text{\# Substitution}}{\text{\# Correct} + \text{\# Deletion} + \text{\# Substitution}} \qquad (1)$$

The 2.3B-parameter Phase 2 model, the distilled 170-M-parameter Phase 2 model, and the 17-M-parameter Phase 2 model were assessed The results are shown in Tables III and IV, respectively. A negative number implies a lower error rate compared to the Stage 1 baseline model with 2.3B parameters.

TABLE III.    FULL FINE-TUNING

| Complete-fine-tuning | | | |
|---|---|---|---|
| Reduced Relative-Intent-Class-Error Versus 2.3-B Phase 1 | | | |
| | *Section 1* | *Section 2* | *Section 3* | *Average* |
| 2.3-B Phase -2 | -4.72% | -1.78% | -6.79% | -2.76% |
| 170-M from 2.3-B | -3.28% | -3.98% | -2.36% | -1.97% |
| 17-M from 170-M | 10.56% | 9.78% | 9.75% | 9.98% |
| Reduced Relative-Slot-Filling-Error Versus 2.3-B Stage 1 | | | |
| | *Section 1* | *Section 2* | *Section 3* | *Average* |
| 2.3-B Phase-2 | -6.02% | -10.05% | -6.68% | -8.01% |

| 17-M from 170-M | 12.99% | 7.49% | 11.89% | 11.78% |
| Improvement in Relative-Slot-Filling-Error Versus 2.3B Stage 1 | | | |
| | *Section* 1 | *Section* 2 | *Section* 3 | Average |
| 2.3-B Phase-2 | -5.56% | -18.98% | -5.79% | -9.31% |
| 170-M from 2.3-B | -6.17% | -11.93% | -2.90% | -6.99% |
| 17-M from 170-M | 18.46% | -6.90% | 2.90% | 5.01% |

TABLE V.    RESULTS FROM A PLATFORM FOR TESTING VIRTUAL ASSISTANTS

| | Experiment 1 | Experiment 2 |
|---|---|---|
| *Non-Embed Base Teacher Parameters* | 85-M | 85-M |
| *FF Size, Hidden Size, and Base Layers* | 4/312/1200 | 4/312/1200 |
| *Non-Embed Base Parameter Count* | 5-M | 5-M |
| *Support for Base Langs* | 1 | 1 |
| *Non-Embedded Parameters for Cand Teachers* | 2.3-B | 2.3-B |
| *Non-Embed Parameters for Cand Teachers* | 170-M | 170-M |
| *FF Size, Hidden Size, and Cand Layers* | 4/768/1200 | 4/768/1200 |
| *Non-Embed Cand Params* | 17-M | 17-M |
| *Cand Langs was backed* | 9 | 9 |
| *Cand Distil Illustrations* | 80-M | 200-M |
| *Testing Position* | 1 | 2 |
| *Entire Solution User Discontent A/B* | -3.74% | -4.91% |
| *Tail A/B for Entire Solution User discontent* | -10.3% | -7.50% |
| *Users' Overall discontent Score* | -14.9% | -7.2% |
| *Inactive SemER* | -15.6% | -2.98% |

In Table V, the findings presented are from two different experiments (Exp) carried out in distinct locations using a virtual assistant experimentation platform comparing our 17-M-parameter candidate model (Cand) is compared to the reference model (Base), which was developed by an 85-M-parameter teacher using Wikipedia data. Relative findings from an A/B test conducted concurrently with a distinct user cohort and an alternating test conducted using identical users are both shown for the computerized metric of whole-system user discontent. The tail A/B results from utterances beyond of the top 500 are also presented.

### C. Discussion

The presented findings and outcomes from the performance evaluation of language comprehension models in the context of virtual assistant systems represent a meticulous and thorough investigation of these models. In order to maximise the utility of these models for practical applications, this research emphasizes the complex nature of the fine-tuning and distillation processes [22]. The study started by exploring the connection between XNLI accuracy, perplexity, and mask-filling accuracy, offering insightful information about how these metrics relate to model performance across various updates [23]. Notably, the mask-filling accuracy showed strong model quality indicators, especially in the absence of fine-tuning, indicating its potential as a more accurate performance indicator that goes beyond tokenization intricacies. As the evaluation progressed, the emphasis shifted to evaluating the performance of the distilled models against publicly accessible models. The distilled models consistently outperformed public models in the assessment, especially in terms of exact match error rate, which took into account a variety of parameters, including non-embedding parameters. Particularly, the compact 17 million-parameter model showed striking improvements over reference models, demonstrating the possibility of developing more effective and efficient models in the context of virtual assistants. The research expanded its evaluation to take into account the overall performance of these models within the more general framework of a virtual assistant system, moving beyond model-centric assessments. This required using multiple datasets, logit matching, and hidden layer matching techniques in a multi-stage distillation process.

In order to simulate real-world situations and gauge user dissatisfaction, particularly for less frequent utterances, the evaluation included parallel A/B testing and sequential testing in addition to the offline Semantic Error Rate (SemER), which assesses intent and slot-filling performance [23]. The outcomes of these studies showed concrete advantages, with decreases in relative intent-class error and slot-filling error compared to baseline models, highlighting the efficiency of the distillation process in improving model performance within the complex environment of virtual assistant systems. User dissatisfaction scores significantly decreased for both the system as a whole and for less frequent utterances, highlighting the tangible enhancements in the user experience. This study offers a thorough and organized assessment of language comprehension models in the context of virtual assistant systems. The results point to a promising development in the development of virtual assistants and their

function in enhancing human-machine interactions: the approach of fine-tuning and distillation can result in more effective, accurate, and user-friendly models.

The full virtual assistant system analyses that, our analysis showcased the comprehensive assessment we conducted. An intermediate-sized model with 170 million non-embedding parameters served as a teacher-assistant, distilling final student models. Our multi-stage approach to distillation, which involved leveraging diverse datasets and employing logit matching and hidden layer matching techniques, showcased the effectiveness of knowledge transfer from teacher to student models [24]. These distilled models were extensively tested using both parallel A/B testing and sequential testing, simulating real-world scenarios. The evaluations encompassed measures of user dissatisfaction across the entire virtual assistant system, particularly focusing on less common utterances (tail dissatisfaction), as well as the Semantic Error Rate (SemER) that evaluates intent and slot-filling performance. The study provides a comprehensive and nuanced understanding of how distilled models perform within the intricate landscape of virtual assistant systems. By addressing challenges related to model size reduction, evaluating performance across various metrics, and testing in real-world usage scenarios, our findings contribute to advancing language understanding technology and optimizing virtual assistant systems for enhanced user experiences.

### D. Challenges and Limitation

A prominent field of research and development is integrating Natural Language Processing (NLP) into virtual assistants since it has the potential to significantly improve these systems' functionality. The current approaches to NLP in virtual assistants, however, have drawbacks and limitations, just like any other technology. Here are some of these difficulties and restrictions:

*1) Challenges:* Natural language presents a significant problem due to its inherent ambiguity and reliance on context. Virtual assistants frequently have trouble understanding the complexities of context, which causes them to misread user requests. This restriction may make it more difficult to have natural discussions and give accurate responses. Another issue is support for several languages [25]. Virtual assistants powered by NLP must be proficient in a variety of languages, each with its own distinctive quirks. For users who speak uncommon languages or participate in multilingual conversations, some may fare very well in one language but fall short in others. For a flawless user experience, real-time processing is necessary. Nevertheless, NLP processing can be computationally demanding, making it difficult to provide immediate or close to real-time solutions [26]. This lag time may irritate users and lessen virtual assistants' general efficacy. Additionally, the difficulty of generalisation looms big. Many virtual assistants struggle to infer knowledge from certain user interactions. Instead, they might rely too heavily on pre-programmed reactions, which would make it harder for them to adjust to different user needs and would lessen their overall value. For virtual assistant technology to advance,

these problems must be solved. The improvement of NLP models, contextual understanding, multilingual support, real-time processing, implementation of strong privacy safeguards, and creation of more generalised and adaptable virtual assistants should be the main areas of research and development. These initiatives will assist NLP be more successfully and conveniently incorporated into virtual assistant technologies.

*2) Limitations:* Virtual assistants' dearth of common-sense reasoning is a key drawback. Their inability to participate in truly natural conversations is hampered by their frequent inability to comprehend fundamental, daily concepts and situations. When customers expect their virtual assistants to understand basic, contextual questions, this shortcoming might result in unsatisfactory and fragmented interactions. Another difficulty is managing lengthy talks. During lengthy conversations, context can be lost by existing NLP models, leading to responses that do not fit the general direction of the discourse. When consumers converse with virtual assistants in-depth or complex topics, this shortcoming may become especially apparent. Misinformation vulnerability is a serious issue, particularly in industries like news or healthcare. If virtual assistants don't have the tools to check the veracity of the information they provide, they might unintentionally spread harmful information or make false claims [27].

Virtual assistants might also have knowledge gaps in specific fields. When asked questions about specialized topics or industries, NLP models might not have current or in-depth knowledge, which results in answers that are incorrect or lacking. This restriction may limit the usefulness of virtual assistants in work-related or contexts requiring in-depth knowledge. Creating and maintaining NLP-driven virtual assistants can be prohibitively expensive and resource-intensive [28]. This restriction may make it difficult for smaller organizations and underserved communities to access this technology, potentially resulting in a digital divide. Another difficulty is the complexity and expense of integrating NLP into current systems. Because of this complexity, it may be challenging for businesses and organizations to adopt these technologies without major time and resource commitments. Continuous research and development efforts are crucial to overcoming these constraints and difficulties. This entails enhancing the capacity for common-sense reasoning, boosting the capacity for lengthy conversations, putting in place fact-checking procedures to thwart false information, honing domain-specific knowledge, and reducing response bias [29].

## VI. Conclusion and Future Prospect

This research offers a comprehensive approach to enhancing language understanding models within the realm of virtual assistant systems. Through a carefully structured series of experiments and in-depth analyses, we have substantiated the effectiveness of distilled models in achieving remarkable performance levels while upholding model efficiency. A noteworthy aspect of our findings lies in the recognition of the pivotal role played by meticulous evaluation metrics,

particularly highlighting the superiority of metrics like mask-filling accuracy over conventional perplexity measurements. This innovation enhances the robustness and practical relevance of our evaluation methods in real-world applications. The results of our study also showcase the significant advantages of the distillation process. By carefully compressing large teacher models into intermediate-sized models, the successful transferred knowledge while overcoming challenges posed by model size reduction. Our distilled models consistently outperformed publicly available models, proving the efficacy of our approach in producing models that are not only more efficient but also more accurate in language understanding tasks. This has direct implications for the development of high-performing virtual assistant systems that can deliver prompt and accurate responses to user queries.

Looking forward to the research opens the door to exciting future prospects in the field of language understanding and virtual assistants. The success of our distillation process encourages further exploration into optimization techniques that can balance model size and performance. Additionally, the innovative evaluation metrics we introduced, such as mask-filling accuracy, offer new directions for evaluating model quality, which can be refined and extended in future studies. As virtual assistant systems continue to evolve, the insights from our research can guide the development of more efficient and effective models. The demonstrated techniques for distillation and evaluation provide a foundation for building even more advanced systems that can understand and respond to user input with increased accuracy and speed. As technology progresses, our work lays the groundwork for continuous improvements in virtual assistant capabilities, ultimately enhancing user experiences and interactions. The presented study contributes valuable knowledge to the field of language understanding in virtual assistant systems, offering practical solutions for optimizing model efficiency and performance. As the field continues to evolve, our research provides a strong stepping stone for future innovations that will shape the way virtual assistants understand and interact with users.

*Abstract*—With the advent of technology and use of latest devices, they produce voluminous data. Out of it, 80% of the data are unstructured and remaining 20% are structured and semi-structured. The produced data are in heterogeneous format and without following any standards. Among heterogeneous (structured, semi-structured and unstructured) data, textual data are nowadays used by industries for prediction and visualization of future challenges. Extracting useful information from it is really challenging for stakeholders due to lexical and semantic matching. Few studies have been solving this issue by using ontologies and semantic tools, but the main limitations of proposed work were the less coverage of multidimensional terms. To solve this problem, this study aims to produce a novel multidimensional reference model using linguistics categories for heterogeneous textual datasets. The categories in such context, semantic and syntactic clues are focused along with their score. The main contribution of MRM is that it checks each tokens with each term based on indexing of linguistic categories such as synonym, antonym, formal, lexical word order and co-occurrence. The experiments show that the percentage of MRM is better than the state-of-the-art single dimension reference model in terms of more coverage, linguistics categories and heterogeneous datasets.

*Keywords—Reference model; computational linguistics; heterogeneous data; context clues; semantic clues; syntactic clues*

## I. INTRODUCTION

"Big Data" refers to data sets with sizes beyond the ability of commonly used software tools to capture, curate, manage, and process data within a tolerable elapsed time. Various industries with heterogeneous data are facing problems related to storing, managing, retrieving, and analyzing of large amount of data. Big Data plays an important role in retrieving useful information from the large datasets with the help of advanced tools and algorithms [1]. Nowadays, data produced in formats such as structured, semi-structured and unstructured data from a multidimensional nature of resources and applications that cannot be processed through simple tools [2].

In general, Big Data can be explained according to three V's: Volume, Velocity and Variety [3]. Also, the other characteristics of Big Data described in [4] are volume, variety, velocity, veracity, valence, and value. Later on, in [5] 10V's

volume, variety, velocity, veracity, variability, viscosity, volatility, viability, validity, and value are exposed.

In Big Data Variety, the heterogeneous types of data formed, and it further classified in three types namely, Structured, Semistructured and Unstructured (SSU) [6], [7]. Structured data is organized data in a predefined format and stored in tabular form whereas semi-structured data is a form of data which cannot be queried as it does not have a proper structure which confers to any data model and unstructured data is heterogeneous and variable in nature such as text, audio, video, and images. Due to heterogeneous data, it cannot be processed with simple tools and techniques which create the problem heterogeneity and similarity matching [2] in result, decision maker cannot make decision based on scattered data.

With the advent of the technology, the computers are nowadays used to retrieve the linguistics information from textual data which is known as Computational Linguistics (CL) [8]-[9]. CL is classified into many categories but among them context clues, semantic, and syntactic [9]-[11] matching is widely used in the domain of linguistics. CL helps in identifying and matching of related words from input datasets with the data dictionary which is known as domain knowledge [12].

The domain knowledge further known as reference model (RM) have been used in the field of NLP and semantic-lexical matching. Vasilieous et al. in [13]–[15] proposed a single dimensional reference model (SRM) for medical data quality of textual dataset. The SRM only matches one token to one term at a time and it was developed for structured dataset whereas the same patient's data can be represented in other forms of terms. Also, in other formats (semi-structured or unstructured). Therefore, this paper proposes a multidimensional reference model (MRM) for one token to many terms matching and as well as for heterogeneous datasets.

The concept of multidimensional reference was adopted from [16]-[17], in which different schemas for one to one and one to many queries for NoSQL Injection were proposed as well in [20]-[21]

The aim of this study is to solve the requestion question i.e. How to build a context, semantic and syntactic based reference model for more data inclusivity? Which can be achieved through this research objective i.e., to develop a multidimensional reference model (MRM) based on context, semantic and syntactic bag of words for a better data inclusivity. The significance of this research is to measure the inclusivity of Semantic, context and syntactic words in MRM.

For further understanding about multidimensional reference model for heterogeneous textual datasets this paper is organized as follows: Section II and III describe the related work and methodology adopted for creating the MRM and experiments conducted on heterogeneous datasets, Section IV presents the results for heterogeneous datasets while Section V discusses the results and Section VI and Section VII presents the conclusion and future work respectively.

## II. RELATED WORK

Ordinarily, the reference model works as a procedure that contains the domain knowledge and relevant indexing of a topic or information of interest. It works as a common template for structured data that contains a set of parameters which are important for generating the domain knowledge [14].

The proposed multidimensional reference model as shown in Fig. 8. It comes with extra features to handle heterogenous datasets. It uses a generalized natural language concept and domain knowledge which helps the input datasets in selection of appropriate multidimensional domain data. Multidimensional indexing is also an added technique which classifies linguistic words into context, semantics, and syntactic clues.

These three categories aim to assist in building the vocabulary and understanding the domain knowledge with respect to meaning, structure and representation of words as opposed to the existing reference models where the selection of terms is solely based on one-to-one relationship (see Fig. 1).

Fig. 1. Existing reference model method.

It can be observed from Fig. 1 that the relationship is one-to-one. Meaning, for any given token, a corresponding match term is retrieved from the reference model. This selection is based on threshold values to identify the best matching term in the corpus. The term with the highest value is selected as a candidate for data curation.

On the contrary, the proposed multidimensional reference model utilizes a multifaceted concept as depicted in Fig. 2 below. Basically, the MRM checks the relationship between the token and its related term in multiple dimensions in order to identify the most appropriate term as shown in Fig. 2 and Fig. 8 (Appendix A)

Fig. 2. Proposed multidimensional reference model core concept.

As illustrated in Fig. 8 (Appendix A), we can see that a token from the input dataset is matched with its potential related term in several dimensions such as synonym [18], semantic, lexical [19], etc. For instance, a token "bank" could score high when matched with a term "boundary", which means the edge of a river. However, if the lexical matching of same word is conducted, a financial institution, or storage may be flagged off. Therefore, it's very important to view one token in different dimensions. This will significantly increase the accuracy of terms matching at different levels of data harmonization.

The categories mentioned in MRM are context clue, semantic and syntactic. Context clues are further classified into synonym and antonym. Sample words and their score are presented in Appendix C and D. The second and most important category used in MRM for indexing the linguistics words is semantics. It plays a vital and significant role in understanding the information related to datasets.

As mentioned earlier, the first type of semantic clue is formal semantics which uses techniques such as logic, philosophy, and math to analyze data within the relationship of language and reality, truth, and possibility. The list of words and their score can be found in Appendix E and F.

The third and last category of MRM is syntactic clue which focuses on the word order and co-occurrences. In order to identify patterns amongst data points (words), the order and co-occurrences are adopted and implemented. The list of words for both the order and co-occurrences is offered in Appendix G and H.

It's important to highlight here clearly that the categories of MRM such as contextual, semantic, and syntactic clues and their score (as shown in Appendix C-H) helped in developing the multidimensional (indexed based) reference model. The MRM provides the input to the section that performs the data harmonization process. The section contains terminology extraction, rules definition, lexical matching and semantic matching which are responsible for producing data harmonization report and harmonized dataset.

## III. METHODOLOGY

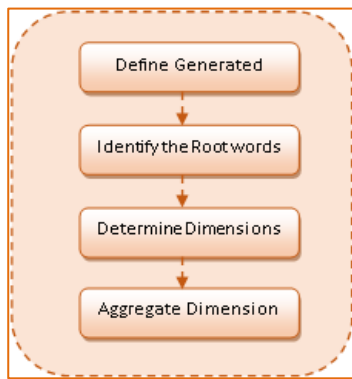
For development of multidimensional reference model, following four steps have been taken (i) defining the generated tokens (ii) identifying the root word (iii) Determining the dimensions (iv) aggregating the dimensions root word. These steps are also shown in the Fig. 3.


Fig. 3.    Steps carried out for MRM development.

Among five datasets, the ACE2020 dataset is XLS (structured) format which contains the information about labeled text news produced and recorded at different news agencies. The dataset comprises of 621 news of different categories. Whereas Aquaint dataset is in TXT (Unstructured) format which contains 50 different news produced in diverse nature and rich in information. This dataset comprises of 729 lines. On the other hand, Sarcasm headline dataset is JSON (semi-structured) format which also contains the information about the news headline. This dataset comprises of 26709 lines. All datasets are purchased by LDC organization for research purpose.

In step one, the tokens are generated from heterogeneous datasets. The input datasets contain news of the daily life including sarcasm (keys and values). Participating datasets are in structured (Xls), semi-structured (JSON) and unstructured (Txt). After preprocessing the input datasets, structured dataset is formed which have been used for token generation.

In second step the root words are identified based on the generated tokens. In the third and fourth steps the determining the dimensions and aggregating them into categories of root words are formed. As stated above, the indexing scheme of dimension follows the concept of one-to-one and one-to-many cardinalities from SQL.

For implementation of MRM, research was carried out on the MMR development stages (see Fig. 3.). The experiment aimed to assess the performance of MRM. A single workstation was used for the experiments. It housed the following specifications: GPU: NVIDIA Tesla P100 12GB Passive GPU, CPU: Intel Xeon E5-2620 v4 2.1GHz, 32 cores, 128GB RAM, 800GB SSD, 1GB bandwidth ethernet card, and windows operating system. Textual datasets with numerous characteristics and sizes of 75KB, 150KB, and 10MB are employed. For performance evaluation, Anaconda and Python 3.7.3 are installed on the workstation along with Jupyter notebook, pandas, NumPy, matplotlib, and orange3 libraries.

Based on the root words and dimensions of MRM, the most common words using the linguistics words categories are retrieved and named as mrm_words. It contains the mrm_score() which will help in DH.

Validations of results (MRM with SRM) are discussed in following section.

## IV.  RESULTS

The proposed Multidimensional Reference Model (MRM) was developed using linguistic word categories i.e., context, semantic and syntactic clues. The main aim of developing MRM is to improve the quality of terms-matching by referring to the target terms in different dimension. This is achieved with the help of indexed based domain knowledge to root-words/tokens. Indexing is generated and classified using synonyms, antonyms, lexical semantics, formal semantics, word-order, and co-occurrence.

Each word has its respective score (mrm_score()) that is empirically assigned which helps in matching terms based on defined rules, semantic, and lexical matching. The total number of words generated from linguistic word categories (i.e., context, semantic and syntactic clues) for MRM repository is 37321.

The performance of proposed MRM with existing single dimensional reference model (SRM) is compared and presented in this section. Five different heterogeneous datasets namely, ACE 2020, Aquaint, Sarcasm, HUA, and UoA are implemented on both SRM and MRM in order to obtain a justifiable conclusion on which reference model is actually better. It's important to mention here that SRM was implemented in a similar comparison on two out of the five aforementioned datasets (i.e., HUA and UoA). This indicates that our comparison is more rigorous in nature as it covers all data structures (heterogenous, to be precise).

The experiment was conducted five times (Batch 1-5) for each dataset. Batch 1 utilizes 20% of each dataset, and continuously increases 20% for the subsequent batches until 100% of each dataset is tested. This is done for both MRM and SRM to evaluate their individual performances. The batches and their respective data distributions are explained in Error! Reference source not found. The Table I (Appendix B) shows the results of the experiments conducted on MRM which presents total terms of input datasets, total matched terms with MRM and percentage of matched terms.

In order to evaluate the performance of best reference models on participating datasets, the experiments are conducted on five different batches of datasets as presented in (Appendix B). The two collaborating reference models are tested five different times for each variable. After that an average of scores for five round is taken and compared, the results of each round are presented separately. Figure Error! No text of specified style in document.1 illustrates the results of round one in which a comparison between the MRM and SRM for total terms and matched terms are discussed.

Fig. 4 depicts a significant result of the round 1 for all participating datasets using SRM and MRM. On left of the figure, the results of existing SRM and on the right the results of proposed MRM are shown. The first set of analysis begins with performance of SRM on participating datasets. Initially, 2564 terms of ACE2020 were tested on SRM, out of which 1212 were matched successfully. Secondly, 2192 terms of Aquaint dataset were examined, out of which only 551were matched. Similarly, 5740 terms of Sarcasm dataset were tested out of which merely 1198 were matched. Subsequently, 16

terms of UoA dataset were examined on SRM, out of which 15 were matched. Lastly, the 12 terms for HUA were tested and out of which 11 were matched. The results show a variation in matching of terms with the use of SRM, but it performed well on the UoA and HUA datasets.

Fig. 4.    Number of succesfully matched terms for MRM and SRm on batch 1.

On the other hand of analysis, the input datasets are used to test the performance of MRM. At first, 2564 terms of ACE2020 were tested on MRM, out of  which 2080 were matched magnificently. Subsequently, 2192 terms of Aquaint dataset were examined, out of which only 1678 were matched well. Similarly, 5740 terms of Sarcasm dataset were tested out of which 4568 were matched perfectly. Afterwards, 16 terms of UoA dataset were examined on MRM, out of which 11 were matched. Last of all, the 12 terms for HUA were tested and out of which seven were matched.

| | ACE | Aqua int | Sarca sm | UoA | HUA |
|---|---|---|---|---|---|
| SRM | 47.27 | 25.14 | 20.87 | 93.75 | 91.67 |
| MRM | 81.12 | 76.55 | 79.58 | 68.75 | 58.33 |
Fig. 5.    Percentage of matched terms for MRM and SRM on batch 1.

The performance findings from this round suggest that the MRM performed better than SRM on ACE 2020, Aquaint and Sarcasm datasets whereas the SRM works better on HUA and

UoA datasets. Fig. 5 illustrates the terms matched (in terms of matched percentage) with both reference models on participating datasets.

The percentage of matched terms using SRM for ACE2020, Aquaint, Sarcasm, UoA and HUA are 47%, 25%, 20%, 93% and 91%, respectively. Whereas the percentage of matched terms using MRM for ACE2020, Aquaint, Sarcasm, UoA and HUA are 81%, 76%, 79%, 68% and 58%, respectively. This is because the proposed MRM covers multiple dimensions such as context, semantic and syntactic clues. One of the significant contributions of MRM is that it checks each participating word/token from input dataset with index based domain knowledge.

With that, the input tokens are checked multiple times and based on the context and similarity score of the index it produces very similar words. It is worth  noting that if any of the tokens' score is high based on the similarity, but the score is less in terms of context than the terms which matched based on the context are selected. Whereas the existing SRM only checks the similarity based on string and lexical similarity and only in single dimension.

Comparative analysis on the results of SRM and MRM shows that the performance of MRM is better than the SRM on ACE 2020, Aquaint and Sarcasm datasets while the SRM performs better on HUA and UoA datasets. The results of MRM on UoA and HUA datasets are low which is due to different domain knowledge (medical) of the datasets. In Fig. 6, the performance of SRM and MRM are measured for batch 5 on contributing datasets. The remaining batches (2-4) are not presented here but the average of all five batches is presented in Table I. (Appendix B).

A significant result of the round five for all participating datasets using SRM and MRM. On left of the figure, the results of existing SRM and on the right the results of proposed MRM are shown. The first set of analysis begins with performance of SRM on participating datasets. Initially, 12820, terms of ACE2020 were tested on SRM, out of  which 5605 were matched successfully. Secondly, 10960 terms of Aquaint dataset were examined, out of which only 2405 were matched. Similarly, 28700 terms of Sarcasm dataset were tested out of which merely 4701 were matched. Subsequently, 82 terms of UoA dataset were examined on SRM, out of which 70 were matched. Lastly, the 60 terms for HUA were tested and out of which 50 were matched. The results show variations in matching of terms with the use of SRM, but it performed well on the UoA and HUA datasets.

On the other hand of analysis, the input datasets are used to test the performance of MRM. At first, 12820 terms of ACE2020 were tested on MRM, out of which 9125 were matched magnificently. Subsequently, 10960 terms of Aquaint dataset were examined, out of which only 7865 matched well. Similarly, 28700 terms of Sarcasm dataset were tested out of which 19998 were matched perfectly. Afterwards, 82 terms of UoA dataset were examined on SRM, out of which 50 were matched. Last of all, the 60 terms for HUA were tested and out of which 31 were matched.
Fig. 6. Number of succesfully matched terms for MRM and SRM on batch 5.

For validation of performance, the SRM and MRM results are presented here. The comparison of performances (in terms of percentage) is depicted in Fig. 6.

| | ACE | Aquaint | Sarcasm | UoA | HUA |
|---|---|---|---|---|---|
| SRM | 43.72 | 21.94 | 16.38 | 85.37 | 83.33 |
| MRM | 71.18 | 71.76 | 69.68 | 60.98 | 51.67 |
Fig. 7. Percentage of matched terms for MRM and SRM on batch 5.

The performance findings from this round suggest that the MRM performed better than SRM on ACE 2020, Aquaint and Sarcasm datasets whereas the SRM works better on HUA and UoA datasets.

Fig. 7 illustrates the terms matched (in terms of matched percentage) with both reference models on participating datasets. The percentage of matched terms using SRM for ACE2020, Aquaint, Sarcasm, UoA and HUA are 44%, 22%, 17%, 85% and 83%, respectively. Whereas percentage of matched terms using MRM for ACE2020, Aquaint, Sarcasm, UoA and HUA are 71%, 72%, 70%, 61% and 52%, respectively. This is because the proposed MRM covers multiple dimensions such as context, semantic and syntactic clues.

One of the significant contributions of MRM is that it checks each participating word/token from input dataset in domain knowledge by adopting the functionality of indexing. With that, the input tokens are checked multiple times and based on the context and similarity score of the index. It's worth noting that if any of the tokens' score is high based on the similarity but the score is less in terms of context then the terms which matched based on the context are selected. Whereas the existing SRM only checks the similarity based on string similarity and only in single dimension.

Comparative analysis on the results of SRM and MRM shows that the performance of MRM is better than the SRM on ACE 20202, Aquaint and Sarcasm datasets while the SRM performs better on HUA and UoA datasets. The results of MRM on UoA and HUA datasets are low which is due to different domain knowledge (medical) of the datasets.

## V. DISCUSSION

The multidimensional reference model has been developed for the domain knowledge. MRM helped in expanding the domain knowledge using the linguistics word categories such as lexical, semantic, and syntactic. In this research MRM was tested in multiple rounds (1-5 batches) on heterogeneous datasets from diverse domain. It enhanced the coverage of words and helped in term harmonization. The MR contains the 37321 words as a rich template in form of domain knowledge /data dictionary. List of words from lexical, semantic, and syntactic clues containing mrm-score() have been formed.

Evaluation of MRM on different datasets is performed using similarity score (in percentage). If similarity score is high, it means the more root words are matched with input words. From all the experiments it shows the proposed work is more scalable and it includes more similar words on basis on mrm_score(). With that, it has been observed that the matched terms for the ACE2020, Aquaint, Sarcasm have been covered more than that of UoA and HUA datasets. This is due to the fact that the ACE2020, Aquaint, Sarcasm covers daily life routine whereas the UoA and HUA contain data of medical domain.

## VI. CONCLUSION

During the literature review and aiming to find solutions to solve the data heterogeneity, it was found that the only possible solution to solve the problem is to harmonize data. By adopting many techniques such as semantic, lexical matching and reference matching template. Based on that, a reference model which was developed by [14] for data curation framework for medical cohort taken as baseline study. In that, the reference model (SRM) contains the domain knowledge of specific terms that were used in medical domain. The performance of MRM has been evaluated on five heterogeneous (structured, semi-structured and unstructured) datasets and in five multiple rounds. The results of each rounds of ACE20220, Aquaint, Sarcasm, UoA and HUA show better performance of MRM over its counterpart reference model i.e., Single dimensional reference model. The overall performance of MRM on all participating datasets is more than 30% on ACE2020, Aquaint, and Sarcasm datasets whereas the performance of UoA and HUA performed better on SRM. To

conclude with the performance of MRM, it has been observed that the use of MRM supports the DHF in selection of key terms based on semantic and lexical matched terms. Design and development of Multidimensional Reference Model which is developed based on the linguistics categories such as context, semantic and syntactic clues. The model enables the use of indexing for any English sentences by introducing the words and their respective score. The proposed MRM produced huge number of words that can be used as a reference for any general domain which contains daily basis data generated in textual formats.

## FUTURE RECOMMENDATIONS

Use of other categories of linguistics and computational linguistics for further improvement in the field of English grammar.

# Application of Lightweight Deep Learning Model in Landscape Architecture Planning and Design

Linyu Zhang

Department of Arts
AnYang University
Anyang 455000, China

*Abstract*—The holistic view of garden construction is firstly reflected in the integration of the elements that make up the garden, and the primary and secondary are distinguished from the perspective of the whole city, the continuation of the upper planning, the coordination with the surrounding groups and the harmony of the internal gardening elements. The primary goal of ANN (artificial neural network) learning is to understand the drawings and to convert information such as plant numbers and positions in digital drawings into standard digital formats for storage. In front of the SSD (Single Shot Multi-box Dettor) network model, a standard architecture network for image classification is adopted, called the basic network and is fused for comprehensive detection. This paper proposes the network model flow of the 3D object voxel modeling method based on the lightweight DL (Deep learning) model. The cyclic 2D encoder, cyclic 3D decoder and view planner are integrated into a unified framework responsible for feature extraction and fusion, feature decoding and view planning. The results show that the pixel accuracy, the average accuracy and the average IU value are the highest, with the pixel accuracy as high as 90.44%, the average accuracy as high as 93.15%, and the average IU value as 92.72%. In landscape image processing, it provides a certain foundation for future landscape planning and design.

*Keywords—Deep learning; landscape architecture; landscape element; neural network; artificial neural network; view planning*

## I. INTRODUCTION

Traditional landscape architecture planning and design methods mainly rely on designers' accumulated and improved experience. For large-scale landscape planning applications, designers must have solid design theory, professional design skills and extensive artistic accomplishment [1]. Scale and pattern process is called two core issues of landscape ecology [2], and scale effect is the core of three major issues in scale grade research: scale effect, scale selection and scale deduction. In today's era of globalization, although economy, culture and customs learn from each other in mutual communication, the different civilisations hidden behind them cannot be converged. The discipline of landscape architecture is developing daily, and the industry is in a rapid development stage, bringing unprecedented opportunities and prosperity to landscape architects. With the development of the social economy and the improvement of people's spiritual level, more attention has been paid to environmental quality. Modern landscape architecture is a "scientific art", which cannot be separated from art, but also from the support of science. Therefore, the discipline of landscape architecture needs to

form its own methodology and theoretical system and become a rigorous and mature discipline.

Landscape planning and design is a highly comprehensive design art that involves the planning and layout of multiple elements such as terrain, plants, water bodies, buildings, etc. In traditional garden planning and design, designers usually rely on experience and personal aesthetics to design. However, this approach often lacks precise data support and scientific decision-making basis, which can easily lead to low design efficiency or not meeting practical needs. The emergence of deep learning models provides new solutions for landscape planning and design. Through deep learning technology which can learn and analyze a large amount of historical garden design data, in order to uncover the laws and features hidden behind the design. These laws and characteristics can be used to optimize the design process, improve design efficiency, and enhance the scientificity and feasibility of design schemes. The application scenarios of deep learning models in landscape planning and design are very extensive. For example, digital terrain simulation is an important part of landscape planning and design, involving multiple steps such as terrain measurement, analysis, and modeling. By utilizing deep learning technology, it can quickly and accurately identify and analyze terrain data, providing designers with reliable terrain data support.

At present, with the development of China's landscape architecture industry, many excellent landscape architecture planning and design concepts have emerged, and they are committed to creating modern landscape architecture with Chinese characteristics based on local conditions—research on shape and space generation is controlled by focusing parameters. Systematic parametric design research has not been carried out according to the characteristics of landscape architecture planning and design; not only the practice of parametric landscape architecture design is rare, but also the research on the theory and method of parametric design of landscape architecture itself is even less. Aiming at the current industry situation, this paper mainly explores the application of the lightweight DL model in landscape architecture planning and design. It summarizes its reference and guiding significance for modern landscape architecture planning and layout to enrich and develop the theory and practice of modern landscape architecture planning and design in China to guide the future landscape architecture planning and design practice. Scientific intervention, adjustment, planning and design of landscape environment through parametric method are an

important development direction and research difficulty of modern landscape architecture planning and design. This article proposes a network modeling process for a three-dimensional voxel modeling method. Integrating the graphic planning of the encoder, the pixel accuracy is improved during the feature extraction process. The innovative points of the method adopted in this article are:

*1)* Lightweight DL models have lower model complexity and computational complexity, enabling fast training and inference under limited computing resources and memory constraints, making 3D object voxel modeling more efficient and real-time.

*2)* Lightweight DL models can improve the accuracy and detail representation ability of 3D object voxel modeling through network structure and algorithm optimization, thereby better reflecting actual 3D scenes and objects.

*3)* Lightweight DL models have a small model volume and parameter quantity, which can be deployed and run on various devices, facilitating model updates and upgrades, thereby supporting the diversity and scalability of 3D object voxel modeling.

## II. Literature Review

Since the 1950s, the destruction of the natural environment caused by industrialization has become increasingly serious, and people have begun to attach importance to the role of natural ecological elements in planning. Various ecological planning schools, led by landscape suitability evaluation methods, have successfully proposed a series of planning strategies to coordinate natural and human elements [3], [4]. Thorne et al. put forward the suitability evaluation method, the core of which is to synthesize and screen all kinds of environmental factors and socio-economic factors in time order to solve practical planning problems [5]. Economic elements are integrated and screened to solve practical planning problems, so it is also called "a thousand-layer cake" figuratively. Parris et al. store all kinds of landscape elements on the map in the form of raster data or vector data and give them specific structures and attributes. This change in the storage mode of map information makes the amount of information in a map much larger than the traditional map [6]. Ankita et al. used Arcview GIS and visualization software to create three-dimensional effects for environmental assessment. If landscape architects can accept such a technology, it will be fundamentally incorporated into the design process and can positively influence the social impact of design [7]. Shuvo et al. segmented the image by the color of the flowers, extracted the features based on texture analysis, and finally combined it with SVM (support vector machine) and other methods to realize the classification and recognition of flowers [8]. DL (Deep learning) is very important in computer vision. With the continuous progress of its technology, its application in the classification and recognition of flower images has greatly improved the effect of classification and recognition [9]. Wei et al. adopted the CNN model of the Keras DL framework and trained the Oxford flower data set to greatly improve the accuracy of flower species identification [10]. Qiang et al. combined the self-coding network structure with the

classification network and, through the post-processing of graphic synthesis technology, input a single-view picture and output the predicted and synthesized three-dimensional model [11]; Li et al. put forward a three-dimensional RNN (Recurrent Neural Network). By building a three-dimensional RNN, pictures taken from multiple perspectives are received, and the network's hidden layer is used to implicitly represent the geometric structure of the current reconstruction, thus establishing a DL three-dimensional reconstruction framework combining single and multiple perspectives [12]. Wang et al. obtained better simulation results than multi-dimensional time series by adopting the fluctuating time series simulation method. Fluctuating time series is a method of making the series conform to Fourier series by using difference, and usually monotonous data can be changed into fluctuating type by contrast [13].

## III. Research Method

### A. General Principles of Landscape Design

The holistic view of garden construction is firstly reflected in the integration of the elements that make up the garden, and the primary and secondary are distinguished from the perspective of the whole city, the continuation of the upper planning, the coordination with the surrounding groups and the harmony of the internal gardening elements. By protecting the natural and cultural landscapes in the site, it can pay attention to the spirit of the site, respect each specific area and strive to create its complementary design and interpret the traditional spirit with modern techniques to achieve the unity of natural harmony with the site itself [14], [15]. Planning and symbolically creating different landscape forms (people and designers transfer their landscape views to space, city and landscape), bringing about spiritual changes.

The technical evolution of the superposition method expands its operation mode and technical purpose. In other words, today's overlay method is no longer limited to a specific technical means or operation process but a set of tools oriented by cascading thinking, which includes a series of techniques. General maps tend to show as much information as possible in one map, while thematic maps focus on expressing one or several elements. This feature of the thematic map makes the main information to be expressed emphasized, while the secondary data is weakened as much as possible.

The thematic map is no longer limited to the traditional division of physical and geographical elements but is replaced by the distribution of various diseases in the study area, and the degree of incidence is expressed by color depth. It should be noted that the superposition between thematic maps of factors or elements is not necessarily the superposition of all drawings. Still, the superposition is carried out selectively according to the research needs. From this, it can summarize the general operation steps of the overlay method as shown in Fig. 1:

The main difference between the application of the superposition method in the above three cases lies in the theoretical basis followed by users and the final results of the superposition method. The theoretical basis determines the classification of landscape elements and the splitting method of their corresponding factors. At the same time, the final result of

overlapping images depends on the goal orientation of landscape architecture planning and design itself. Therefore, the final superposition should draw thematic maps of various diseases, population density maps and environmental maps of health and diseases and also superimpose these maps again to explore the relationship between the elements.

Fig. 1. General operation steps of the superposition method.

According to the connotation of the mechanism, it need to grasp it from two aspects: First, the system, that is, something is a system composed of multiple parts, and each piece is related, which is also the premise of the existence of the mechanism; The second is the operation mode, that is, the specific action mode of the mechanism to coordinate the relationship between various parts of things. Design mechanism, like the "invisible hand" directing the design, guides design behavior and generates design results. As the same research on scientific design methods, compared with design patterns, design mechanism pays more attention to the explanation of action mechanism, the grasp of laws and the exploration of design essence, which is more flexible and instructive. In addition, the design mechanism can be transformed into corresponding design patterns according to different juice designs, which is more suitable and practical.

The core of ancient Chinese culture is local culture, and the countryside is a world close to nature and with disputes over rights, which have always been yearned for by scholars. The essence it pursues is a kind of life close to nature. In the eyes of Western scholars, geography is to explain "the relationship between man and earth". The interaction between human beings and landscape, social and personnel variation will also cause natural changes. Although mixed with some metaphysical colors, its essence reflects the theory of base selection and site planning and design of residential environments such as houses, villages and towns in China. People plan for experience. First of all, it is a clear purpose or experience, and secondly, it is a conscious design with the form and space quality to achieve the project's space effect or create according to the goal set by the task book. Only through the best experience and expressing functions can the most optimized planning experience be produced.

### B. Plant Configuration in Landscape Planning and Design

The analysis and prediction of regional socio-economic status and development trend of planning is the starting point and important basis for planning. In the early stage of planning, it should focus on analyzing the current situation of social and economic structure in the planning area and its dynamic change law, and analyze the impact of social and economic system environment on land use to provide a real and reliable social and economic background for the formulation and implementation of the planning scheme. Through comprehensive balance and full coordination, the planning scheme can reasonably determine the scale and spatial layout of agricultural land, construction land, ecological protection areas, land development and consolidation, and key construction projects. It can reasonably determine the main control indicators such as cultivated land quantity, cultivated land occupied by construction, basic farmland protection area, land development and consolidation area, and the scale of construction land in major cities and towns.

People's cognitive activities begin with feelings. It reflects the objective things, the sensory perceiver touches through the sensory organs. It takes the objective things as the source, the subjective interpretation as the way and result, and the subjective image of the objective things in the mind. People's environmental identification aims to gain a foothold of complete mastery of thinking. If the system needs clarification, a familiar and comfortable environment with a clear and clear orientation system will give people affinity. In contrast, an unfamiliar, monotonous environment with an unclear orientation system will make people feel lost.

The spatial scale effect is a phenomenon that ecological objects show different characteristics and meanings with the change of spatial scale. The spatial dimension of scale can be changed by granularity and amplitude [16]. Time granularity refers to the frequency of object occurrence or the time interval of its dynamic change; Time range refers to the duration of an object in time. The time scale effect is a phenomenon in which ecological objects show different characteristics and meanings with the time scale change. When studying other objects, it should choose the appropriate time scale. Generally speaking, the high level of a nested system is composed of low levels, and the relationship between two adjacent levels is completely contained and completely contained [17], [18].

Taking plant configuration as an example, the primary goal of ANN (artificial neural network) learning is to understand the drawings. This understanding is not to identify what plants are in the drawings like people in the conventional sense or why they are matched like this, but to convert information such as plant numbers and positions in digital drawings into standard digital formats for storage. Many factors will influence the design process of plant configuration, and there are a lot of uncertain nonlinear conditions in the process, so there is a diversity of design results towards the target under specific conditions, similar to the non-convexity of ANN.

The neuron is the basic component and processing unit of the neural network. The structure of the artificial neuron model mainly includes the following three elements: group input and the intensity of input signal is expressed by the weight of each input neuron. The summing unit is used for weighting and summing all input signals. The activation function limits the output value of neurons in a certain range [19].

The $\theta_k$ threshold (or offset $b_k = \theta_k$ ) is expressed mathematically as follows:

$$v_k = \sum_{j=1}^{p} w_{kj} x_j \quad (1)$$

$$\mu_k = v_k + \theta_k \quad (2)$$

$$y_k = \phi(\mu_k) \quad (3)$$

$x_1, x_2, \cdots, w_{k1}, w_{k2}, \cdots, w_{kp}$ is the weight of the neuron, the activation function is $\phi(\cdot)$, and is the output of the $k$th neuron.

BP is the most commonly used ANN model in time series prediction, which is essentially a static network model. The input samples are random, and there is no correlation trend. From a mathematical point of view, the neural network is a nonlinear function. A time series $\{X_n\}$, which can be predicted by the following formula:

$$X_{n+k} = f(X_n, X_{n-1}, \cdots, X_1) \quad (4)$$

The static network is used to fit the function $f$, and then the future value is predicted. This is the basic idea of a neural network for time series prediction.

When the actual design work is carried out, it is necessary to consider the functional requirements put forward by the owner or the government, which requires the system to have certain control and guidance on the design results. Therefore, when constructing the network model, it is necessary to set the result-oriented control ability and the bottom-up generation logic. At the same time, it can adjust the threshold and incentive function of input data and influencing parameters. Fig. 2 shows the model structure of the self-generated system.

Assuming that the garden environment is $W$, the boundary is, and all polygon obstacle areas in the area are $Q_i$, then:

$$W = \{WSB, Q_1, Q_2, \cdots, Q_m\} \quad (5)$$

Where is the number of polygon obstacle areas?

SVD (Singular value decomposition) is an algorithm that can be applied to any matrix decomposition. For example, assuming that the input data of the full connection layer is $u \times v$ in size and the weight matrix is $W$, the calculation formula of the output data of the full connection layer is:

$$y = Wx \quad (6)$$

Its computational complexity is $u, v$. It $W$ is subjected to SVD and $W$ is approximately replaced by the first important eigenvalues after decomposition; the decomposition formula is:

$$W = U \sum V^T \approx U \sum_t V^T \quad (7)$$

$U$ represents an orthogonal matrix of dimension. Represents a diagonal matrix corresponding to the first values in the original diagonal matrix with dimension $t \times t$. It represents an orthogonal matrix of dimension.

Neural networks and traditional regression analysis are similar; both try to find the best fit for the function by minimizing the model's error. The fitting error of its model is given by Formula (8):

$$E = Y - f(X) \quad (8)$$

Because the value of the deviation term is always 1, its weight has the same function as the constant term in the regression model. Similarly, the network with HL (hidden layer) is similar to the nonlinear regression model, and for one HL, it is given by the following formula:

$$y = G\left(\sum_{j=1}^{k} \beta_j G\left(\sum_{i=1}^{m} \gamma_{ji} x_i\right)\right) \equiv f(x, \phi) \quad (9)$$

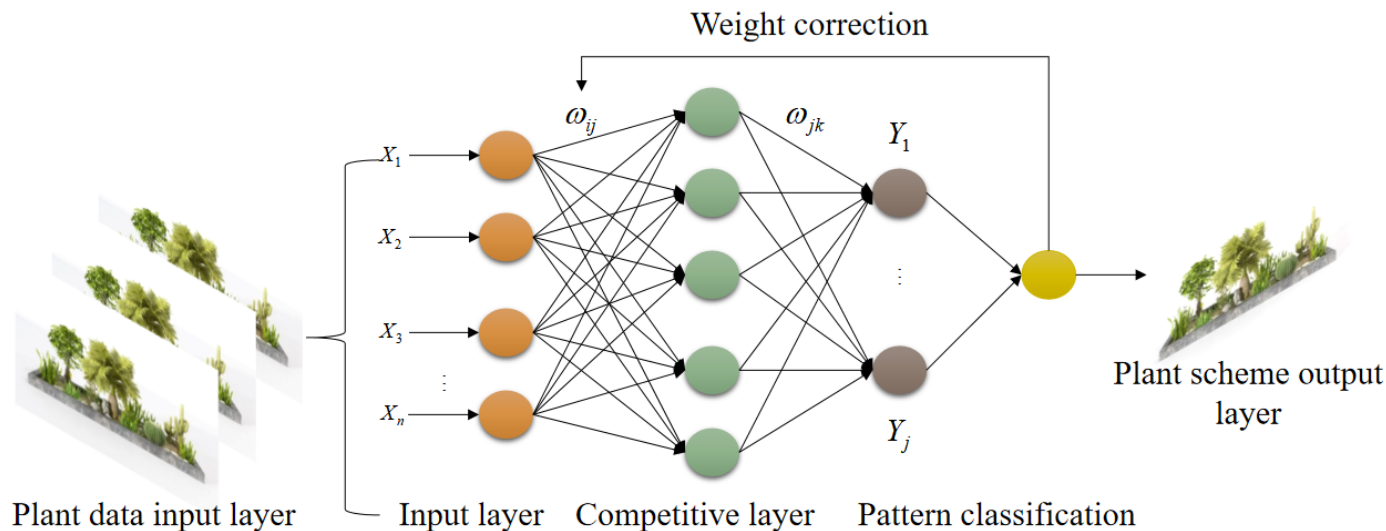

Fig. 2. Self-generated system model structure.

$G$ is the transformation function of HL and output layer in the neural network; $h$ is the number of HL neurons; $m$ is the number of input units; $\beta_j$ is the weight between output neurons and HL neurons, and is the weight between HL neurons and input neurons; $\varphi$ is all the relevant weights in the network, $x_i$ is the input value, and is the output value.

## C. Voxel Modeling Method of a Three-Dimensional Object based on Lightweight DL Model

In the emergence and development of regional humanistic features, the region's natural features play a great role. In the final analysis, no regional culture can exist and develop independently of its dependent environment, no matter how free human beings are in their choice of culture. Historical background, it can deeply study the development context of the region and understand the origin and changes of regional human characteristics. When designing, only by putting the thinking of the land parcel in an overall and macroscopic background of time and space and fully investigating and understanding the historical background of the region can it have a clear and comprehensive understanding of the emergence and development of the humanistic characteristics of the region, and then it can have a targeted and well-founded theory in the middle and later stages of design.

Western gardens are also more influenced by the agricultural rural landscape. No matter the grand royal gardens or the quiet private courtyards, you can see the shadow of the rural landscape at that time. This is completely different from the oriental garden, which has always been greatly influenced by the natural landscape and is good at imitating the natural mountain water potential in the garden construction.

Landscape planning and design is a discipline that integrates space art and time art, and landscape works, as an aesthetic entity, exist in space and time at the same time. Compared with architectural language, the biggest feature of garden design language is that it changes dynamically with time. Landscape elements such as vegetation and water in gardens will change dynamically with the seasons. Find a stable and lasting structure in the present situation of the base, and then plan a whole system based on various parameters, which must evolve with time and produce special coping methods with evolutionary ability.

Positioning and mapping are the position of the image observation point and the corresponding relationship between the observation point and the reconstructed model. In the shooting scene without camera position calibration, it is necessary to position the camera in the shooting process to judge the conversion relationship between the pixels and the 3D model and finally build the 3D map in the global coordinate system. You can use the characteristic point method or the direct method to complete a visual odometer. Taking the feature point method as an example, firstly, the features of the image are extracted, and the features between adjacent frames are matched. Then, based on the matched elements, the epipolar geometry method or nearest point iteration method is used to solve the pose change of the camera.

According to the transformation formula between homogeneous coordinates and pixel coordinates in the world coordinate system, the two-dimensional feature points are transformed into signposts on the three-dimensional map. The transformation relationship is as shown in Formula (10):

$$P_{uv} = KTP_w \qquad (10)$$

Among them are the camera's internal reference matrix, which is fixed after the camera leaves the factory, and its external reference matrix, which represents the camera's rotation and translation and changes with the camera's position.

Landscape images are developing vigorously. Although many drawings, drawings and landscape models are used now, the content brought by different image media is completely different. Now, the task of landscape architects is to keep learning and find suitable image media so that their works can be better displayed and expressed.

When semantically segmenting different landscape pictures, because it is impossible to correctly segment every object, sometimes the landscape element category in a certain image is regarded as another category [20]. In this paper, the model based on CNN (Convective Neural Network) can achieve the goal of semantic segmentation of landscape pixels in complex landscape images. The final output digital result is regarded as the final result of landscape element classification in the final landscape image to judge the final result of landscape element classification in the landscape image. Deep learning reinforcement learning (RL) algorithms can be used to optimize the design process, such as finding the best building materials, design elements, or layouts [21]. This can be achieved by training neural networks to learn and improve based on project requirements and constraints (such as budgets, regulations, etc.). Deep learning can be used to automatically generate 3D models of buildings. These models can not only be used for visualization, but also for structural analysis and optimization [22]. Deep learning can be used to achieve parameterized design, which means that every decision in the design process can be fine-tuned as a variable. For example, the design scheme can be optimized based on factors such as sunlight conditions, wind direction, terrain, etc. [23].

This paper represents the number of pixels that belong to class semantics and are judged to be class and is used to describe the total number of semantic categories. The formula used to calculate the average accuracy is shown in Formula (11):

$$A_{avg} = \frac{1}{n_{cl}} \sum_i \frac{n_{ij}}{t_i} \quad (11)$$

According to the theoretical discussion of 3D image reconstruction methods, it can be concluded that the DL method can make up for the limitations of traditional methods in view angle number, illumination, reflection, etc., to some extent and use less information to complete more efficient reconstruction.

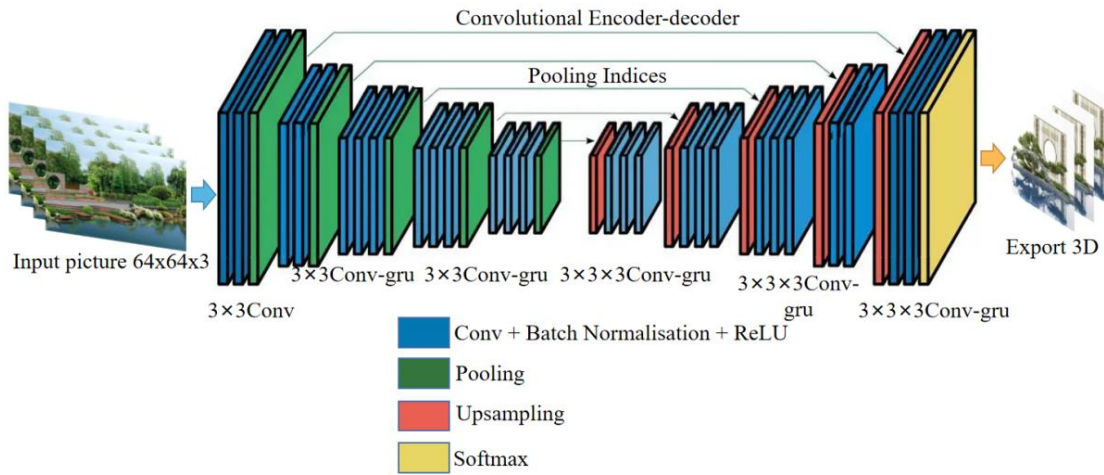
In front of the SSD (Single Shot Multi-box Dettor) network model, a standard architecture network for image classification is adopted, called the basic network and is fused for comprehensive detection. Fig. 3 shows the network model flow chart of the 3D object voxel modeling method based on the lightweight DL model.


Fig. 3.   Network model flow chart of voxel modeling method of a three-dimensional object based on lightweight DL model.

In the network, the cyclic 2D encoder, cyclic 3D decoder and view planner are integrated into a unified framework, which is responsible for feature extraction and fusion, feature decoding and view planning, respectively, so that the system can dynamically plan the view independently and update the reconstructed model in a time step sequence.

In terms of network depth, because the size of the original image is large, redundancy may occur, so the feature changes of the original texture details can be captured by large convolution. When the original image is input, multiple convolution kernels repeatedly act at different positions to extract features in the convolution layer.

If convolution kernels convolve the input image, a $n$ feature map is obtained, and the operation formula is shown in Formula (12):

$$X_n^m = f\left(\sum_{i \in P_x} x_i^{m-1} * k_{in}^m + b_n^m\right) \quad (12)$$

The above formula represents the $n$ th characteristic graph of the convolution layer in the $m$ -th layer, $f$ is the activation function of this layer, $P_n$ represents the set of input images, and $b$ is the corresponding offset.

Because the batch gradient descent method needs to traverse all samples to update parameters, the experimental process is slow, so SGD (Stochastic Gradient Descent) is adopted in this experiment. Use the loss function of each sample to derive the partial derivative of the weight $w$:

$$w_j^i = w_j + \left(y_i - h_\theta(x_i)\right)x_j^t \quad (13)$$

Where $h(x)$ is the function to be fitted, $j(w)$ is the loss function, $\theta$ is the number record, and $j$ is the number of parameters?

$W := T[W]$ Is defined, and the SVD of $W = UDQ^T$ is $W$, then:

$$\hat{V}_k^c(j) = U_{(c-1)d+j,k}\sqrt{D_{k,k}} \quad (14)$$

$$\hat{H}_k^c(j) = Q_{(n-1)d+j,k}\sqrt{D_{k,k}} \quad (15)$$

Where $(\hat{H}, \hat{V})$ is the solution $P1$, and is the filter called a low-rank constrained filter?

The $32 \times 32 \times 32$ grid is used to represent the three-dimensional shape. After the three-dimensional decoding features are obtained, the Sigmoid activation function predicts the occupancy probability. The mathematical formula of the Sigmoid function is shown in Formula (16):

$$Sigmoid\,(x) = \frac{1}{1+e^{-x}} \quad (16)$$

All the calculations of hidden layers are changed to convolution operations to retain the ability to extract spatial neighbourhood relations by convolution calculation, and all the operations on input are all connected layers. After obtaining one-dimensional vectors, the fully combined layers are deformed into three-dimensional features, and the gate calculation with hidden layers continues.

## IV. ANALYSIS AND DISCUSSION OF RESULTS

A simulation test is carried out to verify the algorithm proposed in this paper. Hardware environment: Intel Core i7 2.8 GHz quad-core CPU, 8 GB memory. The simulation environment is Windows 7 operating system and Matlab simulation software.

According to the analysis of the network structure of SSD and MobileNet, in order to reduce the number of parameters and calculation of SSD and improve the detection rate, the lightweight MobileNet network can be applied to SSD. After that, four groups of convolution layers are added, and the output features of six convolution layers are extracted and fused to detect the target to be seen comprehensively. The added network structure of SSD MobileNet V2 is shown in Table I:

The experimental results of the training test data set used in this experiment are shown in Table II and Fig. 4. The speed of MobileNet is slower than that of SSD. Still, on the whole, the model size can be reduced to 15MB, and the rate is about 35 frames/s based on the SSD-fused MobileNet network with the same accuracy, so this algorithm makes it possible that target detection can be transplanted and applied to embedded and mobile devices.

TABLE I.  ADDED NETWORK STRUCTURE

| Input layer | Step length | Output channel |
|---|---|---|
| Conv2d_10 | 1 | 1280 |
| Conv2d_11 | 2 | 512 |
| Conv 2d 12 | 2 | 256 |
| Conv 2d 13 | 1 | 128 |
| Conv 2d 14 | 1 | 128 |
| Conv 2d 15 | 2 | 64 |

TABLE II.  EXPERIMENTAL RESULT

| Target class | SSD | SSD_MobileNet V1 | SSD_MobileNet V2 |
|---|---|---|---|
| Aeroplane | 0.7984 | 0.8477 | 0.8261 |
| Bicycle | 0.8394 | 0.8984 | 0.8035 |

In the process of plant growth, with the competition of individuals for available water, nutrients and light, individuals at a disadvantage gradually die, that is, self-thinning, also known as density-related death. The stand density calculated from the data of all sample plots in each year was used, and the overall regression analysis was carried out among the values of different density indexes to judge the similarity degree of other density indexes. The regression relationship between the stand density index and the Nilson density index shows some differences between the stand density index and the Nilson density index (see Fig. 5), which needs further analysis.

When the density index based on the self-thinning theory measures the uncultivated forest land, it will be larger than the recognized maximum density value to a certain extent, which makes the density index decrease in the late growth stage of the stand. Affected by natural disasters, this decline will start early or increase the number of unnatural death plants. Figure 6 reflects the Nilson density index of sample plots with the same initial density as shown in Fig. 6.

However, the density of Nilson reflects that the density of sample 1 with moderate site conditions in the previous N years is the highest, and the density of sample 3 with the best site index before the disaster is higher than that of sample 1. In different stages, the two density indexes show that the stand density of the medium and best site is the highest, indirectly indicating no obvious linear relationship between density and site index.

Fig. 4.  Experimental results can be viewed.
Fig. 5.    Relationship between stand density index and nilson density.

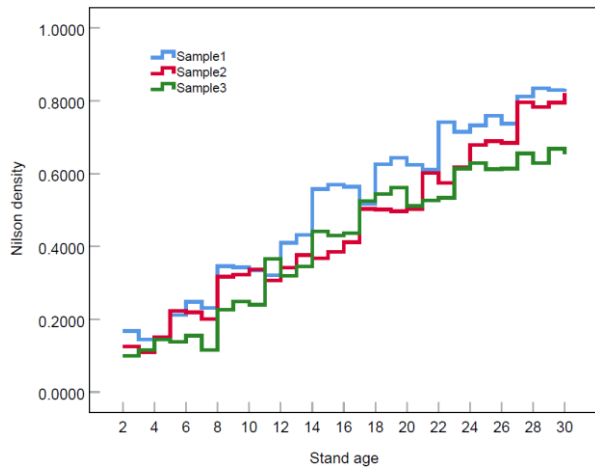

Fig. 6.    Nilson density index of sample plots with the same initial density.

After three stages of training, the 3D object voxel modeling system based on the lightweight DL model can dynamically obtain the optimal visual angle around the object to be reconstructed and the corresponding visual information under the visual angle, and finally reconstruct the 3D voxel through the object reconstruction module. To evaluate the reconstruction quality, IoU (Intersection over Union) is used for quantitative comparison. The experimental results are shown in Fig. 7 and Fig. 8.

Fig. 7.    IoU values of reconstructed voxels with different perspective prediction methods.

Fig. 8.    Information acquisition with different perspective prediction methods.

It can be seen that with the increase in the number of perspectives, the perspective sequence predicted by the network is planned with the perspective of this paper, and the reconstruction quality increases faster, which shows that the method of this paper can obtain more information suitable for object reconstruction and help improve its reconstruction quality. In this paper, the Shannon entropy of the perspective planning network decreases the most, which indicates that more new information can be acquired from the perspective of prediction, thus verifying the information acquisition ability of the network.

Table III shows the results of semantic segmentation, and Fig. 9 shows the accurate comparison between SVM, CNN and three different upsampling structures of this method. By comparing the values of these three upsampling structures, it can find that the pixel accuracy, average accuracy and average IU value of this method are the highest, with pixel accuracy as high as 90.44%, average accuracy as high as 93.15% and average IU value as 92.72%.

TABLE III.    SEMANTIC SEGMENTATION RESULTS OF LANDSCAPE ELEMENTS

| Evaluating indicator | SVM | CNN | our |
|---|---|---|---|
| Pixel accuracy | 0.8377 | 0.8283 | 0.9044 |
| Average accuracy | 0.8474 | 0.9041 | 0.9315 |
| Average IU | 0.8734 | 0.8964 | 0.9272 |

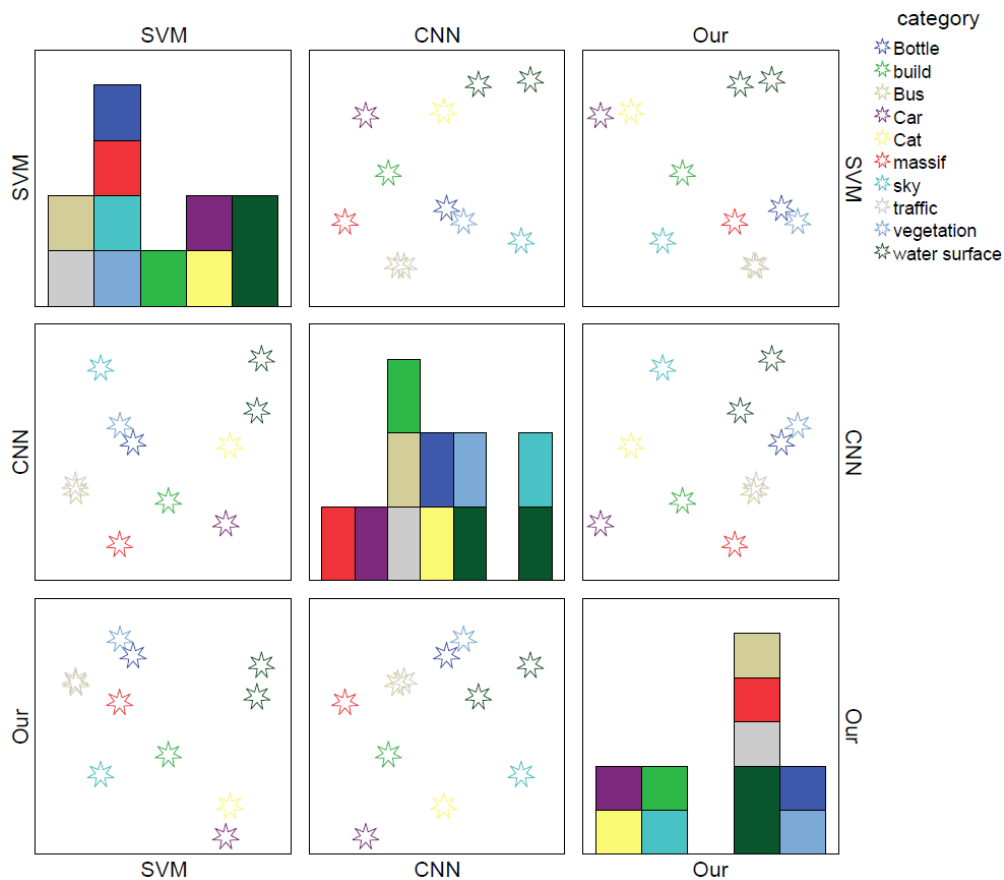
Landscape planning and design are faced with a comprehensive and complex system. Although the system itself is unique, the components of the system are changeable, and the change of a certain variable will have a series of changes, thus affecting the whole system. Accordingly, each element in the system does not exist in isolation, and each element is in a certain position and plays a specific role in the system. The elements are interrelated and form an inseparable whole. Because of the multi-objective design, it has the attribute of a system, that is, the integration and optimization of parameters in the system. It should be noted that the result of system simulation is not planning itself but provides the possibility of open thinking for various possibilities of planning and design.


Fig. 9.    Accuracy distribution of landscape element classification.

The urban environment in any period will reflect the level of scientific and technological development in that period and the aesthetic consciousness of the times and these restrictions will restrict the manifestation of the environment. The rational application of science and technology can make the created environment personalized, establish a modern expression technique that runs through the design from beginning to end, and form a unified expression style with the times. Reconstruct the spatial form of land parcels with modern gardening methods and unique spatial processing techniques, among which organizing garden space with an axis is a common design technique. The space axis can well reflect the value of space, and different space types can be organized together through the axis to form a complete spatial sequence for the viewer.

## V.  Conclusion

The discipline of landscape architecture is developing daily, and the industry is in a rapid development stage, bringing unprecedented opportunities and prosperity to landscape architects. With the development of the social economy and the improvement of people's spiritual level, more attention has been paid to environmental quality. Landscape planning and design is a discipline integrating space art and time art, and landscape works, as an aesthetic entity, also exist in space and time simultaneously. Scientific intervention, adjustment, planning and design of landscape environment through parametric method is an important development direction and research difficulty of modern landscape architecture planning and design. This paper presents the network model flow of the 3D object voxel modeling method based on the lightweight DL model. The stand density calculated from the data of all sample plots in each year was used, and the overall regression analysis was carried out among the values of different density indexes to judge the similarity degree of other density indexes. In this paper, it can find that the pixel accuracy, average accuracy and average IU value are all the highest, with pixel accuracy as high as 90.44%, average accuracy as high as 93.15% and average IU value as 92.72%. Realize the integration and optimization of parameters in the system. It should be noted that the result of system simulation is not planning itself but provides the possibility of open thinking for various possibilities of planning and design.

In the future, deep learning technology can be utilized to better utilize historical design data and planning experience, providing designers with real-time and accurate decision support. For example, a recommendation system based on deep learning can help designers find similar or better design solutions from a large number of historical garden designs based on established design goals. With the development of deep learning technology, it can train models to automatically perform routine and repetitive design tasks, such as landscape layout, vegetation placement, etc., thereby freeing up designers' energy and enabling them to focus more on innovation and detailed design.

# Investigations of Modified Functional Connectivity at Rest in Drug-Resistant Temporal Lobe Epilepsy Patients

Deepa Nath[1], Dr. Anil Hiwale[2], Dr. Nilesh Kurwale[3], Dr.C.Y.Patil[4]

School of ECE, Dr.Vishwanath Karad MIT World Peace University, Pune[1, 2]

Neurosurgeon, Deenanath Mangeshkar Hospital, Pune[3]

Dept of Instrumentation and Control, COEP Technological University, Pune[4]

*Abstract*—**In this experimental study patients with temporal lobe epilepsy and controls have been compared for functional connectivity (FC) using resting-state functional magnetic resonance imaging (rs-fMRI). This research work examines the alterations to better understand the issues with brain activity of individuals suffering from Temporal Lobe epilepsy (TLE), during the rest state. The major objective of this study is to investigate FC-related alterations in the resting state to fully comprehend the complex nature of epilepsy. It is** observed that FC gets altered in specific regions in the case of patients suffering from left-sided Temporal Lobe Epilepsy and right-sided Temporal Lobe Epilepsy as compared to controls. Using rs-fMRI, it is found that the right-sided TLE patient group had altered hippocampus networks than the control right-side group. There are considerable differences between the left and right areas of control and the groups with mesial temporal hippocampal sclerosis on the left and right sides. When compared to control left brain regions, the left-side TLE group exhibits reduced connection between the anterior cingulate gyrus and the affected hippocampus and increased regional connectivity between the affected hippocampus and the default posterior cingulate cortex region.

*Keywords*—*Temporal Lobe Epilepsy (TLE); resting-state Functional Magnetic Resonance Imaging (rs-fMRI); Functional Connectivity (FC); Blood Oxygen Level-Dependent (BOLD)*

## I. INTRODUCTION

Over the past few years, resting-state Functional Magnetic Resonance Imaging, (rs-fMRI), has been used. The rs-fMRI studies of the human connectome have gained popularity, and these studies are extremely valuable for understanding epilepsy networks and improving surgical treatment. Surgery to remove epileptogenic tissues may be a successful course of treatment for 20– 30% of epilepsy patients whose seizures are unresponsive to medication [1]. The most successful method for treating drug-resistant epilepsy is surgery. After thorough presurgical evaluation, seizure freedom can be achieved in approximately 60- 70% of patients [2].

FC of a brain network explains the patterns and degree of temporal correlations of activation patterns across distant brain regions. FC is a metric for the understanding relationship between different brain areas. A significant portion of the current work is based on assumptions regarding which parts of the brain are active when it is at rest. This calls

for monitoring the relative changes of Blood Oxygenated level-dependent (BOLD) signal in comparison to the baseline in different brain regions when it is at rest [3]. Emerging neuroimaging research generally supports the idea that resting-state BOLD variations are at least largely caused by intrinsic brain activity [4, 5]. Consequently, investigations on spontaneous regional interactions happen when the brain is at rest. Epilepsy in the mesial temporal lobe (MTLE) is studied extensively for clinical characteristics and neuropsychological deficits [6, 7].

TLE is associated with various neuropsychological deficits beyond the boundaries of the temporal lobe and apart from memory; other common deficits associated with TLE include the domains of executive function, language, and cognition [4]. Right and left TLE presents visual and verbal memory deficit profiles, which were traditionally used for lateralizing the epileptogenic lesion however; overall neuropsychological deficits were more common with left TLE patients [4]. Moreover, the dominance of the lobe is known to affect the pattern of neuropsychological deficits but the extent of deficits alwaysremains unpredictable.

However, the right and left TLE differ in language, executive function, and social cognition, according to neuropsychological literature on TLE, which is the clinical expression of functional connection. The work presented in the paper aims to examine the variations in resting-state connection networks in well-matched cohorts of patients with right- and left-sided TLE and to compare them to healthy controls in the respective regions of the right and left brain.

Low-frequency neural oscillations have been the subject of novel rs-fMRI research [5] that has progressed in the neuroscience literature. [3,4]. Functional connections of various brain regions using rs-fMRI help explain TLE's neuropsychological deficits [6, 7, and 8]. Most of the methods of the rs-fMRI utilize group analysis using various algorithms and pipelines [9] where different preprocessing steps are applied and signals are averaged for the group and plotted.

Numerous epilepsy network investigation studies [10, 11, and 12] have examined groups with left and right-side involvement. In several studies, the Left TLE (LTLE) or Right TLE (RTLE) is compared to the Healthy Control group. The unique feature of this experiment is that regions related to the

right-side memory circuits of the Control and the right-side TLE groups are compared, and comparable comparisons were made for the left-side group. The functional connectivity between regions of interest (ROI) inside and outside the epileptogenic network was assessed in the right or left regions of patients with treatment-resistant RTLE or LTLE and control participants, respectively. The introduction is mentioned in Section I, the dataset and methods are described in Section II, analysis and results obtained during experimentation are discussed in Section III, the results obtained and their comparison to the work of other researchers are discussed in Section IV, the limitations and future directions of the study are discussed in Section V, and the conclusion is stated in Section VI.

## II. MATERIAL AND METHODS

### A. Study Period

MRI data collection for patients and controls was done for the period of the past two years from 2021 to year 2022.

### B. Participants

Patients with temporal lobe epilepsy who are drug-resistant, with unilateral hippocampal scleroses that were deemed candidates for standard anterior temporal lobectomy and amygdalo hippocampectomy formed the patient group. All the patients had the scans on a single magnetic resonance imaging Siemens make 3T MRI scanner (Skyra). Left and right TLE groups of patients were separated. Separately data was generated for the control group. Our study sample includes right TLE (n=07), left TLE (n=09), and controls (n=16), which makes a total of 32 participants. Demographic data is mentioned in Table I.

### C. Ethical Standards

The present study is approved by the Independent Institutional Review Board (IRB) for all the components of the study. All the ethical practices have been followed while the study is been carried out. Informed consent was taken from all participants.

TABLE I. SUBJECT-SPECIFIC DEMOGRAPHIC DATA

| Subjects | Controls | LTLE | RTLE |
|---|---|---|---|
| N (Male, Female) | 16 (15, 1) | 9 (5, 4) | 7(5, 2) |
| Mean age (years) | 20.83 | 20.87 | 26.14 |
| Epilepsy Duration in years(mean±SD) | | 8.85±5.87 | 14.85±13.04 |
| Antiepileptic Drugs(AED) (mean±SD) | | 2.57±0.53 | 3±0.69 |
| Seizure frequency/month(mean±SD) | | 1.6±1.54 | 1.16±0.408 |

### D. MRI Data Acquisition Parameters

*1) Patient conditioning:* Before the start of the resting state acquisition, patients were advised to recline comfortably with their eyes closed as the regular epilepsy surgery scanning was conducted on a single scanner.

*2) Structural T1 data:* High-resolution structural data which is used to quantify brain structure sequence was acquired in 256x256 matrix, 3D acquisition without any gap with a slice thickness =0.5 mm, echo time = 3.07ms, Repetition time (TR) = 3000 ms, and flip angle= 8∘ with voxel size was 0.5x0.5x0.5 mm

*3) Functional data:* It is employed to research brain activity. BOLD data was acquired in a one-shot gradient echo-planar imaging sequence with parameters in a single direction. A total of seven minutes and 140 volumes of a sequence were recorded using a flip angle of 90 degrees, a repetition time of 3000 ms, and an echo time (TE) of 30 ms.

### E. Imaging

With the aid of a 3T MRI system (Siemens), imaging was carried out. The following settings were used for functional imaging: repetition time (TR) = 3000 msec, echo time (TE) =30 msec, slice thickness = 2 mm, and 36 slices. The same imaging investigation produced high-resolution structural pictures. fMRI recordings, each lasting seven minutes, were made during the imaging sessions.

### F. Pre-processing

Regions of interest (ROI) default for 164 regions were created from T1 scans in the CONN toolbox [13] and used Harvard-Oxford Atlas [14]. All volumes were segmented, and normalized, slice time was adjusted, co-registered to T1, and realigned to the first functional scan using the Montreal Neurological Institute (MNI) 152 template.

The head movement artifacts are eliminated, high-pass filtering is applied for 100 s, and spatial smoothing is performed at 8 mm full-width half-maximum. The SPM12 (statistical parametric mapping) is used for preliminary data processing for each patient. The procedures for realignment and slice-time adjustment are standard and CONN uses the Artifact Detection Tools (ART) to look for outliers. Direct normalization in [15] is the method we choose to utilize to normalize the standard template of MNI152 space. After performing structural segmentation and normalization, the BOLD signal-to-noise ratio is then improved using a Gaussian kernel with an 8mm full width at half maximum(FWHM).

### G. Denoising

Physiological, head-motion and other sources of noise must be reduced to focus on low-frequency oscillations while reducing their overall volume, BOLD data are filtered in the temporal domain using a band-pass filter of 0.008 to 0.9 Hz before further processing. To decrease the influence of variation of FC values is measured between pairs of randomly selected ROIs in the brain to gauge the effectiveness of the procedure (see Fig. 1 for a specific Subject 1).

### H. First-Level Analyses

To describe the functional connectivity between each pair of areas, ROI-to-ROI connectivity (RRC) matrices [16] were calculated. The correlation coefficient's sample distribution, or Pearson's r, can be transformed into a normally

distributed distribution using the Fisher Z-Transformation. The level of functional connectivity is measured using Fisher-transformed bivariate correlation coefficients from a general linear model (weighted-GLM) [17], as stated in (1) which were independently computed for each pair of ROIs and characterized the relationship between their BOLD signal time series. Refer to Fig. 2 for the first-level analyses.

The analyses for this study examined the ROI-to-ROI connections between brain regions for memory circuits. It is limited to a particular set of 12*12 connections (refer to Table II) out of all available connections (164x164). The degree of connectivity between each pair of ROIs among a pre-defined region RRC. Using this selected list of ROI, as described in Table II, an investigation for individual differences wascarried out for RTLE, LTLE, and controls.

$$r(i,j) = \frac{\int R_i(t)dt\, R_j(t)dt}{\int (R_i^2(t)dt\, R_j^2\,(t)dt\,)^{1/2}} \tag{1}$$

$$Z\,(i,\ j) = \tan h^{-1}(r\,(i,j)) \tag{2}$$

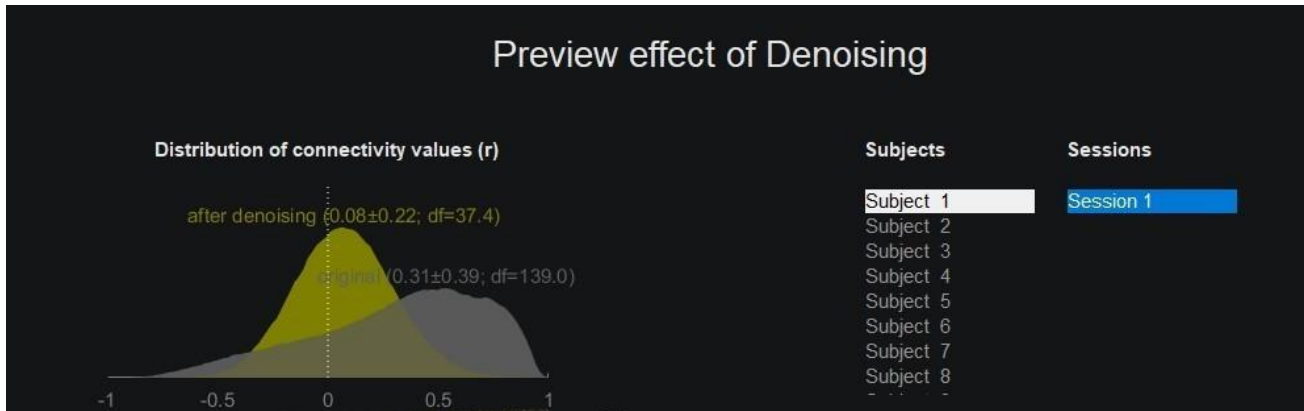

Fig. 1. Denoising effect for a particular subject.

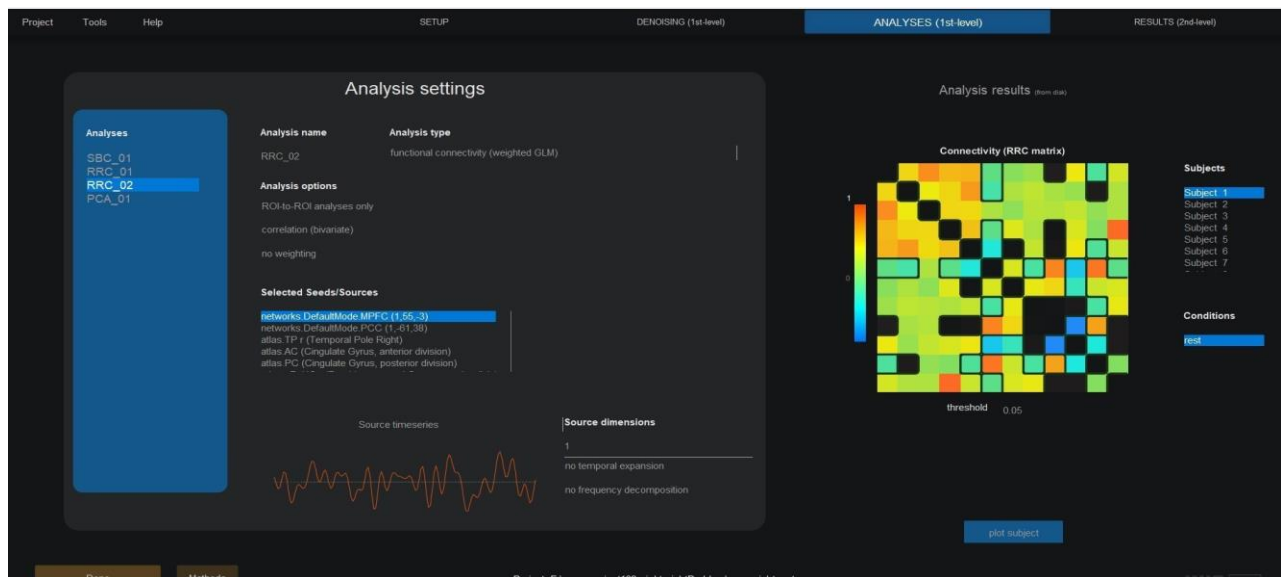

Fig. 2. First level analysis GUI display on CONN toolbox [16].

where R is the BOLD time series inside each ROI, Z is the RRC matrix of Fisher-transformed correlation coefficients,r is a matrix of correlation coefficients(see (2)), and Z is the matrix of Fisher-transformed correlation coefficients (all-time series are assumed to be centered to zero mean here for simplicity). In the first level of analysis we need to choose the method of connectivity like Seed-based connection (SBC) or Region Re gion Connectivity (RRC), Principal Component Analysis, and many more. For this study, 12 ROIs are compared for connectivity analysis as listed in Table II. As a result, connectome rings appear on the

CONN Graphical User Interface (GUI), and the variations between them were quantified visually.

### I. Group/Second Level Analysis

Second-level analyses are used to draw conclusions about the characteristics of groups or populations. CONN uses the General Linear Model (GLM) [17] to examine functional connectivity data at the second level.

Selecting one or more items from the "Subject effects" list and indicating the desired 'between-subjects contrast' establishes a second-level model in CONN. Control and

Patients are the two groups designated in this experiment, and they are originally listed in the covariates tab during setup and enter [1 -1] to evaluate the differences between the groups 'connections. Otherwise, just enter [1 0] or [0 1] and refer to Fig. 3 in the 'Between-Subject Contrast' to understand the individual effects of Controls or Patients independently. The evaluation of the connection-level hypothesis uses multivariate parametric statistics with random effects across participants and sample covariance estimates across different data. The inferences were analyzed on a per-cluster basis (groups of linked connections). Based on parametric statistics between and within each pair of network-level identifiers as independent variables, cluster-level inferences were made. Refer to Fig. 3 for Second Level Analysis. Functional Network Connectivity [13], which employs complete-linkage hierarchical clustering and the ROI-to-ROI physical closeness and functional similarity metrics [16], to discover networks. Results were threshold using a family-wise adjusted p-FDR= 0.05 cluster-level Threshold [18] in addition to a p= 0.05 connection-level threshold [19].The results of the first-level studies of each individual are combined at this stage to analyze the total population. When conducting group-level analysis, the effect estimates of the General Linear Model are frequently combined across participants using the t-test, ANOVA, ANCOVA, multiple regression, or linear mixed-effects (LME) models. The subject-effects (X), conditions (Y),

between-subjects contrast (C), andbetween-conditions contrast (M) matrices are the only ones that must be specified for the GLM framework. As a result,the same GLM framework can be used to specify a very wide range of traditional analyses.

TABLE II.    SELECTED ROI FOR COMPARISON WITH RTLE, LTLE, AND CONTROLS

| Sr.No | Region of Interest | Abbreviations |
|---|---|---|
| 1. | Default Mode.The medial prefrontal cortex (MPFC) | MPFC |
| 2. | DefaultMode.Posterior cingulate cortex(PCC) | PCC |
| 3. | Temporal Pole affected | TP r/l |
| 4 | Cingulate Gyrus, anterior division | AC |
| 5 | Cingulate Gyrus, posterior division | PC |
| 6 | Parahippocampal Gyrus, anterior division affected | aPaHC |
| 7 | Parahippocampal Gyrus, posterior division affected | pPaHC |
| 8 | Planum Temporal affected | PT r/l |
| 9 | Hippocampus affected | Hippo r |
| 10 | Hippocampus contralateral | Hippo l |
| 11 | Amygdala affected | Amy r/l |
| 12 | Insular Cortex affected | IC r/l |

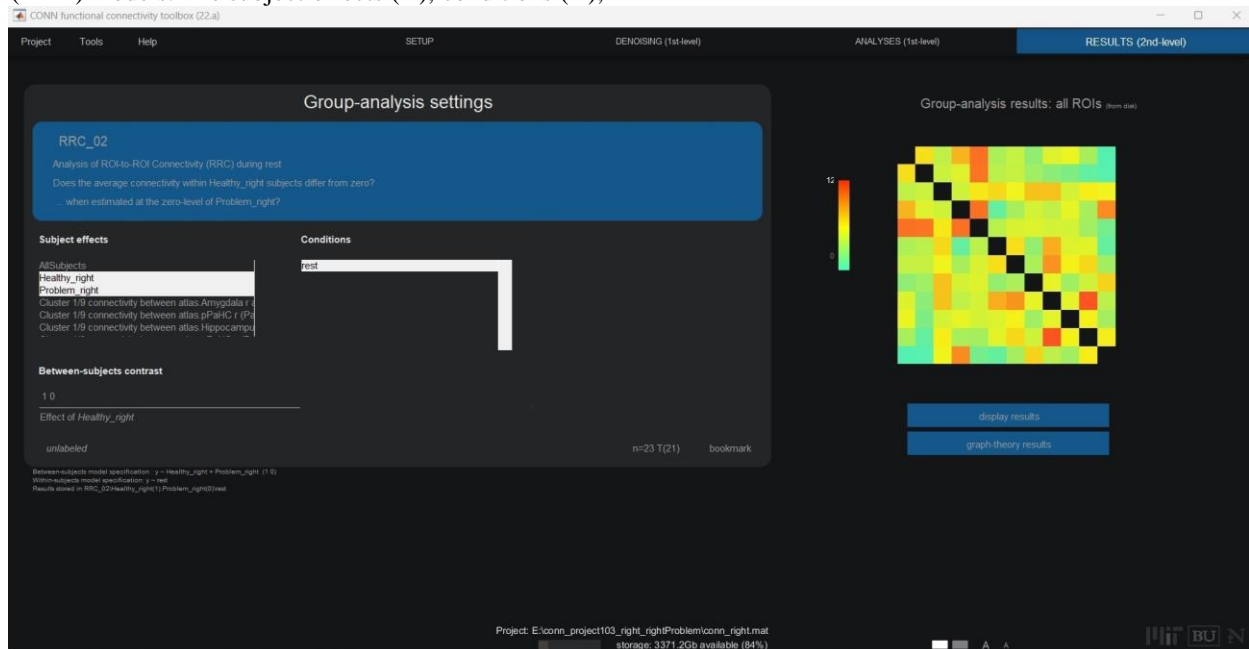

Fig. 3.    Second-level analysis for group level [16].

## III. ANALYSIS AND RESULTS

The analysis is performed on the CONN toolbox, 2022a [13], an SPM-based toolbox that runs on MATLAB 2022a. Two groups were used for the intergroup comparisons: Healthy_l controls for the left side regions of the brain with patients who had LTLE, and Healthy_r controls for the right side parts of the brain with patients who had RTLE. To further investigate the results, all the data is plotted on connectome rings and brain templates. Default Color coding is used to

interpret the connection strength, from the blue to red spectrum where blue is negative and red is an extremely positive correlation or connectivity amongst the ROIs. The second-level results tab of CONN generates a ROI.mat file after processing the images. The intriguing results in this file can be used to draw a conclusion. Here, names provide a list of ROI sources, h value provides the Fisher transformed correlation value based on the particular contrast used during the experiment, F values show the value of the statistic, and P values provide one-sided tail values.

The ROI.mat files produced during the second level analysis can be used to generate graphical results visualization in CONN GUI. Ring Connectome results for the ROI to ROI connections as specified in Table II are displayed. Both graphical visualizations of group-level analysis are compared with the help of ring connection display and RRC matrix.

The data displayed on the ring connectome is as shown in Fig. 4. The 3D brain view displayed in Fig. 5 can be viewed in the same Conn GUI. As shown in Fig. 4, there are apparent differences in the correlation values between Healthy_r and other ROI in the RTLE group. As seen in Fig. 5, the medial prefrontal cortex (MPFC) and posterior cingulate cortex (PCC), two of the default mode networks with the contralateral hippocampus, are no longer connected to one another. Also in the RTLE group, the amygdala and hippocampus both lack connections to the anterior cingulate and PCC regions, respectively. The RRC matrix, which is accessible through the CONN GUI, only outputs color variations between various pairs of ROI. With the help of Python code and the h, F, or P values from the ROI.Mat file, distinct RRC matrices can be produced. Here, the RRC matrix is made using h values, and the correlation values are displayed in the boxes for comparison between the affected RTLE patients and the control group (see Fig. 6).

The 12 interest ROIs are taken into account (see Table II). Additionally, two sample t-tests were run in the second-level analysis to compare the Controls and RTLE groups. In the results explorer GUI's customize menu, under the advanced Family Wise Control Settings, the connectivity threshold set to p< 0.05 and cluster threshold p< 0.1, as shown in Table III.

A plot of Effect Size is displayed in Fig. 7 about clusters of interest. Effect size is the measure of connection, which is commonly shown by Fisher-transformed correlations. From Fig. 7, the default mode posterior cingulate cortex (PCC) connectivity to the impacted Planum Temporal differs between the right TLE and the healthy control right areas of the brain. While this connection is absent in the control right-side memory network regions, significant connectivity between these anterior parahippocampal regions and the temporal pole is observed in RTLE.

TABLE III.    DIFFERENCES IN CONNECTIVITY VALUES

| Sr.No | ROI Region connections | Tstat, p-value |
|---|---|---|
| 1 | ROI 1/12 PCC to PTr | 3.16,p=0.004 |
| 2 | ROI 3/12 PC –AC | 2.89,p=0.008 |
| 3 | ROI 3/12 Hippo-left –AC | 2.39,p=0.02 |
| 4 | ROI 3/12 PC-PTr | 2.39,p=0.02 |
| 5 | ROI 3/12 aPaHC-PTr | -2.40,p=0.02 |

Similar to this, functional connectivity was compared between the Healthy Left Controls and the LTLE patient group. The results displayed on the ring connectome in Fig. 8 can also be viewed in a 3D brain perspective using the same Conn GUI. From Fig. 9, visually what can be observed is in the control group left all the selected ROIs are connected with other ROIs, whereas in the LTLE group, the connections with other ROIs are altered, prominently default

mode networks like medial prefrontal cortex (MPFC) and Posterior Cingulate Cortex (PCC) have connectivity with the affected temporal pole (TPl) and affected Planum Temporal (PT l). Also, the AffectedHippocampus is not connected with the Anterior Cingulate Gyrus.The correlation values heat map is plotted as shown in Fig. 10 for comparing Healthy left side regions of the brainwith the LTLE patient group based on correlation values.In addition, by selecting Subject Effects as both Healthy l andLTLE groups in Second Level Analyses, we attempted to doa two-sample T-Test for the comparison within two groups Healthy left side regions of the brain and LTLE impactedgroup. Similar settings were used like the right side comparison. A plot of Effect size referred to Fig. 11 concerning clusters of interest is shown. Effect size –is the magnitude of connectivity typically Fisher transformed correlations are displayed. Refer to Table IV for Connectivity differences, Fig. 11, the differences observed are listed.

TABLE IV.    CONNECTIVITY DIFFERENCES

| Sr.No | ROI | Region | Tstat, p-value |
|---|---|---|---|
| 1 | ROI 2/12 | PCC to AC | 2.47,p=0.02 |
| 2 | ROI 2/12 | Left Hippocampus -AC | 2.30,p=0.03 |

Differences noted in this intergroup comparison are when compared to the Healthy Control left side regions to the left TLE's- default mode network (PCC) connectivity to the Cingulate Gyrus' anterior division is noticeably different. Also when compared to healthy control left regions the connectivity of the affected hippocampus region with the Anterior CingulateGyrus (AC) dramatically diminished in LTLE.

## IV. DISCUSSION

### A. Alterations Observed in the RTLE Group with Control Right Regions

The results of the experiment as shown Fig. 6 reveal that RTLE patients showed less connection between the affected Planum Temporal, affected Hippocampus, and contralateral Hippocampus with Default Mode MPFC area. Also, it was discovered that the Planum Temporal and Affected Hippocampus in the RTLE group exhibited decreased connection for the Default mode PCC region. Additionally, RTLE revealed a weakening of the connection between the anterior division of the cingulate gyrus and the contralateral hippocampus. Also, the posterior cingulate gyrus showed a weaker connection with the contralateral hippocampus.

### B. Alterations Observed in the LTLE Group with Control Left Regions

With reference to Fig. 10, it is observed that there is a weak link between the afflicted hippocampus and the Amygdala with the default mode MPFC when LTLE patients were compared to groups of healthy control left region. Also discovered that in LTLE group anterior cingulate gyrus has a decreased connectivity with the affected hippocampus. A stronger link between the injured and contralateral hippocampi and the PCC in default mode was also seen. A weakened connection between the Planum Temporal affected with Amygdala is observed in LTLE as compared to the control group.

## C. A Few Relevant Case Studies

Haneef et al. [20] in their study of LTLE 13 patients, RTLE 11 patients, and 16 healthy controls also report similar findings, wherein Default mode connectivity gets more affected in TLE patients, Default mode Network with the hippocampi. Pierera et al. [21] in their study of ROI-ROI analysis of 18 patients and nine healthy controls report asymmetrical loss of connectivity between left and right Hippocampus Sclerosis in a similar fashion but the authors only studied hippocampal seed, unlike our study where all the other important connectivity profiles like DMN and memory networks are also explored.

In a study by Zhao, [22] involving 12 LTLE patients, 11 RTLE patients, and 23 healthy controls, functional connectivity differences were examined using ROI- based analysis. In this study, the LTLE group had a significantly lower link with the anterior and posterior parahippocampus gyrus compared to the controls. The reduced connection between areas in the bilateral temporal lobes and frontal lobes was also discovered on the right side. Pressl [23] et al. used rs-fMRI to investigate a potential link between TLE treatment response and functional network alterations. In individuals with treatment-resistant and well-controlled epilepsy, they looked at variations in functional connectivity between regions of interest (ROI) inside and outside the epileptogenic network. As suggested in their findings the thalomo-hippocampus positively correlated in Controls, while they are negatively correlated in treatment resistance TLE patients and this could serve as a new biomarker for TLE diagnosis and preventive treatment. In another study of Marine Fleury [24] where 43 controls and 29 TLE patients connectivity was studied, Patients with TLE had enhanced regional connectivity between the anterior Mesial Temporal Lobes (MTL) on both sides and widespread decreased connectivity between the frontal lobes and MTLs as compared to controls.

Another study by Barnett [25] found that in persons with temporal lobe epilepsy (TLE), the hippocampus's connections to other parts of the default mode network (DMN) are a reliable predictor of memory function. Using resting state fMRI data from individuals with left-sided TLE (LTLE) and right-sided TLE (RTLE), they divided the hippocampus based on its functional links to the rest of the brain, as well as from a set of neurologically healthy controls. Other Default mode Networks (DMN) regions are less connected to the medial prefrontal cortex (mPFC) and posterior cingulate cortex (PCC), two important sections of the DMN, were reduced in both TLE groups. The anterior region of the hippocampus in the LTLE group also displayed a decreased connection to the DMN. This is in line with the findings made in this experiment, which showed that the hippocampus-to-DMN connection can be used as a helpful marker for persons who have temporal lobe epilepsy. Future research will be useful in determining whether anterior and posterior biases in connection are associated with the impairment of more precise memory functions in TLE patients. The importance of these findings can also be understood with the use of clinical neuropsychology correlation. Here in this study for memory circuits, a selected group of ROI was chosen for analyses. This list of ROI can vary for different network studies.

Fig. 10.  Correlation values for healthy versus LTLE matrix values display. A heat map is created based on Fisher transformed correlation coefficient.

Fig. 11. Plot Effects–average effect sizes with the selected clusters.

## V.   LIMITATIONS AND FUTURE SCOPE

It is not that easy to generate the data for healthy subjects. In this study, data of 16 healthy controls was arranged with proper consent from the volunteers; however, a larger sample size may increase the accuracy of the analysis. The larger dataset may help to validate the variations in connections that are clinically relevant and correlated. It will help to characterize TLE patients and provide more information about neurologic abnormalities. Also with different sets of ROI selections, it can be expanded for attention, language, visual, motor, sensory networks, and many other networks of the brain.

## VI. CONCLUSION

The distinguishing feature of this experimental study is the comparison of right-side memory circuit-related regions of the control group with that of the right-side TLE group as well as the comparison of the left-side memory circuit-related regions of the control group with that of the left-sided TLE group. The mesial temporal hippocampus sclerosis patient group on the left and right sides exhibit distinct changes in the organization of the memory networks in comparison with the control group left and right sides. By comparing the RTLE patient group to the right-side Control group, the differences have been identified in the hippocampal network. The two default mode networks MPFC and PCC have weaker connectivity between the affected and contralateral hippocampi. In the LTLE patient group, reduced connections have been observed for impacted Planum Temporal and Default MPFC. Comparing LTLE to the control group for left brain areas, it has been observed that there was a decreased connection between the anterior cingulate gyrus and the affected hippocampus and more connectivity between the affected hippocampus and the default posterior cingulate cortex.

# Blockchain-based Teaching Evaluation System for Ensuring Data Integrity and Anonymity

Md. Mijanur Rahman, Uttam Kumar Saha, Shohedul Islam, Sanjida Akhter

Department of Computer Science and Engineering, Southeast University, Dhaka, Bangladesh

*Abstract*—The significance of student feedback within educational institutions cannot be overstated, as it serves as a pivotal tool for evaluating faculty performance and identifying potential gaps in course content. Blockchain technology has emerged as an increasingly promising solution for diverse digital applications, owing to its distinctive attributes and robust security features. This study endeavors to explore the use of blockchain technology for secure student feedback systems in education, specifically for analyzing faculty performance in a course. However, a noteworthy challenge that plagues existing feedback systems is their inability to ensure complete anonymity, leading to students' hesitancy in providing candid and honest feedback. Furthermore, these conventional systems often rely on databases for data storage, rendering them susceptible to tampering and data breaches. In response to these pressing concerns, the present paper proffers a comprehensive and innovative solution. The crux of the proposed approach revolves around the implementation of a blockchain-based student feedback system, artfully designed to guarantee both student anonymity and tamper-proof data storage, thereby facilitating the evaluation of teaching effectiveness. By leveraging the potential of an Ethereum-based blockchain, a secure and trusted platform is meticulously established, catering to the sensitive realm of student feedback in an impervious and confidential manner. Concomitantly, a user-friendly web application is deftly developed to complement the proposed system, meticulously documenting the implementation process, Smart Contract and project code. It is noteworthy that this cutting-edge feedback system provides an invaluable layer of security, fostering heightened user trust and engendering an environment conducive to genuine and authentic evaluations.

*Keywords—Blockchain; student feedback system; faculty performance evaluation; anonymity; smart contract, ethereum*

## I. INTRODUCTION

In today's educational landscape, student feedback is a vital component for organizations seeking to analyze and address various issues. This invaluable information is utilized to make important decisions within the organization, assess faculty performance in specific courses, identify solutions for existing problems, as well as inform future improvements. As such, feedback is treated with utmost care and consideration. Feedback plays a crucial role in assessing student achievement, promoting skill development, enhancing understanding, and fostering student motivation and confidence [1]. There is an ever-growing need to measure the activities and performance of faculty members in colleges and universities. Evaluating faculty performance is one of the most critical tasks within an institution and it has become a top priority worldwide [2]. However, most organizations rely on databases to manage their feedback systems. Therefore, the system administrator holds the authority to remove, alter, and manipulate the given feedback [3]. Henceforth, it is evident that the feedback system within the database management system does not provide anonymity [4]. According to a report published in [5], A $2.2 million fine was imposed on an Australian hotel business for deleting negative reviews from their website. A blockchain system that is decentralized, immutable, and auditable is inherently suited to prevent fraudulent and manipulated reviews [6].

Blockchain ushers in a new era of innovation and represents a huge advancement in decentralized information technology [7]. It offers several benefits to the education evaluation process, including decentralization, classification, and secure storage of evaluation data. By leveraging blockchain's inherent security features, such as immutability and tamper-resistance, it can enhance the confidentiality of data and prevent unauthorized access or modification [8]. The faculty members who receive or view feedback may be negatively impacted by the organization and their students if negative feedback is disclosed. Furthermore, faculty members may attempt to uncover the identity of students who have given negative feedback through administrators or databases, which could lead to adverse effects on those students. Administrators with access to databases can also change feedback or reveal the identities of the students who submitted it, thereby this feedback system does not remain fully anonymous. Maintaining confidentiality and safeguarding anonymity are fundamental components of an effective feedback system. Utilizing blockchain technology and its numerous fascinating characteristics, including anonymity, validation, robustness, and potential integration, one can create a feedback system that preserves anonymity effectively [9].

Satoshi Nakamoto introduced the concept of blockchain technology in 2008 by publishing a paper on Bitcoin [10] [11]. Blockchain is a decentralized ledger system that utilizes a network of distributed nodes to create a highly trustworthy ledger system without relying on third-party verifiers. The distinctive structure of the blockchain is data protection, anonymity, transparency, and integrity [12]. Blockchain technology aims to achieve a decentralized consensus among network nodes, where data is distributed and no single node has complete control [13]. It is a decentralized database that stores records in blocks [14]. Every block includes a hash value, timestamp, and the transaction's details. A hash function is employed to transform a collection of data into a compact and fixed-sized data structure referred to as a hash value [15] [16].

We looked over some of the research papers on feedback systems based on blockchain and tried to investigate the gaps. We found some research papers related to feedback systems that showed an opportunity to alleviate the existing challenges in this field. The existing Ethereum blockchain-based feedback system doesn't use any encryption and decryption process while login/registration and storing passwords on the blockchain. But in this paper user password encryption and decryption during login, registering, and storing on the blockchain is done using bcrypt algorithm.

Therefore, we proposed a secure student feedback system for the evaluation of faculty performance using blockchain technology, designed to prioritize user anonymity and tamper-proof features. With this system, data remains unaltered and secure, preventing both administrators and faculty members from accessing the identities of students who submitted feedback. Consequently, this system delivers enhanced security and anonymity, empowering students to provide feedback with confidence.

The subsequent parts of the paper are organized in the following manner. A synopsis of the prior related literature is given in Section II. Section III presents the methodology and implementation of the proposed blockchain-based teaching evaluation system. Section IV describes the results and Section V delves into discussion. Lastly, the paper's conclusion is presented in Section VI.

## II. LITERATURE REVIEW

The existence of blockchain predates its introduction by Satoshi Nakamoto with the advent of Bitcoin [17] [18]. Its influence has been profound and all-encompassing, witnessing widespread adoption across various industries and sectors, driven by its potential to enhance security, efficiency, and transparency. In recent times, blockchain technology has emerged as a frontrunner in the realm of innovation, garnering substantial attention from the global public and academic communities [19]. Blockchain technology attained remarkable prominence, establishing itself as a leading technological breakthrough on a global scale. Consequently, an array of comprehensive research endeavors have been undertaken to delve into the intricacies of this system, culminating in proposed advancements and revisions to existing studies. This surge in interest underscores the profound significance of blockchain technology as an enabler of progressive and transformative solutions across various domains.

In their seminal work, Zheng et al. provided invaluable insights into the architecture of blockchain technology, shedding light on the intricate algorithms that underpin consensus among its participants. The authors also dedicated attention to the technology's inherent limitations, offering innovative solutions to mitigate these challenges. Their rigorous analysis encompasses a comparative evaluation of diverse consensus algorithms, with the overarching goal of identifying the most fitting approach for a multitude of applications [20].

Rahman et al. introduced a pioneering blockchain-based feedback system, meticulously engineered to safeguard user anonymity. The primary objective of this system is to empower users to provide feedback without compromising their privacy. Notably, once feedback is submitted, it becomes immutable. Furthermore, the system meticulously safeguards the privilege of providing feedback for registered users. However, the cloak of anonymity raises the potential for intentional negative feedback to tarnish the reputation of recipients [21].

Chandratre et al. proposed an innovative blockchain-based course feedback system, harnessing the power of Ethereum blockchain for its development. This inventive system integrates a survey management component, enhancing longevity and traceability. The feedback process unfolds through well-defined phases: initiation commences with the administrator crafting a survey form, followed by students sharing their feedback, culminating in the secure storage of this feedback on the blockchain [22].

Salah et al. demonstrated an online review system rooted in blockchain technology, featuring the use of the Solidity programming language and the Remix Integrated Development Environment (IDE) for implementation and testing. The system not only rewards genuine reviewers with tokens and Ether-based compensation for their reviews but also securely archives verified reviews within the InterPlanetary File System (IPFS), thereby ensuring their integrity and reliability. In a forward-looking approach, the authors aspire to develop user-friendly decentralized applications to further facilitate the work of reviewers [23].

Karode et al. presented an innovative blockchain-based online review system aimed at enhancing transparency on business platforms by combatting the prevalence of fake or unreliable reviews. Leveraging the Ethereum blockchain, this system securely stores review data, effectively thwarting data manipulation. Additionally, it ensures the public traceability of actions, significantly elevating the transparency of the online review system through the integration of blockchain technology. However, it's important to note that the adoption of blockchain in this context may introduce challenges, including increased costs and potentially slower response times [24].

The research papers previously mentioned delve into the development of student feedback systems that prioritize anonymity and data integrity. However, our innovative approach takes a step further, encompassing a performance-based evaluation system that serves both as a feedback mechanism and a valuable resource for identifying effective solutions to similar challenges. Diverging from some existing feedback systems, where administrators assign students to specific courses eligible for feedback, our proposed system introduces a seamless and automated validation process. By offering students the opportunity for self-registration, they gain access to provide feedback exclusively for the courses in which they are enrolled. Moreover, we introduce a rating-based system for evaluating faculty performance, a salient feature that bears immense potential for driving organizational improvement.

## III. METHODOLOGY

The principal aim of our system revolves around the seamless facilitation of anonymous feedback while upholding the inviolable integrity of data, thereby empowering students to

express candid opinions without hesitation. To achieve this pivotal objective, we judiciously harnessed the potential of blockchain technology, renowned for its remarkable capacity in safeguarding anonymity and preserving the unassailable authenticity of submitted feedback. Our system, thoughtfully designed, imposes stringent measures to guarantee that solely registered users possess the privilege to proffer feedback, assiduously safeguarding the covert identities of students, and diligently ascertaining that the feedback reaches its intended recipient for meticulous review. Fig. 1 below illustrates the system architecture of our proposed system.

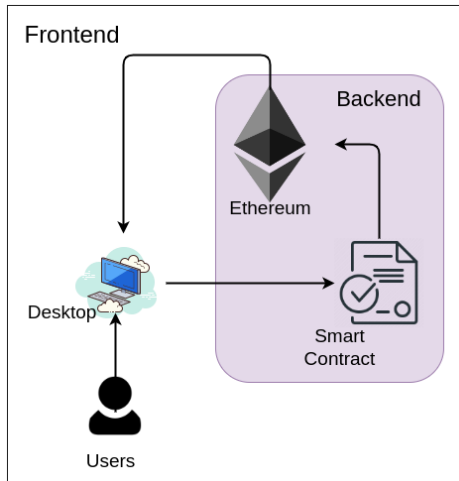

Fig. 1. System architecture.

As depicted in Fig. 1, our system has two distinct parts: front-end and back-end. The front-end is built using React.js and the back-end is developed using the Ethereum blockchain.

Our system involves three key actors: the administrator, faculties, and students, each with a unique set of functionality that will be performed from their particular dashboard. To ensure anonymity, students provide feedback through customized forms accessible from the front-end of the system. This feedback is processed through smart contract and securely stored on the Ethereum blockchain. The administrator and faculties can easily access this feedback through their respective dashboards, which retrieve the data directly from the blockchain.

The student feedback system's diagram is clearly illustrated in Fig. 2 below, which depicts the various actors and their functionality and how the system is working. To initiate their engagement with the system, users are required to establish a connection to their Metamask wallet, followed by a secure login procedure employing a unique username and password. Once the username and password are validated, the system will identify the user's role, which may be administrator, faculty, or student. Depending on their role, users will be redirected to their corresponding dashboard, where they can perform specific functions tailored to their needs. The administrator can use the dashboard to manage user accounts, including registering new faculty and student accounts, creating new courses, and viewing all student feedback. Students, on the other hand, can use their dashboard to get enrolled in courses, and write and send feedback to specific faculty members and courses. Students are only able to submit feedback once in a course and cannot modify their responses afterward. Finally, faculties can access and view all feedback directed to them via their dashboard.

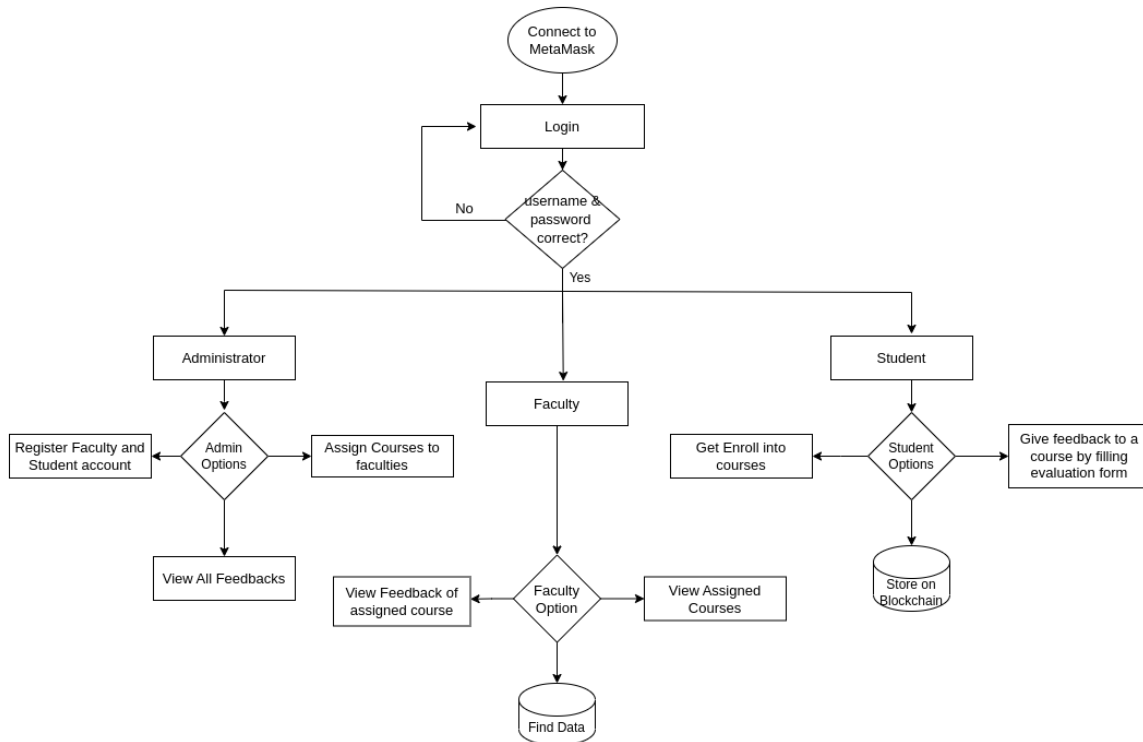

Fig. 2. Diagram of the proposed system.

## A. Working Procedure

We have developed a student feedback web application using blockchain technology. The whole procedure is divided into five phases described below.

*1) Registration phase:* In this phase, the administrator registers new student and faculty accounts by accessing create account option from the dashboard. Once created, these accounts can be used by students and faculties to log in to the system. The user password will be encrypted and stored on the blockchain. Also, the administrator will register all courses offered by the institution. The students can enroll in these courses later, and validation is done during the registration of user accounts and courses.

*2) Login phase:* Our web application begins with a login page where users are required to connect their Metamask wallet and enter their usernames and passwords. The system verifies the password against the encrypted hash stored in the blockchain. If the password matches, users gain access to their accounts and are redirected to their respective dashboards based on their roles (administrator, faculty, or student).

*3) Course enrollment phase:* During this phase, students will self-register for courses by accessing the enrollment option on their dashboard. They can view the institution's course list and enroll in a specific course by clicking on it.

Fig. 3. Student feedback form.

*4) Submit feedback phase:* During this phase, students will provide feedback on courses and instructors by accessing the give feedback option on their dashboard. They select the course and faculty member for evaluation and fill out a

feedback form with questions about the course and instructor. Our application's feedback evaluation form is illustrated in Fig. 3. The evaluation form consists of ten questions collected from the teaching evaluation system of Southeast University, Bangladesh. These questions help to evaluate the performance of the faculty. Each question carries a weight between 1 and 5 using a Likert scale from 1 (strongly disagree) to 5 (strongly agree). We have calculated an average rating point out of 10 from the Likert scale responses submitted by students to assess the faculty's performance. Students are also encouraged to provide comments along with their chosen rating.

*5) View feedback phase:* In this phase, both the administrator and faculty members can access student feedback through their respective dashboards. Administrators have access to all course feedback, while faculty members can only view feedback for their assigned courses. Fig. 4 below shows the feedback page, displaying student ratings and comments. Moreover, we have created a formula to assess faculty performance in each course on a scale of 0 to 100 percent. The formula is the sum of total ratings divided by the number of feedback submissions, then multiplied by 10. Every faculty member will see a performance rating against a course here which is measured by the above formula.

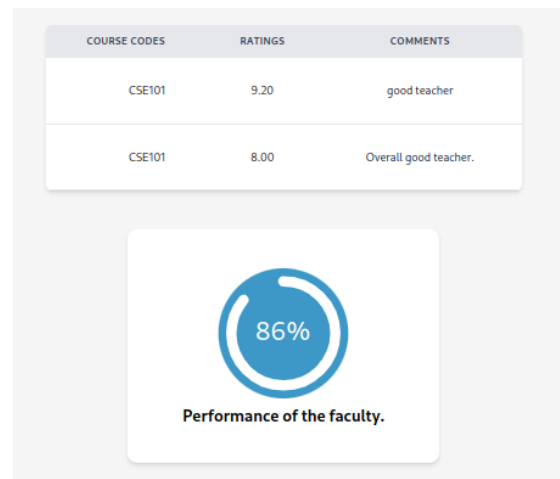

Fig. 4. View feedback page.

## B. Implementation

This section focused on the implementation of the project code. We described the pseudocodes of functions and the tools used to build the project.

---

**PSEUDO CODE 1**: Function to create new user account

```
1: function createUserAccount(username, password, role):
2:     if the caller is the contract owner then
3:             Create → new user account property
4:             Store ← new user account information
5:     else
6:             return "Caller is not the contract owner"
7:     end if
8: end function
```

---

The "createUserAccount()" function serves as a pivotal feature, granting administrative personnel the authority to

create new student and faculty accounts within the system. This function receives username, password, and role as parameters and is triggered when the administrator creates a student and faculty account from the client side.

---

**PSEUDO CODE 2:** Function to submit feedback

---

1:function submitFeedback( userAddress, courseCode, rating, comment):
2:     if the user has already submitted feedback then
3:          return "Your feedback already exists"
4:     else
5:          Create → a new feedback object
6:          Store ← the feedback
7:          Update → feedback track
8:     end if
9: end function

---

submitFeedback() function allows the student to give feedback or do an evaluation against a course. The function validates that a student can submit feedback into a course for once.

---

**PSEUDO CODE 3:** Function to view feedback

---

1: function getFeedback( courseCode ):
2:     return a list of feedback for the specified course code.
3: end function

---

getFeedback() function returns all feedback stored into the blockchain. This function allows the administrator and faculties to view feedback given by the students.

*C. Used Tools*

We utilized a variety of tools to effectively achieve the project objectives and outlined the specific tools used in this project below:

*1) Ethereum blockchain:* Ethereum is a blockchain platform that has its own digital currency known as Ether (ETH)[25]. Vitalik Buterin created it in 2014 [26]. It supports the development and deployment of decentralized applications. It is not controlled by any central authority [27].

*2) Solidity:* It is a powerful, user-friendly, and object-oriented language used to write smart contracts that operate on the Ethereum Virtual Machine.

*3) MetaMask:* It links users to the Ethereum blockchain and allows them to use the Ethereum wallet through a browser extension or mobile app. This allows them to interact effortlessly with decentralized or web3 applications [28].

*4) Remix:* Remix is an open-source online Ethereum IDE. It is the smartest way to write contracts using the Remix IDE[29]. We can use it to write, compile and debug code. We wrote and deployed smart contracts from here.

*5) ReactJS:* It is a JavaScript library created specifically for constructing dynamic and interactive user interfaces using a component-based approach [30]. It is used to develop front-end of our web application.

## IV. RESULTS

We conducted a survey involving a limited number of students to explore their perceptions of the traditional teaching evaluation system. Our findings revealed that a significant portion of the students expressed apprehension about providing honest feedback due to concerns about their anonymity being compromised. They believe that the conventional database-driven feedback system falls short of providing complete anonymity. Subsequently, we introduced our Blockchain-based teaching evaluation system, which garnered significant interest among the student participants. A number of students chose to utilize our system and reported high levels of satisfaction, citing its ability to ensure absolute anonymity.

For the development and experimental validation of our proposed system, the Remix Integrated Development Environment (IDE) serves as the primary tool for composing and assessing the smart contract. Subsequently, to facilitate thorough testing procedures, the smart contract is deployed onto the Remix virtual network, effectively replicating a decentralized environment for examination. Within the context of our smart contract design, a singular entity, known as the "smart contract deployer," assumes the authoritative role of the system's administrator.

Once the smart contract passed the testing phase, we proceeded to deploy it on the Goerli test network. Metamask wallet wanted confirmation during deployment. Upon successful deployment of our smart contract, the contract was created and its address was returned to the Remix IDE. We collected this smart contract address and ABI( Application Binary Interface) from Remix IDE. This contract address and ABI were used to make communication between front-end and blockchain. Our newly deployed smart contract address is 0x6F04207829759752079DEE48136fd447c3F6198f. The source code of our feedback system is made accessible through the following link: https://github.com/uttamsaha/Web3-Student-Feedback-System

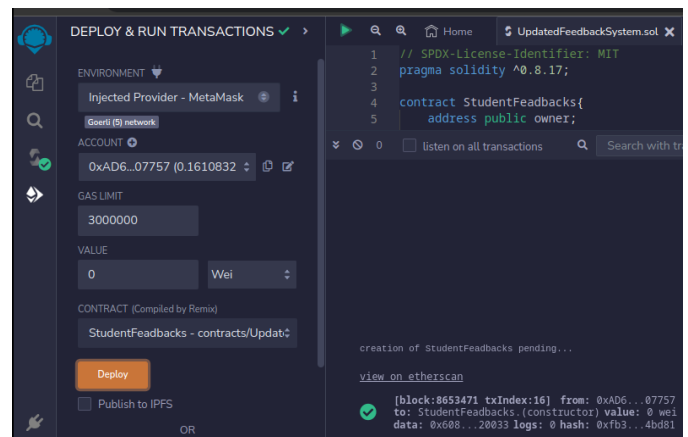

Fig. 5.    Deploy smart contract to Goerlitestnet.

Fig. 5 shows that we deployed our smart contract on the Goerlitestnet network.

## V. DISCUSSIOIN

We have conducted a comprehensive comparison between our newly implemented teaching evaluation system and the existing blockchain-based system, presenting our key findings. The existing system in [22] allows students to give feedback only but the proposed system allows evaluating the

performance of a faculty in a course along with giving feedback. This existing system is quite manual for generating a permission list that maintains who can give feedback in a course, but it was maintained automatically in this work. Instead of knowing all usernames and passwords, the administrator or someone else cannot perform any action or view on student and faculty accounts because we developed and mapped the user information using their Metamask wallet address. This enhances the overall security measures. The traditional and existing system does not give such features

In our system, we implemented a robust encryption mechanism to safeguard user passwords during storage within the blockchain. Subsequently, when the user's login function is called, the stored password is decrypted securely. This encryption-decryption process serves as an integral aspect of our security infrastructure, augmenting the overall protection of user credentials and sensitive data. Furthermore, we devised a comprehensive performance evaluation approach for faculty members, quantifying their performance in courses through a percentage-based assessment. This helped the authority to know how a faculty is performing in the class. To uphold the integrity of the feedback process, we meticulously designed the system to ensure that each student is limited to providing feedback to a faculty member once and also ensured students can get enrolled in a course once.

## VI. CONCLUSION

In today's digital age, feedback stands as a critical element for organizational enhancement and progress. Nonetheless, parallel to the imperative of obtaining valuable feedback is the need to safeguard the security and anonymity of the contributors. Preserving confidentiality emerges as a substantial challenge for any feedback system, as participants might harbor apprehensions about potential identity exposure. Consequently, feedback systems necessitate meticulously crafted designs that incorporate advanced security measures, effectively addressing these concerns and ensuring robust privacy and confidentiality. The challenges of ensuring confidentiality and security in feedback systems find a compelling resolution through the adoption of blockchain technology. Its inherent attributes, including decentralization, tamper-proofing, enhanced security, and anonymity, make it an ideal fit for addressing these concerns. Recognizing the potential of blockchain, our organization has harnessed its capabilities to construct a cutting-edge student feedback system that prioritizes both anonymity and security for its users. By leveraging blockchain, our system empowers users to freely and honestly express their feedback without the fear of their identity being exposed or facing repercussions. That is how our feedback system becomes more effective, reliable, trustworthy, and secure.

The feedback system does not permit modifications. Consequently, if a student inadvertently submits an incorrect evaluation, there is no opportunity to revise it. In our system, where user anonymity is maintained, someone may purposefully provide negative feedback with the intention of harming a candidate's reputation. As the system will rely on blockchain technology for maintenance, the transaction rate is expected to be relatively slow.

The knowledge we've gained through this experience can be applied to other feedback systems or adapted for different applications in the future. Companies that rely on rating mechanisms can seamlessly integrate our feedback system into their operational framework, leveraging its robust features to enhance their feedback collection and analysis processes. Also, this system can be used to develop a survey management and evaluation system using blockchain.

Visvesveraya Technological University, Belagavi-590018, India[2]

*Abstract*—A Mobile Ad-hoc Network (MANET) is a temporary wireless network that configures itself as needed. Each MANET node has a finite number of resources and serves as both a node and a router at the same time. MANET nodes are mobile and move from one location to another. Because MANET nodes are dynamic, choosing an optimal node for data transfer is a difficult issue. Because packets must propagate in a multi-hop manner, they take a longer path and may endure a longer delay, causing them to become lost in the network. The network's overall performance suffers as a result of the re-transmission of those lost packets. We propose a modified version of a nature-inspired algorithm called Petal Ant based Dynamic Routing (PADR) in this research study, which reconstructs data packets to traverse inside a given region and achieves minimal delay during data transmission. The PADR is simulated in Network Simulator (NS2) and compared against nature-inspired routing protocols like PAR and SARA, as well as traditional routing protocols like AODV.

*Keywords*—*Petal ant routing; dynamic petal ant routing; MANET; ant colony optimization*

## I. INTRODUCTION

In our day-to-day lives, wireless communication networks are becoming increasingly crucial [3] [12]. Wireless devices connect, exchange, and transfer data wirelessly, giving them a substantial level of mobility [20]. Infrastructure-based networks and infrastructure-less networks are the two types of wireless networks available [1] [19]. Wireless devices communicate in infrastructure-based networks through a centralized administration, such as a base station or an access point [28]. The wireless device communicates directly with no pre-existing communication infrastructure in an infrastructure-less network, which is known as an Ad-hoc Network. Mobile Ad-hoc Network is an example of an ad-hoc network (MANET) [5].

The Mobile Ad-hoc Network is a transitory wireless network made up of a collection of wireless devices such as laptops, PDAs, and mobile phones that may dynamically configure, communicate, and react with no central administration [6][7]. Because MANET's nodes are mobile, they connect to other networks using a regular Wi-Fi connection [23]. Because MANET mobile nodes communicate with one another over a wireless medium, the devices must establish a communication link and send data to others even when they are not in direct transmission range [14][30]. MANETs, in general, forward data in a multi-hop fashion and

serve as routers even when no infrastructure equipment is present [16][31]. Congestion, routing, security, and other challenges arise as a result of a MANET's absence of infrastructure equipment [18] [29]. One of the most important challenges is routing, because when determining the best way for data transmission, complications like delay, performance, throughput, and overheads can generate a slew of problems and reduce network efficiency [4] [15]. As a result, additional strategies are required to overcome such difficulties with high node mobility, according to [25] [17]. A Routing in a MANET is a common theme that has resulted in numerous routing protocols in the literature and has remained a difficult issue for the past few decades [21] [22].

The key contributions and originality aspects of the proposed routing are as follows:

*1) To* identify the shortfalls of existing PAR route discovery procedure. We provide a cutting-edge technique for obtaining petal width from static to dynamic petal between end nodes.

*2) Our* approach aims to maximize the data delivery rate between end-to-end nodes during data transmission by discriminating the mobile node during the process. We propose an innovative technique of electing the nearest neighboring node so that delay and routing overheads between end nodes is minimum as quoted in the algorithm. This impacts the performance and user experience of various applications and services in the real world.

*3) For* each of the proposed tests, 20 simulation runs were conducted ranging from 15 to 150 mobile nodes, and an average value was calculated at the end of the simulation. The suggested routing algorithm is evaluated for various metrics such as packet delivery fraction, throughput, overhead and delay, and the results are compared with PAR routing.

Overall, this article proposes an extension of the ant colony optimization technique, a nature-inspired algorithm that optimizes both the route discovery and route maintenance mechanisms for data delivery from groups of mobile nodes in MANETs. The proposed technique evaluation results demonstrate its effectiveness in discriminating node during route discovery and provides better performance than PAR routing strategy. The following section contains various related works, our contributions, and an analysis of the results.

## II. RELATED WORK

Hua Wang, Z ao Shi, et al. (2008) [2] proposed a modified Ant Colony algorithm for ad-hoc networks that included a progressive changing orientation component and used it to solve multi-constraint routing problems. The gradual changing orientation factor's directionality allows the ants to consider direction when searching for a path, allowing them to proceed fast to the end node and so improve convergence speed by overcoming the slow convergence setback. According to the author, an ant in the improved algorithm not only uses prior search findings, but also lowers the misguiding influence of pheromones on improper paths, overcoming the sluggish convergence problem. The results of the experiments show that the ant colony algorithm with progressive shifting orientation factor outperforms the standard ant colony algorithm in terms of convergence time while also avoiding the risk of a local best solution.

Saptarshi Benerjee et al., [9] (2015) suggested a new MANET routing strategy based on on-demand multipath power balanced routing. The routing protocol in [9] is a modified version of the ACO architecture, and it consists of three phases: Route Discovery, Route Maintenance, and Route Failure. The routing algorithm updates the pheromone value in the routing table using the battery charge of a mobile node as the major parameter. During the route discovery phase, the routing algorithm uses the identical Forward Ant (FANT) and Backward Ant (BANT) generated by the source and destination. The source establishes the communication channel to the destination based on the pheromone value obtained by the probability of battery charge of mobile nodes. In OMNET++ version 4.5, the routing algorithm is simulated for a small-scale network. The simulation findings show that the ACO algorithms give better packet delivery count convergence than the existing ACO algorithms.

B Jayalalitha et al., (2016) [11] For MANET, the ANT Colony Optimization Routing (ACOR) algorithm was presented as a variation of the ant routing technique. The ACOR is proactive routing, similar to AntHocNet, which sends out control packets regularly. The author of ACOR modified the Ant-route proto-header packet and successfully complied for execution, but the packets were not transmitted from source to destination node. In NS2, the ACOR is modeled and compared to AntHocNet, AODV, and DSR. According to ACOR, AntHocNet, AODV, and DSR simulation results, the ACOR builds the routing table but fails to transport packets between end nodes.

Ajay Kumar et al., (2017) [15] the importance of MANETs is discussed, as well as the disadvantages of routing for temporary networks. The author of [10] introduced the Efficient Fuzzy based Multi-constraint Multicast Routing protocol (EFM- MRP), which uses fuzzy logic to supervise uncertainty issues. The algorithm calculates the fuzzy cost and chooses the best path between end nodes with the lowest fuzzy cost, then sends the data to a group of receivers. In NS 2.35, the EFMMRP is simulated for 15 to 300 mobile nodes. For mobility, the EFMMRP employs the random waypoint network model, while the propagation model is based on the free space propagation model. The EFMMRP is compared to the On-demand Multicast Routing Protocol (ODMRP) and the Multicast Ad-hoc On-Demand Distance Vector Routing Protocol (MAODV). The simulation results of EFMMRP, ODMRP, and MAODV show that EFMMRP outperforms ODMRP and MAODV in terms of delay, bandwidth, and energy metrics when faced with uncertainty.

Dipika Sarkar et al. (2018) [20] proposed the Enhanced Ant-AODV routing protocol for MANET, which is based on Quality of Service (QOS). The Enhanced-Ant-AODV is a reactive technique for MANET route selection that combines AODV with ANT. In the frame format of the AODV route request and route reply packet, an extra field called Pheromone count has been added. Based on the pheromone value, hop count, congestion, and reliability of the path between the end nodes, the Enhanced-Ant-AODV chooses a finite route for data delivery. The path with the highest pheromone value is chosen as the optimum data delivery path. In NS 2.35, the Enhanced-Ant-AODV is simulated and tested with the AODV and DSR MANET routing protocols.

Valanto Alappatt et al. (2020) [18] to solve the issue of routing, the authors proposed Ant Colony Optimization and Binary Particle Swarm Optimization (ACO: BPSO), a modified version of the ant colony optimization technique for mobile ad hoc networks. The ACO: BPSO is a hybrid approach for enhancing the network's lifetime that combines Ant Colony Optimization and Binary Particle Swarm Optimization techniques. In NS2, the ACO: BPSO routing protocol is simulated for 50 nodes and compared to the regular AODV routing system. Based on the simulation results, the author of [18] claims that the ACO: BPSO hybrid strategy outperforms the AODV routing protocol in terms of packet delivery rate, throughput, and residual energy.

## III. PROPOSED ALGORITHM: PETAL ANT DYNAMIC ROUTING (PADR)

As described in several research proposals published in the literature, real ants are able to find the fastest and most efficient road to get from their food source to their nest in response to their environment [26] [13]. Petal Ant based Dynamic Routing (PADR) is a reactive routing system that is a variant of the Ant Colony Optimization (ACO) Algorithm. When a wireless node is out of transmission range, the PADR divides the network into a Petal Region ($P_w$), which makes it easier for the node to choose a destination from the source. The detailed description of the proposed algorithm is as follows:

The Petal Ant based Dynamic Routing (PADR) algorithm has three phases namely

- Route Discovery,
- Route Maintenance, and
- Route Repair

### A. Route Discovery

Consider the example of a small network of 10 nodes shown in Fig. 1. The wireless mobile nodes are represented by the alphabets A, B, C, D, E, F, G, H, and I, with the node S denoting the Source, D denoting the Destination, and the other nodes denoting the Intermediate node in the network. If any

source node seeks to construct a data path to a destination node during the route discovery phase, the PADR divides the network into petal regions ($P_w$). If S does not have a routing table entry for destination D in its routing table, node S divides the network into petal regions as illustrated in the Fig. 1 using equations (1, 2, 3), where ($x_s$ , $x_d$) and ($y_s$ , $y_d$) are the longitudes and latitudes in real-time measurements of node S and D, d is the distance of S & D, "c" is a variable (minor axis), "a" is 50% of d and "b" is 50% of c.

Fig. 1.    PAR - petal region calculation.

$$\sqrt{(x_d - x_s)^2 + (y_d - y_s)^2} \tag{1}$$

$$h = (x_{s+} x_d)/2 \,, \ k = (y_{s+} y_d)/2 \tag{2}$$

$$\mathrm{Pw} = \pi ab \tag{3}$$

Once the petal width between end nodes has been determined, the source propagates P_FANT across the network. The rebroadcasting of the P_FANT packet is delayed until it reaches D, which response with P_BANT as an acknowledgment to the P_FANT packet. The route discovery procedure of PADR is depicted in Fig. 2 and Fig. 3.

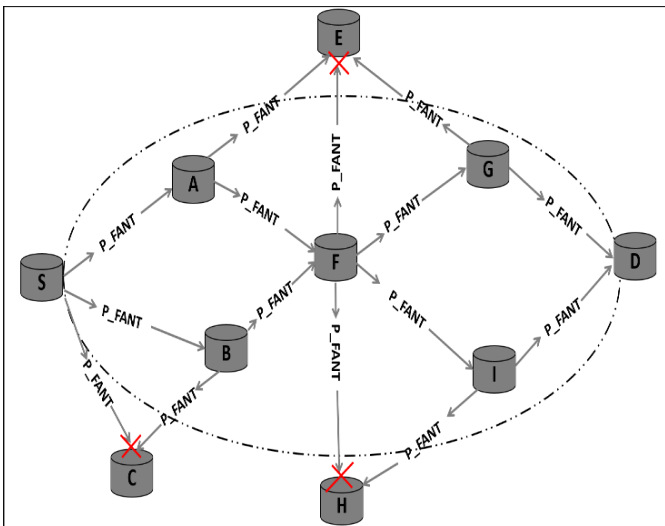

Fig. 2.    PADR – P_FANT propagation.

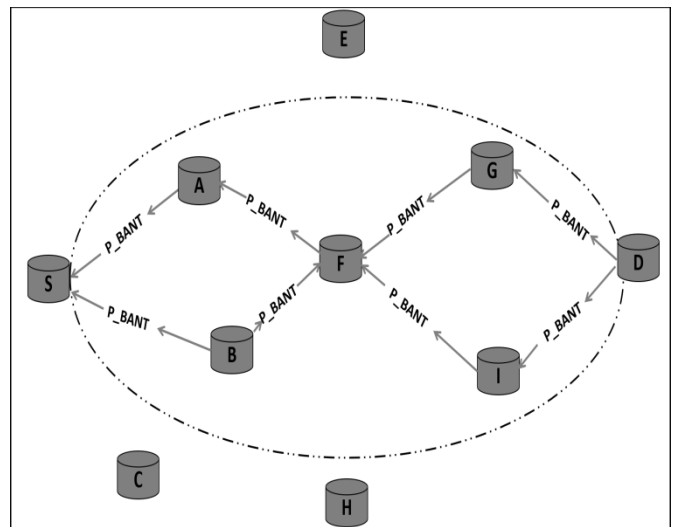

Fig. 3.    PADR - P BANT propagation.

### B. Route Maintenance

By balancing the pheromone concentration, the second phase of the PADR algorithm includes a route management procedure that keeps track of active and updated routes during data communications [24]. A link quality and activity are determined by its pheromone concentration. The link with the most data traffic has the highest pheromone levels, whereas the link with the least data traffic has the lowest.

$$\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} \ \le 1 \tag{4}$$

The analysis of the pheromone difference provides considerable information about the network status, as the authors have already investigated in [2] [6], the data path with the highest pheromone level is the one that draws the most traffic [27]. The routing processing component of the PAR [8] algorithm has been significantly improved to model the PADR. Assume the data flow between the source and destination is via S-A-F-G-D and S-A-F-I-D in the scenario depicted in Fig. 4. PADR proposes an alternative path when a node travels outside the ($P_w$) region, as shown in Fig. 5.

Fig. 4.    PADR - Data Path - 1.

**Onreceiving APacket()**
**if** *recvPADRPkt(Packet* p)* **then**
    **if** (*PADR_DATA_Packet*) **then**
        Increase the pheromone intensity between the intermediate link (i,j)
        **if** *intermediate node observe the link breakage between node link (i,j)* **then**
            Change the pheromone value from i – j to zero
            Broadcast link failure message to all nodes
            Source node tries to obtain alternative path to destination
            **if** (*Source found alternative path*) **then**
                Start sending data packet on the new path
            **else**
                Source initiate new route discovery process
            **end**
        **else**
            **if** (*Intermediate node lies inside $P_w$*) **then**
                Intermediate node increase the pheromone intensity in the link (i,j)
                Source continues to transmit the data packet on the same path
            **else**
                Change the pheromone value from i – j to zero
                Intermediate node drops the packet and does not forward the packet to its neighbor node
            **end**
        **end**
    **end**
**end**

**Algorithm 1: PADR Route Maintenance**

The PADR checks whether the mobile node is inside the ($P_w$) region using Eq. (4). PADR's data transmission is shown in Algorithm 1.

Fig. 5. PADR- Data Path – 2.

*C. Route Repair*

The PADR algorithm's third phase includes a route repair process, which is started when a broken path between end nodes is detected. Due to restricted resources such as inadequate signal strength, bandwidth, congestion, power outage, or failure of radio coverage, broken path situation in MANET might occur often, necessitating a rapid route setup

procedure during active data sessions [8]. PADR finds an alternative path inside the $\pi * a * b$ area if a broken path is discovered during an active data session. PADR initiates a new route discovery procedure if no path between source and destination is discovered.

## IV. RESULTS AND ANALYSIS

This section compares and evaluates the performance of the PAR, SARA, AODV, and proposed PADR algorithms in Network Simulator (NS2) running on Ubuntu Linux version 18.04. The ACO framework method is used in the PAR, SARA, and suggested routing algorithms, but the AODV is a normal traditional-based routing algorithm. The PAR coding implementation in NS2 version 2.35 has been improved to behave like PADR. A network of nodes ranging from 15 to 150 nodes dispersed across a 1000 x 1000 m geographic region was used to test the proposed PADR. Table I lists the essential parameters and exact values used during the simulation investigation.

*A. Study of Packet Generation*

For the PADR, PAR, SARA, and AODV routing algorithms, Fig. 6 illustrates the total number of packets generated and sent by the source node to the destination across the network. The nature-inspired method creates more data packets than the conventional based routing technique, according to the simulation analysis of PADR, PAR, SARA, and AODV. When compared to the PAR, SARA, and AODV algorithms, the number of packets generated by the source node of PADR is higher because the source node receives a faster response from the destination for establishing a path through intermediate nodes, so the source starts transmitting

packets in the network right away. According to the graph in figure 6, the PADR creates 6.16% more packets on average than PAR, 9.61% more packets than SARA, and 26.5% more packets than AODV routing approaches.

TABLE I.      SIMULATION PARAMETERS

| Parameter | Values |
|---|---|
| Interface queue type | Queue/DropTail |
| Radio-propagation model | Propagation/TwoRayGround |
| Number of nodes | 15, 30, 50, 75, 100 & 150 |
| Channel | Channel/WirelessChannel |
| Simulation area Size | 1000 x 1000 |
| Simulation Time | 160s |
| Packet size | 512 bytes |
| Mac type | 802.11 |
| Node speed | 0 m/s to 10 m/s |
| Transport protocol | TCP |
| Routing protocol | PAR and PADR |
| link layer type | LL |
| Network interface | Phy/WirelessPhy |

### B. Study of Packet Received

For the PADR, PAR, SARA, and AODV routing algorithms, Fig. 7 depicts the total number of packets received by the destination node across the network. The routing algorithms PADR, PAR, SARA, and AODV are used. The nature inspired algorithm outperforms the classical based routing technique even at packet acceptance by the destination, according to the simulation analysis of PADR, PAR, SARA, and AODV. This is because in the ACO algorithm, the path with higher pheromones value attracts more data packets in the network. According to the graph in Fig. 7, the PADR's destination receives 11.12% more packets on average than PAR, 14.66% more packets than SARA, and 47.42% more packets than the AODV routing technique.

Fig. 6.   Network size vs. packet sent.

Fig. 7.   Network size vs packet received.

### C. Study of Packet Delivery Fraction (PDF)

The analysis for packet delivery fraction for PADR in comparison to PAR, SARA, and AODV approaches is shown in Fig. 8. There are two main reasons why an intermediate node cannot participate in data transmission in PADR. If the node is outside the $P_w$, the pheromone value of that nearby links is zero, and if node moves outside the Pw, the pheromone value of the neighboring links is zero. In the latter case, data packets from intermediate (upstream and downstream) nodes with the connection value zero are deleted. The delivery rate of data packets is high in PADR because each node traverses all of the data packets within Pw. According to the graph in figure 8, PADR performs 0.103% better than PAR, 0.055% better than SARA, and 11.42% better than AODV routing technique.

### D. Study of End-to-End Delay

The end-to-end latency of PADR is shown in Fig. 9 in comparison to PAR, SARA, and AODV routing techniques.

Fig. 8.   Network size vs. packet delivery fraction.
Fig. 9.   Network size vs. end-to-end delay.

Fig. 10.  Network size vs. throughput.

Because the path with a higher pheromones value attracts more data packets, PADR has better end-to-end delay outcomes than PAR and SARA, but is slower than AODV. Pheromone concentration, on the other hand, lowers as time passes owing to pheromone evaporation. As a result, the ACO algorithm uses a restricted number of paths, which attracts an excess of traffic to the same routes, resulting in a nearly constant high end-to-end delay [2]. Because, in PADR, when a node with a data path travels outside of the $P_w$, the upstream node discovers an alternative path to downstream node within $\pi * a * b$ as shown in Fig. 5. As a result, PADR has a lower delay and latency than PAR and SARA routing approaches. The end-to-end delay of PADR is 8.65% less than PAR, 11.06% less than SARA, and 47.45% more than AODV routing approach, according to the graph in Fig. 9.

### E.  Study of Throughput

The throughput represents the path's quality and the number of data packets delivered to the destination during a given period of time. The throughput of PADR is shown in Fig. 10 in comparison to PAR, SARA, and AODV routing

techniques. In comparison to PAR, SARA, and AODV routing, PADR gives superior throughput simulation time, according to the simulation data. PADR gives an average of 6.17% more throughput than PAR, 9.69% more than SARA, and 32.50% more than AODV routing approach, according to the graph in Fig. 10.

### F.  Study of Routing Overheads

The routing overhead of PADR is shown in Fig. 11 in comparison to PAR, SARA, and AODV routing algorithms. PADR has slightly greater overhead than PAR and SARA, but less than AODV, according to the simulation results. Because nodes move beyond the $P_w$, PADR considers extra Pw computation during route maintenance sessions, the overhead in PADR is slightly higher. Despite the fact that PADR consumes more overhead than PAR and SARA, it outperforms them in all of the listed measures.

Fig. 11.  Network size vs. routing overheads.

### V.   CONCLUSION

This research article introduces Petal Ant Dynamic Routing (PADR), an upgraded version of a nature-inspired method. The proposed work's major goal is to improve Quality of Service (QOS) in terms of performance, throughput, and networking latency. The proposed routing is simulated in NS 2.35 and compared to MANET routing domain related work. According to the simulation results, PADR outperforms AODV, SARA, and PAR in terms of packet generation, packet delivery fraction (PDF), end-to-end delay, and throughput, while using PADR slightly higher routing overheads than PAR.

# Hybrid Syntax Dependency with Lexicon and Logistic Regression for Aspect-based Sentiment Analysis

Mohammad Mashrekul Kabir, Zulaiha Ali Othman, Mohd Ridzwan Yaakub, Sabrina Tiun

Universiti Kebangsaan Malaysia (UKM), Bangi 43600, Selangor, Malaysia

*Abstract*—**Aspect-based Sentiment Analysis (ABSA) is a fine-grained form of SA that greatly benefits customers and the real world. ABSA of customer reviews has become a trendy topic because of the profuse information that is shared through these reviews. While SA also known as opinion mining helps to find opinion, ABSA greatly impact business world by converting these reviews to finer form with aspects and opinion or sentiment. These review words are interwoven internally, which depends on the semantics besides syntax, and sometimes there are long dependencies. Recently, the hybrid methods for ABSA are popular, but most of them merely considered if the syntax and long dependency exist, thus missing the inclusion of multi and infrequent aspects. In addition, in most literature, sentiment classification is shown directly without calculating the sentiment scores in ABSA. To this effect, this paper proposes a hybrid with syntax dependency and the lexicon for aspect, sentiment extraction, and polarity classification by Logistic Regression (LR) classifier to overcome the issues in ABSA. The proposed method is able to address the challenges of ABSA in a number of ways. First, it is able to extract multi-word and infrequent aspects by using syntactic dependency information. Second, it is able to calculate sentiment scores, which provides a more nuanced understanding of the overall sentiment expressed towards an aspect. Third, it is able to capture long dependencies between words by using syntactic dependency and semantic information. The proposed hybrid model outperformed the other methods by an average of 8-10 percent with the standard public dataset in terms of accuracy.**

## I. INTRODUCTION

The extensive growth of the Internet resulted in an evolution in online businesses. The statistics show that the tourism industry's GDP earnings constantly increase between 6% and 10%, which shows tourists' growth [1]. Due to this growth, there is an extraordinary volume of data that includes customer reviews that can be explored to get customer feedback on products or services. Reviews focus on comments or opinions that provide prospective customers with insightful information. Most people are impacted by opinions, particularly product ratings, which have proven to affect customer behaviour. Moreover, web-based information is more accurate and trusted than that supplied by the manager or product supplier [2], which needs to process through sentiment analysis.

Earlier literature only focused on sentiment analysis (SA) or opinion mining [3-14], without aspects. Later, Bing Liu (2012) provided the latest definition of aspect-based SA. According to Liu (2012), 'an opinion is defined as a quintuple' (ei, aij, sijkl, hk, tl), where e is an entity, a is an aspect, and s is sentiment [15]. This provided the foundation of Aspect-based Sentiment Analysis (ABSA). In Aspect-based Sentiment Analysis, deriving aspects and their sentiment or opinion from these text paragraphs is challenging. It is necessary to recognize and connect specific texts for aspects and to look for particular sentiments to derive aspect-based sentiment analysis. For instance, a restaurant review may read, "Foods are wonderful, but the location is awful." The review remarks, in this case, focus on two aspects. The "location" is one aspect, and the "food" is another. In this example, there are two opinion terms. They are both "wonderful" and "awful." Aspect-based Sentiment Analysis comprises three tasks. First is the identification of aspects, the second is the identification of its' sentiment or opinion terms, and last is the orientation detection of sentiment or opinion terms, that is, aspect sentiment classification. Three basic methods are used for ABSA tasks: machine learning-based method, dictionary-based, and hybrid method [16–18].

In the first ABSA task of aspect extraction, there are at least two problems. First is the difficulty of multi aspects extraction. For example, in the review- "The hotel is perfectly located, with good rooms, but we could not eat the food; it was tasteless". In this review, a traveler expresses opinions on multi aspects, such as location, rooms, and food are highlighted in the review. Secondly, extracting infrequent aspects, for example, Wi-fi, swimming pool, and car parking, are less frequent, but these have significant importance in the hotel and restaurant domain. There isn't a single solution in the available aspect identification methods [19-29] that adequately addresses all of the aforementioned aspect identification concerns. Therefore, there is a need for a solution to address these difficulties collectively. Different methods have been offered in the literature for each issue. This inspired us to devise a method for single-aspect extraction that can handle multi and infrequent aspects.

Similarly, in second ABSA task of sentiment classification of recognized aspects, issues with managing multi-aspect reviews exist. Since numerous aspects of a review are presented, and each is favorable or negative, classifying multi-aspect reviews is difficult. Each aspect can have a positive or

negative sentiment among multiple aspects discussed in a review. Thus, classifying multi-aspect reviews is difficult. For example, let us analyze the following quote from a hotel review: "Our room was very pleasant, but the hotel staff was rude. An ideal location for a family with children, offering a clean bathroom and lovely views". The reviewer expresses opinions on the "staff," "room," and "location", among other things. The review demonstrates that different parts have varied sentiments, with 'staff' having a negative and 'room' and 'location' having a positive sentiment.

This challenge of sentiment classification of multi-aspects has not been addressed by the methods presented in the literature [24, 30-36]. To our knowledge, no machine learning (ML)-based approach is currently available for aspect classification that successfully manages this challenging issue. Therefore, we contend that aspect-based sentiment classification can only improve if aspect classification methods can effectively handle multi-aspect problems.

In this article, we propose an aspect-based sentiment classification framework, and our contributions are three-fold; (1) a hybrid method, an extension of syntax, and dependency - based has been proposed for multi-aspect extraction; (2) a method has been devised for accurate identification of infrequent aspects and (3) an effective mechanism with classifier has been developed for calculating reviews score and decide the polarity for classification of aspects. To do this, it put forward a model that used hybrid syntax, lexicons and dependency parsing to extract user aspects, sentiments, and reviews of sentiments. A lexical dictionary called SentiWordNet helps determine each opinion word's positive and negative polarity values [38-40].

There are six sections to this paper. Section II presents the related works. The study methodology is shown in Section III. The performance findings of the experiment and results are described in Sections IV and V respectively.. The research implications and the summary of the study are presented in the last section, in Section VI.

## II. RELATED WORKS

Aspect-based Sentiment Analysis can be divided into two primary tasks: aspect extraction and aspect-based sentiment classification. There are three fundamental methods for aspect-based sentiment analysis: machine-learning-based, dictionary-based, and hybrid methods. The machine learning based method includes a wide range of various rules-based, seed-based, and supervised methods. Rules-based uses importance score and frequency of occurrence to identify aspects. Jime'nez-Zafra et al. [19] have suggested a method that uses a bag of words with aspect terms based on frequency using the Freebase dataset, including tourism. In this method, aspects were compiled from the lexicon and rated by how often they appeared in reviews. Wang et al. [21] have suggested a part-of-speech (POS) tagger method. Frequent morphological and inflexional ends were eliminated using a unique Porter stemming method to pick the possible aspects. This method was used to quickly and automatically identify words with identifiable spellings. Afzaal et al. [24] suggested a better approach based on fuzzy-based learning. This approach involved extracting frequent nouns and noun phrases from the

reviews. But this could not address multi aspects. Despite being simple to use and effective in the identification process, rule-based methods do not address some issues. For instance, rule-based approaches generate small rules, extract irrelevant aspects, and cannot identify infrequent aspects.

Seed-based method use grammatical relationships between seed sets and review terms to identify key aspects. [25] produced a seed set for each of the five most frequent aspects from reviews, using the co-occurrence of various words. This helps to identify the key aspects of a review. Mukherjee et al. [26] suggested a seed-based strategy to determine semantic relationships between review terms. Kayaalp et al. [27] proposed a three-step seed-based feature extraction technique. First, choose the top four restaurant review topics-—food, service, price, and ambience; second, properly tag and index terms; and lastly, classify indexed words based on proximity. Seed-based approaches lack consideration of review words' links, require in-depth topic expertise, and are insufficient for covering entire domains. For instance, the whole domain of a normal hotel or restaurant cannot be covered by food, service, pricing, and ambience since this domain comprises many other vital aspects.

The supervised method predicts sentiment as a combination of themes using topic model-based approaches. Wu et al. [28] utilized a combined probabilistic model to identify aspects based on overall importance, user importance, and likelihood of inclusion in multiple aspect sentiments. Shams et al. [29] proposed an enhanced LDA model using co-occurrence associations for precise aspects of reviews.

After aspect extraction, the aspect sentiment classification literature is reviewed. This task consists of two subtasks: first, sentiment word extraction and then, determining polarity or ABSA. This task also uses three methods: ML, Lexicon and hybrid method. Mubarok et al. [30] used a three-step ML model for classification tasks, pre-processing reviews, applying feature selection using chi-square, and dividing reviews into polarity classes using Naive Bayes classifier. The model achieved 77% accuracy in aspect-based classification. Xu et al. [31] use SVM for ML-based techniques in traveller reviews to predict sentiments about several aspects of reviews. [32] utilized sentence-level reviews of electrical devices and mobile phones for classification after statistical aspect extraction. [33] processed reviews, cleaned, stemmed extracted features and predicted polarity using the BOW model. The literature in [34] used sophisticated pre-processing techniques, including tokenization, word removal, filtering, stemming, and sentiment classification. The research in [35] method involves pre-processing, phrase extraction, BOW extraction, sentiment score calculation, and classification. The procedure involved in [36] were pre-processing, feature extraction, classifier training, testing, and labelling tweets. In [38], document classification methods involved pre-processing, segmentation, feature extraction and SVM.

The second method uses dictionary-based sentiment analysis using lexicon, like SentiWordNet. The literature [41], used pre-processed data using tokenization, removing stop words, noise, duplicates, missing values, and stemming. Sentiment polarity detection was performed using

SentiWordNet, while sentiment classification features included chunking, segmentation, and N-grams. The study in [42] utilized pre-processing techniques, hyper-parameter selection, word vector representation for aspects, and CBOW and skip-gram models for sentiment classification.

In the third sentiment classification method of ABSA, Santhosh et al. [43] used POS tag for aspect-opinion pair formation, and final polarity detection. Nisha et al. [44] used a hybrid with unsupervised ML method LDA with lexicon. Kushal et al. [45] used text formatting with fuzzy matching and domain grouping of synonym words, aspect extraction with POS tagging, association mining and probabilistic approach, opinion extraction with words extraction, and final polarity detection for aspect-opinion pair, and aspect-based summarization. Wu et al. [46] used a hybrid with supervised and dependency POS tagging features, but it cannot extract multiple aspects and doesn't calculate the score of sentiment words.

A chunk-level extraction technique was developed by Wu et al. [47] combined a hybrid of rule-based and supervised learning methodologies to extract neutral aspects of ABSA but could not identify multi aspect. Zainuddin et al. [48] proposed a hybrid sentiment classification approach using Twitter datasets to improve the Twitter Aspect-based Sentiment Analysis using association rule mining (ARM) and a rule-based dependency parser. This hybrid used a dependency parser but missed syntax, therefore, could not find multi aspect. Later, Akhtar et al. [49] hybrid used Conditional Random Field (CRF) and Support Vector Machine (SVM) in the Hindi language. Hu Liu's [50] benchmarking literature combined POS tag and Association Rule Mining to detect the most frequent noun aspects. Zhou et al. [51] used a hybrid with semi-supervised learning algorithm to capture cross-domain features.

The literature above shows different combinations of hybrid, the first one [37] with unsupervised ML method LDA and lexicon. [47] and Hu Liu [50] used POS tags with association rule mining to detect frequent noun aspects, but this literature cannot address infrequent aspects. The study in [51] used a hybrid with semi-supervised learning algorithm. The authors in [46] used hybrid with supervised and dependency POS tagging features. But it could not address multi aspect. Zainuddin's hybrid added dependency parser with association rule mining, but it lacked to find grammatical relationships with syntax, thus missing multi-aspect and infrequent aspects.

These challenges inspired us to develop a technique to handle these difficult aspect extraction situations. This paper proposed a novel hybrid with syntax, dependency, Lexicon and classifier to solve the multi aspects extraction, including infrequent aspects.

## III. PROPOSED HYBRID MODEL

The proposed hybrid model is shown in Fig. 1. The suggested system is divided into four main phases: pre-processing phase; aspect extraction phase; extraction of sentiment words; and finally, sentiment polarity calculations and sentiment classification. The suggested system accepts as input a text (or review) that has been divided up into sentences.

The system pre-processes the input sentences and parses them using a dependency parser, which offers a morphological analysis of each word in the phrase and a dependency structure for the sentence. The algorithm uses POS data and the polarity lexicon SentiWordNet (SWN) to extract the pertinent features and sentiment words. The algorithm then creates a dependency graph for the sentence, aiding in the execution of aspect-based SA. The sentiment word is allocated to the specific aspect, with the shortest distance from the aspect word based on the premise that closely related words combine to create a sentiment toward a particular feature. The proposed hybrid model for aspect sentiment classification is shown in Fig.1.

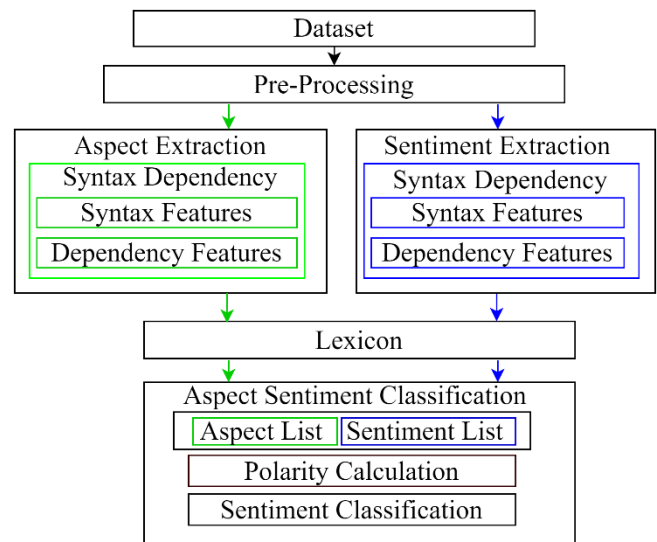

Fig. 1. Proposed hybrid Model for aspect sentiment classification.

The model has four major phases as preprocessing, aspect extraction, sentiment extraction and aspect sentiment classification. These are discussed below:

### A. Pre-processing

Data was gathered from a public dataset of customer reviews from hotels (in Europe and the US). This dataset was pre-processed. This paper used the NLTK library of Python for data preprocessing. This data preprocessing is a critical step that includes cleaning and formatting the data before feeding it into the ML algorithm. For NLP, the preprocessing steps had the following tasks: tokenizing the string, lowercasing, removing stop words, and stemming. Tokenization is used to split the strings into individual meaningful tokens. For the tokenization, NLTK module is used. Then, we converted each word in the string to lowercase. The next step is to remove stop words that do not add significant meaning to the text, such as 'I', 'we', 'own', and 'only', using the NLTK list. Next, stemming is performed, converting a word to its most general form, or stem. NLTK's porter stemmer is used to reduce the size of our vocabulary; for example, the 'using' word stems from 'use'.

### B. Aspect Extraction Phase

This model aims at Aspect-based Sentiment classification task of ABSA but for that it needs to derive aspects. Aspects may be one or many words that typically refer to nouns and noun phrases. The process for aspect extraction is described for

clarity. This paper used a hybrid method with syntax, dependency parsing and lexicon for aspect extraction which is described below:

*1) Syntax features:* The syntax-based approach analyses sentence to seek the links between the words in a phrase to determine its grammatical structure. The difficulty in identifying connections between words is influenced by the structure and pattern of the phrases in a sentence. Words in customer reviews adhere to certain grammatical and linguistic conventions. Syntax based method used syntax-based features. After pre-processing, it first identifies each word's Part of Speech (POS) tag in each review line to extract the aspects. It selects NN (noun, singular), NNS (noun, plural), NNP (proper noun, singular), and NNPS (proper noun, plural) tagged terms from the review file as aspects, tokenizing the review texts using a POS tagger. The frequent aspect terms are extracted with a POS tagger with noun and proper nouns.

*2) Dependency parsing:* This hybrid method first finds frequent aspects. For infrequent aspects, this paper used dependency parsing. The dependency parser is used to identify specific relations, which help determine infrequent aspects. Therefore, the author used nsubj (nominal subject), amod (adjectival modifier), advmod (adverbial modifier) and xcomp (casual component with external subject).

*3) Lexicon:* One important stage in the process of analysing text sentiment is matching aspect terms to a lexicon. The aspect words are matched to the Lexicon. The most popular lexicon SentiWordNet is used here due to its rich vocabulary. SentiWordNet stands out among the numerous lexicons accessible because of its large vocabulary and thorough coverage. Wide-ranging words are included in SentiWordNet, which assigns them sentiment ratings based on their positive, negative, and neutral meanings. A more detailed comprehension of the underlying sentiment in a given text is made possible by the sentiment analysis algorithms' ability to assign sentiment values to aspect words thanks to this broad vocabulary. Sentiment analysis algorithms may more accurately capture the finer details of sentiment conveyed in natural language by using SentiWordNet's lexical resources.

## C. Sentiment Extraction Phase

The important stage in ABSA is to detect and extract opinion words. Opinion words convey a person's opinion on a subject; therefore, it is essential to identify aspect-related opinion terms at this phase. It consists of syntax features, dependency parser and Lexicon module.

*1) Syntax features:* The author finds the opinion words using POS tagging with adjective words. According to Hu Liu (2004), the most opinion words are adjectives. Study suggests that adjectives and adverbs are effective markers of subjectivity and views [48]. An adjective that modifies a noun or noun phrase that is frequently present in aspect-based extraction is referred to as being close. Consequently, if such an adjective is present, it is regarded as a sentiment or opinion term.

*2) Dependency parser:* For infrequent sentiment words, we use a dependency parser. These can be adverbs and verb combinations. Later, the opinion orientation for each aspect was determined. When the context of a sentence is determined, the patterns are separated into segments, such as adjective-noun, adverb-adjective, noun-noun, noun-adjective, and adverb-verb combinations.

*3) Lexicon:* SentiWordNet, a lexicon of opinion words, was used, which aids in identifying each word's positive and negative polarity meaning and scores. Each synset of Wordnet words has been given positive and negative scores. When the context of a sentence is determined, the patterns are separated into segments, such as adjective-noun, adverb-adjective, noun-noun, noun-adjective, and adverb-verb combinations.

## D. Aspect Sentiment Classification

This model aims at aspect-based sentiment classification task of ABSA but for that it needs to derive aspects. Aspects may be one or many words that typically refer to nouns and noun phrases. The process for aspect extraction is described for clarity. This paper used a hybrid method with syntax, dependency parsing and lexicon for aspect extraction which is described below.

*1) Calculation of sentiment polarity:* Some literature, compute a sentiment score for each sentence and then link that sentiment to every aspect that is addressed in that sentence when performing sentiment analysis. However, this makes it impossible to handle phrases correctly when they contain aspects with multi sentiments. Therefore, this hybrid method suggests a system in which every sentence is divided into segments, each of which is assigned to a different aspect of the sentence. The polarity of each segment is then established using a sentiment lexicon, and an aspect-polarity pair is created that reflects the overall polarity for this aspect inside a specific review. SentiWordNet is used for aggregating opinions using the sentence's cumulative score. First, aspects are mapped to opinions, and an aspect opinion pair is formed. The opinion words are matched to the opinion lexicon in SentiWordNet, and the score is calculated. Table I shows calculation of sentiment score. The reviews has one aspect but multi opinion, the 'food' is the aspect and the first opinion 'very good' is positive. The score is 0.91 and the second opinion word of food is 'expensive' which is negative so the score is -0.50.

Table II shows calculation of polarity. At first scores are calculated and negative scores are subtracted from positive, thus the final score is calculated.

TABLE I. CALCULATION OF SENTIMENT SCORE

| Review | Aspect Opinion | Score | Total Score |
|---|---|---|---|
| food is very good but expensive | {'aspect': 'hotel', 'opinion': 'very good'} | 0.91 | +0.41 |
| food is very good but expensive | {'aspect': 'hotel', 'opinion': 'expensive'} | -0.50 | |

TABLE II.      CALCULATION OF POLARITY

| Review | Total Score | Accumulated Polarity |
|---|---|---|
| food is very good but expensive | (+0.91-0.50) = +0.41 | **Positive** |

*2) Handling negations:* The words and phrases known as "opinion shifters" may cause a user's view to shift from favourable to negative or vice versa. The most frequent opinion-shifting words are: not, neither, nobody, none, nowhere, and cannot. For instance, a client may write in their review, "I am not satisfied with the time they take to deliver the purchase." The word satisfied has a positive valence in this statement. However, it contains the negative "not." The polarity of the whole phrase shifts from positive to negative due to the existence of this negative word. Table III & Table IV, showing calculation of sentiment score with negations and polarity.

TABLE III.      CALCULATION OF SCORE (HANDLING NEGATIONS)

| Review | Aspect Opinion | Score |
|---|---|---|
| there is **not** very good food items | {'aspect': 'food items', 'opinion': 'not very good'} | -0.26 |

TABLE IV.      CALCULATION OF POLARITY (HANDLING NEGATIONS)

| Review | Score | Accumulated Polarity |
|---|---|---|
| there is not very good food items | -0.26 | Negative |

*3) Sentiment classification:* The entire number of aspects, together with their sentiment scores, will be calculated, aggregating the sentiment scores of all the opinion terms. At first, aspects' positive and negative scores were individually recorded. As a result, we get the total positive and negative scores for that aspect. These findings created a sentiment profile for each restaurant or product. The scores for each aspect may be added up using the method below. For each jth aspect of the review,

Accumulated_Positive _polarity[j] = Σi Positive_Poly, j

Accumulated_Negative _polarity[j] = Σi Negative_Poly,j

After this, the data was divided into training and test data. Accumulated polarity information from Table III and Table IV above is fed. Finally, classifiers trained with training data and it carry out classification with test data.

*E. Performance Evaluation Measures*

To assess the overall classification performance using binary classes, we employ accuracy metrics (positive and negative). This paper uses the common assessment metrics of precision, accuracy and recall for both positive and negative feelings about things. Based on the output of the confusion matrix, this research employed four efficient measures: True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN) [48].

## IV.   EXPERIMENT

The experiment is implemented using Python, version 3.7. The hotel reviews datasets of Europe & the US hotels are used in the experiment.

*A. Dataset*

This research has collected hotel data from a public dataset of hotel reviews in Europe & the US. The dataset used is huge (515k hotel reviews), containing 515,000 customer reviews and scoring 1493 luxury hotels across Europe & the US [52]. The data was scraped from Booking.com. This data is in an unstructured format in CSV and contains 17 fields, such as: hotel address, review date, Average Score, Hotel Name, Reviewer Nationality, Negative review, Review Total Negative Word Counts, Positive Review, Review Total Positive Word Counts, Reviewer Score, Total Number of Reviews Reviewer Has Given, Total Number of_ Reviews, Tags, Days since review, Additional Number of_ Scoring, lat, and lng.

## V.   RESULTS AND DISCUSSION

The experiment entailed examining the performance levels of the hybrid with classifiers, where the input features included review texts and the output was sentiment classification with aspect's sentiment summary (aspect based). Here this paper gives two-fold results for better understanding. The first one is comparison of the proposed model with other literature and the second is on the application of the result in hotel where, a comparison is made between aspects of various hotels. The hybrid method creates a training set first and then annotates the training data. The training data are then used to extract aspects, sentiments, and score calculating which are subsequently used for test dataset.

*A. Results*

The results shown are twofold. The first is the comparison of the proposed model in Table V and in Table VI, the valuable insights are enumerated.

*1) Comparison of the proposed model:* The comparative result is shown in Table V below. It is observed that, all hybrid of different combination results is measured with precision, recall and accuracy. The hybrid model of Wu et al. [46] with supervised and POS tagging had accuracy of 67.66%, where another literature of the same author with LDA and Lexicon achieved low result with accuracy 64.24%. Zainuddin used ARM and dependency, obtained better accuracy compared to the previous state-of-art method using Twitter dataset. Akhtar used CRF and SVM and it performed accuracy 54.05% (the lowest). Hu Liu literature hybrid with ARM and lexicon achieved better in recall as 80%, accuracy 75.8%. Zhou hybrid achieved the lowest performance with 46.55% in precision. The proposed hybrid used syntax dependency, lexicon and LR and achieved precision, recall and accuracy of 84.7, 86.6 and 84.2% respectively.

TABLE V.     COMPARISON WITH THE PROPOSED MODEL

| Refs. | Method | Measures (in percentage) | | |
|---|---|---|---|---|
| | | Precision | Recall | Accuracy/F1 |
| Wu et al. [46] | Hybrid (supervised+ POS tagging) | - | - | 67.66 |
| Wu et al. [47] | Hybrid (LDA and lexicon) | 58.94 | 70.59 | 64.24 |
| Zainuddin et al. [48] | Hybrid (ARM +dependency) | 77.9 | 76.6 | 76 |
| Akhtar et al. [49] | Hybrid (CRF and SVM) | - | - | 54.05 |
| Hu Liu [50] | Hybrid (ARM and lexicon) | 72 | 80 | 75.8 |
| Zhou [51] | Hybrid (semi-supervised learning + adversarial training) | 46.55 | 44.57 | - |
| Proposed model | Hybrid (Syntax Dependency+ lexicon and LR) | 84.7 | 86.6 | 84.2 |

*2) Experimental output of aspects and sentiments-the valuable insight of aspects:* A sample of 30 hotels with a total of 1057 user reviews is analysed for finding the sentiment score of the basic features of a hotel as "location", "services", "food". After frequency counts, five aspects are generated: food, location, comfort & facilities, staff, and value for money. The experimental output on four of the mentioned aspects, i.e., location, comfort & facilities, staff, and food are shown in Table VI. Location aspects in detailed (Year/ month wise) output is shown. The result of location aspects of five hotels' including the other aspects average (avg) is shown in the Table VI below.

TABLE VI.     COMPARISON OF VARIOUS ASPECTS AND BETWEEN HOTELS

| Hotel Name | Location (Year / Month wise) | | | | | | | | | | Comfort & Facilities (Avg) | Staff (Avg) | Food (Avg) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Fairfield Inn | .55 | .45 | .46 | .93 | .74 | .65 | .55 | .78 | .82 | .77 | .65 | .74 | .55 |
| Little Paradise | .46 | .49 | .44 | .39 | .6 | .94 | .65 | .74 | .52 | .57 | .72 | .6 | .57 |
| Days Inn El Reno | .63 | .65 | .71 | .57 | .37 | .44 | .41 | .45 | .27 | .41 | .44 | .37 | .41 |
| Hawthorn Suites | .38 | .73 | .68 | .41 | .45 | .42 | .48 | .47 | .65 | .45 | .42 | .45 | .65 |
| Comfort Suites | .43 | .36 | .34 | .30 | .27 | .48 | .72 | .63 | .56 | .72 | .48 | .47 | .56 |

"Fig. 2", shows output comparison of location aspects between five hotels of USA. The location score is plotted in Y axis at a scale of 0 to +1, and X Axis shows the time (Year / Month). The average (avg) is calculated and shown beside the name of hotel. Fairfield Inn is number 1 (grey colour dash and dotted) hotel of US in terms of location, with average sentiment score 0.77, Little paradise (dotted lines) is the second hotel in US, followed by Days Inn El Reko (dash dash) with average 0.586, Hawthorn Suites is the fourth (average 0.516, and Comfort Suites is the fifth (ash colour) with average sentiment score 0. 486.Therefore from the result customer who looks for good location will choose Fairfield as it is the best.

Similarly, customer can choose hotel basing on his or her preference of aspects.

Fig. 2.  Comparison of "Location" aspect between US Hotels.

"Fig. 3", below shows sentiment Analysis & overall sentiment score of Hotel Comfort Suites. The Y axis shows the sentiment score from 0 to +0.8, and -0.8. The X axis shows time in Year & Month. This is the time of review. The dotted are expressed for positive and dashed are used for negative sentiment expression. Sentiment Analysis & overall sentiment score of Hotel Comfort Suites is shown in Fig. 3 below.

Fig. 3.  Sentiment analysis & Overall sentiment score of Hotel Comfort Suites.

*B. Discussions*

The discussions are twofold. The first is the proposed model and secondly on the valuable insights from the experiments output as in Table VI. These are described below.

*1) Comparison of the proposed model:* The hybrid model evaluation of comparision results can be summarized as:

- The results suggest that the proposed hybrid model is an effective way to perform aspect-based sentiment analysis on hotel reviews.

- Table V shows a comparison of the proposed hybrid model with other state-of-the-art literature. As it can be seen, the proposed model outperforms all other models in terms of precision, recall, and accuracy.

- The hybrid model was able to extract five aspects from hotel reviews: food, location, comfort & facilities, staff, and value for money.

- The hybrid model was able to generate a sentiment score for each aspect of each hotel.

- Overall, this hybrid performed much better than all state-of-the-art literature compared.

*2) Aspects and sentiments-the valuable insight of aspects:* The hybrid model results can be summarized as:

- Table VI shows a comparison of the different aspects of five hotels in the USA. As it can be seen, Fairfield Inn has the highest average sentiment score for location, followed by Little Paradise, Days Inn El Reno, Hawthorn Suites, and Comfort Suites.

- The sentiment scores for each aspect of each hotel can be used by potential guests to choose the hotel that best suits their needs.

- Fig. 2 shows a comparison of the location sentiment scores of the five hotels in the USA over time. As can be seen, Fairfield Inn consistently has the highest location sentiment score.

- Fig. 3 shows a sentiment analysis of Hotel Comfort Suites over time. As can be seen, the overall sentiment score of the hotel is positive.

Overall, the results of the experiment suggest that the proposed hybrid model is an effective way to perform aspect-based sentiment analysis on hotel reviews. The sentiment scores /polarity generated by the model can be used by potential guests to choose the hotel based on aspect that best suits their needs.

## VI. Conclusion and Limitations

In this paper, we propose hybrid model with syntax dependency, lexicon with logistic regression to extract multi aspects and sentiments. By introducing the positional features with syntax dependency to address long dependencies, to deal with multi aspects. We used aspect-based sentiment analysis of the customer reviews with public hotel dataset of US and Europe. The experiment focused on five generalized aspects location, comfort and facilities, staff, food, and value for money. The score of sentiment polarity for aspects in the review is calculated. Finally, for every aspect as mentioned, the mean of the aggregated score of sentiment polarity generated. The experiment results are quite promising and found better in comparison to the state-of-the-art literature. Clearly, the work is able to summarize the sentiment of customer reviews on the four basic aspects. From a business intelligence perspective, knowing about the aspects a hotel offers is crucial. The aggregated outcome will help user to know which hotel is best for which aspect and can decide better. This research offers insightful conclusions on the aspect-based sentiment analysis of hotel reviews. As future work, we shall try to improve experiment result accuracy by using various dataset. The dataset was limited to hotel only in future the other datasets can be explored. We also would replicate this for other aspects like

value for money, weather, etc. and for reviews written in other languages.

*Abstract*—Cloud computing revolves around storing and retrieving data in a portable manner. However, practical data portability across multiple Database-as-a-service (DBaaS) cloud data stores is challenging. This becomes even more complicated when data needs to be migrated between different types of data storage, such as SQL and NoSQL databases. NoSQL databases have gained significant popularity among developers due to their ability to provide high availability, fault tolerance, and scalability, making them suitable for managing big data in large-scale infrastructures. However, the varied data models in NoSQL databases make it difficult to migrate or port data among data repositories. Object to NoSQL database mappers (ONDMs) solves this problem. However, only a few ONDMs are available for C#.NET development, and the ONDM market used in Java development could be more stable. To address this issue, we propose building a middleware solution using the .NET framework to support cloud data portability, leveraging the capabilities of ONDMs. In this study, we evaluate several frameworks and compare them to our suggested middleware solution through empirical research. Our middleware solution can perform open network data management (ONDM) and object-relational mapping (ORM).

*Keywords—NoSQl; Portability; Cloud; middleware; platform as a service; platform services*

## I. Introduction

Cloud Computing has become a pre-eminent paradigm for hosting modern software systems, and the database layer is the most valuable and extensive layer of a software system [1-2]. The heterogeneity of cloud service providers (CSPs), the data stores they offer, and the software systems pose substantial impedance while developing an approach for cloud data migration. However, the database-related requirements of modern applications call for polyglot persistence [3]. An application that leverages persistent polyglot databases is considerably more arduous to design and implement than an application using just one backend [7]. The overhead of configuration, deployment and maintenance keeps increasing with each DB used. This makes implementing polyglot persistence quite tricky without the detailed know-how of involved DBs.

### A. Data Models

The use of more than one data model within a single system has become a usual practice for modern application development [4]. The cloud computing paradigm supports both of the types of models for data storage:

*1) Relational (SQL) data models:* Relational data models are schema-based, store data in the form of tables, and maintain ACID (Atomicity, Consistency, Isolation, and Durability) properties. They prevailed since the 1970s when E.F Codd proposed they orchestrate the data into tables (or relations) consisting of rows (also known as records/tuples) and columns (also known as attributes). Each table has a unique key called the primary key which identifies each row and may have a foreign key that represents a primary key of some other table for cross-reference [5].

*2) NoSQL data model:* The acrostic for NoSQL means "Not Only SQL" rather than completely against the traditional relational databases (DBs), as is commonly misunderstood. Carl Strozzi1, in 1998 first time, used the term "NoSQL" to name his open-source relational DB "Strozzi NoSQL". This DB used APIs with several plugins and libraries instead of using SQL for accessing the data. NoSQL data stores are distinguished in the following four categories based on data and query models, and persistence design [6]:

*a)* Key-Value DBs represents a model based on keys-values and are easy to implement. These are suitable to store session information, user profiles, or storing shopping cart data. Examples include Redis, Voldemort, Riak.

*b)* Document DBs in which semi-structured documents are stored in JSON format (XML and YAML formats are also supported), are suited for big data storage and better query performance. Examples are MongoDB, Apache CouchDB, and Cosmos DB.

*c)* Column family DBs represent a model for storing and processing huge amounts of data, which is distributed over various machines without rigid consistency. Examples are Apache Cassandra, HBase, and Apache Accumulo.

*d)* Graph DBs which are suitable for storing relationships between entities. Examples are Neo4j, OrientDB, and AllegroGraph.

Each mired data store possesses its specific benefits. Relational DBs are favored if the data to be stored concerns financial transactions, as these DBs abide by transactional properties. On the other hand, the evolution of the Internet, social networking sites, and Cloud Computing has disputed the domination of relational DBs as the only selection of DBMS. Various considerations like prices, the volume of data, and the speed at which the data is being generated as well as consumed, dictate how and where the storage and management of the data.

## II. OBJECT TO NoSQL DATABASE MAPPERS (ONDMS)

A single application may need heterogeneous DBs for the various types of requirements, for example [7]:

- For User Sessions: Redis is best suited for quick access for reads and writes without having to be durable.

- For financial data and reporting: RDBMS (Relational database management system) is required as this kind of data needs transactional updates. Moreover, data would better fit in a tabular structure.

- Product catalog: MongoDB is best as it supports a lot of reads and infrequent writes.

- Analytics and user activity logs: Cassandra can better handle a high volume of writes on multiple nodes.

And there may be many more types of requirements for application data, leading to the selection of appropriate DBs. Therefore, the application may require the simultaneous use of different DBs (relational as well as NoSQL, called Polyglot persistence) on different cloud platforms and also a data migration from one kind of data store to another, of similar type (SQL to another SQL) or dissimilar type (SQL to/from NoSQL). As there is a looming dearth of standardized query languages, it poses an adverse technical lock-in while building applications against the native interfaces of NoSQL data stores [8]. The solution to evade vendor lock-in caused due to selecting a particular database technology is to leverage Object-NoSQL Database Mappers (ONDMs). ONDMs offer a uniform abstraction interface for heterogeneous NoSQLs. ONDM frameworks decouple applications from database specifics and provide data portability [14].

- Handling the conversion of objects to the relational data model and vice versa.

- Managing persistence to the destination DB.

- Providing software developers with a uniform data access interface to store and query objects programmatically.

Our middleware's architectural design is a Repository pattern. Repositories are classes that contain the logic necessary to access data sources. They consolidate common data access functions, improving maintainability and separating database access from the domain model layer. Because of strong typing, the code that must be implemented to use our middleware is simplified. This allows us to concentrate on the business logic rather than the data access plumbing. ONDMs are developer-centric and let the developers carry the application abstractions without having to be cognizant of the database and use these databases without expecting a level of expertise in those [5]. The benefits of using ONDMs include simplifying porting of an application to other NoSQL data stores and database interoperability as well as polyglot persistence [9]. There are ONDMs called Multi Data Store Mappers supporting multiple NoSQL data stores and ONDMs called Single Data Store Mappers supporting only a particular system [10].

- Kundera2: It is a capable JPA-based object-datastore mapping library that greatly cuts down the programming efforts needed to perform CRUD operations on NoSQL data stores.

- Spring Data3: It is an umbrella project that alleviates the use of data access technologies, namely relational and NoSQL, Map Reduce frameworks, as well as cloud-based data services. It provides a Spring-based data access programming model that preserves the special features of the underlying data stores [18].

- DataNucleus4: We also tried another industry-ready ONDM framework, 'Data Nucleus' for the implementation but faced the following difficulties [19].

- Mongo - The library exposed by DataNucleus and JavaMongo lib had clashing classes in the same classpath. This created issues while building the application [20].

- MySQL - Framework was enhancing model classes after running the maven enhancement step, as mentioned in the documentation. Still, it was not able to detect them at the time of attempting to persist the object [23].

So, we dropped DataNucleus for the comparison with our proposed middleware. Our selection of databases to be implemented tried to find the databases that are not only quite prevalent and ripe but also have great applicability in specific fields [22] [24]. MongoDB and Cassandra are the most prominent NoSQL databases in the market. MongoDB produces high throughput, and Cassandra supports horizontal scalability [25]. MongoDB is supported by almost all ONDMs, followed by Cassandra. Our selection of databases tried to find the databases that are not only quite prevalent and ripe but also have great applicability in specific fields [26].

## III. IMPLEMENTATION TECHNOLOGY - .NET CORE

We have created a custom data model based on Twitter data set to benchmark the proposed middleware and the other frameworks. Some of the key features of .NET Core platform are highlighted below.

- The. NET Core is a new version of Microsoft. NET Framework is a free, open-source, general-purpose programming platform. It is a cross-platform framework that works on Windows, macOS, and Linux [28].

- The .NET Core Framework may be used to create a variety of applications such as mobile, desktop, online, cloud, IoT, machine learning, microservices, and so on.

- The .NET Core is developed from the bottom up to be a modular, lightweight, fast, and cross-platform Framework [30]. It offers the essential capabilities necessary to run a basic.NET Core app. Other functionalities are available as NuGet packages, which you may add to your application as needed [30]. As a result, the.NET Core program performs faster, has a smaller memory footprint, and is easier to maintain.

It is a new platform that is gaining traction in the industry, but there are no ONDM frameworks available for it. This is one of the main reasons to opt .NET Core framework for our middleware implementation [31]. Although Microsoft provides its ORM for .NET Core named ENTITY FRAMEWORK, it is strictly an ORM (that means it is only for RDBMS mapping to objects and not for NoSQLs). Table I presents that most of the ONDMs available are for Java language [32] [34]. Although individual NoSQL database drivers [14] or wrappers are available for the C# language, there are no mature ONDM frameworks for C#.

TABLE I.    ONDM FRAMEWORKS SUPPORTED BY DIFFERENT OBJECT-ORIENTED PROGRAMMING LANGUAGES

| OOPL | ONDM Frameworks | Inactive Frameworks |
|---|---|---|
| Java | Apache Gora, Kundera, Data Nucleus, EclipseLink, Eclipse JNoSQL, Spring Data, Hibernate OGM, GORM | Java |
| Python | KEV, pyDAL | NA |
| JavaScript | JS Data | Resourceful |
| Node.JS | Thinodium, Bass, Waterline, JS Data | JugglingDB, Cleverstack, Node Docu- |
| PHP | Lithium, Yii framework, Doctrine | KO3-NoSQL, Vork |
| C#.NET | | Slazure, Charisma |
| Scala | Lift | Activate Framework |

Definitions

- Poly DB: The frameworks support multiple types of database systems (i.e., relational and NoSQL).

- Wrapper: The library is a wrapper around a database system; this means it might not be an object-mapper (e.g. driver). It just interfaces with the application, but it may not have the capability of object mapping [35].

- ODNM: The framework has objected to NoSQL database mapping capabilities.

- Strict OR/NDM: The framework strictly has either ONDM or ORM mapping functionality [36].

OUR proposed middleware [1] is all POLYDB (as it is supporting multiple DBslike SQL Server, MongoDB, and Cassandra) as well as ORM and ONDM.

- Mongo - The library exposed by DataNucleus and JavaMongo lib had clashing classes in the same classpath. This was creating issues while building the application.

- MySQL - Framework was enhancing model classes after running the maven enhancement step, as mentioned in the documentation. Still, it was not able to detect them at the time of attempting to persists the object.

- SpringData - The Challenge was to integrate with the DBs only. Enough documentation is available to make the application ready.

- OBDApi - There was code in the application that was creating issues while building the application. We needed to remove the unnecessary pieces to make it work.

- Kundera SQL - No major challenge apart from integrating with the DB and adding code for our use case. Analyzed the code to identify how it will work.

In the paper [11], the author introduces and defines the term "ONDM (Object-NoSQL Datastore Mapper) is a framework to facilitate the storage and retrieval of persistent objects in NoSQL datastore systems". In [6] it has been studied state-of-the-art ORMs and dedicated ONDMs that are capable of handling disparate NoSQL data stores. This work studies the performance of the abstraction layers for NoSQL data stores with an emphasis on the runtime performance impact. In the paper [9] also, the authors provide a performance evaluation of various ONDM frameworks [9]. The main difference to our work is that we perform a more comprehensive performance evaluation and contemplate with academic frameworks [12] and [13]). Table IV reveals that most of the ONDMs are available for Java language. [14] Although individual NoSQL database drivers or wrappers are available for C# language, there are no mature ONDM frameworks for C#. We compare analytically our proposed middleware with the academic frameworks CDPort and ODBAPI as well as industry-ready ONDMs viz. Kundera and Spring Data. The proposed middleware relieves the user of these saddles of dealing with the specific APIs. All he needs to do is change the connection string in the application configuration file (appsettings.json).

### A. Our Contribution

We offered a middleware solution created in.NET to allow cloud data portability, which corresponded to the capability of ONDMs in terms of performance and functionality. In this study, we compare our suggested middleware solution with the other frameworks and conduct an empirical evaluation of each of the frameworks. This paper demonstrates that our middleware can serve as both an ORM and an ONDM. Some of the core contributions have been mentioned below.

*1)* We discussed various data models used for storing data.

*2)* ONDMs (Object to NoSQL data mappers (Academic and Industrial)) have been also discussed.

*3)* Available ONDMs are mostly developed for Java developers and to the best of us knowledge, no ONDM is available for .NET developers. We developed .NET ONDM in previous paper and validated it by comparing it with other ONDMs (two academic and two industrial).

*4)* The results we got after experimentation proved our middleware have comparable performance with respect to the above said ONDMs.

## IV. RELATED WORK

Data portability has been taken up by researchers in the literature, where it is considered a mechanism that enables the migration of data as well as enhances interoperability across multiple heterogeneous cloud platforms [15]. While working towards data portability among clouds, the requirement of converting one type of database into another rises owing to the numerous types (SQL and NoSQL) and data models (key-value, columnar, document-oriented, and graph) of the databases offered by the providers. One solution is the mapping of objects to NoSQLs which essentially corresponds to the functionality of ODNMs. We have also proposed a solution to support cloud data portability in [1], which maps the objects into cloud NoSQLs (MongoDB and Cassandra). Other solutions include [16]:

- SQL fication of NoSQL databases with SQL-like wrappers which generally provide various features corresponding to those of classical relational database query language while retaining a grammar identical to that of SQL

- Meta-model approaches which abstract from the data models by identifying the common concepts in different NoSQL solutions' data models.

The rivet of the middleware is that the application, the database, and the platform basic services (such as message queues, email, and SMS service) are so loosely coupled that each of these can be ported to any of the clouds (supported by the middleware) without having to rewrite much code in the application. Although a plethora of research efforts has been done towards data portability, our proposed work relates to [12, 13]. To the best of our knowledge, data migration among clouds (where data previously stored in one cloud is shifted/copied to another cloud) is not much covered in the literature. Some notable research works towards data portability are discussed in Table II.

TABLE II. ANALYSIS OF THE RELATED WORK

| Ref. | Solution approach | Work Done |
|------|-------------------|-----------|
| [17] | Design patterns | This paper proposed an effective design pattern method for shifting data from a columnar DB (HBase) to a graph DB (Neo4J) and vice versa. However, this work appears to be only a suggestion, as no implementation work is provided in this or any subsequent publications published by the author (to the best of our knowledge). |
| [18] | Service Delivery Cloud Platform (middleware) and common API | This paper proposed a cloud middleware infrastructure called SDCP and offered a common API to deliver three cloud services viz. Storage, DB, and Notification service. Using JPA (Java Persistence API) methods, they provided abstraction for DB access. |
| [19] | CSAL (Cloud Storage Abstraction Layer) | An abstraction layer is also provided here in order to give common storage abstraction to diverse cloud providers. The layer also creates a namespace that programmers may utilize to support blobs, tables, and queues. |
| [20] | Abstraction layer | This paper presented a mediation-based approach to integrate SQL and NoSQL DBs to retrieve data from either of them. Moreover, their proposed extended SQL can execute join queries as well. |
| [21] | GUI tool, point to point the translator | This thesis work implemented a Graphical User Interface tool that alleviates the data migration from relational DB to NoSQL document data stores. |
| [22] | NoSQLayer | This paper focused on the automatic translation of SQL queries to NoSQL by proposing a framework called "NoSQLayer". The focus here is in query execution rather than data migration. |
| [23] | Middleware, Common interface | This paper described a subset of SQL commands for accessing NoSQL DBs with the help of proposed middleware which uses C# and ANTLR for parsing SQL. |
| [24] | Heuristic-based | This paper presented a 2-phase transformation mechanism from relational DB to HBase. The first phase transformed relational schema to HBase schema, and the second phase expressed the relationships of two schemas as a set of nested schema mappings. |
| [12] | Common data model | This paper focused on the challenge of data portability and proposed a framework called "CDPort" which is equipped with tools for conversion, transformation, and data exchange among disparate data storage models. |
| [25] | Model Transformation | The authors developed a tool called ERWin HAWK for model transformation and accomplishing data migration. Their work reckoned the query characteristics of relational DB, prepared a model transformation algorithm that extracts the ER model and description tags from relational DBs, and based on these model transformations, migrated the data into MongoDB. |
| [26] | Metamodelling approach | This paper proposed SOS (Save Our Systems) tool which provides a uniform Application Programming Interface based on meta-modeling to support heterogeneous NoSQL data stores. |
| [27] | Model-Driven Engineering | This article addressed the issue of data portability and offered a system called "CDPort" that includes tools for data conversion, transformation, and interchange across heterogeneous data storage types. |
| [28] | Model-Driven Engineering | This paper leveraged MDE to harmonize the differences among the storage models of two prominent PaaS namely GAE and Azure. The authors created a DSL (Domain Specific Language) to support portable applications. They also addressed the issue of data portability of the applications. |
| [29] | Data Adapter | This paper proposed a "Data Adapter" system to provide data synchronization which uses both relational and NoSQL DBs at the same time. Their mechanism offered three modes for query in DB: Blocking Transformation mode (BT), Blocking Dump mode (BD mode), Direct access mode (DA mode). |
| [30] | Metamodel (Hegira4Cloud) | This paper proposed an architecture called "Hegira4Cloud" which provides an intermediate metamodel for Columnar DBs especially. The |

| | | |
|---|---|---|
| [31] | Metamodel | authors also focused on the fault tolerance feature of the NoSQL portability of Big Data applications. This dissertation work proposed a metamodel which is used to convert data to different formats via an intermediate state (especially JSON). |
| [32] | MetaModel | This article extracted system knowledge using an ontology called KDM (Knowledge Discovery meta-model) and utilized many pre-defined patterns to help users through the application migration from one cloud platform to another. |
| [33] | Map Reduce framework | This paper proposed a framework called "JackHare" based on Hadoop and HBase which includes an SQL query compiler, JDBC driver as well as MapReduce method to process the unstructured data of NoSQL DB. The data from relational DB as a source is stored on Hadoop and HBase and is processed with SQL queries. |
| [34] | Unified REST API | This paper presented a unified REST API called Open-PaaS-DataBase (ODBAPI) to interact with the different data stores uniformly. |
| [35] | Cloud data patterns | This paper presented pattern-based application refactoring to accomplish the various migration scenarios of data migration and data portability. |

The author in [14] also proposed the common programming interface but the system does not comply with cloud data store specifications as our proposed system does. The reason is that it leverages the XML in conjunction with SQL for modeling the system [15]. CDPort provided a common data model to handle different cloud storage services through a common API whereas, in our middleware, each datastore has its data model which enables it to detect the associated datastore of the user-defined model. While it may seem that a unified data model is better than using different data models for each datastore but when implemented both the approaches are fine and yield similar results. By using different data models, our middleware detects and converts the objects to their associated data store supported queries/models with more precision. We ought to improve on it in terms of implemented clouds and implemented data storage services. Moreover, a thorough examination of the source code depicts that it is prone to SQL injection as it is not using parameterized queries. We are manually implementing the adapters for each database and if there is any change in the API of the database, we must update the adapter manually. But the user using our middleware in his/her application does not need to change the source code to accommodate this update. He/she just needs to update the middleware package in his/her application.

In the paper [13], it includes more latency than our proposed middleware because the REST API server processes the request as follows:

*1)* The user's request goes to the REST API server.

*2)* REST API server processes the request and sends it to the cloud server.

*3)* The cloud server sends the response to the REST API server.

*4)* REST API server sends a response to the user's applicationHowever, in our proposed middleware [1], all the database related services are packaged within the user's application and hosted together with the user's application.

As NoSQLs are further of various types, it is not practical to develop a single query language. So, the proposed solution to this problem is to leverage the middleware to mitigate the requirement of accessing, storing, and migrating the data from and within the implemented DBs. If the proposed middleware is used while developing the cloud application, it extenuates the implementation details of all the supported DBs. The middleware supports homogenous SQL migration between different clouds, homogeneous NoSQL migration between different clouds, heterogeneous SQL to NoSQL migration in the same cloud, heterogeneous SQL to NoSQL migration between different clouds, heterogeneous NoSQL to NoSQL migration in the same cloud, and heterogeneous category NoSQL to NoSQL migration between the different clouds. The factors to be considered for switching the data store and for migrating the data include the heterogeneous categories of the source and target DBs (SQL and NoSQL). Even within the same category, there are different products available e.g., for SQL, there are MySQL and SQL Server and for document DB, there are MongoDB and Cassandra. NoSQLs further have another level of categorization as briefly discussed in previous section "Object to NoSQL Database Mappers (ONDMs)".

## V. The Proposed Middleware

Cloud portability is defined by [36] as "the ability of data and application components to be easily moved and reused regardless of the choice of cloud provider, operating system, storage format or APIs." Out of the categorized scenarios for cloud portability suggested in [37], only the third and fourth categories have been considered by the proposed middleware and this paper describes the benchmarking of the fourth category particularly.

- Virtual machine portability across cloud providers.
- Portability of virtual machines across cloud providers.
- Portability of applications in the context of Infrastructure as a Service (IaaS).
- Portability of PaaS apps.
- Data portability between cloud providers.

All the entities of the user models are stored as objects. To persist these objects in the appropriate data-store, the object's type is determined with the help of reflection (feature of C# language). A user-defined model is a class that inherits from a particular middleware meta-model base class (as we implemented a separate middleware meta-model corresponding to each type of the supported data store). Fig. 1 shows the decision making about the data store to be used by checking the middleware's meta-model class:

Fig. 1. Decision making procedure to select a data store for persistence.
Fig. 2. Data transformation process of the middleware.

The middleware is designed to be extended to support other data stores also. Fig. 2 shows the data transformation process of the proposed middleware where the migration tool takes source and destination data storage service information as an input [37]. Then the connection with the source storage service is established to fetch the records and the tool converts the data from the source to the destination data model [38]. This converted data is inserted into the destination data storage service. A detailed description of the middleware implementation is given in [39]. It was observed that leveraging the middleware makes it quite easy for the user to achieve the data portability decreasing user's efforts greatly [40]. We have experimentally evaluated the industry ready ONDMs namely KUNDERA and Spring Data as well as academic ODNMs namely CDPort and ODBAPI against SQL and NoSQL (MongoDB and Cassandr data-stores [40]. The four candidate methodologies have been evaluated using Twitter dataset and implementing different migration scenarios. An experiment was carried out in the next section to determine the effectiveness of the migration [39]. During the assessment, three cloud platforms were employed (Google Cloud Platform, Microsoft Azure, and Amazon Web Services) [41] [42]. It is also claimed that the suggested middleware is interoperable with various PaaS providers.

## VI. RESULTS AND EVALUATION

We compare our proposed middleware analytically with the academic frameworks viz. CDPort and ODBAPI as well as industry ready ONDMs viz. Kundera and Spring Data. We created a custom data model based on the Twitter data set to benchmark the proposed middleware and the other frameworks. We created two similar applications, one in Java language (to evaluate ODBAPI, Kundera, CDPort, and Spring Data) and another in C#.NET (to evaluate our middleware). Both these applications have minimal functionality to perform just the CRUD operations on the Twitter data set. The time taken to perform these operations using the applications is noted, and these values of readings are compared to know the efficiency of each of them. The experiments were executed on a system with configurations - 2 core machines with 4 GB RAM. The data in Table III was captured for three different

workloads of 1000, 5000, and 10000 no. of tweets/records. In this paper we are using three types of scenarios mentioned below.

Three scenarios are:

1) SQL to/from NoSQL
2) One category of NoSQL to another category NoSQL
3) Even among different SQL data-stores or data stores of the same category NoSQL

In each experiment scenario, the following operations were performed on SpringData, Kundera, ODBAPI and CDPort:

1) Add records (tweets/records)
2) Get all records (tweets/records)
3) Update records (tweets/records)
4) Delete records (tweets/records)

- SpringData It is an enterprise-level ORM with solid developer support and easy integration. SpringData removes all DAO (Data Access Object) implementations. Only the DAO's interface must be defined explicitly. By extending the interface, we obtain all the normal DAO CRUD functions. This informs Spring Data to look for this interface and generate an implementation for it. The problem with Spring Data was merely integrating with DBs [43].

- Kundera - is a "Polyglot Object Mapper"(Single Application Using Multiple Data Storage Technologies) with a JPA interfaces [44]. It serves as a JPA Compliant mapping solution for NoSQL Datastores. After running our scenario, we observed that "Get All" for a lower number of records took more time as compared to "Get All" for a larger number of record [45] (we ran this scenario multiple times to conclude this).

- ODBAPI - This ORM is a unified REST-based API. This API enables to execute CRUD operations on re-lational and NoSQL data stores. There is no support for Cassandra, so we ran our scenario for MySQL and mongo [46]. There was code in the application that was creating issues while building the application, removed the conflicting code to make it work. For SpringData, Kundera, and OBDApi, we ran our scenario by connecting our test application with local DB instances. This helped us by realistically compare the framework performance by not considering network latencies (as compared to if integrated with Cloud DB).

- CDPort - The CDPort's API has been designed to hide the programmatic difference between the different SQL and NoSQL database systems [47]. It enables software developers to easily change their backend cloud-based data storage without the need to change the software code. They expose adapters for each cloud DB and thus client applications need to integrate with these adapters [48]. Thus, providing a clean way to integrate. It provides support for cloud DB. Thus, we have executed our scenario for Amazon RDS and MongoDB (Amazon Document DB) [49].

TABLE III.    COMPARISON OF TIME TAKEN TO PERFORM DATABASE OPERATIONS BY THE MIDDLEWARE VS. OTHER FRAMEWORKS

| Databases & Operations Performed | Proposed Middleware (milliseconds) | | | KUNDERA (milliseconds) | | | ODBAPI (milliseconds) | | | Spring Data (milliseconds) | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| SQL | 1000 | 5000 | 10000 | 1000 | 5000 | 10000 | 1000 | 5000 | 10000 | 1000 | 5000 | 10000 |
| INSERT | 2442 | 11208 | 20056 | 1310 | 4666 | 8458 | 392 | 1539 | 3536 | 3805 | 53203 | 189860 |
| SELECT | 34 | 175 | 281 | 413 | 72 | 86 | 7 | 29 | 37 | 10 | 177 | 76 |
| UP- DATE | 3060 | 16529 | 29047 | 2594 | 8081 | 14867 | 437 | 2087 | 4724 | 4794 | 88932 | 334545 |
| DELETE | 941 | 4630 | 9581 | 1315 | 4762 | 9359 | 533 | 1666 | 3334 | 3183 | 52341 | 178737 |
| MONGO | | | | | | | | | | | | |
| INSERT | 28 | 320 | 317 | 891 | 1238 | 2299 | 547 | 2000 | 3089 | 701 | 1995 | 4880 |
| SELECT | 33 | 74 | 132 | 487 | 36 | 71 | 19 | 83 | 237 | 82 | 131 | 229 |
| UP- DATE | 70 | 324 | 649 | 2709 | 7204 | 1397 | 821 | 13927 | 51926 | 525 | 1861 | 4116 |
| DELETE | 35 | 172 | 357 | 789 | 2966 | 5820 | 809 | 11624 | 42935 | 384 | 1551 | 3166 |
| Cassandra | | | | | | | | | | | | |
| INSERT | 149 | 647 | 1069 | 1220 | 2899 | 5835 | - | - | - | 1221 | 3640 | 5853 |
| SELECT | 2 | 3 | 4 | 332 | 143 | 192 | - | - | - | 413 | 1105 | 1981 |
| UPDATE | 1537 | 1813 | 2369 | 807 | 2021 | 3298 | - | - | - | 1405 | 2893 | 6423 |
| DELETE | 1241 | 1433 | 1963 | 672 | 1880 | 3499 | - | - | – | 797 | 2004 | 3931 |

For SQL databases, ODBAPI performed the best of all the frameworks which can be seen in readings of Table III and graph of Fig. 3. For the Cassandra database, INSERT and SELECT operations took the least time with our middleware [1], and UPDATE and DELETE operations took comparable time which can be seen in Fig. 4. The middleware proposed in this work can be considered as comparable to the two-industry ready ONDMs (Kundera and Spring Data) and academic framework (ODBAPI) [50]. For the Mongo database, our proposed framework performed exceptionally well as seen in Fig. 5. Comparison between different middleware can be seen in Table III. The data in Table IV was captured for three different workloads of 1000, 5000, and 10000 no. of tweets/records.

As the proposed middleware supports cloud data portability, another comparison is done with the CDPort framework which also supports cloud data portability. Except for the SQL INSERT operation, all other operations took lesser time with our middleware.

TABLE IV.    COMPARISON OF TIME TAKEN USSING DIFFERENT WORKLOADS

| AWS cloud | Proposed Middleware | | |
|---|---|---|---|
| SQL | 1000 | 5000 | 10000 |
| INSERT | 84577 | 452959 | 957680 |
| SELECT | 309 | 1180 | 2999 |
| UPDATE | 111278 | 499048 | 913818 |
| DELETE | 80317 | 440182 | 718930 |
| INSERT | 1361 | 6840 | 14290 |
| SELECT | 1300 | 4767 | 11549 |
| UPDATE | 1648 | 11002 | 13954 |
| DELETE | 680 | 3611 | 7982 |

Fig. 4. Comparison of performance of frameworks for Cassandra CRUD operations on 1000 tweets.

The evaluation included performing CRUD operations on the Twitter data set with different workloads viz. 1000, 5000, and 10000 tweet/records through the proposed middleware, KUNDERA, Spring Data, ODBAPI, and CDPort frameworks as seen in reading of Table V. The total time taken to perform these operations were compared which depicted that middleware performs at par to all these frameworks [40] as can be seen in Fig. 6 and Fig. 7. We created two similar

Fig. 3. Comparison of performance of frameworks for SQL CRUD operations on 1000 tweets.

applications, one in Java language (to evaluate ODBAPI, KUNDERA, CDPort, and Spring Data) and another in C#.NET (to evaluate our middleware). Both these applications have minimal functionality to perform just the CRUD operations on the Twitter data set. The time taken to perform these operations using the application is noted, and these values of readings are compared to know the efficiency of each of them [45-46]. We evaluated the impact of the ODNMs based on application runtime performance as response time is very crucial for the users' experience in the interactive modern applications. Also, different ONDMs have different runtime performance. Although adding ONDMs adds to the performance overhead [1], these provide the benefit of easy portability across disparate NoSQLs [38-43]. For Document DB, our middleware performed much better than CDPort which can be seen in Table IV.

Fig. 5. Comparison of performance of frameworks for MongoDB CRUD operations on 1000 tweets.

Fig. 6. SQL CRUD Operations on AWS.

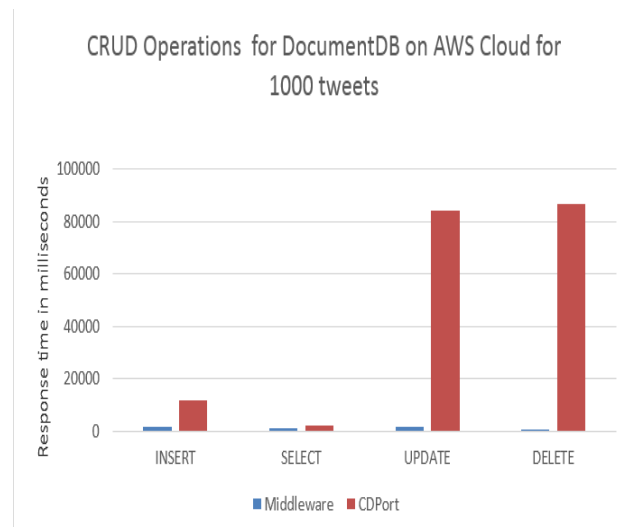

Fig. 7. CRUD operations for document DB.

TABLE V. COMPARISON WITH CDPORT

| AWS cloud | CD Port | | |
|---|---|---|---|
| SQL | 1000 | 5000 | 10000 |
| INSERT | 13939 | 139678 | 183158 |
| SELECT | 568 | 2886 | 4356 |
| UPDATE | 316903 | 1602408 | 2312081 |
| DELETE | 253408 | 1298309 | 1772904 |
| INSERT | 11648 | 12242 | 113997 |
| SELECT | 2032 | 9426 | 19406 |
| UPDATE | 83975 | 409502 | 972376 |
| DELETE | 86491 | 638225 | 982814 |

## VII. CONCLUSION AND FUTURE SCOPE

Compared to an application that only uses a SQL database, a combination of the graph, document, and column-based data stores will have a data access layer that is far more complicated and will require additional work. The developer's knowledge and experience are the primary factors that should be considered when selecting an application's database management system (DBMS). The vast majority of cloud service providers make available various services and application programming interfaces (APIs) that may be used to access and manage the services they offer. A problem with interoperability arises due to the variety of cloud services. Utilizing an intermediary abstraction layer or adhering to pre-existing standards is the recommended action for resolving this problem. This article focuses solely on the database migration process, utilizing a method known as "Object to NoSQL database mappers. Organizations may require transferring the system (software and database layer) among different providers. However, this article only discusses database migration (ONDMs). Evaluation of the effect of the proposed solution's implementation on response time and throughput is used to validate the solution's performance. In addition, the performance is evaluated in relation to other methods described in the published research and commercial solutions currently on the market. According to the findings, our strategy performs noticeably better than the other strategies. The work that will be done in the future will

involve adding support for more clouds and additional data stores that fall into other categories, such as graph and key-value stores.

*Abstract*—The continuous improvement of deep learning technology has led to its deeper application in related fields, especially in the detection of antimicrobial resistance in the medical field. In drug resistance detection, the CNN-ATT-TChan model based on the fusion of CNN algorithm and attention mechanism can classify and organize a large amount of antimicrobial resistance data, achieving standardized processing. Based on mature chemical analysis and testing methods, drug resistance test data was obtained, and the training duration and classification accuracy *F* of the model were discussed in combination with the test data. At the same time, based on relevant research literature, the changes in *ROC* curves and *AUC* values between different models were compared. The results showed that the CNN algorithm using fusion attention mechanism can improve the training time of the model and also improve the classification accuracy of the model. Therefore, the application of CNN-ATT-TChan model combined with attention mechanism in the detection of antimicrobial resistance provides more support for the development of antimicrobial resistance testing.

## I. INTRODUCTION

The development of antibiotics, especially antibiotics, has greatly reduced the incidence rate and mortality of many infectious diseases. However, with the continuous use of antibiotics, bacteria can develop resistance to antibiotics, which has become one of the main challenges threatening global public health. Antibiotic resistance refers to the ability of bacteria to resist or become tolerant to chemotherapy agents, antimicrobial agents, or antibiotics. This tolerance may be achieved through gene mutations or exogenous DNA in the transmission of R-factors. Bacteria that are resistant to multiple antibiotics are also known as multidrug-resistant, while bacteria that are considered to be extensively or completely resistant are referred to as super bacteria [1-2]. Resistance generally occurs when many infectious bacteria gradually adapt to first-line or even second-line antibiotics and develop bacterial resistance in the context of antibiotic abuse and overuse. This type of problem poses a huge burden and impact on medical hygiene, veterinarians, agriculture, and society. Affected by drug resistance, treatment plans may be limited or unavailable, posing a higher risk of death, longer hospital stays, and recovery processes for patients, sometimes even leading to long-term incapacity. Therefore, it is necessary to fully analyze the internal reasons for the formation and development of antimicrobial resistance, and based on this, study the role of antimicrobial resistance as shown in Fig. 1. The process of antibiotic resistance occurrence is presented from the perspective of drug resistance gene transfer.

Fig. 1. Process of antibiotic resistance occurrence.

Antimicrobial resistance analysis is a complex process, and deep learning, as one of the key core technologies of big data analysis, provides more means for the improvement and development of antimicrobial resistance analysis. At present, the basic data in the medical field is complex, and electronic medical records, diagnosis and treatment data, laboratory and inspection data, as well as various management data, have become major issues faced by drug resistance analysis. Therefore, further improving the intelligent analysis and processing technology of antimicrobial resistance in the medical field has become a key link in drug detection in this field [3-4]. In the medical field, although there are already many chemical testing methods such as drug resistance test kits and analysis software being applied, with the continuous improvement of data utilization and analysis requirements, relying solely on traditional chemical testing methods cannot provide better support for drug resistance analysis in the in the medical field. The use of antibacterial drugs is mainly determined based on experience and habits, resulting in a lack of comprehensive analysis of the indications and contraindications of antibacterial drugs, as well as the personal characteristics of patients, and the inability to achieve the best expected treatment effect.

In the medical field, traditional bacterial culture methods are often used for drug resistance testing, which takes at least 3-5 days from identifying bacteria to completing drug sensitivity testing [5]. This traditional testing method delays the optimal time for doctors to analyze patients' antimicrobial resistance, posing challenges and difficulties for clinical drug use. At present, there is relatively little research on data analysis and processing of antibacterial drugs based on deep learning algorithms. Researchers have used the XGBoost algorithm of machine learning to construct MIC prediction models between the genome of non-Salmonella typhimurium and multiple antibiotics. Some scholars have also conducted exploratory research on the rational use of antibiotics using machine learning immune genetic algorithms and deep learning short-term memory network models [6-8]. Based on deep learning algorithms and combined with modern chemical methods, it provides a more accurate and efficient means for the analysis of antimicrobial resistance in the medical field. At the same time, it can significantly shorten the testing cycle and provide testing results in a timelier manner [9-10]. Chemical methods play an important role in drug analysis and research and development. Through their diverse analytical methods, from molecular structure to compound labeling, from component testing to local drug analysis, this method provides an effective way to solve drug analysis problems. In the field of medicine, the updates in deep learning technology and the development of chemical methods have provided more comprehensive analytical methods for the analysis of antimicrobial resistance.

This article combines the convolutional neural network (CNN) algorithm in deep learning and proposes a dual channel CNN terminal model in the medical field that integrates attention mechanisms based on the analysis and summary of completed drug resistance experimental data. Using a CNN model for feature extraction and completing self-learning, assigning different weights to information of different importance, and constructing a classification model between testing samples and antibacterial drugs. Using this model to determine the tolerance level of the test samples to antibiotics can provide auxiliary effects for the rational use of antibiotics in the medical field. At the same time, doctors in Harbin can provide the most suitable decision support for individual patients in clinical medication.

## II. ANALYSIS OF DRUG RESISTANCE IN THE CONTEXT OF DEEP LEARNING

### A. Analysis of Deep Learning Algorithms

Deep learning is an important branch of machine learning. By learning deep nonlinear network structures, deep learning trains features layer by layer, gradually transforming the feature representation of samples in the original space into a new feature space, demonstrating the powerful ability to learn the essential features of datasets from the sample set. The biggest advantage of deep learning is that it can automatically learn features and achieve the abstraction process of features. It adopts multi-layer complex structures or multiple layers composed of multiple nonlinear transformations for data processing. The use of deep learning for drug resistance testing and analysis in the medical field has unique advantages.

It can fully explore the deep relationships hidden in a large amount of medical data, obtain more abstract feature values through learning neural networks, and improve the feasibility and accuracy of antimicrobial resistance analysis in the medical field [11-12]. As shown in Fig. 2, a schematic diagram of the network structure of the deep learning algorithm is provided. The algorithm consists of three dimensions: input layer, hidden layer, and output layer, with relevant nodes processing and analyzing data in each layer.

Fig. 2. Schematic diagram of deep learning algorithm network structure.

### B. Application Status of Deep Learning Algorithms in Drug Resistance Testing

The continuous development of deep learning algorithms has led to the application of more and more technologies in the medical field, promoting the continuous updating and progress of drug resistance testing methods in the medical field. At the same time, thanks to the application of deep learning technology in drug research and development, people have also made many beneficial explorations and attempts [13-15]. The study of gene expression and protein structure, compound screening, and the design and analysis of clinical trials for drug design are all influenced by artificial technology. In addition, the application of various digital devices in clinical trials and daily patient monitoring will also benefit from the help of artificial intelligence technology. Driven by machine learning and deep learning technologies, significant progress has been made in the analysis of antimicrobial resistance testing in the medical field. By using CNN technology in deep learning, testers can obtain more detailed data on antimicrobial resistance testing and analysis, and conduct more effective research and analysis on drug resistance, Furthermore, more accurate drug resistance diagnosis and prediction can be made for patients [16]. The application of deep learning algorithms in the testing of antimicrobial resistance can help evaluate drug resistance in a shorter time with fewer cases and reduce the cost of clinical trials. As shown in Fig. 3, a schematic diagram of the application of the CNN algorithm model in drug resistance testing and analysis is provided.

Based on deep learning algorithms, comprehensive analysis of a large amount of antimicrobial resistance testing data has become a trend in the medical field. In traditional medical practices, doctors also use antibiotics based on their

own experience and habits, lacking a more systematic and comprehensive consideration of the indications and contraindications of antibiotics, as well as the personal characteristics of patients [17]. A deep learning based identification model for antibacterial drug applications. Firstly, the coding distribution representation of the antibacterial drug is obtained. Then, a CNN model is trained for feature extraction and self-learning. Finally, a reasonable rule and feature library for single disease and complications is generated. Therefore, using the CNN model in deep learning algorithms can more efficiently detect and analyze antimicrobial resistance [18].

## III. Construction of a Drug Testing Model Based on CNN Algorithm

### A. CNN Algorithm Theory

CNNs are mainly used in fields such as image processing and recognition. They are a multi-layer perception mechanism mainly used to process two-dimensional images. As shown in Fig. 4, a schematic diagram of the CNN module in deep learning algorithms is provided. The basic structure of CNN consists of an input layer, a convolutional layer, a pooling layer, a fully connected layer, and an output layer. The pooling layer merges adjacent multiple nodes into a similar feature to reduce the amount of training data, extract hidden features from the project, conduct multi-layer training, and perform dimensionality reduction processing. Finally, the CNN is trained as a whole [19-20].

*Input layer* — *Output layer*

*Convolution* — *Pooling* — *Convolution* — *Pooling* — *Convolution* — *Fully connected*
Fig. 4.  Schematic diagram of CNN model.

In the CNN model algorithm, $L$ represents the number of layers of the neural network, $i$ represents the label of a certain layer, then $w_{h,w}^{i}$ represents the connection weight from the wth neuron in layer $i$-1 to the $h$-th neuron in layer $i$, $b_h^i$ represents the bias of the $h$-th neuron in layer $i$, and $Z_h^i$

represents the weighted input of the $h$-th neuron in layer $l$. The weighted input of the $h$-th neuron in the l-th layer can be represented by Formula (1):

$$Z_h^i = \sum_h w_{h,w}^i a_w^{i-1} + b_h^i \qquad (1)$$

For convolutional layers, their main function is to extract features, perform convolution calculations on the vectorized text vector and the convolution sum, and perform operations on extracting word information before and after. The obtained convolution results are processed through activation function operations, and the convolution function results are used as the output results of this layer. The convolutional kernel is represented by $w$, where $w \in R^{hk}$. Where $h$ represents the height of the convolutional kernel window, and $k$ represents the dimensional size of the word vector. $W_{ih}$ represents a sequence of words with a length of h ($W_i$, $W_{i+1}$, …, $W_{i+h}$), Wi represents a word, and the value of each eigenvalue can be calculated using Formula (2):

$$y_i = f(\sum_{h=1}^{n} \sum_{w=1}^{n} \sum_{d=1}^{m} x_{h,w,d} \times w_{h,w,d}^i + b^i) \qquad (2)$$

Among them, $n$ represents the height and width of the convolutional kernel, $m$ represents the depth of the convolutional kernel, $x_{h,w,d}$ represents the value at the region connected to the convolutional kernel ($h$, $w$, $d$), $w_{h,w,d}^i$ represents the weight parameter at the convolutional kernel ($h$, $w$, $d$), $b^i$ represents the bias of the convolutional kernel, and $f(\cdot)$ represents the activation function. In addition, the input layer $x$ is convolved to obtain the feature vector $y$, which can be represented by Formula (3):

$$y = (y_1, y_2, y_3, ..., y_{i-h+1}) \qquad (3)$$

In addition, the pooling layer can reduce the dimensionality of the extracted feature information, reducing the size of the feature map, simplifying the computational complexity of the network, and avoiding overfitting to a certain extent. On the one hand, feature compression is performed to extract the main features. This layer is mainly used to reduce the dimensionality of the feature map obtained by convolution, and the maximum pooling method shown in Formula (4) is often used to extract local optimal values:

$$Y = max(y_i) \qquad (4)$$

The fully connected layer in a CNN is usually located after several convolutional and pooling layers, and is also the last few layers of the CNN. Its essence is a multi-layer perceptron model, where each neuron in the fully connected layer is connected to all neurons in the previous layer. The most direct function of the fully connected layer is to compress the two-dimensional feature map into a one-dimensional feature vector, in order to connect with the final output layer of the network to output the final classification results [21]. At the same time, it can also to some extent integrate local information with class differentiation in convolutional and pooling layers. The role of the previous convolutional and

pooling layers is to map a shallow feature into a deep feature space, while the fully connected layer maps these deep feature representations into the classification space of the class. Therefore, the fully connected layer also has a certain classification effect.

The use of nonlinear factors can better solve complex problems, and activation functions can help introduce nonlinear factors, adding some nonlinear factors to neural networks, and enabling neural networks to better solve more complex problems. Common saturated linear functions include *Sigmoid*, *Tanh* function, and *Tanh* activation function, which converge faster than *Sigmoid*, but there is still a phenomenon of gradient vanishing during training [22-23]. As shown in Formulas (5) and (6), the activation function expression is given:

$$Sigmoidf(x) = \frac{1}{1+e^{-x}} \qquad (5)$$

$$Tanhf(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}} \qquad (6)$$

In this article, the specific method is first based on deep learning methods. The input part involves the name, function, dosage, indication, contraindications, etc. of antibacterial drugs. The word vector tool is used to train the word vector, and then the transformed sentence is input into a CNN for convolution and pooling. Then, the fully connected deep learning features are obtained.

### B. Construction of Drug Testing Model Based on CNN Algorithm

*1) Text classification*: In the medical field, text classification of data is required when using CNN algorithm for antibiotic resistance testing and analysis. Text vector is a higher-level expression of text, which can be used as a partial feature vector for antibacterial drug text data classification. After training and learning through standard neural networks, vector V is obtained as another basis for antibacterial drug text data classification [24]. The weights of feature vectors in classification are α and (1-α). The probability calculation formula for text belonging to a certain type of effect is shown in equation (7):

$$P = softmax\left[\alpha \times W_c C + (1-\alpha) \times W_c H + b_c\right] \qquad (7)$$

Using the negative logarithmic likelihood of the correct label as the training loss, the calculation formula is shown in formula (8):

$$L = -\sum_d log_a x d_j \qquad (8)$$

Where $j$ is the label of text $d$, $R = 1 - \frac{C}{A+C}$ represents the probability that text $d$ belongs to effect $j$.

*2) Modeling of drug sensitivity testing data:* The dual channel CNN model proposed in this article integrates attention mechanism. After preprocessing the original test data, it is vectorized and modeled. As input data, it is sent to the CNN of two independent and different depth channels. After each channel undergoes several convolutional and pooling operations, attention mechanism is introduced. By fitting multiple sets of weight vectors to characterize the importance of each feature component, the feature data of the two channels is fused, and finally, the softmax function is used to achieve classification output. The data source studied in this article is bacterial drug sensitivity testing data. Each test sample includes the patient's age, gender, department, submission date, sample type, bacterial species, testing chemical reagents, testing report date, and other submission data, as well as the patient's minimum inhibitory concentration (MIC) testing results for each antibacterial drug. With the development of physical, chemical, and molecular biology technologies, various new bacterial resistance testing technologies have emerged. As shown in Table I, common chemical methods and their characteristics for detecting antimicrobial resistance are presented.

TABLE I. CHEMICAL METHODS AND CHARACTERISTICS OF ANTIMICROBIAL RESISTANCE TESTING [25-26]

| Method | Characteristics | Application Scenario |
|---|---|---|
| Nucleic acid hybridization technology | Short testing time, time-saving and fast, strong specificity, and high sensitivity | Rapid diagnosis of pathogens in clinical settings |
| PCR | Short testing time, time-saving and fast | Rapid diagnosis of pathogens in clinical settings |
| Disk diffusion | Simple, repeatable, without the need for expensive device support | Qualitative testing of bacterial sensitivity to antibiotics |
| Testing method based on time-of-flight mass spectrometry technology | Microbial cultivation takes a long time and requires exploration of antibiotic usage conditions | Rapid testing of drug resistance |

Select multiple attributes from the submitted data that may affect the tolerance value of antibacterial drugs as input features, and use the testing result MIC as a classification label. Considering that different bacterial strains have different sensitivities to the same antibacterial drug, and the sensitivity values of the same bacterial strain to the same antibacterial drug vary among different specimens [27]. Therefore, it is necessary to establish a classification model for each antibacterial drug, and output its MIC classification value for the current antibacterial drug based on the input multi feature test data. The vectorized representation of sample data containing multiple features is an important prerequisite for feature extraction and fusion using CNNs. This article draws inspiration from the approach of constructing a word vector model in text problems, where each attribute feature value corresponds to a word and is represented by a vector. The dimension of the feature vector is the number of all feature values. As the feature vector dimension of the drug sensitivity data selected in this article is 48, there is no problem of dimensional disaster, and the correlation between various features is relatively weak. Therefore, the traditional *One-hot* method is used to construct the feature vector model. A sample

data containing multiple features corresponds to a sentence in the text problem, which is modeled as a two-dimensional matrix, and each row of the matrix is a feature vector. As shown in Fig. 5, a dual channel convolutional neural network model structure diagram integrating attention mechanism is presented.

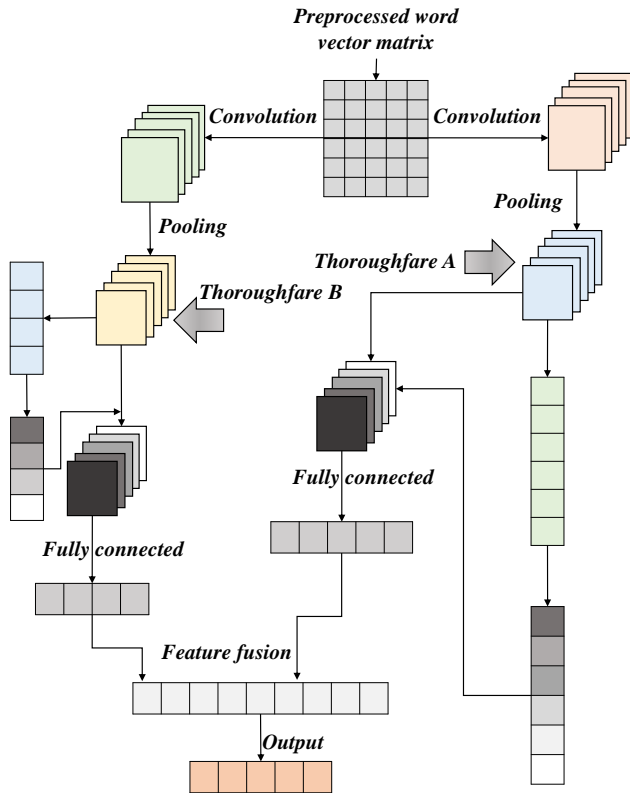

Fig. 5. A dual channel CNN model integrating attention mechanism.

The features extracted by CNNs are often related to the depth of the network. The deeper the network level, the easier it is to extract abstract features that represent the whole. The shallower the network level, the easier it is to extract detailed features that represent local regions. In view of this, this article designs two types of dual channel CNNs with depths of six and four layers, respectively, to extract features at different levels of abstraction in deep and shallow layers. In addition, considering that the feature matrix size of the testing sample is not large, pooling dimensionality reduction is weakened. The upper channel network consists of five convolutional layers with different kernel sizes and numbers, three maximum pooling layers with the same step size, and 1 fully connected layer, the down channel network consists of three convolutional layers with different kernel sizes and numbers, one maximum pooling layer, and one fully connected layer.

*3) Attention mechanism and model training:* The implementation of the Attention Mechanism is achieved by preserving the intermediate output results of the CNN encoder on the input sequence, and then training a model to selectively learn these inputs and associate the output sequence with them when the model outputs [28-29]. Although the model may increase computational complexity after using this

mechanism, its performance level can be improved. In addition, using this mechanism helps to analyze the impact of relevant information on the final generated sequence.

The attention mechanism assigns appropriate weights to each feature component, selects important features, and focuses on this information. It is divided into three parts, namely Squeeze, Excitation, and Attention. Assuming that the feature information after convolution and pooling is a two-dimensional matrix containing $n$ feature vectors, denoted as $U_{m \times n}$, after squeezing, the vector $Z$ is obtained. The calculation of the squeezing function ($F_{sq}$) is shown in Formula (9):

$$Z = \sum_{i=1}^{m} U_i \bigg/ m \tag{9}$$

The vector $Z$ is stimulated by Formula (10) to obtain the attention weight vector $a$. Multiply the weight vector $a$ with the feature matrix $U$ to generate a feature output $U'$ with attention mechanism, and $U'=aU$.

$$a = softmax\left[ w_s \times tanh(w_z \times z) \right] \tag{10}$$

where, $m$ is the dimension of the feature vector, $U_i$ is the *i-th* feature vector, *softmax* (·) and *tanh*(·) are activation functions, and $w_s$ and $w_z$ are learnable weight matrices.

In addition, during the model training process in the CNN algorithm, the *softmax* function is used to classify the feature vectors after dual channel fusion, and the predicted probability value $P(k|x)$ of the output result category is shown in Formula (11):

$$P(k|x) = e^{x|k|} \bigg/ \sum_{i=1}^{n} e^{x|i|} \tag{11}$$

The cross-entropy loss function is used to measure the difference between the predicted probability and the real label, and the calculation is shown in Formula (12). This is used for backpropagation training of the model, with the goal of minimizing the loss of the function [30]:

$$L = \sum_{i=1}^{n} q(k|x) log\left[ P(k|x) \right] \tag{12}$$

where, $q(k|x)$ represents the actual encoding vector of the corresponding category $k$ of the current sample, which is the real label.

## IV. ANALYSIS OF DRUG RESISTANCE TESTING AND MODEL APPLICATION

### A. Drug Resistance Testing

*1) Source of strains and testing instruments:* When using a deep learning CNN algorithm to detect antimicrobial resistance, the relevant data comes from bacterial drug sensitivity testing data in a tertiary hospital's intensive care

unit. 120 strains of Acinetobacter baumannii were isolated from clinical specimens, and duplicate strains from the same patient and site were discarded. The standard strains are Escherichia coli ATCC25922 and Pseudomonas aeruginosa ATCC27853, using drugs such as Ampicillin/Sulbactam (AMP/SCF), Fefepime (FEP), Cefoperazone/Sulbactam (CSL/SCF), Cefotaxime (CTX), Ceftazidime (CAZ), Ceftriaxone (CRO), Ciprofloxacin (CIP), Gentamicin (GEN), Imipenem (IMP), Meropenem (MEM), Piperacillin/Tazobactam (TZP). Piperacillin (PIP), Levofloxacin (LVX), Amikacin (AMK), Compound Sulfamethoxazole (SXT). In addition, the culture medium is Mueller Hunton (M-H) agar and broth. As shown in Table II, the relevant equipment for drug resistance testing is provided.

TABLE II.    DRUG RESISTANCE TESTING EQUIPMENT AND INSTRUMENTS

| Types | Device |
|---|---|
| Main instruments | Ultra low temperature water tank |
| | A400 multi-point vaccination device |
| | Electro-heating standing-temperature cultivator |
| | VITEK Microbial Fully Automatic Identification Instrument |
| | Paper dispenser |
| | JY2002 Electronic Balance |
| | ZHP-2102 Intelligent Constant Temperature Shaker Incubator |
| Other auxiliary instruments | Pipette, glass test tube, PCR tube, EP tube, bacterial culture dish, etc |

*2) Drug resistance testing methods:* The sensitivity of antibacterial drugs was determined using K-B agar diffusion method and M-H agar dilution method. The screening criteria for multiple drug resistance were: Acinetobacter Baumanii against cephalosporins, aminoglycosides, carbapenems, and enzyme inhibitors β Individuals with resistance to three or more antibiotics, including lactams and fluoroquinolones, are identified as multidrug-resistant Acinetobacter baumannii.

For the preparation of flat plates, it is necessary to mark the different concentrations on the plates, dilute the antibiotic stock solution, and then pour the antibiotics into the plates using a double dilution method. Wait for M-H agar to cool to about 50℃, and pour a certain amount of antibacterial drugs into the plate with the calculated final concentration. Inoculate the quality control strain and the test strain onto an M-H agar plate, incubate overnight at 37℃, and then select 4~5 colonies to be cultured overnight in 1ml of M-H broth. Dilute 10 times, which is equivalent to 0.5 Mach's turbidity. Dip the bacterial solution with a multi-point inoculum and inoculate it onto an antibacterial drug plate. The amount of inoculation per point is approximately $10^4$~$10^5$CFU. Place the inoculated antibacterial drug plate in an incubator at 35℃ for 20~24 hours and observe the results. Each operation includes quality control strains.

In addition, for the drug sensitivity testing process, the antibacterial *K-B* method is used to determine the size of the antibacterial zone. The fresh pure bacterial solution with a concentration of 0.5 microns is uniformly coated with sterile cotton swabs on a 4mm thick and 90mm diameter M-H agar drug sensitive plate. Each plate is coated with six pieces of drug sensitive paper, and incubated at 35℃ for 16~18 hours to measure the size of the antibacterial zone on the plate and interpret the results. The results were determined to be sensitive, medium sensitive, or resistant according to the relevant regulations regarding the size of the antibacterial zone.

*B. Application and Analysis of Testing Models*

Based on the above statistics of antimicrobial resistance testing results, a total of 12765 related data were completed. The actual production data is quite complex and must be preprocessed before being used in experiments. The data preprocessing work in this article includes data filtering and screening, outlier testing, and standardization. Firstly, data filtering involves screening raw data, removing irrelevant indicators, and selecting six attribute features that may affect antimicrobial resistance values as inputs. The corresponding feature inputs are patient gender, patient age, source department, specimen type, bacterial species, and related chemical detection methods. Secondly, outlier testing is mainly based on expert testing experience to identify unreasonable testing results in the original data. At the same time, testing samples with more missing values and fewer records are also included in the outlier data. The final dataset used for the experiment consists of 3562 pieces. Then there is the standardization of data processing, mainly for the convenience of later data processing, quantifying the five features using numerical values to achieve unified quantization methods.

*1) Evaluating indicators:* In the process of detecting antimicrobial resistance, this article uses the F metric value as the evaluation criterion for the classification results. The process of classifying the test text d in this method is as follows: first, calculate the text similarity between d and each text in the training sample set. The similarity is generally measured using Euclidean distance, and based on the text similarity, find the most similar K closest training texts. The K sample categories are used as candidate categories for d, Then, based on the similarity between the text to be classified d and these K neighbors, the weight of the K nearest neighbor text category is used. The sum of the class weights of the neighboring texts in each category is used as the similarity between the category and the test text. Then, the text to be classified d is divided into the category with the highest weight. The calculation process of text similarity between the text d and di to be classified is given by Formula (13):

$$Sim(d_i,d) = \frac{1}{d - d_i} = \frac{1}{\sqrt{\sum_{j=1}^{n}(x_{i,j} - x_j)^2}} \qquad (13)$$

For the weight of the sample *d* to be classified and the $c_j$ of each class, Formula (14) can be used to calculate:

$$p(d,c_j)=\sum_{i=1}^{n} sim(d_i,d)\,y(d_i,c_j) \qquad (14)$$

where, $y(d_i,c_j)$ is a class attribute function, and when $d_i \in c_j$, there exists $y(d_i, c_j)=1$. When $d_i \notin c_j$, $y(d_i, c_j)=0$.

In addition, this method takes into account both precision (*P*) and recall (*R*) indicators, with *P*, *R*, and *F* calculated by Formula (15):

$$\begin{cases} P = \dfrac{TP}{TP+FP} \\ R = \dfrac{TP}{TP+FN} \\ F = \dfrac{2 \times P \times R}{P+R} \end{cases} \qquad (15)$$

where, *TP* represents the number of samples divided into positive classes, *FP* represents the number of samples divided into positive classes for negative classes, *FN* represents the number of samples divided into negative classes for positive classes, *TP+FP* represents the actual number of samples classified, and *TP+FN* represents the expected number of samples.

To further analyze the accuracy of antimicrobial resistance testing, Formula (16) can be used to determine the accuracy of the test results:

$$Accuracy=\frac{TP+TN}{TP+FP+TN+FN} \qquad (16)$$

*2) Experimental environment and parameters:* To ensure the objectivity and effectiveness of antimicrobial resistance testing results, a ten fold cross validation method was adopted in the experiment. The dataset was divided into te parts, with 1 part being the test set and the remaining nine parts being the training set. The 10 samples were randomly rotated for 10 experiments, and the average value was taken as the final result of the model. After multiple experiments, a set of optimal model parameters was determined, and the relevant values are shown in Table III.

TABLE III.     SETTING OF MAIN PARAMETERS OF THE MODEL

| Parameters | Parameter Value |
|---|---|
| Number of convolutional kernels in the upper channel (channel A) | 64,128,128,128, 128 |
| Number of convolutional kernels in the lower channel (channel B) | 64,128,128 |
| Upper channel convolution kernel size (channel A) | 2,3,3,3,2 |
| Lower channel convolution kernel size (channel B) | 2,3,2 |
| Output layer ratio | 0.5 |
| Learning rate | 0.001 |
| Maximum number of iterations | 500 |

To better evaluate the classification performance of the dual channel CNN model (CNN-ATT-TChan) proposed in this article, which integrates attention mechanisms, in antimicrobial resistance testing data, comparative experiments were designed between different models. As shown in Table IV, the types and basic information of the models used for comparison are provided.

TABLE IV.     COMPARISON OF DIFFERENT TYPES OF MODELS

| Models | Description |
|---|---|
| CNN-2D | The convolution kernel of this model is two-dimensional, including multi-layer convolution and pooling operations. |
| CNN-2D-ATT | This model adds an attention mechanism based on feature components on the basis of CNN-2D. |
| CNN-2D-TChan | This model is based on CNN-2D and designed with two upper and lower channels, which perform multiple convolution and pooling operations for feature fusion and achieve classification output. |
| CNN-1D-MChan | This model adopts multiple one-dimensional convolutional kernels with different widths but the same length, each with a length equal to the feature vector dimension of drug sensitivity data. |
| CNN-1D-Mchan-NP | This model is based on CNN-1D-MChan and removes pooling operations. After each channel undergoes one-dimensional convolution, it directly performs vector fusion and enters the fully connected layer. |
| ResNet-18 | The basic architecture of this model is *ResNet,* with a depth of 18 layers (referring to the weight layer of the network), excluding the batch normalization layer and pooling layer |
| RF | The random forest algorithm model is a mainstream ensemble learning method used for classification and regression. |

*3) Analysis of model testing results:* Based on the sorting and analysis of the above basic models, in order to verify the impact of adding attention mechanisms in one-dimensional and two-dimensional convolution models on model performance, as shown in Fig. 6, the impact of attention mechanisms on model training duration in one-dimensional and two-dimensional convolution cases is presented. As shown in the figure, for a two-dimensional convolutional model, with the assistance of spatial domain attention mechanism and mixed attention mechanism (spatial+channel), the main role of attention mechanism in one-dimensional convolution and two-dimensional convolution is to significantly increase the training time of the model. For the two-dimensional convolutional model, with the introduction of attention mechanism, when Epochs is 500, the two are 604s and 501s respectively, with a difference of 103s, which is about 20.5% higher overall. In the one-dimensional convolutional model, after introducing attention mechanism, the training duration of the two is 298s and 258s respectively (when Epochs is 500), with a difference of 15.5% between the two. Therefore, it can be seen that when attention mechanism is introduced, the training duration of both will increase to varying degrees. After adding attention mechanism, the training duration has been improved to a certain extent. The training duration of one-dimensional convolutional network

(CNN-1D-ATT) with added attention mechanism is relatively small compared to one-dimensional convolutional network (CNN-1D) without added attention mechanism. The two-dimensional convolutional network (CNN-2D-ATT) with added attention mechanism has significantly improved and improved training time compared to the two-dimensional convolutional network without added attention mechanism (CNN-2D), which also lays the foundation for the accuracy of antimicrobial resistance analysis.

a) Comparison between CNN-2D-ATT and CNN-2D models

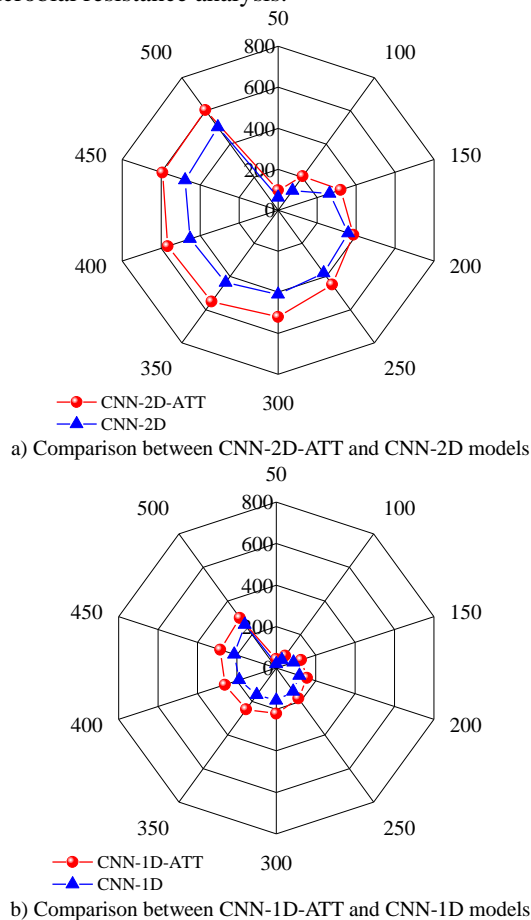
b) Comparison between CNN-1D-ATT and CNN-1D models


Fig. 6.    Impact of introducing attention mechanism into 1D/2D models on training duration.

Based on the analysis of the training duration of relevant models, in order to further analyze the impact of attention mechanism introduction on the accuracy of different models, as shown in Fig. 7, the trend of F values of one-dimensional convolutional models and two-dimensional convolutional models under different Epochs is presented. As shown in the figure, for the two-dimensional CNN model, with the introduction of attention mechanism, the classification accuracy of CNN-2D-ATT is significantly higher than that of CNN-2D. For example, when Epochs is 500, the F values of the two are 76.1% and 66.4%, respectively, with an overall

difference of 9.7%. At the same time, comparing one-dimensional CNN models that also introduce attention training mechanism with two-dimensional CNN models, it can be found that when Epochs is 500, the former has an F-value of 57.2%, while the latter has an F-value of 76.1%, an improvement of about 18.9%, and the improvement effect is significant. The main reason for the improvement and enhancement of this effect is, on the one hand, due to the small number of layers in the one-dimensional convolutional network model, resulting in a decrease in the overall complexity of the network model. On the other hand, the reduction in the size of the convolutional kernel and output feature during the one-dimensional convolutional process leads to a decrease in the time complexity of individual convolutional layers.

Fig. 7.    The influence of attention mechanism on F-value in 1D/2D models.

In addition, in order to compare the overall performance of the model constructed in this article (CNN-ATT-TChan) with other models, based on the analysis of the overall performance of different models, as shown in Fig. 8 and Fig. 9, the F-values of different models and the changes in training time of different models were presented. From Fig. 8, it can be seen that in the comparison of the F values of the above models, the maximum value is the CNN-ATT-TChan model, which is about 72.4%, indicating that the model has better overall performance and can demonstrate better classification accuracy. The model with the lowest F-value is the CNN-1D Mchan model, which is approximately 50.6%. In addition, in Fig. 7, the comparison of the training time of different models with Epoch of 50 is shown. The average time of the above models is about 166 seconds, and the ResNet-18 model with the longest required time is about 653 seconds. The training duration of the CNN-ATT-TChan model is approximately 103 seconds, which is a decrease of 63 seconds compared to the average. Therefore, the CNN-ATT-TChan model constructed in this paper exhibits good classification performance when the experimental data for antimicrobial resistance testing is large and the amount of feature engineering is increased.
Fig. 8.  Comparison of F-values in different calculation models.

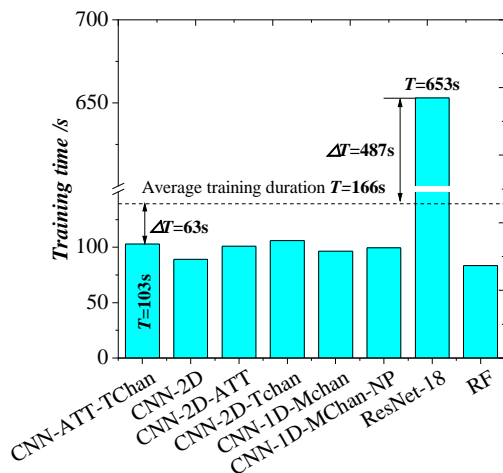

Fig. 9.  Comparison of training time for different models.

As shown in Fig. 10, a comparison of the ROC curves between this model and other model is presented. From the figure, it can be seen that the AUC corresponding to the ROC curve in this paper is 0.86, while the AUC of the VGGC16+LSTM model in study [31] is about 0.71. Therefore, the model in this article has better detection performance.

Fig. 10.  Average ROC curves of different models.

Through the comparison of the above models and related indicators, it can be found that the CNN ATT Tchan model constructed in this article can effectively improve the problems of low detection accuracy and relatively long detection time in traditional models in drug detection. While solving the problem of low detection accuracy, it achieves the goal of shortening the detection cycle of antibiotic resistance. In this article, improvements have been made in model detection efficiency and detection cycle performance, but further research on drug resistance detection is still a worthwhile direction. For example, deeper research can be conducted by combining a large amount of clinical data, providing more support for drug resistance testing work.

## V.  CONCLUSIONS

The continuous development and application of CNN algorithm in deep learning technology have promoted the continuous progress of antimicrobial resistance testing technology in the medical field. This article constructs a CNN-ATT-TChan model based on the application of CNN algorithm in drug resistance testing, and compares and analyzes the performance of this model in antimicrobial drug resistance testing. The changes in the training time and classification accuracy of the model are presented. The main conclusions are as follows:

By combining the CNN algorithm and attention mechanism, the constructed CNN-ATT-TChan antibacterial drug resistance testing and analysis model can achieve better overall testing performance compared to other models. It can effectively improve important parameters such as training time and classification accuracy in the antibacterial drug resistance testing process in the medical field, and achieve improved testing performance.

By integrating attention mechanism into one-dimensional CNN and two-dimensional CNN models, for two-dimensional CNN models, with the introduction of attention mechanism, when Epochs is 500, the training duration is increased by about 20.5%. In the one-dimensional CNN model, the introduction of attention mechanism resulted in a 15.5% increase in training time.

The constructed CNN-ATT-TChan antibacterial drug resistance testing model exhibits better overall classification accuracy and small sample classification, with certain feasibility and effectiveness. Compared to other models, the classification accuracy can be improved by up to 21.8%.

*Abstract*—**Improving medical image quality is essential for accurate diagnosis, treatment planning, and ongoing condition monitoring. A crucial step in many medical applications, the restoration of damaged input images tries to retrieve lost high-quality data. Despite significant advancements in image restoration, two major problems still exist. First, it's important to preserve spatial features, although doing so frequently results in the loss related data. Second, while producing linguistically sound outputs is important, location accuracy can sometimes suffer. To overcome these issues and improve medical imaging, the Multi-Scale Deep Learning-based Recurrent Neural Network (MSDL-RNN) is offered in this paper. The model makes use of various scales during building, in contrast to standard RNN-based techniques, which generally use both full-resolution and gradually reduced-resolution approximations. This multi-scale approach uses deep learning to address problems including noise reduction, defect elimination, and increase of overall image quality. Artificial Bee Colony Optimization is employed for efficient segmentation. By combining local and global data, the MSDL-RNN technique effectively improves and recovers a variety of medical imaging modalities. It generalizes the optimization strategy for model capacity assurance by incorporating crucial pre-processing methods targeted to various medical image types. The suggested approach was implemented in Python software and has an amazing accuracy of 99.23%, which is 4.33% higher than other existing methods like DesNet, AGNet, and NetB0. This study sets the way for important developments in improving the quality of medical images and their uses in healthcare.**

*Keywords*—*Multi-Scale Deep Learning (MSDL); Recurrent Neural Network (RNN); deep learning; medical image; Artificial Bee Colony (ABC)*

## I. INTRODUCTION

A critical step in image processing is the restoration procedure, which seeks to extract high-quality data from a broken or corrupted input image [1]. It uses various techniques and algorithms that examine the data at hand and try to restore the image to its initial condition or enhance its quality. Image restoration is necessary in various contexts, such as imagey with digital cameras, images from satellite surveillance systems and healthcare imaging. The restoration method aims to improve image information, decrease noise and artifacts, and produce attractive and educational images. It utilizes cutting-edge algorithms for image processing and machine learning approaches. The need for high-quality visual content is driving more studies into creating cost-effective and successful restoration techniques. Moreover, image deterioration of different degrees happens frequently due to the acquisition process due to the camera's physical constraints because of challenging illumination circumstances [2]. For example, mobile phone cameras have a tiny detector, wide opening and little range in dynamic. As a result, they frequently generate low-contrast images that are noisy. Comparable to how images are taken in poor illumination can appear excessively dark or excessively bright. Recovery of the distinctive, clear image from its damaged dimensions is the goal of image restoration. Because of the many potential answers, the opposite issue is poorly presented.

Deep learning skills utilization in medical tomography has recently received a portion of interest in image enhancement. One of the challenges that numerous scholars are now interested in is how to identify and split grazes that appear on healthcare images mechanically. Medical image enhancement is essential for several clinical uses because it makes it possible to analyze structures of the body and diseased regions accurately and quickly [3]. According to research, U-Net has displayed exceptional achievement in healthcare image breakdown through various imaging techniques, including magnetic resonance imaging (MRI), computed tomography (CT), ultrasound, and others. The effectiveness of it can be due to the network's capacity to precisely differentiate among

various kinds of tissues, tumours or organs by learning a hierarchical structure of healthcare images. Nevertheless, image restoration (IR), which has a significant practical value in numerous low-level vision software, has proven to be an ongoing problem [4]. Image restoration generally aims at restoring the hidden clear image x from its deteriorated measurement y = T (x) + n, where T is the noise-irrelevant degrading procedure and n is believed to be additive white Gaussian noise (AWGN) with standard deviation. Furthermore, one can obtain distinct IR assignments by defining various degrading procedures.

Consequently, the purpose of numerous image processing issues, such as super-resolution, deblurring, inpainting, colorization, and compression detecting, is to reconstruct an image from relatively noisy information provided by a known linear deterioration pattern [5]. These issues are examples of linear inverse issues. Employing sets of the initial and damaged images, end-to-end supervised training of neural networks can be utilized for image restoration for a particular degrading paradigm. Nevertheless, versatility is frequently needed in practical applications, such as medical imaging, to handle numerous, endless deterioration patterns. Because they can adjust to the particular issue without re-training, unsupervised techniques based on learned priors may be preferable where the deteriorating concept is initially unknown and employed throughout deduction. Considerably, the collection of all essential info from at minimum two images and the basic creation is alienated into fewer image pixels, characteristically into a solitary one, to create the image's standard and decrease repetition, refining all the basic features of the medical image that is second-hand for investigating all medical problems. It is known as a clinical indication combination cycle. These regions are cast-off to switch to the combined phase. The stuffing by the watersheds computation for these sub-images represents determining the regions at individual levels [6]. This watershed computation has become utilized for completing the image separation to maintain the basic enumeration.

Nevertheless, with the introduction of modern technology into the medical industry, medical image enhancement techniques have received a lot of interest. A surgeon needs improved medical images to help with diagnostic and analysis due to noise, other data-gathering equipment, lighting circumstances, etc. It commonly degrades the quality of medical images [7]. Additionally, the major goals of healthcare image improvement are to address issues with a medical image's low brightness and elevated degree of contamination. Moreover, several research efforts have focused chiefly on greyscale and frequency spectrum transformations in healthcare image improvement techniques [8]. Also, Histogram equalization is a widely used technique for image enhancement in the spatial field, while research on the frequency-domain transformation mainly focuses on the Fourier transformation. While most methods for image enhancement are normally used to offer better images for human observers, some are used as an initial processing stage to deliver better images to later techniques for computer-assisted studies. Therefore, the initial category consists of methods for reducing noise, boosting contrary, and sharpening

features. Edge recognition and segmentation of objects for machine learning are the two more methods included in the subsequent type, which largely overlaps with the first [9]. It has been demonstrated that a medical image with a significant contrast can aid in an additional exact valuation of the various tissues in the examined body area.

Therefore, separating the most beneficial data from the processed images is the study's key goal. As a result, many strategies are used to separate the fundamental facts, such as image registration and image fusion [10]. Creating a network of connected images is the goal of image registration. Image registering is also recognized as image merging or pairing and combines more than one image based on how they seem from the outside. Moreover, the healthcare image registration process seeks the ideal spatial transformation assessment that organizes the fundamental physiological frames. Also, healthcare registration of images is used in several healthcare programs, including radiation buildup, tracking of motion, image rebuilding and image navigation. Every procedure performed on an image aims to improve its quality. Because of the issues with the image source of information, there are regular or ad hoc defects and disturbances in the image structure [11]. These flaws and disturbances damage every pixel in the image. For the images to be employed in practice and more intelligible, these flaws must be removed with the use of initial processing techniques.

The key contributions of this research are given below as follows:

- By effectively decreasing noise and maintaining significant image information, the application of a median filter during the pre-processing phase improves image quality and guarantees that the next analysis will benefit from cleaner input data.

- By optimizing the process of locating and isolating regions of interest, the ABC optimization Algorithm is used to image segmentation, enhancing the precision and effectiveness of medical image analysis.

- The GLCM's ability to extract texture features provides insightful information about the structural properties of medical images, enabling more accurate and thorough analysis for diagnostic reasons.

- By using RNN for image classification, the system is able to efficiently classify medical images, which helps with medical condition detection and treatment by using learnt patterns and features. This, in turn, enhances the overall efficiency of the medical image processing pipeline.

This article's remainder is organized as follows: In Section II, a summary of related research is provided. Section III presents the problem statement. The suggested approach's methodology and architecture are explained in Section IV of the article. The findings and subsequent discussion are covered in Sections V and VI, respectively. The conclusion is covered in Section VII.

## II. RELATED WORKS

For historical years, machine learning, especially deep learning, has improved the analysis of medical images said by L. Chen et al. [12]. It takes a lot of labelled information to train an effective deep-learning algorithm. Nevertheless, getting enough annotated images for training is frequently a challenge. The dataset in consideration frequently contains more unlabelled images than tagged ones. Consequently, it is necessary but difficult to improve the efficacy of machine learning models by employing labeled and unlabelled data. Self-supervised learning is one approach to resolving this issue. Existing self-supervised learning techniques that are suitable for medical images are unable to achieve appreciable improvements in performance. They frequently produce very slight benefits as a result. To more effectively utilize unorganized images, researchers offer a new self-supervised learning technique built around background restoration in this research.

In demand to create novel medical image processing methods, deep learning has involved much study care, as said by X. Chen et al. [13]. Deep learning-based replicas have been confirmed to be tremendously active in a series of medical imaging activities that permit disease detection. Several investigations have remained completed in the last five years with the goal line of solving this tricky. Researchers analysed and synthesized this current research to present an in-depth review of the use of deep learning techniques in various medical imaging analysis challenges in the present research. Moreover, researchers concentrate in particular on the furthermost fresh growths and achievements of state-of-the-art unsupervised and semi-supervised deep learning in the analysis of medical images that are outlined according to many different application instances, spanning separation, identification, and registration of images. Furthermore, researchers discuss the main technological difficulties and offer potential fixes for future research projects.

In his paper, Ahuja [13] said that following the combination of machine learning and deep learning methods, medical imaging has undergone a substantial revolution that has resulted in the creation of smart imaging equipment. These devices use artificial intelligence to improve the precision, effectiveness, and comprehension of healthcare images. To help with evaluation and therapy organizing, machine learning techniques enable the computerized evaluation of healthcare images, encompassing the process of segmentation, categorization and registrations. Convolutional neural networks specifically have demonstrated outstanding results in applications like segmentation based on semantics, recognizing objects, and image classification. The developing subject of generative adversarial networks shows potential for exceptional case synthesizing and data augmentation. It is necessary to handle issues like data accessibility and interpretability. The primary problem of this is quality control and governance.

J. Liu et al. [14] discussed in his paper that by taking into account the particular needs of medical image security for the injury regions, a new zero-watermarking method for healthcare images that utilize DTCWT-DCT has been suggested to address safety concerns with healthcare images that are saved and sent in the cloud. Initially DTCWT is applied to healthcare images. A graphical feature vector consisting of healthcare images that resist geometrical attacks is also obtained from the low-frequency DTCWT parameters. The logistic map is then used with the idea of zero-watermarking to secure the watermark. Based on this, the encoding and retrieval of the watermark is implemented by fusing conventional watermarking techniques with random data encryption cryptography and third-party notion. In contrast to conventional watermarking methods, the suggested approach using DTCWT-DCT does not involve deliberately selecting the region of interest, therefore resolving the quick issue associated with integrating the watermark. Additionally, the incorporated watermark is a zero-watermarking, which leaves the genuine healthcare images unchanged. Logistic Map handles the chaotic encrypting processes, which might increase the watermark's safety.

The main medical imaging (MI) issue is the image denoising discussed by Elhoseny and Shankar [15]. The most difficult part of denoising an image is preserving the data-bearing surface and borders while improving Peak Signal to Noise Ratio (PSNR). In this research, the innovative Bilateral Filter (BF) optimization-based clarifying technique is engaged in deliberation for the MI noise reduction process. The conclusion to select the best variables, i.e., Gaussian and spatial weights, is inclined by how the denoising procedure is passed out. These variables are designated in this case using the DF and MFF algorithms. PSNR and VRMSE are used to determine this variable. The denoised image is additionally classified as normal or abnormal using a CNN classifier with a higher classification rate.

Protecting the authenticity and validity of healthcare images is crucial in telehealth said by X. Liu et al.[16]. Two methods, region of interest (ROI) lossless and reversible watermarking, concentrate on these. Nevertheless, the latter pose safety hazards by splitting the image geographically for watermark implantation and distorting diagnostic by altering the region of no interest (RONI). When ensuring image authenticity, the latter lacks a dependable restoration mechanism for the altered portions. In this research, an innovative and resilient reversible watermarking approach is developed to deal with these problems. To prevent distortions in assessment, this approach uses a reversible watermarking technique that employs recursive dither modulation (RDM).

Suri et al. [17] discussed in his paper that radiology is one area of healthcare where artificial intelligence (AI) has made inroads. Since its discovery, the very aggressive coronavirus disease 2019 (COVID-19) has spread to more than ten million individuals. As of July 1st, 2020, it caused more than 500,000 fatalities. Nearly 28,000 publications concerning COVID-19 have been released since the epidemic started, but few have examined the use of radiography and machine learning in COVID-19 patients, particularly those with multiple medical conditions. The four different routes that can result in brain and heart damage after a COVID-19 illness are first described in this research. According to probabilities calculated from COVID-19 symptomatic research, the survey also provides information about the part radiology can play in the

management of comorbidity people. The main objective of this research is the implementation of image-based AI to describe the structures of a COVID-19 patient and categorize the degree of severity of their illness. As the global epidemic spreads and nation's worldwide struggle with limited healthcare facilities for surveillance and treatment, image-based AI is more crucial than before.
