# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

University of Siegen, Business Informatics and New Media Siegen, Germany[6]

*Abstract*—**Project e-VITA is a joined research force from Europe and Japan that examines various cutting-edge e-health applications for older adult care. Those specific users do not necessarily feel technology savvy or secure enough to open up for innovative home tech systems. Thus, it is essential to provide the support that is virtual and human beside each other. Human coaches will provide this support to fulfill this role as a mediator between the technological system and the end-user. Reactance towards the system from the mediator's role could lead to the system's failure with the end user, thus failing the development. The effect of technology reactance in the integration process of a technological system can be the decisive factor in evaluating the success and failure of a technological system. We used part-standardized, problem-centered interviews to understand the human coaches' challenges. The sample included people who act as the mediator role between the user and the technological system in the test application in the study centers. The interviews focused on experienced or imagined hurdles in the communication process with the user and the mediator role as well as the later relationship dynamic between the mediator, end-user, and technological system. The described technological challenges during the testing phase led the human coaches to responsibility, diffusion and uncertainty within their role. Furthermore, they led to a feeling of not fulfilling role expectations, which in the long term could indicate missing self-efficacy for the human coaches. We describe possible solutions mentioned by the interviewees and deepen the understanding of decisive factors for sustainable system integration for e-health applications.**

## I. Introduction

### A. Project e-VITA

Under the EU Horizon 2020 program, as well as MIC funding regarding the Japanese Society 5.0 movement, project e-VITA, a Virtual Coach for Smart Aging, forms a research group that aims at conducting knowledge about new technologies and methods to help an aging society deal with specific problems of their older people. The team of sociological, medical, and technological experts joined in one research team spread all over Europe, and Japan aims at developing an innovative coaching system focused on the needs of older autonomous living adults, i.e., a virtual coaching system that can provide personalized recommendations and everyday help to improve older adults' life quality.

### B. The Human Coach in Project e-VITA

e-VITA is aimed at older adults that not necessarily feel technology savvy or secure enough to open for innovative home tech systems. It is thus essential to provide the support that is virtual and human. At least one human coach will provide this support as a mediator between the technological system and the end-user. As a first step, each study center will recruit human coaches to fulfill this critical role. Project e-VITA has various test centers in Japan, Italy, France, and Germany to conduct a human trial such as feasibility studies and proof of concept studies to evaluate the developed virtual coaching system. The main tasks of the human coach will be as follows:

- Teaching end-users about the e-VITA virtual coach (usage, maintenance, support). If needed, end-users will be trained and supported by a team of researchers daily during the study.

- Regular phone calls between the human coach and end-user to answer questions and provide needed support, e.g., explain the appropriate use of the virtual coach.

- Organize real personal meetings of users once a week in the local community.

- Ensuring the security and safety of users, e.g., checking temperature to avoid overheating, safely placing the technical device in the home environment.

- Mentoring, creating awareness, and encouraging behavioral change, encouraging during the intervention.

- Reporting users' requirements, questions, and feedback to the developers to steadily improve the system.

### C. Problem

In the first step within the e-VITA study, the human coaches will be primarily employees or volunteers with a particular affinity for technology and an advanced training status due to their particular relation to the project. In the

expected application of the final concept in the actual field, the human coaches accompanying the technology integration will be employees of care institutions, care services, social associations, and/or family members and local community volunteers. The effect of technology reactance in the integration process of a technological system should not be neglected because it can be a decisive factor in evaluating the success and failure of the technological system used [20]. The final human coaches will act as a kind of 'salesperson' for the system, thus mediating between the human end-user and the technological system. Reactance towards the system from the mediator's role could lead to the system's failure with the end user, thus failing the development [17]. Potential hurdles and reactance factors [25] from the role of the human coach will be explored in more detail in this study.

### D. Contribution

Even though the participants of this study within project e-VITA might possess a fundamental technological affinity, they will be competent enough to deliver valuable information regarding the potential challenges a later human coach will face and, thus, possible technology reactance factors. As mentioned above, technology reactance factors from human coaches in their mediator role will influence the later successful technology integration in the field and following should be considered during the design phase for the technological system. Thus, this study aims at exploring the following three research questions:

- Which technology reactance factors can we find in the role setting of the human coaches?

- How do these factors influence the later end-user relationship towards the installed technology in private home settings?

- Which prospect aspects can overcome reactance tendencies, and which human coach motivating factors play essential roles?

### II. THEORETICAL BACKGROUND AND RELATED WORKS

Advancing Information and Communication Technology (ICT) in healthcare can revolutionize delivering healthcare. From easy access to medical records to the ability to consult virtually with specialists, ICT has the power to improve the patient experience significantly. For providers, ICT can help improve patient outcomes, reduce costs, and increase efficiency. With access to Electronic Health Records (EHRs), providers can quickly access critical patient data, such as medical history and insurance coverage, without waiting for paperwork to be completed. This leads to more accurate diagnoses and faster treatment.

Additionally, ICT can allow providers to communicate quickly with other healthcare professionals, collaborate on patient care, and refer patients to specialists when needed. Moreover, ICT, installed in older people's homes, can ensure longer independent living situations for older people, especially in countries with vast demographic challenges and/ or labor shortages in elderly care. In short, ICT, as developed in project e-VITA, can revolutionize healthcare, providing older people with better access to care and providers with

more efficient ways of providing it. The following section describes the theoretical backgrounds of these interrelations as a foundation for this study.

### A. The e-Health Ecosystem in General

The healthcare sector is of paramount societal significance, and Information System researchers have long studied it empirically. The e-health ecosystems are emerging as an effective way to deliver healthcare services to older people cost-efficiently. These ecosystems are comprised of a network of entities - including healthcare providers, tech vendors, and other stakeholders - that facilitate the exchange of data and the provision of health services. This can revolutionize healthcare and open new possibilities for providers and older people [7, 12].

The development of e-health ecosystems is driven by the need for healthcare providers to access/ share data quickly and securely and the demand for cost-effective health services. As such, e-health ecosystems comprise various components, including electronic health records (EHRs), patient portals, health information exchanges (HIEs), telemedicine tools, and other technologies. By leveraging these components, healthcare providers can access and share data in real time, reducing administrative costs and providing better patient care access [1].

The e-health ecosystems offer numerous benefits for older people. For example, by providing access to patient or client portals, older people can access their medical records and communicate with their healthcare providers more easily. Furthermore, e-health ecosystems can enable the delivery of care through virtual coaching alongside the personnel in the form of human coaches. However, those technical systems present themselves as another stakeholder in the whole ecosystem, which also comes with several barriers and facilitators [25]. Schreiweis et al. define a list such as limited exposure/knowledge of e-health (e.g., poor digital health literacy), lack of necessary devices, and problems with financing e-health solutions as the top three barriers; as well as facilitating factors such as the involvement of all relevant stakeholders, integration into the overall care, and ease of use [3]. Stephanie and Sharma discuss the critical elements of digital health, including the emergence of digital health ecosystems, formulating a vocabulary of research and sensitizing concepts, and design issues and challenges in creating a viable patient-centric e-health ecosystem. They emphasize the potential of digital health innovations such as evidence-based data analytics, artificial intelligence, Internet-of-Things in remote monitoring and diagnostics, and blockchains for secure, compliant, transparent data management [7]. All authors find common ground in describing the importance of carefully integrating knowledge about the systemic complexity of e-health ecosystems, especially about the formal and informal caregivers as direct contacts to the end-users when integrating technological artifacts for care purposes [8].

### B. Technology Reactance and the use of e-Health Applications

Technology reactance is an important concept to consider when developing and implementing e-health solutions.

Especially the above-mentioned complex ecosystems introduce a variety of critical points with diverse stakeholders in which technology reactance might lead to tech-system-failure [11]. This refers to people's psychological resistance to using technology, particularly when they feel it is being imposed upon them. This can be due to various reasons, such as feeling overwhelmed by the amount of technology available, feeling that technology is intrusive, or feeling that technology is not necessary to reach a desired outcome [20,16]. Technology reactance can potentially hinder the adoption and utilization of e-health solutions. To reduce the likelihood of this happening, developers and promoters of e-health solutions should strive to create user-friendly, intuitive, and reliable solutions that offer clear benefits to their stakeholders. The goal for many years has been to implement health information technology (HIT) for its apparent advantages; however, a significant obstacle to overcome is user resistance. Healthcare professionals should be provided with proper training and support. Attention should be paid to user needs and psychological concerns to create an environment of acceptance and understanding by using Psychological Reactance Theory (PRT) [18]. The psychological reactance theory assumes that people's behaviors are motivated by the desire to protect their "freedom" to carry out a particular behavior in a particular context [13]. The introduction of technology is generally accompanied by new processes demanding the change of (work) routines and task dependencies between employees/people. These processes can potentially cause power imbalances that may lead to perceived helplessness. According to the PRT, resistance is a result of reactance. It is defined as the response to losing freedom [18]. Svioja et al. point out the importance of carefully designed UX in complex systems, especially in safety-critical domains, to overcome stakeholders' possible reactance or resistance tendencies [23]. Subhasisch et al. present a study along the technology acceptance model (TAM) in which they prove that perceived ease of use positively impacts a system's perceived usefulness [4].

Additionally, perceived usefulness and prior use of the system significantly impact the actual use of the system in the end [4]. Parker et al. describe, in general, how work-technologies influence employees such as caretakers. The most publicized risk is the erosion of the need for human workers. Rather than solely speculating about which jobs will vanish, research should address the urgent and prevalent matter of how tasks might best be shared between humans and machines and the consequences of different choices in this respect. It is essential to consider design issues to come to grips with the potential effects of digital technologies and associated changes and to help steer technological development toward desired care futures [19]. Ultimately, technology reactance can significantly impact the success of e-health solutions. By understanding the potential for technology reactance and taking appropriate steps to address it, developers and promoters can help ensure that their intended audiences adopt and utilize their e-health solutions [2,15].

### C. Sustainability Factors in Technology Development

The traditional approach to automation design has focused on optimizing operational efficiency and safety by minimizing human involvement and making systems easier to use for the operator. However, this approach is often met with a lack of acceptance, more severe failures, and an erosion of the sense of purpose that comes with meaningful paid or voluntary work [14]. To address this, more recent theories such as Experience Design, Positive Design, and Design for Well-being propose that technology should be crafted to actively contribute to meaningful, fulfilling work [5,9,10]. Therefore, to place well-being at the center of design efforts, autonomous systems must be created to support meaningful practices. A strong correlation exists between meaningful practices and situational commitment, creativity, and well-being. However, the connection between meaningful practices and technological artifacts is not yet fully understood, especially in work contexts. Smids et al. identify various frameworks that comprise meaningful work, such as pursuing a purpose, social relationships, self-development, self-esteem, exercising skills, and feeling autonomous [25]. Therefore, the design of autonomous systems should consider fulfilling human social needs and ensure sustainable usage based on users' and stakeholders' well-being [21, 22].

### III. Methodological Approach

### A. Interviews and Sample

We used part-standardized, problem-centered interviews [24] to interview the human coaches currently involved in the study at the four test centers (Japan, Germany, France, and Italy). The sample included people who act as the mediator between the user/ older person and the technological system in the test application in our study centers. The part standardized interview focused primarily on experienced or imagined hurdles in the communication process with the user and the mediator role; furthermore, the effects on the mediator and the later relationship dynamic between the mediator, end-user, and technological system. The interviews were conducted in English and German in the EU and Japanese in Japan using Zoom for the meeting and the recording. Two interviewers conducted the interviews. The interviewees were between 21 and 82 years old, with an average age of 49,2 years. We interviewed five persons in Japan, one in Italy, two in France, and two in Germany. The interview length was between sixty and ninety-eight minutes. The interviewees cover a wide range of job expertise shown in Table I. Also shown in Table I are references to the interviewees' role in the test centers, their experience in elderly care, and their self-assessed technology competence. We do not name the interviewees' countries in the table to ensure anonymity.

TABLE II.    INTERVIEW DETAILS

| Age | Job Expertise | Role test entre | Expertise Elderly care | Technology competence |
|---|---|---|---|---|
| 82 | Bank Manager, now civil servant and mediator/ judge | "My role is to listen carefully to the users and be a dedicated listener. I also understood that if they had any problems, I would give them advice." | "When I was a community welfare volunteer, I was also an officer of the local social welfare council, so I had opportunities to listen to the elderly people at their gatherings and so on. When I was a community welfare volunteer, I also visited elderly people who lived alone, so I had opportunities to talk to them." | "I'm not familiar with technology at all. I'd say I'm a three at best." |
| 70 | Project Manager IT, now Freelance same field | "The role of the coach about this project is to first understand the purpose of the project and then to communicate the actual theme of the robot, how easy it is for the user to use, and how to make the robot do what it is supposed to do, and then to help the user to do it." | "I started going to the neighborhood association the year before last, so we are almost the same age. Also, the members of the Go club are almost older than me. The people in the club are so into Go that the members of the club are more of a hobby, and they play against each other on the spot. We play a game about once a week. Those people look forward to playing games, so if anything, I started after 60." | "I've been working with computers all my life, so I don't like to be asked about the level of IT technology involved in networking and things like that when I say with confidence, but I'm between 5 and 10. So then, I'll say 7." |
| 69 | Sales employee for IT | "My job is to guide the assistant robot and help the | "There are so many. There are only elderly people…. | "I'm a ten on the concepts and a 3 or 2 on the |
| | | user." | One is a non-profit organization, one for …. and then another one as a civic contribution, and the third one is the delivery of meals for the elderly and disabled. I am in contact with them through these three. The other thing that I do is with them." | technical aspects of contents. The technical stuff, the details, not at all." |
| 63 | Accounting employee | "I think it is about eliminating the anxiety of users, being close users, and enjoying (the experience) with them." | "My mother is 94 years old, so I also meet people who are close to her. But, just a while ago, not too long ago, people used to come over for tea and chat. Now they have moved away to live with their children… My social interaction is about visiting daycare service…" | "Because I do not know how savvy is 10 (points). About the basic only. Maybe 2 or 3. 2.5." |
| 71 | Call-center employee for mobile phone business, now social activities for the community | "After all, coaching means (to be) fairly well versed in coaching content and able to tell it simply (to users); I think those things are important." | "I participate in my local residents association's salon once a month and I also help the local comprehensive center once a month as long as time permits. Because of those (activity), (I have some interaction with the elderly) to some extent." | "I think (I am) already close to zero." |
| 30 | Psychologist | "I am mainly involved in user recruitment, interviews, and test | | "Maybe nine?" |

| # | Role | | | |
|---|---|---|---|---|
| | | administration." | "I work with senior people, senior with older people, and often with people with dementia or Alzheimer's. And um my, I also work like a psychologist, e-Vita. So outside, e-Vita and I yes, I work with these kinds of people. I do cognitive stimulation or cognitive rehabilitation." | |
| 24 | Research Engineer | "My role is to first create a user guide. And after implementing all the technology in the home of the older person of the participants and to answer their questions when we are in their home." | "I think because I started to work with Senior when I am when I was in a master's degree. So four years old, I think I work with them. In contact." "I had contact in an internship and after my first job as a researcher also." | "I think I'm eight because I like technology, but I'm not a developer, so or gamer, or so like that. So I use them, but I use all the technology like to see what is possible to do, but I'm not touching technical system or like that and it's not my job." |
| 21 | Engineer | "I am currently helping in that project, just like a human coach would do. Calling participants and going to participants' houses to see what's going on." | "Not really. I have done a little project from my engineering, from my engineering formation, which was a sort of remote control for the TV, which was used by the seniors, which were they were doing just like this." | "I really like technology. I'm a bit familiar with them, with it. And I would like to say nine, I think. Nine is great." |
| 28 | Project Manager in Social | "My task as a human coach was, on the one | "(You were already a physiotherapist | "9… Well, I don't understand, |

| # | Role | | | |
|---|---|---|---|---|
| | Science | hand, to install the devices, to introduce them to the devices, and to record the feedback from the users. And when there are technical difficulties, we go to the users and see what's going on and how we can solve it." | in training. Did you then also often deal with senior citizens? Probably also in this context. But-) "Yes mostly actually." | of course not, the complete complexity behind the device, but I can familiarize myself with the practical processes relatively easily and get it down to the chain quickly, quickly. So I can quickly acquire new technologies and new technical knowledge. " |
| 32 | Student Medical and Health Science and Caretaker in part-time | "I'm writing my bachelor's thesis about the study, and then the project manager asked me or asked me if I wouldn't like to take on a role as a human coach." | "So, starting at home with my friend and with his grandmother in his grandmother's house, he has dementia. I also take care of them privately. Then I worked in a nursing home before. Many years. I've always had very close contact with the residents, so there was also an amicable, family atmosphere." | "It all depends on whom you're comparing yourself to. Because I have programming experience, but I'm not exactly a programming expert, and I wouldn't say that at all. Let's say if I compare myself to people who study computer science, I would say a seven." |

## B. Analysis Process

After transcribing the interviews, they were coded for anonymization. According to the different nationalities of the participants, corresponding abbreviations were distinguished to assign them later to possible inductive categories like cultural differences or demographic comparisons. The anonymized texts were then openly coded with the help of four research questions:

- Which technical reactance factors can be found in the role setting of the human coaches?

- How do these factors influence the subsequent relationship of end-users to the installed technology in the home environment?

- Which aspects can overcome reactance tendencies, and which motivating factors of the human coach play an essential role?

- What important information does the interviewee provide concerning their role as an intermediary?

The first category summarizes all statements about the technological reactance factors of the human coach, including the components of their occurrence. In the second group, all quotes were collected on the relationship dynamics between the human coach, end user, and technology. Category 3 dealt with the solution ideas to potential or actual problems, and the last category contained information about how the respondents felt in their mediator role and how they would define it.

The recorded citations were sorted in a table. The individual codes were then analyzed to identify similarities or abnormalities. These were carried out separately by two researchers, whose results were then summarized and processed. In addition, this study explored general knowledge and cultural or demographic characteristics, which we examined as inductive and open-ended.

Based on the collected findings, theories were then formed, and connections developed to filter out the influence of intermediaries on the acceptance of technology and to be able to specify this intermediary role.

### C. Validity Threats and Limitations

Following Engelhardt [6], we can summarize that the interview method was very well suited to finding the needed background information and personal attitudes for this sub-study. The procedure made it possible to ask in-depth questions about certain statements. This ensured that the interviewee was understood correctly and underlying attitudes could be found. This understanding was the basis for further analysis to correctly process the interviewees' statements and not allow personal interpretations to flow in [24]. However, the exact procedure during the interview might differ from the interviewers. One limitation was that different people conducted the interviews due to the language barrier. Each interviewer might have had their interview style, which may have influenced the statements made by the interviewees or even led to certain aspects not being addressed at all or in sufficient depth. In addition, the different cultures of the interviewers and the interviewees could have influenced how openly specific topics were discussed or how vehemently questions were asked about problems of understanding. People of a wide range of ages were interviewed for this study. So, we cannot entirely rule out that questions were understood differently; therefore, comparability might not be entirely given. Probably the most significant limitation of the study was the different languages used. The interviewees gave the interview in Japanese as a native language, English as a non-native language, or German as a native language. Translations were, therefore, necessary for the analysis process. As a result, quotations could have been falsified or statements modified within the translation process, even if a professional translation service proceeded. However, since we conducted the data and proceeded with the analysis under the close supervision of the leading researcher, who also coached the

executing researchers beforehand, we eliminated validity threats as best as possible for this international and complex sub-study.

### IV. RESULTS

#### A. Category 1: Human Coach Technological Reactance Factors

During the analysis process of the first category, we were led by the question of which aspects the interviewees reported about specific use situations and self-responsiveness to the tested technologies. Furthermore, when and where those aspects arose, and which psychological content-wise link can we draw from the given statements?

All those surveyed named the fact that fluent conversations were not possible as probably the most considerable criticism of the tested systems. The devices had limited topics of conversation and had difficulty understanding what was being said, leading to frustration among the seniors. Some seniors were disappointed by how "little" the devices could do. Some of them started the tests with high expectations and were then disappointed. For them, using it was sometimes more severe work than fun.

In general, the interviewees found that the system for communicating with a robot was still in development, making conversation difficult at the beginning due to its response. It was found that the conversation was not going smoothly due to changes in the example conversation in the manual, and it was suggested that the conversation should be more cumulative to improve this. It was mentioned that while care should be taken not to exceed certain limits regarding technology, it should not be intrusive regarding privacy. In addition, it was criticized that the voice would sound metallic and invite only limited conversations. There was sometimes a lack of feedback from the system, for example, when it started processing for a search, but it needed some time. It was repeatedly criticized as unnatural that one had to press a button to start a call. This was also difficult for some seniors to understand. However, it was positively emphasized that the robot would turn its head in the direction of the voice. This made the conversation more natural for the seniors. The simultaneous textual reproduction of what was said on the Gatebox gave seniors certainty that the device understood what was said correctly.

The limited functions were another disappointment for the seniors. They could only perform a few, often simple actions with the devices and needed a smartphone for them. This would make it easier for them only to use the standard apps, so the e-VITA devices hardly offer them any added value. Some seniors also had difficulties using Telegram because they were unfamiliar with this app or Messenger in general and thus had to learn several new technologies at once. According to some seniors, these limitations in connection with the poorly functioning voice control made the devices either just a kind of entertainment without added value or useless. During the experimental period, the users noted that it was a toned-down version of the commercial version, not providing the expected response or reaction. The user hoped that the robot would suggest activities such as going outside

and showing empathy when the user was crying. They raised concerns about how the robot would be used and suggested positioning it as a pet or healing tool. One interviewee expressed surprise at how well the users responded to the robots and found them helpful in relieving loneliness. The interviewee also wonders if the robots could be used to help people with dementia and if those with more difficulty could operate them. The interviewees also reflect on their experience with technology, feeling that their world has opened and expanded. They noted that the older adults they had accompanied were apprehensive about robots but would accept basic conversations about everyday topics. They observed that many of the older adults did not understand how to use the technology or that it was usual for the robot to get hot, which scared them.

Some respondents received feedback from seniors during testing that they felt the systems were inappropriate, which concerned, for example, the design and the character, but also the structure of the functionalities. Some of these were not self-explanatory enough, so they needed help to use them.

Other problems that arose were, for example, that the seniors in small apartments had too little space for the devices. In addition, some voiced concerns about the power consumption and the associated costs or the overheating of the devices. Poor WLAN also sometimes posed a hurdle for use. One of the respondents expressed criticism of the further plans in the e-VITA project, that they were not specific enough about data use. For example, the interviewee mentioned that information should be passed on to health insurance companies through the devices in the future. However, this passing on could also be to the detriment of the senior citizen if he/she does not maintain a healthy lifestyle and the health insurance company refuses to provide benefits.

Overall, it can be said that the tested technologies are not yet failsafe enough for the seniors; the voice control needed optimization, and more possible actions tailored to seniors would have to be implemented so that the systems tested in e-VITA would unite the seniors have actually added value and can therefore be used sustainably.

The mentioned technological challenges during the testing phase led the human coaches to responsibility diffusion and uncertainty within their role. Since we followed a relatively open interview style, those interconnections were steadily mentioned during the recording phase without specific questioning. The technological challenges led to a feeling of not fulfilling their role expectations or job descriptions entirely, which in the long term could indicate missing self-efficacy for the human coaches. This aspect might lead to a problem when integrating a new eHealth system with a sustainability focus.

We will now analyze the mentioned psychological challenges with the following analysis parts.

### B. Category 2: What Relationship Dynamics can we see in the usage Triangle of Human Coach, end user, and Technology?

Both caregivers and seniors in the study expressed disappointment at how little current devices could do. They each had higher expectations and were disappointed. For example, it was criticized that the systems did not respond to the senior as an individual but remained very impersonal or gave generic answers. Overall, the conversations should be more natural and focus more on the senior instead of simple question-and-answer exchanges. There was also criticism that too many individual, non-networked applications should be tried simultaneously. As a result, and due to the limited functionality and personalization, some of these were not tailored to the announced project goal, namely, to increase senior citizens' well-being and advise them on health and social issues.

Several respondents said it was positive that there was a lively exchange between senior citizens, intermediaries, and developers. This allowed them to act as facilitators, giving feedback and getting answers from the developers about how something worked or why it worked a certain way. This social inclusion through involvement in the development of the system that was not initially part of the study phase might be an essential indicator for the later integration of the system and its further development.

The participating older adults often saw the robot as a kind of pet or assistant that reminded them of medication, for example, but also encouraged them to talk and interact. To do this, however, the system must also respond to the character of the individual seniors. For example, it must act if the senior using the device suffers from dementia and needs different treatment than a senior without dementia.

Several intermediaries stated that they considered it crucial to also convey to the seniors what the robot can and cannot do, to deal with their sometimes very high expectations. Some older adults were disappointed when something did not work and reacted angrily. The mediators found this critical since they wanted the systems to enrich the lives of older people. They were convinced that long-term, sustainable use would only come if seniors also wanted to use the technology and could try it out over a more extended period to experience the added value for their lives. This approach to the aspects of enrichment and the limits of technology was described as an essential task of a mediator. However, the seniors were perceived as curious about the technology and interested in interacting with the devices. There were a few exceptions, where some respondents felt that the seniors were only participating in the project to please them and were, therefore, less motivated to try the devices.

The interviewees described as an essential basis for the cooperation that a basic trust between the senior, mediator, and developer is necessary. It is also important not to patronize the seniors but to let them set up the devices themselves if they feel up to it or to accept if they do not want to use specific devices. Several mediators empathized with the seniors, enjoyed the cooperation, and appreciated mutual respect.

### C. Category 3: Which Solution Ideas are Offered by the Respondents?

In conclusion, it is vital to understand the needs of older people individually and in more depth, such as what they need

and want, so it is necessary to collect data more widely, the interviewees summarized. It is essential to make the operations as simple as possible and to explain the vision in a way that is easy to understand for older people. It is crucial to foster mutual understanding between the older user and the robot and create a sense of control for the target group. Finally, it is essential to make sure that the technology is suitable for the needs of older people and that it is entertaining.

To develop technology that is tailored to seniors, the data collection in advance should focus more on their needs and perceive the seniors as individuals, according to the respondents. Some said there is more than one group of seniors, and one needs to identify which groups of seniors have which needs and, therefore, would benefit from a particular technology. In addition, some intermediaries expressed that they would instead test several small functionalities one at a time to be sensitive to feedback and to be able to develop technology in a more tailor-made way. Also, before handing out the technology to the seniors, ensure the systems will improve their lives, not complicate them. They suggested that vocal interaction was better than other forms of interaction and that medical reminders would be beneficial. They also suggested that physical activity advice was essential and that robots should have an emergency button. Finally, they noted that it was unclear whether robots should be rented or bought and that some older adults preferred to rent them monthly, while others preferred to buy them outright.

Respondents would like more time to prepare and try the devices before bringing them to the seniors. In this way, they could familiarize themselves more intensively and, for example, get the missing power adapter or better prepare the presentation to the seniors. The level of this presentation should also be as low-threshold as possible since many technologies are new to seniors, so they must learn them from the very beginning. In addition, the intermediaries wanted to receive a kind of operating manual at the beginning to get a common understanding of the project and the devices.

According to those surveyed, senior citizens and caregivers should not only be provided with operating instructions and explanatory videos, but continuous support from caregivers. In this way, the latter would have the opportunity to explain or practice things several times, thereby optimally supporting the seniors in learning to operate systems. It is also essential to respond to the seniors' level of knowledge and adapt the explanations accordingly.

When introducing the devices, the vision or goal of the development should also be addressed to involve the seniors in the project. In addition, it would have to be communicated that the technology was still in development. In this way, the seniors can be better involved. According to the intermediaries, it is also imperative that nothing is hidden from the user. They must be told openly what the robot is doing or why, i.e., if data is recorded and how it is used. Even if one feels that the seniors do not understand the topic of data protection, for example, everything should still be explained to them openly.

According to those surveyed, the devices themselves should not be too complicated to use and should make the user happy. This requires a specific range of functions since the seniors were disappointed with how little the devices could do. The seniors must be able to switch off the systems at any time and thus control them. Voice interaction must work better if one wants to use social robots, and conversations must be set up and conducted from the user's point of view. The interaction could also be loosened up with jokes, for example, and the seniors should be able to choose between different voices or ways of interacting, such as severe or funny.

According to the interviewees, there should be a direct contact person for technical problems, and a better complaints management system should generally be introduced. This would allow the problems of older people to be addressed more quickly and flexibly. The intermediaries themselves could seldom solve technical problems on their own; they could only pass them on. This led to frustration for both agents and seniors. In addition, the exchange timing should be based more on the everyday life of the seniors instead of being geared toward the developers or mediators.

We argue that considering the solutions given by the human coaches themselves when designing the technological e-health system will help to develop a more sustainable solution.

*D. Category 4: What Important Information does the Interviewee Provide about their Role as Intermediary?*

All respondents agreed they would have needed more time and opportunities to prepare in advance. The interviewees suggest that they could have had more success if they had taken more time to stay with the seniors and explained how the robot works in more detail. They stated that they were often unable to answer senior citizens' questions and therefore felt uncomfortable. They felt that, in this way, they could not meet the needs of the seniors and also did not fulfill their role as mediators. Those surveyed would have liked to have tested the devices more intensively in advance to have more experience using them. One intermediary even reported that the senior knew more about the device and technology than he did, which made him uncomfortable in his role. A technical meeting beforehand, in which the devices and how they work, could have helped them with these problems. In addition, they would have liked to have had a more extensive range of operating instructions or additional in-depth information to better prepare for their role. To do this, the human coach should prepare in advance, including getting familiar with the project, the robot, and the user. The coach should also be aware of the user's age, background, and technical savvy to be able to communicate effectively and teach them. The interviewees felt the university was unprepared, lacked a manual and information, and did not complain. They believe the goal is to eliminate users' anxiety, be close to them, and enjoy the experience together. Technical knowledge is only at a basic level but the basis for building trust in the relationship triangle. The interviewees feel it is better to make users feel interested and have fun with the technology instead of making them feel like they cannot use it.

In addition to providing support with problems and answering seniors' questions, respondents also saw it as part of their role to be there for the seniors, to address their fears, and to build a relationship with them in general. They felt that listening to the seniors and not making them feel like they were being guinea pigs was essential. They wanted to interest users in the technology and motivate them to use it, but not persuade them. It was also important to them to respect the seniors and treat them as equals. The interviewees' self-conception is that the role of the human coach in this project is to listen carefully to the user and provide advice if they have any difficulties. They should be able to explain the project's purpose, how to use the robot and its functions, and how to nurture it. The human coach should also have a good understanding of the technology and hardware involved and can provide clear instructions and explanations. They should also empathize with the user to build a trusting relationship.

When working with the seniors, the mediators wanted to respond to the seniors' level of knowledge to adapt their explanations accordingly. At the same time, it was stated that explaining technologies such as messenger services to seniors unfamiliar with them was challenging.

If they could not answer the seniors' questions, they saw it as their job as mediators to forward them support. However, this sometimes led to frustration because no solution was found due to the long distances, and they could not help the seniors. As a further task, some of those interviewed defined setting up the devices for the senior citizens and picking them up at the end of the project phase. However, one of the facilitators made it very clear that he did not want to feel responsible for programming the robot, installing anything, and making it operational. Another criticized that he felt very uncomfortable going to the seniors with equipment that was not fully working.

In conclusion, human coaches must be outgoing and confident when interacting with people to help them better understand and use technology.

For the future, the wish was expressed to organize an information event before the equipment was set up for the seniors, at which the seniors would be informed about the project goal and what the devices would be like. In addition, some people wished to have more face-to-face meetings with the seniors to provide them with the best possible support and get to know them better. In this way, the intermediaries could first demonstrate the device and then start the explanations, as desired by one of them. There was also a demand that more information should be provided about data collection and processing so that intermediaries can pass on this critical information to older adults.

They also suggest that having a technical meeting with someone experienced with the technology and showing the seniors how the robots work in real life would help them understand how to use the robots better. The problem for the interviewees was that there was not enough time to get used to the devices before the study began. This led to negative feelings and a sense of responsibility as they had to justify any problems that arose. They felt motivated to ensure the study was successful but had to limit their involvement as they were

not a full-time employee. They believed it was essential to be familiar with the devices and technical context to explain while promoting self-efficacy experiences. These discrepancies should be considered for the latter human coaches to enable them for their task and ensure the technological system will be used sustainably.

*E. Cultural Differences and Demographic Aspects*

We could not find any aspects in our data that justify a cultural difference comparison. We could see that depending on the cultural setup for care facilities and care infrastructure, the technical needs of the used technical system differ a lot. However, for examining the role of the human coach, we could not identify cultural specifics that would justify a category on its own within this sub-study. Furthermore, we could not identify specific differences for comparing, e.g., age aspects in perception or role understanding. It was striking that the older respondents often not only report from the perspective of the older adults within the study but also consider their perspectives. In addition to possible functions or possible uses, this also affected the view of the current devices in the study. The younger participants did not have this perspective and remained in a more objective state of the report.

## V. DISCUSSION

*A. Findings*

Based on the interview data, it can be deduced that language interaction was significant to the respondents. They expected fluent conversations and a more comprehensive range of topics to discuss. Some also complained that the robots' voices sounded too technical. We found that the interviewees stated most prominently that the tested technologies had limited functions, poor voice control, and poor design and character. Furthermore, the structure of the functionalities was not self-explanatory enough. For example, respondents would like the system to notify the user when processing an entry or performing a search. The user should therefore be informed about the current system status, including its actions. The ability of the devices to have realistic, profitable conversations, including action explanations, seems to have an important influence on the reactance.

The range of functions also influenced the reactance. The respondents had high expectations of the devices, which were not met. In addition, some felt that the systems were not tailored to them. Therefore, it seems necessary to offer users functions with added value tailored to their needs. The technological challenges led to responsibility diffusion and uncertainty for the human coaches, potentially resulting in a lack of self-efficacy.

Category 2, which introduced the focus of relationship dynamics in the usage triangle of human coach, end user, and technology, indicated that it was felt to be very optimistic that there was a lively exchange between seniors, mediators, and developers. Questions could be answered quickly, and problems or feedback passed on. The mediators found this to be positive since they had a technical contact person and could get help despite the short preparation time and resources. In

this way, an essential trust could also be created as a prerequisite for cooperation. The seniors often viewed the devices as some pet or assistant, so they had certain expectations. These were not always realistic, which could lead to disappointment and frustration. It is, therefore, crucial that the mediators are fully informed about the functions and can also pass this information on to the seniors, right from the start. In combination with a higher level of reliability, the intermediaries could imagine sustainable use. In addition, the mediators would like to be socially included in the development process. Lastly, there seems to be a necessity for essential trust between all involved - mutual respect and appreciation of cooperation. We can thus summarize that for the relationship triangle of technology, user, and human coach; it is vital to consider those possible challenges that might lead to responsibility diffusions mentioned above and false, hindering expectations from all parties.

Category 3, which offered the opportunity to give in participatory ideas from the interviewees, showed us that data collection should be more comprehensive to understand the needs of individual seniors. Intermediaries should test functionalities one at a time and customize technology accordingly. They need to have enough time to prepare for and try out devices to ensure a good user experience. Explanations should be low-threshold and tailored to the individual's knowledge level. The introduction of the devices must also take place at the knowledge level of the seniors; the level must be tailored to them and their understanding of technology. These principles make it possible for the older person to feel in control of the robot and be able to use it without outside help. According to the mediators, this is the only way to achieve sustainable use.

To adapt the introduction for the seniors, the facilitators would need more time and information in advance to prepare optimally and start interacting with the seniors with a feeling of security. In addition, the intermediaries could also help with problems more quickly instead of often going through lengthy detours via the developers.

When setting up the ecosystem, it is thus of essential importance to consider an additional service that might help with upcoming tech challenges.

In Category 4, the interviewees reported in detail about their role as intermediaries. The facilitators agreed they needed more preparation before going to the seniors with the devices. In addition, they would like more time with the seniors to slowly introduce them to the individual devices and to be able to explain their functions in peace.

It would have been essential for their role to feel like a competent contact person for the seniors. This was often not possible for them due to a lack of advanced information and preparation time and, in some cases, the equipment's susceptibility to errors. In the event of problems, the mediators often could not help immediately and had to contact the developers themselves. They said this could have been avoided with better, more intensive preparation and detailed instruction manuals.

In addition to introducing the devices, the facilitators considered the emotional component crucial to their role. They wanted to be able to develop a relationship with the seniors to address their fears and worries and to be able to resolve them. They aimed to meet the older persons on eyelevel and to motivate them to use the device, but not to persuade them.

Summarizing, we can state that respondents wanted more time and opportunities to prepare in advance, as they felt uncomfortable if they could not answer questions from the senior citizens. They also desired to be able to test the devices more extensively before the event and become familiar with the technical context. Furthermore, respondents saw it as part of their role to be there for the seniors, to address their fears, and to build a relationship with them. When setting up the e-health ecosystem, we argue that it is necessary to consider the psychological aspects of the involved human coaches as much as those of the end-users to ensure sustainable technology usage and integration.

*B. Limitations*

A general limitation of qualitative research is a certain degree of subjectivity. The previous experience and working methods of the person carrying out the work can always influence the result. The weighting or interpretation of individual statements may also differ between different researchers. This was at least a little prevented in the present study because two different study participants looked at the results independently and evaluated the citations. The results were then processed together. Nevertheless, a certain degree of subjectivity is difficult to rule out completely.

In the present study, with 10 participants, comparatively few people were interviewed. To make matters worse, they formed a very heterogeneous group. There were several nationalities and an extensive age range represented. In addition, the participant's experience and knowledge about technology and robotics differed significantly. Due to this broad spectrum, whether generalizable results can be derived must be questioned. Technological competence could lead to the participants defining and fulfilling their roles as intermediaries in very different ways.

The unique view of one's role as an intermediary could also have been influenced by how long the respondents had already been employed in the associated e-VITA project and what tasks they had already carried out as part of this activity.

The distribution of nationality and age was very heterogenic. While five Japanese participated in the survey, only two German participants, for example, who were both relatively young, commented. This makes it difficult to compare the individual groups of participants.

Since we interviewed persons currently involved in the study, we cannot entirely ensure that the latter human coaches would present the same assessment as our interviewees. Since we are faced with several open questions regarding the system itself and the surrounding ecosystem, we must consider that those open aspects might influence the relationship dynamics of the triangle of human coach, user, and technological system. For example, we are still not sure about the final legal

aspects. The legal aspects of the system must be clarified: Who will be responsible for its later use and instruction? Furthermore, the target group of the human coaches must be considered: Will they be a diverse target group or a homogenous target group? The community level must also be considered: What part will the community play in supporting or hiring human coaches? Municipalities must determine which of the current ICT instructors will be the final human coaches in the final use of the system. Finally, social services and welfare organizations must consider which services they already offer for tech coaching and if they can be used for the later use of the tech system. To name some aspects that might be relevant for the relationship triangle and the latter assessment of the technology used.

Since we just had access to ten human coaches within this study, we must evaluate the sample as relatively small. However, we discussed in detail and at great length how the human coaches feel about the technological system and its relationship dynamics. We, thus, considered the sample sufficient for a first qualitative approach.

We also expect that conducting data in a group with similar technological savviness or ignorance might influence the results. However, since we could not access this kind of group within the study and concerning the open aspects mentioned above, we consider the results valuable indicators for our study, the development of project e-VITA, and other e-health developments.

*C. Future Studies*

In the future, we see the need to research the differences between different cultures, age groups, and levels of technological savviness to provide an excellent opportunity to explore the potential of future e-health technologies. For example, research into how people from diverse backgrounds interact with technology could reveal ways to bridge the gap between tech-savvy and those who are not. Additionally, research into the potential of human coaches, who are not currently involved in a particular setting, could provide valuable insights into how e-health technology can facilitate learning and growth. Finally, research into the effectiveness of e-health technology in a setting without open aspects and a fixed framework could provide valuable insights into how this specific technology can be used to create a more dynamic learning environment. All of these research opportunities could help us better understand how e-health technology and the ecosystem can be used to benefit people from different backgrounds and provide them with better access to healthy living opportunities at a later stage in life.

# Multispectral Image Analysis using Convolution Neural Networks

Arun D. Kulkarni

Computer Science Department
The University of Texas at Tyler
Tyler, TX 75703, USA

*Abstract*—**Machine learning (ML) techniques are used often to classify pixels in multispectral images. Recently, there is growing interest in using Convolution Neural Networks (CNNs) for classifying multispectral images. CNNs are preferred because of high performance, advances in hardware such as graphical processing units (GPUs), and availability of several CNN architectures. In CNN, units in the first hidden layer view only a small image window and learn low level features. Deeper layers learn more expressive features by combining low level features. In this paper, we propose a novel approach to classify pixels in a multispectral image using deep convolution neural networks (DCNNs). In our approach, each feature vector is mapped to an image. We used the proposed framework to classify two Landsat scenes that are obtained from New Orleans and Juneau, Alaska areas. The suggested approach is compared with the commonly used classifiers such as the Decision Tree (DT), Support Vector Machine (SVM), and Random Forest (RF). The proposed approach has shown the state-of-the-art results.**

*Keywords—Convolution neural networks; machine learning; multispectral images; remote sensing*

## I. INTRODUCTION

Recently there has been a great interest in the research community to adapt CNNs to analyze multispectral images. Machine learning algorithms such as the decision tree (DT), ensemble of decision trees, support vector machine (SVM), Naïve Bayes classifier and fuzzy inference system are used to classify pixels in multispectral images. CNN-based methods have attracted a great deal of attention due to their ability to dig latent representations and features from images. Borisov, et al. [1] in their survey article provided an overview of deep learning methods for tabular data. They point out that CNN models have repeatedly shown excellent performance and have been widely adapted. However, adaptation of CNN models to tabular data remains highly challenging. DCNNs have shown high accuracy in many image classification applications. They are flexible and allow iterative learning. With advances in hardware and availability of graphical processing units (GPUs) deep learning (DL) models can be used in real-life applications. The main drawback of CNN models is that they commonly use gradient decent backpropagation algorithm with Sigmoid activation functions that leads to saturation resulting in slow gradient convergence, which is known as a vanishing gradient problem. To avoid the vanishing gradient problem, CNNs use entropy loss function with rectified linear units (ReLU) in the output layer. Overfitting usually occurs when the dataset is small. To overcome this problem, various regularization techniques such as dropout and bagging are used. CNN models can be trained with large datasets and can classify images with high accuracy. For ML algorithms, data are presented in the table form whereas for CNN input data are presented in the form of images. CNN models generate a feature vector from input images via convolution and pooling layers. The feature vector represents integrated information from various shapes that are present in the input image.

To use available CNN models and take advantage of these models such as high accuracy, we propose a novel approach to convert data in the table form to images. In ML algorithms input data are in table form, where each row in the table represents a feature vector for an entity and columns describe properties. In many fields such as genomics, transcriptomic, spoken words, financial and banking data are in non-image form. A few researchers have proposed techniques to map numeric data in a table form to images [2 - 4].

We propose a method to map a feature vector into an image. The shapes in the mapped image represent features and ratios between the features. The approach was motivated by two factors. The first motivational factor is that band ratios in Landsat images are used for determining soil moisture coefficients and vegetation indices [5], which indicates that feature ratios contain additional information in the sample than features alone. The second motivational factor is that CNN models provide multiple levels of abstraction and generate a feature vector that combine low-level and high-level information of shapes in the image. To validate our framework, we analyzed two Landsat-8 scenes. Landsat-8 OLI provides images with 30-meter resolution in seven spectral bands. Band 1 reflects deeper blue-violet hues and is used in mapping coastal regions. Bands 2, 3, and 4 are visible blue, green, and red are used in land use mapping. Band 5 measures the near infrared (NIR). Bands 6 and 7 cover different slices of the shortwave infrared (SWIR). They are particularly useful for telling wet earth from dry earth, and for geology [6]

We implemented the algorithm to map table data into images using a MATLAB script. In addition, we implemented Alex Net using MATLAB deep learning toolbox. We analyzed two scenes, one from New Orleans, and another from Juneau, Alaska. To classify pixels in the image each pixel is represented by a vector consisting of reflectance values in multiple spectral bands. We extracted training set data by displaying scenes on the monitor and selecting small homogeneous areas that represent distinct categories on the ground. We selected four training areas that represented four

categories for the Alaska scene, and three training areas that represented three categories for the New Orleans scene. We selected reflectance values from spectral bands 2, 3, 4, 5, and 7, as these bands showed the maximum variance. The organization of the paper is as follows. Section II describes the related work. Section III provides the framework for the proposed approach. Section IV deals with the experiment and results, and the whole study is concluded in Section V.

## II. RELATED WORK

In remote sensing data are obtained as multispectral images. Many ML algorithms are being used to classify pixels in a multispectral image. The conventional ML techniques for classification require the sample in the form of a feature vector. In classifying Landsat-8 scene, each pixel is represented by a feature vector obtained by reflectance values in different spectral bands. A few small homogeneous areas representing distinct categories on the ground are identified and the feature vectors associated with pixels in those training areas are used to generate training set data. Conventional ML techniques include the maximum likelihood classifier (MLC), decision tree (DT), support vector machine (SVM), Random Forest (RF), multi-layer perceptron model, and fuzzy inference system. The maximum likelihood classifier assumes normal distribution of reflectance values and is commonly used in remote sensing applications. Huang et al. [7] have used the SVM to classify pixels in multispectral images and their model obtained higher accuracy. The SVM is appealing for Landsat data analysis because it classifies small data sets with high accuracy [8]. Moumtrakis et al. [9] have provided a review of usage of SVM in remote sensing. Another commonly used algorithm to classify pixels in multispectral images is a decision tree (DT). The main problem with the DT is overfitting. DT shows high accuracy with the training data, however; it may not perform well in classifying unknown data samples. Lowe and Kulkarni [10] used the random forest algorithm for classification of pixels in Landsat data.

CNN models represent one of the best learning algorithms for understanding image contents and have shown exemplary performance in computer vision tasks. CNN models use multiple layers of nonlinear information processing units. Machine-learning community's interest in CNN grew after Image-Net competition in 2012, where Alex Net achieved record breaking results in classifying images from the dataset containing more than 1.2 million images from one thousand classes. Alex Net proposed by Krizevsky et al. [11] was based on principles used in LeNet. DCNNs have brought about breakthroughs in processing images, videos, speech, and audio [12]. In general CNN models consists of convolution and pooling layers that are grouped followed by one or more fully connected layers. They are feed-forward networks. In convolution layers, inputs are convolved with a weighted kernel and the output is sent via a nonlinear activation function to the next layer. The purpose of the pooling layer is to reduce spatial resolution. Rawat and Wang [13] provide a comprehensive survey of CNNs. Zhang et al. [14] provide taxonomy of CNN models. CNNs can learn internal representations from raw pixels and are hierarchical learning models that can extract features [15, 16]. Liu et al. [17] provide a survey of deep neural network architectures and their

applications. Khan et al. [18] in their review article classified DCNN architectures into seven categories. Deep learning allows computational models that are composed of multiple processing layers to learn representations of data with multiple levels of abstraction. Recent developments in CNN models were possible because of the availability of faster graphical processing units (GPUs) and availability of large data sets. Kulkarni in [19] used the Alex Net to classify two image datasets. The first dataset contained four hundred animal images of two types of animals and obtained 99.1 percent accuracy. The second dataset contained four thousand images of five types of flowers and obtained 86.64 percent accuracy.

Remote sensing images are often obtained in multiple spectral bands. Traditional ML are used to classify pixels in multispectral images, where each pixel is represented by a feature vector consisting of reflectance values from different spectral bands. There is a great deal of research directed towards CNN architectures for RGB images, while a relative dearth of research directed towards CNN architectures for multispectral and hyperspectral images. Many DCNN models have been deployed to analyze remote sensing data. Castelluccio et al. [20] explored the use of CNN models for semantic classification of remote sensing scenes. They resort to pre-trained CNNs that are only fine-tuned on the target data to avoid overfitting problems and reduce design time. Liu [21] used R-CNN for multispectral pedestrian detection task and then modeled it into a convolution network (ConvNet) for the fusion problem. Xu et al. [22] proposed a CNN framework to extract spectral-spatial features from hyperspectral imagery (HIS) and light detection and ranging (LiDAR) data, and to combine HIS and LiDAR data. Chen et al. [23] used Faster R-CNN for airport detection from Landsat images. Their experimental results show that for the same training samples their CCN based approach outperforms traditional SVM and state-of-the-art CNN based methods. Senecal et al. [24] have created a small CNN architecture capable of being trained from scratch to classify 10 band multispectral images. Osorio et al. [25] used a deep learning approach for weed detection. They used a method YOLOV3 (you only look V3), taking advantage of robust architecture for object detection. Garcia et al. [26] studied the use of different CNN architectures for cloud masking in multispectral images. Yuan et al. [27] proposed a novel DCNN architecture that outperforms the state-of-the-art DCNN-based water body detection methods. Wu et al. [28] proposed a deep-learning-based new framework for multimodal remote sensing data classification.

Tabular data are the most used data. DCNN models have shown excellent performance and have therefore been widely adapted. However, their adaptation to tabular data remains highly challenging. Borisov, et al. [1] provide an overview of deep learning methods for tabular data. They categorize these methods into three groups a) data transformations, b) specialized architectures, c) regularization models. In this work we consider the first category data transformations. DCNNs offer multiple advantages over traditional ML techniques. First, they are flexible and allow iterative learning. Second, tabular data generation is possible using deep networks and can help mitigate class imbalance problems. Third, neural networks can be deployed for multimodal learning problems where tabular

data can be one of many input modalities [1]. To our knowledge there are very few methods that have been reported for analyzing tabular data using CNN models. Sharma et al. [2] developed a method called DeepInsight to transform non-image data to images for CNNs. Their method constructs an image by placing similar features together and dis-similar ones further apart enabling the collective use of neighboring elements. This collective approach of element arrangements can be useful in understanding relationships between a set of features. They employed four distinct kinds of datasets to evaluate their algorithm. They compared the obtained results to state-of-the art classifiers such as the decision tree, Ada-boost, and random forest. Their model had shown better classification accuracy for all datasets. Buturovic and Mitkovic [29] proposed algorithm called TAC (table to convolution) to embed a feature vector into image. They used the base-image, and the feature vector is used as a kernel to obtain the convolved image. Zhu et al. [3] have suggested a method called Image Generator for Tabular Data (IGTD) to transform tabular data into images by assigning features to pixel positions so that similar features are close to each other. The algorithm assigns each feature to a pixel in the image. An image is generated for each data sample, in which the pixel intensity reflects the value of the corresponding feature in the sample. The algorithm searches for the optimized assignment of features to pixels by minimizing the difference between the ranking of the pairwise distances between features and the raking pairwise distances between assigned pixels. To investigate the utility of the IGTD, they applied the algorithm to two datasets CCL gene expression and drug molecular descriptors. They transformed these tabular datasets into images and classified them using CNN. Their results show that the CNNs trained on IGTD images provide the highest average prediction performance in cross-validation on both datasets. Kulkarni [30] has proposed a method to map tabular data into images. Each feature vector is mapped to an image. The number of mapped regions in the image is equal to the number of features and the gray values of the regions represent feature values. The algorithm was used to classify a dataset representing URLs for phishing detection. Sun et al. [4] have proposed a method to convert tabular data into images called SuperTML. The algorithm borrows the concept of the Super Characters method to address tabular data machine learning tasks. For each input tabular features are first projected onto a two-dimensional embedding and fed into fine-tuned two-dimensional CNN models for classification. They validated the algorithm by using four datasets. Their experimental results show that SuperTML method has achieved state-of-the-art results on both large and small tabular datasets.

## III. PROPOSED FRAMEWORK

In machine learning approaches such as decision tree, support vector machine, models are trained using feature vectors from the training set data. In our method, we convert feature vectors into images, which are saved in DataMart. Images are saved in the folders that are labeled with class names. The CNN model is trained with images in Datamart. The framework for the CNN training is shown in Fig. 1. The crucial step in the proposed approach is to convert a feature vector into a 2-D image matrix. In the proposed approach the output image contains $n^2$ rectangles, where $n$ represents the number of features in the feature vector. For example, if there are five features in the feature vector, the corresponding output image contains twenty-five rectangular shapes. The areas diagonal squares represent the features, and the areas of the off-diagonal rectangles represent ratios of the features as shown in Eq. (1), where $A_{ij}$ represents the area of the shape, $i$ and $j$ represent. the row and the column numbers of the shape and $f_i$ represents a feature $i$.

$$A_{ij} = \begin{cases} \left(\dfrac{f_i}{f_j}\right) & if\ i \neq j \\ \left(f_i^2\right) & if\ i = j \end{cases} \tag{1}$$

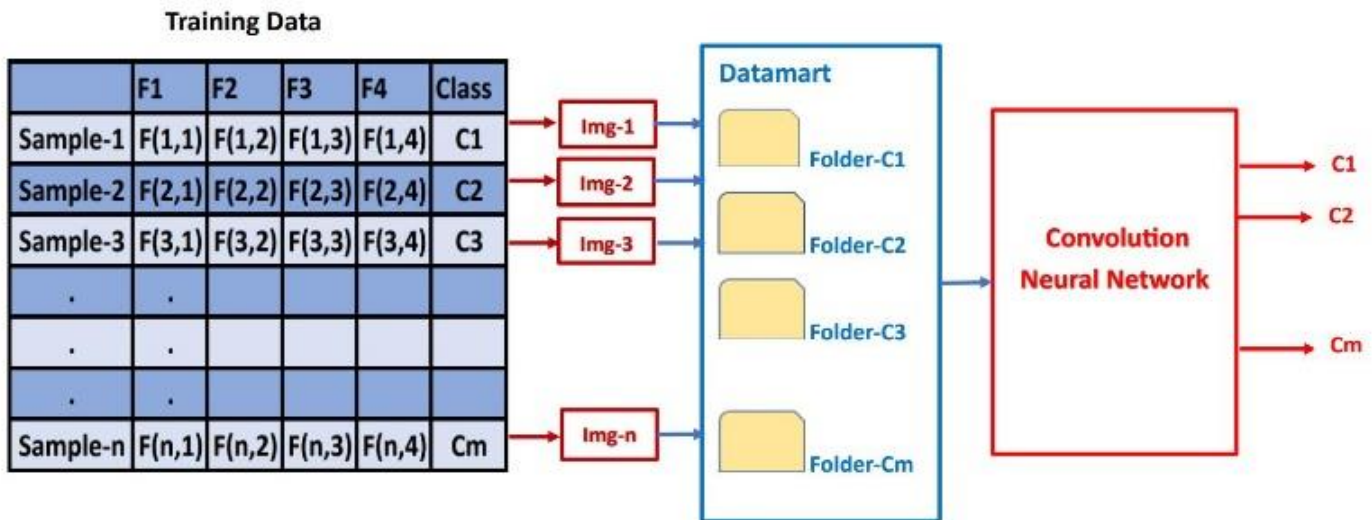

Fig. 1. Framework for CNN learning.

It can be seen from Fig. 2 that the widths and heights of diagonal rectangles represent feature values. The widths of the off-diagonal rectangles represent feature values, and heights of the off-diagonal rectangular shapes represent inverse of feature values.

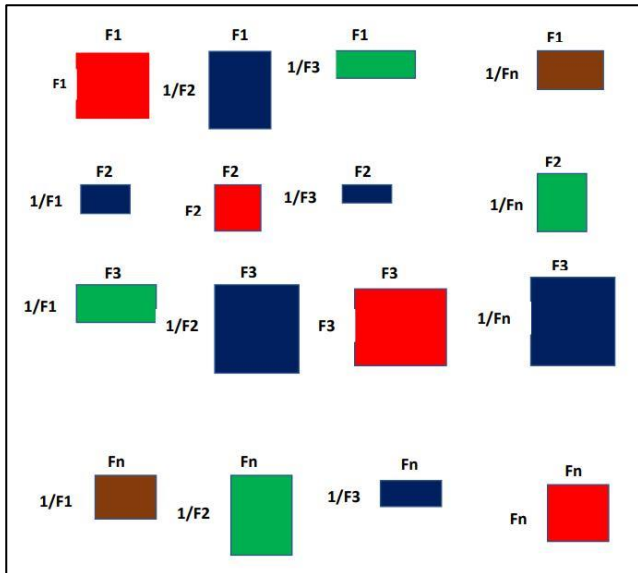

Fig. 2. Mapped image with n features.

Layers of a DCNN include the input layer, convolution layer, batch normalization layer, ReLU layer, max pooling layer, fully connected layer, SoftMax layer, and classification layer. We can specify the input image size at the input layer. Convolution layers serve as feature extractors. Inputs are convolved with learned weights to compute feature maps and results are sent through a nonlinear activation function. The output of the $k^{th}$ feature map is given in Eq. (2).

$$Y_k = f\left(W_k * x\right) \quad (2)$$

where, $x$ denotes the input image, $W_k$ is the convolution filter. The '*' sign refers to the 2-D convolution operator [13] The batch normalization layers normalize the activations and gradients propagating through the network, which makes the training an easier optimization problem. The batch normalization layers are followed by ReLU layers. The purpose of the pooling layer is to reduce the spatial resolution by downsizing and extract invariant features. The max pooling layer is used to downsize the network and extract features. The fully connected, SoftMax and classifier layers map the feature vector to class labels. The output of the SoftMax layer consists of positive numbers that sum up one that are used as class probabilities. We used Alex Net to classify feature vectors. Layers of Alex New are shown in Fig. 3. The model consists of eight layers: five convolution layers and three fully connected layers.

Fig. 3. Layers of alex net.

## IV. EXPERIMENT AND RESULTS

We developed software to map tabular data into images using MATLAB script. The output images were stored in their respective class folders. We also implemented Alex Net using the MATLAB toolbox. The DCNN model was trained with images that were generated from feature vectors in tabular training set data. We classified pixels from two sub-scenes using the trained DCNN model. We considered Landsat-8 scenes that were obtained by Operational Land Imager (OLI).

### A. Example-1 New Orleans Scene

The scene was obtained by Landsat-8 OLI on February 26, 2016. The path and row numbers for the scenes are 22 and 39, respectively. To generate the training set data, we considered the scene of the size 1000 by 1000 pixels. Three small homogeneous areas were selected as training sets that represent three classes water, land, and vegetation. The training set data contains 600samples, 200 from each class. We selected band-2, band-3, band-4, band-5, and band-7. The spectral signatures obtained from mean vectors of the classes are shown in Fig. 4. During training, feature vectors are mapped to images. Each image represents a feature vector representing a pixel in the multispectral image. The mapped images were stored in their

respective class folders. These images were used to train and validate Alex Net. We used 70 percent randomly selected images for training and 30 percent for validation. With Alex Net we obtained the overall accuracy of 98.33 percent. The learning progress curve for Alex Net is shown in Fig. 5. The confusion matrix is shown in Fig. 6 and the ROC curves are shown in Fig. 7. We used the trained network models to classify sub-scene of the size 256 by 256 pixels. Fig. 8 shows the classified scenes for the New Orleans area.

Fig. 7.   ROC curve New Orleans scene.

Fig. 4.   Spectral signatures for New Orleans scene.

Fig. 5.   Training progress curve for New Orleans scene.

Fig. 8.   Classified New Orleans scene.

### B.  Example-2 Juneau Alaska Scene

The scene was obtained by Landsat-8 OLI on June 13, 2016. The path and row numbers for the scene are 58 and 19, respectively. To generate the training set data, we considered the scene of the size 1000 by 1000 pixels. Four small homogeneous areas were selected as training sets that represent four classes' water, vegetation, ice-land, and glaciers.

The training set data contains 400 samples, 100 from each class. We selected band-2, band-3, band-4, band-5, and band-7 as features. The spectral signatures obtained from mean vectors of the classes are shown in Fig. 9. During training, feature vectors mapped into images. Each image represents a feature vector representing a pixel in the multispectral image. The mapped images were stored in their respective class folders. These images were used to train Alex Net. We used 70 percent randomly selected images for training and 30 percent for validation. We obtained the overall accuracy of 98.33 percent. The learning progress curve for Alex Net is shown in Fig. 10. The confusion matrix is shown in Fig. 11 and ROC curves are shown in Fig. 12. We used a trained network model to classify sub-scene of the size 256 by 256 pixels. The classified scene is shown in Fig. 13.

Fig. 11. Confusion matrix Alaska scene.

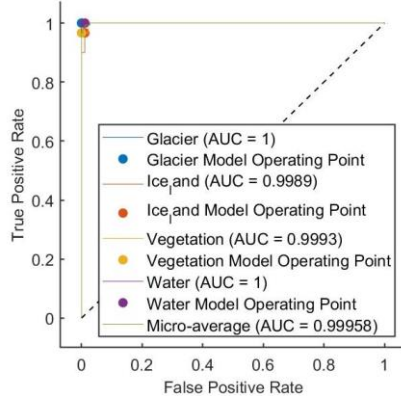

Fig. 12. ROC curve Alaska scene.

Fig. 13. Classified Alaska scene.

## C. Comparison of Classifier Results

We also classified both datasets using DT, SVM, and RF algorithms. The results are shown in Table I. It can be seen from the results that the proposed algorithm provides state-of-the-art results.

TABLE I. OVERALL ACCURACY

| *Dataset* | *Decision Tree* | *Support Vector Machine* | *Random Forest* | *Alex Net* |
|---|---|---|---|---|
| New Orleans Scene | 98.33 % | 97.50 % | 97.50 % | 98.33 |
| Alaska Scene | 96.11 % | 97.22 % | 98.89 | 98.33 |

## V. CONCLUSIONS

In this paper, we proposed a new method to classify tabular data using CNNs. We used the proposed method to classify pixels in a multispectral image. We developed the algorithm and implemented it using MATLAB script. We analyzed two Landsat-8 scenes, one from the New Orleans area and another from the Alaska area. The training set data for these scenes were generated by selecting small homogeneous areas from the displayed scenes. Feature vectors were mapped to images that were used to train the DCNN model. The results show that the proposed approach yields the state-of-the-art results. The limitation of the proposed approach is that the number of features that can be processed. This is due to the limit on the number of rectangular regions that can be accommodated in a transformed image. The maximum size of the transformed image is finite which limits the number of shapes in the transformed image. The future work includes using other complex shapes to represent feature values and using DCNN models such as Resnet-50 and Google Net so that the overall accuracy can be improved. Also, we would like to extend the algorithm for remote sensing images with a greater number of spectral bands.

*Abstract*—Multispectral imaging has become more important in several areas during this decade to overcome the limitations of color imaging. There are several types of multispectral acquisition systems, including single-shot cameras that incorporate Multispectral Filter Arrays (MSFA). MSFA is an extension of the color filter array. Acquisition systems that incorporate spectral filter arrays are very fast, lightweight, and able to acquire moving scenes. But these cameras are manufactured with at best software for filter positioning correction without demosaicing software. Hence there is a need to identify a suitable demosaicing algorithm in terms of image quality, computation time, and decorrelation factor. This paper presents a comparative study of four relevant demosaicing methods in the facial recognition process using images acquired with a single-shot MSFA camera designed in our laboratory. To achieve this goal, the four demosaicing methods named bilinear interpolation, discrete wavelet transform, binary tree, and median vector were adapted to multispectral images acquired using a MSFA camera. Evaluations were first performed using the NIQE performance metric and the correlation coefficient. Then Demosaced images were used to train VGG19 neural network to know which demosacing method better contains relevant features for recognition and better computation time. Results reveal that bilinear interpolation provides the less correlated images and the binary tree gives the best quality images with a NIQE of 8.99 and an accuracy of 100% for face recognition.

*Keywords*—*Multispectral image database; multispectral imaging; multispectral filter array (MSFA); one-shot camera; facial recognition system*

## I. INTRODUCTION

Most of today's color cameras incorporate color Filter Array (CFA) or Bayer filters [1], [2]. The color filter array contains three filters: green, red, and blue, each one responsible for acquiring the image in each spectral band. These cameras are very fast, displaying the acquired image in a matter of seconds. Despite this performance, facial recognition [3] with color cameras is affected by problems of light variations, occlusions, and pose variations [4], [5]. Multispectral imaging corrects these problems, with more information available in the image bands. There are three types of multispectral acquisition systems: multi-camera systems, multi-sensors systems, and one-shot MSFA systems. The first two types are very slow, heavy, and consume more energy. One-shot MSFA cameras help to overcome the problems associated with the other two types. The one-shot MSFA cameras are equipped with MSFA which is an extension of CFA [6]–[8]. The MSFA includes more than three filters. Each filter is responsible for the acquisition of the image on a given wavelength. The acquisition systems that incorporate the multispectral filters array allow the acquisition of a single image on several spectra simultaneously. These are compact, one-shot cameras, very fast, and capable of capturing moving scenes. MSFA one-shot cameras solve the problems associated with conventional multispectral cameras, which are the heaviness and slowness during the acquisition of multispectral images. MSFA one-shot cameras are used in several fields such as agriculture, medical imaging, and pattern recognition [9]–[12].

A recognition system is composed of four main modules namely acquisition, feature extraction, matching, and decision. The performance of the system depends on each of the modules. There are several facial recognition systems in the multispectral but most of them use multispectral cameras consisting of multiple single-shot cameras or a single-shot camera in scanning mode. For the acquisition module, a database of face images was collected with a single-shot MSFA camera for facial recognition. This camera is mainly equipped with a viiamagic CMOS sensor, a MSFA with eight filters, micro-lens, an electronic board to drive the sensor, and a camera board for image acquisition. The MSFA bands were selected theoretically with a genetic algorithm combined with a facial recognition application [13]. This acquisition system covers the spectral range from 650 to 950 nm and produces raw or mosaic images which require demosaicing before use. Demosaicing is a method of estimating the value of missing pixels in a given band. At the end of demosaicing the number of multispectral images obtained is equal to the number of filters that compose the MSFA. Some demosaicing methods [14]–[18] are developed during the theoretical design of the MSFA, but the industrial constraints of MSFA manufacturing mean that effective demosaicing methods are developed after the MSFA is manufactured. In this case, we already have a MSFA camera, and we want to determine suitable demosaicing methods using its images. Demosaicing methods impact the image quality and thus the performance of the facial recognition system with a single-shot MSFA camera. Single-shot MSFA cameras are very efficient and fast, but the quality of the demosaic images depends on the demosaicing method used.

This paper presents the comparative study of four demosaicing methods to identify the one that gives:

- The best image quality result.

- The best decorrelation factor.

- The best facial recognition score.

- And the best computation time.

For these purposes, we adapted some currently used algorithms namely demosaicing algorithms Bilinear Interpolation, Discrete Wavelet Transform (DWT), Binary Tree, and Median Vector to demosaic the images acquired with our camera. A comparison of the demosaiced images is made with the NIQE metric and the intercorrelation between the demosaiced image bands is analyzed with the coefficient correlation. The convolutional neural network VGG19 is used to evaluate the impact of demosaicing on facial recognition in terms of accuracy and computation time. To the best of our knowledge, this is the first study that focuses on demosaicing after the MSFA camera is manufactured.

This paper is structured as follows: Section II briefly presents the MFSA one shot camera, material and methods in Section III, followed by experimental results and discussion in Section IV. The paper ends with the conclusion and future perspectives in Section V.

## II. THE MSFA ONE SHOT CAMERA

Multispectral imaging with a single camera equipped with a spectral or multispectral filter array allows acquiring multispectral images simultaneously on several spectral bands. The concept of a multispectral filter array is an extension to n bands of the color filter array that revolutionized digital cameras. A spectral filter array is composed of n filters and each of them is responsible for the acquisition of the image on a given band. The MSFA camera used in this work is composed of a single Viimagic 9220H sensor, an MSFA for the single-tap imaging system, optical lenses, an electronic board to drive the sensor, and a camera board for image acquisition. This acquisition system was designed in the Imaging and Artificial Vision (ImViA) laboratory formerly known as the Laboratory of Electronics, Informatics, and Image (LE2I) as part of the EU H2020 project called EXIST (Extended Image Sensing Technologies) [13]. It is a light and compact camera that covers wavelengths from 650 to 950 nm. The spectral filter array integrated into this camera is made up eight optimal filters selected in the wavelengths {685, 720,770, 810, 835, 870, 895,930}. The design of this custom filter array uses the Fabry-Perot interferometer. The MSFA system integrated into this camera with dedicated hardware and software calculations allows working in real time with 30 frames per second. The filters used to overcome the problems caused by illumination variation, motion blur noise, and SNR noise that severely affect the performance of facial recognition systems using CMOS. The multispectral filter array is characterized by its moxel which is defined by a mosaic of elementary filters repeated across an MSFA. Fig. 1 illustrates the moxel used.

Fig. 1. Final moxel of the MSFA.

## III. METHODS

### A. Motivation

The literature distinguishes three categories of demosaicing methods: pixel interpolation, frequency transformation, and probability of appearance (POA). Pixel interpolation consists in using the value or weight of neighboring pixels to estimate the value of a missing pixel. Methods such as bilinear interpolation, weighting bilinear interpolation, and binary tree use pixel interpolation. Frequency transformation involves using wavelets to extract essential information from neighboring pixels to estimate the value of the missing pixel. Frequency transformation includes methods such as Discrete Wavelet Transform. Probability of appearance refers to methods that determine the probability of the occurrence of a band and a pixel in a selected band to estimate the value of the missing pixel. These methods include approaches based on binary trees. In general, demosaicing methods depend on the MSFA moxel but nowadays there are generic demosaicing methods that can be adapted to any type of MSFA. Discrete Wavelet Transform, Bilinear Interpolation, Binary three, and vector median filtering were selected for the comparative study. These four demosaicing methods were selected because each one presents some interesting characteristics for the study. These were chosen for the following reasons:

- Bilinear interpolation uses the value or weights of neighboring pixels to estimate a missing pixel in a given band. Most demosaicing algorithms combine their demosaicing technique with bilinear interpolation [17], [19]–[21].

- Binary Tree-based Edge-Sensing method is a generic approach that uses the notion of POA to select the band and the pixel in the selected band. This method combines POA, and bilinear interpolation based on the edge–sensing information [22] to determine the value of the missing pixel.

- Discrete Wavelet Transform based MSFA demosaicing [17] is a technique that uses frequency information and Weighted Bilinear interpolation to approximate the value of the missing pixel.

- Vector median filtering [23] is a demosaicing method whose specificity is to use vector based operations and the concept of pseudo pixel. This method groups neighboring pixels according to the size of the moxel to evaluate the value of the pixel missing.

## B. Preprocess

The images acquired with the MSFA one-shot cameras are raw images or mosaic images and must be process or demosaic before using. Demosaicing is a technique that consists in reconstructing each band of the multispectral according to the number N (N=8 in this study) of filters contained in the MSFA. Before demosaicing, a preprocess of band extraction is first performed. This preprocess consists in multiplying each mosaic image by different binary masks $M^k$ as defined by the Eq. (1).

$$M^k_{(x,y)} = \begin{cases} 1 \ si \ \left( x \ mod \ \sqrt{K} \right) + \left( y \ mod \ \sqrt{K} \right) \times \sqrt{K} = k \\ 0 \ else \end{cases} \quad (1)$$

This transformation gives eight planes of shifted images in which only one component is available at each pixel. Fig. 2 illustrates this transformation.

Fig. 2. Images bands obtained after applying the mask.

After pre-processing, the missing pixels in each image band are estimated using the four selected demosaicing methods.

## C. Bilinear Interpolation based MSFA Demosaicing

The bilinear interpolation based demosaicing is the simplest method for calculating the value of pixels missing during the demosaicing process. Other demosaicing methods combine their specificities with bilinear interpolation [24]. Bilinear interpolation approximates each missing pixel value by means of a distance weighted average of its neighboring pixels. As its name indicates, bilinear interpolation is a succession of two linear interpolations. The linear interpolation can be performed in multiple directions. For a missing pixel $P(i,j)$ at position$(i,j)$, the linear interpolation is defined in Eq. (2), Eq. (3) and Eq. (4) as follows:

* Diagonally

$$P(i,j) = \frac{1}{4} \sum_{(m,n)=(-1,-1),(-1,1),(1,-1),(1,1)} p(i+m, j+n) \quad (2)$$

* Vertically

$$P(i,j) = \frac{1}{2} \sum_{(m,n)=(-1,0),(1,0)} p(i+m, j+n), \quad (3)$$

* Horizontally

$$P(i,j) = \frac{1}{2} \sum_{(m,n)=(0,-1),(0,1)} p(i+m, j+n) \quad (4)$$

For this study, a convolution filter $H$ is used for demosaicing. This filter is defined according to the spatial distance between the neighbors of the central pixel. The interpolated image band $I^k$ is defined by Eq. (5) as:

$$I^k = I'^k \odot H \quad (5)$$

with

$$H = \begin{pmatrix} 5 & 5 & 1 & 1 & 6 & 6 & 8 & 8 & 1 & 1 & 6 & 6 \\ 5 & 5 & 1 & 1 & 6 & 6 & 8 & 8 & 1 & 1 & 6 & 6 \\ 4 & 4 & 8 & 8 & 3 & 3 & 4 & 4 & 5 & 5 & 3 & 3 \\ 4 & 4 & 8 & 8 & 3 & 3 & 4 & 4 & 5 & 5 & 3 & 3 \\ 2 & 2 & 7 & 7 & 5 & 5 & 2 & 2 & 7 & 7 & 8 & 8 \\ 2 & 2 & 7 & 7 & 5 & 5 & 2 & 2 & 7 & 7 & 8 & 8 \\ 5 & 5 & 1 & 1 & 6 & 6 & 8 & 8 & 1 & 1 & 6 & 6 \\ 5 & 5 & 1 & 1 & 6 & 6 & 8 & 8 & 1 & 1 & 6 & 6 \\ 4 & 4 & 8 & 8 & 3 & 3 & 4 & 4 & 5 & 5 & 3 & 3 \\ 4 & 4 & 8 & 8 & 3 & 3 & 4 & 4 & 5 & 5 & 3 & 3 \\ 2 & 2 & 7 & 7 & 5 & 5 & 2 & 2 & 7 & 7 & 8 & 8 \\ 2 & 2 & 7 & 7 & 5 & 5 & 2 & 2 & 7 & 7 & 8 & 8 \end{pmatrix}$$

And $I'^k$ the image band.

## D. Discrete Wavelet Transform based MSFA Demosaicing

A Discrete Wavelet Transform (DWT) is a transform that decomposes a given signal into a number of sets, where each set is a time series of coefficients describing the time evolution of the signal in the corresponding frequency band. When applied to an image, DWT transforms the image into different frequency bands. DWT is used to decompose images into a series of sub-bands with different frequency components. Over the decades, several DWT-based methods have been proposed in [25]–[29] for Color Filters Array (CFA) demosaicing. Xingbo et al. [16] extended the application of DWT into MSFA demosaicing. MSFA demosaicking based on DWT encompasses the concept of Down Sampling images, the Haar wavelet (D2), the "replace" rule for the estimation of high-frequency sub-bands and bilinear interpolation for the estimation of low-frequency sub-bands. This approach is applicable to any MSFA with a regular mosaic pattern, regardless of the number of channels. The algorithm is performed in three successive steps as follows:

* High-frequency estimation: First, the image is divided into K down sampled images and each of them is decomposed into spatial frequency sub-bands by DWT using Haar wavelet. Then, estimate the coefficients of the missing DS images in the high frequency sub-bands according to the "replace" rule.

* Low-frequency estimation: Apply bilinear interpolation to the mosaicked image plane by plane and extract the low frequency by image decomposition using Haar wavelet. Then replace the coefficients of the missing DS images at low-frequency sub-bands with those of the interpolated DS images.

* Recompose the low-frequency and high-frequency components and compute inverse discrete wavelet transform to reconstruct the demosaiced image.

This method has been tested by the authors with CFA and two MSFA of four-bands and eight-bands visible. Given the compatibility of this method with all MSFA with regular patterns, regardless of the number of channels, we have modified it to our eight-bands MSFA described above with two pixels per band. For this algorithm, the wavelengths of the bands have been modified by considering the following wavelengths {685, 720, 770, 810, 835, 870, 895, 930 nm} for the eight bands.

*E. Binary Tree based MSFA Demosaicing*

Lidan Miao et al. [20]–[22] had proposed a generic demosaicing method based on a binary tree. Specifically, this approach uses the Binary Tree Edge Sensing Method (BTES). The missing pixels are estimated progressively using all the edge correlation information of all spectral bands. Binary tree based MSFA demosaicing can be adapted to any $4 \times 4$ MSFA. The generic demosaicing algorithm consists of three interconnected modules: band selection, pixel selection and interpolation [20].

- Band selection: This module defines the interpolation order of the different spectral bands by using the POA. The spectral bands have different POA, and the spectral band with the highest POA contains the most detailed information. Band selection is equivalent to selecting leaf nodes (spectral bands) at different levels of the tree. Nodes located at the same level have the same POA, and the deepest nodes have the smallest POA. The band selection process is described as follows: first, the band with the highest POA is selected, the leaf node at the first level of the binary tree. Then, for levels with more than one leaf, the bands at the next level are randomly selected. Finally, this process is repeated until the last level of the tree.

The band with the most edge information is interpolated first and the edge information from the first interpolated band is used to estimate the other bands.

- Pixel selection: This module determines the order of interpolation of pixel locations in each spectral band. The estimation of the pixel values is done gradually. First, some of the missing pixel values are estimated. The other unknown pixel values are then estimated using these estimated pixel values and the MSFA samples. The algorithm uses the binary tree for the pixel's selection. It takes as input the leaf patterns selected during band selection and interpolates for each of them first the missing band information at the pixel locations where its sibling pattern is located, and then the algorithm goes up one level in the binary tree to find the sibling of its parent pattern. If the latter is an internal node, then the leaf patterns in the subtree below that sibling pattern are examined. This part is repeated until the root of the tree.

- Interpolation is used to estimate the value of the missing pixels with selected pixel for a selected band. The estimate of the value of a pixel $P$ at position $(i, j)$ is calculated by the weighted sum of these four neighboring pixels and their contributions. The weights

of these four pixels are estimated based on their edge magnitudes. The weights of two neighboring pixels along the vertical and horizontally direction are calculated by Eq. (6) and Eq. (7).

Vertically:

$$W_{m,n} = \left(1 + \left|P_{m+2,n} - P_{m,n}\right| + \left|P_{m-2,n} - P_{m,n}\right| + \frac{1}{2}\left|P_{m-1,n-1} - P_{m+1,n-1}\right| + \frac{1}{2}\left|P_{m-1,n+1} - P_{m+1,n+1}\right|\right)^{-1} \quad (6)$$

With $m \in \{i - 1, i + 1\}, n = j$

Horizontally:

$$W_{m,n} = \left(1 + \left|P_{m,n+2} - P_{m,n}\right| + \left|P_{m,n-2} - P_{m,n}\right| + \frac{1}{2}\left|P_{m+1,n-1} - P_{m+1,n+1}\right| + \frac{1}{2}\left|P_{m-1,n-1} - P_{m11,n+1}\right|\right)^{-1} \quad (7)$$

With $m = i, n \in \{j - 1, j + 1\}$

The estimated value $\hat{P}_{i,j}$ of pixel at position $(i,j)$ is defined in Eq. (8).

$$\hat{P}_{i,j} = \frac{\sum_{s,t(|s+t|=1)} W_{i+s,j+t} P_{i+s,j+t}}{\sum_{s,t(|s+t|=1)} W_{i+s,j+t}} \quad (8)$$

The algorithm has been developed for 7 bands. Since the MSFA used has 8 bands, this algorithm was modified for 8 bands, considering the probability of bands appearing.

*F. Vector Median based MSFA Demosaicing*

Gupta et al. [30] had proposed a CFA vector demosaicing algorithm. This approach selects the color vector that minimizes the sum of the distances to the neighboring pixels to estimate the missing colors. This demosaicing approach is based on the notion of pseudo-pixel, which is defined by a group of neighboring values of red, green, and blue pixels (horizontally and vertically). Xingbo et al. [22] had extended this technique for MSFA demosaicing. According to the authors, this method is based on two According to the authors, this method is based on two specificities: first, the pseudo-pixels are formed according to the dimension of a moxel. The Moxel is a mosaic element corresponding to a mosaic of elementary filters repeated via an MSFA. Second, the pseudo-pixels are those that are connected horizontally, vertically, and diagonally.

The median vector $\underline{x}_{VM}$ of $\underline{x}_{1,\dots,}\underline{x}_N$ is defined as follows:

$$\underline{x}_{VM} \in \{\underline{x}_i | i = 1, \dots, N\}$$

For all $j = 1,,,,, N$

$$\sum_{i=1}^{N}\|\underline{x}_{VM} - x_i\|2 \le \sum_{i=1}^{N}\|\underline{x}_j - \underline{x}_i\|2 \quad (9)$$

The algorithm of calculation of the median vector for the demosaicing of the multispectral images proceeds as follows:

- For each vector $x_i$, compute the sum of the distances to all other vectors using the $L^1$-norm or $L^2$-norm as presented in Eq. (10)

$$S_i = \sum_{j=1}^{N}\|\underline{x}_i - \underline{x}_j\|, i = 1, \dots, N \quad (10)$$

- The median vector is $x_{min}$ corresponding to $S_{min}$, which is the minimum of $S_i$

This method was tested by the authors with CFA, 4-bands and 8-bands MSFA. For this algorithm, the wavelengths of the bands have been modified by considering the following wavelengths {685, 720, 770, 810, 835, 870, 895, and 930} nm for the eight bands.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

### A. EXIST Database and Experimental Setup

EXIST is a multispectral image database that was collected with the MSFA one-shot camera described. The EXIST dataset is composed of 2100 raw images of faces of 105 subjects. Each multispectral image is 2072 x 1104 size. After demosaicing, the images obtained are of size 2072 x 1104x8 each corresponding respectively to the wavelengths {685, 720, 770, 810, 835, 870, 895, 930} in nm. Fig. 3 shows some images of the EXIST database.

Fig. 3. Samples of raw images of EXIST database.

The experiments were carried out on Microsoft System Windows, version 2010, with two computers. The first was equipped with an Intel(R) Core (TM) i7-8565U CPU, 8 GB of RAM memory. The second has a NVIDIA Quadro P400 graphics processing unit (GPU) with 32 GB of Random Access Memory (RAM). All code is written in the MATLAB 2020 and Python 3.7 programming languages.

### B. Evaluation Metrics

To identify a suitable demosaicing algorithm, evaluations were performed on three criteria: image quality, decorrelation factor, and recognition rate, using NIQE, correlation coefficient, and recognition accuracy as metrics, respectively. Based on the literature [31]–[33], there are two types of performance metric for image quality: full reference quality, such as Peak Signal Noise Ratio (PSNR), Structural Similarity Index (SSI), Mean Square Error (MSE) and no-reference quality measurements, such as NIQE, Brisqe and piqe. Since the EXIST image database only contains raw images without references, the NIQE performance measure is used to assess the quality of images demosaiced using different methods.

NIQE is developed by researchers of University of Texas [34]. C.Kawan et al. [35] used NIQE to compare demosaicing method for Mastcam Images. NIQE is no-reference image quality metrics that use statistical features of the input image to evaluate the image quality. To calculate NIQE value, the image is divided into smaller patches, and the features are modeled as MultiVariante Gaussian (MVG) distributions.

After image quality evaluation with NIQE, intercorrelation of demosaiced images is evaluate with correlation coefficient computation. This coefficient allows to identify the degree of similarity between a pair of images. Images are identical when the correlation coefficient is equal to 1. To calculate this correlation coefficient, the method described in [36] was used. Also, to identify the best demosacing method with the best image quality, decorrelation factor, the demosaiced images were used to train four models based on the VGG19 architecture. VGG19 is an architecture of VGGNet proposed by K. Simonyan et al. [37] in 2015. VGG19 contains 19 weight layers consisting of 16 convolutional layers with three fully connected layers and the same five pooling layers. VGG-19 CNN is used as a pre-training model. The accuracy is used to evaluate the images after recognition. Accuracy indicates the percentage of correct prediction.

### C. Result and Discussion

To carry out the test, the following steps were followed for each method:

- Demosaicing raw images.

- Computation of NIQE values and time of demosaiced images.

- Calculation of correlation coefficients between demosaic images.

- Calculation of the average demosaicing.

- Recognition of demosaiced images.

- Computation of recognition time.

This algorithm led to the results presented in Fig. 4.

Fig. 4. Demosaic images by methods.

Visually, we can see that the binary tree presents better images in terms of sharpness of the different parts of the face than the other three demosaicing methods. But visual evaluation alone is not enough. The NIQE metric was therefore used to confirm or invalidate this visual assessment. The quality of the image varies according to the value of NIQE. The smaller the NIQE value, the better the quality of the demosaic image.

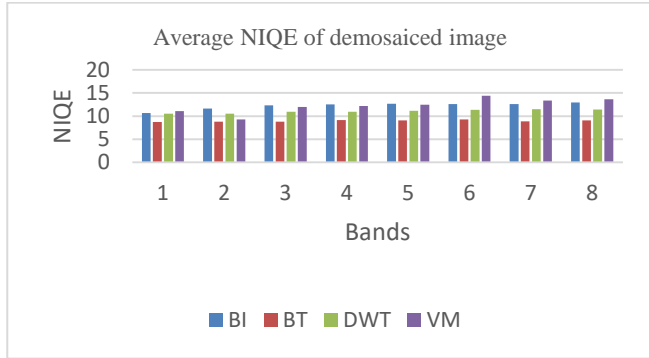

Fig. 5.    Average NIQE of demosaiced image.

The Fig. 5 shows the average NIQE calculated on all images obtained for the four demosaicing methods.

For all demosaicing methods, the NIQE value of the corresponding images varies between 8.75 and 14.38 according to the band and demosaicing method. While the NIQE values of the images demosaiced by bilinear interpolation are between 10.68 and 12.97, those of BT are between 8.75 and 9.29, those of DWT between 10.51 and 11.42, and those of VM between 11.68 and 13.66.

The analysis of the NIQE value per band and per demosaicing method shows that the binary tree has the lowest NIQE value per band and for all methods with average NIQE value of 8.99. Based on this NIQE value, the binary tree provides better quality images than others. This analysis confirms the visual observation made after the experimental results.

Time simulations were then made to compare the four methods. The Figure 6 shows the execution time for each.

Interpretation of Fig. 6 shows that the minimum running time of a demosaicing algorithm is 12.78s and is obtained with bilinear interpolation. This time is slightly less than that of the binary tree. The median vector is the method with the longest execution time. The crossing of the execution time and the NIQE value of the demosaicing algorithms shows that the binary tree is the demosaicing method which allows having best quality images in a reasonable time.

To study the decorrelation factor of demosaiced images, we compute the correlation coefficients between them.

The Fig. 7 shows the average correlation coefficient between each band by demosaicing methods.

The demosaiced images are correlated with an average correlation coefficient of 0.9 for all methods. The analysis of

these different figures allows us to conclude that the intercorrelation factor between the different bands is lower for the Bilinear interpolation than for the other demosaicing methods. Bilinear interpolation allows us to have less correlated images than the other methods.

After the demosaicing process and comparison, the VGG19 convolutional neural network was used for feature extraction and classification of the demosaiced images obtained with each method. The dataset was identical for all the methods. The training and test datasets were separated with random selection with 80% for training, 10% for validation and 20% for test. In all, 2,200 demosaic images of size 300 x 300 pixels, organized into 110 classes and were used.

Tables I to III describe respectively the training parameter of VGG19, the accuracy, and the recognition time for each image by method.

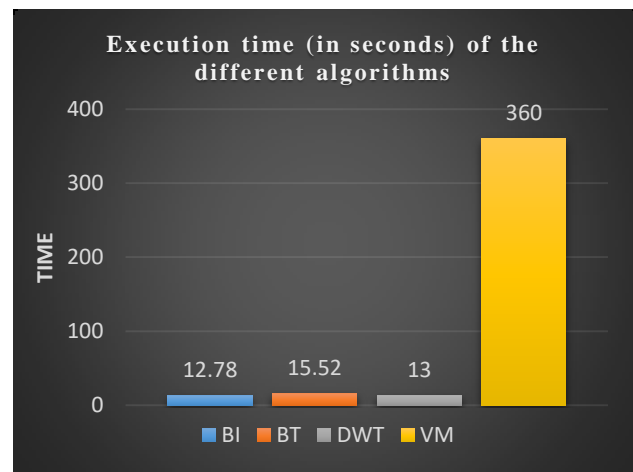

Fig. 6.    Execution time of demosacing algorithms.

TABLE I.    PARAMETERS USED IN THE TRAINING PROCEDURE

| Parameters | VGG19 |
|---|---|
| Batch size | 32 |
| Optimization algorithm | SGD |
| Learning rate | 0.0001 |
| Epoch number | 20 |

TABLE II.    VGG19 RESULT

| Accuracy | BI | DWT | BT | VM |
|---|---|---|---|---|
| VGG19 | 100 | 89 | 100 | 80 |

TABLE III.    EXECUTION TIME

| Accuracy | BI | DWT | BT | VM |
|---|---|---|---|---|
| Time(s) | 3 | 4 | 2 | 6 |
Fig. 7.    Average correlation coefficient between bands by demosaicing methods.

Analysis of the results in Table II shows that the accuracies obtained vary between 80% and 100%. Images demosaiced with bilinear interpolation and binary tree have the best accuracy of 100%. A comparison of the results in Table III shows that the execution time for recognizing demosaiced images varies between two and six sec. Images demosaiced with the binary tree are recognized faster than those of the other methods.

In conclusion, the different results show that the binary tree-based demosaicing method is the best of these four methods in terms of image quality, computational time, and accuracy for facial recognition.

## V. CONCLUSION

We proposed an evaluation of demosaicing methods for facial recognition using MSFA one-shot cameras to identify a suitable demosaicing algorithm in terms of image quality, computation time and decorrelation factor. This study use and compare four demosaicing algorithms on a base of raw images acquired with a MSFA one-shot camera. The binary tree demosaicing method was used to obtain the best quality images with the best computation time and, accuracy for facial recognition. Demosaicing affects the facial recognition system in terms of image quality and time. The better the demosaic images, the better the accuracy of the facial recognition system. The minimum demosaicing time is 12.78 s with bilinear interpolation. This is huge compared to the demosacing time of CFA which is a few milliseconds.

An optimization of this system should be done in our next work to make it real time.

# An Artificial Intelligence Method for Automatic Assessment of Fuzzy Semantics in English Literature

Meiyan LI

Faculty of International Studies
Henan Normal University
Henan 453007, China

*Abstract*—This Online writing and evaluation are becoming increasingly popular, as is automatic literature assessment. The most popular way is to obtain a good evaluation of the essay and article is by the automatic scoring model. However, assessing fuzzy semantics contained in reports and papers takes much work. An automated essay and articles assessment model using the long-short-term memory (LSTM) neural network is developed and validated to obtain an appropriate assessment. The relevant theoretical basis of the recurrent neural network is introduced first, and the quadratic weighted kappa (QWK) elevation method is cited here to develop the model. The LSTM network is then awarded for developing the general automatic assessment model. The available model is modified to get better performance by adding a convolutional layer(s). Finally, a data set of 7000 essays is segmented based on the ratio of 6:2:2 to train, validate, and test the model. The results indicate that the LSTM network can effectively capture the general properties of the essay and articles. After adding the convolutional layer(s), the LSTM+convolutional layer(s) model can get better performance. The QWK values are higher than 0.6 and have an improvement of 0.097 to 0.134 compared with the LSTM network, which proves that the results of the LSTM network combined with the convolutional layer(s) model are overall satisfactory, and the modified model has practical values.

*Keywords—Automatic assessment; recurrent neural networks; long short-term memory (LSTM); quadratic weighted kappa (QWK); convolutional layer*

## I. INTRODUCTION

In the traditional literature evaluation scene, the teacher or organizer designs the tasks, the candidates answer, and the teacher or organizer finally assesses the quality of the candidates' products by scoring. The most tedious part of the whole process is the manual evaluation and marking. It brings a heavy workload to evaluators and is prone to correction errors and long evaluation cycles, negatively impacting assessing. As computer technology and artificial intelligence develop, the automatic identification technology of filling multiple-choice questions in answer sheets has been widely used. The main task of assessment, involving complex processes such as handwritten digit detection, recognition and understanding, still relies on manual correction, especially in literature review and evaluation with fuzzy semantics. The candidates' handwritten text and the printed text of the paper are distributed in the same picture. When assessing, it is necessary to make an accurate distinction. At the same time, it is essential to detect the type of question to which the text belongs so that different correction strategies can be used

according to various tasks. In addition, the handwriting of other candidates is different, and the readers are either compact or sparse, which makes text detection and recognition face greater challenges [1,2]. With the enrichment of computing and data resources and the innovation of various network structures, deep learning has performed well in various tasks, and therefore, artificial intelligence has gradually been widely used in images and text detection [3, 4]. The key technologies required to realize intelligent marking technology, including handwritten character detection, recognition, etc., are also very popular research fields. Recently, many relatively advanced research results have been reported, which makes it possible to achieve comprehensive intelligent evaluation [5, 6].

The continuous development of artificial intelligence and computer performance significantly improved the accuracy and efficiency of automatic essay and article evaluating and scoring models. Also, the development of neural networks has promoted the achievements of natural language processing technology in some related fields. It has brought new research directions to the automatic essay and articles evaluating and scoring research [7, 8]. The most typical is Automated Student Assessment Prize (ASAP) essay-scoring competition organized by Kaggle in 2012, and the appearance of the ASAP made public datasets available for many research efforts. Based on this dataset, researchers in different countries have conducted related research on essays and articles evaluating and scoring tasks. For instance, Alikaniotis D et al. (2016) [9] built a model modified from LSTM by citing the ASAP data set. Then they used this model for t automatic evaluation and scored essays and articles. Similarly, using the ASAP data set, Kaveh et al. developed a model on the basis of recurrent neural networks and tried to use this model to learn the consistency between an essay and articles and real scores [10]. The results show that this method improved the model's ability to understand and capture the essay's main information and reports. Farag Y et al. also developed an automated easy evaluating and scoring model using the ASAP data set and the com. Theetween, a series of baselines and model outcomes, demonstrates its ability on the Automated Essay Scoring (AES) task and the flagging adversarial input, strengthening the effectiveness of neural essay and articles evaluating and scoring models [11]. These significant explorations kicked off the prelude of neural networks for automatic essays and papers evaluating and scoring.

Meanwhile, the successful application of large-scale pre-trained language models has brought breakthroughs to many

natural language processing tasks as well. For instance, Rodriguez et al. compared the BERT and XLNet model based on natural language processing (NLP) neural networks adopted to achieve a high-quality Kaggle AES dataset. The results show that BERT and XLNet can produce more accurate outcomes than manual results and save time and money in grading essays and articles [12]. Mayfield and Black used the pre-trained language model BERT to solve the problem of automatic writing, paperless evaluating and scoring and their experiment. They showed that BERT achieved good results in the automated English essay and articles evaluating and scoring task, indicating that BERT is theoretically and practically feasible to solve the automatic grading of English papers and reports [13]. From the system structure level, it can be seen that using software algorithms to extract the information feature values of standard files is the foundation for achieving accurate translation in non-semantic environments. The similarity between words and sentences is a factor that causes the system to decline in translation in different semantic environments. The relative degree of a sentence includes multiple aspects such as part of speech, syntax, and sentence structure. By calculating sentence similarity, the degree of differentiation of sentences can be found. The larger the similarity value, the more information about word form, syntax, and semantics between the two sentences is resolved.

Through the analysis of the current research about automated essays and article evaluating and scoring, the development of automated essay and article evaluating and scoring technology can be divided into three periods [14,15]. The first period is the artificial feature extraction period. The typical feature of this period is determining which parts of the essay and articles to extract manually and building a regression model based on these features by machine learning-based methods [16]. The advantage of this method is that it can be logically explained. The disadvantage of this method is also obvious. Due to many relevant features that need to be extracted by humans, it is challenging to reconstruct a large number of data sets. At the same time, these features may not directly reflect the deep fuzzy semantics of the essay and articles. The second period is the neural network period. In this period, word vectors are used to build models. Word vectors are developed by learning text information from essays. The main advantage is that it only needs manual feature extraction work. The disadvantage is that the model is not open and transparent since the model's training process is carried out in a black box. The third period is the transfer learning period [17, 18]. In this period, the knowledge learned from a large amount of corpus using the pre-trained language model is transferred to the automatic evaluating and scoring task, which can effectively avoid training the model from the beginning and achieves good results with relatively small datasets.

The application of distributed ultra-large computing power computers and the advent of large-scale data sets jointly promote the further development of neural networks in the field of automatic evaluating and scoring of essays and articles and make the automated essay and articles and articles evaluating and scoring evolve into the third stage as described above. Although the LSTM network is more efficient than the standard recurrent neural network and can effectively improve the model learning ability, capture the features and provide generally acceptable results to some extent. Still, it may not work well when meeting with fuzzy semantics contained in literature. Therefore, in this work, the main model modified from LSTM networks is developed and improved by adding convolutional neural network layers since the introduction of a convolutional neural network layer into the evaluating and scoring model can strengthen the ability of the model to capture local information in the essay and articles. Then the effectiveness of the LSTM networks combined with convolutional neural network layers is evaluated with a relatively large database.

In the process of English translation, the more similar the semantics are, the greater the correlation, which can easily lead to comprehension errors in different contexts and bring difficulties to translation work. Based on this, a similarity calculation model based on a combination of semantic dictionaries and corpora is established, starting from bilingual materials of English and Chinese sentences. Under the conditions of the established corpus, relevant semantic extraction rules and dependencies are determined. Through the English sentence similarity algorithm and the vector space model standard, the calculated similarity is used as a vector element to find the degree of differentiation in sentences, distinguishing between sentences and words in terms of part of speech, syntax, and tense. The research results indicate that the system has high accuracy and recall rate in sentence translation, especially in the English translation process of prepositions, function words, and tenses, with higher translation efficiency and accuracy. Evaluating the fuzzy semantics contained in reports and papers requires a lot of work. This article develops and validates an automated paper evaluation model using Long Short Term Memory (LSTM) neural networks to obtain appropriate evaluations.

This article evaluates the innovation contribution as follows:

*1)* Developed and validated an automated paper evaluation model using Long Short Term Memory (LSTM) neural networks to obtain appropriate evaluations. By adding convolutional layers, modifications were made to the available models to achieve better performance.

*2)* Traditional RNNs are prone to gradient vanishing when dealing with long sequences, making it difficult to train. LSTM introduces a gating mechanism, which can effectively alleviate the problem of gradient vanishing and process longer sequence data.

*3)* LSTM can better capture long-term dependencies in sequence data through cell state and gating mechanisms.

## II. THEORETICAL BASIS OF RECURRENT NEURAL NETWORK

### A. Recurrent Neural Network

Recurrent Neural Networks (RNNs) are mainly used to deal with timing problems. There is a connection between different neuron states in the RNN hidden layer. The input in the neuron state includes the input layer and consists of the outcomes of the previous neuron state. The semantic information before and

after the text sequence is very important to the recognition accuracy of the current series, so RNN is mostly used in text recognition, speech recognition and other tasks. RNNs are also used in artificial intelligence and machine learning. In the development of the automatic essay and articles evaluating and scoring model, essay and articles text is regarded as sequence data because the text information contains contextual semantic information. RNNs have advantages in processing data, and RNNs have advantages in processing textual information because RNNs can memorize previously learned content [19].

(a) General structure of RNNs    (b) Expended structures of RNNs

Fig. 1.    The model structure of the recurrent neural network.

Text information is generally input with unequal lengths, but the word length of each text is different. At the same time, understanding the text information needs to consider the order of words; that is, words are input individually. The recurrent neural network can also accept sequence data with an unequal length not defined in advance [20]. The performance of RNNs is affected by the knowledge learned in the past, which means that the processing output may obtain the features of previously known knowledge. Remembering the features learned from the previous knowledge through the vector representation of the hidden layer, the RNNs model can generate one or more output vectors from one or more input vectors and generate different outputs even with the same input. The recurrent neural network model's structural characteristics are shown in Fig. 1(a).

The figure above depicts the properties of the recurrent neural network at sequence number t. W, U, and V correspond to the weights of the input layer $x_t$ passed to the hidden layer $h_t$, between the hidden layers, and from the hidden layer $h_t$ to the output layer $y_t$, respectively. As can be seen from Fig. 1(b), an important feature of RNNs is parameter sharing, and the meanings of parameters are:

*1)* $x_t$ is the input of the training sample, and $t$ is the sequence number;

*2)* $h_t$ is the hidden state of the model, and it is computed by $x_t$ and $h_{t-1}$;

*3)* $y_t$ is the model's output, which is determined by the $h_t$ at the current hidden state.

The RNNs equation is expressed as follows:

$$y_t = g(Vh_t) \qquad (1)$$

$$h_t = f(Wx_t + Uh_{t-1}) \qquad (2)$$

RNNs can memorize knowledge, but they need help remembering long text information. This is because when ordinary RNNs deal with long sequence problems, passing the gradient from the back of the sequence to the front line through the back-propagation algorithm is difficult. In recent decades, many versions have been developed and built with the research progress of the recurrent neural network, among which the LSTM network is the most successful. This is because the LSTM network solves the long-term dependence problem in the training process.

*B. LSTM Network*

During the predicting process, the recognized text could be infinite because of the variety of the length of the text sequence. Suppose the position of the currently predicted text or the text whose semantic information is consistent with the text is large. In that case, the ordinary recurrent neural network will lose part of its semantic information, thereby reducing the accuracy of prediction results. The network of LSTM is a more advanced version of RNNs and solves this problem very well. The setting of the gate structure prevents the LSTM model from retaining all the information indiscriminately, like the RNN model. It cannot highlight the key points which solve the problem of gradient disappearance in the learning process of the model [21]. The main difference between LSTM and ordinary recurrent neural networks is that LSTM has three gates: the forgotten, input, and output. The model can remind the information of each previous neuron, reducing the loss of information in the transmission process. Therefore, the LSTM model can efficiently retain important data according to the task objective and uses the information judgment as to the parameter of model learning, which greatly increases the learning efficiency of the model [22].

At the same time, LSTM can also solve the problem of gradient descent and thus is widely used in sequence data tasks, such as language understanding, segmentation, and translation. It has been verified in many experiments that LSTM is more effective than standard RNNs, which can effectively improve the model learning ability. Due to the careful design of LSTM, introducing the gating mechanism can alleviate the gradient disappearance of the recurrent neural network, thereby memorizing long text information. The LSTM consists of five different parts [23, 24]:

*1)* Unit state: The internal memory of the LSTM unit.

*2)* Hidden state: This state is used to calculate the prediction result of the model.

*3)* Input gate: It is used to judge the amount of inputted information that can be sent to the unit state.

*4)* Forget gate: It is used to judge the number of previous unit states that can be sent to the current unit state.

*5)* Output gate: It judges how many unit states can be sent to the hidden state.

In a recurrent neural network model, the unit's state changes with each input in the current form. This directly leads to the fact that in the cyclic neural network structure, the team's state is always changing, and this mechanism causes the cyclic neural network to not store long-term dependencies well. In LSTM, the current cell state relies not only on the input of

the current state but also that of at previous step. Therefore, the LSTM can decide to update at a certain moment or forget the internal information stored in each neuron in the cell state. Namely, the LSTM has a mechanism to keep the cell state unchanged so that the LSTM can store long-term dependencies. The data flow diagram in LSTM is shown in Fig. 2.

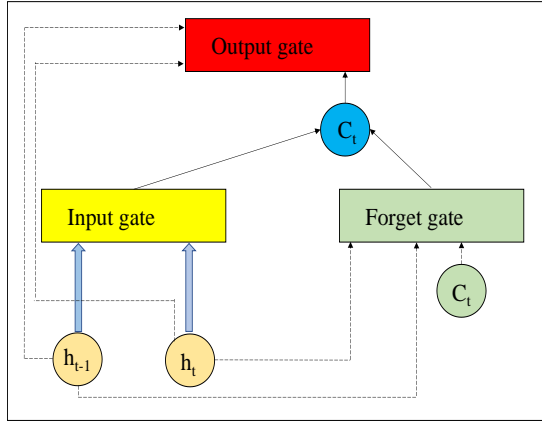

Fig. 2. The data flow diagram in LSTM.

As shown in Fig. 2, LSTM mainly introduces the gating unit concept to control the unit's state. LSTMs have gates for each operation a cell needs to perform. Each gating team takes a continuous value ranging from 0 to 1, where 0 indicates that all the information is blocked and will not be passed to the next step, and 1 means that all information is passed to the next gate. LSTM network uses such gating units for each neuron in the team. The calculation equation of each gate control unit is described below. The calculation equation for the input gate is shown in the following equations.

$$i_t = a(w[h_{t-1}, x_t]^T + b_i) \quad (3)$$

$$\tilde{c}_t = tanh(\psi_{cyt}) - tanh(w_c[h_{t-1}]^T + b_c) \quad (4)$$

where, $i_t$ = represents the information amount of the input state saved to the unit state, and $\tilde{c}_t$ means the information after the Unit State is updated. *A* is defined as an activation function, the weight matrices are $\omega$, and $\omega_c$ and the bias matrices are $b_i$ and $b_c$. The revised equation for the current cell state is shown in Eq. (5).

$$c_t = f_t c_{t-1} + i_t \tilde{c}_t \quad (5)$$

In the equation, $c_t$ represents the information currently saved by the unit state, and $c_{t-1}$ is the information held by the unit state at the previous moment. The calculation equation of the forgetting gate is shown in Eq. (6).

$$f_t = a(w_f[h_{t-1}, x_t]^T + b_f) \quad (6)$$

where, $f_t$ indicates the forget gate at time $t$. The forget gate controls whether the information can be transmitted to the current moment. Calculate $f_t$ is calculated in the matrix formed by the output state of the hidden layer $h_{t-1}$ and the current input state $x_t$ at the previous input, multiply it with the weight matrix $\omega_f$, and finally, add the bias matrix $b_f$. The calculation equation of the output gate is shown in Eq. (7) and Eq. (8).

$$f_t = a(w_0[h_{t-1}, x_t]^T + b_0) \quad (7)$$

$$h_t = u_t \, tanh(c_t) \quad (8)$$

In the equations, $u_t$ is the updated output information of the storage unit, $h_t$ is the output information of the hidden layer at the current moment, $w_o$ is the weight used to calculate the forgotten team, and $b_o$ is the bias matrix.

## III. MODEL CONSTRUCTION AND EXPERIMENTAL SETUP

Based above research, the automatic evaluating and scoring model established is developed. The main model structure of the proposed model can be briefly described by following steps: first, the text in the corpus is segmented, and then the word segmentation result is used to construct a word vector, and the word vector work as the input of the LSTM evaluating and scoring model. At the same time, a convolutional layer is added before the LSTM layer. This can improve the prediction of the LSTM method because the convolutional layer can effectively understand the text's local information and fuzzy semantics.

### A. LSTM-based Essay and Articles Automatic Evaluating and Scoring Model

Since the essay and article text contains contextual knowledge, it can be regarded as sequence information. The model-building process is shown in Fig. 3. Because the long short-term memory network cannot directly take text as input, the next step is to convert the essay and article text into word vectors after the intake of the corpus. Then the obtained word vectors will be passed to the neural network model for prediction, optimize the model through the optimizer, and finally build, the model.

The Adam optimizer is used in this experiment. In the model optimization, the mean squared error (MSE) loss function is selected to make the neural network model better optimized, which is shown in Eq. (9).

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \bar{y}_t)^2 \quad (9)$$

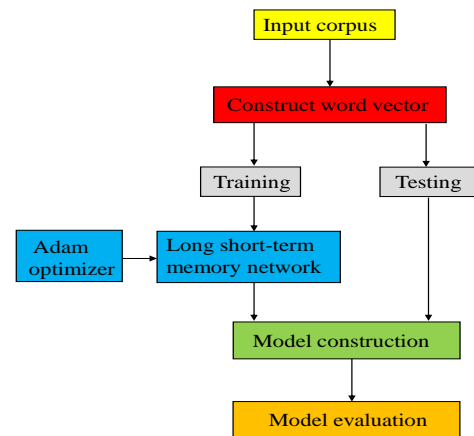

Fig. 3. The model-building process.

### B. Evaluation Method

The QWK coefficient is generally used as an evaluation index in the automatic grading of related essays and articles. It

can well reflect the consistency between the predicted quality index (mostly in the form of score) and the actual quality index of the essay and articles [25] and improves the validity of the evaluation results. The QWK coefficient introduces a penalty mechanism based on the KAPPA coefficient. If the error between the composition's predicted quality index and the composition's actual quality index is larger, the QWK coefficient will be smaller. The penalty mechanism enables the QWK coefficient to reflect the consistency between the quality index predicted by the proposed model and the manual quality index of the essay and articles. Although some algorithms have good performance in certain datasets, they may encounter difficulties in other datasets. In addition, by adjusting the hyperparameters of the algorithm that controls the training process, performance can be improved. The performance of models in machine learning problems largely depends on the dataset and training algorithms. Choosing the correct training algorithm can change the story of the model. Nowadays, an adaptive machine learning algorithm is used for different biological, biomedical, and natural categories [26].

The fuzzy semantic of English literature is a two-sided existence, such as some ambiguous expressions. And due to the differences between cultures, clearer semantic content can result in differences in understanding. The QWK coefficient uses a weighting method to strengthen the result. If the excessive deviation between the model prediction and real quality index, it would penalise the extreme difference by reducing the QWK coefficient. Using the QWK coefficient can not only measure the consistency of the evaluating and scoring model but also improve the recognition accuracy of fuzzy semantic contents in English literature. The equation for calculating the QWK coefficient is shown in Eq. (11). But the first step is to construct the weight matrix, and the calculation equation of the weight matrix is shown in Eq. (10).

$$W_{i,j} = \frac{(i-j)^2}{(n-1)^2} \qquad (10)$$

In the equation, $i$ and $j$ is the quality index given by the experts (real quality index) and essay and articles evaluating and scoring models, respectively. N indicates 9, the number of essays and articles database. After building the weight matrix, the matrix $N$ and the prediction matrix $E$ are built. $N_{i,j}$ is the amount samples with real rating $i$ and model rating $j$. $E$ is the outer product of the real marks and the model quality index vector. The QWK coefficients are calculated using the constructed $E$ matrix and $N$ matrix.

$$k = 1 - \frac{\sum_{i,j}(W_{i,j}N_{i,j})}{\sum_{i,j}(W_{i,j}E_{i,j})} \qquad (11)$$

Evaluators give the essay and article quality index used in this paper, and the essay and articles' real quality index are regarded as a true index of essay and article quality. So, the evaluation of the evaluating and scoring model built in this paper is transformed into the consistency problem between the model results and the real marks. In this paper, the QWK coefficient is used as the measurement method to test the consistency since the QWK coefficient can reflect the model prediction quality index, which can reflect the capability of assessing the English literature with fuzzy semantics. The meaning of the QWK coefficient is shown in Table I.

TABLE I. THE MEANING OF QWK

| QWK | Consistency strength |
|---|---|
| <0.20 | Poor |
| 0.21~0.40 | General |
| 0.41~0.60 | Medium |
| 0.61~0.80 | Good |
| 0.81~1.00 | Best |

This article collects a set of paper data, including papers from various disciplines. Firstly, we use a portion of the dataset for training, and then test the remaining dataset. Table II shows the performance of our model on the test set.

TABLE II. PERFORMANCE INDICATORS OF THE MODEL ON THE TEST SET

| Accuracy | 0.85 |
|---|---|
| Precision | 0.83 |
| Recall | 0.82 |
| F1 Score | 0.80 |

## IV. EXPERIMENT AND RESULT ANALYSIS

### A. Test Setup

*1) Normalization and inverse normalization*: The output of the proposed model is the predicted essay and article quality index. If the input essay and article quality index are in a different grade range, it may impact the model's outcomes.

In most situations, the quality index of essays and articles by scoring can be divided into three categories: the first is 40-95, the second is 65-95, and the third is 50- 95 points. Due to the different range of scores, the normalization of essay and articles scores is firstly performed to get a uniform index, and the core idea of normalization is to map essay and articles scores from different score segments to floating-point numbers between (0, 1), which is more conducive to processing of the model. The normalized calculation equation is shown in Eq. (12).

$$x' = \frac{x - x_{Min}}{x_{Max} - x_{min}} \qquad (12)$$

In Eq. (12), $x$ represents the real essay and articles score, $M_{in}$ and $M_{ax}$ represent the lowest and highest score of the scoring range, and $x'$ represents the normalized result obtained by normalizing the real essay and articles score.

Before inputting into the model, the essay and article scores in the corpus are first normalized. Then the corpus is divided into a training set, validation set, and test set according to the ratio of 6:2:2. In the model's training process; the normalized score will be used as the label. After the training process is completed, the essay and articles in the test set are used as the input, and the trained model is then used to predict the score of the essay and articles. However, the score obtained at this state is not (0-100) but the normalized predicted score. In order to calculate the QWK coefficient between the real score results and the model prediction results, we need to perform inverse normalization on the normalized prediction scores. The inverse normalization calculation equation is shown in Eq. (13).

$$y = y'(xmin_{max} + x_{min}) \qquad (13)$$

In Eq. (13), $y$ represents the normalization result predicted by the model, and $x_{min}$ and $x_{max}$ represent the lowest and highest scores in the real scoring range. After performing the inverse normalization operation, the prediction score of the model can be obtained.

*2) Experimental arrangement and hyperparameter settings*: During the experiment, 7000 essays and articles corpus from the Kaggle dataset were cited and divided into the training set, validation set, and test set with the ratio of 6:2:2. To train the LSTM model on the training set, different numbers of hidden layers were used to observe the effect of other numbers of hidden layers on the results of the model $b_v$. The LSTM network structure used is shown in Fig. 4.

Fig. 4.    The LSTM network structure.

Fig. 5.    The LSTM+ convolutional layer.

At the same time, in the research of Taghipour K et al [10]., it was found that adding a convolutional layer before the recurrent neural network can effectively improve the model's capability of capturing the local information of the text. Therefore, based on the above experiments, adding a convolutional layer before the LSTM layer is embedded and observing whether the additional convolutional layer(s) can improve the model's performance is proposed. The network structure of the LSTM+convolutional layer used in this study is shown in Fig. 5.

Simulation experiments determine the model's hyperparameters after building the LSTM model. The parameters are shown in Table III.

TABLE III.    THE VALUES OF MODEL PARAMETERS

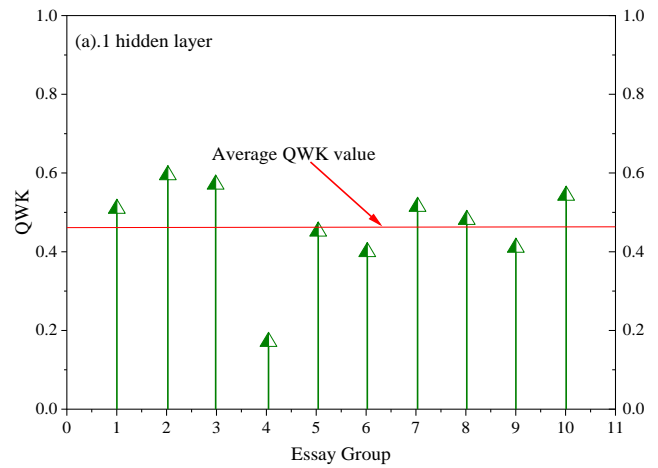
| Parameters | Values |
| --- | --- |
| Learning rate | 0.001 |
| Batch size | 64 |
| Regular optimization | 0.5 |
| Activation function | ReLU |
| Number of iterations | 30 |

### B. Results and Analysis

Based on completing the model construction in the previous section, the number of hidden layers of the network to 1, 5, and 9 layers are built. The QWK results obtained by the LSTM network model are shown in Fig. 6.

Fig. 6 shows that the QWK coefficient of the experimental results obtained by the essay and articles evaluating and scoring model constructed based on the LSTM network is at a moderate level of consistency, according to Table I. The value of QWK ranges from 0.17 to 0.59, which indicates that the accuracy of the LSTM is not satisfactory, as shown in Fig. 6(a). Increasing the number of hidden layers, the model's performance also increases. When the hidden layers are 5 and 9, the value of QWK are 0.31~0.57 and 0.38~0.59, respectively. The average weight of QWK also increases from 0.464 to 0.499 and 0.515 when hidden layers are increased from 1 to 5 and 9. It indicates that as the depth of the LSTM network grows, the model has better nonlinear expression ability and can perform more complex transformations. The experimental results show that deepening the network depth can effectively improve the output results.

(a). 1 hidden layer

(b). 5 hidden layers


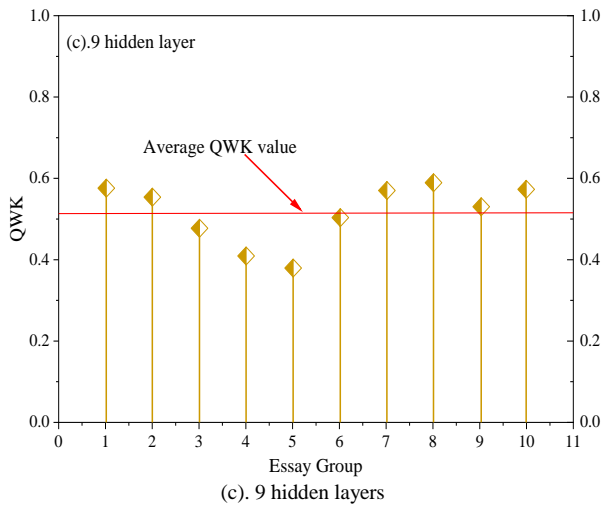


Fig. 6.    The QWK values obtained by the LSTM network model.

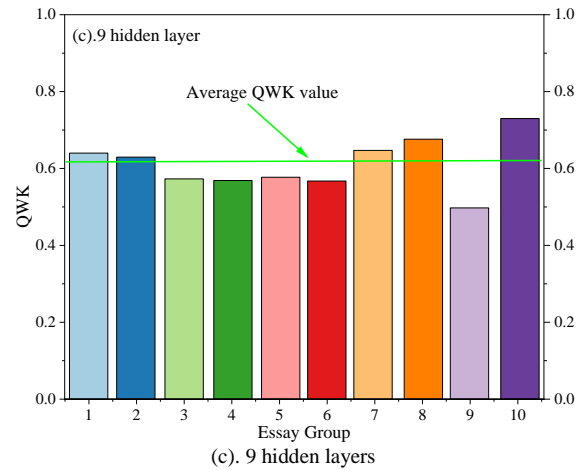
The convolutional layer is added to conduct a comparative neural network experiment based on the above experimental results. The addition of the convolutional layer is to improve the ability to capture the local text information. The QWK results obtained by adding the convolutional neural layer into the Long-Short-Term Memory Network model are shown in Fig. 7.

(a). 1 hidden layer

(b). 5 hidden layers



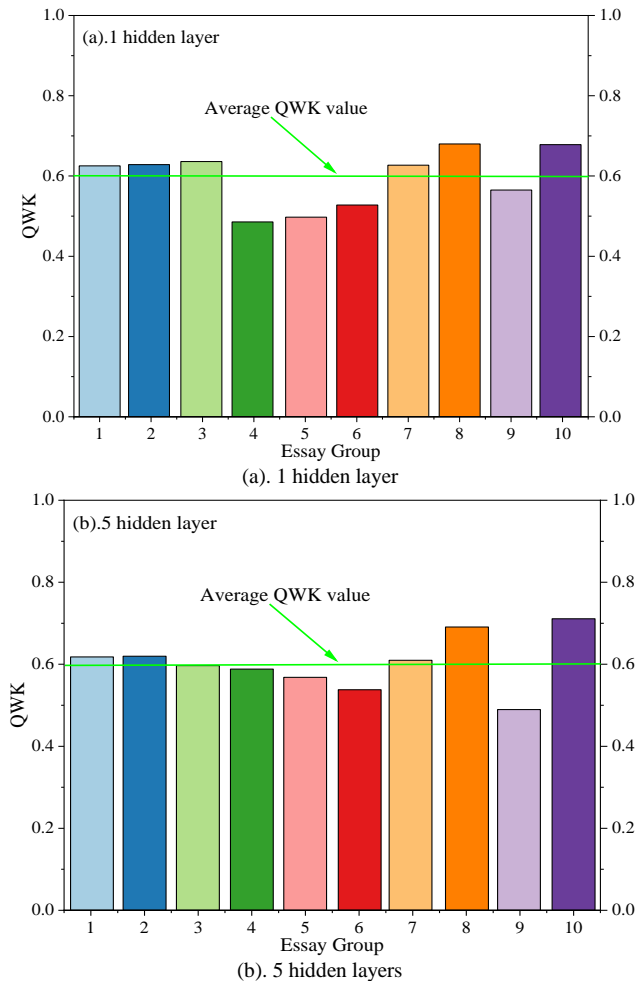


Fig. 7.    The QWK results after adding the convolutional neural layer.

It can be seen from Fig. 7 that using the essay and articles evaluating and scoring the model constructed based on the LSTM network, adding the cumulative neural network layer has significantly improved the experimental results of the model. However, the QWK coefficient could be at a better level of consistency. After LSTM is incorporated with the convolutional neural layer, the value of QWK in 1, 5 and 9 layers are 0.41~0.68, 0.49~0.69 and 0.5~0.68, respectively. The average values of QWK are at a good level of consistency with values of 0.598, 0.604 and 0.612. This experimental result confirms that adding the convolutional layer can capture the local information of the text.

From Fig. 6 and Fig. 7, it is clear that the Long-Short-Term Memory Network model can provide an acceptable experimental result using the QWK coefficient in the evaluation process. Compared Fig. 6 with Fig. 7, adding the convolutional layer(s) can increase the accuracy of the proposed model. By comparing the average QWK values of LSTM and LSTM+ convolutional layer, it can be observed that the QWK values are improved (the improvement is 0.097~0.134), as shown in Fig. 8, indicating that the neural network with the convolutional layer(s) can perform more complex feature learning, and the network has better representation ability. Based on TableI, the LSTM+C can obtain good results and has practical values.

Fig. 8.    The comparison of LSTM and LSTM+ convolutional neural layer.

The research results indicate that using papers and articles to evaluate and grade models constructed based on LSTM networks. This not only increases the cumulative neural network layer, but also significantly improves the experimental results of the model. The calculation for LSTM is feasible. Approximate calculation methods and other dependency methods can be used to accelerate the training process. For example, techniques such as truncation or compression can be used to reduce the number of parameters and calculate Type 2 simplification: in order to solve the problem of STM interpretation. A simpler model can be used, which has fewer parameters and mechanisms than LSTM, but still handles sequence numbers well. If the number of training is insufficient, it is possible to use the number of strong techniques to generate more books, or use transfer learning to utilize data from other tasks to improve model performance.

## V. Conclusion

In this paper, the model construction process and related experimental settings are introduced，and the automatic essay and articles assessment model modified from the neural network is developed and validated in assessing English literature with fuzzy semantics. After comparing the results of the prediction, the following conclusions are drawn:

First, in developing the the model, the QWK elevation method is cited due to its consistency evaluation properties that that can improve the recognition of fuzzy semantics content. And then, the long-short-term memory network is modified by adding the convolutional layer(s) into the LSTM model.

Then, 7000 articles were segmented based on the ratio of 6:2:2 to train, validate, and test the proposed model. The comparison and analysis of experimental results indicate that LSTM can generally capture the real features of the articles. After adding the convolutional layer(s), the proposed model can get better performance by improving 0.097 to 0.134 of the QWK value. These results prove that the automatic essay and articles evaluating and scoring model based on neural network+ convolutional layer(s) can evaluate the English literatures containing fuzzy semantics.

However, an important advantage of neural networks is that they can learn complex patterns from a large amount of data. However, one limitation of this method is that it usually only captures the surface features of the data and may not be able to deeply understand the true meaning of the text. For English literature, this issue may be more severe due to the inherent ambiguity and ambiguity in language. Although English has relatively fixed grammar and vocabulary, the same word or phrase may have completely different meanings in different contexts, and this meaning usually requires in-depth contextual understanding to accurately grasp. Future research can focus on developing more effective models, such as combining natural language processing (NLP) technology and deep learning technology, to improve the model's ability to understand semantics while reducing reliance on a large amount of high-quality data.

# Application of Image Style Transfer Based on Normalized Residual Network in Art Design

Jing Pu, Yuke Li[*]

School of Arts and Media, Sichuan Agricultural University, Ya'an, 625014, China

*Abstract*—**With the development of computer vision technology, image style transfer technology based on deep learning has achieved vigorous development. It has been widely applied in fields such as art design, painting creation, and film and television effect production. However, existing image style transfer methods still have shortcomings, including low efficiency and weak quality of style transfer, which cannot better meet the actual needs of various art and design activities. Therefore, a residual network structure is introduced to construct an image style transfer model based on the convolutional neural networks. Meanwhile, a normalization layer is added to the residual network results to optimize the image style transfer technology. An image style transfer model based on the normalized residual network is constructed. The experimental results show that the accuracy, recall, and F1 values of the improved image style transfer model proposed in the study are 97.35%, 96.49%, and 97.52%, respectively, which can complete high-quality image style transfer. This indicates that the image style transfer model proposed in the study has good performance, which can effectively improve the efficiency and quality of image style transfer, providing effective support for various art and design activities.**

## I. INTRODUCTION

With the development of technology and social progress, various digital media have become an indispensable part of daily life. As a medium for the public to showcase their unique pursuit of individuality, the demand for artistry in images is increasing. Many scholars have begun to explore how to automatically synthesize images with artistic style through computers [1]. Style transfer emerged as the times require. Image style transfer is often regarded as a universal texture generation method for research. Therefore, image style transfer (IST) has become a research highlight. IST technology refers to the process of converting an image into an image that is similar in style or content to the target image through machine learning methods and other techniques [2, 3]. With the progress of deep learning (DL) technology, some scholars build image style migration methods based on the advantages of Convolutional neural network (CNN) feature extraction, while others propose to build image style migration methods using encoder and decoder models [4]. However, existing image style transfer methods have a slower speed during the transfer process. It cannot meet the application requirements in real scenarios. Meanwhile, the comprehensive quality of style images obtained by existing image style transfer methods is not high. In deep learning technology,

convolutional neural networks are feedforward neural networks based on convolutional operations and have deep structures. They are widely used in fields such as image perception, image analysis, image classification, and natural language processing. Therefore, based on the existing CNN structure, an improved image style transfer method is constructed [5]. The structure of CNN is optimized by introducing residual network. At the same time, in the image transfer model, besides adding residual blocks, a normalization layer is added to solve the image quality problems. An image style migration Generative model based on the deep residual network instance normalization (ResNet-IN) is constructed. It is expected to achieve higher quality image style transfer, and improve the speed and efficiency of IST.

The research mainly includes five sections. The Section I is an introduction, briefly introducing the research background. The Section II mainly introduces the research review of residual networks and image generation methods based on deep learning. The Section III constructs an image style transfer method based on a normalized residual network. The Section IV validates the performance of the constructed method. The Section V summarizes the research results and points out the future research direction.

## II. RELATED WORKS

A residual network is composed of multiple residual blocks stacked together, which has the advantages of easy optimization and improved accuracy. The internal residual blocks use jump connection, which relieves the vanishing gradient caused by increasing in depth network. Therefore, it is widely used in various fields. Liu et al. conducted recognition research on Boletus images using residual networks. The Fourier transform near-infrared spectral information of the uneven stipe of Boletus edulis was collected. This information was combined into four data matrices to accurately evaluate and identify different Boletus species. According to the findings, the residual neural network (ResNet) has better performance [6]. Liu et al. proposed a data augmentation method to address the issue of limited and imbalanced sample data for transformer faults. A deep residual network with identified paths was introduced to construct a fault diagnosis model, enabling effective transmission and updating of weight parameters. According to the findings, it can effectively expand the data samples with high similarity to the original data. The ResNet has strong feature extraction ability. It enhances the accuracy of fault diagnosis [7]. The existing automatic sleep staging algorithms have too many parameters and long training time, which leads to poor sleep

staging efficiency. Therefore, Yun L et al. proposed an automatic sleep staging algorithm depending on Transfer learning for random deep residual networks (TL-SDResNet) using single channel EEG signals. Experiments have shown that this model can complete rapid training of data. The overall performance is superior to other classic algorithms, with certain practical value [8]. Yousefzadeh et al. introduced an image retrieval system based on the expanded residual CNN of Triplet loss. This system had fewer parameters and provides acceptable accuracy in top-level retrieval images. Experimental evaluation shows that the model can extract more abundant information by expanding the Receptive field, improving the accuracy of image retrieval without increasing the depth or complexity of the model [9]. Siuly et al. proposed a feature extraction method based on deep ResNet to automatically extract representative features from Electroencephalography signal data of schizophrenic patients to identify schizophrenia. This method includes three stages: average filtering for signal preprocessing, deep ResNet for extracting EEG signals, and softmax layer for schizophrenia classification. The research results indicate that it has the ability to discover important biomarkers for automatic diagnosis of schizophrenia from EEG, which will help experts develop computer-aided diagnostic systems [10].

In recent years, image generation and style transformation based on DL have been widely applied. Many breakthroughs have been made. The process of IST has a common idea, which is to analyze images with a certain style. Then corresponding mathematical or statistical models are established for that style. The image to be transmitted is modified to better fit the established model. Wang J combined k-means and semantic closed natural matting algorithms for image segmentation. Neural networks are used for style and content in images. Then through image reconstruction technology, the obtained images are synthesized to achieve the transfer of Folk costume style. The results show that the average runtime, memory usage, and styles generated by this method are 0.06s, 136.06MB, and 1, respectively, reflecting high efficiency and flexibility [11]. Huang et al. proposed an algorithm involving semantic segmentation and residual networks. VGG16 was used for feature extraction to improve the efficiency and generation speed of local IST. Experiments have shown that it is more useful than other commonly used strategies. It can be applied in many specific fields, such as beauty cameras on smartphones, computer-generated images in advertisements and movies, and computer tomography images [12]. Daneshvar et al. proposed a IST method based on neural networks. By manipulating two given camouflage modes, a mixed camouflage mode is generated. The content and style of a CNN trained on image recognition are represented by the correlation between feature maps. The subjective evaluation results indicate that this method is effective in generating successful camouflage patterns [13]. Tian et al. proposed a new layout analysis and style fusion system structure for image generation and style conversion. The Generative adversarial network and multi style ancient book background model were used to train the model. In the experiment, ancient materials such as Yi characters, ancient Chinese, Jurchen characters and ancient paintings were selected as samples for testing. According to the findings, it

improves the performance of the Generative model [14]. Chen et al. constructed a conversion method consisting of multiple convolutional filter banks to better achieve image style conversion. Each filter bank (FB) clearly represents a style. To convert the image into a specific style, the corresponding FB operates on the intermediate features generated by a single automatic encoder. The style library and automatic encoder are learned in a joint manner. The results indicate that this method can effectively achieve image style conversion [15].

In summary, relatively rich research results have been achieved on residual networks and image style transfer techniques. However, in existing research, various image style transfer techniques proposed are mainly designed for specific images, such as clothing, ancient Chinese characters, etc. The practicality cannot meet the needs of various artistic creation activities. At the same time, existing image style transfer technologies have shortcomings in terms of efficiency and quality, and cannot achieve high-quality style image transfer. Furthermore, with the development of computer vision technology, the application demand for image style transfer in various art designs is becoming increasingly widespread. Therefore, based on existing research results and the advantages of residual network structure in image feature processing, a normalized residual network based image style transfer model is constructed. It is expected to further expand the application scope of image style transfer technology through this method, improve the quality and efficiency of image style transfer, and meet a wider range of artistic design needs.

## III. IST GENERATION NETWORK DESIGN BASED ON NORMALIZED RESIDUAL NETWORK

IST is crucial for in various art and design activities. Therefore, this chapter will design the corresponding IST model based on CNN. Meanwhile, the normalized ResNet is applied to optimize the image style Generative model to better realize the IST.

### A. IST Based on CNN

In the computer vision, IST is a common texture production method, which extracts texture feature information from an image and inputs the extracted texture feature information into the target image to obtain a stylized image. CNN is the most effective machine learning network in image migration processing. CNN is a feedforward neural network based on convolution operation, which is extensively applied in image perception, image analysis, classification and other fields [16]. The CNN is composed of convolution layer, pooling layer and full connection layer. Fig. 1 illustrates the basic structure.

Fig. 1. Structure diagram of CNN.

In the CNN, VGG-Net network structure shows better performance in digital image processing. The research takes VGG-19 as the basic network structure for image style transfer. When the CNN completing the forward propagation task, the convolution core slides in the image matrix. By performing a convolution operation with the pixel values of the convolution kernel coverage position, the corresponding feature map is obtained, as shown in Formula (1).

$$S(i,j) = \sum_m \sum_m I(i+m, j+n)K(m,n) \qquad (1)$$

In Formula (1), $I$ stands for the input image of CNN. $S(i,j)$ stands for the coordinate position of the feature image. $K$ represents a convolutional kernel of size $m \times n$. The convolution operation process of the input image is shown in Fig. 2.

Fig. 2. Schematic diagram of convolution operation.

Firstly, the input image is defined as $x$. The output image is the expected image after transfer, represented as $y$. The convolutional layer used in the style transfer process is $l$. The convolutional features obtained from the input image after calculation in layer $l$ are represented as $M_{ij}^l$. Among them, $i$ stands for the $i$-th channel in the convolutional layer. $j$ stands for the $j$-th position in the convolutional layer. The convolutional features of the image $y$ after style transfer in the $l$-th layer are represented as $F_{ij}^l$. Therefore, the obtained image content Loss function (LF) is shown in Formula (2).

$$Loss(x,y,l) = \frac{1}{2} \sum_{i,j} (F_{ij}^l - M_{ij}^l)^2 \qquad (2)$$

The content Loss function can describe the difference between the style of the input image and the output image. The smaller the value, the smaller the differences between the image before and after the style transfer. Then the style features of the image are defined. The image style is represented by Gram matrix (GM), which is a Symmetric matrix composed of several vector inner products, as shown in Formula (3) [17].

$$G_{ij}^l = \sum_k F_{ik}^l F_{jk}^l \qquad (3)$$

In Formula (3), $G_{ij}^l$ represents the white noise image matrix. $k$ represents the $k$-th position in the convolutional layer. The style error after image transfer is shown in Formula (4).

$$E_l = \frac{1}{4N_l^2 M_l^2} \sum_{i,j} (G_{ij}^l - A_{ij}^l)^2 \qquad (4)$$

In Formula (4), $M_l$ and $N_l$ represent the height and width of the $l$-th layer. $G^l$ represents the $l$-th layer GM of the input image $x$. The GM of the $l$-th layer of the migrated output image $y$ is $A^l$. $E_l$ satnds for the GM of image style. Formula (4) has been simplified as shown in Formula (5).

$$Loss_{style}(x,y) = \sum_l \omega_l Loss_{style}(x,y,l) \qquad (5)$$

In Formula (5), $\omega_l$ satnds for the weight of the $l$-th layer. The content LF and style LF of IST are established through CNN. IST can be seen as the unity of content and style. After copying the target image for style transfer, whether an image is closer in content or more similar in style depends on the proportion of content loss and style loss in the total loss. Thus, the total LF is shown in Formula (6).

$$Loss_{total}(O_{style}, O_{conctent}) =$$
$$\alpha Loss_{style}(O_{style}, R) + \beta O_{conctent}(O_{conctent}, R) \qquad (6)$$

In Formula (6), $O_{conctent}$ stands for the expected content image. $O_{style}$ stands for the expected style image. $R$ stands for the image that needs to be generated. $Loss_{content}(O_{content}, R)$ represents the content LF. $Loss_{style}(O_{style}, R)$ is the style LF. $\alpha$ and $\beta$ are hyperparameters used to measure the proportion of style loss and content loss in total loss. The results of IST based on CNN usually cannot preserve the local texture features of the original image. Therefore, there are issues with the representation of depth features and the accuracy of image transfer models when using this method for image style transfer.

### B. Image Style Transfer Model Construction Based on Improved Normalized Residual Network

The IST network model, as a type of generative network, should have strong feature learning ability and can achieve accurate and reasonable processing of various image features. In response to the shortcomings of the above image style transfer methods, a residual network structure is introduced to construct an improved normalized residual network (ResNet-IN) image style transfer model. The residual module is added to the basic CNN structure. Deep residual neural network is a meaningful branch in the DL. ResNet can effectively solve the defect of gradient disappearance in the training of CNN by introducing residual blocks. It is widely used in fields such as image classification, object detection, and face recognition [18]. The core of ResNet is residual blocks. In the convolution layers with different depths of the CNN, ResNet introduces a special connection layer for information transmission, that is, skip connections, as shown in Fig. 3.
Fig. 3. Schematic diagram of residual block.

Jumping connections can cross a multi-layer network structure to establish a connection between two non-adjacent convolutional layers, thereby achieving information transmission. In Fig. 3, $x$ represents the feature image output from the previous network layer. Then, $x$ is input into the residual block for convolution operation. Finally, the features containing residual information and $F(x)$ are output. The expression of $F(x)$ is shown in Formula (7).

$$F(x) = W_{2\sigma}(W_1 x) \quad (7)$$

In Formula (7), $W_1$ and $W_2$ stands for the weights of the weight layer, respectively. $\sigma$ represents the excitation function. The final output of the residual block is represented as $H(x)$, as illustrated in Formula (8).

$$H(x) = F(x) + x \quad (8)$$

When constructing an image style transfer model, it includes a residual network module and a sampling network module. The image undergoes a two-step convolution operation to achieve down-sampling. Then it is sent to the residual network module for processing. On a convolution with a step size of 1/2, it is sampled and restored to the original size output network. The basic process is shown in Fig. 4.

Fig. 4. The basic process of residual block sampling.

In this process, the output part of the network uses the Tanh function to limit the image pixel value between [0, 255]. The image style transfer generation network constructed through research is regarded as the objective function $y = f(x)$. $x$ represents the initial image. $y$ stands for the image after style transfer. $\hat{y}$ stands for the output value. $\phi_z(x)$ refers to the value of the Activation function of layer $z$. In volume $z$, the output value of the Activation function is a feature mapping of $C_z \times H_z \times W_z$. $C_z$ represents the feature maps. $H_z$ and $W_z$ represent the length and width of the convolutional layer. The Euclidean distance between the feature maps of the objective function to be optimized is shown in Formula (9).

$$l_{feature}^{\phi,z} = \frac{1}{C_z H_z W_z} \left\| \phi_z(y) - \phi_z(\hat{y}) \right\|_2^2 \quad (9)$$

Currently, the commonly used residual generation network can achieve rapid transfer of image styles. However, the final image migration effect cannot achieve the expected results. Therefore, the normalization idea is adopted to improve the residual generation network. In the image transfer model, in addition to adding residual blocks, a normalization layer is also added. This structure is to solve the contrast problem that occurs during the implementation of style transfer in the initial image. The contrast of the migrated image generated by the IST generation network is less affected by the contrast of the content image, resulting in a higher quality IST effect. Specifically, the IST network includes basic operations such as convolution, redundation, sampling, and normalization. $x \in R^{B \times C \times W \times H}$ stands for the image. $x_{bcwh}$ stands for the $bcwh$-th element. $b$ represents the image serial number. $c$ represents the RGB channel of the image. $w$ and $h$ stands for spatial dimensions. The normalization result of image contrast is shown in Formula (10).

$$y_{bcwh} = \frac{x_{bcwh}}{\sum_{w=1}^{W} \sum_{h=1}^{H} x_{bcwh}} \quad (10)$$

However, the basic batch normalization layer defines normalization on all images in the dataset. This normalization method is greatly affected by noise and consumes a lot of storage, resulting in low applicability. Therefore, the Instance Normalization (IN) method is introduced to normalize each sample image one by one. The mathematical definition is shown in Formula (11) [19].

$$\begin{cases} IN(x) = \gamma\left(\frac{x - \mu(x)}{\sigma(x)}\right) + \beta \\ \mu_{bc}(x) = \frac{1}{HW} \sum_{h=1}^{H} \sum_{w=1}^{W} x_{bchw} \\ \sigma_{bc}(x) = \sqrt{\frac{1}{HW} \sum_{h=1}^{H} \sum_{w=1}^{W} [(x_{bchw} - \mu_{bc}(x)]^2} \end{cases} \quad (11)$$

The specific process of instance normalization operation is shown in Fig. 5.

Instance normalization is used to replace the task of batch normalization. It can effectively enhance the learning efficiency of the model and avoid various changes in data statistical characteristics. The effect of IST is often evaluated as Mean Intersection over Union (MIoU). The obtained style transfer images are evaluated using the MIOU indicator [20]. MIoU is the standard metric for semantic segmentation, which is typically used to calculate the intersection and union ratio of two sets. In the measurement of IST, two sets are style images and style transfer images, respectively. The calculation method is shown in Formula (12).

$$MIoU = \frac{1}{k+1} \sum_{i=0}^{k} \frac{p_{ii}}{\sum_{j=0}^{k} p_{ij} + \sum_{j=0}^{k} p_{ij} - p_{ii}} \quad (12)$$
Fig. 5.    Image style transfer process based on instance normalization operation.

In Formula (12), $k$ is pixel quantity. $p_{ij}$ represents the intersection to union ratio of each pixel. $i$ stand for the true value. $j$ stand for the prediction. The larger the MIoU is, the smaller the difference between the predicted and the true value. In IST, the closer the style transfer image is to the initial style image.

## IV. PERFORMANCE ANALYSIS OF IST GENERATION NETWORK BASED ON NORMALIZED RESNET

A Generative model of IST based on normalized residual network is constructed on the basis of CNN. This chapter will test and verify the performance of the image style Generative model. Then the model is applied to actual IST and the transfer effect is analyzed.

### A. Performance Analysis of Improved Normalized Residual Network

To better validate the performance of the image style transfer model based on an improved normalized ResNet, relevant experiments are designed to verify the availability of this method. The environmental design is illustrated in Table I.

TABLE I.        TEST ENVIRONMENT SETTINGS

| CPU Model | Intel@core i7-7700k **CPU@4.2GHz x8** |
|---|---|
| GPU model | GeFore GTX 1080 Ti/PCle/SSE2 |
| Python version | 2.7.13 |
| Tensorflow version | R1.0 |
| CUDA version | 8.0 |
| Bazel version | 0.7.0 |
| Cudnn version | V5.1 |
| Batchsize | 4 |

Firstly, the availability of the IST based on residual network is verified. The dataset used in the model training process is Microsoft COCO, which contains over 80000 images. 5000 images are randomly selected for model training, and an additional 1500 images are selected as the test set. The image feature data is input into the residual CNN for iterative training. The LF is used at the output end of the model to predict the error. The LF and training accuracy of the proposed method under different Learning rate are illustrated in Fig. 6. From Fig. 6, when the Learning rate is 0.0001, the model is prone to over fitting. When the Learning rate is 0.01, the model precision does not get the optimal solution. When the Learning rate is 0.001, the loss value of the model is 0.2. The corresponding accuracy fluctuation under the Learning rate is the smallest and the accuracy is the best. Therefore, 0.001 is taken as the Learning rate of model training.

Fig. 6.    Loss value and accuracy rate under different learning rate.

To better compare the performance of different methods, the IST method based on improved normalized residual network proposed in the study is compared with commonly used methods. CNN algorithm, based on batch normalization of image style transfer model (CNN-BN), Fast Neural Style Transfer (FNST), and A Neural Algorithm of Artistic Style (NAAS) algorithms are used for comparison [21]. The AUC values of several models were compared on the training and testing sets, as displayed in Fig. 7. In Fig. 7(a), on the training set, the AUC value of the ResNet-IN model reaches 0.985, which is significantly higher than the other three methods. In Fig. 7(b), on the test set, the AUC value of the ResNet-IN model reaches 0.993, which is also superior to the other three comparison methods in terms of performance. According to the AUC values, the ResNet-IN model constructed in the study has better performance.

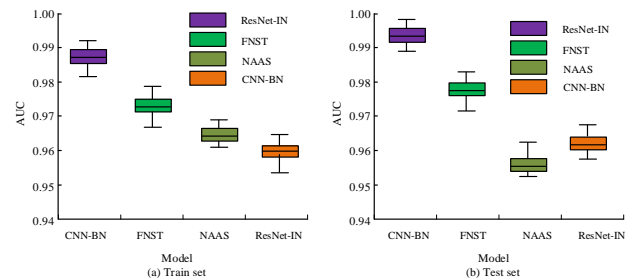

Fig. 7.    AUC value of three models.

The accuracy of several common methods is verified. The changes of Loss function and accuracy of different models are obtained as shown in Fig. 8. In Fig. 8, among the common image style transfer methods, the CNN-BN method has the lowest accuracy, only 82.51%. NAAS has an accuracy of 85.69%. FNST has an accuracy of 91.26%. The ResNet-IN method used in the study has an accuracy of 95.73%. At the same time, considering the loss rates of different methods, the ResNet IN has the best loss value. This indicates that the ResNet-IN image style transfer method has the best performance, which can obtain higher accuracy transfer images.

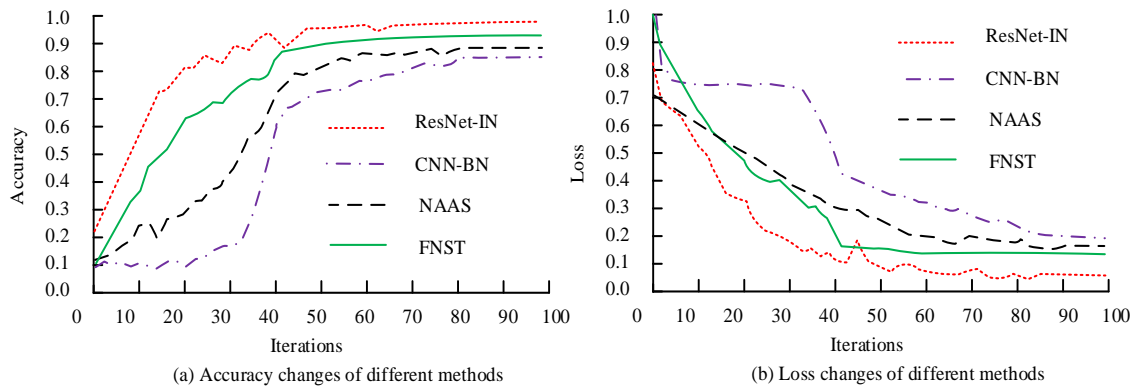
(a) Accuracy changes of different methods   (b) Loss changes of different methods


Fig. 8. Changes in accuracy and loss values of different methods.

## B. Application Effect Analysis of IST Generation Network based on Normalized ResNet

To explore the transfer effect of the image style transfer model based on normalized residual network proposed in the study on different style images, eight types of images with different styles are selected for five tests. Table II illustrates the experimental results. From Table II, in this testing platform, there are small differences in the time required for each style transfer test for eight different style images. However, overall, the actual time required for image transfer with different styles is less than 3.5s, indicating a better efficiency in image style transfer.

To test the performance of the image style transfer model constructed in the research, a satisfaction survey is conducted on the transfer effects of eight different styles of images. The comprehensive satisfaction evaluation indicators include completeness, fluency, and coherence. The satisfaction score is 10 points. The comprehensive satisfaction results of the expert's evaluation are shown in Fig. 9. From Fig. 9, taking Style 1, Style 3, and Style 8 as examples, the satisfaction results are as follows. The satisfaction rates for fluency, coherence, and integrity of the transfer map in Style 1 are 7.02, 8.56, and 7.64, respectively. The satisfaction rates for fluency, coherence, and integrity of the transfer map in Style 3 are 7.86, 8.62, and 7.49, respectively. The satisfaction rates for fluency, coherence, and integrity of the transfer map in Style 8 are 7.43, 7.74, and 8.35, respectively. The experimental results show that the overall satisfaction of the image style transfer model is high, demonstrating the excellent applicability of the model.

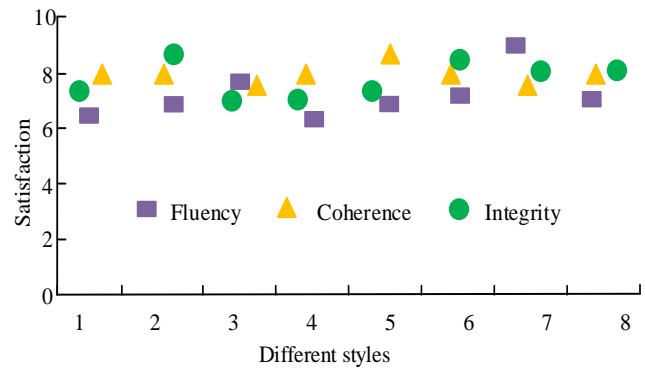

Fig. 9. The satisfaction results of different styles.

Comparing the proposed method with commonly used methods, the MIOU values of the image style transfer method obtained are illustrated in Table III. From Table III, the MIOU value of the CNN based image style transfer method is 0.728, and the image transfer effect of this method is the weakest. The MIOU value of CNN-BN is 0.82, FNST is 0.864, and NAAS is 0.858. The difference between these three methods is relatively small. The MIOU value of the ResNet-IN method is the highest, at 0.9, indicating that the image achieved using this method is closest to the original image, and the difference between the two is the smallest. The image style restoration obtained using this method is the best.

TABLE II. Efficiency Comparison of Different Styles of Images

| Image Style Migration Category | Test Platform | 1 | 2 | 3 | 4 | 5 | Average Time of 5 Tests (S) |
|---|---|---|---|---|---|---|---|
| Style 1 | Android | 2.03 | 2.17 | 2.45 | 1.86 | 1.99 | 2.1 |
| Style 2 | Android | 1.34 | 1.25 | 1.57 | 1.46 | 1.42 | 1.408 |
| Style 3 | Android | 2.34 | 2.16 | 2.75 | 2.09 | 2.45 | 2.358 |
| Style 4 | Android | 2.64 | 3.17 | 2.88 | 3.23 | 3.03 | 2.99 |
| Style 5 | Android | 3.16 | 2.98 | 3.25 | 3.11 | 3.23 | 3.146 |
| Style 6 | Android | 2.94 | 2.56 | 2.73 | 2.46 | 2.38 | 2.614 |
| Style 7 | Android | 2.45 | 2.29 | 2.37 | 2.58 | 2.64 | 2.43 |
| Style 8 | Android | 2.87 | 3.15 | 3.06 | 3.11 | 3.24 | 3.086 |

TABLE III. MIOU COMPARISON OF IMAGES WITH DIFFERENT STYLES

| Model | Number of Tests | | | | | |
|---|---|---|---|---|---|---|
| | *1* | *2* | *3* | *4* | *5* | *Average value* |
| ResNet-IN | 0.85 | 0.89 | 0.94 | 0.87 | 0.95 | 0.90 |
| CNN | 0.64 | 0.69 | 0.67 | 0.85 | 0.79 | 0.728 |
| CNN-BN | 0.78 | 0.84 | 0.85 | 0.81 | 0.82 | 0.82 |
| FNST | 0.87 | 0.86 | 0.80 | 0.91 | 0.88 | 0.864 |
| NAAS | 0.81 | 0.88 | 0.84 | 0.86 | 0.90 | 0.858 |

The performance of several methods in the application process is compared. The results are illustrated in Fig. 10. The accuracy, recall, and F1 values of the ResNet-IN model are 97.35%, 96.49%, and 97.52%, respectively. The three values of NAAS are 95.21%, 94.67%, and 95.23%, respectively. The three values of CNN-BN are 96.38%, 90.77%, and 93.50%, respectively. The three values of FNST are 95.21%, 91.42%, and 93.76%, respectively. The three values of CNN are 90.76%, 91.29%, and 94.08%, respectively. Overall, the ResNet-IN image style transfer method constructed in the study has more advantages in the application process, which can more accurately achieve IST and ensure the quality of style images.

Fig. 10. Accuracy, recall rate and F-measure value of the three models.

V. CONCLUSION

Image style transfer can transfer the style features of one painting to another portrait. With the development of artificial intelligence technology, IST technology based on DL has been widely developed. However, existing image style transfer technologies still have issues of low efficiency and low image quality. Therefore, based on the existing CNN, the ResNet structure is introduced to optimize it. At the same time, the normalization idea is used to improve the contrast problem that occurs during image transfer. The IST network Generative model based on the normalized ResNet is constructed. According to the findings, the AUC values of the ResNet-IN model proposed in the study are 0.985 and 0.993 in the training and testing sets, significantly higher than those of commonly used methods. Among several common image style transfer methods, the CNN-BN method has the lowest accuracy, only 82.51%. The accuracy of NAAS is 85.69%. The accuracy of FNST is 91.26%. The accuracy of the ResNet-IN method used in the study was 95.73%. The ResNet-IN image style transfer method proposed in the study has the best performance and can obtain higher accuracy transfer images. From the perspective of image restoration obtained by different style transfer methods, the proposed image style transfer method has the highest MIoU value of 0.9.

The style transfer image achieved using this method is closest to the original image, with the smallest difference between the two. The image style restoration obtained using this method is the best. Through testing eight different style images, there are small differences in the time required for each style transfer test. Overall, the actual time required for image transfer with different styles is less than 3.5 seconds, indicating a better efficiency in IST. In summary, the IST model proposed in the study can significantly improve the efficiency and quality of image style transfer, provide support for art and design activities represented by painting, and meet the needs of image style transfer in more practical scenarios. However, there are still shortcomings in the research. There are shortcomings in the flexibility of IST. Therefore, in future research, further research is needed on the flexibility of IST. However, there are still shortcomings in the research. The existing image style transfer methods are mainly influenced by factors such as algorithm execution speed, flexibility, and image quality. Although the proposed method has optimized the execution speed and the quality of image extraction, it still has shortcomings in the continuity of image style features. In addition, this model can only complete the transfer of similar image styles after each completion, which has shortcomings in flexibility methods. Therefore, in future research, based on the continuity of image feature extraction and the flexibility of image conversion, the image style transfer ability will be further optimized.

# Establishment and Optimization of Video Analysis System in Metaverse Environment

Dandan WANG, Tianci Zhang

School of Digital Media and Art Design
Nanyang Institute of Technology
Nanyang 473000, China

*Abstract*—The current source space communication architecture has not changed. At present, the key technology of so-called metaverse media only applies its elements to existing communication architectures, and more importantly, this type of integration involves individual examples and promotional marketing methods. How to become a new growth point for the deep collaborative development of metaverse media requires strengthened research and exploration. Although AI analysis technology is powerful, its sensitivity, accuracy and adaptability could be more satisfactory due to the complexity of real-world scenarios. Given the shortcomings of existing research, we designed a video analysis system in the metaverse environment, combining virtual reality and artificial intelligence, with video perception, network, and information technology as the medium and big data as the technical support to build a full intelligence Video analysis system. The system is based on the YOLOv3 model, combined with the actual video scene, and analyzes according to the video's human behavior and environmental changes. Experiments show that the system has obvious advantages in the accuracy and recall rate of video analysis and detection, the system detection performance is significantly improved, and the video target analysis and detection of complex scenes are realized.

*Keywords—Artificial intelligence; metaverse; video perception; big data*

## I. INTRODUCTION

In the 1960s, Ivan Sutherland et al. proposed a method to interact in the virtual world and gain experience, which can have a more real human-computer interaction experience [1], [2]. Subsequently, the first virtual reality system was developed. In the 1980s, James David Foley pointed out three elements of virtual reality: interaction, behavior and imaging. He proposed that the next generation of computers will have the complex computing power to realize the communication between users and computers and put forward the concepts of virtual reality, human-computer interaction and so on [3]. Virtual reality technology simulates the human perception function in the simulated computer environment, provides real interactive feedback, and allows people to have an immersive experience. Virtual reality affects the object form in the physical world by its real interactive feeling and good user experience so that users can gain experience in the virtual environment. Virtual reality technology can simulate the real video scene and detect the target of the real-time monitoring video, which can be adapted to the target detection task under various bad weather and low light conditions. The real-time

video data can be transmitted to the virtual platform to view real-time monitoring in the virtual scene. In 2016, the virtual reality technology innovation and industrial development conference was held so that virtual reality technology has a wider range of applications in 3D printing [4], remote sensing mapping, smart cities, digital museums, teaching and training, game animation, aerospace and other fields.

In 2021, based on virtual reality technology, the concept of "metaverse" was mentioned again. Metaverse integrates virtual reality technology, creates a virtual digital world parallel to the real world through exclusive equipment, and creates a social platform with a strong sense of immersion. Users can produce and live in a virtual environment different from the real world and interact in an immersive metaverse environment. Metaverse includes the following features: user participation in creation, providing exploration space, a fusion of the virtual world and the real world, a fusion of time and space, a fusion of three-dimensional technology and intelligent technology, etc. The primary implementation method of metauniverse is virtual reality technology. VR has the advantages of creating realistic scenes, visualizing abstract content, and creating immersive experiences. Artificial intelligence (AI) technology includes deep learning, natural language processing, etc. [5]. Through the use of AI technology, we can increase the depth of research and improve the accuracy and accuracy of video analysis.

The current application scenarios that can only be monitored are becoming increasingly complex, and its classic abnormal behavior analysis rules can only be applied to some industries in China. The current algorithm rules are difficult to meet in all behavior analysis scenarios. Therefore, many applications are in their early stages and need improvement. The main factors hindering the development of intelligent video surveillance and detection systems are:

*1) Environmental* factors have a significant impact on intelligent video surveillance and detection systems. At present, most video analysis systems are developed based on traditional computer vision technology and do not provide image enhancement functions such as improving video image quality and clarity.

*2) Many* video object analysis lacks objective experimental support. Excessive reliance on reasoning leads to subjective assumptions in the interpretation of unconscious psychological phenomena.

*3)* *There* is a problem of insufficient monitoring accuracy in the experiment. The accuracy of integrated virtual reality technology in video surveillance is not satisfactory.

In the current metaverse environment, the deployment of video monitoring systems plays an important role in preventing and stopping crime, maintaining social and economic stability, and protecting the safety of the life and property of the country and people. For example, video analysis is used in 1300 channels of the Qinghai Tibet railway to comprehensively and effectively protect the safety of the whole railway. The main trend of future development of video analysis is to use deep learning technology to improve detection efficiency and realize real-time and pre-intelligent analysis. Therefore, intelligent video surveillance has become one of the most cutting-edge development fields. High definition, networking and intellectualization are the main development trends of video monitoring technology. Intellectualization refers to using intelligent analysis algorithms to process video data, extract valuable information, and prompt users with key information in the form of alarm, to improve the intellectualization and actual use value of video monitoring systems [6]. Intelligent video analysis technology can transform video monitoring from traditional "passive monitoring" to intelligent "active monitoring" and can free users from monotonous and boring monitoring work, avoid the problem of attention loss caused by long monitoring time, and realize 24-hour monitoring, so it has attracted more and more users' attention.

The research and innovation contributions are as follows:

*1)* *The* metaverse can integrate virtual reality technology and coexist. This means that the research and development of metaverse media is not only reflected in game types, but mainly in social media full scene CNC.

*2)* *This* article constructs a fully intelligent video analysis system. The system is based on the YOLOv3 model, combined with actual video scenes, and analyzed based on human behavior and environmental changes in the video.

*3)* *YOLO3* draws on the residual network structure to form deeper network layers and multi-scale detection, improving the performance of mAP and small object detection.

*4)* *The* system has improved prediction accuracy while maintaining its speed advantage, especially enhancing its ability to recognize small objects.

This article analyzes video analysis and monitoring issues in the metaverse environment. The video analysis system in the metaverse environment has the advantages of high real-time accuracy and strong robustness, fully meeting production needs. The first part introduces the current status of the metaverse environment and video analysis technology. Section II analyzes the problems and development prospects of existing video analysis and detection methods. Section III mainly introduces the requirement analysis, design, and implementation of an intelligent video analysis system based on the metaverse environment. Section IV provides a detailed introduction to the development and testing of the system. Section V provides a summary of the entire text. The experiment shows that the system has significant advantages in terms of accuracy and recall in video analysis and detection,

and the detection performance of the system is significantly improved, achieving video object analysis and detection in complex scenes.

## II. RELATED WORK

Intelligent video analysis technology is gradually applied in digital video surveillance and has been developed for over 10 years. However, regarding the current development level and actual use of intelligent video analysis technology, smart video analysis technology has only made small-scale applications in some industries, such as banking, transportation, and justice, and more often, it is only used as a highlight demonstration of the project. The market for intelligent video analysis technology has remained the same. The main reason is a large deviation between the user's cognition and demand for smart products and the degree of intelligence that intelligent products can achieve. This problem is more prominent because some manufacturers adopt the propaganda method of exaggerating performance to occupy the market. From the perspective of the long-term development of intelligent video analysis technology, it should be based on the current technical level, improve adaptability and robustness to different scenarios, simplify product settings, improve ease of use, bring real value to customers, and truly make intelligent video Analytical techniques are widely used. For example, the original monitoring images collected at the front end are structurally analyzed through intelligent video analysis technology. The original video image data are automatically transformed into quasi-structured and structured data to form the corresponding subject database. The data are submitted to the big data platform for relevant data models, technical methods and other uses, developing rich practical applications, such as human and vehicle trajectory characterization, foothold analysis, prediction and early warning and other services, giving full play to the reasonable value of monitoring images.

The rise of artificial intelligence technology and the development of network technology have pointed out new research directions for video analysis technology. Connect the hardware device to an IP network, and the webcam can be read by any device on the network via IP access. At the same time, the connection between various devices in the network relies on the standardized TCP/IP protocol. As long as the machines that meet the requirements of the protocol can access the network, the system's scalability has been greatly enhanced. In terms of algorithm, combined with the current deep learning algorithm, a role in a neural network is constructed to analyze and recognize video targets, which greatly improves the accuracy of analysis and detection. Combined with various embedded devices, controllable management is realized through the Internet/WiFi/LAN. It is highly integrated with access control, voice system, alarm devices, etc., combined with artificial intelligence algorithms to realize automatic detection, personnel identification, identity control and other functions between various machines [7].

Abnormal behavior detection of moving targets is one of the main functions of an intelligent video analysis system. Its primary task is to determine the moving targets then realize the tracking of moving targets in video and abnormal behavior analysis [8]. The traditional method to determine the moving

target is mainly realized by motion detection methods, including (1) the inter-frame difference method, which expands each frame taken by the camera according to the time sequence. Then it makes a difference between the images of the previous and subsequent frames and then regards different places in the video frame as moving targets. The biggest advantage of the inter-frame difference method is that it is simple and fast, while the biggest disadvantage is that it is difficult to separate the complete moving target. (2) Background difference method, first establish the background model of the video, then make a difference between the video frame of the monitoring system and the background model, and then locate the moving target in the video [9]. The biggest advantage of the background difference method is that it can adapt to the complex and changeable surrounding environment, and the biggest disadvantage is that it is easily affected by light. In order to make the background difference method have a good effect, it is necessary to update the background model in time. (3) The optical flow method infers the moving direction and speed of the object according to the change law of the recognized image pixel value with time. Its disadvantage is that it requires a large amount of calculation and a high computer processing capacity.

With the in-depth study of deep learning, target detection based on neural networks has higher accuracy and better stability than traditional target detection methods. It can meet the real-time requirements of video analysis. At present, deep learning algorithms for target detection are mainly divided into two categories: the two-stage method, whose principle is to divide the whole detection process into two parts to generate candidate frames and to identify objects in structures. It mainly includes: (1) region-based convolutional neural networks (R-CNN) target detection method, which greatly improves the accuracy of target detection [10]. The principle is to obtain candidate regions through selective search, then extract the features of each candidate region using a deep convolution network and carry out support vector machines (SVM) classification, and then obtain preliminary detection results. Finally, to get a more accurate boundary box, we use the deep convolution network feature combined with the SVM regression model again. (2) Fast R-CNN, this method no longer convolutes the candidate regions but convolutes the whole image and completes the fitting of the bounding box and the classification of candidate regions through the structure of the dual task network. Compared with R-CNN, Fast R-CNN shortens the training and testing time by nearly nine times [11]. (3) Faster R-CNN, this method directly generates candidate regions through the convolutional neural network, composed of regional candidate generation network and Faster R-CNN, which realizes candidate region classification and border

regression. This method's training and testing time is 1/10 of that of Faster R-CNN [12]. However, the target detection method based on a convolutional neural network needs to input a fixed-size image, and the normalized production organism is truncated or stretched, which will lead to the loss of some information in the input image. The other is one stage method, whose principle is to unify the whole process and get the detection results directly, which makes the target detection process simple and efficient. It mainly includes (1) YOLO (you only look once), which directly obtains the category and location information of the target through a neural network convolution operation and realizes the real recognition and judgment in one step [13]. YOLO target detection process is very simple, and compared with the above detection algorithm, its efficiency is very high, and the processed image can reach 45 frames per second. (2) Single shot multi-box detector (SSD) [14], this method carries out detection and classification together and filters out some detected results with unclear classification and low scores. It is a detector based on a full convolution network, which can detect objects of different sizes with different layers. However, the target detection model trained by this algorithm will have the problem of positioning errors when identifying targets.

In summary, the nonlinear transformation ability of neural networks is also stronger. In target detection tasks, we need to map the input low dimensional features to a high-dimensional space in order to better represent and distinguish different targets. Traditional methods often require the design of complex mapping functions, and neural networks can learn this mapping relationship from data through automatic learning, avoiding complex design processes. Finally, the training process of neural networks can be automated and parallelized, which greatly shortens training time and improves efficiency. Of course, there are also some challenges and limitations in the target detection methods of neural networks. For example, they require a large amount of data for training and require high-performance hardware and software to run. In addition, the design and training of neural networks also require certain experience and skills, such as selecting appropriate network structures, optimizing algorithms, loss functions, etc.

## III. Establishment and Optimization of Video Analysis System in Metaverse Environment

### A. Traditional Video Detection and Analysis Theory

The traditional target detection system generally comprises three modules, including a region selection module, feature extraction module and classifier classification module, as shown in Fig. 1.

Fig. 1. Traditional food detection and analysis steps.

*1) Region selection:* The main function of the area selection module is to locate the target's location. Because the

mark may appear anywhere in the image, and the target's size and length-width ratio is uncertain, the sliding window

strategy is initially used to traverse the whole picture, and different scales and length-width ratios need to be set. Because the appearance of the target is random, in the selection of the area where the target is located, the target can only be found by traversing and selecting by sliding on the original map, which leads to more redundant target boxes, which not only affects the speed, but also consumes many computing resources, and the detection results are also unsatisfactory. The higher the structure levels, the worse the system's accuracy.

*2) Feature extraction:* The main function of the feature extraction module is to calculate and count the image's local or global feature descriptors to get a feature map with richer semantic meaning. Affected by complex environments and scenes, in the face of diverse scene changes, traditional feature extraction methods are difficult to meet high accuracy requirements, so they can not be adapted to application scenarios. The previous feature extraction is all manually designed features, such as Haar features, hog features, etc. Still, due to the ever-changing world and limited cognitive ability, the artificially created features have various problems, such as poor robustness and unreliability, which makes it difficult to improve the efficiency of traditional target detection.

*3) Classifier classification:* The function of the classifier is to judge the category of a new observation sample based on the training data of the marked category. Traditional classification is mainly realized by AdaBoost and SVM [15]. Two main reasons affect classification: the structure of the classifier itself and the feature parameters extracted through the previous layer.

*B. Overall Function Design of Video Analysis System in Metaverse Environment*

According to the requirements of the system, five functions are realized, including the function of visual interface, the process of controlling the ball machine to track the moving target in real-time, the function of detecting the abnormal behavior of the target, the function of image enhancement and the process of panoramic stitching. The functional structure of the system is shown in Fig. 2.

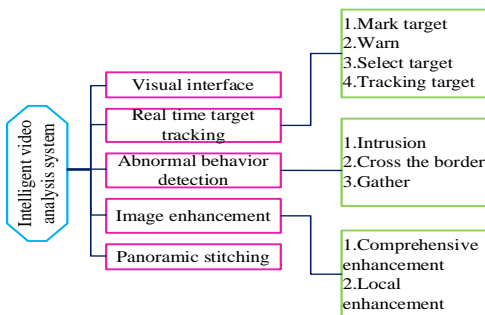

Fig. 2. System function structure diagram.

*C. System Hardware Design*

The main functions of the hardware system in the overall system architecture include data acquisition, video recording,

result display and other parts. The data collected by different hardware is transmitted and summarized into the system software through network communication, and then the collected information is analyzed and processed through the system software. Finally, the results are stored and displayed. For the whole system, the hardware system is the premise to ensure the stability of information collection and the comprehensiveness of information collection. A reasonable hardware system architecture can ensure the stability of information collection. The correct hardware installation method and the appropriate hardware layout position are the prerequisites for comprehensive information collection. The hardware system structure is shown in Fig. 3. In this study, the hardware architecture is constructed using a network camera, network HD hard disk video recorder, monitoring hard disk, display, computer, switch and other hardware.

Fig. 3. Hardware system structure diagram.

*D. System Software Design*

The software of the intelligent video analysis system for regional control is mainly composed of four parts: data acquisition module, image processing module, database storage and processing module and result display module. First, the system obtains real-time video information and access control information through the data acquisition module, and then the image processing module performs real-time detection and processing for the monitoring area. The database storage and processing module stores and processes the results of the image processing module and the entry and exit records of the access control all-in-one machine. The result display module displays the real-time processing results of the image processing module, and the database on the interface queries the results or exports them as CSV files. The software flow chart of the intelligent video analysis system is shown in Fig. 4.

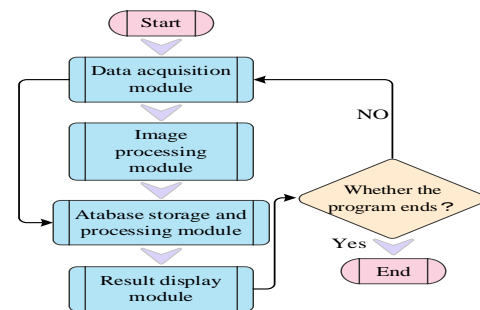

Fig. 4. Flow chart of the video analysis system.

*1) Data acquisition module:* There are two kinds of hardware devices used in the data acquisition module, one is

the surveillance camera, and the other is the integrated access control machine. Among them, the data acquisition of the access control all-in-one machine uses the alarm callback function in its SDK. When someone opens the door through the access control, the alarm callback function is triggered to obtain the personnel job number, access control machine IP, travel time and other related information. The information acquisition of the surveillance camera needs to cooperate with the image processing module. The data acquisition completes the equipment login, decoding, format conversion and other operations in the main thread, and the image processing module processes the converted image in the sub-thread. The multithreading processing method used in this system can not only strengthen the robustness of the system operation but also speed up the system processing speed.

First, the system needs to initialize the device SDK to prepare for the subsequent program operation. Then, the system reads the login device information. Due to different devices, the login and following processing processes are separate. The access control all-in-one machine does not need to maintain a link with the system for data transmission at all times after successful login. Only when someone triggers the alarm callback function when passing through the access control will it return a message containing the device IP to the system? It occupies relatively few computing and memory resources through the personnel job number and passing time, so its data acquisition process is in the same thread. However, the surveillance camera's image information needs to carry out real-time data transmission with the system, so it is necessary to set the disconnection reconnection time and an abnormal callback function to ensure the system's stable operation. After the surveillance camera logs in, each camera will return a device ID number, which will be used to identify subsequent code stream data differentiation of different cameras. After the camera logs in, you need to open the playback library and call the real-time stream callback to set the parameters of the video stream. Then, start the decoding callback to decode the video stream into UV12 format and convert UV12 format into RGB format for subsequent image processing.

Opening up threads and caches for each camera can first make the system process the images of each camera without interference, improve the system's stability, improve the system's computing efficiency, and enhance the real-time performance of the system. Collect image information for each camera's image cache in the system's main processing thread, process the image data in the corresponding sub-processing thread, and empty the processed image cache to keep the video frame cache updated in real-time.

*2) Image processing module:* The image processing module of this system is mainly used in the sub-thread of each camera of the system. The image processing module is the core of this system, which needs to combine the detection algorithm based on a convolutional neural network with the database to complete the work. Among them, the detection algorithm based on a convolutional neural network is used to detect intruders in the set deployment scenario. The database

part is responsible for analyzing the time when the intruders are detected and recording the start time and end time of each intrusion. After obtaining the current frame from the video frame buffer, the image processing module uses the YOLOv3 detection algorithm after fine-tuning the scene to detect the staff. When personnel are detected, the current detection time is determined. If the current detection time is within the preset deployment time, the current detection time is compared with the intrusion time in the database. The design idea of this module is that if there is a repeated intrusion within three seconds, it will be regarded as the same intrusion event. If the interval between the latest and last detected intrusion is greater than three seconds, it will be considered a new intrusion. Therefore, the current detection time is first compared with the latest intrusion end time. If the time difference is less than three seconds, the newest intrusion end time is updated to the current detection time. If the time difference exceeds three seconds, it must be compared with the latest intrusion start time. If the time difference exceeds three seconds, the current time is recorded as the new intrusion start time. Otherwise, it is recorded as the new intrusion end time. After completing the above operations, clear the current frame data, obtain and process the next frame.

*3) Database storage and processing module:* This system's database storage and processing module is mainly used to process the access information returned by the access control machine. Through access control information and face comparison based on video frame images, the system can realize several functions, such as attendance management, overtime detection of non-secret related personnel in hidden related areas, detection of non-secret related personnel entering illegally, and reminder of VIP visits. The four functions of this module are realized by hardware information triggering the query and processing of the database.

*a) Attendance management*: First, the real-time access information returned by the access control is written into the database, and the database information of the previous day is processed at 0:00 every day. Each person's first access is recorded as the time of work, and the time of the last entry is recorded as the time of departure. Then, they are compared with the preset on-off time, the day of the week and other information to obtain whether there are late, early leave, absenteeism or overtime on that day, and store the analysis results.

*b) Overtime* detection of non-secret related personnel in hidden related areas. The deployment site of this system requires that when non-secret-related personnel enter the secret-related room, whether the door is locked or not, they must pass the access control and stays for no longer than the specified time. Therefore, when the system detects that non-classified personnel enter the classified area after a specified time of waiting, it will query the access information of the classified site during the waiting period. If the non-classified person has no record of entering and leaving the classified site within this period, the non-classified person will be recorded as an overtime stay.

*c) Detection of illegal entry of non-secret related personnel*: When the camera at the entrance of the classified area detects that a non-classified person has entered the classified area through face comparison, it determines whether the non-classified person has passed the access control when entering the classified area by querying and analyzing the database. If the result is that he has yet to enter the classified area through access control, record the illegal entry behavior.

*d) Important guest visit reminder*: When the camera outside the main door detects the person through face comparison, it determines whether the visitor is a VIP by querying the VIP information in the database. If it is a VIP, it will send a reminder message.

*e) Result display module*: The results show that the module's structure is relatively simple and consists of two parts. One part displays the real-time detection effect of the image processing module on the software interface, and the other part displays the data queried from the database on the interface in the form of a list and exports it to a CSV format file. This module only displays image data and database data without processing.

### E. Key Technologies of the Video Analysis System

*1) Back propagation algorithm:* The backpropagation algorithm is important for convolutional neural networks to calculate gradients. Dr Paul proposed the backpropagation algorithm werbos in his doctoral thesis in 1974, but it was only widely recognized once David proposed it again in 1986. At present, this is one of the most commonly used algorithms for training neural networks. The input of the neural network structure is a two-dimensional vector $(x_1, x_2)$, and the corresponding parameters to be optimized are $w_1$, $w_2$ and b. The last step of the nonlinear transformation operation is completed by a ReLu [16]. The calculation is divided into the most basic multiplication and addition operations. When backpropagation is required, multiply all the gradients on the dotted line from y to the leaf node.

At present, the most widely used function is the ReLu function. Its linear and unsaturated characteristics give it strong convergence ability in model training.

$$y = \begin{cases} 0 & (x \leq 0) \\ x & (x > 0) \end{cases} \tag{1}$$

In the ordinary ReLu function, for the input less than 0, the derivative is constant to 0, which may cause too many silent neurons. Leaky ReLu [17], as an improved version of the ordinary ReLu, avoids this problem by introducing a normal number $\lambda$ predefined to be close to 0.

$$y = \begin{cases} x & (x > 0) \\ \lambda x & (x \leq 0) \end{cases} \tag{2}$$

Compared with the ReLu function, the PReLu function introduces value α, which is obtained by adaptive learning based on data. The introduction of a can prevent the gradient from disappearing, accelerate the convergence speed and reduce the error rate.

$$y = \begin{cases} x & (x > 0) \\ \alpha x & (x \leq 0) \end{cases} \tag{3}$$

Leaky ReLu and PReLu have the best relative performance based on the above common activation functions. Their linear and unsaturated characteristics can help the model converge quickly. At the same time, they both solve the problem of training termination caused by silent neurons caused by gradient disappearance. However, parameter a in PReLu needs adaptive learning, and the YOLOv3 algorithm is relatively sensitive to speed, so it is necessary to reduce the number of learning parameters so the activation function selected in YOLOv3 is Leaky ReLu.

*2) Gradient descent algorithm:* When YOLOv3 uses the back-propagation algorithm to calculate the gradient, it also uses the gradient descent algorithm [18]. Generally, there are three kinds of gradient descent algorithms: full batch gradient descent, random gradient descent (SGD) and small batch data gradient descent. The full data gradient descent algorithm is to calculate all the training sample data every time the gradient is calculated. If the total number of samples in the training set is N, calculate the entire loss function by calculating the loss function for all N sample data and then calculate the mathematical expectation. The calculation formula is shown in Eq. (4).

$$l(\theta) = \frac{1}{N} \sum_{i=1}^{N} L(\theta; xi, yi) \tag{4}$$

In Eq. (4), *N* is the total amount of training sample set, $(x_i, y_i)$ represents a set of random components, and θ is the parameter to adjust the component weight.

The distance measurement formula used in K-means clustering is shown in Eq. (5).

$$d(box, centroid) = -IOU(box, centroid) \tag{5}$$

In Eq. (5), *d* represents the distance from the centroid to the bounding box, (*box, centroid*) is the geodesic distance from the centroid to the bounding box. IOU (Intersection over Union) is a measure of the accuracy of detecting corresponding objects in a specific dataset.

The second is to improve the problem of unstable model fitting in the traditional anchor algorithm. The instability in the conventional anchor algorithm is mainly caused by predicting the coordinates (*x, y*) of the bounding boxes. The calculation formula is shown in Eq. (6).

$$x = (tx * wa) - xa$$
$$y = (ty * ha) - ya \tag{6}$$

In Eq. (6), $(x_a, y_a)$ represent the coordinates of the center of the bounding box, $t_x$ is the *x* coordinate movement step size, $t_y$ is the *y* coordinate movement step size, $w_a$ is the direction parameter of the *x* coordinate, $h_a$ is the direction parameter of the *y* coordinate. In Eq. (6), no constraints are imposed on the bounding boxes, and any bounding box can fall on any area of the image, which is relatively difficult to stabilize. In YOLOv3, the improved anchor algorithm directly predicts the relative

position of the bounding box relative to the grid unit, and the calculation formula is shown in Eq. (7).

$$bx = \sigma(tx) + cx$$
$$by = \sigma(ty) + cy$$
$$bw = pw\,e^{tw}$$
$$bh = ph\,e^{th} \qquad (7)$$

In Eq. (7), $(c_x, c_y)$ is the coordinate of the upper left corner of the grid, $p_w$ and $p_h$ are the width and height of the anchor box, respectively, and $(b_x, b)$ is the central coordinate of the bounding box, and $b_w$ and $b_h$ are the width and height of the bounding box. After the above constraints, the network becomes more stable.

Compared with the YOLO algorithm that does not use the anchor idea, the map has a slight decrease, but the recall rate has a significant increase, as shown in Table I. Where AP represents the average accuracy of target detection, the map represents the average AP value, and recall represents the ratio of correctly identified targets to the number of all flying targets in the test set. This is because each graph can only give dozens of prediction boxes before using the anchor idea. After using the anchor idea, the model can have more than 1000 prediction boxes, giving the algorithm more room for improvement.

TABLE I.        COMPARISON OF RESULTS WITH AND WITHOUT ANCHOR

|  | **Map** | **recall** |
|---|---|---|
| Without anchor | 69.5 | 81% |
| With anchor | 69.2 | 88% |

*3) Loss function:* In YOLOv3, the key prediction information in the final result mainly includes four categories: prediction frame length and width (w, h), coordinates (x, y), category class and confidence. According to these four information characteristics, the appropriate loss function is selected, and then the weighted average is obtained to obtain the final loss function. Among them, the loss function used in the prediction frame length and width (w, h) is the sum of squares of the errors of the corresponding points of the original data and the fitting data, and its calculation formula is shown in Eq. (8). The closer the SSE result is to 0, that is, $y_i = \hat{y}_i$, it means that the predicted parameters are equal to the real value, the network reaches the convergence state, and the higher the target detection rate, the stronger the fitting ability of the final model.

$$SSE = \sum_{i=1}^{n} wi(yi - \hat{y}i)^2 \qquad (8)$$

The loss function used for the remaining three types of information is the cross entropy loss function binary_crossentropy; the calculation Formula is shown in Eq. (9) and Eq. (10).

$$loss = \sum_{i=1}^{n} \hat{y}i \, log\, y\,i + (1 - \hat{y}i)\, log(\, - \hat{y}i) \qquad (9)$$

$$\frac{\partial loss}{\partial y} = -\sum_{i=1}^{n} \frac{\hat{y}i}{yi} - \frac{\hat{y}i}{yi} \qquad (10)$$

Eq. (10) shows that only when $y_i = \hat{y}_i$, the loss value is 0, and in other cases, the loss is constant as a positive number and the greater the difference between *you* and the greater the loss value.

## IV.  RESULT AND ANALYSIS

According to the video scene's personnel management and control requirements, a detection and analysis scheme suitable for this scene is designed. YOLOv3 is fine-tuned on the video scene data set, and the accuracy of the fine-tuned algorithm is verified through experiments. Finally, the stability of the system is verified.

The CPU of the hardware platform used in this study is i5 4590, and the main frequency is 3.3GH; The GPU is NVIDIA's Teska K40, and the video memory is 12GB; Memory is 16GB; The system is a 64-bit ubuntu16.04 high-performance host. It needs to be done on Darknet. Before installing Darknet, you must first configure CUDA and OpenCV, recompile Darknet on the configured host, and finally get the Darknet framework loaded with CUDA and OpenCV.

After completing the above preparations, set the response path in the program and start the training. After training, a fine-tuned YOLOv3 model with a size of 246.3mb is obtained. The loss image obtained from training is shown in Fig. 5. The loss function is a function to measure the detection performance of the algorithm. In Fig. 5, at the beginning of training, the loss value decreased rapidly, indicating that the fitting speed of the model quickly increased. With the progress of the training process, the decline speed of loss value gradually slows down, indicating that the model fitting is slowly completed. When the training times reach 40000, the loss value is the minimum. In the 40000 and 45000 training, the learning rate is adjusted to the current 1/10, and the loss value tends to be stable and minimum. At this time, the training is completed, and the model reaches the optimal state.

Fig. 5.   Loss function training curve.

Five hundred pictures are cut from the live video images of the sample set as the test sample set. The selected pictures cover as many scenes as possible, and the proportion conforms to the actual application scene. The final test sample focuses on 300 pictures of outdoor areas under natural light during the day, with a total of 1924 personnel targets; 100 pictures of

indoor areas under natural light during the day, with a total of 563 personnel targets. There are 100 pictures in the street backlight scene, with a total of 125 personnel targets. Fig. 6 shows a group of image comparisons under the same angle, natural light in the day and light at night. The performance of system target detection under different light can be studied through the comparison test.

Fig. 6. Training set samples.

There are 2612 personnel targets in the test data, of which 2518 targets were correctly detected, 94 targets were missed, and the background was detected as personnel targets eight times, with accuracy P=0.997, recall rate R=0.964, false alarm rate FA=0.003, and missing alarm rate FNR=0.036. Under the condition of natural light in the daytime, the accuracy P=0.997, the recall rate R=0.960, the false alarm rate FA=0.003, and the missed alarm rate FNR=0.040; Under the condition of night light, the accuracy P=0.996, recall rate R=0.973, false alarm rate FA=0.004, missing alarm rate FNR=0.027; Under the state of the strong backlight at the sightseeing elevator entrance, the accuracy P=1, the recall rate R=0.984, the false alarm rate FA=0, and the missing alarm rate FNR=0.016. The specific test results are shown in Table II.

TABLE II. STATISTICAL TABLE OF OBJECT DETECTION RESULTS OF YOLOv3 MODEL PERSONNEL

|  | TP | FN | FP | R | P | FNR | FA |
|---|---|---|---|---|---|---|---|
| **Daytime indoor conditions** | 1847 | 77 | 6 | 0.960 | 0.997 | 0.040 | 0.003 |
| **Daytime outdoor conditions** | 548 | 15 | 2 | 0.973 | 0.996 | 0.027 | 0.004 |
| **Backlight condition** | 123 | 2 | 0 | 0.984 | 1 | 0.016 | 0 |
| **total** | 2518 | 94 | 8 | 0.964 | 0.997 | 0.036 | 0.003 |

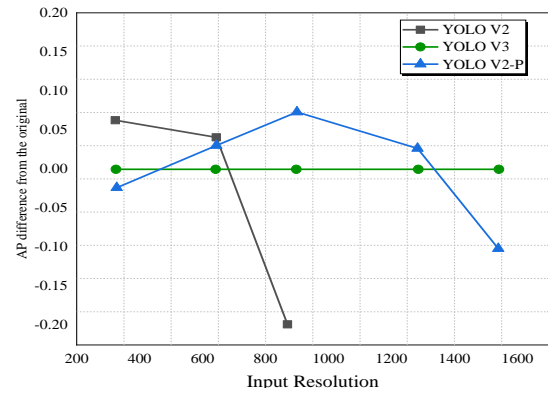

Fig. 7. AP comparison of networks under different resolutions.

As shown in Fig. 7, in the experiment, images of different resolutions are selected to input the network, and the AP of the network is tested. We can find that YOLOv3 has the best AP at high resolution, while YOLOv2 and YOLOv2-p have the best AP at middle and low key, respectively. This means that we can use sub-nets of YOLOv3 models to execute the object detection task well. Moreover, we can perform a compound scale-down of the model architectures and input size of an object detector to get the best performance.

Fig. 8. Dataset precision-recall curves.

The experiment compares the traditional deformable parts model (DPM) target detection algorithm and the target detection algorithm based on RCNN with this method for human detection in the data set. As shown in Fig. 8, it can be seen that the YOLOv3 model still has a high correct detection rate when the recall rate reaches 60%, but the detection rate of the DPM algorithm and the RCNN method decreases significantly. Because the DPM target detection method is characterized by manual marking, it has certain limitations, which leads to performance degradation. After transforming the detection problem into the classification problem of the local area of the picture, the RCNN method cannot fully use the context information of the local features of the image in the whole picture and loses the global attributes, resulting in performance degradation.
Fig. 9.   Object classification detection accuracy comparison.

As shown in Fig. 9, the experiment selects six types of detection targets in the data set for classification and detection and compares the detection accuracy. It can be seen that the YOLOv3 network model maintains high detection accuracy for six categories of targets. Category three is a selected low-resolution group, contrasting categories with light interference, and the detection accuracy is slightly reduced. Fig. 10 is a simulation of the classification and prediction results of the detection targets by the network; the target classification method is based on the target detection technology to locate the targets in the image, analyze the characteristics, and cluster the targets with the same features to form a certain category. It can be seen from the figure that the network has more accurately classified and identified the detection targets of the two categories.

Fig. 10. Object classification prediction simulation.

## V. DISCUSSION

Obviously, the root filter model describes the overall characteristics of a person, and if only one model is used to detect objects, it is definitely not as effective as detecting multiple models. So DPM also has a component filter model, and the number and parts of the component filters can be designed by oneself. The component filters describe the local features of a person's head, hands, and feet.

The local feature position detected by the component filter must not be too far from the position of this local feature in the root filter. Imagine if the distance from the hand to the body is twice the height, then is this still a person. So DMP added the position offset between the component filter model and the root filter model as the offset coefficient. As shown in the spatial model in the figure, the center of each box naturally represents

the rational location of the component model. If the position of the detected component model happens to be here, the offset coefficient will be 0, and a certain value will need to be subtracted from the surrounding area. The further the deviation, the greater the value will be subtracted. That is to say, subtracting the offset coefficient from the comprehensive score essentially involves using the spatial prior knowledge of the root model and component model.

Compared with the traditional anchor idea, YOLOv3 mainly makes two improvements. First, the method of manually selecting bounding boxes in the conventional anchor idea is changed, and a more reasonable K-means clustering method is selected. Compared with the manual selection of bounding boxes, some tall, thin and short boxes appear in the boxes obtained after K-means clustering [19]. Although unsupervised feature selection can remove some irrelevant and redundant features in some cases, it is usually more difficult than supervised feature selection because it does not have class information to help determine which features are relevant [20]. During detection, the inner product of the DMP feature vector of the input image and the filter operator is calculated to obtain the response value of this filter operator. After comprehensive different filtration the response value of the wave operator can be calculated as a comprehensive score, and then trained as a score threshold to detect humans.

## VI. CONCLUSIONS

With the change and development of society, information technology has had a wide and profound impact on today's society. Making full use of modern information technology has become an objective trend of social development; as one of the overall goals of information construction, current personnel area monitoring and management system needs to combine advanced digital image processing technology, advanced computer information technology and exchange network technology to meet the needs of high reliability, stability, security and applicability. This study constructs an intelligent video analysis system based on the metaverse environment. The procedure takes the YOLOv3 model as the core and fine-tunes it to enhance its detection ability. Experiments show that the fine-tuned YOLOv3 model has been significantly improved.

From the perspective of model structure, the YOLOv3 model does not use pooling layers and fully connected layers, but instead sets the convolutional stripe to two to achieve downsampling. Every time this convolutional layer is passed, the size of the image will be reduced to half. However, mainstream systems such as Windows, MacOS, Linux, Android, iOS, and Chrome OS do not have such model structure characteristics. Secondly, in terms of setting prior boxes, YOLOv3's method uses K-means clustering to obtain the size of prior boxes. On the COCO dataset, YOLOv3 clustered a total of 9 sizes of prior boxes. These prior boxes are set based on different scales of image features, enabling the model to better adapt to target detection at different scales. However, this method is not adopted by mainstream systems. Combined with the development of intelligent video surveillance, pedestrian detection technology and deep learning at home and abroad, this research constructs a smart personnel

area management ad control system that meets the actual needs. The construction scheme covers both hardware and software. This study selects the hardware equipment suitable for this system and designs an appropriate layout scheme according to the actual situation on site. In terms of software, this study combines a data acquisition module, image management module, database storage and processing module and result display module to complete various intelligent management requirements. Although this research realizes the simultaneous detection of multiple video streams, the detection results of each video stream need to be more connected. In the future, we can combine the detection results of each video stream by using technologies such as Reid to form a more powerful system.

# An Evaluation Method of English Composition Automatic Grading Based on Genetic Optimization Algorithm and CNN Model

Li Wang

School of Foreign Studies, Henan University of Urban Construction, Pingdingshan 467000, China
University of the Cordilleras, Baguio City,2600, Philippines

*Abstract*—In response to the problems of traditional genetic algorithms in evaluating English compositions, the stability of automatic grading of English compositions has been further enhanced. This article evaluates the teaching effectiveness of automatic grading of English compositions using an optimization fusion algorithm combined with genetic optimization algorithm and CNN model. By analyzing genetic content and optimization algorithms, a corresponding fusion optimization model was obtained, and the automatic evaluation of English compositions was analyzed and predicted through experimental verification. The results indicate that the curves corresponding to different parameters exhibit typical segmentation features through the variation curves of individual numbers under different scale factors. And through quantitative description and analysis of the curve, it can be seen that the change in proportion factor has an absolute advantage in the impact of genetic algorithm on the number of children. As the number of samples increases, the performance of genetic optimization algorithms under the f function shows an upward trend. Research has shown that the writing content index has the greatest impact on English writing, while the corresponding grammar errors have the smallest impact on English writing. Finally, the accuracy of the optimized model was verified by comparing the model curve with experimental data. This study provides theoretical support for the use of genetic optimization algorithms and CNN models in English, and provides ideas for the use of optimization algorithms in other fields.

## I. INTRODUCTION

Researchers have proposed various evaluation methods for the quality of English teaching in universities, such as grey relational analysis and fuzzy comprehensive evaluation [1]. However, these methods are suitable for linear models and are difficult to adapt to nonlinear teaching quality evaluation problems. They have subjective and random defects and cannot effectively achieve teaching quality evaluation. In terms of natural language processing models, researchers mainly use neural network-based models and convolutional neural network-based models. These models can convert text information into vectors and perform part of speech analysis, word form restoration, and other processing to ultimately obtain a feature vector related to text information [2]. In terms of scoring algorithms, researchers mainly used machine learning based algorithms and deep learning based algorithms.

Among them, machine learning based algorithms mainly improve the accuracy of prediction by training models [3]. The algorithm based on deep learning mainly falsely optimizes the structure and weight of the neural network to improve the accuracy of prediction [4]. The evaluation of teaching quality for university teachers is an important way to improve teaching management level and teaching ability of teachers. By utilizing teaching quality evaluation, students can provide feedback on the teacher's teaching situation, and teachers can reflect on the teaching effectiveness. Schools can effectively implement teaching management improvements and provide targeted training for teachers. English teaching is an important part of higher education, and the evaluation process of English teaching quality is relatively complex. Therefore, constructing an objective and scientific evaluation model for English teaching quality is a hot research direction [5]. Given the problems existing in chemical reactions, genetic optimization algorithm was used to improve the accuracy of chemical reduction reactions [6]. Firstly, the chemical reaction data were imported into the optimization model, and then the characteristic parameters of the test data were derived through further analysis of the model. Finally, the optimized model was used to modify the derived information. To verify the correctness of the model, relevant experiments were applied to verify and analyze the results of chemical reactions. In order to further improve the quality of tea, the traditional genetic algorithm can be optimized to reflect and describe the relevant properties of tea [7]. Different evaluation indexes can be obtained by extracting the characteristic parameters of tea leaves. Through the arrangement and analysis of the evaluation indexes, the optimized index data can be obtained, and the quality of tea can be judged through the analysis of the data. Finally, a large number of data were used to evaluate the correctness of the model. The convolutional neural network also has applications in various domains: Aiming at the issues of rock identification, the convolutional neural network can be modified to obtain the optimized convolutional neural network. The optimization model can better identify and analyze the rock [8]. The corresponding influencing factors can be found by extracting the rock's data features. Thus, the variation curves of rock characteristics under different influencing factors were obtained. Experiments were carried out to verify the model. The results show that the model can describe the characteristic parameters of rock well. Convolutional neural networks can also play a greater role in medical monitoring [9]. Specific medical parameters can be obtained through scanning

and extracting samples, different etiologies can be studied through description and analysis, and accurate results can be finally obtained.

Lightweight encryption (LWC) is an emerging technology used to develop encryption algorithms or protocols for implementation in restricted environments, such as WSNs, RFID tags, smart medical devices, and many other embedded systems. It is expected that LWC will play an important role in ensuring the Internet of Things and universal computing. The term 'lightweight' can be considered from two perspectives, namely hardware and software. However, portability in hardware does not necessarily mean portability in software, and vice versa. The above studies were mainly from medicine, architecture, and so on, but applying genetic algorithms in English composition was relatively rare. To further improve the application of the genetic algorithm and CNN model in English composition evaluation, based on the genetic theory, the fusion optimization model of the genetic algorithm and CNN theory was adopted to study the automatic scoring of English composition. The evaluation rules of scoring effects under different factors were obtained by analysing English composition's characteristics and related indicators. Eventually, the accuracy of the model was confirmed by associated experiments. This optimization model can improve the research ideas for applying genetic optimization algorithms and the CNN model in other fields.

This article optimizes the problems that exist in traditional evaluation of English compositions. The research has the following innovations:

*1)* The method proposed in this article is suitable for linear models and for teaching quality evaluation problems with nonlinearity. It solves the defects of subjectivity and randomness, and can effectively achieve teaching quality evaluation.

*2)* The corresponding fusion optimization model was validated through experiments to analyze and predict the automatic evaluation of English compositions.

As the number of samples increases, the performance of genetic optimization algorithms under the f function shows an upward trend. The curve corresponding to the g function is stable.

Section I analyzes the relevant background of automatic grading and evaluation of English compositions using genetic optimization algorithms and CNN models. Section II analyzes the relevant theories of genetic optimization algorithms. Section III further analyzes and understands the computational process and structural unit of convolutional neural networks. By organizing and analyzing relevant data, a convolutional neural network structure diagram was drawn. Section IV elaborates on the application of genetic optimization algorithms and CNN models in English writing, and analyzes the basic content of the evaluation method for the teaching effectiveness of automatic grading of English writing. The model curve in Section V indicates that the optimized model can effectively illustrate and characterize the trend of changes in English composition indicators. Therefore, in order to study

the impact of automatic grading of English compositions on teaching, an optimization model can be used.

## II. RELATED THEORY OF GENETIC OPTIMIZATION ALGORITHM

A biological individual is considered a response to the optimization algorithm in a genetic algorithm, a random search algorithm [10]. The population, which consists of many individuals, is the algorithm's solution set. Next, the weaker individuals are continuously eliminated through genetic processes like selective crossover and mutation. The genes with the favorable mutation are passed on to the next generation through probabilistic choice. The output individual is the ideal one that endures after screening when the termination condition is reached after continuous iteration. Both discrete and continuous optimization problems can be solved using the genetic algorithm, which is simple to use. Its multi-direction global optimization performance has good theoretical value for addressing challenging optimization problems today.

The existing cryptography relies on mathematical algorithms and key size, which can take decades to hundreds of years to crack. In theory, quantum computing can break existing encryption faster, possibly within days or even minutes. PQC is a new encryption method that resists quantum computing attacks by using very difficult mathematical problems that quantum computers cannot solve in a reasonable amount of time.

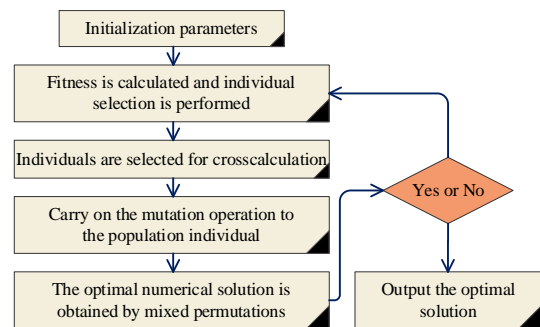

Fig. 1. Genetic algorithm solution flow chart.

Side channel attack is a cryptographic analysis method that uses information other than the encryption algorithm itself to infer certain information in the encryption algorithm, which may lead to the leakage of encrypted data. Power analysis uses the changes in power consumption during the encryption process to derive the state of the encryption algorithm and then crack the key. Time analysis uses the execution time differences of different encryption operations to infer the internal state of the encryption algorithm. Lightweight cryptography is a cryptographic method targeting resource constrained environments such as IoT devices, mobile devices, and embedded systems. Due to the limited computing power, storage resources, and energy supply in these environments, lightweight cryptography requires less computational and storage resources, while ensuring the security and integrity of encrypted data. To analyze the solving process of the genetic optimization algorithm, it summarized and analyzed different genetic algorithms and thus obtained the flow chart of genetic

optimization calculation under other algorithm theories as shown in Fig. 1. Considering the calculation process in the figure, initialization analysis should be carried out on relevant data first, making the study results more accurate. Initialization parameters include population size, iteration times, etc. The features of parameters can be extracted through initialization, and then the extracted feature parameters can be imported into the next calculation. In the next step, individuals can be selected through fitness calculation to obtain optimized genetic optimization data. Then, it is imported into the genetic optimization algorithm for cross-calculation, and the characteristics of the population are optimized and modified through cross-calculation. Then, the relevant data of population quantity are imported into the variation feature module for mutation operation, and then the data obtained from mutation operation are mixed and arranged, and the optimal number solution is obtained through calculation. Finally, judge whether the termination condition is met. If not, further iterative analysis is required. If so, the data will be output.

### A. Genetic Algorithms

Genetic algorithm is an optimization algorithm that simulates the process of biological evolution. It seeks the optimal solution by simulating processes such as gene combination, crossover, and mutation. In networks that require multi-agent management, genetic algorithms can be used to optimize transmission quality. For example, by simulating the interaction and competition process between agents in a network, genetic algorithms can automatically find an optimal network transmission strategy [11]. The process of using a genetic algorithm mainly involves two aspects such as cross-real number recombination and mutation [12], [13]. (1) Crossover and recombination of real numbers: the commonly used methods mainly include discrete and intermediate recombination in the recombining real numbers.

*1) Discrete recombination*: The operation of discrete recombination is relatively simple; that is, the genes on the above individuals before optimization are equally probabilistic and randomly inherited into the optimized individuals to realize individual renewal.

*2) Intermediate recombination*: The intermediate recombination completes the individual update process by calculating the expression as follows:

$$X = X_1 + a(X_2 - X_1) \tag{1}$$

X represents the child produced, $X_1$ and $X_2$ are the two selected parents, and a is the scaling factor.

Different scale factors influence the number of individuals in the genetic algorithm. To evaluate the influence of scale factors on the number of individuals, it draws the change curves of the number of individuals under different scale factors. Fig. 2 reveals that the number of individuals of the scale factor corresponding to additional parameter a shows different variation trends, as shown below: When a=-1, the corresponding curve shows typical two-stage variation features. In the first stage, the curve shows a gradual decline as the number of iterative steps increases, and the curve slope indicates that the curve at this stage is linear. However, when the number of iterations exceeds 60, the corresponding curve

manifests an approximate constant trend of change, indicating that the number of sub-individuals decreases gradually with the increase of the number of iterations. A two-stage variation trend is still visible in the corresponding curve when parameter a equals to 1. With more iterations in the first stage, the curve gradually gets better. As opposed to this, the slope of the corresponding curve is greater than that of the parameter a = -1, demonstrating that the influence of the parameter a = 1 on the number of sub-individuals is greater than that of the parameter a = 1. The corresponding curve shows a slight or gradual decline when the number of iterations exceeds 60. The overall curve thus demonstrates that when parameter a = 1, the influence of the number of corresponding sub-individuals still affects the change in volatility as a whole. When a=0, the associated curve exhibits a trivial change trend, and when its scaling factor is greater than 60, the related curve shows a slight growth trend. The number of sub-individuals under the three parameters above demonstrates that the influence of neutron individual numbers has a clear advantage in changing the scale factor. Therefore, when calculate the scale factor of the genetic optimization algorithm, it need to consider the specific variation of parameters.

Fig. 2. Scale factor variation diagram.

*3) Variation*: Variation refers to the change of some genes in the calculation process of the genetic optimization algorithm so that the characteristics of the number of offspring are different from those of other individuals. The variation of the genetic optimization algorithm can be divided into real number variation and binary variation according to separate research contents and calculation methods.

*a) Real number variation*: The following formula is generally used for real number variation.

$$X_3 = X \pm 0.5L\Delta \tag{2}$$

$$\Delta = \sum_{i=0}^{m} \frac{a(i)}{2^i} \tag{3}$$

$X_3$ is the individual after mutation, and L is the value range of the variable. $\triangle$ is the coefficient of variation, m is an artificially set integer, and a (i) is the probability function.

*b) Binary Variation*: Binary variation is relatively simple. For the binary code of characters, several positions are randomly selected on the individual gene sequence first, and then the gene values on these loci are reversed.
Fig. 3.    Diagram of changes of two variation indicators.

Through variation calculation, it can see that different calculation methods have other influences on the number of variations. To study the effect of real number variation and binary variation on the number of variations, the change curves under two variation indicators were drawn, as shown in Fig. 3. As the figure displays, with the gradual increase in the number of samples, the two different variation modes show typical variation trends. Firstly, it can be seen from the real number variation method that the real number variation shows a distinct piecewise change as the number of iterations increases. When the number of samples is odd, the corresponding sample variation is 1. When the corresponding variation sample reaches an even number, the corresponding sample variation is zero. Therefore, the real number variation shows the typical characteristics of the 01 variation. As can be seen from the curve corresponding to the binary variation method, when the variation gradually increases, the corresponding number of variations shows a gradual decline, and the slope of the curve corresponding to the downward trend is approximately constant. When the number of samples exceeds 200, the corresponding curve gradually increases. Through the above analysis, it can see that binary variation shows different trends with different sample numbers. Therefore, relevant studies show that to improve the accuracy of the genetic optimization algorithm, it is necessary to use a wide range of samples for iteration and analysis.

### B. Genetic Algorithms Update Content

It can be seen from the above research that the genetic algorithm conducts targeted research on input data through real number variation and binary variation and finally outputs neurons through an iterative updating calculation method [14], [15]. Therefore, the individual update method can be adopted to optimize the genetic algorithm, and the corresponding optimization and update steps are as follows:

*1) Determine the neural network of the genetic algorithm*: To solve the neuron j corresponding to the initialisation data of the optimization problem and the corresponding weight

vector $W_j$, the connected structural network of the genetic algorithm should be adopted [16], [17].

*2) Select individual samples from the individuals:* Produced by the genetic algorithm as input data into the genetic algorithm structural network. The corresponding calculation formula is as follows:

$$\text{dis}(W_j, X_t) = \sqrt{\sum_{k=0}^{k=n}(w_j^k - x_j^k)^2} \qquad (4)$$

where is the gene value at the kth position on the j-th neuron, $x_j^k$ represents the gene value at the kth position on the i-th individual, and $X_t$ is the sample vector.

*3) Solve the best matching unit*: determine the relationship and distance between the genetic algorithm data in the above way, and find the neuron data with the closest distance.

*4) Calculate the neighborhood radius of the neuron*:

$$\begin{cases} \sigma = \sigma_0 \exp(-t/\lambda) \\ \lambda = N_0 / lg(\sigma_0) \end{cases} \qquad (5)$$

Where is the initial field radius; $\lambda$ is the time constant?

Fig. 4.    Effect of the coefficient on neuronal spacing.

According to the above formula and analysis, it can be seen that the specific parameters of neurons greatly influence the spacing of neurons, and the different parameters will lead to differences in the calculation methods and theories of the spacing of neurons. To study the influences of two factors on neuron spacing, it drew the variation curves of neuron spacing of the genetic optimization algorithm under two parameters, as shown in Fig. 4. It can be seen from the curves that the variation trend of neurons under two different parameters presents typical nonlinear changes. In contrast, the corresponding neuron curve shows a gradual downward trend. Moreover, it can be seen from the slope that the linear characteristics of neuron data are obvious. Specifically, first of all, it can see through the initial field radius curve rise gradually. The linear decline, when it reaches the minimum spacing of neurons and shows the increasing trend, gradually

declines, then hits the stage when it rises again, showing the typical volatility change trend. As shown in the influence curve of the time constant, the corresponding curve first exhibits a stable change trend as time increases gradually, and then the corresponding curve gradually increases. And when it reaches its highest point, the corresponding curve slowly decelerates. The slope of the corresponding curve also exhibits a gradual increase trend. The overall data feature of the curve with time parameter has the comprehensive effect of linear and nonlinear. Therefore, it must comprehensively consider the impact of the initial domain radius and time constant on neuron spacing.

*5) Solve the neuron update formula*: Through the above analysis and solution, the influence of parameters on the spacing between different neuron data can be obtained, and the corresponding update formula is as follows:

$$w_j^k(t+1)=w_j^k(t)+L(t)\theta(t)(x_j^k(t)-w_j^k(t)) \quad (6)$$

where is the gene value at the position after the update, is the learning speed factor, and is the best Euclidean distance?

*6) Determine whether the termination conditions are met*: The neuron data are compared by setting the termination conditions of the corresponding predictive optimization algorithm.

*7) Update individual data and location information*. The corresponding update formula is as follows:

$$X=w^* + \sum_{k=0}^{m-1} a_j^k U_j^k + N(0,\sigma I) \quad (7)$$

Where represents the best matching unit with the individual; $a_j^k$ is the Euclidean distance between adjacent spirit longitude elements; $U_j^k$ is the unit vector of adjacent neurons; m is the number of targets; $U_j^k$ is a normally distributed noise vector; I am the identity matrix.

For analyzing the impact of various parameters in the update formula on the updated data of the genetic optimization algorithm, relevant data were obtained through iterative calculation. The influence curves of four different parameters on the genetic algorithm were drawn, as shown in Fig. 5. Different parameters exhibit typical variation characteristics, as can be seen in the figure. As can be seen, the updated data for the corresponding parameter a shows a trend of slow increase with the gradual increase of iteration times and time. However, a slight nonlinear variation can be seen on the corresponding fitting curve. As shown by the parameter U, the curve initially declines gradually. When there are more than four iterations, the corresponding appropriate curve initially shows a nonlinear change before fluctuating and exhibiting a sharp downward trend. It can be seen from parameter m that the overall curve remains at about 70, indicating that parameter m has the least influence on genetic algorithm update. Still, it also shows that the parameter has a relatively clear specific value of genetic algorithm update and good corresponding stability. It can be seen from parameter I that the curve shows typical linear characteristics, the corresponding quasi-sum curve has obvious smoothness, and the corresponding data presents a trend of a gentle rise. Through the above analysis, various parameters have different influences on the genetic algorithm, and it is necessary to select specific parameters according to the actual situation to analyze the genetic optimization algorithm to acquire precise outcomes.

*C. Test Function Selection of Genetic Optimization Algorithm*

Since the complexity of optimization problems affects the computational efficiency of swarm intelligence algorithms [18], [19], it is necessary to select four commonly used test functions, and their corresponding forms are shown as follows:

*1) Test function f(x)*: Test function f(x) is an optimised test function with a simple structure consisting of two variables and a constraint condition.

$$f(x)=x_1 + (x_2\text{-}1)^2 \quad (8)$$

*2) Test function g(x)*: This function is a test function of multidimensional single constraint conditions.

$$g(x) = (\sqrt{n})^n \prod_{i=1}^n x_i \quad (9)$$

*3) Test function h(x)*: Test function H (x) is a low-dimensional multi-constraint single-objective optimization problem.

$$h(x) = \frac{\sin^3(2\pi x_1)\sin^2(2\pi x_2)}{x_1^3(x_1+x_2)} \quad (10)$$

*4) Test function k(x)*: This function is a multi-dimensional and multi-constraint complex nonlinear optimization problem, which is representative of verifying the algorithm's feasibility.

$$k(x) = (x_1 - 10)^3 + 5(x_2 - 12)^2 + x_3^4 + 3(x_4 - 10)^2 \quad (11)$$

It can be seen from the above analysis that genetic optimization algorithms contain different test functions, and the other test functions lead to different solving processes and methods for nonlinear problems of genetic algorithms. To analyze the influence of the four tests performs on the performance of the genetic algorithm, the variation curves of the genetic optimization algorithm under different samples were obtained by summarizing the data, as revealed in Fig. 6. Regarding the change curve in the figure, it can be seen that the performance of the corresponding genetic optimization algorithm shows a gradually increasing trend with the gradual growth of the number of samples of the f function. However, when the number of samples is about 65, the corresponding genetic optimization performance data shows a sudden decline because when the number of samples is 65, the corresponding calculation method will further propose the characteristics of this parameter. As a result, the corresponding genetic optimization performance index has declined. From the change rule of g performance, it can be seen that the corresponding bar chart has a constant adjusted trend. And the slope is the same up and down. It shows that the genetic optimization performance of the g function is stable. It can be seen from the change of the h function that the corresponding genetic optimization performance index decreases gradually from the maximum to the minimum, which indicates that the data of the genetic optimization performance corresponding to this function has a large fluctuation, showing a trend of gradual decline. Finally, it can be seen from the change of the k

function that the corresponding data index shows an incremental improvement. When the corresponding data reaches the maximum, it indicates that the data of the genetic optimization algorithm of the corresponding k function shows a gradual increase trend of change.

Fig. 5. Influence of different parameters on genetic algorithm update.

## III. CNN MODEL

A convolutional neural network is a typical structure of artificial neural networks, which has the characteristics of local connection, weight sharing and pooled sampling and has gradually become a representative network for feature extraction in deep learning networks [20], [21].

To further analyze and understand the convolutional neural network's computation process and the structural unit, the convolutional neural network, the structure diagram of the convolutional neural network was drawn by sorting out and analyzing relevant data, as shown in Fig. 7. It can be seen from relevant studies that convolutional neural networks can be divided into five modules according to different research contents and methods; corresponding contents mainly include the convolution layer, pooling layer and full connection layer. In the corresponding computing module of the convolutional neural network, the model data is first imported into the specific computing module. Then the data features are analyzed and processed by further data feature extraction module. The optimised results are output through data optimization and modification analysis, and experimental data further verify the optimized data. Thus, the optimized convolutional neural network calculation results are obtained. The main calculation steps of the convolutional neural network are as follows:

*1) Similarity measurement and analysis*: In the similarity measurement process of the convolutional neural network, the correlation distance formula is widely used in similarity measurement, and the corresponding procedure is shown as follows:

$$d(\text{x,y}) = \left(\sum_{i=1}^{n} \left|x_i \text{-} y_i\right|^p\right)^{1/p} \qquad (12)$$

where x and y respectively represent the vector representation of two image samples, n represents the length of the vector representation, and p is a constant.

The similarity measurement method of the i-th element can be measured as follows:

$$z_i = \frac{1}{h \times w} \sum_{i=1}^{h} \sum_{j=1}^{w} F(\text{i,j}) \qquad (13)$$

where h represents the height of the feature graph, w represents the width of the feature graph, and F represents the channel of the feature graph.

Fig. 7. Structure diagram of convolutional neural network.

*2) Sample generation*: When the directional pin-mixing augmented method is used to analyze the genetic optimization algorithm, the corresponding implementation process is shown as follows:

$$\begin{cases} \text{I}=(1-\text{M}_\lambda) \odot I_m + \text{M}_\lambda \odot I_m \\ \text{y}=\lambda\text{y}_m + (1-\lambda \times y) \end{cases} \qquad (14)$$

where I represent sequence mixing and y represents sequence category label. Describes the specific gravity of data, I'm representing the sequence of training samples, and $y_m$ represents the sequence of category tags. It is the dot product operation.

*3) Training sample evaluation*: In data recognition of convolutional neural network, classification accuracy R is generally used as the evaluation result, and the corresponding formula is shown as follows:

$$R=\frac{I_r}{I} \qquad (15)$$

$I_r$ represents the data quantity of classification, and I represent the data quantity of total evaluation.

To analyze the influence of convolutional neural network with accuracy index, the accuracy change curves under different iterations and accuracy index were drawn through experimental analysis, as shown in Fig. 8. The research shows that the accuracy index and rate are typical two-stage

structures. In the first stage, the corresponding accurate index $I_r$ shows a trend of gradual decline. And its slope remains constant, indicating that the data of the precise index shows a linear change characteristic, while the same accurate total I show a gradually increasing trend with the increase of the number of iterations. This is because the accuracy index increases with the rise of characteristic parameters corresponding to the number of iterations, leading to an increase in calculation results. It can see an obvious trend of gradual decline through the curve of the corresponding accuracy R. This indicates that when the number of iterations is from 0 to 100, the corresponding accuracy rate decreases gradually with the increasing number of iterations. In the second stage of the curve, with the further increase in the number of iterations, the corresponding accurate index shows the same linear change. It belongs to the evolution of linear increase. The total number of corresponding indicators declined rapidly with the rise in iteration times, and the corresponding downward trend showed an obvious linear decline. As can be seen from the accuracy curve, with the increase in the number of iterations, the related accuracy shows a gradually increasing trend. This indicates that when the number of iterations exceeds 100, the accuracy of the connected convolutional neural network gradually improves. Therefore, in the actual use and calculation process, it needs to iterate and calculate the genetic optimization algorithm and convolutional neural network many times so as to obtain more accurate results.

Fig. 8.   Change in accuracy chart.

## IV. APPLICATION OF GENETIC OPTIMIZATION ALGORITHM AND CNN MODEL IN ENGLISH COMPOSITION

### A. The basic Content of English Composition Automatic Grading Teaching Effect Evaluation Method

English composition is very important for English teaching and assessment. Still, there are a series of problems in the practical application of English composition evaluation, mainly including: (1) English composition scoring efficiency is low: In the useful application process, the efficiency of English

composition is low because of the artificial evaluation. (2) The standard of English composition scoring is not unified: There is no unified standard for English composition evaluation, which is greatly influenced by human factors in the actual evaluation process, resulting in the corresponding English composition evaluation results are not unified. (3) Single evaluation method for English compositions: English compositions are analyzed by single evaluation index in the evaluation process, resulting in the corresponding evaluation results are too single.
Fig. 9. English composition automatic scoring index distribution map.

To further analyze the influence of different indicators of automatic English composition scoring on English teaching effect, five various indicators are obtained through statistical analysis, including 1) high-frequency vocabulary, 2) composition format, 3) blackboard writing, 4) grammatical errors and 5) writing content, to analyze further the problems existing in self-scoring of English composition, the distribution chart of the comprehensive scoring index of English composition was obtained by summarizing and analyzing different data, as shown in Fig. 9. Regarding the results in the figure, the proportion of grammatical errors is the highest (30%), the content of writing is 25%, the handwriting on the blackboard is 20%, the composition format is 15%, and the proportion of high-frequency words is the lowest (10%). The original CNN neural network has a high accuracy in evaluating the quality of English teaching, both exceeding 81%. However, the evaluation accuracy of genetic algorithm optimized CNN neural network is better than that of the original CNN neural network The statistical results show that in the test samples, the genetic algorithm optimized CNN neural network model has an evaluation accuracy of more than 90%,. And some of the group evaluations have accuracy greater than 93%, indicating that the model has high approximation accuracy.

To further test the performance of the CNN neural network based on genetic algorithm optimization for English teaching quality evaluation constructed in this article, it is compared with the GA-BPNN evaluation model and the support vector machine (SVM) based evaluation model for performance testing. The simulation data remains unchanged.The experimental results show that the genetic algorithm optimized CNN neural network model constructed in this paper has high evaluation accuracy and operational efficiency This is because there is overfitting in the BP neural network in the GA-BPNN evaluation model, which affects the accuracy of the evaluation. In the SVM evaluation model, there are too many evaluation indicators, which interfere with each other, affecting the accuracy of the evaluation and increasing the computational cost.

## B. Results

The above analysis and research show many problems applying the teaching effect of automatic scoring English composition. According to the related theory of genetic algorithm, a new optimization model is adopted to evaluate and analyze the teaching effect of automatic scoring of English composition based on the genetic optimization algorithm and CNN algorithm to further analyse the indicators related to automatic scoring of English composition. Thus, the flow chart of automatic scoring of English composition under the combined action of the genetic optimization algorithm and CNN model is obtained, as shown in Fig. 10. The specific calculation process is as follows: First of all, the basic calculation parameters of the genetic optimization algorithm and CNN fusion model are also set, and then relevant imported data are extracted specifically to obtain different types of data features. Then the automatic scoring scheme of English composition is analyzed and determined according to the various data characteristics. Then the relevant English data is imported into other genetic optimization algorithm calculation modules on the basis of determining the scheme. It may be divided into three diverse modules, and the contents of each type of module are basically the same, including data import, extraction of corresponding parameters, update of English indicators, discrimination of corresponding standards and output of final results. The data calculated by different modules are imported into the final local termination condition, and the data can be decided whether to continue the iteration or directly output the results through the discrimination of the termination condition.

By adopting the fusion optimization model of the genetic optimization algorithm and CNN model calculation method, the evaluation analysis diagram of the automatic scoring teaching effect of English composition under different indexes was finally obtained, as shown in Fig. 11. It can be seen from the variation trend of other indicators in the figure that the increase in time greatly influences the proportion of indicators. The specific changes are as follows: With the gradual increase of high-frequency words over time, the proportion of the corresponding English composition index displays a slight decline, and the nonlinear characteristics of this trend are obvious. This indicates that the influence of high-frequency words on the evaluation effect of English compositions is relatively simple, and this index cannot be used only to evaluate and analyze English compositions. With the increase of time, the corresponding composition format shows a fluctuating change; that is, it increases slowly at first and then decreases gradually. The writing index on the blackboard shows a relatively stable trend at different times, which indicates that the writing index is less affected by time, indicating that this index is an inherent attribute of English composition, which can be used to evaluate the teaching effect of English composition scoring under the genetic optimization algorithm and CNN model. The variation trend of grammatical errors is basically the same as that of blackboard writing. Still, the corresponding data is less than that of blackboard writing, indicating that grammatical errors' influence on English composition is less than that of blackboard writing. Finally, through the specific content index of the paper, it can be seen that with time, the proportion of English composition as a

whole shows a gradually increasing trend. And the corresponding data are higher than the related data of other indicators in the same period. This indicates that the writing content index influences English writing most among all indicators.

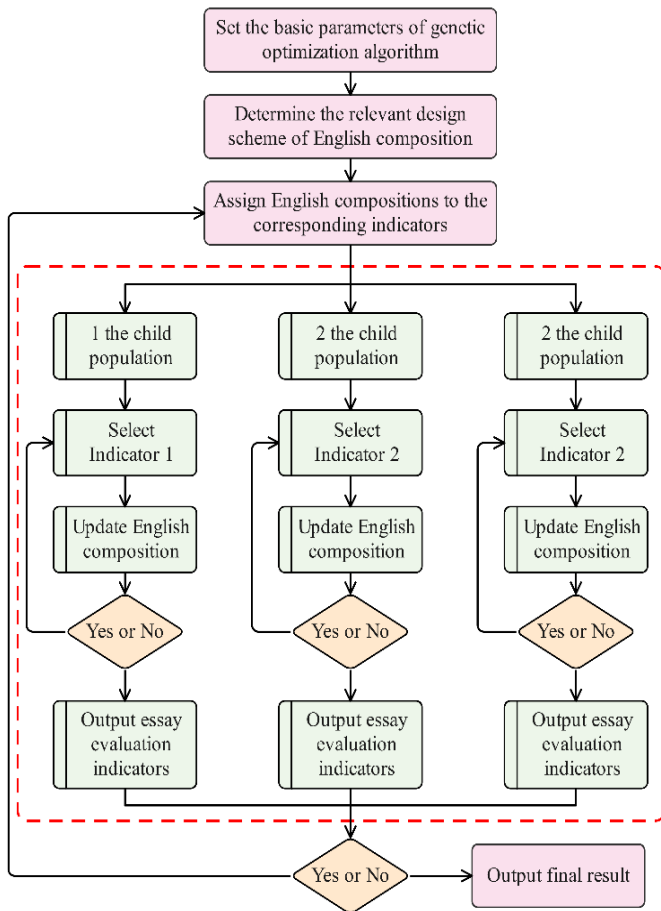
## V. DISCUSSION

Genetic optimization algorithm is an optimization algorithm that mimics natural selection and genetic processes, and can find the optimal solution by iteratively optimizing the objective function. In automatic grading of English compositions, genetic optimization algorithms can be used to optimize grading standards and rules to better meet practical teaching needs and English language characteristics. Convolutional neural networks (CNN), as a deep learning model, are suitable for processing data such as images and text. In the automatic grading of English compositions, the CNN model can be used to automatically correct English compositions, achieving automated grading by learning a large amount of English composition sample data. The combination of genetic optimization algorithm and CNN model can first optimize the grading rules of English compositions using genetic optimization algorithm, and then automatically grade English compositions using CNN model. This combined method can fully leverage the advantages of both and improve the effectiveness and accuracy of automatic grading of English compositions.

Neural networks can be used to learn and predict the QoS of a given service combination. Historical data can be used for training, and then this model can be used to predict the QoS of new service combinations. Genetic algorithms can be used to find service combinations that meet certain QoS requirements. This may involve encoding services (such as using genetic coding), and then finding service combinations that meet QoS requirements under the predictive guidance of neural networks [22]. In QoS aware service composition, multiple service quality indicators need to be considered, such as processing time, throughput, latency, etc. By calculating the skyline, it is possible to find the optimal SFC that meets multiple QoS indicators simultaneously in a set of candidate service node combinations. Genetic algorithm is an optimization algorithm that simulates natural selection and genetic processes, suitable for solving the optimal solution of complex problems. In the process of combining service function chains, genetic algorithms can be used to generate initial solutions and perform selection, crossover, and mutation operations on the solutions to continuously optimize the quality of the solutions [20]. Correlation analysis and research show that the genetic optimization algorithm and CNN model can jointly evaluate the teaching effect of English composition automatic scoring better. In addition, relevant data show that different evaluation indexes impact English writing differently. To further verify the influence of the genetic optimization algorithm and CNN model on evaluation indexes of English writing. The validation and prediction curves of the optimization model are drawn, as shown in Fig. 12.

It is seen from the curve changes in the figure, the data on English composition increases linearly at first and then slowly decreases with the number of steps. Model curve presents that the optimization model can well elaborate and represent the changing trend of English composition indicators, so to investigate the impact of automatic English composition scoring on teaching, use the optimization model.


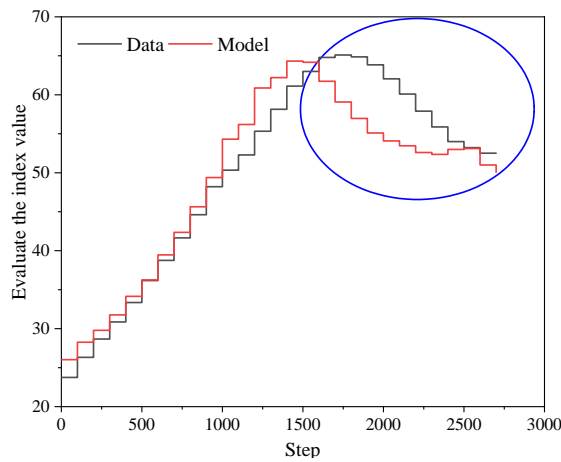


Fig. 12. Model validation and prediction diagrams.

## VI. CONCLUSION

*1)* The real number variation method shows obvious 01 bidirectional variations with the increased iteration number. The corresponding binary variation method displays the linear change of two sections with different slopes. It is worth explaining that the increasing of samples can promote the improvement of test accuracy.

*2)* The neuron data under the genetic algorithm has typical linear variation characteristics, while the neuron spacing curve under the influence of initial domain radius and time constant presents distinct nonlinear characteristics. This indicates that the original model cannot describe the changes in the test data well, and further optimization and analysis of the model are needed.

*3)* As the number of iterations increases, the influence curves of the genetic algorithm under four different parameters are shown as follows: Parameter A increases slowly at first and then presents a relatively gentle nonlinear change; Parameter U decreases gradually and then rapidly; Parameter m stays at about 70 on the whole. The parameter I shows typical linear characteristics.

*4)* The accuracy of the corresponding genetic optimization algorithm can be obtained by calculating the corresponding accuracy index and the accurate total number, and the relevant change curve can be drawn as follows: The curve of accuracy R first showed a significant downward trend and then linearly increased. And the increase in iteration and calculation times can improve the accuracy of calculation results.

However, this article also has certain limitations. The CNN model based on genetic algorithm requires a large amount of computing resources, which will consume significant time during training and usage. Meanwhile, for small image datasets, this may not achieve good performance. This may be difficult to solve specific problems such as accurate positioning of objects in images. The scale and quality of the corpus on which an automatic scoring system relies directly affect the accuracy of the system. Therefore, future research should focus on establishing more complete, standardized, and representative corpora. Expand coverage and classification fineness, improve

the universality and accuracy of the system. Natural language processing can only process textual information, while English automatic scoring includes not only text but also information such as voice and images. Therefore, future research should focus on integrating multimodal information to achieve multimodal automatic scoring systems, improving the comprehensiveness and accuracy of scoring.

*Abstract*—Information blast makes it harder for clients to channel the substance they are keen on. This study aims to combine big data and video semantic comprehension technology to realize the recommendation of sports culture videos by exploring the semantics of video and taking advantage of multi-source heterogeneous information. The semantic structure of unstructured video data is defined first, and on this basis, Converse3D (C3D) - Connectionist Temporal Asifationon (CTC) is employed to complete the extraction of sub-action semantics and the integration of behaviour semantic sequences. In adjustment to break the botheration of low accurateness of the model for the semantic abstraction of unlabeled videos, this study proposes an unsupervised semantic abstraction adjustment based on Converse3D(C3D)-RAE, which completes the compression and affiliation of the semantic sequences and verifies the accurateness of both two models through experiments. In order to solve the problem of insufficient accuracy of video recommendation algorithms based on single video semantic similarity and topic similarity, this study comprehensively considers video semantic similarity and video topic similarity and proposes a multi-modal video recommendation algorithm. The experimental results show that the accuracy of the COMSIM-based algorithm is 7.8% higher than that of Video+ CNN + K-NearestNeighbor (KNN) and 15.9% higher than that of CLIP + CNN +Ncut+LDA.

*Keywords*—*Big data; video semantic comprehension; sports culture; semantic sequences; convolutional neural networks (CNN)*

## I. INTRODUCTION

With the rapid advancement of information technology in recent years, the Internet has brought convenience to people's lives, providing them with a large amount of data and information resources, greatly satisfying people's demand for network information, and moving the Internet industry into the big data era [1], [2]. However, excessive information from multiple sources has also become an obstacle for people to enjoy convenience. Specifically, information in the new era is no longer delivered to users by websites or media in one direction, but more often than not, users and media have formed an effective two-way transmission, which has significantly expanded the existing data stock [3], [4]. In addition, the continuous sinking of the user market has led to the exponential expansion of the user community and the exponential growth of data [5]. However, instead of enjoying convenient services, the huge amount of data and information has plunged people into the vast data mud, a trap known as

"information overload". For Internet users, it is undoubtedly difficult to find the data knowledge they need in the exponentially growing data information, and users usually need to spend a lot of time and effort to find this information, which leads to a very poor user experience [6], [7]. For service providers, it is difficult to fully explore users' interests and preferences due to the large amount and complex types of log information generated by users, so they cannot accurately determine the content of users' needs, which greatly reduces the service quality and may push inaccurate information to users, which destroys users' trust in the system and leads to user churn [8], [9]. Faced with the information overload network environment and multiple sources of heterogeneous data types, how to make users less frustrated when searching for information, how to deepen users' trust in service providers, and how to enable service providers to maximize the benefits of efficiency are hot issues that need to be solved in the current data mining field.

At present, there are two main ways to solve this problem: information retrieval technology and information filtering method [10], [11]. The content presented by search engines for different users is often the same, which cannot meet the personalized needs of each user. The personalized recommendation technology based on information filtering does not require users to give their specific needs [12]. It can mine users' interests and preferences through users' historical behaviour logs and browsing habits to generate relevant recommendations [13], [14]. In today's big data era, personalized recommendation technology can greatly improve the efficiency of processing problems and meet the personalized needs of users. This technology has been successfully applied to many fields and has become a research hotspot in the computer application field.

Digital video data contains abundant spatial and temporal information, but it is difficult to describe the video content because of its huge amount of data and the semantic gap between low-level features and high-level semantics [15], [16]. With the rapid development of deep learning, especially the development of cross-modal learning, people's understanding of video semantics has reached a new level. Therefore, based on the video semantic understanding model, this paper proposes a sports culture video recommendation method that integrates video semantics and video topic text similarity.

This article analyzes the construction technology of sports culture models that combine video semantics. The accuracy of the model was verified through data recommendation of diverse and heterogeneous information. The innovation points include:

*1)* By exploring the semantics of videos and utilizing heterogeneous information from multiple sources, sports culture videos can be recommended.

*2)* This article uses C3D-CTC to extract sub action semantics and integrate behavioral semantic sequences. In order to overcome the problem of low accuracy in unlabeled video semantic abstract models.

*3)* This article addresses the issue of insufficient accuracy in video recommendation algorithms based on single video semantic similarity and topic similarity.

Section I analyzes the background of uncertainty when users search for information in the face of information overload in the network environment and the multi-source nature of heterogeneous data types. How to deepen users' trust in service providers has become a current issue worth studying. Section II analyzes video recommendation algorithms as a popular component of recommendation systems. Considering the issue that topic modeling techniques cannot cluster short texts that ignore semantic relationships between words. Section III recommends methods for sports culture videos that consider multiple modes and analyzed the semantic extraction of sports videos in C3D. Section IV conducted validation analysis on the dataset used, including the UCF-12 dataset and the sports video dataset captured from the video website Vine.com. Section V summarizes the entire text. This study proposes an unsupervised semantic abstraction adjustment method based on C3D-RAE, which completes the compression and membership of semantic sequences, and verifies the accuracy of the two models through experiments.

## II. Related Work

Video recommendation algorithms, as an important component of recommendation systems, have always been a hot research direction. Considering the disadvantage of topic modeling technology not being able to cluster short texts that ignore semantic relationships between words, M S Tajbakhsh et al. [17] proposed a topic modeling method for semantic relationships between words in Twitter social network tweets. Yaduv U et al. [18] proposed a recommendation system method based on linked open data and social network features. This method solves the problem of pure new user cold start by constructing user profiles based on collaborative features of linked public data and features of social networks. Nikolakopoulos et al. [19] proposed the EIGENREC recommendation model based on the existing PureSVD algorithm, which comprehensively utilizes multiple recommendation strategies. The created model can modify recommendation results in real-time based on the popularity of the project. Salah et al. proposed a weighted clustering method to address the issue of data sparsity in dynamic incremental collaborative filtering. The experimental results showed that the constructed model has fast computational speed and low computational cost [20]; Hewitt et al. classified eight types of

emotions and proposed three improved convolutional neural networks to implement a music recommendation interface based on predicting user influence [21]. In order to solve the cold start problem caused by the lack of correlation score when adding new videos, Li Y et al. [22] proposed directly calculating video correlation from the content. And use deep convolutional neural networks to process video information, thereby constructing a video correlation table. Li X et al. [23] proposed a multi-directional pyramid common attention module for learning the attention values of two modalities in different dimensional spaces. Fan C et al. [24] viewed the semantic information of videos as a series of ordered events that occur in sequence as a whole and are continuously read and written to memory. The input sequence can be understood from a global perspective to prevent local capture due to information interference.

In summary, the current research model cannot perform sparsity analysis on dynamic incremental collaborative data. This indicates that there are certain shortcomings in the video correlation of emotional users. For a long time, users have been plagued by low accuracy of unlabeled video semantic abstract models. On this basis, this article optimizes multi-source heterogeneous information. Using C3D-CTC to extract sub action semantics and integrate behavioral semantic sequences. It breaks the problem of low accuracy in unlabeled video semantic abstract models.

## III. Sports Culture Video Recommendation Method Considering Multi-Modality

### A. Semantic Extraction for Sports Videos based on C3D

*1) Video behaviour semantic extraction based on supervised learning*: Since video data is unstructured data, in order to analyze and process video more accurately, video data must be structured, which is the basis of video feature extraction and semantic extraction. Video is a continuous frame sequence with no obvious segmentation point. It isn't easy to extract the semantics of the entire video directly. Therefore, it is necessary to divide the video into multiple segments and extract the semantics of the segments respectively. Video can be divided into the following levels according to its physical level: video, scene sequence, shot sequence and frame sequence, as shown in Fig. 1.

Fig. 1. Hierarchical structure of video.

Scene: A group of shots expressing the same theme. These shots record an event at the same time and place from different angles in space. Together, they describe the semantic concepts related to this event. For example, the scene of "air relay" can be composed of multiple shots such as "player passing", "another player is catching the ball in the air", "player shooting", or "player dunking", "ball in", etc. Shots: a recording process of a camera. Shots are the logical component unit of video and are also the smallest unit that can be used in indexing video. As the physical unit of video, a frame is defined as the frame is the smallest unit of video image - a single picture.

According to the physical hierarchy of video, this study defines the semantic structure of video as shown in Fig. 2.

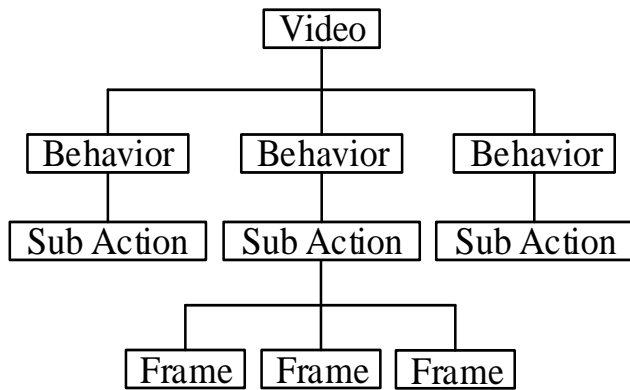

Fig. 2. Semantic structure of video.

Convolutional Neural Networks (CNN) have been extensively used in computer vision-related research in recent years, whose structure mainly includes a convolution layer, pooling layer and full connection layer. In image processing, CNN generally adopts the "planar convolution" with the dimension of convolution kernel of 2. However, when analyzing video, 2D convolution has a poor ability to capture timing information, leading to the loss of video timing information.

Therefore, 3D Convolutional Neural Network (C3D) with a convolution kernel dimension of three is adopted in this study, which can capture features in both temporal and spatial dimensions. The concrete implementation of 3D convolution operation is as follows: a three dimensions frame cube is obtained by stacking several consecutive frames, and the cube is convolved with the 3D convolution kernel, as shown in Fig. 3, where the connection of the same colour represents the shared weight, that is, there are weight values of three dimensions. Through such a convolution operation, the feature map obtained by convolution is connected with several consecutive frames of the previous layer to capture the timing information. D. Tran et al. [25] found that the same convolution kernel structure of 3*3*3 has the best accuracy on C3D. Therefore, the same convolution kernel of 3 * 3 * 3 is employed in this study.

Fig. 3. 3D convolution.

Due to the large amount of redundant information between video frames and sub-actions, as well as the repetition of video frames in the time dimension, the extraction of video semantics will be affected. Therefore, this study puts to use the connectionist temporal classification (CTC) to solve the above problems. CTC algorithm was first applied in the acoustic training model, which is a complete end-to-end training without strict alignment of data in advance. For example, to understand intra coding, most areas of the image have the same color. False i will encode the red area, assuming that the colors in the frame remain consistent in the vertical direction. This means that the color of the unknown pixel is the same as that of adjacent pixels. Although this prior prediction technique (intra frame prediction) is used, the actual value is subtracted to calculate the residual. The residual matrix obtained in this way is easier to compress than the original data [26]. Yang improved the recognition algorithm by analyzing graph regularization and constructing a model, and compared and analyzed feature extraction methods. Meanwhile, the experiment aims to investigate the improvement of the improved recognition algorithm on English semantic translation after feature extraction [27]. Traditional content-based video retrieval algorithms typically only utilize the underlying features of video images, resulting in insufficient content description and unsatisfactory retrieval results. Guo studied how to combine the underlying features of videos with semantic features, improved the existing indexing structure, and designed an efficient sports video retrieval algorithm [28].

C3D is applied to model the sub-action features first, and different kinds of probability distributions of each sub-action are obtained. $x$ represents the sub-action sequence, and $y$ represents the output sequence of C3D.

The output of the C3N model is the probability of the category corresponding to each sub-action, which is a vector of N+1-dimensional probabilities, representing the different probabilities of N+ 1 category, N represents the number of sub-action categories, and 1 represents blank. We employ $N_w$ to represent the convolutional neural network, and then the network output can be expressed as:

$$y = N_w(x) \quad (1)$$

For any sub-action input sequence of length $T$, whose corresponding label sequence is $z$, we can obtain that the

occurrence probability of label sequence $z$ is the product of label probabilities at each moment.

$$P(\pi|x) = \prod_{t=1}^{T} P(\pi_t|x) \quad (2)$$

Where $\pi$ denotes the decoding path and $\pi_t$ represents the $t$-th sub-action label in the decoding path.

The probability of decoding path $\pi$ can be calculated from the output of the C3D model as follows:

$$P(\pi|x) = \prod_{t=1}^{T} y_{\pi_t}^t \quad (3)$$

where, $y_{\pi_t}^t$ denotes the probability that the $t$-th sub-action label is $\pi_t$.

Define a many-to-one mapping B to remove all blank symbols and merge duplicate labels, transforming the decoding path $\pi$ into label $l$. For example, (-,A,-,-,E,-) and (-,A,-,E,-,-) are both mapped to label (A,E). B$^{-1}$ represents the inverse process of mapping B, which is a one-to-many mapping, that is, mapping label (A, E) into a sequence of labels with duplicate labels and blank symbols for all possible decoding paths so that the final decoding path $\pi$ is the sum of the probability of each sequence with the probability of the label sequence given the input sequence $x$.

$$P(l|x) = \prod_{t=1}^{T} P(\pi|x), \pi \in B^{-1}(l) \quad (4)$$

Given an input sequence $x$ and the corresponding label $l$, the loss function of the C3D-CTC model adopts the maximum likelihood error, that is, to minimize the negative logarithm of the probability:

$$\text{C3D-CTC}(x) = -\log P(l|x) \quad (5)$$

In Eq. (4), the calculation of the objective function requires an exhaustive enumeration of all decoding paths, which is very difficult. In fact, only a small part of all paths are effective. Therefore, this study adopts the Forward-Backward Algorithm (FBA), a kind of dynamic programming algorithm, to calculate the objective function of the model.

For a given label $l$ of length T, in order to find all paths $\pi$ satisfying $l = B(\pi)$, we need to construct an extended label $l'$, whose length is 2T+1 by adding a blank at the beginning, end and middle of each character. For example, the sequence (A, E), whose extension label L 'is (-,A,-,E,-). The legal decoding path must meet the following conditions: (1) The path conversion can only be right or down; (2) There must be a

For the part without connection in the upper right corner, it represents the node that cannot be reached by the legal decoding path, so we can add restrictions and set the probability of these paths to 0.

$$\begin{cases} \alpha_t(s) = 0, \forall s < 1 \\ \alpha_t(s) = 0, \forall s < |l'| - 2(T - t) - 1 \end{cases} \quad (9)$$

Therefore, the loss function of the C3D-CTC model can be expressed as follows:

$$-\ln(P(l|x)) = -[\ln(\alpha_T(2T+1) + \alpha_T(2T))] \quad (10)$$

blank between the same characters; (3) Only blank symbols can be skipped; (4) The path must start with the first two symbols; (5) The path must end with the last two symbols. The conversion process of all decoding paths of label $l$ is shown in Fig. 4.

Fig. 4. All decoding paths of the label 'AE'.

To calculate the sum of the probabilities of all the above decoding paths, define the forward probability $\alpha_t(s)$ to denote the sum of the forward probabilities of all paths at the $t$-th input with $s$ as the endpoint:

$$\alpha_t(s) = \sum_{B(\pi_{1:t})=l_{1:s}} \prod_{t'=1}^{t} y_{\pi_{t'}}^{t'} \quad (6)$$

Where $s$ denotes the number of rows, the initial state of the forward probability $\alpha_t(s)$ can be calculated as follows:

$$\begin{cases} \alpha_1(1) = y_{blank}^1 \\ \alpha_1(2) = y_{l_1}^1 \\ \alpha_1(s) = 0, \forall s > 2 \end{cases} \quad (7)$$

The decoding path shows that: (1) there are only two possibilities from blank, either blank or $l_i$, i.e., the $i$-th element of label $l$; (2) there are threecases from $l_i$, that is, $l_i$, blank and $l_i$+1, with 3 possible output cases; (3) the input case of the blank is two and the input case of $l_i$ is 3. We can obtain $\alpha_t(s)$ with the following iterative formula.

$$\alpha_t(s) = \begin{cases} (\alpha_{t-1}(s) + \alpha_{t-1}(s-1))y_{l_s}^t, & \text{if } l_s = blank \text{ or } l_{s-2} = l_s \\ (\alpha_{t-1}(s) + \alpha_{t-1}(s-1) + \alpha_{t-2}(s-1))y_{l_s}^t, & \text{otherwise} \end{cases} \quad (8)$$

The video behaviour semantic extraction model based on C3D-CTC is shown in Fig. 5.

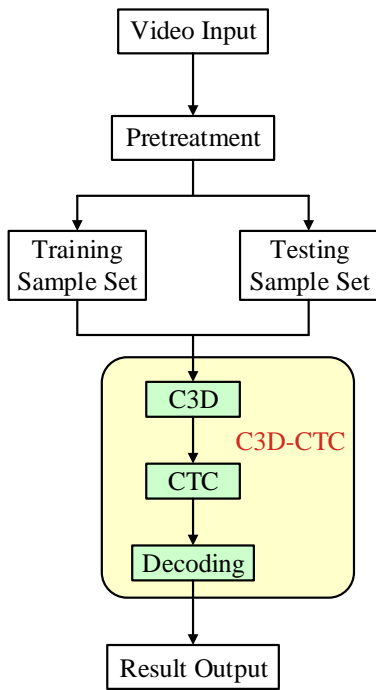
*2) Video latent semantic extraction Based on unsupervised learning*: For some videos with blurred boundaries between actions, the C3D-CTC model is difficult to get accurate labels by action decomposition, and its scalability for new types of videos is poor. In order to solve the above problems, this study proposes a Recursive Auto-Encoder (RAE) based video latent semantic extraction method.


Fig. 5. C3D-CTC model.

RAE is an auto-encoder that searches for variable-length input structures, which is put to use in both NLP and computer vision. When the input is a sequence of word vectors, RAE uses neural networks to sense the score of all two adjacent word vectors. By measuring the probability of synthesizing a word for each pair of word vectors, the one with the largest probability is selected as the representative of the two-word vectors, the vector of the two words is removed from the sequence, and the synthesized vector is inserted into the position of the previous two words in the sequence. This is done recursively until the entire input statement is mapped to a vector at the root of the binary tree.

The input word vector sequence is $(x_1, x_2, x_3, x_4, x_5)$, then the encoding process of word vector pair $(x_1, x_2)$ transforming to parent node $y_1$ is defined as:

$$y_1 = f(W^{(1)}[x_1, x_2] + b^{(1)}) \quad (11)$$

where, $W^{(1)}$ represents the $n*n$ matrix parameters and $b^{(1)}$ is a bias term.

The decoding process of the parent node $y_1$ reconstructing $x_1$ and $x_2$ can be presented as follows:

$$[x_1', x_2'] = W^{(2)} y_1 + b^{(2)} \quad (12)$$

The reconfiguration error of the auto-encoder is as follows:

$$E_{rec}([x_1, x_2]) = \frac{1}{2} \| [x_1, x_2] - [x_1', x_2'] \|^2 \quad (13)$$

Define A($x$) as all adjacent node pairs of the input sequence $x$, and define T($y$) as the case where the binary child node is transformed into the parent node. We define the objective function of the recursive auto-encoder as:

$$VE(x) = \underset{y \in A(x)}{argmin} \sum_{s \in T(y)} E_{rec}([x_1, x_2]_s) \quad (14)$$

When generating weights, in order to avoid weight skew, the reconstruction errors generated each time should be normalized.

$$E_{rec} = \frac{n_1}{n_1 + n_2} \| x_1 - x_1' \|^2$$

$$+ \frac{n_2}{n_1 + n_2} \| x_2 - x_2' \|^2 \quad (15)$$

The binary tree recursive structure of the RAE is shown in Fig. 6.

Fig. 6. Binary tree recursive structure of the RAE.

The input feature sequence is paired by $(x_0, x_1),(x_1, x_2),...,$ $(x_{n-1}, x_n)$, calculate the reconstruction error of all the paired nodes, select the pair with the smallest error value to generate the parent node into the input sequence, then remove the pair from the input sequence, and repeat the above steps until only one node remains in the input sequence. At this point, this node is the potential semantic feature of the input sequence.

The video latent semantic extraction model encodes the output of the fully-connected layer of 3D-CNN by unsupervised RAE to obtain video latent semantic features, and its specific model structure is shown in Fig. 7.

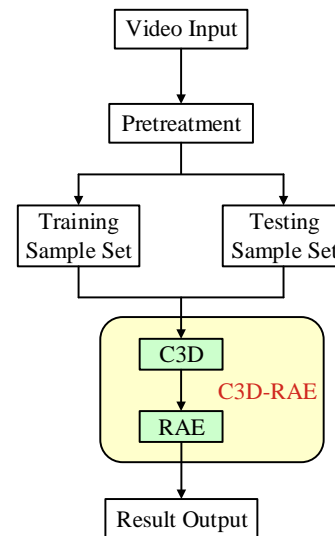

Fig. 7. C3D-RAE model.

## B. Sports Culture Recommendation Model

*1) Video recommendation based on text topic similarity*: This research adopts the Latent Dirichlet Allocation (LDA) topic model to accomplish the topic extraction of video description information. The goal of the LDA topic model is to find the distribution of topics in each document and the distribution of words in each topic. How to calculate similarity specifically? This article calculates the similarity between two videos based on the metadata information of the videos. Simultaneously, using similarity ranking from high to low, obtain the most similar topN of a certain video as an association or similarity recommendation. Although both long and short videos use the same algorithm system, the front-end product form varies due to different video types. Due to the short duration of a single short video, it usually takes a few minutes to play. Therefore, the recommended method for associating short videos is to use information flow to play the original video. The videos associated with it will be played as information streams, which will greatly improve the overall user experience. When training the LDA topic model, the number of topics $K$ needs to be given first, and all distributions are expanded based on $K$ topics. The specific LDA topic model algorithm is shown in Fig. 8.

Fig. 8. LDA algorithm.

LDA assumes that the prior distribution of document topics is Dirichlet distribution; that is, for each document $d$, its topic distribution $\theta_d$ is:

$$\theta_d = Dirichlet(\alpha) \qquad (16)$$

Where $\alpha$ is a hyperparameter in the distribution and is a $k$-dimensional vector. LDA has a premise that the prior distribution of the words in the topic satisfies the Dirichlet distribution; that is, for each topic $k$, the distribution $\beta_k$ of its words is:

$$\theta_k = Dirichlet(\eta) \qquad (17)$$

Wherein, $\eta$ is a hyperparameter in the distribution and is a $v$-dimensional vector. v here stands for the number of words in the total vocabulary. For the $n$-th word in each document $d$, we can obtain the distribution of its topic number $z_{dn}$ from the topic distribution $\theta_d$ as follows:

$$z_{dn} = multi(\theta_d) \qquad (18)$$

And for that topic number zdn, the probability distribution of the word wdn is obtained as:

$$w_{dn} = multi(\beta_{z_{dn}}) \qquad (19)$$

In the LDA model, there are $M$ Dirichlet distributions of document topics, and the corresponding data have $M$ multinomial distributions of topic numbers, so $(\alpha \rightarrow \theta_d \rightarrow z_d)$ forms Dirichlet-multi conjugate. The posterior distribution of document topics based on Dirichlet distribution can be obtained by the Bayesian inference method. Defined in the $d$-th document, the total number of the $k$-th subject word is $n_d^{(K)}$, then the corresponding multinomial distribution can be expressed as follows:

$$n_d = (n_d^{(1)}, n_d^{(2)}, \ldots, n_d^{(K)}) \qquad (20)$$

By using the Dirichlet-multi conjugate, the posterior distribution of $\beta_k$ is obtained as follows:

$$Dirichlet(\beta_k | \eta + n_k) \qquad (21)$$

The specific process of the recommendation algorithm based on LDA topic model is as follows: (1) select the initial topic number $K$ value, train the LDA model, and calculate the similarity between each topic in the trained LDA model; (2) increase or decrease the value of $K$ according to whether the topic similarity decreases, retrain the LDA model, and calculate the similarity between the topics again; (3) repeat the second step until the optimal $K$ value is obtained when the similarity between topic is minimized.

*2) Sports culture video recommendation considering multi-modal characteristics*: In order to make full use of the multi-source heterogeneous information of videos, this study proposes a video recommendation algorithm considering multi-modal characteristics (RAMM) to improve the accuracy of video recommendations. The RAMM recommendation algorithm is a fusion of three different algorithms which are applied to different problems. When the video belongs to a labelled video, the recommendation based on C3D-CTC is employed. When the video belongs to an unlabelled video, the recommendation based on C3D-RAE is employed, and when the video has description information, the recommendation based on LDA is employed. The specific structure is shown in Fig. 9.

Fig. 9. Recommendation considering multi-modal characteristics.

This study constructs a comprehensive method for calculating video similarity considering the multi-modal characteristics ComSim.

$$Comsim(x, y) = \beta \cdot SimSemantic(x, y)$$

$$+(1 - \beta) \cdot SimTopic(x, y) \qquad (22)$$

Where $\beta$ is a hyperparameter, *SimSemantic* represents semantic similarity, and *SimTopic* represents text similarity. The larger $\beta$ is, the higher the model's bias towards semantics and, conversely, the higher the bias towards topic information.

## IV. EMPIRICAL ANALYSIS

The datasets employed in this study contain the UCF-12 dataset and sports video set crawled from the video website Vine.co. The UCF-12 dataset is a specific set of 12 categories of videos excerpted from the UCF-101 video set, mainly including basketball shooting, basketball dunking, bowling, high jump, soccer free throw, cycling, skiing, volleyball dunking, table tennis hitting, pole vaulting, fencing, and rope skipping. Each of these categories consists of 25 groups, each group containing four to seven videos, with the shortest video lasting three seconds and the longest video lasting eight seconds, for a total of 1760 videos. The videos in this dataset have better stability and high similarity of actions in each category, with fewer interfering factors unrelated to the videos. The Vine dataset is crawled from the video website Vine.co sports category videos, consisting of a total of 2400 videos, and because this video set is directly crawled from the website and has not been processed manually, its content similarity is lower than the UCF-12 dataset. The videos contain some interfering factors that are not related to the video content.

Before training the model, the video data needs to be reprocessed. First, all test videos are converted into image sets at 20 frames per second, and for videos whose number of images does not meet a multiple of eight, the last frame is copied and added at the end. Then, to prevent spatial jitter, we scale the images to a uniform size of 112*112. We divide the dataset into a training dataset and a test dataset in a ratio of 9:1 for completing model training and model testing. The topic text similarity and potential semantic similarity of different videos are calculated by the cosine theorem, and the behavioural semantic similarity (*SimBs*) of different videos is defined as follows:

$$SimBs(m, n) = \begin{cases} ecp(m, n), |m| = |n| \\ ncp(m, n), |m| \neq |n| \end{cases} \qquad (23)$$

When the lengths of semantic sequences *m* and *n* are equal, the value is the ratio of the total number of semantic equivalents to the length of *m*. When the lengths of semantic sequences *m* and *n* are unequal, the value is the ratio of the length of the common maximum continuous subsequence of *m* and *n* to min (*m*, *n*).

### A. Training Parameter Selection

Parameter tuning is crucial to the final performance of the model, and appropriate parameter selection can effectively improve the generalization ability of the model. In order to measure the impact of various parameter changes, this study adopts the control variable method to select the learning rate and batch size of the model. The results are shown in Fig. 10 and Fig. 11.

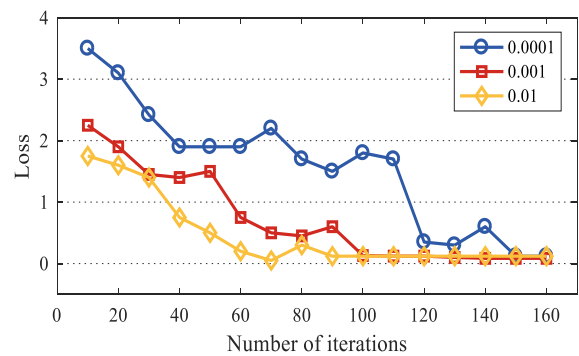

Fig. 10. The impact of learning rate on the Loss function.

Fig. 11. The impact of batch size on model.

As it can be seen from Fig. 11, when the learning rate is 0.01 and 0.001, the model loss decreases rapidly for a period with the increase of training times and then gradually becomes stable at last. For the learning rate of 0.0001, when the number of training iterations reaches 160, the model is still in a state of oscillation and cannot converge, and the loss value is higher than the other two learning rates. When the learning rate is 0.01, the model reaches the convergence point at the fastest speed, and the loss value is lower than that of 0.0001 but higher than that of 0.001. That is, if the learning rate is too low, the trained model will be more reliable, but it will take longer for the model to reach the convergence point, and it still cannot converge on the basis of the same training time. If the learning rate is too high, the model will reach the convergence point very early. The learning rate is chosen as 0.001 for the model through the experiment of learning rate in this section.

It can be seen from Fig 12 that under the same model and the same data set, different values of Batchsize have an impact on the test accuracy of the model. It can be observed that the larger the value of Batchsize is, the less iteration will be required to process the same amount of data, and the less convergence time will be lost, but the accuracy will also be reduced. Through selection, the batch size value selected in this study is 10.

### B. Impact of Different Algorithms on the Accuracy of Video Semantic Comprehension

Different algorithms lead to different accuracy of video semantic comprehension of the model, and this study compares the accuracy of the model behavioural semantic comprehension model and latent semantic comprehension model when adopting different algorithms, and the results are shown in Fig. 12 and Fig. 13 respectively.

Fig. 12. Semantic comprehension accuracy of different algorithms.

Fig. 13. Cosine similarity of different algorithms.

In Fig. 13, the horizontal coordinates indicate basketball shooting, basketball dunking, bowling, high jump, riding, soccer free throw, skiing, volleyball dunking, table tennis hitting, pole vaulting, fencing, and rope skipping, respectively. It can be seen that the accuracy of the C3D-CTC model is higher than the other algorithms except for the sport of riding, which is due to the fact that the result sequence of riding has a boosting behaviour, which affects the accuracy of C3D-CTC. By analyzing the test results, we found that the categories with no significant differentiation between sub movements achieved higher accuracy on the models in this section than those with significant differentiation between sub movements.

As it can be seen from Fig. 14, the box plot should start from the statistical points, and it can be seen that the C3D-RAE clustering accuracy used in this article is 0.57, while the statistical position of KF-CNN is 0.35. Therefore, C3D-RAE has a clustering accuracy of 22% higher than KF-CNN. Therefore, under unsupervised conditions, C3D-RAE has higher clustering accuracy than keyframe image semantic extraction algorithms and measured through average cosine similarity. Compared with the KF-CNN algorithm using video key frame image semantics, the C3D-RAE model has a larger average similarity between each data type and the center point in the clustering results, and the distribution of the clustering results is more uniform.

### C. Sports Culture Video Recommendation Considering Multi-Modal Characteristics

Normalized Discounted Cumulative Gain (NDCG@N) is used as an evaluation indicator for sorting results to evaluate the accuracy of sorting. Firstly, to calculate NDCG, we need to calculate Gain, which is the definition of the quality of each result. NDCG adds all the results together to ensure that the higher the overall quality of the list, the larger the NDCG value. At the same time, the design of discounted results in higher weights for higher results. This ensures that the first, more relevant results ranked higher will have a larger NDCG value. From these two points of view, with NDCG as the optimization objective, it ensures that the search engine ranks higher quality results even though the overall quality of the returned results is good. Information retrieval metrics（MAP@N）actually' MAP@N The indicator is to measure the UUUU of all users AP@N Average the indicators. Overall, the MAP indicator takes into account both prediction accuracy and relative order, thus avoiding the disadvantage of traditional Precision indicators being unable to depict the relative position differences of recommended products. In the sports culture video recommendation model considering multi-modal characteristics proposed in this study, the top-$T$ videos with the highest similarity are returned as the recommendation results. To select the appropriate $\beta$, this study adopts the variable control method to compare the values of NDCG and MAP under different $T$ and $\beta$ values, and the experimental results are shown in Fig. 14.
Fig. 14. NDCG@N and MAP@N under different $T$ and $\beta$ values.

When $\beta$ is 0, the algorithm similarity calculation value only depends on the topic similarity, so the algorithm accuracy is the lowest. With the gradual increase of $\beta$, the recommendation algorithm accuracy gradually rises, indicating that the influence of semantic similarity on the algorithm accuracy is greater than the influence of topic similarity on the algorithm. When $\beta$ is 0.7, and $T$ is 10 and 15, the algorithm accuracy reaches the peak, and when $\beta$ is 0.7, and $T$ is 20, the accuracy of the algorithm increases only slightly as the value of $\beta$ continues to increase, so the hyperparameter $\beta$ is selected as 0.7. At the same time, it can also be seen that the integrated model considering multi-modal characteristics is more accurate than the video recommendation by only the video semantic model or only the text topic model.

The results of the comprehensive model considering multi-modal characteristics and the recommendation system using other models are shown in Fig. 15.

Fig. 15. Comparison of different recommended methods.

The horizontal coordinates from left to right represent Video+CNN+KNN, Clip+CNN+Ncut+LDA and the ComSim algorithm proposed in this paper. Video+CNN+KNN adopts a 3D convolutional neural network to extract the features of all frames of the video and uses the output of the fully connected layer as the video feature representative, then uses the KNN algorithm to find the nearest $K$ neighbours to generate the recommendation list; Clip+CNN+Ncut+LDA adopts 3D convolutional neural network to extract the features of 16 randomly selected frames and adopts NormalizedCut clustering algorithm to generate clustering points, followed by Linear Discriminant Analysis to detect the top-$T$ returned values. It can be seen the accuracy of ComSim is 7.8% higher than Clip+CNN+Ncut+LDA and 15.9% higher than Video+CNN+KNN.

## V. CONCLUSION

After years of development, recommendation systems have made a number of research results in theoretical research and have been widely applied in industry. A well-performing recommendation system can accurately recommend the content that users are interested into users, avoiding a lot of time spent on searching and greatly improving the service experience of users, as well as maximizing the attraction and retention of users, improving the conversion rate of users, and helping the platform achieve profitability.

This study first defines the semantic structure of unstructured video data. On top of that, a 3D convolutional neural network and continuous temporal classification algorithm are used to complete the extraction of sub action semantics and integration of behaviour semantic sequences, and finally, a sports video semantic extraction model for specific sports categories is obtained. In order to solve the problem of the low accuracy of the model for semantic extraction of unlabeled videos, this paper proposes an unsupervised semantic extraction method based on a recursive self-encoder, which uses a recursive self-encoder to construct a semantic spanning tree to complete the compression and integration of semantic sequences and verifies the accuracy of the above two models through experiments. In order to improve the accuracy of the video recommendation algorithm based on single video semantic similarity and topic similarity of this paper, this study integrates video semantic similarity and video topic similarity. It proposes a video recommendation algorithm considering multi-modal characteristics. And it is experimentally demonstrated that the ComSim-based algorithm improves by 7.8% in accuracy over Video+CNN+KNN and 15.9% over Clip+CNN+Ncut+LDA.

However, this article has certain limitations. With the continuous growth of computing resources and dataset size, unsupervised semantics based on C3D-RAE have dominated many tasks. However, the continuous increase in unsupervised semantic depth has also introduced training challenges. Traditional supervised training methods only use supervision in the last layer, allowing errors to propagate from the last layer to the hidden layer, leading to intermediate layer optimization problems such as gradient vanishing. In the future, it is necessary to increase the amount of data, improve the robustness of the model, and avoid overfitting. At present, data augmentation is mainly applied to image data, and there are no good methods for other types of data such as text.

# Immersive Virtual Reality: A New Dimension in Physiotherapy

Siok Yee Tan, Meng Chun Lam, Joshua Faburada, Monirul Islam Pavel
Center for Artificial Intelligence and Technology, The National University of Malaysia, UKM, Selangor, Malaysia

*Abstract*—**Physiotherapy treatments often necessitate patients to perform exercises at home as part of their rehabilitation regimen. However, outside the clinic, patients are often left with inadequate guidance, typically provided in the form of static images or sketches on paper. The ongoing COVID-19 pandemic has further disrupted the ability for patients and physiotherapists to engage in face-to-face sessions, leading to suboptimal compliance and concerns about the accuracy of exercise performance. In recent years, there has been a growing body of scientific literature on the application of virtual reality (VR) in physiotherapy. This emerging trend highlights the potential of VR technology to enhance the guidance and effectiveness of physiotherapy regimens. This research paper aims to investigate the impact of VR-based physiotherapy on the guidance and completion of prescribed exercises. To address the limitations faced by patients unable to access in-person physiotherapy due to the pandemic or geographical constraints, we propose the FisioVR application, specifically designed for Android devices. What sets FisioVR apart is its intrinsic guidance and support from physiotherapy experts. To evaluate the effectiveness of FisioVR, we conducted tests with eight respondents who provided valuable feedback via an online form. The results clearly demonstrate that each physiotherapy session carried out using FisioVR has a positive impact and is conducive to achieving the intended therapeutic objectives, effectively promoting recovery. In summary, FisioVR has the potential to bridge the gap between patients and care providers, facilitating home-based and individualized physiotherapy. This innovative application leverages the power of virtual reality to offer a more accessible, guided, and personalized approach to physiotherapy, especially crucial during times when in-person sessions are challenging.**

*Keywords—Android; COVID-19; physiotherapy; virtual reality*

## I. INTRODUCTION

The COVID-19 pandemic has significantly disrupted traditional healthcare practices, including physiotherapy, which often requires patients to perform prescribed exercises at home. In the absence of face-to-face guidance from physiotherapists, patients are left with limited resources, such as static photographs or sketches, to assist them in correctly completing their exercises [1].

In response to these challenges, the field of virtual reality (VR) rehabilitation has gained momentum in recent years [1]. Scientific reports and research studies, published in reputable journals, have highlighted the potential of VR in enhancing physiotherapy guidance and improving patient outcomes [1]. The integration of VR technology into physiotherapy offers a promising solution to address the constraints imposed by the pandemic, as well as the geographical barriers that prevent individuals from accessing physiotherapy facilities [4].

This paper aims to investigate the impact of VR-based physiotherapy on the guidance provided to patients for completing their prescribed exercises. It introduces the "FisioVR" application, designed for Android platforms, as an innovative solution to the current challenges faced by patients seeking physiotherapy [2]. FisioVR is developed in collaboration with physiotherapy experts, ensuring that it aligns with established rehabilitation principles and practices [2].

To assess the effectiveness of FisioVR, eight respondents participated in testing and provided valuable feedback through an online form [3]. The results of this study indicate that each physiotherapy session conducted using FisioVR positively impacts patients and demonstrates a tendency to achieve the intended therapeutic objectives effectively [3]. Thus, FisioVR has the potential to offer patients and care providers an opportunity to engage in home-based and personalized physiotherapy, overcoming the limitations imposed by the pandemic and geographical distance [3].

In this rapidly evolving landscape of healthcare technology, this research paper contributes to the growing body of evidence supporting the utilization of VR in physiotherapy, highlighting the potential benefits it offers in guiding patients through their rehabilitation exercises. Through this investigation, we aim to provide a comprehensive understanding of the role of VR in modern physiotherapy and its implications for improving patient care and outcomes [4].

The remainder of this study is structured as follows: Section II presents related works. Section III deals with the propose application. The experimental results are described in Section IV. Section V presents the testing and evaluation. Lastly, in Section VI, the study concludes by summarizing the key findings and future works.

## II. RELATED WORKS

Numerous research studies have suggested that different therapy approaches are evolving to meet market demands. One of these innovations is Mirror Therapy VR, as highlighted in study [8]. This therapy leverages feedback tools to enable users to immerse themselves in therapeutic exercises. The exercises featured in this application are straightforward and involve repetitive hand movements. The primary goal of these exercises is to enhance motor skills while reducing sensory and perceptual issues.

The user's experience involves being presented with a camera screen that mirrors both the left and right hands, as depicted in Fig. 1. This setup allows users to concentrate their efforts on a single limb, potentially enhancing the effectiveness of the therapy process. However, it's worth noting that this function may induce a sense of dizziness, as the movement of the left and right eyes is not synchronized, which can disrupt the user's focus. Additionally, this exercise typically requires guidance from a specialist who can provide oral instructions throughout the therapy session.

Fig. 1. Screenshot of mirror physiotherapy VR application.

Enhancements to this application could be achieved by introducing a 3D animation feature. This 3D animation would serve as a visual aid, effectively illustrating the instructions provided by the instructor. It would play a crucial role in guiding users step by step through the therapy regimen. Moreover, the 3D animation component could offer valuable support and motivation through verbal encouragement, thereby ensuring users' successful completion of the therapy. The advantages, disadvantages, and improvement suggestion for the Mirror Therapy VR application have been thoughtfully consolidated in Table I.

TABLE I. SUMMARIZE OF MIRROR PHYSIOTHERAPY VR APPLICATION

| Mirror Physiotherapy VR Application | | |
|---|---|---|
| *Advantages* | *Disadvantages* | *Improvement Suggestion* |
| Both left and right camera views are synchronized to help increase focus | Only one camera but separate into two lens view which users will lose focus and feel dizzy | Focus on only a single hand when doing the therapy |
| Only have two simple option in the main menu | Requires attention and guidance from a specialist when using the application | Develop an animation to guide the users while doing the therapy |
| | Paid application (USD 0.99) | Provide a free version of the application |

The Computer Assisted Rehabilitation Environment (CAREN) system has garnered a notably positive response from patients, as mentioned in study [5]. The core of CAREN lies in its incorporation of gaming elements. This sophisticated multi-sensory VR system was specifically developed to address human locomotion, encompassing aspects such as posture and motor control integration [6]. However, it's essential to note that this system's magnitude necessitates specialized personnel for operation.

Moreover, the CAREN system fosters cognitive skills by requiring users to make decisions and solve problems, depending on their chosen therapy level, as evident in Fig. 2. It's a substantial system that predominantly operates within the realm of non-immersive VR technology. Nonetheless, its relatively large scale and dependency on interaction with other devices or resources can pose logistical challenges, as it is not very compact and can be time-consuming to set up and dismantle [5].

Fig. 2. CAREN system.

Additionally, complex systems often entail substantial operational expenses, especially when they rely on extensive equipment and facilities. Even with single-user operation, the need for assistants or operators persists, making resource utilization somewhat inefficient. To address these issues, there is a compelling need for a mobile application that can enhance the system's accessibility, allowing users to experience it from any location. This can be achieved by packaging the framework into an APK file that can be downloaded and utilized on smartphones. Such an introduction would not only improve overall usability but also invigorate users by providing the sensation of being in a different environment, thus mitigating the need for large screens. Table II conveniently summarizes the advantages, drawbacks, and suggestions for enhancing the CAREN system application.

TABLE II. SUMMARIZE OF CAREN SYSTEM APPLICATION

| CAREN System Application | | |
|---|---|---|
| *Advantages* | *Disadvantages* | *Improvement Suggestion* |
| Unique for each of the patients. The games will be based on the ability of the users | It can't be carried anywhere because of the bigger size | Create a mobile phone application to make it remotely |
| Only have two simple options on the main menu | High maintenance cost | Apply the VR feature which is immersive |
| Most advanced technology in the biochemical laboratory | Requires many experts to help one patient | Provide a free version of the application |
| Games with physiotherapy features | | |

Table III serves as a valuable repository of pertinent information pertaining to the three chosen applications. Delving into the specific attributes of each application equips us with a comprehensive understanding of their respective functionalities and contexts. Moreover, drawing comparisons between these applications and leveraging their individual

strengths and weaknesses is vital when it comes to enhancing the current application. By digitally transforming these attributes into features, we can create a more robust and user-centric physiotherapy VR experience. This proactive approach ensures that the user's evolving needs are met and that their physiotherapy journey is continually improved.

TABLE III. COMPARISON BETWEEN THE TWO APPLICATIONS

| Application Name | Main Menu | Content Presentation | Animation | Physiotherapy demonstration | User Manual | Camera Usage |
|---|---|---|---|---|---|---|
| Mirror Therapy VR [7] | ✕ | Requires experts help | ✕ | ✕ | ✕ | ✓ |
| CAREN System [8] | ✓ | Requires experts help | ✓ | ✓ | ✓ | ✕ |

In conclusion, the CAREN system is challenged by its significant costs, intricate nature, dependence on clinical settings, and the need for specialized training. Conversely, mirror therapy's limitations lie in its restricted applicability, reliance on patient motivation, absence of structured feedback mechanisms, and its simplicity, which may be inadequate for cases requiring advanced technology. A comprehension of these shortcomings aids in making informed decisions when choosing the most suitable rehabilitation approach for a particular patient or condition. Hence, this research paper aims to introduce FisioVR, a solution designed to address the shortcomings of traditional physiotherapy methods, such as the high costs and complexity associated with advanced systems like the CAREN system and the limited applicability and feedback mechanisms in the case of mirror therapy. FisioVR, as outlined in the conclusion above, strives to provide an accessible, cost-effective, adaptable, and patient-centric approach to rehabilitation, ensuring that each patient's unique needs and circumstances are effectively addressed. Through this introduction, we hope to shed light on the potential of FisioVR to transform the landscape of physiotherapy by offering a more inclusive and tailored rehabilitation experience.

III. PROPOSE APPLICATION

The purpose of the study is to facilitate the features in VR, driven by the purpose of making physiotherapy remotely, enhancing the capabilities and effectiveness of the home-based physiotherapy with minimal supervision. The prototype of the application is developed using the open-source programming which is C#, 3D models, API plugin and external software in which all of them integrated to bringing the best outcome possible made for the user.

*A. FisioVR Flow Chart*

In Fig. 3, the corresponding flowchart describes more information regarding this application. This application allows to be initiated by the user and will be immediately taken to the main menu. The second task is signing in, but the user is expected to register if they already do not have an account. If the registration has done, the user will be taken straight to the select physio menu. The user will be taken back to the login menu if the login information is incorrect. The application verifies until the user can reach the FisioVR application by

checking the cloud database used, Firebase, and grants the user access with the right username and password [9].

Otherwise, the correct username and password have to be entered again by the user. Once logged in, the user will be given several physiotherapy options to choose, making it easy for them to perform more than one therapy as soon as the first therapy is completed. When the therapy starts and the user exits the therapy, the user will be asked to finish automatically or exit to the physiotherapy options menu. From the physiotherapy options menu, users can exit the application by pressing the log out button and will be taken directly to the main menu which is the menu before logging in.

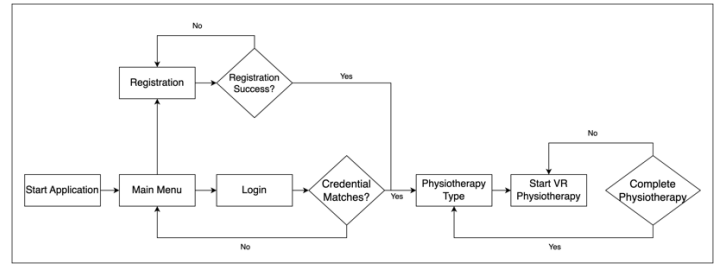

Fig. 3. FisioVR flow chart.

*B. Application Architecture*

Development of the application highly prioritise user experiences and the outcome of using the application. Contributing to the main objectives, few approaches are taken which the development will take place in UNITY 2018.3.6f1 version. Storing user's basic data into firebase enables users to log in into the applications with the correct credential. Integrating few other external resources which are Mixamo website for the 3D model, Rest API for log in features and UMotion for creating the animation movements from the scratch. This animation Editor also consists of a wide library that developer wish to design including controlling the face expression of a model and other basic movements. Fig. 4 shows the FisioVR Application Architecture. By utilizing the features in all of the sources, FisioVR Application were developed and consists of Login Menu, Registration Menu, Pick Physiotherapy Menu, Elbow Tennis Physiotherapy World, Knee Physiotherapy World, Leg Physiotherapy World, Shoulder Physiotherapy World and Exit Menu. All of the features offered in the application is in conjunction with user's request based on the data and feedback provided.

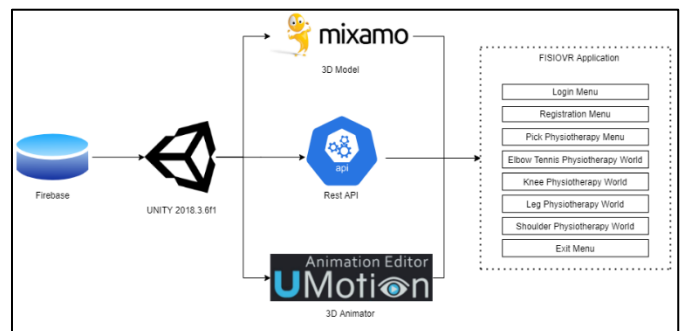

Fig. 4. FisioVR application architecture.

## C. Activity of Feature-based in FisioVR

This step involves in identifying the scope and context of this application to avoid unnecessary and redundant features. The application menu consists of eight modules: Login Menu, Registration Menu, Pick Physiotherapy, Elbow Tennis Physiotherapy World, Knee Physiotherapy World, Leg Physiotherapy World, Shoulder Physiotherapy World and Exit Menu which Login Menu, Registration Menu and Pick Physiotherapy World are connected to the Firebase Database as shown in Fig. 5. With all modules progressively integrated, an overall model are made.

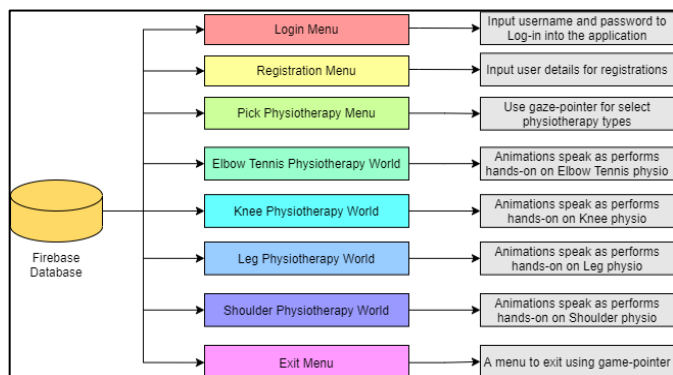

Fig. 5. FisioVR modules.

## D. Basic Movement of Physiotherapy

Physiotherapy is processed in this application using a system named UMotion. This software is freely accessible at the Unity Asset Store and facilitates the power of 3D animation for simple physiotherapy. Each movement is considered a node and matches human bone movement as seen in Fig. 6 where the following UI is the UMotion interface. UMotion uses a skeleton to regulate 3D animation activity in the human body [10] and for up to 13 seconds, UMotion can assist limb movement [11, 12]. UMotion software will generate short clip animations and integrate all animations then render them using the Unity software's animators. This movement network requires trigger mechanism based on the user chooses. Advancing from the login menu into the pick physiotherapy world, user will use gaze-pointer with the timer of three seconds on any type of physiotherapy featured in this VR application which will divert the user the physiotherapy world.

Fig. 6. Umotion user interface.

1) *3D animated movement chain (shoulder):* As shown in Fig. 7 and Fig. 8, it is a series of 3D animated movement for shoulder physiotherapy based on previous researcher [13]. Each movement must start with the "Entry" button where it is the starting point of this animation. "Phy_standing" means "idle" or empty animation movement such as standing alone without doing any action. After a few seconds, this animation will do shoulder physics slowly down first and start shoulder physiotherapy from left to right, right to left, then got up again. Each physiotherapy will be done repeatedly according to the user's wishes until the user exits this interface.

(a)

(b)

Fig. 7. 3D animation for shoulder physiotherapy.

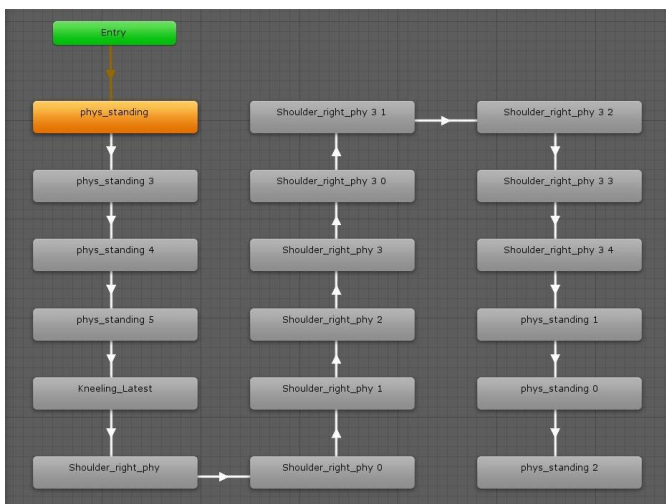

Fig. 8. Chain movement 3D animation – shoulder physiotherapy.

*2) 3D animated movement chain (elbow):* Fig. 9 and Fig. 10 represent a chain of movement of this 3D animation which also begins with the Entry pint. Each movement should start with an idle phase where it gives instructions on how to do the physiotherapy using sounds and text displayed on the screen. After a few seconds, this 3D animation starts its physiotherapy by raising the virtual avatar's hand in half and then turning it by 90° and turning back to the original position and lowering it. It is connected by raising one hand to do the same thing. This same process will be repeated several times and ask the user if they want to repeat it. If so, the animation will repeat the same process until the user wants to stop, then this 3D animation will stop and the user will exit manually using the button provided.

*3) 3D animated movement chain (foot):* Foot movement is one of the relatively tricky physiotherapies, it must start from the foot's base to strengthen the foot movement. Therefore, this physiotherapy option requires the user to stand. If there is a problem to stand, it is recommended to have a caregiver who can consist of his own family to provide assistance to stand if necessary. In this animation, the user should bend the body by 35% - 45% to ensure the legs get a moderate load. Next, the user will lift the left leg first, move to the left and slowly turn until the foot is forward and return to the original position at a slow pace. This process as usual will be repeated according to the needs of the user. Both the left and right legs will do the same physiotherapy. Fig. 11 and Fig. 12 show that this 3D animation's movement is controlled and in order so that the user can slowly adjust to this pain and physiotherapy.

(a)

(b)

Fig. 9. 3D animation for elbow physiotherapy.

(a)

(b)
Fig. 11. 3D animation for leg physiotherapy.

Fig. 10. Chain movement 3D animation – elbow physiotherapy.

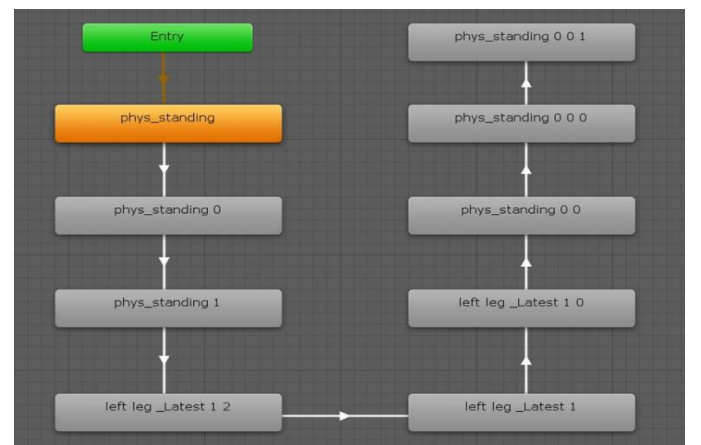

Fig. 12. Chain movement 3D animation – leg physiotherapy.

*4) 3D animated movement chain (squat):* The basic human movement must have strong support from the lower body. Therefore, physiotherapy should be included the lower limbs exercise to make them stronger. This physiotherapy involved simple movement where the animation will teach users to do basic squats. Fig. 13 and Fig. 14 represent the animation network that was successfully compiled and became a large network to move this animation to perform squats exercise carefully according to their ability.

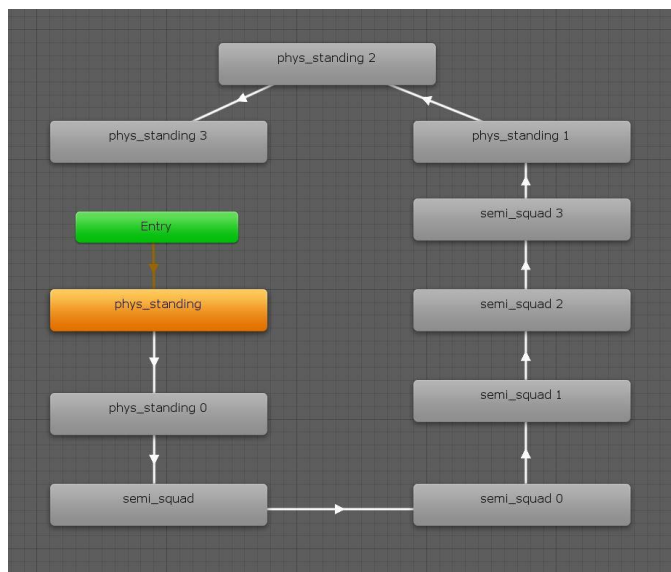

Fig. 14. Chain movement 3D animation – squat physiotherapy.

## IV. RESULTS

he FisioVR application places a strong emphasis on delivering a virtual reality (VR) interface that immerses users into an alternative realm, a concept known as "immersive reality" [1]. Studies, such as the one featured in Physiopedia 2018, provide compelling evidence that therapists can effectively manipulate the virtual environment to positively impact patients [3]. In addition to the therapeutic content, the application's interface plays a pivotal role in ensuring the efficiency of therapy sessions and capturing the users' attention and focus [5].

Advanced cognitive skills come into play as users engage with 3D animations and assimilate pertinent knowledge within the therapy context. Fig. 15 illustrates the key aspects of the FisioVR application:

*1) User login:* Users initiate their FisioVR journey by logging in or becoming a member. The main menu serves as the entry and exit point for the application, and background music accompanies the user upon entry, persisting as they revisit the application from the beginning.

*2) Registration:* The FisioVR registration interface, as shown in Fig. 15(b), caters to individuals who are not yet members. Here, users are prompted to provide essential details such as their name, gender, username, and password. This information is securely stored in the cloud database for future login verification.

*3) Scene selection:* Within Fig. 15(c), users choose their preferred types of physiotherapy. The serene background music contributes to a sense of inner calm and mental tranquillity, preparing users for the physiotherapy experience ahead.

*4) Expert guidance:* Fig. 15(d) captures the phase where users actively engage in physiotherapy, guided by an expert. This scene features animations and written instructions to aid users in their therapy journey. While discomfort may arise during physiotherapy, the accompanying music is designed to soothe and ease any tension. Upon completing the therapy session, users can exit the application by directing their gaze towards the left rear button in Fig. 15(d). This action returns them to the scene where they select their preferred type of physiotherapy as sown in Fig. 15(c). To exit the application entirely, users must select the back button, which returns them to the main menu as shown in Fig. 15(a).

*5) Exiting the application:* The "exit" button, displayed in Figure 15.e, provides users with the option to leave the application. Choosing "yes" allows users to exit, while those wishing to engage in physiotherapy again will need to log in by entering their correct username and password.

In essence, the FisioVR application offers an immersive and structured platform for users to engage in physiotherapy while incorporating interactive elements to ensure an effective and engaging experience.

## V. TESTING AND EVALUATION

Users will get a set of questions after using the FisioVR application to get detailed feedback on the user experience while using the FisioVR application. The questions contain several factors, namely the application's applicability to the user, the level of pleasure, effectiveness and satisfaction for this application [14-17]. As shown in Table IV, it is about the Likert scale and the level of performance for each usability in this application. The beginning of this scale is one that means

strongly disagree and has a maximum of five which is strongly agreed.

TABLE IV.    LIKERT SCALE AND PERFORMANCE LEVEL

| Likert Scale | Performance Level |
|---|---|
| 0-1.67 | Poor |
| 1.68-3.34 | Average |
| 3.35-5 | Good |

The Likert scale is used only to find the overall average [18]. Getting information with very minimal errors requires several approaches. One of them is to make a feedback experiment from some respondents who have a high probability of becoming regular users of this application. A total of eight respondents successfully tested this application. The respondents consisted of several potential users who did physiotherapy at a private physiotherapy clinic. They had successfully provided feedback through the online feedback form. Table V determine each of these factors depending on the survey questions.

TABLE V.    QUESTIONNAIRE RESULTS

| Factor | Mean ± SD |
|---|---|
| **Application Functionality** | **4.25 ± 0.44** |
| FisioVR manages to fulfill my needs | 4.25 |
| FisioVR helps me to be more pro-active | 3.63 |
| FisioVR contains all the functions that I need | 4.25 |
| 3D animation is handy to me to do physiotherapy | 4.88 |
| **Ease of Use** | **4.40 ± 0.52** |
| FisioVR contains content that is compact and details | 4.5 |
| FisioVR is user-friendly | 4.63 |
| FisioVR is very easy to use | 4.75 |
| Minimal attempts to get used to the virtual world | 4.63 |
| Entering data input is relatively easy | 3.25 |
| It can be done without the user manual | 4.63 |
| **Efficiency** | **4.59 ± 0.22** |
| FisioVR uses minimal time taken to use | 4.5 |
| The application has zero to minimum errors | 4.38 |
| 3D animation visualization helps the interpretation of physiotherapy (motion style) | 4.9 |
| **Satisfaction** | **4.58 ± 0.12** |
| Interesting user interface | 4.75 |
| FisioVR has unique features for virtual reality | 4.5 |
| I am very satisfied with the functionality of the application | 4.5 |

The results unambiguously demonstrate that respondents have unwavering confidence in the effectiveness of this application. They assert that it not only fulfills its intended objectives but also leaves room for further enhancements, with the potential to create a product akin to FisioVR that can cater

to a wider user base. Table V is instrumental in this regard, as it encapsulates four distinct factors, accommodating diverse individual needs, application contexts, and overall software usability. Feedback, for the most part, aligns with a positive outlook, marked by "good" and "satisfactory" ratings. However, one exception stands out—moderate ratings are assigned to the ease of data entry and input functionality, primarily owing to the absence of virtual reality keyboards.

In terms of application functionality, the positive impact is clearly articulated. Users report a higher degree of proactivity and, significantly, a potential life-changing experience as they gradually regain their spirits and motivation. FisioVR distinctly exhibits its ability to meet users' requirements. The incorporation of 3D animations contributes to clearer message visualization, supported by low standard deviations. Notably, the 3D animations stand out with high scores in both functionality (Likert Scale: 4.88) and efficiency (Likert Scale: 4.9) within FisioVR. This feature enhances the application's reliability and furnishes vital functionalities.

The application's assistance is specifically acknowledged for its role in helping users become more proactive and enhancing their overall well-being. This transformative aspect holds the promise of positively impacting users' lives as they gradually regain their spirits and motivation. FisioVR effectively addresses users' needs and provides clear message visualization through 3D animations. The application's content is highly informative and compact, making it both user-friendly and comprehensible at first use. While user feedback may not always be straightforward due to time and space constraints, it is poised for ongoing improvements. Favorable recommendations play a pivotal role in discerning priorities, ensuring that patients and users can perform their physiotherapy conveniently and receive positive feedback on ease of use. FisioVR places a stronger emphasis on performance rather than sheer ease of use. Understanding the simple and harmonious relationship between humans and machines yields a captivating user experience and efficient use of time. FisioVR records the highest average for total 3D animation interpretations in this context, with the animation timescale aiding users in understanding their virtual environment and navigating it through gaze pointers and user-driven interactions.

Satisfaction, a crucial component, keeps users engaged and delighted while using the application. Overall user satisfaction rates relatively high, with a standard deviation of 0.12, which is the highest among all variables. This underlines the successful achievement of the main objectives—identifying users' fundamental needs for the application and developing a VR application that empowers users to perform physiotherapy at home through practical and accessible methods. The efficiency section ranks highest in terms of user satisfaction, and the third point, emphasizing the role of animated 3D visualization in making physiotherapy more efficient and effective, garners the highest average rating. In contrast, the lowest average is associated with the "Convenience of Use" and the fifth point, where data entry and input present challenges and necessitate experimentation, with an average rating of 3.25. Table V distinctly underscores the significant importance of this application as an innovation that is much needed in today's context.

In comparison to the CAREN system and mirror therapy system, the advantages of the FisioVR application primarily revolve around accessibility, cost-effectiveness, adaptability to remote conditions, patient engagement, and potential for customization with expert support. FisioVR offer a practical solution for patients facing barriers to traditional physiotherapy, including those related to the COVID-19 pandemic and geographical limitations. However, the choice between these systems would ultimately depend on the specific needs and conditions of the patients and the goals of the rehabilitation process.

## VI. CONCLUSION AND FUTURE WORKS

The FisioVR application employs highly effective 3D animations to illustrate the preferred types of physiotherapy in a visually engaging and user-friendly manner. This innovative application, developed in the course of this study, enables users to execute physiotherapy sessions with ease. The success of this output was confirmed through a comprehensive evaluation conducted via an online feedback form. The results unequivocally demonstrate that this application has significantly benefited users, effectively addressing their specific needs.

With UMotion, each physiotherapy movement becomes a unique and easily comprehensible 3D animated motion. Auditory cues and visual indicators elucidate the steps and techniques involved in performing physiotherapy, ensuring that users can follow the instructions seamlessly. Importantly, this application relies minimally on the internet, primarily for tasks such as account registration and login. The core scenes involving animation and VR operate independently of internet connectivity.

However, certain limitations should be acknowledged regarding the FisioVR application's scope. It currently offers support for only a selection of fundamental physiotherapy types, including knee, shoulder, elbow, and leg physiotherapy. Expanding support to encompass a wider array of physiotherapy categories would enhance the application's versatility and user experience. To address potential challenges faced by users in adapting to the application, suggestions have been proposed.

One such suggestion is the creation of a VR keyboard, which would streamline registration and login processes, ultimately saving users time and reducing complexities. Implementing these improvements would render the framework more proactive and user-friendly. Additionally, enhancing the application's animations to convey a narrative and human-like movements would further engage users of all ages, making the guidance more relatable and appealing.

Moreover, extending compatibility to iOS-based devices is recommended to expand the commercial value of the FisioVR application. This step would enhance the application's reach and align with marketing strategies aimed at assisting a broader audience, particularly those in need of physiotherapy support.

# Ensembling of Attention-based Recurrent Units for Detection and Mitigation of Multiple Attacks in Cloud

Kalaivani M[1], Padmavathi G[2]

Ph.D. Scholar, Department of Computer Science,
Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore, India.[1]
Dean-School of Physical Sciences and Computational Sciences and Professor in the Department of Computer Science,
Avinashilingam Institute for Home Science and Higher Education for Women, Coimbatore, India[2]

*Abstract*—**In the recent years, number of threats to network security increases exponentially as the Internet users which poses serious threat in cloud storage application. Detection and defending against the multiple threats are currently a hot topic in industry and considered as one of the challenging research in academia. Many methodologies and algorithms devised to predict the different attacks. Still, most of the methods cannot simultaneously achieve high performance of prediction with a small number of false alarm rates. In this scenario, Deep Learning (DL) algorithms are appropriate and intelligent to categorize the multiple attacks. Still, most of the existing DL techniques are computationally inefficient that may degrade the performance in predicting the both normal and attack information. To overcome this aforementioned problem, this paper proposes the hybrid combination of attention maps with deep recurrent networks to mitigate the multiple attacks with low computational overhead. Initially, the pre-processing step is proposed to the inputs in a specified range. Later on, input data are fed into the Attention Enabled Gated Recurrent Networks (AEGRN) which is used to remove the redundant features and select the optimal features that aids for the better classification. Further to enhance the faster response, deep feed forward layers are proposed to replace the traditional deep neural networks. Numerous metrics for performance, including accuracy, precision, recall, specificity, and F1-score, are examined and analyzed as part of the thorough experimentation utilizing multiple datasets, including NSL-KDD-99, UNSW -2019, and CIDC-001. Comparisons of performance between the method that is suggested and existing models developed with DL are used to demonstrate the proposed algorithm's supremacy. The suggested framework surpasses the other DL models and has the best accuracy in predicting with little computational overhead, according to an investigation.**

*Keywords—Multiple threats; deep learning algorithm; attention enabled gated recurrent networks; NSL-KDD; UNSW; CIDC-001*

## I. INTRODUCTION

Internet Based Communication is used for managing big industry and transformed the scenario of monitoring and interaction methodology. Its scope of services also included the medical industry and was applicable to banking, schooling, government departments, military, and recreation. In addition, time, network development gives hackers and intruders opportunities to find illegal ways to break into an organization.

Multiple assaults that have the capacity to deny services to legitimate customers are one of the main risks to the IP network on which numerous researchers have focused their attention. Therefore, maintaining the security and protection of various websites operating on the Internet is primarily required of the secured network [1-2]. Due to their qualities, such as quick access and primitive ways of attack detection, these attacks have expanded significantly.

It can be difficult to distinguish between malicious and lawful network data because intruders have unexpected behavior [3-5]. Applications run through anytime, anything, and anywhere in an internet context and interact remotely with a variety of devices or appliances. This makes it easier for bad actors to get devices. Despite these guidelines, interruption of devices or assistance is likely to be the first stage of many attacks due to factors such as ease of comprehension, simplicity of execution, lack of extensive technical knowledge on the part of the attacker, and variety of platforms and applications for aided attack orchestration [6–8].

These attacks can be single-source assaults commencing at just one host or multi-source attacks that distribute attack packages to the target across numerous hosts. Also, attack toolkits have been developed and therefore are easily accessible in online today [9–10]. But these tools can be exploited by the intruders to enforce the attacks with least effort. As a result, more examinations are performed in recent years through the use of numerous algorithms to develop the defensive system for cloud attacks. But these traditional systems possess the various problems such as high memory, high bandwidth and processing capacity. It is vital to design Intrusion Detection Systems in order to counteract this lack of security assaults, in which the network attacks can be prevented primarily. With exponential increase, information is steadily moved from separate networks. IDS needs improvisation in predicting the intrusion in such huge data environment.

IDS has been using deep computing and machine learning techniques in the last ten years to help classify the observed data using known characteristics or attributes that have been learned from training datasets. The purpose of ML and DL-based techniques, which have some limitations, is to evaluate network traffic packet properties and set a reasonable threshold

for separating attacks from genuine traffic. For instance, tatistical recognition methods [15], Neural Networks [11], Support Vector Machine [12], nearest neighbor [13] andclustering [14]. These current studies reveal that various studies have been conducted to offer treatments to deal with this difficulty by outlining particular treatments for emerging network assaults.

Since these intelligent-based IDS have only recently been introduced, a number of issues need to be resolved. Here are a few of the current issues that studies on attack detection systems are now facing:

*1)* The majority of currently used techniques concentrate on identifying a single attack with a low false alarm rate, although they typically fall short of reaching a high detection rate.

*2)* Knowing the many characteristics of attacks is important, but identifying the ones that can really help in the detection of assaults is even more crucial. However, because of redundant information and excessive computational expense, certain existing techniques commonly have high false positive rates. A well-organized network attack detection method remains a promising research subject because earlier methods also fall short in terms of attaining efficient accuracy.

Considering these problems, this research article proposes the novel integration of the Attention layers with the Gated recurrent NN to achieve the high classification ratio in mitigating the network attacks with less computational complexity. Following are the paper's main contributions:

*1)* Self-Attention Maps are introduced in Gated Recurrent Neural Network (RNN) to achieve the better feature selection that in returns support for the better detection ratio.

*2)* Data-Pre-processing technique is employed for the increasing the speed in detecting the attacks.

*3)* Feedforward Learning Layers- They are introduced in the place of the conventional neural networks to achieve the faster training with less error detection.

Following is how the manuscript is organised: Details on the background and related works are provided in Section II. The description of the dataset, data pre-processing, and suggested approach are shown in Section III. The following Section IV provides further details on the experimental findings. The Section V provides a conclusion and future enhancements.

## II. History and Related Works

Abirami et al. (2022) demonstrated how "Deep Reinforcement Learning (DRL)" might be used in a cloud network to offload tasks while also recognizing generalized attackers. Techniques for identity-based linear classification are used in virtual machine attack categorization channels. This proposed system supports methods for remote information analysis. Reinforcement learning has the potential to reduce data secrecy and improve cooperation. The sole drawback of this system is the prolonged computation time [16].

In 2022, Tao et al., developed a "Continuous Duelling Deep Q-Learning (C-DDQN)" technique for protecting the cloud. The suggested Dynamic Field Adaptive System and improving are the fundamental ideas of this system. The convergence and learning capabilities of the aforementioned structure are preferable than those when transfer learning methods weren't used. But this framework's primary problem is the rising energy consumption [17].

Recurrent and convolution neural networks were combined in 2021 by Hizal et al. to create a DL method for threat detection in security of the cloud. Any discovered or forbidden traffic cannot be sent to the cloud server using this method. The recommended method is 99.86% accurate for classification into five classes. But this framework's primary drawback is the higher connectivity cost [18].

In 2020, Karri et al. proposed a three-stage abnormality detection framework that utilized DL for intrusion attack detection. CNN, GANomaly, and K-means clustering algorithms are all used by the system. The effectiveness of the network and automated intrusion detection had been either greatly improved. The main advantage of the aforementioned structure is that it reduces the level of computation without reducing cost [19].

By Wang et al. in 2022, stacking contractive auto encoder (SCAE) system was unveiled. The Support Vector Machine configuration serves as the framework's core. By using the unfiltered network information, this structure enables the automatic learning of improved as well as more trustworthy low-dimensional properties. This paradigm significantly reduces the analytical complexity. This technique leads to improved detection efficiency. This framework's drawback, nevertheless, is that it cannot be used in contexts where events happen in the present [20].

PredictDeep was introduced in 2020 as an approach for prediction of anomaly in big data environments by Elsayed et al. GCNs, or Graph Convolutional Networks, form the basis of the system. This solution produced better outcomes in regards of the fast discovery and forecasting of incidents of security and was able to cope with the multifaceted nature of clouds. The problem with this technique, though, is that it doesn't recognize and classify irregularities in a range of classifications in accordance with the changes in system function they cause [21].

Nguyen et al. (2021) examined the difficulties associated with compute offloading and cybersecurity in a multiple-user-friendly mobile edge-cloud computing framework utilizing blockchain. The above structure provides an effective authorization mechanism powered by blockchain that may protect servers in the cloud from incorrect offloading practices in order to boost offloading security. A complex DRL method called a double-dueling Q-network was developed by this framework to do this. This framework is lowering the latency, energy consumption, and intelligent contract fees. But this approach has the drawback that efficiency degrades as the amount of information increases [22].

RNN-based DL approaches were examined by Kimmel et al. (2021) for their efficacy in identifying malware in cloud.

The focus of the framework was on LSTMs and bidirectional RNNs. Such frameworks progressively understand malware behaviors based on the course of operation, minute activities, and system statistics such as CPU, memory, and disc usage. With this architecture, there are high detection rates. but, cannot maintain the identical degree of performance when dealing with diverse data [23].

Loukas et al. (2018) introduced a recurrent NN with a deep multilayer perceptron architecture which is capable of understanding the temporal context of several attacks. A computational framework was developed to determine whether compute offloading is favorable utilizing detection latency as the criterion, given networking operational parameters and DL framework processor needs. When the processing requirements are more severe and the network has become more reliable, offloading lowers detection delay to a greater extent. The biggest problem with this structure though, is the additional communication complexity [24].

By fusing a Convolutional NN with Grey Wolf Optimization, Garg et al. (2019) created a composite data mining method for identifying network abnormalities. The GWO and CNN learning procedures were improved in order to enhance the framework's abilities for initial sample creation, exploring, taking advantage of and discarding functionality. The above structure works better in terms of precision, false alarms, and recognition rate. This strategy does have a disadvantage, too, in that it increases computing difficulty [25]. Table I following provides an overview of several relevant studies.

TABLE II.    LIST OF RELATED WORKS FROM LITERATURE

| Author's name | Proposed methodology | Merits | Demerits |
|---|---|---|---|
| Abirami et al., (2022) | DRL | Minimises the data secrecy | Increased computational delay |
| Tao et al. (2022) | Continuous duelling deep Q-learning | Fast convergence | Increased energy consumption |
| Hizal et al., (2021) | K-means clustering, GANomaly and CNN algorithms | Reduced the computational complexity | fails to lower down on time overhead |
| Karri er al., | GANomaly and CNN algorithms | Reduced the computational complexity | However, fails to reduce time overhead |
| Wand et al., (2022) | Stacked Contractive Autoencoder and Support Vector Machines (SVM) | Reduced the analytical overhead | Not suitable for real time environment |

## III.    PROPOSED ARCHITECTURE

According to Fig. 1, the hybrid suggested network's framework is made up of three sub modules. In the first module, multiple datasets are pre-processed and inputted to the proposed network. The second module consists of the proposed SA-GRU-FF framework in which attention layer is integrated to remove redundant and non-optimal temporal features. These features are then fed into the fully connected deep feed forward networks based on Extreme Learning Machines (ELM) for classification of the multiple attacks.

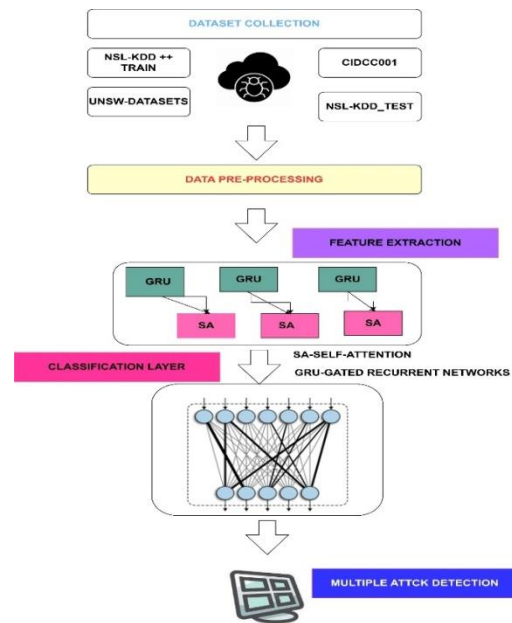

Fig. 1.    Proposed architecture for the GRU-SA-FF based multiple classifications of attacks.

### A.  Materials and Methods

Three distinct datasets, namely CIDDS-001 [27], UNSW-NB15 [28], and NSLKDD [29], are employed in this investigation. We choose the CIDDS-001 and UNSW-NB15 datasets because they are the most current statistics produced and include real data traffic, which makes them beneficial for designing accurate IDSs for tracking and finding novel forms of denial of service attacks in cloud networks. An IDS based on anomalies may now be created with the help of the CIDDS-001 dataset, which was just made accessible. In all, the collection contains around 32 million tracks, covering both normal and attack traffic. This dataset is composed of 12 identifying features and two distinguishing traits. Random sampling is applied to acquire 80,000 normal and 20,000 DoS attack events from the relational database of server traffic data, totaling 100,000 events. Using the extracted sample, the cross-fold validity and hold-out of the classifiers are tested. A new contribution to the public domain, the UNSW-NB15 dataset,

was also utilized for the purposes of testing. In the dataset, there are 49 characteristics and 1 class attribute. A subset of the dataset uses the training and test establishes, "UNSW NB15 Train & UNSW NB15 Test". There are 175,341 occurrences in the train set compared to 82,332 in the test set. "There are 56,000 occurrences of ordinary traffic and 119,341 illustrations of attack traffic on the platform set. Additionally, there are 37,000 examples of ordinary traffic and 45,332 cases of attack traffic in the test set". Hold-out confirmation makes use of both the whole train set and the test set, while cross-fold assessment solely utilizes the set that has been tested. The NSL-KDD dataset is then utilized to do classifier validation as well. 41 measures including 1 class attribute are part of the dataset. The NSL KDD dataset's KDDTrain+ (training) as well as KDDTest+ (testing) sets are utilised in this study. 13,499 attack traffic instances and 11,743 regular traffic instances make up the total 25,192 instances in the KDDTrain+ set. While the KDDTest+ set has a total of 22,544 instances, including 12,833 instances of regular traffic and 9,711 incidents of attack traffic. On each dataset separately, hold out as well as cross fold validation of classifers are performed. The selection of these sets was made to prevent randomly selecting cases from the entire NSL-KDD dataset.

### B. Data Reorganizing

The input data are first analysed, and then they are fed into a standardization approach, which assists to convert the bulk of attributes with numerical data to a specified numeric domain. Min-Max normalisation is used in conjunction with the linear transformation concept to accomplish this. After pre-processing step, new pre-processed datasets is formed from the original raw datasets. These pre-processed data is given for feature extraction module.

### C. Feature Extraction using Self –Attention Gated Recurrent Networks

The operation of gated recurrent sections, self-attention, and mixed combinations of self-attention gated recurrent units are covered in this section.

*1) Gated recurrent units – An overview*: One of most interesting form of LSTM is known as GRU the architecture is depicted in Fig. 2. The forget gate with input vector are intended to be combined into a single vector according to the concept set out by Chung et al. [30]. Both long-term sequences and memories are supported by this network. When contrasted to the LSTM network, the complexity is drastically reduced.

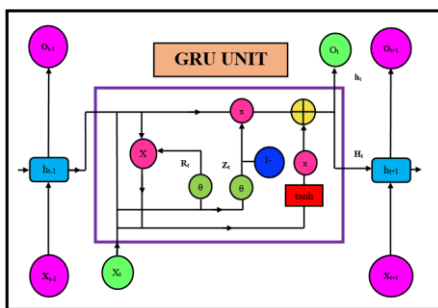

Fig. 2. GRU's architecture.

Chung developed the following equations to illustrate the traits of GRU.

$$h_t = (1 - x_t) \odot h_{t-1} + x_t \odot h_t \quad (1)$$

$$\tilde{h}_t = g(W_h x_t + U_h(r_t \odot h_{t-1}) + b_h \quad (2)$$

$$z_t = \sigma(W_h x_t + U_z h_{t-1} + b_z) \quad (3)$$

$$r_t = \sigma(W_h x_t + U_r h_{t-1} + b_r) \quad (4)$$

The following is the general GRU characteristic equation:

$$R = GRU(\sum_{t=1}^{n}[x_t, h_t, z_t, r_t(W(t), B(t), \eta(tannh))] \quad (5)$$

where, "xt ⇨input feature at the present state, yt ⇨output state , ht ⇨ output of the unit as of this moment, Zt & rt⇨update & reset gates, W(t) ⇨ weights, B(t) ⇨ bias weights at present instant".

*2) Self-awareness maps:* In 2014, the attentive map was proposed to describe the appropriate words in a sequence-to-sequence structure. In the vast mainstream of contemporary works, redundant characteristics that support accurate categorization mechanisms are imitated using attention layers. The self-attention process, commonly alluded to as the intra-attention procedure, generates the three vectors Q, K, and V for each input pattern. Thus, the results sequences are created by transforming the input patterns from all of the layers. It is a technique that, in its simplest form, maps the query string to the set of key-pair collections using logarithmic dot processes. The mathematical formula that follows can be used to get the dot multiplying for self-attention.

$$F(K, Q) = ((K), Q^T))/(V_K)^{0.5} \quad (6)$$

### D. Proposed Feature Extraction

BiGRU networks, which combine forward and backward GRU, are built for gathering meaningful information from the many dataset streams. Eq. (9) delivers data on the precise properties of the BiGRU network. In order to classify data, the BiGRU network collects spatiotemporal characteristics that incorporate a variety of different pieces of data. Although the training time, which makes up the overhead in the classification layer, may be affected by the more varied information in these characteristics. Self-attention layers that are inserted among the BiGRU network and classification layer help to diminish the resulting classification cost. Eq. (6) is used to create the attention characteristics retrieved from the input features of the BiGRU network that are then given to the feed-forward level of classification via the softmax layer.

$$P(F) = GRU\left(\sum_{t=1}^{n}[x_t, h_t, z_t, r_t(W(t), B(t), \eta(tannh))]\right) \quad (7)$$

$$P(B) = GRU\left(\sum_{t=1}^{n}[x_t, h_t, z_t, r_t(W(t), B(t), \eta(tannh))]\right) \quad (8)$$

Combining the Eq. (7) and Eq. (8)

$$P(BiGRU) = P(F) + P(B) \quad (9)$$

The following information is related to integrated Self-Attention (SA) with BiGRU feature extraction.

$$Y = Softmax (P(BiGRU), F(K, Q)) \quad (10)$$

## E. Feed Forward Classification Layers

After receiving these attributes for the fully connected forward feed-forward network, the final classifying is carried out. Layers are entirely linked using the ELM principle. The principle of auto-tuning capacity underlies the operation of a particular class of neural network known as an ELM, which only uses one hidden unit. In regards to dependability, speed, and computational burden, ELM performed better than other learning models like "Support vector machines (SVM), Bayesian Classifier (BC), K-Nearest Neighbourhood (KNN), and even Random Forest".

There is just one hidden layer in this specific neural network; therefore it may not require to be modified. Compared to other learning algorithms like Random Forest and Support Vector Machines, ELM operates better, more quickly, and with lower computational cost. Small training error and improved approximation are the ELM's main benefits. ELM uses non-zero activation functions and weight biases that are automatically tuned. The ELM's intricate operating mechanism is covered in [26]. Following Attention maps, the ELM's input features maps are represented by:

$$X = F(Y) \qquad (11)$$

where, Y $\Rightarrow$ features from Self Attention BiGRU network ,

*The ELM's output function is represented by the symbol*

$$Y(n) = X(n)\beta = X(n)X^T(\frac{1}{C}XX^T)^{-1}O \qquad (12)$$

ELM's comprehensive training is provided by:

$$S = \alpha(\sum_{n=1}^{N}(Y(n), B(n), W(n)) \qquad (13)$$

Finally, the softmax activation layers are applied for the above feedforward layers to achieve the best accuracy.

## IV. EXPERIMENTATION DETAILS

The entire algorithm was designed on an Intel Workspace with a 3.2 GHz of frequency, I7 CPU (NVIDIA GPU) and a16GB of RAM. Utilizing Keras (Tensorflow) as the rear end, the suggested baseline infrastructure was created.

## A. Performance Metrics

Deep feed forward training networks that classify the necessary classifications into typical sensitive and malicious information as well as the suggested design are validated as part of the experiment. Metrics including "accuracy, sensitivity, selectivity, recall, and f1-score" are used to gauge the suggested design's effectiveness. The calculations for the metrics used to assess the suggested architecture are shown in Table II in their respective computation formulae. Additionally, Table III shows the experimental hyperparameters that were utilized to train the suggested network.

## B. Results and Discussion

The experimentation is carried out based on component structures with the same parameters as the proposed framework. In detail, the existing structures were one dimensional Long Short Term Memory [30], Gated Recurrent Units [31], Optimized LSTM [23], and BiGRU [32]. The technique was

validated and a comparison study was performed using four different datasets.

TABLE III. ALGEBRAIC EQUATIONS FOR THE CALCULATION OF PERFORMANCE METRICS

| SL. NO | Validation Metrics | Formulae |
|---|---|---|
| 01 | Accuracy ($A_{cc}$) | $\frac{TP + TN}{TP + TN + FP + FN}$ |
| 02 | Sensitivity or recall ($R_{ll}$) | $\frac{TP}{TP+FN}$x100 |
| 03 | Specificity ($S_{ty}$) | $\frac{TN}{TN + FP}$ |
| 04 | Precision ($P_{cn}$) | $\frac{TN}{TP + FP}$ |
| 05 | F1-Score ($F_{cr}$) | $\frac{Precision * Recall1}{Precision + Recall1}$ |

Where, "TP – True Positive Values, TN – True Negative Values, FP – False Positive and FN – False Negative"

TABLE IV. HYPER PARAMETERS USED IN THE NETWORK'S TRAINING

| SL. NO | Hyper-Parameters | Specifications |
|---|---|---|
| 1 | GRU cell count | 10 |
| 2 | Epochs count | 200 |
| 3 | Batch Size | 30 |
| 4 | Learning Rate | 0.001 |
| 5 | Momentum | 0.2 |
| 6 | Dropouts | 0.2 |

TABLE V. USING THE CIDCC-001 DATASETS, EFFICIENCY STATISTICS OF THE DISTINCT ALGORITHMS

| Algorithms | Validation Metrics | | | | |
|---|---|---|---|---|---|
| | $A_{cc}$ | $P_{cn}$ | $R_{ll}$ | $S_{ty}$ | $F_{cr}$ |

(d)

Fig. 3.    Validation performance of the suggested model using distinctive datasets a) CIDCC-001 datasets b) UNSW-datasets c) NSL-KDD datasets (Train) d) NSL-KDD datasets (Test).

Tables IV, V, VI, and VII demonstrates the proposed algorithm's performance metrics for categorizing several assaults using various datasets. The Table IV represents, the outcomes of proposed and existing frameworks when testing under CIDCC-001 Datasets. The Table V, Table VI and Table VI represents, the outcomes of proposed and existing model when testing under UNSW2019, NSL-KDD+(Train) and NSL-KDD+(TEST) datasets respectively. From Table IV, V, VI and VII, it is observed that, the suggested model GRU-SA-FF has demonstrated the best performance in detecting the numerous attacks. The integration of Self-attention maps has provided the best results in contrast to different DL techniques. Additionally, the validation effectiveness of the suggested model (see Fig. 3) is assessed using various datasets, and it is discovered that the RMSE (root mean square error) in between training and testing data is 0.001.
TABLE IX.    MBT IN SUPPORT OF DIFFERENT ALGORITHMS USING DIFFERENT DATASETS

| Datasets | (MBT)-secs | | | |
|---|---|---|---|---|
| | LSTM | GRU | Op-LSTM | Proposed Model |
| CIDCC001 | 0.5 | 0.45 | 0.37 | 0.23 |
| UNSW | 0.45 | 0.39 | 0.31 | 0.21 |
| NSL-KDD++ Train | 0.5 | 0.45 | 0.37 | 0.22 |
| NSL-KDD++ Test | 0.43 | 0.42 | 0.38 | 0.22 |

Model building times for various classifiers are shown in Table VIII for four datasets employing hold-out evaluation. Recognising how essential it is to deliberate how long a system needs train until it is successful at spotting various risks, the main driver aimed at estimating MBT is this realisation. Because of this, MBT helps to achieve a good trade-off among computational complexity and the accuracy of classifiers. The suggested model's average MBT when trained on the different sets of data is 0.22s, according to the above table, compared to 0.36s, 0.41s, and 0.48s for Op-LSTM, GRU, and LSTM, respectively, for Op-LSTM. According to the evaluation, the suggested framework uses only 0.22 seconds and excels at designing countermeasures against several threats.

V.    CONCLUSION AND FUTURE ENHANCEMENT

In this work, investigation on integration of Self-attention maps with GRU for securing the cloud against the multiple attacks is carried out. The role of self –attention network with the BiGRU to select the optimal features that can aid for the classification layers is proposed in this paper. Additionally,

role of feed forward layers which works on principle of ELM has been used in the proposed research to achieve the better classification with reduced computational burden and quick speed. Precision, specificity, susceptibility, false alarm rate, and region under the curve of receiver operating characteristics are used to assess the performance of the suggested model. On the CIDDS-001, UNSW-NB15, & NSL-KDD datasets, all of the classifiers are benchmarked. Results demonstrate in terms of a superior detection ratio and so little overhead, the proposed approach have done better over the other DL models. As the future scope, performance of the proposed model is required for the validation with real time datasets and also brighter light of deploying in the resource constraint in Cloud.

# An Efficient Method for Implementing Applications of Smart Devices Based on Mobile Fog Processing in a Secure Environment

Huaibao Ding, Xiaomei Ding*, Fang Xia, Fei Zhou

School of Computer Engineering, Anhui Wenda University of Information Engineering, Hefei 231201, China

*Abstract*—Smart technology and the Internet of Things (IoT) are advancing and growing daily in the modern world. The demand for solutions to execute complex applications and protect user security and privacy increases as the number of smart devices in our surroundings increases. Mobile fog processing aids us in this situation by providing a fresh and effective method for running smart device applications in a safe setting. Due to the delay and high volume of requests, the centralized and traditional architecture of cloud processing cannot handle the high user demand and effectively implement delay-sensitive and real-time programs. To address these issues, a virtual mobile fog processing architecture that establishes a layer between mobile apps and the cloud layer was developed in this work. In this layer, storage, processing, and encrypted communication occur on separate nodes not connected to the cloud. These nodes are virtually implemented on a single server. An Android smart system-based augmented reality application that uses a marker to display dynamic 3D objects has been introduced. Its functioning has been assessed in both the cloud-based architecture and the suggested architecture in two 4G and telecom mobile internet networks. The evaluation findings demonstrate the suggested architecture's superior performance in both communication networks. The suggested mobile fog-based architecture makes use of the Internet of Telecommunications to create high-volume 3D models quickly and to the satisfaction of a real-time application. In addition to these accomplishments, the results demonstrate that the suggested architecture outperforms typical cloud-based architecture in terms of lowering overall energy consumption by up to 34%.

*Keywords—Cloud environment; IoT; real-time systems; smart devices; mobile fog; energy consumption*

## I. INTRODUCTION

The administration of networks, storage, and computation has all faced numerous difficulties with the growth of the mobile Internet and the IoT [1]. High latency, a lack of storage space, scarce resources, round-the-clock services, and security are problems that can't be accurately solved with a cloud computing architecture [2]. A computer is a subset of computer resources, such as servers, storage, and processing space, used to centrally collect and process data from many clients at once [3]. These resources are accessible via customary means and are active in the network [4]. Network delays are caused by the allocation of resources among end users and clouds due to resource concentration in cloud spaces. Solving these issues is crucial for a number of delay-sensitive applications, including transport networks and augmented reality [5].

For this reason, the processing power in various Internet of Things networks has recently increased with the development of cloud and fog computing, and by shifting a portion of the processes to data centers in the fog, the amount of delay and limitations of the Internet of Things have been reduced and improved [6]. Mobile edge computing (MEC) and mobile cloud computing (MCC) are new technologies that have arisen as a result of the substantial role that smart mobile devices play in the expansive realm of the Internet of Things [7]. The use of cloud computing capabilities at the network's edge is a trait shared by all of these systems. When IBM and Siemens' Nokia Networks created an infrastructure that could run applications on a mobile base station in 1923, the term mobile edge computing was first used to describe the implementation of services at the network's edge [8].

European Telecommunications Standards Institute (ETSI) has created reference architecture since 2016 whose functional components support services like program execution at the radio network's edge [9]. Edge computing was developed to address issues with reaction speed, limited battery life, reduced bandwidth costs, and data security and privacy [10]. Additionally, processing and storage facilities at the edge can work together or independently. The control approach in the MEC design is dispersed hierarchically and centrally, in contrast to the centralized control of resources in the MCC [11]. Cloud computing (FC), a different horizontal architecture that distributes resources and services and offers computing, storage, and network control prior to reaching the cloud, was introduced at the system level for networks. When used with mobile devices, cloud computing technology offers quicker and higher-quality services [12]. In order to connect smart devices and provide services in a virtual form (VMFC), mobile processing can be used. All processing and operational services can be accessed through these virtual machines or a network of virtual machines [13]. In addition to providing MEC services, virtualization infrastructure can offer other related services, like the virtualization of software-defined network operations [14]. This article aims to offer a VMFC-based approach that can be utilized to construct a fog layer employing virtual nodes before the cloud layer. This layer's use for applications in smart devices, which have a dedicated node for each network of smart devices, including those for gaming, education, and health, is its unique feature. The author's contribution to this work can be summed up as follows:

- A virtual mobile fog processing architecture is offered to meet the increased user demand and ensure that real-time and delay-sensitive applications are run correctly.

- Two 4G mobile internet and telecommunication networks have been assessed for a pointer-based augmented reality application with dynamic 3D object presentation on Android smart systems.

The various sections of the article are further explained in the sections that follow: In Section II, a summary of the work completed in the MEC, MCC, and FC contexts is provided, and the benefits and drawbacks of each are compared to the proposed work. The suggested methods are provided in Section III. In Section IV, we demonstrate how this strategy is used using an example from an augmented reality application. In Section V, we discuss the suggested method and analyze the outcomes. A summary of this study's findings is provided in Section VI.

## II. RELATED WORKS

Mobile phone networks make up a sizable portion of the Internet of Things. Because of their great computational capacity, they need to develop a second network layer to minimize the processing burden on the devices, reduce delay, and conserve bandwidth and energy when connected. The distant cloud server is displayed. Applications for active mobile phones in the Internet of Things networks, such as monitoring stations and smart houses, traffic data transfer, health data transmission in medical networks, augmented reality programs, large data processing in smart cities, and learning through mobile devices The mobile phone and the games utilize less computing and processing power and have shorter battery lives since the computing and processing load is offloaded to the cloud layer. The term "augmented reality" refers to a live physical perspective that instantaneously adds components to the real world of people, either directly or indirectly, and typically in contact with the user [15]. Programs for augmented reality that run on mobile devices need. The proper presentation of information requires high-speed data processing and minimal delay [16]. Cisco first developed cloud computing in 2022 [17], which is an expansion of the cloud computing platform that provides processing, storage, and network services between end devices and traditional cloud servers. In addition to network virtualization and traffic engineering via network performance virtualization, the researchers defined an architecture that supports some edge technologies, including ZigBee, Bluetooth, LoRa, and Wi-Fi [18]. Other investigations have been into edge processing's interoperability with the Internet of Things software. Fog nodes were created in this study as edge devices for various machine-to-machine services and machine-to-machine device management systems, such as road processing units in-vehicle networks. This approach did not take into account other factors like application migration or compatibility and was only effective for a small number of locations. This interpretation states that MEC offers a technological environment with cloud computing capabilities at the mobile network's edge. Utilizing cloud services at the edge of a network of smart devices has several benefits, including low latency, high bandwidth, access to radio network information, and local awareness. An edge

scheduler that reduces the device's typical traffic delay is an example. It was demonstrated that the average energy cost in fog computing is 40.48% less than the model in a quantitative examination of energy consumption in a scenario where 25% of Internet of Things applications require real-time services and low latency [19]. Processing in the cloud is usual. In one study, they used the cloud and cloud computing to boost the processing capability of a network of wireless sensors for military applications and real-time execution to get around program limits and damage. A different work sample has offered a collection of applications that enable virtual machines to connect to cloud nodes and offer services. These applications enable virtual computers to access regional data, including sensor data, network statistics, etc. In a project, multiple researchers produced numerous copies of portable programs and several smart gadgets in the cloud [20]. They were moved from the machine to the duplicate. Consequently, a virtual copy of the gadget exists in case the actual one is destroyed or lost. This method also has the benefit of addressing the hardware constraints of smart devices. In a project, they demonstrated the viability of combining the 5G network platform with MEC and the accessibility of underused indoor and external spaces. Another project in the area of big data analysis utilized the convergence of MCC and Hadoop. The traffic congestion and time delay for their task were not resolved by paying attention to the amount of processing data in this strategy. Another piece of work on the subject of smart health involved gathering sensor data and sending it to a mobile device so that it could be processed and used to generate an alarm in an emergency [21]. None of the MCC or MFC services were used in this work. In one project, a mobile cloud server was used to develop an intelligent communication architecture for unmanned air transport networks. Their suggested design may maintain communication over a long period of time, even in the event of network failure, by improving network dependability and stability. Additionally, it can defeat DDoS, Sybil, and Wormhole attacks. In the MEC environment, a location-based augmented reality program has been built. Based on the tracking and identification of the user's position on the edge of an object, it is loaded. Utilizing this architecture significantly reduced mobile phones' computational load and energy usage [22]. Through the use of augmented reality technology, a different program on the topic of digital education was put into place. An image was recognized and exhibited in its static, three-dimensional surroundings. A cloud server was employed in this program to lessen the computational load and energy usage. The more straightforward steps of diagnostics were carried out on the mobile phone, while the more complex programs were moved to the cloud [23]. The program for augmented reality now loads frames more quickly, thanks to the evaluation of this effort. In another application dealing with augmented reality based on cloud processing, a photo of the book columns was taken, the features extracted, and sent to the cloud on the mobile phone [24]. Then, using the information obtained, a search was conducted among the database records in the cloud environment. Information about comparable works is gathered and sent back. In the studies and the use of cloud processing reduced the computational workload and energy consumption of the mobile phone, but the issue of high cloud latency and its

distance from availability limited the use of MCC architecture for delay-sensitive applications [25-27]. It was immediately noted that this delay increased the mobile phone's energy use.

The delay issue has been largely resolved in [28], but if base station traffic volume rises, we will need to impose traffic limitations. The study proposed a successful approach to shorten the transfer time from users to distant clouds by utilizing the edge environment [29-30]. In this work, data and objects were entirely moved to the edge environment in order to conserve memory and processing in an electronic learning program based on augmented reality. The effectiveness of the study that was given demonstrated how the suggested strategy could significantly enhance memory storage performance. Edge nodes were created as road units in-vehicle networks in [31] to provide IoT services using OpenM2M in order to reduce network delay and traffic. For the purpose of reducing the typical scheduling and delay time, the authors of [32] investigated the multi-user computing partitioning problem (MCPP). To overcome the issue in delay-sensitive applications, they employed an offline exploratory technique called search in the model (SAPRL). Because of the work done in the MEC environment, all augmented reality applications based on 2D images, 3D edge detection, and sensor detection can be implemented. It is more suited for location-based augmented reality programs and is not extensively employed in health, education, or architecture networks. Due to the limited ability of control units and operator base stations to locate mobile phone devices, this feature is possible. Fog computing is actually a way of processing data from its point of generation to its point of storage. Only processing data close to its original location is attributed to edge computing. In addition to edge computing, fog computing refers to the network connections required to transport data from the edge to its terminus [33]. The use of mobile computing, particularly in mobile and network environments, offers users several advantages while lowering program running costs and conserving computer resources. In general, as mobile phone base stations improve and information technology and telecommunications networks converge, the use of mobile computing is a logical progression. Edge computing, where part of the data processing takes place at the network's edge rather than wholly in the cloud, was made possible by the Internet of Things' congestion and the constraints of cloud services. The problems of latency, mobile device battery life, bandwidth costs, security, and privacy can be resolved via edge computing. The comparison of the three described architectures is shown in Table I. The activities that have been completed have made use of MCC architecture to improve services for mobile devices, which are limited in their ability to run delay-sensitive programs due to the high delay of the cloud layer and the difficulty in accessing it. The fog support service has not been employed in many projects that have been simulated on smart devices. Some of the issues with MCC architecture, such as slowness, have been resolved through the use of MEC architecture. However, there is an issue of delay in the event of crowding when one is in an area of service stations because of the use of a high number of mobile phone devices. The inability to easily access the servers of mobile phone network carriers is another issue with deploying MEC. Applications cannot be uploaded to operators' servers without special authorization. One of our aims in writing this post is to offer programmers and consumers an approach that is simple to use and affordable. As part of the ongoing study, we will show an approach based on MEC and fog processing that is simple to use, and based on this architecture, we will use augmented reality technology to create a portion of a delay-sensitive application. The VMFC approach facilitates the study of local data by building a hierarchical infrastructure and moving global coordination and analysis to the cloud.

TABLE I.    COMPARISON OF MCC, MEC, AND VMFC ARCHITECTURES IN TERMS OF FEATURES

| Specification | MCC | MEC | VMFC |
|---|---|---|---|
| Expandability | high | Medium and limited | high |
| location | A higher level than the devices and out of reach | The edge of mobile devices | Between devices and the cloud |
| Hierarchical architecture | Two levels | Three levels | More than three levels |
| Server Hardware | Very large data centers | Small data centers | Small data centers |
| Control systems | Central | Distributed centralized hierarchy | Non-distributed hierarchy |
| amount of delay | high | medium | Low |
| They use it | Lots of devices and networks | The average number of devices and networks | The average number of devices and networks |
| How to connect | All internet networks | Base stations and operators | All internet networks |
| Interaction and cooperation between nodes | Does not exist | Does not exist | There is |
| Energy consumed by devices | medium | Low | Low |
| Implementation cost | medium | medium | low (virtualization capability) |
| User access | In a remote place and in case of heavy traffic, it isn't easy to access | Close and easy with the condition of being in the service area and having a service | Close and easy access |
| Access to programmers to develop all kinds of programs | Almost as easy with registration or fees | Easy if you have a license to access the servers located in the license base station | Easy with registration |
| Implementation of a delay-sensitive application such as augmented reality | Reduced computational load - high latency | Lack of support for the implementation of various augmented reality programs in case of medium delay congestion | Very low latency suitable for most augmented reality applications |

## III. PROBLEM IDENTIFICATION AND SUGGESTED SOLUTION

The problem's definition and the suggested model are covered in this section. You can upload computational jobs to the fog layer or run them locally on the device. The speed of the processing process can be greatly increased by uploading processing tasks to be completed at the network's edge. Fog nodes execute applications alongside centralized cloud servers, but they are not required to run for services since fog nodes can process applications independently and reply to users. Between the application and the cloud layer, this layer serves as a backup. The internal organization of this layer is utilized to speed up user access to the services they need. ETSI has provided the web foundation for MEC servers, templates, and software. We proposed a hierarchical architecture based on MFC in this article by researching and analyzing this architecture, as seen in Fig. 1. This design uses active networks of smart devices to deliver specific services to networks that are connected to it as well as the larger Internet of Things. The administration of network connectivity, processing, speed, storage, and control are a few examples of tasks that can be carried out at each fog node in this architecture. At a higher level, each mobile network is connected to a set that comprises one or more fog nodes. Nodes can communicate with one another wirelessly or over connected connections.

There are two options for loading programs in the cloud node: loading the complete executable program or just a portion of it. Depending on the application, each VMFC layer of the MFC layer is made up of a number of nodes. Nodes are interconnected for application management, data processing, storage, and security services. Each node is in charge of offering the designated services at both the level of that node and a higher level. Each VMFC layer collaborates with its neighboring layers as necessary. In the MCC layer, big data collection takes place at a higher level. This layer is in charge of overseeing and supporting MFC, which is a lower-level layer. Additionally, this layer is in charge of documenting, confirming, and securing access for VMFC nodes to connect with one another as needed. This layer houses data centers and big data storage.

The MFC layer and the MCC layer communicate with each other over the Internet. Active technologies like WLAN, ZigBee, 4G LoRa, and 5G are used to connect applications on smart devices to the cloud layer so they can receive service and storage in a secure environment. Frameworks like: NET and Java are frequently used to create applications since they make the process of transferring code easier.

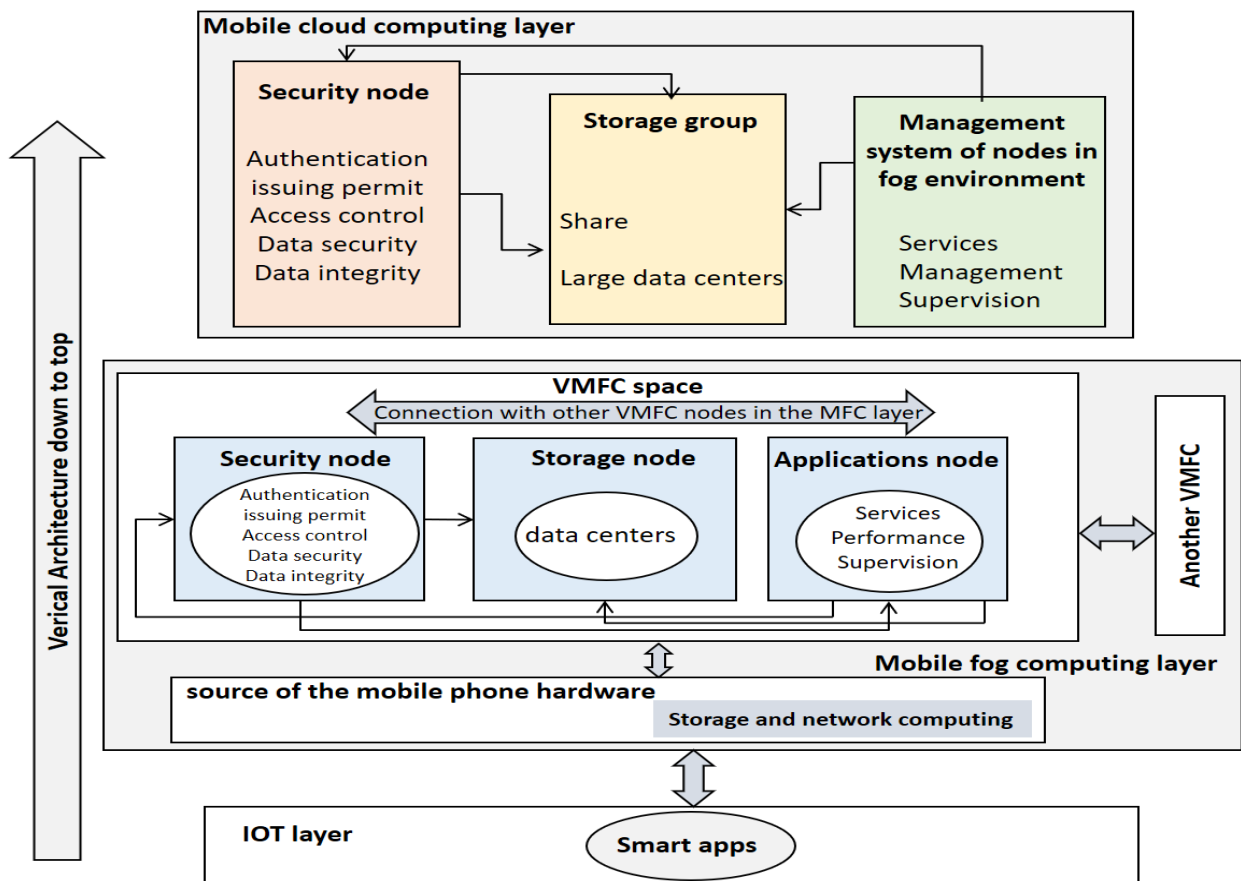

Fig. 1. Block diagram of the proposed model.

## IV. IMPLEMENTATION OF THE ARCHITECTURE

This section explains how to put the suggested method into practice. In this system, two fog nodes were employed for program execution, processing, and authentication. The fog layer is made up of two distinct nodes: one is used for security, and the other is used to store and process the application program. The two nodes here are linked. These two nodes are implemented and set up using two virtual computers. The data storage node is not taken into account independently [34]. Every node used for processing has a database for storing the sent and necessary data related to other data. The Java framework has been used to implement the application program. Fig. 2 demonstrates how to use two nodes for the application and security to create the application based on the suggested way described in Section III. Each node contains the node database, which is not a separate entity. On the needed server, each user registers their information and builds a profile. The executable application responds to the user's request for some space. The user is allotted a specific amount of space for each component of their profile, which is separated into many sections. An individual identification number is assigned at random to each segment [35]. The address of the user's profile and the ID of each section written in a piece of code is used to direct the program in order to log in and run the program uploaded in the virtual space. The security node receives the data entered in the processing and storage node and enters it into the profile for registration and verification. The initial step in accessing the cloud server to carry out processing is user authentication. A software ID is generated for the user when they register their information.

Each piece of software is identified by a special key called software ID. With this special key, all requests are signed, and it is also used to verify signatures. The procedure for getting the token in a mobile edge scenario is the same as this one.

The authentication header bears the signature. The time tag and request identification features in this header guard against broadcast and propagation attacks. The signature also changes if the person's ID changes [36]. In order to verify and register the user's codes in his profile database, this signature must be written in a section of the application's Android code that is utilized while loading program data and performing the necessary cloud-based operations. Using a browser to connect to the Internet, the user can access his profile and read and update his data from any location. The application uses an image-based augmented reality program to run dynamic 3D objects. Each 3D object depends on a pointer, which means that it can only be seen by scanning the pointer. The second fog node is utilized in this architecture to store and process the pictures needed to execute the augmented reality software. The outcome of the image processing is then compared to the user's pointer, and the appropriate three-dimensional image is presented. Everywhere the user's marker is, a 3D image of it can be seen. Visual indicators are the type of indicators employed in this project. Between ID-based markers and markerless technology, there is an image marker. With this technique, any image can be used as a target by being printed out; the target should be a colored border against a light background. The image's border need not be black; it might be a dark hue.

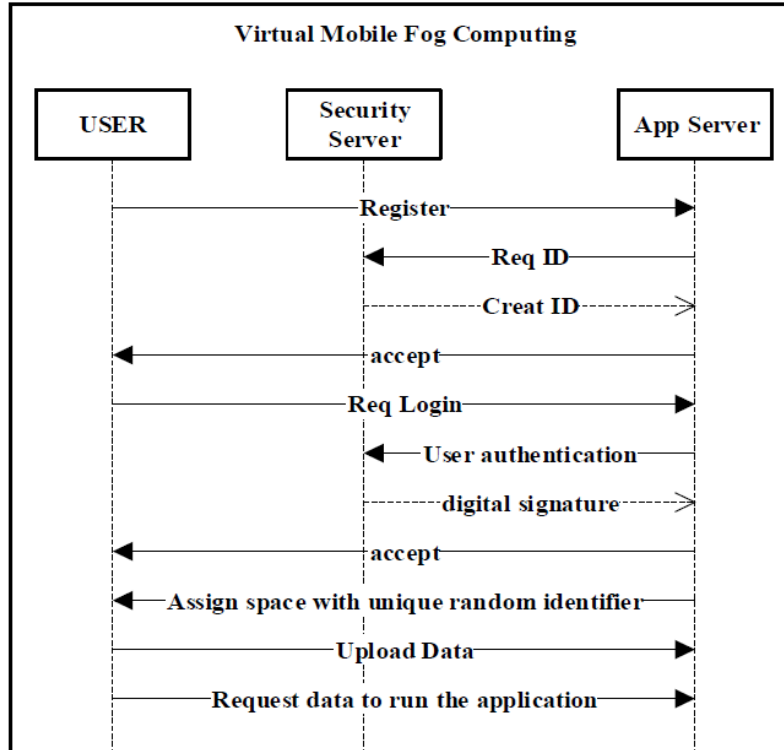

Fig. 2.   Data recording and transfer flow in the proposed method.

Developers can use images and track them in pointer-based programs, depending on the requirements of the program. A low-poly model is a low-poly model, and a high-resolution model is a high-poly model. These classifications are based on the tool and how the models are applied. Models of lower resolution, or low-poly models, are frequently employed in real-time systems to boost program efficiency and speed up execution. In a 3D model, a polygon is defined by a number of other polygons. This unit is typically represented by a collection of triangles. The quantity of triangles produced on the 3D model determines how clear the implemented models are. The application node processes a portion of the software in such a way that the user can load a sample of the marker in addition to the desired 3D model. According to each marker with a 3D object and its properties, the.xml file is saved and loaded. The marker that identifies the mobile phone camera and its application is delivered to the fog node each time, the program is run and is compared to the markers in the processing node. If they match, the matching 3D model is presented. When matching and running, 3D models are merely loaded and presented from the node and are not saved on the mobile device. An.xml file with the 3D object's properties is loaded into the user's profile.

## V. DISCUSSION

In this section, we describe the assessment of the developed technique in two scenarios: local execution while using the suggested VMFC approaches and using a mobile phone. According to the volume difference, we look at two frame execution rate parameters in each 3D model, and then we compare how long it takes to load data from VMFC and a ready cloud service. To upload data, we took advantage of the Junaio cloud storage service. With the help of the augmented reality browser Junaio, users may build and use augmented reality programs on a variety of platforms [37]. You must first create a channel in this browser in order to upload the augmented reality programs you have generated and assigned to each channel. Dynamic 3D models have restrictions on mobile phones since they require a lot of processing speed to operate and a lot of storage space as the number and volume of data increase. These models, which can move and animate, are made up of a number of layers, each of which mimics a movement. A frame or polygon is the name given to each of these layers. To show a specific movement that has been applied to the object, it is imperative to execute these polygons one after the other. On the other hand, augmented reality programs are real-time programs, and one of the crucial aspects in this sector is the quick execution rate of an event. Six 3D objects with extensions.FBX,.md2,.mm3d, and.ms3d are utilized in this software, ranging in size from 180 to 450 KB. As was already noted, the number of created polygons and the speed at which they are executed determine the resolution of models. In this case, triangles, each 80KB, comprise around 10,000 polygons. A bandwidth of 29 MB/s is required to implement this flow. In frames per second, 3D models are executed. This unit specifies the vertex of the polygons transferred from memory to the screen. If a program loads less than 20 frames per second while running, it indicates that the program is not operating smoothly and rapidly. It is reasonable for programs to transfer at least 20 frames per second while

running. Depending on the size of the model, the mobile phone uses a specific amount of device energy to load each of the models and transport them on the screen. Data is loaded into the ES FileExplorer environment and then transferred for presentation to the main program. Eq. (1) is used to compare the difference in program execution time between VMFC and cloud services:

$$T = \frac{R}{S} \times (T_r + T_h + T_s) \quad (1)$$

where, R is the anticipated request ratio, S is the total number of requests that the machine can handle concurrently, $T_r$ is the amount of time it takes for data to travel from the user's mobile device to the virtual machine, $T_h$ is the amount of time it takes for the virtual machine to respond to the request, and $T_s$ is the amount of time it takes for data to travel from the virtual machine to the user's mobile device. We assumed the value for both services to be the same and constant in this R equation. The amount of data being transferred and the network conditions—which are typically poor for mobile networks when handling heavy data loads—determine how long it will take to complete. The user response waiting period has been left out of this calculation because it is not crucial to resource allocation. Six different data sets with varying volumes were examined using the program's implementation on two separate platforms, including WLAN and 4G mobile internet. The software was implemented in three parts based on a cloud server, mobile device, and VMFC and the evaluation metrics were looked into and examined. Internet telephony was utilized to compare the frame transfer rate of 3D models in VMFC. In Fig. 3, the speed and quantity of transitions of the 3D model polygons corresponding to the marker in the minimal normal state are displayed after the mobile phone camera recognizes and processes a marker. For the 3D models incorporated into the program, this value is computed. Fig. 4 illustrates the frame transmission rate to the screen from the mobile phone and the VMFC in contrast to the minimum normal speed. The application takes into account a certain number of polygons for processing on the model and transfers them for display based on the volume of the models being utilized. The 3D model and its dynamic movements must be executed and displayed at a minimum speed of 20 frames per second. For low-volume models, the transfer speed of the frames processed in the application in the mode where the model is loaded from the mobile phone memory is acceptable, and it almost exactly matches the transfer speed from the VMFC to the mobile phone's temporary memory. However, compared to a mobile phone, the transfer speed from a VMFC is faster and offers greater performance when the model volume and count are both raised.

The FBX model has a larger volume than other models, and its memory consumption is also higher. The speed of frame transfer in this model and larger model is higher than loading in a mobile phone. Loading 3D models in VMFC in this program has saved about 1 gigabyte in mobile phone memory. Data transfer from the mobile phone to the Ebro VMFC server was checked in two Internet communication networks. The present research compares the transmission speed values frames in mobile application execution and transmission speed after using VMFC. Paired t-analysis was used after and before

using VMFC to determine if there was a change in the transmission speed of frames.

Table II shows the details of this statistical survey. As can be seen in Table II, the rate of frame transfer before using

VMFC was 84.250, and after using VMFC, it increased to 83.333, and this increase was statistically significant (p=0 /032) is significant.

Fig. 3.    Volume and number of frames and normal speed of loading seven objects in the program.

Fig. 4.    Comparison of frames transmission speed in two modes of uploading from mobile phone and uploading from VMFC.

TABLE II.        PAIRED T-TEST TO CHECK THE DIFFERENCE IN TRANSMISSION SPEED BEFORE AND AFTER USING VMFC

| Variable | level | Average | standard deviation | t | p-value |
|---|---|---|---|---|---|
| Speed | After using VMFC | 89.33 | 28.73 | 2.98 | 0.032 |
| | On mobile and without VMFC | 84.25 | 25.89 | | |

**(a) Mobile Internet**

**(b) Internet communication**

Fig. 5.  (a) Data transfer time delay in mobile internet. (b) Time delay of data transfer in Internet telecommunications.

Based on Eq. (1), Fig. 5(a) and 5(b) present the time costs of data transmission in two telecommunication networks and mobile internet, respectively. The transmission of huge amounts of data, including FBX that took place in Junaio had a maximum delay of about 56 seconds, roughly 10 seconds longer than the maximum delay on the mobile Internet network. This quantity becomes apparent when there are more requests made and a lot of data being transferred. The suggested architecture's maximum latency has been achieved utilizing mobile internet, roughly 23 seconds less than the maximum delay in Junaio on the same platform. This number indicates that VMFC offers greater performance than cloud servers. It demonstrates the benefits of a high-speed network for delivering superior service. Additionally, there is a very small- and acceptable-time delay in the transmission of small-volume data, including M2D. In VMFC, as opposed to Junaio, this value is ideal.

Additionally, it takes the Junaio service roughly five minutes for every request to validate, send, and get a response link for a new request from a mobile device. As a result, while employing both platforms, Junaio's average time delay is substantially higher than VMFC's. Paired t-analysis was used after using VMFC and before using it in Junaio to compare the time delay in the transmission of communications with the Internet during the execution of the program on the Junaio server and the time delay after using VMFC to see if there was a change in the amount. Has it just recently been produced? The specifics of this statistical study are shown in Table III and IV. The maximum delay in VMFC varies by roughly 18 seconds, and Table III demonstrates how the maximum delay has decreased after utilizing Junaio to 29.316 seconds and VMFC to 16.770 seconds.

With a value of (p=0.047), this reduction is likewise statistically significant. Table IV shows that there is a decrease in time delay with a value of (P=0.014) between the time delay in 4G Internet transmission while the software is running on the Junaio server and the time delay after utilizing VMFC. Table V shows a comparison of the implemented program with related programs from [29] and [27] in the cloud environment and mobile edge, respectively. The implemented program in Table V was an image-based augmented reality application. Based on the comparison table in [27], the comparison parameters are set. It is evident that the software used in the VMFC environment performs better than its equivalent program.

Additionally, study [29] performs better than study [27] since it was completed in an environment comparable to the fog, the edge environment, which has largely solved the problems associated with delay and waiting in cloud environments. The work [29] makes no mention of the adaptation time. Based on the average data collected in the evaluation section by computing the evaluation circumstances, the parameters in this table were obtained. Due to fewer time delays and faster data transfer speeds throughout, adopting fog processing services is more appropriate for delay-sensitive applications like augmented reality, as shown in Table V. For data in various quantities, this number varies. The benefit of employing fog is that it has decreased the time delay above the cloud in all stages.

Due to the significant delay and large user base, cloud-based program deployment requires a lot of parameters. Of course, the fact that we are unaware of the circumstances under which the programs in [27] and [29] execute leads to significant variation in the numbers, particularly in the value of the model detection time. On the other side, dynamic models are employed because there are more details and animation motions, which result in a larger volume and longer detection times.

*A. Energy Consumption in Mobile Fog Processing*

Due to their extensive coverage and low energy requirements, low-power technologies (LPWA) have opened the way for data storage in virtual mobile fog computing. The long-range system (LORA), which increases its effectiveness because it is a defined protocol for data transport, is one of these technologies. It gives coverage for kilometers or even more and consumes little electricity. In addition to LoRa, a number of wireless technologies, including IoT, WiFi, Zigbee, and 5G, can be employed for coverage areas. Low-cost fog processing has been accomplished using ZigBee technology. However, the wireless data transmission's effectiveness is diminished by the relatively short range of coverage (approximately 25 meters). Table VI provides a thorough comparison of the various IoT wireless network technologies (Zigbee, LoRa, NB-IoT, and 5G).

TABLE III. PAIRED T-TEST TO INVESTIGATE THE DIFFERENCE IN THE USE OF VMFC AND JUNAIO IN INTERNET TELECOMMUNICATIONS

| Variable | level | Average | standard deviation | t | p-value |
|---|---|---|---|---|---|
| Speed | After using VMFC | 16.77 | 5.57 | -2.63 | 0.047 |
| | After using Junaio | 84.25 | 29.31 | | |

TABLE IV. PAIRED T-TEST TO CHECK THE TIME DELAY DIFFERENCE IN USING VMFC AND JUNAIO IN 4G

| Variable | level | Average | standard deviation | t | p-value |
|---|---|---|---|---|---|
| Speed | After using VMFC | 22.27 | 11.21 | -3.68 | 0.014 |
| | After using Junaio | 32.66 | 18.04 | | |

TABLE V. COMPARISON OF THE PROGRAM IMPLEMENTED IN [27] AND [29] AND THE PROGRAM BASED ON VMFC (TIMES IN MILLISECONDS)

| | | Program based: | |
|---|---|---|---|
| parameters | VMFC | Cloud in [27] | Cloud in [29] |
| Early time | 1.8 | 3.1 | 2.4 |
| Time of diagnosis | 23.47 | 82.78 | 40.31 |
| Compliance time | 8 | 10 | -- |
| Similar sample | 0.7 | 1.5 | 0.85 |
| response time | 25 | - | 23 |
| Delay time | 18 | 23.22 | 18.7 |
| Loading time | 10 | 18 | 11.3 |
| loading time | 0.007 | 0.1 | -- |

The amount of energy used is examined in this part based on several parameters in this layer. The amount of time that each fog node spends processing data determines how much energy each fog node consumes. The fog node's energy usage rose along with the processing time. Thus, it can be concluded that the processing time at each fog node directly correlates with the energy usage in the fog. Consequently, as indicated by Eq. (2), we will have:

$$Em_{wi} \propto \frac{1}{\mu wi - \sum_{wh \in f} a_{whwi}} \quad \forall wi \in f \quad (2)$$

The energy relation in each fog node can be expressed as follows, using $e^f$ as the unit of energy consumption per unit of time:

$$Em_{wi} \propto \frac{1}{\mu wi - \sum_{wh \in f} a_{whwi}} \times e^f \quad (3)$$

The data rate, range, device count, number of gateways or base stations, and energy consumption of both gateways or base stations and sensors are the categories utilized to group all fog-based wireless network technologies in this work, as indicated in Table VI. According to this research, various fog-based wireless network solutions almost all consume the same amount of energy, as illustrated in Fig. 6. Zigbee only has a range of 25 meters, so deploying it in an urban setting is not the ideal option. To transmit and store data over a vast region, hundreds or thousands of gateways are required.

Since using technology to cover a large area while using the least amount of energy is the objective, as illustrated in Fig. 6, LoRa has been chosen as a fog-based wireless communication technology between IoT sensors and gateways that supports remote communication with minimal energy usage. Processing mobile fog is taken into account. In contrast to conventional cloud-based architecture, Fig. 7 compares the energy usage of various tasks in an edge-fog-cloud design. Additionally, it displays the position of each task or application inside the edge-fog-cloud architecture as well as the energy usage figures for each one separately. The findings demonstrated that the edge layer is laden with sensor jobs since it has sufficient capacity. Because the fog layer has enough resources to execute jobs like data transfer and storage, normal processing tasks are sequentially loaded into the fog. The edge and fog layers are unable to fulfill demanding processing duties, so all remaining requests are offloaded to the cloud layer. Fig. 8 compares the energy usage of mobile and fixed Internet using LoRa technology based on fog processing. The energy usage of telecom internet is superior to that of mobile internet, accounting for up to 34% of the overall electricity consumption. However, energy savings based on various wireless solutions based on fog processing range somewhat between 32.4% and 34.3%. Zigbee has higher energy savings since it uses less energy to transmit sensor data.

TABLE VI.     COMPARISON OF TECHNOLOGIES BASED ON MOBILE FOG PROCESSING

| Technologies based on mobile fog | Data Rate | Range | Device Count | Power consumption(gateway) | Power consumption(sen) |
|---|---|---|---|---|---|
| Zigbee | 240 Kb-ps | 25m | 250 [23]] | 2W [26] | 0.2W[25] |
| Lora | 60 Kb-ps | 15km | 12000 [28] | 35W [21] | 0.45W[22] |
| NBIOT | 250 Kb-ps | 25km | 56 [13] | 7421W[39] | 0.66W[38] |
| 5G | 25 Gb-ps | 30km | 1 mil. Per 2km [40] | 12500W[14] | 0.5W[23] |

Fig. 6.   Compares the energy usage of several wireless network solutions based on mobile fog processing.
Fig. 7.   Energy consumption of telecom Internet versus mobile Internet, considering LoRa technology based on mobile fog processing.

Fig. 8.   Energy saving of the proposed architecture versus the traditional cloud-based architecture, using different wireless technologies based on mobile fog processing.

## VI. CONCLUSION

The proposed method presented in this article has reduced the limitations of MCC services, including access delay, serial processing and network traffic, as well as the limitations of smart devices in running real-time programs such as augmented reality programs and programs that require. As they have more storage in the environment, it has been solved. Due

to user profile registration and encryption with digital signature, providing a unique ID for each user and software ID for each program transferred to the cloud node, using this architecture increases the security of authentication for access to resources and data. And it is not possible to reuse the unique identifier of a user by another person. The image-based augmented reality program was implemented based on the

presented method. The transfer of polygons processed on the 3D model to the screen in two modes of loading from a mobile phone and loading from VMFC was compared and it was observed that for models with a larger volume, the use of VMFC technology works faster and this is an advantage in the implementation of sensitive programs. It is delayed and immediate. Data transfer was done in two modes using Junaio and VMFC servers in two platforms, Wi-Fi internet and 4G mobile phone internet. The use of a large number of cloud nodes in mass form is necessary for a wide network of mobile devices, and this method should be able to support a large number of devices, followed by many programs, and run at an acceptable speed.

One of the limitations of this research is the small number of nodes for implementing programs, which should be resolved in future works. For future work, implementation and optimization of architecture layers to provide better and more efficient services, communication in the context of 5G networks should be given more attention, which minimizes delays.

*Abstract*—**Word embedding models have been widely used by many researchers to extract linguistic features for Natural Language Processing (NLP) tasks. However, the creation of an adequate Word embedding model depends on choosing the right language model method and architecture, in addition to fine-tuning the various parameters of the language model. Each parameter combination could result in a different model, and each model can behave differently according to the targeted NLP task. In this paper, we present an approach that combines a range of Word embedding models, multiple clustering and classification methods, and Irace for automatic algorithm configuration. The goal is to facilitate the construction of the most accurate Arabic Named Entity Recognition (NER) model for our dataset. Our approach involves the creation of different Word embedding models, the implementation of these models in different classification and clustering methods, and fine-tuning these implementations with different parameter combinations to create an Arabic NER System with the highest accuracy rate.**

*Keywords—Algorithm automatic configuration; natural language processing; named entity recognition; word embeddings; finetuning; irace*

## I. INTRODUCTION

For NLP applications like machine translation, information retrieval and sentiment analysis, it is crucial to have high-quality systems for lower tasks that return necessary features for machine learning systems [1] [2]. NER is an essential component for such tasks, its most important aspect is information extraction, and it can be carried out in two steps; the detection of the Named Entities, and the classification of these entities into a predefined set of categories (e.g., organizations, places, people, …). The term "Named Entity" was introduced during the sixth Message understanding conference [3]. The NER task was limited to the recognition of the people's names, organizations, places, temporal expressions and certain types of numerical expression [4]. These classification tags were divided afterwards into these categories: ENAMEX for people names, organizations and places, TIMEX for temporal expressions, NUMEX for numerical expression, and MISC for proper names that are not in the ENAMEX category.

NER systems utilize several linguistic features, in fact detecting these features is considered more important than the used model itself, especially when handling languages with a complex morphology like Arabic [5]. Lately, there has been a hype on using unlabeled data to learn word representation or Word Embeddings that can capture morphological, semantic and syntactic features of words, which consequently can be helpful in many learning algorithms of NLP including NER. However, there are various methods for learning Word Embeddings (e.g. Word2Vec [6], GloVe [7], FastText [8], BERT [9], ELMO [10]), and each method has many parameters that can be adjusted to create different models. Further, the machine learning algorithm that will use these Word embedding models can also have a major effect on the performance of the resulting NER system. In addition, for each model and machine learning algorithm, several training parameters can be tuned and adjusted to get more accurate results.

In this work, we adopt Irace [11] as a finetuning tool to find the most accurate NER system for our dataset. Our dataset includes two Arabic varieties: Modern Standard Arabic (MSA) and Arabic Dialects (AD) [12]. The Objective is to choose automatically one Word Embedding model from several models created using four methods (i.e., Skip-Gram, CBOW, GloVe, FastText) and one machine learning algorithm with its suitable hyperparameter combination. We use Irace to fine-tune between different created Arabic Word Embeddings, and different classification algorithms (i.e., LSTM [13], GRU [14]) and clustering algorithms (i.e., K-Mean [15], Mean-shift [16], DBSCAN [17], and Agglomerative [18]) to get the most accurate system possible for the NER task.

The rest of this paper follows this structure: Section II provides an overview of the key concepts and introduces the Irace package, a crucial component of the proposed methodology. Section III outlines the step-by-step process employed to develop the NER system. Section IV presents and analyzes the results obtained from the experiments. Finally, Section 5 concludes the work described in this paper.

## II. THE PROPOSED METHOD

In prior work [19], we have created word Embedding models with four methods (i.e. Skip-Gram, CBOW, Glove, FastText). These models were trained on three different datasets (i.e., Wikipedia, Facebook, Twitter) containing two

different Arabic varieties (i.e., MSA and Arabic Dialects). Then, we investigated the quality of the trained models using 12 hyperparameter combinations. We used different intrinsic evaluations (i.e., Word Analogy Task, Concept categorization) and different extrinsic evaluations (i.e., POS tagging, NER, Text Classification, Sentiment Analysis). In conclusion, our study raised three outcomes; The different stylistic properties of the datasets and the tuned hyper-parameters had an impact on the semantic and syntactic properties of the generated word representations and, subsequently, an impact on the NLP tasks. Further, even though the hyperparameters have a major impact on the accuracy of different NLP tasks, these changes are inconsistent and random [19].

As a consequence, we propose the solution of fine-tuning between the different hyperparameters to get the most accurate system for a specific application. Nevertheless, fine-tuning between 12 combinations to create the Word Embeddings model, and the different classification or clustering methods will be computationally expensive and time-consuming. Thus, we needed an approach that would automatically fine-tune between these hyperparameters and deduce the most accurate hyperparameter combination for a specific NLP task.

In this section, we present a detailed description of the tools that we used, afterwards in Section 3, we explain in depth the algorithms of our approach.

### A. The Irace Package

In NLP, creating an efficient system is relevant to the selection and fine-tuning of the training algorithms' parameters. In Machine Learning, this is known as the automatic algorithm's configuration. The goal is to find beneficial parameter settings to solve unseen problem instances by trying automatic learning on a set of training problem instances [11]. We opted to use the Irace package to facilitate the combined use of Word Embeddings' models and machine learning methods. Irace executes an automatic tuning of a set of parameter combinations, consequently, we avoid the manual adjusting of these parameters.

The Irace package is an R software tool that implements iterated racing procedures. It was created for the automatic configuration of optimization and decision algorithms, thus, its goal is to find the most accurate settings of an algorithm where a set of probabilities' instances is given [20],[21]. This package is suitable for our application since it can automatically configure the training algorithm where their performances depend greatly on parameter settings.

Irace deduces the most accurate algorithm configuration by implementing an elite principle on the iterated racing algorithm [20]; In the first iteration, initial algorithm configurations are randomly generated, and the best configuration is determined by a race [11]. Each configuration is evaluated on the training problem instances to set the "elite" configurations from the prior configuration iterations. Afterwards, a statistical test is used to determine the eliminated configurations once they perform worse than the other configurations. The remaining configurations will be known as the surviving configurations that will run on the next instance.

### B. The Word Embeddings Models

We opted for several Word Embeddings models using different architectures and different hyper-parameters, Table I shows the Dataset's sources and the hyperparameters used to train the models for every architecture. In prior work [19], we used a Python implementation of Word2Vec to create Skip-Gram and CBOW Word Embeddings models using Word2Vec's both architectures (i.e., Hierarchical SoftMax - HS) and Negative Sampling (NS) [22])[1]. The models were trained on four different training Arabic Datasets containing both MSA and Arabic Dialects content. We used the Glove-Python implementation to create Glove Word Embeddings models. We opted to use pre-trained word vectors created by the Facebook Artificial Intelligence Research team using Fast Text's CBOW and Skip-Gram architectures [23].

The used datasets were collected and pre-processed in prior work from different sources [24]. The first source is the online encyclopedia; Wikipedia. This corpus presents the two varieties Classical and Modern Standard Arabic. The second source is social media; Twitter and Facebook. This corpus presents the various Arabic Dialects content. The datasets were pre-processed afterwards; non-Arabic characters and diacritical marks were removed, several characters were normalized to unify the shape of some Arabic letters, and several Arabic stop words were disregarded as well [24].

### C. Machine Learning Methods

Different works have shown that the combined use of both the supervised and the unsupervised methods has a positive impact on the performance of several NLP applications [25], [26],[27]. These methods are called semi-supervised methods, where labelled and unlabeled data are used to perform certain learning tasks [28]. In our case, we harnessed large amounts of unlabeled Arabic text data and created word representations that have the potential of carrying semantic and syntactic word properties as explained in the previous section, we used relatively smaller sets of labelled data to perform the NER task as it will be explained in the next section. There is a wide range of classification and clustering algorithms that can be used as the supervised part of our application, and since we can automatically configure and fine-tune between different decision algorithms using Irace, we can utilize several algorithms. For the clustering algorithms, we chose K-mean [29], Mean-shift [16], DBSCAN [30], and Agglomerative [31]. For the classification algorithms, we chose LSTM [32] and GRU [33]. Each method had its parameters and learning activation and optimization layers that can be fine-tuned using Irace. We chose these specific machine learning algorithms since they prove to be useful for many machine learning fields other than the NLP applications like the works cited in [34], [35] and [36].

## III. METHODOLOGY

### A. NER Template

To create an NER System using Word Embeddings, we opted to use annotated existing corpora along with classification and clustering algorithms. Our NER application is performed on an annotated corpus provided by the AQMAR project [37]. This dataset was preprocessed following the steps described in Section II (B). The AQMAR dataset version that we used contains 28 articles hand-annotated to nine named entities, using the BIO system tags i.e., O (outside), B-PER (Beginning of person's entity), B-MIS (Beginning of miscellaneous' entity), B-ORG (Beginning of an organization's entity), B-LOC (Beginning of location's entity), I-PER (Inside of person's entity), I-MIS (Inside of miscellaneous' entity), I-ORG (Inside of an organization's entity), I-LOC (Inside of location's entity). Table II illustrates the statistics of the NER annotated dataset and an example of the annotated tokens.

Our NER approach is illustrated in Fig. 1. The Auto NER configuration class fine-tunes between Word Embeddings models and different machine learning algorithms. The Word Embeddings models were created using Word2Vec, Glove and FastText models. The machine learning algorithms include classification and clustering methods (i.e., LSTM, GRU, K-Means, Mean-Shift, DBSCAN, and Agglomerative).

The Autoconfiguration class calls either an implementation of LSTM networks or GRU networks as classification algorithms or an implementation of K-Means, Agglomerative, DBSCAN or Mean-Shift as clustering algorithms. These algorithms were used to compute for each word representation a score of the considered classes using the BIO system adopted in the annotated corpus. Furthermore, the dataset was split into training, validation and testing sets. The word representations of the training and validation sets were fed to the chosen classification or clustering layer, followed by a sigmoid activation layer if it was set, and complied by Adam, a stochastic Optimization layer again if they were chosen by the Auto NER configuration class of Irace. The optimization of each classification and clustering hyper-parameters is achieved by creating several hyperparameter combinations using different Word Embeddings models, then ranking the results of each NER classifier or cluster with Irace.

To start building an NER system using one of several classifications and clustering algorithms in addition to one of the Word embedding models, we created an Auto NER Configuration class. Fig. 2 illustrates the created methods for our NER Auto parametrization executable Python script[2]. This script is the input of Irace Target Runner.

The Auto parameterization class contains two major methods: 1) The first method is the prediction method. It gets the clusters' prediction using the inputs set by Irace. These inputs are the Word Embedding models and the training algorithm. The NER models are created by preparing the tokens, splitting the training document from the AQMAR dataset into validation and testing sets, and then creating the weight matrix for the words in the sets after loading the chosen Word Embedding model. After defining the training algorithm, the method calls the chosen classification, clustering or activation layer into the compiler in addition to the stochastic optimizers' epochs and batch sizes. 2) The second method calculates the accuracies of the created NER model, by predicting the probabilities of the model, reducing the probability array to speed up the compilation time, and then returning the accuracy value that will be ranked using Irace.

The main objective of Irace is to minimize the cost value returned by the target algorithm, to find the best solution. In our case, the returned cost value of the target algorithm runner is the NER model accuracies multiplied by -1 before returning it to Irace. To calculate the accuracy of each NER model which is the cost value used to find the best solution, we opted for the F1 score if it's a classification method as it was used in [38], and the purity score if it's a clustering method.

Due to the accuracy paradox, which asserts that the accuracy score is unclear when evaluating classification models, the F1 score was utilized to evaluate classification models rather than accuracy. To measure a model's performance, the F1 score uses Precision P and Recall R as shown in Eq. (1).

$$F_1 = \frac{2}{R^{-1} + P^{-1}} = 2 \cdot \frac{P \cdot R}{P + R} \qquad (1)$$

$$P = \frac{number\ of\ true\ postives}{number\ of\ true\ positives + number\ of\ false\ positives} \qquad (2)$$

---

TABLE II.        STATISTICS OF THE NER ANNOTATED CORPUS

| Number of tokens | Examples of the annotated tokens | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 57858 | ... | مرورا | بنظريات | التوحيد | الكبرى | ، | و | انتهاء | بنظرية | الأوتار | الفائقة | . | ... |
|  | ... | O | B-MIS | I-MIS | I-MIS | O | O | O | B-MIS | I-MIS | I-MIS | O | ... |

Fig. 1.   NER approach using word embeddings.

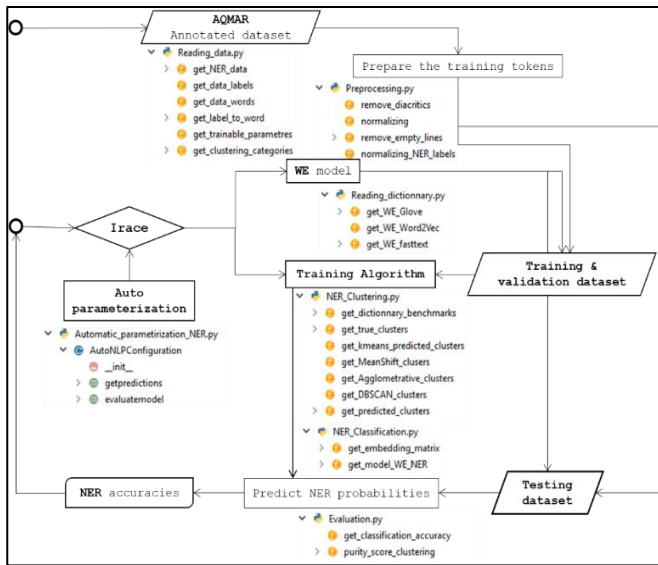

Fig. 2.   Auto NER configuration.

$$R = \frac{number\ of\ true\ postives}{number\ of\ true\ positives + number\ of\ false\ negatives} \qquad (3)$$

The purity score $purity(\Omega, \mathbb{C})$ is calculated by assigning for each cluster the most frequent class in this cluster, then the accuracy of the assigned class is measured by counting the number of the correct assigned classes and dividing it by $N$ the

number of clusters in Eq. (4). $\Omega$ presents the set of clusters, and $\mathbb{C}$ is the set of classes.

$$purity(\Omega, \mathbb{C}) = \frac{1}{N} \sum_k \max_j |\omega_k \cap c_j|$$
$$\Omega = \{\omega_1, ..., \omega_K\}, \quad \mathbb{C} = \{c_1, ..., c_J\} \qquad (4)$$

### B. Autoconfiguring NER

*1) Parameter's file.* To configure an algorithm, Irace requires a text file that contains all parameters to be tuned, including their type (categorical, ordinal, real, and integer) and sets of their possible values. The algorithm must be prepared to be configured externally with any valid parameter combination from the parameters' file. This was taken into account while creating the Auto NER Configuration class. Our parameters file contains all the parameters that can be taken by the NER auto parametrization class: Embedding file, Method, Flatten Layer, Global Average Pooling Layer, LSTM Layer, LSTM Dropout Layer, GRU Layer, GRU Dropout, GRU recurrent Dropout, Dense activation, Compile optimizer, The Number of batch size, The Number of epochs, K-Means, Mean-shift, DBSCAN or Agglomerative.

*2) Forbidden parameter combinations.* In addition to the parameters file, Irace provides the option of declaring sets of forbidden parameter combinations. For the Automatic NER parametrization class, several parameter combinations will result in a compilation error or will not be logical to compile.

There is a total of 15 forbidden parameter combinations. If the clustering method was chosen by Irace, the parameters related to the classification methods would not be finetuned, and vice versa for a classification method. Furthermore, one classification or clustering method has to be chosen to train the training weight matrix, the different dense activation and compile optimizer layers can be overlayered and fine-tuned. The rest of the forbidden parameter combinations were set to avoid error compilations.

The total number of possible parameter combinations is around 10 648 combinations, while the mean compilation time is 1.5 to 2 hours depending on the Embedding file the training method and the machine performance. To minimize the compilation time, we had to use the parallelization option offered by Python and Irace to use 23 parallel multiprocessing sessions.

## IV. RESULTS AND DISCUSSION

The objective of this experimentation is to rank the performance of the different Word embedding models, classification layers and clustering methods in an NER system. The different parameter combinations produced some impressive accuracies, while the higher accuracy being 0,9536 was achieved by training a CBOW model using an LSTM neural network, a SoftMax dense activation, and an Adam compile optimizer. Irace tuned between 1024 parameter combinations to get the best result.

To properly rank all the accuracies, we divided them into four quartiles. The first one contains the best 25% of the accuracies, the second one contains the next 25% best accuracies and so forth. Table III shows the intervals of the quartiles.

Fig. 3 illustrates the different training algorithms that achieved accuracies in the four quartiles. The first observation we can conduct from these results is that the classification algorithms outperformed the clustering ones since the best 25% of the accuracies were obtained by GRU and LSTM neural networks. In the second and third quartiles, the majority of the accuracies refer to the clustering algorithms. While the fourth quartile represents the lowest accuracies obtained by classification algorithms. From Fig. 3 (b), it's obvious that the accuracy performances of the algorithms that belong to the same category (classification or clustering) are relatively similar. So, besides the machine learning approach, the training hyperparameters could highly affect the accuracy of an algorithm.

In the previous graphs, we noticed that even though the best results ranked by Irace were obtained by the classification methods, several mediocre accuracies were also obtained by these classification methods, this can be explained by the fact that we used several layers to create the classification models. Fig. 4 and Fig. 5 illustrate the performance of LSTM and GRU layers in the four accuracy quartiles. LSTM and GRU layers performed relatively differently for both algorithms. The maximum batch size had better results for LSTM, and a minimum batch size gave better results for GRU. However, a minimum number of epochs performed better for LSTM and GRU. Furthermore, SoftMax and Sigmoid dense activations outperformed the ReLU dense activation, and the Adam optimizer architecture resulted in the majority of accuracies in the first quartile for both LSTM and GRU algorithms.

TABLE III. THE QUARTILES OF ACCURACIES

|  | Quartile 1 | Quartile 2 | Quartile 3 | Quartile 4 |
|---|---|---|---|---|
| **Max** | 0,9536773 | 0,90623109 | 0,86445103 | 0,4216347 |
| **Min** | 0,90640394 | 0,86495761 | 0,42272924 | 0,3184785 |

Fig. 3. (a) Classification vs. clustering performances. (b) The performance of all the different classification and clustering methods.

Each training algorithm resulted in both good and mediocre accuracies. Fig 6 illustrates the scale accuracies of the different training algorithms. This illustration enables us to study the distributional characteristics of the accuracy level of each algorithm. Consistently, the median of each box plot of each training algorithm is relatively the same; around 0.86 for clustering algorithms, and 0.89 for classification algorithms. The upper quartile of the clustering algorithms is around 0.93, but the lower quartile of the classification algorithms is around 0.41. The clustering algorithms, however, had an upper quartile of 0.87 but a lower quartile of just around 0.83. For GRU and LSTM, the box plots are comparatively long which means that there is a range of results that behaved differently as a result of different factors. On the contrary, for Agglomerative, K-Means, mean-shift, and DBSCAN, the box plots were significantly shorter with few outliers, which means that even though they were different factors including the Word Embeddings' models, the accuracies for clustering methods had a high level of agreement.

All of the parameters and factors that were used affect the accuracy of a model and its performance in an NLP application, thus, Irace and the use of Word Embeddings was the ideal solution to find the parameters combination that will result in the most accurate model for a NER system or any other NLP applications.

## V. Conclusion

In this paper, we have proposed a NER approach that fine-tunes between different Word Embedding models and different hyperparameters of a different machine learning algorithm to obtain the most accurate NER system. The Word Embedding models were trained on different Arabic datasets that we collected from different sources to obtain all the Arabic varieties. The NER models were obtained by training the word Embedding representations of annotated Named Entities datasets, the training algorithms included several classification and clustering methods. The Irace package served as an automatic parameter configuration and optimization solution for an Arabic NER system. We have developed a program that was fed to the Irace package, it trains the Word Embeddings representation of the annotated Named Entities according to the selected parameters combination and returns the model accuracy that was ranked by Irace. The most accurate NER model achieved an accuracy of 0.9536.

Several promising directions remain to be explored using Irace and Word Embeddings models; other uprisings Word Embeddings models like Elmo, Bert and XLNET could result in more accurate systems for NER and other NLP applications.

*Abstract*—**Agriculture significantly contributes to economic growth, generating employment opportunity also simulating the small-scale agriculture experiences. However, unforeseeable weather patterns, natural disasters, and unwelcome intruders are significant threat which brings severe financial losses for the owner. To overcome these challenges, this study aims to develop IoT-based automation greenhouse integrated with intrusion detection and prevention system. Automation greenhouse provides optimal environmental conditions for crop growth and enhances agricultural productivity, additionally inclusion of intrusion detection and prevention practices could detect and give immediate responses towards intrudes approaches. The automation greenhouse with intrusion detection and prevention with IoT-based provides the real-time monitoring and control as instant intrusion notification will be send to user through mobile application remotely. Thus, IoT-based automation greenhouse invention provides the sustainable environment condition for crop growth and reducing crop losses from treats.**

*Keywords—IoT-based; automation greenhouse intrusion detection and prevention; real-time monitoring*

## I. INTRODUCTION

Greenhouse horticulture involves a completely enclosed structure that separates the indoor environment from the external environment, creating ideal conditions for plant growth [1]. Typically, a framed structure is covered entirely with transparent cladding that allows sunlight to penetrate into the greenhouse. Prefect environmental condition accelerates the speed of plant growth, increase the crops productivity, and shorten the harvest duration also minimize the effect from pests or diseases [2]. In contrast to the traditional farming practices of ancient times, where farmers relied primarily on their experience and visual observations, modern greenhouse horticulture leverages advanced technology for precision and efficiency. Historically, the reliance on visual observations often led to inaccuracies and occasional mistakes in managing crops, which could have significant negative consequences for yields. As the global population continues to grow, so does the demand for food production. With the emergence of Industry 4.0, technologies are occupying the agriculture sector, leading to the development of IoT-based greenhouse systems. IoT-

based systems are equipped with an array of sensors and telecommunication technologies that gather data on the greenhouse's conditions. The data collected by these systems are transmitted to cloud platforms through network interconnections, where they are recorded and analyzed to improve crop productivity [3]. High-tech urban agriculture (HTUA) is an innovative solution applied in big cities like Amsterdam, where space is limited. It incorporates environment controlling systems and horticultural lighting to optimize crop growth and maximize the harvest quantity within a shorter duration. As a result, the Netherlands has become one of the world's most food-productive countries, relying heavily on exporting agricultural goods. This paper aims to explore the advantages of IoT-based greenhouse systems and HTUA in enhancing food production, sustainability, and efficiency in the agriculture sector [4], [5]. The agriculture industry has always been vulnerable to risks that can cause significant crop reduction, one of which is the intrusion of wild animals. Traditional methods of deterring such intrusions, including scarecrows and physical fences, have limitations in terms of effectiveness and cost-efficiency [6]. However, over time, birds become familiar with scarecrows and their effective-ness is reduced. The destruction caused by these animals can resulted up to a 50% loss in farmers' finances. In India, the elephant-human conflict has shown the intensity of the intrusion of wild animals, as elephants cross human habitats to raid crops, posing a menace to both lives and property [7], [8], [9]. Adding to the problem, there are also unpleasant thefts who steal valuable crops from owners and sell them for personal benefits. Some farmers resort to armed protection, but this is illegal and only limited to certain occupations such as policemen or bodyguards. In Malaysia, legally owned guns are only available to those who need to protect themselves from predators or to safeguard their property. However, it is crucial to remember that with power comes responsibility, and the intentional shooting of someone can result in strict penalties, including the death penalty. This paper aims to explore the challenges of crop protection against wild animals and theft in the agriculture industry and discuss possible solutions to mitigate these risks. Some farmers have employed a range of techniques to address these challenges. Some have turned to

wire-netting fencing, which, while providing a physical barrier, remains vulnerable to larger animals. Electric fencing, on the other hand, is an effective deterrent but has drawbacks, including high electricity consumption and the need for government approval due to wildlife regulations [10]. Conventional greenhouse agriculture struggles to maintain optimal temperature and humidity levels for plant growth during hot weather, resulting in stunted growth and plant death. Manual operation of the greenhouse makes it difficult to obtain accurate environmental parameters to support plant growth and maximize crop production. Additionally, there is a lack of security to protect against pest attacks and theft of crops by intruders, both human and wild animals. An automated greenhouse can revolutionize the monitoring and controlling management with technology, allowing for optimal environmental conditions through sensors and automatic controls while providing high-level security against crop theft and harm to young seedlings. This work aims to develop an advanced and sustainable automation greenhouse system to increase crop production while implementing an intrusion detection and prevention system to protect against attacks by wild animals and theft. The system integrates with cloud analytics to enhance traditional greenhouse technology. The adoption of this automated greenhouse with IoT technology holds the potential to revolutionize crop productivity in the agriculture sector, allowing for remote monitoring and control through a dedicated mobile application. [11], [12], [13]. Motivated by the merits of greenhouse horticulture automation with crop protection this paper presents a laser fence mechanism, alarming system, and automation gate for intrusion detection and prevention. The installation of a laser fence intrusion detection system will enhance security by alerting researchers of any intrusion into the greenhouse. Additionally, an automated gate will respond accordingly to ensure the safety and security of the greenhouse. The Blynk application and ThingSpeak cloud database provide real-time monitoring and control of the greenhouse environment, while weather condition monitoring, internet speed, and accuracy of intrusion detection were analyzed and tested. The study successfully provided an efficient solution to maximize crop production and ensure crop safety against natural disasters and unauthorized access.

The remainder of this paper shall be arranged in the following manner: Section II will introduce related research. Our mechanism is motivated and described in Section III, followed up by related results and discussion in Section IV. Finally, in Section V, we will conclude the paper and outline potential areas of future research.

## II. RELATED WORK

According to [14], automated greenhouse systems are crucial for efficiently controlling the climate and other environmental conditions within greenhouses. With the world's increasing population, the need for sustainable food production has become a significant concern. These systems often rely on microcontrollers, such as the Atmega328, as their central control units. These automated greenhouse systems are equipped with various sensors, including temperature, soil moisture, humidity, and light sensors. These sensors work together to create and maintain optimal growing conditions for plants. The microcontroller collects data from these sensors and, based on predefined threshold values, generates digital commands to control temperature, humidity, water valves, and even trigger light-dependent resistors (LDRs) when necessary. In [15], an Automatic Watering System based on Arduino was developed to address the challenge of controlling the precise amount of water needed for plant growth. The system utilizes a soil moisture sensor to detect the moisture level in soil and automatically irrigate the plant according to its demand. The sprinkler system determines the watering progress based on the received moisture level with-out any human intervention. According to [16], an automation irrigation project has been developed based on the readings from a soil moisture sensor. The Arduino microcontroller is used to control all the devices connected to the system. A drip irrigation system is used to efficiently water plants through narrow tubes and valves, and a Liquid Crystal Display (LCD) displays the moisture level of the soil. The relay module is used to turn ON and OFF the water pump based on the voltage readings received by the microcontroller, which is in turn based on the moisture level of the soil. According to the book by [17], an Internet of Things (IoT)-based system for greenhouse farming using Arduino and an ESP8266 module. This project aims to control and monitor environmental parameters within a greenhouse where Aloe Vera crops are cultivated. The system is integrated with the Blynk application via cloud computing, enabling remote access to greenhouse conditions. This IoT-based approach demonstrates the potential for technology to enhance and modernize greenhouse farming. In this paper, the authors describe a monitoring and controlling system for a greenhouse. The system collects data from various sensors, such as water, humidity, light, and temperature sensors, and sends the information to a base station, which is essentially a microcontroller circuit. The base station then stabilizes the environmental parameters to maintain optimal growing conditions inside the greenhouse. Actuators such as pumps, light bulbs, and fans are used to control the various environmental parameters.

The use of Internet of Things (IoT) technology in greenhouse cultivation has led to significant improvements in microclimate control and data sharing, as well as long-term artificial light source utilization. According to [18], precision technology in advanced greenhouses provides optimal plant growth conditions and increased productivity. Wireless Sensor Networks (WSN) plays a crucial role in these systems, enabling real-time monitoring of climate conditions and remote control. Commercial greenhouses now integrate communication devices, mobile applications, and decision support systems, leading to improved crop condition optimization and predictive capabilities. The paper discusses the importance of microclimate control in greenhouse cultivation and the use of sensor nodes for data collection. To create the perfect environment for plant growth, the microcontroller system regulates temperature, humidity, and light intensity within the greenhouse. Precision irrigation and temperature-humidity control are common techniques utilized in greenhouse cultivation, and the sensor nodes are used to measure moisture levels in the soil for a consistent watering process. The dynamic monitoring system is used to measure the environment conditions and synchronize the approaches to

maintain the greenhouse microclimate. The Internet of Things has significantly improved management systems in greenhouses, but challenges arise when network connections vary in strength, affecting the accuracy of information and system response time. However, according to a study by [19], the Internet of Things in Greenhouse Farming is a viable solution to the food crisis, as it enables the maintenance of optimal environment conditions for plant growth and protection from harsh outdoor conditions.

In a study by [20], a remote monitoring system for greenhouse environment parameters was developed using the NodeMCU ESP 8266 Microcontroller and Blynk Application. Components such as DHT11, light sensor, and TDS sensor were integrated with an Arduino board to collect data and transmit it to a web server for precise monitoring. The system aimed to replace manual monitoring and enable more efficient control of the greenhouse environment. Similarly, [21] presents a study on dynamic monitoring and remote control in a greenhouse using the ESP8266 NodeMCU as the central unit. The system allows for real-time monitoring and control of environmental parameters such as temperature, humidity, light intensity, and moisture level using IoT technology. The collected data is sent to the cloud for storage and analysis, and users can remotely control the system through an instruction controller. The Wi-Fi network connection is established using the HTTP protocol with private API keys for data security. Overall, this project demonstrates the potential of IoT technology in improving greenhouse monitoring and management. The paper presents a greenhouse monitoring system that utilizes an Organic-Light Emitting Diode (OLED) module to display real-time parameters. The Android application Blynk enables data visualization on mobile phones via Internet of Things technology. With the NodeMCU, the system continuously sends current measurements to the cloud for remote monitoring and control. The research highlights the importance of modern technology in regulating microclimates for optimal crop growth.

An Environmental Monitoring System is proposed that utilizes the Arduino and Thing-Speak to monitor weather conditions inside a greenhouse. ThingSpeak, an open-source application and Internet of Things platform, stores and displays live data streams in the cloud, allowing for real-time analysis and interpretation. The system is designed to continuously update and transmit data from sensors to ThingSpeak for further analysis and display. In a related project, [22] developed an automatic sprinkler system for greenhouse using an Arduino microcontroller AVR Atmega328 and a soil moisture sensor. The system is connected to the ThingSpeak platform through the Internet of Things (IoT) network for real-time monitoring and control. Users can register for a new account, obtain the channel ID and Application Programming Interfaces (API) keys to access their data on ThingSpeak. Once data is collected, users can analyze it through charts and graphs presented on the platform. This automation technology is widely used for irrigation to simplify the watering process and increase crop yields. Similarly, [23] proposed a design that utilizes ThingSpeak and Arduino to automate the irrigation system in a greenhouse. The goal is to reduce water usage and prevent waste. ThingSpeak creates a channel in the cloud

platform that enables data exchange. Users can access the environment parameters in the green-house by logging into their account using the same credentials they used during registration. ESP8266 is used to establish a Wi-Fi module and link the Graphic User Interface (GUI) to the ThingSpeak database. This allows users to retrieve all the measurement parameters in the greenhouse and visualize the soil moisture values through an Android application on their electronic device.

Agriculture automation using IoT is becoming increasingly popular and the ThingSpeak platform is often used for data aggregation and visualization. As described in [24], [25], Thing-Speak serve as a database for storing and analyzing data collected from greenhouse sensors. In [26], IoT system for greenhouse automation is presented, employing an Arduino Mega microcontroller and Wi-Fi module in conjunction with ThingSpeak. This system is divided into a monitoring and control system, with real-time sensor data display and remote-control capabilities via ThingSpeak. It effectively monitors and controls various greenhouse parameters, such as temperature, soil moisture, and light intensity, using sensors and relays to trigger actions based on sensor readings. On the wildlife protection front, the study in [27] introduces the Smart Laser Fence, a non-harmful method to deter animals from protected areas using laser beams. This innovation is considered safer and more practical compared to traditional methods like chili and electric fences.

The IOT Based Security System (IBSSS) discussed in [28] supports the implementation of a laser fence as a protective boundary. The laser fence is designed to detect the presence of wild animals by using laser beams and PIR sensors placed on the opposite side of the laser source. When the connection between the laser and PIR sensor is broken, an alarming system activates. Additionally, the system includes an automatically targeted laser gun that points in the direction of the intrusion present. The laser gun uses an ultrasonic sensor fixed on a servo motor to detect the position of the intruder and fires accordingly. According to [29], an intelligent surveillance security system has been developed using a laser fence with GSM communication. The system is energy efficient, utilizing a laser beam, LDR, and mirrors to save costs. Total internal reflection of light is employed by placing two parallel mirrors and receiving incident light from the laser, creating a sub-layer with a zigzag shape. The system also features an image monitoring camera and a GSM module for network communication, notifying the user when an intrusion occurs.

The implementation of a junction box as a protection measure against wild animal intrusion is discussed in [30], [31]. An intelligent agriculture system, using the XBee networking system, is proposed to prevent crop damage. The system utilizes four laser sources placed at different angles and paired with LDR sensors, with each junction box containing a laser gun and LDR sensor. Additionally, precision agriculture techniques are employed, utilizing a smart sensor system to monitor environmental conditions and a watering system, with data transmission facilitated by a GSM module. A junction box is developed for crop field protection, utilizing a virtual fence made of laser and LDR sensors. The system uses GSM communication to send alerts to users in case of intrusion. Each

junction box contains an Arduino microcontroller, RTC, XBee communication system, laser transmitter, and LDR sensor. The RTC is used to record the time of intrusion and send it through the XBee. The virtual fence is constructed by aligning the laser and LDR sensors across different junction boxes. In [32], introduces a wireless sensor network for crop protection against animal intrusion, featuring laser emitters, PIR sensors, XBee, and an Arduino MEGA microcontroller. The system utilizes automatic intrusion detection and aims to maintain ecological balance while deterring animals from crop fields through non-harmful means.

## III. PROPOSED METHOD

In this section, we present our innovative smart greenhouse system with integrated crop protection. The flowchart illustrates the transceiver module workflow. Our advanced microclimate control involves long-distance monitoring, system configuration, and crop condition prediction via Wi-Fi connectivity. The ESP8266 acts as both transmitter and receiver, enabling real-time monitoring and remote control via the Blynk Android app. Additionally, environmental and intrusion data are continuously transmitted to the cloud for future analysis and investigation. All the environmental parameters are adjustable with the help of electronics devices to perform the prefect environmental condition for maximize the crop production. Besides, the laser fence will detect and respond when the intrusion happens. Blynk end users enable to constantly tracking the live stream parameters, receiving the intrusion notification also perform the decision making on system. The block diagram of automation greenhouse is shown in Fig. 1.

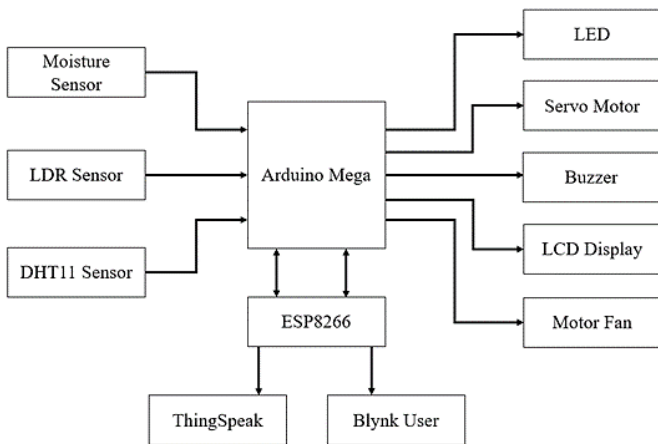

Fig. 1. Block diagram of remote monitoring greenhouse system.

The proposed system follows a structured workflow, as depicted in Fig. 1 and Fig. 2. Fig. 1 outlines the workflow for the transceiver module, which serves as a central component of the system designed for greenhouse monitoring and control. To achieve this, a network of sensors is strategically positioned within the greenhouse. These sensors include moisture sensors for soil moisture measurement, DHT11 sensors for temperature and humidity monitoring, and LDR sensors for assessing light intensity. The data gathered by these sensors is transmitted to an Arduino Mega microcontroller, which assumes the role of data processing and decision-making. Based on the collected

data, the Arduino Mega implements various solutions. For security purposes, the LDR module detects intrusions at two levels, with the red LED and buzzer activated for the first level, and the yellow LED and buzzer for the second level. The NodeMCU transceiver module enables Wi-Fi connectivity, allowing the Arduino Mega to transmit real-time data and notifications to end-users via the Blynk platform. Simultaneously, all greenhouse parameters are sent to the ThingSpeak cloud platform for aggregation over time, enabling graphical visualization and comprehensive data analysis.

The flowchart shows in Fig. 2 states the developed smart greenhouse with crop protection mechanism. In greenhouse, ventilation system functions as balancing the temperature and humidity while the moisture sensor will acts as measure also estimate the water amount in soil. Laser fence will classify the intrusion level then the intrusion prevention system will activate once the intrusion event approaches. All the environmental parameters and intrusion notification enable to view from end user by Blynk application. The details for this architecture will explained on section below.

Fig. 2. Flowchart for greenhouse horticulture automation with crops protection.

Upon conducting repeated tests, the initial circuit for the greenhouse has been assembled and is presented in Fig. 3, depicting the connections between the Arduino Mega, NodeMCU ESP8266, sensor devices, and actuators. The TX pin of NodeMCU is connected to the RX pin for Arduino Mega and TX pin of Arduino Mega is connected to the RX pin of NodeMCU so it will establish the serial communication which allows data exchange between these two devices.
Fig. 3.   Circuit design for greenhouse horticulture automation with crops protection.

## IV.   Result and Discussion

An effective automated greenhouse must meet several essential criteria, such as providing an optimal environment for crop growth, accommodating every stage of plant development, increasing yield quantity, reducing costs, and ensuring crop safety at all times. This section will describe the development of an automated greenhouse that incorporates a laser fence mechanism. The integration of sensors and actuators will also be discussed in the following section.

### A.  Hardware Implementation

The purposed automation greenhouse system functions as constantly environmental parameters up-to-do, climate control system together with crop protection mechanism. Automatic greenhouse always monitoring parameters then activates the actuators device to respond towards the sudden change in the greenhouse. Virtual laser fence mechanism can prevent the hazards from intruder also carried out the high pitch alarming system to chase away the intruder without any physical damaged towards it.

*1) Automation greenhouse with climate control capability*: The researcher employed several hardware components to construct the greenhouse system, such as Arduino Mega, NodeMCU Lua V3 ESP8266 WIFI with CH340C, LDR, LED, Buzzer, DHT11, Soil Moisture sensor, and laser diode, each with their unique function and specifications. The hardware device Arduino Mega is configured to continuously read all the real-time environmental parameters from attached sensor device includes DHT11, LDR sensor also the moisture sensor then converting all inputs into human visual. LCD display will constantly present the current reading like temperature, humidity, light intensity in greenhouse and moisture value of soil in greenhouse. NodeMCU is a powerful IoT development board based on the ESP8266 WiFi module with 128KB RAM and 4MB flash program memory. It features in-built Wi-Fi/Bluetooth, Deep Sleep mode, and CH340 USB converter

for easy installation. With 9 GPIO pins and 1 Analog input pin, NodeMCU is perfect for IoT projects. The DHT11 sensor is a reliable and accurate digital output sensor that uses a digital signal acquisition technique. It has a small size, low power consumption, and easy-to-use four-pin package. It operates on 3.5V to 5.5V with an operation current of 0.3mA. The temperature range is 0°C to 50°C, and the humidity range is 20% to 90%, with 16-bit resolution. The temperature and humidity accuracy are $\pm1˚C$ and $\pm1\%$, respectively, with anti-interference ability and long-distance signal transmission. The moisture sensor measures soil moisture by passing current through the soil via two probes, with the module calculating the water content and providing results as moisture levels. The external probe serves as a variable resistor, modifying its resistance value based on the amount of water present. Both analog and digital outputs are produced. Analog Output (A0) creates the output voltage, while digital Output (D0) digitalizes the resistance value via the LM393 High Precision Comparator on board. Low analog voltage readings indicate higher water content, while high readings indicate lower water content. The laser diode has an electrically isolated case with lead electrical connection and a high reflective index glass lens that produces long-distance beams. It can be controlled by a GPIO pin from the Arduino board and requires power input from 3.3V to 5.0V.

The ventilation system is designed to run continuously to maintain the appropriate temperature and humidity levels for plant growth. The fan speed is controlled by the DC motor's duty cycle, which varies depending on the DHT11's readings. If the temperature exceeds 35˚C or the humidity falls below 65%, the fan speed will increase to raise the duty cycle from the normal 55% to 82%. Soil moisture is crucial for healthy plant growth and must be monitored to ensure proper irrigation.

In this moisture detection mechanism, the moisture sensor will detect analog measurement and classify into three status includes wet, dry and prefect. At first, the analog measurement received more than 800 will classify as dry condition where there are lack of water in plantation area. In greenhouse, LCD display will display "Plant is too DRY" and the red LED will be triggered to notified farmer. Then, analog measurement 500 will assigned to wet condition where the planation area had too much of water. LCD display will "Plant is too WET" then blue LED triggered. Lastly, analog measurement between 501 to 799 is the prefect range of moisture value. Prefect soil condition will show the statement "Soil is PREFECT" on LCD together with triggered green LED. After then, artificial light installed become the lighting supplement for entire greenhouse in Fig. 4 and Fig. 5. The installed hardware implemented can be control by user based on Blynk application. End user can interactive with artificial light by widget button on Blynk according to user's decision. All the current greenhouse measurements and widget buttons will be displayed on Blynk Application in Fig. 6.
Fig. 4. The prototype of the greenhouse.

Fig. 5. The front view for greenhouse.

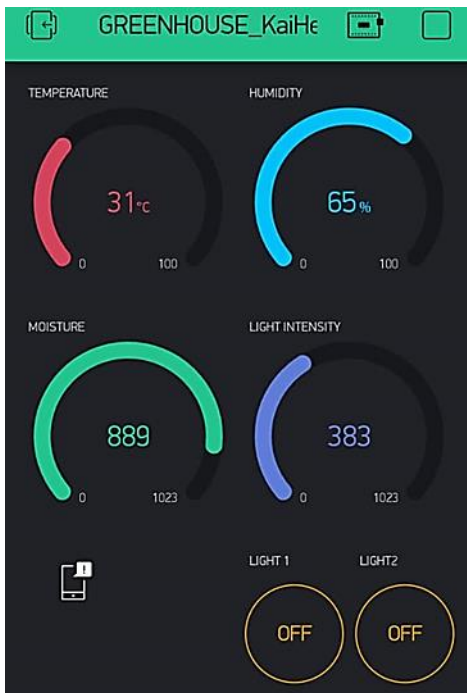

Fig. 6. Current measurement and widget button on blynk application.

## B. Software Implementation

Blynk provides server that connecting managed deployed system also enables remotely take control the internet connected electronic devices with designed widget on interface builder. In the purposed system, end user will constantly view the actual environmental parameters, enables to control artificial light source remotely also receive the intrusion notification details. Then, ThingSpeak allows the instant line graph visualizations for the posted data received. All the parameters received will recorded and displayed into line graph. Line graphs construct the time-series relating between scale object that helps to analyze the trend of read parameters over the time line.

Fig. 7. Data visualization for environmental parameters and intrusion events happens.

*1) Data analysis in thingspeak*: To analyze the data, changes in the temperature, humidity, soil moisture level, and light intensity within the greenhouse are measured over time. In Fig. 7, the selected environmental parameters of the greenhouse are displayed on specific channels on the ThingSpeak cloud service over a certain time period. The intursion event can be interpreted where intrusion status "1" indicates intrusion happens, while "0" means no intrusion. Based on Table I, the average temperature inside the greenhouse is 31 degrees Celsius, while the average humidity level is approximately 73%. Additionally, the average analog measurement for soil moisture is 569, and the light intensity

averages 547. Then, Table II express nterusion events happens on the left, main, right gate. On the figure explained there are two intrusion happen on right gate while no intrusion happen on left and main gate.

TABLE I.    MEASURING AVERAGE PARAMETERS IN A GREENHOUSE ENVIRONMENT

| SELECTED ENVIRONMENT PARAMETER | AVERAGE MEASUREMENT |
|---|---|
| HUMIDITY | 73% |
| LIGHT INTENSITY | 547 |
| TEMPERATURE | 31˚C |
| SOIL MOISTURE | 569 |

TABLE II.    INTRUSION EVENTS HAPPENS IN GREENHOUSE ALONG CERTAIN TIME PERIOD

| LASER FENCE LOCATION | INTRUSION EVENTS |
|---|---|
| LEFT GATE | 0 |
| MAIN GATE | 0 |
| RIGHT GATE | 2 |

*2) Intrusion detection and prevention mechanism*: Intrusion detection fence system built by surround the greenhouse from left, center and right. Each fence consists two pair of laser beam and LDR sensor align up and down that differentiate the intrusion level approaches based on body size of intruder in Fig. 8. At the same time, the alarming system and prevention will be activated also the end users will receive the intrusion notification from Blynk application. Blynk notification will states the information details about the actual location intrusion happens together with intrusion level involved immediately. When an intruder approaches, the system promptly detects their presence and analyses their size shown. Two intrusion levels are defined: the first for large-bodied intruders and the second for smaller ones. The detection is triggered when an intruder obstructs both the up and down laser beams and their respective LDR pairs in Fig. 10. For the first intrusion level is triggered when big body size of intruder step-into and blocked both up and down laser beam and LDR pair installed. Then, second intrusion level is triggered by smaller-bodies intruders as it only managed to block down laser beam LDR pair in greenhouse. Simultaneously, the system communicates with the Blynk application, sending out a detailed intrusion notification. This notification includes vital information about the intrusion event, such as the precise location within the greenhouse and the specific intrusion level involved. Yet, if there are no intrusion happens in greenhouse, LCD display will update the statement "GREENHOUSE IS SAFE!", intrusion prevention will not have activated also Blynk application user will not receive any notification shown in Fig. 9.

*3) A comparison of results obtained on-site and via the blynk application*: In this section, we will be comparing the results obtained on-site with those obtained via the Blynk Application at the same time. The LDR sensor is utilized to

measure any intrusion events, and the NodeMCU is responsible for transmitting the intrusion event to the Blynk Application. The application displays the notification details regarding the level and location of the intrusion. Three scenarios were tested to determine whether they can trigger notifications on the Blynk mobile application simultaneously. Referring to Fig. 11, it is observed that no intrusion event occurred in the greenhouse, and consequently, no notification was displayed on the Blynk application. Fig. 12 and Fig. 13 illustrate that intrusions occurred in the greenhouse. However, in the second test, the first level of intrusion was detected, and in the third test, the second level of intrusion was detected. Table III describes the intrusion events that occurred and the corresponding Blynk application notifications. Then, Table IV shows the status of the automation gate along with the occurrence of intrusion events. Therefore, the comparison between the on-site intrusion events and the notification results on the Blynk Application display accurate and real-time information about the intrusion events that occur.

Fig. 8.    The position of the laser fence at the left, main, and right gate.

Fig. 9.    The display statement that no intrusion happen in greenhouse.

Fig. 10.  The approach of a large intruder towards the left gate.
Fig. 11. First test in main gate.

Fig. 12. Second test in main gate.

Fig. 13. Third test in main gate.

TABLE III. COMPARISON RESULT BASED ON INTRUSION EVENT AND BLYNK APPLICATION DISPLAYED

| LASER FENCE AT MAIN GATE | SITUATION | | NOTIFICATION DETAILS DISPLAYED ON BLYNK APPLICATION |
|---|---|---|---|
| | FIRST INTRUSION LEVEL | SECOND INTRUSION LEVEL | |
| FIRST TEST | NO | NO | NO |
| SECOND TEST | YES | NO | YES |
| THIRD TEST | NO | YES | YES |

TABLE IV. COMPARISON RESULT BASED ON INTRUSION EVENT AND AUTOMATION GATE STATUS

| LASER FENCE AT MAIN GATE | SITUATION | | AUTOMATION GATE TURNING DOWN |
|---|---|---|---|
| | FIRST INTRUSION LEVEL | SECOND INTRUSION LEVEL | |
| FIRST TEST | NO | NO | NO |
| SECOND TEST | YES | NO | YES |
| THIRD TEST | NO | YES | YES |

*4) Comparison with internet speed and performance of automation greenhouse*: In this section, the performance of the greenhouse system will be evaluated. The time taken for the system to respond was observed by comparing the internet

speed and NodeMCU's time response to receive an instruction. Internet speeds of 10.1 Mbps, 20.0 Mbps, 45.7 Mbps, and 98.9 Mbps were selected for this testing section shown in Fig. 14.

Fig. 14. Results of internet speed testing.

Fig. 15. The time taken for activates LIGHT1.

Fig. 16. The time taken for activates LIGHT2.

Fig. 17. The time taken for activates both LIGHT1 and LIGHT2.

TABLE V. AVERAGE ACTIVATION TIME FOR LIGHT1

| INTERNET SPEED (MBPS) | AVERAGE TIME RESPONSE (S) |
|---|---|
| 10.1 | 2.67 |
| 20.0 | 2.18 |
| 45.7 | 1.69 |
| 98.9 | 0.67 |

TABLE VI. AVERAGE ACTIVATION TIME FOR LIGHT2

| INTERNET SPEED (MBPS) | AVERAGE TIME RESPONSE (S) |
|---|---|
| 10.1 | 2.85 |
| 20.0 | 2.57 |
| 45.7 | 2.10 |
| 98.9 | 1.10 |

TABLE VII. AVERAGE ACTIVATION TIME FOR BOTH LIGHT1 AND LIGHT2

| INTERNET SPEED (MBPS) | AVERAGE TIME RESPONSE (S) |
|---|---|
| 10.1 | 3.04 |
| 20.0 | 2.75 |
| 45.7 | 2.20 |
| 98.9 | 0.79 |

Fig. 15, 16, and 17 depict the response time of the NodeMCU to receive a signal in relation to the internet speed. Five tests were conducted under three different scenarios, each with varying internet speeds. After analyzing the results, the average response time for different internet speeds, including 10.1 Mbps, 20.0 Mbps, 42.7 Mbps, and 98.9 Mbps, was calculated and recorded in Tables V, VI, and VII based on the respective event situations. Table V presents the average response time required to activate only LIGHT1, with the highest response time recorded at 10.1 Mbps internet speed, which took 2.67 seconds. The next highest response time was recorded at 20.0 Mbps, taking 2.18 seconds, followed by 45.7 Mbps at 1.69 seconds. The lowest response time was recorded at 98.9 Mbps, which took only 0.67 seconds. Then, Table VIdisplays the average time response, indicating that the shortest response time was observed for internet speed 98.9 Mbps, with 1.01 seconds, followed by internet speed 10.1 Mbps with 2.85 seconds, internet speed 20.0 Mbps with 2.57 seconds, and internet speed 45.7 Mbps with 2.10 seconds. Other than that, Table VII displays the average time required to activate both LIGHT1 and LIGHT2. The shortest time taken was observed with an internet speed of 98.9 Mbps, which was 0.79 seconds. This was followed by 10.1 Mbps, which took 3.04 seconds, internet speed 20.0 Mbps, which took 2.75 seconds, and internet speed 45.7 Mbps, which took 2.20 seconds. Thus, the finding in graphs and table provides evidence that the higher of internet speed the shorter time taken to response.

## V. CONCLUSIONS

The greenhouse automation with crops protection prototype underwent both hardware and software testing to ensure its proper implementation. The hardware component was used to measure and provide information about environmental parameters and intrusion notifications to enhance plant growth and improve crop security. The Blynk mobile application served as an interface for users, while ThingSpeak acted as the cloud database that collected and displayed all the recorded data over time. The automated greenhouse is designed to mimic the real-time conditions of a greenhouse by maintaining suitable environmental conditions automatically. Users can remotely view, control, and receive intrusion alerts via the Blynk Application. The protection system for this automated greenhouse includes a laser fence, an alarming system, and an automated gate. The laser fence is used to detect any unauthorized encounters and estimate the body size and level of danger of approaching objects. Upon detection of intrusion events, the alarming system buzzer will be activated and the automation gate will be automatically closed. The triggered alarm serves to deter intruders and notify the relevant authorities of the threat of intrusion. The automation gate, when closed, protects the crops from damage or theft by unauthorized persons. Once intrusion event happens, the Blynk end user will immediately receive the intrusion notification with details like intrusion event location together with intrusion level involved.

Furthermore, the analysis of the weather condition in the automation greenhouse was conducted, and the average results were tabulated. Additionally, the performance of the greenhouse was tested by comparing the average time taken at different internet speeds. As fast internet speed, al-lows the actuators to perform quickly respond onto the unexpected change in greenhouse. However, there remains a research gap related to the long-term performance and reliability of the system. Future studies should explore the system's performance over multiple growing seasons to assess its durability, adaptability to changing environmental conditions, and overall reliability in real-world agricultural settings. The results indicate that higher internet speeds lead to shorter response times and increased accuracy. Additionally, the accuracy of the laser fence was investigated, and it was found that the notifications displayed on the Blynk application were exactly the same as the on-site situation. Blynk end user straight away received current intrusion event together with intrusion information details regardless of location or time periods. At the end, all objectives of this purposed system had achieved successfully. Researcher enable to prove previous discussed research paper which mention automation greenhouse enable to solve traditional farming issues, enhancing the quality and quantity of crops which simulate the sales practically. As well, laser fence mechanism is the best choice in term of cost-efficiency, generate incomes also humane.

The proposed automation system for greenhouses with crop protection holds immense potential for commercialization within the agricultural and floral industries. In an era where these sectors are under increasing pressure to deliver high yields and exceptional quality, this innovative solution offers a multitude of benefits. Firstly, it promises to significantly boost production by optimizing critical growth conditions, including temperature, humidity, and lighting. This enhanced control not only results in higher crop yields but also ensures the consistency and quality demanded by these industries. Additionally, the system contributes to cost savings, as it minimizes labor requirements and reduces resource wastage. Moreover, it mitigates the need for excessive pesticide and chemical treatments, not only saving on costs but also aligning with environmentally sustainable practices. Ultimately, the primary goal of this proposed work is to maximize crop productivity while increasing the income of the agriculture industry, making it an enticing prospect for commercialization.

# Reinforcement Learning-based Answer Selection with Class Imbalance Handling and Efficient Differential Evolution Initialization

Jia Wei

College of Education Science, Bohai University
Jinzhou 121000, Liaoning, China

*Abstract*—Answer selection (AS) involves the task of selecting the best answer from a given list of potential options. Current methods commonly approach the AS problem as a binary classification task, using pairs of positive and negative samples. However, the number of negative samples is usually much larger than the positive ones, resulting in a class imbalance. Training on imbalanced data can negatively impact classifier performance. To address this issue, a novel reinforcement learning-based technique is proposed in this study. In this approach, the AS problem is formulated as a sequence of sequential decisions, where an agent classifies each received instance and receives a reward at each step. To handle the class imbalance, the reward assigned to the majority class is lower than that for the minority class. The parameters of the policy are initialized using an improved Differential Evolution (DE) technique. To enhance the efficiency of the DE algorithm, a novel cluster-based mutation operator is introduced. This operator utilizes the K-means clustering approach to identify the winning cluster and employs an upgrade strategy to incorporate potentially viable solutions into the existing population. For word embedding, the DistilBERT model is utilized, which reduces the size of the BERT (Bidirectional encoder representations from transformers) model by 40% and improves computational efficiency by running 60% faster. Despite the decrease, the DistilBERT model maintains 97% of its language comprehension abilities by utilizing knowledge distillation in the pretraining phase. Extensive experiments are carried out on LegalQA, TrecQA, and WikiQA datasets to assess the suggested model. The outcomes showcase the superiority of the proposed model over existing techniques in the domain of AS.

*Keywords*—*Answer selection; imbalanced classification; reinforcement learning; DistilBERT; differential evolution*

## I. INTRODUCTION

Question Answering (QA) systems, a notable application within natural language processing (NLP) and artificial intelligence (AI), facilitate enhanced human-computer interaction by efficiently processing expansive data and information. Two dominant strategies for developing QA systems include the deployment of Generative Adversarial Networks (GANs) [1] and the utilization of AS techniques. While GANs can generate rich and varied responses, their application comes with challenges related to ensuring grammatical and semantic accuracy in answers. In contrast, AS focuses on meticulously selecting the most apt response from a set of potential answers to a given query, taking into account

the inherent variability and complexity of language and potential multiple suitable responses, thereby finding extensive application in various domains including machine comprehension [2]. Both methodologies bring their respective benefits and limitations, influencing their applicability in different use-cases within the broader QA landscape.

Conventional and deep learning techniques offer various methods for AS according to existing literature [3]. While traditional models, like those based on information retrieval, handcrafted rules [4], and machine learning (ML) methods [5] provide certain utilities, they also exhibit limitations in semantic understanding and generalization due to reliance on keywords, manual features, or rigid rules. SVM classifiers within ML approaches have been utilized to connect AS pairs through editing distance and implied matches, yet traditional ML methods often neglect semantic data and demonstrate confined generalizing capacity. Deep learning methods leverage LSTM or CNN architectures to extract semantic features, utilizing their ability to gauge semantic similarity between questions and answers [6]. CNNs model hierarchical sentence structures, while LSTMs ensure representations contain coherent and pertinent information [7]. Notwithstanding their advancements, deep learning models still face challenges in encapsulating comprehensive semantic relationships between questions and answers. To address this, new models, like BERT, harness next-word/phrase prediction and masked word prediction to assimilate complex linguistic relations, outperforming previous models and widely impacting the NLP field [8].

The success of deep algorithms relies heavily on factors like architecture, learning method, and training features, making network design a sophisticated optimization task. Various researchers [9] have addressed this by training neural networks with fixed topologies using several optimization approaches, such as tabu search, ant colony optimization, genetic algorithm, and simulated annealing [10]. Critical to deep models' performance is the optimization of parameter sets, heavily influenced by their initialization [11]. While gradient descent algorithms like Backpropagation (BP) and Levenberg-Marquardt (LM) [12] have been utilized for weight optimization in deep learning methods for AS, their sensitivity to initial weights may lead to local optimum issues. Addressing this, Pretraining weights using Population-based Meta-Heuristic algorithms (PBMH) [13], [14] like DE [15], which incorporates mutation, crossover, and selection steps, has

proven effective for optimizing learning processes by avoiding local minima and ensuring generation of potentially promising solutions [16], [17].

Furthermore, while BERT has established its dominance in NLP tasks due to its deep architecture and ability to capture bidirectional contexts in textual data, its complexity often renders it computationally expensive, especially for real-time applications. Recognizing this challenge, researchers introduced DistilBERT, a distilled version of BERT. The principle behind DistilBERT lies in the concept of knowledge distillation. This technique involves training a smaller model, in this case, DistilBERT, to mimic the behavior and performance of its larger counterpart, BERT. By transferring the knowledge from the cumbersome BERT model to the more lightweight DistilBERT, there is a significant reduction in model size—about 40% smaller than BERT [18]. Notably, despite this reduction, DistilBERT retains a substantial portion of BERT's language comprehension capabilities, making it an efficient alternative for applications demanding both speed and accuracy.

The proposed AS methods utilize binary classifications defined in positive-negative pairs, presenting challenges due to data imbalances as the positive class tends to be smaller than the negative class. This imbalance can degrade model performance but can be addressed through data-level and algorithm-level approaches. Data-level strategies manipulate training data distribution via over/under-sampling of classes, using methods like Synthetic Minority Over-sampling Technique (SMOTE) [19] for creating new samples, and Near Miss [20] for under-sampling by randomly removing samples from the larger class. While under-sampling can omit valuable data, over-sampling might increase over-fitting risk. Algorithmic-level strategies emphasize minority classes through ensemble learning, decision threshold changes, and cost-sensitive learning, which penalizes misclassification of minority class samples. Ensemble learning, in particular, leverages majority voting among multiple classifiers. Additionally, Deep RL has shown promise in various [21] and can manage data imbalance by assigning higher rewards to minority classes in its reward functions [22].

In the realm of AI-driven AS, a pertinent inquiry often raised revolves around the possibility of artificial intelligence (AI) providing a singular, definitive answer. Traditional AS models, by design, sift through potential options to select the most fitting response. However, the rapidly evolving nature of AI and its profound capabilities in understanding intricate data patterns pose a thought-provoking question: can a sophisticated model predict just one conclusive answer, thereby eliminating the need for answer selection? In such a scenario, the fundamental nature of AS would undergo a paradigm shift. The model presented in this paper, with its intricate interplay of RL, DistilBERT word embedding, and enhanced DE, is primarily designed to make the most informed choice from a range of potential answers. While our model showcases efficacy in the AS paradigm, it's worth considering its adaptability in a landscape where AI's aim shifts towards forecasting a singular, precise answer. This perspective not only paves the way for further enhancements to the existing AS models but also encourages a rethinking of AI role in QA systems.

The work introduces an AS model that integrates RL, DistilBERT word embedding, and an enhanced DE method. The model employs two attention-mechanism-based LSTM networks and a feed-forward network, focusing on learning both positive and negative question-answer pairs, utilizing DistilBERT for semantic matching without pre-engineered features. An improved DE algorithm navigates the search space to apply BP algorithms in LSTMs and feed-forward networks, using a selective mutation operator and a novel updating strategy to generate candidate solutions. RL addresses data imbalance in the BP step by treating as a sequential decision-making process. The agent uses environment states for training examples to classify and earn rewards based on correct/incorrect classifications, favoring minority groups in the reward system. The efficacy of the method is demonstrated on three benchmark datasets: TrecQA, LegalQA, and WikiQA, showing superiority over existing models.

Our primary contributions are as follows:

- The adoption of DistilBERT, the state-of-the-art language representation model, for the purpose of attaining sophisticated word embedding, which aims to enrich the semantic understanding of financial texts.

- The introduction of a novel model grounded in RL designed specifically to navigate and mitigate the challenges presented by data imbalance, thereby enhancing the reliability and robustness of the analysis.

- The deployment of an advanced DE algorithm for the crucial task of weight initialization, which is anticipated to augment the predictive accuracy and computational efficiency of the proposed model.

The remaining sections of this article are organized as follows. In Section II, a summary of the relevant work is provided; in Section III, the required background is presented; in Section IV, the structure of the proposed model is described; and in Section V, evaluation metrics, data sets, and results are provided. In Section VI, the study concludes by detailing the lessons learnt and suggesting further work.

## II. RELATED WORK

The early studies on AS marked the initial attempts to tackle the task using feature engineering techniques. These methods, such as counting common words, Bag-of-phrases, and Bag-of-grams, provided a basic understanding of the structure and content of questions and answers [23]. However, their reliance on surface-level features limited their ability to capture the deeper semantic nuances inherent in natural language. Recognizing the need to overcome this limitation, subsequent research endeavors delved into more sophisticated approaches for AS. Linguistic tools like WordNet emerged as valuable resources for incorporating semantic knowledge into the selection process [24]. WordNet enabled researchers to enrich the analysis of questions and answers by considering the meanings and associations conveyed by individual words.

Furthermore, researchers sought to exploit the syntactic structure of sentences to enhance AS performance. Techniques like dependency tree analysis and tree distance processing algorithms were employed to capture the relationships between

words and their syntactic roles within a sentence. By considering the hierarchical structure and dependencies encoded in these linguistic representations, researchers aimed to gain deeper insights into the meaning and coherence of questions and answers, enabling more effective selection algorithms. The incorporation of semantic and syntactic analysis in AS research represented a significant shift towards a more comprehensive understanding of language. These approaches recognized that the success of answer selection lies not only in surface-level matching but also in capturing the underlying meaning and context conveyed by questions and answers. As a result, the field witnessed the emergence of more sophisticated methods that combined linguistic tools, syntactic analysis, and semantic knowledge to improve the accuracy and relevance of answer selection algorithms.

In recent years, deep learning models have emerged as powerful tools for AS, leveraging automated feature extraction capabilities to improve performance and enhance the understanding of question-answer pairs [25], [26]. When searching using question-answer pairs, researchers have explored two main approaches. The first approach involves calculating distinct elements in the Q&A pair, with deep networks generating independent representation vectors for questions and answers. To measure the interdependence between these vectors, various criteria have been employed, enabling the comparison and similarity assessment of question-answer pairs [25], [26]. For instance, Wang and Jiang proposed a comparative model that incorporates multiple indicators to measure similarity, taking into account different aspects of the question-answer relationship [25]. Similarly, Yun et al. showcased the advantages of language-based models, utilizing the language model Elmo to capture contextual information and semantic meaning in the question-answer pairs [26]. The second approach treats the query and answer as standalone sentences, allowing researchers to employ specific techniques for their analysis. Severin and Moschitti utilized CNNs to assess the similarity between question-answer pairs, exploiting the local dependencies and patterns within the sentences [27]. On the other hand, Van and Newberg utilized bidirectional LSTM networks, which consider the embedding of words in both directions to capture the contextual information of the question and answer [28]. The resulting relation between the answer and the question is fed into a feed-forward network for further processing and classification. Siamese Networks have also gained popularity in QA tasks, providing separate representation vectors for questions and answers [29], [30]. These networks enable the comparison of the similarity or dissimilarity between question-answer pairs by computing the distance or similarity metrics in the learned feature space. For instance, Yu et al. proposed a deep learning model for AS tasks, employing CNNs and logistic regression to capture the relevant features for answer selection [29]. Similarly, Dryer et al. implemented a similar approach using CNNs and distributed vector representations, enabling the model to learn more nuanced features for question-and-answer representation [30]. To further enhance candidate response selection, researchers have explored pre-processing operations. One such operation involves fixing named entities with unique tokens, simplifying the selection process and enabling better identification of potentially correct answers [31], [32]. This pre-processing step

can help alleviate the challenges posed by named entities and improve the accuracy of answer selection. In addition to pre-processing, attention mechanisms have emerged as a valuable strategy in AS research. Initially introduced for machine translation, attention methods have found applications in QA tasks [33]–[35]. These mechanisms allow the model to focus on the most relevant parts of the question and answer by considering the contextual interplay between them. Researchers, such as Jan et al., have proposed using Recurrent Neural Networks (RNNs) with attention mechanisms for response selection, effectively capturing the informative parts of the question-answer pairs [33]. Tay et al. suggested bidirectional alignment and a generalized method based on RNNs further to improve the attention mechanism's performance [34]. Additionally, He et al. demonstrated that combining CNNs with attentional mechanisms can lead to improved performance compared to using RNNs alone [35]. Knowledge-based approaches have also been explored, aiming to leverage external knowledge sources to enhance answer selection. Shen et al. developed a knowledge-based approach that utilizes an attentive bidirectional LSTM network combined with a knowledge graph (KG) to represent questions and answers, enabling the model to leverage structured knowledge to enhance the understanding and selection process [36]. Other techniques have addressed specific challenges in AS, such as data imbalance. Researchers have utilized separate LSTM networks for questions and answers, followed by a Multi-Layer Perceptron (MLP) network for classification, and incorporated per-class penalties to tackle data imbalance and improve classification performance [37]. Matsubara et al. utilized a search engine and a transformer model to select the correct answer, employing models like Jaccard Similarity and Compare Aggregate to assess the relevance of question responses [38]. Furthermore, Kim et al. proposed an architecture based on proximity reference, using an attention mechanism to retain information and automatic encoders better to reduce the information volume, enhancing the model's efficiency and effectiveness [39]. The recent advancements in deep learning models for AS have showcased the versatility and power of these approaches in capturing the complex relationships and semantics present in question-answer pairs. By leveraging techniques such as attention mechanisms, linguistic tools, knowledge graphs, and pre-processing operations, researchers have made significant strides in improving AS performance, ultimately enabling more accurate and relevant answer selection.

Despite the advantages of automatic feature extraction in deep models for AS, there are still several challenges that affect their performance. Typically, these models employ random weight initialization and are trained using the backpropagation BP algorithm to avoid local optima. However, they face difficulties in learning binary classification tasks, particularly when dealing with imbalanced datasets in the context of AS.

## III. BACKGROUND

In this section, the prerequisites required to study the rest of the paper are briefly reviewed.

## A. Long Short-Term Memory (LSTM)

The LSTM framework, initially brought forward by Hochreiter and Schmidhuber [40], signifies a category of neural structure specifically formulated to proficiently manage the interrelationships within a chain of elements that don't possess a fixed length. The innovative structural design makes it distinctive from conventional neural structures by integrating a storage component within its concealed layer, granting it the capability to comprehend relationships within chains that extend beyond immediate surroundings. This feature equips LSTMs with a particular competence in modelling and interpreting extended dependencies. At the heart of the LSTM architecture is storage elements designed to retain and modify data over a period. This storage unit is made of three critical constituents, often referred to as controllers: the ingress controller ($i_t$), the oblivion controller ($f_t$), and the egress controller ($o_t$). These controllers manage the stream of data within the LSTM unit, facilitating accurate regulation of what data is conserved, disregarded, and exported. The ingress controller ($i_t$) establishes the extent to which fresh data is incorporated into the storage unit. It considers the present ingress ($x_t$) and the preceding state of the storage unit ($h_{t-1}$), and grounded on their interaction, resolves which data is pertinent to refresh the unit state. The oblivion controller oversees the volume of data preserved in the storage unit from the preceding moment. It assesses the current ingress and the preceding storage unit state and resolves what data should be forgotten or discarded from the unit. The egress controller establishes the volume of data from the storage unit that is passed to the egress and influences the concealed state of the LSTM. The egress controller considers the current ingress and the refreshed storage unit state and decides what data should be communicated as the egress. Through the amalgamation of these controllers, the LSTM network can selectively preserve and refresh data over time, equipping it to comprehend both short-term and extended dependencies within sequences. This ability to comprehend and retain pertinent data at appropriate time steps makes LSTMs remarkably competent in an array of assignments such as linguistic processing, speech recognition, and time series prediction.

Mathematically, the LSTM equations can be defined as follows:

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i) \qquad (1)$$

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f) \qquad (2)$$

$$c_t = f_t c_{t-1} + i_t \tanh(W_j x_t + U_j h_{t-1} + b_j) \qquad (3)$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o) \qquad (4)$$

$$h_t = o_t \tanh(c_t) \qquad (5)$$

A bidirectional LSTM (BLSTM) extends an LSTM network to process input from both sides. This can be useful in AS since the answer may be generated by moving the words in the question. In a BLSTM network, the state vectors $\overrightarrow{h_t}$ and $\overleftarrow{h_t}$ are generated by parsing the input and combining them as $h_t = [\overrightarrow{h_t}, \overleftarrow{h_t}]$. LSTM and BLSTM networks treat all the input samples equally important, leading to network confusion. To cope with this problem, an attention mechanism can be considered. To this end, each state $h_t$ is accompanied by the coefficient $\alpha_t$ so the final state $h$ for a sequence of length $T$ is computed as:

$$h_t = \sum_{t=1}^{T} \alpha_t h_t \qquad (6)$$

## B. Differential Evolution

Differential evolution (DE) [41] has gained widespread recognition as a powerful population-based method capable of effectively solving a wide range of optimization problems [42] DE operates through three essential operations: mutation, crossover, and selection. The DE algorithm commences by initializing a population, usually obtained by sampling from a uniform distribution. This population serves as the foundation for the subsequent evolutionary process. The mutation operator plays a pivotal role in DE, as it generates a mutation vector that introduces diversity and exploration into the population. Through the mutation process, new candidate solutions are created by perturbing the existing individuals in the population. This perturbation is achieved by combining the information from multiple individuals and forming a new candidate solution, often through vector arithmetic operations. The mutation operator in DE typically involves randomly selecting a set of individuals from the population and using their information to compute the mutation vector. This is accomplished by multiplying the difference between two randomly selected individuals by a scaling factor and adding it to a base individual. The resulting mutation vector represents a potential new solution that explores the search space in an attempt to discover better regions of the optimization landscape. The mutation operator in DE plays a crucial role in maintaining population diversity and facilitating exploration. By introducing novel solutions, DE can effectively navigate the optimization landscape and overcome local optima. The quality and diversity of the mutation vector greatly influence the overall performance of DE and its ability to converge to an optimal solution.

The following is the mutation operator that creates a mutation vector:

$$\vec{v}_{i,g} = \vec{x}_{r_1,g} + F\,(\vec{x}_{r_2,g} - \vec{x}_{r_3,g}) \qquad (7)$$

where, $\vec{x}_{r_1,g}$, $\vec{x}_{r_2,g}$ and $\vec{x}_{r_3}$ three distinctive candidate solutions are randomly chosen from the current population, and $F$ is a scale factor.

Mutant and target vectors are combined during the crossover. This can be done using the well-known Binomial crossover:

$$u_{i,j,g} = \begin{cases} v_{i,j,g} & \text{if rand}(0,1) \leq \text{ CR or j } = j_{rand} \\ x_{i,j,g} & \text{otherwise} \end{cases} \qquad (8)$$

where, $CR$ is the crossover ratio, $j_{rand}$ is a random number selected from $\{1,2,\ldots,D\}$ and $D$ is the dimensionality of a candidate solution. After performing crossover, the selection operator selects the target and trial vectors' best solution.

## IV. PROPOSED MODEL

Fig. 1 depicts the general framework of the suggested technique. Pre-processing, word embedding, and prediction are the three key stages of the proposed technique. As a

preliminary stage, unnecessary words and symbols are eliminated. Using DistilBERT, the embedding vector of each word is retrieved in the second stage, and the similarity between the two sentences is predicted. The suggested method employs a clustering-based differential evolution technique to determine the initial seeds of the network weights, while the RL-based algorithm is used to address the class imbalance.

### A. Pre-Processing

Pre-processing is a vital part of any NLP system because the essential characters, words, and sentences identified in this stage are passed to the later stages. Therefore, the pre-processing output has a significant impact on the quality of the final results.

Common stop-word elimination and stemming techniques are employed in the approach. Stop words are part of sentences that can be regarded as overhead. The most common stop words are articles, prepositions, pronouns, etc. They should thus be removed as they cannot function as keywords. For decreasing the dimensionality of the term space, stemming is used to identify the stem of a word. For instance, the terms 'go', 'went', 'going', 'watcher', etc., all can be stemmed from the word "watch". Stemming removes ambiguity and reduces the number of words, time and memory requirements.

### B. Word Embedding

Word embedding is used in deep learning algorithms to compare words with semantic vectors. The best technique to produce accurate context-based representations of highlighted words is to insert words.

Many experiments determine the most effective approach to represent words in neural network models. Recently, predefined language models (PLM), previous natural language information boxes, and tuning have been widely used for NLP activities. PLM models frequently use unlabeled data to learn about the model's parameters.

In this article, DistilBERT is considered as one of the newer methods of the PLM model for word input. DistilBERT is an interactive language model designed on large data sets, such as Wikipedia, in order to produce contextual representations. It is common practice to fine-tune the linear layers of DistilBERT for addressing different classification tasks. Some configuration tools teach classification tasks by extracting semantics from common semantic problems or contexts. Models other than DistilBERT build one-directional embeddings which ignore contextual differences. On the contrary, DistilBERT utilizes a bidirectional transformer by conditioning its representations on the left and right context simultaneously.

### C. Prediction

Our predictive model comprises two attention-based BLSTMs and one feed-forward network. The two BLSTMs extract embeddings for the question and response sentences. The feed-forward network predicts the degree to which two sentences are similar. Consider $Q = (w_1, w_2, \ldots, w_n)$ and $A = (v_1, v_2, \ldots, v_m)$, where $w_i$ and $v_i$ represent the $i$-th word in the question and response, respectively.

Because of the length restriction in BLSTM, $Q$ and $A$ can include only $n$ and $m$ words, respectively (in this work, $n = m$). After feeding $Q$ and $A$ into their respective BLSTMs, the attention mechanism computes their embeddings in the following manner:

$$q = \sum_{i=1}^{n} \alpha_i h_{q_i} \quad (9)$$

$$r = \sum_{i=1}^{m} \beta_i h_{r_i} \quad (10)$$

where, $h_{q_i} = [\overleftarrow{h}_{q_i}, \overrightarrow{h}_{q_i}]$ and $h_{r_i} = [\overleftarrow{h}_{r_i}, \overrightarrow{h}_{r_i}]$ represent the $i$-th hidden vectors in the BLSTM, and $\alpha_i, \beta_i \in [0,1]$ are the $i$-th attention weights for each unit in the BLSTM, calculated as:

$$\alpha_i = \frac{e^{u_i}}{\sum_{j=1}^{n} e^{u_j}} \quad (11)$$

$$\beta_i = \frac{e^{v_i}}{\sum_{j=1}^{m} e^{v_j}} \quad (12)$$

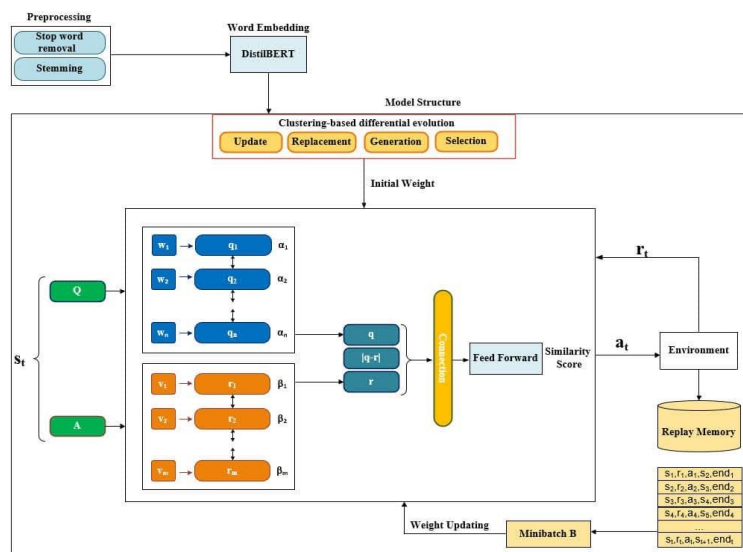

Fig. 1. Overall structure of the proposed model.

$$u_i = tanh(W_u h_{sou_i} + b_u) \qquad (13)$$

$$v_i = tanh(W_v h_{sus_i} + b_v) \qquad (14)$$

where, $W_u$, $W_v$, $b_u$ and $b_v$ are the trainable parameters. As shown in Fig 1, the input of the feed-forward network is the connection of $q$ , $r$ , and $|q - r|$ . The training dataset comprises pairs of positive and negative values. Each positive pair comprises a question and its proper response. Each pair of negatives comprises a question and an improper response. Two training phases comprise the model: pretraining and fine-tuning. During pretraining, the augmented differential evolution algorithm is used to determine the optimal initial weights. The initial weights for the fine-tuning phase are the weights obtained during the pretraining phase.

*1) Pretraining*: The weights of the LSTM, the attention mechanism, and the feed-forward neural network are initialized at this stage. To achieve this, an improved differential evolution method is introduced, incorporating a clustering scheme and a novel fitness function. A clustering-based mutation and update technique is used in the changed DE algorithm to boost the optimization efficiency.

A promising region of the search space is distinguished by the suggested mutation operator, which was inspired by [40]. The k-means clustering algorithm does this by dividing the current set $P$ into $k$ clusters, each representing a distinct region of the search space. The number of clusters was picked at random from $[2, \sqrt{N}]$ . The cluster with the lowest sample means the fit is selected as the optimal group.

The proposed clustering-based mutation is defined as:

$$\overrightarrow{v^{clu}_\iota} = \overrightarrow{win}_g + F \left( \vec{x}_{r_1,g} - \vec{x}_{r_2,g} \right) \qquad (15)$$

where, $\overrightarrow{win}_g$ is the most acceptable solution in the promising region, and $\vec{x}_{r_1,g}$ and $\vec{x}_{r_2,g}$ are two randomly determined candidate solutions from the current population. It should be noted that $\overrightarrow{win}_g$ is not always the population's most acceptable solution. The clustering-based mutation procedure is implemented $M$ times.

The current population is updated when $M$ new solutions have been provoked through clustering-based mutation. The steps are as follows:

- Selection: Generate $k$ individuals randomly as initial seeds of the $k$-means algorithm;

- Generation: Generate $M$ solutions using clustering-based mutation as set $v^{clu}$;

- Replacement: Choose $M$ solutions at random and determine as $B$;

- Update: The best $M$ solutions from the $v^{clu} \cup B$ determined as the $B'$. The new population is afterwards calculated as $(P - B) \cup B'$.

The fundamental structure of the proposed model comprises two LSTM networks with their respective attention mechanisms and a feed-forward network. As depicted in Fig. 2, in the proposed DE algorithm, all weights and bias terms are organized into a vector to generate a candidate solution.

To assess the quality of a candidate solution, the fitness function is defined as:

$$Fitness = \frac{1}{\sum_{i=1}^{N}(y_i - \tilde{y}_i)^2} \qquad (16)$$

where, $T$ is the total number of training samples, $y_i$ is the $i$-th desired target, and $\tilde{y}_i$ is model prediction.

*2) Classification*: An RL-based algorithm is employed to tackle the imbalance problem caused by varying data volumes in the classes. Each question-and-answer pair in the training dataset makes up a state of the environment, and the network is the agent that performs a sequence of classifications on all pairs. When the agent predicts the class label of a pair, it is taking an action: the pair seen at the $t^{th}$ time-step is the state $s_t$ , and the classification performed is $a_t$ . In return, the environment provides a reward, $r_t$, to guide the agent. Reward values are assigned such that classifying a sample from the majority class garners a lower absolute value compared to the minority class. The reward function is:

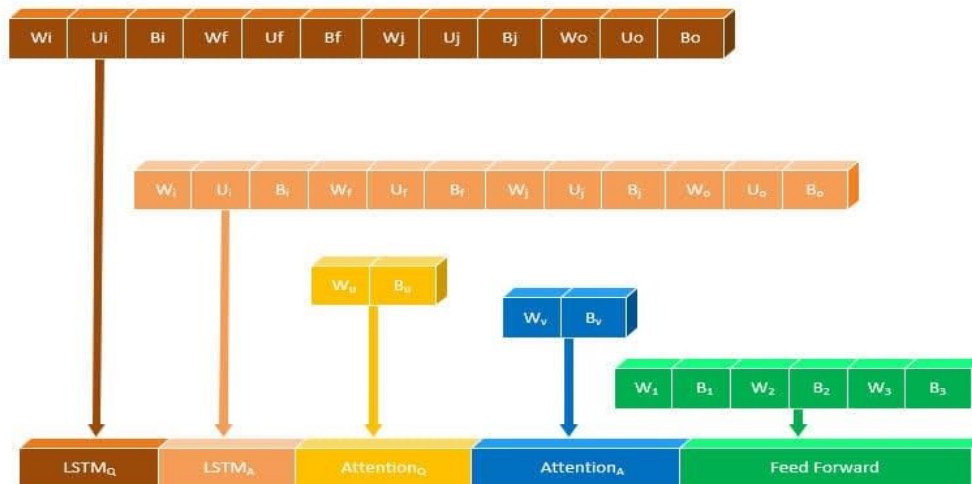

Fig. 2.     Encoding strategy in the proposed algorithm.

$$(s_t, a_t, l_t) = \begin{cases} +1 \,, a_t = l_t \text{ and } s_t \in D_P \\ -1 \,, a_t \neq l_t \text{ and } s_t \in D_P \\ \lambda \,, a_t = l_t \text{ and } s_t \in D_N \\ -\lambda \,, a_t \neq l_t \text{ and } s_t \in D_N \end{cases} \quad (17)$$

where, $D_P$ and $D_N$ are the means of the minority and majority classes, respectively. Correct/incorrect classification of a sample from the majority class yields a reward of $+\lambda / -\lambda$, where $0 < \lambda < 1$.

The agent's objective in deep Q-learning is action selection such that the sum of discounted future rewards ($R_t$) are maximized:

$$R_t = \sum_{t'=t}^{T} \gamma^{t'-t} r_{t'} \quad (18)$$

where, $\gamma$ is the discount factor, $r_{t'}$ is the immediate reward at time step $t'$, and $T$ is the last time-step of the episode. Using $\gamma$, more importance is given to rewards in the near future (closer to the current time step $t$) compared to the distant future. Each episode is terminated if all of the samples are classified correctly or at least one sample from the minority class is misclassified. The expected return of taking action $a$ in state $s$ at time step $t$ and following policy $\pi$ afterwards is computed as:

$$Q^\pi(s, a) = E[R_t | s_t = s, a_t = a, \pi] \quad (19)$$

where, $Q^\pi(s, a)$ is called the action-value function. At each state $s$, the optimal action is the one that maximizes the action-value function:

$$Q^*(s, a) = max_\pi E[R_t | s_t = s, a_t = a, \pi] \quad (20)$$

where, maximization is taken over all possible policies, the recursive form of equation 20 can be written as:

$$Q^*(s, a) = E[r + \gamma \, max_{a'} Q^*(s', a') | s_t = s, a_t = a] \quad (21)$$

The best action-value function can be estimated iteratively using the Bellman equation:

$$Q_{i+1}(s, a) = E[r + \gamma \, max_{a'} Q_i(s', a') | s_t = s, a_t = a] \quad (22)$$

During training, upon observing state $s$, the policy network outputs action $a$. After executing this action, the environment returns a reward $r$, and the next state becomes $s'$. The tuple $(s, a, r, s')$ is then saved into the replay memory $M$. Minibatches $B$ of these tuples are drawn randomly from the replay memory, which is used to update the network parameters via gradient descent. The update is done based on the following loss function:

$$L_i(\theta_i) = \sum_{(s,a,r,s') \in B} (y - Q(s, a; \theta_i))^2 \quad (23)$$

where, $\theta_i$ is the network parameters at $i$-th training iteration, and $y$ is the estimated target for the $Q$ function. The desired target $y$ is equal to the immediate reward for the state-action pair plus the discounted maximum future Q value:

$$y = r + \gamma \, max_{a'} Q(s', a'; \theta_{k-1}) \quad (24)$$

For terminal states, $y$ is equal to $r$. At $ith$ iteration, the gradient of the loss function is calculated as follows:

$$\nabla_{\theta_i} L(\theta_i) = -2 \sum_{(s,a,r,s') \in B} (y - Q(s, a; \theta_i)) \nabla_{\theta_i} Q(s, a; \theta_i) \quad (25)$$

The network weights are updated using the gradient of loss function computed as follows:

$$\theta_{i+1} = \theta_i + \alpha \nabla_{\theta_i} Q(s, a; \theta_i) \quad (26)$$

where, $\alpha$ is the learning rate.

## V. EXPERIMENTAL RESULTS

In this section, the conducted experiments are detailed.

### A. Datasets

The following three benchmark databases are used during the experiments (see Table I for their statistics):

- TrecQA [43] is taken from the TREC trace dataset. Yao et al. [44] used two training datasets, TRAIN, and TRAIN-ALL, to construct an extended set of positive and negative pairs. The soundness of answers in the TRAIN-ALL dataset is verified automatically by matching pairs with regular expressions. The TRAIN, DEV, and TEST data set' responses were all manually assessed. To teach the model, the TRAIN-ALL set is utilized.

- LegalQA [45] is a database of legal question-and-answer submissions from the Chinese community. Inquiries were answered online by a licensed attorney. The four fields that make up LegalQA are Question Title, Question Text, Answer, and Label. A straight line designates real positive couples.

- A Wikipedia page that is regarded as a subject of the year is linked to each question in the open-source quality assurance dataset known as WikiQA. [46]. To avoid ambiguity in the answer sentences, all the answers at the bottom of the page are the candidates' answers.

### B. Metrics

According to earlier research, the most popular reference points for the answer-selection task are MAP and MRR [47]. MAP evaluates the capacity to categorize responses and return solutions. If a high score match is found, the MRR is repeated. The average accuracy is derived using the Mean Average Precision (MAP) findings:

TABLE I. STATISTICAL INFORMATION FROM THE LEGALQA, TRECQA AND WIKIQA DATASETS

| dataset | Question | | | QA pairs | | | Correct | | |
|---------|----------|-----|------|----------|-----|------|---------|------|------|
| | train | dev | test | train | dev | test | train | dev | test |
| LegalQA | 10,526 | 1,593 | 3,035 | 100,590 | 11,965 | 26,913 | 21.8 | 24.4 | 22.9 |
| TracQA | 1,229 | 82 | 100 | 53,417 | 1,148 | 1,517 | 12.0 | 19.3 | 18.7 |
| WikiQA | 873 | 126 | 243 | 20,360 | 1,130 | 2,352 | 12.0 | 12.4 | 12.5 |

$$MAP(Q) = \frac{1}{|Q|}\sum_{i=1}^{|Q|}\frac{1}{n_i}\sum_{j=1}^{n_i} Precision\ (R_{ij}) \quad (27)$$

where, $Q$ is the questions set, $n_i$ is the number of relevant answers to $i$-th question, and $R_{ij}$ is the set of j best candidates selected from the $n_i$ available answers. The position of the first correct response is used to determine the Mean Reciprocal Rank (MRR) calculated as follows:

$$MRR\ (Q) = \frac{1}{|Q|}\sum_{i=1}^{|Q|}\frac{1}{r_i} \quad (28)$$

where, $r_i$ denotes the first response's placement for $i$-th question. Details of model

The experiments were implemented using Python and PyTorch. For natural language processing in Python, the NLTK package was leveraged. A two-layer LSTM with a hidden size of 64 was employed. Also, because there are connections between the vectors in the two LSTM networks, the batch must be normalized before it is sent to the feed-forward neural network. The tests were conducted using a computer with 64 GB Memory, a 64-bit Windows operating system, and a graphics processing unit (GPU). The most effective models for LegalQA, TrecQA, and WikiQA were identified after 50, 60, and 100 epochs. For the three datasets, training took 5, 20, and 60 hours, respectively.

*C. Model Performance*

First, the system was tested against nine deep learning-based strategies, including KABLSTM [48], EATS [49], AM-BLSTM [50], BERT-Base [51], DRCN [52], P-CNN [53], DARCNN [54], DASL [55], IKAAS [56]. The outcomes for the three datasets—LegalQA, TrecQA, and WikiQA—are presented in Table II. All the trials were carried out five times to avoid the randomness of heuristic algorithms influencing the

findings. Results using random weight initialization (Proposed (no RL and DE)), enhanced DE (Proposed (no RL)), RL use (Proposed (no DE)), and the entire model are shown for the suggested method (Proposed).

Table III displays the extent to which the proposed method outperforms other methods. The proposed model consistently demonstrates a significant advantage over other widely-recognized methods in the domain. When examining the MRR and MAP metrics specifically for the LegalQA dataset, the proposed model exhibits enhancements ranging from +0.077 to +0.231, with the most pronounced improvement observed against the DARCNN method. This consistent performance is evident across all datasets, underscoring the robustness and adaptability of the proposed approach. Notably, even the variants of the proposed model, such as "Proposed (no RL and DE)" and "Proposed (no RL)", consistently outpace most other techniques. These modified versions, despite lacking certain features, still deliver commendable results, emphasizing the intrinsic strength of the primary model. An intriguing point is the comparison between the BERT-Base and its more streamlined version, DistilBERT. While BERT-Base stands as a powerful model in the NLP realm, the margin table shows that the approach of the proposed model surpasses it, attesting to the innovative methods integrated into the new model. Addressing Imbalance: The performances of models like P-CNN and DARCNN, especially the substantial gains in specific metrics such as +0.285 for TrecQA (MRR) and +0.231 for LegalQA (MRR), shed light on the challenges presented by data imbalance in the AS domain. The resilience and adaptability of the proposed model to such challenges, coupled with its ability to deliver top-notch results, underscore its potential in addressing imbalanced datasets effectively.

TABLE II. PERFORMANCE COMPARISON OF THE PROPOSED MODEL WITH THOSE ALREADY IN USE ON THREE DATASETS: RESULTS USING THE DAG MARKER WERE FOUND IN EARLIER STUDIES

| Method | LegalQA | | TrecQA | | WikiQA | |

*1) Comparison with other metaheuristics*: In this section, a variety of meta-heuristic optimization algorithms are compared to the enhanced DE algorithm. To do this, a variety of meta-heuristics are employed while maintaining the integrity of the other model elements, such as pre-processing, word embedding, LSTM, network structure, and RL, in order to gain the initial model parameters. Eight different algorithms, including (standard) DE [57], grey wolf optimization (GWO) [58], bat algorithm (BA) [59], dragonfly algorithm (DA) [47], salp swarm algorithm (SSA) [60], cuckoo optimization algorithm (COA) [61], human mental search (HMS) [40], whale optimization algorithm (WOA) [62], and artificial bee colony (ABC) [63] are investigated.

The overall size of all algorithms and their predicted capacities were calculated to be 150 and 4,000, respectively. In Table IV, the default settings can be observed. Table V displays the findings for each of the three data sets. On every dataset, the suggested DE algorithm performs better than any other algorithm, as shown. Normal DE is the runner-up.

TABLE IV.    SETTING PARAMETERS FOR META-HEURISTICS

| algorithm | parameter | value |
|---|---|---|
| DE | scaling factor | 0.4 |
| | crossover probability | 0.7 |
| BAT | loudness update constant | 0.60 |
| | emission rate update constant | 0.50 |
| | initial pulse emission rate | 0.001 |
| COA | alien solutions discovery rate | 0.25 |
| HMS | Maximum mental processes | 5 |
| | C | 1 |
| | loudness update constant | 0.50 |
| WOA | b | 1 |
| ABC | limit | ne× dimensionality |
| | no | 50% of the colony |
| | ne | 50% of the colony |
| | ns | 1 |

TABLE V.    RESULTS OF META-HEURISTIC ALGORITHMS ON THE DATASETS FROM LEGALQA, TRECQA, AND WIKIQA

| Method | LegalQA | | TrecQA | | WikiQA | |
|---|---|---|---|---|---|---|
| | *MRR* | *MAP* | *MRR* | *MAP* | *MRR* | *MAP* |
| DE | $0.915 \pm 0.019$ | $0.933 \pm 0.015$ | $0.890 \pm 0.046$ | $0.916 \pm 0.191$ | $0.872 \pm 0.036$ | $0.911 \pm 0.009$ |
| GWO | $0.774 \pm 0.116$ | $0.771 \pm 0.090$ | $0.741 \pm 0.075$ | $0.783 \pm 0.134$ | $0.742 \pm 0.038$ | $0.771 \pm 0.016$ |
| BAT | $0.855 \pm 0.013$ | $0.809 \pm 0.028$ | $0.867 \pm 0.088$ | $0.874 \pm 0.295$ | $0.842 \pm 0.071$ | $0.863 \pm 0.090$ |
| DA | $0.809 \pm 0.085$ | $0.819 \pm 0.039$ | $0.859 \pm 0.015$ | $0.876 \pm 0.053$ | $0.816 \pm 0.090$ | $0.850 \pm 0.083$ |
| SSA | $0.739 \pm 0.030$ | $0.756 \pm 0.081$ | $0.745 \pm 0.082$ | $0.756 \pm 0.017$ | $0.739 \pm 0.053$ | $0.753 \pm 0.023$ |
| COA | $0.857 \pm 0.091$ | $0.883 \pm 0.015$ | $0.880 \pm 0.073$ | $0.895 \pm 0.249$ | $0.870 \pm 0.013$ | $0.860 \pm 0.019$ |
| HMS | $0.841 \pm 0.010$ | $0.875 \pm 0.193$ | $0.875 \pm 0.018$ | $0.890 \pm 0.047$ | $0.837 \pm 0.159$ | $0.863 \pm 0.159$ |
| WOA | $0.752 \pm 0.016$ | $0.753 \pm 0.027$ | $0.769 \pm 0.05$ | $0.789 \pm 0.085$ | $0.731 \pm 0.000$ | $0.760 \pm 0.018$ |
| ABC | $0.873 \pm 0.014$ | $0.896 \pm 0.038$ | $0.875 \pm 0.025$ | $0.889 \pm 0.015$ | $0.872 \pm 0.020$ | $0.881 \pm 0.010$ |

*2) Reward function*: The reward function directs the agent toward achieving its aim by giving the right ratings to certain activities. ±1 and ±$\lambda$ were selected as the rewards for the minority and majority classes, respectively. The ratio of the sample size of the majority class to the minority class determines the $\lambda$ value. As the majority/minority ratio rises, the $\lambda$ value decreases. The majority class bonus is held constant, and $\lambda$ is chosen from the set {0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1} to see how changing $\lambda$ affects the reward earned by the model. The evaluation findings for the three datasets are displayed in Fig. 3. The reward plots in Fig. 3(a), Fig. 3(b), and Fig. 3(c) all have an ascending trend for $\lambda < 0.4$ and a decreasing trend for $\lambda > 0.4$. The relevance of majority classes is disregarded for $\lambda = 0$, while for $\lambda = 1$, both classes are regarded as equally significant. Even though the minority is more important to us, the impact of the majority should not be ignored.

*3) Examples*: A qualitative example is provided to evaluate the efficacy of RL in the model, focusing on the question "Who is the president or chief executive of Amtrak?" from the TrecQA dataset. The results of the top five answers

retrieved by the model with and without using RL are shown in Fig. 4. As seen, models without RL are more likely to select negative answers. The model with RL gives the highest possible score for answering the question.Word embeddings.

In this section, performing the DistilBERT adopted in the method for word embedding is compared against five other word embedding methods. One-Hot Encoding [64] creates binary properties for each class and assigns values to the properties in each instance that corresponds to a specific class. CBOW and Skip-gram [65] use neural networks to compare words with insertion vectors. GloVe [66] is an unattended learning algorithm implemented for full word set statistics. FastText [67] [65] extends the Skip-gram model, in which each word is represented by an n-gram character instead of learning a vector for words. Table VI shows the results of the conducted experiment. As expected, One-Hot cryptography has the lowest performance among the evaluated methods. CBOW and Skip-gram perform similarly, and both yield better performance compared to GloVe, while FastText gives better results. However, the best performance is claimed by the DistilBERT model, which is the motivation behind its use in the approach.

Fig. 3. Reward vs. $\lambda$ for (a) LegalQA dataset, (b) TrecQA dataset, and (c) WikiQA dataset.

| Rank | Ranked answers w/o RL | Ranked answers by RL |
|------|----------------------|----------------------|
| 1 | **george warrington**, amtrak's president, said ridership was up because service was better and because" the marketplace is feeling increasingly frustrated with the alternatives, " namely jammed highways and delayed airplanes. | "long-term success here has to do with doing it right, getting it right and increasing market share, "said **george warrington**, amtrak's president and chief executive. |
| 2 | amtrak president **george warrington** said settling out-of-court was the right thing to do. | amtrak president **george warrington** said settling out-of-court was the right thing to do. |
| 3 | amtrak is offering a deal it hopes few travelers can resist: get good service or a free ride. | amtrak president **george warrington** told the committee that the railway expects delivery next week of the first of 20 high-speed trains for the boston -to- washington northeast corridor. |
| 4 | amtrak spokesman john wolf estimated that only one out of every 1,000 passengers will request a refund voucher. | "amtrak is committed to treating all employees fairly, "amtrak president **george warrington** said in a statement. |
| 5 | amtrak president **george warrington** told the committee that the railway expects delivery next week of the first of 20 high-speed trains for the boston-to-washington northeast corridor. | **george warrington**, amtrak's president, said ridership was up because service was better and because" the marketplace is feeling increasingly frustrated with the alternatives," namely jammed highways and delayed airplanes. |

Fig. 4. " Who is the president or CEO?" This table shows the top 5 answers for models with and without RL. " George Warrington" is the field answer, and the underlined word refers to that term.

TABLE VI.    RESULTS OF DIFFERENT WORD EMBEDDINGS ON THE THREE DATASETS

| Word embedding | LegalQA | | TrecQA | | WikiQA | |

*4) Discussion*: The proposed model in this study addressed the class imbalance issue in AS by employing a reinforcement learning-based technique. Unlike traditional methods that treat it as a binary classification problem, the proposed approach formulated it as a sequence of sequential decisions. An agent classified each instance and received a reward at each step. To handle class imbalance, the reward assigned to the majority class was intentionally lower than that for the minority class. The parameters of the policy were initialized using an improved DE technique. To improve the efficiency of the DE algorithm, a novel cluster-based mutation operator was introduced. This operator utilized the K-means clustering approach to identify the winning cluster and incorporated potentially viable solutions into the existing population. In terms of word embedding, the model employed the DistilBERT model, which reduced the size of the BERT model. To evaluate the effectiveness of the proposed model, extensive experiments were conducted using LegalQA, TrecQA, and WikiQA datasets. The results demonstrated the superiority of the proposed model compared to existing methods in the field of answer selection. However, it is important to acknowledge certain limitations of the proposed model, which can be considered in future work:

*a) Limited Scope*: While the article introduces a novel reinforcement learning-based technique to address class imbalance in AS, it is important to acknowledge that class imbalance is a widely recognized challenge in machine learning, and various approaches have been proposed in the literature. A more comprehensive discussion that explores alternative methods, such as data resampling techniques (e.g., oversampling, under sampling), cost-sensitive learning, or ensemble-based methods, would provide a broader perspective on addressing the class imbalance in AS tasks. Comparing the proposed technique with these alternative approaches in terms of effectiveness and applicability would enhance the understanding of its limitations and potential alternatives.

*b) Lack of Real-World Application*: The evaluation of the proposed model on LegalQA, TrecQA, and WikiQA datasets provides insights into its performance within specific domains. However, it is important to recognize that these datasets might not fully capture the complexities and variations present in real-world AS scenarios. To overcome this limitation, future research should consider evaluating the proposed technique on diverse datasets from different domains, such as medical, finance, or customer support, to assess its generalizability and robustness across various real-world applications. This would provide a more comprehensive

understanding of the technique's effectiveness and limitations in practical settings.

*c) Performance Metrics and Statistical Significance*: While the article claims superiority over existing methods, it is essential to provide a detailed analysis of the performance metrics used for evaluation. Precision, recall, F1-score, and other relevant metrics should be reported, along with the corresponding confidence intervals or statistical tests, to establish the statistical significance of the results. A thorough analysis of these metrics would provide a clearer understanding of the proposed technique's performance and its potential limitations in different AS scenarios.

*d) Computational Efficiency*: While the utilization of the DistilBERT model is mentioned to enhance computational efficiency, it would be beneficial to provide more specific details about the computational resources required by the proposed technique. Comparing the computational requirements, such as memory usage and processing time, with other state-of-the-art AS methods would allow for a more comprehensive assessment. Additionally, considering the scalability of the technique for larger datasets or real-time applications would provide insights into its feasibility and practical utility in various contexts.

*e) Interpretability and Explainability*: The article lacks discussion on the interpretability and explainability of the proposed technique. In AS tasks, understanding the decision-making process and providing explanations for selected answers are important factors for trust and transparency. Discussing methods or approaches used to interpret and explain the decisions made by the reinforcement learning-based model would enhance its applicability in real-world scenarios. Consideration of techniques like attention mechanisms or post-hoc interpretability methods (e.g., LIME, SHAP) would provide insights into the reasoning behind answer selections and potential biases or limitations associated with the model's decisions.

*f) User Feedback and Adaptability*: The article does not discuss the potential for incorporating user feedback or adapting the AS system over time. AS models that can learn from user interactions, such as reinforcement learning with online learning or active learning approaches, have the potential to improve their performance based on user preferences and changing information needs. Investigating the integration of user feedback and methods for continuous adaptation would be valuable for enhancing the proposed technique's effectiveness and user satisfaction.

*g) Comparison with Human Performance*: The article focuses on comparing the proposed model with existing methods, but it does not include a comparison with human

performance. AS tasks often involve subjective judgments, and comparing the performance of the proposed technique with human experts or crowd-sourced annotations can provide valuable insights into the model's strengths and limitations. Conducting experiments that involve human evaluations would help contextualize the performance of the proposed technique and highlight areas where further improvements are needed.

*h) Ensuring Data Quality and Model Performance*: Another aspect warranting discussion is the challenge of recognizing datasets that may potentially misguide the classifier. Any model's efficiency is contingent upon the quality and reliability of its training data. Datasets that contain noisy, inconsistent, or unrepresentative samples can induce biases in the model, leading to flawed predictions. Regular monitoring of performance metrics on validation sets can provide early indications of a model being misguided by its data. A substantial divergence between training and validation performance may hint towards potential dataset issues. Tools like ChatGPT and other advanced language models can offer benefits in this scenario. These models, with their vast training on diverse textual data, can be harnessed to validate the coherence and authenticity of data samples. For instance, they could generate synthetic samples for augmentation, thereby balancing datasets and mitigating risks. They can also be employed to highlight potential anomalies or inconsistencies within a dataset, aiding in its refinement and preprocessing. In future studies, integrating insights from these tools could be an invaluable step for data validation, ensuring models are trained on high-quality, representative datasets.

## VI. CONCLUSION

In this paper, an approach for efficient AS is proposed, which employs enhanced DE algorithms for pretraining and RL for instructing the BP algorithm. The method is based on LSTM with an attention mechanism and DistilBERT word embedding. The proposed model categorizes both positive and negative classes and comprises pairs of positive inquiries and detailed responses. Because the dataset contains many negative pairs, the proposed model produces an unbalanced classification. To address this issue, the approach is framed as a logical decision-making process. Correct classification of minority samples is rewarded with higher values at each episode step than the correct classification of the majority samples. Each episode is repeated until a minority sample is misclassified or all samples are correctly classified. The policy weights were initialized using an improved DE algorithm. The improved DE algorithm clusters the current population and finds promising regions in the search space using a new upgrade strategy. The evaluation of the proposed method was conducted using the LegalQA, TrecQA, and WikiQA datasets, demonstrating its superior performance compared to other methods.

In addition to the proposed classification approach, there are several promising avenues for future research in the field of Natural Language Processing (NLP). One area of interest is exploring the utility of the proposed approach in various NLP applications beyond answer selection. By applying the same reinforcement learning-based technique to tasks such as sentiment analysis, text summarization, or named entity recognition, Insights into the effectiveness and generalizability across different domains can be gained through the study.

Another promising direction for future research is the provision of candidate answers to given questions. While the proposed approach focuses on selecting the best answer from a given list of options, the generation of candidate answers could further enhance the AS process. One potential approach to generating candidate answers is through the use of Generative Adversarial Networks (GANs). GANs have shown promise in generating realistic and coherent text, and their application in generating diverse and plausible candidate answers could greatly enrich the AS process. Further investigation into the integration of GANs with the proposed classification approach could lead to more comprehensive and accurate answer selection systems.

# Evaluation Method of Physical Education Students' Mental Health based on Multi-source and Heterogeneous Data

YongCheng WU

Anhui Technical College of Mechanical and Electrical Engineering, Anhui Wuhu, 241000, China

*Abstract*—To enhance the ability to evaluate the mental health status of physical education students, a method of evaluating the mental well-being state of physical education students based on multi-source heterogeneous data mining is proposed. A fuzzy information detection model of multi-source heterogeneous data on the mental health status of physical education students is constructed, with four factors as dependent variables: compulsion, interpersonal sensitivity, hostility, and depression. Combined with the hierarchical index parameter detection and analysis method, the statistical analysis of multi-source heterogeneous info is accomplished. Based on the factor extraction outcomes of multi-source heterogeneous info, combined with the subspace heterogeneous fusion method, an estimated parameter feature clustering model is established. Combining the results of characteristic distributed clustering and linear regression analysis, the psychological well-being state evaluation of physical education students is realized. The results of empirical analysis show that this method has higher accuracy and better feature resolution in the evaluation of the mental well-being state of physical education students, which improves the reliability and confidence level of the assessment of the mental well-being status of physical education students.

*Keywords—Multi-source heterogeneous data; sports major; students; mental health; assess the situation; confidence level; linear regression analysis*

## I. INTRODUCTION

Based on the analysis of the rules of school physical education, the physical education major teaches the basic theory, knowledge, and skills of physical education major, and trains students who have talents and expertise in the field of education, can engage in physical education teaching, extracurricular sports activities, extracurricular sports training, and competitions, and can conduct scientific research, management, and guidance. There are obvious differences between physical education majors and other majors in the ways of attending classes, practicing after class, and conducting experiments and different training methods will develop students' different ways of thinking and attitudes toward life [1]. For example, "Research on Personality Differences between Physical Education Majors and Students of Science and Liberal Arts" indicates that there are great disparities in personality among physical education majors and students of other training methods. The research on the differences in personality and thinking mode between domestic liberal arts students and science students also shows that there are significant differences in personality and thinking mode

among students cultivated under different training modes. "Combined with the research, it is found that because of the different training methods, the mental well-being status of university students majoring in physical education will be different from that of other majors [2]–[4]. Therefore, knowing the mental health status of university students majoring in physical education and carrying out targeted mental health education are also beneficial to better professional talents who meet the training objectives of physical education [5].

Chinese scholars have summarized mental health. Broadly speaking, mental well-being implies an effective, satisfying and stable mental status. In a narrow sense, mental well-being implies the full and consonant procedure of individuals' primary mental actions, that is, the complete and coordinated knowledge, emotion, will, behavior, and personality that can adjust to the community and keep pace with the community. By studying the evaluation model of physical, intellectual, and emotional development of physical education students' mental health, combined with multi-source heterogeneous data fusion analysis of physical education learners' psychological wellness performance, the evaluation level of physical education learners' psychological wellness can be improved, and the study on related calculation methods of physical education students' mental health has attracted great attention [6].

In response to the above issues, this article proposes a method for evaluating the mental health status of sports major students based on multi-source heterogeneous data mining. This method utilizes a fuzzy information detection model and a hierarchical indicator parameter detection analysis method to evaluate four factors: compulsion, interpersonal sensitivity, hostility, and depression. Establish an estimation parameter feature clustering model through multi-source heterogeneous data feature extraction and subspace heterogeneous fusion methods. By combining the results of feature distributed clustering and linear regression analysis, the evaluation of the psychological health status of sports major students is achieved. Empirical analysis shows that this method has good performance in evaluating accuracy, feature resolution, and reliability.

## II. RELATED WORKS

The study on the evaluation of physical education students' mental well-being is on the basis of the reliability fusion and cluster analysis detection of data. Joined with the correlation feature detection and extraction way, the evaluation and feature fusion of physical education students' mental health can

improve the balance of multi-source heterogeneous data output of physical education students' mental health [7]. In the traditional method, there are mainly fuzzy aggregation scheduling methods, PID scheduling methods and self-adaptive equilibrium scheduling methods for the evaluation of physical education learners' psychological wellness under the coordinated improvement of physical intelligence and emotion. The author in [8] used symptom checklist to test 15392 freshmen from 2013 to 2019, with P values <0.001 However, this method cannot fully consider the factors of gender, nationality, and professional category when carrying out psychological counselling. The author in [9] proposed an automatic evaluation method of College Students' mental health based on multimodal data fusion calculation Build a multimodal psychological assessment data set (ja-ipad) model to improve students' psychological files, accurately intervene in students' psychology, and optimize mental health services to provide decision-making basis and technical support, but this method has problems of poor anti-interference and weak feature resolution in the procedure of College Students' mental well-being assessment.

## III. MULTI-SOURCE HETEROGENEOUS DATA MINING THEORY

In the procedure of informatization construction, because of the stage, technicality, and other economic and human features of the construction and implementation of data management systems of various business systems, a huge amount of business info with several storage ways has been accumulated in the development process, including different data management systems[10], [11]. From simple file databases to complex system databases, they constitute multi-source heterogeneous info. Multi-source data fusion is to combine several info data, capture the specification of distinct info origins, and then extracts unified, better and richer data than single info. Multi-source heterogeneous data comes from multiple data sources, including data sets collected by different database systems and different devices in their work. Heterogeneous data includes many types of structured data, semi-structured data, and unstructured data. There is no uniform standard in the formation of different types of data, which leads to the "heterogeneous" characteristics of data. According to the requirements, the data are calculated and the data model is automatically established, which effectively reduces the burden of statistical work and improves the efficiency of data analysis.

## IV. DATA ANALYSIS AND STATISTICAL ANALYSIS ON EVALUATION OF PHYSICAL EDUCATION STUDENTS' MENTAL HEALTH

### A. Spatial Cluster Distribution Structure of Evaluation Data of Physical Education Students' Mental Wellness

Aiming to conceive the assessment of physical education students' mental wellness under the coordinated development of physical intelligence and emotion, a fuzzy information detection model of multi-source heterogeneous data of physical education learners' psychological wellness under the

coordinated improvement of physical intelligence and emotion is constructed[12], [13]. According to the SCL-90 questionnaire, among various factors, if the score of a certain factor is more than or equal to 3, the subject may have a moderate degree of mental health problems, while the score of any one of the 10 symptom factors ≥2 indicates. If any factor scores 2.2 and < 3, the subjects can be considered to be in a sub-health psychological state. Less than or equal to 2 has no mental health problems. According to the survey, the number of students with medium or above mental disorders accounted for 4.69% of the total number, which was 13. The amount of students in the sub-health state is 86, accounting for 31.05% of the whole. The amount of students in mental wellness is 178, accounting for 64.26% of the whole amount. The fuzzy correlation analysis of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is accomplished using the feature extraction algorithm of high-order statistics, and the fuzzy decision figure of mining multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is established. The fuzzy information cluster analysis of multi-source heterogeneous data of physical education learners' psychological wellness under the coordinated improvement of physical intelligence and emotion is carried out, and the distributed detection model of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is established[14] . The statistical spatial information category distribution of multi-source heterogeneous data of physical education trainees' psychological well-being under the coordinated improvement of physical intelligence and emotion is shown in Fig 1.

Based on the statistical spatial information category dispensation pattern of multi-source heterogeneous data of physical education trainees' psychological wellness under the coordinated improvement of physical intelligence and emotion shown in Fig 1, the attribute scheduling of multi-source heterogeneous data of physical education trainees' psychological well-being under the coordinated improvement of physical intelligence and emotion is accomplished using pointer fusion indicator way, and the spatial coordinate block distribution model of multi-source heterogeneous data of physical education trainees' psychological wellness under the coordinated improvement of physical intelligence and emotion is established[15]. Improve the statistical analysis and mining ability of multi-source heterogeneous data of physical education trainees' psychological well-being under the coordinated improvement of physical intelligence and emotion and build a pointer scheduling model of multi-source heterogeneous data of physical education trainees' psychological wellness under the coordinated improvement of physical intelligence and emotion as presented in Fig 2.

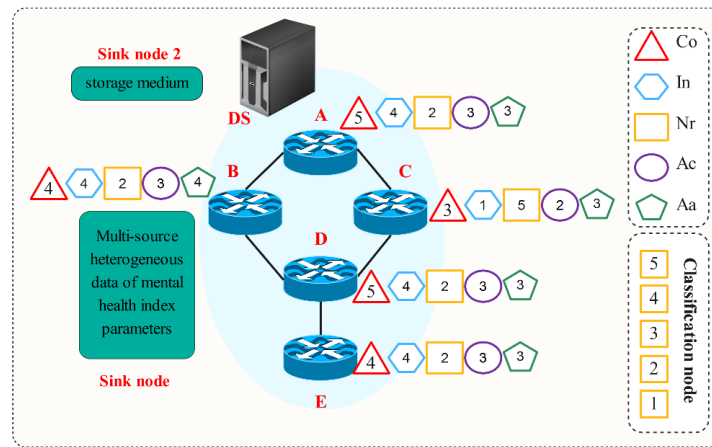
Based on the mental wellness state evaluation model of physical education students shown in Fig 2, the fuzzy correlation of the mental wellness state evaluation data of physical education students is analyzed.


Fig. 1.   Statistical spatial information category distribution of mental health evaluation data of physical education majors.

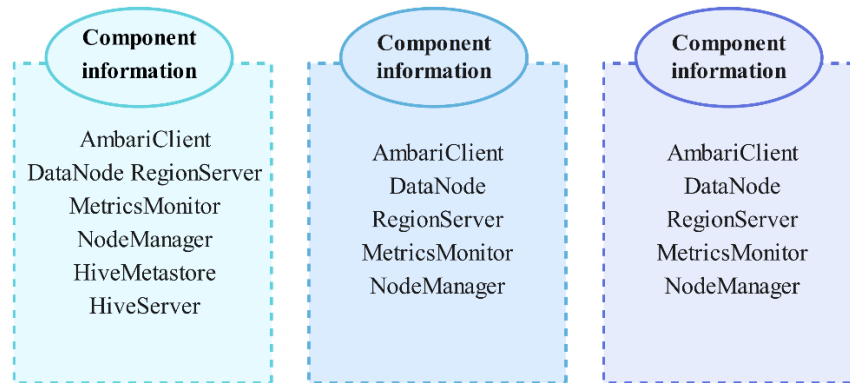

Fig. 2.   Evaluation model of the mental wellness status of physical education majors under the coordinated improvement of physical intelligence and emotion.

*B. Fuzzy Correlation Analysis of the Evaluation Data of Physical Education Students' Mental Health Under the Coordinated Development of Physical Intelligence and Emotion*

The fuzzy correlation analysis of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is accomplished using the feature extraction way of high-order statistics[16]–[18]. The outcome autocorrelation factor accordant type of multi-source heterogeneous info of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is constructed, and the fuzzy clustering feature coefficient of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is calculated[19]–[21], which is defined as:

$$A_j(L+1) = \frac{1}{n_j} \sum_{i=1}^{k} X_i^j \quad j = 1,2,\ldots,k \qquad (1)$$

Wherein, $n_j$ is a multi-source feature of the physical education students' mental health status, $X_i^j$ is a multi-source heterogeneous spatial distribution set of physical education students' mental health status, and $k$ is an embedded dimension. By analyzing the output difference features of multi-source heterogeneous data of physical education learners'

psychological well-being status under the coordinated improvement of physical intelligence and emotion, the fuzzy cluster analysis of multi-source heterogeneous data of physical education learners' psychological well-being status under the coordinated improvement of physical intelligence and emotion is carried out by using high-order statistical analysis method, and the discrete scheduling formula of multi-source heterogeneous data of physical education learners' psychological well-being status under the coordinated improvement of physical intelligence and emotion is defined as[22], [23]:

$$C(l) = \sum_{j=1}^{k} \sum_{k=1}^{n_j} (||x_k^j - A_j(L)||)^2 \qquad (2)$$

Wherein $x(t)$ is the fuzziness of multi-source heterogeneous data sets of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion and $A_j(L)$ represents the similarity characteristic quantity. Fuzzy data clustering and distributed discrete scheduling ways are adopted to control the output reliability of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion. Establishing the attribute cluster distribution model of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion can realize the statistical detection of multi-source heterogeneous data sets of physical education learners' psychological well-being under the

coordinated improvement of physical intelligence and emotion[24], [25]. Combining with the similarity feature analysis method, the multi-source heterogeneous data mining feature quantity of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is established, and the residual distribution matrix of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is as follows:

$$D(x_i, A_j(L)) = min\{ D(x_i, A_j(L)) \} \qquad (3)$$

Wherein, $D(x_i, A_j(L))$ is the global weighted value of the evaluation of physical education students' mental health under the coordinated development of physical intelligence and emotion at the $i$ point. A fuzzy information detection model of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is constructed. The fuzzy correlation analysis of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is accomplished using a high-order statistical detail mining way, and data mining and fuzzy clustering are carried out according to the feature extraction results.

## V. EVALUATION AND OPTIMIZATION OF PHYSICAL EDUCATION STUDENTS' MENTAL HEALTH STATUS

### A. Multi-source Heterogeneous Data Mining of Physical Education Students' Mental Health Under the Coordinated Development of Physical Intelligence and Emotion

Based on the fuzzy information detection model of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion, and the fuzzy correlation analysis of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion by using high-order statistical feature extraction method, the communication link data mining is carried out. This paper puts forward an evaluation method of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion according to multi-origin heterogeneous info mining. The outcome autocorrelation factor accordant type of multi-source heterogeneous info of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is formed, and the numerical evaluation of multi-source heterogeneous info of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is carried out by combining the hierarchical index parameter detection and analysis method. By adopting the multi-source heterogeneous data mining algorithm, the feature distribution set of data sampling node I at time T is expressed as $V = \{v_{ij} | i = 1,2,\cdots,c, j = 1,2,\cdots,s\}$, $t$ is the offset characteristic quantity of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion, and S is the

weighting coefficient of evaluation of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion. Combining the semantic factor evaluation way with a fuzzy semantic factor rule set for evaluation of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is formed, and the adaptive weighting coefficient of multi-source heterogeneous data of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is as follows[26]:

$$H(t) = \overset{\wedge}{h}(t) * p(t) * p(-t)$$
$$= (\sum_{i=1}^{M} h'_i(t) * h_i(-t)) * p(t) * p(-t) \qquad (4)$$

Wherein, $\overset{\wedge}{h}(t)$ is the regression analysis value, $p(t)$ is the dynamic fitting parameter, $h'_i(t)$ is the distribution function of transmission reliability, and $max_l Freq_{i,j}$ is the residual specification amount of physical education students' mental wellness analysis and optimization under the coordinated development of physical intelligence and emotion among $d_j$. $k_i$ is defined as the fuzziness of multi-source heterogeneous data mining of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion;

$$p_{ri}(t) = p(t) * h_i(t) + n_{pi}(t) \qquad (5)$$

$$S_{ri}(t) = S(t) * h'_i(t) + n_{si}(t) \qquad (6)$$

Wherein, $S(t)$ and $h'_i(t)$ are the fuzzy rule features of the physical education students' mental health evaluation under the coordinated development of physical intelligence and emotion and $n_{si}(t)$ is the interference item of multi-source heterogeneous data mining. The fuzzy clustering way is attained to optimize the shortest path of physical education students' mental wellness evaluation under the coordinated development of physical intelligence and emotion[27], and its calculation formula is:

$$r_i'(t) = S_{ri}(t) * p_{ri}(-t)$$
$$= S(t) * p(-t) * h'_i(t) * h_i(-t) + n_{1i}(t) \qquad (7)$$

Wherein, $S_{ri}(t)$ is the joint matching coefficient, $S(t)$ is the similarity characteristic quantity, and $n_{1i}(t)$ is the dynamic interference component. Using the statistical information analysis method, this paper establishes the correlation distribution set of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion. On this basis, the spherical test of KMO and Bartlett is carried out on the scale (the test results show whether the scale can be used for exploratory feature evaluation), and then the exploratory feature evaluation is accomplished. Generally speaking, when the KMO test value is above 0.8, it is suitable for exploratory factor analysis, and Bartlett's spherical test value needs to reach a significant level, that is Sig<0.05, then exploratory factor analysis can be carried out on this scale. Therefore, the spherical test of KMO and Bartlett is required for the pre-test

psychological resilience scale, and the experiment outcomes are presented in [28], [29] (12 direction scoring questions have been preprocessed). The fuzzy data factor evaluation way is attained to perceive the outcome autocorrelation factor accordant of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion and to improve the ability of mining multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion.

### B. Evaluation of Mental Health Status of Students Majoring in Physical Education Under the Coordinated Development of Intelligence and Emotion

Based on the multi-source cluster analysis method of the split grid, a multi-source heterogeneous data mining model of the physical education students' mental health status under the coordinated development of physical intelligence and emotion is established. The feature extraction results are evaluated by the hierarchical index parameter detection method. The global variables are set, and the fuzzy partition coefficient of physical education students' mental health status evaluation under the coordinated development of physical intelligence and emotion is established as follows:

$$V_i = \frac{\sum_{k=1}^m (\mu_{ik})^m x_k}{\sum_{k=1}^n (\mu_{ik})^m} \qquad (8)$$

Where, $\mu_{ik}$ represents the median of mental wellness evaluation of physical education students under the coordinated development of physical intelligence and emotion, $m$ is the lower bound of mental wellness evaluation of physical education students under the coordinated development of physical intelligence and emotion, and it is the median of multi-source heterogeneous data of mental wellness of physical education students under the coordinated development of physical intelligence and emotion, and n represents the minimum statistical characteristic quantity of multi-source heterogeneous data of mental wellness of physical education students under the coordinated development of physical intelligence and emotion in all dimensions. Based on the detail mining outcomes of multi-source heterogeneous info of physical education students' mental health under the coordinated development of physical intelligence and emotion, the hierarchical index parameter detection method is adopted to evaluate the mental health of physical education students under the coordinated development of physical intelligence and emotion. The great info extraction model is shown below:

$$P_u = \frac{\left| \sum_1^{N_R} s(i,t) \right|}{V} = \frac{N_R}{V} \qquad (9)$$

Wherein, $s(i,t)$ is a linear fitting parameter of multi-source heterogeneous data of physical education students' mental health status, $N_R$ is a multi-source decision function, and $V$ is KMO test value. Under the decision tree model of physical education students' mental health evaluation data distribution under the coordinated development of physical intelligence and emotion, this paper adopts a multi-source heterogeneous data mining algorithm to carry out self-adaptive optimization in the procedure of physical education students' mental wellness evaluation under the coordinated development of physical

intelligence and emotion, with four factors of compulsion, interpersonal sensitivity, hostility and depression as dependent variables. Combined with the hierarchical index parameter detection and analysis method, this paper makes a statistical analysis of multi-source heterogeneous data on physical education students' mental health under the coordinated development of physical intelligence and emotion. Based on the detail mining outcomes of multi-source heterogeneous data of physical education students' mental health, the analysis of physical education students' mental wellness is perceived.

## VI. SIMULATION AND RESULT ANALYSIS

Aiming to confirm the applying performance of this way in the analysis of physical education students' mental wellness, a simulation examination evaluation was applied. In order to ensure the effectiveness of the experiment, the experimental parameters of this article are set as follows:

*1) Fuzzy information detection model:* clustering number 4.

*2) Detection* and analysis method for hierarchical index parameters: significance level 0.05.

*3) Feature* extraction and subspace heterogeneous fusion methods: Dimension 10 of principal component analysis (PCA), hyperparameter lambda=0.5 of subspace fusion methods.

Among them, the comparative method uses the corresponding parameters used in its experiment, and will not be introduced in detail here.

Matlab was used for the algorithm processing of the analysis of physical education students' mental wellness, and the number of nodes for multi-source heterogeneous data sampling of the physical education students' mental well-being was set to 400. The Sink root node of the physical education students' mental well-being evaluation is 35, the Sink source node number of the physical education students' mental well-being evaluation is 6, the length of multi-source heterogeneous data sampling of physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion is 3000, and the distribution characteristic resolution of association rules of physical education students' mental health evaluation is 34Bps/s, The sampling frequency of multi-source heterogeneous statistical features for the analysis of physical education students' mental well-being is 24Hz, and the sampling frequency of autocorrelation features is 46Hz. Based on the earlier principles, the evaluation of physical education students' mental wellness under the coordinated development of physical intelligence and emotion is carried out. Same to the exploratory factor analysis method used in the preliminary investigation, the test results of KMO and Bartl ett are shown below. Cronbach's Alpha Reliability Analysis Table, a positive scale of psychological toughness, is constructed. The KMO value of this scale is 0.915, and Bartlett's test value is 0.000 (<0.05). This scale is very suitable for factor analysis. By using principal component analysis and tilt rotation method, 10 common factors were extracted, the maximum convergence iteration times were 25, and the cumulative contribution rate reached 60.00% for observation. Factor analysis one by one

eliminated KL3, KL10, KL29, KL47, KL17, KL18, KL51, KL57, KL6, KL15, KL34 and KL. After 15 times of factor extraction, the load value of each factor is above 0.4, and the cumulative variance is 60.00%, that is, the total explanation rate of the factors is 60.00%, which has a high explanation rate. The reliability of 60 items in 602 questionnaires of middle school students' mental health scale was analyzed, and Cronbach's Alpha coefficient was 0.929, a> 0.85, which indicated that the reliability of the formal survey scale was good.

Combined with the results of the exploratory factor analysis of the formal psychological resilience scale, the confirmatory feature evaluation was applied with statistical software AMOS 20.0, the path significance was estimated by maximum likelihood estimation, and the fitting degree of the structural equation model was tested. The model was modified by combining factor load and model fitting index, and four factors, compulsion, interpersonal sensitivity, hostility, and depression, were taken as dependent variables. The distribution of multi-source heterogeneous data on physical education learners' psychological well-being under the coordinated improvement of physical intelligence and emotion was obtained as shown in Fig. 3.

The analysis shows that the factor loads of C15, C16, and C17 are negative, and the factor loads of C19 and C22 are less than 0.4. The load of the C18 factor in interpersonal assistance is negative, so there is only one factor in the dimension of positive cognition, so the dimension of positive cognition is deleted.

Fig. 3 shows that there are three impulse response waves in the obsessive-compulsive mental health state, two impulse waves in the interpersonal sensitive state and hostile state, and two shock waves in the depression state. The pattern in this article is able to precisely detect the multi-source heterogeneous data feature points of physical education majors' mental health state. At the same time, it is found that the fitting degree of the first model is not good in the absolute fitting index and relative fitting index of the model fitness test.

According to the correction index given by AMOS software, the model is modified by the residual correction method, with four factors of compulsion, interpersonal sensitivity, hostility, and depression as dependent variables. The final verification path correction result of the psychological resilience scale is shown in Fig. 4.

Force

Interpersonal sensitivity

(a) Compulsion, interpersonal sensitivity.

Hostile

Depression

(b) Hostility and depression.
Fig. 3. Multi-source heterogeneous data distribution of physical education students' mental health status.
Fig. 4.    Validation path correction results of the psychological resilience scale.

According to the analysis of Fig. 4, the multi-source heterogeneous mining is realized by this method, which reduces the risk of university students' mental well-being, suppresses the impulse wave of mental wellness risk state, establishes the regression analysis model of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion, and extracts the statistical characteristic quantity of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion. Based on the factor mining outcomes of multi-source heterogeneous info of physical education students' mental health, the health assessment is realized. It is concluded that all fitting indexes of the psychological resilience scale have reached an acceptable or good level. It proves that the structure of the revised psychological resilience scale has reached a stable state and is suitable for later research and analysis. The path coefficients of D12 and D23 in the obsessive-compulsive dimension, D4, D45, and D59 in the interpersonal tension and sensitivity dimension, D36 in the learning stress dimension, and D1 and D9 in the maladjustment dimension are all less than 0.4. Therefore, these items are deleted and combined with the model fitting index, it is found that the first Chinese middle school students' mental health scale model is not good. This way is able to effectively perceive the multi-source heterogeneous data mining of physical education students' mental health, improve the clustering ability and output balance of the info, and test the accuracy of several ways in evaluating physical education students' mental health. The comparison results are shown in Table I. From the analysis of Table I, it is known that the accuracy of this method in evaluating physical education students' mental health is high.

This algorithm is for analyzing the abnormal risk probability of mental wellness of physical education students in the 2019 academic year. The statistical results are shown in Fig. 5.

Through the simulation results in Fig. 5, it can be seen that the obtained probability coefficient is highly compatible with the actual probability coefficient. Using this algorithm can effectively evaluate the normal probability and abnormal

probability of mental health of sports students in the 2019 academic year, which shows that this algorithm can effectively evaluate the mental health status of sports students.

On this basis, by comparing the methods of [5] and [7], the calculation complexity of the proposed algorithm is counted (Table I). The shorter the time of the algorithm, the lower is the calculation complexity. Therefore, the experiment is carried out with the evaluation time as the test index, and the experimental results are shown in Fig. 6.

As shown in Fig. 6, under the same conditions, the proposed method takes the shortest time, indicating that the proposed method has the lowest computational complexity, the strongest operability, and high practical applicability.

TABLE I.    COMPARISON OF EVALUATION ACCURACY OF THE MENTAL HEALTH STATUS OF STUDENTS MAJORING IN PHYSICAL EDUCATION UNDER THE COORDINATED DEVELOPMENT OF PHYSICAL INTELLIGENCE AND EMOTION

## VII. Discussion

Based on the above research results, it can be concluded that this method provides a more comprehensive perspective for the evaluation of the mental health status of sports majors by integrating data from different sources and types.

In reality, the mental health issues of sports major students are of great concern. Using multi-source heterogeneous data for evaluation can better capture multidimensional information of individuals and identify potential mental health risk factors. In addition, the introduction of fuzzy information detection models, hierarchical index parameter detection and analysis methods, feature extraction, and subspace heterogeneous fusion techniques make the evaluation indicators more accurate and reliable.

However, there are still some challenges and room for improvement in further applications. The effective integration and processing of different types of data is a complex task that requires further optimization and exploration of methods and models suitable for different data types. In future research, it is recommended to further expand the scope of multi-source heterogeneous data evaluation and strengthen research on data preprocessing, feature selection, and model optimization.

## VIII. Conclusions

In this article, an evaluation method of physical education students' mental health based on multi-source heterogeneous data mining is proposed. The output autocorrelation characteristic matching model of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion is constructed, and the statistical analysis of multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion is carried out by combining the hierarchical index parameter detection and analysis method, and the fuzzy segmentation model of evaluation of physical education students' mental health under the coordinated development of physical intelligence and emotion is established. Multi-source heterogeneous data mining algorithm is used to self-adaptively optimize the evaluation process of physical education students' mental health under the coordinated development of physical intelligence and emotion, so as to realize the evaluation of physical education students' mental health under the coordinated development of physical intelligence and emotion. The analysis shows that this method has good balance and high accuracy in scheduling multi-source heterogeneous data of physical education students' mental health under the coordinated development of physical intelligence and emotion. Through empirical analysis, the following conclusions are also drawn:

First, the overall situation of physical exercise of students majoring in physical education is good. The overall average of psychological resilience is high, and the overall average of mental health is high.

Secondly, the physical exercise behavior of students majoring in physical education shows significant gender and grade differences at the overall level; there are significant grade differences in its sub-dimensions, and there are significant gender differences in the intensity and time of physical exercise.

Thirdly, there are significant grade differences in the overall level of physical education major students' psychological resilience and its sub-dimensions; there are significant gender differences in their sub-dimension goal concentration and emotional control.

Fourthly, there are significant gender and grade differences in physical education students' mental health as a whole and its sub-dimensions; there are significant differences in their sub-dimension maladjustment in the only child.

Although this study has achieved good research results, there may be biases in the selection of samples in the study, resulting in inaccurate evaluation results or lack of widespread applicability. Therefore, further consideration will be given to the randomness and representativeness of sample selection in the next step of research.

Kuala Nerus, Terengganu, Malaysia

*Abstract*—Assessing students is a common practice in educational settings. Students will be evaluated using several methods or tools to determine how well they have acquired knowledge or progressed. There are two distinct types of assessment is summative and formative. Rubrics are used to evaluate student performance. However, the development of the rubric is challenging because subject-matter expertise is required. Ontology has been utilized in certain research to communicate knowledge relevant to rubrics, but these studies do not map to the important learning outcomes. Rubrics are developed in Malaysia to support outcome-based education (OBE) based on the Malaysia Qualification Framework (MQF). It is essential to discover if the technology supports rubrics that leverage learning outcomes to produce the best possible rubric. A systematic review of the literature (SLR) was used to carry out this analysis. In the years 2018 through 2022, 42 papers were reviewed. In conclusion, the key finding of this work is that rubric-based outcome learning is the most recent research area to get attention and that only a small number of studies have used ontologies to develop rubrics based on learning outcomes.

*Keywords—Assessment; higher education; learning outcomes; Malaysia Qualification Framework (MQF); ontology; rubric*

## I. INTRODUCTION

The practice of enhancing students' educational experiences by accomplishing learning outcomes through curriculum design is known as outcome-based education (OBE). The OBE process's results are crucial in enabling educational institutions to assess student's performance in an accurate and objective manner and to reassure pertinent stakeholders about the quality and competency of graduates. The OBE process is a crucial tool for promoting the quality of educational institutions, programs, and student employability [1]. OBE is employed in education because it organizes everything in a system of learning around what is essential for all students to be able to do at the end of their studies. [2]. To enhance student performance and learning experiences, OBE must link the curriculum, teaching and learning approaches, and assessment with learning outcomes.

One of the first proponents of OBE, Spady, characterized this approach as the design, production, and documentation of instruction with pre-specified goals and outcomes [3]. The term "outcomes" refers to the learning objectives for any proposed curriculum. These objectives must be clearly defined in order to choose a realistic set of topics and activities that will make up the students' experience [4]. The learning outcomes of the

students are rated according to the Malaysia Qualification Framework (MQF) domain [5].

The curriculum should be developed when a Higher Education Institution (HEI) demonstrates the Program Learning outcome (PLO) that it wants its graduates to achieve. LOs are what the educated can perform because of education. It links with the Course Learning Outcome (CLO). Most courses are expected to foster problem-focused learning skills against the backdrop of academic convergence, improve problem-solving ability, instill criticality, and support creative faculty in the creation of new knowledge. The handling of sophisticated equipment in laboratories and workshops as well as experience with computer-simulated experiments, are expected outcomes of all scientific and technology courses.

The instructional design outlines the process by which students can complete a series of tasks utilizing the resources available in their environment and still meet the learning objectives. Experts claim that objectives oversee connecting general skills to specific knowledge so that learners may prove they can solve specific types of challenges. As a result, various taxonomies pertaining to students' abilities that serve to symbolize the acquisition of information have been constructed. Among them, Bloom's taxonomy is the most widely used [6]. It comprises three important domains: cognitive, affective, and psychomotor. The cognitive domain includes the intellectual area and learning related to knowledge, comprehension, and critical thinking [7]. The affective domain comprises the abilities to communicate and understand feelings, i.e., learning related to senses, emotions, and personal growth in attitudes [8]. The psychomotor domain covers people's abilities to make voluntary movements, skills, and actions [9].

One of the methods to achieve the objectives is through assessment. They need to scale the student's performance. One of the methods is based on assessment, which is done via a platform learning management system (LMS) that store and delivers learning content for training and educating the students. Academic evaluation of students is part of the learning process to monitor their learning progress. The evaluation of the learning process is a thorough and continuous procedure for determining a student's academic performance level in accordance with educational regulations. The assessment will indicate whether the student will succeed or fail, and it will serve as guidance for a teacher in future performance reviews [10].

## A. Assessment

The evaluation criteria, definition criteria, and marking approach are the three key criteria of a rubric, a tool used to evaluate student work [11]. The assessment process requires monitoring of student progress throughout the instructor's planned instruction sequence in the LMS [12]. The objective of the evaluation is to infer, from the students' behavior, what learning objectives were achieved and the level of student knowledge. In this process, the use of a Taxonomy of Educational Objectives is highly recommended [13], [14]. Taxonomy of Educational Objectives can contribute to the evaluation of the student's academic performance.

## B. Rubric

A rubric is a method that educators use to evaluate their students. It is critical to follow the learning objective. Every subject has objectives that need to be archived to qualify the subject and help the educator archive the output from learning. A rubric is used to notify students of expectations, provide informative and timely feedback, help with to grading consistency and fair assessment, and foster student learning and self-assessment [15]. There are two (2) types of rubrics which are analytic and holistic. The analytic rubric breaks down the objective into specific component parts. Every section is scored independently using a rating scale. It is a two-dimensional rubric with levels of achievement as columns and assessment criteria as rows. A holistic rubric consists of a single scale, with all criteria to be included in the evaluation being considered together. It may use a percentage or text-only scoring method.

The performance of the students was evaluated more methodically and objectively, and academics were better informed using standardized rubrics [1]. The educator needs to create teaching and learning activities and assignments that are directly related to the learning outcomes. The knowledge, skills, attitudes, and manners that are the subject of these learning outcomes won't be attained through lectures, tutorial classes, or written tests. The expectations for the performance of students and programs will be better understood with the standardization of a set of rubrics and the appropriate setting of learning outcomes since students will be more inclined to take ownership of their studies [1], [16]–[18]. Rubric is important to teacher/instructor/teaching assistant – Graduate teaching assistants also indicated that they could effectively use the rubrics to assess student work and that the rubrics clarified the instructor's expectations for how they should assess students [19].

In the meantime, the MQF's rubric domain is the evaluation and assessment of students' work using the Integrated Cumulative Grade Point Average (iCGPA) system, which assesses knowledge, skill, and attitude acquired from general subject courses as demonstrated in the Malaysia Qualification Framework's Learning Outcomes Domain (LOD-MQF) [5]. The criteria that educators want to evaluate must point to learning outcomes based on LOD-MQF. Every institution needs to follow Malaysia's Qualification Framework in education to evaluate students. Most of the rubric is created manually with the criteria that want to evaluate [20].

## C. Ontology

Educators can create rubrics easily when using computational approaches. Educators can use ontology to map rubric criteria to related learning outcomes. Ontology is a technology used to represent knowledge domains in an understandable form that can be manipulated by machines. Ontology was created to share a common understanding of the structure of information among people, to enable the reuse of domain knowledge, to make domain assumptions explicit, to separate domain knowledge from operational knowledge, and to analyze the domain knowledge [21]. Developing ontology from scratch is hard and wastes time, however, the study in [22] state that using an existing ontology can save money and effort. The effort of this study, which adapts the pre-established ontology developed by [6], is motivated by the idea of reusing pre-made ontologies.

As employed in this study, a systematic review is an examination of a defined issue that employs methodical and clear techniques to identify, select, and assess pertinent research papers as well as analyze their data [23]. Systematic reviews also try to analyze secondary data by gathering, synthesizing, and rating the available data on a subject in a logical, intelligible, and analytical manner [24]. Given the current discourse issue surrounding this topic, it is imperative to do a thorough study of it. Gaps can be identified and future studies on how educators approach assessment and respond to student learning outcomes can be directed in the right direction using the methodology employed in this analysis.

Based on Systematic Literature Review and meta-analytical analysis, it may show patterns, identify gaps, and offer comparison results [25], [26]. A systematic review aids in understanding pertinent issues that may throw light on various assessments used by educators and enables researchers to identify trends in prior research. It is intended that the learning outcomes of assessments, such as student knowledge, abilities, competencies, and attitudes, will be clearly identified.

## II. Methods

A systematic review needs to do as detail to get accurate result on how the research works. The recommended Preferred Reporting Items for Systematic review and Meta-analysis (PRISMA) guideline technique was used to conduct this systematic literature review. The research in [26], state that identification, screening, and inclusion are the three stages of preparation for papers prepared to utilize the PRISMA approach [27]. Research questions were first developed, and then papers on assessment and the creation of student learning outcomes, competencies, and performances were found. The researchers also talked about data extraction, analysis, and quality evaluation. Many researchers do some research to upgrade or modify the method in teaching and learning. Although, they need to be evaluated to identify the missing knowledge or the part where they are weak. Educator used a rubric to evaluate the student based on formative assessment.

## A. Research Question

Currently, many methods are used to evaluate students using various computational approaches. The research questions for this research are:

- Are there any suitable computerization solutions that could be applied to help educators evaluate the students based on learning outcomes?

- Why ontology for rubric-based assessment is necessary to be used?

### B. Preliminary Research

Preliminary research is used to validate the proposed idea, identify relevant articles, and avoid duplication of the article, and to ensure the article enough to conduct the analysis. This research is about education, and more specifically, is in higher education domain. Therefore, the article that related with the themes will be collected. The issues that appear will be analyzed and considered as important to people.

Search engines such as Google Scholar, Scopus, and Science Direct were used to get the information and documents that related to the research. The key words that used are 'learning', 'teaching', 'problem learning', and 'evaluate student'. The search was too wide, general document was found such as 'SMART learning; and 'Recommender system'. Then the search needs a specific keyword to get a more accurate result on what the research question is about. The specific keywords are 'rubric', 'learning objectives', 'outcome-based education', 'student feedback' and 'taxonomy'. According to the article, there is a gap in the research that has not yet been conducted in the higher education domain.

### C. Inclusion and Exclusion Criteria

To get the desired information and avoid bias from a selection of papers and publications, inclusion and exclusion criteria must be established. Table I lists the article's inclusion and exclusion criteria, the studies in evaluation using the rubric on computational approach. The article was published between 2018 and 2022 and was written in English and was eligible for inclusion in the review. Meanwhile, publications were disqualified if they were studies that are not for evaluation using the rubric, written in a language other than English, did not specifically address the topic of evaluation using rubrics, and were duplicated studies.

TABLE I. INCLUSION AND EXCLUSION CRITERIA

| Inclusion criteria | Exclusion criteria |
|---|---|
| Studies that present OBE, LO, CLO and PLO. | Studies that not for evaluation using rubric |
| Studies in evaluation using rubric | Article that not available in digital library |
| Studies of computation approach in rubric | Non-English written article |
| Studies about conceptual model or theory in Outcome based | Technical reports and documents in the form of summaries |
| Study published between 2018 and 2022 | Studies that related with learning object |
| English written papers | Duplicate studies |

Two levels of inclusion and exclusion criteria were used: first, when reading the title and abstract, and then, after reading the complete article. There are titles, contents, and abstracts for every piece of writing and publication. Some of the book titles don't accurately describe the content. Reading the abstract might therefore save time before reading the entire article by providing an overview of the publication's substance. In addition, it saves us from having to read the full piece to learn what the publication is about and identify its goal or objective. The PRISMA flow diagram template that is used in studies can be found in Fig. 1.

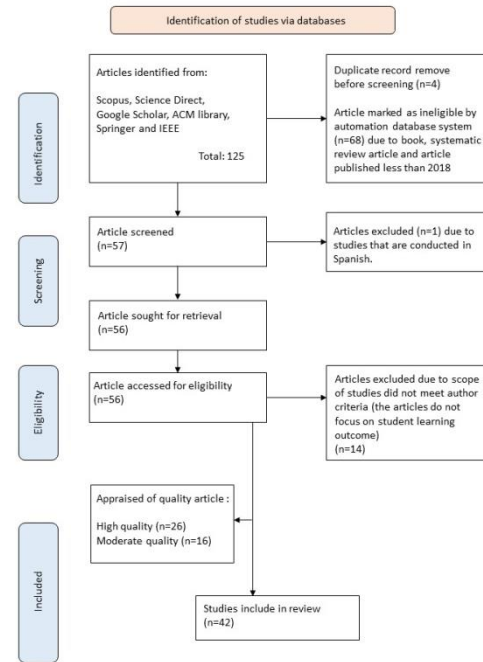

Fig. 1. PRISMA flow diagram.

### D. Search Strategy

The formulation of the research question forms the foundation of the fundamental search strategy. With the assistance of a subject matter expert in the review topic area or an information specialist, search methods are created to include free-text phrases (in the title and abstract) and any applicable subject indexing expected to return acceptable studies. Additionally, because the result is not stated explicitly in the papers, using terms for the outcome may make it more difficult to find qualifying studies in the database because their inclusion. While conducting a trial search and looking for a different pertinent term within each concept from the papers that were collected, the search term is improved.

### E. Search Database, Import and Export Data

According to the A MeaSurement Tool to Assess systematic Reviews (AMSTAR) criteria, the systematic review must search at least two databases [28], but as you increase the number of databases you search, the yield increases and the results become more precise and thorough. The review questions dominate how the databases are arranged. The studies used three databases. While some databases do not permit the usage of Boolean or quotation, others have unique searching methods. To obtain useful results, the original search keywords for each database must change. Lastly, all records are collected into Mendeley library to delete duplicates. All references that have same title and author and published in the same year and also the same title and author and published in the same journal would be deleted.

## F. Title and Abstract Screening

Duplications will be eliminated in this step using Mendeley whenever the reviewers discover them. The team should be inclusive rather than exclusive when there is uncertainty regarding an article decision, at least until the main leader reaches a conclusion after discussion and consensus. There should be an explanation for every excluded record.

## G. Full Text Downloading and Screening

Links to full text articles can be accessed for free using many search engines. If nothing is discovered, the researcher can search on research portals like ResearchGate, Science Direct, which provide the possibility of direct full-text requests from authors.

## H. Manual Search

By explicitly hand-searching for reports that may have been missed in the initial search, one must exhaust all options for reducing bias [29]. The process for manual search; First, reviewing reference lists of articles that were included; second, performing citation tracking, in which reviewers track all the articles that cite each of the articles that were included; this may require using electronic databases; and third, following all "related to" or "similar" articles.

Following the same records produced by electronic databases, every potentially relevant article must be subjected to further examination against the inclusion criteria. To maximize retrieval and reduce bias, the author did an independent evaluation by giving each team member a "tag" and a unique approach before compiling all the data for discussion and comparison of the differences. In a similar vein, the number of included articles must be specified before being added to the total number of included records.

## I. Data Extraction

By gathering data relating to the current issues in education, data extraction was carried out. All the published articles underwent a strengths and weaknesses analysis in this step. Articles are grouped based on the process used to identify rubric-based ontology after the data is extracted. The author's name and, more significantly, the publication year of the piece are listed after that. The article's advantages and disadvantages are combined to assess whether it can help the researcher identify a practical way to know the rubric in the computational approach.

## J. Manuscript Writing, Revision, and Submission to a Journal

Writing that follows a four-part scientific structure which are introduction, methods, results, and discussion, with a conclusion in most cases. A necessary stage that has a template is creating a characteristic table for the study and patient characteristics. When the team has finished writing the manuscript and creating the characteristics table and PRISMA flow diagram, they should send it a leader or thorough revision, respond to his comments, and then choose a suitable journal for the manuscript with a high impact factor and relevant field. Before submitting the work, reading the author's rules of the journals is important.

## III. Result and Discussion

Education is important and required for all people, so they have a wide range of knowledge. Education should be upgraded and use technology to provide many benefits. The majority of researchers have a focus on the university context, mainly in undergraduate research. Some issues in education concern the appropriate learning material [30], such as assessment; students also have issues with their senses, such as visual and auditory [31], and providing feedback [32]. Teachers also have some issues related to their teaching and need to improve learning and teaching methods with Information and Communication Technology (ICTs) [33], [34], and the Internet of Things (IoT) [35]. Students also have a problem choosing the path that they will take. The researcher should take these issues and try to solve the problem by creating a framework for smart learning to personalize learning material, generic smart education design, adaptive learning [36], [37], predict student performance [38], identify learning style [39], and make course recommendations [40] to help students with their studies and choices. Various studies indicate that the learning process may vary depending on the learner [31].

To produce the desired result, the systematic literature review went through each step. The first step was to conduct a thorough search. To search publications and gather data for the research, three Internet databases were employed which is Scopus, Science Direct, ACM library, Springer and IEEE and Google Scholar. There are 78 articles from the identification of the article that are related. Articles, papers, journals, web pages, manuscripts, and books that might be utilized as references for the research were produced from these sources [41]. The main keyword search was 'rubric' followed by the keyword 'evaluation student performance'. The other keyword that was used is already explained in Section B (Preliminary Research). The scope was decreased based on the amount of data retrieved during the search.

Every piece of information, including the research topic, sample type, methodology, evaluation method, participant type, and relevant details, was documented. This will assist the researchers in their data analysis and in determining whether the article is relevant. To gain a different perspective on the publications and to spot the research gaps between the articles, the data was saved as a table. How does it relate, then? It ought to respond to a research question. The author has read that there are four (4) scopes in the field of higher education that have been extensively used and studied. There are numerous perspectives, including (1) instructor perceptions of rubric use, (2) academic achievement in conjunction with rubrics, (3) rubrics for instructional and program assessments, and (4) validity and reliability of rubrics that was support by [42].

In step two (2), all the retrieved articles and publications' inclusion and exclusion criteria were determined. All the articles are then identified and reviewed critically in order to comprehend them. To get precise outcomes from the reading, comprehension is crucial. It is difficult to assess the student's performance on learning objectives using this reading evaluation. As a result, to suggest a remedy to the issue, the research should be in that field.

The data must then be extracted from each and every one of the gathered articles. The article is then extracted and classified using conventional methods, web-based expert systems, ontologies, etc. Based on whether they are PLO or CLO, these four techniques are utilized to determine how learning outcomes are implemented. Articles that discuss the validity and dependability of rubrics, as well as how instructors perceive the usage of them are not included in this article.

In the learning outcome domain research, there are up to 20 articles, as shown in Table II. This study has received considerable consideration from earlier researchers. All the details, including the research topic, sample type, methodology, assessment method, participant type, and relevant information, were documented. This will make it easier for the researchers to assess the data and determine whether the article is relevant. To gain a different perspective on the publications and to spot any gaps in the research among the articles, the data was recorded as a table. How does it relate as a result? A research question should be addressed.

The first analysis is by method that researcher used aim to evaluate, improve, give feedback and verities of solution and method that solve specific problem that related to outcome-based approach. Research used traditional or manual method to conduct exam [43], comparison between different rubric [44], evaluate coursework [20] and performance-based assessment [45], design curriculum [46], [47], improve process skill [19] and creating path [48]. Learning outcome also can be archive by using web based [49]–[53] and expert system such as text mining [54], ontology [6], [55], [56], natural language programming [57] and data mining [58], approach also analytic [59] that need the researcher to develop application. Based on analysis, it shows that only a few researches have been conducted to relate the learning outcome to a rubric evaluation approach using the LOD. The first method that will be employed is a computational technique that makes it simple for educators to assess students based on their learning. Educators can communicate their rubric evaluations using this method of communication virtually. The learning outcome of the student's assessment can also be clearly known, and thus it can be targeted. As a result, the learning objective can be met automatically.

In addition, using the data from the study, the researchers discovered additional ontologies with additional approaches or methodologies for using the expert system to categories individuals according to traits. The topic of the field is the computational method utilizing the scope of research, other than field education; there are two other fields (construction [50] and disaster [52]) that are evaluated based on learning outcomes. It is important to check the quality that greatly benefits others. It gauges how well the initiative succeeds in achieving the desired outcome(s) and how much more justifiable work is needed to attain and/or improve benefits. It offers data that could be utilized to guide decisions in the future. To determine the learning outcomes were focused on is shown in Table III. In the scope of the research, two other fields (building [51] and disaster [52]) are studied based on learning outcomes as well as to field education. It is crucial to look for qualities that are highly advantageous to others. It evaluates the initiative's effectiveness in reaching the desired

outcome(s) and the amount of additional reasonable work required to achieve and/or improve benefits. It provides information that could be used as future decision-making input.

TABLE II. ANALYSIS OF THE LITERATURE REVIEW IN THE OUTCOME BASED APPROACH

| Author and year | Method | Aim |
|---|---|---|
| Parmar et al., 2018 [43] | Traditional/ Manually | To conduct the exam through model making and assessing the graduate students of mechanical engineering |
| Yune et al., 2018 [44] | | To compare holistic rubric and analytic rubric |
| Yaacob & Mahmud, 2019 [20] | | To evaluate subject coursework |
| Dascalu et al., 2019 [46] | | To design curriculum |
| Ram et al., 2020 [47] | | To design curriculum using OBE and LO |
| Gresse Von Wangenheim et al., 2021 [45] | | To evaluate performance-based assessment based on learning outcomes |
| Koutra et al., 2022 [48] | | To creating path and assessment to patient |
| Aji et al., 2018 [49] | Web-based | To develop application in form of mobile apps |
| Demaidi et al., 2018 [50] | | To give personalized feedback |
| Probst et al., 2019 [51] | | To measuring construction safety climate |
| Johnson et al., 2019 [52] | | To design observation rubric |
| Schoch-spana et al., 2019 [53] | | To predicts post-disaster community functioning and resilience |
| Yago et al., 2018 [6] | Expert System | To support student learning |
| Hussain et al., 2018 [58] | | To improve the student performance and to prevent drop out |
| Azmi et al., 2019 [57] | | To automatically evaluate student essay |
| Nouira et al., 2019 [56] | | To support student learning |
| Czajka et al., 2021 [59] | | To give feedback by rubrics |
| Thirumoorthy & Muneeswaran, 2021 [54] | | To identify the best students based on their Course Outcome attainment |
| IMS caliper, 2022 [55] | | To support student learning |

As demonstrated in Table IV, the researcher was also able to locate ontology-based rubrics that link to learning outcomes. A systematic literature review, as opposed to the conventional method, increases the accuracy of the analysis' output and enables more knowledge about the study's topic to be gleaned from the data.

TABLE III.     COMPUTATIONAL APPROACH EVALUATED USING RUBRIC

| Filed | Author and year | Tools/ Project |
|---|---|---|
| Construction | Probst et al., 2019 [51] | Rubric-based Safety Climate Assessment Tool (S-CAT) |
| Disaster | Schoch-spana et al., 2019 [53] | Composite of Post-Event Well-being (COPEWELL) |
| Education | Yago et al., 2018 [6] | Ontology Network-based Student Model for Multiple Learning Environments (ON-SMILLE) |
| | Aji et al., 2018 [49] | e-rubric |
| | Hussain et al., 2018 [58] | WEKA |
| | Azmi et al., 2019 [57] | Automatic evaluation of essay (AAEE) |
| | Nouira et al., 2019 [56] | Experience API (xAPI) |
| | Czajka et al., 2021 [59] | Enhancing Learning by Improving Process Skills in STEM (ELIPSS) analytic rubrics |
| | Thirumoorthy & Muneeswaran, 2021 [54] | Student Recruitment System |
| | IMS caliper [55] | IMS Caliper |
| Special education | Johnson et al., 2019 [52] | Explicit Instruction observation rubric |

TABLE IV.     RUBRIC-BASED ONTOLOGY

| Author and year | Aim |
|---|---|
| Yago et al., 2018 [6] | To do assessments based on rubrics, various sorts of objectives, and learning units should be given to students to determine their knowledge levels. |
| Nouira et al., 2019 [56] | To obtain information from student interactions and disseminate it into different contexts using ontologies and users |
| IMS caliper [55] | To support student learning |

The process of receiving or imparting systematic instruction, especially at a school or university, is referred to as education. Many issues that arise in the education domain that covered by researchers to solve the problem and give appropriate solutions. Education should be upgraded and used technology to provide benefits. MQF is a point of reference to explain and clarify qualifications and academic achievement in higher education with learning outcomes as the target, the MQF includes the eleven Learning Outcome Domains (LODs). This necessitates the curriculum to be designed through the mapping of the course and PLO onto the LODs. A little research has been conducted to relate the learning outcome to a rubric evaluation approach using the LOD-MQF, which can be used as a tool to evaluate students. It is supported by [6] that only used learning objectives in education as course learning outcomes for criteria that were evaluated using rubrics. However, there is no mapping between PLO and CLO. The research in [60] describes another study that focused on the assessment process, evaluation system, and assessment result of the mini project for module Digital System and Microprocessor (ECE511). The project delivered specifications based on existing CLO and aligned with PLO. However, the project does not include a rubric to evaluate student work.

Most researchers just map the course and PLO onto the CLO manually. It is also supported by [20] used the MQF to evaluate the subject coursework. However, the researcher creates a rubric by manually, which can lead to errors in the criteria that must be evaluated. The skill of the educator is lacking, though they follow the MQF to create rubrics. It is because there are some limitations to the impacts of the evaluator's evaluation skills, which encompass several criteria in evaluating proficiency [44]. The educator needs to have knowledge and experience to create a rubric.

According to socioformative methodology by [61], rubric design needs to be reviewed by an expert. The rubric also cannot be shared by other educators in the institution because the knowledge-based which is static. A computational approach using technologies that are ontologies can help the educator define rubric-based learning outcomes, support decision-making using MQF, and make the knowledge easily shareable. It is supported by [62] that state only 12% of researcher applications of ontologies in Higher Education focus on academic evaluation. It is proof that the evaluation of students is vital.

Other ontological approaches to curriculum exist, such as a curriculum ontology for EXTEND centres (international centres that can share data in a network of centers), knowledge transfer between centres in different countries and regions, exchange activities between those centres, double graduation certificates, and so on [46]. However, this curriculum was not implemented in Malaysia and was only exploited in Russia and Tajikistan. Another development is a website that used IMS Caliper model that apply ontological approach for framework. It also creates 16 rubrics based on learning outcomes [55]. The model also focuses on learning analytics [63]. The IMS Caliper framework is described in a way that is not entirely apparent, but it comprises of an ontology model that is applied to the rubric notion without having a learning outcome. Additionally, this rubric is not applicable in Malaysia because Malaysia has its own OBE framework.

According to the [56], xAPI specifications enable learning environments to capture data from student interactions and to share it with other environments using ontologies and users, but this model of xAPI does not have evaluation of students by assessment that is used rubric based learning outcome. The research by [64] shows that the researcher used an ontology approach in the engineering education field using the MQF. It is proposed that an ontology present a common vocabulary that facilitates electrical engineering curriculum development. The researcher, however, did not concentrate on evaluating students using a rubric-based map with learning outcomes. Fig. 2 show a part of ontological xAPI data model.

Research by [6], ON-SMMILE aims to promote student learning by developing a theoretical framework that makes use of the AR (Assessment Rubric) ontology model of rubric ontology. This ontology was modified from the rubric ontology [65]. The model of the rubric ontology is depicted in Fig. 3. The approach still doesn't apply to learning outcome based. An overview of the ON-SMMILE model is presented in Fig. 4.

This literature review demonstrates a few studies on an ontology design for PLO linked with CLO in higher education domain, particularly in support of the outcome-based learning and design rubric. With ontology, researchers or experts that conduct studies in the field of higher education can exchange and reuse the knowledge included in the model. It can also expressly state any domain assumptions. It is simple to alter the domain knowledge if it changes.

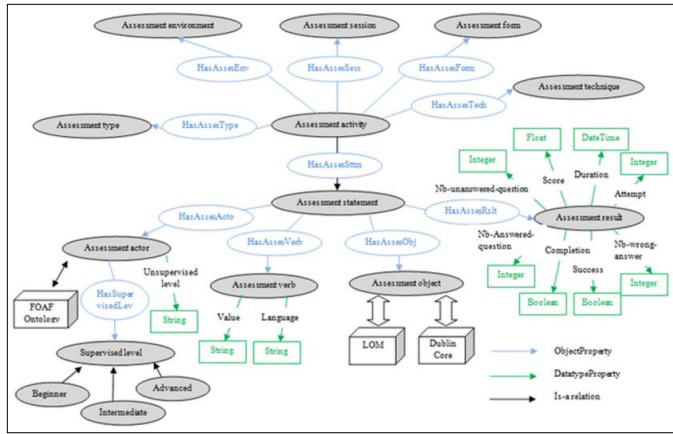

Fig. 2. A part of ontological xAPI data model [56].

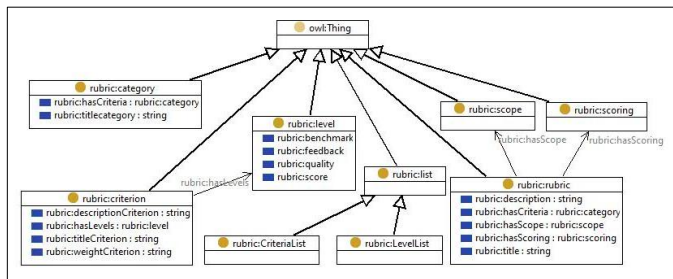

Fig. 3. Rubric based ontology [65].

In comparison to the standard method of conducting a literature review, a systematic literature review improves the accuracy of the analysis's output and makes it possible to glean more information about the subject of study from the data. It aids in the development of a structured literature review. The final step is to write a technical report or article about the complete systematic literature review process.

A structured literature review is beneficial. The final step is to write a technical report or article about the complete step in the systematic literature review process. Based on researchers' findings in the existing literature, none of the researchers used a rubric-based ontology to map CLO and align them with PLO. This rubric helps the educator create a rubric based on learning outcomes guided by the MQF.

## IV. CONCLUSION

A systematic approach to the literature review is necessary to produce accurate results from relevant studies. To stay current with the research and to include new discoveries by other researchers, a literature review may need to be updated frequently. The steps in a systematic review or meta-analysis include developing a research question and validating it,

creating criteria, searching databases, importing all results into a library, and exporting them to an Excel sheet. They also include writing a protocol and registering it; screening titles, abstracts, and full texts manually; extracting data and evaluating its quality; conducting statistical analysis manually; double-checking the data; writing a manuscript and revising it.

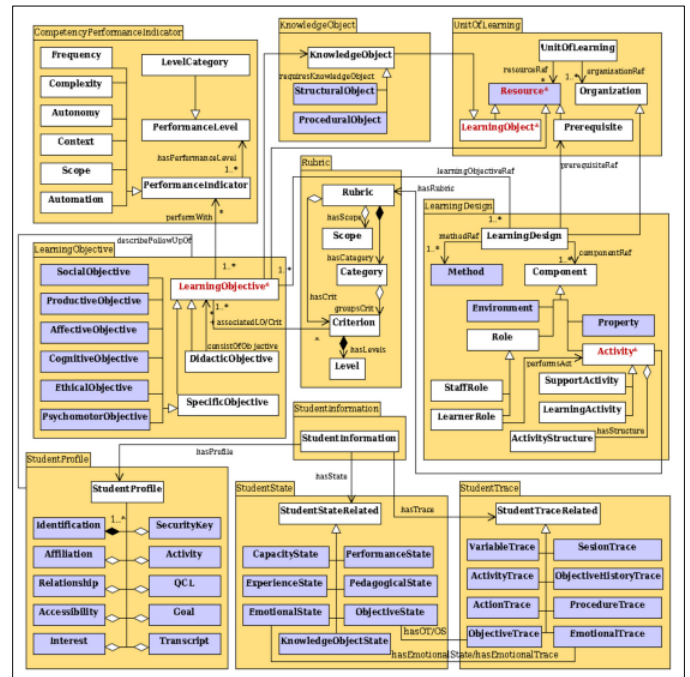

Fig. 4. The overview of the model of ON-SMMILE [6].

In this comprehensive research analysis, the characteristics of the most recent studies about the development of rubrics for student evaluation have been outlined and synthesized. The following is a summary of the key results from the literature review and the studied that were examined:

RQ1: Computational methods are now more frequently used in higher education to make complex problems simpler. However, there is still a need for a thorough analysis that provides an overview of how and to what extent computational approaches are integrated and implemented to address different concerns in higher education. To create a rubric based on learning outcomes, none of the scholars have employed the ontology technique or model. This aids in developing an appropriate framework for creating rubrics that are based on PLO and CLO.

RQ2: Ontology for rubric-based assessment is necessary to be used in PLO links with CLO because it is easy for educators to design rubric-based outcome-based learning that is guided by the MQF. Aside from that, the rubric ontology can be shared by other Malaysian educational institutions.

With these findings, researchers believe that scholars will better understand how the stages of computational techniques are employed when constructing a rubric, particularly for evaluating students, due to this thorough literature study. Researchers propose a study that focuses on the design of rubric-based outcome learning as future work to find solutions to fill gaps in this systematic literature review, such as the

interoperability issue and the understudied area of software needs. Focusing on the technology and approach techniques utilized in the development of a rubric utilizing outcome-based learning is another possibility.

# A Prediction of South African Public Twitter Opinion using a Hybrid Sentiment Analysis Approach

Matthew Brett Shackleford[1], Timothy Temitope Adeliyi[2], Seena Joseph[3]*

Department of Information Technology, Durban University of Technology, Durban, South Africa[1, 3]

Engineering, Built Environment, and Information Technology, University of Pretoria, Pretoria, South Africa[2]

*Abstract*—Sentiment analysis, a subfield of Natural Language Processing, has garnered a great deal of attention within the research community. To date, numerous sentiment analysis approaches have been adopted and developed by researchers to suit a variety of application scenarios. This consistent adaptation has allowed for the optimal extraction of the authors emotional intent within text. A contributing factor to the growth in application scenarios is the mass adoption of social media platforms and the bondless topics of discussion they hold. For government, organizations and other miscellaneous parties, these opinions hold vital insight into public mindset, welfare, and intent. Successful utilization of these insights could lead to better methods of addressing said public, and in turn, could improve the overall state of public well-being. In this study, a framework using a hybrid sentiment analysis approach was developed. Various amalgamations were created – consisting of a simplified version of the Valence Aware Dictionary and sEntiment Reasoner (VADER) lexicon and multiple instances of classical machine learning algorithms. In this study, a total of 67,585 public opinion-oriented Tweets created in 2020 applicable to the South African (ZA) domain were analyzed. The developed hybrid sentiment analysis approaches were compared against one another using well known performance metrics. The results concluded that the hybrid approach of the simplified VADER lexicon and the Medium Gaussian Support Vector Machine (MGSVM) algorithm outperformed the other seven hybrid algorithms. The Twitter dataset utilized serves to demonstrate model capability, specifically within the ZA context.

*Keywords*—*Sentiment analysis; opinion mining; machine learning; government; public service delivery; twitter*

## I. INTRODUCTION

Communication has become more dynamic due to the widespread adoption of both mobile devices and the Internet; this has allowed for people to express themselves regardless of location. In both the public and private sectors, organizations have either begun or currently leverage technical methods of analyzing public opinion [1-4]. Governments and organizations deemed the assessment necessary to gain a full understanding of the emotional state of a specific group in relation to that of their own performance [5].

Sentiment analysis or alternatively referred to as opinion mining, is a branch of Natural Language Processing that uses a variety of methods to determine an author's positive, negative, and neutral emotional stance from snippets of their writing [6]. Typically, analysis takes place at an aspect, sentence, or document level, however a combination of levels is an additional possibility and at times - can offer a more comprehensive perspective. Successful sentiment analysis would be the precise extraction of the emotions surrounding a viewpoint within the context in which correct interpretation was intended by the author [7].

A significant proportion of the sentiment analysis attempts in the South African (ZA) context have been geared toward specific events or themes, such as gauging perspectives on ethnic division [8], sexual violence [9], and the #FeesMustFall campaign [10]. This focus on judging instances ignores the importance of attaining a multidisciplinary model qualified to assess the emotional state of the ZA population, throughout a multitude of varying scenarios.

Sims determined in [11] that losing track of the public's opinion or neglecting a society's overall emotional state can lead to unfavorable public behavior, such as protests, which has a multifaceted and detrimental influence on the country. One can conclude that an accurate means of analyzing the Tweets of ZA public perception, would result in the emotional state of the public being handled in a more proactive and effective manner. Furthermore, such a model might be used to detect future communication patterns that may fluctuate the emotional state of the targeted demographic (positively or negatively). As more people around the world utilize social media to communicate their thoughts and feelings, the necessity to iteratively construct a better system of assessing an author's sentiment, using various sentiment analysis approaches that are suitable for the intended provided circumstances, becomes a challenge [12].

This study serves as an example that the created model may additionally work within the context of other countries, as the Valence Aware Dictionary and sEntiment Reasoner (VADER) lexicon is not specific to the ZA domain in which it succeeded - but rather likely the American domain from whence it came. The testing and creation of a novel sentiment analysis hybrid geared toward social media is highly beneficial, as it serves globally as an option for social media text analysis. Additionally, it was created with the hopes of effectively analyzing social media within the ZA context. As mentioned later in the related works section, hybrids have the tendency of outperforming standalone lexicon and machine learning models. As suggested, a social media hybrid model such as the hybrid in this study might be better suited to reanalyze the #FeesMustFall dataset [10].

The layout hereafter is as follows. A brief overview of the literature in Section II. Section III focuses on: the VADER and Twitter dataset; hardware and software used; study

architecture; planned approach; data preparation and processing; machine learning model parameters; evaluation criteria; as well as Twitter dataset preparation, processing, and evaluation. Section IV focuses on an analysis of the results. Section V consists of speculation over the results. Limitations of the study are highlighted in Section VI. The concluding remarks are found in Section VII. Future research is briefly discussed in Section VII.

## II. Related Work

There are four supervised classification algorithm types that contain models commonly used for sentiment analysis, according to Birjali et al., [13]. The first is a Linear approach, a statistical method for categorizing sentiment using hyperplane or linear decision boundaries. The linear approach ultimately outputs the most probable class (either negative or positive within the sentiment analysis domain) of a prescribed input. Secondly and in contrast to the linear technique, the probabilistic classifier – typically founded on Bayes' theorem – works by predicting a probability distribution over a set of classes. The third approach is rule-based classification, which refers to any classification scheme that uses IF-THEN rules to predict class membership. As a result, a set of rules ultimately guides the classifier in this technique to accomplish sentiment classification. The fourth option is the decision tree strategy, which decomposes the training data space hierarchically using an attribute value condition to classify input data into a limited quantity of predetermined classes. Additionally, the ensemble approach exists as a varied combination of the above approaches. The fundamental proposition behind this idea is to form an ensemble of different classifiers that outperform their standalone examples.

The authors in [14,15] attempted to apply and compare a variety of machine learning models, however, their results varied depending on the methodologies and datasets employed. This is mainly because a machine learning model that performs well in one trial does not necessarily guarantee equivalent performance in subsequent studies, due to varying circumstance. As results differ, models need to be tested separately under exact circumstances. Traditional machine learning approaches use a single learner method; however, an ensemble approach uses numerous learner methods to better leverage each learner's unique strengths while also covering any shortcomings that may exist, resulting in increased model precision and reliability [16,17]. When opposed to using a single classifier model, the most significant disadvantage of ensemble techniques is the additional processing time and power required [13].

Bagging, boosting, stacking and voting are the ensemble approaches leveraged to better the results of traditional standalone machine learning models [15, 18]. Bagging is a bootstrap aggregating prediction ensemble machine learning technique. Boosting ensemble is a strategy for training a set of weak classifiers that were previously poorly trained [19]. When presented with noisy data, such as unstructured Twitter text, boosting is more sensitive, while bagging is more resistant [20]. Despite this, boosting strategies have been utilized in several studies to increase model performance [21, 22]. Stacking is an ensemble model where various diverse methods

are devised using training data [18]. The use of the ensemble machine learning method to analyze sentiment is limited [23]. This additionally holds true with the analysis of ZA citizen text via digital platforms.

An ensemble machine learning strategy that focuses solely on learning classifier combinations is successful in multiple investigations [15, 24]. To obtain a final prediction, the voting ensemble approach uses pre-processing sentiment analysis, feeding several algorithms, and then integrating the results into a voting average method. Other models may use various components at different stages while still adhering to the same process. An ensemble method in the literature performed well throughout the evaluation when different classical machine learning algorithms were placed via a vote on average probability approach.

Pre-trained word embeddings are created using Bidirectional Encoder Representations from Transformers (BERT), an ensemble of binary classifiers [25]. The feature selection and feature extraction processes used in sentiment analysis pre-processing are not required because this approach takes tokenization as input [26]. As a result, researchers in [25] observed that a combination of BERT supplied pre-trained word embeddings along with the Random Forest classifier led to an accuracy of 94%, exceeding current models at the time of publication. The study in [26] achieved comparable success when creating a BERT - Support Vector Machine hybrid model, attaining 94% accuracy.

Hybrid sentiment analysis models typically exist as a combination of machine learning and lexical approaches. Hybrid sentiment analysis models are popular as an alternative for sentiment analysis as they combine the versatility of machine learning algorithms with the superior performance of lexicons [27, 28]. When compared to the state-of-the-art machine learning and lexicon approaches available, Abd El-Jawad et al [14] discovered that hybrid models tended to outperform the latter. As a result, it is concluded that hybrid sentiment analysis approaches would seem to offer top results.

One of the more widely used supervised machine learning techniques within the sentiment analysis domain is the Support Vector Machine (SVM) algorithm [29]. While the original SVM model uses a linear hyperplane, non-linear hyperplane models are often accommodated using a kernel method such as the Gaussian function. The Medium Gaussian Support Vector Machine (MGSVM) deals well with data of medium complexity and adopt the kernel scale $\sqrt{P}$ – where the value $P$ refers to the dimension size or the number of features of the vector $x_i$ [30, 31].

Many lexical approaches exist such as the manual, dictionary-based, corpus-based, and statistical approaches to name a few, and within these approaches lay a variety of lexicons [13]. One lexical approach that has proven to be a valuable outlier within the social media sentiment analysis domain is the VADER lexicon. The VADER lexicon is tuned towards assessing contents like that of a microblog and has particularly succeeded in the social media domain [32].

Based on the advantages of both the MGSVM and VADER approaches as well as the hybrid approaches tendency to

outperform standalone models, a gap in the literature was found where a hybrid of the two was yet to be created. This study sought to create a hybrid of the two as well as various other hybrid approaches, to compare and establish an effective means of assessing ZA public Twitter opinion.

## III. MATERIALS AND METHOD

The VADER lexicon contains a lexical corpus that holds a variety of words and their associated negative or positive numerical weighting depending on the keyword's perception and has been empirically validated by various individuals [32]. The VADER lexical dataset was obtained and is freely accessible via GitHub [32]. Based on the keyword sentiment weighting, the July 2019 version of the VADER lexical dataset contains 7517 keywords, 3344 of which are classed as positive and 4173 as negative. The hybrid model was also evaluated on a dataset of ZA public Tweets from the public repository site Kaggle. The experiment was performed using MATLAB R2021b on a Windows 10 Professional machine.

The study architecture is depicted in Fig. 1. The hybrid model creation and selection process takes place in the first stage, whereas the capability of the chosen hybrid model is tested on a ZA public dataset in the second stage. In this study,

a hybrid strategy with two stages is developed to overcome the shortcomings of the separate techniques.

### A. Stage 1 – Creating a Top-Performing Hybrid Model:

Five-fold cross-validation was used to train each model. The use of this validation method minimizes the effects of sampling bias. This is done through the random division of the lexical dataset – into five equal sections. Four of the five equal sections are used to train the algorithm, with the remaining section set aside to test the algorithm. This is repeatedly done until all combinations of the test/training set have been exhausted and, the resultant model produced is the mean of the training iterations [33]. Additionally, this procedure was opted for as it prevents both overfitting and underfitting to provide a more exact result.

Simplified VADER lexicon – The original VADER lexicon is acquired, and the keywords are assigned polarity, either positive or negative depending on their allocated numerical rating. The simplified VADER dataset is utilized to train various classical machine learning models. These hybridized models are evaluated utilizing performance evaluation measures at a later stage.

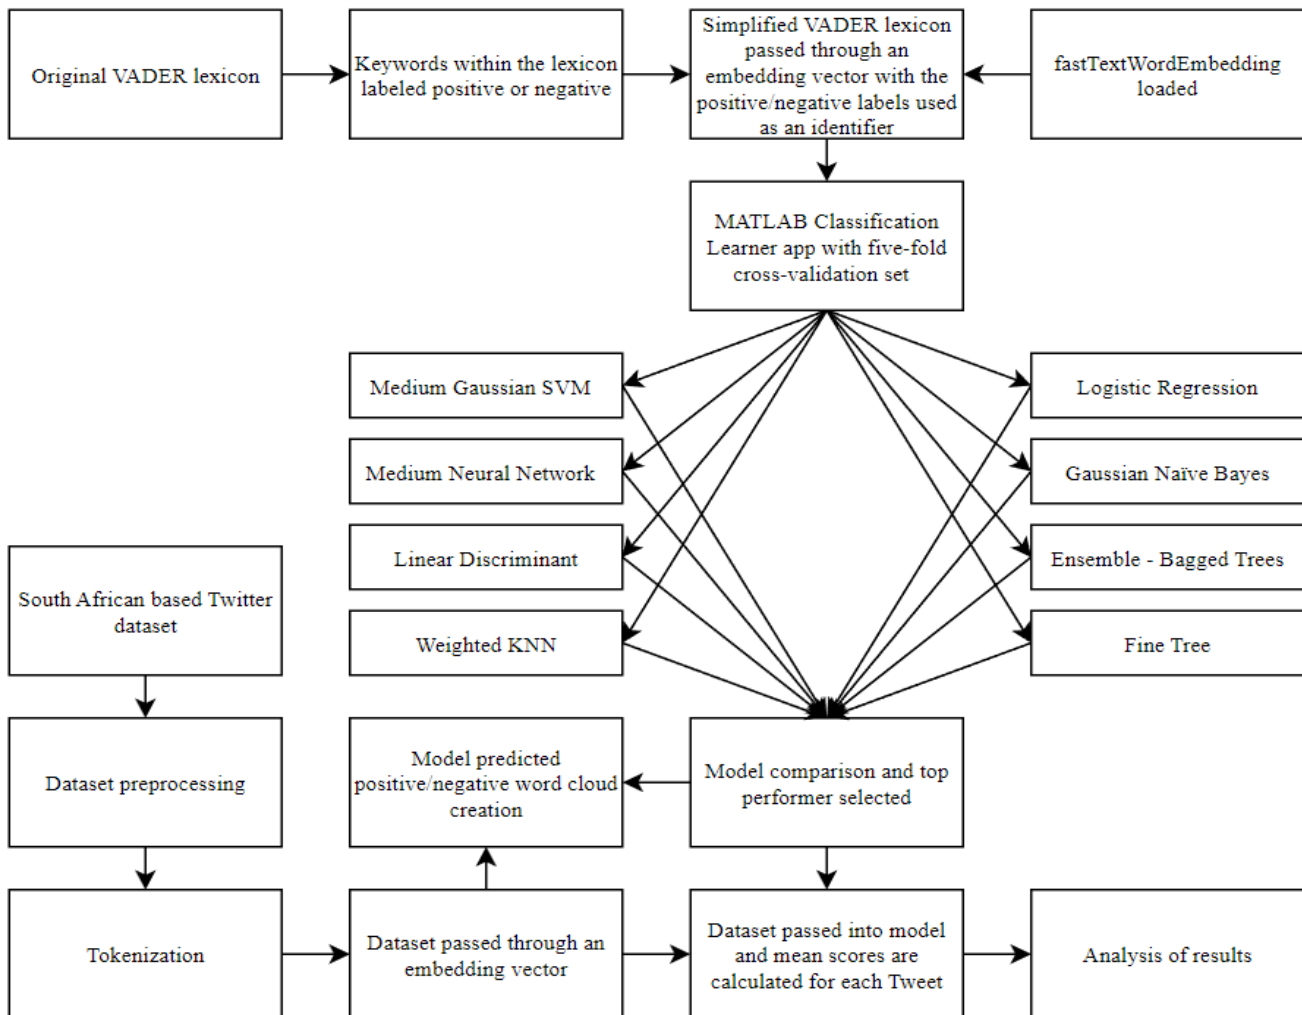

Fig. 1. The study architecture.

Vectorizing the simplified VADER Lexicon - A subfunction of the fastTextWordEmbedding function in MATLAB, word2vec is obtained via the "text analytics toolbox". The need to pass the simplified lexical corpus through word vectoring originates from distributed representation; the function assists in passing the words into numerical vectors [34], which assist the algorithm to better correlate words with their planned outcome.

Reconnecting the sentiment and the lexical vector - The linked sentiment is substituted as the vector's "predictor" after the lexical keywords have been vectorized.

Learner application for MATLAB classification - To check the generalization capacity of predictive models and avoid overfitting, the transformed lexicon is entered into the MATLAB classification learner program, and the validating method is set to five-fold cross-validation.

Training the machine learning models - The various hybrid models are created from a selection of classical models from the MATLAB classifier learner program. The chosen classical models are: Fine tree (FT), Medium Neural Network (MNN), Logistic Regression (LR), Gaussian Naive Bayes (GNB), MGSVM, Linear Discriminant (LD), Weighted K Nearest Neighbor (WKNN) and Ensemble-Bagged Trees (EBT). The models were programmed to make use of parallel processing. Table I highlights the parameters used to train each of the models. Additionally, hyperparameter options and principal component analysis was disabled for all the chosen models. The various models ran on default parameters, assigned to each model based on the way in which MATLAB interpreted the training dataset.

Having trained the various classical models on the VADER lexicon, the various hybrid models are compared using the following performance metrics: Validation confusion matrix (VCM), Accuracy, Recall, Precision, Receiver Operating Characteristic (ROC) curve, Area Under the Curve (AUC), F1-score, training time, and prediction speed.

### B. Stage 2 - An Overview of how the Hybrid Model was Utilized to Process the ZA Public Twitter Dataset:

Obtaining a Twitter based ZA public opinion dataset - The dataset of ZA public Twitter opinion is regarded as crucial for carrying out the experiment and creating a suitable environment. Because the presence of any manipulation could skew the results and compromise the authenticity of the simulated environment, the dataset must include the raw text from users' Tweets. This dataset might be retrieved through a selection of internet-based data repository sources, for instance "Kaggle," or it could be retrieved by leveraging the Twitter research Application programming interface (API) through an authorization process. As the researcher was unable to secure Twitter research API access, the dataset used in this article was obtained through Kaggle.

Data preparation - This part of the research entails processing the dataset into a suitable state for the trained hybrid model to process and output an authentic result.

TABLE I.        MATLAB CLASSIFICATION LEARNER MODEL PARAMETERS

| MATLAB Preset | Other |
|---|---|
| Medium Gaussian SVM (MGSVM) | Kernal function: Gaussian<br>Kernal scale: 17<br>Box constraint level: 1<br>Multiclass method: One-vs-One<br>Standardize data: true<br>Cost matrix: default |
| Medium Neural Network | Number of fully connected layers: 1<br>First layer size: 25<br>Activation: ReLU<br>Iteration limit: 1000<br>Regularization strength ($\lambda$): 0<br>Standardize data: yes |

| Fine Tree (FT) | Maximum number of splits: 100<br>Split criterion: Gini's diversity index<br>Surrogate decision splits: off<br>Cost matrix: default |

- Removing columns - The Kaggle sourced Twitter dataset holds columns such as - "Tweet author", "Tweet created at", "Tweet coord", "Tweet favorite count", "Tweet hashtag", "Tweet retweet count", "Tweet place", and "Unique ID" - that are deemed extraneous. All irrelevant columns are eliminated, leaving the column "tweet text," which contains the textual data required.

- Erasing hexadecimal Unicode - The Kaggle obtained dataset was originally extracted by the author (Mbuso Makitla) utilizing the Tweepy API. Due to decryption limitations and time constraints, the MATLAB function "regexprep(str,expression,replace)" is used to remove the Unicode, with the "expression" and "replace" values of '\\[a-z0-9]3}' and ' respectively'.

- URL removal - To exclude URLs from the Twitter text, the erase URL (str) function in MATLAB is used. These occurrences usually happened because of Tweet authors retweeting or linking to other websites within their Tweets.

- Stop word elimination – According to [5] common phrases like "an", "it", and "the" are removed. The function removeStopWords(documents) in MATLAB is used to accomplish this. This is necessary to mitigate the consequences of noisy data.

- Normalization - This phase involves removing punctuation using MATLAB's erasePunctuation(str)

function, furthermore lower(str) is used to transform all Tweet text to lower case. The goal of normalization in the preprocessing stage is to increase text homogeneity [35].

- Tokenization - This is used to break down Tweets into smaller text samples for sentiment analysis; word tokenization is leveraged as the text is evaluated on a per word basis.

Using word2vec to transform the preprocessed ZA Twitter dataset – To produce distributed word representations, and to match the database to the training dataset, word2vec was used on the preprocessed ZA Twitter dataset.

Word cloud evaluation - This visual tool is leveraged to roughly assess the classificational ability of the hybrid model. The word cloud outputs assumptions for those words on which the hybrid model was trained, and new words the hybrid model has yet to encounter. The compilation of the word cloud is based off words contained in the ZA Twitter dataset.

Hybrid model implementation - The hybrid classifier is used once again to run the preprocessed ZA Twitter dataset. The classifier calculates the sentiment of each word in the Tweet and the segment of code thereafter assigns a mean score to the entire text sample. The outcome is responsible for determining the polarity of the text, negative values equate to negative sentiment as does a positive value indicate positive sentiment. Naturally the closer the sample is to zero the more neutral the Tweet text.

Sentiment analysis system evaluation – A function in MATLAB is leveraged to record the duration required to run the preprocessed ZA Twitter dataset through the hybrid model. Additionally, the final estimated outcome of the hybrid classifier and original Tweet is to lightly undergo a comparative observational analysis. This comparative analysis helps to identify instances where the hybrid model may have succeeded, misjudged, or failed to appropriately determine the sentiment of the Twitter text.

## IV. RESULT ANALYSIS

### A. A Comparison of the Various Created Hybrid Models:

The True Positive (TP) value serves as an indicator of the successful positive predictions made by the various hybrid models, as indicated in Fig. 2. The leading hybrid model (MGSVM) surpasses the runner-up (MNN) by a margin of 64 predictions. The False Positive (FP) value denotes how many positive samples the various hybrid models predicted incorrectly, as indicated in Fig. 2. The leading hybrid model (MGSVM) predicts more accurately than the runner-up (EBT) by a margin of 58 less incorrect predictions. The False Negative (FN) value indicates how many negative samples the various hybrid models predicted incorrectly, as indicated in Fig. 2 The MGSVM hybrid model makes fewer prediction errors than the runner-up (MNN) by a margin of 64 less inaccurate predictions. The True Negative (TN) value serves as an indicator of the successful negative predictions made by the various hybrid models, as indicated in Fig. 2. Where the MGSVM hybrid model surpasses the runner-up (EBT) by a margin of 58 predictions. In terms of VCM performance, the

MGSVM hybrid model is undoubtedly the winning hybrid model – as it outshone the remaining hybrid models in all four VCM categories. However, it is important to note that in the runner-up category, MNN (second best for TP and FN) was bested by EBT in the FP and TN categories FN, however EBT almost placed last in the TP and FN categories - this suggests that the MNN hybrid model is the rightful runner-up to the MGSVM hybrid model. Subject to a larger training dataset, the EBT algorithm does have the possibility of excelling, but the likelihood is that the EBT algorithm would continue to call an excessive number of values - negative. The WKNN and EBT hybrid model share similar patterns despite the different degree of extremes, which means the WKNN hybrid model may also possibly benefit from a lager training dataset. A possible cause of the labelling bias may stem from the fact that the VADER dataset contains 829 more negative than positive samples, this translates to a skew of 55.51% negative to 44.49% positive.

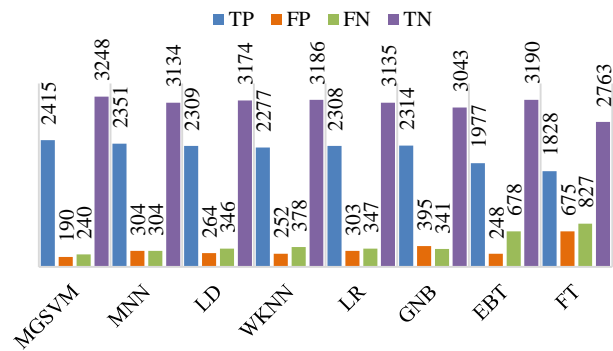

Fig. 2. A grouped bar chart comparing the VCM values of the eight hybrid models.

Table II holds performance metrics such as: accuracy, precision, recall and f1-score. These metrics are a resultant of calculations derived from VCM values. Table II additionally highlights the dominant stance the MGSVM hybrid model holds in every category in comparison to the several other hybrid models. The MGSVM hybrid model generates: an accuracy lead of 2.9% in comparison to the runner-up MNN; a precision of 92.7%, which in turn corresponds to a substantial contrast of 2, 7% in comparison to WKNN at 90%; a recall difference of 2.5% in comparison to the runner-up MNN at 88.5%; and finally, a specificity ratio at 0,945, in comparison to the runner-up EBT at 0,928.

TABLE II. THE PERFORMANCE EVALUATION METRICS FOR THE EIGHT HYBRID MODELS

| Model | Accuracy (%) | Precision | Recall | Specificity | F1-Score |
|---|---|---|---|---|---|
| MGSVM | 92,9 | 0,927 | 0,910 | 0,945 | 0,918 |
| MNN | 90,0 | 0,885 | 0,885 | 0,912 | 0,885 |
| LD | 90,0 | 0,897 | 0,870 | 0,923 | 0,883 |
| WKNN | 89,7 | 0,900 | 0,858 | 0,927 | 0,878 |
| LR | 89,3 | 0,884 | 0,869 | 0,912 | 0,877 |
| GNB | 87,9 | 0,854 | 0,872 | 0,885 | 0,863 |
| EBT | 84,8 | 0,889 | 0,745 | 0,928 | 0,810 |
| FT | 75,3 | 0,730 | 0,689 | 0,804 | 0,709 |

When compared to the other hybrid models, the MGSVM hybrid model is the overall best performer in the F1-score category – at 91.8% it secures a marginal triumph of greater than 3%. Following the MGSVM hybrid model in the F1 performance metric was MNN at 88.5% and LD at 88.3%. Comparatively the FT hybrid model performed terribly and only achieved an F1-score of 70.9%.

The ROC curve serves as a graphical representation of the relationship between the TP rate and FP rate indices of a model. It additionally serves as a visual means of assessing the model's diagnostic capacity. The MGSVM hybrid model steadily outperforms the other hybrid models, as seen in Fig. 3. MNN, LD, WKNN, and LR, the middle runners, are all close to each other. Furthermore, falling just short of the middle runners is the GNB hybrid model, and despite the smooth curve, the EBT hybrid model lags to an even greater extent. Finally, the FT hybrid model curve shows how the slow to train and erratically the hybrid model behaves as it places in the last position.

Fig. 3. The ROC curve of the eight hybrid models.

The area beneath the ROC is also of great importance as larger AUC values are often desired and this number falls between 1 and 0. Fig. 3 shows the superior area beneath the curve which the MGSVM hybrid model holds, and subsequently has a very good AUC score of 0.98 as per Fig. 4. The majority of the other hybrid models fall between 0.95 and 0.93, resulting in a minimum 0.02 deficit in favor of the MGSVM hybrid model. At 0.79, FT performs dismally once more. Fig. 4 highlights both the AUC, and the "co-ordinates" where the "current classifier" point exists on the ROC in Fig. 3, although not depicted; these co-ordinates may be found along the columns labelled "True Positive Rate" and "False Positive Rate".

As presented in Table III, each hybrid model furnished generic training results with metrics, such as 'total misclassification cost' and 'prediction speed'. The entire misclassification cost of the MGSVM hybrid model was 430, and the forecast speed was approximately 7, 5 objects per millisecond.

Fig. 4. AUC, TP, and FP rate of all hybrid models.

TABLE III. ADDITIONAL GENERAL HYBRID MODEL TRAINING RESULTS

| Created Hybrid Model | Training Results (General) | |
|---|---|---|
| | *Total Misclassification Cost* | *Prediction speed (objects/milliseconds)* |
| MGSVM | 430 | ~7,5 |
| MNN | N/A | ~72 |
| LD | 610 | ~23 |
| WKNN | 630 | ~1 |
| LR | N/A | ~25 |
| GNB | 736 | ~45 |
| EBT | 926 | ~22 |
| FT | 1502 | ~43 |

Training time – another important model value – is predominantly evaluated in two scenarios: firstly, a constant supply of emerging data which in turn leads to frequent retraining of the model; secondly, more complex or lager datasets can also lead to a dramatic increase in training times. Due to the use of the smaller simplified VADER corpus, training time is less of a concern in comparison to a larger lexicon, such as SentiWordNet, which includes around 117000 keywords.

Fig. 5 shows the LD hybrid model was trained in a mere 5, 18 seconds – making it undoubtedly the quickest to train in this instance. Second to this was GNB at 9,39 seconds followed by LR at 12,12 seconds. The favored MGSVM hybrid model achieved fifth position at 23,78 seconds. Following from here onward the training times of the other hybrid models, except for the FT hybrid model, rapidly deteriorated to approximately the 70-80 second domain. Keeping the context of the study in mind, training times would only be relevant should the dataset: grow in some way; be replaced by the production or disclosure of a larger more suitable lexical dataset; or require frequent retraining. In the context of training time, the LD hybrid model may only be worth taking into consideration as a backup option should it not require frequent retraining, as it is not susceptible (more so than other hybrid models) to dramatic increases in training time (relative to the size of the new dataset) or should the MGSVM hybrid model fail. Finally, one can concur that

the MGSVM is more than acceptable for this application, because of the one-time training requirement and a more than bearable training duration.

### B. Hybrid Model Performance Regarding Twitter Dataset Sentiment Analysis:

Pre-processing the ZA public Twitter dataset was determined as a straightforward task that was successfully completed. Prior to allowing the MGSVM hybrid model to determine the sentiment of the pre-processed ZA public Twitter dataset, it was crucial to consider how the hybrid model will handle both in terms of data it had encountered and that in which it hadn't. Fig. 6 shows two-word clouds: the one on the left highlights terms that the hybrid model predicts will have a positive opinion, while the one on the right highlights phrases that the hybrid model predicts will have a negative emotion. This step is crucial as it allows for basic visual conformation that the hybrid model is behaving reasonably and within expected range when judging sentiment for both words it has yet to encounter, as well as those contained within the lexical corpus training dataset.

As per the positive word cloud in Fig. 6, it is observed that the hybrid model correctly classified most new terms supplied as positive. For instance, enriching, excellence, happy, inspirational, and wholesome have an undeniably positive connotation. However, there were several unusual predictions made by the hybrid model:

- Kelly - a proper noun used to provide someone/something a name. Due to the lack of emotion behind the word it remains commonly regarded as neutral.

- Cuppa - a traditionally British colloquialism for "a cup of tea". It does not feature in the VADER lexicon; however, it tends to carry a positive sentiment.

- Polo - a term that refers to either an equestrian sport or a popular Volkswagen automobile model. Although traditionally the word is neutral, the positive sentiment may have incorrectly been derived from either apology or one of its derivatives that VADER deems a positive term - the derivative "apologizing" is the only derivative seen as negative.

Fig. 5.    A hybrid model training time comparison.

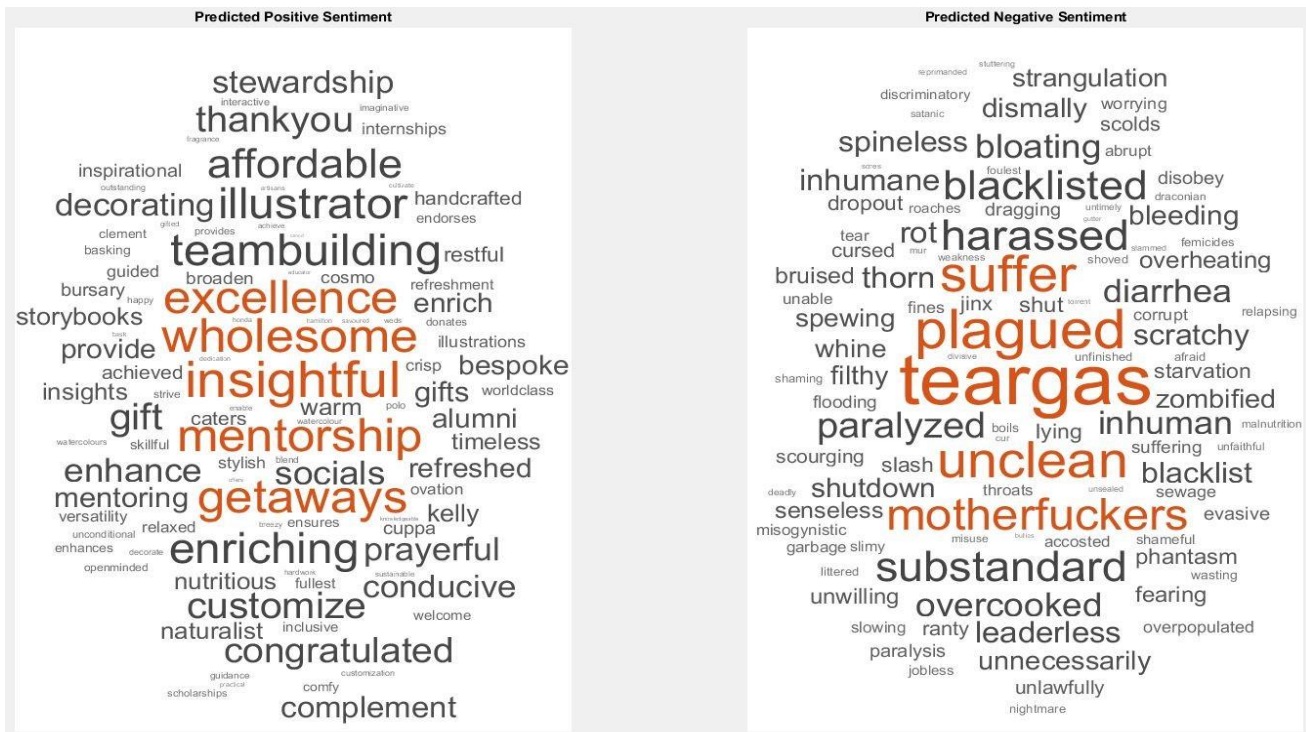

Fig. 6.    A word cloud containing words of positive (left) and negative (right) sentiment that the hybrid model has labelled from the ZA Twitter public dataset.

The word cloud consisting of 'positive' words tended to contain terms of a predominantly positive nature - with only a few neutral exceptions. It did not contain any negative words.

Observably the negative word cloud in Fig. 6, highlights that the hybrid model correctly classified most of the new terms provided as negative. Corrupt, inhumane, misogynistic, plagued, and suffer are all words that have a negative connotation. Only words with a negative emotional context were found to be in the 'negative' word cloud, with no discernible words of a neutral or positive nature detected. That said, an argument could be made that the 'negative' word cloud contained a few words that held contextually varying sentiment. This can be demonstrated with the word "cut", which should appear as neutral in "my new knife has a brilliantly clean cut." Considering the word "cut" as negative in this context risks throwing the sentiment of a clearly positive string of text into an overall neutral result.

After successfully running the pre-processed ZA public Twitter dataset through the MGSVM hybrid model, the results were further processed utilizing an aggregate scoring technique to achieve document-level sentiment analysis – that output a resultant Tweet sentiment score. Overall, it took 45 minutes and 25 seconds to run the hybrid model on the entire pre-processed ZA public Twitter dataset (67585 total Tweets) to get the mean sentiment of each Tweet.

## V. DISCUSSION

The hybrid model identified the below five Tweets in the dataset as the most positively oriented in terms of prediction efforts (any duplicate Tweets by users are ruled out):

- "Neymar enjoying his @redbull https://t.co/rb1JxQiIct" – Perceivably positive. Neymar is pictured in the post as being in a celebratory mood posing with an energy drink.

- "Thank you @shotsbysbu this is so beautiful #bbnajia2020 #SSDiski #MotoGP https://t.co/NJ6kAClvdq" – Perceivably positive. The Twitter shortened link leads to the image of a wonderful art piece that the author refers to.

- "Together with her beauty #SkeemSaam https://t.co/I99y40BxUP" – Perceivably positive. The author further complements and connects with a Twitter shortened link, to which another Twitter user encourages the wedlock of a TV personality.

- "Children? Goodluck https://t.co/Y3FPLJkwmA" – Perceivably negative. The author is either implicating that complex matters may be difficult to educate children on, or alternatively believes the Twitter linked author has had a lapse of judgement for wanting to educate their children about the LGBTQI+ community. The hybrid model can only analyze the textual component and is unable to study the context required from the additional Twitter shortened link, resulting in the prediction error.

- "This is nice. #CouplesDay https://t.co/AeEaNPIGA4" – Perceivably positive. The author expresses enthusiasm towards couple's day. Although doubtful, the term of phrase "This is nice." could also be taken sarcastically. However, there are no grounds to support either assertion as the URL is no longer available.

The hybrid model identified the below five Tweets in the dataset as the most negatively oriented in further prediction efforts (once again, any duplicate Tweets by users are ruled out):

- "Neymar the Dangerous https://t.co/np6RzEMoxp" – Perceived as either negative or positive. The author is either a fan or an oppositional critic of Neymar, a professional football athlete. The link leads to an image showing Neymar in possession of the ball and closely surrounded by three oppositional players. The hybrid model is clearly focused on the negative connotation of the term dangerous. Due to the inability to further explore image sources the hybrid model is unable to gain greater contextual understanding.

- "YOU ARE CURSED https://t.co/ftP4t4eG0y" – Perceivably negative. The Tweet author is damning another user. The original Tweet author implies that the author in the link is possessed, as they would like to begin teaching children about homosexuality from the age of seven.

- "Mama boyza she lying jerrrrrrr #SkeemSaam" – Perceivably negative. The author is upset and frames a female character on the TV show "Skeem Saam" as dishonest.

- "Wow, Im sad #RIPNdlovu" – Perceivably Negative. The author is grieving the loss of a figure in their lives.

- "Zimbabwe. We are in trouble. #PutSouthAfricansFirst. #SAMediaMustFall https://t.co/EPo3JS4E4N" – Perceivably Negative. The author may share a negative sentiment with the link's author, who is concerned about the asylum issue and believes that South Africa suffers the brunt of the responsibility.

The below Tweets were deemed neutral by the hybrid model, despite the positive sentiment intended by the author:

- "Same. https://t.co/xesDjgfA4d" – Perceivably positive. The author and link author share the same mindset to teach their children about relationships and the LBGTQI+ community. Due to model limitations, the hybrid model has no further context and the Tweets main text "Same." ends up taking on a neutral sentiment.

- "Saving this https://t.co/354EU4auV1" – Perceivably positive. The author agreeingly feels that educating their children about homosexuality and relationships is essential, hence the desire to save the content for future reference. The term "saving this" is interpreted as neutral by the hybrid model as it is unable to further explore the contents behind the Twitter shortened link.

The below Tweets were deemed neutral despite the hybrid model having acquired clear direction in the training dataset:

- "Thank you @chrishemsworth https://t.co/VCFxtYuYLG #motivate #sundaymotivation #covid" – Perceivably positive. The author is thanking a famous film actor via their Twitter handle and using hashtags of a positive nature, except for "#covid" which has a negative stigma. Even though the hybrid model had previously identified, within the positive word cloud, the closed compound word "thankyou", the inability of the hybrid model to further perceive the open compound of "thank you" as positive is uncertain.

- "Wtf is this? https://t.co/hffp9iOFBU" – Perceived as either negative or positive. The author is confronted by the image of a French Poodle on a red sofa followed by the heading "nothing to see here", this method of notifying a user of a missing page is done by Twitter to try and lift the users' spirits. In this instance the author might use the phrase "Wtf is this?" as a positive means to show their followers the amusing content. Alternatively, the author may be frustrated by the missing content hence the use of "Wtf". Further analysis reveals that the acronym 'wtf' is classified as negative in the VADER lexicon, as to why the Tweet was deemed as neutral is a mystery.

## VI. LIMITATIONS

Throughout the research several limitations were discovered, this is to be expected. Effort was made to overcome several of the limitations – however the list below highlights unresolved limitations faced:

- Twitter API access and the use of a publicly available dataset. Despite numerous attempts the researchers could not gain research access to the Twitter API, this meant that a publicly available dataset became the next best available option. However, the use of a publicly available dataset means that search selection criteria are lost, and one could argue that it leads to an imperfect artificial environment for model testing.

- Punctuation removal. Certain entries in the VADER lexicon are punctuation based emojis. Additionally, the general use of punctuation adds to sentiment. The removal of punctuation resultantly leads to a loss in sentiment.

- Twitter dataset Hexadecimal Unicode removal. Aside from punctuation based emojis which were ultimately removed, the VADER dataset does not contain any hexadecimal Unicode emojis. The removal of hexadecimal Unicode, however, ultimately results in a loss of sentiment when assessing the Twitter dataset.

- The removal of certain words that do not appear in the isVocabularyWord subfunction of the function fastTextWordEmbedding. To effectively use the word2vec subfunction in MATLAB textual data should pass through the isVocabularyWord subfunction. However, passing certain misspelled, unknown slang, or other forms of other unknown words – means that

they are eradicated from both the training dataset and the tested Twitter dataset.

- Lack of contextual inclusion. Despite Twitter predominantly being a text-based platform, social media contains text, images, videos, and URLs. These other forms of medium are unreadable by a text-based sentiment analysis model.

## VII. CONCLUSION

The research evaluated several hybrid sentiment analysis models, of which a state-of-the-art simplified VADER centered hybrid sentiment analysis model was produced. In accordance with the results, the MGSVM hybrid model outperformed the other hybrid models by a significant margin. Training time was identified as the key disadvantage of the MGSVM hybrid model creation process, demonstrated to be inconsequential in the future as instances of retraining would be rare and the use of a more expansive and/or intricate corpus was not a necessity. Additionally, the LD, LR, MNN, WKNN, and GNB hybrid models, albeit the latter to a lesser extent, were among the middle runners. By far the FT hybrid model was deemed as the poorest performer amongst the hybrid models. The chosen MGSVM-VADER hybrid proved to be highly effective when applied to a ZA Public Twitter opinion dataset. Ultimately, the research question "Will the MGSVM-VADER hybrid model approach produce accurate sentiment analysis of public Twitter opinion in South Africa?" was in turn effectively answered.

## VIII. FUTURE WORK

The following work would build upon the MGSVM-VADER hybrid in this study. A specialty language/slang modified VADER lexicon poses as a research possibility for a particular future audience. The creation of a system that also considers emojis, hexadecimal Unicode, and punctuation, and then translates them into the textual equivalent to be used with purely text-based sentiment analysis models. Additionally, the creation of a contextually aware hybrid sentiment analysis model – that could possibly explore subject matter behind URL links, videos, and images – could be an interesting future prospect.

### DATA AVAILABILITY

The full VADER Dataset is available online at: https://github.com/cjhutto/vaderSentiment/blob/master/vaderSentiment/vader_lexicon.txt.

The SA Twitter dataset is available online at: https://www.kaggle.com/mbusomakitla/south-african-twitter-dataset.

### CONFLICTS OF INTEREST

The authors declare that there are no conflicts of interest.

# Analysis of Depression in News Articles Before and After the COVID-19 Pandemic Based on Unsupervised Learning and Latent Dirichlet Allocation Topic Modeling

Seonjae Been[1], Haewon Byeon[2]*

Department of Digital Anti-Aging Healthcare (BK21), Inje University, Gimhae 50834, South Korea[1]
Department of Medical Bigdata, Inje University, Gimhae 50834, South Korea[2]

*Abstract*—As of 2023, South Korea maintains the highest suicide rate among OECD countries, accompanied by a notably high prevalence of depression. The onset of the COVID-19 pandemic in 2020 further exacerbated the prevalence of depression, attributed to shifts in lifestyle and societal factors. In this research, differences in depression-related keywords were analyzed using a news big data set, comprising 45,376 news articles from January 1st, 2016 to November 30th, 2019 (pre-COVID-19 pandemic) and 50,311 news articles from December 1st, 2019 to May 5th, 2023 (post-pandemic declaration). Latent Dirichlet Allocation (LDA) topic modeling was utilized to discern topics pertinent to depression. LDA topic modeling outcomes indicated the emergence of topics related to suicide and depression in association with COVID-19 following the pandemic's onset. Exploring strategies to manage such scenarios during future infectious disease outbreaks becomes imperative.

*Keywords*—*COVID-19; depression; news articles; LDA topic modeling*

## I. INTRODUCTION

South Korea has consistently reported the highest suicide rate among OECD countries. Since 2004, South Korea has implemented a five-year suicide prevention plan called the Basic Plan for Suicide Prevention. However, the suicide rate in South Korea has remained the highest among OECD countries for an extended period, with a rate 2.2 times higher than the OECD average as of 2019 [1]. Previous studies have emphasized low treatment rates for depression as one of the causes of high suicide rates [2], indicating a significant number of individuals with depression in South Korea who do not receive treatment. Particularly, since the outbreak of COVID-19 in 2020, the prevalence of depression in South Korea has worsened. According to surveys conducted by Statistics Korea, while the pre-COVID-19 prevalence of depression was 20% [3], it increased nearly twofold to 36.8% after the COVID-19 pandemic [4].

The long-term COVID-19 pandemic has led to social changes in South Korea due to measures such as social distancing, reduced outings and gatherings, and economic difficulties [5]. As a result, issues such as social isolation due to disrupted social networks, economic hardships, weight gain, and concerns about COVID-19 infection spread have arisen [5]. These problems have had significant societal impacts in

South Korea to an extent that gave rise to a new term called "corona blue."

As described above, depression in South Korea has been exacerbated socially due to the COVID-19 pandemic. According to a study by Lee et al., there was an increase in incidence rates of depression and prevalence rates for moderate and severe depression after the COVID-19 pandemic outbreak [6]. Furthermore, during periods of high transmission rates like during outbreaks or when Omicron variant spread internationally, significantly higher levels of excess mortality were observed [7]. In other words, the COVID-19 pandemic has had substantial effects not only on depressive symptoms but also on increased suicide rates among individuals. This study aims to analyze changes in keywords related to depression before and after the COVID-19 pandemic using news big data from South Korea through unsupervised learning algorithms such as Latent Dirichlet Allocation (LDA) topic modeling. By identifying hidden topics within collections of words or documents and grouping them based on documents or keywords using LDA topic modeling technique this research visualized key issues related to depressive symptoms before and after the COVID-19 pandemic.

## II. RESEARCH METHODOLOGY

### A. Data Collection

To analyze news articles related to depression before and after the COVID-19 pandemic, we utilized the BIGKinds service provided by the Korea Press Foundation. BIGKinds is a news big data analysis service that allows for the analysis of social phenomena using structured text data. In this study, we collected data from a total of 26 media outlets, including 11 national daily newspapers, eight economic daily newspapers, five broadcasting companies, and two specialized magazines (see Table I).

This study aimed to investigate depression before and after the COVID-19 pandemic by searching for keywords such as "depression," "feeling depressed," "depressive symptoms," and "depressive disorder." The search was divided into two periods: before and after the COVID-19 pandemic. The analysis period was determined considering the introduction of the COVID-19 pandemic in South Korea and the declaration of

*Corresponding Author.

an endemic. The period before the COVID-19 pandemic was set from January 1, 2016, to November 30, 2019. The period after the COVID-19 pandemic was set from December 1, 2019, to May 5, 2023 (the date of endemic declaration). After excluding duplicate articles and those unrelated to the topic, a total of articles used for analysis is shown in Table II.

TABLE I.     MEDIA BIGDATA SET SUBJECT TO TABLE ANALYSIS

| Category (Number) | Daily newspaper name |
|---|---|
| National daily newspaper (11) | Kyunghyang Shinmun, Kookmin Ilbo, Naeil Shinmun, Donga Ilbo, Munhwa Ilbo, Seoul Shinmun, Segye Ilbo, Chosun Ilbo, JoongAng Ilbo, Hankyoreh, Hankook Ilbo |
| Economic daily newspaper (8) | Maeil Economy, Money Today, Seoul Economy, Asia Economy, Aju Economy, Financial News, Korea Economy, Herald Economy |
| Broadcasting company (5) | KBS, MBC, OBS, SBS, YTN |
| Professional journals (2) | Digital Times, Electronic Newspaper |

TABLE II.     NUMBER OF ARTICLES USED FOR ANALYSIS

| | Before the outbreak of COVID-19 pandemic | After the outbreak of COVID-19 pandemic |
|---|---|---|
| Total number of articles | 47,905 | 52,707 |
| Number of excluded articles | 2,529 | 2,396 |
| Number of analysis articles | 45,376 | 50,311 |

### B. Data Preprocessing

To investigate depression before and after the COVID-19 pandemic, we conducted keyword-based searches using combinations of terms such as "depression," "feeling depressed," and "depressive disorder." The analysis period was divided into two parts: pre-COVID-19 pandemic (from January 1, 2016, to November 30, 2019) and post-pandemic declaration (from December 1, 2019, to May 5, 2023), considering the timing of the COVID-19 outbreak in South Korea and the declaration of an endemic state. We excluded duplicate articles and those unrelated to the research topic.

### C. Analysis Method

The analysis in this study was conducted using Python and involved frequency analysis, TF-IDF (Term frequency–inverse document frequency), and LDA (Latent Dirichlet Allocation) topic modeling.

First, we analyzed the frequency of word occurrences based on the collected articles. Then, we used TF-IDF to evaluate the relevance of words to the articles [8]. Subsequently, LDA topic modeling was applied to analyze the main topics within the collected articles.

LDA is a generative probabilistic model developed by Blei et al. and is one of the most well-known topic modeling techniques [9-11]. LDA analyzes data based on words used in documents or text data. It assumes that there are several topics and randomly selects a distribution of topics. Each word is then extracted from one of the topics, which is selected from the distribution specific to each document [11]. Therefore, LDA

automatically discovers topics in documents and infers hidden semantic structures by outputting sets of words that have a high probability of co-occurrence within each topic [9-11].

### III. RESULTS

#### A. Network Analysis

The network analysis of the relationship between depression and related keywords before and after the COVID-19 pandemic is shown in Fig. 1, Fig. 2 and also in Table III. The network analysis provided by BIGKinds is based on the top 100 articles with the highest accuracy among search results. It extracts noun phrases and applies Structured SVM (Support Vector Machine) to assign weights considering the number of related articles [12]. In Fig. 1, weights ranging from 4 to 34 were applied, while in Fig. 2, weights ranging from 6 to 51 were applied.

Fig. 1 represents the network analysis of depression-related keywords before the COVID-19 pandemic. The top keyword identified in this analysis is "program." This keyword is associated with programs related to depression operated by local governments and the central government. Additionally, the relationship diagram shows that it is related to Okcheon County due to its implementation of a project called "Zero Depression" [13]. The relationships associated with workers and Asan City are attributed to a depression screening conducted as part of mental health initiatives for workers by Asan City. The results showed that Asan Police Station had the lowest depression score, while call center counselors at Asan City Hall had the highest depression score [14].

Fig. 2 represents the network analysis of depression-related keywords after the COVID-19 pandemic. The top three keywords identified in this analysis are "COVID-19," "Mental Health Welfare Center," and "Ministry of Health and Welfare." This suggests that there has been an increase in experiences of depressive feelings and the prevalence of depression due to various social changes resulting from the COVID-19 pandemic.

#### B. Frequency Analysis Results

The frequency analysis of depression-related words before and after the COVID-19 pandemic revealed that "depressive disorder" had the highest frequency in both periods. However, there were additional keywords related to the COVID-19 pandemic (such as "COVID-19 outbreak," "corona," "coronavirus") in the post-pandemic period. It can be observed that the frequency and weight of keywords related to the COVID-19 pandemic are higher.

#### C. LDA Topic Modeling

*1) LDA topic modeling design:* Using Python, we calculated the coherence score, as shown in Fig. 3. The coherence score is a metric used to determine the optimal number of topics to be set for topic modeling. The number of topics with the highest coherence score is considered appropriate. In this study, based on the coherence scores, we set seven topics for the pre-COVID-19 pandemic period and six topics for the post-pandemic period.
Fig. 1.    Keyword network analysis of depression before the COVID-19 pandemic.

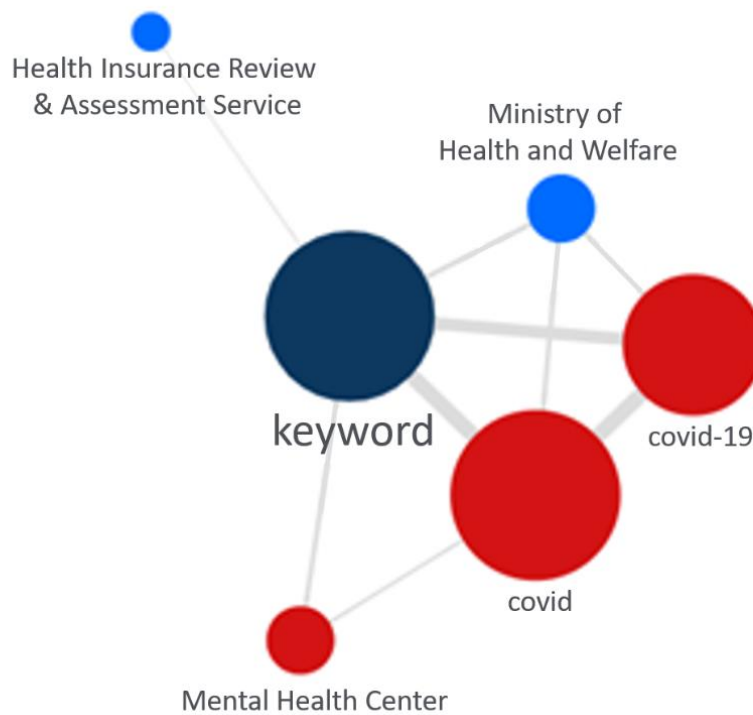

Fig. 2.    Keyword network analysis of depression after the COVID-19 pandemic.

TABLE III.    TOP 15 KEYWORDS BEFORE AND AFTER THE COVID-19 PANDEMIC

| Before the outbreak of COVID-19 pandemic | | | After the outbreak of COVID-19 pandemic | | |

Fig. 3.    Consistency score before and after COVID-19 pandemic outbreak.

TABLE IV.    TOPIC MODELING BEFORE THE OUTBREAK OF COVID-19 PANDEMIC

| Group | Topic name | Top 5 words |
|---|---|---|
| 1 | Depression of celebrity | Depression, Person, Broadcasting, Depression, Self |
| 2 | Depression and crime | Depression, Victim, Seoul, Court, Lawyer |
| 3 | Depression and female crime | Depression, Police, Investigation, Charges, Woman |
| 4 | Depression around the world | USA, Depression, Korea, UK, China |
| 5 | Overcoming depression | Confidence, Things, Friends, Viewers, Tears. |
| 6 | Depression in the general public | Seoul, Depression, Children, Korea, Office workers |
| 7 | Symptoms and causes of depression | Depression, Depression, Insomnia, Health, Stress |

*2) LDA topic modeling:* In the LDA topic modeling results of this study, we have provided the top five words for each topic, as the weight of the 6th word in some topics was low. The results of topic modeling before the COVID-19 pandemic are presented in Table IV. The topics identified include famous individuals' confessions and overcoming depression, crime-related topics, global depression issues, and discussions on symptoms and causes of depression.

The results of the LDA topic modeling after the COVID-19 pandemic are presented in Table V. The differences between the topics before and after the COVID-19 pandemic can be observed, such as Topic 3 (COVID-19 pandemic and depression) and Topic 6 (depression and suicide), which specifically focus on the COVID-19 pandemic-related issues and suicide.

TABLE V.    TOPICS MODELING AFTER THE OUTBREAK OF THE COVID-19 PANDEMIC

| Group | Topic name | Top 5 words |
|---|---|---|
| 1 | Depression of celebrity | Depression, Agency, MBC (broadcasting), People, Fans |
| 2 | Covid-19 pandemic and depression around the world | United States, Depression, Korea, COVID-19 pandemic, Confirmed cases |
| 3 | Covid-19 pandemic and depressive symptoms | COVID-19 pandemic, Corona, Seoul, Depression, Coronavirus |
| 4 | Depression and crime | Depression, Seoul, Court, Victim, Defendant |
| 5 | Government and depression | Blue House, Immunity, Depression, Victims, Seoul |
| 6 | Depression and suicide | Police, Discovery, Selection, Investigation, Death |

## IV. DISCUSSION

In this study, we analyzed social issues related to depression before and after the COVID-19 pandemic using LDA topic modeling based on a large dataset of news articles (95,687 articles). We found that keywords related to "suicide" appeared prominently after the COVID-19 pandemic, unlike before the pandemic. The emergence of these keywords as potential key topics can be attributed to the prolonged duration of the COVID-19 pandemic, which has led to an increase in feelings of depression and suicidal ideation.

According to the Ministry of Health and Welfare, in 2020 when the initial wave of the COVID-19 pandemic occurred, there was a slight decrease in suicide deaths compared to 2019. This was attributed to factors such as a decrease in copycat suicides and social tension and cohesion resulting from a national disaster [15]. However, in 2021, both the number of suicide deaths and suicide rates increased by 1.2% compared to 2020 [16]. This suggests that with the prolonged duration of the COVID-19 pandemic, there has been an increase in feelings of depression and suicidal ideation [16], leading to an increase in youth suicide rates during the mid-term period of the COVID-19 pandemic [17].

The phenomenon of increasing youth suicide rates has also been reported overseas. In Japan, there was a 41.3% increase in youth suicides compared to 2019 [18], while overall adolescent suicides increased during the COVID-19 pandemic period in the United States [19]. Taking all these factors into account, it is speculated that there has been an increase in suicide deaths due to various social changes after the onset of the COVID-19 pandemic.

Another finding of this study is the discovery of topics related to the COVID-19 virus and depression after the onset of the COVID-19 pandemic. According to an online survey conducted by the Korea Health Promotion Institute targeting individuals aged 20 to 65, 40.7% of respondents reported experiencing "COVID-19 depression" [5]. In addition, a mobile survey conducted on individuals aged 15 and above in 17 metropolitan cities and provinces nationwide found that 47.8% of respondents reported experiencing depression and anxiety due to COVID-19 [20]. These survey results indicate

that due to the prolonged duration of the COVID-19 pandemic, a significant number of people have experienced varying degrees of depression. Therefore, it is necessary for the government to explore measures to monitor mental health among all citizens on a national level, and prepare strategies to reduce depression and anxiety in future outbreaks or pandemics.

Although this study examined social changes related to depression before and after the onset of the COVID-19 pandemic using news big data and employed LDA topic modeling to identify issues, it has several limitations. Firstly, the data used in this study does not include time-series information, so we cannot examine trends over time. Therefore, future research should consider incorporating time-series analysis to observe changes in trends. Secondly, the collected data is limited to domestic news articles, so generalization to other cultural contexts may not be possible. Thirdly, the topic names derived from LDA are researcher-inferred labels; therefore, future research should consider applying algorithms that can complement this process.

## V. CONCLUSION

In this study, we utilized BigKinds to analyze news articles related to depression before and after the onset of the COVID-19 pandemic using LDA topic modeling. We aimed to identify the main issues and differences between these periods. The results revealed that topics related to suicide emerged after the COVID-19 pandemic, as well as topics related to the COVID-19 virus and depression. Based on these findings, it is necessary for national-level policies to be developed in order to manage the mental health of citizens, such as depression, in future situations like infectious disease outbreaks.

# Construction of an Intelligent Robot Path Recognition System Supported by Deep Learning Network Algorithms

Jiong Chen*

Department of Artificial Intelligence, Shanxi Polytechnic College, Taiyuan, 030006, China

*Abstract*—In recent years, intelligent robots have been widely used in fields such as express transportation, industrial automation, and healthcare, bringing great convenience to people's lives. As one of the core technologies of intelligent robots, path planning technology has become a research highlight in the field of robotics. To achieve path planning in unknown environments, a path planning algorithm based on an improved dual depth Q-network is proposed. In both simple and complex grid environments, the planned path inflection points for the improved dual depth Q-network is 4 and 9, respectively, with path lengths of 27.21m and 28.63m, respectively. Both are less than double depth Q network and adaptive Ant colony optimization algorithms. The average reward values of the improved dual depth Q network in simple and complex environments are 1.12 and 1.02, respectively, which are higher than those of the dual depth Q network. In a random environment, the lowest probability of the improved dual depth Q network successfully reaching the destination without colliding with obstacles is 95.1%, which is higher than the other two algorithms. In the Gazebo environment, when the number of iterations reaches 2000, the average cumulative reward value is positive. The average cumulative reward value in the range of iterations from 3500 to 4000 and iterations from 4000 to 4500 exceeds 500. The average cumulative reward value of the dual depth Q network is only positive within the two intervals of iterations 2500-3000 and 3000-3500. The average cumulative reward value does not exceed 100. According to the findings, the path planning ability of the improved dual depth Q network is better than that of the dual depth Q network and the adaptive Ant colony optimization algorithms.

*Keywords—Deep learning; reinforcement learning; intelligent robots; path planning*

## I. INTRODUCTION

With the progress of computer technology, intelligent robots have gradually entered people's lives. They play an important role in their respective fields. At the same time, due to the technological reform of intelligent robots, humans have gradually raised their requirements for the mobility of intelligent robots. Intelligent robots are expected to quickly plan a route to the destination in unfamiliar environments. The path planning of robots consists of global path planning and local path planning based on their mastery of environmental information. In local path planning, the motion trajectory of the robot has uncertainty. It needs to constantly obtain information from the environment to determine the next step. At the same time, it is necessary to obtain data information on obstacles to

avoid unknown obstacles [1]. Reinforcement learning (RL) is a good solution to how to avoid unknown obstacles. However, in a complex environment, RL will have an exponential growth problem of state-action collection, resulting in a "Curse of dimensionality" [2]. The deep reinforcement learning (DRL) obtained from deep learning (DL) combined with Reinforcement learning can effectively improve the above problems. The deep learning in Deep reinforcement learning can extract the data information characteristics of the environment through neural network, realizing the fitting between the state-action value function (SAVF) and the environment [3]. At present, DRL has become a popular algorithm in the research of robot path planning (RPP) for unknown environments. However, due to the overestimation of DL, the output state-action values in DRL applications are higher than the true values. Therefore, to realize the path planning of the robot in an unknown environment, the influence of overestimation on the robot action selection is reduced. A RPP based on Improved Double Deep Q-Network (IDDQN) is proposed in the research. This algorithm effectively avoids the "dimension disaster" problem, ensures the action speed and accuracy of the robot, enriches the application scenarios of the robot, and provides strong support for the future intelligence of the robot.

The article consists of four sections. Section I is the introduction. Section II deals with related works. Section III deals with RPP algorithm based on DRL. Section IV is the simulation experiments and result analysis and Section V concluded the whole study.

## II. RELATED WORKS

In the current research on various technologies of intelligent robots, path planning is a hot research direction. The way and quality of path planning determine whether a robot can safely and quickly reach the destination. Rath A K and his team proposed a navigation control algorithm based on genetic algorithm (GA) and neural network for robot navigation problems in complex environments. The GA controller is used to generate the initial turning angle of the robot. Then, the GA controller and neural network controller are mixed to generate the final steering angle. After testing, the navigation parameter error of this algorithm is relatively small [4]. Nie B et al. proposed a path planning method based on value iteration for intelligent agents with complex kinematics. The state-action transition probability is used to encode the ability of the agent. According to the findings, it has higher precision, faster

convergence rate and lower random seed sensitivity [5]. Wang G and other scholars proposed a dynamic path planning method based on fuzzy neural networks for intelligent robots. Compared with the traditional Particle swarm optimization (PSO), it can significantly improve the control accuracy and robustness of the model [6]. Oultiligh A and his team proposed a trajectory planning method based on PSO and gray wolf optimization for mobile robot trajectory optimization. This algorithm can effectively balance global and local search capabilities. After testing, the optimal trajectory search ability of PSO-GWO has significantly improved [7]. Raheem F A et al. proposed a RPP method based on probabilistic landmarks and artificial potential fields. The PSO is applied to obtain the optimization weight required by each control point participating in the formation of the spline curve. After testing, this method can ensure the feasibility and rationality of the path [8].

As an artificial intelligence method close to human thinking mode, DRL is an effective way to solve complex perception problems. Therefore, it is widely used in automatic driving, robotics, game control, machine translation and other fields. Guang zheng W et al. proposed a DRL based collision detection and avoidance method for distributed multiple unmanned aerial vehicles. Human experience is also integrated into training. Compared to traditional DRL methods, DRL that integrates human experience has significant improvements in multi drone collision detection and avoidance. In addition, the flight safety brought by the hybrid control method has also been verified [9]. Cao D and his team proposed an analysis method based on MDP and PPO to analyze the optimal power flow problem of distribution networks containing renewable energy and energy storage devices. This method obtains knowledge from historical data through neural networks and provides online decision-making based on the real-time status of the power grid. The experimental results show that the real-time control strategy proposed by this method is more flexible, which has better performance [10]. Zhao J et al. proposed a dynamic multi micro grid formation method based on CNN and DDQN to develop a multi micro grid formation plan. In this method, the dynamic micro grid formation problem is transformed into a Markov decision process. The topology changeable micro grid is designed through the DRL framework. According to the findings, this method has strong elasticity, which can respond to changing system conditions in a timely manner [11]. Zhang D et al. proposed a two-stage deep Q-learning algorithm based on pre-exploration for intelligent train control. After testing, this algorithm smoothes the acceleration curve. It can effectively complete train control tasks in multi train tracking scenarios [12]. Shihab S A M and Wei P proposed a strategy formulation method based on DRL for developing optimal seat inventory control strategies. In this method, DNN is used to calculate the expected optimal return for all possible state action combinations. Various factors such as random demand, passenger arrival, and booking cancellation have been fully considered. According to the findings, interacting with the market can learn the optimal airline revenue management strategy [13].

In summary, with the development of intelligent robot technology, RPP methods for mobile robots have become a hot

research topic. There have been significant achievements in current research on RPP. In local path planning, DRL is a popular algorithm. However, due to the inherent overestimation problem of RL, the path chosen by the robot is not necessarily the optimal path. To address the above issues, a RPP method based on IDDQN is proposed, aiming to achieve local path planning in unfamiliar environments.

## III. RPP ALGORITHM BASED ON DRL

With the progress of science and technology, robot technology is receiving increasing attention from people. As one of the core technologies of intelligent mobile robots, path planning has become a research highlight in the robotics. To achieve safe movement of robots in unknown environments, a RPP method based on improved DDQN is proposed-IDDQN. The IDDQN algorithm effectively avoids the DDQN over estimation through more moderate Q update method and improves the utilization efficiency through the sequencing of priority playback mechanism. It effectively reduces the disadvantage of slow DDQN training speed.

### A. RPP based on DDQN

The core of DRL is Reinforcement learning. Reinforcement learning guides behavior through rewards gained from interaction with the environment. However, the reinforcement learning model is more complex. Therefore, MDP is introduced into the reinforcement learning model to simplify it. In RPP, the probability of state transition and the immediate reward return function are generally unknown. Therefore, robots need to constantly interact with the environment. The state transition probability reflecting actions is displayed in Eq. (1).

$$P_{ss'}^a = P\left[ S_{t+1} = s' \middle| S_t = s, A_t = a \right] \quad (1)$$

In Eq. (1), $P_{ss'}^a$ represents the execution of action $a$ in state $s$. $s'$ represents the probability that the robot can reach the state. $P$ represents the probability of state transition. $S_t$ represents the set of state spaces at time $t$. $A_t$ stands for the set of action spaces at time $t$. The calculation method for cumulative reward value (CRV) is shown in Eq. (2).

$$G_t = R_{t+1} + \gamma R_{t+2} + L = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \quad (2)$$

In Eq. (2), $R$ represents the immediate reward function. $\gamma$ represents the discount factor. $G_t$ represents the CRV. The state VF is shown in Eq. (3)

$$v_\pi(s) = E_\pi\left[ \sum_{k=0}^{\infty} \gamma^k R_{t+k+1} \middle| S_t = s \right] \quad (3)$$

In Eq. (3), $v_\pi(s)$ represents the state value function (SVF). $\pi$ stands for strategy. $E_\pi$ represents the expected cumulative reward return in strategy $\pi$. The SAVF is shown in Eq. (4).

$$q_\pi(s,a) = E_\pi\left[\sum_{k=0}^{\infty}\gamma^k R_{t+k+1}\,\middle|\,S_t = s, A_t = a\right] \tag{4}$$

In Eq. (4), $q_\pi(s,a)$ represents the action SVF. The calculation of the SVF is to construct the data in the algorithm to obtain the optimal strategy. The Bellman optimal equations for the SVF and the SAVF are shown in Eq. (5).

$$\begin{cases} v^*(s) = \max_a R_s^a + \gamma\sum_{s'\in S}P_{ss'}^a v^*(s') \\ q^*(s,a) = R_s^a + \gamma\sum_{s'\in S}P_{ss'}^a \max_{a'} q(s',a') \end{cases} \tag{5}$$

In Eq. (5), $v^*(s)$ and $q^*(s,a)$ represent the optimal SVF and the optimal SAVF, respectively. If the optimal SVAF is already specified, the optimal strategy is determined by maximizing the optimal SVAF. At this point, the optimal strategy expression is shown in Eq. (6).

$$\pi^* = \begin{cases} 1 & a = \arg\max_{a\in A} q^*(s,a) \\ 0 & otherwise \end{cases} \tag{6}$$

Eq. (6) indicates that the SVAF is the maximum. At this point, under strategy $\pi$ and state $s$, the probability of the robot executing action $a$ is 1. The execution probability of other actions is 0. The value function of the DQN algorithm utilizes DNN for approximation. The network structure of DQN is illustrated in Fig. 1.

In Fig. 1, the parameters corresponding to the DQN value function represent the weight size of each layer in DNN. At

this point, updating the value function means updating the network parameters. If the network structure is determined, the network parameters are the value function [14-15]. When using DNN to approximate a value function, the strong correlation between data sample tuples can easily lead to instability and non-convergence issues. Therefore, experience playback technology is used to address this issue. The experience of each time step is stored in the data pool. When updating network parameters, random samples are taken from the data pool for training. The method for updating network parameters is shown in Eq. (7).

$$\theta_{t+1} = \theta_t + \alpha\left[\begin{matrix}r + \gamma\max_a Q(s',a',\theta) \\ -Q(s,a,\theta)\end{matrix}\right]\nabla Q(s,a,\theta) \tag{7}$$

In Eq. (7), $\theta$ represents the network parameters. $Q(s,a,\theta)$ represents the value function of Q-Learning. $\alpha$ represents a parameter. $r$ represents timely return. However, when calculating the SAVF, the parameters used are the same as those approximated by the value function, which can easily lead to unstable training. Calculating the time difference optimization objective through target network parameters can effectively solve this problem. At this point, the parameter update formula is shown in Eq. (8).

$$\theta_{t+1} = \theta_t + \alpha\left[\begin{matrix}r + \gamma\max_{a'} Q(s',a',\theta^-) \\ -Q(s,a,\theta)\end{matrix}\right]\nabla Q(s,a,\theta) \tag{8}$$

In Eq. (8), $\theta^-$ stands for the parameters of the target network. The training process of DQN is shown in Fig. 2.

Fig. 1. Network structure of DQN.

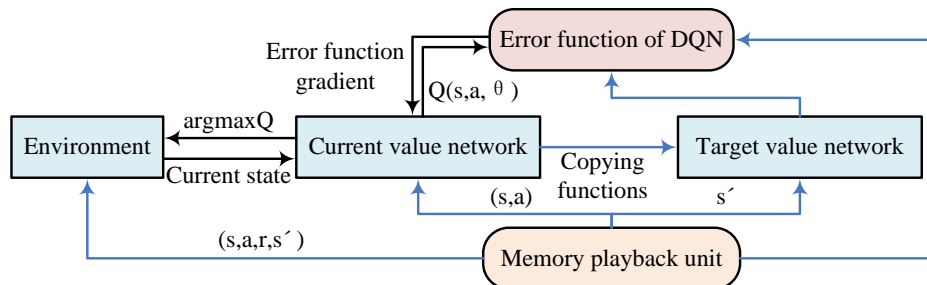

Fig. 2. Training process of DQN.

In Fig. 2, for each step reached, the parameters of the current value network are assigned to the target value network. In the playback memory unit, several samples are selected and their states are fed into the current value network. In the network output results, the Q value corresponding to the sample action is extracted and the target value is calculated. The loss function of Q value and target value is calculated. The current value network is updated by back-propagation. Although the DQN algorithm uses DNN instead of Q-table to approximate the SAVF, it still has overestimation issues [16-18]. The selection and evaluation of actions in network parameter updates are separated. Different value function networks are used to express action selection and evaluation. This can alleviate the problem, which is known as the DDQN algorithm. At this point, the calculation of the time difference optimization objective is shown in Eq. (9).

$$Y_t^{DDQN} = r + \gamma Q\left(s', \arg\max Q\left(s', a', \theta\right), \theta^-\right) \quad (9)$$

In Eq. (9), $Y_t^{DDQN}$ represents the optimization objective. $\theta$ and $\theta^-$ represent estimated network parameters and target network parameters, respectively.

### B. RPP based on Improved DDQN

In DDQN, the overestimation problem has a negative impact on the selection of the optimal action for robots, making it difficult to find the optimal action strategy and path. At the same time, as the interaction between robots and the environment deepens, the playback proportion of important samples decreases when playing back experience samples, resulting in the decline of robot learning effect. To address the above issues, an improved DDQN for RPP is proposed. The RPP training model is illustrated in Fig. 3.

From Fig. 3, the sample data is fed into the memory cache unit based on the current environment, the next state, and the obtained instant returns. Then, samples are selected from memory buffer units to train the parameters of the IDDQN. Then, based on the network output and improved exploration strategy, the optimal action is selected. The robot is sent to the next state [19-20]. In DDQN, there is a situation where the absolute error values of the value functions of the optimal and suboptimal actions are equal, resulting in the robot selecting a suboptimal action. To avoid the above issues, the range of error values can be reduced. To minimize the error, the ε-Greedy

strategy is introduced into DDQN. The improved optimization objective is shown in Eq. (10).

$$Y_t^{IDDQN} =$$
$$\begin{cases} r + \gamma Q\left(s', \arg\max Q\left(s', a', \theta\right), \theta^-\right) & \text{Probability} = 1 - \varepsilon' \\ r + \gamma Q\left(s', a', \theta^-\right) & \text{Probability} = \varepsilon' \end{cases} \quad (10)$$

In Eq. (10), $\varepsilon'$ represents a parameter, which is a fixed value, with a value range of $(0,1)$. $a'$ represents a random action. To better select actions, a ε-Greedy action selection strategy based on prior knowledge is proposed. The probability of action selection for strategy ε-Greedy is shown in Eq. (11).

$$\pi(a|s) = \begin{cases} 1 - \varepsilon + \dfrac{\varepsilon}{|A(s)|} & a = \arg\max_a Q(s,a) \\ \dfrac{\varepsilon}{|A(s)|} & a \neq \arg\max_a Q(s,a) \end{cases} \quad (11)$$

In Eq. (11), $A(s)$ represents the set of actions in state $s$. $\varepsilon$ represents the exploration factor. When the robot selects actions, a random number is generated. If the random number is less than the exploration factor, the robot randomly selects actions. Otherwise, the average Q value of previous generations will be calculated. Based on improved ε-Greedy strategy, corresponding actions are selected and executed. The average Q value is calculated as Eq. (12).

$$Q^A(s,a) = \frac{1}{K} \sum_{k=1}^{K} Q(s,a,\theta_{t-k}) \quad (12)$$

In Eq. (12), $K$ represents the algebraic difference between the current parameter and the previous parameter. $Q^A(s,a)$ represents the average Q value of the previous $K$-generations. In model training, the playback frequency of experience fragments with low time difference error values is low due to the influence of environmental noise. The lack of diversity in training samples leads to over fitting issues. Combining greedy finite and uniform sampling can ensure the playback probability of experience fragments with low time difference error values. The calculation formula for playback probability is shown in Eq. (13).

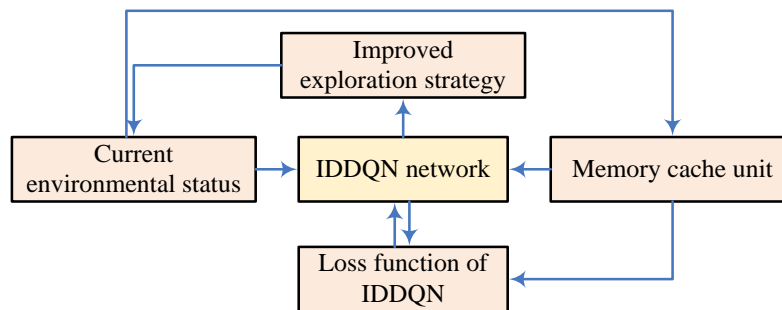

Fig. 3. Training model for robot path planning.

$$P_i = \frac{p_i^\alpha}{\sum_k p_k^\alpha} \qquad (13)$$

In Eq. (13), $P(i)$ represents the playback probability of the $i$-th segment. $p_i$ represents the priority of the $i$-th segment. $\alpha$ represents the degree of control priority. The priority calculation formula is shown in Eq. (14).

$$p_i = 1/rank_i \qquad (14)$$

In Eq. (14), $rank_i$ represents the sequence number sorted by the absolute value of time difference error. To prevent over fitting and ensure the diversity of experience fragments, weight is introduced for adjustment. The weight calculation formula is shown in Eq. (15).

$$w_i = 1 \Big/ \left( \frac{p_i}{p_{min}} \right)^\beta \qquad (15)$$

In Eq. (15), $p_{min}$ represents the minimum probability of the experience segment. $\beta$ represents the correction degree. At this time, the expression of loss function is shown in Eq. (16).

$$L = \sum w(t) \left( Y_t^{IDDQN} - Q(s,a,\theta) \right)^2 \qquad (16)$$

In Eq. (16), $Q(s,a,\theta)$ stands for the output Q of the estimated network. The IDDQN algorithm process is shown in Fig. 4.

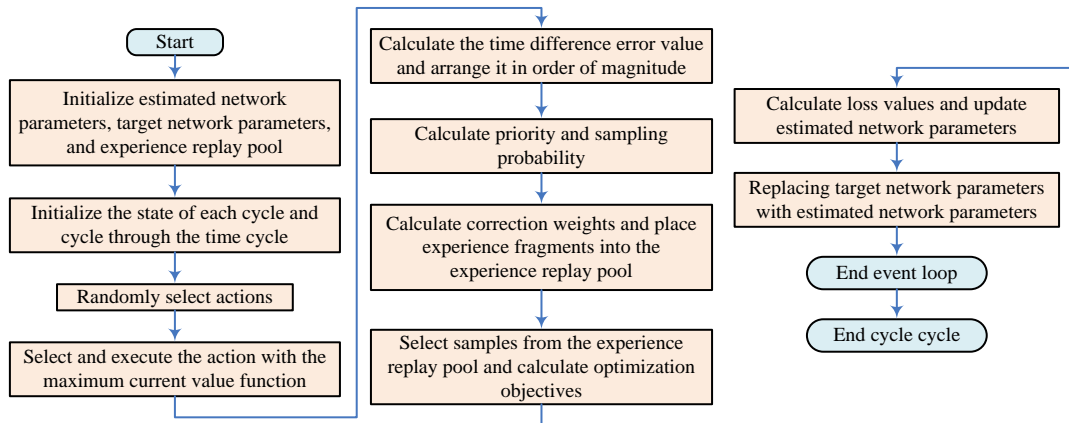
From Fig. 4, the IDDQN algorithm first initializes the estimated network parameters, target network parameters, and experience playback pool. The event is cycled. Then the state of each cycle is initialized and cycled throughout the time cycle. Actions are randomly selected based on probability. If a small probability event does not occur, the action with the highest current value function is selected and executed. Next, based on the reward feedback of the environment and the transferred state, the time difference error value is calculated. The calculation results are arranged in order of size. According to the sequence number, priority is calculated. Based on priority, the sampling probability is obtained. Then the correction weight is calculated by sampling probability, and the experience fragments are put into the experience playback pool according to the probability. Next, samples are selected based on probability from the experience replay pool and optimization objectives are calculated. Then, the estimated parameters are updated according to the calculation results of the loss function. The target parameters are replaced by these parameters. The application process of IDDQN algorithm in robot path planning is shown in Fig. 5.


Fig. 4.   Flow of IDDQN algorithm.
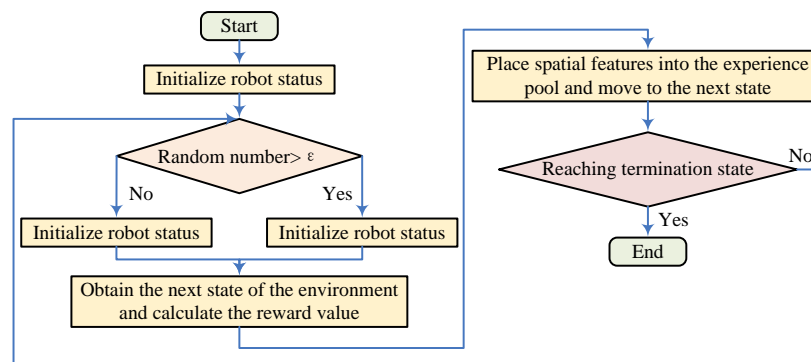

Fig. 5.   Application process of IDDQN in RPP.

In Fig. 5, this algorithm first initializes the state of the robot. The current coordinates of the robot are determined. Then the generated random numbers are compared. If it is greater than the exploration factor, the average output value of the improved optimization objective network is calculated and an action is selected. Otherwise, the action is randomly selected. Then the next state of the environment is obtained and its reward value is calculated. Then the spatial features are placed in the experience pool and moved to the next state. Finally, the current state is judged. If the termination state is reached, the process ends. Otherwise, the operation is returned to the second step.

## IV. Simulation Experiments and Result Analysis Based on Grid Environment and Gazebo Environment

To verify the path planning ability of the IDDQN, testing experiments are carried out in both grid and Gazebo environments. The proposed method is compared with DDQN algorithm and adaptive Ant colony optimization algorithms. The grid environment is divided into simple environment, complex environment, and random environment. The processor used in this simulation experiment is Xeon (R), the CPU is NVIDIA GeForce GTX 1080Ti, the running memory is 32 GB, and the software environment is Python and TensorFlow. The exploration factor for grid and Gazebo environments has an initial value of 1 and an end value of 0.1. The convergence of

DDQN, adaptive ant colony algorithm, and IDDQN algorithm is shown in Fig. 6.

From Fig. 6, the DDQN value converges after approximately 270 iterations, with a loss value of approximately 0.24. The adaptive Ant colony optimization algorithm starts to converge after about 220 iterations, and the loss value is about 0.21. IDDQN begins to converge after approximately 180 iterations, with a loss value of approximately 0.19. The convergence rate of IDDQN is faster. The RPP results of the three methods in a simple environment are shown in Fig. 7.

Fig. 6. Convergence of DDQN, adaptive ant colony, and IDDQN.

(a)DDQN Planning Path

(b)Adaptive Ant Colony Planning Path

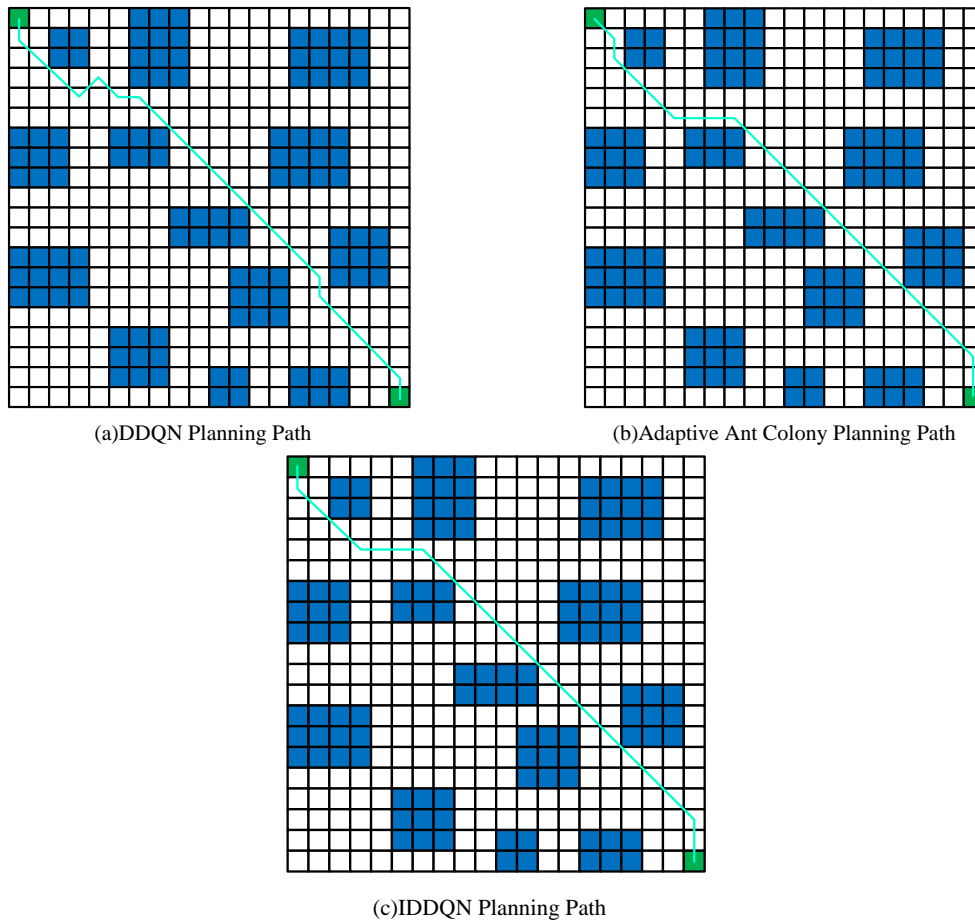
(c)IDDQN Planning Path


Fig. 7. RPP results of three methods in a simple environment.
Fig. 8. The average reward values of IDDQN and DDQN, as well as the path length and collision frequency of the three algorithms.

From Fig. 7 (a), the path inflection points planned for DDQN are 8. In Fig. 7(b), the path inflection points planned by the adaptive Ant colony optimization algorithms are 5. In Fig. 7(c), the inflection points in the planned path of IDDQN are 4. IDDQN has fewer inflection points in the planned path, which can effectively reduce the movement time from the starting to the target position. The average reward values of IDDQN and DDQN, as well as the path lengths and collision times of the three algorithms, are shown in Fig. 8.

In Fig. 8(a), the average reward value of DDQN is approximately 1.03. IDDQN has an average reward value of approximately 1.12, which is higher than the DDQN algorithm. In Fig. 8(b), the path length planned by the DDQN is approximately 29.46m, and the number of obstacle collisions is 19806. The optimal path length of the adaptive Ant colony optimization algorithms is about 28.63m, and the collisions with obstacles are 16275. The optimal path length for IDDQN planning is approximately 27.21m, and the number of collisions with obstacles during training is 15613. The IDDQN algorithm not only has the shortest planned path length, but also reduces the probability of robot collision with obstacles. The RPP results of the three methods in complex environments are illustrated in Fig. 9.

In Fig. 9(a), the inflection points planned by the DDQN algorithm are 10, the inflection points of the path planned by the adaptive Ant colony optimization algorithms are 13. The path inflection points planned by IDDQN are 9. From Fig. 9(b), in complex environment 2, the path inflection points of both the ant colony algorithm and DDQN are redundant with IDDQN. The length is also longer than the IDDQN algorithm. From this, in complex environments, the IDDQN algorithm can still move to the endpoint with as few inflection points as possible. In a complex environment, the path lengths and collision times of the three algorithms, as well as the reward values of IDDQN and DDQN, are shown in Fig. 10.

From Fig. 10(a), the optimal path length for DDQN planning is approximately 29.22 m, and the number of collisions during training is 26671. The optimal path length for the adaptive Ant colony optimization algorithms is about 29.80 m, and the number of collisions is 19374. The optimal path length for IDDQN is approximately 28.63m and the number of collisions is 17389. In Fig. 10(b), the average reward values for DDQN and IDDQN are approximately 0.92 and 1.02, respectively. The average reward value of IDDQN is higher. IDDQN can still maintain a small collision probability in complex environments. The success rates and path length differences of the three algorithms in a random environment are shown in Fig. 11.

(a) Complex Environment 1

(b) Complex Environment 2

(a)Path length and collision frequency

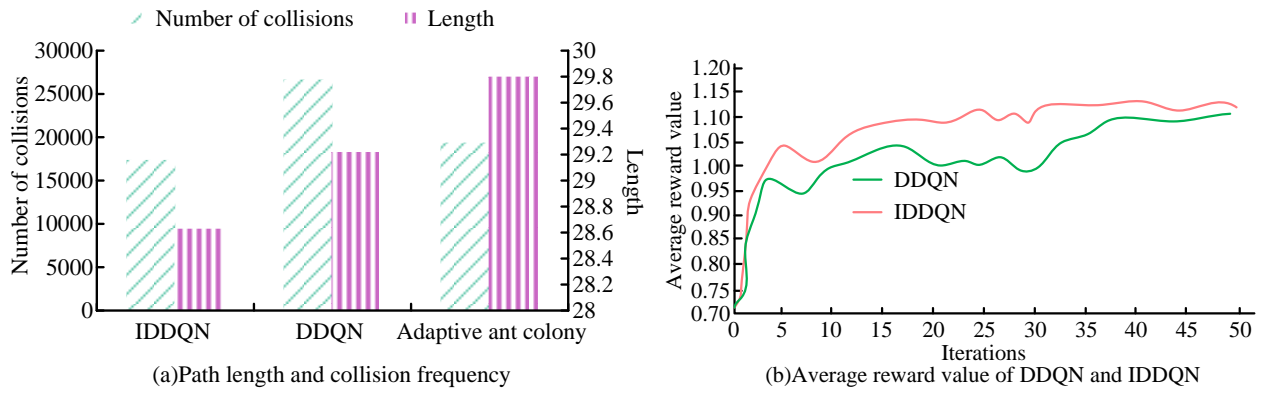
(b)Average reward value of DDQN and IDDQN


Fig. 10. The path length, collision frequency, and reward values for IDDQN and DDQN of the three algorithms are shown in the figure.

(a) Success rate

(b) Path length difference
Fig. 11. Success rates and path length differences of three algorithms in a random environment.

Fig. 12. Accumulated reward values of DDQN and IDDQN.

In Fig. 11 (a), in a random environment, the probability of DDQN successfully reaching the destination without colliding with obstacles is approximately 95.2%, 93.1%, 91.8%, and 91.2%, respectively. The success rate of adaptive Ant colony optimization algorithms in random environment is about 96.7%, 94.8%, 93.5% and 92.6% respectively. The success rates of IDDQN in random environments are approximately 97.4%, 96.5%, 95.9%, and 95.1%, respectively. IDDQN has the highest success rate in a random environment. In Fig. 11(b), the path length difference of DDQN in different environments is about 1.04 m, 1.17 m, 1.25 m, and 2.06 m, respectively. The path length difference of the adaptive Ant

colony optimization algorithms is about 0.86 m, 0.98 m, 1.07 m and 1.52 m respectively. The difference in path length for IDDQN is approximately 0.59 m, 0.83m, 0.91m, and 1.33m, respectively. The path length difference of IDDQN is the smallest, indicating that IDDQN has a stronger ability to plan the optimal path. The CRVs of DDQN and IDDQN in the Gazebo environment are shown in Fig. 12.

In Fig. 12, the CRV of IDDQN is significantly higher than that of DDQN. The average CRV of DDQN is the highest in the range of 2500 to 3000 iterations. At this point, the average CRV is approximately 76.12. Secondly, there is an interval of

3000 to 3500 iterations, with an average CRV of approximately 29.83. The above two intervals are also the only ones with a positive average CRV. The average CRV of IDDQN is highest in the range of 3500 to 4000 iterations. The average CRV is around 748.62. Next is the interval of 4000 to 4500 iterations, with an average CRV of approximately 584.46. When the number of iterations reaches 2000, the average CRV is all positive. The average CRV between the iterations of 2000-2500 and 3000-3500 exceeds 100.

## V. CONCLUSION

A RPP algorithm based on the improved DDQN - IDDQN algorithm is proposed for the mobile RPP problem of intelligent robots in unknown environments. Simulation experiments are conducted in both grid and Gazebo environments. According to the results, IDDQN begins to converge after approximately 180 iterations. The loss value is approximately 0.19. The convergence rate is faster than DDQN algorithm and adaptive Ant colony optimization algorithms. In a simple grid environment, the optimal path length, inflection points, and collisions during training for IDDQN are 27.21m, 4, and 15613, respectively. In a complex grid environment, the optimal path length, number of inflection points, and number of collisions during training planned by the IDDQN algorithm are 28.63m, 9, and 17389, respectively. In a random environment, the path length differences of IDDQN are 0.59m, 0.83m, 0.91m, and 1.33m, respectively. It is less than the path planned by DDQN and adaptive Ant colony optimization algorithms. The success rates of the IDDQN algorithm in random environments are approximately 97.4%, 96.5%, 95.9%, and 95.1%, respectively, which are higher than other algorithms. In the Gazebo environment, the interval with the highest average cumulative reward value for DDQN is between 2500 and 3000 iterations. At this point, the average cumulative reward value is about 76.12, and there are only two intervals where the average cumulative reward value is positive. The average cumulative reward value of DDQN is the highest in the range of 3500 to 4000 iterations. The average cumulative reward value is around 748.62. When the number of iterations reaches 2000, the average CRV is all positive. The average CRV of two intervals exceeds 100. The above results indicate that the intelligent RPP based on IDDQN can achieve optimal RPP in unfamiliar environments. Research has achieved static path planning for robots by improving DDQN. However, the proposed method does not take into account the dynamic variable environment. At the same time, when several robots cooperate to complete a certain work, the proposed algorithm cannot provide reasonable task assignment and collaboration instructions for the robot. Therefore, future work will focus on path planning, multi-robot collaborative task assignment, and path planning in dynamically variable environments.

*Abstract*—Cardiovascular diseases (CVDs) remain a significant global health concern, demanding precise and early prediction methods for effective intervention. In this comprehensive study, various machine learning algorithms were rigorously evaluated to identify the most accurate approach for forecasting heart disease. Through meticulous analysis, it was established that precision, recall, and the F1-score are critical metrics, overshadowing the mere accuracy of predictions. Among the classifiers explored, the Decision Tree (DT) and Random Forest (RF) algorithms emerged as the most proficient, boasting remarkable accuracy rates of 96.75%. The DT Classifier exhibited a precision rate of 97.81% and a recall rate of 95.73%, resulting in an exceptional F1-score of 96.76%. Similarly, the RF Classifier achieved an outstanding precision rate of 95.85% and a recall rate of 97.88%, yielding an exemplary F1-score of 96.85%. In stark contrast, other methods, including Logistic Regression, Support Vector Machine, and K-Nearest Neighbor, demonstrated inferior predictive capabilities. This study conclusively establishes the combination of Decision Tree and Random Forest algorithms as the most potent and dependable approach for predicting cardiac illnesses, providing a groundbreaking avenue for early intervention and personalized patient care. These findings signify a significant advancement in the field of predictive healthcare analytics, offering a robust framework for enhancing healthcare strategies related to cardiovascular diseases.

## I. INTRODUCTION

### A. Background and Motivation

Modern lifestyles and population change have led to widespread stress, anxiety, and health issues [1]. Sedentary living has increased mortality due to chronic diseases [2-4]. The heart's vital role in transporting nutrients makes its proper function crucial [5-6]. Machine learning extracts valuable insights from large databases. Various techniques, including clustering, association, and classification algorithms, are used to predict heart disease [45]. Cardiovascular diseases cause significant mortality, warranting urgent research [7]. Chronic illnesses, like cancer and diabetes, surpass infectious diseases in causing death and disability. The epidemiologic transition marks this shift. Globally, cardiac diseases account for 17.3 million deaths yearly, projected to rise [8-9]. Machine learning aids early heart disease diagnosis. Defining disease is complex; it generally refers to disrupted bodily functions. Heart disease is universal and results from plaque buildup in coronary arteries. Plaque narrows vessels, causing reduced blood supply, leading to heart attacks or strokes. Symptoms include chest discomfort, pain, and anxiety [46]. Disease causes, recognition, diagnosis, and risk assessment are discussed. This paper delves into heart disease's global burden, machine learning's role, problem statement, research goals, and research article structure.

### B. Heart Disease Mortality Rates

Heart disease is a leading cause of death in both developing and developed countries. WHO data reveals significant mortality (region wise distribution of mortality rate is shown in Table I), with 3.8 million deaths in men and 3.4 million deaths in women attributed to heart disease [10]. In the UK, heart disease constitutes 26% of all fatalities [10]. Reports from the Australian Bureau of Statistics (ABS) and the Economic and Social Commission of Asia and the Pacific (ESCAP) indicate mortality rates ranging from 20% to 33% in 2010 [11].

TABLE I.    INCIDENCE OF HEART-RELATED DEATHS

| Sr. No. | Region | Mortality Rate |
|---|---|---|
| 1 | Australia | 33.7% |
| 2 | East Asia and Pacific Region | 35.2% |
| 3 | Middle East and North Africa | 47% |
| 4 | South Asia | 10.6% |
| 5 | Sub-Sahara in Western Africa | 13% |
| 6 | Europe | 20-26% |

Diverse regions exhibit varying heart disease-related mortality rates. Notably, heart disease accounts for 10.6% of reported fatalities [11], with 13% attributed to cardiovascular diseases. Circulatory diseases, predominantly heart diseases, dominate mortality in regions spanning Asia-Pacific, Australasia, Western Europe, and North America. Heart disease emerges as a universal cause of death, regardless of a nation's income level.

## C. Global Burden of Heart Disease

Heart disease presents a significant global challenge, impacting individual mortality, family well-being, and economic costs. In the UK, heart disease costs approximately £9 billion yearly, covering premature death and disability expenses [10]. The USA spends around $312.6 billion annually on stroke and heart disease, projected to reach $1.1 trillion by 2035 [9]. China allocates over $40 billion, constituting about 4% of GNI, to heart disease treatment. South Africa's heart disease treatment costs range from 2% to 3% of GNI, a quarter of primary care expenses. Globally, heart disease treatment cost about $370 billion in 2001, accounting for 10% of global healthcare costs [12]. Eastern Europe's high blood pressure expenses reach nearly 25% of healthcare costs. The American Heart Association (AHA) devised a method to forecast medical costs for conditions like high blood pressure, coronary artery disease (CAD), and stroke [13]. By 2030, 40.8% of Americans are predicted to have heart disease. Costs are set to rise from $320 to $818 billion between 2013 and 2030. Early diagnosis is crucial to prevent worsening conditions.

## D. Heart Disease Recognition and Diagnosis: Current Scenario

The surge in heart disease incidence stems from preventable factors [1], including unhealthy lifestyles and risk factors like poor diet, obesity, high blood pressure, and elevated triglyceride levels. Warning signs encompass insomnia, abnormal heartbeat, leg swelling, and rapid weight gain [2], often misinterpreted in elderly populations. Growing hospital and research data availability aids precision diagnosis and early detection. AI and ML revolutionize healthcare, enhancing diagnostics, data analysis, and risk prediction. Genetic data analysis benefits from machine learning, expanding medical evaluations and pandemic anticipation. Cardiovascular diseases account for over a third of annual deaths [6], attracting machine learning application in detecting heart disease from medical databases. Diagnostic accuracy, speed, and lifesaving insights improve through these procedures [7].

Dataset diagnosis draws on multiple patient pathology features [46], influenced by varying factors. Critical indicators often determine disease presence. Specialized feature selection enhances predictive accuracy. Addressing class imbalance and dataset rebalancing improves model reliability. Machine learning excels in complex, nonlinear problems, solving classification and prediction tasks like prenatal cardiac defect diagnosis [47] and ECG early warning systems [48]. Ensemble learning's base underlies many techniques, combining classifiers for enhanced performance. Xgboost mitigates overfitting.

Research presents numerous models for cardiac disease classification and prediction. Computerized classifiers assess congestive heart failure risk. Machine learning achieved 93.3% sensitivity and 63.5% specificity [51]. ECG-based deep neural networks improve performance [52]. Clinical decision support systems aid early heart failure detection [53]. SVM identifies diabetes and predicts heart disease with 94.60% accuracy [55]. In "curse of dimensionality," massive data's exponential growth hampers analysis, causing overfitting. Weighting characteristics reduce dataset duplication, easing processing [57, 58, 59]. Feature engineering and selection methods decrease dataset dimensionality [50].

Despite preventability efforts, heart disease persists globally. Pharmacies and health maintenance tests are crucial for rising heart disease rates. Expensive screening tests are used initially, prompting the need for cost-effective community-level alternatives. Identifying risk factors like age, alcohol, diet, smoking, and inactivity is vital to combat heart disease. Exposure to these factors increases hypertension, diabetes, dyslipidemia, obesity, and stroke risks [16].

Heart disease's high mortality demands accurate diagnosis tools. A systematic, accurate diagnostic tool based on death rates, disability rates, and costs is needed. Screening tools for cost-effective early diagnosis exist but require invasive blood sampling [16]. Main objective of this work is to study ML Algorithms (LR, KNN, SVM, RF, and Decision Tree), optimize algorithms to combat overfitting, apply ML for Classification, evaluate, and compare performance metrics.

The study evaluates and compares classifiers such as decision trees, Naive Bayes, logistic regression, SVM, and random forests. It suggests an innovative ensemble classifier strategy, which combines both strong and weak classifiers. This approach is designed to accommodate diverse sample requirements for training and validation, ensuring a robust and reliable predictive model for heart problems. By harnessing the synergistic strengths of multiple classifiers, this research aims to provide a comprehensive and accurate prediction framework for cardiovascular diseases, thereby contributing significantly to the advancement of predictive healthcare analytics.

## E. Research Paper Outline

The Research paper is organized into five sections including conclusion and discussion. Section I introduce the spread of heart disease, its prevalence, diagnosis, and economics of early cure including research goals. Section II provides an in-depth review of heart disease prediction using machine learning techniques. The Section III is used to describe machine learning techniques and their applications. Performance evaluation via various techniques is highlighted in Section IV. Finally, the paper is concluded in Section V with limitations of proposed technique and future research directions.

## II. LITERATURE REVIEW

This section provides an in-depth exploration of the significant contributions made by researchers in the realm of heart disease assessment using various machine learning techniques. The focal point is on recognizing the importance of

early diagnosis and prognosis, while concurrently highlighting the gaps and limitations present within the existing literature.

Ignoring heart issues can be detrimental, with men at higher risk [10]. A pivotal dataset from 1988 combines Cleveland, Hungary, Switzerland, and Long Beach V data. 80% of heart disease can be averted through healthy living [14]. Primary, secondary, and tertiary preventions obstruct disease progression [15]. Early diagnosis reduces serious illness and cost. A reliable tool for high-risk classification is crucial. AHA's goals could prevent millions of heart disease deaths [14]. Early detection prevents severe conditions [15]. Resource constraints in LMICs require cost-effective, community-level screening for higher-risk individuals. Early prediction and cost-effective prevention strategies are essential [15].

Researchers have harnessed supervised machine learning techniques to predict heart disease. Nguyen and Davis [23] introduced the KMIX algorithm for heart ailment prognosis. Shouman, Turner, and Stocker [24] advanced Naive Bayes through K-Means clustering. Tsipouras et al. [25] innovated a fuzzy rule-based model. Aqueel and Hannan in [26] integrated SVM, genetic algorithms, rough set theory, association rules, and neural networks. Amin, Agarwal, and Beg [27] crafted a hybrid model integrating neural networks and genetic algorithms. Chaurasia and Pal in [28] envisioned heart disease forecasts by deploying Naïve Bayes, decision trees, and bagging. Bialy et al. [29] forged a hybrid model that amalgamated Bay's theorem and Perceptron. In Table II some of the recent work is listed with research methodology, limitations, and contribution. Modepalli et al. [52] embraced a hybrid approach of DT and RF. L. Sathish Kumar and A. Padmapriya [58] employed the ID3 algorithm to anticipate diseases.

Some latest results show that in one study, logistic regression exhibited notable accuracy, achieving 90.16% on the Cleveland dataset, while AdaBoost outperformed with 90% accuracy on the IEEE Dataport dataset [60]. Another comparative analysis scrutinized traditional machine learning methods against deep learning algorithms, highlighting the superiority of artificial neural networks (ANN). The ANN model demonstrated a remarkable accuracy of 93.44%, surpassing the support vector machine (SVM) model by 7.5% [61].

TABLE II.        SUMMARY OF LITERATURE REVIEW

| Reference No. | Methodology | Outcome | Advantages | Limitations |
|---|---|---|---|---|
| [17] | Machine Learning Models for CHD | Risk estimation over short and long term | Improved risk assessment | Focus on short-term forecasting |
| [18] | Cross-Validation and Multi-class Classification | Robust prediction model | Effective evaluation on multiple classes | Focus on cross-validation |
| [19] | Heart Rate Variability Analysis | CAD diagnosis using HRV | Utilization of medical domain knowledge | Focus on HRV analysis |
| [20] | Neural Network Model | Risk assessment using neural networks | Utilizing AI for risk assessment | Specific to neural network model |
| [21] | Various Machine Learning Algorithms | Heart disease prediction using ML | Comparative evaluation of algorithms | Focus on multiple machine learning models |
| [22] | Decision Trees and Risk Model | Risk assessment model for CHD | Effective use of decision trees | Focus on specific algorithms |
| [23] | KMIX Algorithm for Clustering | Improved clustering for disease prediction | Enhanced performance with KMIX algorithm | Specific to KMIX clustering method |
| [24] | K-Means with Naive Bayes | Enhanced prediction using K-Means and NB | Improved handling of continuous attributes | Specific to K-Means and NB |
| [25] | Fuzzy Rule-Based Model | CAD prediction using fuzzy rules | Improved classification with fuzzy rules | Utilization of fuzzy rules |
| [26] | Ensemble Techniques with Genetic Algorithms | CHD diagnosis using various algorithms | Enhanced predictive capability | Focus on ensemble and genetic algorithms |
| [27] | Hybrid Model (Neural Network and Genetic Algorithm) | Initial risk assessment model | Utilizing hybrid model for prediction | Specific to neural network and GA |
| [28] | Naïve Bayes, Decision Trees, Bagging | Accurate heart disease prediction | Effective use of multiple algorithms | Specific to certain algorithms |
| [29] | Ensemble Techniques with Weighted Average | CAD assessment using ensemble methods | Improved accuracy with ensemble approach | Focus on ensemble techniques |
| [52] | Artificial Intelligence for CHD | Severity prediction using K-Star algorithm | Utilizing AI for cardiac diagnosis | Focus on severity prediction |
| [58] | ID3 Algorithm in TV and Mobile Phones | Disease prediction and prevention | Effective education and prevention | Specific to certain algorithms |

Furthermore, a distinct research endeavor proposed an innovative heart disease prediction model. This model incorporated embedded feature selection techniques and deep neural networks, resulting in an impressive accuracy of 98.56% on the Kaggle dataset [62]. Additionally, a neural networks model utilizing a Multilayer Perceptron (MLP) achieved commendable accuracies, recording 85.71% on the UCI Heart Disease dataset and 87.30% on the cardiovascular disease dataset [63].

### A. Research Gaps

Despite the strides in heart disease prediction, the extant literature grapples with several limitations:

- Crafted models struggle with generalizability and potential sluggishness due to intricate risk rules.

- Experimentation tools entail complications and inherent limitations.

- Majority of models are circumscribed to clinical attributes, neglecting non-invasive risk elements.

- Scarce research leverages multiple feature selection techniques alongside their mean values.

A pressing need exists for further exploration into novel heart disease revelations and their effective integration into machine learning techniques. Continued research is essential to heighten diagnostic precision through machine learning methods and surmount the prevailing gaps in heart disease anticipation and detection.

### III. MACHINE LEARNING METHODS FOR HEART DISEASE PREDICTION

Machine learning techniques are used to extract hidden information in an explicit structure from these large datasets because the medical industries are overrun with noisy and incomplete data. Machine learning techniques should be used in the healthcare industry to support specialists rather than replace them [54]. The feature selection methods used to identify the significant non-invasive subset of risk attributes for the early diagnosis of heart disease are described in this Section. The machine learning methods used to create a risk evaluation model are covered in this section. Various performance measures are used in this section to assess the risk models' performance. The importance of non-invasive risk factors for the initial diagnosis and care of cardiac patients is also discussed in this section.

Exploring the heart disease dataset provides valuable insights that can significantly aid in early detection and prediction of cardiovascular conditions. In this Section, Davis' machine learning methodology was employed in the study to construct a comprehensive cardiovascular disease model. The focal point of this Section lies in outlining the research procedures, designing the study's framework, and expanding its applicability through well-defined objectives. By harnessing the power of machine learning techniques, this research effectively identifies a substantial subset of risk factors crucial for the initial prognosis of individuals with heart disorders.

### A. The Methodology of Prediction

The process of transforming raw data into a dataset that can be used to produce knowledge for users is referred to as "machine learning" and a machine learning methodology is a method that uses alternative techniques to accomplish this transformation. The utilization of this methodology in particular is warranted due to the fact that it exemplifies the objectives of our research. The following is an outline in Fig. 1. The first step of the process is called data selection, and it entails selecting the pertinent information about heart disease from a variety of different sources so that it can later be entered into the standard database.

*1) Data Preparation:* In the first step, known as "data preparation," the dataset containing information about heart disease is analyzed and prepared so that the machine learning algorithms can derive useful insights from it and achieve the best possible results.

*2) Data Task Filter:* In this step, the heuristic decision rules are used to establish expected outcomes for the prognosis of heart disease in subsequent steps. The dataset that was selected is then stored in what is called the "Machine learning Task Warehouse."

*3) Selecting Appropriate Algorithms and Datasets:* It is for the Task Specified in Step 3. This step involves selecting an appropriate algorithm and dataset for the task that was specified in Step 3.

*4) Comparison and Evaluation:* The results of the classification are compared to one another and estimated using a variety of different machine learning evaluation metrics during this phase.

In the process of developing new models, the recently finished supervised classification models have been filed away in the data warehouse in order to be ready for any upcoming issues with prediction. For each new prediction task, the procedure starts over at step three and continues through step five.

Fig. 1.   Detail steps of research design.

### B. Exploratory Data Analysis (EDA) Process

Fundamental statistical descriptions are conducted to enhance understanding of the myriad attribute values within the Kashmir heart disease dataset. Knowledge of these basic statistics facilitates addressing noisy values, detecting outliers, and handling missing values. The dataset contains both nominal and numerical values, all serving as risk factors for coronary heart disease. Simple mean imputation is applied to address missing numerical values, while mode imputation is used for missing values in categorical data.

## C. Examination of Class Imbalances and Distributional Issues

Before engaging in any operations related to heart disease dataset, assessing class balance is crucial. Highly imbalanced data can lead to biased machine learning algorithms. Statistical analysis is applied to the data to evaluate its kurtosis, skewness, and class balance. Skewness assesses symmetry to determine if data distribution is equal on both sides of the center point. Kurtosis identifies whether data tails are light or heavy compared to a normal distribution. Skewness and Kurtosis tests reveal that the Kashmir heart disease dataset follows a normal distribution.

## D. Establishing Feature Correlations

Since datasets can contain intricate interconnections between variables, quantifying the degree of attribute relationships is vital. The correlation process involves assessing the level of connection between dataset attributes. Understanding these connections is essential for data preparation before applying machine learning algorithms. Pearson's correlation method is used to explore the relationship among heart disease attributes. A heatmap depicts Pearson's correlation coefficients applied to heart disease variables (see Fig. 2).

The heatmap grid showcases associations between cardiovascular disease-related factors and associated coefficients. The matrix presents all attributes horizontally across the top and vertically down the side, offering correlations among feature combinations. The diagonal line's connection from bottom right to top left indicates perfect correlation between attributes and themselves. Correlation coefficients near zero suggest weak relationships between heart disease attributes, while values of 1 and -1 signify ideal positive and negative correlations, respectively.

Fig. 2. Correlation in risk attributes through heat map representation.

## E. Feature Selection

Feature selection is crucial as irrelevant or redundant attributes can impede classifier performance. To attain a non-invasive subset of risk attributes for precise heart disease prediction, the heart disease dataset (as listed in Table IV) undergoes five distinct Feature Elimination techniques. These techniques assign values to potential risk factors based on their disease prediction accuracy, assigning weights from 0 to 1 to each attribute associated with coronary heart disease. The final weights are determined by individual feature selection techniques, where attributes with mean values close to 1 are considered significant, while those near 0 are less significant.

These heart disease-linked characteristics are presented in descending order of mean values derived from five distinct feature selection strategies in Table V. Attributes with higher weights are more important for predicting early heart disease, while those with lower values are less significant. The model predicting the risk of heart disease development is constructed using the highly weighted significant subset of risk factors.

*1) Feature selection techniques*: Precise and concise prediction model subsets are identified using feature selection techniques [30]. To obtain the best non-invasive subset of risk factors for heart disease prediction, this research investigates a combination of filter, wrapper, and embedded feature selection methods.

- Extra Tree Classifier: The extra tree classifier, also known as extremely randomized trees, is an ensemble learning technique creating multiple trees without eliminating any existing ones. Decision tree nodes are divided through random splits, enhancing accuracy while significantly reducing the computational load associated with determining optimal cut-points in random forests and standard trees [31].

- Gradient Boosting Classifier: Gradient boosting is employed to address classification and regression challenges. It entails constructing decision trees in a greedy manner to optimize a loss function, adding these trees one at a time to minimize the loss function [32].

- Random Forests: Random forests involve decision tree predictors for regression and classification tasks, using multiple decision trees in a randomly selected training set to counter individual decision tree overfitting [33]. Further explanation of the random forest classifier can be found in the machine learning techniques section.

- Recursive Feature Elimination: Recursive feature elimination (RFE), a greedy optimization technique, builds the feature model until all features are used. Features are then ranked based on their elimination order [34].

- XG Boost Classifier: The XG Boost classifier employs a gradient boosting algorithm with optimized regularization to counter bias and overfitting. Its scalability enables swift learning and efficient memory usage [35].
Fig. 3.    Decision tree model working for heart disease prediction.

### F. Predictive Analysis

Machine learning tasks capitalize on discovered patterns to learn from the machine learning process. These tasks are typically categorized into predictive and descriptive categories [36]. Predictive tasks focus on predicting the value of a dependent (target) attribute based on independent (exploratory) attributes. Descriptive tasks aim to extract patterns describing underlying relationships within data, often requiring post-processing techniques for validation and explanation due to their exploratory nature [37].

*1) Machine learning techniques*: Predicting heart condition from different symptoms is a stratified problem that is bound to erroneous assumptions and has impulsive effects. We use various machine learning methods to extract knowledge from the heart disease dataset. The purpose of blending machine learning methods in health care is not to take over specialists or assistants, but to give support to where they struggle [38]. Some of the popular Machine Learning algorithms are shown in Fig. 4 and described below:

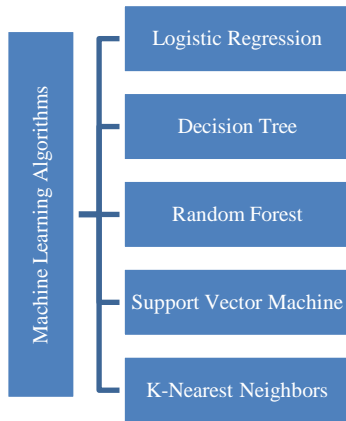

Fig. 4. Machine learning algorithms.

- Decision Tree: The decision tree is a widely used tool, especially for classification tasks [39]. It is constructed using a top-down, recursive divide-and-conquer approach, following a greedy (nonbacktracking) strategy. This is depicted in Fig. 4. There are various types of decision trees, distinguished by the mathematical model they employ to select the attribute for splitting, thereby forming decision tree rules. The attribute that effectively divides the tuples into distinct classes is chosen based on the Information Gain attribute selection measure. The Information Gain approach aims to maximize the reduction in uncertainty by selecting the splitting attribute with the lowest entropy value. The Information Gain for each attribute is determined using Eq. (1):

$$Gain\,(A) = Info\,(D) - InfoA(D) \tag{1}$$

Where:

- Info (D) represents the entropy of the entire dataset.

- InfoA (D) represents the weighted average of the entropies of subsets obtained by splitting based on attribute A.

The entropy of a set is calculated using Eq. (2):

$$Info\,(D) = \Sigma - p * log2(p)\square \tag{2}$$

where, p is the proportion of instances belonging to a specific class.

Fig. 5. K nearest neighbour classification.

- K-Nearest Neighbor (KNN): K-Nearest Neighbor (KNN) is a fundamental instance-based machine learning technique that operates in a non-parametric manner [40, 49]. It relies on learning by analogy, where a new unclassified record is compared to existing records using a distance metric. The class of the closest existing record is then assigned to the new unclassified record. Fig. 5 provides an example of KNN classification. The optimal value of k (the number of neighbors) is typically determined experimentally. This involves starting with k = 1 and gradually increasing k to account for more neighbors. The error rate of the classifier is calculated using a test set. In the KNN algorithm, a new instance is classified based on its proximity to its neighbors, determined by a distance function. Various distance measures such as Euclidean, Manhattan, and Minkowski can be utilized. In this study, due to the nature of the heart disease data, the Euclidean distance measure is used. To prevent attributes with higher values from dominating those with lower values, attribute values are normalized before applying the Euclidean distance measure. The Min-Max normalization technique is employed, which transforms a numerical attribute's value P to a value P| in the range [0, 1]. The KNN technique is used in this study for predicting heart disease.

Fig. 6. Linear SVM classifier for two-class representation.

- Support Vector Machine (SVM): Support Vector Machine (SVM) is a supervised machine learning technique used for both classification and regression tasks. SVM works by translating the original training data into a higher-dimensional space through a nonlinear mapping. It seeks to find the best separating hyperplane in this new dimension. Support vectors and margins are utilized by SVM to determine this hyperplane [41]. The linear support vector machine is illustrated in Fig. 6, where red circles denote data points of class x2, and light green circles represent data points of class x1. However, if there is no obvious hyperplane in the original feature space, SVM requires moving to a higher-dimensional view known as kernelizing. The principle behind kernelizing is that the data will be mapped into higher dimensions until a hyperplane can be established to separate it. The choice of the SVM's kernel function, such as polynomial, radial basis, and Gaussian kernel functions, plays a critical role. There are other kernel functions available as well, in addition to the ones mentioned.

- Random Forests: Random Forests are an ensemble learning technique that utilizes a collection of individual decision trees for both classification and regression tasks. They are designed to address the issue of overfitting that can occur with individual decision trees. In random forest classification, the final class of a test object is determined by the majority votes from each decision tree in the forest [42]. Random Forests have significantly extended bagging, a technique that aggregates a large set of decorrelated trees. The process of the random forest algorithm is depicted in Fig. 7, where each tree is grown using a different subset of the original data. In each of the k iterations, approximately one-third of the samples are left out from the new bootstrap training set and are not used in constructing the tree. The class with the highest number of votes from the trees in the forest becomes the final classification for a given sample. The random forest algorithm is applied in this study for diagnosing and predicting heart disease, and Section IV provides further details on the outcomes.

- Naive Bayes: Naive Bayes is a classification algorithm that operates based on statistical probabilities and follows the principles of the Bayesian theorem. It is particularly effective when dealing with high-dimensional inputs. The algorithm works under the assumption of "class conditional independence," which means that the attribute values' impact on a specific class is considered unrelated to the outcomes of other attributes. This assumption is referred to as "naive" because it simplifies calculations [43]. The Naive Bayes classifier can handle both continuous and categorical variables, and it can accommodate any number of independent variables. By assuming that the probabilities are independent of each other, Naive Bayes simplifies probability calculations, leading to a fast and efficient method. In this study, the Naive Bayes algorithm is employed using the non-invasive

risk attributes to predict and diagnose heart disease at its early stages. Section IV provides a detailed discussion of the Naive Bayes model's predictions for heart disease.

Fig. 7. Random forest algorithm working.

*2) Model evaluation techniques*: Model evaluation is a critical aspect of practical machine learning development. In order to interpret patterns from the provided dataset, systematic methods are required to assess the effectiveness of machine learning techniques and to compare them, helping to decide which method to use for a given problem. The performance of algorithms in classification problems can be evaluated using various metrics, including the confusion matrix, cross-validation, error rate, sensitivity, specificity, accuracy, and precision. These evaluation metrics are discussed below [44]:

*a) Confusion Matrix*: The confusion matrix is a fundamental tool for assessing performance in classification problems. It is particularly useful for understanding the types of classification errors that can occur in two-class classification scenarios. The confusion matrix provides insight into how well the model's predictions align with the actual outcomes. In a two-class confusion matrix, as shown in the Table III below, various classifications are categorized based on their correctness or incorrectness:

- True Positives (TP): Instances that are correctly classified as positive.

- False Negatives (FN): Instances that are actually positive but are incorrectly classified as negative.

- False Positives (FP): Instances that are actually negative but are incorrectly classified as positive.

- True Negatives (TN): Instances that are correctly classified as negative.

The confusion matrix allows for a deeper understanding of the model's performance and the types of errors it makes, such as Type We and Type II errors.

TABLE III.    CONFUSION MATRIX FOR BINARY CLASSIFICATION

| | | Predicted Values | |
|---|---|---|---|
| | | Positive | Negative |
| **Actual Values** | **Positive** | True Positive (TP) | False Negative (FN) |
| | **Negative** | False Positive (FP) | True Negative (TN) |

- Error Rate (Misclassification Rate): The error rate, also known as the misclassification rate, is a measure that quantifies the proportion of misclassified instances in a classification model. It's a combination of both training errors and generalization errors.

- Training Errors: These are the mistakes made by the model when classifying instances within the training dataset.

- Generalization Errors: These are the expected mistakes that the model will make when classifying instances that it hasn't seen before, i.e., on unseen data.

The goal of a good classification model is to have both low training and generalization errors. This indicates that the model has learned the underlying patterns in the data without overfitting to the training data.

The error rate can be calculated using the formula in Eq. (3):

$$Error\ Rate = \frac{(False\ Positives + False\ Negatives)}{(Total\ Positive + Total\ Negative)} \qquad (3)$$

Where False Positives are instances that are wrongly classified as positive, False Negatives are instances that are wrongly classified as negative, and Total Positive and Total Negative are the total number of positive and negative instances, respectively.

- Cross-Validation: Cross-validation is a technique used to estimate the performance of a machine learning model on unseen data. It involves dividing the dataset into multiple subsets (folds), using some folds for training and others for testing. This process is repeated multiple times with different combinations of training and testing sets. By evaluating the model's performance across different subsets of data, cross-validation provides a more robust estimate of its generalization ability. In a common method called k-fold cross-validation, the dataset is divided into k subsets of approximately equal size. The model is trained on k-1 folds and tested on the remaining fold in each iteration. The results from all iterations are then averaged to provide an overall assessment of the model's performance. Cross-validation helps to mitigate the risk of overfitting and provides a more accurate estimation of how well the model will perform on new, unseen data.

## IV. RESULTS AND DISCUSSION

In conclusion, the development of a robust risk evaluation model for cardiac disorders involves careful selection and preprocessing of data, integration of diverse information sources, and the utilization of appropriate algorithms. By prioritizing non-invasive risk factors and optimizing data quality, accurate and reliable risk assessment strategies can be implemented.

### A. Dataset Selection

For the development of the risk evaluation model, we sourced a dataset from the Kaggle Machine Learning library. This dataset comprises 1025 data points, each characterized by 14 distinct attributes, encompassing 13 predictive features and 1 target class. These attributes encompass various factors such as age, sex, chest pain, high blood pressure, cholesterol levels, fasting heart rate, ECG readings, and more [5]. In order to comprehensively analyze the risk factors associated with heart disease and to construct a highly accurate model, five different algorithms are employed. The field of cardiac disorder detection encompasses various tests, some of which require invasive procedures and multiple blood tests. To implement more practical risk recognition strategies, a focus on non-invasive risk factors is essential. These factors, such as age, height, weight, and smoking habits, can be easily obtained without the need for complex equipment. While measurements like body weight and blood pressure do require devices, these tools are readily available at home or local pharmacies, eliminating the necessity for hospital-based procedures for data acquisition. Data fields are shown in Table III.

### B. Data Balancing

Notably, many medical databases exhibit an imbalanced distribution of positive and negative samples. To enhance the model's reliability, it may be necessary to apply specific data processing techniques to rectify this imbalance [56]. Moreover, real-world data often contains duplicates and missing values, which can distort the analysis. Through careful data preprocessing, including techniques like smoothing, normalization, and grouping, we ensured that the input data was accurate, devoid of noise, and effective for analysis [6].

### C. Data transformation

The process of transforming raw data into a more understandable format involves translation. This translation process is supplemented by steps such as smoothing, normalization, and grouping to ensure that the data is prepared optimally for analysis. Moreover, integration of information from various sources is often required to produce refined and comprehensive datasets.

### D. Data Preprocessing

Within the dataset, 526 instances represent individuals with cardiac disease, while 499 instances pertain to individuals without the condition. While it can be challenging to limit the amount of data collected, it's crucial to present the data effectively to derive meaningful insights. In certain cases, specific attributes may hold a high correlation with the target variable. For instance, in analysis, the fasting blood sugar attribute displayed significant correlation, leading to eliminating the corresponding column to enhance the model's

accuracy. Table V lists out the ranking of different attributes as per the importance of attributes.

*1) Splitting data into test train set*: Following data preprocessing, the dataset is organized into training and validation subsets into 80:20 ratio. The performance of different algorithms is then assessed to ascertain their predictive capabilities [7]. The process of data preparation, including feature selection and data uniformity, can significantly enhance the dataset's utility and subsequently improve the accuracy of the model.

TABLE IV.    THE HEART DISEASE DATASET ATTRIBUTES

| Variable Name | Role | Type | Units | Missing Values |
|---|---|---|---|---|
| Systolic BP | Feature | Integer | mm Hg | no |
| Diastolic BP | Feature | Integer | mm Hg | no |
| BMI | Feature | Integer | Number | no |
| Age | Feature | Integer | Years | no |
| Healthy Diet | Feature | Categorical | No Unit | no |
| Hereditary | Feature | Categorical | No Unit | no |
| Smoking | Feature | Categorical | Binary | no |
| Physical Activity | Feature | Categorical | Binary | no |
| Socio-Economic Level | Feature | Categorical | No unit | no |
| Sex | Feature | Binary | No Unit | no |
| Alcohol Consumption | Feature | Categorical | Number | no |
| CHD | Target | Integer | No unit | no |

TABLE V.    MEAN RANKING OF WEIGHTAGE OF ATTRIBUTES

| Sr. No. | Attributes | Mean ranking of attributes |
|---|---|---|
| 1 | Systolic BP | 0.82 |
| 2 | Diastolic BP | 0.80 |
| 3 | BMI | 0.78 |
| 4 | Age | 0.76 |
| 5 | Healthy Diet | 0.54 |
| 6 | Hereditary | 0.42 |
| 7 | Smoking | 0.28 |
| 8 | Physical Activity | 0.24 |
| 9 | Socio-Economic Level | 0.16 |
| 10 | Sex | 0.14 |
| 11 | Alcohol Consumption | 0.12 |

*E. Experimental Results of the Proposed Machine Learning Techniques*

The existing models employed for assessing the risk of heart disease have demonstrated inherent flaws that undermine their effectiveness. These models often yield inconsistent results when applied to diverse datasets, thereby compromising their reliability. In this study, the focus is on leveraging machine learning techniques, specifically Decision Tree (DTC), K-Nearest Neighbor (KNN), Random Forest (RFC), Support Vector Machine (SVM), and Naive Bayes (NBC), to extract objective and dependable outcomes from the cardiovascular disease dataset. To achieve this, a range of performance metrics relevant to the medical domain, including sensitivity, specificity, accuracy, and precision, are employed to ensure the generation of accurate and reliable results. The

following subsections elucidate the experimental findings yielded by various models in the context of disease assessment.

The central aim of this study revolves around predicting the likelihood of an individual developing heart disease. To fulfill this objective, a variety of supervised classification approaches, including Support Vector Machine, Random Forest, K-Nearest Neighbor, and Logistic Regression, are explored. The experimentation encompasses the utilization of diverse computational models, particularly Decision Trees, facilitated by the SkLearn package. The experimental setup utilized a 6th generation Intel Core i3 processor with a 3300H CPU, operating at up to 2.1 GHz, and 4 gigabytes of RAM. A prompt data analysis procedure was employed to swiftly provide a comprehensive accuracy assessment for the adopted methods. The dataset partitioning involved allocating 55% (563 instances) of the data for training purposes and 45% (462 instances) for testing purposes. The subsequent graph depicts the distribution of training and testing activities undertaken during the study:

Fig. 8.    SVM train-test split.

Fig. 9.    LR train-test split.

| Actual(P) | 35 | 204 |

TABLE XI.     MODEL EVALUATION RESULTS IN %

| Algorithm Used | Accu-racy | Precision | Recall | F1-score |
|---|---|---|---|---|
| LR Classifier | 85.93 | 81.68 | 91.85 | 86.47 |
| SVM Classifier | 85.28 | 81.44 | 91.88 | 86.35 |
| KNN Classifier | 79.87 | 77.86 | 85.36 | 81.44 |
| DT Classifier | 96.75 | 97.81 | 95.73 | 96.76 |
| RF Classifier | 96.75 | 95.85 | 97.88 | 96.85 |

Fig. 8 to 10 showcase the division of the test dataset and the train dataset's performance, indicating that optimal performance was achieved within the 60%–80% split range. Several options were experimented to find out the best test train split. The binary label's confusion matrix for each tested method is depicted in Tables VI to X. While accuracy is a valuable metric, we place greater significance on precision, recall, and the F-1 score, all of which can be found in Table XI. Among the methods tested, K-Nearest Neighbor (KNN) yields the least favorable results, while regression and Support Vector Machine (SVM) methods perform moderately. Notably, Decision Tree and Random Forest methods exhibit the highest accuracy and F-1 score, as evidenced by this dataset. Thus, it can be inferred that Random Forest is a versatile method capable of achieving substantial accuracy with ease.

The table presents the results of different classification algorithms employed to predict heart disease, showcasing their performance metrics. These metrics are vital in assessing the accuracy and effectiveness of each algorithm in identifying individuals at risk of cardiovascular or heart-related ailments.

Logistic Regression (LR) Classifier achieved an accuracy of 85.93%, meaning it correctly predicted the presence or absence of heart disease in individuals 85.93% of the time. Its precision, which measures the accuracy of its positive predictions, stood at 81.68%, indicating that 81.68% of the cases it classified as positive were indeed true positives. With a recall rate of 91.85%, this model identified 91.85% of the actual positive cases. The F1-score, a balance between precision and recall, was 86.47%.

The Support Vector Machine (SVM) Classifier, on the other hand, achieved an accuracy of 85.28%. It exhibited a precision of 81.44%, indicating that 81.44% of its positive predictions were accurate, while its recall rate was 91.88%. The F1-score for this model was 86.35%.

The K-Nearest Neighbor (KNN) Classifier exhibited an accuracy of 79.87%, with a precision rate of 77.86%, suggesting that 77.86% of its positive predictions were correct. It had a recall rate of 85.36%. The F1-score for KNN was 81.44%.

Now, the Decision Tree (DT) Classifier stood out with a remarkable accuracy of 96.75%. Its precision rate was an impressive 97.81%, indicating a high accuracy in positive predictions. The model captured 95.73% of the actual positive cases (recall), resulting in a high F1-score of 96.76%.

Lastly, the Random Forest (RF) Classifier shared the same accuracy as the Decision Tree at 96.75%. It had a precision rate of 95.85% and an outstanding recall rate of 97.88%. The F1-score for Random Forest was 96.85%.

In summary, the Decision Tree and Random Forest classifiers exhibited the highest accuracy and strong F1-scores among the algorithms, signifying their effectiveness in predicting heart disease. These models excelled in both accurately identifying positive cases and capturing a substantial portion of actual positive cases. These results emphasize the potential of these algorithms in aiding the diagnosis and prediction of cardiac conditions with a high degree of accuracy.

While other machine learning algorithms, including Logistic Regression, SVM, K-Nearest Neighbor, and Random Forest, were explored, they were found to be comparatively less effective in predicting instances of cardiac illness. In essence, this research article underscores the combination of the Decision Tree and Random Forest algorithms as the most accurate approach for forecasting heart disease. This amalgamation offers a dependable means of predicting the potential development of cardiovascular or heart-related disorders in the future. While other algorithms were assessed, such as Logistic Regression, SVM, K-Nearest Neighbor, and Random Forest, they were not found to be as potent as the methods discussed in this study for predicting cardiac conditions.

## V. CONCLUSION AND FUTURE WORK

In the pursuit of advancing predictive analytics for cardiovascular diseases, this study meticulously examined various machine learning algorithms, aiming to identify the most effective approach for accurate and early prediction. The results presented in this research, encompassing a thorough analysis of different classifiers, unveil valuable insights into the realm of cardiac health forecasting.

The experiments demonstrated that the optimal performance was achieved within the 60%–80% split range of the test and train dataset. This meticulous evaluation led to the conclusion that precision, recall, and the F-1 score are pivotal metrics, often surpassing the significance of mere accuracy. Among the array of methods explored, K-Nearest Neighbor (KNN) emerged with comparatively less favorable outcomes, while regression and Support Vector Machine (SVM) methods exhibited moderate performance.

However, the spotlight of this research undoubtedly falls upon the Decision Tree (DT) and Random Forest (RF) classifiers. The DT Classifier showcased an exceptional accuracy of 96.75%, coupled with an impressive precision rate of 97.81% and a robust recall rate of 95.73%. This translated into an outstanding F1-score of 96.76%, underlining its proficiency in positive predictions. Equally noteworthy, the RF Classifier mirrored the DT's accuracy at 96.75% while achieving a remarkable precision rate of 95.85% and an outstanding recall rate of 97.88%, resulting in an exemplary F1-score of 96.85%. These results clearly indicate that the Decision Tree and Random Forest classifiers possess the highest accuracy and robust F1-scores, making them exceptionally effective in forecasting heart disease.

In contrast, Logistic Regression, SVM, K-Nearest Neighbor, and even Random Forest, despite its overall competence, fell short when compared to the superior predictive capabilities of Decision Tree and Random Forest classifiers. This study unequivocally establishes the amalgamation of Decision Tree and Random Forest algorithms as the most potent and dependable approach for predicting instances of cardiac illness. This combination not only accurately identifies positive cases but also captures a substantial portion of the actual positive instances, emphasizing their potential in aiding the diagnosis and prediction of cardiac conditions with an unparalleled degree of accuracy.

### A. Research Limitations

However, as with any research endeavor, certain limitations must be acknowledged. The study's predictive approach focuses on a subset of non-invasive attributes, potentially missing out on the broader spectrum of factors that influence heart disease risk. Additionally, while the model's performance is evaluated through metrics, usability testing of the prediction tools remains unexplored, leaving room for understanding user interaction and practical implementation challenges. Moreover, the study's reliance on a specific dataset categorized by a particular ethnic group might restrict the generalizability of the findings to other populations.

### B. Future Scope

The research's future trajectory offers opportunities for refinement and expansion. Further investigations could explore the efficiency of other robust machine learning techniques, such as genetic algorithms, neural networks, and hybrid models, to provide a comparative analysis of predictive performance. Expanding the model's scope to include additional non-invasive characteristics like socioeconomic status, depression severity, and ethnicity could enrich its accuracy and applicability. This might illuminate the relative importance of controlled non-invasive factors across various age and gender groups.

Furthermore, embracing diverse real-world datasets featuring multiple population groups and attributes can enhance the model's robustness and generalizability. An exciting future direction lies in the development of a comprehensive and universally applicable risk model. This model could not only predict cardiac disorders but also offer personalized treatment plans, amplifying its utility for medical professionals and patients alike. Through iterative refinement and continuous exploration, machine learning techniques hold the potential to revolutionize the landscape of heart disease prediction and prevention.

# Virtual Reality in Training: A Case Study on Investigating Immersive Training for Prisoners

Abdulaziz Alshaer

Dept. Computer Science, Jamoum University College, Umm Al-Qura University, Makkah, Saudi Arabia

*Abstract*—**This study addresses the pressing issue of prison rehabilitation by comparing traditional and Virtual Reality (VR) based training services offered by the General Directorate of Prisons in Saudi Arabia. Utilising Technology Acceptance Model (TAM) metrics such as perceived usefulness, ease of use, and enjoyment, the study evaluates the acceptance of VR technologies across two different headset platforms. Findings reveal that VR-based training services received significantly higher acceptance ratings than traditional methods. Both VR platforms were highly rated in terms of perceived usefulness, ease of use, and enjoyment but showed no significant differences between the headsets. These results indicate that VR-based methods could be more effective, engaging, and safer alternatives in correctional rehabilitation programs. Importantly, this research contributes to the field of Human-Computer Interaction (HCI) by suggesting design frameworks tailored for effective interventions in training and rehabilitative contexts where safety and psychological health are of high concern.**

*Keywords*—*Component; virtual reality; correctional services; technology acceptance; rehabilitation*

## I. INTRODUCTION

Prison rehabilitation has been a growing concern in recent years, as the recidivism rate remains high and the need for effective rehabilitation programs continues to grow. There are more than 60 thousand prisoners in Saudi Arabia [1] and more than 11 million globally [2]. Prisoners are a vulnerable group with mental disorders and infectious diseases compared to the general population [3]. They may show reluctance or lack interest in rehabilitation services and programs. In addition, the reluctance and lack of interest may result from the lack of interest in the traditional methods often used in prisons, including old, ineffective motivation techniques for rehabilitation.

In Saudi Arabia, prisoners are offered numerous rehabilitation services by Trahum (The National Committee for the Welfare of Prisoners and Released Prisoners and their Families in Saudi Arabia). Due to limited resources, safety, and individual mental status, not all services can be offered to them. Many prisoners struggle with substance abuse, mental health problems, and trauma, which can interfere with their rehabilitation and reintegration into society [4]. Nellis [5] added that the prison environment could be detrimental to rehabilitation efforts, with overcrowding, violence, and poor living conditions affecting prisoners' physical and psychological health.

Recently, interest in using VR technology in prisons has grown as a potential way to improve the outcomes of prisoner rehabilitation. VR technology can place users in safe learning environments by immersing them in realistic, regulated environments. Prisoners can engage in various rehabilitative, educational, and training activities in a safe, controlled, and immersive setting using VR [6]. VR technology can improve the delivery of social problem-solving treatment and successfully enhance psychological disorders [7]. Studies have investigated the use of VR in forensic mental health treatment [8]. According to a systematic review, VR can be utilised as a tool for assessment and treatment in forensic psychiatric settings. Exposure therapy, for example, is one potential application.

In addition, VR is an effective tool for teaching coping skills to users with disabilities [9]. In this study, participants with disabilities were trained in coping skills through VR simulations, and the results showed improved coping skills and increased self-efficacy. VR simulations can provide job training, cognitive behavioural therapy, and exposure therapy for Field individuals with mental health conditions [10]. VR can also address substance abuse and other high-risk behaviours through guided simulations that allow prisoners to experience the consequences of their actions [11]. VR technology in prisons has been shown to impact prisoners' well-being positively, behavioural change, and overall rehabilitation outcomes [11], [12].

VR has been used for crime prevention and rehabilitation [13]. In this study, the author explores the potential of VR as a rehabilitation tool to reduce recidivism and promote pro-social behaviour in criminal justice settings. According to a systematic review by [14], VR has shown potential as a tool for addressing various issues in criminal justice and rehabilitation, including anxiety disorders, post-traumatic stress disorder (PTSD), and teaching coping skills to people with disabilities. However, implementing and using VR in prisons requires careful consideration of ethics, security, and inmate acceptance.

VR acceptance depends on several factors, including perceived ease of use, usefulness, and enjoyment. Perceived ease of use refers to the ease with which a user can learn and use VR technology. In contrast, perceived usefulness refers to the extent to which VR technology is perceived as helpful and valuable [15]. Perceived enjoyment refers to the extent to which VR technology is experienced as a fun and enjoyable experience [16]. These three factors positively affect user adoption and acceptance of VR technology, and they are more likely to engage with and benefit from rehabilitation programs.

This study evaluates prisoners' acceptance of VR-based rehabilitation systems as an alternative to traditional methods. By leveraging the Technology Acceptance Model [15], it seeks to assess the perceived ease of use, usefulness, and enjoyment of VR in rehabilitation settings for two VR headsets. Our study's findings could have far-reaching implications for policymaking and prison management strategies, revolutionising how we approach rehabilitation and reintegration of prisoners into society. We hypothesised that 1) VR-based training and rehabilitation have a higher level of perceived ease of use, 2) VR-based training and rehabilitation have a higher level of usefulness, 3) VR-based training and rehabilitation have a higher level of enjoyment, and 4) VR-based training and rehabilitation have a higher level of prisoner acceptance compared to traditional training and rehabilitation services.

Following the introduction, Section II will delve into the 'Material and Methods' used in the research, providing insight into the study's methodology and data collection procedures. Section III will then present the findings of our study, followed by Section IV which deals with 'Discussion,' where the result is analysed and interpreted in the context of existing literature. Finally, the paper concludes in Section V by outlining potential directions for future work.

## II. MATERIAL AND METHODS

### A. Participants

The study comprised a group of 46 male inmates from Makkah prison in coordination with Tarahm. The age range of the participants was 18 to 41 years, with an average age of 23. Most participants were either single or divorced. Educational levels varied among the participants: three had completed primary education, eight had intermediate education, 28 had graduated high school, and few held university degrees. All participants were unemployed. On average, the duration of their incarceration was 3.6 years. The following figure shows the experiment setup (see Fig. 1).

Fig. 1. Experiment setup where prisoners take turns to participate.

In preparation for the forthcoming experiments, participants were asked to evaluate their computer skills, experience, and weekly usage of computers using a rating scale ranging from 1 to 5, with 5 indicating the highest level of proficiency. The outcomes of this assessment were as follows: Participants provided an average rating of 3.04 out of 5 for their computer skills, indicating a moderate level of competence. Regarding weekly computer usage, participants demonstrated an average

rating of 2.66 out of 5, suggesting a moderate frequency of interaction with computers. Moreover, participants show a notable interest in computer games, as evidenced by an average rating of 3.68 out of 5 for their level of engagement. Importantly, it's noteworthy that none of the participants had prior exposure to VR tools. These initial assessments aimed to provide insights into participants' familiarity with computer-related activities, informing their readiness to interact with the VR system during the experimental sessions.

### B. Apparatus

In this study, both software and hardware components were integrated. Through deliberations with the prison administration, a consensus emerged on employing a VR scenario that centred around mechanical training. Consequently, a VR environment was built, specifically designed for engine assembly. Within this immersive setting, participants were tasked with reassembling engine components, employing a VR controller as their interface. To facilitate this process, the system provided visual cues in the form of distinct colours, strategically guiding participants on the appropriate sequence of assembly steps (see Fig. 2)

In terms of hardware, the computational demands were adeptly met by an HP OMEN Gaming Laptop to power the VR headsets. For the immersive experience, two headsets were selected: the HTC Vive and the Oculus Rift. These cutting-edge devices were chosen to deliver a level of visual fidelity and interactivity, thus enhancing the realism and engagement of the participants within the virtual environment.

Fig. 2. The top picture shows the engine components to be installed next. The bottom picture shows picked-up components to be placed on the engine base.

### C. Data Collection

The research methodology entails the employment of a structured questionnaire as the primary data collection tool. This method uses various dimensions such as demographic information, proficiency in general skills, computer aptitude,

the acceptance model comprising perceived ease of use, perceived usefulness, and perceived enjoyment, along with an evaluation of preference. Additionally, insights into the utilisation of traditional rehabilitation services offered by Tarahm were obtained. The data amassed through the questionnaire was analysed through the Statistical Package for the Social Sciences (SPSS) software.

### D. Design and Procedure

In a within-subject experiment design, each participant was asked to perform the same task in each of the headsets (HTC Vive and the Oculus Rift) in a randomised and counterbalanced order, where across all participants, each headset was exactly 23 times the first and second. The task was to reassemble the whole engine.

Upon arrival, participants were welcomed and asked to sit down comfortably. After the introduction and provided written consent, participants were asked to complete a general demographic questionnaire. The information provided in the demographic questionnaire was then used to educate participants about using the headset and controllers. The participant started with a training session to get used to using the headset, followed by the actual experiment conditions. After each condition, participants were asked to complete a post-condition questionnaire. A self-report sheet was filled out by the researcher while the participant performed all three conditions. The report was then finished with the participants' verbal feedback gathered at the end of the experiment to help with future studies. The experiment was concluded by asking the participants to complete a preference questionnaire, and the participant was thanked for their participation.

### III. RESULTS

### A. Services Provided by the Prison and Tarahm

The prisoner receives their education and training from either the correctional service department in the prison or a third-party institution (Tarahm). This study compares the services provided by those two to compare that later to our proposed VR-based training. Three questions were asked for both as follows: 1) How do you evaluate the correctional services provided to you by the Prisons/Tarahm in general? 2) How do you evaluate the practical educational and training services provided to you by the Prisons/Tarahm? and 3) How is your interest in the educational and training services provided to you by the Prisons/Tarahm? The results of these metrics offer a general idea of how well these services are perceived, as well as their variability among the respondents. The following graphs represent subjects' responses to questions 1, 2, and 3 (see Fig. 3).

Fig. 3. Boxplots of all 3 questions: Q1: general service, Q2: training and education service, Q3: interest.

The means and standard deviation are reported in Table I. For the Evaluation of Correctional Services in General, the higher mean for the Prison (4.304) compared to Tarahm (3.722) suggests that, on average, respondents evaluate the services provided by the General Directorate of Prisons more favourably. There was no significant difference between the two groups .A paired-sample t-test revealed a t-statistic of 1.127, with df=45 ($p < .263$). The effect size was small, with a Cohen's d of 0.251.

Regarding the Evaluation of Practical Educational and Training Services, the Prison services (5.043) scored higher on average than Tarahm (4.083), indicating a preference for the educational and training services offered by the Prisons. There was no significant difference between the two groups .A paired-sample t-test revealed a t-statistic of 1.739, with df=45 ($p < .086$). The Cohen's d value of 0.387 suggests a small-to-medium effect size.

Prisoners' interest in Educational and Training Services shows similar results. The mean score for the Prison (4.696) is higher than for Tarahm (4.111), indicating that respondents are generally more interested in the educational and training services provided by the Prison. There was no significant difference between the two groups .A paired-sample t-test revealed a t-statistic of 1.041, with df=45 ($p < .301$). The Cohen's d value of 0.232 indicates a small effect size.

TABLE I. MEANS AND STANDARD DEVIATION FOR THE SERVICES PROVIDED BY THE PRISON AND TARAHM

| | Q1 | | Q2 | | Q3 | |
|---|---|---|---|---|---|---|
| | Prison | Tarahm | Prison | Tarahm | Prison | Tarahm |
| **Mean** | 4.304 | 3.722 | 5.043 | 4.083 | 4.696 | 4.111 |
| **SD** | 2.346 | 2.288 | 2.394 | 2.590 | 2.439 | 2.627 |

### B. Perceived Usefulness

Certainly, in the realm of Human-Computer Interaction (HCI), the perceived usefulness of a technology is a critical factor in its adoption and sustained usage [15]. Our study sought to assess the perceived usefulness of two prominent VR platforms, HTC Vive and Oculus, across three dimensions: general benefit (Using VR technology is good for me), efficiency and effectiveness (The use of VR technology makes me more efficient and effective), and ease of life (Using VR technology makes my life easier).

Employing a paired samples t-test, no statistically significant differences were found between the two platforms

for all three dimensions (p-values ranging from 0.816 to 0.897), as reported in Table II. The effect sizes, represented by Cohen's d, were negligible, ranging from 0.019 to 0.035, suggesting that any observed differences are not meaningful.

Participants consistently rated both platforms highly, with mean values ranging from 6.298 to 6.596 on a seven-point scale and standard deviations between 1.228 and 1.841. This suggests a strong and consistent perception among participants that both HTC Vive and Oculus are beneficial, efficient, and make life easier. Moreover, the uniformly high perception of usefulness across platforms provides strong empirical support for the integration of VR technologies in educational and training contexts.

TABLE II. PAIRED SAMPLE T-TEST FOR PERCEIVED USEFULNESS QUESTIONS

| Oculus | HTC Vive | t | df | p | Cohen's d | SE Cohen's d |
|---|---|---|---|---|---|---|
| Q1 | - Q1 | 0.130 | 45 | 0.897 | 0.019 | 0.219 |
| Q2 | - Q2 | 0.218 | 45 | 0.828 | 0.032 | 0.220 |
| Q3 | - Q3 | 0.234 | 45 | 0.816 | 0.035 | 0.213 |

### C. Perceived Ease of Use

In extending the investigation into the user experience of VR platforms, perceived ease of use was analyzed, a construct known to be highly correlated with technology adoption and sustained use in Human-Computer Interaction (HCI) research [15]. Three questions, in the form of a seven- point scale, assessed ease of use: 1) Using VR technology is easy, 2) Learning to use VR technology is easy, and 3) It's easy to use VR technology to complete tasks. A paired samples t-test revealed no statistically significant differences between the two platforms across these questions, with p-values ranging from 0.613 to 0.799. Furthermore, the effect sizes, as calculated by Cohen's d, were minimal and ranged from -0.051 to 0.075 as shown in Table III.

The means for all questions were exceedingly high (ranging from 6.596 to 6.761 on a seven-point scale) and exhibited low standard deviations (ranging from 0.705 to 1.258). This suggests not only a high perceived ease of use for both platforms but also a consistency in this perception among respondents.

TABLE III. PAIRED SAMPLE T-TEST FOR PERCEIVED EASE OF USE QUESTIONS

| Oculus | HTC Vive | t | df | p | Cohen's d | SE Cohen's d |
|---|---|---|---|---|---|---|
| Q1 | - Q1 | 0.256 | 45 | 0.799 | 0.038 | 0.201 |
| Q2 | - Q2 | 0.509 | 45 | 0.613 | 0.075 | 0.207 |
| Q3 | - Q3 | -0.345 | 45 | 0.732 | -0.051 | 0.214 |

### D. Perceived Enjoyment

The perceived enjoyment of technology is increasingly recognized as a key variable affecting its adoption and

sustained use, particularly within immersive platforms [17], [18]. This experiment aimed to explore the perceived enjoyment of HTC Vive and Oculus across four different dimensions, encompassing aspects of fun, enjoyment, impressiveness, and willingness to use VR technology for services and rehabilitation programs. The questions are as follows: 1) Using VR technology is fun, 2) Using VR technology is enjoyable, 3) Using VR technology is impressive, and 4) I am ready to use VR to benefit from the services program offered by the prison.

A paired samples t-test revealed that the perceived enjoyment does not significantly differ between the two platforms, ranging from 0.581 to 0.914. The effect sizes were marginal, with Cohen's d ranging from 0.016 to 0.082, indicating that any observed differences are practically insignificant, as shown in Table IV.

The mean scores for all the questions were remarkably high, ranging from 6.435 to 6.804 on a 7-point scale, with relatively low standard deviations (0.886 to 1.628). The consistency in these scores across dimensions and platforms suggests a high level of perceived enjoyment for VR technologies, regardless of the specific hardware.

TABLE IV. PAIRED SAMPLE T-TEST FOR PERCEIVED ENJOYMENT QUESTIONS

| Oculus | HTC Vive | t | df | p | Cohen's d | SE Cohen's d |
|---|---|---|---|---|---|---|
| Q1 | - Q1 | 0.139 | 45 | 0.890 | 0.020 | 0.218 |
| Q3 | - Q3 | 0.556 | 45 | 0.581 | 0.082 | 0.219 |
| Q4 | - Q4 | 0.187 | 45 | 0.853 | 0.028 | 0.219 |
| Q5 | - Q5 | 0.109 | 45 | 0.914 | 0.016 | 0.211 |

### E. Hardware Preference

Understanding users' preferences towards different VR headsets is pivotal in the HCI domain, particularly for tailoring experiences that are both engaging and comfortable [19], [20]. To this end, participants' preferences were evaluated based on four dimensions: comfort, presence, dizziness, and visual perception in the virtual world. Paired samples t-test indicated that there are no statistically significant differences in users' preferences between HTC Vive and Oculus for these dimensions, with p-values ranging from 0.587 to 0.916. This is corroborated by minimal effect sizes, where Cohen's d values varied between -0.081 and 0.069. See Table V for more details.

TABLE V. PAIRED SAMPLE T-TEST FOR PREFERENCE QUESTIONS

| Oculus | HTC Vive | t | df | p | Cohen's d | SE Cohen's d |
|---|---|---|---|---|---|---|
| Q1 | - Q1 | -0.548 | 45 | 0.587 | -0.081 | 0.222 |
| Q2 | - Q2 | 0.467 | 45 | 0.643 | 0.069 | 0.218 |
| Q3 | - Q3 | 0.106 | 45 | 0.916 | 0.016 | 0.226 |
| Q4 | - Q4 | -0.183 | 45 | 0.856 | -0.027 | 0.224 |

The descriptive statistics provided additional insights into the subjective experiences with the headsets. For instance, both

headsets scored high for comfort and presence (mean scores ranged from 6.213 to 6.426), suggesting that users generally felt comfortable and immersed while using VR. Interestingly, dizziness, a potential downside of VR experiences known as VR sickness [21], had a lower mean score (ranging from 3.298 to 3.596), which is a positive indication of the usability and acceptance of these platforms.

In sum, the data suggest that both HTC Vive and Oculus provide similarly positive experiences across multiple dimensions. As such, the choice between these two platforms may depend less on inherent qualities like comfort or immersion and more on other factors like cost, available software, or specific use cases, such as educational or therapeutic interventions.

### F. Comparison

Comparative analysis's most salient finding lies in the acceptance ratings, which represent a synthesis of perceived usefulness, ease of use, and enjoyment. The average acceptance rating for traditional services was 4.709 (SD = 2.148), significantly lower than the VR-based approach, with a mean rating of 6.601 (SD = 0.629). The paired samples t-test confirmed this difference as statistically significant (t = -5.516, df = 46, p < .001, Cohen's d = -0.805, SE = 0.259). Fig. 4 shows a graphical comparison between the two factors.

The stark disparity in ratings substantiates the compelling advantage of VR-based interventions over traditional methods in the context of correctional and rehabilitation services at the prison. the effect size is not just statistically significant but also practically meaningful.

Fig. 4. Boxplots of participants' average rating for traditional services compared to VR-based training.

### IV. DISCUSSION

The integration of VR into various sectors, including training and rehabilitation, is gaining traction as a transformative technology. This study sought to evaluate and compare traditional methods of training and education by the Prisons and Tarahm, with a VR-based approach. Users' experiences were evaluated, comparing two major VR platforms, HTC Vive and Oculus, across several dimensions: perceived usefulness, perceived ease of use, perceived enjoyment, and headset preference.

Findings revealed that traditional services provided by the General Directorate of Prisons scored slightly better on average than those offered by Tarahm, though not to a level of statistical significance. This could be attributed to various factors such as service quality, accessibility, or even inmate familiarity with the correctional service department.

On the front of VR, data paints an optimistic picture of the perceived usefulness, perceived ease of use, and perceived enjoyment of using VR technology, regardless of the platform. Across all these dimensions, the scores were statistically indistinguishable between HTC Vive and Oculus. Interestingly, the perceived enjoyment scores were particularly high, aligning with extant literature that posits enjoyment as a crucial factor for the adoption and sustained use of technology [17], [18].

Importantly, both VR platforms scored highly on comfort and presence while scoring lower on inducing dizziness, a common VR issue. These findings imply that modern VR headsets have improved to the point where comfort and dizziness are less of a concern, thus potentially boosting their viability in applications like training and rehabilitation services. The lack of significant differences between the two platforms suggests that choices could be made based on other criteria, such as cost or specific features, rather than user experience [19], [20].

The VR-based approach demonstrated a significantly higher acceptance average rating when compared to traditional services. These results echo the comparative analysis presented in the results section and provide compelling evidence for VR's potential to be more favourably received than traditional methods and a safer option to adopt for prisoners. Findings support the notion that VR-based training could be an alternative to traditional correctional services in some cases or scenarios, given the high levels of perceived usefulness, ease of use, and enjoyment. Second, the platform-agnostic nature of these experiences points to the greater importance of content and application design in achieving successful outcomes. Third, for decision-makers in correctional services, it serves as a compelling argument for investment in VR technologies. Furthermore, it presents a new avenue for HCI researchers focused on rehabilitation and correctional technology, underscoring the need for a design framework that leverages VR's strengths in delivering effective interventions. Limitations of this study include the focused task scenario and the limited number of platforms evaluated.

### V. CONCLUSION AND FUTURE WORKS

This study represents a comprehensive evaluation of the role of VR technologies, specifically HTC Vive and Oculus, in comparison to traditional educational and training methods provided by prison facilities and third-party institution (Tarahm). It was found that while traditional services had no statistically significant advantages over one another, both HTC Vive and Oculus demonstrated exceptional performance in perceived usefulness, ease of use, and enjoyment among users.

Significantly, when comparing VR-based training to traditional methods, the VR-based approach exhibited considerably higher levels of user acceptance. This finding not only supports the potential of VR as a viable alternative but also presents compelling empirical evidence for its integration into training and rehabilitation services. Given that there was little to no difference in the perceived quality of experience between HTC Vive and Oculus.

These results serve as a roadmap for decision-makers in correctional services contemplating investment in VR technologies. They also highlight the necessity for further research in this area, especially for understanding long-term outcomes and expanding the number of platforms evaluated.

This study opens new doors for HCI researchers, particularly those focusing on technology design in training and rehabilitative contexts. It underscores the imperative to establish a design framework that exploits VR's unique strengths, leading to more effective interventions in training and education settings.

Future research should expand on these variables and consider long-term impacts and outcomes. For example, future studies could evaluate learning outcomes and extend to other fields of study, such as therapy. One potential area to investigate is the use of VR to allow participants to live situations outside the prison wall, for instance, visiting family or walking on a beach. This would serve as an adaptation method for prisoners before they are released into society.

Dept. Plant Protection, IPB University, Bogor, Indonesia[5]

*Abstract*—Leaf diseases in melon plants cause losses for melon farmers. However, melon plants become less productive or even die. Downy mildew is a foliar disease that spreads rapidly in melon plants. Determining the level of downy mildew in melon leaves is important. Determining the level of downy mildew disease, farmers can carry out preventive treatment according to the severity level of downy mildew disease. This study aimed to create a classification model for the level of downy mildew disease on melon leaves using combined features and to compare the classification models, namely the LGBM, Random Forest, and XGBoost models. The combined features consist of colour, texture, Shannon entropy, and Canny edge features. The combined features are used as input for a classification model to predict the level of downy mildew leaf disease in melon plants. Model evaluation was carried out with three scenarios of data sharing: the first scenario, 90% training data and 10% test data; the second scenario, 80% training data and 20% test data; and the third scenario, 70% training data and 30% test data. The results of the evaluation of the model with the confusion matrix show that for the first and second scenarios, the highest accuracy was achieved by the Random Forest algorithm, with 72% and 73% accuracy, respectively. For the third scenario, the highest accuracy was obtained using the XGBoost algorithm.

*Keywords—Classification; Downy mildew; LGBM; disease level; melon leaves*

## I. INTRODUCTION

Melon is a fruit commodity with a high selling price, and many farmers cultivate it. Cultivating melons is difficult because there are many diseases associated with melon plants. Based on their causes, melon plant diseases are divided into three types: viruses, bacteria, and fungi [1]. One type of disease that infects the leaves is downy mildew. Downy mildew disease spreads very quickly, and if it is not controlled correctly, it can cause melon plants to die [2]. Determining the level of downy mildew disease on melon leaves is essential; this is done to determine the development of downy mildew disease that infects the leaves. In addition, by determining the level of downy mildew disease, farmers can carry out preventive treatments according to the level of development of downy mildew disease.

To overcome this problem, image processing (IP) and machine learning (ML) approaches can be used to classify the levels of downy mildew disease on melon leaves to help farmers treat downy mildew disease on melon leaves. IP and ML have been widely used to detect, identify, and classify leaf diseases [3]. This has been proven by many related scientific publications, including the classification of tomato leaf disease with public datasets using multiple feature extraction techniques, namely colour histograms, Hu Moments, Haralick and Local Binary Pattern features and classification models using Random Forest and decision tree classification; model evaluation results in decision tree classification with 90% accuracy and 94% Random Forest model [4]. Classification of banana leaf disease into four disease classes: healthy leaves, Sigatoka-infected leaves, Pestalotiopsis infected leaves, and Cordana-infected leaves using DenseNet and Inception. The result is that the model using the DenseNet method with an oversampling scheme is superior, with an accuracy of 84.73% [5]. Classification of grape leaf disease into two classes, namely healthy leaves and leaf spot (Cercospora), using Deep Forest, the evaluation results showed an accuracy of 96.25% [6]. Segmentation of cucumber leaf disease to detect cucumber leaf disease points using an improved saliency method and deep feature selection with an accuracy of 97.23% [7]. To detect and classify leaf diseases, feature extraction is required, and the feature extraction results are used as a dataset for classification [8]. In general, the feature extraction used by researchers is colour, texture, shape, and edge features [9]. The feature extraction results are then classified using a classification algorithm. Currently, many leaf disease classification algorithms have been developed, including SVM, Naive Bayes, Decision Tree, KNN, Random Forest, AdaBoost, Neural Network, Rule Base Classifier, Fuzzy Classifier [10] [11].

Classification of the severity of tea leaf blight using deep learning methods such as VGG16 deep networks is an interesting application in the fields of agriculture and pest management. In this case, the tea leaf blight was divided into two levels: mild and severe. The test results of the proposed model had an average accuracy of 84.5%, which was considered a good result [12]. To classify the severity of leaf diseases in tomato plants, deep learning using the ResNet architecture was used. This classification differentiates tomato leaves into three categories: healthy leaves, leaves affected by mild diseases, and leaves affected by severe diseases. The test

results of this model showed an average accuracy of 88.2% [13]. To classify the severity of bacterial leaf streak leaf disease in rice plants, deep learning with BLSNet architecture was used. This classification divides the severity of the disease into five levels: level 0, leaves with no lesions; level 1, lesions less than 10%; level 2: Lesions 11-25%, level 3: Lesions 26-45%, level 4: Lesions 46-65%, and level 5, lesions > 65%. The BLSNet model test results showed an average accuracy of 98.2% [14].

A melon leaf image dataset was collected from a farmer's garden under natural conditions. Furthermore, the dataset is extracted for colour features by calculating the average colour value, standard deviation, skewness, texture, Shannon entropy, Canny edge, and colour histogram. Extraction of GLCM texture features with distances of 1, 3, and 5 and angles of $0^0$, $45^0$, $90^0$, and $135^0$ to obtain homogeneity, entropy, energy, contrast, and correlation values. Shannon entropy feature extraction is a feature extraction method used to obtain the value of the information acquisition between classes. Edge feature extraction values were obtained using Canny Edge.

The results of feature extraction were then combined into combined features. The combined features are used as inputs for the LGBM, Random Forest and XGBoost classification models. The model was evaluated using a confusion matrix and a scenario of dividing the training data and test data into three scenarios: 90% training data and 10% test data, 80% training data and 20% test data, and 70% training data and 30% test data. A confusion matrix was used to determine the best model for predicting the level of downy mildew disease in melon leaves.

The purpose of this study was to create a classification model for the levels of downy mildew disease on melon leaves, namely healthy leaves (DS), downy mildew level 1 (DM1), downy mildew level 2 (DM2), and downy mildew level 3 (DM3), using a combination of texture, colour, entropy Shannon, and edge features. The second was to compare the classification models, namely, LGBM, Random Forest, and XGBoost.

## II. RESEARCH METHOD

A melon leaf image dataset was collected from a farmer's garden under natural conditions. Furthermore, the dataset is extracted for colour. This study has several stages; namely, data collection, pre-processing, feature extraction, classification, and evaluation of the model created using the confusion matrix (see Fig. 1).

### A. Data Acquistion

Melon was planted from 17 October 2022 to 20 December 2022. The planting site was in Sukatani village, Sukatani sub-district, Purwakarta district, West Java. Melon plants were planted with as many as 30 plants, and for each melon plant, a sample of five leaves was selected randomly and then marked to differentiate. After 26 days after planting (HST), pictures of melon leaves were taken every two days from 11 November 2022 to 15 December 2022. Using a smartphone camera, smartphone specifications are shown in Table I.

Fig. 1. Research stages.

TABLE I. SMARTPHONE SPECIFICATIONS

| No | Name | Description |
|---|---|---|
| 1 | Smartphone | Infinix Note 11 NFC |
| 2 | Camera resolution | 50 MP, f/1.6, (wide), PDAF, 2 MP, f/2.4, (depth) |
| 3 | Operating system | Android 11 |

When photographing melon leaves, it is necessary to consider technical factors. The technical factors considered are listed in Table II.

TABLE II. PHOTOGRAPHING TECHNIQUE

| No | Parameter (variabel konfirmasi) | Description |
|---|---|---|
| 1 | Shooting frequency | Once every two days |
| 2 | The distance between the leaf object and the camera | 20 cm and 30 cm centred on the leaf object, and the leaf object does not exceed the camera frame |
| 3 | Angle position between camera and object (leaf) | Centered on the leaf object |
| 4 | Position between camera frame and object (leaf) | The leaf object is centred and does not exceed the smartphone camera frame. |

### B. Melon Leaf Image Dataset

The melon leaf data collected for a total of 1861 images were then labelled with the grading of melon leaf downy mildew disease. The labelling process involves a plant protection lab to determine the grading of downy mildew. The labelling process included healthy leaf labels (DS), downy mildew level 1 (DM1), downy mildew level 2 (DM2), and downy mildew level 3 (DM3). Table III shows the number of images from the DS, DM1, DM2, and DM3.

TABLE III.     DETAILS THE AMOUNT OF DATA

| No | Level of disease severity | Amount of data |
|---|---|---|
| 1 | Healthy Leaves (DS) | 665 images |
| 2 | Downy Mildew level 1 (DM1) | 449 images |
| 3 | Downy Mildew level 2 (DM2) | 253 images |
| 4 | Downy Mildew level 3 (DM3) | 494 images |
| Total amount of data | | 1861 images |

Labelled downy mildew level 1 begins to show signs of disease until it spreads 20% on leaves, labelled downy mildew level 2, downy mildew disease begins to spread 20% - 30% on leaves, and downy mildew level 3 on melon leaves is more than 30% level of leaf disease. Fig. 2 shows (a) DS, (b) DM1, (c) DM2, and (d) DM3.

(a)                                        (b)

(c)                                        (d)
Fig. 2.   Examples of melon leaves (a) DS, (b) DM1, (c) DM2, and (d) DM3.

### C. Preprocess

Melon leaf image data were then preprocessed. The preprocessing involved cutting the image data and changing the size of the image data. Cutting the melon leaf image data aims to remove unwanted objects so that only melon leaf objects are produced. After cutting, the size was changed from the initial size of 2087 pixels × 2087 pixels to 128 pixels × 128 pixels. Changing the image data size aims to accelerate the computational process when performing feature extraction. Subsequent preprocessing changes the colour from RGB to grayscale.

### D. Colour, Texture, and Edge Feature Extraction Melon Leaf Image Database

After preprocessing, the feature extraction process was performed. Feature extraction is performed to obtain the value from the image. In this study, the feature extraction included colour, texture, and shape features. Feature extraction obtains the average colour value in Eq. (1), standard deviation in Eq. (2), and skewness in Eq. (3) [15].

$$\text{Mean} = \frac{1}{M \, X \, N}\sum_{X=1}^{M}\sum_{y=1}^{n}M_{xy} \qquad (1)$$

$$SD = \sqrt{\frac{1}{M \, X \, N}\sum_{x=1}^{M}\sum_{y=1}^{N}\left(M_{xy} - m\right)^2} \qquad (2)$$

$$Skewness = \frac{\sum_{x=1}^{M}\sum_{y=1}^{N}\left(M_{xy} - m\right)^3}{(M \, x \, N) \, x \, SD^3} \qquad (3)$$

The extracted colour feature values are blue mean, green average, red average, blue standard deviation, green standard deviation, red standard deviation, blue kurtosis, green kurtosis, red kurtosis, blue skewness, green skewness, and red skewness.

The subsequent colour feature extraction is a histogram obtained by extracting the histogram values using Eq. (4) [16].

$$h(r_k) = n_k \qquad (4)$$

where is $n_k$ the number of pixels with intensity level.

Texture feature extraction was carried out to obtain the distance and angle values by taking energy in Eq. (5), correlation values in Eq. (6), contrast in Eq. (7), entropy in Eq. (8), and homogeneity in Eq. (9) [4].

$$Energy = \sum_{i,j}(p(i,j))^2 \quad (5)$$

$$Correlation = \frac{\sum_i \sum_j (ij)P\,(i,j) - \mu_x\mu_y}{\sigma_x\sigma_y} \quad (6)$$

$$Cont = \sum_{n=0}^{N_g-1} N^2 \left\{\sum_{i=1}^{N_g}\sum_{j=1}^{N_g} P(i,j)\right\}, |i - j| = n \quad (2)$$

$$Entropy = -\sum_i \sum_j P(i,j)log\big(P(i,j)\big) \quad (8)$$

$$Homogeneity = \sum_{i,j}\frac{p(i,j)}{1+|i-j|} \quad (9)$$

The extracted GLCM feature values with variations of distance 1, 3, 5 and angles $0^0$, $45^0$, $90^0$, $135^0$.

The extracted edge feature value is Canny. The canny edge feature removes noise by using a Gaussian filter with the following Eq. (10) [17].

$$G(x.y) = \frac{1}{2\pi\sigma^2}exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right) \qquad (10)$$

where $y$ is the distance from the origin on the vertical axis, $x$ is the distance from the origin on the horizontal axis, and σ is the standard deviation of the Gaussian distribution.

The next step is calculating the image gradient by calculating the gradient magnitude ($G$) and angle gradient ($\theta$) with the Eq. (11) and Eq. (12).

$$G = \sqrt{\left(G_x^2 + G_y^2\right)} \qquad (11)$$

$$\theta = tan\left(\frac{G_y}{G_x}\right) \qquad (12)$$

$G_x$ represents the horizontal and $G_y$ vertical gradients, respectively.

Shannon stated that the measure of the amount of information $H(p)$ contained in a series of events $p_1 \dots p_n$ must meet three conditions, namely, $H$ must be continuous in $p_i$, secondly if all $p_i$ have the same probability, so $p_i = \frac{1}{N}$, then $H$ should be a monotonic rising function of $N$, and $H$ must be additive [18]. Eq. (13) extracts Shannon entropy features.

$$H(p) = -k \sum_{i=1}^{N} p_i ln p_i \quad (13)$$

## E. Combined Feature Dataset

The results of colour, texture, edge, and entropy feature extraction were in the form of colour, texture, edge, and entropy feature datasets. DFColour denotes the colour feature dataset, DFTexture denotes the texture feature dataset, DFEdge denotes the edge feature dataset, and DFEntropy denotes the entropy feature dataset. Then, the combined feature dataset can be formulated using Eq. (14).

$$DFCombined = DFColour \cup DFTekstur \cup DFEdge \cup DFEntropy \quad (3)$$

where DFCombined is the combined feature dataset. The total DFCombined has as many as 838 features.

## F. Train Data, and Test Data

The DFCombined feature divides the data, namely, training data and test data. The scenarios for dividing the training and test data are shown in Table IV.

TABLE IV. DATA DIVIDING SCENARIO

| Scenario | Training Data % | Test Data % |
|---|---|---|
| 1 | 90 | 10 |
| 2 | 80 | 20 |
| 3 | 70 | 30 |

## G. LGBM Random Forest, XGBoost

Furthermore, the combined DF dataset will be classified for grading downy mildew using three classification models, namely LGBM, Random Forest and XGBoost, according to the scenario of dividing the training data and test data. The results will be compared based on the accuracy values of the three models.

## H. Evaluation of the Confusion Matrix Model

It is necessary to develop an evaluation model to measure the performance of the LGBM algorithm. The confusion matrix measures the performance of a classification algorithm by creating a detailed table of the amount of data that is classified correctly or incorrectly. The confusion matrix measures the accuracy, precision, recall, and F1 score [19]. The accuracy value is obtained from the amount of positive data predicted to be positive and the amount of harmful data predicted to be negative divided by the total amount of data, as shown in Eq. (15). The precision value is obtained from the number of opportunities for positive predictive data and the reality of the positive data, as shown in Eq. (16). The recall value is obtained from the number of positive data opportunities, and the prediction results are positive, as shown in Eq. (17). The F1 score was obtained from the recall and precision between the predicted and actual data as shown in Eq. (18).

$$Accuray = \frac{TP+TN}{TP+FP+FN+TN} \quad (15)$$

$$Precision = \frac{TP}{TP+FP} \quad (16)$$

$$Recall = \frac{TP}{TP+FN} \quad (17)$$

$$F1 = \frac{2 \; x \; Recall \; x \; Precision}{Recall+Precision} \quad (18)$$

Where TP = True Positive, FP = False Negative, TN = True Negative, FN = False Negative F1 = F-Measure.

## III. RESULTS AND DISCUSSIONS

The melon leaf disease image dataset consisted of healthy leaves (DS), downy mildew grade 1 (DM1), downy mildew grade 2 (DM2), and downy mildew grade 3 (DM3), which were divided into four classes: DS, DM1, DM2, and DM3.

## A. Preprocess

Melon leaf image data were preprocessed. Pre-processing involved cutting the image data and changing the size of the image data. Cutting the melon leaf image data aims to remove unwanted objects such that only melon leaf objects are produced. The original and cropped images are shown in Fig. 3(a) original image and Fig. 3(b).

(a) Original image      (b) Cropping image

Fig. 3. (a) Original image and (b) Cropping image.

After cutting, the size was changed from the initial size of 2087 pixels × 2087 pixels to 128 pixels × 128 pixels. Changing the image data size aims to speed up the computational process when performing feature extraction, and the subsequent preprocessing changes the colour from RGB to grayscale, as shown in Fig. 4(a) and Fig. 4(b).

(a) RGB image      (b) Grayscale image

Fig. 4. Image conversion (a) RGB color (b) grayscale.

## B. Feature Extraction

Colour feature extraction was performed to obtain the colour feature values. The extracted colour feature values are the average red, green, and blue colour values. Column Sample leaf number is sample of leaf, column meanR is the average value of red, Column meanG is the average value of green, and Column meanB is the average value of blue see Table V.

TABLE V. THE AVERAGE VALUE OF THE COLOURS R, G, AND B

| Sample leaf number | meanR | meanG | meanB |
|---|---|---|---|
| 1 | 130.8272 | 131.0041 | 130.8621 |
| 2 | 130.806 | 130.9863 | 130.8507 |
| 3 | 130.8316 | 131.0139 | 130.8828 |

Variants of colour features were extracted from red, green, and blue variances. Column Sample leaf number is sample of leaf, column VarianceR is the red variation value, column VarianceG is the green colour variation value, and column VarianceB is the green colour variation value (see Table VI).

TABLE VI.    VARIANCE VALUES R, G, AND B

| Sample leaf number | varianceR | varianceG | varianceB |
|---|---|---|---|
| 1 | 3373.02 | 3491.309 | 3611.722 |
| 2 | 3371.538 | 3489.867 | 3610.48 |
| 3 | 3371.666 | 3489.709 | 3610.031 |

Skewness values were extracted to obtain the red, green, and blue skewness values. Column Sample leaf number is sample of leaf, column SkewnessR is the red skewness value, column SkewnessG is the green skewness value, and column SkewnessB is the blue skewness value (see Table VII).

TABLE VII.    SKEWNESS VALUES R, G, AND B

| Sample leaf number | skewnessR | skewnessG | skewnessB |
|---|---|---|---|
| 1 | -0.06524 | -0.05881 | -0.04562 |
| 2 | -0.06546 | -0.05898 | -0.04581 |
| 3 | -0.06603 | -0.05949 | -0.04637 |

The results of the colour feature extraction obtained the feature values of the nine features.

Subsequent colour feature extraction uses a histogram. A histogram was used to determine the distribution of colours in the image. The histogram feature value was obtained by calculating the histogram value of each pixel in the image. The histogram feature extraction resulted in 512 histogram features.

The subsequent feature extraction is a texture feature using GLCM. The values extracted from the GLCM texture features were the energy, correlation, dissimilarity, homogeneity, and contrast. Variation in GLCM values at distances of 1, 3, 5 and angle variations, namely $0^0$, $45^0$, $90^0$, $135^0$. The following iteration 1 is used:

---
**Iteration 1**

```
distances = [1, 3, 5]
angles = [0, np.pi/4, np.pi/2, 3*np.pi/4]
        for d in distances:
            for a in angles:
                GLCM = graycomatrix(img, [d], [a])
                GLCM_Energy = graycoprops(GLCM,
                'energy')[0]
                df[f'Energy_d{d}_a{a}'] = GLCM_Energy
                GLCM_corr = graycoprops(GLCM,
                'correlation')[0]
                df[f'Corr_d{d}_a{a}'] = GLCM_corr
                GLCM_diss = graycoprops(GLCM,
                'dissimilarity')[0]
                df[f'Diss_sim_d{d}_a{a}'] = GLCM_diss
                GLCM_hom = graycoprops(GLCM,
                'homogeneity')[0]
                df[f'Homogen_d{d}_a{a}'] = GLCM_hom
                GLCM_contr = graycoprops(GLCM, contrast')[0]
                df[f'Contrast_d{d}_a{a}'] = GLCM_contr
```

Thus, the distance and angle texture features formed 60 texture features. Table VIII shows an example of the feature extraction results for a distance of 1 and an angle of $0^0$. Column Sample leaf number is sample of leaf, column Energy_d1_$0^0$ is the energy value, column Corr_d1_$0^0$ is the coorelation value, column Diss_sim_d1_$0^0$ is the dissimiliarity value, column Homogen_d1_$0^0$ is the homogeinity value, column Contrast_d1_$0^0$ is the contrast value.

TABLE VIII.    TEXTURE VALUE EXTRACTION

| Sample leaf Number | Energy_d1_$0^0$ | Corr_d1_$0^0$ | Diss_sim_d1_$0^0$ | Homogen_d1_$0^0$ | Contrast_d1_$0^0$ |
|---|---|---|---|---|---|
| 1 | 0.01236 | 0.85204 | 17.16683 | 0.08106 | 659.80450 |
| 2 | 0.01156 | 0.76719 | 22.35888 | 0.06753 | 1088.4191 |
| 3 | 0.01532 | 0.76395 | 15.14720 | 0.08373 | 504.07068 |

The entropy feature is used to make it easier to deal with uncertainty in classifying diseases into DS, DM1, DM2, and DM3 classes, so that the presence of entropy can increase the value of information between classes in the classification so that it can improve prediction results by measuring the highest information gain. The following is an example of the entropy shanon feature value. Column Sample leaf number is sample of leaf, column Entropy is the entropy value which is shown in Table IX.

TABLE IX.    EXTRACTION OF ENTROPY VALUES

| Sample leaf Number | Entropy |
|---|---|
| 1 | 7.542966 |
| 2 | 7.573822 |
| 3 | 7.020211 |

Edge feature extraction is used to determine points that experience a drastic change in brightness, typically in a line or curve, known as an edge. The edge feature values can be extracted using the Canny edge method [20]. The Canny edge feature extraction results are in the form of 256 features.

### C. The Combined Features

The extraction results of colour, texture, entropy, and Canny features yielded 521 colour features, 60 texture features, one entropy feature, and 256 Canny edge features. Then, these features are combined so that the total number of features extracted from feature extraction is 838.

### D. The Scenario of Dataset Division

After the combined features were obtained, they were used as datasets. The combined feature dataset was divided into training and test data for modelling. The scenario of dividing the dataset into training and test data was performed using three comparison scenarios for further details (see Table X).

TABLE X.        THREE SCENARIOS FOR DIVIDING DATA

| No | Level of disease severity | Total Data | Scenario 1 | | Scenario 2 | | Scenario 3 | |
|----|---------------------------|------------|-----|-----|-----|-----|-----|-----|
| | | | 90% | 10% | 80% | 20% | 70% | 30% |
| 1 | DS | 665 | 598 | 67 | 532 | 133 | 465 | 200 |
| 2 | DM1 | 449 | 404 | 45 | 359 | 90 | 314 | 135 |
| 3 | DM2 | 253 | 227 | 26 | 202 | 51 | 177 | 76 |
| 4 | DM3 | 494 | 444 | 50 | 404 | 99 | 345 | 149 |

*E. LGBM, Random Forest, and XGBoost Models*

*1) Scenario 1*: The dataset was divided into training and test data at a ratio of 90% training data and 10% test data. The classification results for LGBM, Random Forest, and XGBoost are shown in Fig. 5.

Fig. 5.    Accuracy with 90% training data and 10% test data.

The results of the accuracy test for the classification of downy mildew with classes DS, DM1, DM2, and DM3, with a comparison of 90% training data and 10% test data, showed that the accuracy performance of the LGBM model was 60%, Random Forest was 72%, and XGBoost was 67%. The best accuracy performance of 72% was obtained by the Random Forest model.

*2) Scenario 2*: The dataset was divided into training and test data at a ratio of 80% training data and 20% test data. The classification results for LGBM, Random Forest, and XGBoost are shown in Fig. 6.

Fig. 6.    Accuracy with 80% training data and 20% test data.

The results of the accuracy test for the classification of downy mildew with classes DS, DM1, DM2, and DM3, with a comparison of 80% training data and 20% test data, showed that the accuracy of the LGBM model was 63%, Random

Forest 73%, and XGBoost 71%. The best accuracy performance of 73% was obtained by the Random Forest model.

*3) Scenario 3*: The dataset was divided into training and test data in a ratio of 70% training data and 30% test data. The classification results for LGBM, Random Forest, and XGBoost are shown in Fig. 7.

Fig. 7.    Accuracy with 70% training data and 30% test data.

The results of the accuracy test for the classification of downy mildew disease with classes DS, DM1, DM2, and DM3, with a comparison of 70% training data and 30% test data, showed that the performance accuracy of the LGBM model was 85%, Random Forest was 82%, and XGBoost was 86%.

## IV. DISCUSSION

The classification of melon leaf disease is divided into four classes, namely DS, DM1, DM2, and DM3, with feature extraction that uses colour, texture, Shannon entropy, and canny edge features. The results of feature extraction are in the form of combined features, with a total of 838 features. The combined features were then modelled using the LGBM, Random Forest, and XGBoost. Results of evaluating the confusion metrics with a comparison of training and test data scenarios, namely scenarios 1, 2, and 3. The results of testing the first scenario showed that the best accuracy performance model obtained by Random Forest was 72%. The results of testing scenario 2 with the best accuracy performance were obtained by Random Forest, that is, 73%. The results of testing scenario 3 showed that the best accuracy performance of 86% was obtained by the XGBoost model. The best average accuracy for testing the Random Forest, LGBM, and The use of more test data can be seen in scenarios 1, 2, and 3, and the accuracy performance of the Random Forest, LGBM and XGBoost models increased. The combined features of 838 features caused when the model was executed, the running process took a long time, and the accuracy of the model performance was at most 90%. While there were 838 combined features, there were still redundant and irrelevant features. The problem of redundant and irrelevant features requires further investigation.

## V. CONCLUSION

Melon leaf disease, namely downy mildew, spreads very quickly; therefore, if it is not controlled properly, it can cause melon plants to die. Determining the level of downy mildew disease on melon leaves is important; this is done to determine the development of downy mildew disease that infects the leaves. One method to determine the level of downy mildew disease is to use a melon leaf disease classification model. The aim of this study was to create a classification model for downy mildew disease levels in melon leaves, namely DS, downy DM1, DM2, and DM3, using combined features, namely texture, colour, Shannon entropy, and edge features. The results of the extraction of colour, texture, entropy, and canny features resulted in 521 colour features, 60 texture features, 1 entropy feature, and 256 canny edge features; thus, the total number of combined features was 838 features. The model was evaluated using a confusion matrix, and a scenario was created by dividing the training data and test data into scenarios 1, 2, and 3. The results of accuracy testing for the classification of downy mildew disease with classes DS, DM1, DM2, and DM3 in scenario 1 showed that the accuracy performance of the LGBM model was 60%, Random Forest was 72%, and XGBoost was 67%. Accuracy comparison with scenario 2 and testing was carried out, with the accuracy performance results of the LGBM model being 63%, Random Forest 73%, and XGBoost 71%. Accuracy comparison with Secanrio 3 and model testing was carried out with the results of LGBM model accuracy performance testing of 85%, Random Forest 82%, and XGBoost 86%. Based on testing with scenarios 1, 2, and 3, the best average accuracy of testing the Random Forest, LGBM, and tested more data than in scenarios 1 and 2. The use of more test data can be observed in scenarios 1, 2, and 3, and the accuracy performance of the Random Forest, LGBM and XGBoost models increased.

*Abstract*—**Effective posture identification in smart home applications is a challenging topic for people to tackle in order to decrease the occurrence of improper postures. Vision-based posture identification has been used to construct a system for identifying people's postures. However, the system complexity, low accuracy rate, and slow identification speed of existing vision-based systems make them unsuitable for smart home applications. The goal of this project is to address these issues by creating a vision-based posture recognition system that can recognize human position and be used in smart home applications. The suggested method involves training and testing a You Only Look Once (YOLO) network to identify the postures. This Yolo-based approach is based on YOLOv5, which provides a high accuracy rate and satisfied speed in posture detection. Experimental results show the effectiveness of the developed system for posture recognition on smart home applications.**

*Keywords*—*Posture identification; smart home applications; vision-based recognition; YOLO network; accuracy*

## I. INTRODUCTION

Recognition of human body position has been extensively utilized in the fields of detection and rescue, intelligent monitoring, and other areas of computer vision as one of the most significant research paths. Its major objective is to study different human body areas, extract posture information, and eventually recognize human body position using computer vision technology [1].

Healthcare concerns are suddenly becoming more and more crucial as the number of senior individuals worldwide rises. Human motion capture technologies are necessary for older adults who live alone in order to address these problems. Seniors' health may also be tracked by observing their posture, and if high-risk postures, such as falling over, are noticed, a warning can be sent. These solutions will ease the strain on human resources while enhancing posture recognition effectiveness [2]. However, due to variables such as shifting viewing angles, human body occlusion, and appearance variations, determining the human posture with accuracy is a highly difficult process [1, 3].

In recent years, there has been remarkable progress in image processing, thanks to the advancements in deep learning, particularly convolutional neural networks (CNN). These networks draw inspiration from the hierarchical processing observed in the human visual cortex. By employing CNN, the process of feature extraction and classification has been revolutionized, as it allows the network to discern crucial features from the provided training data automatically. As a result, CNN has demonstrated remarkable success in accurate image processing [4]. A multi-layer neural network called CNN is mostly employed to scale and recognize displacement in two-dimensional visuals. The convolutional neural network's layers each represent a change. Common methods include convention and pooling transformation. Each transformation expresses different features from the input features as well processes the input data in a specific way. Each layer is made up of several two-dimensional planes containing the feature map that each layer has processed [5]. Each output characteristic is also an input feature; however, the value's computation process is the same. It is compatible with the generic neural network since it is the dot product of the weight and the input before the bias is imposed.

Within the realm of posture detection algorithms based on CNN, two primary types can be identified. The first category consists of two-stage detection algorithms, which involve a two-step process: locating the target and then recognizing it. Among these, the Region-Convolutional Neural Network (R-CNN) is a well-known traditional technique. However, it has shown poor performance and fails to meet real-time processing demands [6]. To address this limitation, subsequent advancements were made, giving rise to the Fast regions with CNN (Fast R-CNN) and faster regions with CNN (Faster R-CNN). Despite these improvements, they still do not fully satisfy real-time expectations [6]. The second category involves a one-stage detection technique, streamlining target localization and identification into a single action. Within this approach, examples like the single shot multi-box detector (SSD) series and the you only look once (YOLO) series are commonly cited as traditional instances of this methodology [7]. These methods have been developed to achieve faster and more efficient posture detection compared to the two-stage approaches.

The YOLO is regarded as one of the most effective and least time-consuming posture identification techniques. The YOLO model is used in several applications, including recognizing pedestrians and cars in traffic situations, monitoring livestock, aerial analysis, and even helping the visually handicapped identify faces. YOLO is an accurate posture detection method that combines a grid methodology

with the CNN architecture [8]. The YOLOv5 algorithm has been proposed as a modification of the YOLO algorithm version. On the basis of greater precision and a smaller model, YOLOv5's detection speed has significantly increased when compared to YOLOv3. The YOLOv5 technique has not yet found widespread application in the field of fall detection. Thus, this paper will enhance the model based on YOLOv5 research and apply it to the detection of senior fall behavior. The four network models of the target detection network based on YOLOv5 are YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. The three models of YOLOv5m, YOLOv5l, and YOLOv5x are the results of continual deepening and broadening based on YOLOv5s, which have the least depth and the smallest feature map width among them [7]. The YOLOv5 network is divided into the following four sections: the neck, the backbone, and the prediction.

The research contributions of this study are listed as follows:

*1)* The research contributes to the field of smart home applications by addressing the challenges of effective posture identification. It proposes a vision-based posture recognition system that overcomes the limitations of existing systems, such as complexity, low accuracy, and slow identification speed, thus making it suitable for integration into smart homes.

*2)* The study introduces a novel approach to posture recognition by leveraging the You Only Look Once (YOLO) network, specifically YOLOv5, which significantly improves accuracy and detection speed. This innovation enhances the viability of posture recognition systems for real-time monitoring and intervention in smart home environments.

*3)* Experimental results confirm the effectiveness of the developed YOLO-based posture recognition system in smart home applications. This research contribution showcases the practical applicability of the proposed method for reducing improper postures and enhancing the overall well-being of smart home residents.

The paper is organized as follows: Section II provides an introduction to the background of the study, offering essential context to the reader. In Section III, a comprehensive explanation of the methodology is presented, covering both the training and testing processes involved in human posture detection using the YOLO 5 network. Section IV delves into a detailed discussion and analysis of the obtained results, shedding light on the outcomes of the experiments and their implications. Finally, in Section V, the paper concludes with a summary of the findings and potential future directions for further research in this domain.

## II. RELATED WORKS

In study [9], a technique for skeleton-based online HAR employing ST-GCN with a sliding window and majority voting approach using convolutional neural networks (STGCN-SWMV) has been developed in order to address the issue of online HAR for continuous flow skeleton data. Two online skeleton-based datasets called OAD and UOW have been used to assess this approach. By automatically learning geographical and temporal information, this method offers greater prediction power and generalizability. The goal of this work is to increase online recognition performance, and it is suggested that in order to do this, textual information about item appearance or human interaction may be integrated to provide more learning characteristics.

A deep convolutional neural network has been proposed as a method for recognizing human action from depth maps and posture data. To maximize feature extraction, three convolutional neural network channels and two action representations are combined. The trials demonstrate that employing three channels instead of one or using two channels alone produces superior outcomes. In order to classify human activities using one or two CNN channels at most for quick computations, the challenge of this work is to reduce the number of CNN channels [4].

To address these problems, the study in [10] demonstrates the Trajectory-weighted Deep Convolutional Rank-Pooling Descriptor (TDRD) for fall detection, which is resilient to surrounding settings and can successfully represent the dynamics of human motions in extended films. The SDUF all dataset had better results with TDRD, and the UR dataset and multi-camera datasets with SVM classifiers saw equivalent performance. The problem with the TDRD algorithm is that although it excels at detecting single falls, it struggles to do so in scenarios involving many people. Additionally, TDRD is a problem with characterizing prolonged static postures.

The author in [11] presented an innovative approach to human fall detection, leveraging the Fast Pose Estimation technique. The proposed method involves classifying data extracted from image frames using two models: Time-Distributed Convolutional Neural Network Long Short-Term Memory (TD-CNN-LSTM) and 1-Dimensional Convolutional Neural Network (1D-CNN). The results demonstrate impressive accuracy, making this technique a valuable addition to the realm of reliable human fall detection. One notable advantage of this approach is its suitability for implementation on edge devices, thanks to its low computational and memory requirements. This is achieved by integrating the previously untapped potential of the Fast Pose Estimation method, which had not been utilized for this specific purpose before. With its efficient utilization of resources and strong performance, the suggested technique holds significant promise in enhancing human fall detection systems.

The paper in [17] presented an approach to human fall detection in smart home environments by utilizing YOLO (You Only Look Once) networks. The research aims to enhance the safety and care provided in smart homes by addressing the critical issue of detecting human falls. The YOLO-based approach, specifically YOLOv5, is proposed as an efficient and accurate method for real-time fall detection. The paper discusses the development and implementation of this system, emphasizing its potential to improve the quality of care and response within smart home setups, thereby contributing to the broader field of healthcare and assisted living technology.

The paper in [18] developed a method for analyzing and deducing errors in human posture to mitigate musculoskeletal disorders among construction workers. The study employs

vision-based techniques to monitor and assess the postures of construction workers, aiming to identify and rectify potentially harmful positions. The findings suggest that this approach effectively reduces the risk of musculoskeletal disorders in the construction industry by providing real-time feedback and guidance on proper posture. However, a limitation of the study is not extensively discussing the practical implementation challenges and feasibility of the proposed vision-based system in real-world construction settings, which may require further investigation and adaptation.

The paper in [19] provided a comprehensive overview of the current state of research in vision-based indoor Human Activity Recognition. The review delves into the latest advancements in this field, highlighting the diverse applications and methodologies employed for recognizing human activities indoors using computer vision techniques. It discusses the challenges encountered, such as occlusions, variability in lighting conditions, and the need for large annotated datasets, which affect the accuracy and robustness of existing systems. The paper also presents future prospects, emphasizing the potential of deep learning models like Convolutional Neural Networks (CNNs) and recurrent networks to improve HAR accuracy, as well as the integration of multimodal sensor data to enhance performance. Overall, this review offers valuable insights into the current landscape of vision-based indoor HAR, pinpointing areas where further research and innovation are required to overcome existing challenges and unlock its full potential in various applications.

## III. METHODOLOGY

YOLO was developed as a pretrained posture detector that can identify common items, including tables, chairs, automobiles, phones, and more. To develop a model capable of detecting human postures, such as those associated with walking, sitting, and falling. A detection technique based on YOLOv5 is what we suggest. Additionally, real-time is needed to detect and track the target [12]; therefore, our model performs well when used in real-time.

### A. Dataset

For dataset preparation, images were collected from various sources, including Internet's webpages, and the Kaggle dataset [13], and created a custom posture dataset. This dataset involves images with three human posture classes: walking, sitting, and falling. The images directory contains two subdirectories (374 images) used for training and Val (111 images) for validation. The Labels directory contains two subdirectories, train and Val, and here in this directory, we have text files with labels for that particular image. Fig. 1 shows some examples of our dataset.

To enhance the performance of our model, we expanded the dataset from 374 images to 1092 images through augmentation using Roboflow. For each original image, up to five augmented versions were generated. These augmentations were applied randomly, involving rotations with hue variations ranging from -50° to +50°, adjustments in brightness within -40% to +40%, exposure changes between -35% to +35%, blurring up to 1 pixel, and the introduction of noise up to 5%-pixel value. Regarding the validation dataset, it consists of three distinct sets. The primary dataset remains unchanged, while the other two sets were obtained by applying different preprocessing techniques and augmentations.

In one of the preprocessing suites, the images were resized to 416x640, followed by automatic contrast adjustment using adaptive equalization, grayscale conversion, and incremental adjustments in brightness (between -40% and +40%) and exposure (between -21% and +21%). In another preprocessing set, the images were resized to 640x480, followed by automatic contrast adjustment using adaptive equalization. Additionally, brightness adjustments (between -40% and +40%), exposure alterations (between -21% and +21%), and 90° rotations (both clockwise and counterclockwise) were applied. For illustrative purposes, Fig. 2 showcases some examples of the augmented images resulting from these transformations.

Fig. 1.    Sample images from the dataset.

Fig. 2.    Sample images of augmented images.

### B. Google Colab

To conduct our experiments, we took advantage of the resourceful GPUs available through Google Colab, which offers free access to this powerful computing technology. Specifically, we utilized a 12GB NVIDIA Tesla T4 GPU for all our training and testing tasks. During the training phase, our model underwent 20 epochs, with a batch size 16, and the images were resized to a dimension of 640. Additionally, we maintained YOLOv5s's default settings for other hyperparameters to ensure consistency and fair comparison. For optimization purposes, we employed the Stochastic Gradient Descent (SGD) optimizer, setting the learning rate (lr) to 0.001, which further contributed to the effectiveness of our model during training.

### C. Training and Testing

When embarking on the training of a posture detector, a highly effective strategy involves commencing with a pre-existing model that has been trained on extensive datasets. In this approach, the weights of this existing model are utilized as a starting point for training, even if the model's pre-trained weights do not directly encompass the specific postures required for the current experiment. This technique is commonly referred to as transfer learning. To expedite the learning process and enable faster convergence, we opted to utilize a pretrained model that incorporates weights previously trained on the COCO dataset. By leveraging this pretrained model as a starting point, our network can grasp and adapt to the novel posture detection task more swiftly and efficiently.

In this study, our total dataset consists of 1425 images, 70% of which are used for training, 20% for validation, and 10% for testing. 70% of training includes 1092 images, 20% of validation includes 333 images, and the rest of the images are considered for testing.

## IV.    RESULTS AND ANALYSIS

In this section, we introduce the experiment's details, and then we show the training results using pretraining weights and compare the three models of YOLOv5. Then we validated the model on 333 photos. The experimental results adopt the average precision mean mAP and the number of frames per second (FPS). Correspondingly, for each category of postures, we calculated the Precision rate and Recall rate [2]. The results are shown in Fig. 3.

### A. Performance Analysis

This section presents the performance analysis of Yolo models. The analysis justifies the usage of the Yolo algorithm and the specified version as YOLOv5. To perform this analysis, a comparison of Yolo models is presented.

When comparing different versions of YOLO models, accuracy and speed are two key metrics to consider. Accuracy refers to how well the model can detect and classify posture correctly. A more accurate model will have higher precision and recall in identifying postures in an image. Speed, on the other hand, relates to the inference time required for the model to process an image and provide the output. Faster models are desirable for real-time applications where quick posture detection is essential. Fig. 4 shows the comparing different versions of YOLO models on accuracy and speed [14].

As shown in Fig. 5, it's important to strike a balance between accuracy and speed, as a highly accurate model might sacrifice speed, while a faster model might compromise accuracy. Thus, when evaluating YOLO models, it is crucial to assess their performance based on accuracy and speed to choose the most suitable option for the intended use case. When comparing YOLO models based on accuracy and speed metrics, YOLOv5 stands out as a superior choice. YOLOv5 showcases significant improvements in both accuracy and speed compared to its predecessors, YOLOv3 and YOLOv4. Through optimized architecture and advanced training

strategies, YOLOv5 achieves better accuracy by accurately detecting and classifying postures in various scenes.

Additionally, YOLOv5 introduces model scaling options, allowing customization for specific requirements and striking a balance between accuracy and speed based on the task. Furthermore, its efficient inference techniques and streamlined design lead to faster processing times, making YOLOv5 ideal for real-time applications where quick posture detection is crucial. The overall enhancement in both accuracy and speed positions YOLOv5 as a top-performing posture detection model, making it a preferred choice for a wide range of computer vision applications.

Moreover, another graph is presented to represent the comparison of various YOLO models in terms of average precision (AP) while conducting the evaluation on YOLOv5l

across different releases, YOLOv4 with different releases, and YOLOv3. The x-axis represents GPU time with a batch size of 8, indicating the time taken by the GPU to process the images. The y-axis represents the average precision (AP), which measures the accuracy of posture detection. Fig. 6 demonstrates the comparison of various YOLO models in terms of AP [15, 16].

As shown in Fig. 5, in analyzing the graph, it becomes evident that YOLOv5 consistently demonstrates better AP compared to YOLOv4 and YOLOv3. This indicates that YOLOv5 achieves more accurate posture detection across the evaluated releases. The higher AP scores attained by YOLOv5l across different releases suggest that its advancements in architecture, training strategies, and inference optimizations have significantly improved detection accuracy.

Fig. 3. Samples of experimental results.

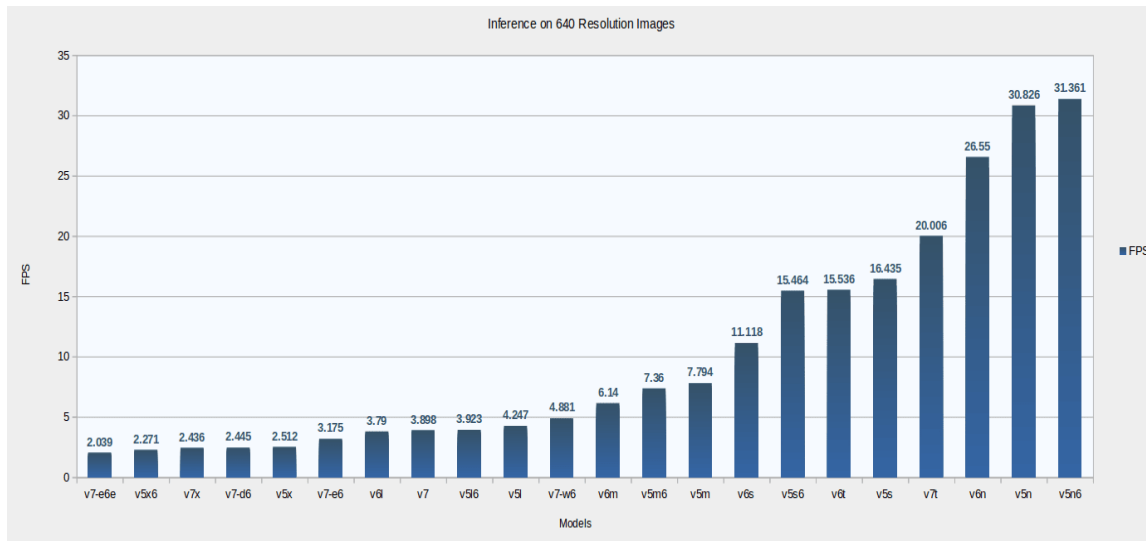

Fig. 4. Comparison of Yolo models based on accuracy and speed.
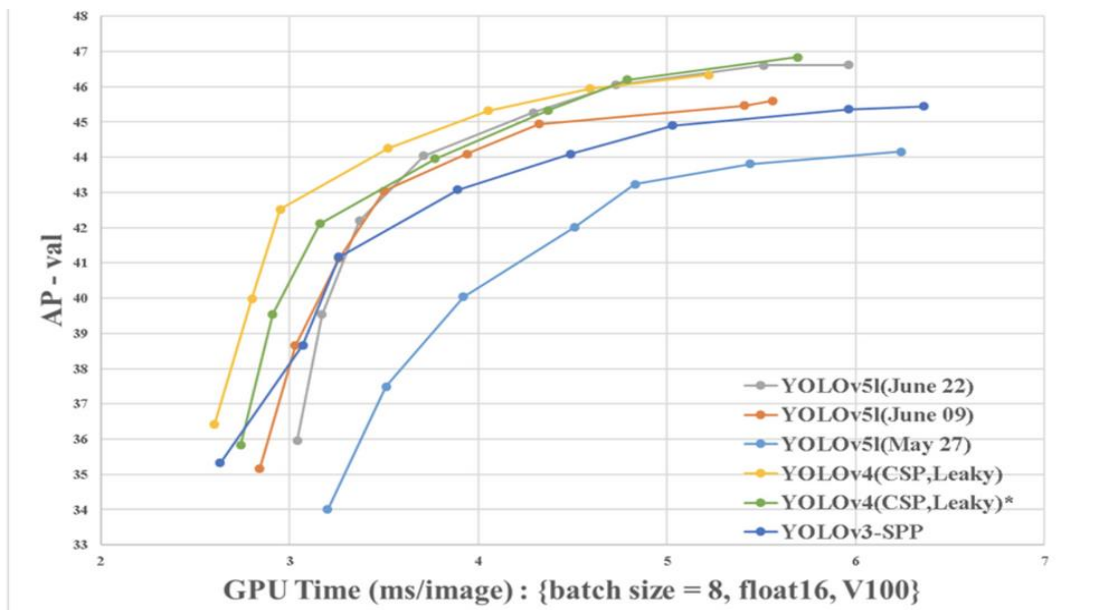

Fig. 5.    Comparison of Yolo algorithm on average precision (AP).

Furthermore, the graph allows us to observe the trade-off between GPU time and AP for each model. By analyzing the trend lines or data points, it becomes apparent that YOLOv5 strikes a favorable balance between accuracy and GPU processing time. It manages to achieve higher AP scores while maintaining comparable or even faster GPU processing times compared to the other models.

Finally, the performance of the proposed method is evaluated based on precision, recall, and mAP. When evaluating the performance of a generated model for human posture detection, precision, recall, and mean Average Precision (mAP) are key metrics to consider. Precision measures the accuracy of positive predictions, indicating how well the model identifies true positives and minimizes false positives. Recall quantifies the model's ability to detect all relevant human postures, minimizing false negatives. These metrics help assess the model's accuracy and completeness in detecting human postures. Additionally, mAP combines precision and recall across various confidence thresholds, providing an overall measure of the model's performance. It allows for a comprehensive evaluation of the model's accuracy at different recall levels, offering insights into its performance across the entire range of detection thresholds.

By analyzing precision, recall, and mAP, one can gain a comprehensive understanding of the model's ability to accurately detect human postures while striking a balance between false positives and false negatives. Based on our experimental results, the first version of our model was trained with 1092 photos. This model achieved relatively good results. Table I shows the model evaluation in our proposed approach.

As shown in Table I, the table provides detailed performance metrics for a human posture detection model across different classes: "all," "fall," "walking," and "sitting." Let's examine each column as Class: This column represents the specific class or category of human postures for which the performance metrics are provided. Images: It indicates the

number of images in the dataset that contain instances of the corresponding class. Instances: This column shows the total number of instances or occurrences of the specific class within the dataset. Precision: Precision measures the accuracy of the model's positive predictions for each class. It indicates the proportion of correctly identified instances out of all the predicted instances for that class. Higher precision values indicate a lower rate of false positives. Recall: Recall, also known as sensitivity, represents the model's ability to detect all relevant instances of the class. It calculates the proportion of correctly identified instances out of all the actual instances for that class. Higher recall values indicate a lower rate of false negatives. mAP50: (mAP at IoU threshold 0.50) evaluates the overall detection accuracy of the model. It measures the average precision across all classes at a specific Intersection over the Union (IoU) threshold of 0.50. Higher mAP50 values indicate better overall detection performance. mAP50-90: mAP50-90 represents the mean Average Precision averaged across all classes, but with IoU thresholds ranging from 0.50 to 0.90. This metric provides a broader assessment of the model's performance by considering a range of IoU thresholds.

As depicted in Fig. 6, analyzing the table, we can observe the overall performance of the model, represented by the "all" class, achieves a precision of 0.814, recall of 0.794, mAP50 of 0.825, and mAP50-90 of 0.529. Among the specific classes, the "fall" class achieves the highest precision of 0.909, recall of 0.834, mAP50 of 0.924, and mAP50-90 of 0.539. This indicates that the model performs particularly well in detecting instances of falling postures. The "walking" class shows a high recall of 0.899, indicating that the model effectively detects walking postures while achieving a precision of 0.827 and mAP50 of 0.886. The "sitting" class exhibits lower precision (0.705) and recall (0.649), suggesting that the model faces challenges in accurately detecting instances of sitting postures. It achieves a mAP50 of 0.664, indicating moderate overall performance.

TABLE I.        MODEL EVALUATION METRICS

| Class | Images | Instances | Precision | Recall | mAp50 | Map50-90 |
|---|---|---|---|---|---|---|
| all | 333 | 342 | 0.814 | 0.794 | 0.825 | 0.529 |
| fall | 333 | 216 | 0.909 | 0.834 | 0.924 | 0.539 |
| walking | 333 | 69 | 0.827 | 0.899 | 0.886 | 0.619 |
| sitting | 333 | 57 | 0.705 | 0.649 | 0.664 | 0.429 |

Fig. 6.    Performance analysis of our generated model.

## V.    CONCLUSION

Human posture detection is a challenging task in smart home applications. This study deals with the high complexity, low accuracy, and speed challenges of human posture detection in smart home applications. It intends to develop a vision-based posture recognition system to utilize in smart home applications that can identify human posture. In the proposed approach, a YOLO network is trained and tested to recognize the postures in our custom dataset. This Yolo-based approach is based on YOLOv5, which provides a high accuracy rate and satisfied speed in posture detection. Experimental results show the effectiveness of the developed system for posture recognition on smart home applications. Future research directions could involve refining real-time detection capabilities and exploring user-centric applications, expanding the utility of posture recognition beyond health and safety monitoring to enhance user comfort and experience in smart home environments.

# Object Detectors in Autonomous Vehicles: Analysis of Deep Learning Techniques

Lei Du[*]

Henan Polytechnic Institute Nanyang Henan 473000, China

*Abstract*—**Autonomous vehicles have emerged as a transformative technology with wide-ranging implications for smart cities, revolutionizing transportation systems and optimizing urban mobility. Object detection plays a crucial role in autonomous vehicles, accurately identifying and localizing pedestrians, vehicles, and traffic signs for safe navigation. Deep learning-based approaches have revolutionized object detection, leveraging deep neural networks to extract intricate features from visual data, enabling superior performance in various domains. Two-stage algorithms like R-FCN and Mask R-CNN focus on precise object localization and instance-level segmentation, while one-stage algorithms like SSD, RetinaNet, and YOLO offer real-time performance through single-pass processing. To advance object detection for autonomous vehicles, comprehensive studies are needed, particularly on two-stage and one-stage algorithms. This study aims to conduct an in-depth analysis, evaluating the strengths, limitations, and performance of R-FCN, Mask R-CNN, SSD, RetinaNet, and YOLO algorithms in the context of autonomous vehicles and smart cities. The research contributions include a thorough analysis of two-stage algorithms, a comprehensive examination of one-stage algorithms, and a comparison of different YOLO variants to highlight their advantages and drawbacks in object detection tasks.**

*Keywords—Autonomous vehicles; object detection; deep learning; two-stage object detectors; one-stage object detectors; comprehensive analysis*

## I. INTRODUCTION

Autonomous vehicles have emerged as a groundbreaking technology with wide-ranging implications for smart cities [1, 2]. These vehicles, equipped with advanced sensors and intelligent systems, have the potential to revolutionize transportation systems, enhance road safety, and optimize urban mobility [3]. As autonomous vehicles continue to evolve, their applications in smart cities are becoming increasingly significant, paving the way for efficient and sustainable transportation networks.

Object detection plays a crucial role in the operation of autonomous vehicles [4, 5]. It involves the accurate identification and localization of various objects, such as pedestrians, vehicles, and traffic signs, from sensor data [5]. Reliable object detection is essential for autonomous vehicles to perceive their surroundings, make informed decisions, and navigate complex environments safely [6, 7]. By detecting and tracking objects in real-time, autonomous vehicles can anticipate potential hazards, react accordingly, and ensure the safety of both passengers and pedestrians.

Deep learning-based approaches have emerged as a dominant paradigm in object detection [8, 9]. Leveraging the capabilities of deep neural networks, these approaches have revolutionized the field by automatically learning and extracting intricate features from visual data [10, 11]. They have demonstrated superior performance in a variety of domains, including autonomous vehicles [12], surveillance systems, and robotics [9]. Deep learning-based object detection methods have paved the way for significant advancements in accuracy and real-time processing, enabling more robust and efficient autonomous driving systems.

Two-stage and one-stage object detection algorithms are two popular categories in the field of deep learning-based object detection [13]. In the two-stage category, algorithms such as R-FCN and Mask R-CNN have gained prominence [14]. R-FCN focuses on precise object localization using position-sensitive score maps, while Mask R-CNN introduces instance-level segmentation alongside object detection. In the one-stage category, widely recognized algorithms include SSD, RetinaNet, and YOLO. These models operate with a single pass over the input data, offering real-time performance [15]. SSD utilizes a multi-scale approach with default anchor boxes, RetinaNet addresses class imbalance with the Focal Loss, and YOLO achieves efficient object detection by simultaneously predicting object locations and class probabilities.

To further advance object detection algorithms in autonomous vehicles, there is a need for comprehensive studies that focus on both two-stage and one-stage approaches. Additionally, a comparison of YOLO algorithms, given their popularity, would provide valuable insights into their strengths and weaknesses.

The existing literature on object detection in the context of autonomous vehicles and smart cities tends to prioritize algorithmic performance without delving deeply into real-world implementation, which is a significant gap. To address this, the proposed study should give prominence to how these algorithms function in the dynamic and complex environments of urban areas, considering variables such as weather changes, diverse road users, and intricate traffic scenarios. Additionally, the research should establish a comprehensive and tailored set of evaluation metrics, as the conventional ones might not fully capture the distinct challenges presented by autonomous vehicles in smart cities. Novel metrics, especially those accounting for safety and real-time performance, may be required to provide a more accurate assessment of algorithm effectiveness in this context.

In this study, our aim is to conduct an in-depth analysis of deep learning methods for object detection, with a particular focus on two-stage and one-stage algorithms. This analysis will involve reviewing previous studies, identifying their research contributions, and examining these algorithms' performance, efficiency, and suitability in the context of autonomous vehicles and smart city applications.

The research contributions of this study are as follows:

- Providing a thorough analysis of two-stage object detection algorithms, including R-FCN and Mask R-CNN, and evaluating their strengths and limitations in the domain of autonomous vehicles and smart cities.

- Conducting a comprehensive examination of one-stage object detection algorithms, namely SSD, RetinaNet, and YOLO, and assessing their performance, efficiency, and suitability for real-time applications.

- Comparing and contrasting different YOLO algorithms to highlight their respective advantages, drawbacks, and performance in object detection tasks.

## II. RELATED WORKS

In study [16], a performance analysis of object detection algorithms is presented for traffic surveillance applications, specifically focusing on the use of neural networks. The study evaluates the effectiveness and efficiency of various neural network-based algorithms in detecting and tracking objects in traffic scenes. By analyzing the performance metrics of these algorithms, the paper provides insights into their strengths, limitations, and applicability in traffic surveillance. The aim is to enhance the understanding of object detection and tracking techniques using neural networks, enabling the development of more effective and efficient solutions for traffic surveillance applications.

In study [17], the implementation of a real-time system for detecting traffic signs and road objects was investigated using mobile GPU platforms. The study focuses on developing an efficient and robust algorithm that can accurately identify and classify traffic signs and other objects in real-time. By utilizing mobile GPU platforms, the system achieves high-performance processing and responsiveness. The paper discusses the implementation details, performance evaluation, and practical implications of the proposed approach. The aim of the study is to provide a practical solution for real-time traffic signs and road object detection on mobile devices, contributing to the advancement of intelligent transportation systems.

The study in [18] presented a comparative study of deep learning-based algorithms for road object detection. The study focuses on two-stage and one-stage object detection methods, analyzing their strengths, limitations, and performance in various applications. The algorithms examined include R-FCN, Mask R-CNN, SSD, RetinaNet, and YOLO. The paper reviews previous studies, identifies research contributions, and highlights the need for further analysis and exploration in this field. The objective is to contribute to the advancement of object detection techniques, particularly in the context of road and traffic scenarios.

Finally, in [19], small-object detection in autonomous driving systems is explored using the YOLOv5 algorithm. The study addresses the challenge of accurately detecting small objects, such as pedestrians or traffic signs, which are crucial for safe autonomous driving. By utilizing YOLOv5, the paper proposes an approach that improves the detection performance for small objects in real-time. The study evaluates the effectiveness of the YOLOv5 algorithm and its suitability for autonomous driving applications. The aim is to enhance the object detection capabilities in autonomous driving systems, particularly for small objects, contributing to safer and more reliable autonomous vehicles.

## III. METHODOLOGY

This study conducts a comprehensive analysis of deep learning methods for applications in road object detection, with a specific emphasis on both two-stage and one-stage approaches. Our objective is to address the most superior algorithms in the field. Additionally, it conducts a thorough comparison of the YOLO algorithms, which are widely recognized as the most popular object detection algorithms. By focusing on two-stage and one-stage methodologies and conducting this comparative analysis, it aims to provide valuable insights into the strengths, weaknesses, and performance of these algorithms. The study will contribute to a better understanding of deep learning methods in object detection and help identify the most effective approaches for various applications.

### A. Two-Stages Object Detectors

Two-stage object detectors are a type of deep learning architecture used for object detection tasks. They typically consist of two main stages: region proposal generation and object classification/refinement. These detectors have been widely adopted due to their ability to accurately localize and classify objects in images with complex backgrounds. Inspired from [18], two popular two-stage object detectors are R-FCN [20] and Mask R-CNN [21].

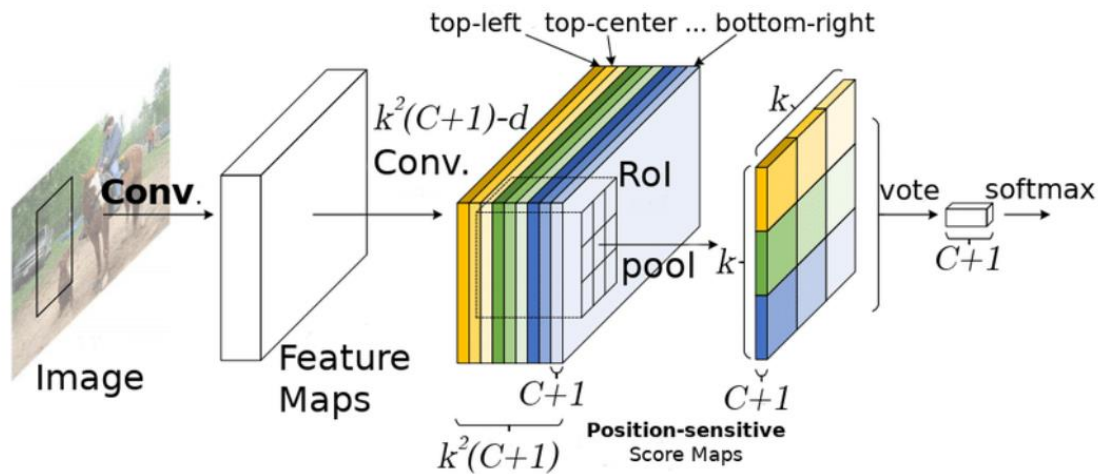
The R-FCN is an object detection model that operates in a fully convolutional manner. In R-FCN, the first stage involves generating a set of region proposals using an external algorithm such as Selective Search. These region proposals serve as potential object locations. In the second stage, R-FCN performs region-based classification and refinement. Instead of using fully connected layers, R-FCN utilizes position-sensitive score maps, which are computed using convolutions. These score maps encode the class probabilities at different spatial locations within each region proposal. Finally, a position-sensitive pooling operation is applied to obtain a fixed-length feature vector for each class. R-FCN achieves state-of-the-art object detection accuracy while being more computationally efficient compared to other two-stage detectors. Fig. 1 shows R-FCN architecture.


Fig. 1.   R-FCN architecture [22].

The Mask R-CNN is an extension of the Faster R-CNN object detection framework. Similar to Faster R-CNN, Mask R-CNN has two main stages. The first stage involves generating region proposals using a region proposal network (RPN). These proposals are refined and classified in the second stage, similar to Faster R-CNN. However, Mask R-CNN introduces an additional branch that performs instance mask prediction for each region of interest (RoI). This branch produces a binary mask indicating the object's precise boundary. This allows Mask R-CNN to simultaneously handle object detection and segmentation tasks, making it a powerful framework for a wide range of applications, including instance segmentation and object tracking. Fig. 2 shows Mask-RCNN architecture.

*B. One-Stage Object Detectors*

One-stage object detectors are a type of deep learning architecture used for object detection tasks. Unlike two-stage detectors, they directly predict object bounding boxes and class probabilities in a single pass without the need for explicit region proposal generation. This makes one-stage detectors faster and more efficient, making them suitable for real-time applications. Similar to two-stage and inspiring from [18], this study selected three popular examples of one-stage object detectors Single Shot MultiBox Detector (SSD) [24], RetinaNet [25], and You Only Look Once (YOLO) [26].

SSD, also known as the Single Shot MultiBox Detector, is an efficient one-stage object detection model that strikes a balance between high accuracy and real-time processing. The approach employed by SSD involves dividing the input image into a grid of different sizes. Each grid cell takes on the responsibility of predicting bounding boxes and class probabilities for objects within its designated region. This multi-scale strategy enables SSD to effectively detect objects of varying sizes. Additionally, SSD incorporates default anchor boxes with diverse aspect ratios and scales, enhancing the precision of object localization. Through a sequence of convolutional layers that progressively reduce spatial dimensions, SSD efficiently predicts object bounding boxes and class probabilities across multiple scales in a single pass. The architecture of SSD can be visualized in Fig. 3.

Fig. 2.   Mask-RCNN architecture [23].
Fig. 3. SSD architecture [27].

Fig. 4. RetinaNet architecture [25].

RetinaNet is another well-known one-stage object detection system that addresses the issue of imbalanced classes in training. It introduces a unique loss function called Focal Loss, which concentrates on challenging examples that are misclassified or hard to classify. The Focal Loss assigns lower weights to easy examples that are already well-classified, enabling the model to focus more on the difficult examples during the training process. By utilizing this loss function, RetinaNet achieves a better trade-off between accuracy and efficiency. Like SSD, RetinaNet incorporates a feature pyramid network (FPN) that captures multi-scale features and facilitates object detection. The FPN integrates features from different levels of the feature pyramid to effectively handle objects of diverse sizes. The architecture of RetinaNet is depicted in Fig. 4.

YOLO, a groundbreaking one-stage object detection framework, is renowned for its ability to perform in real-time [28]. In contrast to SSD and RetinaNet, YOLO employs a singular neural network that enables simultaneous prediction of object locations and class probabilities, resulting in quicker inference times. Additionally, YOLO incorporates anchor boxes of varying scales and aspect ratios to handle diverse object characteristics. However, earlier versions of YOLO encountered challenges in accurately detecting small objects. The subsequent releases of YOLOv4 and YOLOv5 have introduced enhancements to overcome this limitation, delivering improved speed and competitive performance.

For the parameter setting of the algorithms, following configuration are used, for the YOLOv4, network architecture, image size, learning rate and batch size are set to Darknet-53, 416x416, 0.001, 64. For the Mask R-CNN, backbone architecture, image size, learning rate, mask resolution are set to ResNet-50, 800x800, 0.001, 28x28. For the RetinaNet, backbone architecture, image size, learning rate and batch size are set to ResNet-50, 800x800, 0.0001 and 4. For the R-FCN, backbone architecture, image size, learning rate and batch size are set to ResNet-50, 800x800, 0.001a nd 1. For the SSD, backbone architecture, image size, learning rate and batch size are set to ResNet, 512x512, 0.001 and 32.

## IV. RESULTS AND DISCUSSION

This section discusses the performance analysis of two and one-stage object detectors and the performance analysis of Yolo-based object detectors.

*A. Performance Analysis of Two and Stages Object Detectors*

The PR-curve provides valuable insights into the performance of object detection algorithms [18]. By analyzing this curve, it is possible to assess the precision and recall trade-offs and make informed comparisons between different models.

In Fig. 5, it is evident that YOLOv4 consistently outperforms other models in terms of performance. It achieves the highest precision and recall rates across all levels, demonstrating its effectiveness in accurately detecting objects in various scenarios. The two-stage detection model of Mask R-CNN exhibits commendable precision and recall, surpassing RetinaNet, R-FCN, and SSD, indicating its superior overall detection accuracy and efficiency.

When comparing R-FCN with SSD, it is observed that R-FCN outperforms SSD in terms of precision for target detection at all levels. This indicates that R-FCN provides more precise detection results, enhancing the reliability of the object detection process. Furthermore, the recall of Mask R-CNN closely matches that of YOLOv4, specifically for target detection with occlusion and truncation, suggesting that Mask R-CNN can accurately detect objects even in challenging scenarios where occlusion and truncation are present.

However, it should be noted that SSD exhibits the lowest recall among all the models, indicating a higher rate of missed detections for targets at all levels. This suggests that SSD may struggle to detect objects accurately compared to the other models. Therefore, based on the PR-curve analysis, YOLOv4 emerges as the best-performing model overall, followed by Mask R-CNN. R-FCN surpasses SSD in terms of precision, while SSD exhibits the lowest recall rate. These insights provide valuable guidance for selecting the most suitable object detection algorithm based on specific requirements and priorities.

### B. Performance Analysis of Yolo-based Object Detectors

In this section, inspired from [29], the performance of YOLO object detection models on different CPU and GPU architectures is investigated. For this comparison, YOLO base models are first explored on NVIDIA GPUs, including the TESLA P100, TESLA V100, GTX 1080Ti, and RTX 4090. The objective is to determine the fastest YOLO model for each GPU, considering factors such as speed and efficiency. This analysis will provide valuable insights for selecting the most appropriate YOLO model based on specific hardware configurations and real-world application requirements.

The YOLO models are designed for real-time object detection and rely on dividing the input image into a grid, predicting bounding boxes and class probabilities for each grid cell. Different versions of YOLO, such as YOLOv5, YOLOv6, and YOLOv7, offer trade-offs between speed and accuracy. The Nano and Tiny variants prioritize lightweight and faster performance, while larger versions like YOLOv7 provide higher accuracy at the cost of slightly reduced speed. By comparing the performance of these models on the specified NVIDIA GPUs, it is possible to identify the fastest model for each GPU, aiding in the selection of the optimal YOLO model based on the desired balance between speed, accuracy, and specific hardware requirements.

As shown in Fig. 6, the graph provides information on the performance of different YOLO (You Only Look Once) models on various GPU devices. Based on the data presented, we can discuss the better method in terms of speed and throughput.

Firstly, from the graph, it is evident that YOLOv5 Nano performs the best in terms of speed on the RTX 4090 GPU and TESLA P100. This indicates that if the primary concern is achieving the highest frames per second (FPS) for real-time object detection, YOLOv5 Nano would be the preferred choice. Secondly, YOLOv7 Tiny stands out as the model that provides the highest throughput on the GTX 1080 Ti and TESLA V100. Throughput refers to the number of objects detected per unit of time, and YOLOv7 Tiny excels in this aspect on these specific GPU devices. This is particularly beneficial in scenarios where accurately detecting a larger number of objects is more important than achieving the highest FPS.

On the other hand, the YOLOv6 Nano and Tiny models, while not performing at the same FPS as YOLOv5 and YOLOv7, are still not considered very slow. Although the graph does not provide specific data on their performance, it suggests that these models strike a balance between speed and accuracy. They may be a suitable choice when moderate speed is desired while still achieving satisfactory object detection results.

In conclusion, the better method depends on the specific requirements of the task at hand. YOLOv5 Nano is ideal for real-time applications where achieving the highest FPS is crucial. YOLOv7 Tiny excels in scenarios where high throughput is prioritized over real-time performance. Meanwhile, YOLOv6 Nano and Tiny models offer a compromise between speed and accuracy, making them a viable option in cases where moderate speed is desired without sacrificing too much on detection quality.

As shown in Fig. 7, in the CPUs platform, the YOLOv5 Nano models, specifically the P5, are expected to provide the highest speed. These models can achieve real-time frames per second (FPS) performance, surpassing 30 FPS. This means that they can process and analyze images or video streams in real-time, providing quick object detection results. The YOLOv5 Nano models are optimized for efficiency and speed, making them well-suited for consumer-grade CPUs where real-time performance is a priority.

On the other hand, the YOLOv7 Tiny model, while still capable of real-time object detection, operates at a slightly lower speed compared to the YOLOv5 Nano models. It typically runs at around 20 FPS, which is still quite impressive and suitable for many real-time applications. Although it may not match the speed of the YOLOv5 Nano models, the YOLOv7 Tiny model strikes a balance between speed and accuracy. It provides satisfactory results while ensuring efficient processing on general consumer CPUs.

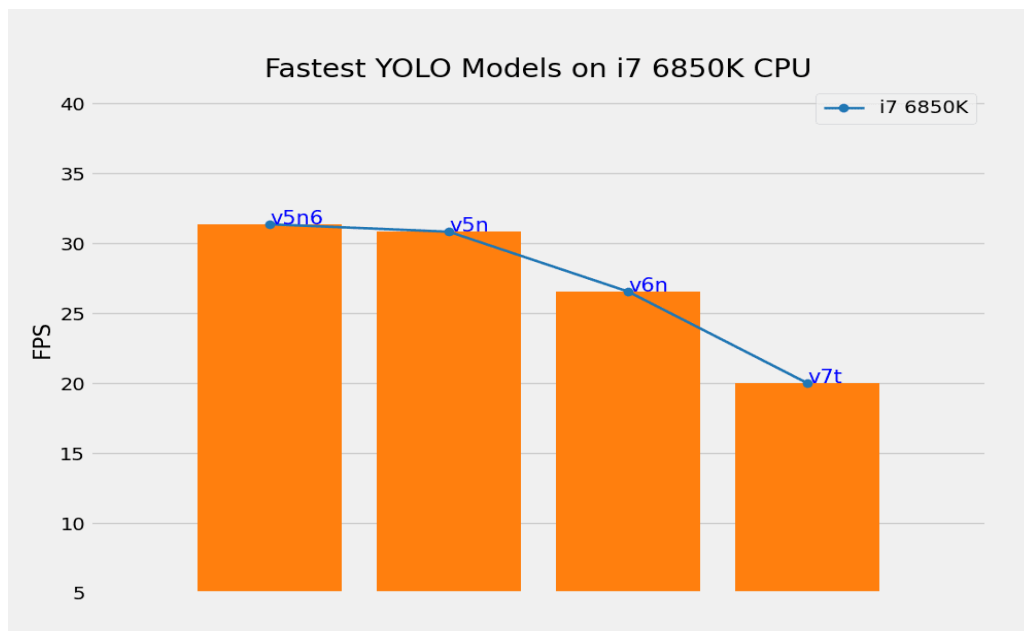
Fig. 6.    The fastest YOLO models on each GPU platform [29].


Fig. 7.   The four fastest YOLO object detection models on the i7 6850K CPU.

In conclusion, as a result shown, regardless of the specific CPU architecture, it observed that smaller models tend to exhibit faster performance. This is evident in these findings, where the YOLOv5 Nano and Nano P6 models emerged as the fastest options. Remarkably, even on an older generation i7 CPU, these models were able to achieve impressive speeds of over 30 frames per second (FPS). This demonstrates the efficiency and optimization of the YOLOv5 Nano and Nano P6 models for CPU processing, making them excellent choices for real-time object detection on consumer-grade CPUs.

## V.    CONCLUSION

This study conducted a thorough and comprehensive analysis of deep learning methods for object detection, focusing specifically on both two-stage and one-stage approaches. The main objective of this study is to identify the most superior algorithms in this domain and provide valuable insights into their unique strengths, limitations, and overall performance. It placed particular emphasis on comparing and contrasting the YOLO object detection models, including YOLOv5, YOLOv6, and YOLOv7, with respect to their frames per second (FPS) and accuracy. To ensure the reliability of our results, this study performed experiments using various NVIDIA GPU models such as GTX, RTX, and TESLA. This multi-platform evaluation allowed us to establish a solid foundation for this analysis and draw meaningful comparisons between the different YOLO versions. The findings from the study contribute to a better understanding of deep learning methods in object detection, enabling researchers and practitioners to make informed decisions when selecting the most suitable algorithms for their specific requirements. For future works, one potential future research direction is to investigate the fusion of two-stage and one-stage object detection algorithms to leverage their respective strengths and improve overall performance. Another promising avenue for future work is the adaptation of object detection algorithms for edge computing, aiming to optimize models for resource-constrained edge devices and enable real-time object detection at the network edge.

# A Survey of Structural Health Monitoring Advances Based on Internet of Things (IoT) Sensors

Hao DENG, JianHua CHEN

Chongqing Industry Polytechnic College, Chongqing 401120, China

*Abstract*—**Structural Health Monitoring (SHM) is a technique that ensures the safety and reliability of structures through continuous and real-time monitoring. IoT-based sensors have become a popular solution for implementing SHM systems, and research in this area is essential for improving the accuracy and reliability of SHM systems. A review of the current state-of-the-art is necessary to identify the challenges and opportunities for further development of SHM systems based on IoT sensors. This study presents a survey to comprehensively review of SHM, focusing on IoT sensors. Secondly, the categorization of the current civil structural monitoring methods is established, and the advantages and disadvantages of the methods are addressed. Thirdly, an analysis is performed, and the result is compared to civil structural monitoring methods. Finally, key features of the methods are discussed and summarized, and at last, some directions for future studies are presented.**

*Keywords*—*Structural health monitoring; civil structures; internet of things; sensors; survey*

## I. INTRODUCTION

Structural monitoring is especially critical for aging infrastructure, which can suffer from wear and tear over time [1, 2]. By detecting early signs of damage or deterioration, it is possible to implement repairs or replacements before more extensive damage occurs [3, 4]. This can help prevent catastrophic failures and ensure the safety of the public and infrastructure workers. Structural Health Monitoring (SHM) is a method that facilitates the continuous and real-time monitoring of various structures such as bridges, buildings, and pipelines [5, 6]. SHM systems employ different sensors and technologies to detect structural damages or defects. This allows for timely repair or maintenance, thus avoiding catastrophic failures [7]. In civil engineering, SHM plays a critical role in ensuring the safety and reliability of important infrastructure.

Advancements in SHM systems have the potential to enhance the longevity, safety, and sustainability of structures, resulting in significant social and economic benefits [8]. Consequently, SHM has become a significant research area in this field and other civil structures [4, 9]. The goal of structural monitoring is to identify early signs of damage or deterioration and assess the structural integrity of the infrastructure to ensure safety and longevity [10, 11]. Many techniques and technologies are used in civil structural monitoring, including sensors, cameras, and other monitoring equipment [12, 13]. The data collected from these devices is often analyzed using machine learning algorithms to identify patterns and detect anomalies [14].

The integration of Internet of Things (IoT) technology with SHM systems allows for remote and real-time monitoring of structures, providing valuable data that can be analyzed to detect any damage or defects [15]. IoT-based SHM systems use various sensors and devices that can detect environmental conditions, vibrations, and strains in the structures, allowing for timely maintenance or repair before a failure occurs [16]. This approach has the potential to significantly improve the accuracy and reliability of SHM systems, making it an exciting and promising area of research in the field of civil engineering.

This study presents a comprehensive overview of SHM using IoT sensors. Section II deals with the categorization of the current civil structural monitoring methods is established, and the advantages and disadvantages of the methods are addressed. In Section III, an analysis is performed, and the result is compared to civil structural monitoring methods. Section IV presents key features of the methods are discussed and summarized, and finally conclusion of this paper and some directions for future studies are presented in Section V and Section VI, respectively.

The uniqueness of this paper, when compared to the review of the literature, lies in its multifaceted approach to Structural Health Monitoring (SHM) with a specific focus on IoT sensors. While the existing literature provides some insights into SHM, this study goes beyond by not only offering a comprehensive overview but also categorizing the current civil structural monitoring methods. By addressing the advantages and disadvantages of these methods and conducting a detailed comparative analysis, this paper provides a more in-depth understanding of the state-of-the-art in SHM based on IoT sensors. Furthermore, the paper concludes by presenting key features and directions for future research, adding a forward-looking dimension that sets it apart from a mere literature review.

## II. RELATED WORKS

This section presents a review of previous studies on structural health monitoring with the covering of IoT-based sensors. Tokognon et al. [15] presented a comprehensive survey of the existing literature on Structural Health Monitoring (SHM) frameworks based on the Internet of Things (IoT). The authors discuss the importance of SHM and how IoT technologies can be used to enhance SHM systems. They review the various IoT-based sensors and devices that can be used for SHM and the different techniques for data collection and analysis. The authors also identify the challenges and limitations of IoT-based SHM systems and the potential solutions to address them. Overall, this paper provides a

valuable resource for researchers and practitioners working on IoT-based SHM systems, highlighting the current state-of-the-art and future research directions in this field.

Ye et al. [17] provided a comprehensive review of the recent developments in deep learning-based structural health monitoring (SHM) of civil infrastructures. The paper discusses the benefits of using deep learning techniques, such as artificial neural networks and convolutional neural networks, for SHM applications and reviews the different types of deep learning models that have been developed for civil infrastructure monitoring. The authors also provide case studies of deep learning-based SHM in various civil infrastructure projects, demonstrating the potential of these techniques in improving the accuracy and efficiency of SHM. Overall, the paper is a valuable resource for researchers, engineers, and practitioners working in the field of SHM and civil infrastructure, especially those interested in applying deep learning techniques to enhance the reliability and safety of civil structures.

Mishra et al. [18] presented an overview of the use of the Internet of Things (IoT) for structural health monitoring (SHM) of civil engineering structures. The authors discuss the benefits and challenges associated with using IoT technologies for SHM, including improved data collection, analysis, and communication. The paper also provides case studies of IoT-based SHM in different civil engineering structures, demonstrating the potential benefits of these technologies in improving the safety and reliability of civil engineering structures. Overall, the paper is a useful resource for researchers, engineers, and practitioners working in the field of civil engineering and structural health monitoring.

A survey of the recent developments in fiber-optic sensing technologies was presented for structural health monitoring (SHM) of civil infrastructure by Wu et al. [19]. The paper discusses the benefits of fiber-optic sensors, including their sensitivity, durability, and resistance to electromagnetic interference, and reviews different types of fiber-optic sensors that have been developed for SHM applications. The authors also provide case studies of fiber-optic sensor applications in various civil infrastructure projects, demonstrating the potential of these sensors in improving the safety and reliability of civil infrastructure. Overall, the paper is a valuable resource for researchers, engineers, and practitioners working in the field of SHM and civil infrastructure.

Malekloo et al. [20] presented a comprehensive overview of machine learning (ML) techniques for structural health monitoring (SHM) applications, with a focus on emerging technologies and high-dimensional data sources. The paper discusses the benefits of using ML techniques, such as support vector machines and random forests, for SHM applications and reviews different types of ML models that have been developed for civil infrastructure monitoring. The authors also highlight the importance of using emerging technologies, such as unmanned aerial vehicles and wireless sensor networks, to enhance the effectiveness of ML-based SHM. The paper provides case studies of ML-based SHM in various civil infrastructure projects, demonstrating the potential of these techniques in improving the accuracy and efficiency of SHM. Overall, the paper is a valuable resource for researchers, engineers, and practitioners working in the field of SHM and civil infrastructure, especially those interested in applying ML techniques to enhance the reliability and safety of civil structures.

An overview of the subspace system identification (SSI) method was presented for the health monitoring of civil infrastructures by Shokravi et al. [21]. The paper discusses the benefits of using the SSI method for SHM applications, such as its ability to identify system parameters accurately and detect damage in civil infrastructures. The authors provide case studies of SSI-based SHM in various civil infrastructure projects, demonstrating the potential of this method in improving the accuracy and efficiency of SHM. Overall, the paper is a valuable resource for researchers, engineers, and practitioners working in the field of SHM and civil infrastructure, especially those interested in applying the SSI method to enhance the reliability and safety of civil structures.

## III. STRUCTURAL HEALTH MONITORING TECHNOLOGIES

Various types of monitoring methods are available, including visual inspections, non-destructive testing, and structural health monitoring using sensors, among others. Each method has its strengths and limitations, and the selection of a monitoring method depends on factors such as the type of structure, its location, and the available resources. Fig. 1 shows the categorization of civil structural monitoring methods.

### A. Visual Inspections

Visual inspections are one of the most common methods used in civil structural monitoring to assess the condition of a structure [22]. The visual inspection is used computer vision algorithms to extract useful information from the images and videos [41]. This method involves the visual examination of a structure's surface and other visible components to identify signs of damage or degradation. Visual inspections can be conducted by trained professionals or by using automated technologies such as drones equipped with cameras [23, 24]. Table I presents visual inspection methods used for civil structural monitoring.

### B. Structural Health Monitoring (SHM)

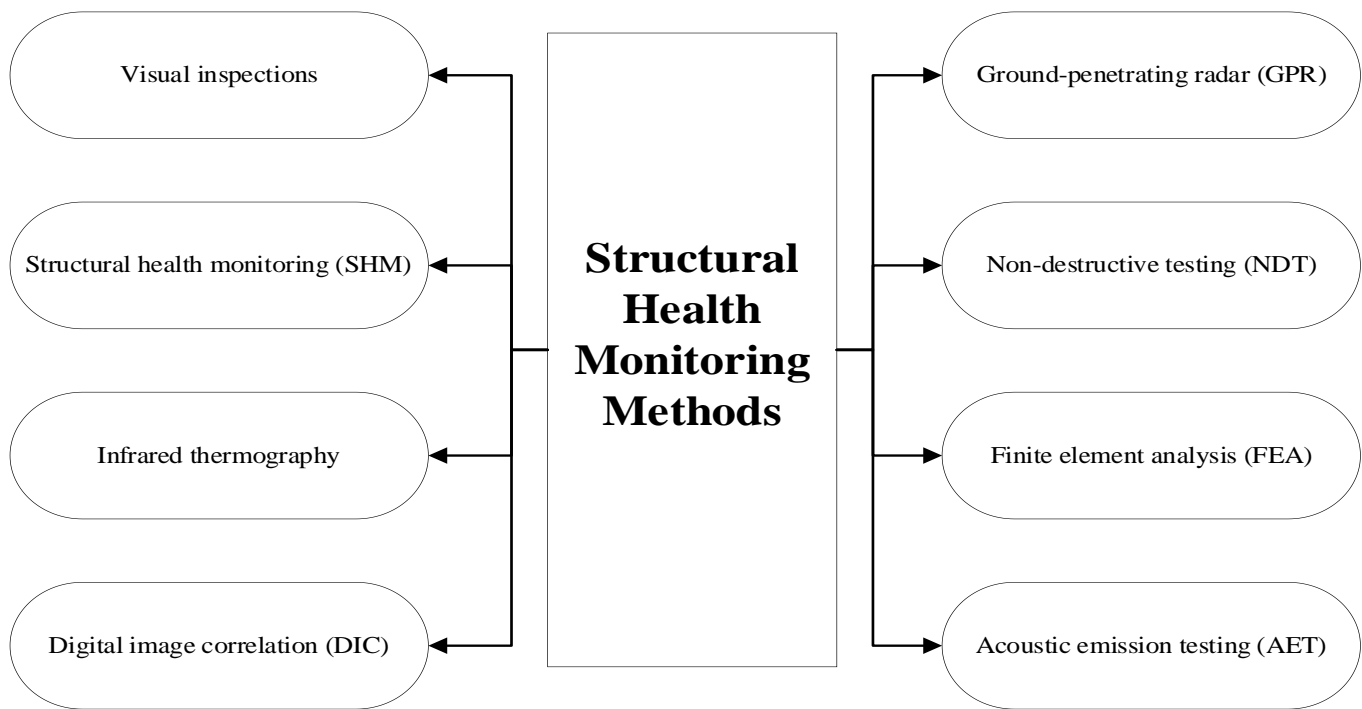
The SHM is a method of continuously monitoring a structure's condition to detect any signs of damage or degradation [5]. SHM involves the use of sensors to measure various parameters such as strain, vibration, temperature, and displacement, which are then analyzed to assess the structure's condition [25]. SHM can help to identify potential problems before they become serious, allowing for timely repairs and maintenance to be performed [26]. Table II presents the Infrared SHM used for civil structural monitoring.


Fig. 1. Categorization of civil structural monitoring methods.

TABLE I. THE VISUAL INSPECTION METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Bridge inspection using unmanned aerial vehicles (UAVs) | Inspection of bridges using UAVs equipped with high-resolution cameras | Non-intrusive can access hard-to-reach areas | Limited ability to detect internal damage |
| Crack detection using digital image correlation (DIC) | Detection of cracks and deformations using high-resolution cameras and computer vision algorithms | High accuracy, non-intrusive | Limited to surface damage |
| Tunnel lining inspection using LiDAR | Inspection of tunnel linings using LiDAR scanners | Rapid data collection, accurate mapping of interior surfaces | Limited ability to detect internal damage |
| Corrosion detection using electrochemical techniques | Detection of corrosion on metal structures using electrochemical sensors | Highly sensitive can detect early-stage corrosion | Limited to metal structures |
| Building facade inspection using drones | Inspection of building facades using drones equipped with high-resolution cameras | Non-intrusive can access hard-to-reach areas | Limited to surface damage |

TABLE II. THE SHM METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Fiber optic sensors | Sensors that use light to measure strain and temperature | High accuracy, non-intrusive | Expensive, require specialized installation |
| Wireless sensor networks | Networks of sensors that communicate wirelessly to a central monitoring system | Real-time monitoring, easy installation | Limited range, may require battery replacement |
| Piezoelectric sensors | Sensors that measure mechanical stress using electric charge | High sensitivity can detect damage at early stages | Limited to certain types of structures |
| Acoustic emission sensors | Sensors that detect and analyze acoustic signals emitted by structures | Non-intrusive can detect damage at early stages | Limited to certain types of structures |
| Electrochemical corrosion sensors | Sensors that detect corrosion on metal structures using electrochemical reactions | Highly sensitive can detect early-stage corrosion | Limited to metal structures |

TABLE III.    THE INFRARED THERMOGRAPHY METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Building envelope inspection using Infrared thermography | Inspection of building envelopes to detect heat loss and insulation issues | Non-intrusive can detect hidden damage | Limited to surface damage |
| Concrete inspection using Infrared thermography | Inspection of concrete structures to detect internal defects such as voids and delamination | Non-intrusive can detect internal damage | Limited to certain types of structures |
| Bridge inspection using Infrared thermography | Inspection of bridges to detect delamination and corrosion on the surface | Non-intrusive can detect hidden damage | Limited to surface damage |
| Electrical equipment inspection using Infrared thermography | Inspection of electrical equipment to detect overheating and potential electrical faults | Non-intrusive can detect hidden damage | Limited to electrical equipment |

## C. Infrared Thermography

Infrared thermography is a method of detecting changes in temperature on a structure's surface to identify potential defects or damage [27, 28]. This method involves the use of infrared cameras to capture thermal images, which can then be analyzed to identify areas of the structure with abnormal temperature patterns [29]. Infrared thermography can be used to identify defects such as water infiltration, heat loss, and insulation issues [30]. Table III presents the Infrared thermography methods used for civil structural monitoring.

## D. Digital Image Correlation (DIC)

Digital image correlation (DIC) is a non-destructive testing method that uses digital images to measure the deformation and strain of a structure [31, 32]. This method involves capturing images of the structure at different intervals during loading and then using specialized software to analyze the images and determine the deformation and strain. Table IV presents the DIC methods used for civil structural monitoring.

## E. Ground-penetrating Radar (GPR)

Ground-penetrating radar (GPR) is a non-destructive testing method that uses electromagnetic waves to detect and map features within structures and materials [33, 34]. This method involves transmitting a high-frequency electromagnetic pulse into the structure or material and measuring the reflections and diffractions that occur as the pulse travels through it. Table V presents the GPR methods used for civil structural monitoring.

## F. Non-destructive Testing (NDT)

Non-destructive testing (NDT) methods are techniques that allow for the assessment of the condition of civil infrastructure without causing damage to the structure [35, 36]. Table VI presents popular existing NDT methods used for civil structural monitoring.

TABLE IV.    THE DIC METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Bridge load testing using digital image correlation | Testing the load-carrying capacity of bridges using DIC | Non-intrusive can provide accurate data | Limited to certain types of structures |
| Concrete deformation measurement using digital image correlation | Measuring the deformation and strain of concrete structures | Non-intrusive, high accuracy | Limited to surface measurements |
| Structural deformation measurement using digital image correlation | Measuring the deformation and strain of various types of structures | Non-intrusive can provide accurate data | Limited to surface measurements |
| Material testing using digital image correlation | Measuring the deformation and strain of materials under different loading conditions | Non-destructive can provide accurate data | Limited to laboratory conditions |

TABLE V.    THE GPR METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Concrete inspection using ground-penetrating radar | Inspecting concrete structures for defects such as cracks and voids | Non-destructive can detect internal defects | Limited to certain types of structures |
| Detection of buried utilities using ground-penetrating radar | Detecting buried utilities such as pipes and cables | Non-destructive can provide accurate data | Limited to certain types of soils and materials |
| Assessment of pavement thickness using ground-penetrating radar | Measuring the thickness of pavement layers | Non-destructive can provide accurate data | Limited to certain types of pavements |
| Assessment of bridge decks using ground-penetrating radar | Detecting delamination and reinforcing steel within bridge decks | Non-destructive can provide accurate data | Limited to certain types of bridge decks |

TABLE VI.    THE NDT METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Ultrasonic testing | Ultrasonic waves are transmitted into the structure, and the reflections are measured to detect defects such as cracks and voids. | Non-destructive can detect internal defects, highly accurate | Limited to certain types of structures, requires specialized equipment and training |
| Magnetic particle inspection | A magnetic field is applied to the structure, and magnetic particles are introduced to the surface. Any defects in the structure cause a disruption in the magnetic field, allowing them to be detected. | Non-destructive can detect surface and near-surface defects | Limited to ferromagnetic materials, may not detect small defects |
| Eddy current testing | An alternating current is applied to the structure, inducing eddy currents which generate a magnetic field. Any defects in the structure cause a disruption in the magnetic field, allowing them to be detected. | Non-destructive can detect surface and near-surface defects highly accurately. | Limited to conductive materials, may not detect small defects |

TABLE VII.    THE FEA METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Static analysis | The structure is modeled as a system of linear equations which are solved to determine the stresses and deformations under static loads. | Highly accurate, can model a wide range of structures and loading conditions | Assumes linear behavior of materials, cannot account for dynamic effects |
| Dynamic analysis | The structure is modeled as a system of differential equations, which are solved to determine the response under dynamic loads such as earthquakes and wind. | It can account for dynamic effects, useful for assessing the risk of failure under extreme loading conditions. | It can be computationally intensive and requires accurate modeling of damping and material behavior |
| Fatigue analysis | The structure is modeled under cyclic loading conditions to predict the accumulation of damage over time. | Can predict the expected life of a structure under cyclic loading, useful for designing maintenance schedules | Requires accurate modeling of material behavior and loading conditions, may not account for all sources of damage |

TABLE VIII.    THE AET METHODS USED FOR CIVIL STRUCTURAL MONITORING

| Method | Description | Pros | Cons |
|---|---|---|---|
| Passive monitoring | AET sensors are installed on the structure to monitor for acoustic emissions continuously. | It can detect small or incipient damage, is non-invasive, and can monitor large areas. | Limited to detecting events with significant energy release, cannot pinpoint the location of the damage. |
| Active monitoring | AET is performed while the structure is under load or undergoing testing. | It can detect damage as it occurs and identify the location and extent of damage. | It may require access to the structure and may not be practical for continuous monitoring. |
| Source location | Multiple AET sensors are used to triangulate the location of acoustic emissions. | Can pinpoint the location of damage, useful for determining the extent of damage | It may require a large number of sensors, limited by the ability to detect signals in noisy environments. |

*G. Finite Element Analysis (FEA)*

Finite element analysis (FEA) is a computational method that uses numerical models to simulate the behavior of civil infrastructure under various loading conditions [37, 38]. Finite element analysis (FEA) is a computational method that uses numerical models to simulate the behavior of civil infrastructure under various loading conditions. Table VII shows some existing FEA methods used for civil structural monitoring.

*H. Acoustic Emission Testing (AET)*

Acoustic emission testing (AET) is a non-destructive testing (NDT) method that detects acoustic signals produced by the internal deformation of a material or structure [39, 40]. Table VIII presents popular AET methods used for civil structural monitoring.

IV.    ANALYSIS OF CIVIL STRUCTURAL MONITORING METHODS

In this study, the analysis of the methods is conducted through a meticulous examination of previous research and a thorough review of the data presented in the original papers. Our approach involves a comprehensive assessment aimed at identifying and elucidating the advantages and disadvantages of these methods. To ensure the accuracy and reliability of our analysis, we rely on the data reported in the original papers as our foundational source, supplemented by our own investigations. These investigations are carried out using standard performance metrics, allowing us to provide a rigorous and objective evaluation of the methods under consideration. This combined approach ensures a robust and well-informed analysis, contributing to the depth and credibility of our research findings. For this analysis qualitative and quantitative analysis are conducted, the detail of each discuss as follows,

## A. Qualitative Analysis

The qualitative analysis for the SHM method involves comparing different monitoring methods across several criteria to determine their effectiveness in detecting changes or damage in civil structures. These criteria include cost, ease of implementation, resolution, and range. By analyzing each method based on these criteria and assigning a numerical score, a comprehensive comparison can be made to identify the most suitable method for a specific application. The analysis uses data and information from previous studies and research, allowing for a data-driven approach to evaluating each method.

- Cost: The estimated cost associated with implementing the monitoring method. This includes equipment, labor, and any other expenses associated with the method.

- Ease of implementation: How difficult it is to set up and utilize the monitoring method. This takes into account factors such as the expertise required to operate the equipment, as well as any additional equipment needed to implement the method.

- Resolution: The level of detail that the monitoring method can provide in measuring changes or damage in the structure being monitored.

- Range: The distance from the structure that the monitoring method can effectively measure changes or damage. This takes into account the maximum effective range of the equipment used in the method.

Based on the performance analysis criteria, Table IX presents the performance analysis for civil structural monitoring methods.

According to Table IX, the cost of the different methods ranges from low to high, with visual inspections being the least expensive and SHM, NDT, and FEA being the most expensive. Ease of implementation ranges from easy to difficult, with visual inspections being the easiest and SHM and FEA being the most difficult. Sensitivity, accuracy, and resolution are all high for SHM, NDT, FEA, GPR, and DIC, while visual inspections and infrared thermography have lower values for these parameters. The range of each method varies from short to medium, with most methods being limited to the immediate vicinity of the structure. Overall, the choice of method will depend on the specific needs of the project, including the level of detail required, the available budget, and the location and accessibility of the structure.

## B. Quantitative Analysis

The quantitative analysis for Civil Structural Monitoring methods involves comparing different monitoring methods across several criteria to determine their effectiveness in detecting changes or damage in civil structures. For this analysis, image processing, machine learning and deep learning approaches are considered. In the following section, the quantitative analyses are conducted for these methods.

*1) Analysis of image processing methods:* In this analysis, the most popular image processing methods are analyzed. These methods involve Edge Detection, Thresholding, Morphological Operations, Region-based Segmentation, Contour Analysis, Texture Analysis, Template Matching, Hough Transform and Connected Component Analysis.

For this analysis, popular performance metrics are considered, which include precision, recall and F-score. The precision, recall and F-score values are typically calculated based on the true positive, false positive, and false negative rates. In this study, we collected the values from previously published research works. Fig. 2 demonstrates the analysis of image processing methods.

*2) Analysis of traditional machine learning methods:* For analysis of traditional machine learning methods, we selected the most used methods in the literature. These methods involve Support Vector Machines (SVM), Random Forests, k-Nearest Neighbors (k-NN), Decision Trees, Naive Bayes, Ensemble methods (AdaBoost), Logistic Regression, and Neural Networks.

Similar to image processing analysis, popular performance metrics are considered, including precision, recall and F-score. Fig. 3 demonstrates the analysis of image processing methods.

TABLE IX. PERFORMANCE ANALYSIS FOR CIVIL STRUCTURAL MONITORING METHODS

| Method | Cost | Ease of implementation | Resolution | Range |
|---|---|---|---|---|
| Visual inspections | Low | Easy | Low | Short |
| Structural health monitoring (SHM) | High | Difficult | High | Short to medium |
| Infrared thermography | Medium | Moderate | Medium | Short to medium |
| Digital image correlation (DIC) | Medium | Moderate | High | Short to medium |
| Ground-penetrating radar (GPR) | High | Moderate | Medium to high | Short to medium |
| Non-destructive testing (NDT) | High | Moderate to difficult | High | Short to medium |
| Finite element analysis (FEA) | High | Difficult | High | Short to medium |
| Acoustic emission testing (AET) | Medium to high | Moderate to difficult | High | Short to medium |
Fig. 2. Quantitative analysis of image processing methods.

Fig. 3. Quantitative analysis of traditional machine learning methods.
Fig. 4.    Quantitative analysis of deep learning methods.

*3) Analysis of deep learning methods:* For analysis of deep learning methods, we also selected the most used approaches in deep-based structural health monitoring systems. These methods involve Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), Generative Adversarial Networks (GAN), Autoencoders, Graph Convolutional Networks (GCN), Long Short-Term Memory (LSTM), Capsule Networks, Attention Mechanisms, Variational Autoencoders (VAE), Deep Belief Networks (DBN).

Similar to image processing and machine learning analysis procedures, popular performance metrics include precision,

recall and F-score. Fig. 4 demonstrates the analysis of image processing methods.

*4) Comparison of the methods:* This section presents a comparison of performance measurements for image processing, machine learning and deep learning methods. Correspondingly, this comparison is conducted in terms of precision, recall and F-score. For this comparison, we calculated the average of precision, recall and F-score for each category of methods. Fig. 5 shows the comparison of the methods.

Fig. 5.    Average precision, recall and F-score for the methods.

## V. DISCUSSION

As discussed above, civil structural monitoring methods refer to techniques and approaches used to detect, monitor, and analyze changes in the behavior and condition of civil structures such as bridges, buildings, and tunnels. In the following, according to the evaluation and analysis section, the key features of the methods used are discussed.

The visual inspection method involves a visual examination of the structure, looking for signs of damage, deterioration, or deformation. It is a cost-effective method that does not require any special equipment, but it is subjective and dependent on the inspector's experience and expertise.

The Infrared thermography method uses thermal imaging cameras to detect changes in surface temperature caused by structural changes. It is non-destructive and can detect changes that are not visible to the naked eye, but it is sensitive to environmental factors such as sunlight and wind.

The DIC method uses two-dimensional images of the structure to detect changes in shape and deformation. It is a non-contact and non-destructive method that provides high-resolution data, but it requires specialized equipment and expertise.

The GPR method uses radar waves to detect changes in the composition and structure of the subsurface materials. It can detect voids, cracks, and other defects that are not visible to the naked eye, but it is dependent on the materials being scanned and can be affected by environmental factors such as moisture.

The FEA method uses computational modeling to simulate the behavior of a structure under different conditions. It is a highly detailed method that provides accurate data on the stresses and strains in the structure, but it requires specialized software and expertise.

The AET method uses sensors to detect high-frequency sounds generated by changes in the structure. It is a non-destructive and sensitive method that can detect changes in real-time, but it can be affected by environmental noise and requires specialized equipment.

## VI. CONCLUSION

This study has offered a comprehensive survey and review of Structural Health Monitoring (SHM) techniques, with a particular emphasis on the integration of IoT sensors. The categorization of existing civil structural monitoring methods has provided a valuable framework for understanding the landscape of monitoring methodologies. By critically assessing the advantages and disadvantages of these methods and conducting a comparative analysis, we have enhanced our insights into the current state-of-the-art in SHM, specifically concerning IoT-based sensors. This paper has underscored the importance of method selection in civil structural monitoring, with each approach having distinct merits and limitations tailored to specific structural requirements and monitoring objectives. The unique contribution of this study lies in its multifaceted approach, combining literature review, categorization, and comparative analysis, to offer a more comprehensive perspective on SHM. there are several promising directions for future research in the field of

Structural Health Monitoring. First, the integration of emerging technologies such as machine learning and artificial intelligence into IoT-based monitoring systems could significantly enhance the accuracy and efficiency of SHM techniques. Investigating these innovative approaches holds great potential for advancing the field. Additionally, further exploration of interdisciplinary applications of SHM, such as its utilization in disaster resilience and predictive maintenance, could expand its practical utility. Moreover, research into the development of cost-effective and scalable IoT sensor networks for large-scale infrastructure monitoring is an area that warrants attention. Finally, investigations into the long-term durability and reliability of IoT sensor deployments in real-world scenarios would contribute valuable insights to ensure the sustainability of SHM systems. These future directions have the potential to shape the evolution of Structural Health Monitoring, making it an even more robust and indispensable tool in ensuring the safety and integrity of civil structures.

*Abstract*—The Internet of Things (IoT) represents a new paradigm where various physical devices interact and collaborate to achieve common goals. This technology encompasses sensors, mobile phones, actuators, and other smart devices that work together to perform tasks and applications. In order to ensure optimal performance of these tasks and applications, task allocation becomes a critical aspect in IoT networks. Task allocation in IoT networks is a complex problem due to the intricate connections and interactions among devices. The task allocation issue is generally recognized as NP-hard, necessitating the development of effective optimization solutions. This paper proposes a solution using the Whale Optimization Algorithm (WOA) to address the task allocation problem in IoT networks. By leveraging the capabilities of the WOA, our algorithm aims to improve energy efficiency and enhance network stability. The performance of the algorithm was tested comprehensively on the MATLAB simulation platform. Our algorithm outperforms existing algorithms in the literature, especially in terms of energy efficiency, as per the findings.

*Keywords—Task allocation; internet of things; energy efficiency; optimization; whale optimization algorithm*

## I. INTRODUCTION

With the rise of the Internet of Things (IoT), a significant technological revolution has occurred over the past few years. The IoT envisions a network where various devices, including actuators, sensors, RFID tags, smartphones, and servers, with different capabilities can interconnect [1, 2]. The objective is to empower these network entities to collaborate efficiently and share their resources to achieve specific goals, such as executing assigned applications [3, 4]. However, the resources available in IoT networks, including electrical energy, memory, processing power, and node capabilities, are often limited. For instance, wireless sensor nodes are typically powered by batteries, resulting in constrained energy levels [5].

Similarly, RFID tags have limited processing capabilities. Considering the size of IoT networks and their heterogeneous nature, resource allocation becomes a non-trivial task to improve network performance [6]. Moreover, IoT networks exhibit dynamic behavior due to widespread deployment in smart settings like smart homes and cities [7]. These applications often rely on opportunistic sensing and networks. Opportunistic networks are characterized by the dynamic creation of connections among nodes without relying on a fixed infrastructure [8]. When forwarding a message, nodes opportunistically choose the next hop based on the probability of bringing the message closer to the recipient. Opportunistic sensing involves deploying sensors to sporadically capture data from the environment whenever their state aligns with the requirements of the application [9]. As dynamic scenarios are characterized by continuous and rapid adjustments, it is not feasible to allocate resources in a centralized manner [10]. Hence, in this context, a decentralized approach to resource allocation is necessary to deal with the dynamic nature of IoT networks [11]. Such an approach should enable nodes to autonomously manage and allocate resources based on local observations and interactions with neighboring nodes. Decentralized resource allocation methods can provide flexibility and adaptability to changing network conditions, making them suitable for IoT networks operating in dynamic and opportunistic environments [12].

IoT task allocation is a critical challenge since tasks must be assigned and fulfilled within specific deadlines. IoT environments present many challenges due to their unique properties and complexities. Task allocation belongs to the class of NP-hard problems, which makes it difficult to find optimal solutions using traditional approaches. Consequently, meta-heuristic algorithms, such as evolutionary algorithms, have emerged as effective tools for addressing this problem. Improving customer service quality is a significant concern in the IoT, and task allocation plays a crucial role in achieving this objective. Tasks represent the requirements of customers, and making appropriate decisions on how to allocate and execute these tasks can greatly enhance network performance and response quality. Various evolutionary algorithm-based strategies have been proposed to solve the task allocation problem in the IoT. These strategies aim to optimize task execution time and improve overall system efficiency compared to traditional methods.

Meta-heuristic algorithms and machine learning offer valuable solutions to address the inherent complexity of task allocation in IoT networks. Meta-heuristic algorithms, such as genetic algorithms, simulated annealing, imperialists competitive algorithm, and particle swarm optimization, provide efficient optimization strategies to tackle the NP-hard nature of task allocation problems [13, 14]. These algorithms iteratively explore the solution space, iteratively refining task assignments based on predefined objectives like energy efficiency, latency, or resource usage. Their adaptability and

ability to find near-optimal solutions make them well-suited for the dynamic and diverse IoT environment. Machine learning, on the other hand, leverages data-driven models and predictive analytics to enhance task allocation decisions. These algorithms can analyze historical task allocation patterns, device capabilities, network conditions, and application requirements to predict the most efficient task-device assignments [15, 16]. By learning and adapting from data, machine learning enables IoT systems to dynamically allocate tasks in real-time, optimizing resource utilization and response times. Furthermore, reinforcement learning approaches can allow devices to autonomously learn and improve their task allocation strategies over time based on feedback from the environment [17].

This paper proposes a novel solution using the Whale Optimization Algorithm (WOA) to address the challenging task and resource allocation problems in IoT networks. By leveraging the capabilities of the WOA, our algorithm aims to improve energy efficiency, enhance network stability, and optimize resource allocation. The performance of the algorithm is tested comprehensively on the MATLAB simulation platform, and our results demonstrate its superiority over existing algorithms in the literature, particularly in terms of energy efficiency. Our approach also involves considering two criteria, the optimal path length and the compatibility between the features of nodes and the task requirements, to determine the best nodes to execute tasks, as well as utilizing the WOA to evaluate and determine the optimal path nodes based on the defined criteria and assigning task allocation abilities to the nodes along the determined optimal path, ensuring efficient and effective task execution. In this paper, we highlight the following objectives:

- Considering two criteria, namely the optimal path length and the compatibility between the features of nodes and the task requirements, to determine the best nodes to execute tasks;

- Utilizing the WOA to evaluate and determine the optimal path nodes based on the defined criteria;

- Assigning task allocation abilities to the nodes along the determined optimal path, ensuring efficient and effective task execution.

The paper is structured as follows: Section II discusses related work in the field, Section III outlines our proposed approach in detail, Section IV presents the results of simulations conducted on the MATLAB platform, and finally, Section V summarizes the key findings and contributions.

## II. RELATED WORK

Multi-cloud computing, which combines multiple cloud providers, has emerged as a high-performance and secure platform for data processing, offering enhanced security measures against potential threats. In this context, Cai, et al. [18] developed a distributed scheduling model that integrates task scheduling and multi-cloud in IoT. The model encompasses multiple criteria, including load balancing, resource utilization, energy consumption, throughput, and cost. To address this complex scheduling problem, a multi-objective

adaptive strategy based on the sine function was proposed. The algorithm leverages the sine function's ability to capture variation tendencies in the population's diversity strategy. The outcomes from experiments prove the effectiveness of the proposed approach in achieving efficient scheduling and enhancing security measures. This work presents a novel solution for tackling the challenging task of data processing in the IoT environment.

Due to limitations in network infrastructure, efficiently transmitting the sheer volume of sensory data generated by IoT to distant data centers poses challenges in the rapidly growing era of big data. The emergence of fog computing, which uses local mini data centers near sensors, is a promising solution for real-time applications. This approach eases the main data center's burden, and cloud-based IoT is fully utilized. In this context, Boveiri, et al. [19] suggested a high-performance mechanism based on the Max-Min Ant System (MMAS), a variant of the ant colony optimization algorithm. The focus of their approach lies in the scheduling of static task graphs in homogeneous multiprocessor environments, which are commonly incorporated in fog computing systems. The key objective of the developed strategy is to effectively adjust task priority values to achieve optimal task order. By incorporating heuristic values derived from previous experience, the proposed approach demonstrates robustness and efficiency. Experimental evaluations using statistical task graphs of varying dimensions validate the effectiveness and reliability of the proposed approach compared to its traditional competitors, highlighting its performance advantages in fog computing environments.

Javanmardi, et al. [20] propose a fog task scheduler called FPFTS that combines PSO and fuzzy theory. The scheduler takes into account network utilization and application loop delay. To assess the performance of FPFTS, simulations are conducted using an IoT-based scenario in iFogSim. The experiments involve varying user movement, data rate, and response time. The findings demonstrate that FPFTS outperforms the delay-priority and first-come, first-served approaches. Specifically, FPFTS achieves an average reduction of 85.7% in delay-tolerant application loop delay compared to first-come, first-served. For delay-sensitive application loop delay, FPFTS achieves an average reduction of 87.1%. Furthermore, FPFTS achieves an average increase of 80.3% in network utilization. These findings highlight the effectiveness of FPFTS in optimizing performance metrics for fog-based IoT applications.

Bu [21] combined PSO and Genetic Algorithms for load balancing in IoT. The algorithm aims to achieve resource balance and alleviate server overload by considering various occupancy rates such as CPU, memory, and network bandwidth. These occupancy rates are used to develop the resource balance model, and a fitness function is used to estimate the influence and adjust the weights accordingly. The PSO algorithm, incorporating a disturbance factor and contraction operator, optimizes fitness functions to arrive at an optimal weight solution. The proposed hybrid algorithm is then implemented, validated, and evaluated against other approaches. The test results indicate that the proposed

algorithm outperforms other ones in terms of resource utilization, request error rate, throughput, and response time.

IoT networks frequently experience node failures due to various factors such as signal disruptions, battery drain, or hardware malfunctions. In extensive IoT networks with complex tasks, the prospect of node failures amplifies in particular regions of the network. Weikert, et al. [22] have conducted a study on node failures and proposed a new task allocation algorithm based on multi-objective optimization to address this challenge. Their algorithm, labeled as the multi-objective task allocation algorithm (MOTA), involves a specialized archive-selection mechanism to increase diversity in the search space. The reliable selection of alternative task assignments in the IoT network is facilitated by maintaining a diverse archive in case of node failures. To examine the effectiveness of their approach, they use a network simulation model and compare the findings with the baseline MOTA and the dynamic task allocation scheduler (DTAS). The performance metrics considered include network lifetime, latency, and availability. The findings of their research indicate that the suggested method leads to substantial enhancements in performance as compared to the current algorithms, especially in situations with a high ratio of tasks to nodes. This highlights the effectiveness of their approach in mitigating the impact of node failures and enhancing the overall performance of the IoT network.

Bali, et al. [23] propose a meta-heuristic algorithm called the Hybrid Artificial Bee Colony Whales Optimization (HAWO) algorithm to optimize energy consumption and time delay in task allocation for edge-based processing devices in the IoT. The HAWO algorithm is formed by combining the ABC algorithm with WOA. This integration overcomes the premature convergence issue observed in the Artificial Bee Colony algorithm, which arises from the local search in the Employee Bee phase and Onlooker Bee phase, leading to looping problems. Through simulation experiments conducted in MATLAB, the researchers observed promising results with the integrated HAWO method. Additionally, compared to benchmark works, the HAWO algorithm exhibits significant enhancements of 60% in the optimum cost metric, 50% in energy consumption, and 25% in time delay.

The rapid advancement of IoT technology has led to the development of various applications and services, including cognitive computing systems and AI-powered chatbots. Nevertheless, due to the restricted computational capacity of IoT devices, cloud services are frequently required to manage data-intensive tasks. This approach, while offloading the processing burden, results in high latency, traffic congestion, and increased energy use. To address these challenges, Fog Computing (FC) is proposed as a solution to enable faster and more efficient data processing in time-sensitive IoT applications. Nematollahi, et al. [24] present a novel architecture for offloading jobs and allocating resources in the IoT environment. This architecture consists of sensors, controllers, and Fog Computing (FC) servers as part of an

enhanced system. The later layer of the architecture operates a subtask pool approach for job offloading and employs a combination of the Opposition-based Learning (OBL) and Moth-Flame Optimization (MFO) algorithm for resource allocation, called OBLMFO. To avoid system load imbalance, a stack cache method is utilized for resource allocation in the subsequent layer.

Additionally, the architecture employs blockchain technology to ensure the precision of transaction data, enhancing resource allocation in the IoT. The evaluation of the OBLMFO model was conducted using the Python 3.9 environment, which involved a variety of different jobs. The outcomes indicate that the OBLMFO model accomplished a 12.18% drop in the delay factor and a 6.22% decline in energy usage. These findings highlight the effectiveness of the proposed architecture and OBLMFO model in enhancing the performance of resource allocation in the IoT, leading to reduced delays and improved energy efficiency.

Aghapour, et al. [25] present a method that utilizes deep reinforcement learning to address the challenges of offloading and resource allocation in the IoT. The proposed algorithm divides the problem into two sub-problems: offloading policy optimization and resource allocation optimization. The strategy for sending tasks to external devices is updated based on information obtained from the environment, and the resource allocation is optimized using the Salp Swarm Algorithm (SSA). By combining deep reinforcement learning with SSA, the proposed method aims to achieve efficient offloading and resource allocation in IoT infrastructures. The performance of the proposed algorithm is evaluated through simulations involving different deep-learning tasks executed on IoT devices with varying capacities of cloudlet devices. The results demonstrate that the proposed algorithm achieves the lowest cost in terms of energy consumption and latency. On average, it outperforms other methods, such as complete domestic processing, complete decentralization, and Jointly Resource allocation and computation Offloading PSO (JROPSO), by 92%, 17%, and 12%, respectively.

Our proposed method, based on the WOA, stands out for several reasons. In contrast to previous approaches that often struggled to optimize energy usage in IoT networks, our WOA-based method explicitly focuses on enhancing energy efficiency. Through rigorous simulations, we demonstrate that our approach significantly reduces energy consumption, making it well-suited to resource-constrained IoT devices. IoT networks are inherently dynamic and face network stability challenges. Our approach leverages the decentralized nature of the WOA to adapt dynamically to changing network conditions. This adaptability results in improved network stability, even in opportunistic and dynamic environments. Previous approaches often lacked the capability to efficiently allocate resources. Our method considers both optimal path length and compatibility between node features and task requirements, ensuring that resources are allocated to nodes best suited to execute tasks efficiently.

## III. PROPOSED APPROACH

This section introduces an algorithm aimed at addressing the task allocation problem in IoT networks. The distribution of tasks is determined by two key parameters: the ability of a particular node to perform subtasks and the distance required to execute those subtasks. The section is divided into three subsections: the problem statement, the network model, and the explanation of the proposed solution.

### A. Problem Definition

The task allocation problem is formulated using a complete graph $G = (V, E)$, where $V$ refers to the nodes representing tasks, and $E$ stands for the edges indicating the routes between the tasks. The user application is divided into multiple tasks that have specific sequential dependencies, and these dependencies are represented using a Directed Acyclic Graph (DAG). A DAG is a directed graph consisting of a collection of nodes and a collection of edges such that all the edges are in the form of $i{\rightarrow}j$, where $i$ and $j$ stand for nodes. Each node in the DAG represents a task, and an edge from node $i$ to node $j$ represents the dependency between task $i$ and task $j$. Task $j$ cannot be executed until task $i$ has been completed, and task j becomes a ready node once all its parent tasks have been completed. In the context of the DAG, node $i$ is considered a parent node of node $j$, and node $j$ is a child of node $i$. To model the costs associated with computation and communication, weights are assigned to each node and edge in the DAG. The weight assigned to a node represents the cost of computation for that task, while the weight assigned to an edge represents the cost of communication between the corresponding tasks. Fig. 1 provides an example of a DAG, illustrating the task dependencies and associated weights. This example demonstrates how the DAG representation captures the sequential relationships between tasks and the corresponding computation and communication costs.

### B. Network Model

The IoT architecture adopted in this study consists of four layers: perception, network, service management, and application, illustrated in Fig. 2. RFID tags and barcodes make up the perception layer. This layer is responsible for collecting and processing real-time information using sensors and smart devices. These devices play a crucial role in capturing data from the environment. The network layer utilizes various technologies to provide networking capabilities. It enables connectivity and communication between sensors, smart devices, and other components in the IoT ecosystem. This layer handles the high volume of data generated by sensors and smart devices, ensuring efficient data transmission and management. The service management layer focuses on analyzing information, handling security, modeling processes, and managing devices. It plays a critical role in handling the collected sensor data, analyzing it for insights, and ensuring the security and integrity of the data. Task allocation, which involves assigning tasks to appropriate resources, is also a responsibility of this layer. Finally, the application layer encompasses programs and applications classified into network type, convergence, business models, and real-time requirements. This layer provides the interface for users to interact with the IoT system and offers various services and functionalities tailored to specific application domains.

Fig. 1. A streamlined DAG for allocating IoT tasks.

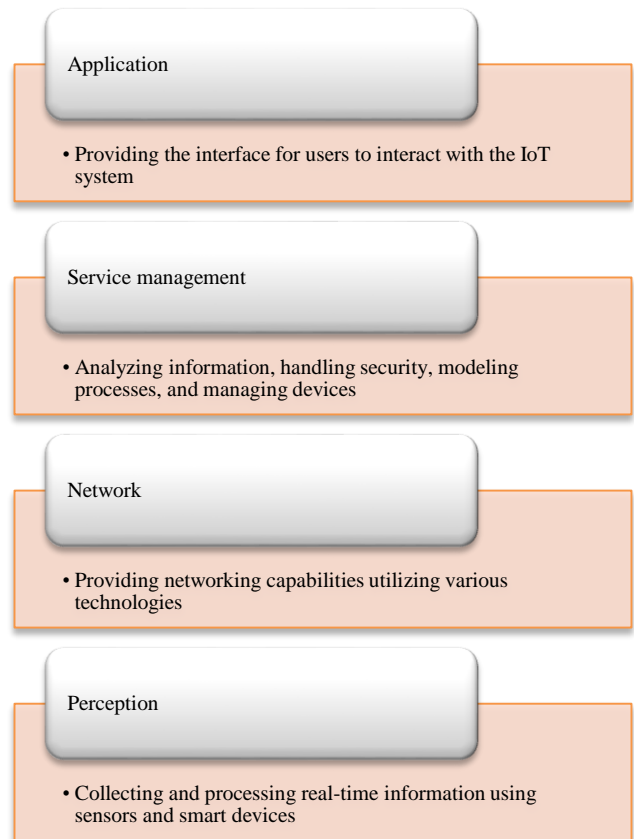

Fig. 2. IoT architecture.

## C. WOA for IoT Task Allocation

The WOA draws inspiration from the hunting behavior of humpback whales searching for food in a multidimensional space. The locations of the whales serve as decision variables, and the objective costs are represented by the distances between the whales and their food source. The algorithm consists of three main operational processes: searching, encircling, and attacking the prey. These processes determine the time-dependent location of each whale [26]. The primary presentation of the WOA is depicted in Fig. 3. Each of the operational processes is described and mathematically expressed to guide the optimization process. The search for prey involves updating the position of each whale based on its current position and velocity. The encircling method simulates the collaboration between whales to encircle the prey and optimize the search process. The shrinking encircling prey process further refines the search space by adjusting the positions and velocities of the whales.

Fig. 3. Position update in a spiral.

The encircling behavior of whales during optimization is mathematically modeled using Eq. (1) and Eq. (2). These equations describe how whales update their positions to imitate the encircling behavior found around the best search agent at the moment.

$$\vec{D} = \left| \vec{C}.\overrightarrow{X^*}(t) - \vec{X}(t) \right| \quad (1)$$

$$\vec{X}(G+1) = \overrightarrow{X^*}(t) - \vec{A}.\vec{D} \quad (2)$$

*X* stands for the position vector, *C* and *A* refers to the coefficient vectors, and *t* is the current iteration. *X\** denotes the position vector of the most optimal solution found thus far. *X\** will be updated if there is a better solution for each iteration. Eq. (3) and Eq. (4) are used to calculate the coefficient vectors *A* and *C*.

$$\vec{A} = 2\vec{a}.\vec{r} - \vec{a} \quad (3)$$

$$\vec{C} = 2\vec{a} \quad (4)$$

Eq. (3) and Eq. (4) contain a coefficient vector $a$ that gradually diminishes from 2 to 0 during the iterations and an unpredictable vector $r$ that change from 0 to 1.

The bubble net attacking strategy serves as the basis for modeling the attacking behavior. To simulate the bubble-net behavior of humpback whales, two main approaches are employed. These approaches are the shrinking encircling mechanism and the spiral updating position mechanism, as depicted in Fig. 3. Humpback whales can utilize either of these mechanisms to capture their prey, with each mechanism occurring randomly with a 50% probability. To introduce randomness, a variable "p" is introduced that ranges between 0 and 1. In the shrinking encircling mechanism, the value of "a" in Eq. (3) is progressively decreased. The value of "A" is determined randomly within the range of [-a, a], while "a" itself decreases gradually from two to zero over a specified number of iterations.

On the other hand, the spiral updating position mechanism mimics the helix-like maneuvering pattern of humpback whales. During the prey attack phase, the optimization algorithm focuses on exploiting potential solutions. Exploitation involves searching within a restricted yet promising region of the search space, with the aim of improving the quality of solutions in the vicinity of a solution denoted as 'S'. This operation intensifies and refines the search around 'S'. The value of "A" ranges between -1 and 1. When |A| is less than 1, exploitation is induced, and all search agents converge to obtain the best possible solution. The updating model can be described using Eq. (5).

$$\vec{X}(t+1) = \begin{cases} \overrightarrow{X^*}(t) - \vec{A}.\vec{D} & if \; p < 0.5 \\ \overrightarrow{D'}.e^{bl}.\cos(2\pi l) + \overrightarrow{X^*}(t) & if \; p \geq 0.5 \end{cases} \quad (5)$$

During the exploration phase, the focus shifts towards exploring new areas of the search space in order to discover potentially better solutions resembling a global search. This phase relies on the variation of the vector "A" to mobilize the search agents. By setting the absolute value of "A" greater than 1, the search agent is forced to diverge significantly in the search space. This stands in stark contrast to the exploitation phase. In the exploration phase, the search agents update their positions by referencing a randomly selected search agent rather than the best search agent, as in the exploitation phase. This introduces a stochastic element into the search process, enabling the exploration of different regions. The searching mechanism can be mathematically represented by Eq. (6) and Eq. (7).

$$\vec{D} = \left| \vec{C}.\overrightarrow{X_{rand}} - \vec{X} \right| \quad (6)$$

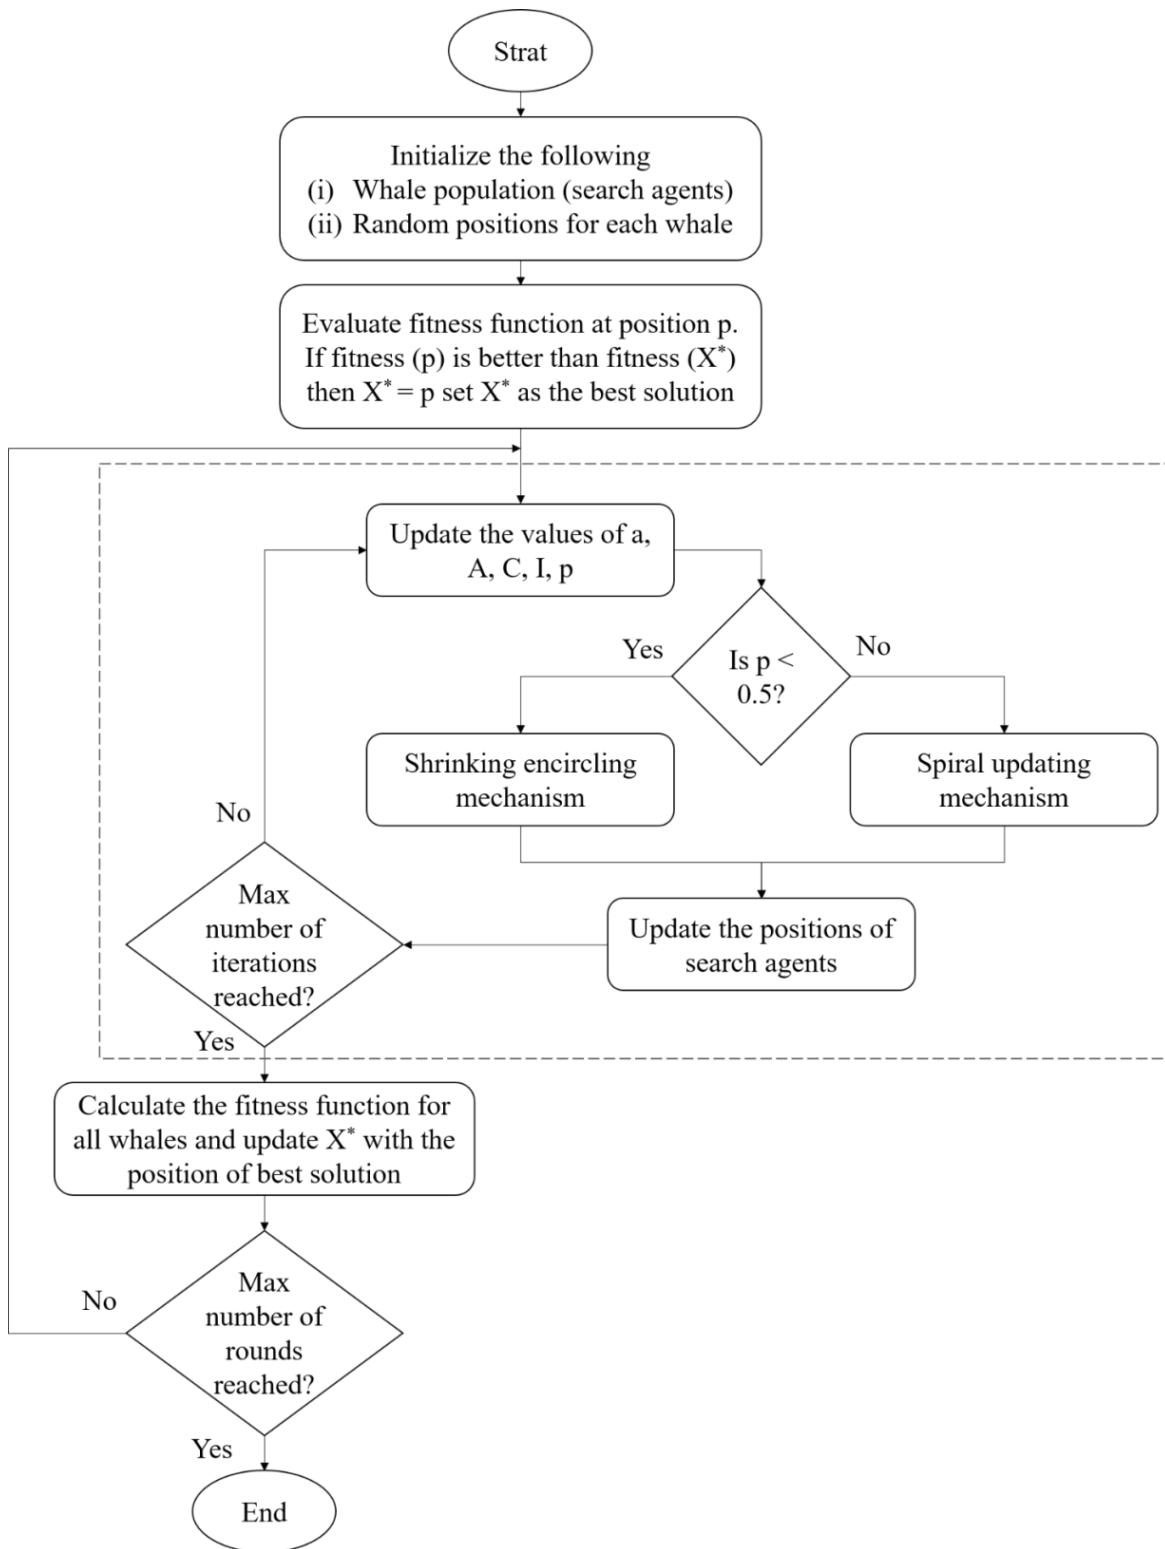
$$\vec{X}(t+1) = \overrightarrow{X_{rand}} - \vec{A}.\vec{D} \quad (7)$$


Fig. 4. Flowchart of the proposed algorithm.

The IoT task allocation problem is addressed using the WOA, where the solution is mapped to the positions of whales. The allocation results are represented by a matrix $x = [x_{ij}]$, where $i$ and $j$ represent the indices of tasks and resources, respectively. If task $T_i$ is allocated to resource $R_j$, then $x_{ij} = 1$.

Conversely, if $x_{ij} = 0$, it indicates that the corresponding whale group's position can be used for task allocation. The WOA simulates the movement and feeding behaviors of whales to find the optimal positions for whale groups, which correspond to the optimal allocation of IoT tasks. The flowchart of the

proposed algorithm is shown in Fig. 4. The process of IoT task allocation using the WOA typically involves the following steps:

- Initialization: Initialize the whale population and set the parameters for the optimization process, such as the maximum number of iterations and the convergence threshold.

- Fitness evaluation: Evaluate the fitness of each whale group based on the task allocation solution represented by the matrix x. The fitness function considers various factors, such as energy efficiency, stability, and resource utilization.

- Updating the best solution: Keep track of the best task allocation solution found so far, and update it whenever a better solution is discovered during the optimization process.

- Movement and feeding: Apply the movement and feeding behaviors of whales to update the positions of the whale groups. This step involves exploring the search space to find better task allocation solutions.

- Exploration and exploitation: Balance the exploration and exploitation of the search space by adjusting the parameters of the WOA, such as the search range and the degree of randomness in the movement and feeding behaviors.

- Convergence check: Check if the optimization process has converged, either by reaching the maximum number of iterations or by achieving a satisfactory level of task allocation performance.

- Termination: End the optimization process and output the best task allocation solution obtained.

## IV. RESULTS AND DISCUSSION

In this section, a comparative analysis of the proposed task allocation method is presented, taking into account the application DAG and connection costs, as depicted in Fig. 1. MATLAB is selected as the programming platform for its capability in matrix calculations, practical functions, and seamless data exchange with different programming languages. It offers high-level programming capabilities and is widely used for computational methods and mathematical problem-solving in academia. For the simulation of the proposed method, MATLAB R2022 is utilized. The dataset from [27] serves as the foundation for this study. Task allocation policies in the IoT have a direct impact on application performance and efficient resource utilization. Finding the optimal approach for task assignment in the IoT presents a significant challenge. The procedure for task assignment in the IoT environment is as follows: initially, tasks and resources are mapped based on the available task and resource data. This mapping ensures task completion and QoS by assigning appropriate resources to tasks. Finally, the submitting user receives an overview of the results, providing an overall understanding of the task allocation outcomes. The convergence diagram for the proposed method is illustrated in Fig. 5. The results indicate that approximately 350 generations of the proposed algorithm

were required to achieve the correct answer, showcasing the effectiveness and convergence of the proposed approach.

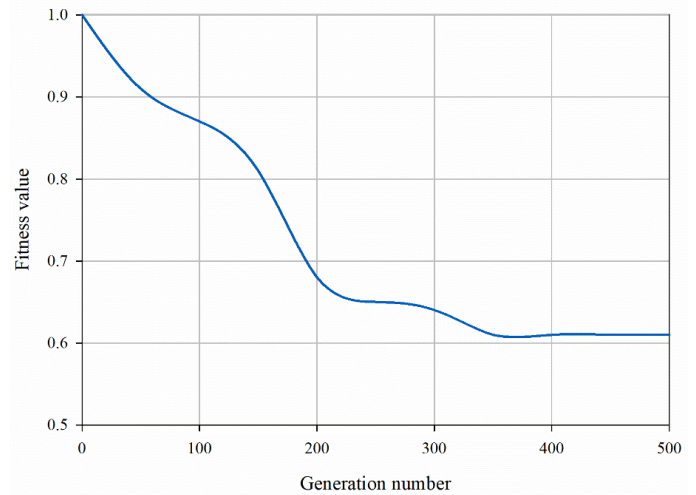

Fig. 5. Convergence diagram.

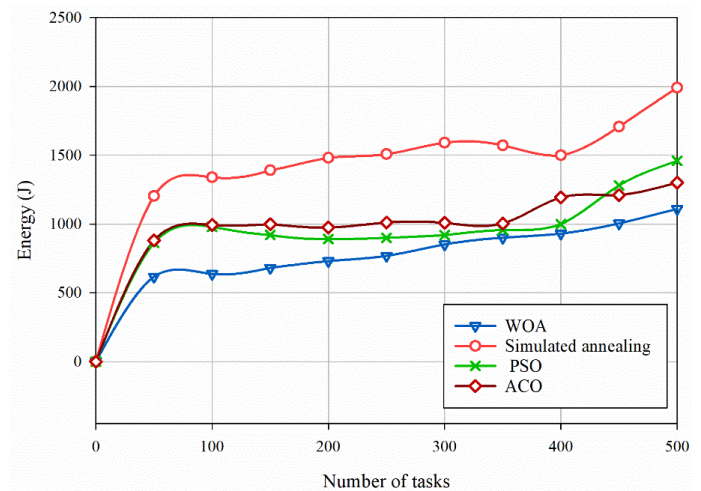

Fig. 6. Energy consumption comparison.

Task allocation in the IoT plays a significant role in energy consumption. In IoT architectures, data centers have the potential to optimize their energy usage by employing strategies such as migrating low-load or idle servers to other servers, shutting down underutilized servers, and transferring idle workloads to different servers. Fig. 6 presents the energy consumption of various algorithms for different task counts. The results demonstrate that as the number of tasks increases, the suggested algorithm exhibits superior energy efficiency compared to other algorithms. This indicates that the proposed algorithm effectively manages energy consumption, making it a favorable choice for IoT task allocation. The IoT offers a favorable environment for users, providing access to software and hardware resources at a reduced cost. In such a network, effective allocation of resources is crucial, benefiting both IoT service providers and ensuring prompt response to user requirements. One of the most critical challenges in the IoT is cost-effective resource allocation. Therefore, it is vital to employ efficient algorithms to address this issue. Fig. 7 illustrates the cost diagram of the proposed method in

comparison to other algorithms, highlighting its effectiveness in reducing the overall cost. The diagram illustrates the superior capability of the proposed method in minimizing costs when compared to alternative approaches. This emphasizes the algorithm's power in optimizing resource allocation and achieving cost efficiency in the IoT environment.

Fig. 7. Cost comparison.

## V. CONCLUSION

With the rapid advancement of IoT technology, the convergence of multiple networks has become the prevailing trend in the IoT landscape. This paper addresses the challenge of optimizing network resource allocation in multiple heterogeneous IoT networks to facilitate seamless information exchange across different services. To achieve this, the proposed approach utilizes a resource allocation algorithm based on the WOA. The primary objectives of this algorithm are to enhance energy efficiency and minimize network latency within IoT networks. Compared to other optimization algorithms such as ACO, simulated annealing, and PSO, our proposed solution demonstrates superiority in selecting optimal assignment decision policies for task allocation and scheduling. Optimizing local and global processes, our approach promises energy efficiency and low-latency communication in the heterogeneous IoT environment. We plan to explore task capability similarity to predict task execution paths in our future work, which could lead to better outcomes. Furthermore, we aim to compare task capabilities to effectively coordinate them, leading to improved outcomes in IoT resource allocation.

# An Optimized Deep Learning Method for Video Summarization Based on the User Object of Interest

Hafiz Burhan Ul Haq, Watcharapan Suwansantisuk, Kosin Chamnongthai

Faculty of Engineering-Department of Electronics and Telecommunication Engineering,
King Mongkut's University of Technology Thonburi (KMUTT), Bangkok, 10140, Thailand

*Abstract*—Surveillance video is now able to play a vital role in maintaining security and protection thanks to the advancement of digital video technology. Businesses, both private and public, employ surveillance systems to monitor and track their daily operations. As a result, video generates a significant volume of data that needs to be further processed to satisfy security protocol requirements. Analyzing video requires a lot of effort and time, as well as quick equipment. The concept of a video summary was developed in order to overcome these limitations. To work past these limitations, the concept of video summarization has emerged. In this study, a deep learning-based method for customized video summarization is presented. This research enables users to produce a video summary in accordance with the User Object of Interest (UOoI), such as a car, airplane, person, bicycle, automobile, etc. Several experiments have been conducted on the two datasets, SumMe and self-created, to assess the efficiency of the proposed method. On SumMe and the self-created dataset, the overall accuracy is 98.7% and 97.5%, respectively, with a summarization rate of 93.5% and 67.3%. Furthermore, a comparison study is done to demonstrate that our proposed method is superior to other existing methods in terms of video summarization accuracy and robustness. Additionally, a graphic user interface is created to assist the user with summarizing the video using the UOoI.

*Keywords—Video summarization; deep learning; user object of interest; surveillance systems; SumMe*

## I. INTRODUCTION

Globally, everyone's first priority is security. On both private and public assets, video surveillance cameras have been deployed as well as other security measures to address this difficulty. At homes, businesses, airports, banks, and other public locations, a variety of security surveillance cameras—both stationary and mobile—have been placed. These cameras are extremely important for monitoring and spotting anomalous activities. They are also useful for assisting with the investigation of incidents or crime scenes, such as car accidents, robberies, murders, and terrorist activities. Additionally, there are presently expected to be over 770 million cameras in use worldwide [1]. Over 2,500 petabytes of video data are produced each day by these cameras, which are typically always in use [2]. It is also estimated that projection growth will exceed 120 zettabytes in 2023 [3]. Every minute, 500 hours of videos are posted to YouTube [4]. Fig. 1 displays daily statistics on the actual data generated by the video surveillance cameras around the world.

Motion detection, time monitoring, facial recognition, recognition of license plates, and other content-based video analysis technologies have already made great progress in the development of video analytic technology. The issue is that manual analysis of the video recordings still needs human intervention (camera operator, security personnel, etc.). Because visual inspection requires concentration and watching the entire video, it is challenging and time-consuming to extract useful information from video footage. In the event of lengthy videos, it could potentially lead to false negatives. Therefore, it is imperative to find a solution that reduces the human time and effort required for manual analysis. To solve this issue, attempts are being made to create a video summary that quickly conveys the essence of the entire video [5]. By identifying and presenting the most interesting and up-to-date content to potential consumers, video summarizing (VS) creates a summary of substantial video content. Security surveillance systems use video surveillance to detect and analyze suspicious or anomalous activity. Individuals also use VS to share sporadic videos on social media, create highlights of different sports, create movie and television trailers, index video content to enable quick browsing of large amounts of video through video search engines, etc. [6, 7]. There have been various attempts by the researchers to propose an automated VS. The majority of VS approaches provide a summary based on choosing key frames that best depict the video during the skimming procedure. For video summarization, the shot boundary detection techniques [8–15] are widely known. Instead of concentrating on a single item, feature-based techniques [16–34] for VS provide a generalized video summary. These methods have trouble accurately recognizing the item, which prevents them from meeting the user's needs. The video is distilled using trajectory-based [6, 25] and clustering [17, 22, 35–38] algorithms that highlight related objects, actions, and events. These methods, however, do not produce a summary of any video that provides information based on the user's interests. As a result, these methods restrict the usage of retrieval tasks and do little to improve users' observing experiences. The summarizing of a video may be accomplished during the video skimming process by choosing shot portions with the use of video editing software like Filmora [38], SpenShot [39], and Davinci [40].

The aforementioned tools are expensive, need extensive storage, and require user skill. In order to capture the user's attention, it is also important to carefully choose segments that accurately portray the complete video. However, the key-frame extraction process appears appropriate for bandwidth-constrained devices and gives the video's core subject in a few frames. Similarly most of the existing techniques work on the principle of key-frame selection by eliminating the redundant

frames that may result in loss of important information related to a user's interest and create vagueness. Many surveillance cameras have been erected in public locations to monitor suspicious actions such as mobile phone snatching, terrorism, robbery, and so on, where the information contained in every single frame is critical. As a result, these strategies restrict the usage of retrieval tasks and do not contribute to improving the users' observing experience. Due to the limitation (disappearance of object and event), these techniques are unable to produce significant results. Though there are various ways that summarize the video based on the user's interest, their fundamental issue is their high processing power needs and limited accuracy.

Fig. 1.    Yearly production of the video's data [3].

This paper proposes a powerful VS method built on the User Object of Interest (UOoI) to address the challenges of video summarizing. The UOoI is the object that a user selects to collect all of the frames in which the selected object appears to summarize the movie. Examples of such objects are people, purses, mobile phones, motorcycles, etc. The proposed VS method has three main steps: i) the selection of the UOoI phase; ii) the detection of the object phase; and iii) the summarization of the video based on the UOoI phase. In order to exclude the unneeded noisy items (other than the OoI) that are essential for the object segmentation, the UOoI selection is first carried out from a database. Then, in order to detect an object that is thought to be a UOoI, the detector YOLOv3 is used. The VS algorithm detects the objects and then summarizes the video, relying on the UOoI. The implications of the proposed method may be summed up as follows, based on the discussion above:

- Initially selection of UOoI is done. The proposed technique chooses the object from the repository and automatically throws out any unnecessary objects; the YOLOv3 is then utilized to discover the needed object.

- The VS technique may identify a single object as well as several objects in a video clip.

- The proposed technique effectively summarizes the video and outperforms all difficulties demonstrated in the SumMe [40] and self-created Dataset.

- The experiments analysis demonstrates that the proposed method works better than cutting-edge techniques in the field of VS.

The remainder of the article is structured as follows: The literature review for departing strategies is described in Section II. The proposed VS method that describes the video summarizing technique is presented in Section III. Section IV discussed the experimental analysis and results. However, the comparative analysis is performed in Section V. Section VI provides an overview of the graphical user interface. Finally, Section VII addresses the conclusion and future work.

## II.    LITERATURE REVIEW

Several VS approaches have been put forth in the literature. A technique for summarizing the video developed by Ngo et al. [33] is based on content balance and perceptual quality. The task was completed by immediately identifying moving objects, which were then used to apply video optimization. An event-based video clarification approach has been presented by Damnjanovic et al. [19]. The method first totals the absolute difference in pixel values between the current frame and the reference frame before calculating each frame's energy. All of the current events in the frames are identified in this manner. The technique for video summarization is then used to extract keyframes. Using three processes to produce the video summary: extracting visual elements, summarizing the movie, and filtering it.

A two-stage technique is presented by Miniakhmetova and Zymbler [10] to produce a personalized summary of the video. The first step is video structure, which involves using different scene identification algorithms to produce a video summary. Using the detection bank, items are picked out of the frames of videos in the second step. The most influential sequences in which items are recognized, which later form a region of the user's interest, are included in the video summary that is produced. Three primary steps—shot boundary identification, redundant frame reduction, and stroboscopic imaging—can be used to summarize video according to a method suggested by Varghese and Nair [8].

The neighboring frame is compared to the current frame to determine the shot boundary. After that, the Structural Similarity Index (SSI) is adopted to eliminate repeating frames. The strobe is also used to display the activities that are already taking place in the film and to grasp the common backdrop. In comparison to the original video, the summarized video's overall volume has decreased by 55%. Lai et al. [15] developed a frame re-composition-based technique utilizing a clustering algorithm, optical flow, and background reduction with the goal of recognizing foreground elements. The foreground object has been identified thanks to the fusion of several pixels. Once the objects or actions have been seen, a sliding window has been utilized to integrate the recognized elements in succeeding frames to produce a spatiotemporal trajectory. The full spatiotemporal trajectory is combined to produce the video summary, and the algorithm has a 97% accuracy rate.

Three factors may be employed to determine a video's summary, according to Srinivas et al. [17]. First, each frame is given a score based on a variety of factors, such as color,

statistical attention, quality, demonstration, temporal segment, and uniformity. After that, it assigns a weight to each value based on the position of the attribute for producing key frames. The weighting is determined using the standard deviation. Lastly, the repeated frames are removed, with frames being gathered in ascending order by considering score. In comparison to previous strategies, this keyframe selection method yields outcomes that are 1.8% better. Frame selection in lecture clips has been studied by Davila and Zanibbi [32], who focused on segmentation by reducing content section conflicts, deleting objects, and re-building every frame to produce a summary of the video. The Kalman filter has been used to monitor human movements in Ajmal et al.'s [27] approach to determining the trajectory. The properties of color are useful for video since the color histogram may be utilized to identify shots and provide a synopsis of the video.

To identify an aberrant frame and eliminate noisy information from the video, Ma et al. [9] have developed a shared representation of neighboring frames. Keyframes are chosen using minimal sparse reconstruction to minimize noise and preserve critical information. A keyframe is the frame with a significant aberrant representation inaccuracy. The average percentage of reconstruction (APOR) and the sparse border are used to manage the keyframe count in a greedy iterative technique for model optimization. A cloud-based system called HOMER was introduced by Meyer et al. [41] for the creation of video highlights. With this technology, the user's emotions may be detected in order to provide a video summary. A dataset captured using a dual-camera system and a video of a home randomly chosen from Microsoft's Video Titles in the Wild (VTW) dataset are both used for experimental research. As a result, HOMER improved by 38% above baseline. Uncertainty detection and image processing technique in decision making has been presented [42-43]. ResNet 152 and a Gated Recurrent Unit (GRU) were used in tandem to summarize a movie, according to Afzal and Tahir [44]. The deep features that were present in the movie are extracted using ResNet 152 in this technique. Similarly, a GRU is utilized to increase the approach's performance and resilience. Utilizing the F-measure 43.7 and the SumMe dataset, an experimental study is conducted. A brief overview of current VS approaches is discussed in Table I.

The majority of current solutions remove unnecessary frames and a few key frames that can lose crucial information pertaining to a user's interest. In order to monitor suspicious actions like mobile theft, terrorism, robberies, etc., where the information contained in each single frame is crucial, numerous surveillance cameras have been erected in public spaces. These methods are unable to yield meaningful results because of the restriction (the disappearance of objects and events). Additionally, no method produces a summary of a video according to the user's specifications, such as one based on a single item (person, car, etc.). The proposed VS method is straightforward and incredibly reliable; it quickly and accurately generates a summary of a video depending on the user's requirements. The user chooses the UOoI as an input in the proposed method, and the algorithm generates the output in accordance with the user's requirements.

TABLE I.     BRIEF OVERVIEW OF EXISTING VS METHODS

| Sr. No. | Authors | Methodology | Remarks |
|---|---|---|---|
| 1 | Varghese and Nair [8] | For the purpose of inspecting the common backdrop frames, stroboscopic effect is used. | 55% reduces of video duration. |
| 2. | Lai *et al.* [15] | By using frame re-composition, it is deleting the irrelevant spatio-temporal segments. For the purpose of creating a video summary, the extracted items are reconnected in the spatiotemporal trajectory. | Only a stationary camera is capable of detecting objects. |
| 3. | Ma *et al.* [9] | To optimize the model based on the adjacent frame, utilize the iteration method that use the average percentage of frame reconstruction. | Dedicated only to fixed-size frames. |
| 4 | Davila and Zanibbi [32] | Focusing the lecture video on the hand-written material that was present on the whiteboard and summarizing the film by removing any uncertainty between the topic sections. | Lower in term of accuracy. |
| 5 | Damnjanovic *et al.* [19] | Identifying and grouping the events shown in CCTV footage. Additionally, two summary types static and dynamic were added. | The main drawback is the possibility of falsely detecting events when the backdrop environment changes. |
| 6 | Ngo *et al.* [33] | This method of video summary caught both attention values and the structure of the video. Video can be organized in a hierarchical tree depending on scenes, groups, etc. to eliminate redundancy. | Low summarization rate about 10-15% |
| 7 | Miniakhmetova and Zymbler [10] | Make a description of the video based on user comments that include likes, dislikes, and neutral criticism in light of aspects influencing the scenario, including item appearance. | Prototype is missing. |
| 8 | Ajmal *et al.* [27] | The Support Vector Machine (SVM) classifier may be used to recognise the individual using a Histogram of Oriented Gradient (HOG), and the Kalman filter can be used to monitor mobility. | By making browsing quickly, the technology decreases video storage and saves time. |

## III. PROPOSED METHODOLOGY

Fig. 2 depicts the architecture of the proposed VS system based on the UOoI. The following key modules make up the suggested system:

- UOoI detection module: detect UOoI in videos using deep learning.

- Dictionary: The UOoI's data repository.

- The video summary is produced by the video summarization module using the frames having a UOoI in the video.
Fig. 2.    Proposed method flow diagram.

### A. *User Object of Interest (Repository)*

Defining the UOoI is the initial stage for VS. An 80-item UOoI dictionary is made specifically for this purpose. The COCO dataset, which comprises 330 thousand pictures and more than 200 thousand labeled images, is used to define the UOoI. It also offers 80 categories for things like cars, people, and handbags [45].

### B. *Object Type Detection*

Yolo (You Look Only Once) v3 is employed in the intended attempt to identify the OoI. The position of the scene and picture where the UOoI is detected and categorized according to the category, such as a person, automobile, bicycle, etc., is determined by the object's detection. Yolo v3 employs a 53-layer modified darknet that is trained on Imagenet. In addition, 53 more layers have been added for job identification, giving Yolo v3's underlying architecture a total of 106 layers. To avoid losing low-level data, there is no pooling layer, and the feature maps are down-sampled using a convolutional layer with stride 2. YOLOv3 is substantially quicker at identifying objects than other object recognition methods [46]. The entire video is processed by Yolo v3 using just one neural network. The network divides the images into areas and generates bounding boxes and probabilities for each region. Logistic regression is used in YOLO v3 to forecast each class score, and a threshold may be used to predict an object's multiple labels. The courses that have scores over a certain level, however, are put in the box [47]. Fig. 3 describes the prediction of bounding box.

where, the bounding-box's x and y dimensions are ($b_x$,$b_y$). However, four coordinates predicted by YOLO v3 such $t_x$, $t_y$, $t_w$, $t_h$ for each bounding box. The predictions are shown as follows if the cell is offset by ($C_x$,$C_y$) from the image's top-left corner and the bounding box prior has dimensions of $p_w$,$p_h$:

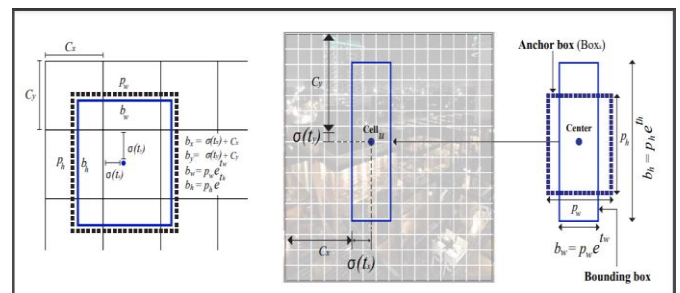

Fig. 3.    Prediction of the bounding box.

$$b_x = \sigma(t_x) + c_x \tag{1}$$

$$b_y = \sigma(t_y) + c_y \tag{2}$$

$$b_w = p_w \, e^{t_w} \tag{3}$$

$$b_h = p_h \, e^{t_h} \tag{4}$$

$$Cofindence = \Pr(Obj).IOU_{Prediction}^{truth} \tag{5}$$

$$IOU = \frac{area(box_{prediction} \cap (box_{truth})}{area(box_{prediction} \cup (box_{truth})} \tag{6}$$

However, Pr(obj) is the value of the probability that an object existed in the grid. The value of Pr(obj) as well as confidence are dependent on object existence in grid. For example, the score of Pr(obj) is 1 if the object is in a grid. Similarly, the score is 0 if the confidence is 0. Eq. (6) describes the $IOU_{prediction}^{truth}$ which is the ratio between predicted objects and real objects. ($box_{prediction} \cap (box_{truth})$) describes the area of the intersection between predicted and real objects; whereas $area(box_{prediction} \cup (box_{truth})$ describe the area that is combined regarding predicted and real objects. Similarly, the object class is predicted $Pr(cls|Obj)$ and defined when it appears in the grid. In such a case, the confidence is measured by the multiplication of the predicted class by the probability of

an object with box convergence, as mentioned in the following equations:

$$Confidence(M) = \Pr(cls|Obj).\Pr(Obj).IOU_{Prediction}^{truth} \quad (7)$$

$$= \Pr(cls_M).IOU_{Prediction}^{truth} \quad (8)$$

### C. Comparison in Terms of Speed and Accuracy

In terms of speed, when compared to other models, Yolo v3 is the best object detection model. YOLO v3 processes data at a rate of 45 fps, which is rather fast in contrast to single-shot detectors (SSD), Faster-RCNN, and R-FCN. YOLO v3's speed performance against other object identification models is shown in Fig. 4. Accuracy, taken into account for the comparison, is another crucial element, as mentioned in Fig. 5. The model Faster-RCNN executes with an accuracy rate greater than YOLO v3, but YOLO v3 has significantly better accuracy than most of the other models. It operates in a realistic situation considerably more slowly than Yolo v3 does. Many other algorithms, like the R-CNN family and SSDs, operate similarly but take longer to complete because of their numerous, intricate phases. On the other hand, YOLO v3 uses single-stage detection to complete the same task using a single neural network. When compared to other models, YOLO v3 operates precisely and executes more quickly, for example, detecting 45 frames per second as opposed to the Faster-RCNN family's detecting just five frames per second [48–49].

Fig. 4. Comparison of object detection models in term of speed.

Fig. 5. Comparison of object detection models in term of accuracy coco dataset [48-49].

### D. Video Summary Generation Algorithm

The key collection process based on objects of interest in videos using the YOLOv3 deep learning model can be described mathematically as follows:

Let:

Vs be the collection of videos, it is denoted by $vs_i$, $i \in [1, n]$.

UO be the collection of desired object, it is denoted by $uo_j$, $j \in [1, m]$.

Fm($vs_i$) be the set of frames in video $v_i$, where each frame is denoted by $fm_{ik}$, $k \in [1, p]$.

The YOLOv3 model calculates the bounding-boxes ($b_{ik}$) and associated class-probabilities ($p_{ik}$) for each frame $fm_{ik}$ in the video $v_i$. The item's size, location, and bounding box coordinates (x, y, w, h) are displayed, and the likelihood that it belongs to a certain class is indicated by the class probabilities. Confidently selecting the frames that include interesting items is a necessary step in the key collection process. This may be achieved by setting a threshold for the class probability. The symbol α will be used to represent this threshold, where $0 \le \alpha \le 1$.

The mathematical method for key collection using YOLOv3 depending on desired object is defined below:

$$Key = \{(vs_{ik}, fm_{ik})|vs_{ik} \in Vs, fm_{ik} \in fm(vs_i), \exists\, uo_j \in O, p_{ik}(uo_j) \ge \alpha\} \quad (9)$$

where:

Key is the set of key frames containing user objects of interest. $p_{ik}(uo_j)$ represents the class probability of user object $uo_j$ in frame $fm_{ik}$.

In this equation, each video $vs_i$ and its frames $fm_{ik}$ are repeated a number of times. We include the video-frame pair ($vs_i$, $fm_{ik}$) in the set of key frames K if an object uoj appears in frame $fm_{ik}$ with a class probability $p_{ik}(uo_j)$ greater than or equal to the threshold. Additionally, to summarize the video using all crucial frames, we may alter the equation mentioned earlier as follows:

$$Smv = \{(vs_{ik}, fm_{ik})|vs_{ik} \in Vs, fm_{ik} \in fm(vs_i), \exists\, uo_j \in uO, p_{ik}(uo_i) \ge \beta\} \quad (10)$$

where:

Smv is the collection of frames containing interesting items whose class probabilities are larger than or equal to the summary threshold β, and where $0 \le \beta \le 1$.

Now that we have set a threshold on the class probabilities, we may collect n important frames and also summarize the video by looking at all frames that meet the threshold and include relevant elements. With these adjustments, the key frame collection procedure is more adaptable, and YOLOv3-based movie summaries are now possible. Utilizing the suggested architecture, the process for creating video summaries is depicted in Algorithm.

Algorithm : YOLOv3-Based Video Key Frame Selection and Summarization

## IV. EXPERIMENTAL ANALYSIS AND RESULT

Python is used as the programming language, and all experiments are done on a computer with specifications such as an Intel Core i5 6th generation with 8 GB of RAM.

In this study, the effectiveness of the proposed method is assessed using a subjective technique. Each test stream has a summarized movie that is produced both manually (using the video editing application Davinci) and automatically using the proposed scheme. In simple terms, this is considered a frame-level comparison. Precision, recall, F1-score, and accuracy are used to assess the performance of the proposed method. The following equations provide the mathematical expressions for various evaluation parameters:

$$Precision(P) = \frac{TP}{TP+FP} \qquad (11)$$

$$Recall(R) = \frac{TP}{TP+FN} \qquad (12)$$

$$F1 - Score(F1) = \frac{2 \times P \times R}{P+R} \qquad (13)$$

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \qquad (14)$$

Two distinct datasets, the SumMe dataset and the author's dataset, are utilized to evaluate and compare the effectiveness of our approach with the manual method. 25 videos that have each had at least 15 human video tags are included in a video summarizing dataset called SumMe. The videos gathered from various sources are included in our own dataset. The videos

come in numerous sizes, including 320 x 240, 352 x 240, 640 x 360, 854 x 480, and 1920 x 1080, and are in the AVI and MP4 formats. The example test video sequences from the SumMe dataset and our self-created datasets are listed in Tables II and III, along with their parameters.

TABLE II.       SUMME DATASET STATISTICS

| Sr. No. | Sequences | Duration | No. of Frames |
|---|---|---|---|
| 1 | River Crossing | 408 sec | 10,200 |
| 2 | Playing ball | 104 sec | 3,120 |
| 3 | Kids playing | 106sec | 3,180 |
| 4 | St Maarten Landing | 70 sec | 1750 |
| 5 | Documentary1 | 74sec | 2220 |

The efficiency of our approach is assessed by a number of tests on video of various lengths and resolutions. The following sections discuss the evaluation of both datasets.

### A. Evaluation of SumMe dataset

For the evaluation of the SumME dataset, different scenarios have been taken from it, as mentioned in Table III. However, the first scenario belongs to a river crossing where several people are crossing the river. In which some of them have a handbag. So, in this scenario, collect all those scenes where a handbag (a user object of interest) appears.

TABLE III.       SELF CREATED DATASET STATISTICS

| Sr. No. | Sequences | Duration | No. of Frames |
|---|---|---|---|
| 1 | Car mirror breaking | 10 sec | 300 |
| 2 | Robbery | 7 sec | 210 |
| 3 | Dog Activity | 9 sec | 900 |
| 4 | Street video | 10  sec | 300 |
| 5 | Person Activity | 15 sec | 450 |

Similarly, the second scenario is related to playing ball, in which a dog is playing with the ball, so in this video, keep tracking all the movements of the dog. In kid's scenarios, a bicycle appears for a limited duration, so it is taken as an object of interest. In the next video, St. Martin is taken as UOoI, and the final video is related to the documentary Under Water, where people are searching for different things, so here the person is taken as UOoI. Fig. 6 describes these scenarios, and Fig. 7 shows the efficiency of our approach by presenting UOoI-detection shots.

*1) Results of SumMe dataset:* As can be seen, the proposed method showed tremendous results on the SumMe dataset. However, some frames can be falsely predicted as well as missed, as mentioned in Scenario 2 of Fig. 7. This is because of distortion in the video, so such frames can only be viewed with the naked eye. In the best case, like Scenario 5, all the frames are properly detected by the proposed method and achieve the highest accuracy. Fig. 8 shows the confusion matrices. The SumMe dataset results are mentioned in Table IV.

TABLE IV.  RESULT OF PROPOSEED METHOD ON SUMME DATASET

| Sr. No. | Scenarios | UOoI | Duration of Video | Duration of summary | P (%) | R (%) | F1 score (%) | Accuracy (%) |
|---|---|---|---|---|---|---|---|---|
| 1 | River Crossing | Handbag | 408 sec | 7.8 sec. | 100 | 79.5 | 88.64 | 98.82 |
| 2 | Playing ball | Dog | 104 sec | 20.17 sec. | 95.8 | 100 | 97.89 | 98.40 |
| 3 | Kids playing | Bicycle | 106sec | 8.02 sec. | 93.6 | 96.4 | 95.03 | 98.54 |
| 4 | St Maarten Landing | Airplane | 70 sec | 13.21 sec. | 100 | 100 | 100 | 100 |
| 5 | Documentary 1 | Person | 74sec | 4.13 sec. | 100 | 83.2 | 90.84 | 97.74 |
| | | | Total Time 762 seconds | Total video summary = 49.20 seconds (93.5%) | 97.8% | 91.8% | 94.48% | Overall accuracy 98.7% |

## B. Evaluation of Self Created Dataset

For the evaluation of the self-created dataset, different scenarios have been taken from online repositories, as mentioned in Table III. However, the first scenario belongs to a car mirror breaking, in which a person broke the car mirror and took the car from it, so the handbag is considered an object of interest. The second scene belongs to a robbery, so the person is taken as UOoI. The third scene is related to monitoring dog activity, so the dog is UOoI. In the fourth and fifth scenarios, bicycles and people are taken as UOoI. Fig. 9 describes these scenarios along with UOoI detection shots in order to show the efficiency of our method. Fig. 10 shows UOoI-based shot detection in order to show the efficiency of the proposed method.

*1) Result of self created dataset:* On a self-created dataset, as can be seen, the proposed strategy yields superior results. However, some frames can be falsely predicted as well as missed because of low resolution or low light in the video, so such frames can only be viewed with the naked eye. In the best case, like Scenarios 1, 3, and 5, all the frames are accurately detected by our method with the highest accuracy. The confusion matrices are shown in Fig. 11. Table V describes the result of the self-created dataset.

Fig. 6.  Sample shot of SumMe dataset.

TABLE V.  RESULT OF PROPOSEED METHOD ON SELF-CREATED DATASET

| Sr. No. | Scenarios | UOoI | Duration of Video | Duration of summary | P (%) | R (%) | F1 score (%) | Accuracy (%) |
|---|---|---|---|---|---|---|---|---|
| 1 | Car mirror breaking | Car | 10 sec | 10 sec. | 100 | 100 | 100 | 100 |
| 2 | Robbery | Person | 7 sec | 1.17 sec. | 100 | 100 | 100 | 100 |
| 3 | Dog Activity | Dog | 9sec | 1.07 sec. | 100 | 83.12 | 90.7 | 95.17 |
| 4 | Street video | Bicycle | 10 sec | 3.20 sec. | 100 | 82.7 | 90.5 | 92.48 |
| 5 | Person Activity | Person | 15 sec | 1.23 sec. | 100 | 100 | 100 | 100 |
| | | | Total Time 51 seconds | Total video summary = 16.67 seconds (67.3%) | 100% | 93.1% | 96.2% | Overall accuracy 97.5% |

## V. COMPARATIVE ANALYSIS

The comparative analysis of the proposed method with the existing state-of-the-art method is done in this section. The following core characteristics serve as the foundation for the comparison analysis:

- C1.Customised User object type (UOoI),
- C2. Frame Extraction based on UOoI,
- C3. Accuracy.
- C4: Rate of Summarization

Table VI demonstrates that the majority of the strategies now in use focus on the general detection of objects rather than one particular, specific object (UOoI). Similar to this, numerous algorithms extracted the video summary by eliminating unnecessary frames and scenes rather than concentrating on the objects. This research demonstrates that our method is distinctive in that it includes the most important qualities for VS. Like the proposed method, it considers the user's input to summarize the video and produce the output according to the user. So the proposed method extracted those frames that were in the region of the user's interest. Furthermore, the proposed method is more accurate and achieved 98.7% accuracy with the highest summarization rate of 93.5% as compared to existing state-of-the-art methods.

Table VII provides another comparison of the proposed work with the existing method.

TABLE VI. COMPARATIVE ANALYSIS WITH EXISTING METHODS BASED ON FACTORS

| Authors | C1 | C2 | C3 | C4 |
|---|---|---|---|---|
| Srinivas et al. [17] | ✗ | ✗ | ✗ | 1.8 % Improved block frame method |
| Ma at el. [9] | ✗ | ✗ | ✗ | 35%-48.28% |
| Varghese and Nair [8] | ✗ | ✗ | ✗ | 55% |
| Ngo et al. [33] | ✗ | ✗ | ✗ | 25% |
| Davila and Zanibbi.[32] | ✗ | ✓ | ✗ | 50% |
| Wang and Ngo [16] | ✗ | ✓ | 94% | 50% |
| **Proposed Model** | ✓ | ✓ | **98.7%** | **93.5%** |

TABLE VII.    ANALYSIS OF THE PROPOESED METHOD'S EFFICIENCY IN COMPARISON TO MODERN TECHNIQUES

| Authors | Precision (%) | Recall (%) | F1-Score (%) |
|---|---|---|---|
| FSM[16] | 40.73 | 54.43 | 46.59 |
| SVM[16] | 49.7 | 71.2 | 58.53 |
| A-HHMM[16] | 77.2 | 74.83 | 75.99 |
| DT[9] | 42.57 | 32.04 | 35.30 |

| VSUMM[9] | 50.43 | 45.34 | 46.51 |
| MSRa[9] | 40.03 | 52.05 | 43.56 |
| SOMP[9] | 41.83 | 55.02 | 45.33 |
| AGDS[9] | 41.35 | 58.40 | 46.27 |
| CRavg[9] | 44.94 | 56.44 | 48.28 |
| DSNET on SumMe[50] | 50.8 | 51.9 | 51.2 |
| **Proposed method on SumMe dataset** | **97.8** | **91.8** | **94.48** |
| **Proposed method on Self- created dataset** | **100** | **93.1** | **96.2** |

## VI.    GRAPHIC USER INTERFACE (GUI APPLICATION)

In the current study, a desktop application is also created utilizing PYQT5 and a Python-based GUI to give users an interactive interface for performing VS after finding objects. The interface of the application created for the selection of input video is shown in Fig. 12. Additionally, it does validation to verify the supplied input's format and contains information about the input. The system requires a video file in MP4 or AVI format as input. The explanation is that MP4 and AVI are both standardized file types. The application does not regard the input as a video if it has fewer than two frames. As a result, it issues a warning notice to the user. The next step is choosing the object type (UOoI) that will be recognized in the input video after the video has been chosen. There are several possibilities for choosing an object in this section. As a result, a user may choose UOoI with ease based on his or her preferences.

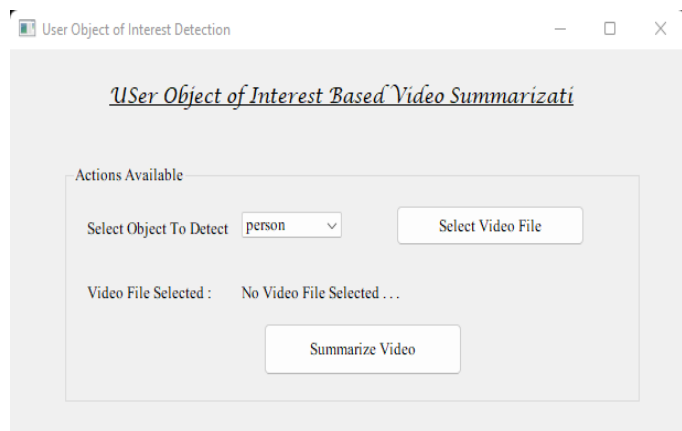

Fig. 12.  Graphical user interface.

## VII.    CONCLUSION AND FUTURE DIRECTION

This article provides a useful VS technique for summarizing videos using the UOoI. The proposed approach is notably more efficient, optimal, and quick as compared to current state-of-the-art techniques for summarizing the video. The UOoI-based solution increases the user's ability to reliably and flexibly construct the pertinent video summary. The proposed method can detect diverse object types accurately and efficiently using YOLOv3. The proposed approach is extensively tested on two different datasets, including the SumMe dataset and my personal dataset. The proposed approach achieves an accuracy of 98.7% with a quick processing rate and a time savings of 93.5% when the complete video is viewed to detect the UOoI on the SumME dataset. Accuracy is 97.5% on the self-created dataset, and overall time reductions are 67.3%. Similarly, a comparative analysis has been performed that shows the proposed work contains novelty with the highest accuracy as well as the highest summarization rate. Furthermore, a GUI that provides ease and configurable object selection is also developed. Future work on this project will expand it to include multiple objects of interest and concentrate on improving its accuracy and summary rate.

# Enhanced System for Computer-Aided Detection of MRI Brain Tumors

Abdullah Alhothali, Ali Samkari, Umar S. Alqasemi*

Dept. of Electrical and Computer Engineering, King Abdulaziz University, Jeddah 21589, Saudi Arabia

*Abstract*—The categorization of brain images into normal or abnormal categories is a critical task in medical imaging analysis. In this research, we propose a software solution that automatically classifies MRI brain scans as normal or abnormal, specifically focusing on glioblastoma as an abnormal condition. The software utilizes first-order statistical features extracted from brain images and employs seven different classifiers, including Support Vector Machine (SVM) and K-Nearest Neighbors (KNN), for classification. The performance of the classifiers was evaluated using an open-source dataset, and our findings showed that SVM and KNN classifiers performed equally well in accurately categorizing brain scans. However, further improvements can be made by incorporating more images and features to enhance the accuracy of the classifier. The developed software has the potential to assist healthcare professionals in efficiently identifying abnormal brain scans, particularly in cases of glioblastoma, which could aid in early detection and timely intervention. Further research and development in this area could contribute to the advancement of healthcare technology and patient care.

*Keywords—Computer-aided detection; MRI; brain tumor; MATLAB; machine learning; support vector machine; KNN*

## I. PREFACE

Brain tumors are abnormal cell growths in the brain or the tissues around it. They can develop from several types of brain cells and can either be benign (non-cancerous) or malignant (cancerous). Patients may experience a variety of neurological symptoms and functional impairments as a result of brain tumors, which can have a serious influence on their health.

The National Cancer Institute (NCI) reports that only 1.4% of all new occurrences of cancer in the United States each year are caused by brain tumors, which makes them very uncommon. Unfortunately, they can have a terrible effect on patients' survival rates and quality of life. There has been a rise in the prevalence of brain tumors in recent years, with an estimated 87,720 new cases being diagnosed in the United States in 2021 [1].

Primary brain tumors and metastatic brain tumors are two broad categories of brain cancers. Primary brain tumors are those that develop inside the brain itself, and they can be further divided into groups according to the cells they originate from. The majority of primary brain tumors, gliomas, which arise from glial cells, make up roughly 81% of malignant brain tumors [2]. Meningiomas, which develop from the meninges (the brain's protective coverings), and pituitary tumors, which develop from the pituitary gland, are other primary brain tumor forms.

Based on their cellular features and aggressiveness, gliomas are further divided into distinct classes. Glioblastoma multiforme (GBM), commonly known as grade IV gliomas, is the most aggressive and malignant type of glioma and is regarded as the least aggressive [2]. Despite rigorous treatment methods, glioblastoma multiforme has a terrible prognosis with a median survival of only approximately 15 months [3].

The symptoms and treatment options of patients may be significantly impacted by the location of brain tumors within the brain, which can also vary. For instance, tumors in the cerebral hemispheres, which control motor, sensory, and cognitive abilities, might result in symptoms including seizures, weakness, language problems, and cognitive deficits. Other parts of the brain, such as the brainstem or cerebellum, can also develop tumors, which can result in deficiencies in the cranial nerves and symptoms including balance and coordination issues [2].

In conclusion, brain tumors can be benign or malignant abnormal cell growths in the brain or its surrounding tissues. They may develop from glial cells, meninges, and the pituitary gland, among other types of brain cells. Examples of primary brain tumors include gliomas, meningiomas, and pituitary tumors, whereas metastatic brain tumors are malignant cells that have traveled to the brain from other parts of the body. Patients who have brain tumors may have a variety of symptoms depending on where in the brain the tumor is located.

## II. INTRODUCTION

### A. Research Goals

The development of early detection and diagnostic tools is essential for enhancing patient outcomes in the case of brain tumors. The development of accurate and sensitive techniques for the early detection and identification of brain cancers should be the main emphasis of research. In order to achieve early identification and precise diagnosis of brain tumors, this may entail investigating cutting-edge image processing techniques. A better prognosis and better patient outcomes might result from early diagnosis, which enables prompt intervention and treatment. There are Computer Aided Detection (CADe) algorithms concerned with zero-one decision identifying normal from abnormal images. However, Computer Aided Diagnosis (CADx) algorithms can identify the type of malignancy within the image. In this research, we are developing a CADe system to identify normal from abnormal images; we are not investigating the type of malignancy.

### B. Literature Review

In a study by Kim et al, deep learning techniques were used to create a computer-aided detection (CAD) system for MRI brain cancers. The algorithm was trained using a dataset of 700 MRI brain scans, and the researchers were able to identify brain cancers with a remarkable 92.5% accuracy. For feature extraction and classification, they used the ResNet-50 convolutional neural network (CNN) architecture. The CAD system has shown encouraging results in helping radiologists quickly and reliably identifying brain cancers. The research by Kim et al shows how ResNet-50 CNN architecture, a deep learning system, can improve the identification of brain cancers in MRI scans. Their CAD system's excellent accuracy indicates that it might be an effective tool for radiologists in the early diagnosis of brain tumors, which might improve patient outcomes. The integration of CAD systems into clinical practice and the assessment of their effects on patient care could be the main topics of future study in this field [4].

Li et al Used a 3D deep convolutional neural network, proposed a CAD system for brain tumor segmentation in MRI data (DCNN). By using a dataset of 392 MRI scans to train their classifier, they were able to segment brain tumors with a high dice similarity coefficient of 0.91. They came to the conclusion that their 3D DCNN model has the potential to help radiologists in precise tumor segmentation for treatment planning because their CAD system performed better in tumor segmentation than other systems currently in use [5].

Dhara et al proposed a CAD system that combines region-based active contour and fuzzy clustering to segment brain tumors in MRI images. To segment MRI images and extract tumor patches, they used the region-based active contour model. Fuzzy clustering was then applied to further refine the tumor regions. Their CAD system outperformed other current techniques, achieving a high accuracy of 96.4% in tumor segmentation [6].

CAD system for brain tumor diagnosis in MRI images was proposed by Raza et al using a combination of machine learning and level set-based active contour. To categorize tumor locations taken from MRI images, they used machine learning methods like decision tree and SVM. Their CAD technology demonstrated promising results in detecting brain cancers with a 97.3% accuracy rate [7].

Patel and Patel (2020) conducted an extensive review on computer-aided detection/diagnosis (CAD) of brain tumor types in MRI images. The authors provided a comprehensive analysis of various computational methods and algorithmic strategies used in CAD systems, including traditional machine learning and deep learning models. They found that while the CAD systems showed promise in enhancing diagnostic accuracy, there were still significant challenges, including handling heterogeneous tumor shapes, sizes, and locations. The research highlights the need for enhanced CAD systems that can effectively address these challenges [8].

Chen et al. (2021) explored the efficacy of deep learning models for brain tumor classification and segmentation in MRI images. They noted that deep learning-based solutions outperformed traditional machine learning methods in terms of accuracy, efficiency, and generalizability. However, they pointed out the need for larger, more diverse datasets and more computing power to fully leverage deep learning's potential for CAD of brain tumors. This work underscores the significance of leveraging advanced machine learning architectures in the development of enhanced CAD systems [9].

Mallah et al. (2022) evaluated the potential of radiomics and machine learning for brain tumor classification. They found that combining radiomics features with machine learning models significantly improved the classification accuracy. However, the researchers also noted limitations, such as overfitting due to high dimensionality of radiomics features. This study suggests the need for CAD systems that integrate radiomics and machine learning while addressing potential limitations such as overfitting [10].

Dutta, Gupta, and Zisserman (2021) reviewed the role of artificial intelligence (AI) in the detection and classification of brain tumors. They noted that AI, particularly machine learning and deep learning, showed great potential for improving diagnostic speed and accuracy. However, they also highlighted the need for systems that can handle real-world variations and provide interpretability of the decision-making process. This work further supports the development of enhanced CAD systems that incorporate AI while addressing real-world variations and interpretability [11].

Bakas et al. (2022) discussed the challenges and opportunities in MRI brain tumor segmentation. They noted that despite the advancements in CAD systems, segmentation of brain tumors is still a challenging task due to the high variability of tumor appearance. They suggested the need for systems that can adapt to the variability of brain tumors and provide reliable and robust segmentation. This research underscores the need for enhanced CAD systems that can effectively segment brain tumors in MRI images [12].

In their study, Verma and Dev (2020) compared various machine learning techniques for MRI brain tumor classification. They revealed that while several techniques show promise, there is no one-size-fits-all solution, and the choice of technique depends on the specific characteristics of the dataset. They emphasized the need for systems that can choose the optimal technique based on the dataset characteristics. This study highlights the importance of adaptability in the design of enhanced CAD systems for MRI brain tumor detection [13].

Using MATLAB-based image processing techniques, several researches have suggested computer-aided detection (CAD) systems for finding brain tumors in MRI data. For instance, Moshavegh et al. created a CAD system that segmented tumor regions from MRI images using region growth and active contour methods in MATLAB, followed by morphological procedures for post-processing. Their CAD system demonstrated outstanding tumor segmentation accuracy of 94.6%, demonstrating the promise of MATLAB-based methods for precise tumor detection [14].

Similar to this, Jeyalakshmi et al. created a CAD system for classifying brain tumors utilizing feature extraction from MATLAB data and support vector machine (SVM)

classification. They used MATLAB to extract several image features—such as intensity, texture, and shape features—and trained an SVM classifier to recognize tumors. Their system successfully classified brain tumors with a high accuracy of 95.7%, illustrating the value of MATLAB-based methodologies for precise tumor classification [15].

In another paper, Shanthi and Kanmani proposed a CAD system for brain tumor detection in MRI images using MATLAB-based image processing techniques such as intensity-based thresholding, morphological operations [7], and feature extraction. To categorize tumor areas, they used pixel intensity and texture information extracted from MRI scans. Their CAD system identified brain tumors with an accuracy of 94.5%, demonstrating the potential of MATLAB-based techniques for precise tumor diagnosis [16].

Moreover, Shukla et al. suggested a CAD system for level set-based MATLAB-based brain tumor segmentation in MRI images. After extracting tumor regions from MRI images using the level set method in MATLAB, they processed the data with morphological procedures. Their CAD system successfully segmented tumors with a high accuracy of 96.3% [8], demonstrating the potency of the level-set method based on MATLAB for precise tumor detection [17].

Using magnetic resonance imaging (MRI) scans, Khan et al. (2019) created a computer-aided diagnostic (CAD) method for classifying brain tumors. Their system was built using a MATLAB implementation of a deep belief network (DBN), a subtype of deep neural network. Automatically extracting hierarchical features from MRI images was done using the DBN, and a classifier was trained to identify different types of tumors. The potential of DBNs for precise tumor classification is shown by the suggested system's accuracy of 92.4% in classifying brain tumors [18].

Convolutional neural networks (CNNs) and recurrent neural networks (RNNs), among other deep learning methods, were combined with MATLAB to create a CAD system by Choudhury et al. (2020) for the detection of brain tumors in MRI scans. CNNs are effective for image recognition jobs because they can automatically identify pertinent characteristics from unprocessed picture input. For modeling the dynamic changes in image sequences over time, RNNs, on the other hand, are built to capture temporal relationships in sequences of data. In this study, RNNs were used to predict the temporal progression of picture sequences, and CNNs were utilized to extract features from MRI scans. The proposed CAD system identified brain cancers with a high accuracy of 95.6%, demonstrating the value of deep learning algorithms for accurate tumor detection [19].

In MATLAB, Kumar et al. combined the watershed technique and k-means clustering to create a CAD system for segmenting brain tumors in MRI images. The common image segmentation algorithm K-means clustering involves assembling groupings of pixels with comparable brightness. On the other hand, the watershed algorithm is a method for improving the borders between various sections in an image. In this study, tumor regions from MRI scans were segmented using k-means clustering, and the watershed technique was then utilized to further refine the tumor borders. The proposed

CAD system successfully segmented tumors with a high accuracy of 95.2% [20].

From [21]-[25], these researches show how MATLAB may be used to create CAD systems for finding brain tumors in MRI images. The creation of precise and effective CAD systems to aid radiologists in the early detection and categorization of brain tumors is made possible by the robust and adaptable platform provided by MATLAB for image processing and machine learning. These studies have achieved great accuracy in tumor segmentation and classification using MATLAB-based algorithms, demonstrating the promise of MATLAB as a useful tool in the study of brain cancer.

In summary, several CAD systems have been proposed for brain tumor detection and classification using MRI images. These systems utilize various deep learning algorithms, such as deep belief networks (DBNs), convolutional neural networks (CNNs), recurrent neural networks (RNNs), as well as optimization algorithms like genetic algorithms (GAs), and clustering algorithms like fuzzy c-means and k-means clustering. These CAD systems demonstrate impressive accuracies ranging from 92.4% to 97.8% in accurately detecting and classifying brain tumors, indicating the potential of these approaches for improving the accuracy and efficiency of brain tumor diagnosis. Further research and development in this field hold promise for advancing the field of medical imaging and enhancing the clinical decision-making process in brain tumor diagnosis and treatment.

## III. METHODOLOGY

In this research paper, data of 167 brain images were analyzed using MATLAB. The analysis took place in five steps in order to discern the normal images from the abnormal ones. These steps are as shown in Fig. 1.

Fig. 1. Flowchart of proposed CAD system for brain tumor.

## A. Data Collection

The dataset was obtained from The Cancer Imaging Archive (TCIA) [26], which consists of 167 brain images that are well-suited for the research purpose. Out of these, 117 images were used for training, with 47 labeled as normal and 70 labeled as abnormal (brain tumor Glioblastoma). The remaining 50 images were used for testing, with 20 labeled as normal and 30 labeled as abnormal. The dataset is labeled, making it easy to interpret and use.

Fig. 2 shows a sample of tumor image, and a normal brain image. The dataset from TCIA contains a variety of images with different angles and views, which can be utilized for classification and feature extraction in the research process. It is open source and can be accessed online, with full details and descriptions available. The full dataset consists of 8798 images from 20 patients, providing a good number of images for analysis.

Fig. 2. Sample of MRI brain images. (top) brain tumor (bottom) normal brain.

## B. Feature Extraction

We want to choose features that might distinguish between benign and malignant conditions or those that are highly accurate, as well as those that do not correlate with disease and are not independent. Only first-order statistical features are taken into account in this study because they haven't been employed exclusively in other studies. The features that are employed are the absolute mean of the derivative of each image, the standard deviation of each image, and the mean of integration of the real images. Also, the same features were retrieved from the photos following a quick Fourier transformation. MATLAB functions like "mean," "std," "mode," "median," and "diff" are used to extract features.

The most noticeable color pixel and frequency of repetition in an image will be determined by the image's mean. The remaining pixels will depart from the mean brightness to a certain extent, as measured by the standard deviation. The derivative is then calculated and employed as a feature to determine which boosts abrupt variations in image brightness. Each type of tumor's retrieved features was plotted in a single figure. Each characteristic is derived from a compilation of photos taken from various perspectives and showing the same condition. Feature extraction from the combination of photos is then applied in the classification procedure.

## C. Classification

The next step in the process is to classify the data after choosing a database and extracting features from the database's photos. We utilize two methods to determine the classifier that performs best: Support vector machine (SVM) with four kernels (Linear, RBF, Polynomial Order2, and Order3), and k-voting nearest neighbor (KNN) classifiers are some examples of diverse classifier types [7]. The information is divided into two categories—normal and pathological brain images—in this step.

The classifier utilized in that software will have the highest accuracy among the roughly seven classifiers that will be employed and compared in this paper. SVM classifiers with discriminant functions of the types "RBF," "POLYNOMIAL," and "LINEAR" make up the classifiers. The remaining classifiers are KNN classifiers with k values of 1, 3, and 5.

## IV. Results and Discussion

Most of the research's findings are numerical. The accuracy of the image classification is the key criterion for the outcomes. The accuracy of the classifier's classification of the two brain states is the most crucial aspect that is being evaluated. The accuracy and error are the most crucial factors for the purpose of this research because they show how effective the classifier is. The TCIA datasets' MRI images were binarily categorized as benign vs. malignant instances by feature extractions; the two classifiers (support vector machine (SVM) and K-voting Nearest Neighbor (KNN)) were evaluated while the system was being trained on 70% of the datasets. Signal & Image Processing: The 11th issue of SIPIJ, published in February 2020 All of these operations were carried out using the MATLAB R2023b programmed, which was tested by 30%.

Furthermore, each classifier uses the same selected feature parameters, with the results displayed in Table I. The accuracy and error of the classifiers are shown in the table. These factors are crucial in choosing the optimal classifier to employ in such software or applications. Tables II and III show comparison of our results with the results of [21]-[25], the comparison is in terms of standard performance indicators including sensitivity, specificity, accuracy, error, and area under the curve (AUC) of the receiver operator characteristic (ROC). There is a very good enhancement in classifiers SVM Linear and KNN with K=5. Also, it shows similarities with the best results of other studies.

TABLE I.      RESULTS OF CLASSIFIERS

| Classifiers | KNN | | | SVM | | |
|---|---|---|---|---|---|---|
| | K1 | K3 | K5 | Liner | RBF | polynomial |
| Sensitivity | 100 | 96.3 | 95.9 | 97.3 | 100 | 100 |

| Proposed Results | 95.9 | 100 | 96.3 | 3.7 | 95.4 |

## V. CONCLUSIONS

The purpose of this research is to create software that automatically divides brain images into two categories. Images can be categorized as either normal or abnormal. The unique aspect of this study is that the program will distinguish between normal and abnormal brain scans. Glioblastoma is the only condition of the brain taken into consideration for this study. In this study, the created software was trained and tested using brain scans from an open source.

The features were then retrieved from the photos after further analysis. First order statistical features were taken into consideration in this investigation. The photos were classified using seven distinct classifiers in order to properly complete the investigation. To ensure that the most precise classifier is chosen, this was done. In addition to a KNN classifier, the classifiers included an SVM classifier. Our findings suggested that SVM and KNN classifiers were equally as accurate.

Future work can adopt more photos and the acquisition of more features is advised since this will undoubtedly improve the classifier's accuracy. Also, it is recommended to apply the method on some other disease like Alzheimer.

*Abstract*—**Quantum technology has been introduced in the IR 4.0, breeding a new era of advanced technology revolutionizing the future. Hence, understanding the key resources of quantum technology, quantum entanglement is vital. Growing interests in quantum technologies has raised comprehensive studies of quantum entanglement, especially on the entanglement classification. Special Linear group, *SL(n)* of multipartite entanglement classification under the SLOCC protocol is not widely studied due to its complex structure, creating a curb in developing its classification method. Therefore, this paper developed and delivered a classification method of pure multipartite, three-qubit quantum state using a combination of Special Linear group, *SL(2)* x *SL(2)* x *SL(2)* model operator under the SLOCC, classifying entanglement using the model operator with certain selected parameters. Further analysis was done resulting in the determination of the six subgroups, namely fully separable (*A-B-C*), bi-separable (*A-BC*, *B-AC* and *C-AB*) and genuinely entangled (*W* and *GHZ*).**

*Keywords*—*Quantum entanglement; entanglement classification; three-qubit quantum system; special linear group; SL(2); stochastic local operations and classical communication; SLOCC*

## I. INTRODUCTION

The utilization of quantum entanglement is important in quantum computing, quantum cryptography, and quantum teleportation. This research main focus is the three-qubit quantum system entanglement classification as multipartite entanglement is considered complex and still an open problem [1, 2].

Quantum entanglement is one of the key resources in quantum information processing [3]. An entanglement can be described simply as multiple quantum subsystems states that cannot be described independently, regardless the distances between the subsystems [4]. To put it simply, an object's properties between two or more objects are dependent to each other. Over the years, quantum entanglement has sparked a massive interest of research in numerous fields namely quantum computing, quantum cryptography and quantum teleportation [5-15].

In quantum computing, the utilization of quantum entanglement principles would be a great power fuel [16, 17]. The concept of superposition and quantum bit also known as qubit is the core of a quantum computer. Yu [15] coined, superposition and qubit allows a quantum computer to process information at a significantly higher rate compared to its classical counterpart. It is reported that the most recent achievement made by one of the leader in the game, IBM quantum computer has exceeded over 1000 qubits and the organization has mapped their journey for the next few years [18].

Kumari and Adhikari [19] and Walter, et al. [20] has stated that in multipartite entanglement classification, there exists six inequivalent classes under Stochastic Local Operations and Classical Communication: One fully separable state ( $A-B-C$ ), three bi-separable state ( $A-BC$ , $B-AC$ , $C-AB$ ), and two genuinely entangled state ( $W$ and $GHZ$ ). To ensure a successful quantum information processing tasks, entanglement classifications is definitely a must.

In a three-qubit system classification, three main transformation protocols are Local Unitary (LU) protocol, Local Operations and Classical Communication (LOCC) protocol and Stochastic Local Operations and Classical Communication (SLOCC) protocol [21]. In this research, SLOCC protocol is utilized. According to Zha, et al. [22], SLOCC is the key in classifying higher dimensions qubit states and assists in dictating its entanglement within. However, Zha, et al. [22] added along with Lin and Wei [23], the entanglement classification can be challenging with a higher qubit quantum system mainly due to its infinite inequivalent SLOCC classes.

The classification of entanglement under the SLOCC protocol remains a significant challenge in multipartite entanglement. This event is still not well understood and rather complicated to be generally analysed [3, 20-22, 24-26]. Consequently, any transformed quantum state cannot be observed to execute the similar quantum information processing tasks [24].

The purpose of classifying entanglement under the SLOCC is to class the quantum states respectively to its tasks [21, 27, 28]. Two states $|\psi\rangle$ and $|\phi\rangle$ are SLOCC equivalent if both can execute a similar quantum information processing tasks [22]. According to M. Cunha, et al. [29], pure three-qubit GHZ and W states are non-equivalent under SLOCC. It means that it is unfeasible to transform a class state into another class state conversely. Li, et al. [30] stated SLOCC holds an advantage over LOCC that is SLOCC take on an uncomplicated mathematical form.

Research on a different group and protocol, namely Special Unitary group, $SU(n)$ under Local Unitary (LU) protocol has been conducted to unfold the issue in multipartite state transformation. Nevertheless, the classification of multipartite entanglement in Special Linear group, $SL(n)$ has its limitation in determining the particular quantum state classes as a consequence of the complexity of multipartite concept under SLOCC protocol [20, 31, 32]. Reason for this complication is that there are infinite number of SLOCC classes and the overlapping Special Linear group, $SL(n)$ subgroups [20, 31].

The main purpose of this research is to develop a straightforward multipartite entanglement classification model under the SLOCC protocol. This study employed Von Neumann entropy measurement, $S(\rho_i) = -\text{Tr}(\rho_i \ln \rho_i), \quad i = A, B, C$, specifically to detect an entanglement of the quantum states. The paper is organized as follows. The research methodology is detailed in Section II, followed by results and discussion in Section III and Section IV concludes the research.

## II. METHODOLOGY

The modeling process of the $SL(2) \times SL(2) \times SL(2)$ operator model included the following steps:

*1)* Understanding the measurement for $SL(2)$ parameterization. The variables of both the generator and parameters were thoroughly investigated at this stage.

*2)* Aligning the selected parameters with the used generator. This step established the parameter range to be used.

*3)* Developing the matrix for the operator model and implementing it in Mathematica 13.2.

*4)* The $SL(2) \times SL(2) \times SL(2)$ operator model full development. The process starts with combining the developed operator model with the initial pure quantum states to create a three-qubit quantum system.

Mathematica 13.2 software was chosen for its symbolic and numerical computations processing capabilities, making it suitable for simulations and mathematical modeling. It offers a powerful platform for creating and manipulating mathematical expressions and formulations, which is crucial for the development of the $SL(2) \times SL(2) \times SL(2)$ operator model.

Three parameters were selected and incorporated into the $SL(2) \times SL(2) \times SL(2)$ operator model because they have a significant influence on the correlated qubits:

*1)* The translation parameter *w* was represented within the range of $-\infty \to +\infty$, illustrating the position of a particle, which can take both positive and negative values.

*2)* The scaling parameter *r* was represented within the range of $0 \to +\infty$, illustrating the size of a particle, which can only take a positive value.

*3)* The rotation parameter *t* was represented within the range of $0 \to 2\pi$, illustrating the precise position of a particle within a plane.

The specific parameter values selected for every initial pure quantum state system are presented in the results section. Both operator model, $SL(2)$ and $SL(2) \times SL(2) \times SL(2)$ was developed in Mathematica 13.2. Fig. 1 shows the steps in developing the matrix for $SL(2) \times SL(2) \times SL(2)$ operator model.

Fig. 1.    SL(2) x SL(2) x SL(2) operator model matrix development.

The development of the $SL(2)$ operator model began with the representation of $SL(2)$ as series expansions of exponential, cosine, and sine functions. The mathematical model was extended after completing the matrix development of the initial $SL(2)$ operator model. The $SL(2) \times SL(2) \times SL(2)$ model is designed to represent a multi-qubit quantum system, as the initial $SL(2)$ operator model only accounted for a single-qubit quantum system. The tensor product of $SL(2) \times SL(2) \times SL(2)$ operator model resulted in a large $8 \times 8$ composite matrix. Illustrated in Fig. 3 is the operator model for $SL(2) \times SL(2) \times SL(2)$. The $SL(2) \times SL(2) \times SL(2)$ operator model is denoted as $SL2$ from this point onward. The development went through several critical steps for its completion as illustrated in Fig. 2.

Fig. 2 shows the $SL2$ operator model in action on a fully separable quantum state, resulting in $SL2|000\rangle$. In this study, the $SL2$ operator model is also applied to bi-separable ($A-BC$) and genuinely entangled (*W* and *GHZ*) quantum states. The combination procedure of $SL2$ is illustrated in Fig. 4.
Fig. 2. SL(2) x SL(2) x SL(2) operator model development.

$$SL(2) = \begin{pmatrix} 2.718282\left(\cos[b1]\right) - i\sin[b1] & 0.3678794\left(\cos[b1]\right) - i\sin[b1] \\ 0 & 0.3678794\left(\cos[b1]\right) - i\sin[b1] \end{pmatrix}$$

$$SL(2) \otimes SL(2) \otimes SL(2) = \begin{pmatrix} 20.08554\left(\cos[b1] - i\sin[b1]\right)^3 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)^3 \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)^2\left(\cos[b1] + i\sin[b1]\right) \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)^2\left(\cos[b1] + i\sin[b1]\right) \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)\left(\cos[b1] + i\sin[b1]\right)^2 \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)^2\left(\cos[b1] + i\sin[b1]\right) \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)\left(\cos[b1] + i\sin[b1]\right)^2 \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] - i\sin[b1]\right)\left(\cos[b1] + i\sin[b1]\right)^2 \\ 0 & \dots & \dots & \dots & \dots & \dots & \dots & 0.049787\left(\cos[b1] + i\sin[b1]\right)^3 \end{pmatrix}$$

## III. RESULTS AND DISCUSSION

As shown in Fig. 4, the $SL2$ operator model is applied to a fully separable quantum state, resulting in a new combined quantum state denoted as $|\psi\rangle$. It was also applied to bi-separable ($A-BC$) as well as genuinely entangled ($W$ and $GHZ$) quantum states. Each quantum state was simulated using two sets of translation and scaling values, each of which contained 24 rotation values. The simulations provide valuable insights into the characteristics of the quantum states when acted upon by the operator model under various values of translation, scaling, and rotation.

The translation parameter was selected within the range of $-\infty \rightarrow +\infty$ while the scaling parameter is selected within the range of $0 \rightarrow +\infty$. The rotation angle parameters were determined and selected within $0 \rightarrow 2\pi$, which encompassed all four quadrants of the Cartesian plane. There are two main case simulations: Case 1 and Case 2. In each case, the translation and scaling values were fixed while different rotation angles were used. Table I shows the values used for translation and scaling, while Table II shows the values used for rotation.

TABLE I. TRANSLATION (*W*) AND SCALING (*R*) PARAMETERS

| Case | Parameters |
|---|---|
| 1 | $w = 1, r = 1$ |
| 2 | $w = -1, r = \frac{1}{2}$ |

The classification process was influenced by the values of all three parameters, as listed in Table I and II. The von Neumann entropy is given by $S(\rho_i) = -\mathrm{Tr}(\rho_i \ln \rho_i), \quad i = A, B, C$. The value of this entropy range between $0 \pounds S(r) \pounds 1$ for all density matrix $r$, with 0 indicating a fully separable quantum state and 1 indicating the maximum value of entanglement. These values enable us to observe the degree of entanglement for specific quantum states and further classify them based on the parameter combinations used in each simulation.

The simulation's initial quantum states cover four out of six entanglement classes under the SLOCC protocol: fully separable ($A-B-C$), bi-separable ($A-BC$, $B-AC$, $C-AB$), and genuinely entangled ($W$ and $GHZ$). The other two classes of bi-separable ($B-AC$ and $C-AB$) were not considered separately because their attributes are similar and can be represented by the $A-BC$ class. The combination of these initial quantum states with the operator model generated a new quantum state, representing the combination after the transformation. The new quantum state was then acted upon by three selected parameters: translation, scaling, and rotation.

Table III summarizes the classification of pure three-qubit entanglement simulations for fully separable, bi-separable, and genuinely entangled states using a special linear group under the SLOCC protocol and the von Neumann entropy measurement. The study successfully classified pure three-

qubit entanglement of the initial quantum states as fully separable, bi-separable, and genuinely entangled. The simulations revealed that the final quantum state remained unchanged from the initial quantum state in some cases, while the parameter selection manipulation changed the final quantum state in others. The simulation results demonstrated that the entanglement class of a quantum state can be altered or maintained by controlling the translation, scaling, and rotation parameters while adhering to the SLOCC protocol. This demonstrates the significance of these parameters in influencing the entanglement properties of a quantum system.

TABLE II. ROTATION (*T*) PARAMETERS

| Quadrant | Angle (π) | Angle (°) |
|---|---|---|
| 1st | $\frac{\pi}{2}$ | 90 |
| | $\frac{\pi}{4}$ | 45 |
| | $\frac{\pi}{6}$ | 30 |
| | $\frac{\pi}{8}$ | 22.5 |
| | $\frac{\pi}{10}$ | 18 |
| | $\frac{\pi}{12}$ | 15 |
| 2nd | $\pi$ | 180 |
| | $\frac{3\pi}{4}$ | 135 |

## IV. CONCLUSION

This study focused on the entanglement classification of the pure three-qubit quantum system using a novel mathematical operator model $SL2$ based on the special linear group principles under the SLOCC protocol. The $SL2$ operator model derived was successfully developed using Mathematica.

The utilization of special linear group definitely has its advantage over special unitary group, as it can principally increase and decrease the degree of entanglement of the quantum systems, while special unitary group maintains the entanglement of quantum states. The simulations resulted in the entanglement classification of the three-qubit quantum system into fully separable ($A-B-C$), bi-separable ($A-BC$), and genuinely entangled ($GE$) states, which were validated with previous studies to demonstrate the success of the developed operator model.

Additionally, the operator model has the potential to be extended to entanglement classification for mixed quantum states for three-qubit quantum systems. Valuable conclusions about the effects of parameter manipulation on entanglement states can be drawn, contributing to a better understanding of quantum entanglement and its potential applications in quantum information processing.

*Abstract*—**Human posture recognition is an essential link in the development of human-computer interaction. Currently, the existing dance movement training methods often require students to constantly watch videos or find a tutor to correct them during practice to achieve good results, which not only takes a lot of time and energy but also creates some difficulties and challenges for students. The research goal of this paper was to use computer recognition technology to detect dance movements and identify body postures. This paper develops a Kinect dance auxiliary training system based on the body skeleton tracking technology of the Kinect 3D sensor, combined with auxiliary dance training. This article not only introduced a fixed axis-based expression method for joint angles to improve the stability of joint angles but also improved the body position detection algorithm using the angle of joint spots to realize the accurate recognition of human body posture. In the experiment, the trainee's arm was raised to the highest position, which could not meet the requirements, and the trainer's wrist should be raised by another 200 mm. Moreover, retracting the hand was too fast, which did not meet the standard action. The test results showed that the system could effectively improve the dance movements of the students.**

*Keywords—Dance motion detection; computer vision; human posture recognition; Kinect 3D sensor*

## I. INTRODUCTION

Dance is a captivating and culturally significant form of expression that has gained popularity not only in the realm of entertainment but also in educational and daily life contexts. Achieving excellence in dance requires rigorous adherence to standards, often necessitating the guidance of specialized instructors. However, the subjective nature of human judgment and the lack of standardized guidance in dance practice present challenges for learners. Furthermore, relying solely on expert feedback can limit the flexibility and accessibility of dance training. This underscores the increasing importance of leveraging intelligent machinery to provide precise regulation and supervision of dance movements, particularly in scenarios where human guidance is unavailable.

In the backdrop of a rapidly evolving society, the field of dance motion detection has seen a surge in research interest. Recognizing the crucial role of subtle, momentary cues in synchronized movements, recent studies have delved into exploring multifaceted dimensions of dance. For instance, Skoe et al. [1] have investigated the nuanced objectives of worldly dance, shedding light on the intricate connection between dance cognition and auditory perception. Thornquist [2] has explored the potential of dance exercise therapy as a means to reduce individuals' reliance on self-expressive substances. Additionally, research methodologies have emerged to assess the efficacy of diverse dance modalities. Reddy and Pereira [3] have proposed a compelling link between performers' and audiences' inner experiences, suggesting the possibility of generating non-local interactions through dance. Sun et al. [4] have introduced a pioneering dance self-learning framework grounded in Laban Movement Analysis (LMA) principles, enabling trainees to autonomously analyze and refine their. However, the algorithm for dance motion detection can be described in combination with sensors and human bones. Shiratori et al. [5] investigated motion structure detection by use of musical information and classified them as primitive motions. Chang et al. [6] employed the Feature Interaction Augmented Sparse Learning algorithm for motion detection based on three public Kinect-based entertainment.

Computer vision has become increasingly important and effective in recent years due to its wide application in many fields. Barbu et al. [7] proposed a new efficient learning scheme that tightens the sparsity constraint by gradually removing variables based on criteria and schedules. His experiments on real and synthetic data showed that the proposed method outperformed other state-of-the-art methods in regression, classification, and ranking while being computationally efficient and scalable and providing a foundation for dance motion detection. Cha et al. [8] proposed a damage detection method by integrating nonlinear recursive filters and non-contact computer vision-based algorithms to measure structural dynamic responses. His experimental results showed that the prediction of stiffness and damping characteristics was reasonable and accurate compared with dynamic analysis calculations, which gave a new idea for dance motion detection. Khan et al. [9] described and discussed case studies on applying Convolutional Neural Networks (CNN) in computer vision, including image classification, object detection, and semantic segmentation. The case study provides more contrastive content for dance motion detection algorithms. Fang et al.[10] developed an automatic computer vision-based method that uses two CNN models to determine whether a worker is wearing a seat belt while working at heights, which plays a good role in promoting a dance motion detection algorithm. However, these algorithms do not consider the complex factors affecting reality, so the algorithm's performance needs to be improved. In another study, Cha et al. [11] proposed a CNN architecture for diagnosing the weaknesses of concrete cracks with no fault detection extraction. Roberts et al. [12] employed the CNN for the classification of cranes to monitor the safety dangers with

utilizing UAVs (Unmanned Aerial Vehicles). Ding et al. [13] recommended an integrated learning model that employs the CNN and long-short-term memory (LSTM) combination to examine the unsafe treatment of the workers. Lecun et al. [14] investigated a combination of CNN and the Mixed National Institute of Standards and Technology (MNIST) for handwritten number detection.

Aiming at the problem of the regulation and supervision of dance movements when performing independent dance exercises without human guidance, this paper used the Kinect method to detect dance movements. Through gesture recognition, key point feature processing, and action classification, a human pose estimation algorithm was established, and motion recognition was performed. The innovation of this paper is that a set of dance assistant training systems based on Kinect is constructed based on Kinect. The system is able to receive and identify trainers' dance steps automatically. Standard moves are not compared in the database and evaluated regarding joint point coordinates and angles, so corresponding operation comparison charts and guidance can be provided.

In the presented paper, a comprehensive methodology is presented in Section II. The experimental procedure to train the dance according to Kinect in conjunction with a discussion on the obtained data is presented in Section III. Eventually, a brief conclusion is brought out about the conducted study.

## II. METHODS OF HUMAN POSE RECOGNITION

### A. Computer Vision

Humans obtain information through hearing, vision, taste, touch, and other senses, among which vision is the most important source of information. Therefore, replacing human eyes with computers for observation has become a hot topic. The perceptron of a computer is generally composed of different image sensors and electronic images. It functions like the human brain, which collects, transmits, stores, and processes image information. Computer vision technology aims to enable computers to observe the outside world independently, recognize the specific information it contains, and adapt to the environment. It can observe and understand the world like a human instead of using the eyes to do specific work. In computer vision technology, acquiring and understanding static objects is relatively easy. However, for the human body, the activities of the body are more dynamic, so it is very meaningful to capture and analyze the action posture of the human body [15], [16].

Dance training is complex and multifaceted, while basic training cultivates basic skills. The purpose of the training is to exercise the strength of each part of the trainer's body and the extensibility of the joints so that the trainer can better control his body when performing actions such as jumping, rotating, and kicking, thereby achieving better results [17], [18]. Based on retaining the original dance form has become a difficult problem in the current dance teaching to achieve accurate and graceful movements.

Kinect was originally used in games and has been used in other ways, as shown in Fig. 1. Since Kinect has open source

code, low prices, rich imaging, and powerful performance, many scholars have combined the Kinect platform to develop many different applications while developing somatosensory games [19].

Kinect can get profundity pictures of the human body through profundity distance. Kinect's imaging guideline depends on optical coding. Its functioning standard is displayed in Fig. 2. The laser shoots the laser light on the article, which the crooked medium dissipates. The laser produces a dot, which is projected on the item. Then, the spot is caught by the sensor. Because of the arbitrariness of the spot, it is important to utilize likelihood and factual techniques to break down the dot's differentiation, force dispersion, and development laws. The dissemination of laser spots is likewise arbitrary and has specific factual regulations [20], [21].

In order to solve the problem of frame rate, the theoretical frame rate of the Kinect sensor is 30 frames per second, and the depth map of each frame can reflect the true depth of a person. The depth image taken after a period can record the next person's real-time location [22]. Kinect can identify and track human bones. First, 25 key spots of the body are identified. Then, the body's skeletal structure is constructed and combined with depth information to form a three-dimensional human skeleton. The skeleton joint point model is shown in Fig. 3.

In order to identify the human body and track the bones of the target, it is first necessary to perform a deep scan on it to obtain the corresponding bone point information, which is then converted into a complete human body model. The color image is a two-dimensional image coordinate system (X, Y), and the depth image is a three-dimensional coordinate system. In the human skeleton coordinate system, (X, Y, and Z) are used as the coordinates. Bone tracking technology separates the background from the human body. Methods such as matrix transformation and machine learning are used to identify the key parts and three-dimensional coordinates of human skeletons combined with depth data, which provides convenience for future research [23]. Fig. 4 shows the skeleton tracking process of Kinect.

Fig. 1. Application of Kinect.
Fig. 2.   Depth imaging system.

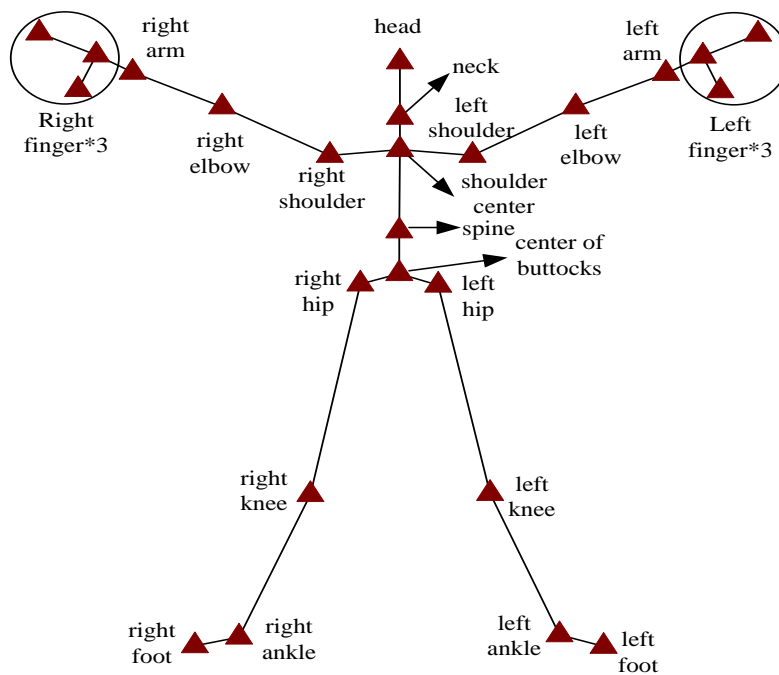

Fig. 3.   Human skeleton joint spot figure identified by Kinect.

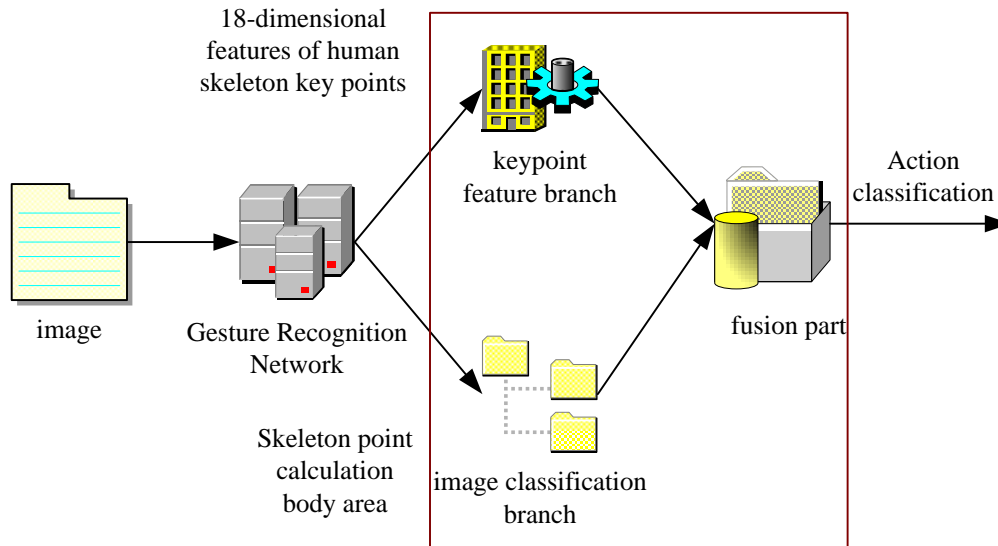
Fig. 4.   Specific steps of Kinect bone tracking.


Fig. 5.  Dance action detection based on gesture recognition.

The per-pixel information can be obtained through body part recognition inference, which defines a density estimate for the body part as follows:

$$f_v(\hat{c}) \propto \sum_{o=1}^{M} e_{ov}\, exp\left(-\left\|\frac{\hat{c}-\hat{c}_o}{q_v}\right\|^2\right) \quad (1)$$

Through Formula (1), the coordinate $\hat{c}$ in a three-dimensional space is obtained. $M$ is the number of pixels and $e_{ov}$ is the weight of the pixels. $\hat{c}_o$ Represents the projection of pixel $\hat{c}$. $q_v$ represents the width of each component. $e_{ov}$ is balanced between pixel inference and the probability of spatial regions.

$$e_{ov} = A(v|O, c_o) \cdot h_z(c_o)^2 \quad (2)$$

This approach improves joint prediction accuracy while guaranteeing a constant density estimate for depth.

This paper introduces a gesture-based action recognition method. First, the image is divided into a posé recognition network with a size of 368*368. The residual network recognizes the key spots of the body. Combining the feature classification of key points and image classification, the classification of the human body can be completed, and the classification of dance movements can be achieved. The specific process of dance action detection based on gesture recognition is shown in Fig. 5.

### B. Establishment of the Human Skeleton Model

In attitude estimation, when using computer vision for attitude estimation, the first thing to solve is how to detect the human body, that is, the detection of moving objects. The recognition of moving objects is the premise of pose estimation and action recognition, and it is also the basis of skeleton tracking technology in pose estimation. The detection of moving objects is a method of using the flow information of light, or according to the difference between frames, to find the moving points of moving objects to realize the extraction of moving objects [24]. The algorithm is the first step in the human body's pose estimation and poses recognition. The moving objects are extracted to remove redundant background information, which is only analyzed for moving objects to achieve better results and accuracy.

Because the data acquisition in Kinect is 30 frames per second, the movement of the human skeleton can be regarded as an accelerated linear movement. L's the number of frames, that is, discrete moments. Then, $x_o(l)$ can represent the position of the joint point o in the X-axis direction at time $l\Delta u$. $\dot{x}_o(l)$ Is the speed of the joint point o in the X-axis direction at time $l\Delta u$. If any point in the body is defined as o, then the Taylor expansion of the formula for the position and velocity of the articulation point on the x-axis is as follows:

$$x_o(l) = x_o(l-1) + \dot{x}_o(l-1)\Delta u + \frac{\Delta u^2}{2!}\ddot{x}_o(l-1)+... \quad (3)$$

$$\dot{x}_o(l) = \dot{x}_o(l-1) + \ddot{x}_o(l-1)\Delta u + \frac{\Delta u^2}{2!}\dddot{x}_o(l-1)+... \quad (4)$$

Similarly, in the Y-axis and Z-axis directions, the position and velocity can be expanded by Taylor. Then, according to Formula (3) and Formula (4), the mathematical model is filtered:

$$x_o(l+1) = SX_o(l) + E(l) \quad (5)$$

Among them:

$$x_o(l+1) =$$

$$\begin{vmatrix} x_o(l+1) \\ \dot{x}_o(l+1) \\ y_o(l+1) \\ \dot{y}_o(l+1) \\ z_o(l+1) \\ \dot{z}_o(l+1) \end{vmatrix} \quad S = \begin{vmatrix} 1 & \Delta u & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & \Delta u & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & \Delta u \\ 0 & 0 & 0 & 0 & 0 & 1 \end{vmatrix} \quad (6)$$

$$E(l) = \left[e_{x_o}(l) \quad e_{\dot{x}_o}(l) \quad e_{y_o}(l) \quad e_{\dot{y}_o}(l) \quad e_{z_o}(l) \quad e_{\ddot{z}_o}(l)\right]^U \quad (7)$$

S is the state transfer matrix of the system. It estimates the movement of skeletal points through the $W(l)$ -diagonal matrix method and the process noise covariance matrix $E(l)$.

The following is the mathematical model for the observation matrix :

$$Z_o(l) = JX_o(l) + B(l) \qquad (8)$$

Among them:

$$Z_o(l) = \begin{vmatrix} x_o^n(l) \\ y_o^n(l) \\ z_o^n(l) \end{vmatrix} \cdot J \begin{vmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{vmatrix}, B(l) \begin{vmatrix} b_x(l) \\ b_y(l) \\ b_z(l) \end{vmatrix} \qquad (9)$$

The observed variable is $Z \in T^n$. J is the measurement matrix. $T(l)$ is used as the covariance matrix of measurement noise $B(l)$.

The above Formulas (5) and (8) are the mathematical model and observation model of the state matrix in the three-dimensional coordinate system of the joint points of the human body. Among them, the joint point models are the position and velocity components under the X, Y, and Z axes. $X_o(l)$, $E(l)$, $Z_o(l)$, $B(l)$, etc. are the results in six dimensions. In the actual solution, the X, Y, and Z axes are independent and similar to each other, which can be calculated under the X, Y, and Z axes, respectively, by using the dimensionality reduction method. Then, the estimated value of the current skeleton point in the x dimension is as follows:

$$x_o(l) = \begin{bmatrix} x_o(l) \\ \dot{x}_o(l) \end{bmatrix} = \begin{bmatrix} 1 & \Delta u \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_o(l-1) \\ \dot{x}_o(l-1) \end{bmatrix} + \begin{bmatrix} e_{x_o}(l) \\ e_{\dot{x}_o}(l) \end{bmatrix} \qquad (10)$$

$$z_o(l) = \begin{bmatrix} 1 & 0 \end{bmatrix} \begin{bmatrix} x_o(l) \\ \dot{x}_o(l) \end{bmatrix} + b_o(l) \qquad (11)$$

With extensive data collection, $S = \begin{bmatrix} 1 & \Delta u \\ 0 & 1 \end{bmatrix}$, $J = \begin{bmatrix} 1 & 0 \end{bmatrix}$, $W(l)$ and $T(l)$ can be derived. Through multiple data acquisition and calculation, $W(l)$ is a diagonal matrix with a value of 0.25 on the diagonal. $T(l)$ Is a diagonal matrix with values three on the diagonal. Then, the Kalman gain matrix $L_l$ of the intermediate operation is derived from this formula. The estimated position of the skeletal joint point o in l frame time is obtained.

*C. Trainer Gesture Recognition*

In dance training, a trainer's posture assessment is an important factor in measuring the standard of his movements. The images produced by Kinect contain dance trainers and training scenes. Therefore, the target is extracted from the training object. In this paper, the inter-frame difference method is used to extract the moving objects of athletic dance trainers.

When using the inter-frame difference method to extract the moving target of the athletic dance trainer, it is necessary to compare the two frames of images and set the threshold. If the difference between two adjacent images is less than a threshold, the content of this image is a training scene, not a training object. If the difference between two adjacent images is greater than a threshold, then the content of this image is the trained object. This program can be expressed as:

$$Q(x,y) = |O_{l+1}(x,y) - O_l(x,y)| \qquad (12)$$

$$F(x,y) = \begin{cases} 0, Q(x,y) < U \\ 255, Q(x,y) \geq U \end{cases} \qquad (13)$$

In the formula, $Q(x,y)$ is the difference image of $O_{l+1}(x,y)$ and $O_l(x,y)$ for two adjacent two frames. $F(x,y)$ To $Q(x,y)$ binarized image. U is the set threshold.

After identifying the training object, feature extraction is performed. In this paper, the Canny algorithm is used to extract the features of the training objects. The Canny algorithm detects the boundaries of the objects being trained. Then, feature extraction is performed by connecting edges. When Canny's algorithm extracts features, it must smooth them:

$$G(x,y) = \frac{1}{2\pi\delta^2} exp\left(-\frac{x^2+y^2}{2\delta^2}\right) \qquad (14)$$

Next, in the image $(x,y)$, the gradient magnitude $Z(x,y)$ and the direction $f(x,y)$ on the pixel point are found :

$$Z(x,y) = \sqrt{a_x^2(x,y) + a_y^2(x,y)} \qquad (15)$$

$$f(x,y) = arv\, tan\left(\frac{a_x(x,y)}{a_y(x,y)}\right) \qquad (16)$$

Then, the non-maximum denoising of gradient magnitude $Z(x,y)$ and direction $f(x,y)$ are used to get candidate edges. An edge point extraction method based on the double-threshold method is proposed and stitched to realize the feature extraction of images.

In response to this situation, a gradient direction-based suppression algorithm is proposed, which is used to extract and connect candidate edge points.

By detecting human body points, the location of the human body can be realized through the point information in the sample library. This paper uses the Euclidean distance method to perform the matching operation between nodes. The specific steps are as follows:

$$J = \sqrt{(x_1, x_2)^2 + (y_1, y_2)^2} \qquad (17)$$

In the formula, J is used to represent the corresponding pose, and the node coordinates and joint point coordinates detected in the sample library are $(x_1, x_2)$ and $(y_1, y_2)$.

Using the above steps, the body poses estimation of the sports dance trainer is completed.

## III. EXPERIMENT OF DANCE-ASSISTED TRAINING BASED ON KINECT

In light of Kinect, this paper fosters a dance partner preparing framework in view of Kinect. This paper utilizes Kinect innovation to gather standard movement information for a PC. A data set of standard dance acts is made and utilized format. The mentor's development information and the layout pose are contrasted to understand the assessment of the learner's development pose, which brings the digitalization of dance preparation into another stage.

Ballet is the most logical and standard dance. It focuses on the accuracy of the developments and communicates the artists' feelings and contemplations with exclusive requirement dance steps. Expressive dance essential preparation is an expert, standard, and logical dance education. To this end, this article treats fundamental artful dance preparation as a trial dance-helped workout.

## A. System Design

The centre substance of the framework incorporates information securing, handling, and examination. On this premise, the movement boundaries are investigated. A set of standard dance developments is built using the mentor's development data. The information handling is, for the most part, to fix the impeded joints and re-establish them. Information examination is to think about the development data between the mentor and the standard developments. The related preparation plan is acquired in order to work on the capacity of the mentor rapidly. The engineering of the framework is displayed in Fig. 6.

Hardware for this article includes Kinect for Microsoft Windows 2.0 and a PC with Windows 8. The Kinect is connected to the computer using a USB interface. Kinect is used to acquire 2D, deep images of the human body, which are also analyzed and processed.

In terms of software, it mainly includes capturing the action and analyzing action information. The motion information collection part mainly completes the collection of two-dimensional images of the human body, skeletal nodes, and depth. The movement information analysis compares the couch's motion information with the corresponding data in the confirmed dance motion database. The key point is to compare each link's positions and joint angles. Fig. 7 shows the operation interface design of the system.

## B. Data Collection

To justify the dance steps of the students, it is necessary to have a standard dance step for comparison. This part uses the trainer's action extraction and the occlusion point information to restore and obtain the standard motion data.

This article maps each data label to an action name. It is stored uniformly as exercise information for training personnel to compare. There is a whole of 30 sets of primary instructing moves in the info archive. Every group is divided into four decomposing movements, with a total of 120 movements, which meets the basic requirements of the students.

Using Kinect technology, data collection of ballet hand positions is carried out. The trainer performs a series of dance steps before the Kinect. Kinect can capture the trainer's dance in real time and correct it through the occlusion point to obtain the trainer's physical condition. Finally, the training results are compared with the standard motion data.

Fig. 6. Block diagram of the Kinect-based dance assistant training system.

Fig. 7. Design of the software interface of the auxiliary training system.

*C. Dance Auxiliary Training*

This section of dance-assisted training mainly analyzes the trainer's key parts and the joints' angles. The auxiliary training system (see Tables I and II) collects each trainee's movement key point coordinates, which are compared with the standard movements of the choreographer (see Table III). By comparing the movement trajectories of various points, it is easy to find the dissimilarity between the couch's move and the approved move.

TABLE I.        COUCH 1 ACTION JOINT COORDINATES

| Part | Standard dance joint point coordinates | |
| --- | --- | --- |
| | *Abscissa* | *Y-axis* |
| head | -79.2 | 217.1 |
| Neck | -24.6 | 31.7 |
| left shoulder | -149.9 | -49.1 |
| left elbow | -376.1 | -51.8 |
| left hand | -652.9 | -60.2 |
| Right hand | 96.5 | -7.4 |
| Right elbow | 81.4 | 222.7 |
| Right shoulder | 48.0 | 508.4 |
| Right knee | -106.4 | -864.6 |
| Right foot | -67.0 | -1158.7 |
| left knee | -236.7 | -936.7 |
| left foot | -312.5 | -1169.7 |

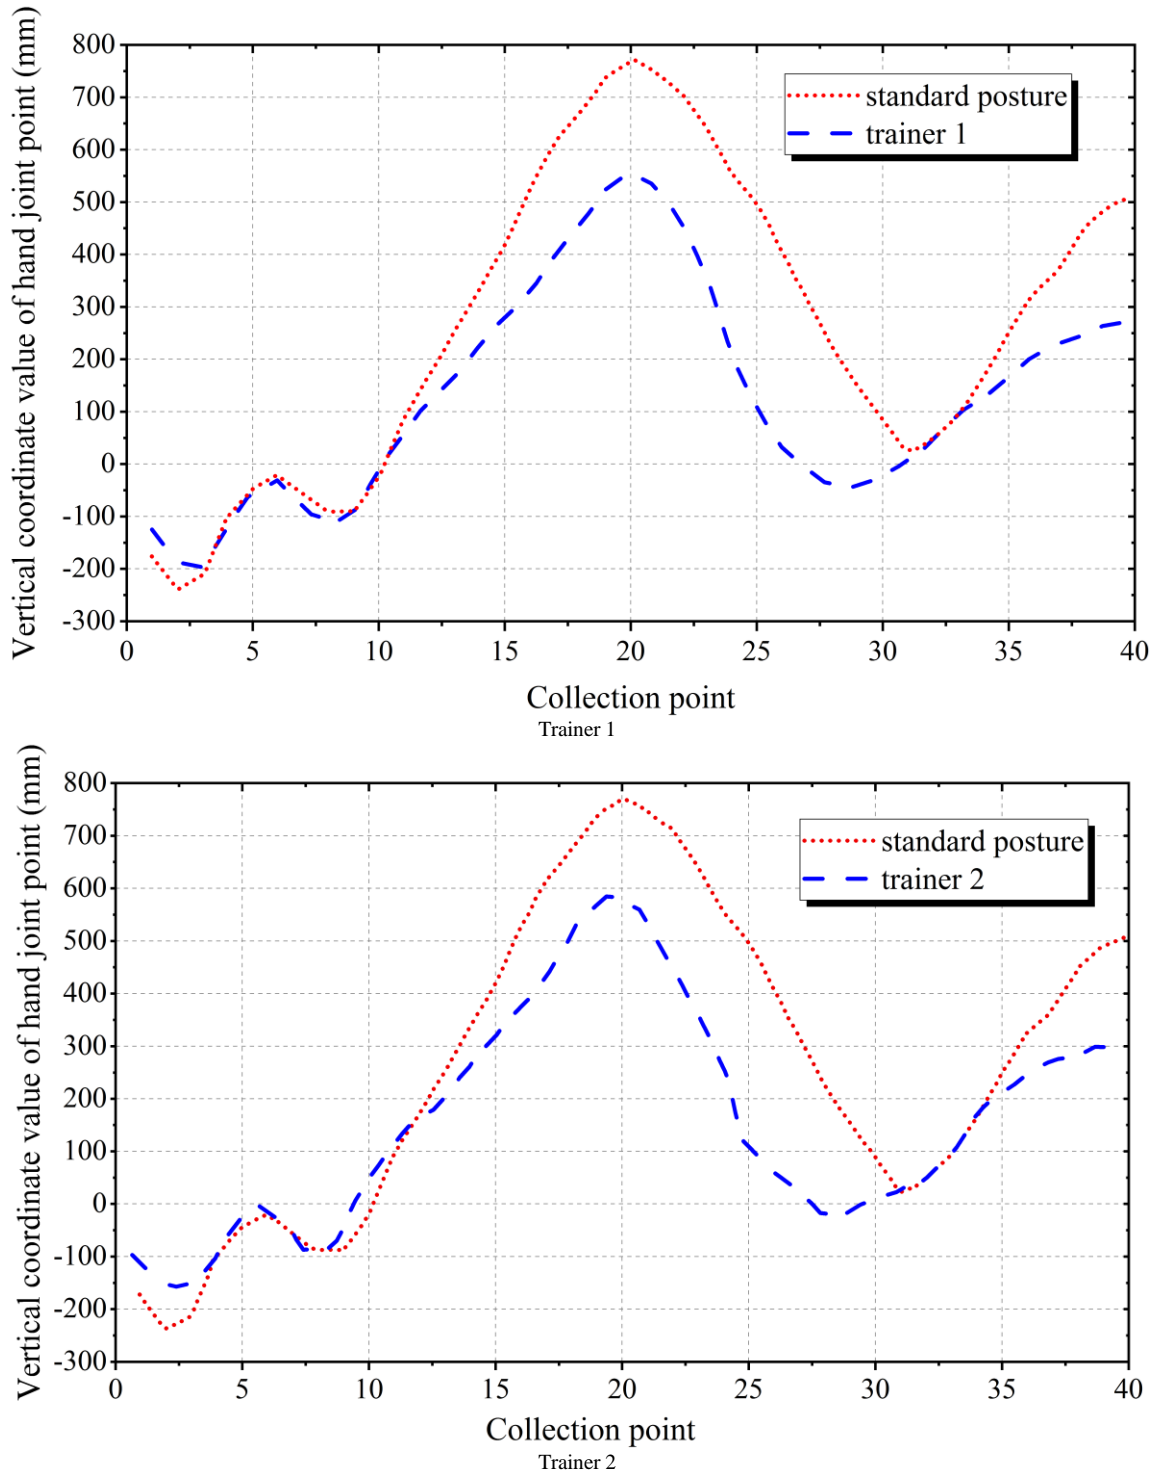
TABLE II.        TRAINER 2 JOINTS ACTION COORDINATES

| Part | Standard joint dance spot coordinates | |
| --- | --- | --- |
| | *Abscissa* | *Y-axis* |
| head | -81.4 | 217.2 |
| Neck | -26.6 | 31.0 |
| left shoulder | -151.5 | -51.3 |
| left elbow | -376.1 | -53.6 |
| left hand | -652.8 | -62.5 |
| Right hand | 96.8 | -9.6 |
| Right elbow | 80.9 | 222.7 |
| Right shoulder | 47.4 | 508.1 |
| Right knee | -108.0 | -866.4 |
| Right foot | -68.8 | -1160.2 |
| left knee | -238.5 | -938.4 |
| left foot | -314.6 | -1172.0 |

TABLE III.        STANDARD ACTION JOINT COORDINATES

| Part | The trainer's joint spot coordinates | |
| --- | --- | --- |
| | *Abscissa* | *Y-axis* |
| head | -68.5 | 269.9 |
| Neck | -68.5 | 74.9 |
| left shoulder | -208.7 | -2.4 |
| left elbow | -407.7 | -108.5 |
| left hand | -634.8 | -180.2 |
| Right hand | 309.9 | 373.1 |
| Right elbow | 237.0 | 153.2 |
| Right shoulder | 91.2 | 1.6 |
| Right knee | -127.4 | -828.1 |
| Right foot | -161.0 | -994.5 |
| left knee | -23.6 | -856.9 |
| left foot | -12.4 | -1000.3 |

It can be seen from Table I, Table II, and Table III that the height of the trainer's arm raises to the highest point does not meet the requirements. The difference between the data of Trainer 1 and Trainer 2 is not particularly large, which is within a certain range. It can be seen that the abscissa of the coordinates of the two trainers is slightly different from the abscissa of the standard dance joint point. The standard abscissa is -12.4. Trainer 1 is -312.5, and Trainer 2 is -314.6, which is over 300 errors. The comparison of Fig. 8 can be drawn from the above data. As can be seen from the graphs in Fig. 8(a) and 8(b), the trainer's wrist should be raised by approximately 200 mm. Moreover, the speed of closing the hand is too fast, which does not meet the standard action.



Trainer 1

Trainer 2

Fig. 8. Comparison of the movement trajectories of the two trainers and the standard movement trajectories.

On this basis, three hand movements in dance are analyzed. The included angle of each joint in this action is obtained. It can be seen that there is a certain difference between the movements of the trainer and the standard movements. Teachers of different ranks would be able to carry out aimed teaching based on their own abilities. Fig. 9 shows the disparity of the joint angles between the trainer and the standard movement. Fig. 9(a), (b), and (c) are the comparisons between Action 1, Action 2, and Action 3, respectively.

The following description is made with reference to operation 1 (operation at five positions) of Fig. 9(a). As can be seen from the figure, the angle between the trainer's right wrist-right elbow-right shoulder is rather big. The included angle of the waist-right knee-right ankle is also rather big. Therefore, the next time the trainer exercises, the five elbows and right arms should be straightened. At the same time, the trainer should lean the waist slightly forward and bend the right leg. The angle between the neck-right shoulder-right elbow is too big, and the angle between the left wrist-left elbow-left shoulder is relatively tiny. Therefore, in the next exercise, the trainer should try to reduce the curvature of the left elbow and left wrist as much as possible.

(a) Action 1

(b) Action 2

(c) Action 3
Fig. 9. Comparison of the joint angles of the trainer and the standard movement.

(a) Trainer's five-position hand movement

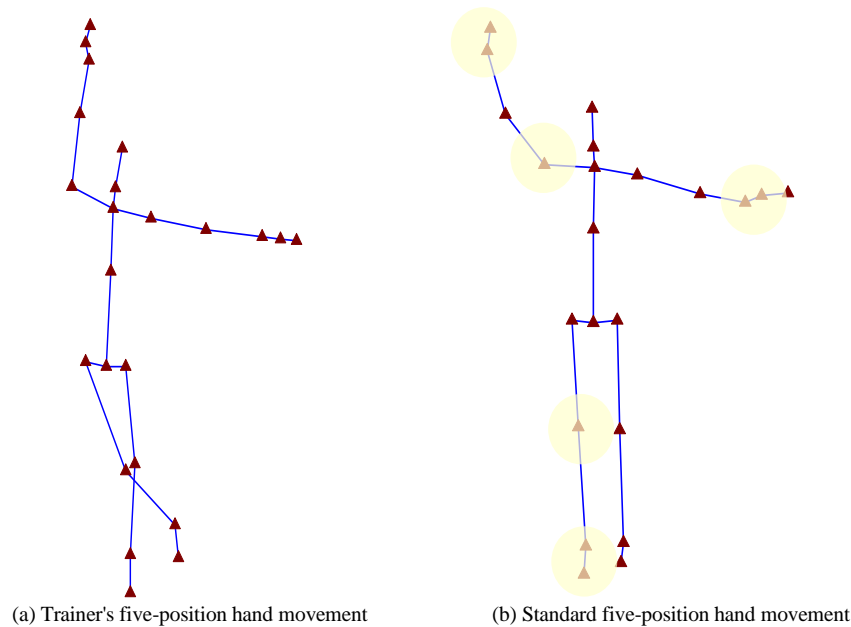
(b) Standard five-position hand movement


Fig. 10. Comparison of the five-hand movements of the trainer and the standard five-hand movements.

In order to more intuitively compare the movements of the trainer and the dance instructor, the system shows the dissimilarity between the teacher's and the approved moves, as shown in Fig. 10. Fig. 10(a) is the operation of five hand exercise trainers. Fig. 10(b) is a standard five-hand exercise.

The equipment and programming portions of the framework are talked about exhaustively above as far as information assortment and standard dance moves are placed into the framework. A standard human dance present data set is built. The information handling part fixes the covered key parts and re-establishes the skeleton of the human body. Assistant preparation incorporates joint point situating and joint point-based helper preparation. The artist's dance act is examined by the directions of the endpoint and the point framed by the joints. The framework can acquire the related preparing program through correlation, which empowers understudies to make fitting changes as indicated by the prompts of the product in order to accomplish the impact of helper preparing.

## IV. Conclusion

In this study, we leveraged the capabilities of the Kinect3D sensor and harnessed its skeletal tracking technology to capture comprehensive dance movements and training data. These data were meticulously compared to standard movements, providing users with a valuable tool to discern the nuances of their own performance. This innovative approach has far-reaching implications for dance instructors, professional dancers, and dance enthusiasts seeking to refine their skills through dedicated training and self-education.

The primary achievement of our work lies in its capacity to empower individuals to make precise adjustments to their dance postures, thereby ensuring the utmost accuracy in their dance practice. A significant advantage of this method is the liberation from the constraints of geographical location, time limitations, and spatial boundaries. Dancers can now engage in training sessions at their convenience, transcending traditional barriers. This expanded accessibility to training opportunities enhances the versatility and adaptability of our dance motion detection algorithm.

Furthermore, our system offers an interactive experience that not only facilitates correct posture adjustments but also cultivates a sense of rhythm among users through computer-assisted feedback. By embracing digitalization and informatization, we contribute to the ongoing modernization of dance training methods.

In conclusion, our work demonstrates the potential of computer vision and Kinect technology to revolutionize dance training. The ability to receive real-time feedback and guidance, combined with the freedom of practice, opens new avenues for dancers to hone their skills. However, it is essential to acknowledge that our approach does have limitations, including [mention limitations here], and we envision several exciting directions for future research. As we continue to explore these frontiers, we anticipate further advancements in the field of dance motion detection and its application in enhancing dance education and practice.

## Data Availability

Data is available in our manuscript.

## Conflicts of Interest

We confirm there are no potential competing interests in our manuscript.

# Seamless Data Exchange: Advancing Healthcare with Cross-Chain Interoperability in Blockchain for Electronic Health Records

Reval Prabhu Puneeth[1], Govindaswamy Parthasarathy[2]

Assistant Professor, Department of Computer Science and Engineering,
NMAM Institute of Technology - Affiliated to NITTE (Deemed to be University)[1]
Research Scholar, School of Computing and Information Technology, REVA University, Karnataka, India[1]
Professor, School of Computing and Information Technology, REVA University, Karnataka, India[2]

*Abstract*—The rapid digitization of healthcare records has led to the accumulation of vast amounts of sensitive patient data, stored across various systems and platforms. To ensure the secure and efficient exchange of Electronic Health Records (EHRs) among healthcare providers, researchers, and patients themselves, the concept of cross-chain interoperability within blockchain technology emerges as a promising solution. Nevertheless, existing blockchain platforms exhibit several limitations. In order to address the issue of non-interoperability, the suggested method involves creating a connection between two similar blockchain networks. This solution is exemplified through the use of an Electronic Health Records (EHR) structure, which is distributed across distinct Ethereum Testnets and implemented via a Solidity Smart Contract. The paper aims to demonstrate the viability of bridging the gap and fostering seamless interoperability between blockchain networks. However, establishing effective communication between these smart contracts proves to be a complex endeavor, whether within a singular blockchain or spanning multiple blockchains. This complexity presents a formidable obstacle, particularly when diverse hospitals require the sharing or exchange of critical information. Consequently, a solution becomes imperative to facilitate cross-chain communication among smart contracts. This solution provides seamless operation both within the confines of a single blockchain and across disparate blockchains. By achieving this, cross-chain interoperability can be realized, enabling distinct blockchain networks to mutually comprehend and actively engage with each other.

*Keywords—Electronic health records; data sharing scheme; blockchain technology; solidity smart contract; cross-chain interoperability*

## I. INTRODUCTION

Telecare Medicine Information System (TMIS) takes use of the dramatic improvement in telecommunications and information technologies to deliver healthcare to patients in their homes. TMIS enables doctors to collaborate and share vital information about their patients' conditions, even when they are physically separated by long distances and working from different offices. In this way, TMIS drastically reduces the price of care by making it more accessible to more people. If the most recent state of a patient's health is to be taken into account while making medical decisions, then an effective electronic-health (e-health) system is essential. However, it might be difficult for doctors to effectively diagnose and treat new patients because they lack immediate access to the patient's complete medical history and other relevant data [1]. EHRs contain information about patients, including demographics, lab results, medical scans, clinical notes, billing data, sensor data, medical history, medications, insurance details, and more; in an e-health system, these restrictions may be less of an issue. Ensuring the confidentiality, privacy, and integrity of data within this system is unquestionably crucial. Nevertheless, the specific needs of different e-health systems may vary depending on the privacy laws in place in the country where the system is located [2]. Although there is still work to be done on interoperability and privacy concerns, EHR are now widely recognized as an integral element of the healthcare business.

Many scholars have proposed confidential data-sharing strategies to meet the expanding demands of the healthcare industry. Conventional healthcare data-sharing systems, on the other hand, rely on a centralized system that does not provide a safe method of exchanging data with other medical-related organizations. However, because regulatory bodies may lack access to data held by medical institutions, there is a significant opportunity for improper exploitation of patients' medical information [3]. Consequently, in the event of resource sharing, data-sharing methods cantered around a centralized framework are not appropriate for the advancement of e-medical records.

### A. Blockchain Technology

Blockchain stands as an advanced database technique that fosters transparent data exchange across a network. It operates on the principle of organizing data into interconnected "blocks" that form an unbroken "chain." In this analogy, the blocks in the blockchain are akin to nodes in a linked list, collectively constituting the chain [4].

Within each block of the blockchain, you find data and a hash value that establishes its connection to the preceding block. A significant feature of this technology is the inherent inability to modify links or alter the chain without gaining widespread consensus. This ensures that the information remains meticulously arranged in chronological order. As a result, blockchain technology provides an immutable ledger capable of recording a diverse range of transactions.

Blockchain solves problems by generating a decentralized, unchangeable method of recording transactions. Each party in a real estate deal may have their own ledger thanks to blockchain technology. Both parties must agree to a transaction before it is finalized, and the ledgers will be updated simultaneously. If any transaction in the past is changed, the integrity of the entire ledger is compromised [5]. These features of blockchain technology have led to its use in several fields, most notably the creation of digital currencies like Bitcoin.

The privacy concerns associated with the implementation of EHRs as healthcare data increasingly moves into the digital realm. Governments globally have introduced legislation and regulations to protect personal information, yet data breaches within electronic health records continue to rise, with theft and loss being the primary causes. This underscores the critical need for stricter control and limited access to patients' private medical data [6]. The blockchain technology could offer a potential solution. It describes blockchain as a decentralized, distributed ledger system that encrypts and links data in a secure and transparent manner. Consensus algorithms ensure agreement among network nodes regarding legitimate data access, and data is only added to the blockchain after undergoing validation for accuracy and relevance [7].

Blockchain is noted for its advantages, including user autonomy, increased data sharing transparency, and heightened data privacy and security. The importance of decentralization lies in its ability to create a robust and tamper-resistant system where altering data becomes difficult without alerting other nodes in the blockchain network. Encrypting data within each block using cryptographic hashes like the SHA-256 algorithm for enhanced privacy and security. These hashes make it extremely difficult to reverse-engineer the original data from the hash value, thereby protecting the blockchain against tampering by malicious actors. Through a combination of encryption, decentralization, and consensus mechanisms, blockchain offers a promising solution for safeguarding sensitive healthcare data in the increasingly digital healthcare landscape [8].

*B. Blockchain Interoperability*

Blockchain interoperability is the ability to view, access, and share data across various blockchain networks. It emphasizes the significance of interoperability in making blockchain applications more transparent and efficient. In the healthcare context, the term "interoperability" refers to the exchange of patient data between different electronic health record systems, with challenges arising from hardware and software heterogeneities. The idea of smart contracts, which are programs that execute, predefined operations on a blockchain [9]. However, it points out limitations in the inter-network communication between smart contracts, highlighting the need for solutions to enable cross-chain communication among them [10]. The ultimate goal is to achieve cross-chain interoperability, allowing different blockchains to understand and interact with each other. The importance of addressing non-interoperability issues and suggests building a bridge between similar blockchain networks, using Electronic Health Records (EHR) as an example.

The structure of the upcoming sections in this paper is as outlined below: Section II elaborates on the prior approach to utilizing blockchain-based EHR. In Section III, the techniques proposed for this study are introduced. The advancement of the experiment, which validates the assertions of this research and includes the results, is covered in Section IV. Lastly, Section V provides the experiment's conclusions.

## II. Literature Review: Related Studies

Blockchain is a decentralized ledger that records and shares a comprehensive history of transactions and electronic events among its participants. A significant feature is that most participants validate all public transactions, ensuring the permanence and non-disputability of stored information. This addressing the vital need to safeguard and maintain sensitive patient data in a secure cloud-based environment, addressing concerns related to data creation, distribution, storage, and retrieval in the healthcare sector [11].

The solution involves using Blockchain technology to protect cloud-based medical records. By combining distributed computing with blockchain, disparate healthcare providers can establish secure connections, facilitating remote access to patient information while ensuring its confidentiality. Data undergoes encryption before uploading to the cloud, and healthcare providers must decrypt it for access. The use of cryptography during encryption ensures secure data transmission between clients and servers [12].

Personal health records (PHRs) are often stored and processed in centralized client-server architecture in conventional healthcare systems. Due to technological and infrastructure limitations, PHR kept at a healthcare facility remain in repository and cannot be easily shared with other institutions [13]. There is no efficient and confidential data exchange process in place if a patient has to see many doctors or hospitals. Health Insurance Portability and Accountability Act (HIPAA) may safeguard patients' privacy; however this is questionable because it does not take into account whether or not the patient is personally involved.

According to the author [14], studies on the use of blockchain technology to ensure confidentiality and safety in healthcare are commonplace on the distributed ledger. However, they have diverted emphasis from the distribution of the encryption/decryption key needed to ensure PHR confidentiality and instead cantered it on the maintenance of individual health records. In order to construct trustworthy and decentralized systems, blockchain offers a shared, immutable, and visible history of all transactions. This opens the door for the use of blockchain technology in the creation of a safe and reliable PHR data management system. This study introduces an approach that empowers patients by necessitating them to possess the information required to deduce the encryption /decryption key from previous transactions within blockchains. Through this key-based access restriction, patients gain control over their own medical records. If you're looking for a vibrant industry that embraces technology to provide superior care with a focus on the patient, look no further than healthcare.

Artificial intelligence (AI), the Internet of Things (IoT), and blockchain provide a diverse set of uses that may be put to good use in the healthcare industry. Potentially improving monitoring processes and decreasing clinical-related mistakes is one role that healthcare environments may play. To improve healthcare delivery, [15] presents a new architecture that integrates ambient intelligence into the healthcare infrastructure. As the foundation of the network, blockchain ensures the safekeeping and sharing of data among all of its participants. In order to collect data on vital signs, a hardware prototype is created using a Raspberry Pi Model 4B.

The high-performance computing system, integrated with machine learning algorithms and blockchain capabilities, is employed to efficiently store critical patient data and notify healthcare professionals of any discrepancies. Comparative analysis reveals that this new system surpasses existing models in terms of reliability and latency. Metrics like mean average error (MAE), mean square error (MSE), and root mean square error (RMS) are used to comprehensively evaluate algorithm performance. Notably, this system offers the seamless integration of pre-existing models and demonstrates effective functionality overall.

However, the security challenges associated with patient data storage in IT systems have hindered the progress of e-healthcare. The introduction of blockchain technology offers a potential solution, which is explored in the work outlined in reference [16]. This research establishes the foundation for blockchain-based health information management, encompassing a public ledger, private ledger, smart contracts, and context-based access control. The proposed design ensures patient data access, security, and system compatibility, while also presenting an efficient approach to managing complex medical processes. Furthermore, the report delves into the application of blockchain technology in healthcare, emphasizing its potential for confidential patient data exchange for scientific research. Smart contracts are recommended for maintaining patients' medical histories, described as innovative, accessible, interoperable, and auditable.

Prominent healthcare communication networks generate data and information, but recent years have seen these systems become targets for cyberattacks due to inadequate security measures. The ease of conducting such attacks is attributed to the widespread availability of powerful computers and various malicious tools. The article compares several technology types and examines blockchain-based approaches to firmware enhancement, addressing their limitations such as large storage requirements and centralized firmware storage.

Additionally, the study in [17] outlines a general architectural framework for Internet of Healthcare Industry (IoH) applications, incorporating blockchain technology, Local Differential Privacy, and cloud computing (Icedrive). The study highlights the potential uses and challenges in integrating blockchain and cloud computing into IoT applications while also considering the application of blockchain in the future of the healthcare industry. This research is anticipated to facilitate the development of blockchain-based IoT applications.

At present, distinct blockchains within the same network lack the capability to seamlessly interact with each other. For instance, the exchange of data between Ripple and Ethereum remains infeasible. Furthermore, achieving blockchain interoperability entails navigating intricate procedures.

## III. METHODOLOGY

A patient-centered approach has been put into practice, wherein patients take responsibility for controlling access to their Electronic Health Records (EHRs). The architectural plan is designed around the concept of hospitals using distinct EHR platforms. Both platforms require healthcare participants to register through smart contracts or chain code. The attending physician engages in consultations with the relevant patients and inputs their EHRs into the system. These EHRs are then hashed, and the resulting hash value is used to create a blockchain block, establishing ownership of the EHR. The proposal suggests dividing the EHR into offline and online sections, with the patient's identity characteristics linked to the offline data during online data uploads. Any document-oriented database can be used to store the offline data. Access requests to the electronic health record are routed to the patient for approval when initiated by a system participant. Patients retain control over their Electronic Health Records (EHRs) and can determine who has access to their records and the extent of information shared. A crucial element in our system is the use of hash locks, particularly when connecting to an EHR from an external system. For instance, if a stakeholder from System B requires access to a patient's EHR in System A, a hash lock is created for that specific EHR, as outlined in study [18]. This hash lock grants the stakeholder in System B access to the patient's EHR, facilitating information retrieval. Fig. 1 provides a graphical representation of our architecture, illustrating how blockchain technology can streamline the exchange of electronic health records.

Proposed system has two major components. The system design along with appropriate representation and explanation has been given below:

Fig. 1.    Electronic health record framework.

### A.  Smart Contract Structure

Within a specific hospital's smart contract, two distinct user types are present: Doctors and Patients. Users can register themselves via the user interface and receive a private-public key pair to facilitate secure data sharing. Once registered, users can log in using their credentials, granting them access to their respective functionalities, as detailed in study [19]. Doctors have the ability to create records and perform record searches, while Patients can access their own records and share data when required.

The execution of these functions is achieved through a Solidity contract, accessed via a Python script. To ensure data security during storage and retrieval, a secure approach is maintained by utilizing the IPFS protocol. Data is securely stored on IPFS and the resulting hashes are recorded within the Ethereum blockchain for traceability and verification purposes. Fig. 2 illustrates the architecture of an individual smart contract.

Fig. 2. Architecture flow of individual smart contract.

Certainly, the individual smart contract that operates within the context of a specific hospital for managing user interactions between Doctors and Patients, the individual smart contract streamlines the interactions between healthcare providers (Doctors) and patients, enhancing communication and data sharing. Patients have greater control over their medical records, promoting privacy and data autonomy [20, 21].The integration of IPFS and Ethereum blockchain ensures data security, traceability, and transparency. In essence, the individual smart contract serves as a pivotal component within Hospital X's digital infrastructure, providing a secure, efficient, and transparent means of managing medical records and interactions between healthcare providers and patients. Fig. 3 shows the flow of the user interface.

Fig. 3. Flow of the user interface.

### B. Cross-Chain Interoperability

When two or more blockchain networks or platforms are able to interact with one another without any hitches in the flow of information or transactions, we say that they are cross-chain interoperable. It addresses the challenge of isolated blockchains that operate independently and cannot directly interact with each other [22, 23]. Achieving cross-chain interoperability is crucial for creating a more connected and efficient blockchain ecosystem.

Different blockchain networks, such as Ethereum, Binance Smart Chain, Polkadot, and others, have their own protocols, consensus mechanisms, and features. Traditional blockchains operate in isolation, and transactions within a specific blockchain are not easily accessible or verifiable by other blockchains. Cross-chain interoperability aims to enable communication, data sharing, and asset transfers across multiple blockchain networks.

### C. Interoperability Structure

In Fig. 4, the architecture of the interoperability approach is depicted. It involves an Intermediate Contract that holds the Name, network, and address of each hospital contract. Every hospital must register its details with the intermediate contract. When Hospital A requires access to data from Hospital B, the following steps occur:

- Switch to the Intermediate contract network.

- Retrieve the network and address of Hospital B.

- Switch to the network of Hospital B.

- Retrieve the contents from Hospital B's contract.

- Revert back to the original contract network and return the data.

This process allows for secure and controlled data sharing between different hospital contracts.

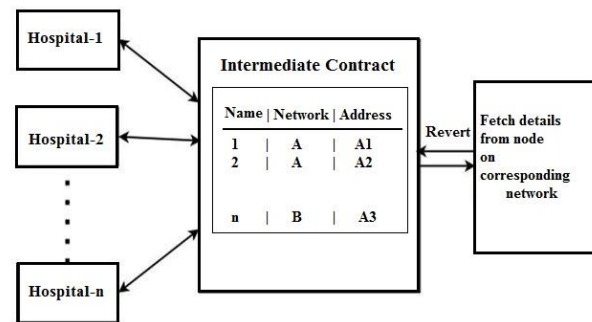

Fig. 4. Architecture of interoperability approach.

### D. Approaches to Cross-Chain Interoperability:

Atomic Swaps: These allow users to directly exchange assets between different blockchains without the need for intermediaries. Wrapped Tokens: Tokens on one blockchain are "wrapped" to create a representation on another blockchain, enabling their use in a different ecosystem. Sidechains: Separate blockchains, known as sidechains, are linked to the main blockchain, allowing for specific tasks to be performed on the sidechain while retaining the connection to the main chain. Cross-chain Bridge: Specialized smart contracts act as bridges between different blockchains, facilitating the transfer of assets and data. Polkadot and Cosmos: These platforms are designed with native cross-chain interoperability features, allowing multiple blockchains to be connected within a larger network.

Cross-chain interoperability enables the use of specialized features from different blockchains within a unified ecosystem. Assets can be moved seamlessly between

blockchains, enabling more efficient trading and utilization. Interoperability can help alleviate congestion on a single blockchain network by distributing transactions across multiple chains. Cross-chain interoperability supports collaboration between different projects and platforms, fostering innovation [24, 25]. Cross-chain interoperability plays a vital role in overcoming the limitations of isolated blockchains and creating a more interconnected and versatile blockchain landscape. As the blockchain ecosystem continues to evolve, solutions for cross-chain communication and data sharing will be crucial for achieving widespread adoption and realizing the full potential of decentralized technologies.

## IV. RESULTS AND DISCUSSION

The effectiveness of the suggested model is measured in terms of the following indicators. The success of a blockchain network may be measured by the following indicators, which have been developed with consideration for real-world use cases:

### A. Transaction Throughput

This indicator tracks how many deals the blockchain can handle in a given time frame. It's a measure of the network's ability to process several transactions at once.

### B. Latency

Latency refers to the time taken for a transaction to be confirmed and included in the blockchain. Lower latency signifies quicker transaction validation and responsiveness of the network.

### C. CPU Utilization

CPU usage is the rate at which a network's nodes use their central processing units. In our current use-case, each Hospital is associated to one smart contract instance. This smart contract provides various functionalities as required for the user operations. Each of these functions is explained in detail below:

### D. Register

This function handles registration of the new users. For every new user created, it generates a key pair i.e., private key and the public key which will be used for data encryption and decryption. This function triggers the Register() in the smart contract which works as follows:

```
Function Register(UserDetails, keys, flag):
    For i = 0 to Number of Users:
        User = ith User
        If k256(User.username) == k256(UserDetails.username):
            Return False  // Username is already in use
    Add UserDetails to UserList
    If flag == 1:
        Add UserDetails to Ddetails  // For doctors
    Else:
        Add UserDetails to Pdetails  // For patients
    Return True  // Registration successful
```

After the execution of the above function, it displays the corresponding success/fail message. Following is a preview of the register window shown in Fig. 5.
Fig. 5. Register window.

### E. Login

This function handles the login functionality for the existing users if the credentials provided are valid. It first triggers the Login() in the smart contract which works as follows:

```
Function Login(username, password):
    For i = 0 to Number of Users:
        User = ith User
        If  k256(User.username)  ==  k256(username)  &&
User.password == k256(password):
            Return UserType  // Successful login, return user type
        End If,
    End For
        Return  FailMessage   // Login failed, return a failure
message
```

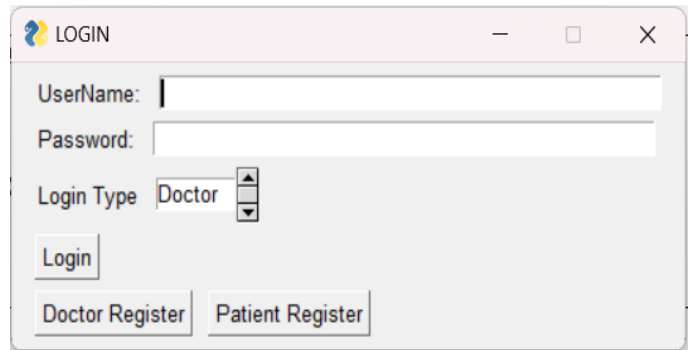
The login window appears as shown in Fig. 6. If the login is successful, the above function returns the user type as doctor or patient. If the type is doctor then available functionalities will be add and search, and if the type is patient then available functionalities will be View-data, Send-data, view-share and set-permission.


Fig. 6. Login window.

### F. Add Record

This function handles the addition of new records. It is executable only if the user type is doctor. The doctor enters the required details in the form provided as shown in Fig. 8. Doctors can also upload files using the provided option. The file is uploaded to the IPFS Server which returns a hash. These details along with the address hash are converted to a JSON record. This record is again hashed using IPFS. Then AddRecord() is triggered in the smart contract which works as follows and UI is shown in the Fig. 7.

*(IJACSA) International Journal of Advanced Computer Science and Applications,*
*Vol. 14, No. 10, 2023*

```
Function AddRecord(hash, PID):
    Add the record to the Records array
    If PID is present in the Hashlist:
        Add the current index to the corresponding PID in
Hashtable
        Set the flag
    If flag is not set:
Push the PID and current index to the Hashtable as a new
entry
```

Fig. 7.    Add record window.

### G. Search Record

This function is used for searching and displaying patient records in tabular form. The search operation can be done based on two parameters, PID or SSN. For internal references, searching is done using PID, whereas, for cross-chain references, searching is done through SSN.

For the purpose of this explanation, let's focus on the internal reference using PID. First, a "Filtered Data" array is created to store the records that match the given pid. Then, the function iterates through a hash table that contains patient records. For each record in the hash table, the function checks if the pid matches the given pid. If there is a match, the function loops through all the indexes associated with the given pid. It pushes all matching records to the Filtered Data array. After all records have been checked, the function returns the Filtered Data array containing all the records that matched the given pid or returns error output as shown in Fig. 8. The pseudo code for SearchRecord() is as follows:

```
Function SearchRecord (PatientRecords, GivenPID):
    Create an empty array called FilteredData
        For each record in PatientRecords:
        If record.PID matches GivenPID:
            For each index associated with GivenPID:
                Add the matching record to FilteredData
        If FilteredData is not empty:
        Return FilteredData
    Else:
        Return ErrorOutput
```

Fig. 8.    Output for search record (positive and negative).

### H. Interoperability Operations

Certainly, let's elaborate on the provided pseudocode steps and explain the process in detail:

*1) Retrieving SSN with getSSN()*: The first step involves retrieving the Social Security Number (SSN) associated with the provided Patient ID (pid). This information is obtained by executing the getSSN() function. This function likely queries a smart contract or database to fetch the SSN based on the given patient ID.

*2) Switching to intermediate network*: After obtaining the SSN, the pseudocode suggests disconnecting from the current network. This indicates a transition from the main network to an intermediate network, which acts as a backup or alternative in case of network downtime or delays.

*3) Choosing an intermediate network*: Users are presented with the option to choose between two intermediate networks: Sepolia and Goerli. These networks serve as contingency plans, ensuring that even if one network experiences issues, the process can continue using the other network.

*4) Connecting to intermediate network*: Based on the user's selection, the pseudocode connects to the corresponding intermediate network (Sepolia or Goerli).

*5) Accessing intermediate contract*: Once connected to the chosen intermediate network, the pseudocode suggests accessing a previously deployed intermediate contract. This contract likely contains functions and logic required for the subsequent steps.

*6) Retrieving list of hospitals*: Within the intermediate contract, the pseudocode fetches a list of all hospitals using the GetH() function. This list likely contains identifiers or addresses of different hospital contracts.

*7) Iterating over hospitals*: For each hospital in the retrieved list, the pseudocode enters a loop. This loop iterates through the list of hospitals one by one.

*8) Switching to hospital network*: Within the loop, the pseudocode disconnects from the current intermediate network and connects to the network associated with the specific hospital's contract. This allows interaction with the smart contract of the hospital.

*9) Searching and adding records*: With access to the hospital's network, the pseudocode utilizes the SearchRecordSSN() function. This function likely searches for medical records associated with the retrieved SSN and adds any matching records to a temporary storage.

285 | P a g e
www.ijacsa.thesai.org

*10)Completing hospital search*: Once records have been searched and added for the current hospital, the pseudocode disconnects from the hospital's network and reconnects to the intermediate network.

*11)Displaying stored records*: After searching all hospitals, the pseudocode ends the loop and reconnects to the original network. The medical records that have been temporarily stored during the search process are now displayed to the user for viewing.

*12)Visualization*: The entire process described above, from SSN retrieval to displaying records, can be visualized using a diagram or flowchart, shown in Fig. 9.

In summary, the pseudocode outlines a process where the SSN of a patient is used to search for and retrieve medical records from multiple hospitals' contracts. It employs intermediate networks and contracts to ensure data availability and accessibility even in the face of network issues. The process involves several steps of switching networks, accessing contracts, and iterating through hospitals to ultimately present the user with the aggregated medical records.

The pseudocode for the logic is given below:

```
Function Interoperable()
Input:
pid = GetUserInput()  // Get the Patient ID from the user.
// Retrieve SSN
SSN = GetSSN(pid)  // Call a function to retrieve SSN based
on the PID.
 // Disconnect from the current network
Network.Disconnect()
// Connect to the intermediate network
Network.Connect('intermediate')
// Get a list of hospitals from the intermediate contract
 Hosplist = IntermediateContract.GetHospitalList()
// For each hospital in the Hosplist
For i in Hosplist:
 nw, link = i[1], i[2]   // Get the network name (nw) and
contract address (link).
Network.Disconnect()
// Connect to the hospital's network
 Network.Connect(nw)
// Access the hospital's smart contract
 Temp = SmartContract.At(link)
 // Search for patient records using SSN
 Records = Temp.SearchRecordSSN(SSN)
Network.Disconnect()
// Reconnect to the original network
Network.Connect(curNetwork)
```

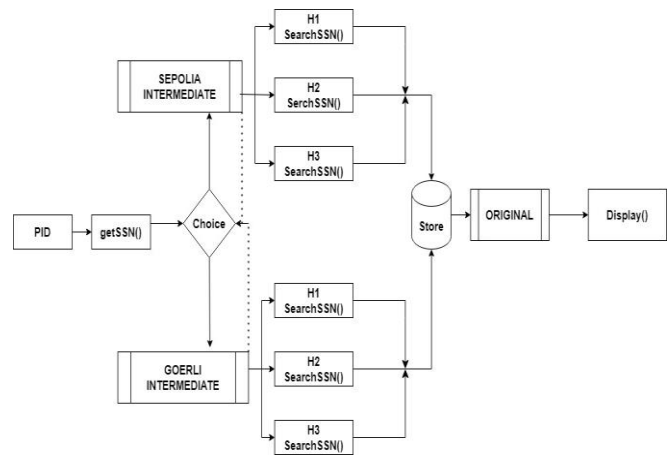

Fig. 9.   Interoperability implementation.

Fig. 10.  Transaction flow during cross-chain call.

In the figure given above Fig. 10, shows clearly about the transaction calls that take place. In current scenario the example encompasses three hospital contracts, in Sepolia and Goerli respectively. The intermediate contract is deployed on Sepolia as well. Certainly, here's an elaboration of the cross-chain search operation we have outlined:

Cross-Chain Search Operation Steps:

*1)  Initial network setup*

- The network is initially set to Sepolia, representing the primary network for the operation.

*2)  Switch to intermediate contract network*

- To ensure a robust and reliable search operation, the process begins by connecting to the intermediate contract network, which is also Sepolia in this case.

*3)  Fetching list of hospitals*

- Using the intermediate contract on the Sepolia network, the pseudocode fetches a list of hospitals: H1, H2, and H3. These hospitals represent the targets for the cross-chain search.

*4) Searching hospital 1 (sepolia)*

- The network connection switches to Hospital 1's network on Sepolia.

- The search transaction, likely involving the SearchRecordSSN() function, is executed for the patient's records associated with the retrieved SSN.

- Once the search transaction is confirmed, the retrieved records from Hospital 1 are temporarily stored.

*5) Searching hospital 2 (sepolia)*

- The network connection switches to Hospital 2's network on Sepolia.

- The search transaction for the same patient's records is executed within Hospital 2's network.

- After confirmation, the records from Hospital 2 are also temporarily stored.

*6) Searching hospital 3 (goerli)*

- The network connection switches to Hospital 3's network on Goerli. This represents a change in network from Sepolia to Goerli, emphasizing cross-chain operation.

- The search transaction for the same patient's records is executed within Hospital 3's network on the Goerli chain.

- Once confirmed, the records from Hospital 3 on the Goerli chain are temporarily stored.

*7) Aggregating and returning records*

- After successfully searching across multiple hospitals and networks, the temporary storage of retrieved records is aggregated.

- The aggregated records are then returned to the user, presenting a comprehensive overview of the patient's medical data from all the participating hospitals and chains.

This cross-chain search operation demonstrates the flexibility and versatility of the proposed model, allowing for seamless interaction with multiple hospital networks on different blockchain platforms (Sepolia and Goerli, in this case). By employing intermediate contracts and network switches, the model ensures data availability and continuity, even if issues arise in individual networks, enabling efficient retrieval and presentation of medical records across various chains.

Fig. 11 and Fig. 12 show the time taken for the operations GetH(), network switching and Searching times. These visual representations clearly indicate that fetching times and switching times are very low compared to the major search transaction.

Fig. 11. Transaction logs with time measures.

Fig. 12. Average time taken for operations.

TABLE I.    PERFORMANCE ANALYSIS FOR NUMBER OF RECORDS SEARCHED

| Hospitals | Record 1 | Record 2 | Record 3 |
|---|---|---|---|
| 1 | 15.53 | 15.63 | 15.66 |
| 2 | 30.12 | 30.33 | 30.45 |
| 3 | 45.45 | 45.66 | 45.89 |

Fig. 13. Performance analysis for number of records searched.

The study involved measuring the average time required for searching records while varying the number of hospitals and records involved. It was observed that the search time was independent of number of records being searched shown in Table I and Fig. 13. The time taken was directly proportional to the number of hospitals involved in the search. This shows that the actual search operation takes place in the order of milliseconds but the majority of the time is due to transaction delay. The time taken for each of the above operations can be optimized if the average time taken for each transaction is relatively reduced by the Ethereum network.

## I. Average Latency Comparison

Fig. 14 displays the results of measurements of the delay required to perform various blockchain operations locally as well as between blockchain networks. The Ethereum test bed consists of two virtual computers running on the same physical computer, each of which hosts a different set of test network components. Fig. 14 shows that the suggested approach requires between 4s and 50ms to complete the transaction across the two blockchains, whereas a local transfer on Ethereum requires just 14ms. Therefore, although there is a significant increase, 4s for a transaction in the analyzed use case is manageable.

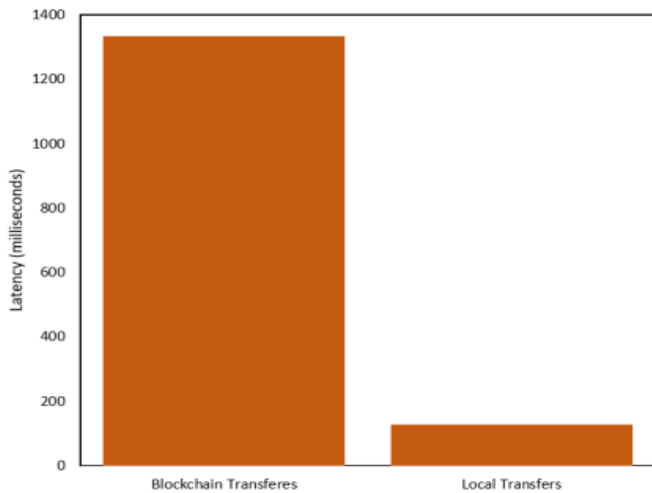

Fig. 14. Latency assessment.

Table II and Fig. 15 provide an illustration of the total CPU utilization for both test networks, denoted as B1 and B2. Throughout the test period, B1 exhibits a CPU consumption of around 66%. As the transaction load increases, this utilization gradually climbs and peaks at approximately 74%. In contrast, B2, involving the operation of four healthcare entities, exhibits a higher CPU consumption of around 80% when the transaction load is 500. This stands as a 10% increase over B1 at the same transaction load. With a rise in the transaction load, B2's CPU consumption further escalates. At a transaction load of 6000, B2's CPU utilization reaches approximately 86%, leading to the occurrence of an average of 411 failed transactions. In conclusion, the findings emphasize the importance of considering and to optimizing CPU resources as the network accommodates a larger number of participants or entities.

TABLE II. CPU UTILIZATION

| Transaction Rate | CPU Utilization | |
| --- | --- | --- |
| | B1 | B2 |
| 1000 | 67 | 78 |
| 2000 | 66 | 80 |
| 3000 | 70 | 80 |
| 4000 | 71 | 83 |
| 5000 | 73 | 85 |

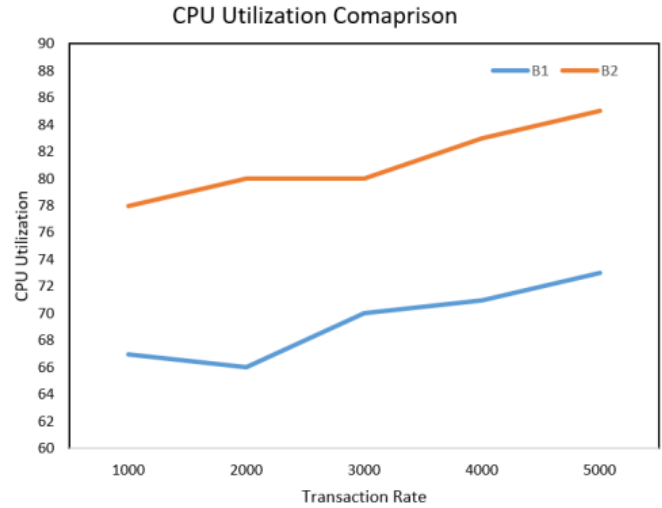

Fig. 15. CPU Utilization.

## V. CONCLUSION AND FUTURE SCOPE

In conclusion, the utilization of blockchain technology introduces a promising solution to address the persistent challenges of interoperability and privacy within Electronic Health Records (EHR). This technology empowers patients by granting them centralized access to their medical histories while simultaneously relieving healthcare providers of the lifelong responsibility of safeguarding medical data. Nevertheless, current implementations of blockchain-based EHR systems can address crucial concerns such as efficiency, fairness, and trust. Integrating blockchain with EHR is a multifaceted issue that surpasses the realm of technical expertise and requires collaboration from various stakeholders. To counteract the challenge of non-interoperability, our approach involves constructing a bridge between two similar blockchain networks. Proposed approach illustrates the solution through an EHR Structure, stored across distinct Ethereum Testnets, and enacted via a Solidity Smart Contract. This enables to establish the feasibility of bridging the gap and fostering a seamless interoperability experience between different blockchain networks. The main intention is to utilize a smart contract to embody the EHR Structure specific to individual hospitals. However, the need arises for deploying separate smart contracts for each hospital. Ensuring effective communication between these smart contracts presents a complex challenge, whether within a single blockchain or spanning multiple blockchains. The presented protocol successfully achieves objectives such as privacy conservation, time-controlled annulment, search

functionality, and data security, according to by our extensive security study. It is very resistant to both large-scale and low-key attempts to breach its security. There appears to be an opportunity for the integration of various blockchains to enable the sharing of Electronic Health Records (EHR) within a healthcare consortium from an external viewpoint. The emphasis is on achieving heightened security and efficiency, which could be compared comprehensively with existing solutions in this domain. This ongoing effort seems dedicated to refining the approach for the advantage of the healthcare industry and its stakeholders.

# A Comparison of Sampling Methods for Dealing with Imbalanced Wearable Sensor Data in Human Activity Recognition using Deep Learning

Mariam El Ghazi[*], Noura Aknin

Information Technology and Modeling, Systems Research Unit, Abdelmalek Essaadi University, Tetouan, Morocco

*Abstract*—**Human Activity Recognition (HAR) holds significant implications across diverse domains, including healthcare, sports analytics, and human-computer interaction. Deep learning models demonstrate great potential in HAR, but performance is often hindered by imbalanced datasets. This study investigates the impact of class imbalance on deep learning models in HAR and conducts a comprehensive comparative analysis of various sampling techniques to mitigate this issue. The experimentation involves the PAMAP2 dataset, encompassing data collected from wearable sensors. The research includes four primary experiments. Initially, a performance baseline is established by training four deep-learning models on the imbalanced dataset. Subsequently, Synthetic Minority Over-sampling Technique (SMOTE), random under-sampling, and a hybrid sampling approach are employed to rebalance the dataset. In each experiment, Bayesian optimization is employed for hyperparameter tuning, optimizing model performance. The findings underscore the paramount importance of dataset balance, resulting in substantial improvements across critical performance metrics such as accuracy, F1 score, precision, and recall. Notably, the hybrid sampling technique, combining SMOTE and Random Undersampling, emerges as the most effective method, surpassing other approaches. This research contributes significantly to advancing the field of HAR, highlighting the necessity of addressing class imbalance in deep learning models. Furthermore, the results offer practical insights for the development of HAR systems, enhancing accuracy and reliability in real-world applications. Future works will explore alternative public datasets, more complex deep learning models, and diverse sampling techniques to further elevate the capabilities of HAR systems.**

*Keywords—Human activity recognition (HAR); class imbalance; sampling methods; wearable sensors; deep learning; synthetic minority over-sampling technique (SMOTE); random undersampling; PAMAP2 dataset; bayesian optimization*

## I. INTRODUCTION

Human Activity Recognition (HAR) is a multidisciplinary field focused on the automated identification and categorization of human activities, primarily relying on data collected from diverse sensors. Its applications extend into critical domains, particularly Sports or healthcare [1]. The automatic detection and classification of human activities can significantly improve the quality of life for elderly individuals and dependents, enhancing their safety, well-being, and independence [2].HAR systems play a vital role in smart home environments by providing context-aware services to residents, monitoring their activities, and alerting caregivers in case of any abnormal situations[3].

Deep learning models have revolutionized HAR due to their capacity to process and analyze sensor data effectively. Long Short-Term Memory (LSTM) networks and Convolutional Neural Networks (CNN) are two prominent deep learning architectures that excel at learning complex patterns and temporal dependencies from sensor data. These models have demonstrated remarkable performance in HAR, making them the focal point of this study [4] [5]. While deep learning models have shown promise in HAR, one significant challenge is posed by imbalanced datasets [6]. In many real-world scenarios, certain activities or classes are more frequent than others in the data, creating an imbalance. This imbalance can adversely affect the performance and accuracy of HAR models, as they may become biased towards the majority class, leading to poor recognition of minority activities [7].

In summary, Human Activity Recognition (HAR) holds vital implications for various domains. Deep learning models, such as LSTM and CNN, enhance HAR by effectively processing sensor data. The use of sampling techniques to address class imbalance significantly boosts model performance. This research underscores the importance of balanced datasets in HAR and provides practical insights for real-world applications.

The primary contributions of this study are as follows:

- The profound impact of class imbalance on the performance of deep learning models in HAR is investigated, and a range of sampling techniques designed to alleviate this issue is introduced and rigorously evaluated, offering valuable insights into enhancing model performance within imbalanced datasets.

- Three distinct sampling techniques are evaluated: SMOTE Random Undersampling, and a hybrid approach combining both methods.

- A detailed comparative analysis of the efficacy of these sampling methods in enhancing learning from imbalanced human activity data through deep machine learning algorithms is provided. Specifically, a test is conducted on Vanilla LSTM, 2 Stacked LSTM, 3 Stacked LSTM, and the Hybrid CNN-LSTM model.

The findings consistently demonstrate that the hybrid sampling techniques consistently outperform state-of-the-art models across critical performance metrics, including accuracy, precision, recall, and F1 score.

The paper is organized into distinct sections to effectively present the research findings. Section II presents the Related Works, reviewing prior research in the field related to the problem. Section III elaborates on the Materials and Methods employed in the experimental approach. Section IV presents the outcomes of the experiments and engages in a thorough discussion of the findings. Finally, in Section V, the Conclusion presents the key findings, and future directions of sensor -based HAR using deep learning models.

## II. RELATED WORK

In the field of Human Activity Recognition (HAR), addressing imbalanced data presents a significant challenge, a common issue observed in various public datasets, including Opportunity [8], WISDM V1.1[9], SPHERE [10] and PAMAP2 [11]. Imbalanced data can profoundly affect the performance of deep learning models utilized in HAR tasks. To tackle this challenge, several studies have explored the integration of deep learning models with sampling methods specifically designed for Human Activity Recognition based on sensor data.

Jeong et al. (2022) conducted a comprehensive study focusing on the influence of undersampling and oversampling techniques for classifying physical activities using an imbalanced accelerometer dataset. Their findings proposed that ensemble learning, coupled with well-defined feature sets and undersampling, exhibits robustness in the classification of physical activities within imbalanced datasets. This approach proves particularly effective in real-world scenarios, where imbalanced class distributions are commonplace. Furthermore, the study underscored the superiority of ensemble learning over other machine learning and deep learning models in handling small datasets with subject variability [12].

Hamad et al. (2020) evaluated the efficacy of imbalanced data handling methods in the context of deep learning applied to smart home environments. Leveraging a CNN LSTM model and a dataset comprising daily living activities collected from two real intelligent homes, their research demonstrated a significant performance improvement by applying the SMOTE oversampling method. This enhancement resulted in a notable increase in accuracy (from 0.60-0.62 to 0.71-0.73) when compared to training on the original imbalanced data [13].

Alani et al. (2020) delved into the classification of imbalanced multi-modal sensor data for HAR within smart home environments, using deep learning techniques in conjunction with oversampling (specifically, SMOTE) and undersampling methods. The results unequivocally favored the SMOTE method over undersampling in effectively addressing imbalanced data challenges within HAR tasks using the SPHERE dataset [14].

Alharbi et al. (2022) made significant contributions by investigating the effectiveness of oversampling methods, such as SMOTE and its hybrid variations, in improving the classification of minority classes in diverse datasets. For instance, on the PAMAP2 dataset, the MLP achieved an F1 score of 0.7185 using the SMOTE sampling method, compared to its baseline score of 0.7473. [7].

In addition to the aforementioned studies, recent research has showcased the potential of deep learning models for HAR:

- Wan et al. (2020) introduced deep models for real-time HAR using smartphones, including CNN and LSTM models, achieving high accuracies of 91.00% and 85.86%, respectively on the PAMAP 2 Dataset [15].

- Xu et al. (2022) proposed several methods, including classical CNN, LSTM, and Inception-LSTM with attention mechanisms, achieving F1 scores ranging from 0.8949 to 0.9513 [16].

- Tehrani et al. (2023) utilized a deep multi-layer Bi-LSTM model for sensor-based HAR, obtaining promising results with F1-score, Precision, Recall, and Accuracy all reaching 93.41% [17].

- Thakur et al. (2022) demonstrated that a hybrid model combining CNN and LSTM with an autoencoder for dimensionality reduction achieved an impressive F1 score of 0.9446 and an accuracy of 94.33% for HAR [4].

- Challa et al. (2022) proposed a multibranch CNN-BiLSTM model for human activity recognition using wearable sensor data, achieving an impressive accuracy of 94.29% [18].

Table I summarizes the performance of various deep learning models on the PAMAP2 dataset using different sampling methods for sensor-based HAR.

These studies collectively emphasize the positive impact of oversampling techniques, particularly SMOTE, in enhancing model performance when compared to training on imbalanced datasets. These insights lay the foundation for this research, which aims to build upon this foundation and further investigate the efficacy of sampling methods in improving the performance of deep learning models for HAR on the PAMAP2 dataset.

In the field of HAR, a significant gap in existing research has been found. There hasn't been enough focus on how different sampling techniques affect the performance of deep learning models in HAR. While some studies have tackled imbalanced data in HAR, they often overlook the critical role that sampling methods play. This gap highlights the need for a more thorough investigation into how sampling techniques and deep learning intersect in HAR. That's where the research steps in. The commitment is to address this gap by thoroughly studying how various sampling methods impact the performance of deep learning models in real-world HAR scenarios. The goal is to provide a clearer picture of how sampling methods and deep learning models work together, ultimately improving the accuracy and reliability of activity recognition in sensor-based applications.

TABLE I.    PREVIOUS STUDIES PERFORMANCE ON PAMAP2 DATASET USING DEEP LEARNING MODELS AND SAMPLING METHODS FOR SENSOR BASED HAR

## III. MATERIAL AND METHODS

In this research, the impact of class imbalance on HAR using wearable sensor data and deep learning models was investigated. To address this issue, three sampling methods were thoroughly examined: SMOTE, Random Undersampling, and a hybrid combination of the aforementioned techniques. The study involved the training of four deep learning models, including Vanilla LSTM, 2 Stacked LSTM, 3 Stacked LSTM, and Hybrid CNN-LSTM, on the PAMAP2 dataset. Through rigorous experimentation and evaluation, the aim was to identify the most effective sampling approach to improve model performance and generalization in HAR. The findings are expected to contribute valuable insights towards enhancing the accuracy and reliability of HAR systems deployed in real-world scenarios.

### A. PAMAP2 Dataset

The PAMAP2 dataset [11], which stands for "Physical Activity Monitoring using a Multipurpose Sensor" holds a prominent role in the realm of Human Activity Recognition (HAR) research. Its comprehensive data collection approach, diverse participant demographic, and meticulous data organization make it a valuable resource for the research community.

Here are some key characteristics of the PAMAP2 dataset, as extracted from the dataset documentation [11] :

- Participant Diversity: One noteworthy aspect of the PAMAP2 dataset is the diversity of its participant pool. This dataset comprises data contributed by both genders, with a broad age range spanning from 23 to 32 years. Moreover, it includes individuals with varying physical characteristics, such as weights ranging from 65 to 95 kilograms and heights spanning between 168 and 194 centimeters. This demographic diversity

empowers researchers to develop activity recognition models applicable to a broad spectrum of individuals.

- Data Collection: Researchers collected the dataset using a range of wearable sensors, including those worn on the wrist, chest, and ankle. These sensors operated at a high sampling rate of 100Hz, enabling the capture of an extensive volume of data, essential for detailed analysis of activities and movements (see Table II).

- Activity Variety: The PAMAP2 dataset offers an array of data related to various physical activities. It encompasses 12 distinct activity types, with detailed descriptions provided in Table III. This categorization serves as a valuable reference for activity labeling and model development.

- Data Format: The dataset is thoughtfully organized, with raw data from all sensors synchronized and labeled, and then consolidated into a single data file per participant and session. These files are presented in text format (.dat), simplifying structured data manipulation and analysis.

TABLE II.    PAMAP2 DATASET DESCRIPTION

| Dataset | Labels | Sampling Rate | Windows Size | Overlap | # Subjects |
|---------|--------|---------------|--------------|---------|------------|
| PAMAP2 | 12 | 100 Hz | 1s | 50% | 9 |

Table III provides an overview of the data distribution within the PAMAP2 dataset, highlighting a significant class imbalance among different activity labels in both the training and testing datasets. This issue is further underscored in Fig. 1, where it becomes evident that the "Rope jumping" activity exhibits notably fewer instances compared to other activities. This skewed data distribution can exert a substantial impact on the performance of deep learning models. Consequently, it becomes imperative to implement suitable sampling strategies to guarantee the reliability and accuracy of results.

TABLE III.     Data Distribution per Activity in the PAMAP2
Dataset

| Class id | Activity label | # Instances Training Set 70% | # Instances Testing Set 70% |
|---|---|---|---|
| 0 | Lying | 100298 | 42633 |
| 1 | Sitting | 58380 | 25358 |
| 2 | Standing | 70165 | 29808 |
| 3 | Walking | 86117 | 36789 |
| 4 | Running | 30100 | 12950 |
| 5 | Cycling | 63755 | 27585 |

| 11 | Rope jumping | 10889 | 4564 |

Fig. 1.     Data distribution by activity in PAMAP2 dataset.

## B.  Deep Learning Models

*1) Long short-term memory (LSTM)*: LSTM networks belong to the category of recurrent neural networks (RNNs) and hold significance in time series applications, particularly HAR, that involve the classification of activities based on sensor data, such as accelerometers and gyroscope readings from smartphones. The strength of LSTM networks in HAR lies in their capability to capture and model long-term dependencies present within the sensor data [19].

*2) Hybrid deep learning model (CNN-LSTM)*: This research harnesses the power of hybrid models, specifically the integration of Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) networks. This combination, as evidenced by several studies [14][4], holds promise for achieving high performance in HAR tasks. The rationale behind selecting this hybrid model is compelling: CNN excels at capturing spatial relationships within data, while LSTM is adept at modeling temporal dependencies. This combination allows us to leverage the strengths of both architectures [20]. One notable advantage of the hybrid model is that CNN accelerates the feature extraction process,

enhancing training efficiency. This synergy between CNN and LSTM contributes to the model's overall effectiveness in recognizing human activities based on sensor data.

*3) Deep learning models configurations:* In the following deep learning configuration for multiclass HAR classification, various layers play distinct roles. These include the LSTM layer, dropout layer, dense layer with Softmax activation for probability estimation, convolutional (Conv1D) layer, and max pooling layers. Each layer plays a specific role in a deep learning architecture for multiclass classification. The LSTM layer captures sequential dependencies in the data, making it suitable for time series or sequential data. The dropout layer helps prevent overfitting by randomly deactivating a fraction of neurons during training, enhancing the model's generalization. The dense layer, often found in the final stage, produces class scores. The softmax activation function applied to these logits converts them into class probabilities. The convolutional (Conv1D) layer extracts spatial features from the input data. Max pooling layers reduce the spatial dimensions while retaining essential information, aiding in feature selection and computational efficiency. Combined, these layers enable the deep learning model to process, understand, and classify data efficiently and accurately.

In this study, several configurations of deep learning models for HAR are explored. These configurations include:

*a) Vanilla LSTM*: This straightforward LSTM setup consists of a single hidden layer of LSTM units and an output layer for prediction. It has proven its effectiveness in various small sequence prediction tasks [21].

Fig. 2 illustrates the architecture of the Vanilla LSTM model. It provides a visual representation of the model's structure, showcasing the flow of data through its layers, including the LSTM layer, dropout layers, and dense layers, ultimately leading to the output layer for activity classification.

Fig. 2.   Structure of vanilla LSTM model.

*b) 2-Stacked LSTM*: Variants of the Stacked LSTM model, featuring two hidden layers, are also investigated in this study. Emerging from research findings, Stacked LSTM networks exhibit improved recognition efficiency by iteratively extracting temporal features [21].

Fig. 3 provides an overview of the 2-Stacked LSTM model's architecture. This model is specifically designed for Human Activity Recognition (HAR) and excels in capturing intricate temporal patterns within sensor data. It consists of two LSTM layers with 64 units each, enabling the understanding and modeling of complex temporal relationships. Dropout layers are strategically placed to prevent overfitting during training. The model then utilizes two Dense layers, with 96 and 12 units, for feature extraction and final classification. Overall, the 2-stacked LSTM model's structure is optimized for accurate and robust activity recognition in HAR applications.

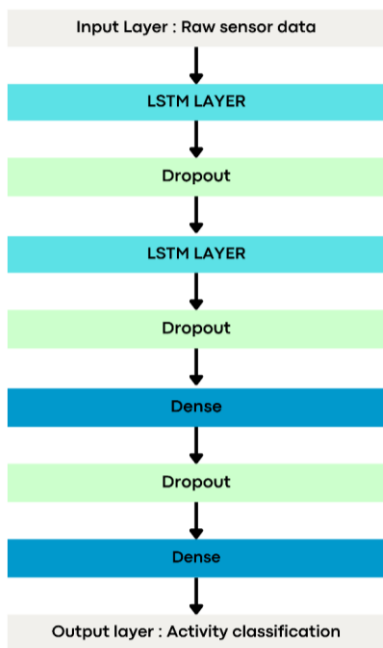

Fig. 3. Structure of 2-stacked LSTM model.

*c) 3-Stacked LSTM*: Similar to the 2-Stacked LSTM but with an additional layer of LSTM units, this configuration aims to further enhance the model's capacity for temporal feature extraction [21].

Fig. 4 provides an overview of the 3-Stacked LSTM model's architecture, designed for Human Activity Recognition (HAR). This model excels at capturing intricate temporal patterns within sensor data. It comprises three LSTM layers, each with 32 units, to model complex temporal relationships. Dropout layers are integrated to prevent overfitting during training. The model also includes two dense layers with 64 and 12 units, respectively, for feature extraction and final activity classification. In summary, the 3-Stacked LSTM model is engineered to achieve robust and accurate activity recognition in HAR scenarios by effectively handling temporal data dependencies and ensuring generalization through dropout mechanisms.

Fig. 4. Structure of 3-stacked LSTM model.

*d) Hybrid Model (CNN-LSTM)*: The CNN-LSTM model, a hybrid architecture that seamlessly combines Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) layers.

Fig. 5 outlines the Hybrid CNN-LSTM model for HAR. The architecture starts with a CNN layer followed by dropout and max pooling for feature extraction. Subsequently, an LSTM layer captures temporal patterns with dropout for regularization. The final dense layer performs activity classification. This design effectively handles spatial and temporal aspects of sensor data, ensuring robust activity recognition in HAR.

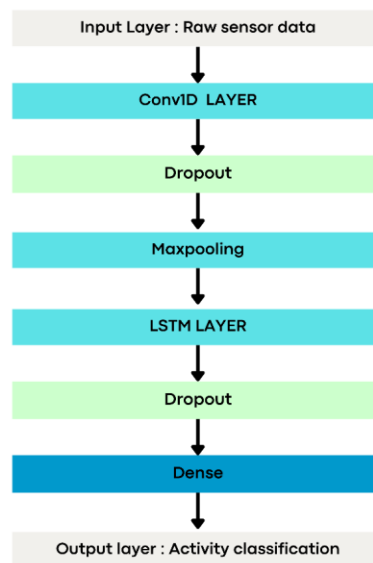

Fig. 5. Structure of hybrid CNN-LSTM model.

## C. Sampling Techniques

To tackle the challenge of imbalanced data, three different sampling techniques were applied:

*1) SMOTE (Synthetic minority over-sampling technique):* This Sampling technique serves as an effective tool for addressing imbalanced datasets in the realm of machine learning. Its function involves creating synthetic data points for the underrepresented class by bridging the gap between existing samples. In the context of sensor-based Human Activity Recognition (HAR) using deep learning, SMOTE plays a vital role in enhancing the classification accuracy of models like Multi-Layer Perceptrons (MLPs) [7].

Deep learning models require a high amount of data and are very sensitive to the imbalanced class problem. This is where SMOTE steps in, generating artificial samples for the minority class, thereby balancing the dataset and significantly improving the classification accuracy of these deep learning models [14].

*2) Random undersampling:* This Sampling method addresses imbalanced datasets by randomly removing samples from the majority class to achieve balance. In sensor-based Human Activity Recognition (HAR) with deep learning, is employed to boost deep learning model classification accuracy [14]. Deep learning models require a high amount of data and are sensitive to class imbalances. Thus, Random Undersampling eliminates samples from the majority class, balancing the dataset and improving classification accuracy [14]. However, this method can lead to the loss of critical information from the majority class, potentially impacting the model's classification accuracy [7]. Hence, it is crucial to carefully select the samples for removal to prevent the loss of vital information.

*3) Hybrid sampling:* Hybrid sampling is a technique used to deal with imbalanced datasets in machine learning. It involves combining oversampling and undersampling methods to balance the dataset. This method generates synthetic samples for the minority class using SMOTE and randomly removes samples from the majority class using Random Undersampling. The combination of these two methods helps to balance the dataset and improve the classification accuracy of deep learning models [7][14]. Hybrid sampling is particularly effective in sensor-based Human Activity Recognition (HAR) when combined with deep learning models. This technique successfully addresses the challenge of imbalanced classes while simultaneously mitigating the risk of losing valuable information from the majority class that can occur with random undersampling alone. By generating synthetic samples for the minority class through SMOTE, hybrid sampling ensures a well-represented minority class in the dataset. This balanced dataset significantly enhances the classification accuracy of deep learning models, while also promoting data diversity [14].

Table A1 in Appendix A provides a comprehensive overview of the dataset instances before and after the application of various sampling methods. The table allows for a clear visualization of how each sampling technique impacts the dataset composition.

## D. Hyperparameter Tuning with Bayesian Optimization

The Model Hyperparameters are crucial in deep learning, shaping training algorithms and model performance. Bayesian optimization offers an effective means to optimize these parameters, particularly in complex, function-based problems lacking simple analytical solutions. To apply Bayesian optimization to time series and sensor-based Human Activity Recognition (HAR) using LSTM models, the following steps can be followed:

Step 1: Define the hyperparameter search space.

Step 2: Specify the objective function to evaluate model performance.

Step 3: Initialize the Bayesian optimization algorithm with hyperparameter values.

Step 4: Iteratively use the algorithm to suggest hyperparameters for evaluation.

Step 5: Continue until predefined convergence criteria are met, like a set number of iterations or desired performance levels.

## E. Evaluation Metrics

In the experiment, various evaluation metrics were used to assess the HAR model's performance. These metrics included accuracy, F1 score, precision, recall, and the confusion matrix. These evaluation metrics determine the performance of a model on a dataset. The most common metric is the confusion matrix which is a two-dimension table of class labels; one represents the current class and the other represents the predicted one. Accuracy is the most used one to evaluate model classification. It defines a ratio of correct predictions and overall predictions. The accuracy can be a good measure when the dataset class is balanced. Otherwise, this metric is not appropriate for evaluation. In the case of imbalanced datasets, other metrics are used such as precision, recall, f-measure, and specificity. Table IV presents the definition of all these metrics [22].

Understanding these performance metrics requires knowledge of four fundamental terms used in their measurement: true positive (TP), true negative (TN), false positive (FP), and false negative (FN).

TABLE IV. PERFORMANCE METRICS

| Metric | Formula | Definition |
|---|---|---|
| Accuracy | $\dfrac{tp + tn}{tp + tn + fp + fn}$ | the ratio of correct predictions and overall predictions |
| Precision | $\dfrac{tp}{tp + fp}$ | the ratio of correct predictions to the total predicted |
| Recall of sensitivity | $\dfrac{tp}{tp + fn}$ | the ratio of correct predictions to the samples in the actual class |
| Specificity | $\dfrac{tn}{tn + fp}$ | The ratio of actual class 0 to the correctly predicted 0 |
| F1 score / F-measure | $\dfrac{2(recall * precision)}{recall + precision}$ | The weighted average of precision and Recall if the data is imbalanced |

## IV. Experiments and Results

### A. Experimental Design

This research aims to investigate the impact of data balancing techniques on the performance of deep learning models for Human Activity Recognition (HAR) by addressing the following research questions:

*1)* How does class imbalance affect the performance of deep learning models in Human Activity Recognition (HAR) when applied to wearable sensor data?

*2)* What are the comparative effects of different sampling techniques, such as SMOTE, Random Undersampling, and Hybrid Sampling, in addressing the class imbalance in wearable sensor data for HAR?

*3)* What role does hyperparameter tuning play in improving the accuracy and performance of deep learning models for HAR, particularly in the context of imbalanced datasets?

*4)* Which combination of sampling technique and hyperparameter tuning strategy yields the most significant performance improvements in HAR using deep learning models for imbalanced wearable sensor data?

The hypothesis guiding this study is that balancing the dataset will result in enhanced classification accuracy in HAR using deep learning models. The experiments were carried out using the PAMAP2 dataset collected from wearable sensors, encompassing wrist, chest, and ankle devices. Four deep learning models were employed: Vanilla LSTM, 2-Stacked LSTM, 3-Stacked LSTM, and CNN-LSTM.

### B. Experimental Setup

The conducted experiments are performed on an NVIDIA GPU V100 using the Google Collaboratory Pro+ platform. The four models' hyperparameters were optimized through Bayesian Hyperparameter Optimization, utilizing the Keras Tuner library[23]. The experiment setup is detailed in Table V.

TABLE V.    EXPERIMENTAL SETUP

| Platform | Google Colab Pro+ |
|---|---|
| **GPU** | NVIDIA GPU V100 |
| **RAM** | 15 GB |
| **Tenserflow version** | 2.12.0 |
| **Keras Version** | 2.12.0 |
| **Keras Tuner Version** | 1.3.5 |

### C. Experiment Pipeline

To evaluate the models' performance on the PAMAP2 dataset, a comprehensive experiment pipeline was executed.
This pipeline is composed of multiple stages, each playing a vital role in the experiments (see Fig. 6):

*1) Data collection*: Initially, the raw sensor data from wearable devices were collected.

*2) Data preprocessing*: The dataset goes through a preprocessing phase, involving actions like data cleaning, noise reduction, and normalization.

During this stage, the raw sensor data from wearable devices is readied for the proposed model. The subject-specific files containing activity records are consolidated into one data frame. To adhere to PAMAP2 guidelines, invalid orientation columns are removed, and transient activity rows are dropped. Non-numeric data is transformed into numeric form, and missing values are interpolated to ensure data integrity. Scaling is applied to normalize input features, ensuring data uniformity. Labels are encoded and converted into categorical variables, a critical step for activity classification during model training.

The data is then split into training and testing sets, with 70% allocated for training and 30% for testing. Data is segmented into overlapping windows, with a window size of 1 second and a 50% overlap. This segmentation process creates segments and associated labels for both training and testing. The segments and labels are reshaped to align with the LSTM model's input format. The experiment validates the shape of training and testing segments before moving on to model training and evaluation phases.

*3) Data class balancing*: In the data balancing stage, three different sampling techniques were applied to tackle class imbalance in the experiments: SMOTE, Random Undersampling, and a hybrid approach. SMOTE was used to generate synthetic instances for minority classes, Random Undersampling involved reducing instances in the majority class, and the hybrid approach combined both methods. The objective was to create balanced datasets to enhance model training. These sampling techniques were exclusively applied to the training set to ensure class balance for improved model performance.

*4) Data segmentation*: Data were segmented into overlapping windows, following a window size of one second with a 50% overlap. This facilitated the data's suitability for deep learning models.

*5) Training and hyperparameter optimization*: Deep learning models performed feature extraction automatically to identify relevant patterns in the segmented data.

Fig. 6.   Experiments pipeline.

The four models were trained using Bayesian Optimization to fine-tune hyperparameters for optimal model performance. The Keras Tuner library is utilized to search for the best hyperparameters.

The models are fine-tuned by adjusting several critical hyperparameters: the LSTM units, which determine the number of LSTM units in each LSTM layer, are explored within the range of 64 to 256, with a step size of 32. Similarly, the dense units, specifying the number of units in the dense layer, are considered within the range of 32 to 128, with a step size of 32. The batch size hyperparameter, significant for model training, is chosen from the options of 32, 64, or 128. The learning rate, influencing the optimizer's learning rate, is selected from values like 1e-3, 1e-4, or 1e-5. Furthermore, the dropout rate, responsible for controlling the dropout applied after each LSTM layer and the dense layer, varies from 0.1 to 0.5, with a step size of 0.1. The optimizer hyperparameter allows the choice of ADAM or RMSprop as the optimizer used to compile the model. The number of epochs in this experiments ranges from 50 to 100.This extensive exploration and fine-tuning of the models ultimately result in enhanced accuracy and robust performance for HAR tasks. All these hyperparameters are summarized in Table VI.

TABLE VI. HYPERPARAMETER RANGES FOR BAYESIAN OPTIMIZATION

| Hyperparameter | Search Space |
|---|---|
| Lstm Units | [32, 64, 96, 128] |
| Dense Units | [32, 64, 96, 128] |
| Dropout Rate | [0.1, 0.2, 0.3, 0.4, 0.5] |
| Optimizer | ['adam', 'rmsprop'] |
| Learning Rate | [1e-2, 1e-3, 1e-4] |
| Batch Size | [32, 64, 128] |
| Epochs | [50, 51, ..., 100] |

*6) Model evaluation*: To evaluate the models performance on the PAMPA2 dataset. The evaluation metrics were used including accuracy, precision, recall, F1-score and confusion matrix. These metrics were compared against those reported in previous literature studies conducted on the same dataset, enabling a comprehensive assessment of the proposed model's effectiveness and advancements in HAR.

Four experiments were conducted:

- Experiment 1: Train and test the four models on an imbalanced dataset.

- Experiment 2: Train and test the four models on the balanced dataset with SMOTE.

- Experiment 3: Train and test the four models on the balanced dataset with Random Undersampling.

- Experiment 4 : Train and test the four models on the balanced dataset with hybrid Sampling(SMOTE & Random Undersampling).

*D. Experiments Results*

*1) Experiment 1: Baseline*: In Experiment 1, the baseline was established to compare the effects of various data balancing techniques.

TABLE VII. THE SUMMARIZED HYPERPARAMETERS OF THE FOUR MODELS FOUND BY KERAS TUNER ON IMBALANCED DATA

| Hyper parameter | Vanilla LSTM | 2Stacked LSTM | 3 Stacked LSTM | CNN LSTM |
|---|---|---|---|---|
| Lstm Units | 32 | 64 | 96 | CNN units:128 Lstm units : 64 |
| Dense Units | 32 | 96 | 128 | - |
| Dropout Rate | 0.1 | 0.3 | 0.2 | 0.4 |
| Optimizer | RMSPROP | ADAM | ADAM | ADAM |
| Learning Rate | 0.001 | 0.001 | 0.001 | 0.001 |
| Batch Size | 32 | 32 | 128 | 128 |
| Epochs | 82 | 78 | 78 | 65 |

Subsequently, the four deep learning models were trained on the preprocessed imbalanced dataset. The optimization of hyperparameters for these models was carried out using Keras Tuner Bayesian optimization. The best hyperparameters of each model are summarized in Table VII.

Table VIII presents the results of Experiment 1, showcasing the performance metrics of the models, which include accuracy, precision, recall, and F1-score. These metrics were measured to establish a baseline for comparison.

*2) Experiment 2: Balancing data with SMOTE*: In this experiment, the evaluation of model performance was conducted when trained on a dataset balanced using the Synthetic Minority Over-sampling Technique (SMOTE). The four models underwent training on the SMOTE-balanced dataset, and the search for the best hyperparameters for each

model was facilitated by Keras Tuner, as shown in Table VIII .

Performance metrics achieved in this experiment were observed and reported in Table IX, with a comparison to those from Experiment 1. Fig. 11 to Fig. 14 depicts the confusion matrices for the Vanilla LSTM model, 2-Stacked LSTM, 3-Stacked LSTM, and CNN-LSTM, respectively, on the balanced data with SMOTE (see Table X).

*3) Experiment 3: Random undersampling*: Experiment 3 entailed the assessment of the models' performance when trained on a dataset balanced through Random Undersampling. The four models underwent training on the randomly undersampled Training set. The search for the best hyperparameters for each model was conducted using Keras Tuner, as indicated in Table XI and Table XII shows the Experiment 3on balanced data with random undersampling.

Performance metrics achieved in this experiment were observed and reported in Table XIII, with a comparison to those from Experiment 1. Fig. 15 to Fig. 18 illustrate the confusion matrices for the Vanilla LSTM model, 2-Stacked LSTM, 3-Stacked LSTM, and CNN-LSTM, respectively, on the balanced data achieved through Random Undersampling.

*4) Experiment 4: Hybrid sampling*: In Experiment 4, the examination of the models' performance was carried out when trained on a dataset balanced using hybrid sampling, combining SMOTE and random undersampling. The four models underwent training on the hybrid-sampled dataset. The search for the best hyperparameters for each model was conducted using Keras Tuner, as indicated in Table XIII.

Performance metrics from this experiment were documented in Table XIV and compared with the results from Experiment 1. Fig. 19 to Fig. 22 illustrate the confusion matrices for the Vanilla LSTM model, 2-Stacked LSTM, 3-Stacked LSTM, and CNN-LSTM, respectively, on the balanced data achieved through hybrid Sampling.

*E.  Comparative Results Analysis*

In this research paper, a comparative study was conducted employing four distinct deep learning models: Vanilla LSTM, 2 Stacked LSTM, 3 Stacked LSTM, and hybrid CNN-LSTM. The study aimed to address the challenge of class imbalance in Human Activity Recognition (HAR) through the utilization of three sampling techniques: SMOTE, Random Undersampling, and a novel Hybrid Sampling approach. The performance of these models was evaluated based on key metrics, including accuracy, F1 score, precision, and recall.

Accuracy Comparison of Deep Learning Models on Different Sampling Techniques (illustrated in Fig. 23):

- For models trained on imbalanced data, the 2 Stacked LSTM model exhibited the highest accuracy, achieving 0.9531. It was closely followed by the Vanilla LSTM model with an accuracy of 0.9257.

- When using SMOTE to balance the data, the Vanilla LSTM model performed remarkably well, with an accuracy of 0.9499. The 2 Stacked LSTM also showed strong performance with an accuracy of 0.9438.

- For Hybrid Sampling, the models reached even higher accuracy. The 2 Stacked LSTM achieved an accuracy of 0.9755, and the Vanilla LSTM excelled further with an impressive accuracy of 0.9821. The 3 Stacked LSTM model with Hybrid Sampling exhibited the most remarkable performance, achieving an accuracy of 0.9828.

F1-score Comparison of Deep Learning Models on Different Sampling Techniques (see Fig. 24):

- In terms of F1 score, similar trends were observed. The 2 Stacked LSTM model performed exceptionally well

Fig. 21.  Confusion matrix of 3 stacked LSTM on balanced data with hybrid sampling.

across all sampling techniques, reaching an F1 score of 0.9529 for imbalanced data and 0.9415 for data balanced with SMOTE.

- The models with Hybrid Sampling outperformed the others in F1 score. The 2 Stacked LSTM model achieved an F1 score of 0.9752, and the Vanilla LSTM excelled with an impressive F1 score of 0.9821. The 3 Stacked LSTM model with Hybrid Sampling exhibited the most remarkable performance, with an F1 score of 0.9828.

Precision Comparison of Deep Learning Models on Different Sampling Techniques (see Fig. 25):

- Precision results followed a similar pattern. The 2 Stacked LSTM model consistently showed high precision across all sampling techniques, with values ranging from 0.9536 to 0.9470.

- When using Hybrid Sampling, precision levels were remarkably high, with the models achieving precision values ranging from 0.9764 to 0.9537.

- The 3 Stacked LSTM model with Hybrid Sampling exhibited the most exceptional performance, with a precision of 0.9828.

Recall Comparison of Deep Learning Models on Different Sampling Techniques (see Fig. 26):

- Recall rates were also in line with accuracy and F1 score trends. The 2 Stacked LSTM model exhibited high recall, especially with Hybrid Sampling, where it reached a recall rate of 0.9755.

- The Vanilla LSTM model also performed well, achieving recall rates ranging from 0.9438 to 0.9499.

- The 3 Stacked LSTM model with Hybrid Sampling showed the most impressive result, with a Recall of 0.9828.

In summary, this study conclusively demonstrates the efficacy of hybrid sampling techniques in effectively addressing class imbalance challenges in HAR. The proposed models consistently achieve good results, especially the 3 Stacked LSTM, surpassing other models in terms of accuracy, precision, recall, and F1 scores. This underscores the crucial importance of balancing data for better-performing deep models. The comparative plots in Fig. 23 to Fig. 26 provide a visual representation of these findings.

Comparison with Previous Studies:

Previous research has extensively explored diverse deep-learning models for Human Activity Recognition (HAR) using the PAMPA2 dataset. As demonstrated in Table XV, these prior studies have yielded impressive outcomes. In 2022, an exemplary convLSTM Autoencoder (AE) model exhibited remarkable accuracy, recording a value of 0.9433, along with an F1 score of 0.9446 [4]. Similarly, in 2023, a Bi-LSTM model demonstrated commendable performance, achieving a high accuracy of 0.9341 and an F1 score of 0.9341, complemented by notable precision and recall values [17].

TABLE XV.    COMPARISON WITH PREVIOUS WORKS

| Study | year | Dataset | Classification method | Accuracy | F1 score | Precision | Recall |
|---|---|---|---|---|---|---|---|
| [15] | 2020 | PAMAP2 | LSTM | 0.8580 | 0.8534 | 0.8651 | 0.8467 |
| [15] | 2020 | PAMAP2 | LSTM | 0.8580 | 0.8534 | 0.8651 | 0.8467 |
| [16] | 2022 | PAMAP2 | LSTM | 0.8920 | 0.8949 | 0.8969 | 0.8928 |
| [4] | 2022 | PAMAP2 | convLSTM AE | **0.9433** | **0.9446** | - | - |
| [18] | 2022 | PAMAP2 | CNN-BiLSTM | 0.9429 | **-** | - | - |
| [16] | 2022 | PAMAP2 | LSTM | 0.8920 | 0.8949 | 0.8969 | 0.8928 |
| [18] | 2022 | PAMAP2 | CNN-BiLSTM | 0.9429 | **-** | - | - |

Finally, our study demonstrates the effectiveness of Hybrid Sampling techniques in addressing class imbalance in HAR, leading to higher accuracy, precision, recall, and F1 scores. These models consistently outperformed the best-performing models from previous research, underscoring their potential to significantly enhance the accuracy and reliability of HAR systems and demonstrating the importance of tackling the imbalanced data problem.

## V.  DISCUSSION

Prior studies such as [6], [24] have highlighted the lack of works that address and investigate the impact of the class imbalance problem in human activity recognition. This present study fills this gap by comparing three sampling approaches, SMOTE, Random Undersampling, and Hybrid sampling to reduce the class imbalance and substantially improve human activity recognition (HAR) performance.

In this section, a comprehensive discussion of the experimental findings and their implications for the field of HAR using deep learning models is presented. The consideration encompasses the following key aspects: the impact of class imbalance, the effectiveness of sampling techniques, and the significance of hyperparameter tuning.

*1) Hyperparameter tuning enhances model adaptability and performance*: In all the experiments, hyperparameter tuning was applied in each scenario, proving to be a highly beneficial approach. The optimization of hyperparameters for each experiment ensured that the deep learning models were tailored to perform optimally under specific conditions. This adaptability is crucial in real-world applications where data characteristics and sampling techniques may vary. Moreover, hyperparameter tuning significantly contributed to the fairness of this comparative analysis. It prevented any model from having an unfair advantage due to suboptimal hyperparameters, ensuring a more equitable evaluation of different sampling techniques.

Overall, the inclusion of hyperparameter tuning in this experimental design serves as a robust foundation for meaningful comparisons and insights into HAR.

*2) Addressing class imbalance with sampling techniques:* The experiments aimed to investigate the impact of different sampling techniques on the performance of deep learning models in HAR. To address this, four experiments were conducted, each involving variations in data preprocessing and

sampling, and each of them incorporated hyperparameter tuning.

The results clearly demonstrate the notable impact of sampling techniques on model performance, further enhanced by hyperparameter tuning.

In Experiment 2, following the application of SMOTE and Hyperparameter Tuning, substantial improvements in accuracy, F1 score, precision, and recall were observed across all models. This underscores the effectiveness of SMOTE in addressing the class imbalance issue, especially when combined with optimal hyperparameters. The balanced dataset led to enhanced recognition efficiency, with significant gains in accuracy and F1 score.

In Experiment 3, involving Random under-sampling and Hyperparameter Tuning, the models exhibited decreased performance compared to the baseline.

In Experiment 4, employing hybrid sampling and hyperparameter tuning, remarkable results were achieved. By combining the strengths of SMOTE and Random Undersampling with fine-tuned hyperparameters, high accuracy and F1 scores were achieved, surpassing the baseline. This confirms the potential of hybrid sampling as a powerful technique for enhancing model performance, especially when hyperparameters are tuned effectively.

Hybrid sampling demonstrates its effectiveness in balancing data by leveraging the strengths of both oversampling (SMOTE) and undersampling (Random Undersampling) techniques. It begins by oversampling the minority class, increasing its representation, and then follows with undersampling the majority class to reduce redundancy. This approach enhances model performance, mitigates overfitting, and ensures that deep learning models are exposed to a more representative and diverse distribution of data. Consequently, these factors contribute to improved generalization, enabling models to make more accurate predictions. It is the combination of these advantages that positions hybrid sampling as an outperforming technique compared to other sampling methods.

*3) Model performance and generalization*: The findings suggest that deep learning models trained on balanced datasets exhibit improved performance compared to those trained on imbalanced data. This result highlights the significance of addressing class imbalance in HAR applications. Furthermore, these models demonstrated robust generalization capabilities, indicating their potential for real-world deployment.

*4) Practical implications*: The practical implications of this research extend to various applications, including healthcare, fitness tracking, and human-computer interaction. By improving the accuracy and reliability of HAR systems through both sampling techniques and hyperparameter tuning, this work contributes to enhancing user experiences and promoting healthier lifestyles.

*5) Limitations and future work*: It's important to acknowledge the limitations of this study. The choice of datasets, model architectures, and hyperparameters may

impact the generalizability of the findings. Future research could explore additional datasets, and more complex model architectures, and further investigate hyperparameter tuning techniques. Additionally, the real-world deployment of HAR systems should consider challenges related to sensor placement, data privacy, and user variability.

In conclusion, this study emphasizes the critical role of both sampling techniques and hyperparameter tuning in improving the performance of deep learning models for HAR. SMOTE and hybrid sampling methods, when coupled with effective hyperparameter tuning, demonstrate their effectiveness in addressing class imbalance. The achievement of enhanced accuracy and F1 scores through these combined techniques paves the way for more reliable and efficient HAR systems with broader applications.

## VI. CONCLUSION

In this extensive study on Human Activity Recognition (HAR) using deep learning models and wearable sensor data, the goal was to enhance the accuracy and reliability of HAR systems, which are crucial in healthcare and sports analytics. The challenge of imbalanced datasets in HAR was addressed by exploring different sampling techniques: Synthetic Minority Over-sampling Technique (SMOTE), random undersampling, and hybrid sampling (a combination of SMOTE and random undersampling). These techniques were tested with various deep learning models, including Vanilla LSTM, 2 Stacked LSTM, 3 Stacked LSTM, and Hybrid CNN-LSTM. The findings showed significant improvements in model performance when using sampling techniques to balance the data. SMOTE and hybrid sampling were particularly effective in countering class imbalance, leading to notable enhancements in model accuracy, precision, recall, and the F1 score. The importance of hyperparameter tuning, involving adjustments to specific model settings, was also highlighted. By fine-tuning these parameters, even better model performance was achieved, emphasizing the critical connection between data preprocessing and parameter configuration. As wearable sensors become more prevalent, this research contributes to the creation of systems that can better understand and interpret human actions in various real-world scenarios. Future work will involve experiments with more diverse public datasets, the exploration of more complex deep learning models, and the investigation of additional sampling techniques to further advance the field of Human Activity Recognition

# Design of an Advanced Distributed Adaptive Control for Multi-SMA Actuators

Belkacem Kada[*], Khalid A. Juhany, Ibraheem Al-Qadi, Mostefa Bourchak
Aerospace Engineering Department, King Abdulaziz University, Jeddah, KSA

*Abstract*—**Aerospace applications place high demands on designing Shape Memory Alloy (SMA) actuators, including accuracy, dependability, high-performance criteria, and cooperative activation. Because of their portability, durability, and performance under extreme conditions, SMAs have found a home in the aerospace industry as single and array actuators. This paper presents the development of a control scheme for thermally activating rotary SMA actuators as single and cooperative actuators. The control scheme is a hybrid adaptive robust control abbreviated as HARC. The immersion and invariance adaptive (I&I adaptive) and L2-gain control frameworks are utilized in developing the HARC approach. To create stable transient responses despite parametric and non-parametric errors, recursive backstepping is utilized for asymptotic stability. At the same time, L2-gain control is applied to ensure the global stability of the transient closed-loop system. Both techniques are used in conjunction with one another. In contrast to the conventional I&I, the robust control law can be developed without needing a target system or the solution of PDEs to satisfy the I&I condition. The parametric uncertainty is estimated with the help of an adaptive rule, and the non-parametric uncertainty brought on by the phase change of the SMA material and modeling mistakes is accounted for with the help of asymptotic nonlinear functions. The designed HARC is then extended to cover the actuation of multi-SMA or array actuators to respond to the increasing demand for cooperative controllers using distributed control protocols. It has been demonstrated through simulation testing on a rotational NiTi SMA actuator that the suggested control approach is both practical and resilient.**

*Keywords—Adaptive backstepping; hysteresis; I&I control; L2-gain control; rotary actuator; shape memory alloy*

## I. INTRODUCTION

Shape memory alloy (SMA) materials are promising materials for enhanced aircraft actuation because to their excellent physical and thermomechanical properties. SMA materials outperform other materials in terms of shape memory effect (SME) and superelasticity. The capacity of distorted SMA to regain its original shape following heating is referred to as superelasticity. Because of their superior performance qualities, SMA actuators can be employed in place of more traditional actuation solutions like solenoids, motors, thermometers, and even vacuum and pneumatic systems. SMA actuators have excellent control characteristics such as rapid response time, oscillation damping, and low power consumption. SMA actuators are of tremendous interest and usage in many cutting-edge industries, such as aerospace, automotive, information technology, and biomedical engineering [1-3]. Additionally, SMA actuators are highly effective at absorbing and dissipating mechanical energy. They can be used in numerous forms, including wires, springs, and strips. Typically, the actuation frequency of SMA actuators is much lower than that of conventional actuators such as DC/AC motors and hydraulic systems.

SMA twist or rotational actuators are a feasible solution for traditional step motors. They can be used to make helical torsion springs, twisted wires, twisted strips, thin-sheet torsional actuators, and antagonistic multiple-wire designs [4,5]. Applications for SMA torsional actuators include self-reconfigurable and modular robots, surgical instruments, and transformable wings [6-8]. SMA thermal activation via Joule heating with an electrical current is an efficient way for optimizing the effect of shape memory [9,10]. Understanding the heat activation and heat transport mechanisms of shape memory alloys is essential for employing them creatively and increasing their possible uses. However, the solid-state phase transformation and its accompanying physical phenomena, such as hysteresis, make regulating SMA-based actuators a difficult task.

To address the problem of SMA twist actuator control, various nonlinear control approaches were used. Sliding mode control (SMC) has been used in a variety of topologies to address nonlinear dynamics and hysteresis in SMA materials, as well as parameter uncertainties in system modeling. A wide range of SMC-based rotary SMA controllers have been designed and implemented for a wide range of engineering systems, including morphing airplanes [11], artificial muscles inspired by the human arm [12], multi-rod bars for flexible robotic arms [13], and flexible needles for clinical applications [14]. Despite applying various strategies, such as the saturation boundary layer function, the SMC-based controllers displayed control input chattering, which is damaging to the actuation systems. The challenges of SMA modeling and control have been overcome, for example, by employing fuzzy logic control (FLC) and artificial neural networks (AINN). Several studies on FLC and ANN for SMA have been published [15-20]. However, both FLC and ANN implementation necessitate sophisticated and time-consuming techniques.

Adaptive backstepping control (ABC) is a powerful robust control approach that is commonly used in the control design of nonlinear, dynamically unpredictable, and nonsmoothed systems. ABC is a promising new method for industrial applications, particularly in electrical, medical, and aerospace systems. Few studies have been conducted to address the problem of SMA hysteresis control using nonlinear adaptive backstepping control. Recently, [21] addressed the problem of hysteresis in control systems by employing a unique hysteresis

model and an ABC to assure stable and accurate control. In [22], authors used ABC to design a control system for a soft robotic muscle inspired by biology. The authors demonstrated that ABC outperforms adaptive sliding mode control regarding time-domain response performance. This paper presents a new hybrid adaptive robust control (HARC) method to thermally activate SMA rotary actuators in the presence of parametric and non-parametric uncertainties. The technique combines I&I-adaptive control with $L_2$-gain control. A Lyapunov-based analysis of the controller's stability is presented. The proposed controller can provide robust and rapid tracking of the desired system response despite its asymptotic convergence. The following is the outline for the paper. In Section II, the thermomechanical modeling of a rotary SMA actuator is presented along with the control objective of this paper. Section III presents the design of a nonlinear backstepping controller and an adaptive parameter law. Additionally, a stability analysis is investigated. Section IV presents numerical results, while Section V provides a conclusion and future perspectives.

## II. MATHEMATICAL MODELING OF A ROTARY SMA ACTUATOR AND CONTROL OBJECTIVE

In this study, the angular position response of a rotary SMA actuator is controlled by the thermally induced shape-memory effect (SME) under electrical current input where the electrical power is converted to heat. Typically, this mechanism is used to control the SMA actuator. Under the influence of heat, the SMA actuator phase transitions from martensite to austenite and then back to martensite upon cooling. Fig. 1 shows some aerospace applications of SMA actuators.

a)

b)
Fig. 1. SMA actuators applied in aerospace control i: a) SMA actuator for Boeing 777-300ER airplane engines [24]; b) SMA actuator for torque control of the outboard wing section.

A heating or cooling process governs the phase transformation of SMAs from martensite to austenite and vice versa. During the heating process, unloaded martensite begins to transform into austenite at the austenitic start temperature $A_s$ with a martensite volume fraction $\xi = 1$. The transformation continues until the austenitic transition temperature $A_f$ and $\xi = 0$ are reached. The hysteresis loop depicted in Fig. 1(b) explains the irreversible nature of the crystalline structure change during thermally induced SME.

### A. Thermomechanical Modeling

Consider an SMA model wire with a small diameter and a lumped capacitance, where the internal thermal gradient is small and the latent heat effects are negligible. The following lumped-capacitance thermal and Liang-Brinson phenomenological model was found to be adequate for this study [24].

$$\begin{cases} mC_p\dot{T} + hA_c[T - T_0] = R\,u \\ \dot{\sigma} = E\dot{\epsilon} + \Omega\dot{\xi} + \Theta\dot{T} \end{cases} \quad (1)$$

where, $\sigma$, $\epsilon$, $T$ denote the stress, strain, and temperature states; $m$, $C_p$, $h$, $A_c$, $R$ denote the actuator's mass, specific heat, convection heat transfer coefficient, convection area, and resistor, respectively; $\Omega$ denotes the phase transformation, $T_{amb}$ is the ambient temperature and $u = i_c^2$ denotes the control input where $i_c$ is the electrical current. The elastic deformation $\epsilon$ is given by

$$\epsilon = (l - l_0 - r\theta)/l_0 \quad (2)$$

where, $l_0$ is the initial length of the SMA actuator. The lumped-capacitance thermal model exhibits mathematically simple behavior and conforms to Newton's law of cooling.

$$T_{cool}(t) = T_0 + (T_w - T_0)e^{-\lambda t} \quad (3)$$

where, $T_0$ is the ambient temperature, $T_w$ is the initial temperature of the wire, and $\lambda = hA_c/mC_p$. The stress-strain model is a macro-mechanical or phenomenological constitutive law developed by Tanaka and updated by Liang and Brinson [25]. The model considers both thermomechanical and phase transformations. In Liang-Brinson model, the phase transformation volume fraction is modified to include the effect of complex loadings using cosine function rather than the exponential function used in Tanaka model.

### B. Enhanced SME Model

We use the Elahinia-Ahmadian phase transformation model to predict the SMA behavior under complex fast stress and temperature loadings, which is the case for most rotary actuators. Experiments have demonstrated that the modified model can predict SMA behavior under complex loading conditions [26, 27]. The martensite volume fraction is calculated using the following equation during the reverse transformation of martensite to austenite by heating.

$$\xi = \frac{\xi_M}{2}\{cos[a_A(T - A_s) + b_A\sigma] + 1\} \quad (4)$$

The reverse phase transformation occurs under the following heating and unloading conditions.

$$\begin{cases} A_s + \frac{\sigma}{C_A} < T < A_f + \frac{\sigma}{C_A} \\ \dot{T} - \frac{\dot{\sigma}}{C_A} > 0 \end{cases} \quad (5)$$

Similar conditions were developed for the modified austenite to martensite phase transformation using cosine equation. The martensite volume fraction is computed as follows:

$$\xi = \frac{1-\xi_A}{2} cos[a_M(T - M_f) + b_M\sigma] + \frac{1+\xi_A}{2} \quad (6)$$

with

$$\begin{cases} M_f + \frac{\sigma}{C_M} < T < A_s + \frac{\sigma}{C_M} \\ \dot{T} - \frac{\dot{\sigma}}{C_M} < 0 \end{cases} \quad (7)$$

In this formulation $C_M$ and $C_A$ are material properties which describe the relationship between temperature and critical stress to induce transformation, and the parameters $a_M$ and $a_T$ are defined by

$$a_M = \frac{\pi}{M_s - M_f}, \quad a_A = \frac{\pi}{A_f - A_s} \quad (8)$$

### C. Kinematic and Dynamic Modeling

The SMA actuator model is a bias-type actuator whose general kinematics and dynamics equations are given as follows:

$$\begin{cases} \dot{\theta} = \omega \\ J\dot{\omega} + b(\theta)\omega + k\theta = \tau_s(\sigma) \end{cases} \quad (9)$$

where, $\theta, \omega, J, b, k$ are the actuator's angular position, angular velocity, effective inertia, damping, and stiffness, respectively; $\tau, \sigma$ denote the control effort and the Piola-Kirchhoff's stress. The input torque $\tau_s(\sigma)$ is supposed to be a linear function of the mechanical stress $\sigma$

$$\tau(\sigma) = Ar\sigma \quad (10)$$

### D. Control Objective

The control objective is to guarantee that the transient trajectories of the angular position, angular speed, the temperature are globally bound and converge to a new equilibrium despite hysteresis. We introduce, in systems (1) and (9), the new states $x_1 = \theta, x_2 = \omega, x_3 = T$ with an initial steady-state operating equilibrium defined as $[\theta_0 \quad \omega_0 \quad T_0]^T$

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -a_1 x_1 - \beta x_2 + a_2 x_3 + f_1(\xi, T) \\ \dot{x}_3 = -b_1(x_3 - T_0) + b_2 u + f_2(\xi, T) \end{cases} \quad (11)$$

with

$$\begin{cases} a_1 = k/J, \ a_2 = \alpha Ar/J, \ \beta = b/J, \\ b_1 = hA_c/(mC_p), \ b_2 = R/(mC_p) \end{cases}$$

The model in (11) is a nonlinear dynamic model where $\beta$ denotes the uncertainty in the damping properties of the actuator and $f_1(\xi)$ and $f_2(\dot{\xi})$ are uncertain bounded functions denoting the nonlinear hysteretic terms. The upper limits $f_1(\xi)$ and $f_2(\dot{\xi})$ satisfy

$$|f_i| \le l \in \mathbb{R}^+ \quad (12)$$

For simplicity, in the following $f_1(\xi)$ and $f_2(\xi)$ are substituted by $f_1$ and $f_2$. The control input $u$ in (11) is designed to provide a robust and adaptive control input to the thermal actuation system of the SMA actuator. The adaptive law $\hat{u} = u(x, \hat{\beta})$, where $\hat{\beta}$ denotes the estimator of $\beta$ provided by a proper adaptive law, is designed to compensate for parametric and non-parametric uncertainties. The robustness control component is designed using dissipation theory for which an energy storage function $V(x(t))$ is selected to guarantee the following condition.

$$V(x(t)) - V(x(0)) = \int_0^T L(f(\xi))dt \quad (13)$$

where $f = [f_1 \ f_2]^T$ and $L$ is an energy supply function. The parameter adaptive law is designed as follows.

$$\dot{\hat{\beta}} = \Phi(x, \hat{\beta}) \quad (14)$$

In absence of phase transformation, the control input $u(x, \hat{\beta})$ with the parameter adaptive law (14) guarantee the global asymptotic stability of the closed loop (11). For the case $f_i \ne 0 \ (i = 1,2)$, a global asymptotic stability is provided by the control law $u(x, \hat{\beta})$ under L₂-gain control bound.

### III. ADAPTIVE ROBUST SMA CONTROLLER DESIGN

#### A. Parameter Adaptive Law

The parameter adaptive law is designed to alleviate the influences of nonlinear parameter uncertainties. To construct the adaptive law (14), a parameter estimation error is defined as follows:

$$\varphi = \hat{\beta} - \beta + \rho(x_1, x_2) \quad (15)$$

where, $\rho(x_1, x_2)$ can be chosen as function of the actuator's motion states and be designed such that $\lim_{t\to\infty} \varphi = 0$. For simplicity $\rho(x_1, x_2)$ is denoted by $\rho$. The time derivative of expression (15) along the trajectories (11) gives

$$\dot{\varphi} = \dot{\hat{\beta}} + \frac{\partial \rho}{\partial x_1}\dot{x}_1 + \frac{\partial \rho}{\partial x_2}\dot{x}_2 \quad (16)$$

Using the dynamic model in (11), the time derivative $\dot{\varphi}$ is written as follows

$$\dot{\varphi} = \dot{\hat{\beta}} + \frac{\partial \rho}{\partial x_1}x_2 + \frac{\partial \rho}{\partial x_2}(-a_1 x_1 - \beta x_2 + a_2 x_3 + f_1) \quad (17)$$

Consider the case of $f_1 = 0$ and suppose that $\varphi$ is asymptotically convergent function with $\lim_{t\to\infty} \varphi = 0$, the estimator $\hat{\beta}$ can be chosen as

$$\dot{\hat{\beta}} = -\frac{\partial \rho}{\partial x_1}x_2 - \frac{\partial \rho}{\partial x_2}(-a_1 x_1 - (\hat{\beta} + \rho)x_2 + a_2 x_3) \quad (18)$$

which yields to

$$\dot{\varphi} = -\frac{\partial \rho}{\partial x_2}(\varphi x_2 - f_1) \quad (19)$$

## B. Robust Control Law Design

To design a robust SMA controller, we define for the dynamic system the following tracking errors

$$\begin{cases} e_1 = x_1 - x_1^* \\ e_2 = x_2 - x_2^* \end{cases} \tag{20}$$

where, $x_1^*, x_2^*$ are of class $C^{(0)}$ and define the desired states that serve as virtual control inputs to the first and second equations of model in (11).

Step 1: Angular position subdynamics stabilization

From the first equation in system in (20), the dynamic of $e_1$ is obtained as

$$\dot{e}_1 = x_2 = e_2 + x_2^* \tag{21}$$

With $e_2 = 0$, the system in (21) is stable under the following virtual control law.

$$x_2^* = -k_1 x_1 \tag{22}$$

Step 2: Angular velocity subdynamics stabilization.

$$\dot{e}_2 = -a_1 x_1 - \beta x_2 + a_2 x_3 + f_1 + k_1 x_2 \tag{23}$$

For the effect of the phase transformation on the actuator dynamics, we propose the following dissipation function.

$$L_1 = \frac{d}{dt} \sum_{i=1}^{2} \left( \frac{1}{2} e_i^2 \right) + \frac{1}{2} (\|\boldsymbol{h}\|^2 - \mu^2 f_1^2) \tag{24}$$

where $\boldsymbol{h} = [p_1 x_1 \quad p_2 x_2]^T$ is the output vector and $\mu \in \mathbb{R}^+$. Substituting (16) and (18) into (19) gives

$$L_1 = [e_1 x_2 + e_2(-a_1 x_1 - \beta x_2 + a_2 x_3 + f_1 + k_1 x_2)] + \frac{1}{2}(p_1^2 x_1^2 + p_2^2 x_2^2 - \mu^2 f_1^2) \tag{25}$$

One can write (23) as follows:

$$L_1 = -\alpha_1 e_1^{2.} - \frac{1}{2} \left( \mu f_1 - \frac{e_2}{\mu} \right)^2 - \frac{1}{4} \mu^2 f_1^2 + e_2 [\alpha_2 x_1 + (-\beta + \alpha_3) x_2 + a_2 x_3] \tag{26}$$

with

$$\alpha_1 = k_1 - \frac{1}{2} p_2^2 k_1^2 - \frac{1}{2} p_1^2, \quad \alpha_2 = k_1 \left( \frac{1}{\mu^2} - \frac{1}{2} p_2^2 \right) + 1 - a_1,$$
$$\alpha_3 = k_1 + \frac{1}{2} p_2^2 + \frac{1}{\mu^2}$$

To satisfy the dissipation condition for the function $f_1$, a virtual control $x_3^*$ is chosen as follows

$$x_3^* = \frac{-\alpha_2 x_1 - (\hat{\beta} + \rho + \alpha_3) x_2}{a_2} \tag{27}$$

where $\hat{\beta}$ is the estimation of $\beta$ to be provided by the adaptive law and $\rho$ is a smooth function to be designed later. Substituting (26) into (27), the function $F_1$ becomes

$$L_1 = -\alpha_1 e_1^{2.} - \frac{1}{2} \left( \mu f_1 - \frac{e_2}{\mu} \right)^2 - \frac{1}{4} \mu^2 f_1^2 - e_2 x_2 (\hat{\beta} - \beta + \rho) \tag{28}$$

It follows that the condition $F_1 < 0$ is satisfied only if

$$\hat{\beta} - \beta + \rho > 0 \tag{29}$$

Step 3: Real control law

The real control input to system in (11) is designed to ensure the dissipation condition in (13). Thus, a new function $F_2$ is constructed as follows

$$L_2 = \frac{d}{dt} \sum_{i=1}^{3} \left( \frac{1}{2} e_i^2 \right) + \frac{1}{2} \left( \|\boldsymbol{h}\|^2 - \mu^2 \sum_{i=1}^{2} (f_i^2) \right) \tag{30}$$

With $e_3 = x_3 - x_3^*$, one can obtain

$$\dot{e}_3 = -b_1(x_3 - T_0) + b_2 u$$
$$+ f_2 - \left[ \frac{a_2 \dot{x}_1 - (\hat{\beta} + \rho + \alpha_3) \dot{x}_2 - (\dot{\hat{\beta}} + \dot{\rho}) x_2}{a_2} \right] \tag{31}$$

It follows that

$$L_2 = -\alpha_1 e_1^{2.} - \frac{1}{2} \left( \mu f_1 - \frac{e_2}{\mu} \right)^2 - \frac{1}{4} \mu^2 f_1^2 - e_2 x_2 (\hat{\beta} - \beta + \rho)$$
$$e_3 \left( -b_1(x_3 - T_0) + b_2 u + f_2 - \left[ \frac{a_2 \dot{x}_1 - (\hat{\beta} + \rho + \alpha_3) \dot{x}_2 - (\dot{\hat{\beta}} + \dot{\rho}) x_2}{a_2} \right] \right) \tag{32}$$

The real control law for system in (11) is obtained as follows

$$u = \frac{1}{b_3} \left[ b_1(x_3 - T_0) + \frac{a_2 \dot{x}_1 - (\hat{\beta} + \rho + \alpha_3) \dot{x}_2 - (\dot{\hat{\beta}} + \dot{\rho}) x_2}{a_2} \right] \tag{33}$$

## C. Stability Analysis

To address the global stability of the SMA actuator, the dynamic model in (11) is put in an error form using the definitions (21), (23), and (30).

$$\begin{cases} \dot{e}_1 = e_2 + k_1 e_1 \\ \dot{e}_2 = -a_1 x_1 - \beta x_2 + a_2 x_3 + f_1 + k_1(e_2 - k_1 e_1) \\ \dot{e}_3 = (b_1 x_2(x_3 - T_0) + b_2 u + f_2 \\ \quad - \left[ \frac{a_2 \dot{x}_1 - (\hat{\beta} + \rho + \alpha_3) \dot{x}_2 - (\dot{\hat{\beta}} + \dot{\rho}) x_2}{a_2} \right] ) \end{cases} \tag{34}$$

Consider a Lyapunov candidate function $V = \sum_{i=1}^{3} \left( \frac{1}{2} e_i^2 \right)$, the function $L_2$ given in (30) can be written as follows.

$$L_2 = \dot{V} + \frac{1}{2} \left( \|\boldsymbol{h}\|^2 - \mu^2 \sum_{i=1}^{2} (f_i^2) \right) \tag{35}$$

From (33), it follows that $L_2 \le 0$ if and only if $\lim_{t \to \infty} (\hat{\beta} - \beta + \rho)$, thus.

$$\dot{V} \le -\frac{1}{2} \left( \|\boldsymbol{h}\|^2 - \mu^2 \sum_{i=1}^{2} (f_i^2) \right) \tag{36}$$

The integration of (36) for the case of $f_1 = f_2 = 0$ gives

$$V(t) \le V(0) - \frac{1}{2} \int_0^t \|\boldsymbol{h(t)}\|^2 \, dt \le V(0) \tag{37}$$

It can be seen from system in (35), that the origin ($e_1 = e_2 = e_3 = 0$) is globally stable. For the case of non-parametric uncertainties where $f_1 \neq 0, f_2 \neq 0$, the following semi-defined function is considered

$$W(\boldsymbol{e}, \boldsymbol{f}) = -\alpha_1 e_1^2 - \frac{1}{2}\left(\mu f_1 - \frac{e_2}{\mu}\right)^2 - \frac{1}{2}\left(\mu f_2 - \frac{e_3}{\mu}\right)^2$$

$$-\left(\frac{1}{2}\mu f_1 - \frac{(\alpha_2 + \hat{\beta} + \rho)e_3}{\mu a_3}\right)^2 - \left(e_2 - \frac{(\alpha_2 + \hat{\beta} + \rho)e_3}{\mu a_3}\right)^2 \varphi x_2 \tag{38}$$

From (35), it follows that

$$\dot{V} \leq -W(\boldsymbol{e}, \boldsymbol{f}) \leq 0 \tag{39}$$

According to Lasalle-Yoshizawa theorem [26], all solutions of (11) are globally uniformly asymptotically stable and satisfy the following condition $\lim_{t \to \infty} W = 0$.

### D. SMA-based Array Actuator

Consider the case of an array actuator where all the individual actuators are connected to the power supply source. The following distributed heat law is considered for thermal activation of the $i^{th}$ SMA actuator.

$$u_i = \frac{1}{b_3}\Big[b_1(x_{3,i} - T_0)$$

$$+ \frac{\alpha_2 \dot{x}_{1,i} - (\hat{\beta} + \rho + \alpha_3)\dot{x}_{2,i} - (\dot{\hat{\beta}} + \dot{\rho})\, x_{2,i}}{a_2}$$

$$k\left[\sum_{j \in \mathcal{N}} a_{ij}(\boldsymbol{x}_i - \boldsymbol{x}_j) + a_{i0}(\boldsymbol{x}_i - \boldsymbol{x}_d)\right] + \tag{40}$$

with $k \in \mathbb{R}^+$ is a control gain.

The control objective is achieved when all the actuators' states reach the desired value according to the following consensus

$$\left\{\lim_{t \to t_s}\|\boldsymbol{x}_i - \boldsymbol{x}_d\|_2 = 0\right. \tag{41}$$

where, $t_s$ is the settling time and $a_{ij}$ are the coefficients of the adjacency matrix of the activation topology.

### IV. NUMERICAL RESULTS

To demonstrate the efficacy of the theoretical developments, numerical calculations have been performed. Since the twist angle $\theta$ measures the actuating capability of the SMA rotary actuator, two desired twist angle paths are considered. First, the SMA wire is heated to its final austinite temperature $A_f$ to achieve the desired steady angle $\theta_t = 100°$. The SMA actuator was then heated between $A_s$ and $A_f$ to track a desired time-varying sinusoidal twist angle in the presence of external disturbances. The non-parametric uncertainties $f_1$ and $f_2$ are determined as follows:

$$\begin{cases} f_1 = ae^{b(T - T_0)}\sin(\xi) \\ f_2 = ae^{b(T - T_0)}\cos(\xi) \end{cases}$$

with $a = 1e - 7, b = 0.25$.

The thermomechanical properties of the selected $NiTi$ material and the actuator parameters used in this simulation are shown in Table I.

TABLE I. NiTi MATERIAL AND ACTUATOR PROPERTIES

| NiTi material | | Actuator wire | |
|---|---|---|---|
| property | Value | property | Value |
| $M_s, M_f$ (°C) | 18.4, 9 | $\rho$ ($kg/m^3$) | 6450 |
| $A_s, A_f$ (°C) | 34.5, 49 | $C_p$ ($J/Kg°C$) | 2046 |
| $C_m, C_a$ ($Pa/°C$) | 8e6, 13.8e6 | $d$ (mm) | 1.0 |
| $\sigma_{s_{cr}}, \sigma_{a_{cr}}$ (Pa) | 100e6,100e6 | $L_0$ (mm) | 100 |
| $\alpha_s, \alpha_f$ | 1.1e-6, 6.6e-6 | $R(\Omega)$ | 3.0 |
| $\epsilon_L$ | 0.067 | $T_0$ (°C) | 25 |

*Scenario 1*: A simulation of angle-temperature actuation was run to validate the single actuator control law (33). The twist angle achieved the desired $\theta_t = 100°C$ without overshooting, the temperature $T$ saturated around $70°C$ and the equivalent stress $\sigma$ reached $600\ MPa$. Fig. 2 shows the simulation results for with tuning of parameter $\mu$.

Fig. 3 demonstrates that when the suggested HARC method is applied, the transient response of the actuator states converges faster and without oscillation compared to other conventional adaptive backstepping control (CABC) methods.

Fig. 2. Actuator transient response with tuning of parameter $\mu$: a) Twist angle $\theta$, b) rotary velocity $\omega$, and c) heating temperature $T$.

Fig. 4.   Actuation topology for a four-SMA actuator.

Fig. 3.   Comparison between proposed HARC and CABC methods: (a) Twist angle $\theta$, (b) rotary velocity $\omega$, and (c) heating temperature $T$, d) parametric estimator $\beta$.

*Scenario 2:* To simulate the cooperative actuation of an array SMA actuator to overcome individual actuator load bearing limitation, a cooperative task is attributed to a set of four actuators to track a sinusoidal twist angle $\theta_t(t) = 60sin(0.5t)(°)$. The actuators were put under initial conditions of temperature $T = [\ 25\ 50\ 65\ 80]^{°}C$ and initial twist angle $\theta = [-20\ -60\ 60\ 120]^{°}$. A disturbance of $\Delta T = 5°C$ is introduced at $t = 20\ s$ simulating a sudden change in the electrical current and checking the controller's robustness.

The four actuators were actuated according to activation topology shown in Fig. 4. The distributed control law in (41) is used to activate the array controller and the results are shown in Fig. 5.

Fig. 5. Simulation results for a multi-SMA actuator under time-varying actuation topology: a) twist angle, b) angular speed, c) temperature, and d) stress-strain diagram.

*Remark 1:* Fig. 3 shows a fair comparison between the proposed hybrid adaptive robust control scheme and one of the conventional backstepping control approaches. The comparison shows that the hybrid approach provide high-performance and more stable transient response rather than the conventional solution that ignores the nonlinear effect of the system parameters.

*Remark 1*: Fig. 3(d) shows that the parameter estimator $\hat{\theta}(t)$ starting from the initial condition $\hat{\theta}(0) = 0$ converges to its steady-state value $\theta_{ss} = 2$ without oscillation.

*Remark 2*: Changing the design parameter $\mu$ in (24), the transient response of the twist angle, angular speed, and temperature states are affected as shown in Figure 4. The tuning of the parameter $\mu$ directly affects the convergence of the actuator states. Short settling time, small fluctuations, and stable response are obtained with small values of $\mu$.

## V. CONCLUSION

This paper proposed a hybrid adaptive robust control approach for thermal activation of a multi-SMA rotary actuator in the presence of parametric and non-parametric uncertainties using adaptive backstepping control. First, a control method that integrates adaptive immersion and invariance (I&I adaptive) control, $L_2$-gain control, a parameter estimation law, and asymptotic smooth disturbance functions for induced effect of SMA phase transformation was developed. Pre-defined target system and PDEs solving process, presented in the conventional adaptive backstepping methods, were skipped altogether. Then, the developed control scheme was extended to actuate a multi-agent or array controller where a cluster of controllers are used together to cooperate for load bearing beyond their individual capabilities. The distributed control protocols were designed to work in coordination under switching activation topology to avoid excessive current supply and minimize the activation cost. Different simulation scenarios for tracking the target twist angle, thermal load disturbance, and parameter tuning have been carried out to demonstrate the effectiveness of the suggested control method. From what can be seen in simulation results, the suggested hybrid adaptive robust control method offers a viable solution for improving the performance of SMA actuators mainly in terms of stability and robustness. Future works will consider the trade-off between actuator performance and parameter tuning and will extend the proposed control method to other types of SMA controllers.

*Abstract*—**Indoor localization presents formidable challenges across diverse sectors, encompassing indoor navigation and asset tracking. In this study, we introduce an inventive indoor localization methodology that combines Truncated Singular Value Decomposition (Truncated SVD) for dimensionality reduction with the K-Nearest Neighbors Regressor (KNN Regression) for precise position prediction. The central objective of this proposed technique is to mitigate the complexity of high-dimensional input data while preserving critical information essential for achieving accurate localization outcomes. To validate the effectiveness of our approach, we conducted an extensive empirical evaluation employing a publicly accessible dataset. This dataset covers a wide spectrum of indoor environments, facilitating a comprehensive assessment. The performance evaluation metrics adopted encompass the Root Mean Squared Error (RMSE) and the Euclidean distance error (EDE)—widely embraced in the field of localization. Importantly, the simulated results demonstrated promising performance, yielding an RMSE of 1.96 meters and an average EDE of 2.23 meters. These results surpass the achievements of prevailing state-of-the-art techniques, which typically attain localization accuracies ranging from 2.5 meters to 2.7 meters using the same dataset. The enhanced accuracy in localization can be attributed to the synergy between Truncated SVD's dimensionality reduction and the proficiency of KNN Regression in capturing intricate spatial relationships among data points. Our proposed approach highlights its potential to deliver heightened precision in indoor localization outcomes, with immediate relevance to real-time scenarios. Future research endeavors involving comprehensive comparative analyses with advanced techniques hold promise in propelling the field of accurate indoor localization solutions forward.**

## I. INTRODUCTION

Indoor positioning has become a prominent research area in recent years, driven by the increasing demand for location-based services in various applications, such as indoor navigation, asset tracking, and context-aware services. Traditional positioning systems relying on Global Positioning System (GPS) are not always reliable indoors due to limited satellite signals penetration and multi-path effects, making them less accurate for indoor environments. This limitation has led to the emergence of alternative techniques, with machine learning proving to be a promising approach for indoor positioning tasks. Machine learning methods offer the ability to model complex relationships between Wi-Fi Received Signal Strength Indicator (RSSI) measurements and indoor locations, enabling accurate predictions in indoor settings [1]. Among the diverse machine learning algorithms, the K-Nearest Neighbors (KNN) algorithm has garnered significant attention and success in indoor positioning applications [2, 3]. KNN is a non-parametric and instance-based learning algorithm that classifies or predicts a target value based on the similarity of features from neighboring data points. Its simplicity and effectiveness have made it a popular choice for indoor positioning tasks. However, the conventional KNN algorithm can be sensitive to noise and imbalanced data, necessitating the exploration of specialized variants to improve performance.

One such variant is the Weighted K-nearest neighbors (WKNN), which assigns different weights to neighboring data points based on their distance or other factors [4]. This enables WKNN to give higher importance to closer points, leading to more accurate predictions and better handling of imbalanced data distributions. The authors in study [4] propose a method that utilizes Improved W-KNN to enhance indoor localization performance based on fingerprinting by leveraging the relationship between the nearest fingerprint and (K-1) auxiliary fingerprints to determine the position. In the quest for enhanced adaptability, Adaptive KNN adjusts the number of neighbors (K) based on the local density of data points, dynamically tailoring the algorithm to varying spatial distributions within the indoor environment [5]. The paper introduces an enhanced KNN algorithm featuring a variable K. The fundamental concept revolves around dynamically modifying the K value according to the discrepancies between measured signals and the corresponding values within the database. In this paper, adaptability contributes to improved performance across different regions with distinct data densities. Additionally, KNN Regression is used when predicting continuous target variables, such as indoor coordinates, making it particularly suitable for regression tasks in indoor positioning. Apart from KNN-based methods, deep learning techniques have also been explored for indoor positioning. Convolutional Neural Networks (CNN) [6, 7] and Long Short-Term Memory (LSTM) [8] networks are notable examples. CNN can effectively extract spatial features from Wi-Fi images, while LSTM can model temporal dependencies in time-series data, such as RSSI signals. In [7], the authors introduces an innovative method for converting Wi-Fi signatures into

images, establishing a scalable fingerprinting framework utilizing convolutional neural networks (CNNs), These deep learning models have shown promise in achieving high accuracy in indoor positioning tasks, but they may require more extensive datasets and computation resources.

The authors in [9, 10] conducted an overview study on several data dimensionality reduction methods and their effectiveness in reducing computation time while preserving information. Data preprocessing is of paramount importance in indoor positioning tasks to enhance model performance and reduce computational complexity. High-dimensional Wi-Fi RSSI data can be computationally intensive and challenging to handle. To address this issue, dimensionality reduction techniques are applied to retain critical information while significantly reducing the number of features. Principal Component Analysis (PCA) is a popular method for dimensionality reduction, but it may not be ideal for all scenarios due to its requirement for the data to be centered and scaled. As an alternative, Truncated Singular Value Decomposition (Truncated SVD) [11] is employed, which is a variant of PCA that can efficiently handle large datasets and does not require data centering. In this paper, we propose an approach for indoor positioning that combines Truncated SVD for dimensionality reduction of Wi-Fi RSSI data with KNN regression for accurate indoor location estimation. The solutions mentioned above all aim to reduce errors in location estimation. However, a challenge arises in studies using Wi-Fi signals, where the use of high-dimensional data complicates the training process due to the time required for both training and prediction. Therefore, reducing data dimensionality is considered an effective solution to reduce model complexity and simultaneously enhance data processing flexibility. Combining Truncated SVD and KNN Regression yields a flexible method applicable to various indoor positioning scenarios, not constrained by specific data structures or characteristics. The proposed approach will be extensively evaluated and compared with other state-of-the-art methods to demonstrate its effectiveness and applicability.

In the subsequent sections, we will delve into the details which are as follows: Section II is about the related works, Section III deals with the proposed approach. Section IV gives results, and discussion, and concludes with implications for future research in Section V, thereby contributing to the advancement of indoor positioning technology and its real-time applications.

## II. RELATED WORKS

### A. Challenges in Indoor Localization using Wi-Fi Signals

Addressing the problem of enhancing accuracy in indoor positioning still encounters numerous difficulties due to the persistence of challenges such as limited GPS signals. Unlike outdoor environments where Global Positioning System (GPS) signals are readily available, indoor spaces often lack direct access to GPS signals due to signal attenuation caused by walls, ceilings, and other structural elements. This limitation hampers the effectiveness of traditional GPS-based localization techniques. Multipath effects further complicate indoor positioning. Indoor environments introduce multipath effects, where wireless signals bounce off surfaces and create multiple

signal paths. This leads to signal interference, phase shifts, and fluctuations, making signal strength-based localization less accurate and reliable. Moreover, signal propagation variability within indoor spaces can vary significantly due to factors such as furniture placement, architectural elements, and interference from electronic devices. This variability challenges the establishment of consistent and reliable signal patterns for accurate localization. Non-line-of-sight (NLOS) conditions due to obstructions like walls and obstacles can block the direct line between the transmitter and receiver, introducing additional complexities in signal propagation and affecting accuracy. The phenomenon of multipath fading, where signals arriving via different paths interfere constructively or destructively, contributes to signal fluctuations and inaccuracies in distance estimation. Dealing with high-dimensional data, such as Wi-Fi Received Signal Strength Indicator (RSSI) readings from multiple access points, is a computational challenge in indoor localization. The presence of interference and noise from electronic devices further impacts the accuracy of localization algorithms. Different indoor environments with unique layouts and architectural features add complexity to localization algorithms, as a one-size-fits-all approach may not be effective. Privacy concerns arising from collecting and analyzing personal data in indoor localization require careful consideration of data handling and user consent. Furthermore, many indoor localization applications demand real-time accuracy for guiding users or tracking assets, posing a challenge in achieving both precision and speed. Addressing these challenges necessitates innovative techniques that consider the intricacies of indoor environments. The proposed methodology aims to tackle these obstacles by combining dimensionality reduction and regression techniques for accurate indoor localization. In the context of employing methods such as K-Nearest Neighbors (KNN), Weighted K-Nearest Neighbors (WKNN), Adaptive K-Nearest Neighbors (Adaptive KNN), Convolutional Neural Networks (CNN), and Long Short-Term Memory (LSTM) for indoor position prediction, various limitations become apparent. For K-Nearest Neighbors (KNN), its sensitivity to the choice of K neighbors introduces computational complexities as K increases. Additionally, KNN is sensitive to noise and imbalanced data. Weighted K-Nearest Neighbors (WKNN) presents challenges in effectively setting weight parameters to enhance prediction performance. Adaptive K-Nearest Neighbors (Adaptive KNN) involves uncertainty in dynamically determining the optimal number of neighbors (K) for individual cases. Convolutional Neural Networks (CNN) demand substantial training data and computational resources, especially in real-time scenarios. Long Short-Term Memory (LSTM) requires longer time-series data for complex pattern recognition. Overall, while these methods offer unique strengths to tackle indoor positioning challenges, they also exhibit limitations, necessitating careful customization and consideration of the specific environment for an effective solution.

To address these challenges comprehensively, innovative techniques that account for the intricacies of indoor environments are indispensable. The proposed methodology aims to overcome these hurdles by synergistically employing dimensionality reduction techniques and regression methodologies for accurate indoor localization. The ensuing

sections delve into the details of this approach, experimental evaluation, and results, underscoring its efficacy in tackling these persistent challenges and enhancing indoor positioning accuracy.

### B. Dimensionality Reduction Techniques

In the realm of indoor positioning, addressing the challenges posed by high-dimensional data is crucial for achieving accurate and efficient results. This section provides an overview of various dimensionality reduction techniques that have been employed to tackle the complexity of indoor positioning datasets. Dimensionality reduction aims to extract essential information from the data while reducing its dimensionality, thus enhancing the efficiency of subsequent analysis and prediction processes.

One commonly used technique is Principal Component Analysis (PCA) [12-14], which projects the original data onto a new orthogonal coordinate system defined by its principal components. By retaining the most significant dimensions and discarding less informative ones, PCA simplifies the data representation while preserving as much variance as possible. Another approach, [15] Truncated SVD, is a variant of PCA that efficiently approximates the original data matrix by retaining only the top singular values and corresponding singular vectors. This method is particularly suitable for large datasets and offers advantages in terms of computational efficiency.

In addition to these techniques, various other methods can also play a role in dimensionality reduction. However, the choice of method depends on the characteristics of the data and the specific requirements of the indoor positioning task. By effectively reducing the dimensionality of the input data, these techniques contribute to enhancing the performance of subsequent algorithms and models for accurate indoor positioning. The following sections will delve into the details of how these techniques are applied and their impact on the proposed methodology.

*1) Truncated* singular value decomposition (Truncated SDV) Method: The Truncated Singular Value Decomposition (Truncated SVD) method is a dimensionality reduction technique commonly employed to mitigate the challenges associated with high-dimensional data in various applications, including indoor positioning. This approach builds upon the concept of Singular Value Decomposition (SVD), which decomposes a data matrix into three separate matrices representing its singular values and corresponding left and right singular vectors. In the context of indoor positioning, Truncated SVD involves retaining only the top singular values and their corresponding singular vectors, effectively reducing the dimensionality of the data while preserving its essential information. This process is particularly beneficial for managing large datasets, as it significantly decreases the computational burden and enhances the efficiency of subsequent analysis. The core idea of Truncated SVD is to approximate the original data matrix using a lower-dimensional representation that captures the most significant patterns and relationships within the data. By selecting a

specific number of singular values to retain, this method allows researchers and practitioners to balance between dimensionality reduction and preserving relevant information.

Truncated SVD finds applications in various fields, including image processing, natural language processing, and data compression. In the context of indoor positioning, it offers a valuable tool for preprocessing Wi-Fi Received Signal Strength Indicator (RSSI) data, effectively reducing its dimensionality while maintaining its inherent structure. The reduced-dimension representation obtained through Truncated SVD can then be used as input for subsequent algorithms, such as K-Nearest Neighbors (KNN) regression, to enhance the accuracy and efficiency of indoor positioning predictions. The goal of Truncated SVD is to reduce the dimensionality of the data by retaining a limited number of important singular values and vectors. This helps to simplify the complexity of the original data and create a reduced version that can be used in various tasks such as classification, prediction, and indoor positioning. Algorithm 1 presents Truncated SVD Algorithm.

---

**Algorithm 1: Truncated SVD Algorithm**

**Input:** The initial data is a matrix A with dimensions m x n, where m is the number of samples and n is the dimensionality of the data.

**Output:** The matrix A_reduced represents the reduced data and includes the most important components from the original data.

**Step 1: Compute Singular Value Decomposition (SVD):** Perform the Singular Value Decomposition on the data matrix **A**: $A = U * \Sigma * Vt$
Where:

- **U** is the matrix containing the left singular vectors (columns) of A.
- **Σ** is the diagonal matrix containing the singular values of A.
- **Vt** is the matrix containing the right singular vectors (rows) of A.

**Step 2: Select Number of Components:** Choose the number of components (singular values and vectors) that you want to retain after dimensionality reduction. This is an important parameter to adjust the level of dimensionality reduction.

**Step 3: Truncate Singular Values and Vectors:** Keep only the singular values and vectors corresponding to the number of components selected in the previous step. Create the truncated matrices **U** reduced and **Vt** reduced.

**Step 4: Reconstruct Reduced Data:** Generate a new data matrix (reduced data) by multiplying the truncated matrix **U** reduced, the diagonal matrix **Σ** reduced (containing singular values), and the transpose of the matrix Vt_reduced: $A\_reduced = U\_reduced * \Sigma\_reduced * Vt\_reduced$

---

*2) K nearest neighbors regression algorithm:* KNN regression is a non-parametric algorithm that relies on the similarity of feature vectors to make predictions. It assumes that similar instances will have similar target values. The algorithm doesn't involve model training like some other regression algorithms; instead, it stores the entire dataset and calculates predictions based on the K nearest neighbors of the

query instance. The choice of K is crucial, as a small K might lead to noisy predictions, while a large K might lead to overly smoothed predictions. KNN regression can be sensitive to outliers and irrelevant features, so preprocessing the data and feature selection can impact its performance. Fig. 1 describes the KNN regression for improving the accuracy of indoor localization.

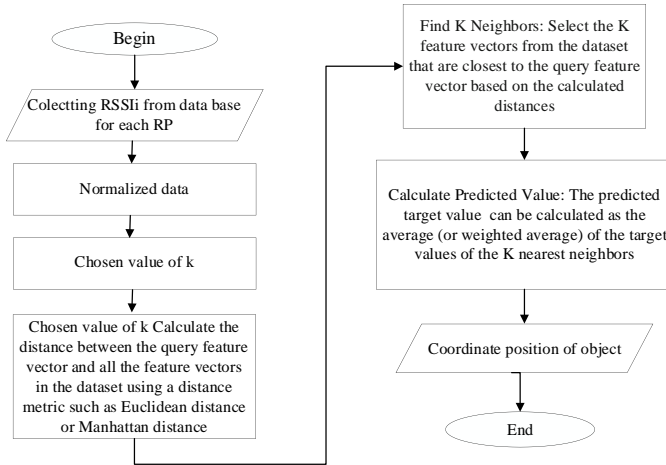

Fig. 1. The algorithm of WKNN for indoor positioning system.

### III. PROPOSED APPROACH

This section presents the proposed solution that combines dimensionality reduction using Truncated Singular Value Decomposition (Truncated SVD) with KNN regression for indoor position prediction.

### A. Proposal Model Block Diagram

Fig. 2 describes the block diagram illustrates the proposed approach that integrates two main components: Truncated Singular Value Decomposition (Truncated SVD) and K Nearest Neighbors (KNN) regression. The process begins with the collection of Wi-Fi RSSI data, which is the initial step for indoor position prediction.

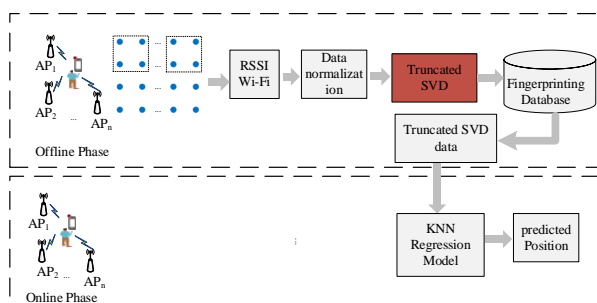

Fig. 2. The structure of proposed approach based on KNN regression.

**Data collection and preprocessing:**

- Wi-Fi RSSI data is gathered from multiple access points within the indoor environment.

- The collected data is preprocessed to remove noise, handle missing values, and normalize the features.

**Truncated Singular Value Decomposition (Truncated SVD):**

- The preprocessed Wi-Fi RSSI data undergoes Truncated SVD, a dimensionality reduction technique.

- Truncated SVD reduces the dimensionality of the data while retaining the most significant features that capture the underlying patterns.

- The transformed data is then ready for further processing.

**K Nearest Neighbors (KNN) regression:**

- The transformed data from Truncated SVD serves as input to the KNN regression model.

- KNN regression aims to predict the indoor position based on the similarity of the transformed data points.

- The model identifies the K nearest neighbors to the input data point and uses their positions to estimate the target position.

**Indoor position prediction:**

- The combination of Truncated SVD and KNN regression results in an accurate indoor position prediction.

- The estimated position is output as the final result of the model.

The block diagram demonstrates how the proposed method utilizes Truncated SVD for dimensionality reduction to handle the high-dimensional Wi-Fi RSSI data effectively. The reduced-dimensional data is then fed into the KNN regression model, which leverages the spatial relationships between data points to predict the indoor position accurately. This integrated approach aims to overcome the challenges of noise, signal variability, and dimensionality while providing enhanced precision in indoor position prediction.

### B. Indoor Positioning Dataset

In this study, we assessed our proposed solution using an online dataset [16], previously standardized for indoor positioning research. This dataset, employed in previous work including [17] aimed to enhance indoor positioning precision by LSTM algorithms. The study in [6] achieved a positioning error are range 2.5 meters to 2.7 meters on the public dataset [16]. The paper [16] verified the dataset's normalization and reliability for indoor localization research. The dataset covered a library space of over 300 square meters on the 3rd and 5th floors, collected over 15 months, and comprising 60,000 measurements. It included object positions, Wi-Fi AP access point RSSI values, execution time, and identification data. With 448 Wi-Fi AP access points at around 2.65 meters above the ground on both floors, a fingerprint database was created from multiple locations and directions, including front, back, left, and right measurements. Offline training involved known reference points and a Samsung Galaxy S3 phone equipped with an application to capture RSSI data. The dataset was divided into training (16,704 fingerprints from 24 reference points) and test sets (46,800 fingerprints from 106 reference points), each containing 448 RSSI indicators from access points. Following the approach of [6], our experiments on the

normalized public dataset utilized the Minmaxscale() function and Formula (1).

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \qquad (1)$$

where $X$ is the initial value of the feature, $X_{max}$ and $X_{min}$ are the maximum and minimum values in the feature.

## C. Error Estimation Criteria

We employed four machine learning-based evaluation criteria to assess the proposed solution's effectiveness. Initially, we used the mean absolute error (MAE) to gauge the average absolute error within the prediction dataset. Further evaluation employed mean squared error (MSE) or RMSE, widely utilized in machine learning regression problems, to quantify the squared error between predicted and actual values. Additionally, the determination coefficient R2 was employed as a measure of the model's predictive capability. R2 assesses how well the model predicts the dependent variable based on independent variables, showcasing the goodness-of-fit. Higher R2 values signify better model fit, with a range from 0 to 1. Negative values can emerge if the model performs worse than a constant model predicting the mean. Despite its usefulness, R2 has assumptions and limitations that warrant consideration. This coefficient's range lies between 0 and 1. A value closer to 1 indicates strong model fit and accurate prediction of position.

Furthermore, we introduced the EDE as an additional metric to measure prediction accuracy. The EDE calculates the direct geometric distance between predicted and actual positions, offering a straightforward measure of how far the predictions deviate from the true positions. This distance was calculated using the Euclidean distance formula, providing valuable insight into the spatial accuracy of the proposed solution.

$$MAE = \frac{1}{N_{test}} \sum_{i=1}^{N_{test}} \left| Pos_{itrue} - Pos_{iest} \right| \qquad (2)$$

$$MSE = \frac{1}{N_{test}} \sum_{i=1}^{N_{test}} \left( Pos_{itrue} - Pos_{iest} \right)^2 \qquad (3)$$

$$RMSE = \sqrt{\frac{1}{N_{test}} \sum_{i=1}^{N_{test}} \left( Pos_{itrue} - Pos_{iest} \right)^2} \qquad (4)$$

$$R^2 = 1 - \frac{\sum_{i=1}^{N_{test}} \left( Pos_{itrue} - Pos_{iest} \right)^2}{\sum_{i=1}^{N_{test}} \left( Pos_{itrue} - avg(y) \right)^2} \qquad (5)$$

$$avg(y) = \frac{1}{N_{test}} \sum_{i=1}^{N_{test}} Pos_{itrue}$$

$$EDE = \frac{1}{N_{test}} \sum_{1}^{n} \sqrt{\left( Pos_{itrue} - Pos_{iest} \right)^2} \qquad (6)$$

Where $Pos_{itrue}$ is the $i-th$ observed position, $Pos_{itest}$ is the $i-th$ estimation position. $i-th$ is the number of samples in the test dataset.

## IV. RESULTS AND DISCUSSION

In this study, we conducted a thorough investigation to determine the optimal number of principal components (components) to retain when applying the truncated SVD technique. The objective was to minimize the EDE, a critical metric for assessing the accuracy of our proposed indoor positioning solution.

The process of choosing the appropriate value for components began with a systematic survey across a range of values, assessing the performance of the solution at each step. We employed the EDE as the primary evaluation criterion, aiming to identify the component's value that yielded the lowest error. Our experimentation revealed that at the number of components = 35, the solution achieved the minimal EDE. This observation was consistent with our goal of minimizing error while ensuring computational efficiency, as retaining 35 principal components struck an optimal balance between accuracy and resource consumption. By retaining 35 principal components, we effectively reduced the dimensionality of the data while preserving the critical information necessary for accurate indoor localization. This choice optimized the model's ability to capture relevant spatial relationships among data points, resulting in a significant reduction in the EDE. In conclusion, our survey and experimentation led us to select the number of components = 35 as the optimal configuration for the truncated SVD algorithm. This choice aligns with our objective of achieving the lowest EDE while maintaining efficiency, demonstrating the effectiveness of this approach in improving indoor positioning accuracy.

The analysis of Fig. 3, which depicts the relationship between the number of components in truncated SVD (n) and the EDE, reveals several key insights:

Firstly, at n = 35, we observe the lowest EDE, indicating that this configuration results in the most accurate indoor positioning predictions. This point aligns with our earlier discussion, highlighting n = 35 as the optimal choice for retaining principal components. When n is smaller than 35, the reduction in dimensionality becomes excessive, leading to a loss of critical information required for accurate localization.

Fig. 3. The relationship between the number of truncated SVD components and euclidean distance error.

Conversely, when the numbers of components (n) are greater than 35, the model becomes overly complex, potentially introducing noise and diminishing its predictive capabilities. The fact that the EDE consistently rises for values of n smaller or larger than 35 emphasizes the importance of careful parameter tuning in the truncated SVD technique. It highlights the delicate balance between dimensionality reduction and information preservation.

Fig. 4.   The relationship between k and euclidean distance error.

Fig. 4, which illustrates the relationship between the number of nearest neighbors (k) and the EDE, provides crucial insights into our study. The plot demonstrates a clear trend that supports the idea that selecting k = 30 is an optimal choice for our KNN regression-based indoor positioning solution. This specific k-value results in the lowest EDE, indicating the highest precision in predicting indoor positions. When k deviate from this optimal k-value, either by choosing k values smaller or larger than 30, we consistently observe an increase in EDE. This pattern emphasizes the sensitivity of our model's performance to the choice of k. If k is smaller than 30, the model may not adequately capture essential spatial relationships, leading to less accurate predictions. Conversely, when k exceeds 35, the model might over smooth the data, potentially losing critical local information, which results in increased prediction errors. The observation that EDE increases for k values smaller or larger than 30 underscores the importance of selecting the appropriate parameter for KNN regression. It reinforces the idea that finding the right balance in the number of neighbors considered is vital for achieving accurate indoor localization. Fig. 4 highlights the significance of choosing k = 30 as the optimal parameter for our KNN regression-based indoor positioning solution. This choice leads to the lowest EDE value, indicating the highest accuracy in position prediction. Deviating from this value consistently results in increased EDE, affirming the effectiveness of our proposed approach in enhancing indoor localization accuracy.

Fig. 5 provides a visual representation of 100 randomly selected real positions (depicted as blue dots) and their corresponding predicted positions (depicted as red dots). This graph serves as a valuable illustration of the performance of our indoor positioning model. The meanings of the parameters on Fig. 5 are described below:

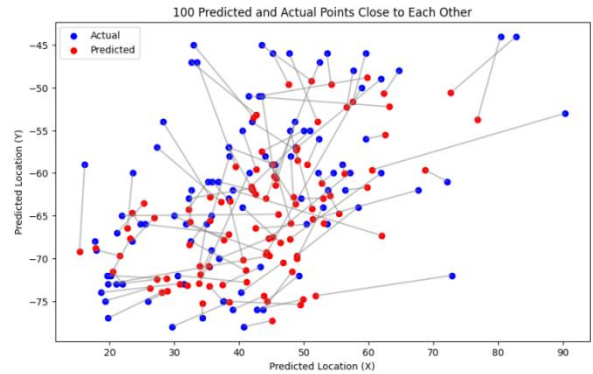

Fig. 5.   100 predicted and real positions.

*1) Blue dots - real positions:* The blue dots represent the actual positions of objects in the indoor environment, providing a reference for the ground truth. These positions are based on the collected dataset.

*2) Red dots - predicted positions:* The red dots, on the other hand, signify the positions predicted by our proposed indoor positioning model. These predictions are generated using the combination of Truncated SVD for dimensionality reduction and KNN regression for position estimation.

*3) Visual comparison:* By visually comparing the red and blue dots, it's evident that our model's predictions are generally very close to the actual positions. This alignment between the predicted and actual positions highlights the accuracy and effectiveness of our proposed solution.

*4) Scattered distribution:* The distribution of both red and blue dots across the graph demonstrates that the model is capable of predicting positions in various locations throughout the indoor environment. This showcases the versatility and applicability of our approach across different scenarios.

*5) Few outliers:* While most of the red dots closely match the blue dots, there may be a few outliers where the predicted positions slightly deviate from the actual positions. These outliers could be attributed to factors such as signal interference or complex spatial relationships in the indoor environment.

Fig. 5 visually reinforces the accuracy and reliability of our proposed indoor positioning solution. The close alignment between the predicted and actual positions across a range of locations underscores the model's effectiveness in accurately estimating indoor positions, thus contributing to enhanced indoor localization.

Fig. 6 shows the CDF of our proposed solution compared to the research [15]. The results in Fig. 6 clearly indicate that our solution performs significantly better in predicting locations when compared to the reference paper on the same

public dataset and similar situations. Fig. 6 also demonstrates that, for distance errors of two meters or less, our solution achieves an accuracy rate of over 50%, while the research [15] reaches around 30%. These results provide valuable insights into the performance distribution of the solution concerning distance errors. Observing this relationship, it is evident that:

For distance errors less than or equal to 1 meter, the probability of achieving such accuracy is approximately 20%.

Fig. 6.  CDF of the positioning error distance.

Expanding the acceptable error threshold to two meters significantly increases the probability of success to around 52%.

This visualization is further reinforced by the visual representation in Fig. 7, which vividly illustrates the proportion of predictions falling within different error ranges. It is evident that the proposed solution demonstrates a notable capability in achieving sub-2 meters accuracy, making it suitable for a range of indoor positioning applications. In accordance with the evaluation criteria outlined in Section III(C), the performance metrics for our model are as follows: a Root Mean Square Error (RMSE) stand is 1.97 meters, EDE is 2.23 meters, Mean Squared Error (MSE) is calculated at 3.91 meters, and R-squared ($R^2$) demonstrates a value of 0.69. Additionally, our model shows promising results in terms of error percentages, with 19.41% of errors falling within a 1-meter range and 52.36% within a 2-meter range. The RMSE value is approximately 1.97 meters, indicating a relatively small average deviation between predictions and actual values. This reflects the model's accuracy in estimating positions. The average Euclidean distance is around 2.23 meters, signifying the average difference between predictions and actual values. This is a critical evaluation criterion widely used in location-related tasks. Mean Squared Error (MSE) value is approximately 3.91 meters, representing the average squared error between predictions and actual values. This value indicates the variability of errors and can be used for model comparison. R-squared (R2): The R2 value is approximately 0.69, indicating the model's accuracy in explaining data variance. A high R2 value close to 1 suggests that the model is

reasonably good at explaining the data. Percentage of errors within 1 meter: Around 19.41% of predictions have errors within 1 meter, demonstrating that the model achieves a relatively good level of accuracy in predicting positions with errors less than 1 meter. Percentage of errors within 2 meters: Approximately 52.36% of predictions have errors within 2 meters, which is an acceptable threshold for many real-time applications.

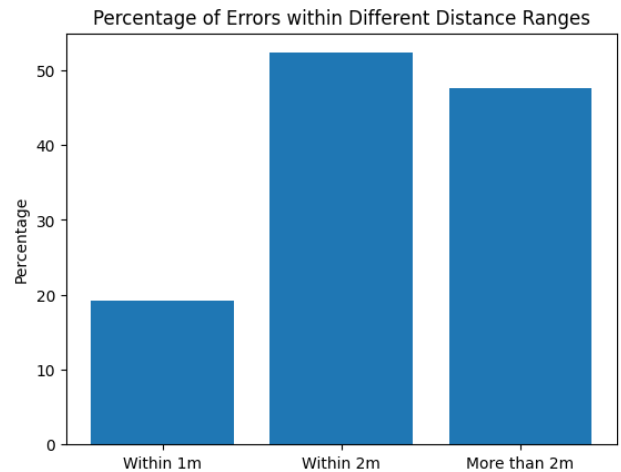

Fig 7. The chart of prediction errors with varying error distances.

In [17], the authors applied deep learning models, specifically RNN/LSTM, to predict indoor positions, achieving accuracy with distance errors ranging from 2.5 meters to 2.7 meters. A significant contribution of our study lies in the substantial enhancement of position prediction accuracy offered by our proposed solution. More precisely, we reduced the error margin from the range of 2.5 meters - 2.7 meters to a mere 2.23 meters, marking a remarkable improvement ranging from 10.8% to 17.4%. The simulation results demonstrate the effectiveness of the Truncated SVD and KNN Regression combination in significantly bolstering position prediction capabilities, particularly in error reduction. Furthermore, our solution also made substantial strides in prediction time efficiency when compared to the findings in reference [17]. As indicated in [17], the training time using the RNN model was 564.1396 seconds, with 10.0848 seconds required for testing. When LSTM was employed, the training process took 581.3599 seconds, and testing consumed 10.1721 seconds. In contrast, our solution demonstrated remarkable efficiency, taking only 4.5523 seconds to complete the same experimental scenario. These results underscore not only the enhancement in accuracy achieved by our approach but also its superior efficiency in prediction time. Additionally, our method simplifies the intricate training process commonly associated with traditional machine learning and deep learning methodologies.

## V. CONCLUSIONS

In conclusion, our study highlights the significant effectiveness of the proposed solution, which combines Truncated Singular Value Decomposition (Truncated SVD) with K-Nearest Neighbors (KNN) regression for indoor positioning. This innovative approach brings about a substantial improvement in prediction accuracy while meeting

real-time requirements. One of the notable advantages lies in the simplicity and efficiency of KNN regression. Unlike traditional machine learning and deep learning solutions that require complex pre-training processes, our method does not burden the user with such complexities. This streamlines the implementation and makes it an attractive choice for various indoor localization scenarios. By integrating Truncated SVD as a dimensionality reduction technique, we enhance the model's robustness and precision. Through rigorous experimentation, we determined that setting Truncated SVD's number of components to 35 minimizes EDEs in predictions, further showcasing the effectiveness of this hybrid approach. This combined methodology not only advances indoor positioning accuracy but also ensures that the solution is practical for real-time applications. In summary, our work presents a powerful and efficient solution for indoor positioning, opening doors to improved location-based services and applications.

# Text Simplification using Hybrid Semantic Compression and Support Vector Machine for Troll Threat Sentences

Juhaida Abu Bakar[1], Nooraini Yusoff[2], Nor Hazlyna Harun[3], Maslinda Mohd Nadzir[4], Salehah Omar[5]

Data Science Research Lab, School of Computing, Universiti Utara Malaysia, Kedah, Malaysia[1, 3, 4]
Faculty of Data Science and Computing, Universiti Malaysia Kelantan, Kota Bharu, Kelantan, Malaysia[2]
Department of Information Technology and Communication, Sultan Abdul Halim Mu'adzam Shah Polytechnic, Kedah, Malaysia[5]

*Abstract*—Text Simplification (TS) is an emerging field in Natural Language Processing (NLP) that aims to make complex text more accessible. However, there is limited research on TS in the Malay language, known as Bahasa Malaysia, which is widely spoken in Southeast Asia. The challenges in this domain revolve around data availability, feature engineering, and the suitability of methods for text simplification. Previous studies predominantly employed single methods such as semantic compression, or machine learning with the Support Vector Machine (SVM) classifier consistently achieving an accuracy of approximately 70% in identifying troll sentences—statements containing threats from online trolls notorious for their disruptive online behavior. This study combines semantic compression and machine learning methods across lexical, syntactic, and semantic levels, utilizing frequency dictionaries as semantic features. Support Vector Machine and Decision Tree classifiers are applied and tested on 6,836 datasets, divided into training and testing sets. When comparing SVM and Decision Tree with and without semantic features, SVM with semantics achieves an average accuracy of 92.37%, while Decision Tree with semantics reaches 91.21%. The proposed TS method is evaluated on troll sentences, which are often associated with cyberbullying. Furthermore, it is worth noting that cyberbullying has been reported to be a significant issue, with Malaysia ranking as the second worst out of the 28 countries surveyed in Asia. Therefore, the outcomes of the study could potentially offer means, such as machine translation and relation extraction, to help prevent cyberbullying in Malaysia.

*Keywords—Text simplification; semantic compression; machine learning; natural language processing; cyber bullying*

## I. INTRODUCTION

Natural Language Processing (NLP) represents a branch of artificial intelligence dedicated to enabling both machines and humans to comprehend, interpret, and deduce significance from human languages [1]. In the contemporary landscape, NLP encounters its most noteworthy challenges in the complexity of human communication. The process of deciphering and manipulating language is highly intricate, hence the common practice of employing diverse techniques to address a multitude of challenges.

This area of research encompasses numerous expanding and valuable applications. Natural Language Processing (NLP) encompasses a wide spectrum of tasks, ranging from straightforward ones like spell checking, keyword search, synonym identification, data extraction, classification, summarization, and text simplification, to more complex tasks like machine translation. In the future, NLP holds the potential to revolutionize task assistance. In this chapter, we will delve into past research related to a specific NLP task—text simplification.

Text simplification involves the transformation of a sentence into one or more straightforward sentences, making it more understandable for both machines and humans while preserving the original context and content. Additionally, text simplification serves as a valuable application that can improve various Natural Language Processing (NLP) tasks. Study by [2] highlights that text simplification tasks encompass several operations, including theoretical simplification to streamline content and structure, elaborate modification to clarify key points, and text summarization to remove peripheral or irrelevant information. The primary goal of text simplification is to enhance the accessibility of information for individuals with disabilities [3-4], those with low literacy levels [5-6], and non-native speakers [7].

In the Malay language, the exploration of text simplification is a relatively new area of study. Recent years have witnessed extensive research in Malay language studies, particularly in the domains of text summarization and sentence compression [8-11]. Researchers have been keen on enhancing the quality and cohesiveness of generated summaries. Sentence compression, a technique that involves eliminating non-essential details while preserving sentence grammar patterns, has garnered significant attention. This process identifies and removes frequently occurring sequences of adjacent words across a collection of documents, resulting in heuristic knowledge for sentence compression with an 85% confidence value [8].

Study by [8] primarily focuses on the Frequent Pattern growth tree, which stores compressed and critical information related to frequent patterns in large databases. However, it's worth noting that this study of text summarization does not encompass semantic compression, potentially leading to issues of ambiguity. Existing literature suggests that Malay language studies primarily concentrate on text summarization, specifically sentence compression, without delving into semantic comprehension. Fig. 1 illustrates the distinction between text simplification and text summarization.

---

***Example sentence:***
Google began in January 1996, as a research project by Larry Page, who was soon joined by Sergey Brin, when were both PhD students at Stanford University in California.
text simplification:
Google **was started** in January 1996, as a research project by Larry Page, who was soon joined by **and** Sergey Brin, when were both **two** PhD students at Stanford University in California, **USA**.
text summarization:
Google began in January 1996, as a research project by Larry Page, who was soon joined by Sergey Brin, when were both PhD students at Stanford University in California.

Fig. 1. Text simplification versus text summarization [31].

In Text Simplification (TS), information extraction stands as a pivotal phase. The primary output of the information extraction process is the Syntax Tree, which illustrates the sentence's structure [12]. However, the syntax tree can become ambiguous when a sentence adheres to multiple grammar rules. To address this issue, machine learning techniques are commonly employed. These methods encompass Support Vector Machine (SVM) (e.g., [13-14]), Maximum Entropy (e.g., [15]), Decision Tree (DT) (e.g., [16]), and Conditional Random Field (e.g., [17]).

Among these techniques, the Support Vector Machine (SVM) has been recognized as the most effective classifier for text simplification, achieving an accuracy of approximately 70% [18]. It is important to note that studies employing SVM for text simplification have predominantly concentrated on the English language. In contrast, there is a lack of research on text simplification in the Malay language.

Furthermore, within the domain of Text Simplification, the primary objective is to condense a given sentence. This task necessitates a process of comprehending the inherent meaning of the sentence, commonly referred to as semantic compression.

In many text simplification approaches, a singular method is typically employed, whether it's a machine learning method or semantic compression. Studies solely focused on machine learning methods tend to overlook the significance of sentence structure properties crucial for semantic interpretation. Conversely, research exclusively centered on semantic compression may encounter challenges in predicting syntax trees, leading to potential ambiguity problems. Therefore, there is a growing recognition of the necessity to combine machine learning methods and semantic compression. In this hybrid approach, machine learning is applied to identify ambiguous sentence structures, while semantic compression is employed to simplify sentences based on relevant semantic content.

Troll is a prime example necessitating text simplification, as it often comprises sentences laden with concealed meanings. Originally, trolling involved the use of deceptive posts as bait to elicit responses from other online community members, often luring them into engaging with a fabricated story. Trolling encompasses various forms, and the term "trolling" has been broadly applied to describe various malicious or harassing activities on the internet. These activities may include instigating contentious discussions, targeting individuals or groups with harassment, sharing offensive content, vandalizing community-contributed pages, defacing memorial pages, and even being used interchangeably with cyberbullying. As a result, this study focuses on trolls associated with cyberbullying as the domain for testing a proposed text simplification method.

The motivation by engaging in TS research in a minority language offers the opportunity to develop language-specific techniques and tools, enriching the broader NLP field while deepening insights into the unique linguistic features and challenges of that language. This paper introduces a hybrid approach for text simplification in the Malay language. The model effectively distinguishes between complex and non-complex words, offering a potential solution to combat cyberbullying in Malaysia through means like machine translation and relation extraction. The key steps involve developing text simplification features that emphasize semantic aspects. Additionally, lexical features, including stemmed words, are incorporated into the study. Subsequently, hand-crafted features encompassing lexical, syntactic, and semantic attributes are organized and classified using machine learning techniques to attain the highest accuracy results.

## II. RELATED WORKS

The NLP components employed in TS encompass five levels: lexical, syntactic, semantic, discourse, and pragmatic. According to [19], the TS process primarily involves the lexical and syntactic levels. However, it's worth noting that semantic considerations play a crucial role in both the lexical and syntactic approaches to ensure the preservation of word and sentence meanings.

The lexical level, referred to as lexical simplification (LS), concentrates on replacing complex words with simpler synonyms. For instance, it involves substituting "facile" with "easy." Previous research in psycholinguistics has shown that such substitutions of complex terms within a sentence, as done by comprehensive lexical simplification, have significant potential to enhance sentence readability [20]. LS involves altering the intricate or unusual phrasing within a sentence by replacing it with a synonymous word that is more straightforward and comprehensible [21].

In the realm of syntactic simplification, it encompasses distinct elements like idiomatic phrases, apposition, coordination, subordination, and voice. Study by [22] employ the typed dependency representations provided by the Stanford Parser. They argue that these formatted dependencies offer a high level of precision, facilitating the creation of straightforward standards and the automation of corporate acquisition processes.

Recent research demonstrates that the semantic approach has been applied in text simplification tasks, as evidenced by studies such as [22-27]. Study by [28] also highlights that

semantic compression can serve as a valuable technique for intelligently generalizing terms while minimizing information loss. To address structural mismatches, study by [29] suggests employing semantic parsing to rephrase sentences.

There are various approaches employed for text simplification (TS) tasks. Recent research has shown a growing interest in hybrid approaches that integrate multiple techniques for simplification such as deep semantic and monolingual machine translation have been combined in the hybrid approach, as demonstrated by [30], structural semantics and neural methods are another focus in recent studies, exemplified by [27], hybrid approaches may involve a combination of hand-crafted transformation rules, machine learning (ML) techniques, and semantic parsers, as explored by [31], these hybrid approaches often merge natural language processing (NLP) components with machine learning techniques. The research conducted by [20] advocate for the use of Machine Learning (ML) techniques as a means to achieve more reliable solutions in text simplification. These hybrid methods represent a multifaceted approach to text simplification, leveraging various techniques to enhance the quality and effectiveness of simplification processes.

As a relatively new language within the field of text simplification, a more comprehensive investigation of each feature is essential to achieve higher accuracy. The study in [32] involved the utilization of all relevant features, with a subsequent comparison of results to identify the most effective features for future use. Thus, the primary objective of this study is to combine the strengths of semantic compression and machine learning methods through hybridization. This approach aims to leverage the benefits of both techniques to enhance the practice of text simplification.

## III. METHODOLOGY

The research methodology of the study can be segmented into five distinct phases: a literature review phase, a phase dedicated to defining data sets and specifications, a phase focused on designing text simplification features for the TS model, a phase involving the construction of the TS model based on SVM classifier and selected features, and finally, a phase dedicated to performance evaluation.

### A. Datasets

In this study, the primary data sources include news articles, online resources, and existing datasets for the Malay language. Additionally, a corpus from previous studies, including [33-36], covering Parts of Speech (POS) and Noun Phrases, was used to create the Malay Text Simplification Dataset (Malay TS Dataset) with 6,836 instances categorized as complex or non-complex.

The work begins by utilizing the state-of-the-art corpus developed by [34], known as the Malay corpus. This corpus comprises 18,387 tokens, each of which is accompanied by word category information and is written using the Rumi script. It includes 21 word categories for part-of-speech (POS) tagging, following the standard provided by the Dewan Bahasa dan Pustaka (DBP). You can find the Malay part-of-speech tagset within the corpus in Table I.

TABLE I. PART-OF-SPEECH DBP TAGSET IN MALAY CORPUS [34]

| Tag Set | Description | Example in Malay language with English gloss | Number of tokens |
|---|---|---|---|
| KN | Noun | chair (*kerusi*) | 6108 |
| KK | Verb | eat (*makan*) | 2539 |
| ADJ | Adjective | black, beautiful, deep (*hitam, cantik, dalam*) | 1623 |
| KSN | Preposition | at, to, from, to (*di,ke, dari, kepada*) | 1409 |
| KB | Auxiliary verb | will, not yet, can (*akan, belum, boleh*) | 390 |
| KG | Pronoun | me, you (*saya, awak*) | 496 |
| KH | Conjunction | which, and, or (*yang, dan, atau*) | 1608 |
| ADV | Adverb | perhaps (*bahasawanya, barangkali*) | 817 |
| KT | Question | what, how much (*apa, berapa*) | 49 |
| KBIL | Cardinal | one, two (*satu, dua*) | 258 |
| KPM | Narrator | is (*adalah, ialah*) | 100 |
| KP | Command | don't, please (*jangan, sila*) | 5 |
| KAR | Direction | in, up, down (*dalam, atas, bawah*) | 48 |
| PW | Discourse mark | even, then (*hatta, maka*) | 9 |
| KEP | Short form | *UNCR, PBB* | 179 |
| #E | Clitic *lah* | try it (*cubalah*) | 31 |
| KN@ | Clitic *nya* | His/her book (*Bukunya*) | 235 |
| KNF | Deny | No, it's not (*tidak, bukan*) | 171 |
| KNK | Proper noun | *Allah, Muhammad* | 236 |
| SEN | List number | *(i), (ii), (iii), etc* | 3 |
| SYM | Any symbol or punctuations | *. , " - + etc* | 2073 |

The study in [37] established a process for identifying complex words in three languages. This study follows the same process developed by Yimam, known as Complex Word Identification (CWI). In this process, a survey was conducted using 10 TS control samples and 10 TS non-control samples from the Malay corpus. For instance, the study focuses on TS users, who are non-native speakers. Therefore, 10 non-native speakers of the language were selected as a control sample, along with 10 native speakers. Native speakers are individuals who learned their first language in childhood, often referred to as their mother tongue [38]. Non-natives are individuals who learned a different language as their first language in childhood. Respondents were provided with texts from the Malay corpus and asked to annotate each word based on its complexity.

The results of the answers provided by the 10 native speakers and the 10 non-native speakers will determine whether a word is classified as complex or not. The label assigned to the target word is based on the responses of these 10 native and 10 non-native speakers. If at least one annotator marks the word as complex, the label will be "COMPLEX" (1); otherwise, it will be "NOT COMPLEX" (0).

Afterward, data cleaning is an integral part of this study, which involves removing punctuation and converting all letters to lowercase. This is done to address data sparsity within the dataset. The dataset comprises original sentences, target word indices, counts of annotations by native and non-native speakers for the sentences, counts of markings by native and non-native speakers for the target words, and binary and classification labels for the target words. Subsequently, a dataset consisting of 6,836 instances with labels indicating complexity or non-complexity is created. The detailed description of the Malay TS Dataset, including complexity information after data cleaning, is provided in Table II.

TABLE II.    PART-OF-SPEECH DBP TAGSET IN MALAY TS DATASET WITH THE COMPLEX INFORMATION

| Tag Set | Description | Number of tokens | Complex word | Non-complex word |
|---------|-------------|------------------|--------------|------------------|
| KN | Noun | 2459 | 299 | 2160 |
| KK | Verb | 1103 | 88 | 1015 |
| ADJ | Adjective | 687 | 82 | 605 |
| KSN | Preposition | 591 | 3 | 588 |
| KB | Auxiliary verb | 136 | 1 | 135 |
| KG | Pronoun | 210 | 6 | 204 |
| KH | Conjunction | 735 | 14 | 721 |
| ADV | Adverb | 332 | 12 | 320 |
| KT | Question | 22 | 2 | 20 |
| KBIL | Cardinal | 112 | 2 | 110 |
| KPM | Narrator | *None* | *None* | *None* |
| KP | Command | *None* | *None* | *None* |
| KAR | Direction | *None* | *None* | *None* |
| PW | Discourse mark | *None* | *None* | *None* |
| KEP | Short form | 6 | 6 | 0 |
| #E | Clitic *lah* | 1 | 1 | 0 |
| KN@ | Clitic *nya* | 10 | 10 | 0 |
| KNF | Deny | *None* | *None* | *None* |
| KNK | Proper noun | 3 | 3 | 0 |
| SEN | List number | *None* | *None* | *None* |
| SYM | Any symbol or punctuations | *None* | *None* | *None* |

## B. Proposed Method

Generally, the method begins by importing the raw Malay text dataset. The proposed approach encompasses three stages before obtaining the output of text simplification. Initially, the raw Malay text Part-of-Speech (POS) dataset is converted into feature extractions. Two types of feature extractions are employed: semantic compression features and lexical features. Text compression is achieved by using a semantic network and information on term frequencies from a frequency

dictionary. Subsequently, lexical features are constructed based on Part-of-Speech (syntactic), vowels (lexical), characters (lexical), and syllables (lexical). Handcrafted features combine semantic compression and lexical features. Finally, machine learning classifiers, specifically Decision Tree (DT) and Support Vector Machines (SVM), are used to identify complexity patterns in the Malay language. This hybrid method is configured for these two machine learning classifiers using the frequency dictionary. Additionally, the study evaluates this method on previously unseen troll sentences. Fig. 2 illustrates the proposed method during this phase.

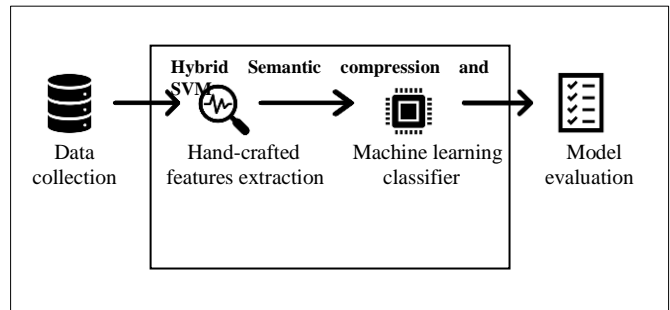

Fig. 2.   Proposed method.

This phase assessed the validity of the hypotheses derived from the literature review. It primarily involved the preparation and development of lexical, syntactic and semantic features based on the findings from the preceding step. The experimental aspect of this phase focused on extracting features related to factors like length, frequency, lexical, syntactic, and semantic characteristics. Additionally, base words in the Malay language were extracted and incorporated as features. The Part-of-Speech (POS) tags present in the Malay corpus were also employed as syntactic features. To align with semantic requirements, a frequency dictionary was generated. The lexical features, as presented in Table III, were ultimately adopted for this study. Subsequently, each feature in token form underwent a normalization process to facilitate the development of learning models based on Decision Trees (DT) and Support Vector Machine (SVM) classifiers.

TABLE III.    LEXICAL, SYNTACTIC AND SEMANTIC FEATURES IN MALAY TS DATASET

| Type | Features | Abbreviation |
|------|----------|--------------|
| Lexical | Number of syllables | SYL |
| | Length of word | CHAR |
| | Base word | STEM |
| | Frequency of word | FREQ |
| | Number of token (not stem) | VOW |
| | Number of token (after stem) | Vow |
| Syntactic | Part-of-speech  Tagging | POS |
| Semantic | Frequency dictionary | DF |

Algorithm 1 outlines the features for constructing the Malay TS method for the Malay language.

| **Algorithm 1:** Malay TS method |
|---|
| 1: Input: text T, word_feature W, gaps G, discard_empty D, flags F |
| 2: read T sequence, |
|    read word_feature W, |
|    *feature_type1*: Syllable feature, |
|    *feature_type2*: Character feature, |
|    *feature_type3*: Stem feature, |
|    *feature_type4*: Frequency feature, |
|    *feature_type5*: Part-of-Speech tag feature, |
|    *feature_type6*: Vowel feature, |
|    *feature_type7*: Frequency distribution feature, |
|    read gaps G, read discard_empty D, read flags F, |
| 3: If feature_type3 exists in T sequence |
| 4:  Enhance with the modification rules and steps |
| 5:   If not |
| 6:       Continue to machine learning algorithms (SVM, DT) |
| 7:   Fit to gaps G, discard_empty D, flags F |

As a result of the above works, two classifiers were utilized, specifically the SVM and DT classifiers. The experiment is partitioned into two segments: one that takes semantic features into account and one that does not take semantic features. Data was divided using k-fold cross-validation (k=10), and subsequently, the average outcomes are computed. These results will be analyzed and discussed in the Experiment and Results section.

*C. Performance Evaluation*

In the domain of machine learning, particularly in the context of statistical classification, a confusion matrix, alternatively referred to as an error matrix, is a structured table format that provides a means to visually assess the effectiveness of an algorithm, often in the context of supervised learning. Fig. 3 illustrates the configuration of the confusion matrix. Its primary purpose is to evaluate the performance of a classification algorithm. In this study, four metrics were employed: accuracy, precision, recall, and F1-measures, to gauge the performance of the classification algorithm.

Fig. 3.   Confusion matrix.

## IV.   EXPERIMENTS AND RESULTS

The hybrid method proposed in this study was employed on a dataset comprising 6,836 instances. This original dataset encompasses lexical details, syntactic information, sentences, base words, and semantic information, as illustrated in Table IV.

TABLE IV.   FEATURE ENGINEERING FOR MALAY TS DATASET

| POS | CHAR | VOL | SYL | Sentence | STEM | DF | Vow | Binary | Class |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 4 | 2 | 2 | Asid Alfa Li | asid | 4 | 2 | 1 | Complex |
| 1 | 4 | 2 | 2 | Asid Alfa Li | alfa | 3 | 2 | 1 | Complex |
| 1 | 6 | 3 | 3 | Asid Alfa Li | lipoik | 3 | 3 | 1 | Complex |
| 1 | 7 | 3 | 3 | Asid Alfa Li | manfaat | 3 | 3 | 1 | Complex |
| 2 | 5 | 2 | 2 | Asid Alfa Li | untuk | 73 | 2 | 0 | Not complex |
| 1 | 5 | 2 | 2 | Asid Alfa Li | saraf | 13 | 2 | 0 | Complex |
| 3 | 4 | 2 | 2 | Saya menga | saya | 9 | 2 | 1 | Complex |

Subsequently, a frequency dictionary and vowel characteristics dictionary are constructed for base words, contributing to the generation of semantic features. The frequency dictionary tallies the occurrences of base words within the corpus, while the vowel characteristics dictionary calculates the count of vowels in each base word. The POS features encompass a set of 31 labels, including nouns, prepositions, pronouns, verbs, denies, and more, as shown in Table V. The stem feature is then removed from the final dataset, leaving the DF (frequency dictionary) and Vow (vowel characteristics) features as representations of the stem word, as illustrated in Table VI.

TABLE V.   PART OF SPEECH FEATURES WITH 31 LABELS

| Tagset | Labeling | Numbering |
|---|---|---|
| Noun | kn | 1 |
| Preposition | ksn | 2 |
| Pronoun | kg | 3 |
| Verb | kk | 4 |
| Deny | knf | 5 |
| Conjunction | kh | 6 |
| Adjective | adj | 7 |
| Adverb | adv | 8 |

| Deny with clitics -lah | knf# | 30 |
| Deny with clitics -nya | knf@ | 31 |

TABLE VI.    FEATURE ENGINEERING FOR MALAY TS DATASET WITH SEMANTIC FEATURE

| POS | CHAR | VOW | SYL | DF | Vow | Class |
|---|---|---|---|---|---|---|
| 1 | 4 | 2 | 2 | 4 | 2 | Complex |
| 1 | 4 | 2 | 2 | 3 | 2 | Complex |
| 1 | 6 | 3 | 3 | 3 | 3 | Complex |
| 1 | 7 | 3 | 3 | 3 | 3 | Complex |
| 2 | 5 | 2 | 2 | 73 | 2 | Not complex |
| 1 | 5 | 2 | 2 | 13 | 2 | Complex |
| 3 | 4 | 2 | 2 | 9 | 2 | Complex |

In the realm of machine learning, data normalization is employed to reduce the impact of feature scales on model training. The preparation of data for machine learning in this study involves the utilization of numerical data, ensuring that our model converges to optimal weights and, ultimately, resulting in a more precise model. To achieve this, min-max normalization has been implemented. Regarding class labels, they are assigned values of 0 (indicating simplicity or non-complexity) or 1 (indicating complexity), as illustrated in Table VII. Subsequently, the dataset has been divided into training and testing sets using a 10-fold cross-validation approach, denoted as Tr:Te dataset.

TABLE VII.    DATA AFTER NORMALIZATION PROCESS

| | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|---|---|---|---|---|---|---|---|
| 0 | 0.000 | 0.1667 | 0.250 | 0.086957 | 0.010714 | 0.33333 | 1.0 |
| 1 | 0.000 | 0.1667 | 0.250 | 0.086957 | 0.007143 | 0.33333 | 1.0 |
| 2 | 0.000 | 0.2778 | 0.375 | 0.130435 | 0.007143 | 0.50000 | 1.0 |
| 3 | 0.000 | 0.3333 | 0.375 | 0.130435 | 0.007143 | 0.50000 | 1.0 |
| 4 | 0.033 | 0.2222 | 0.250 | 0.086957 | 0.257143 | 0.33333 | 0.0 |

The learning process is subsequently executed using DT and SVM classifiers. To ensure a robust evaluation, the dataset has been split into an 80% training set and a 20% testing set, denoted as 80Tra:20Test. For the SVM classifier, the RBF kernel and class weighting have been applied, particularly beneficial for handling imbalanced datasets. Following the completion of the experiment table containing

semantic features, the most effective classifier was determined. This optimal classifier is then saved as a "pickle" file, enabling it to be used for testing new data. In the context of this study, the aim is to classify troll data as either complex or non-complex.

After completing the feature engineering process, the training datasets undergo several performance evaluations. Two algorithms are employed to predict text simplification, distinguishing between complex and non-complex words. To ensure the suitability of the chosen model, a score test model is utilized. The algorithms in use are Decision Tree classifiers and Support Vector Machine (SVM). The modeling is implemented in a Jupyter notebook using Python code, and both datasets, one with semantic features and one without, are tested. The Decision Tree classifier achieves its highest accuracy of 92.98% when using semantic feature information. On the other hand, the SVM achieves its highest accuracy of 93.20% with or without the semantic feature information. This suggests that semantic features may or may not be necessary for the SVM classifier, but there is a significant difference for the Decision Tree classifiers.

The average accuracy of both classifiers indicates that SVM outperforms the DT classifier by a margin of 0.6%. Table VIII provides a performance comparison between the two classifiers, revealing that the frequency dictionary does not significantly impact the results. Both cases, with and without a frequency dictionary, yield similar accuracy levels. The presence or absence of the frequency dictionary doesn't result in a noticeable difference in average accuracy in this experiment.

However, when examining each production of the classifier model individually, the significance of semantic features in the training dataset becomes evident. Table IX and Table X present precision, recall, and F1-score for the best models of SVM and DT, respectively, highlighting the importance of semantic features in improving these metrics.

TABLE VIII.    PERFORMANCE OF TWO CLASSIFIERS WITH TWO DIFFERENCE FEATURES

| Data Split / ML classifier | Frequency distribution | | | |
|---|---|---|---|---|
| | *With frequency distribution* | | *Without frequency distribution* | |
| | DT (%) | SVM (%) | DT (%) | SVM (%) |
| 90Tr:10Te | **92.98** | 92.40 | 92.69 | 92.40 |

The top-performing model from the Malay TS Dataset, as determined by the research conducted by [40], is utilized to categorize unannotated troll threat sentences. The research materials comprise vlogs, which are video content sourced from the YouTube platform. The study scrutinizes 30 videos recorded by Mat Luthfi between 2011 and 2014. This investigation delves into the use of sarcastic language in YouTube videos, utilizing modern technology as the primary medium of contemporary society. Sarcasm is the examination of employing irony to ridicule or express disdain. On the other hand, "trolling" refers to a predominantly indirect form of communication. The term "trolling" is widely used to describe various malicious or harassing activities on the internet, such as initiating inflammatory discussions, among others, as noted by [39]. To the best of the researcher's knowledge, there is no publicly accessible Malay language troll dataset, so the work by [40], which examines sarcasm, serves as a suitable substitute for a troll dataset.

Before classifying unannotated troll threat sentences as either complex or non-complex words, these sentences (unseen data) must undergo a feature extraction process. This study investigates three different types of sarcasm: Irony Sarcasm, Sarcastic Sarcasm, and Sinise Sarcasm. There are 173 instances in 11 scripts for Irony Sarcasm, 101 instances in seven scripts for Sarcastic Sarcasm, and 303 instances in 10 scripts for Sinise Sarcasm, totaling 578 instances used for testing the Malay TS model.

The initial step involves data cleaning, which includes removing punctuation, converting words to lowercase, and applying the stemming process. Subsequently, a Malay Part-of-Speech tagging system, developed based on the ID3 algorithm by [41], is employed. Table XI provides an overview of the unseen dataset and its preparation process.

TABLE XI.     UNSEEN DATASET

| INPUT | POS | CHAR | VOW | SYL | STEM | DF | Vow |
|---|---|---|---|---|---|---|---|
| *Test* | 4 | 4 | 1 | 1 | *test* | 1 | 1 |
| *Ke* | 2 | 2 | 1 | 1 | *ke* | 1 | 1 |
| *Facebook* | 1 | 8 | 4 | 2 | *facebook* | 1 | 4 |
| *Dalam* | 2 | 5 | 2 | 2 | *dalam* | 2 | 2 |
| *hidup* | 4 | 5 | 2 | 2 | *hidup* | 1 | 2 |
| *aku* | 3 | 3 | 2 | 2 | *aku* | 3 | 2 |
| *tak* | 5 | 3 | 1 | 1 | *tidak* | 13 | 2 |
| *da* | 4 | 2 | 1 | 1 | *ada* | 8 | 2 |
| *sapa-sapa* | 9 | 9 | 4 | 4 | *siapa* | 1 | 3 |

Table XII displays the proportions of complex and non-complex sentences in the troll threat dataset. Language experts have thoroughly evaluated the test results on these troll threat sentences. Table XIII presents the marks assigned by expert analysts to each test data sample generated by the Malay TS model.

TABLE XII.     PROPORTION OF COMPLEX AND NON-COMPLEX TROLL SENTENCE

| Sarcasm types | Non-complex | Complex |
|---|---|---|
| Irony | 151 | 22 |
| Sarcastic | 88 | 13 |
| Sinise | 284 | 19 |

TABLE XIII.     EXPERT RESULT FOR TROLL SENTENCE BASED ON SVM

| Test sample | Irony | Sarcastic | Sinise |
|---|---|---|---|
| Total token | 173 | 101 | 303 |
| Token wrongly label | 22 | 13 | 19 |
| Token correctly label | 151 | 88 | 284 |
| Accuracy (%) | 87.28 | 87.13 | 93.73 |
| Average accuracy (%) | **89.38** | | |

As indicated in Table XIII, the SVM model effectively recognizes only non-complex words. It encountered difficulties in identifying complex words within this unseen dataset, resulting in a low success rate for complex words. When testing with unseen data using SVM, it shows that there are no instances of Type II errors, but Type I errors are present. The SVM model struggles to predict the complex class in three separate unseen datasets.

According to Table XIV, the Decision Tree (DT) model demonstrates success in identifying both non-complex and complex words. However, it occasionally misclassifies words, leading to a lower accuracy percentage compared to the SVM model. Testing on the unseen data reveals the presence of both Type I and Type II errors in the predictions made by the DT model. Notably, the DT model can predict complex classes in the Sarcastic and Sinise datasets, although the number of accurate predictions in these cases is relatively small.

TABLE XIV.    EXPERT RESULT FOR TROLL SENTENCE BASED ON DT

| Test sample | Irony | Sarcastic | Sinise |
|---|---|---|---|
| Total token | 173 | 101 | 303 |
| Token wrongly label | 41 | 11 | 26 |
| Token correctly label | 132 | 90 | 277 |
| Accuracy (%) | 76.30 | 89.11 | 91.42 |
| Average accuracy (%) | **85.61** | | |

## V.    DISCUSSIONS

In this project, a novel dataset called the Malay TS Dataset has been introduced. Additionally, a new Malay TS method has been developed by integrating three levels of NLP components with ML classifiers. The proposed method combines lexical, syntactic, and semantic features with an SVM classifier. To assess the classifier model, a comparison has been made between SVM and DT classifiers, and the findings of this comparative study are presented.

Based on the readings, the SVM classifier exhibits the highest accuracy in identifying troll sentences. The experiment involved utilizing K-fold cross-validation to split the data. To assess the method's effectiveness, the outcomes of the proposed approach were compared with another classifier, specifically DT. The proposed approach demonstrates promising results with a robust classifier model. The findings indicate that the SVM classifier, utilizing an 80-20 split of training and test data, performs as the best classifier model. However, when applied to troll data, the developed SVM model struggles to predict complex words. In contrast, the DT model, while encountering fewer complex words, exhibits better performance in predicting them.

In this research, an automated Malay TS model has been successfully developed. A novel approach, referred to as the Hybrid Semantic Compression-SVM method, has been introduced. This method aims to identify complex words within text. The research utilizes a dataset extracted from the Malay corpus by [33], containing a total of 6,836 instances. Previous studies have typically employed these two methods independently, while this study seeks to combine them for enhanced accuracy. The primary objective of this research is to hybridize semantic compression and Support Vector Machine to enhance text simplification performance. This overarching goal is complemented by three sub-objectives. Firstly, the creation of a Malay TS lexical dataset is undertaken. Secondly, the design of text simplification features for the TS model is carried out, drawing from prior work by [42]. Lastly, the results of the proposed method are evaluated against an existing Python-based classifier.

## VI.    CONCLUSION

Text simplification is a subfield of NLP that has seen significant development in recent years. While research in English has been extensive, tackling simplified text in other languages presents challenges due to limited resources and associated data. This study focuses on analyzing lexical, syntactic, and semantic features to identify troll threat sentences in the Malay language, and the development of resources marks the beginning of this effort.

In summary, this study exclusively incorporates frequency dictionary features within the semantic compression method. Looking ahead, there are several avenues for enhancing this project. Malay, being a minority language, has limited potential for leveraging semantic information. Semantic compression is a component of semantic analysis and comprises two crucial stages: the frequency dictionary and the semantic network. In this research, to the best of our knowledge, only the frequency dictionary has been implemented, as the code is available for development alongside existing features (lexical and syntactic). However, due to the constraints in accessing tools freely for building syntactic information based on dependencies and constituent trees, the discussion of semantic networks is omitted in this study.

To enhance the application of this project, it can be extended with three additional stages in the development of Complex Word Identification (CWI). These stages encompass Substitution Generation, Substitution Selection, and Substitution Ranking, constituting the second, third, and fourth steps in CWI. The second step involves generating potential substitutions for the target words identified in the initial step. Subsequently, the system selects the most appropriate replacement, and the final step entails organizing the hierarchy of replacement options that can be applied to the previously identified target word.

Exploring higher-level Natural Language Processing (NLP) components, such as syntactic analysis, proves more suitable for analyzing social media data compared to mere word-level comprehension. Lexical feature analysis, on the other hand, aligns better with users facing language difficulties (e.g., dyslexia, aphasia) and non-native speakers. Investigating patterns in troll sentences as compared to standard Malay sentences could yield valuable insights if developed further.

Social network datasets necessitate a distinct approach from conventional language sentences. There are additional preprocessing steps required to analyze such data effectively. Handling text abbreviations, dialects, slang, and other variations is essential before arriving at the base words within the text. Techniques like lemmatization are more appropriate for word recognition than stemming. Furthermore, resources like WordNet Bahasa should be considered in this analysis. A comprehensive study integrating social network analysis and data analytics is essential for identifying troll threat sentences.

*Abstract*—**High dimensionality in variable-length feature sets of real datasets negatively impacts the classification accuracy of traditional classifiers. Convolutional Neural Networks (CNNs) with convolution filters have been widely used for handling the classification of high-dimensional image datasets. However, these models require massive amounts of high-dimensional training data, posing a challenge for many image-processing applications. In contrast, traditional feature detectors and descriptors, with a minor trade-off in precision, have shown success in various computer vision tasks. This paper introduces the Nearest Angles (NA) classifier tailored for a handwritten character recognition system, employing Speeded-Up Robust Features (SURF) as local descriptors. These descriptors make local decisions, while global decisions on the test image are accomplished through a ranking-based classification approach. Image similarity scores generated from the SURF descriptors are ranked to make local decisions, and these ranks are then used by the NA classifier to produce a global class similarity score. The proposed method achieves recognition rates of 96.4% for Tamil, 96.5% for Devanagari, and 97 % for Telugu handwritten character datasets. Although the proposed approach shows slightly lower accuracy compared to CNN-based models, it significantly reduces the computational complexity and the number of parameters required for the classification tasks. As a result, the proposed method offers a computationally efficient alternative to deep learning models, lowering the computational time multiple times without a substantial loss in accuracy.**

*Keywords—Image processing; feature extraction; Convolutional Neural Networks; SURF; handwritten character recognition; optical character recognition system*

## I. INTRODUCTION

Human-machine interaction is increasingly becoming a cornerstone in various applications that span daily life. Among these applications, Optical Character Recognition (OCR) stands out as a key technology that facilitates the conversion of different types of handwritten or printed characters into machine-encoded text, generally in ASCII or UNICODE formats [1]. This technology finds various applications ranging from document digitization to automated data entry. For economically deprived and rural populations in India, an effective handwritten OCR system in native languages can significantly enhance computer usability and information accessibility, thereby bridging the digital divide [2].

Despite advances in OCR technologies, there are still significant challenges that affect the performance of OCR systems for handwritten texts, especially in Indian languages [3] [4]. These challenges include inconsistencies in writing styles, structural similarity between symbols, and noise in input images [5] [6]. In addition, existing solutions such as Convolutional Neural Networks (CNNs) require massive computational resources and extensive high-dimensional data for training, making them less feasible for resource-constrained environments [7] [8] [9]. Moreover, CNN-based solutions might not be effective in handling variable-length feature sets or high-dimensional data without a large corpus of training samples [10] [11] [12]. Speeded-Up Robust Features (SURF) descriptors are a type of feature descriptor that is commonly used in image processing and OCR [13]. However, they have been shown to be less effective for handwritten text, due to the structural variations and noise that can be present in input images. This can lead to inaccurate feature extraction, which can in turn degrade the performance of the OCR system. Singular value decomposition (SVD) is a technique for reducing the dimensionality of high-dimensional data [14]. It is often used in OCR to improve the performance of feature extraction and classification. However, SVD can be computationally expensive, especially for large-scale applications. This can limit the practical applicability of SVD-based OCR systems.

The primary aim of this research is to tackle the challenges associated with the OCR system for handwritten characters in Indian languages by introducing a computationally efficient and yet accurate classifier. Specifically, this study introduces the Nearest Angles (NA) classifier, designed for a handwritten character recognition system. This classifier operates in tandem with SURF as local descriptors. Unlike CNN-based solutions that need to process high-dimensional data as a whole, the NA classifier breaks down the problem into more manageable parts by making local decisions based on the SURF descriptors.

The SURF descriptors are employed to extract features from the handwritten characters. These descriptors capture local features from images, making them less sensitive to writing inconsistencies and noise. Upon feature extraction, the NA classifier comes into play. The classifier uses a ranking-based classification approach that relies on generating image similarity scores from the SURF descriptors. These scores are then ranked for making local decisions. Based on the ranks, the NA classifier generates a global class similarity score that is used for classifying the test data. The overall method leverages local decision-making to reduce the computational burden and achieves classification accuracy rates of 91.0% for Tamil, 94.7% for Devanagari, and 88% for Telugu handwritten character datasets.

*1) Introduction of nearest angles (NA) classifier*: Developed a new classifier specifically tailored for handwritten character recognition systems, which is computationally more efficient than existing deep learning approaches.

*2) Integration with SURF descriptors*: Demonstrated the efficacy of using SURF as local descriptors in combination with the NA classifier, thus offering a balanced trade-off between computational complexity and classification accuracy.

*3) Ranking-based classification approach*: Introduced a unique ranking-based classification method that generates a global class similarity score based on local decisions, simplifying the classification task without a significant loss in accuracy.

*4) Multilingual support*: Validated the approach across multiple Indian languages including Tamil, Devanagari and Telugu, thus showing its versatility and wide applicability.

*5) Resource efficiency*: Demonstrated that the proposed method significantly reduces the computational time and the number of parameters required for classification tasks, making it suitable for resource-constrained environments.

These contributions collectively highlight the novel aspects of this research, showcasing its importance in the fields of OCR and machine learning, especially in the context of Indian languages and resource-constrained environments.

## II. LITERATURE REVIEW

First, the Indian scripts lack a sound HCR system due to their complex nature. Most image processing applications use deep-learning-based models such as CNN and produce promising results [15]. The algorithms for deep learning have substantially improved, functioning exceptionally in a variety of fields with robust safety features [16], [17], [18]. In the context of supervised learning, CNN needs a lot of data to enhance its ability to learn and generalization. Else, it leads to overfitting and data shortage [19]. CNNs have emerged as the method of choice for computer vision tasks involving classification, clustering, and other image-processing applications. But here, general-purpose object recognition tasks frequently appear to produce low-level characteristics [20]. Many studies are made to evaluate the complexity of CNN models. In a recent study on the time complexity of

eight deep-learning models, the number of convolution layers, filters, pooling layers, and fully connected layers are varied and tested. The authors found that these layers directly affect the system's performance [21]. Speeded-Up Robust Features (SURF) [22] provides a patented local feature detector and descriptor. Handwritten character images vary in shape and size, and each image has a distinct number of SURF descriptions derived from it. That means the feature vector of each character image is variable in length. Since most classifiers are intended to use fixed-length strings, a variable-length vector of features poses a challenge. On the part of handling variable length feature vectors, Singular Value Decomposition (SVD) is used along with SVM [23]. An approach in which feature vectors are the chromosomes of GA where two variable length strings are handled by padding one of them with {1,0,#} and the classifier was defined as VGA-classifier [24]. In the previous approach called 'Modified-GA', feature vectors are variable length in nature and are handled by appending '00' at the end [25]. However, these methods amplify the complexity in terms of storing and processing the information.

To incorporate a deep-learning-based classification approach, Surf-CNN was proposed, in which local features are extracted by SURF, and CNN is used for classification [20]. In a study, the presence and location of crack information in concrete structures are determined using SURF features and CNN [26]. When SIF and SURF descriptions are incorporated, the deep-learning-based methods can outperform traditional VGG16 and MobileNetV2 [27]. The number of parameters used in CNN is huge which leads to complexity in the classification systems which can be avoided if the accuracy can be slightly compromised.

Simple algorithms such as Nearest Neighbor (NN) can address a variety of classification issues [28]. The fundamental goal of NN is computing the distances globally between the competing patterns, and then ranking them to select the NN that characterizes a test pattern's class most accurately. Computing the distances between patterns is done by distance metrics and which can be degraded by noise and natural variability. If the feature vector is very large and if there exists a falsely assumed correlation, it may produce an irrelevant distance correlation. A rise in feature dimension causes a classification process to converge more slowly and erroneously [29]. The NN classifier is modified to address the aforementioned challenges and the classification of the test data is made by choosing the Nearest Features (NF) of the train data [30]. However, this method only works with feature vectors of the specified length. Due to these reasons, developing a classifier that deals with variable-length high-dimensional input is still an unresolved challenge in technology. In this paper, a novel Nearest Angle (NA) classification algorithm based on SURF descriptors and angles between the matching Interest Points is proposed. This method produces local-level similarity scores and rankings and finally generates the overall result of the classifier for a global decision on the test pattern.

SURF is a scale and rotation invariant feature detector and a simple and accurate descriptor with good repeatability, robustness, and distinctiveness [31]. The feature extraction

process of SURF is composed of two steps. First, detect interest points (IP) from the meaningful structures of an image, which means finding the same physical structures under diverse viewing conditions. This method gives local features with the required level of invariance due to its focus on scale and rotation invariant feature detector and descriptor. These IPs which are characterized by feature descriptors are matched between different images. The search of correspondence requires the comparison of IPs in images where they are seen at different scales. The descriptor space of two images is considered at a time and the descriptor distances of all possible combinations of IP pairs between the images are calculated. These IP pairs along with a classification approach with a small number of parameters play a major role in the proposed method for the classification of the handwritten character recognition system that is considered for this study.

## III. PROPOSED METHODOLOGY

In this section, we discuss the algorithms and methods involved in the proposed Nearest Angles (NA) classifier for handwritten character recognition. First, we resize all images to a uniform size of 256x256 pixels. Then, we extract SURF descriptors from each image. SURF descriptors are a type of feature that is robust to noise and changes in illumination. Next, we find the nearest interest point in each training image for each interest point in the test image using a minimum distance criterion. The crux of our method is to calculate the angle between each pair of corresponding interest points. We then use these angles to classify the test image by assigning it to the class of the training image with the nearest angle. To improve the accuracy of our classification, we use a "top-rank" technique that considers the highest-scoring training images to be more representative of their class. Finally, we use a global decision-making phase to assign the test image to one of the established classes. This phase involves systematic calculations and normalizations. The overall process flow of this proposed method is represented in Fig. 1.

### A. Nearest Angles (NA) from SURF Feature Detector and Descriptor

A simple variant of the Nearest Neighbor classifier called the Nearest Angles (NA) classifier is proposed that is robust during recognition of the text recognition system, with the variable-length feature vector. The utilization of deep learning techniques and the complexities of computation brought on by larger dimensions and parameters can be minimized if an easy-to-use method is created to handle the IPs produced by SURF descriptors [32]. The proposed approach extends the classification decision at the local level and at the global level. This increases the chance of overcoming the misclassification of local classifiers. The following sections explain how to determine different NAs for local-level decisions and finally, the classification of the test data using the NA classifier is given in detail. As the number of SURF descriptors is large and varies in number from image to image, only a few of them are shown in Table I-II, to illustrate the proposed method.

### B. Determination of Matching Interest Point Pairs from SURF Descriptors

The proposed method extracts Nearest Angles (NAs) from the SURF matching points between two images in the spatial coordinate domain. The previous approach, the NIP classifier, illustrates a sample training set and test image with few *IPs[32]*. The training data contains 3, 3 and two images from the classes C1, C2, and C3 respectively. The training data: $G \in \{C_{11}, C_{21}, C_{31}, C_{12}, C_{22}, C_{32}, C_{13}, C_{23}\}$. Let $C_{jc}$ is the $j^{th}$ image of class *c*. For each image, a different number of IPs are produced. Let $In_{ijc}$ be the $i^{th}$ IP of $j^{th}$ object of the class *c*. Each IP is described by a local descriptor vector of fixed size. Two images are compared by computing the IP-to-IP distance between M IPs of each image $C_{jc}$ *with M IPs and the test image Z.*

Evaluating the Distance between IPs

Considering the training data, where the IPs of each image with a class label c is $\{T = \{In_{pj_c}, \forall p, j, c \in [1, X], X \in$ Integer $\}$ and IPs of the image n with a label $\bar{c}$ is $\{H = \{In_{qn_{\bar{c}}}, \forall m, n, \bar{c} \in [1, X], X \in$ Integer $\}$ where $c \neq \bar{c}$ and $c, \bar{c} \in$ Class Label and p and q varies from 1 to number of IPs of images j and n respectively. Let us calculate the distance between two images j and n by calculating the distance between their IPs. $In_{ij_c}$ is $i^{th}$ IP of image j from class c and $In_{mn_{\bar{c}}}$ is $m^{th}$ IP of image n from class $\bar{c}$. The distances among IPs $In_{ij_c}$ and $In_{mn_{\bar{c}}}$ are computed using simple trigonometry [32]. The distance between two IPs $In_{ij_c}$ and $In_{mn_{\bar{c}}}$ is calculated using Eq. (1).

$$d = |In_{ij_c} - In_{mn_{\bar{c}}}|/\sqrt{2} \quad (1)$$

The minimum distance is determined after repeating this method for every IPs of n in H and using Eq. (2).

$$di = min\{|In_{ij_c} - In_{qn_{\bar{c}}}|/\sqrt{2}\}, \quad (2)$$

where q ranges from 1 to the total number of IPs in the image *n*. The $m^{th}$ IP of n $In_{mn_{\bar{c}}}$, with minimum distance *di* is taken to form a matching pair $(In_{ij_c}, In_{mn_{\bar{c}}})$. The meaning is $i^{th}$ IP of image *j* from class produced minimum distance with $m^{th}$ IP of image *n* from class $\bar{c}$. Repeat the above technique for all the IPs in set *G* to determine the matching pairs of *IPs* of image *j* (see Fig. 2).

Fig. 3(a) to Fig. 3(b) shows the images and IPs forming correct matching pairs (each straight line represents a line connecting the IPs of each matching pair at comparing images). The angle between the two points in the matching pair is computed by the principle of trigonometry as shown in Fig. 3(c) to Fig. 3(d). For every matching IP pair, four angles can be generated. But any one of the angles is sufficient to decide NAs. Fig. 3 shows the two Tamil character images 'Ah' and the points A and B are the IPs in a matching pair after applying the distance Eq. (2) over SURF descriptors in both images. Let PQ and RS be the lines drawn parallel to these points. The ∠ABR and ∠BAQ are alternate interior angles and are equal. As when parallel lines get crossed by another line, alternate interior angles are equal and are calculated as given in Definition 1. Similarly, ∠PAB and ∠ABS are also alternate interior angles.
Fig. 1. Overall process flow of the proposed nearest angles (NA) classifier for handwritten character recognition.

Two values are obtained from each alternate interior angle, so four angles are obtained from each matching pair of IPs. Only one angle value is used for processing for each matching IP pair as the proposed method works for all four angles at the same time. Initially, the bounding box of both the test and training images are calculated and resized to 256 x 256, then SURF features are extracted and matching pairs are generated using the IPs of both the images used for comparison. A line is drawn to connect both the IPs of the matching pair. Parallel lines are drawn to detect the angles between the line drawn and the corresponding axis (see Definition 1).

**DEFINITION 1:** *When a line crosses parallel lines, alternate interior angles $An = (\frac{y2-y1}{x2-x1}) * \frac{180}{\pi}$ are equal where (x1, y1) and (x2, y2) are the coordinates of the line crossing the parallel lines.*

### C. Determination of NAs

For each matching pair between the test and training image, two pairs of angles are produced as alternate interior angles as in Fig. 2(d) ∠PAB and ∠ABS are alternate interior angles and so ∠PAB =∠ABS. Similarly, ∠ABR and ∠BAQ are

alternate interior angles and so ∠ABR = ∠BAQ). And there are two distinct values out of four angles as alternate interior angles are equal. But, any one of the values out of two can be used for processing. Table I shows the angle generated between the IPs of test image Z and each of the training images (only one angle of particular IP matching pair is given). There are seven images in the training set and each image is with different number of IPs. The test image Z produces IPs matching pair with *IPs* of the training image, and the angles between IPs from the matching pair are calculated using Definition 1 and are shown in Table I. After determining the angle between IPs in the matching pair, the next step is to determine the NAs of each of the training images.

**DEFINITION 2:** *An angle $a_n$ between the IPs from the test image and training image j in the matching pair is classified as one of the NAs of training image j if and only if $|\theta_{lan}| \leq a_n \geq |\theta_{uan}|$ where $\theta_{lan}$ and $\theta_{uan}$ are the upper and lower bounds of NA detection threshold.*

After calculating the angle $a_n$ of IPs from each matching pair of the training image j, a comparison is made with the $\theta_{lan}$ and $\theta_{uan}$, which are lower and upper bound NA detection threshold values respectively. When compared with the threshold values $\theta_{lan}$ and $\theta_{uan}$, based on Definition 2, these angles give the measure of closeness of *IP* of test image Z, with the training image j and which is used to make a local decision using NAs. An angle $a_n$ is said to be NA of training image j, if it is greater than $\theta_{lan}$ and less than $\theta_{uan}$. The process of determining the NAs is given by voting as shown in Eq. (3).

$$vi(NA) = \begin{cases} 1, & if\ \theta_{lan} \leq a_n \leq \theta_{uan} \\ 0, & otherwise \end{cases} \quad (3)$$

If vi(NA)=1, the angle $a_n$ is considered as NA between the training and test image.

### D. Local Decision using NAs Classifier

The angle $a_n$ from a training image is said to be the Nearest Angle (NA), if and only if $|\theta_{lan}| \leq |a_n| \leq |\theta_{uan}|$ where $\theta_{lan}$ and $\theta_{uan}$ are lower and upper bounds of NAs threshold values which are assumed to be 80 and 100 respectively. Each NA of the training image carries a vote *vi(NA)*of 1. For each of the training images, the image similarity score is calculated by summing up its *votes* on *NAs which are* shown in Table I.

The training image $C_{11}$ produces the matching pairs *(In$_{111}$, InZ_1), (In$_{211}$, InZ_3), (In$_{311}$, InZ_5)* and *(In$_{411}$, InZ_4)* with test image Z and the angles $a_n$ calculated are 80,110,102 and 96 respectively. The votes are generated by comparing the angles with the threshold values of NA $\theta_{lan}$ and $\theta_{uan}$. Using (4) the Image similarity score for training image $C_{11}$ is 2 as angles 80 and 96 are greater than the threshold $\theta_{lan}$ (i.e.,80) and are less than $\theta_{uan}$ (i.e.,100) and 110 and 102 are greater than $\theta_{uan}$ (i.e.,100). These image similarity scores at the local decision phase are maintained to determine the class of the test image at the global level.

TABLE I. THE PROPOSED NA VOTE AND IMAGE SIMILARITY SCORE COMPUTATION TO DETERMINE THE CLASS OF Z FROM THE TAMIL HANDWRITTEN CHARACTER DATABASE

| Class-label | Object label | Matching-pair | Angle | Matching-pair | Angle | Matching-pair | Angle | Matching-pair | Angle | Matching-pair | Angle | Image similarity score based on NAs | Normalized image similarity score |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

(a)      (b)      (c)

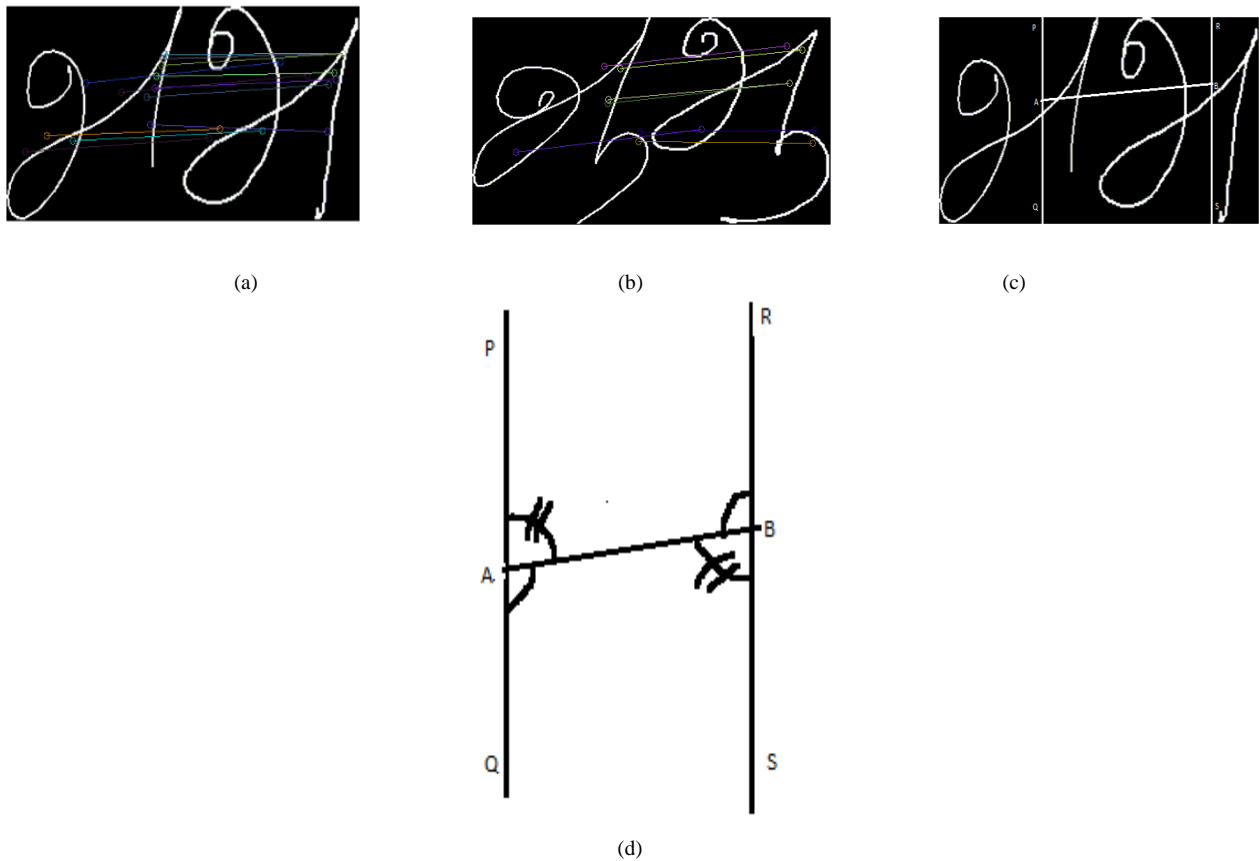
(d)


Fig. 3.  (a) and (b)Two intra-class Tamil Character images, 'Ah' and 'AAh', respectively, showing Matching pair with minimum distance. (c) Two Tamil Character images 'Ah' with matching IPs at points A and B. (d) The line connects the two points A and B and four angles can be produced between these two points, ∠PAB, ∠BAQ, ∠ABR and ∠ABS. (b)∠PAB and ∠ABS are alternate interior angles and so ∠PAB =∠ABS. Similarly, ∠ABR and ∠BAQ are alternate interior angles and so ∠ABR = ∠BAQ.

The Image similarity score gives the local decision on the closeness of IPs of the test data with training data.

### E. Classification using Global Decision on Similarity Scores

The global decision on the recognition of test images is done by considering the 'top-rank' technique. Accordingly, the image in the training set, at each class, with the highest value in the 'image similarity score' is considered for further processing. In this method, the training image with the highest 'Image similarity score' in each class is considered to represent the whole class. That means, the training image in each class with a higher similarity value is calculated and is termed as collective class similarity score $S_g(c)$ at 'Rank 1' and is given in Table II. Class probability scores $S_p$ is calculated by normalizing the collective class similarity score $S_g(c)$ by dividing it by the maximum similarity score across the classes. The highest value of Sp across the classes is considered as the class of the test image Z, c*, which can be denoted as Eq. (4).

$$c^* = arg\ max\ S_p(c) \qquad (4)$$

The top-rank approach generally gives many classes as outputs despite the fact that it facilitates decision-making at the global level. Therefore, the image similarity score at lower rankings is taken into account, and an algorithmic sum is performed at each ranking level. The image-level similarity scores at first and second ranks from each class are summed up to calculate the collective class similarity score $S_g(c)$ at Rank 2. This process is repeated for the subsequent lower-ranking levels. The rank-wise normalization *of $S_g(c)$* throughout all the classes yields *class probability scores, $S_p$.* A tie-in-the-top-rank method is solved by adding the $S_p$ values at the lower rankings. It would eliminate the ambiguity in class assignments caused by ties. The rank 1 $S_p$ score of C1 yields the highest value of 1 with no ties (see Table II). The model is evaluated up to three ranking levels since an acceptable recognition is obtained close to rank 3 in the NA classification.

### F. Overall Process Flow of Proposed NA Classifier

The Nearest Angles (NA) Classifier for Text Recognition using SURF Descriptors is a novel algorithm designed to address the challenges of text classification in images. It leverages Speeded-Up Robust Features (SURF) to capture unique descriptors and interest points from a set of pre-labelled training images across multiple categories. This approach enhances the conventional techniques by employing angle-based metrics to establish the nearest matches between the features of a test image and those in the training dataset. The algorithm then computes similarity scores based on these angle metrics to classify the test image into one of the predefined categories. The efficacy of the method lies in its ability to deliver accurate classifications while effectively handling variations in scale, orientation, and illumination. The proposed Nearest Angles (NA) Classifier's process flow is explained in Algorithm 1.

---

**Algorithm 1 NA Classifier for Text Recognition**

1: **Input:**
2: Training image set $G$ with class labels $C1, C2,..., Cn$
3: Test image $Z$
4: Lower bound NA detection threshold $\theta_{lan}$
5: Upper bound NA detection threshold $\theta_{uan}$
6: **Output:**
7: Classified label for the test image $Z$
8: **Steps:**
9: **SURF Feature Extraction**
10: **for** each image $C_{jc}$ in $G$ and test image $Z$ **do**
11: Extract SURFdescriptors and Ips ($IP_{ijc}$ for $C_{jc}$ and $IP_{zn}$ for $Z$)
12: **end for**
13: **Calculate IP-to-IP Distances**
14: **for** each $IP_{ijc}$ and $IP_{zn}$ **do**
15: $d = \frac{|IP_{ijc} - IP_{zn}|}{\sqrt{2}}$
16: **end for**
17: **Find Minimum Distances** 18: **for** each $IP_{ijc}$ **do**
19: $d_i = \min\left(\frac{|IP_{ijc} - IP_{zn}|}{\sqrt{2}}\right)$
20: **end for**
21: **Determine Matching Pairs**
22: **for** each $IP_{ijc}$ **do**
23: Pair $IP_{ijc}$ and $IP_{zn}$ if $d_i$ is minimum
24: **end for**
25: **Calculate Angles for Matching Pairs**
26: **for** each matching pair **do**
27: $Angle(An) = \frac{(y_2 - y_i)}{(x_2 - x_i)} \times \frac{180}{\pi}$
28: **end for**

30: **for** each angle $a_n$ **do**
31: **if** $\theta_{lan} \leq a_n \leq \theta_{uan}$ **then**
32: $v_i(NA) = 1$
33: **else**
34: $v_i(NA) = 0$
35: **end if**
36: **end for**
37: **Compute Image Similarity Score**
38: **for** each image $C_{jc}$ **do**
39: Image Similarity Score $= {}^P v_i(NA)$
40: **end for**
41: **Local Decision**
42: Image similarity scores of $m$ top-ranked images are taken to obtain local decisions at 2 NAs.
43: **Global Decision**
44: Calculate class similarity score followed by class probability score to make a more robust global decision

The Nearest Angles (NA) Classifier for Text Recognition using SURF Descriptors is an algorithm designed to classify text images into pre-defined categories. The algorithm starts by extracting Speeded-Up Robust Features (SURF) descriptors and interest points (IPs) from both the training image set, labelled with classes $C1, C2, \dots, Cn$, and a test image $Z$. It calculates the IP-to-IP distances between these features and identifies the minimum distances to form matching pairs of IPs between each training image and the test image. Angles are calculated for these matching pairs, and a "Nearest Angle" (NA) is identified based on lower and upper angle thresholds $\theta_{lan}$ and $\theta_{uan}$. An image similarity score is computed for each training image based on these NAs. The algorithm then classifies the test image $Z$ into the category of the training image with the highest similarity score. Optionally, a global decision can be made by aggregating multiple local decisions.

## IV. RESULTS AND DISCUSSION

### A. System Setup

To evaluate the effectiveness of the NA Classifier, the experiments were conducted on a system equipped with an Intel i7 processor, 16 GB of RAM, and a 1 TB SATA hard drive. The system also featured an NVIDIA GPU. The software environment was MATLAB 2020, specifically utilizing its Deep Learning Toolbox, all running on a Windows 10 operating system.

### B. Experimental Setup

The primary objective of this section is to assess the effectiveness of the proposed NA Classifier for handwritten text recognition, which is designed to reduce the computational burden commonly encountered in existing AI algorithms. The experimental framework is divided into three key components: computational efficiency, accuracy and comparative analysis: Intra-Class vs. Inter-Class Matching. These aspects are rigorously evaluated against a range of state-of-the-art algorithms and models. In the first component, the computational efficiency of the NA Classifier is analyzed to determine whether it effectively reduces processing time without sacrificing performance. In the second component, the method's error rate is examined to assess its reliability in various classification tasks. Finally, the accuracy of the NA Classifier is evaluated, serving as the critical measure of its overall effectiveness. The accuracy of the NA Classifier was evaluated against state-of-the-art methods, including: SurfCNN (A. M. Elmoogy et al. [20]), CNN-based Models (M. Rai and P. Rivas [19]), SURF with SVM (Shagun Katoch et al. [21]), SVD with SVM (Li C et al. [23]), VGG16 and MobileNetV2 (Ardiant Utomo et al. [27]), Nearest Neighbor (Nitin Bhatia, Vandana [28]), Modified-GA (Ashlin Deepa R N, Rajeswara Rao R [32]), Nearest Angle (NA) Algorithm (Alex Pappachen James [30]). The proposed method was also benchmarked against the popular machine learning and deep learning algorithms, including k-nearest neighbors (k-NN), k-means clustering, support vector machines (SVM), decision trees, Naive Bayes, Random Forest, VGG-19, MobileNet, and gradient boosting.

### C. Dataset Details

In this research, we employ three distinct Indic handwriting datasets sourced from HP Lab, focusing on the Tamil, Devanagari, and Telugu scripts. These datasets serve as the foundational testing ground for the evaluation of our proposed method, encompassing a wide array of handwritten textual samples in these languages to validate the robustness and applicability of our approach. Tables III, IV, and V provide details about the Tamil, Telugu, and Devanagari datasets, respectively.

TABLE III. TAMIL DATASET ATTRIBUTE DETAILS

| Criteria | Details |
|---|---|
| Total Classes | 156 |
| Data Format | UNIPEN v1.0, bilevel TIFF images |
| Training Set | 70% of samples from each class, randomly selected |
| Test Set | Remaining 30% of samples from each class |

TABLE IV. TELUGU DATASET ATTRIBUTE DETAILS

| Criteria | Details |
|---|---|
| Total Classes | 166 |
| Data Format | UNIPEN v1.0 |
| Training Set | 70% of samples from each class, randomly selected |
| Test Set | Remaining 30% of samples from each class |

TABLE V. DEVANAGARI DATASET ATTRIBUTE DETAILS

| Criteria | Details |
|---|---|
| Total Classes | 111 |
| Data Format | UNIPEN v1.0, bilevel TIFF images |
| Training Set | 70% of samples from each class, randomly selected |
| Test Set | Remaining 30% of samples from each class |

### D. Computational Efficiency Analysis

Computational efficiency is a critical criterion in the evaluation of deep learning and machine learning algorithms. In recent years, there has been significant research on mitigating the computational overhead associated with deep learning and machine learning techniques. This section evaluates the computational efficiency of the proposed NA classifier on three handwritten datasets: Tamil, Telugu, and Devanagari. For each dataset, 70% of the samples from each class were allocated to the training set, and the remaining 30% constituted the test set. First, we evaluate the training efficiency of the proposed method against state-of-the-art handwritten character recognition methods, deep learning algorithms, and machine learning algorithms.

According to the Fig. 4, the proposed Nearest Angle (NA) classifier demonstrates a notable advantage in computational efficiency across three handwritten datasets: Tamil, Telugu, and Devanagari, with training times of 3.0, 3.2, and 3.4, respectively. These times are significantly lower than those of existing state-of-the-art methods and standard machine learning and deep learning algorithms, such as VGG-19, MobileNet, and SVM, which have training times up to three times higher. This reduced training time implies a lower computational burden, fewer resource requirements, and faster deployment capabilities, thereby making the NA classifier an ideal choice for applications where computational resources and time are critical constraints.
Fig. 4. Comparative analysis of training time across various algorithms and datasets.

To assess the classification time efficiency of the proposed method in a rigorous manner, we adopted a systematic testing approach. Specifically, we randomly selected five samples from each of three different datasets. Each set of five samples was classified using the proposed method and various existing methods for comparison. For each set, we measured the time required to complete the classification and then calculated the average classification time for that set. Finally, we computed an overall average classification time across the three sets to obtain a robust estimate of performance.

The Fig. 5 comparing average classification times reveals that the proposed NA method is the most time-efficient with an average of 0.15 seconds, closely followed by the method proposed by A. M. Elmoogy et al. at 0.18 seconds. Traditional machine learning algorithms like k-NN, k-means, and SVM exhibit moderate speed, ranging from 0.29 to 0.38 seconds, while ensemble methods such as Random Forest and Gradient Boosting are slightly slower within the same category. Notably, deep learning models like VGG-19 and MobileNet are significantly slower, taking around 0.95 and 0.90 seconds respectively, likely due to their complex architectures and higher computational requirements.

Compared to traditional deep learning methods, the proposed NA classifier for text recognition systems significantly reduces classification and training time. This efficiency is largely due to its localized decision-making approach, which focuses on calculating angles between matching Interest Points (IPs) in the spatial coordinate domain. Instead of computing high-dimensional feature vectors and performing complex operations, the NA classifier uses simple calculations to evaluate the closeness of IPs. By considering only angles that fall within predefined upper and lower bound thresholds, the system effectively performs dimensionality reduction. This limits the computational complexity, which is especially beneficial when dealing with large sets of SURF descriptors that can vary in number across images. As a result, this method not only minimizes the chances of misclassification at the local level but also reduces computational overhead, leading to faster classification and training times.

*E. Accuracy Analysis*

Accuracy is a crucial metric for evaluating the performance of the NA Classifier in handwritten text recognition. Specifically, we are interested in the algorithm's effectiveness in identifying individual characters in three datasets: Tamil, Telugu, and Devanagari. In this section, we will outline the metrics used to assess accuracy and present the results in comparison with state-of-the-art models and algorithms. The following metrics are primarily involved in the evaluation of accuracy:
Fig. 5. Average classification time in seconds.

*1) True positives (TP)*: These represent instances where the NA Classifier accurately identifies a character as belonging to a specific class within the dataset.

*2) True negatives (TN)*: These denote situations where the NA Classifier accurately concludes that a given sample does not belong to a targeted class.

*3) False positives (FP)*: These occur when the NA Classifier incorrectly ascribes a sample to a particular class when it should not have.

*4) False negatives (FN)*: These represent the scenarios where the NA Classifier fails to identify a sample as belonging to a specific class when it actually does. Based on these, we calculate the following metrics: Accuracy (ACC), Sensitivity (SEN), Specificity (SPEC), F1-Score, and Matthews Correlation Coefficient (MCC) which are calculated by using following formulas.

$$ACC = \frac{(TP + TN)}{(TP + TN + FP + FN)} \quad (5)$$

$$SEN = \frac{TP}{(TP + FN)} \quad (6)$$

$$SPEC = \frac{TN}{(TN + FP)} \quad (7)$$

$$F1 = 2 * \frac{(precision * recall)}{(precision + recall)} \quad (8)$$

TABLE VI. BENCHMARKING ACCURACY OF NA CLASSIFIER AGAINST STATE-OF-THE-ART METHODS ON TAMIL DATASET

| Methods | ACC | SEN | SPEC | F1-Score |
|---|---|---|---|---|
| Nearest Angle (NA) | 96.4% | 95.8% | 97.3% | 96.0% |

According to the data in Tables VI, VII, and VIII, the NA classifier consistently outperforms traditional machine learning algorithms such as k-NN, k-means, SVM, and Decision Trees across all datasets. In the Tamil dataset, for example, the NA classifier achieved an accuracy of 96.4%, which is notably higher than the closest traditional competitor, Ardiant Utomo et al, at 92.3% (see Table VI). Similar trends are observed in the Telugu and Devanagari datasets as well, where the NA classifier scored 96.5% and 97.0% respectively. In terms of sensitivity and specificity, the NA classifier also performs excellently. It managed to attain 95.8% sensitivity and 97.3% specificity on the Tamil dataset, again superior to

any traditional algorithm (see Table VI). The high sensitivity and specificity scores mean that the NA classifier is proficient at correctly identifying true positives and true negatives, making it a reliable choice for real-world applications. The F1-Score serves as a balanced measure of a model's performance, taking into account both precision and recall. The NA classifier achieves a high F1-Score of 96.0%, 96.1%, and 96.7% on the Tamil, Telugu, and Devanagari datasets, respectively as shown in Table VI, Table VII and Table VIII. This is a significant achievement compared to traditional classifiers. While deep learning methods like VGG-19 and MobileNet slightly outperform the NA classifier in terms of accuracy, they do so at the cost of computational resources. The NA classifier is designed for lightweight applications and is three times more computationally efficient than these deep learning models. In scenarios where computational resources are a concern, this efficiency makes the NA classifier an appealing choice without significantly compromising accuracy.

The NA classifier for handwritten character recognition that is both accurate and efficient. It is not as accurate as deep learning models, but it is much faster. This makes it a good choice for applications where speed is important, such as real-time text recognition on mobile devices. The NA classifier has been shown to work well on multiple datasets, which shows that it is reliable and robust.

### F. Comparative Analysis: Intra-Class vs. Inter-Class Matching

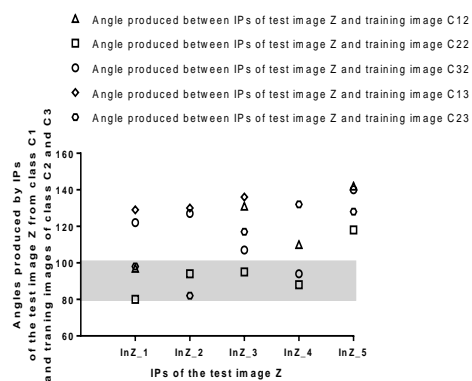
Intra-class and inter-class matching discrimination is a crucial component of image matching in our study. Intra-class matching refers to matching pairs of data points that belong to the same class. Inter-class matching refers to matching pairs of data points that belong to different classes. Fig. 6(a) shows an example of intra-class matching. Both IPs A and B point to the same local physical structures in the two Tamil character images of 'Ah'. However, the NA classifier generates a vote of '0' because the alternate interior angles violate the lower and upper bounds of the NA detection thresholds. This means that the two images are not considered to be NAs. Fig. 6(b) shows an example of inter-class matching. The two IPs point to different local physical structures in the two character class images. The NA classifier also generates a vote of '0' in this case because the alternate interior angles violate the rule of NAs.

(a)
(b)

Fig. 6.   (a) Two intra-class images of Tamil alphabet 'Ah' showing incorrect IPs matching at A and B, so that the angle ∠BAC and ∠ABD have more than 100° and the angle ∠EAB and ∠ABF have less than 80°. (b) Two inter-class images of Tamil alphabet 'AAh' and 'Ah' showing incorrect IPs matching at A and B, so that the angle ∠BAD and ∠ABC have more t100° and the angle ∠EAB and ∠ABF have less than 80°.

(a)

(b)



(b)

Fig. 7.   Effect of parameters used in the NA classifier.  (a) Most of the angles produced between IPs of test image Z and training images of class C1 are inside the shaded region which illustrates the allowed boundaries of NA classifier. (b) Most of the angle s produced between IPs of test image Z and training images of class C2 and C3 are outside the shaded region which illustrates the allowed boundaries of NA classifier.

Fig. 7(a) shows the reliability of the threshold values $\theta uan=100$ and $\theta lan=80$ for intra-class matching. Most of the IPs between the test image Z of class C1 and the intra-class

training images C11, C21, and C13 produce angles within the upper and lower bounds. This means that the test image Z is correctly classified as not being an NA. Fig. 7(b) shows the angles formed between inter-class training images and the test image Z. Most of the angle values are out of the upper and lower bounds of the threshold values. This means that the test image Z is correctly classified as being an NA. The comparative analysis of intra-class vs. inter-class matching for NA detection shows that the NA classifier can produce good accuracy on the datasets used for the study, even though SURF features are scale and rotation-invariant. This is because the NA classifier uses additional information about the geometry of the local physical structures to detect NAs.

## V.   DISCUSSION

The Nearest Angle (NA) classifier demonstrates promising performance for handwritten text recognition (HTR) tasks across a diverse range of datasets, including Tamil, Telugu, and Devanagari. Several key observations can be made from the study:

Superiority over Traditional Classifiers: The NA classifier consistently outperforms traditional machine learning methods such as k-N), k-means clustering, SVM, and decision trees in terms of accuracy, sensitivity, specificity, and F1-score. This highlights its potential as a robust and efficient classifier for HTR tasks.

Comparison with Deep Learning Models: While deep learning architectures such as VGG-19 and MobileNet marginally surpass the NA classifier in terms of accuracy, they do so at the expense of computational efficiency. The NA classifier's rapid classification time presents an optimal trade-off between speed and accuracy, especially critical for resource-constrained devices and real-time applications.

Reliability across Datasets: The NA classifier's consistent performance across Tamil, Telugu, and Devanagari datasets underscores its generalizability. This versatility is essential for a classifier, especially in applications where diverse scripts might be encountered.

Intra-class vs. Inter-class Matching: The comparative analysis on intra-class and inter-class matching reinforces the NA classifier's robustness. By exploiting the geometry of local physical structures, the NA classifier effectively differentiates between characters that may look visually similar, thereby minimizing false matches.

Thresholding in NA: The use of threshold values ($\theta uan=100$ and $\theta lan=80$) for angle classification serves as a vital mechanism for the NA classifier. As the presented figures depict, the chosen thresholds enable effective discrimination between intra-class and inter-class matches. The robustness of these thresholds in classifying the characters accurately showcases the model's resilience to typical variances seen in handwritten data.

Potential for Real-World Applications: Given its quick classification time, combined with high accuracy, the NA classifier is particularly suited for real-world scenarios, especially those demanding swift recognition such as mobile OCR applications or real-time transcription services.

## VI. Conclusion

Local feature detectors and descriptors are powerful in many object recognition tasks. The complexity of deep-learning-based approaches can be avoided by using effective local descriptors such as SURF for feature extraction. In this study, the concept of local feature detection along with a similarity-voting-based classifier is introduced at the local level and a ranking-based classifier at the global level. The proposed Nearest Angles classifier is applied effectively with SURF descriptors for handwritten character recognition of Tamil, Devanagari, and Telugu scripts. With a slight compromise in the recognition accuracy, the proposed method facilitates the features of variable length as well as high dimensionality and reduces complexity. Benchmark databases are used to demonstrate robust recognition performance.

The usage of the collective class similarity score produces excellent results in the NA classifier as the false similarities are removed by selecting the IPs based on the angles between them. NA handles high dimensionality and variable-length feature vectors (IPs of training images). The study proves that local feature descriptors extract a huge number of informative features and can produce good results if used wisely with an efficient classifier. The proposed method utilizes local decision-making to reduce the computational overhead and achieves high classification accuracy rates of 91.0% for Tamil, 94.7% for Devanagari, and 88% for Telugu handwritten character datasets.

The capabilities of HCR systems can be improved in several ways. Transfer learning can be used to transfer knowledge from one script to another, which can reduce the need for large script-specific datasets. Additionally, HCR systems can be adapted for online recognition, allowing for real-time processing and feedback. This would be useful for applications such as digital signature verification and interactive systems. These enhancements would make HCR systems more adaptable, precise, and user-friendly, which would expand their usefulness in a variety of domains.

*Abstract*—The unregulated buildup of waste results in the occurrence of flames. This phenomenon poses a substantial threat to both the ecological system and human welfare. To tackle this problem, the current study proposes the implementation of Machine Learning technology to automate the sorting of waste. The methodology being examined incorporates the utilization of SqueezeNet as an image embedding method in conjunction with XGBoost as the final classifier. This work examines the efficacy of the aforementioned technique by doing a comparative analysis with many alternative final classifiers, including LightGBM, XGBoost, CatBoost, Random Forest, SVM, Naïve Bayes, KNN, and Decision Tree. The experimental results indicate that the integration of SqueezeNet and XGBoost produces the highest level of performance in the field of garbage categorization, as supported by an F1-score of 0.931. SqueezeNet is a method employed for image embedding that enables the extraction of salient features from images. This procedure enables the recognition of unique characteristics linked to different classes. Therefore, XGBoost may be utilized to enhance classification tasks. XGBoost has the ability to generate a feature importance score. Therefore, enabling the recognition of the most prominent attributes. This methodology possesses the capacity to alleviate the risk of fire that arises due to the accumulation of unregulated trash. This work makes a substantial contribution to environmental conservation and the improvement of public safety.

## I. INTRODUCTION

Landfill fires are caused by human and environmental factors [1]. Uncontrolled burning causes flames. When heated, plastic, paper, and biological materials can catch fire. Due to the high population, a fire from a pile of waste spreads quickly and uncontrollably, making containment difficult. Chemical reactions can occur in hot and humid situations [2], [3], especially in areas where organic waste decomposes, generating heat and fire-starting gases. Fermentation and breakdown can produce methane. Direct sunlight and extreme temperatures can heat gathered rubbish [4-5]. The risk of fire increases when waste contains combustible materials. When mixed, hazardous trash like solvents, batteries, and other poisons can create heat or burn. Sometimes exterior fires, maybe caused by humans, enter the building. For instance,

illegally incinerated garbage [6-8] or environmental components like embers from nearby forest fires. These sites release toxic gases like methane. In the presence of an igniting source and a gas leak, a fire may occur. Environmental factors including high winds and severe weather might affect fire growth [9–11]. Strong winds may help a fire spread quickly. Fires in this area harm the environment, health, and infrastructure. Thus, garbage segregation and other waste management measures are crucial.

The field deployment of garbage segregation has numerous hurdles that may hinder waste management programs [12–14]. Public comprehension of waste segregation and its environmental benefits is sometimes lacking. Educational and socialization efforts are needed to raise awareness of waste segregation. Additionally, many places lack the capacity to segregate trash. Without separate receptacles, recycling infrastructure, and clear instructions, waste segregation may be difficult. Trash segregation by communities may not guarantee long-term landfill diversion without proper recycling facilities. Without recycling facilities, rubbish sorting may be less appealing. Insufficient or inaccurate waste sorting may reduce sorting efficiency. Recycling is difficult when separated items are mixed together.

Efficient and effective waste segregation technology has several benefits for waste management and environmental preservation. Advanced sorting technology can precisely separate various materials. Segregating materials improves recycling efficiency and produces higher-quality products. By using good segregation technology, landfill garbage may be reduced [15]. This approach extends landfill life and reduces habitat damage. Effective waste segregation reduces environmental deterioration, especially soil and water pollution. Sorting technology separates pollutants to protect ecosystems and human health. Manual sorting is laborious and error-prone. Sorting technology can improve material separation and save manual labor, solving the problem.

Technology has improved segregation precision and consistency, exceeding hand sorting. Organic trash, including food scraps, leaves, and other biodegradable materials, may be distinguished from recyclable garbage like plastic, paper, and metal with great precision [16–21]. Implementing waste separation techniques requires a categorization system that can

independently distinguish organic and recyclable components. The merging of computer vision and artificial intelligence (AI) has improved rubbish categorization precision and efficacy [22]. The seamless integration of these two sophisticated technologies allows the system to independently identify and classify waste items. Computer vision is an academic field that lets computers view and understand visual data like images and movies like humans [23-27]. Computer vision systems can recognize trash items' unique traits. Advanced cameras and optical sensors enable discernment by effectively examining and interpreting color, shape, and texture. Additionally, it shows the capacity to critically evaluate a variety of visual representations and data from different angles. A powerful image processing algorithm allows the system to distinguish patterns, characteristics, and qualities that distinguish organic from recyclable trash. Artificial intelligence, especially machine learning, is crucial to trash categorization.

Machine learning algorithms may learn from training data, allowing them to recognize and understand patterns and make accurate classification judgments [28]. Computer vision and AI require model training for categorization. This complex procedure uses massive quantities of sample images and waste material data. By using many samples, the model can identify biological waste from recyclable waste. The trained model can automatically and instantly categorize garbage after training. The process uses a camera or optical sensor to capture an image of the garbage. An artificial intelligence algorithm then analyzes the image and accurately classifies the garbage.

Convolutional Neural Networks (CNNs) are highly effective in processing image data [29–31]. This neural network uses convolutional layers to identify complex visual properties from a garbage image and categorize it by kind. Large amounts of data are needed to train CNN models. However, training data is sometimes limited, especially for specialized or rare image recognition assignments. To overcome deep neural network model training challenges, transfer learning in CNNs has become a feasible option. Transfer learning lets you use pre-trained models on large datasets to solve new problems using small datasets. Training multi-layer deep CNN models requires a lot of time, computer resources, and complex optimization methods. Transfer learning is a popular machine learning approach that uses pre-trained models to speed up model training. Using an existing model as a starting point reduces the time and computing resources needed to train a model from scratch.

SqueezeNet, a neural network architecture designed for image recognition, contains fewer parameters than AlexNet, VGG, and ResNet [32-34]. The SqueezeNet framework develops models with low parameter counts and great image recognition accuracy. SqueezeNet extracts visual features, which other approaches use as embedding representations. SqueezeNet embeds images by condensing visual input into numbers. This altered representation can help machine learning systems classify rubbish.

Bai studied garbage classification [35]. Machine vision, item recognition, and check categorization are performed sequentially. The hierarchical system development framework uses Struts2, spring, and Hibernate. Optical identification,

convolutional neural networks, and Naive Bayes are crucial garbage categorization technologies. Ghanshala et al. use machine learning to categorize areas into two categories: garbage-free and high-garbage-filled [36]. The study used four algorithms, achieving 98.6% accuracy with kNN and Naïve Bayes, 85.4% with Decision Tree, and 98.4% with Random Forest.

Another classification has been done using Histogram of Oriented Gradients (HOG) features and an SVM boosting algorithm [37]. The submitted image is preprocessed to improve recognition. A HOG is used to extract properties. The classification device is trained to send relevant data to the image set. From this premise, the categorization scenario is identified. The algorithm's classification accuracy is 95% or better, a 10% improvement over the single SVM classification strategy. The garbage classification method is accurate and practical.

The current work suggests utilizing XGBoost as the final classifier once SqueezeNet features are generated. XGBoost, or Extreme Gradient Boosting, is a popular categorization machine learning approach. The ensemble technique combines predictions from numerous simpler machine learning models, known as "weak learners," to improve accuracy and resilience. The system automatically identifies and categorizes various waste materials into two classes (organic, and recyclable) using these two advanced technologies.

## II. MATERIAL AND METHODS

The approach employed in the present study can be seen in Fig. 1. Furthermore, this study not only implemented the suggested method but also did a comparison with alternative methods.

Fig. 1. Research methodology.

### A. Dataset Collection

The dataset employed in this study was provided by Sashaank Sekar. The data may be accessed from the following source: https://www.kaggle.com/techsash/waste-classification-data. The initial dataset obtained from Kaggle has a total of 25,077 images, with 13,966 images depicting organic materials and 11,111 images representing recyclable materials. The images obtained are in the form of colored .jpg files, displaying a variety of portrait and landscape orientations. The resolution

of these imagegraphs varies, with a minimum of 191 pixels and a high of 264 pixels.

### B. SquezeeNet

SqueezeNet serves as a technique for producing image embeddings through the process of extracting features from images [31]. This stage involved running images through the convolution and pooling layers inside the SqueezeNet model, afterward extracting the output from one of these layers as a feature representation, also known as an embedding, of the image. The mechanism can be described as follows:

- Image preprocessing

It involves applying several techniques to prepare images in a dataset for further analysis. These techniques include pixel intensity normalization, resizing, and noise reduction, among others. The purpose of image preprocessing is to ensure that the images meet specific requirements and are ready for further analysis tasks.

- Feature extraction

It employs pre-processed images as the input data for the SqueezeNet architecture. The process involves passing images through convolutional and pooling layers inside the SqueezeNet architecture.

- Embedding layer

It designs a certain layer inside SqueezeNet as the desired location for extracting the feature representation (embedding) of the image. The inclusion of this layer is recommended prior to the implementation of the fully linked layers.

- Feature representation

It obtains feature representations involves passing images through the SqueezeNet architecture until a certain layer is reached, resulting in a vector representation of the image's features, also known as embeddings.

- Feature vectors

The vector can serve as image embeddings by utilizing the feature representation vectors derived from the preceding stage. These vectors were utilized as input in XGBoost, to perform the classification task.

### C. XGBoost

XGBoost, also known as Extreme Gradient Boosting, is a commonly employed machine learning method that is particularly recognized for its effectiveness in classification problems [38-40]. The method in issue can be classified as a type of ensemble learning technique, wherein the outcomes of several smaller and less powerful models are combined to create a more robust model. XGBoost places emphasis on employing decision trees as its foundational model, while integrating the principles of gradient boosting and regularized regression to get exceptional performance across diverse tasks. Fig. 2 illustrates a simplified version of XGBoost. The components of XGBoost are as follows:

- Decision Trees

The method employed as the fundamental model in XGBoost. A decision tree is a hierarchical arrangement comprising of nodes and branches, which symbolize decisions or predictions made at each node.

- Gradient Boosting

XGBoost employs an ensemble learning technique with gradient boosting methodology. Initially, a preliminary (suboptimal) model is constructed, often in the form of a basic decision tree. Subsequently, a subsequent model is constructed with the purpose of addressing the errors committed by its predecessor. This procedure is iteratively conducted, with particular attention on data points that demonstrate persistent prediction mistakes.

- Boosting

In the context of XGBoost, the model addition process involves the incremental inclusion of a new decision tree into the existing ensemble at each iteration. The proposed model aims to predict the residual, which refers to the difference between the observed target value and the current representation, based on the preceding model.

- Penalty and Regularization

The XGBoost algorithm incorporates regularization techniques to enhance the performance of the decision trees it constructs. The successful completion of this job is helped by the utilization of an objective function that integrates objective regression alongside a penalty function, often L1 or L2, to mitigate the problem of overfitting.

Fig. 2. Flowchart of XGBoost.

XGBoost possesses different benefits in comparison to other algorithms due to its unique operating mechanism. The XGBoost algorithm is a machine learning methodology that integrates regularization methods to effectively mitigate the problem of overfitting. The objective of this approach in this study was to develop models that demonstrate enhanced generalization and less sensitivity to the specific attributes of the training data. The XGBoost technique, which is widely used in machine learning, offers a wide range of hyperparameters that may be tuned to enhance the performance of the model. Furthermore, the failure to get the ideal value for the hyperparameter might be seen as an adverse result.

### D. Evaluation

To optimize the evaluation process, it is imperative to partition the dataset into distinct subsets, namely a training set and a testing set [41]. The current study leveraged a dataset of considerable scale, thereby justifying the adoption of a five-fold cross-validation methodology. The utilization of cross-

validation (CV) is a widely adopted methodology within the realm of machine learning for the purpose of evaluating the performance and effectiveness of prediction models [42]. The proposed methodology involves partitioning the provided dataset into multiple distinct subsets, commonly referred to as folds. This approach aims to assess the generalization capabilities of the model by simulating real-world scenarios where the model encounters novel data samples [43]. In each iteration of the experiment, a single fold is designated as the testing set, while the remaining four folds are allocated as the training set. In each iteration, it is imperative to compute the evaluation metric. Upon the completion of the five iterations, it becomes imperative to calculate the mean value of the evaluation metrics acquired throughout each iteration.

The present study incorporates a comprehensive set of evaluation metrics, namely accuracy, precision, recall, and the F1 score. The accuracy is computed by dividing the number of correctly classified instances by the total number of instances in the dataset. This ratio provides a clear representation of the model's ability to correctly classify data points. In such scenarios, relying solely on accuracy as an evaluation metric may introduce bias. The metric of precision is employed as a quantitative measure to evaluate the degree of accuracy exhibited by a model in generating positive predictions. The notion of recall is a fundamental aspect within the realm of machine learning, which concerns the model's capacity to effectively recognize and encompass all instances that are genuinely positive. The computation of the F1 score involves the utilization of the harmonic mean to combine accuracy and recall metrics. By calculating the harmonic mean of these two measures, the F1 score ensures a balanced evaluation, assigning equal importance to both accuracy and recall.

This study aim to conduct a comprehensive comparison between the SqueezeNet combination and an alternative final classifier, distinct from the widely used XGBoost algorithm. The objective is to evaluate the performance and efficacy of these two approaches in the context of machine learning. By undertaking this comparative analysis, it seek to shed light on the relative strengths and weaknesses of these methodologies, thereby contributing to the existing body of knowledge in the field of machine learning research. In the realm of machine learning, a multitude of algorithms have emerged as prominent contenders for various tasks. Among these algorithms, Random Forest, SVM with a Radial Basis Function (RBF) kernel, Naïve Bayes, K-Nearest Neighbor (KNN) with a value of K equal to 5, and Decision Tree have garnered significant attention and utilization. Random Forest, a versatile ensemble learning method, has proven to be highly effective in tackling classification and regression problems. By constructing a multitude of decision trees and aggregating their predictions, Random Forest mitigates overfitting and enhances generalization capabilities. SVM, a powerful algorithm for both classification and regression tasks, utilizes a kernel function to map data into higher-dimensional feature spaces. The RBF kernel, in particular, has exhibited remarkable performance in capturing complex relationships within data, enabling SVM to excel in diverse problem domains. Naïve Bayes, a probabilistic classifier, leverages Bayes' theorem with the assumption of feature independence. Despite its simplistic

nature, Naïve Bayes has demonstrated remarkable efficiency and effectiveness, making it a popular choice for text classification and spam filtering tasks. KNN is a non-parametric algorithm that classifies data points based on the majority vote of their K nearest neighbors. With K set to 5, KNN strikes a balance between capturing local patterns and avoiding excessive noise, rendering it a valuable tool in pattern recognition and recommendation systems. In addition to the aforementioned Boosting variants, it is worth noting the existence of several other implementations in the field. Notably, two prominent examples are the Light Gradient Boosting Machine (LightGBM) and CatBoost, which both leverage the power of Gradient Boosting in conjunction with Decision Trees.

## III. RESULTS AND DISCUSSION

Tables I, II, and III provide a comprehensive overview of the performance metrics associated with the algorithms employed for the classification of organic, recyclable, and mixed wastes. The three tables demonstrate that the suggested method shows superior performance. The many variations of Boosting, including LightGBM, XGBoost, and CatBoost, exhibit superior performance with the K-Nearest Neighbors (KNN) algorithm.

TABLE I.    THE AVERAGE PERFORMANCE OF EACH FINAL CLASSIFIER FOR THE "ORGANIC" CLASS DATA WAS EVALUATED

| Final Classifier | Accuracy | Precision | Recall | F1 Score |
|---|---|---|---|---|
| LightGBM | 0.912 | 0.917 | 0.926 | 0.921 |
| XGBoost | 0.931 | 0.935 | 0.942 | 0.939 |
| CatBoost | 0.925 | 0.931 | 0.934 | 0.932 |
| Random Forest | 0.893 | 0.890 | 0.922 | 0.906 |
| SVM | 0.706 | 0.672 | 0.924 | 0.778 |
| Naïve Bayes | 0.844 | 0.870 | 0.845 | 0.857 |
| KNN | 0.921 | 0.916 | 0.944 | 0.930 |
| Decision Tree | 0.859 | 0.866 | 0.884 | 0.875 |

The performance of the system achieved a score over 0.9 for all assessment parameters. Despite being lightweight convolutional neural network (CNN) architecture, SqueezeNet had remarkable proficiency in extracting features from image input. It implies that the features produced by SqueezeNet may possess greater informativeness and relevance compared to features provided by alternative models. Ensemble models, like LightGBM, XGBoost, and CatBoost, provide the ability to enhance overall performance by combining predictions from a limited set of basic models represented as decision trees.

TABLE II.    THE AVERAGE PERFORMANCE OF EACH FINAL CLASSIFIER FOR THE "RECYCLABLE " CLASS DATA WAS EVALUATED

| Model: R | Accuracy | Precision | Recall | F1 Score |
|---|---|---|---|---|
| LightGBM | 0.912 | 0.906 | 0.894 | 0.900 |
| XGBoost | 0.931 | 0.926 | 0.918 | 0.922 |
| CatBoost | 0.925 | 0.917 | 0.913 | 0.915 |
| Random Forest | 0.893 | 0.897 | 0.857 | 0.877 |
| SVM | 0.706 | 0.819 | 0.433 | 0.567 |
| Naïve Bayes | 0.844 | 0.812 | 0.842 | 0.827 |
| KNN | 0.921 | 0.927 | 0.891 | 0.909 |
| Decision Tree | 0.859 | 0.850 | 0.829 | 0.839 |

TABLE III.    THE AVERAGE PERFORMANCE OF EACH FINAL CLASSIFIER FOR ALL CLASS DATA WAS EVALUATED

| Model: All | Accuracy | Precision | Recall | F1 Score |
|---|---|---|---|---|
| LightGBM | 0.912 | 0.912 | 0.912 | 0.912 |
| XGBoost | 0.931 | 0.931 | 0.931 | 0.931 |
| CatBoost | 0.925 | 0.925 | 0.925 | 0.925 |
| Random Forest | 0.893 | 0.893 | 0.893 | 0.893 |
| SVM | 0.706 | 0.737 | 0.706 | 0.684 |
| Naïve Bayes | 0.844 | 0.844 | 0.844 | 0.844 |
| KNN | 0.921 | 0.921 | 0.921 | 0.920 |
| Decision Tree | 0.859 | 0.859 | 0.859 | 0.839 |

Mechanisms such as boosting were employed to adaptively assign greater weight to samples that pose challenges in recognition, hence enhancing the system's capacity to effectively process intricate data. By engaging in mistake correction and prioritizing the analysis of challenging samples, individuals could enhance their proficiency in data classification. The utilization of secondary information obtained by decision trees in the boosting process is a common practice in boosting models. One potential approach is to incorporate the weight or score assigned to each tree in order to arrive at a conclusive determination. This intervention has the potential to enhance the overall efficacy of the model. The optimization of the parameters in this study led to the development of a model that effectively aligns with the observed data. The integration of SqueezeNet as a feature extractor with a boosting algorithm facilitated the combination of the robust feature extraction skills inherent in convolutional neural networks (CNNs) with the powerful ensemble capabilities offered by the boosting method. In contrast, the K-nearest neighbors (KNN) method employed in this work was classified as an instance-based approach, wherein the selection of K values determines the appropriate number of neighboring instances.

The utilization of SqueezeNet as a feature extractor for further application by classification models like Random Forest, Naïve Bayes, or Decision Tree encounters many obstacles that might potentially impact the performance of those models. CNN designs, such as SqueezeNet, often generate feature representations that possess quite large dimensions. The utilization of high-dimensional characteristics in models such as Random Forest, Naïve Bayes, or Decision Tree gives rise to a circumstance known as the "curse of dimensionality." This phenomenon implies that when the number of features is enormous, the potential sample space needed to generate accurate estimates grows much more expansive. Consequently, the models encounter difficulties in identifying pertinent patterns from the data, as evidenced by the findings of this study. The interdependence among the features produced by SqueezeNet is substantial, potentially leading to the confusion of outcomes in models that assume feature independence, such as Naïve Bayes. The performance of these models will be enhanced in cases when the characteristics exhibit a high degree of independence. The efficacy of a classification model is heavily influenced by the inherent attributes of the data employed. If the data has an apparent pattern that is more compatible with straightforward models or does not need very intricate feature representation, then models such as Random Forest, Naïve Bayes, or Decision Tree may be more appropriate. The intricate characteristics examined in this study were attributed as the underlying factor for the ineffectiveness of these algorithms non the categorization process. However, this was also due to the fact that these algorithms had not yet been calibrated with specific parameters.

TABLE IX.    THE CONFUSION MATRIX WAS DERIVED FROM THE INTEGRATION OF SQUENZEENET AND NAÏVE BAYES MODELS

| | Total | 13560 | 11517 |

The study evaluated the performance of various machine learning methods. The Support Vector Machine (SVM) approach exhibited the lowest performance across all three tables. The attainment of precise classification frequently necessitates the inclusion of superior and discerning features. In the context of machine learning, it is imperative to ensure that the features extracted from a given model, such as SqueezeNet, effectively capture the salient and discriminative characteristics relevant to a specific task. Failure to achieve this may result in a detrimental impact on the performance of subsequent classification algorithms, such as Support Vector Machines (SVMs). The potential exists for SqueezeNet and Support Vector Machines (SVM) to demonstrate dissimilar scales in relation to the distribution of feature values. Introduction: In the context of machine learning, the issue of scaling mismatch has been identified as a potential challenge that can adversely affect the performance of Support Vector Machines (SVM). This research report aims to explore the difficulties that may arise due to scaling mismatch and the subsequent impact on the performance of SVM. Scaling Mismatch: Scaling mismatch refers to the situation where the scales of different features in a dataset are not aligned. In other words, the range or magnitude of values for different features varies significantly. This discrepancy in scaling can To mitigate the aforementioned concern, it is imperative to incorporate normalization or scaling methodologies. The performance of Support Vector Machines (SVMs) is significantly impacted by the selection of hyperparameters, which encompass the penalty parameter (C) and the kernel type. The observed suboptimal performance can potentially be attributed to the presence of inaccurate hyperparameter configurations. The impact of data type on the performance of Support Vector Machines (SVM) for model training was found to be statistically significant. The efficacy of Support Vector Machines (SVM) may be influenced by the congruity between the training data employed for generating the embedding and the data that necessitates categorization. The present study investigates the impact of SVM parameter values on its ability to handle complex data. The findings reveal that the utilization of certain parameter values in SVM leads to diminished efficacy in effectively handling intricate datasets.

TABLE X.    THE CONFUSION MATRIX WAS DERIVED FROM THE INTEGRATION OF SQUENZEENET AND KNN MODELS

In relation to the evaluation of algorithm performance in this work, the confusion matrix is employed as a metric to assess and comprehend the efficacy of the used Machine Learning algorithm in classification. This matrix facilitates an in-depth evaluation of the algorithm's performance, providing a deeper understanding of the model's strengths and limitations within the scope of this study. The confusion matrices for each method are displayed in Tables IV to Table XI. The table consists of a total of two rows and two columns. The initial row in the primary column displays instances of true positives (TP). The classification model accurately predicts occurrences that truly belong to the positive class. It refers to the count of instances where the model accurately predicted a good outcome and the actual result likewise turned out to be positive. The cell located at the intersection of the first row and the second column is referred to as false negative (FN). The model erroneously classifies occurrences that should belong to the positive class as negative. Put simply, it refers to the instances in which the model incorrectly predicted a negative outcome while the actual result was positive. The element located in the second row of the first column is classified as false positives (FP). The model erroneously classifies occurrences that should belong to the negative class as positive. It refers to the count of instances where the model made a positive prediction despite the actual outcome being negative. The cell located in the second row and second column represents the number of true negatives (TN). The categorization model accurately predicts occurrences that truly pertain to the negative class. It refers to the count of instances where the model made a negative prediction and the actual result was likewise negative.

The XGBoost and CatBoost classifiers demonstrated superior performance in accurately categorizing both organic and recyclable categories, with misclassified instances numbering less than 1000. The K-nearest neighbors (KNN) technique is considered to be one of the top three algorithms in machine learning. However, it has been shown that when used to certain datasets, especially those including recyclable classes, a significant number of misclassifications occur, with the misclassified instances exceeding 1000 in number. The data shown in Table VIII relates to the misclassification of the recyclable class in SVM specifically in cases where the achieved results exceeded 6000 data points. This numerical value exceeds the amount of accurately identified data.

## IV. CONCLUSION

This study proposes a comprehensive analysis of the significant consequences of uncontrolled garbage accumulation in initiating fires that have adverse effects on both the natural environment and human society. A unique solution has been developed to address this issue, employing Machine Learning techniques to autonomously segregate garbage through the

utilization of a highly efficient algorithm. The findings from the experimental analysis demonstrated that the utilization of SqueezeNet as an image recognition technique, coupled with XGBoost as the final classifier, emerges as the most optimal selection in the investigation, exhibiting exceptional performance.

This study also examined the effectiveness of SqueezeNet as a feature extractor in conjunction with a final classifier that differs from XGBoost. Various machine learning methods, including Random Forest, Support Vector Machine (SVM), Naïve Bayes, K-Nearest Neighbor (KNN), and Decision Tree, are commonly employed in the field of machine learning. The K-Nearest Neighbors (KNN) algorithm has exceptional performance, with a score exceeding 0.9 for all evaluation metrics. The lightweight convolutional neural network design of SqueezeNet enabled it to extract features that possess higher levels of informativeness and relevance in comparison to alternative models. Ensemble models such as LightGBM, XGBoost, and CatBoost improved overall performance by aggregating predictions from a restricted collection of fundamental models, which are typically shown as decision trees. Enhancing the system's ability to handle complex data may be achieved by the use of boosting techniques, such as error correction and prioritization of tough samples. The utilization of a confusion matrix was employed to assess the efficacy of a Machine Learning algorithm in the task of categorization. The classifiers XGBoost and CatBoost demonstrated exceptional performance in reliably classifying organic and recyclable categories, with a minimal number of misclassified examples, namely less than 1000. The K-nearest neighbors (KNN) approach, which is widely recognized as one of the leading algorithms, has been found to exhibit notable misclassifications in some datasets, notably in relation to recyclable classes.

The primary advantage of this research has great significance in addressing the issue of waste management. The use of automated trash segregation via Machine Learning techniques has the potential to mitigate the occurrence of fires, hence safeguarding ecosystems and infrastructure from detrimental impacts. Furthermore, the implementation of automated waste segregation has the potential to enhance operational effectiveness and safety within waste management systems, mitigate the likelihood of contamination, and contribute to the promotion of sustainable waste management practices. In addition, the utilization of this technology has the potential to mitigate the potential harm caused by human contact with dangerous compounds and foster ecological hygiene. Therefore, this research study significantly contributes to the preservation of the environment, mitigation of fire hazards, and enhancement of the community's quality of life. The utilization of Machine Learning technology, namely through the utilization of SqueezeNet and XGBoost, holds significant potential in the realm of automated waste segregation. This approach represents a crucial stride towards effectively tackling pressing waste-related issues and fostering sustainable advantages for both the society and environment.

# An IoT-based Smart Plug Energy Monitoring System

Lamya Albraheem*, Haifa Alajlan, Najoud aljenedal, Lenah Abo Alkhair, Sarab Bin Gwead

Department of Information Technology, College of Computer and Information Science,
King Saud University, KSU, Riyadh, Saudi Arabia

*Abstract*—Over the years, considerable efforts have been made to maintain electricity. However, there is still a significant need to explore new technologies and solutions conserve and enhance electricity supply. This project discusses research studies and applications conducted in the field of energy control, including a comparison of these applications undertaken in order to highlight constraints that need to be further addressed. This can be considered as the first step in developing a system that helps building owners to control their electricity consumption using Internet of Things (IoT) technologies. The main phases of the proposed system are data collection, data analysis and mobile application development. The project utilizes Wi-Fi smart plugs to collect active power consumption data, of which analysis is conducted on the cloud. The mobile application allows the building owner to manage buildings, and to obtain active and accumulated consumption data of plugged-in devices. This paper involves the architecture design of the proposed system, and the experimentation, testing, and implementation. The application was tested and the active and accumulative consumption per device and per building were reported. To confirm the accuracy of the active power consumption measurements from the smart plugs, a comparison is performed between these values and the active power consumptions measured by the company and shown on the labels. The results showed that using IoT-based smart plugs gives accurate readings.

*Keywords—Internet of things; IoT; smart plugs; electricity; energy consumption*

## I. INTRODUCTION

Electricity plays an important role in different aspects of our lives ranging from homes, industries, education, business, health, and transport [1]. The production of electricity may utilize a range of different resources, including non-renewable natural resources such as fossil fuels, in addition to renewable energy resources (RES) such as solar and wind. The burning of fossil fuels to produce electricity can cause various types of environmental damage, such as depletion of resources, increased pollution and waste generation [2][3]. Consequently, electricity consumption is becoming a major public concern and many countries and scientific communities are dedicating their effort to the search for solutions to control and manage the use of electricity [4].

In Saudi Arabia, efforts to conserve electricity have been intensified. According to the 2030 vision, the plan is to reduce energy consumption in different sectors by 20%, which will contribute significantly, saving about one million barrels of oil per day [5], [6]. Accordingly, the Saudi Energy Efficiency Center (SEEC) was established with the aim of conserving natural resources and enhancing energy efficiency. In addition, SEEC developed the Saudi Energy Efficiency Program (SEEP) which implemented a number of campaigns, including 35

initiatives to increase energy efficiency and improve society's awareness. SEEP also established the National Energy Services Company (Tarshid) to achieve two main objectives which are: the rehabilitation of government buildings to reduce consumption and support for the private sector with investment in the energy efficiency services sectors [7]-[9]. Therefore, to contribute to these initiatives, innovative ideas are needed which support and enhance recent technologies in order to monitor the electricity consumption of buildings.

The existing solutions can be classified according to meters' types into traditional meters and smart meters. For the traditional meter, manual consumption readings need to be conducted by humans for each building. Smart meters, on the other hand, can store the data themselves and send it automatically to the electricity company [10]. However these meters are only capable of recording the electricity consumption of the building as a whole; they are not capable of providing more detailed information, for example the consumption of each individual appliance. Richer information of this type could potentially support building rehabilitation projects by identifying those appliances consuming most power, providing a case for replacing them with more energy-saving ones. More detailed consumption information could also enhance the consumption awareness of building owners, supporting them in understanding electricity usage patterns.

To address the above-mentioned problems, a new technology is needed, capable of collecting and measuring building electricity consumption to inform understanding of usage behaviors. The IoT, in conjunction with smart plugs, can collect electricity consumption information in respect of plugged-in devices, supporting enhanced user awareness and helping to identify those devices that consume the most electricity [11]. This project will therefore develop a mobile application using the IoT and smart plugs to enable the building owners to access their electricity consumption data. The application will also allow building owners to understand the electricity consumption of appliances, which may assist in cost reductions.

The contributions from this study are the following:

- A review and comparison of different applications that have been developed for electricity monitoring systems highlighting any limitations and areas for improvement.

- Development of an IoT-based smart plug energy monitoring system utilizing smart plug devices and the cloud service for data analysis. The data collected and stored on the cloud can be further deployed within an artificial intelligence model, to detect consumption patterns and identify anomalies.

- An experimental, real-world case study to test the functionality of the proposed system and report the results.

The remainder of this paper is organized as follows: Section II presents the background information necessary for the understanding of the project; in Section III, related studies of similar applications are reviewed and compared with the presented application; Sections IV and V provide a description of the proposed solution, together with the hardware and software specifications; Section VI describes and discusses the experiment based on a real-world case study and reports the results; finally, Section VII provides the conclusion and recommendations for future work.

## II. BACKGROUND

### A. Electricity Consumption

A range of different concepts, measurements and equations is necessary to the understanding of electricity consumption, as well as an appreciation of the distinction between power (Watts/kW) and energy (Watthour/kwh). Firstly, electricity can be defined as the main source of energy that provides a flow of electrical power. It is measured in Watts (W), which is the unit of electrical power. The power is calculated by multiplying the current (Ampere A) and the voltage (V) as shown in Eq. (1) [12][13]:

$$Power\ P\ (Watts)\ =\ Current\ (A)\ *\ Voltage\ (V)\ \ (1)$$

Power is the electricity currently being used, which is also referred to as active power consumption [13]. Energy can be defined as the total amount of electricity consumed over a period of time (i.e. accumulative power consumption) and is computed according to Eq. (2) [13][14]:

$$Energy\ (Wh)\ =\ Power\ (W)\ *\ hours\ (h)\ \ \ (2)$$

$$Energy\ (kWh)\ =\ Energy\ (Wh)/\ 1000\ \ \ \ (3)$$

For example, if you use a device that gives active power equal to 500 Watt (0.5 kW) for five hours, then the energy or the total amount of electricity that has been consumed is 2,500 Wh or 2.5kWh. To sum up, in order to compute the electricity consumption of any device, the active power consumption (W) and the number of daily working hours of the device (h) must be known. Then the daily and monthly electricity consumption can be calculated as follows [14]:

$$Daily\ Electricity\ consumption\ of\ the\ device\ =$$
$$Power\ (watt)\ *\ Daily\ working\ hours\ \ \ \ \ \ (4)$$

$$Monthly\ Electricity\ consumption\ of\ the\ device\ =$$
$$Daily\ Electricity\ consumption\ *\ 30\ \ \ \ \ \ (5)$$

### B. Smart Plugs

The smart plug is defined as 'a separate electronic piece of hardware that serves as a proxy between the energy source and energy-consuming device'. So, it is an electronic device that allows the user to obtain real-time data of electricity consumption of the electric appliance or device, which is plugged in using a web panel or mobile application. The plugs also convert the appliances into smart devices to control them remotely [15], [16].

The hardware components of the smart plug, can be described as consisting of four sub-systems units which are: power meter; power switch; network node; and processing. The power meter is responsible for collecting the active energy consumption of the appliances connected to the smart plugs. Different information can be measured including active power consumption W, voltage V and current A. The power switch can be used to control the devices connected to the plugs by turning them to on or off, using the application. The network node allows a connection to be made with different external devices such as gateways using wireless technology, for example Wi-Fi, or Bluetooth low energy. The primary core components of the plug are the processing unit, which arranges the interaction between the power meter and the network unit [17].

Regarding commercial smart plugs products, a number of different companies provide plugs with a range of features. The consumer wishing to select the most appropriate product for their needs will need to understand their requirements. Table I presents brief information regarding the features of some examples of the commercial smart plugs that are available.

According to Table I, electricity consumption data may be transmitting utilizing different wireless technologies such as Wi-Fi, BLE, Zigbee. It is evident that the majority of the products use Wi-Fi, while Mokosmart products provide different wireless configurations. Regarding the transmission range, the coverage range will equate to that of the Wi-Fi router to which the plug is connected. If, as in the case of Mokosmart, BLE is used, the range will be 100 meters to connect with the mobile application or gateway. Regarding the maximum power of the connected devices, all plugs can be connected with devices that have a maximum power of 1800 W, while Mokosmart can be connected with 2400 W. For the power consumption of the plug itself, it can be seen that Eve and Mokosmart provide the lowest power with 0.001 and 0.075 respectively. Regarding pricing, D-Link and Mokosmart are the cheapest products.

Regarding the features, it can be seen that smart plug products provide one or both of two main functions: remote controlling and monitoring electricity consumption. The remote controlling allows the switching on and off of electronic devices using the mobile phone application or a hands-free voice control. The electricity consumption monitoring function allows power consumption of any plugged-in device to be monitored, using a mobile application or a web panel. Consumers need to exercise caution when selecting a product, as may items provide remote controlling only, for example D-Link. In addition, a critical feature to be considered by consumers who interested in developing the application is the provision of a software development kit (SDK) and the compatibility of the smart plug with IoT cloud services.

TABLE I.    SMART PLUG PRODUCTS

| Company | Transmission Technology | Transmission range | Maximum power (W) | Power consumption of the plug (W) | Price (SR) | Features |
|---|---|---|---|---|---|---|
| Mokosmart[28] | Bluetooth ,Wi-Fi, Zigbee | Above 100 meters for the BLE. Internet-connected in the Wi-fi | 2400 | 0.075 | 75 | • Monitoring energy consumption.<br>• Remote controlling.<br>• Support API for APP and cloud server development.<br>• Measures active and accumulative power consumption.<br>• Support SDK. |
| Eve [29] | Wi-Fi | Internet-connected. | 1800 | 0.001 | 263 | • Monitoring energy consumption.<br>• Remote controlling.<br>• Schedule devices. |
| TP-Link [30] | Wi-Fi | Internet-connected. | 1800 | 3.50 | 131 – 188. | • Monitoring energy consumption.<br>• Remote controlling.<br>• Amazon Echo Voice Control.<br>• Schedule devices. |
| WeMo(Belkin) [31] | Wi-Fi | Internet-connected | 1800 | 1.5 | 188 – 375 | • Monitoring energy consumption.<br>• Remote controlling.<br>• Hands-free voice control.<br>• Schedule devices |
| Insteon [32] | Insteon | Everywhere | 1800 | < 0.4 | 487 | • Monitoring energy consumption.<br>• Remote controlling.<br>• Schedule devices. |
| D-Link[33] | Wi-Fi | Internet-connected. | 1800 | < 3 | 59 | • Remote controlling.<br>• Hands-free voice control.<br>• Schedule devices. |

The SDK allows the user to interact with the plugs in the implementation phase. In case the user wishes to utilize IoT cloud services, the plugs should be compatible with cloud platforms using well-known IoT protocols such as MQTT (Message Queuing Telemetry Transport). In accordance with the conclusions from this discussion and in light of the available features, the smart plug to be used in this project is the Mokosmart. This provides different wireless configuration; can be connected with high power devices up to 2400 W; has the lowest power consumption; and is compatible with the IoT Cloud platform that supports MQTT. These plugs represent the sensors to be used in the project.

## III. RELATED WORKS

A number of research studies and applications conducted and developed in the field of energy monitoring systems are presented in this section. The significant work is reviewed, which contributed to the development of the energy monitoring systems including both multi-sensor and single-point sensor approaches. Moreover, the section considers the different applications developed for energy monitoring and presents a comparison between them, to reveal the limitations and any issues that require improvement.

### A. Research Studies

In this section, existing research studies in the field of appliance load monitoring are presented. These studies can be categorized into smart meter approaches or smart plugs approaches. This categorization is based on the location of the sensors used to collect electricity consumption data. For the smart meter approaches, the meter is placed at the entrance of the building and can measure the overall electricity consumption. The smart plugs, on the other hand, are located into each socket to measure the electricity consumption for each device [18]. These studies can be also categorized into multi-sensor or single-point sensor projects, according to the number of sensors used to collect the electricity consumption

data. In the multi-sensor approaches, the sensors should be installed at the power outlets or at each device, while, in case of single-point approaches, there is only one sensor to monitor the building [19]. All of these approaches aim to monitor the electricity consumption of appliances used in a building.

*1) Single-point sensor approaches:* The smart meter can collect the overall electricity consumption of any building; however, it does not provide any appliance-specific (that is, device-level) consumption information. Therefore, in order to recognize the appliances according to their electricity consumption, there is a single sensor attached to the smart meter to collect different characteristics of electrical load. Machine learning techniques are then applied to recognize different appliances. Each of these approaches involves its own issues; for example, in the case of the smart meter, a technical expert is required to undertake the setup of the smart meter in accordance with requirements; the results may be inaccurate; and previous knowledge of appliance power signatures is required in order to implement the machine learning techniques as these require a training phase [18], [19].

*2) Multi-sensor approaches:* Artur et al. proposed a study of an IoT-based solution to identify household appliances, monitor their consumption and detect anomalies in these devices. The identification of these appliances is possible where they possess a unique Electric Load Signature (ELS). The ELS can be defined as an electrical characteristics unique to each appliance which includes: voltage, current, active, reactive and powers. The proposed solution is a Home Energy Management (HEM) system capable of exposing and identifying appliances, and measuring their electricity consumption. The smart plugs are used to read the electrical parameters of each appliance, and the data is sent to HEM using the internet (Wi-Fi) or ZigBee. The ELS thus created is then stored in a database. The data is subsequently analyzed using a machine-learning algorithm to detect the appliance. The results demonstrate that 10,799 records were collected and that the system perform the required training and analysis to classify these records and identify the appliances. The records created included 3,600 records for the refrigerator, 3,599 records for the washing machine and 3,600 records for the TV [2].

In 2019, Ashwin and Krishnamoorthy proposed an IoT-based smart plug load energy management system for an office environment. The main objectives of the study were to improve energy management, and to controlling devices. The project used smart plugs to measure the total consumption of each appliances in the office. The appliances used to test the system included a printer and a coffee vending machine. The developed system is a web application to monitor the smart plugs, collect data and send notifications to the users where a pre-determined limit is exceeded. The system also implemented a scheduling method in which the devices could be turned off at a specific time. Moreover, the system could identify consumer behavior. An analysis performed to compare the total energy consumed before and after implementing the system demonstrated a reduction in electricity consumption [20].

Ahmed et al. propose a method that aims to monitor electric power using smart plugs. It targets analyzing and understanding of the energy consumed by appliances. A mobile application has been developed on a Windows phone to control appliances in a room by an on-and-off switch and the establishment of operating schedules. The application also provides features to design the layout of the user's house in addition to the behavior of connected devices. On the other hand, an interactive web application has been designed to show the energy consumed by different houses on the map, to help the Power Distribution Companies to analyze and study consumption behavior. The results of this study contributed to increased awareness of energy conservation in UAE and to reductions in consumption [1].

In 2020, Shohin Aheleroffa et al. proposed an IoT-enabled framework that aims to transform any appliance into a smart appliance and to allow the collection of data using sensors and actuators. As a case study, researchers integrated an IoT board within the central control board of a traditional refrigerator to transform it into a smart refrigerator. This board can collect data which includes: temperature and cooling level, and which also reads the states of different actuators such as the heater, the compressor, or the air fan. The data collected is periodically sent to the IoT platform using Wi-Fi technology to store data in a database called Ubidots. This study in [21] also lists suggestions for different IoT platforms which could be utlilized in similar systems such as: AWS IoT, IBMWatson IoT, and Azure IoT. The IoT platform can support the analysis and visualization of the received and can display the results on the dashboard. The user can also control their refrigerator using a mobile phone connected to the device by Bluetooth technology. It should be noted that this proposed framework can be applied in respect of all home appliances[21].

According to the studies outlined above, it is clear that different approaches exist which may be categorized into single-point-based approaches or multi-sensor-based approaches. The single-point sensors can provide data about overall consumption and anticipated consumption per device based on machine-learning algorithms. However, they do require technical expertise to achieve the correct setup in attaching the sensor to the smart meter as well as a priori knowledge of appliance power signatures. On the other hand, multi-sensor-based approaches can provide device-level electricity consumption information, but requires a separate smart plug for each individual device.

*B. Applications*

In this section, a number of applications in the field of electricity monitoring are presented, and their features outlined. A comparison is also provided between these applications and the proposed application, so that the best features of similar applications may be incorporated and to identify limitations and areas for improvement.

*1) SmartLife application:* SmartLife is a smart device management application which is used to control smart devices such as smart plugs, smart cameras, or smart vacuum

cleaners. It is compatible with multiple smart plugs such TECKIN Smart Plug, Tan Tan Smart Plug and YTE Smart Plug and with multiple smart devices [22]. SmartLife Application measures electrical consumption of the smart devices only where they include an energy monitoring feature. Bluetooth low energy technology connects the application to the smart plugs. The application provides building owners with features such as the ability to add and control multiple devices, and to receive notifications when scheduled events occur. Additionally, it provides a monthly report including statistics of electrical consumption, a timer or scheduling tool for automatic control of devices, and cloud storage using an Amazon server. Furthermore, it provides a family control facility to allow differential control permissions to different family members — for example limiting the ability to control settings to a single family member while allowing all to control the devices. [23]

*2) Insteon hub application:* The Insteon system consists of a web and smartphone application which converts the home into a smart home. This facilitates the control of home appliances. Insteon requires a hub to exert control over compatible devices. The hub is plugged into the wall and connected to router via Ethernet [24]. There is no limit to the number of devices that may be added on Insteon hub which Insteon connects to the router using the home's existing power wires. This helps Insteon signals to transfer commands in the house unaffected by walls or other Wi-Fi blocking materials. To prevent signal overload [25], the radio frequency used by Insteon for communication is distinct from the one used by Wi-Fi. The Insteon app enables the building owners to manage smart plugs by adding devices, and by adding rooms that can group devices according to their position, and defining zones that can group rooms within the same building. In addition, it permits the user to establish schedules for controlling devices, receives notification relating to its sensor, and can flag up warnings relating to water leaks, motion, and door/window breaches if the necessary sensors are in place. [26].

*3) Zuli application:* The mission of Zuli application is to track and manage the building's appliances. This is a smartphone application compatible with a Zuli smart plug. Communication with the smart plug through Bluetooth is necessary for use of the features of the application [27]. The Zuli application contains numerous features, for instance supporting interaction between devices able based on the owner's location, through the utilization of iBeacon technology using Bluetooth low energy. The application can monitor energy usage and obtain the number of Watts, Volts, and Amps that proceed through the plug. It can additionally obtain the anticipated monthly costs, can assign a schedule for every day on the week and assign a timer to automatically turn on and off the devices [28].

*4) Sense application:* Sense is a web and smartphone application for monitoring electricity consumption. It requires hardware called the Sense monitor to be installed in the electrical panel of the building. Two sensors, clamp around

the main power leads to ascertain the amount of electricity being used [29]. Sense uses a machine learning algorithm to automatically classify the active devices based on historical data of similar devices collected from other users. The device name may then be confirmed or modified by the consumer [30].To run the Sense application, the application should be connected to the Sense monitor via Wi-Fi technology [29]. The Sense monitor collects energy usage data and sends it through Wi-Fi to the cloud. Consumers may thento track thir electricity consumption using either their smartphone or computer. Sense helps consumers to reduce electricity utilization by encouraging them to set targets and track progress. It also allows them to monitor their electrical consumption in real time. Additionally, it provides daily, weekly, and monthly reports which include energy consumption measurements, average usage, and statistics related to specific devices [31]. In addition, the Sense application can detect the value of the monthly bill. Furthermore, Compatible with Wemo and Kasa smart plugs, it is therefore capable of utilizing the multi-sensor approaches represented by the smart plugs to identify devices faster, to compute consumption per device more accurately and to allow consumers to control their devices directly [32].

*5) EnergyCloud application:* EnergyCloud is a mobile application that uses machine learning technology to analyze usage patterns. It aims to reduce electricity consumption and costs through the ready availability of energy data [33]. The requirements of this application include: the EnergyCloud Sensor which is installed within the electricity meter to transmit meter readings to a gateway called CloudConnector. This gateway sends all the electrical consumption data to the cloud [34]. The EnergyCloud Sensor is compatible with analog disk meters and digital meter [35]. The mobile application provides many services which include real-time consumption measurement and make a monthly consumption comparisons. The application also provides tools to encourage reductions in consumption, such as notifications where usage has been successful decreased, or where a predefined consumption limit has been exceeded [36]

Table II shows the availability of a range of different types of applications, for example: single-point sensor applications such as EnergyCloud and multi-sensor based applications such as SmartLife, Insteon, and Zuli. One application, Sense, is capable of operating using both approaches. The EnergyCloud application requires installation of a sensor within the electrical meter to collect the overall energy consumption data. It uses a machine-learning algorithm to identify devices and provides anticipated readings of device-level consumption. However, as discussed in the literature review section, above, there are problems attendant upon the single-point approach, such as the production of inaccurate results, more complex sensor installation requirements necessitating the services of an electrician,, and the need for previous knowledge of the consumption profiles of the devices [18], [19]. In the case of multi-sensor based applications, it can be seen that smart plugs play an essential role, and are utilized for different objectives:

they allow remote controlling of the devices without energy monitoring or may provide energy monitoring in addition to the remote controlling features. Insteon is an example of an application solely providing remote control functionality for devices, though it is important in terms of the objective of this paper to maintain the focus on applications which deliver energy monitoring functionality, such as Zuli. It may also be seen in Table II that none of the applications currently available supports the Arabic language—a gap in the energy monitoring market that urgently needs to be filled. In addition, the majority of available applications do not support the 'manage building' feature which provides the capability for managing multiple buildings. Smartlife is the only application to benefit from this feature. In terms of a notifications facility to support users in reducing energy consumption, this is available in only one application, EnergyCloud. Applications providing effective monitoring consumption typically support smart plug management, appliance management, provision of historical as well as active power data, and cloud storage utilization. Consequently, the user is recommended to review products carefully before selecting, to ensure they incorporate these essential capabilities.

We will develop an IoT- based smart plugs system which is informed by the domain analysis presented in this section and which assists owners to monitor the electricity consumption of their buildings. The system will allow building owners to register their details within the application, to use the application features, will support Arabic language and provide multiple features including smart plug management, appliance management, active and historical consumption data per appliance, monthly reports covering consumption and anticipated costs. Additionally, a 'manage building' capability will be included as well as alerts to support reductions in consumption.. Further development may be undertaken in future to develop features relating to the on/off control of the smart plugs and the use of voice control.

## IV.    PROPOSED SOLUTION

### A. System Architecture

This study proposes a solution consisting of an IoT smart electricity monitoring system which assists building owners to monitor electricity consumption. The main components of the solution are: smart plugs, server, and mobile application. The application will operate as presented in Fig. 1. Smart plugs will be installed and configured in the buildings which, once connected to the building will, using Bluetooth Low Energy (BLE), transmit information to a gateway, including: smart plug ID; active power consumption (watt); real-time current (A); and voltage (V). The gateways will collect the information and send them to the server. Once active power consumption data collection becomes operational, a processing and analysis task must then be undertaken to calculate the accumulative electricity consumption of the appliances connected to the plugs. The mobile application enables building owners to manage smart plugs and appliances, to monitor the active and accumulative consumption of the appliances, and to identity those appliances consuming the most electricity. The proposed solution will thus contribute to enhancing user awareness, encouraging the replacement of older devices, and better energy conservation, thus reducing electricity bills and achieving the sustainability objectives.

The architectural design of the proposed system has four layers as shown in Fig. 2: the perception layer, the network layer, the data storage layer, and the application layer. The perception layer is the first layer of the IoT architecture, in this which the smart plugs are used to detect and collect information including smart plug ID, active power consumption (watt), real-time current (A), and voltage (V). The second, or network layer connects the smartplugs and the network equipment (that is, the gateway), to transfer

information to the servers. The data storage layer is represented by the IoT platform that can receive information from the sensors and store it in a cloud-based database. The application layer allows user interaction with the system, using the mobile application, and is responsible for the provision of application-specific services to the user.

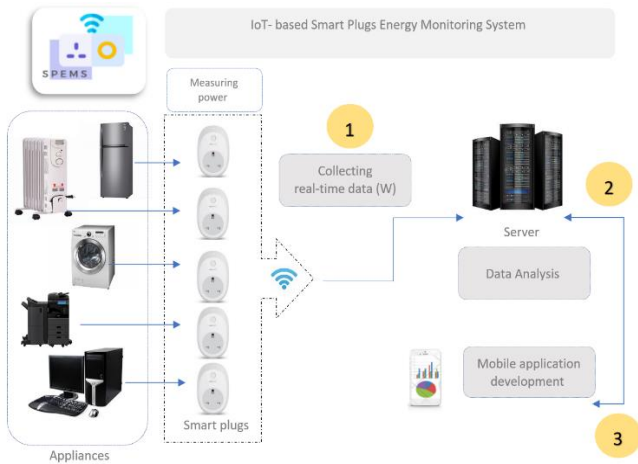

Fig. 1.   The proposed solution.

Fig. 2.   The IoT architecture of the proposed solution.

## V.   SYSTEM IMPLEMENTATION

The main goal of the proposed system is the collection of active power consumption data for any device and the computation of the energy consumption. The Wi-Fi smart plug is utilized as a hardware component. In accordance with the findings of the comparative enquiry, presented in Table I, the smart plugs selected for this project are Mokosmart. These plugs provide a range of potential wireless configurations, which are Wi-Fi, BLE and Zigbee. BLE smart plugs must be connected first with gateway and then with the Wi-Fi modem, while the Wi-Fi plugs are connected directly to the modem. This project used the Wi-Fi plugs, as the most cost-effective choice, we used the Wi-Fi plugs.The Mokosmart Wi-Fi plugs can be connected with high power devices up to 2400 W, have low power consumption, and are compatible with the IoT Cloud platform that support the Message Queuing Telemetry Transport (MQTT) protocol. These plugs represent the sensors that will be used in the proposed project. Samsung phones were

for this project, since the application is designed to be compatible with Android platform.

In terms of the software, a range of different tools are used to develop the proposed system which includes three main processes: data collection, data analysis and mobile application development. For data collection, the Amazon Elastic Compute Cloud (Amazon EC2) is used, which is a cloud service provided by Amazon which provides cloud computation [37]. It is compatible with the MQTT protocol, so it is used as server to receive records from smart plugs. The MQTT protocol, a publish/subscribe protocol for messaging transport with minimal network bandwidth, is a standard messaging protocol that serves IoT devices. The smart plugs used in the project support the MQTT protocol, once they are connected to the internet. They will publish power data to MQTT Broker and the MQTT Client will subscribe to the topic to get the power data [38].

Subsequently, a python script was developed from scratch, as shown in Fig. 3, to read data from smart plugs using the MQTT protocol and to store it in the database. The python code is written using Jupyter Notebook [39] which provides an online python environment. A python code was also written to analyze received data and to compute daily, monthly consumption of each device, and also the daily, monthly consumption of each building, in addition to the anticipated cost of electricity consumption per month.  For the database, the Firebase was utilized, a platform provided by Google with many services for developed mobile and web applications [40]. It is used to store user information and data received from the smart plug.  The mobile application was developed using Android Studio 2020.3.1 [41].

```python
def start_plug():
    try:          # try to connect to AWS EC2 with provided ip and port
        client = mqtt.Client("digit_mqtt_test")
        client.on_connect = on_connect
        client.on_message = on_message
        client.connect('3.142.240.110', 1883)
        client.loop_forever()     # loop forever while true
    except Exception as e:
        print(e)
```

Fig. 3.   Code segment of connect to MQTT protocol.

The steps followed to connect the system components are set out below:

*1) Configuring* the smart plugs to connect them to the EC2 cloud service;

*2) Implementing* the python code to read data from the smart plugs using the MQTT protocol as presented in Fig. 3;

*3) Connecting* EC2 to the database to store the data;

*4) Connecting* the mobile application to the database.

## VI.   THE EXPERIMENT

The IoT-based smart electricity monitoring system is developed as a mobile application that use the Internet of Things (IoT) and Smart Plugs to enable building owners to access their electricity consumption data and to understand the electricity consumption of individual devices connected to the plugs which can contribute to reducing electricity bills. This experiment was conducted in residential buildings. The experiment consists of three phases:

- Installation phase: The actual installation of the smart plugs in the building and connecting them to devices.

- The execution phase: The demonstration of the use of the proposed application to monitor real-time data and compute daily and monthly electricity consumption.

- Testing phase: To conduct performance and stress testing.

### A. Installation and Deployment Phase

In terms of the hardware used, a number of home appliances were tested in this experiment including refrigerator, hair dryer, television and washing machine). These devices are attached to Wi-Fi smart plugs according to the specification presented in Table III.

TABLE III. SPECIFICATIONS OF HOME APPLIANCES

| Device | Consumption range measured by company (W) that exist on the label | Model no | Company |
|---|---|---|---|
| Refrigerator | 400 - 550 | ASKN – SBS - 521-RFG | ASKEMO |
| Hair dryer | 1000 - 1200 | EW - 920 | Easy Way |
| Television | 120 - 155 | 65UJ670V - TD | LG |
| Washing machine | 2000 - 3000 | WF21T6500GV | Samsung |

### B. Execution Phase

In the execution phase, various home appliances are monitored. The system will start to receive the sensor readings from home appliances and to perform different functions including the following:

*1) Active power consumption per device:* The proposed system lists all the connected home appliances with their active power consumption measured using Watt (W). As shown in Table IV and Fig. 4, different readings are taken for each device. This gives building owners an indication which are the devices that have high consumption. It can be seen that the hair dryer and washing machine have higher active consumption that the refrigerator and the television.

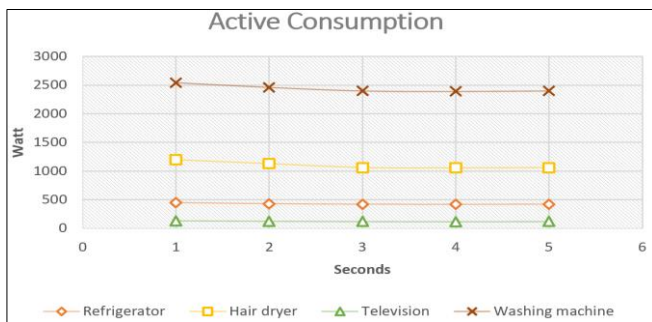

Fig. 4. Active power consumption for different appliances.

It is important to make sure that all electrical appliances are efficient in consuming energy. Consumers can know the efficiency of any appliance by referring to the attached energy efficiency label. Accordingly, the proposed system should transmit an efficiency alert to building owner if a device exceeds the standard consumption or has a normal consumption. The standard consumptions are typically defined by the electricity company to increase consumer awareness. To confirm the accuracy of the active power consumption measurements from the smart plugs, a comparison is performed between these values and the active power consumptions measured by the company and shown on the labels. The results are shown in Table V and Fig. 5.

TABLE IV. ACTIVE POWER CONSUMPTION PER DEVICE (W)

| Device | Reading 1 | Reading 2 | Reading 3 | Reading 4 | Reading 5 |
|---|---|---|---|---|---|
| Refrigerator | 450 | 430 | 420 | 417 | 420 |
| Hair dryer | 1200 | 1130 | 1060 | 1055 | 1060 |
| Television | 130 | 125 | 120 | 118 | 120 |
| Washing machine | 2540 | 2460 | 2400 | 2391 | 2400 |

Fig. 5. The device consumption efficiency.

TABLE V. COMPARISON BETWEEN THE MEASURED AND ACTUAL ACTIVE CONSUMPTION

| Device | Consumption measured by smart plug (W) (average of the actual active consumption ) | Consumption range measured by company (W) (that exist on the label) |
|---|---|---|
| Refrigerator | 420 | 400–550 |
| Hair dryer | 1060 | 1000-1200 |
| Television | 120 | 120–155 |
| Washing machine | 2400 | 2000-3000 |

*2) Accumulative power consumption per device:* As mentioned previously, in order to compute much the electricity consumption of any device, there is a need to know the active power consumption (W) and the number of daily working hours of the device (h). Then the daily and monthly electricity consumption can be calculated, as shown in Table VI and Fig. 6. The active power of the refrigerator is 420 Watt for 24 hours, so the energy or the total amount of electricity consumed is 10800Wh or 10.8kWh. The monthly consumption can calculated according to the number of days the device is used. Additionally, the building owner shall be able to display a monthly report of device consumption of a

building and the expected monthly cost of the electricity consumption, based on the electricity company tariff.

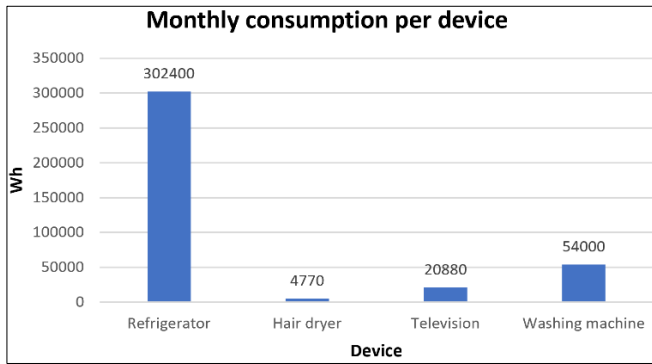

Fig. 6.    The monthly consumption per device.

TABLE VI.    DAILY ELECTRICITY CONSUMPTION PER DEVICE

| Device | active power consumption (W) | # of hours the device is used (h/day) | Daily consumption (Wh) | monthly consumption (Wh) |
|---|---|---|---|---|
| Refrigerator | 420 | 24 | 10080 | 302400 |
| Hair dryer | 1060 | 0.15 | 159 | 4770 |
| Television | 120 | 5.8 | 696 | 20880 |
| Washing machine | 2400 | 0.75 | 1800 | 54000 |

*C. Testing Phase*

*1) Performance testing:* Performance testing is a type of software testing that is used to analyze a system's capabilities and performance under a certain workload. To test our application's performance, we used activity monitor software which tracks operation. As shown in Fig. 7, the test results over a 30-minute period demonstrate that the CPU usage of the program was 1% of the total available CPU as a minimum value, though the CPU usage may potentially reach 32 % as a maximum value in specific situations.

Fig. 7.    Minmum and maximum CPU performance.

With regard to memory usage, during a 30-minute testing period, it was observed that the proposed application allocates around 395MB of the total available memory.

*2) Stress testing:* Stress tests are used to test a system's capacity beyond its top limit, which can cause performance degradation. To perform the stress testing we used monkey which is a command-line utility that provides the system with a pseudo-random stream of user events. The command, (adb shell monkey-pcom.example.log_in 10000 > testfinal.txt ) was utilized to run stress testing in the proposed system. The number of user events was 1000. The system is capable of handling 7340 random user actions, such as clicks, touches, and addition of a device, as shown in Fig. 8. The test completed 7340 occurences, demonstrating that the system has no unhandled exceptions and will work successfully under the stress of unexpected activities.

Fig. 8.    Stress testing.

## VII.    CONCLUSION

IoT has a huge benefit to consumers in terms of energy efficiency. The proposed system which is an IoT-based Smart Plugs electricity monitoring system allows consumers to measure, analyze and check energy active and accumulative consumption per devices and per building. This can help consumers to make rapid adaptations and corrective actions to control their energy consumption and costs. The system also can be useful for individuals to increase awareness, to know their electricity consumption and to replace high energy consuming devices. Furthermore, the system can support rehabilitation projects, identifying devices that need to be replaced.

For future work, the collected data can be used in an AI model to detect anomalies and use machine learning techniques to predict patterns of future consumption to recognize the devices connecting automatically to smart plugs. The system also can provide suggested corrective actions that will lead to improvements in energy efficiency.

# Implementation of a Web System with Chatbot Service for Sales Management - A Review

Jorge Barrantes-Saucedo[1], Cristian García-Leandro[2], Orlando Iparraguirre-Villanueva[3] ,
Rosalynn Ornella Flores-Castañeda[4]

Facultad de Arquitectura e Ingeniería, Universidad César Vallejo, Lima, Perú[1, 2, 4]
Facultad de Ingeniería-Universidad Tecnológica del Perú, Chimbote, Perú[3]

*Abstract*—The objective of the research was to analyze various researches about web systems with chatbot service in the sales management process between the years 2018-2022, employing four databases, such as: Science Direct, Taylor & Francis, IEEE Xplore and Springer. The PRISMA methodology was applied, selecting 60 manuscripts where the year of highest publication was 2021 (35%), leading the USA as the country with the highest scientific production equivalent to 23.33%; in addition, the type of research that predominated were scientific articles with the percentage value of 70% and being entirely in the English language. Finally, it was found that there are two relevant components regarding the implementation of a web system with chatbot service for Sales Management, the first are the evaluated aspects, explained as those that focus on the analysis of the intelligent system, chatbot, website, Google API, e-commerce, machine learning, IBM service, mobile application, web, relationship with customer service, sales management, digital transformation, information system, algorithm and innovation and as the second component, according to the conditional factors refers to the context in which the use of chatbot in sales management occurs, being such technical features as algorithm, type of system, chatbot-customer relationship, sales and innovation and sales-system relationship.

*Keywords*—*Web system; chatbot; chatbot service; sales management; sales automation*

## I. INTRODUCTION

In recent years, a great evolution has been identified at the enterprise level due to the cultural variations of most organizational entities, one of them being the use of technological tools focused on sales; however, there is insecurity on the part of management and collaborators on how to optimize processes using such tools [1]. Likewise, innovation in any organization is seen as a capacity and willingness to change on the part of the company, besides being influential in the success or failure of any entity; therefore, it is necessary to identify the factors that induce organizational innovation [2].

The sales process is constituted by two terms: sales and management, the former being considered as the art of planning while the latter is understood as a process in which sales are planned, directed, and controlled in each entity [3]. Consequently, success or failure depends on the sales force, so that decision making primarily affects the quality and ability to strengthen sales; however, most companies spend money on personal sales instead of investing in advertising and promotions, which is why it is necessary to raise awareness and prioritize economic investment in factors that allow every business entity to grow [4].

Therefore, continuous changes have transformed the way of doing things on a daily basis, with the arrival of the internet era has split the access to the information era by raising new requirements in the traditional sales model, considering the needs in the market whose objective is to provide services supported by IT tools for the automation of processes, as well as the organization and control of information [5]. Therefore, at the technological level, software construction ranges from static interfaces to dynamic functionalities, alluding to the website architecture, design, or client/server commands [6].

The technology uses chatbot services for the exchange of information between the user and the software that through the network allows achieving a purchase; therefore, they are considered as conversational software agents that carry out an easy process of dialect and automatic learning; however, it was identified that despite having a technological evolution, there is still an abandonment in online shopping given that it is deficient and confusing for users without having an advisor who can support them and give suggestions in their purchase process [7].

However, the process of buying and selling online is called e-commerce and this has increased and transformed the business aspect, establishing an optimal relationship between the customer and seller [8]. In Japan, salespeople work as a unit to meet the requirements; specifically, years of experience stand out, since the more years of experience, the greater the relationship between sales knowledge and performance, allowing inferring that the competitiveness of salespeople is reflected in the ability to learn through their experiences [9]. In this regard, the sales process involves handling a large volume of customer data, employers, products, and others; the good use of this information allows to achieve effective marketing in sales that through the passage of days achieve a positioning of the business entity and, therefore, optimal results [10].

Companies are facing an increasing challenge in sales management due to the need to maintain effective and constant interaction with customers in digital environments because online sales continue to expand. The problem focuses on the technical, strategic, and implementation challenges that companies may encounter when adopting this technology and balancing automation with human interaction in the online sales process. The questions posed in this research are three:

RQ1: What digital technologies allow the application of the web system in sales management? RQ2: What are the technological tools necessary for the application of the web system in sales management? And RQ3: What are the benefits of implementing a chatbot service in sales management?

This research is important to take advantage of the benefits of technology, improve efficiency, strengthen customer relationships, and remain competitive in an ever-changing business environment. The rationale for this research lies in the increasing relevance of this technology in today's business environment. Companies are looking to improve efficiency, deliver exceptional customer experiences, and stay competitive in an ever-changing marketplace. The adoption of chatbots is a growing technology trend that can contribute to these goals by optimizing resources, improving customer interaction and providing valuable data for decision making. Researching this implementation is essential to understand its benefits and challenges, contribute to knowledge in the field and promote innovation in sales management.

The objective of the research was to analyze the research related to web systems with chatbot service in the sales management process. This work is organized as follows: Section II specifies the methodology used for this type of research. Section III specifies the results obtained through tables and figures. Section IV delves into the discussion of the findings found and Section V concludes the research.

## II. METHODOLOGY

Systematic review can be conceptualized as the collection of evidence at a practical level to demonstrate the eligibility criteria previously specified to answer specific questions using systematic methods that are selected to minimize bias, generating reliable findings that allow the extraction of conclusions and optimal decision making; it is worth mentioning that the primary attributes are: criteria of choice, methodology, systematic search, and validity [11].

In this research, the collection of scientific literary material on a web system with chatbot service for sales management has been carried out in the period of 2018-2022. The collection process involved searching and selecting information based on the parameters established by the Prisma methodology [12]. For this, identification, eligibility, and inclusion criteria were considered. For the acceptance of scientific papers in this systematic review, the following aspects were considered:

- Date of publication belonging to the last decade (2018 - 2022) since it is considered as the appropriate period of antiquity to obtain adequate and accurate information about the conceptual constructs of the problem.

- Coming from scientific databases with a high level of reliability and originality, since it guarantees the scientific validity of what is described in this systematic review.

- Existence of words or phrases related to the chatbot and sales management, since this guarantees the relationship between the scientific documents found and the object of study.

- Writing in English, to obtain more information of an international nature related to the study variables.

For the discarding of scientific documents, the following aspects were considered:

- That the date of publication is prior to 2018, given that the information is considered outdated for the research purposes of a systematic review.

- That the research object of the documents found is not completely related to that of the present systematic review because, if so, it will not be helpful for the resolution of the current research question.

- It is too far from the one proposed for this inquiry, because, if so, the information described in those documents will not be of help for the relation of this systematic review.

In this sense, the following databases were considered in the search process:

- Taylor & Francis

- Science Direct

- IEEE Xplore

- Springer

As a first step, the search was performed using keywords such as "chatbot" and "sales management". After said search, the filter was applied according to the year of publication, considering for the research only those that were published between the years 2018 and 2022.

This resulted in the inclusion of 42 articles and 18 conferences under the papers structure, of which, after being filtered under criteria such as the linkage with the objective of study of this systematic review, the existence of keywords in the title that are related to the web system with chatbot service, as well as, sales management and the existence of a correct access link to the complete document in its digital format.

The documents included in the systematic review had the following distribution:

- Science Direct: From a total of 2,518 scientific articles, 10 were selected.

- Taylor & Francis: From a total of 758 scientific articles found, 12 were finally selected.

- IEEE Xplore: From a total of 1,627 scientific articles found, 15 were taken.

- Springer: Out of 7,129 articles found, 23 were selected.

After that, a list of the selected documents was made considering their source. Duplicates were checked and no document was found to be in more than one database. Finally, the documents were ordered according to aspects such as the country where the research was carried out, the year and type of publication, among others.

Fig. 1 shows the number of manuscripts identified in the search for information by database, following the parameters of the PRISMA methodology.

Fig. 1. PRISMA methodology.

## III. RESULTS

The results have been structured according to a database made up of 23,810 explorations, which after a severe analysis according to the established filters gave way to a database with methodological data made up of 60 studies. As shown in Fig. 3, the Preferred Reporting Items for Systematic reviews, and Meta-Analyses method, known by its acronym PRISMA, was applied to explain how and what results were generated with the literature review. Starting by identifying four bibliographic sources: Science Direct, Taylor and Francis, IEEE Xplore and Springer, as the first phase, identification, the first selection was carried out based on the search by key words and phrases, obtaining 23,810 inquiries, where 23.27% corresponded to Science Direct, 14.87% to Taylor & Francis, 10.66% to IEEE Xplore and 51.20% to Springer.

In the second phase, placing on screen, with the second selection criterion considering the year of publication, in this case from 2018 to 2022, there were 12,032 studies where 20.93% came from Science Direct, 6.30% from Taylor & Francis, 13.52% from IEEE Xplore and 57.25% from Springer. In the third phase, eligibility, the third selection was carried out considering the title with words or phrases related to the subject of the present systematic review, resulting in 7,900 documents excluded and 4,132 selected of the latter 29.48%

registered in Science Direct, 1.40% from Taylor & Francis, 17.59% from IEEE Xplore and 51.52% from Springer.

Finally, in the fourth phase, included, the criteria for reading the abstract (identification by components such as methodology and results found was applied to clarify the relevance of the study), relationship with the objective of the study (considering that it has the same unit of analysis and variables or constructs addressed) and correct access link (including how to identify an access link to the document) were incorporated, with 4042 documents excluded, and 60 documents selected. Of the latter 10 (17%) were from Science Direct, 12 (20%) from Taylor & Francis, 15 (25%) from IEEE Xplore and 23 (38%) from Springer.

Fig. 2 identifies the percentage of contribution to the information from each of the databases. The two databases with the highest contribution are Springer and IEEE Xplore, with a contribution of 38% and 25%, respectively. They are followed by Taylor & Francis with 20% and Science Direct with 17%.

Fig. 2. Percentage data of the data bases.

The number of articles found was 23810, and after applying the exclusion criteria, 60 articles were found as shown in Fig. 3.

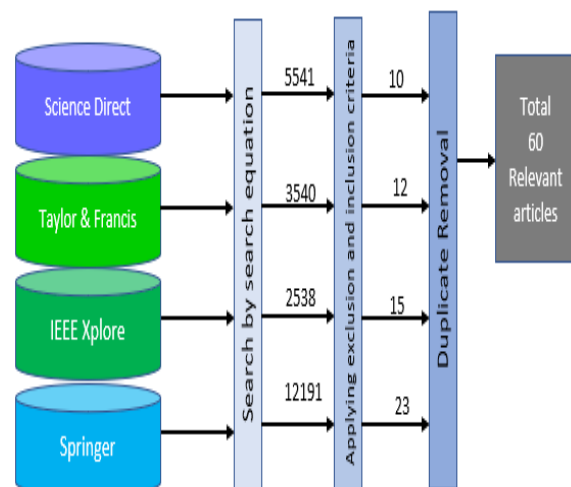

Fig. 3. Number of studies identified by each database.

Fig. 4 shows the selection process of studies identified in the databases considering four stages: identification, put on screen, eligibility and including. In the first stage 11778 were excluded because they did not meet the criteria of search by key words and phrases, in the second stage 7900 were excluded because they were not in the range of years of publications from 2018 to 2022, in the third stage 4072 manuscripts were excluded because they were not related to the research. Finally, 60 publications were selected.

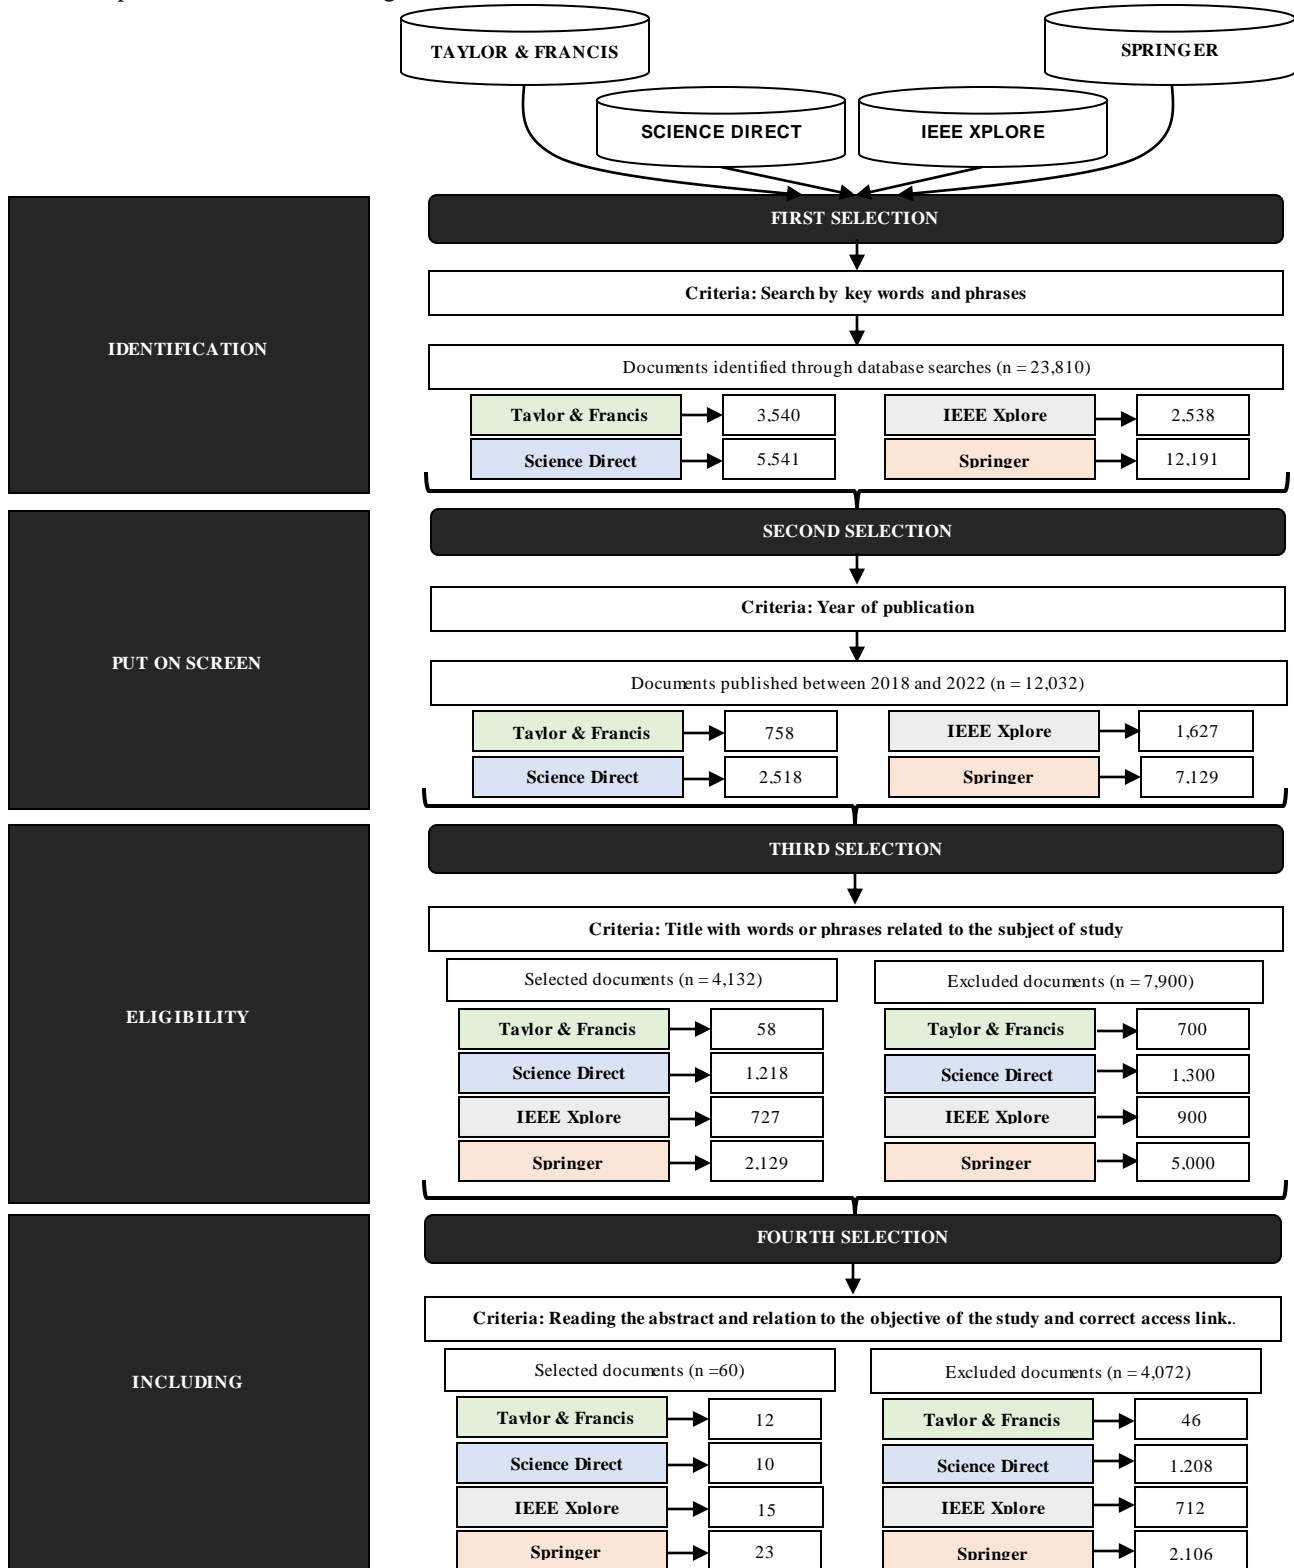

Fig. 4. Selection process of studies identified in the databases.

According to the analysis of the 42 articles and 18 conferences, 20% were published in 2018, followed by 15% in 2019, 13.33% in 2020, 35% in 2021 and 16.67% in 2022. Regarding the lines described above, 2021 was the year that had the greatest approach to the subject matter given that previous years there has been little scientific production; in the following year the percentage value decreases, as shown in Fig. 5.

Fig. 5.   Documents included in the research by year of publication.

Also, accordingly, it was identified that in 2018 1.67% belong to Science Direct, 6.67% Taylor & Francis, 3.33% IEEE Xplore and 8.33% to Springer; in 2019 6.67% to Science Direct, 1.67% to Taylor & Francis, 3.33% to IEEE Xplore and Springer; in 2020 3. 33% to IEEE Xplore, 5% Taylor & Francis and Springer; in 2021 6.67% to Science Direct, 5% to Taylor & Francis, 11.67% to IEEE Xplore and Springer; finally, in 2022 1.67% represented Science Direct and Taylor & Francis, 3.33% to IEEE Xplore and 10% to Springer, such are seen in Fig. 6.

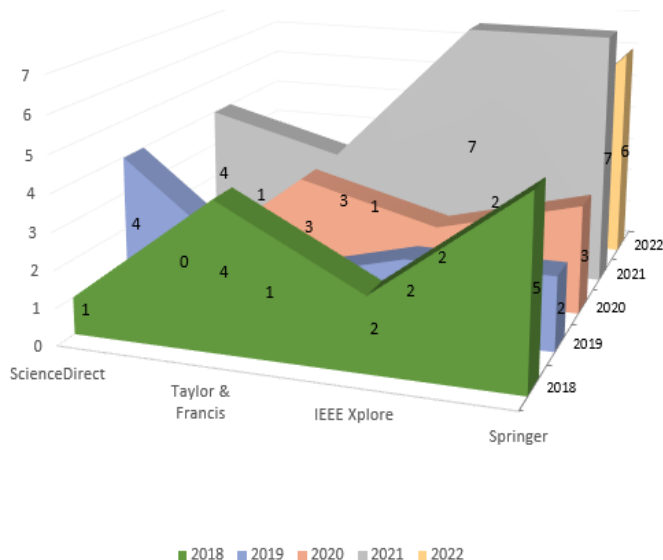

Fig. 6.   Documents included in the research according to year of publication and database.

Fig. 7 shows the research considered according to country, in which the USA leads in representation with 23.33%

equivalent to 14, followed far behind by India and Norway with 11.67% and 8.33%, respectively.

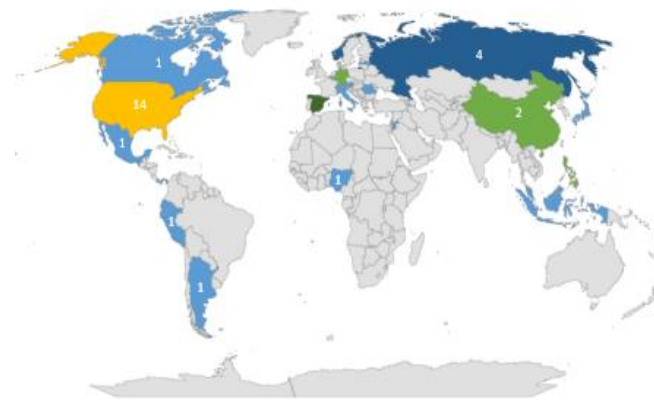

Fig. 7.   Documents included in the research according to country of origin grouped by continent.

Fig. 8 classifies the bibliography according to the type of research, with 42 articles (70%) and 18 (30%) conferences.

Fig. 8.   Documents included in the research according to bibliographic classification.

Fig. 9.   Documents included in the research according to research approach.

On the other hand, the studies have been classified according to the research approach according to the database, being from the qualitative approach 21.67% for IEEE Xplore, 11.67% for Science Direct, 10% for Taylor & Francis and 30% for Springer; likewise for the quantitative approach, 3.33% were identified for IEEE Xplore, 5% for Science Direct, 10% for Taylor & Francis and 8.33% for Springer. These results are shown in Fig. 9.

Table I presents each of the 60 authors of the researches addressed within the systematic review, where, based on the reading of each one, two relevant components were stipulated, on the one hand according to the aspects evaluated, explained as the one that focuses the analysis of the intelligent system, chatbot, website, Google API, its relationship with e-commerce, machine learning, IBM service, mobile application, web, relationship with customer service, sales management,

digital transformation, information system, algorithm and innovation.

As the second component, according to the conditional factors refers to the context in which the use of chatbot in sales management occurs, being such technical characteristics as algorithm, type of system, chatbot-customer relationship, sales and innovation and sales-system relationship.

Specifically, within the first component, 33.33% of the 60 studies addressed evaluated aspects of sales management, followed by 26.67% in chatbot, 6.67% in customer service, 3.33% in sales management and ERP, innovation, mobile application and web, ending with 1.67% in digital transformation, sales, Google API, intelligent system, information system, e-commerce, neural network, social networks, LSTM algorithm, artificial intelligence, machine learning and IBM service.

TABLE I.        ORIENTATION OF THE WEB SYSTEM APPLICATION UNDER TWO COMPONENTS

| Components: web-based system with chatbot service for sales management | | Reference |
|---|---|---|
| 1 | 2 | |
| According to evaluated aspects | According to conditioning factors | |
| Intelligent system, chatbot | Technical characteristics (algorithm, type of system) | [13] |
| Website, chatbot and Google API | Technical characteristics (algorithm, type of system) | [6] |
| Chatbot, system | Technical characteristics (algorithm, type of system) | [7] |
| Chatbot, e-commerce | Technical characteristics (algorithm, type of system) | [14] |

| Sales management, information system | Sales and system relationship | [50] |
| Sales management and web system | Sales and system relationship | [5] |
| Sales management | Relationship between sales and innovation | [55] |
| Sales management and ERP | Sales and system relationship | [56] |
| Sales management | Relationship between sales and innovation | [57] |
| Sales management and innovation | Relationship between sales and innovation | [58] |
| Sales management | Relationship between sales and innovation | [2] |
| Sales management | Relationship between sales and innovation | [59] |
| Sales management | Relationship between sales and innovation | [60] |
| Sales management and LSTM algorithm | Sales and system relationship | [10] |

Fig. 10. Component 1: aspects evaluated.

Fig. 10. Count of documents included in the research, according to component 1: aspects evaluated.

Regarding the second component, 43.33% of the identified articles focused on mentioning about the technical characteristics of any web system with the chatbot service, such as the algorithm, software development methodology, APIS used and so on; while 38.33% refer to the relationship of sales management and innovation, as well as 11.67% for its relationship with the system and ending with 6.67% referring to the relationship of the chatbot with customer service.

Fig. 11. Count of documents included in the research, according to component 2: conditioning factors.
Fig. 11. Component 2: conditioning factors.

## IV.  DISCUSSION

RQ1: What digital technologies allow the application of the web system in sales management?

The implementation of a Web System with Chatbot Service for Sales Management involves the integration of several key digital technologies, such as Natural Language Processing (NLP), chatbots, Google API, Artificial Intelligence, similarity algorithms like Jaccard, intent recognition, usability evaluation, social penetration theory, DSSM and Regression Forest models, generative methods, SuperAgent with Seq2seq, Ad-hoc, Condor system, Tribefinder, Natural Language Processing techniques, domain ontologies, Chatfuel Bots, measurement tools such as Attrakdiff, web crawling, knowledge bases, AIML and technology acceptance models. These technologies work together to enable more efficient and effective interaction with users, improving the understanding of their needs and providing accurate answers in the context of sales management [6] [13] [15] [17] [18] [22] [25] [34] [36] [38]. Therefore, the analysis of the 60 selected research allowed concluding that the necessary technologies for the development of a system with chatbot service are those that make use of artificial intelligence to improve the processes within a company. However, in the systemic review not all of them use artificial intelligence, since it depends on the problem they want to solve.

Table II presents the digital technologies that allow the development of a web system.

RQ2: What are the technological tools necessary for the application of the web system in sales management?

In relation to this topic, it has been identified that in several studies analyzed, the most prominent tools are JavaScript, HTML, CSS, Bootstrap, front-end web development, SQLite, Laravel, PHP, MySQL, Dialogflow, Python, JSON, HCR, C#, and .NET. These tools play a key role in addressing the complexities of web systems development, providing efficient and robust solutions depending on the programming language used. The choice of these tools not only ensures the proper development of the web system, but also significantly influences its performance, scalability, and ease of maintenance.

The toolset ranges from the creation of the user interface, using technologies such as HTML, CSS, and Bootstrap, to the implementation of business logic using languages such as

JavaScript, PHP, and Python. In addition, databases such as SQLite and MySQL play an essential role in efficient data storage and retrieval. The integration of technologies such as Dialogflow enables the creation of chatbots, a crucial element in the context of the proposed system.

TABLE II.    DIGITAL TECHNOLOGIES THAT ENABLE THE DEVELOPMENT OF A WEB SYSTEM

| N° | Technology | Quantity | Reference |
|---|---|---|---|
| 1 | Natural Language Processing (NLP) Algorithm | 4 | [13] [14] [28] [15] |
| 2 | Google API | 1 | [6] |
| 3 | Artificial intelligence | 15 | [7] [16] [17] [18] [23] [29] [32] [8] [58] [30] [35] [31] [40] |
| 4 | Jacquard similarity algorithm | 1 | [15] |
| 5 | Intent recognition algorithm | 1 | [15] |
| 6 | Usability scal | 1 | [15] |
| 7 | Heuristic evaluation | 1 | [19] |
| 8 | Social penetration theory | 1 | [21] |
| 9 | DSSM Model | 1 | [22] |
| 10 | Regressioon forest model | 1 | [22] |
| 11 | Generative method | 1 | [24] |
| 12 | Ad-hoc | 1 | [24] |
| 13 | Condor tribefinder system | 1 | [25] |
| 14 | Bots chatfuel | 1 | [24] |
| 15 | Web tracking | 1 | [24] |
| 16 | AIML | 1 | [36] |
| 17 | Technology acceptance model | 1 | [38] |
| 18 | Intrusion Detection Algorithm | 1 | [40] |
| 19 | Contingency approach | 1 | [42] |
| 20 | DBSCAN Method | 1 | [50] |
| 21 | ERP, SOA | 1 | [57] |

It is important to emphasize that, although these tools have great potential and versatility, their choice should be based on the specific needs of the project and compatibility with the selected programming language. Each tool presents its own advantages and challenges, and it is crucial to evaluate how they complement each other to achieve a complete and effective web system. In this context, the right combination of these tools can be decisive for the successful development and implementation of web systems in various environments and applications [6] [14].

Table III presents the technological tools necessary for the implementation of the web system.

RQ3: What are the benefits of implementing a chatbot service in sales management?

The literature review of the last five years addressed the knowledge of sales management and chatbot, in which it was founded that the use of IT tools can improve the internal processes of a business entity regardless of the category to which they are dedicated, one of the benefits is to establish a

relationship between digital transformation, sales, innovation, e-commerce and machine learning [6] [13] [29]. Similarly, it was identified that the use of technological tools in purchasing, and sales processes leads to the growth of e-commerce and, consequently, to market positioning [14] [37] [61].

TABLE III.     Technological Tools Necessary for the Application of the Web System

| Nº | Technology | Quantity | Reference |
|----|------------|----------|-----------|
| 1 | JavaScript | 4 | [13] [6] |
| 2 | Front-end web development | 2 | [18] [6] |
| 3 | HTML | 2 | [18] [6] |
| 4 | CSS | 1 | [6] |
| 5 | Bootstrap | 1 | [6] |
| 6 | SQlite | 1 | [6] |
| 7 | Laravel | 1 | [14] |
| 8 | PHP | 1 | [14] |
| 9 | MySQL | 1 | [14] [28] |
| 10 | Dialogflow | 2 | [28] |
| 11 | Python | 1 | [15] |
| 12 | JSON | 1 | [15] |
| 13 | HCR | 1 | [21] |
| 14 | C# | 1 | [5] |
| 15 | .NET | 1 | [5] |

Therefore, day by day they are considered as important doors for the management of digital information in different areas; therefore, it is necessary to emphasize that their objective is to optimize the relevant processes at a business level [31], [32].

Likewise, it is stated that chatbots allow interaction in various contexts and streamlines them on a daily basis, i.e., it allows 24-hour customer service, provides required information, answers doubts and queries; that is why its implementation is considered quick and simple being useful for those who have not had any approach with technology [20] [19] [16] [23] [35] However, the speed of development can cause problems if tests are not performed to validate functionality and usability [21] [30] [31] [24].

In sales management, it was identified that most companies have initiated the use of cognitive chatbots to verify real-time information about the reliability and accessibility of products/services, automatic responses for a better customer experience [28] [50] [26]. Also, for their adaptation, it is paramount that users trust their use to provide the required support [38] [62] [11] [63].

It is also considered that e-commerce is increasingly threatened, and attacks are becoming more serious, frequent security incidents in the network have generated losses that when analyzed it is inferred that it must be safeguarded with security in the network for its solution [45] [53] [40]. Consequently, in this era there are a myriad of technologies that allow changes to be made to obtain greater productivity, efficiency, and quality [58].

## V.    Conclusions

It is concluded that the systematic review analyzed the theoretical and practical studies about the web system with chatbot service for sales management between the years 2018-2022 that by applying the inclusion and exclusion criteria only conforming a total of 42 articles and 18 conferences under the paper structure using PRISMA methodology, of which 10 (16.67%) were Science Direct articles, 12 (20%) Taylor & Francis articles, 15 (25%) IEEE Xplore conferences and 23 (38.33%) of them, 20 are articles and three conferences in Springer. In the studies it was identified that to carry out an optimal sales process it is necessary to consider strategies that can be achieved through a joint work by the company.

The development of this research allowed to explore the various studies that allow to explain and analyze the level of knowledge about web systems with chatbot service applied in the sales management process, from the identification of technological tools, programming languages; as well as the processes that influence sales management, the way of organization of the sales manager, collaborators and what is the perception of their customers against the traditional process and how it has been evolving.

Future research can delve deeper into the identification and evaluation of the technical requirements necessary for a successful implementation of chatbots in this context. This involves not only interaction with customers, but also integration with business management systems and e-commerce platforms. In addition, it would be valuable to explore how collaboration strategies between sales and technology development teams influence system design and effectiveness. This research could include case studies in various companies to analyze how the implementation of chatbots affects the efficiency of sales processes, customer satisfaction and overall company performance. Ultimately, the goal would be to establish practical guidelines and recommendations for the successful design and development of sales-oriented chatbot systems in today's business environment.

Finally, in reference to limitations include challenges in the complexity of human-machine interaction, technological challenges in terms of natural language processing and personalization, as well as the inability of chatbots to empathize and understand complex human situations. In addition, implementation, and maintenance costs, along with the need for continuous learning and the possibility of rejection by users, may influence the perception and acceptance of this technology. Data security, cultural change and employee training are also crucial factors to consider in this process. Understanding these limitations provides a solid foundation for addressing the challenges and making informed decisions in successfully integrating chatbots into sales management processes.

# Deep Learning Driven Web Security: Detecting and Preventing Explicit Content

Ganeshayya Shidaganti, Shubeeksh Kumaran, Vishwachetan D, Tejas B N Shetty

Dept. of Computer Science and Engineering, M S Ramaiah Institute of Technology, Bangalore, Karnataka, India

*Abstract*—In today's digital age, the vast expanse of online content has made it increasingly accessible for users to encounter inappropriate text, images and videos. The repercussions of such exposure are concerning, impacting individuals and society adversely. Exposure to violent content can lead to undesirable human emotions, including desensitization, aggression, and other harmful effects. We utilize a machine learning approach aimed at real-time violence detection in text, images and videos embedded in the website. The foundation of this approach lies in a deep learning model, highly trained on a vast dataset of manually labeled images categorized as violent or non-violent. The model boasts exceptional accuracy in identifying violence in images, subsequently filter out violent content from online platforms. By performing all processing intensive tasks in the Cloud, and storing the data in a database, an improved user experience is achieved by completing all the necessary detection processes at a lower time frame, and also reducing the processing load on the user's local system. The detection of the violent videos is done by a CNN model, which was trained on violent and non-violent video data, and the detection of emotions in the text is taken in by a NLP based algorithm. By implementing this highly efficient approach, web safety can undergo a significant improvement. Users can now navigate the web with confidence, free from concerns about accidentally encountering violent content, fostering improved mental health, and cultivating a more positive online environment. We are able to achieve 67% accuracy in detecting violent content at approximately 2.5 seconds at its best scenario.

*Keywords*—*Web safety; machine learning; cloud computing; natural language processing; web-scraping, big data*

## I. INTRODUCTION

The Internet has become an integral part of modern life, transforming the way we access information, communicate, and interact with the world. However, with its many advantages, the digital realm also presents various challenges, especially in terms of ensuring network security for users. One of the greatest concerns is the proliferation of overt cases of violence which pose a significant risk, particularly to vulnerable individuals such as children and adolescents. To address this critical issue, we propose a novel approach that uses machine learning techniques, specifically a natural language processing technique for text processing and deep learning Convolutional Neural Network (CNN), propose real-time disturbance detection in images and videos. The unrestricted access to the internet has led to an increase in explicit violent content on online platforms. This disturbing trend poses serious risks to users, ranging from psychological injury to desensitization to violence. In addition, children and young people exposed to such substances that can have long-

term negative effects on their mental and emotional well-being. Existing manual filtering methods and traditional keyword-based methods are often unable to effectively identify and prevent violent events, requiring advanced automated solutions. Insights into how the Internet has changed as a communication tool and the expanding demand for site filtering services was inferred from [1]. The suggested real-time violence detection system, which aims to combat dangerous and inappropriate information on the Internet, was motivated by this concept. From [2] a deep understanding of the difficulties brought about by the enormous volume of data and the persistent infractions on social media platforms can be obtained. The decision to use deep learning for real-time violence detection was motivated by this realization because it would effectively filter content without only depending on human interaction. [3] Shed some light on the growing use of algorithmic content filtering systems for popular websites like Facebook, YouTube, and Twitter. In response to the growing demand for efficient content filtering, we decided to use similar technical methods for real-time violence detection based on this knowledge.

The inspiration from [4] which suggested classifying web pages using artificial neural networks as a part of content filtering. In the beginning we started with a deep learning Convolutional Neural Network (CNN) model for identifying explicit information in web photos as we realized the potential of neural networks for in-the-moment content analysis. Comparative scarcity of research on detecting aggressive/violent behaviors and fights within video content was highlighted in [4]. This knowledge informed the choice to concentrate on violence detection since we recognized its usefulness in situations like the proposed real-time web safety system, when identifying explicit content is crucial. Inspired by the proposed method's utilization of extreme acceleration patterns as discriminant features in [5], we used similar ideas into the CNN model. By implementing this method, the accuracy of the violence identification by a large margin and displayed the potential of using the unique qualities of violent behaviors for better content filtering. The goal of developing a highly accurate and efficient violence detection system was in line with [6]'s emphasis on the use of local spatio-temporal elements in characterizing multimedia information. We were able to improve the system's capacity to differentiate between violent behaviors and regular activities by incorporating this understanding the CNN model, hence enhancing content filtering precision.

The main objective of this research is to enhance web security using a real-time violence detection system that

automatically filters and filters images with obvious violent content using the power of machine learning, we aim to create efficient and accurate solutions. The proposed method has two main steps. In the first step, a web page listener on the user's machine picks up the link from the visited web page and sends it to the server. The server checks its database to see if the website has been previously tagged or indexed for explicit content. If the content is available, it is immediately redirected to the user's device, and if there is violent content, the site is invisible. In the second stage, information about web pages that are not listed in the database is forwarded to the cloud computing service. There, images from various websites are processed using CNN's deep image learning algorithm, which is trained to detect clutter in images. The search results are then sent back to the server, where the web page information is added to the database. The results are then transmitted to the user's device, making clear images unrecognizable in real time. The proposed machine learning-based violence detection system has a great potential to significantly affect web security and protect users from obviously harmful content through the violence detection method an automated and incorporating real-time responses, the system ensures instant protection and enables users to have a secure online experience. Furthermore, the research contributes to the growing field of applying machine learning techniques to content filtering, paving the way for more advanced solutions in the future.

## II. LITERATURE REVIEW

Through a thorough study of important research papers, this literature review aims to highlight the symbiotic link between deep learning, cloud computing, and real-time communication. Collectively, the chosen papers highlight how these technologies have a revolutionary effect on a variety of applications, shedding light on how their integration promotes creativity, improves efficiency, and lessens difficulties in a variety of fields.

The methodology was heavily motivated by the [7]'s classification of violence detection algorithms based on conventional machine learning, support vector machine (SVM), and deep learning techniques. Within the limits of the framework offered by the evaluated classification techniques, we customized and updated the deep learning CNN model for violence detection. The research in [8] had an unique approach of eliminating violent scenes from movies through a three-step process that stood-out with the content filtering objective. To ensure quick and accurate detection of explicit content, we utilized a similar technique of analyzing frames and applying deep learning for violent detection, but in the context of web pages as opposed to movies.

The method of using a deep learning CNN model for violence detection was motivated with the research involving fully connected networks and long short-term memory (LSTM) networks for frame-level violence detection as seen in [9]. The idea of showing the features through attention mechanisms influenced the enhancement approach for recognizing explicit/violent content in real-time, even though the focus is on web content and not video frames. The development of models for accurate face recognition, such as the multi-foot input CNN model and the SPP-based CNN model in [10],

combined with the view on picture analysis and identification in the real-time violence detection system. The idea of improving accuracy through specialized CNN models influenced the optimization methods for content filtering, even though the concentration is on content rather than faces. The urge to develop a system that reduces such mistakes was influenced by [11]'s acknowledgment of the difficulty presented by false positives in violence detection, evidently those brought on by friendly behaviors. The strategy for improving the accuracy and applicability of the real-time system was inspired by the paper's presentation of three deep learning-based models for violence detection, including those based on transfer learning and training from scratch. The optimization methods for developing a highly reliable and effective violence detection system were influenced by the [12]'s assessment of improvements in CNNs, including layer design, activation functions, loss functions, regularization, optimization, and fast computation.

The understanding of the difficulties involved in delivering an easy-to-use access to information in different situations was influenced by [13] in examination of the mobility features in mobile client-server computing. This influenced how we approached developing a real-time violence detection system that takes into consideration the various situations in life in which people access web material. The study in [14] highlighted the critical working of client-server systems in information technology view, including a range of tasks like web-based applications, unified computing, mobile apps, and cloud computing. We understood the importance of both logical and physical components, such as programming scripts and networking, in providing effective and accurate content filtering. The architectural design choices were influenced by the [15]'s study of issues including the in-depth learnings of responsibilities between clients and servers and the thinking of client/server systems. In order to ensure the effectiveness and efficiency of the real-time violence detection system, we understood how important it was to assign defined tasks and organize the system to become more efficient. The overarching objective revolves around ensuring a seamless and efficient link between the real-time violence detection system and the clientele. This objective harmonizes with the insights from study [16], which illuminates the role of Web sockets as a conduit for establishing dynamic two-way communication within HTML5 compliant browsers. The emphasis on the singular socket prowess of Web sockets profoundly informed the system's design blueprint. Notably, the techniques for optimizing the construction of a real-time violence detection system drew inspiration from the principles elucidated by the works of [17]. These principles, underscored by a devotion to minimal latency and expansive scalability in the realm of web sockets, were intricately woven into the developmental fabric.

Light is shed on cloud computing's transformational effects and its ability to use machine learning methods in [18]. This understanding is in line with how we use cloud computing to combine deep learning CNN models for real-time violence detection and content filtering. The idea of using cloud computing for deploying and managing deep learning models was in line with the [19]'s analysis of the effects of cloud computing on the area of machine learning. Its examination of

parallelization using cutting-edge parallel computing frameworks like MapReduce, CUDA, and Dryad helped us better grasp how to analyze large data sets quickly. As managing vast amount of data is essential for precise content analysis, this realization was in line with the intention to apply deep learning CNN models for real-time violence detection. The research in [20] stressed the significance of reliability in cloud computing systems, admitting that errors are unavoidable even with architectures built for high service availability. We understood the importance of locating critical characteristics that are associated with application failures because doing so would help us better manage computational resources and mitigate wasteful resource consumption as a result of failed tasks. The study in [21] focuses on the difficulties associated with computationally effective data-driven prognostics and health management (PHM) was in line with the goal of effectively processing and analyzing massive amounts of web content in real time using cloud-based data management solutions. The research in [22] provided a comprehensive survey, which highlighted the challenges and future directions in this area, and [23] proposed a text classification approach, achieving an excellent performance on a benchmark dataset. Table I represents the comparative analysis and limitations of existing approaches as in [24], [25], [26] that this study is trying to overcome.

TABLE I.        COMPARISON AND ANALYSIS OF MODULAR APPROACHES

| Feature | [24] | [25] | [26] |
|---|---|---|---|
| Focus | Explicit content detection | Audio-visual-textual cyberbullying detection | Cyberbullying detection and prevention |
| Methods | Rule-based, machine learning | Deep learning | Data mining, psychological perspective |
| Findings | Rule-based methods are effective for detecting explicit content, but machine learning methods can achieve higher accuracy. | Deep learning methods can be effective for detecting cyberbullying across multiple modalities. | Data mining and psychological methods can be used to identify cyberbullying behaviour. |
| Limitations | Rule-based methods can be difficult to maintain as new forms of explicit content emerge. | Although powerful, deep learning methods can be computationally expensive. | Data mining methods can be difficult to interpret. |

The knowledge gained from these foundational publications guides the future work because deep learning, cloud computing, and real-time communication are all interconnected in this context. The lessons learned from the studied works give us a wealth of strategic viewpoints, practical suggestions and methodological strategies.

## III.    SYSTEM ARCHITECTURE

The system architecture is explained in three parts, Client-Side Setup, Server hosted Database, Cloud Computing as visually represented in Fig. 1.

### A.  Client-Side Setup

A node-JS based setup is chosen due to its ability to run on the user's inbuilt Chrome Browser with event listeners for extraction of Text, Images and Videos as and when the data is being loaded on the application. This is achieved using the Puppeteer modules that gives us the access to the requires data even before it appears on the user's screen. By using this module, we have more control over the happenings of this browser instance in real-time. This is a more convenient approach as opposed to other implementations where an iframe where the content of a website is being broadcasted into a container of the service provider's website and then host the processed website in a third-party browser. This does not just make the entire process tedious, but also causes delays throughout the user's browsing experience.

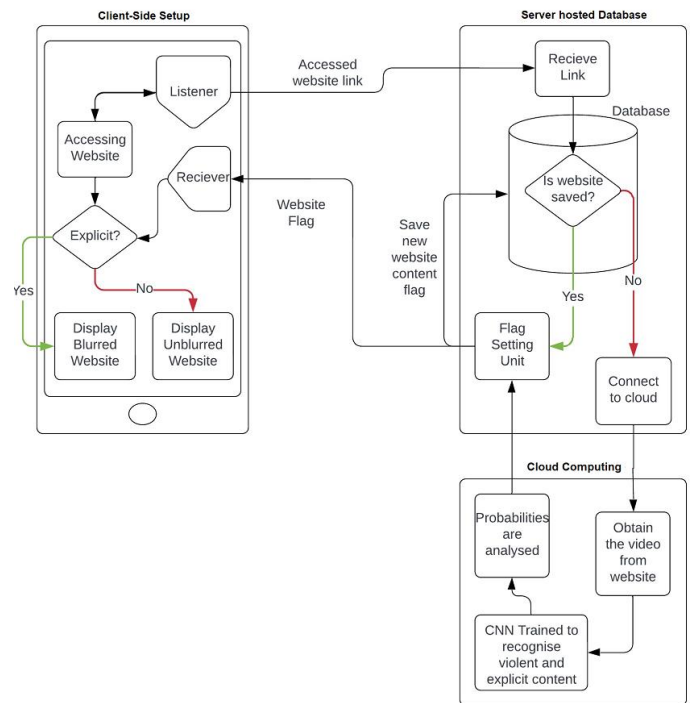

Fig. 1.   System architecture.

### B.  Server Hosted Database

The website data in the database is accessed via a hosted server connected to the Node-JS program firing the client's website. This server is responsible for handling URL inputs from the client and responding with safety-related information about the accessed websites either by going through the Database list, or by performing ML based Data analysis. This analysis is made on a Cloud Computer equipped to perform resource-intensive computations efficiently which directly updates the database in the Server. This dynamic process ensures that the database remains in a state of continuous enhancement, after every process and increase the accuracy over time.

### C.  Cloud Computing

Amazon AWS machine learning services provides both a cost effective and high-performance infrastructure. By deploying a Natural Language Processing and CNN model-

based ML programs in this platform, we achieve optimal performance to obtain a seamless user experience without utilizing local processing resources at all. AWS's Auto scaling capabilities allows the system to dynamically adjust resources based on demand, maintaining efficiency while avoiding unnecessary costs. The Amazon S3 storage solution ensures highly reliable data storage. Meanwhile AWS Lambda is a server less computing service that supports event driven executions. Key specifications and features to consider when deploying ML programs based on using Amazon AWS machine learning services are in Table II.

TABLE II.   AWS FEATURES OPTED

| Specification/Feature | Description |
|---|---|
| Instance Types | Choose compute-optimized instances (e.g., C5, M5) for efficient ML processing. |
| Auto Scaling | Implement dynamic resource adjustments to match varying workload requirements. |
| Storage Solutions | Leverage Amazon S3 for reliable and scalable data storage. |
| AWS Lambda | Utilize serverless computing for event-driven ML executions. |
| Amazon Sage Maker | Explore a managed service for end-to-end ML development and deployment. |
| Elastic Inference | Optimize inference performance and cost with GPU acceleration. |
| GPU Instances | For CNN-based models, consider GPU-equipped instances for enhanced performance. |
| AWS Lambda Edge | Use edge computing for low-latency execution near users. |
| AWS Step Functions | Orchestrate complex workflows for ML data processing and analysis. |
| AWS Data Analytics | Explore data analysis services for extracting insights from ML results. |
| AWS Cost Management | Monitor and control costs with AWS Cost Explorer and Budgets. |

## IV. METHODOLOGY

In this section, we outline the step-by-step methodology employed to realize the proposed real-time violence detection system. As represented in Fig. 2, the methodology encompasses two primary phases: the web page processing phase, which determines whether a website is flagged or indexed, and the image analysis phase, where a deep learning Convolutional Neural Network (CNN) model is utilized for detecting violent content in images.

### A. Web Page Processing Phase

In this initial phase, the system seeks to determine the nature of the accessed website by checking its status in the database and providing real-time feedback to the user.

*1) Web page listener and data transmission:* We implement a lightweight web page listener utilizing a Puppeteer based Node.JS approach on the user's device. This allows us to access the data flowing into the device when a web page is being requested from the client side. This enables us to grab the text, images and videos embedded in the website. When a user accesses a web page, the listener captures the webpage link and transmits it to the server through an encrypted HTTPS connection. This ensures the secure transfer of user data while maintaining their privacy

and at the same time transferring the minimal amount of information required for further processing.

*2) Database check for flags or indexing:* The server hosts a relational database containing website information, including URLs, content flags, and indexing status. When the server receives the webpage link, it queries the database to determine if the website has been flagged for violent content or previously indexed in the past processing of the system. If such information is found to be previously flagged, the relevant data is relayed back to the user's device and appropriate actions are taken on the website view in the client application immediately. This approach's motive is to bypass the necessity to perform unnecessary processing of text, images and videos for every request and hence reducing the overall processing time, therefore trying to provide a seamless user experience.

*3) Web page blur/unblur:* If the database query confirms the presence of explicit content on the website, the user's device receives a notification instructing it to blur the explicit text, images, videos using the puppeteer module's capability. This user-friendly approach minimizes direct exposure to harmful content and maintains a safe browsing environment with quick processing.

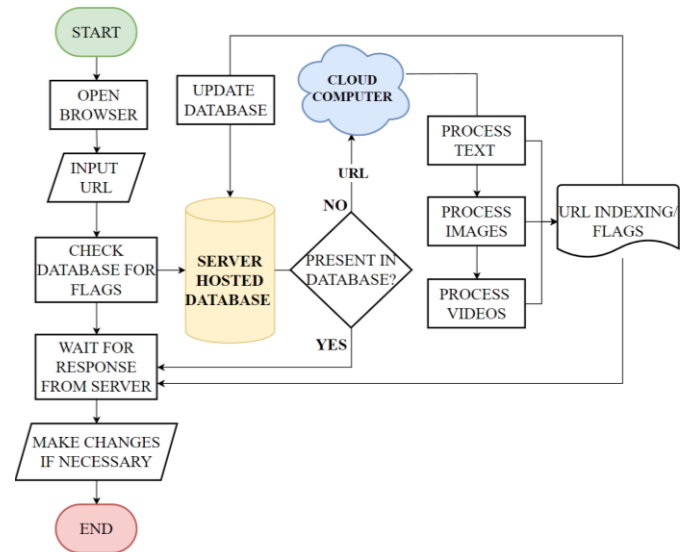

Fig. 2.   Flow diagram of the system.

### B. Data Analysis Phase

For websites without prior database information, the system initiates the data analysis phase, involving the application of a Natural Language Processing and deep learning CNN model to detect violent content in text and images/videos respectively.

*1) Cloud computing service setup:* To accommodate the computational demands of image analysis, we set up a cloud-based environment using Amazon Web Services (AWS). The cloud service is equipped with sufficient computational resources to handle multiple requests simultaneously, ensuring real-time responses. The major benefit of utilizing a cloud-based approach is the reduced load on the local user's system.

Hence the entire process will not affect the user's browsing experience, additionally the other background tasks running in the client-side systems will not be pulled out of its resource allocations for this purpose.

*2) Text processing:* The text is first extracted and analyzed using NLTK modules for sentiment analysis. The Sentiment Intensity Analyzer class of the NLTK's 'sentiment module' is utilized to score the text as polarity_scores. The score of all sentences is combined to form a compound score which is then classified as positive, neutral, and negative. Each sentence's polarity score is combined to generate a compound score, computed as in Eq. (1).

$$Compound\ Score = \sum Polarity\ Score\ of\ Sentences \quad (1)$$

This is done by using threshold values of -0.05 and +0.05 to categorize them as disturbing content or not as seen in Table III. Once it is determined as inappropriate, it halts the Data Analysis Phase and blurs the entire page.

TABLE III.    TEXT CLASSIFICATION

| Compound Score Range | Sentiment Classification |
|---|---|
| Less than -0.05 | Negative Sentiment |
| -0.05 to 0.05 | Neutral Sentiment |
| Greater than 0.05 | Positive Sentiment |

*3) Data preprocessing:* Images extracted from the accessed website's content, including frames from videos, are pre-processed to standardize dimensions and enhance the model's performance. The images are resized to 224x224 pixels irrespective to their original size or resolution or aspect ratio using Eq. (2).

$$Resized\ Image = Resize\ (Original, Target) \quad (2)$$

After resizing, the images are normalized to the [0, 1] range. This normalization process involves scaling the pixel values to fit within the specified range, which is vital for consistent input across the entire process.

$$Normalized\ Image = \frac{Resized\ Image}{255} \quad (3)$$

Eq. (3), where 255 represents the maximum pixel value in an 8-bit image. This allows that all inputs are maintained with consistency and is standard across the entire process.

*4) Deep learning CNN model:* For image analysis, we employ a Convoluted Neural Network model to analyze the images. To be specific, a pre-trained VGG16 CNN architecture, fine-tuned to detect violent content. The VGG16 model has demonstrated effectiveness in image classification tasks due to its deep 16-layer intensive ability to extract vital and meaningful information regarding the input images. By utilizing the VGG16 model to analyze individual frames extracted from videos, the system gains the ability to examine the video content frame by frame. This enables the detection of violent elements or patterns within the vide.

*5) Violent content detection:* Pre-processed images are fed through the CNN model to obtain predictions. The model outputs a probability score indicating the likelihood of the image containing violent content.

The program that analyzes the video consists of the modules and packages as seen in Table IV. Additionally, the parameters and variables assigned certain values to ensure the perfect working of this system is included in Table V.

TABLE IV.    MODULES AND PACKAGES

| Modules and Packages | Description |
|---|---|
| Asyncio | Employed for asynchronous programming, allowing efficient handling of WebSocket connections. |
| Websockets | Utilized to facilitate communication through WebSocket connections, crucial for real-time interaction. |
| OS | Enables essential file operations, such as handling paths and file removal. |
| PIL | Facilitates image processing tasks, aiding in resizing and other operations. |
| cv2 | Integral in reading and manipulating video frames, a key step in content analysis. |
| NumPy | Supports numerical operations, aiding in array manipulations and calculations. |

TABLE V.    PARAMETERS AND VARIABLES

| Parameters and Variables | Description |
|---|---|
| CLASSES_LIST | An array of class labels, specifically "Non-violence" and "Violence," used for classification. |
| model | The pre-trained CNN model loaded using Keras' **load_model** function, essential for content analysis. |
| SEQUENCE_LENGTH | A parameter determining the number of frames utilized for sequence analysis within the CNN model. |
| IMAGE_HEIGHT and IMAGE_WIDTH | Parameters dictating the dimensions to which frames are resized, ensuring consistency during analysis. |

To classify an image as violent or not, we set a threshold of 0.5 as in Table VI, based on validation results, above which an image is categorized as violent. The CNN model assigns a probability score $F_{violent}P_{violent}$ to each image. This score represents the likelihood of the image containing violent content. It can be expressed as in Eq. (4).

$$F_{violent}P_{violent} = CNN_{Model(Pre-processed\ Image)} \quad (4)$$

TABLE VI.    VIDEO CLASSIFICATION

| Probability Score | Classification |
|---|---|
| $P_{violent} > 0.5 P_{violent} > 0.5$ | Violent Content |
| $P_{violent} \leq 0.5 P_{violent} \leq 0.5$ | Non-Violent Content |

*6) Result transmission and database update:* The predictions from the CNN model are transmitted back to the server, which subsequently updates the database with the

violence detection result for the accessed website. This dynamic database enhancement ensures the continual improvement of the system's accuracy over time. This shows that the cloud is only communicating with the database and not with the client device directly. This method ensures that this process is not susceptible to external cyber-attack.

*7) User feedback and blurring:* The user's device receives the result of the violence detection process. If the result confirms the presence of explicit content, the user's device applies blurring to the corresponding images or videos, ensuring a safer browsing experience. In this case only the and all the non-violent images/videos stays unblurred, inferring that its just the specific violent content that are blurred. This is to provide the user with the best possible experience.

## V. RESULTS

To demonstrate the working of this system, local websites are utilized. This system is implemented by using a local cloud instance to run the Machine Learning programs that analyzes the text, images and videos. Additionally, a MongoDB database is fired-up to store the website information. All communications are made using web sockets to best emulate the real implementational results. In this implementation, the entire content is first blurred and eventually the content safe to be viewed are unblurred ensuring that no disturbing content is viewed in the small timeframe of computation. Multiple cases are considered to portray the working of the system. The result images depict the results in case of both when it's present and not present in the database.

### A. CASE 1: Non-Violent Text & No Videos in the Website

The text is classified as neutral and hence the website is unblurred as seen in Fig. 3.

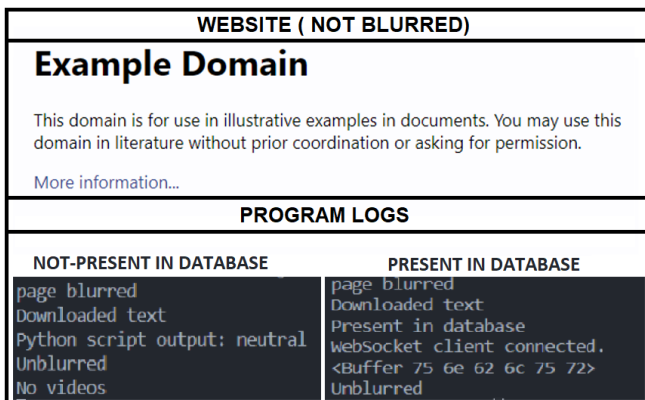

Fig. 3. Non-violent text and no videos in the website.

### B. CASE 2: Violent Text & (No/Violent/Non-Violent) Videos

The text is classified as negative and no other content is considered (videos). Hence the website is completely blurred as in Fig. 4.

### C. CASE 3: Non-Violent Text & Non-Violent Videos

The text is classified as neutral, the video is declared positive. Hence the website is unblurred as in Fig. 5.

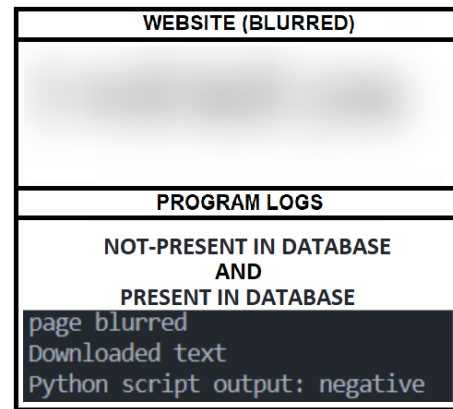

Fig. 4. Violent text and (no/violent/non-violent) videos.

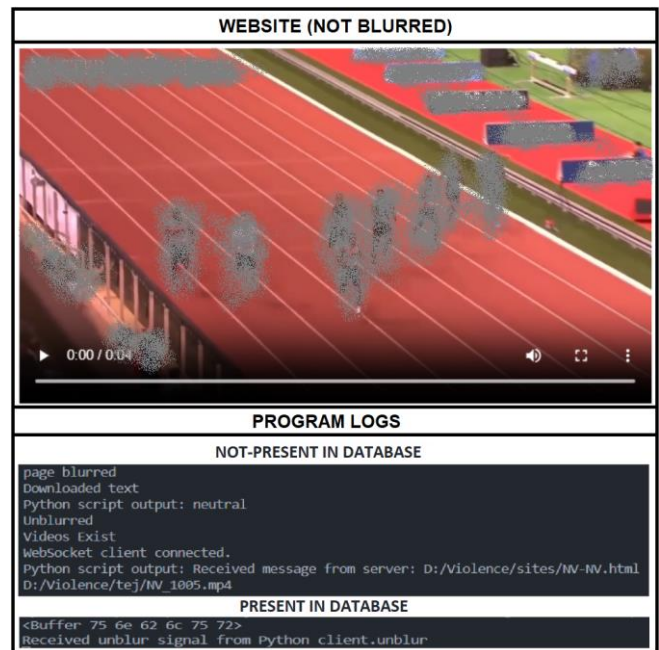

Fig. 5. Non-violent text and non-violent videos.

### D. CASE 4: Non-Violent Text & Violent Videos

The text is classified as neutral and video as negative. Hence the video portion of the website is only blurred as in Fig. 6.

The time taken to perform the various cases discussed is shown in Table VII. The data is visualized in the form of line graph. It can be easily noted that the Computation time is proportional to the length of the text or video being analyzed in the website. This noticed that, with the support of the database, we have continuous Time frame of two to three seconds. Except the case when the text in small and no video is present in the website, all other iterations require a considerably longer duration to process the content. Fig. 7 shows the ability to identify violent images quickly.

Even though the Fig. 8 shows 100% successful results in case of those four iterations, the model has an accuracy of 67% overall. Hence, utilizing this architecture, we are able to achieve exceptional speed and minimal computational load. Therefore, ensuring that the browser users are protected from

disturbing content, and without much interruption due to quick the shift between unblur and blur during the processing phase.

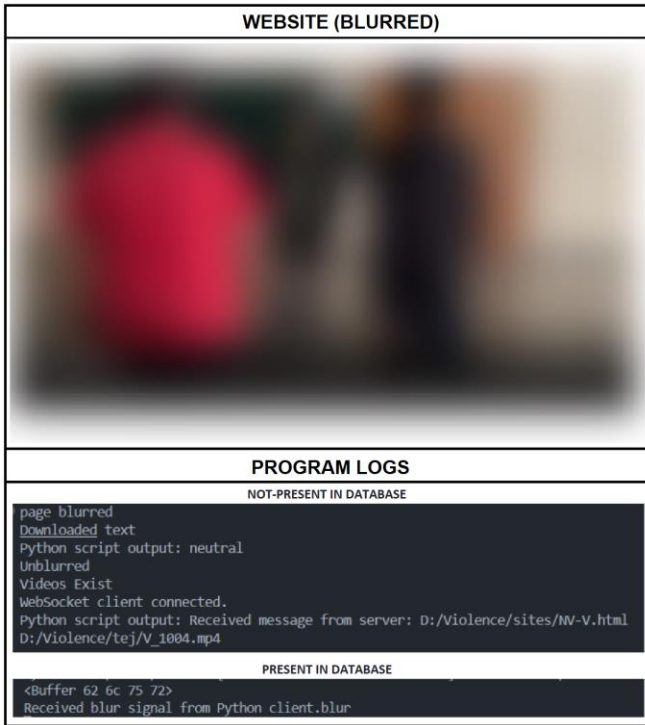

Fig. 6.  Non-violent text and violent videos.

Fig. 7.  Comparing the implementation time with and without database.

TABLE VII.  PROCESSING TIME

| CASE | Text Processing Time | Video Completion Time | Total Time when not in database | Total time when URL is in the database | Probability Score |
|---|---|---|---|---|---|
| 1 | 1.7 sec | NULL | 1.7 sec | 2.4 sec | 0.2 |
| 2 | 1.3 sec | NULL/ 0 – 15 sec | 1.3 – 16.3 sec | 2.3 sec | 0.7 |
| 3 | 1.2 sec | 13.7 sec | 14.9 sec | 2.6 sec | 0.3 |
| 4 | 1.4 sec | 18.1 sec | 19.5 sec | 2.8 sec | 0.8 |

Fig. 8.  Detection performance comparison graph.

## VI.  CONCLUSION

Considering the evolution of internet in the modern society, it is the duty to protect its users' security and welfare, particularly in light of the skyrocketing risks posed by explicit and violent content. In this paper, we describe a complete method for improving web safety through real-time violence detection in text, photos and videos using machine learning methods, more specifically deep learning Convolutional Neural Networks (CNNs). By performing all processing intensive tasks in the Cloud, and storing the data in a database, as and when the analysis is completed for any website, we can achieve an improved user experience by not just completing all the necessary detection processes at a lower time frame, but also reduce the load on the user's local system. Machine learning models can be used to handle new explicit data with improvement and expansion of training datasets, making sure that the relevance of the system and ability to change in an online dynamic environment.

In conclusion, the effectiveness of utilizing machine learning to improve web safety is demonstrated by the suggested real-time violence detection system. Incorporating mainstream technologies such as Cloud Computing and Bigdata, we consistently achieved an accuracy of 67% over thousands of trials at a time. Moreover, the proposed system architecture achieves all this in under 2.5 seconds at its best-case condition, i.e. results stored in the database. Thus, we have made great progress towards fostering a safer digital environment for all users by fusing technology innovation with ethical considerations.

*Abstract*—**ASD may be caused by a combination of genetic and environmental factors, including gene mutations and exposure to toxins. People with ASD may also have trouble forming social relationships, have difficulty with communication and language, and struggle with sensory sensitivity. These difficulties can range from mild to severe and can affect a person's ability to interact with the world around them. Autism spectrum disorder (ASD) is a developmental disorder that affects people in different ways. But early detection of ASD in a child is a good option for parents to start corrective therapies and treatment. They can take action to reduce the ASD symptoms in their child. The proposed work is the detection of ASD in a child using a parent's dialog. The most popular Bert model and recent ChatGPT have been utilized to analyze the sentiment of each statement from parents for the detection of symptoms of ASD. The Bert model has been developed by the transformers which are the most popular in the natural language processing field whereas the ChatGPT model is a large language model (LLM). It is based on Reinforcement learning from human feedback (RLHF) that can able to generate the sentiment of the sentence, computer language codes, text paragraphs, etc. The sentiment analysis has been done on parents' dialog using the Bert model and ChatGPT model. The data has been prepared from various Autism groups on social sites and other resources on the internet. The data has been cleaned and prepared to train the Bert model and ChatGPT model. The Bert model is able to detect the sentiment of each sentence from parents. Any positive sentiment detection means parents should be aware of their children. The proposed model has given 83 percent accuracy according to the prepared data.**

## I. INTRODUCTION

Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by challenges in verbal communication, restricted interests, and repetitive behaviors as in [1]. The wide variability observed in individuals with ASD makes it difficult to establish universally applicable markers. As a result, there is a growing need for simpler and more accessible measurement techniques that can be routinely implemented for early detection purposes as in [2]. ASD may be caused by a combination of genetic and environmental

factors and is characterized by challenges with social skills, communication, and repetitive behaviors. Early diagnosis is important, as early intervention and treatment can improve outcomes and help those with ASD reach their full potential. Depending on the type of ASD, individuals may have difficulty with communication and social interaction, have repetitive behaviors, have difficulty with change, or have sensory sensitivities. Treatment plans are tailored to the individual and may include therapy, medication, and other services as in [3]. This is because autism is a complex disorder, and its symptoms can vary greatly from person to person. In addition, the symptoms of autism may not be obvious at first and can take some time to manifest. The 'spectrum' in ASD refers to the wide range of symptoms and their severity sometimes called Asperger's syndrome as in [4]. Thus, a comprehensive screening process is needed to properly detect autism. This means that the earlier the detection, the sooner the person can receive the necessary treatment and support, which can help to improve the quality of life for those with autism. In addition, early detection can also help to reduce the costs associated with the disorder, as treatments can be more effective when started early. This is because the signs and symptoms of autism can be very subtle in this age group and can be difficult to identify. Furthermore, the behavior of young children is constantly changing, which makes it even harder to accurately diagnose autism in this age group as in [5]. According to the autism report, the worldwide rate of increment of autism over the past decade is six children among 1000 children as in [6].

People with autism have difficulty in social interaction and communication and may have restricted and repetitive patterns of behavior, interests, or activities. Additionally, they may experience sensory sensitivities, have difficulty with transitions between activities, and have difficulty understanding abstract concepts as in [7]. Early detection of autism is important as it can help children to receive the necessary interventions and support to aid in their development. However, the lack of access to resources and the costs associated with screening tests make it difficult for families to get the help they need. While there is no cure for autism, there are effective treatments that focus on helping individuals with autism learn and develop skills and cope with

the challenges they face. These treatments may include behavior therapy, speech and language therapy, and occupational therapy. These symptoms can include difficulty with communication, sensory processing, and motor skills, as well as problems with memory, self-regulation, and social interactions. Additionally, these symptoms should interfere with the child's ability to function in home, school, and other social settings. Early diagnosis of ASD is a key to helping children reach their full potential and receiving the necessary treatment and interventions. Early diagnosis also allows for timely referral to other specialists and access to educational and behavioral therapies, which can help improve outcomes for children with ASD as in [8]. AI can analyze patterns and trends in large amounts of data more quickly and accurately than a human can. AI algorithms can be used to study genetic data, environmental factors, and symptom progression over time in order to identify or predict ASD. Higher dimensional data requires more sophisticated algorithms for analysis. Also, data from multiple sources can have different formats and structures, making it even more difficult to analyze. Therefore, artificial intelligence methods are needed to better analyze these types of data, which can be used for the prognosis and diagnosis of ASD as in [7]. Machine learning algorithms have the capability to analyze large amounts of data and identify patterns in the data that can be used to distinguish between individuals with ASD and those without as in [9]. Any machine learning model can be used but improvement of accuracy, precision, and recall will reduce the time complexity of the ASD diagnosis model as in [10]. Classification models are good to use for the detection of ASD of a person after improving the accuracy of the classification model as in [11]. By using these algorithms, physicians can better diagnose individuals with ASD and ensure they are receiving the proper treatment. By speeding up the autism diagnosis process, doctors and caregivers can quickly identify symptoms and provide the appropriate treatments that can help improve the quality of life for those with ASD as in [12].

The proposed research work detects the sentence that contains positive words that are pointing to ASD symptoms. The proposed system contains two machine learning models that are BERT model, and the ChatGPT model. A dataset has been prepared to train the BERT model. The dataset has been prepared from parents' dialogues who are actually parents of autistic children. Their experiences have been utilized to detect ASD symptoms. Parents of autistic children are spent most of their time with their children and their experience is the key to detecting ASD symptoms perfectly. The data has been collected from organizations that are working with autistic children. Some data has been collected from the social networks group. The dataset has been prepared according to the binary classification. A sentence containing positive words regarding autism sentence denotes true (1) and without positive words in a sentence denotes false (0). BERT model follows the most popular transformer architecture to do sentiment analysis where this model is trained with the prepared dataset that has been described in Section III. The ChatGPT model of OpenAI is another popular large language model in recent years. The architecture of this model uses reinforcement learning from human feedback (RLHF) architecture to solve many critical tasks. The example data

from the dataset has been sent to this model to understand the data structure and then new data send for predicting the sentiment for the detection of ASD symptoms. Both models are used to detect ASD symptoms. The detail of both models with the dataset has been discussed in Section III. The result of both models has been discussed in Section IV. The limitation and conclusion have been given in Sections V and VI respectively. Finally, this research paper ends with a future work.

## II. RELATED WORKS

Autism Spectrum Disorder (ASD) is a significant healthcare concern among children today, and it is considered one of the primary domains of interest in healthcare research. Artificial intelligence (AI) has become an increasingly popular approach for studying and treating ASD, and numerous studies have explored the use of AI in this field. In this section, we review some of the most important AI-based research on mental health issues, including ASD that have been conducted to date. These acoustic features are indicative of the underlying neurological mechanisms of the disorder. By analyzing these features, researchers can identify patterns that are unique to ASD speech and can identify individuals with autism at an early stage, which can then allow for early intervention and increased success in managing the disorder. These features are used to quantify the differences in speech production between children with ASD and those of a normal population. By analyzing these features, filter features formants (F1 to F5) researchers can identify potential differences in speech production between the two groups and better understand the impact of ASD on speech production. Significant changes in a few acoustic features are observed for ASD-affected speech as compared to normal speech. These changes indicate a difference in the production of speech sounds in individuals with ASD. This can help researchers understand the impact of ASD on speech production and suggest areas for further investigation. This is because the formants and dominant frequencies of the vowel /i/ are the most distinct between ASD and normal children. Additionally, the vowel 'I' is the most common vowel in speech and thus has the most data points to compare between groups. It provides a detailed analysis of how computer algorithms can be used to detect signs of autism in children. The authors provide evidence of how accurate these systems can be and how they can be used to aid in early diagnosis and intervention as in [13]. Early diagnosis of ASD is important in order to provide the necessary interventions and therapies to improve the quality of life for those affected. The development of easily implemented and effective screening methods can help to identify children with autism at an earlier age and provide them with the support they need. By using the Logistic Regression model, the researchers are able to capture the complex patterns of the dataset and accurately predict the outcome of ASD disease. Additionally, the algorithm will allow for rapid classification of the behaviors in the dataset, allowing for faster and more accurate predictions. These challenges include the need to ensure data privacy, to be able to trust the results of the AI system, to have the right infrastructure in place, and to ensure that the system is able to properly interpret the data. Additionally, healthcare

organizations must be able to adjust the system as new data becomes available and as the needs of the organization change as in [14]. What is often overlooked, however, is the importance of the quality of the interaction between the child and the caregiver. A supportive and responsive environment with frequent turns and back-and-forth exchanges between the adult and the child is essential for language development. We use observational methods to analyze the language used by caregivers in interactions with their children to see how well it predicts language development. The authors in [15] looked at the child's cognitive, social, and linguistic abilities to see if they are contributing factors to language development. Authors in [15] have used a longitudinal corpus of conversation data to measure how much caregivers repeat their children's words, syntax, and semantics, and whether this repetition is predictive of language development beyond other established predictors. Results: This is because by repeating and mirroring the child's language, the caregiver is providing the child with immediate feedback and reinforcement. This helps the child to better understand their language and helps them to develop their language skills in a more effective manner. Language acquisition is a process that relies on more than just memorization of information. It requires an interactive conversational model where the learner is engaged in meaningful dialogue with a teacher. Our open-source scripts provide a platform for researchers to explore this model in different languages and contexts as in [15]. NLP techniques are used to analyze the text and identify language patterns and emotions. This allows the system to identify users who may be experiencing depression, anxiety, or other mental health issues, and direct them to appropriate resources or suggest personalized interventions to help them cope with their issues. It also provides a comprehensive review of the literature on the various techniques and approaches used for data collection, processing, and analysis, as well as their advantages and limitations. Furthermore, this paper outlines the opportunities and challenges associated with the use of online data writing in mental health support and intervention. By using data from social media and other sources, researchers can detect certain patterns in language and behavior that can be used to identify individuals who may be in need of psychological assistance. Additionally, computational techniques can be used to label and diagnose mental health issues. Finally, through the use of machine learning and natural language processing, interventions can be generated and personalized for individuals in order to help them manage their mental health. This review seeks to provide a comprehensive overview of the existing literature in these fields and to identify gaps in the research and opportunities for future research and development. Additionally, it seeks to provide a common language to facilitate further collaborations between the different disciplines as in [16]. People with autism struggle with communication, interaction, and understanding social cues. They may be overly sensitive to sound, light, and other sensory inputs. They often have difficulty in understanding other people's feelings, and may also have difficulty forming relationships. They may also have unusual behavior patterns, such as repetitive movements or focusing on one topic for long periods of time. By using machine learning algorithms, doctors can identify potential markers of autism in a child at a much earlier stage than before. Early detection of autism can allow parents to seek out treatments and therapies that may help reduce the severity of autism in their children. We will use data from clinical studies, medical records, and other sources to develop a model that can accurately predict the outcome of autism diagnosis in children. We will analyze the data to identify patterns and develop an algorithm that can be used to predict outcomes. We will also evaluate existing machine learning models to determine which ones may be suitable for our proposed work. This method allows us to compare the results of the two groups of patients and look for any correlations between the data and how it may impact the diagnosis and treatment of future patients. Additionally, this approach can help us to identify any potential trends in the data which could further inform our understanding of the condition. By using LR, NB, DT, and KNN algorithms, we can apply different techniques to the data set, such as feature engineering and feature selection. This will help to ensure that the most important factors influencing the diagnosis of autism is being taken into account and that the predictive models are accurate and reliable as in [17]. The ASD QA dataset provides a unique challenge for MRC models, as it requires them to understand the context of the reading passage in order to correctly identify the answer. It is particularly difficult because the answers are not always straightforward and may require some inference or deduction. The dataset was created by selecting a set of questions from the ARC dataset and extracting the corresponding answer segments from passages in Wikipedia. The questions are generated from the passages using a variety of techniques. By adding these questions, we can evaluate the system's ability to identify and classify unanswerable questions. This is important to ensure that the system is not simply guessing, but rather, it is using the contextual information in the reading passage to accurately identify answerable and unanswerable questions. Each answer contains also positional tags (start and end) denoting the numerical positions of the first and last symbols of the answer span in a reading passage. 5% of the questions in ASD QA are unanswerable, which means that corresponding reading passages do not contain any answers to them. This split was chosen so that the model could be trained on the majority of the data, tested and validated on a smaller portion of the data to ensure accuracy, and then tested on an unseen portion of the data to ensure that it is generalizing correctly. Byte pair encoding is a method of compressing words into smaller units of meaning, which reduces the overall vocabulary size and makes it easier for the models to learn. This is beneficial for both types of models, as it reduces the amount of noise in the data, allowing for more accurate predictions as in [18]. One possible risk factor that has been identified is the presence of co-occurring mental health conditions, such as depression, anxiety, and obsessive-compulsive disorder. These conditions can be exacerbated in young people with ASD due to the difficulties they face in forming social relationships, communicating effectively, and coping with sensory overload. EHRs can provide a large amount of data, but they are often not standardized, making it difficult to accurately extract the data needed to create a valid cohort. Developing systems to accurately extract and organize the data would allow researchers to better understand the

relationship between ASD and suicide risk. The systematic approach utilizes NLP to identify the suicidal language in the EHR corpus and determine if the language is positive or negative. The performance of the classification tool is then evaluated on a subset of 500 patients. The precision score indicates the proportion of relevant results to the total relevant results retrieved, and the recall score measures the proportion of relevant results retrieved to the total amount of relevant results. The F1 score combines these two scores, providing a single value that is indicative of the system's overall performance. In this case, all of these scores were very high, indicating that the NLP classification tool was highly accurate in recognizing positive suicidality. The application has been validated against existing research and has been found to be effective in identifying potential risk factors for suicidality among individuals with ASD. It has also been found to be useful in predicting suicide risk and providing automated surveillance within clinical settings as in [19]. MRI imaging modalities have the capability to detect subtle brain abnormalities that are associated with ASD, such as changes in the brain's structure, connectivity, and even in its chemistry. This makes it an invaluable tool for diagnosing and monitoring ASD. fMRI uses magnetic fields and radio waves to measure blood flow in the brain and identify any abnormalities or discrepancies in brain activity. sMRI uses high-resolution images to map the structure of the brain and detect any abnormalities in the brain anatomy. These two modalities work together to help clinicians diagnose ASD with greater precision. These systems use AI to analyze brain images, such as MRI and fMRI scans, to assess an individual's brain structure and connectivity. The AI algorithms can detect subtle differences in brain structures which can be used to diagnose ASD more accurately and quickly by specialists. ML algorithms are used to analyze the image data, identify the relevant features, and detect any abnormalities that could be indicative of ASD. DL applications are used to further analyze the data and identify patterns that may be indicative of ASD. This allows for more accurate and reliable diagnoses. Deep Learning (DL) techniques employ large datasets of MRI images and AI algorithms to create models that can detect patterns in the images that are associated with ASD. These

models can then be used to automate the diagnosis of ASD and provide more accurate and timely results. We compare the accuracy and training times of ML and DL models to show that DL models can learn faster and achieve higher accuracy. We also discuss the importance of feature selection and data pre-processing in improving the accuracy of the models. Finally, we suggest the potential of combining AI techniques with MRI neuroimaging to detect ASDs as in [20]. Diagnosis of ADHD is typically based on a combination of self-reported symptoms, observations by parents and teachers, and psychological tests. Therefore, it can be difficult to accurately diagnose ADHD since there is no concrete, medical evidence to support a diagnosis. The proposed method was tested on a publicly available ADHD-200 dataset, which showed that 4-D CNN had better performance than traditional methods in terms of accuracy, specificity, and sensitivity. Furthermore, it was also demonstrated that 4-D CNN could effectively detect subtle differences in RS-fMRI data between ADHD and healthy individuals. These models take advantage of the spatiotemporal information of the RS-fMRI images to extract useful information about the brain. For example, the feature pooling model can be used to detect patterns in the data that are consistent across multiple time frames, while the LSTM model can be used to analyze the temporal dynamics of the data. The spatiotemporal convolution model can be used to identify spatial structures in the data. The approach is designed to reduce the computational cost of training deep learning models on fMRI data. By breaking the fMRI frames into shorter pieces with a fixed stride, the data can be processed more quickly and efficiently. The results of the evaluations demonstrate that our 4-D CNN method is more effective at accurately diagnosing ADHD than traditional methods. This method can be used to create a powerful and efficient tool that can be used to accurately diagnose ADHD and provide clinicians with the information they need to make informed decisions as in [21]. A comparative analysis has been done with proposed models and some similar machine learning models that are able to detect mental disorders. The proposed analysis has been described in Table I. This table contains 'Models', 'Description', 'Dataset', 'Accuracy', and 'Remarks' as attributes.

TABLE I.    COMPARATIVE ANALYSIS BETWEEN PROPOSED MACHINE LEARNING MODELS AND SIMILAR MACHINE LEARNING MODELS BASED ON MENTAL DISORDER DETECTION

| Sl.No. | Models | Description | Dataset | Accuracy | Remarks |
|---|---|---|---|---|---|
| | | **Similar Type Machine Learning Models in Mental Disorders** | | | |
| 1 | Logistic Regression [14] | The Logistic Regression model has been used in the diagnosis and detection of ASD. | Screening data of a group of toddlers related to autism | 100% | The proposed dataset has been prepared with 1054 instances and 18 attributes to train and test the model to detect ASD. |
| 2 | Logistic Regression(LR), Naïve Bayes(NB), Decision Tree(DT), K-Nearest Neighbour(KNN) [17] | These models are used to predict ASD using ASD patients and normal patients' data. | The dataset contains data related to normal patients and ASD patients. | 99.37%, 96.59%, 100%, and 97.73% | The dataset contains a large number of irrelevant and missing data. Many pre-processing techniques have been applied to clean datasets. |
| 3 | 4-D CNN [21] | This deep learning model training is based on the fMRI frames dataset to detect ADHD automatically. | This dataset consists of the fMRI frames data. | 71.3% | The proposed deep learning model 4d-CNN is able to detect ADHD using resting-state functional magnetic resonance imaging (rs-fMRI). |

| 4 | Random Forest, Ridge, SVM [20] | ,These models use sMRI and fMRI neuroimaging data to detect ASD. | NDAR and ABIDE datasets have been used that are containing sMRI and fMRI neuroimaging data. | 72%, 71%, and 75.3 | Software tools are needed to pre-process these kinds of MRI data. The brain extraction tools (BET), FMRIB software libraries (FSL), statistical parametric mapping (SPM), and Free Surfer are used to preprocess MRI data. |
|---|---|---|---|---|---|
| 5 | KNN, RF, SVM [20] | These models use sMRI and fMRI neuroimaging data to detect ASD. | NDAR and ABIDE datasets have been used that are containing sMRI and fMRI neuroimaging data. | 81%, 81%, and 78.63% | Software tools are needed to pre-process this kind of MRI data. The brain extraction tools (BET), FMRIB software libraries (FSL), statistical parametric mapping (SPM), and Free Surfer are used to preprocess MRI data. |
| 6 | Logistic Regression, Random Forest [20] | These models use sMRI and fMRI neuroimaging data to detect ASD. | UCI dataset has been used which is containing sMRI and fMRI neuroimaging data. | 97.54% and 100% | Software tools are needed to pre-process this kind of MRI data. The brain extraction tools (BET), FMRIB software libraries (FSL), statistical parametric mapping (SPM), and Free Surfer are used to preprocess MRI data. |
| 7 | Siamese Verification Model and GERSVMC [20] | These models use sMRI and fMRI neuroimaging data to detect ASD. | NDAR and ABIDE datasets have been used that are containing sMRI and fMRI neuroimaging data. | 87% and 96.8% | Software tools are needed to pre-process this kind of MRI data. The brain extraction tools (BET), FMRIB software libraries (FSL), statistical parametric mapping (SPM), and Free Surfer are used to preprocess MRI data. |
| **Proposed Models in Mental Disorder (Autism Spectrum Disorder)** | | | | | |
| 8 | Proposed BERT Model | The BERT model has been proposed to predict positive ASD symptoms from parents' dialogue. | Parents' Dialogues of Autistic Children in text format from SAHAS-Durgapur, India, and Social Sites. | 83% | The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns. |
| 9 | Proposed OpenAI ChatGPT Model | ChatGPT model has been used to predict positive ASD symptoms from parents' dialogue. | Parents' Dialogues of Autistic Children in text format from SAHAS-Durgapur, India, and Social Sites. | Fine-Tuned and Pre-trained model of OpenAI with High Accuracy | The data has been collected in text form. The parents' dialogues about their autistic children are very useful because they shared their experiences and thoughts about their autistic children. A parent of an autistic child is the best source to understand the ASD symptoms patterns. |

## III. ARCHITECTURE

Two advanced machine learning models have been used to identify ASD symptoms from parents' dialogues. BERT has been used as the first model to detect the symptoms from the parents' dialogue whereas the ChatGPT model has been used as a second model to detect ASD symptoms from the given dataset. KNN and Random forest are the last two classifiers that are also used to identify ASD symptoms from a given dataset.

### A. Dataset

The dataset is prepared by analyzing parents' dialogues in which they described their thoughts and experiences related to their own child with Autism Spectrum Disorder (ASD). These dialogues were obtained from various social networks and organizations where children with special needs receive therapies for communication, speech, and behavior. Table II provides a few examples of these dialogues. Parents' dialogues are a valuable source of data for identifying all possible symptoms of ASD. We used these dialogues to create a dataset for training and testing our proposed machine-learning models.

The dataset was meticulously curated from the content presented in Table II, with a thorough examination of each sentence to ascertain its relevance as a potential symptom of Autism Spectrum Disorder (ASD). It is important to note that the identification of ASD symptoms is not constrained by a fixed set of criteria, allowing for a comprehensive exploration of various indicators. To enhance the dataset and bolster the accuracy of machine learning models, a promising avenue could involve the augmentation of dialogues from parents who have firsthand experience with autistic children. This approach not only facilitates the discovery of additional symptoms but also offers a valuable opportunity to refine machine learning algorithms. Table III provides a glimpse of the dataset, offering illustrative examples of the data's composition.

Table III provides a comprehensive overview of the dataset structure proposed in this research endeavor. The dataset comprises three distinct columns: Serial Number, Comments, and Sentiment. To compile this dataset, textual excerpts were extracted from parents' dialogues, wherein each sentence underwent a rigorous evaluation to determine its association with Autism Spectrum Disorder (ASD) symptoms. Sentences that were indicative of ASD symptoms were categorized with a label of 1 (representing true), while those not exhibiting such symptoms were assigned a label of 0 (indicating false). Referring to Table III, it becomes evident that the Comments column, under serial numbers 1, 3, and 4, highlights sentences bearing true ASD symptoms, while serial numbers 2 and 5 correspond to sentences devoid of ASD symptoms. This meticulously curated ASD symptom-based dataset is now poised for the training of advanced machine learning models such as BERT and ChatGPT, holding promise

for enhancing our understanding and analysis of ASD-related linguistic cues.

TABLE II. EXAMPLE OF PARENTS' DIALOGUES

| Sl. No. | Parents' Dialogues |
|---|---|
| 1. | My son is 20, has autism, high functioning. Drives, works but still struggles with socializing like most. eye contact can be minimal, talking is minimal ( no small talk) He is being bullied now in the work place to the point his ptsd from childhood bullying is affecting him. I try to empower him but he is scared of getting Hit by his coworker |
| 2. | He cries every night and every day about going to nursery. Unfortunately the past few weeks have been awful, he is very upset about going to nursery again and is now asking if he is going the next day at bath time and then when he wakes up in the morning he screams and cries and has to be physically dressed and put in the car. |
| 3. | I am new here I just want to ask about any private speech and language therapist in ENGLAND at Oldham, my 2 years baby is not talking yet, sometime not responding. I am very worried for my son. Please help me for guiding. |
| 4. | My daughter-in-law spoils him let's him have and do whatever he wants. I'm sure it's because they don't want to hear his screams Now she's temporary out of the picture. Her oldest son age 12 opens the fridge and lets him grab whatever because mom let him. I put a stop to it because food is going to waste within a day it makes it hard when the one year old wants milk and there's none because it gets spoiled. Am I wrong in not letting the 5 year old not have his way? |
| 5. | My 9 year old little man was recently diagnosed with Autism and waiting for further appointments for ADHD. Does anyone else's child suffer with bad meltdowns and constantly angry and stressed? |

TABLE III. EXAMPLE DATA IN THE PROPOSED DATASET

| Sl. No. | Comments | Sentiment |
|---|---|---|
| 1. | He is playing with toys and spin wheels every time | 1 |
| 2. | Please help me understand autism because my son is 4 years old now | 0 |
| 3. | My little girl is 3 years old but she is able to speak. | 1 |
| 4. | She mumbles but can speak any proper word. | 1 |
| 5. | I was really surprised when she came home and asked her mom about me. | 0 |

TABLE IV. LIST OF LABELS WITH ASD PROBLEMS

| Sl. No. | Label | ASD Problems |
|---|---|---|
| 1. | 1 | Speech Problem |
| 2. | 2 | Sensory Problem |
| 3. | 3 | Behaviour Problem |
| 4. | 4 | Special Education |
| 5. | 5 | Social Interaction |
| 6. | 6 | Eye Contact |
| 7. | 7 | Cognitive Behaviour |
| 8. | 8 | Hyper Active Problem |
| 9. | 9 | Child Psychological Problem |
| 10. | 10 | Attention Problem |

Table IV serves as a reference for the association between ASD problems and their respective labels. Each label in Table

IV represents a specific ASD problem, with Label 1 indicating "Speech Problem," Label 2 denoting "Sensory" issues, and Label 3 representing "Behavior" problems. Additionally, Table IV includes labels for other ASD problems. Once the sentiment of a sentence related to ASD symptoms is predicted, the proposed system utilizes Table IV to determine the corresponding label associated with the identified problem. In the system flow, when a sentence is classified as positive (1), it becomes the input for the Spacy cosine similarity model. This model compares the positive sentence with the dataset presented in Table V, which contains numerous positive sentences accompanied by their respective labels. Each label in Table V corresponds to an ASD problem as defined in Table IV. As described in the Proposed System Flow section, the cosine similarity model performs a similarity check between the predicted positive sentences and the sentences within the dataset. This process aims to identify the sentence in the dataset that is most similar to the input sentence. The label associated with this highly similar sentence is then selected by the system. By utilizing the information from Table IV and Table V, the proposed system matches positive sentences, which indicate ASD symptoms, with their respective labels. This matching process allows for the identification of specific ASD problems based on the BERT cosine similarity scores calculated by the system.

TABLE V. DATASET FOR COSINE SIMILARITY CHECK

| Sl. No. | Positive Sentences | Label |
|---|---|---|
| 1. | I am unable to demonstrate potty training to him during the daytime when his father is at work. | 7 |
| 2. | He primarily mumbles and doesn't use coherent words. | 1 |
| 3. | When I beckon him, he doesn't respond by coming to me. | 10 |
| 4. | He requires visual cues to comprehend my communication. | 6 |
| 5. | Her frustration deeply affects me and I'm hoping to hear some success stories. | 9 |

In the subsequent sections, we have detailed each model, including the algorithm employed in its implementation. This dataset served as the foundational training data for these models, and the outcomes of each model have been extensively examined and deliberated upon in the Results and Discussion section.

*B. BERT Deep Learning Model*

BERT is a deep learning model for natural language processing that helps to understand the meaning of a text or sentence according to the context. The BERT model is trained with the Wikipedia dataset and it can be fine-tuned for better accuracy. BERT stands for Bidirectional Encoder Representations from Transformers which means the entire model is based on transformers which is itself a deep learning model. Each output is well connected with each input in this deep learning model and weights are calculated dynamically according to the input-output connection. BERT has the capability of a Masked Language Model (MLM) where a word from the sentence is hidden at the training time and later

this model predicts the hidden word based on the context. BERT is dependent on the self-attention mechanism which is possible for the bidirectional transformers. The encoder and decoder are connected in the form of sequence to sequence model inside the transformer. The mathematical representation is-

$$Attention\,(A, B, C) = softmax\,(AB^T / \sqrt{d_b})\,C$$

A, B, and C are the embedding vector that is transformed by a weight matrix inside the transformer and training of transformers means finding weight matrices. The transformer model becomes a language model when weight matrices are learned. The BERT model contains a set of rules to represent the input text. Input text converts into the embedding parts which is a combination of three embeddings. According to Fig. 1, the token embeddings will be created from the tokenization of the input text. The segment embedding is needed to understand unique embedding from the given two sentences like "my baby is Autistic, she likes to play". The model can understand better the sentence to distinguish between them. The BERT model uses positional embedding which helps to understand the position of each word in a sentence. Summations of These three embeddings are representing the input inside the BERT model.

Fig. 1. Input text embedding in BERT model.

Fig, 2 of the Transformer architecture in [22] shows that it has two parts. The first part is Encoder and the second part is Decoder. After the conversion of input text to input embeddings, Encoder starts to handle input embeddings. The Encoder block contains two layers. The first layer is the Multi-Head Attention layer which is connected to the second layer named Feed Forward Neural Network. The encoder block encoded the data and sends it to the Decoder block where the Multi-Head Attention layer and Feed Forward Neural Network are connected but one extra layer is also connected which is Masked Multi-Head Attention. Different masked are handled by this layer. The proposed autism-related dataset has been applied in the BERT model to understand the sentence sentiment for identifying positive and negative symptoms of an autistic child.

The proposed system using the BERT model reads data from the proposed prepared dataset. Some NLP-related tasks have been done that are tokenization and embedding. The embedding and labeled data will be split for creation train and test data for the BERT model. The training data will be used for model training purposes as well as testing data will be used for the model performance purpose. The algorithm of the proposed system using BERT model has been given below:

Fig. 2. The architecture of the transformer [22].

*Proposed BERT Algorithm:*
*Pseudo Code:*
*Step 1: Read data from CSV file.*
   *Step 2: X=data from csv*

      $x_l = [a_1, a_2, a_3, a_4, a_5, \ldots \ldots a_n]$ *is a user text column inside the dataset.*

      $y_l = [r_1, r_2, r_3, r_4, r_5, \ldots \ldots r_n]$ *is a label data column inside the dataset*
*Step 3: BERT model name selection.*
*// Set BERT model name*
*MODEL_NAME = 'bert-base-cased'*
*// Build a BERT based tokenizer*
*tokenizer = BertTokenizer.from_pretrained(MODEL_NAME)*
*Step 4: Train and test data creation.*
*df_train, df_test = train_test_split(X, test_size=0.2, random_state=RANDOM_SEED)*
*df_val, df_test = train_test_split(df_test, test_size=0.5, random_state=RANDOM_SEED)*
*def create_data_loader(df, tokenizer, max_len, batch_size):*
  *ds = GPReviewDataset(*
    *reviews=df.Comments.to_numpy(),*
    *targets=df.Sentiment.to_numpy(),*
    *tokenizer=tokenizer,*
    *max_len=max_len*
  *)*
  *return DataLoader(*
    *ds,*
    *batch_size=batch_size,*
    *num_workers=0*
  *)*

*// Create train, test and val data loaders*
*BATCH_SIZE = 16*

```
train_data_loader = create_data_loader(df_train, tokenizer,
MAX_LEN, BATCH_SIZE)
val_data_loader = create_data_loader(df_val, tokenizer,
MAX_LEN, BATCH_SIZE)
test_data_loader = create_data_loader(df_test, tokenizer,
MAX_LEN, BATCH_SIZE)
```

*Step 5: Create BERT model for sentiment analysis.*
```
bert_model = BertModel.from_pretrained(MODEL_NAME)
```

```
# Build the Sentiment Classifier class
class SentimentClassifier(nn.Module):

   // Constructor class
   def __init__(self, n_classes):
      super(SentimentClassifier, self).__init__()
      self.bert = BertModel.from_pretrained(MODEL_NAME)
      self.drop = nn.Dropout(p=0.3)
      self.out     =      nn.Linear(self.bert.config.hidden_size,
n_classes)

   // Forward propagaion class
   def forward(self, input_ids, attention_mask):
      _, pooled_output = self.bert(
         input_ids=input_ids,
         attention_mask=attention_mask,
         return_dict=False

      )
      // dropout layer addition
      output = self.drop(pooled_output)
      return self.out(output)
```

```
// Instantiate the model and move to classifier
model = SentimentClassifier(len(class_names))
```

The result of this proposed algorithm has been discussed in the Result and Discussion section.

### C. ChatGPT (Large Language Model)

Today, ChatGPT has taken a very strong position to handle natural language processing tasks. ChatGPT model is an advancement of Large Language Model (LLM). ChatGPT model has been developed using reinforcement learning from human feedback (RLHF). RLHF is a reinforcement learning which is a machine learning algorithm where an agent learns everything from the environment using policy. According to Fig. 3, the agent may take action ($A_t$) according to the policy which affects the environment where the agent is present. According to Fig. 4, the agent may take action ($A_t$) according to the policy which affects the environment where the agent is present. According to this action taken, a new state ($S_t$) is generated and it returns a reward ($R_t$). Rewards are nothing but the feedback signals which indicated the reinforcement learning agent to tune action policy. In the next step, The RL agent modifies the policy to take sequences of actions when it goes through training episodes and as a result, it maximizes the rewards.

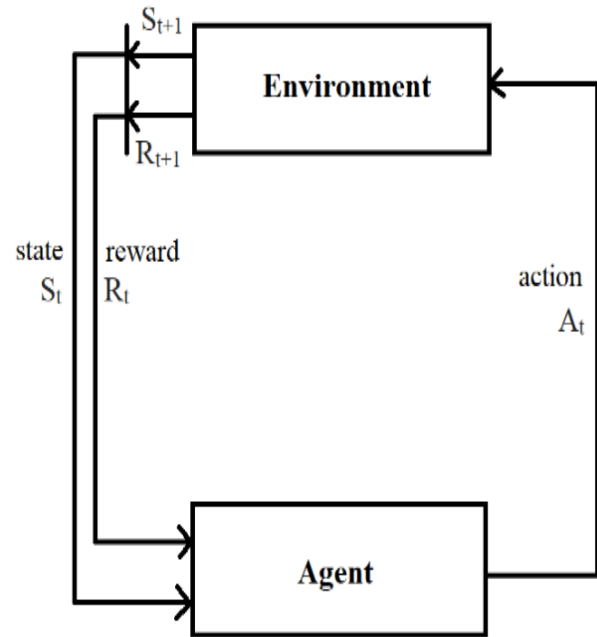

Fig. 3. Reinforcement learning basic diagram.

ChatGPT (GPT stands for Generative Pre-trained Transformer) is a large language model (LLM) developed by OpenAI. ChatGPT is trained on a massive amount of text and code data from the internet. The dataset includes text from books, articles, websites, and code from GitHub repositories. A brief description has been given according to Fig. 4.

*1)* The training process for ChatGPT involves several stages. First, the model is initialized with a data transformation stage where tokenization and vectorization methods are used to prepare text data for training. These are important steps because they help the ChatGPT model to understand the meaning of the text and generate text that is both coherent and grammatically correct.

*2)* The tokenization stage involves breaking down text into smaller units, called tokens. Tokens can be individual words, phrases, or even characters. The type of tokenization used for ChatGPT is called WordPiece tokenization. In this tokenization method text breaks down into tokens that are still meaningful, even if they are not individual words. For example, the word "running" would be broken down into the tokens "run" and "ing".

*3)* After completion of tokenization, it is converted into vectors. Vectors are mathematical objects that represent the meaning of a token. The vectors for each token are learned during the training process. The vectors are then used by the CHATGPT model to generate text, translate languages, and perform other tasks.

*4)* Once the text data is vectorized then, it is trained using a transformer Model (unsupervised learning) which is a neural network architecture that has been shown to be very effective for natural language processing tasks. It consists of encoder and decoder layers. The encoder layers take in a sequence of

text tokens and transform them into a sequence of hidden representations. The decoder layers then use these hidden representations to generate a new sequence of text tokens. to process the new sequence of text tokens distributed learning is a technique used. It involves splitting the model across multiple machines, each of which is responsible for training a subset of the model's parameters. This allows the model to be trained more quickly and efficiently than if it were trained on a single machine.

*5)* In distributed learning technique, two methods are involved, data parallelism and model parallelism. In data parallelism, the training data is split across the machines, and each machine trains its own copy of the model. In model parallelism, the model's parameters are split across the machines, and each machine trains its own subset of the parameters. ChatGPT used this distributed learning technic to train massive datasets of text and code, which allowed it to achieve the best performance on a variety of natural language processing tasks. It uses an Azure-based supercomputing platform to process the data and models.

*6)* After completion of model training, it can be fine-tuned for specific natural language processing tasks, such as language translation, text summarization, and question answering. Fine-tuning involves training the model on a smaller amount of task-specific data, which allows it to learn to perform the task more accurately and efficiently.

*7)* After completion of model training, it can be fine-tuned for specific natural language processing tasks, such as

language translation, text summarization, and question answering. Fine-tuning involves training the model on a smaller amount of task-specific data, which allows it to learn to perform the task more accurately and efficiently.

The Reinforcement learning from human feedback helps to enhance the training process of RL agents where humans are also included. An architectural diagram of LLM has been given in Fig. 5. According to Fig. 5, RLHF in language models consists in three phases where the first phase is related to the huge data training because LLM requires a huge amount of data to be trained. The LLM is pre-trained using unsupervised learning and it creates coherent outputs. Some of the output may be aligned or not aligned according to the goal of users. In the second phase, a reward model has been created where another LLM model uses the generated text from the main model to produce quality scores. The second LLM has been modified for scalar value instead of a sequence of text tokens. A dataset of LLM-generated text labeled will be generated for quality. A prompt will be given to the main LLM to generate several outputs. The human evaluator will intervene here to evaluate generated output on the basis of good and bad. In the third phase, the main LLM is an RL agent where it takes several prompts from a generated text and training set. The output of this LLM model is passed to the reward model that provides the score and aligns with the human evaluator. Finally reward model creates output according to the higher score. ChatGPT uses this RLHF framework to handle a large number of natural language queries. The engineers of OpenAI have modified the model for fine-tuning on pre-trained GPT-3.5.

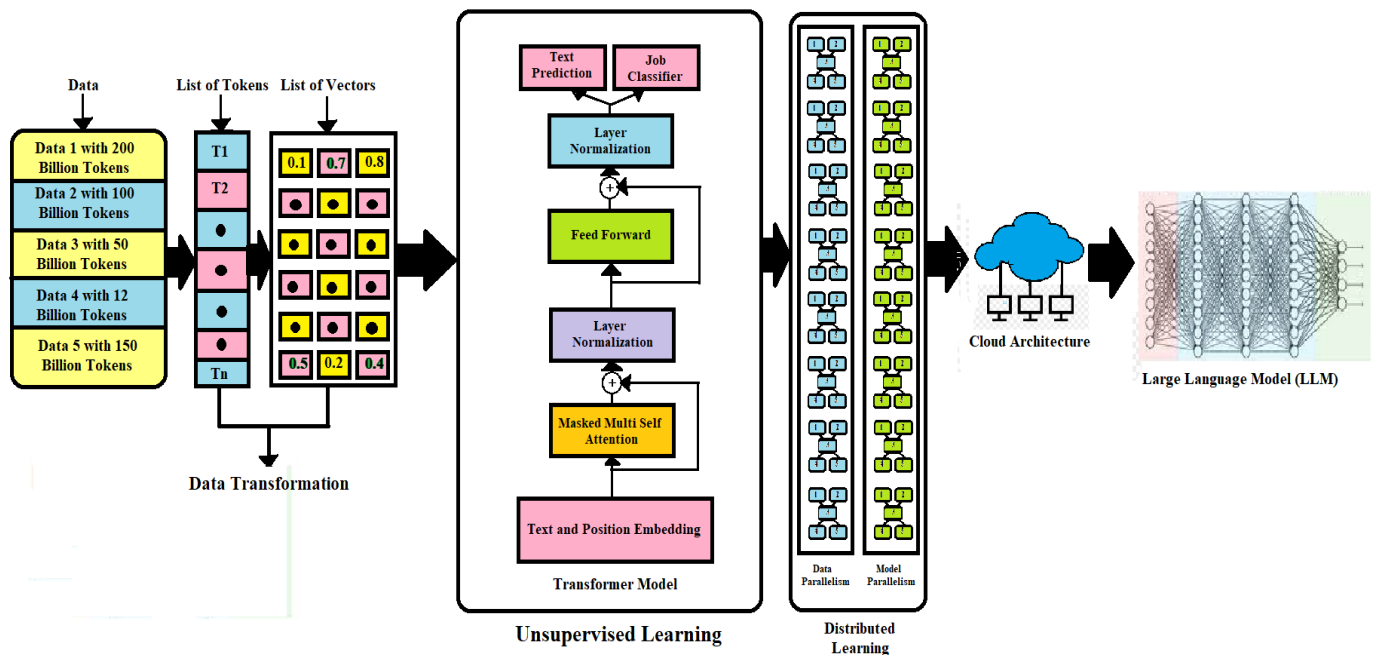

Fig. 4. ChatGPT model architecture.
Fig. 5. Large language model diagram.

Fig. 6. ChatGPT request-response basic diagram.

According to Fig. 6, the pre-trained ChatGPT model accepts example data to understand the structure of the data. The dataset is containing structured data. ChatGPT needs example structured data to understand the pattern for response

generation but there is a limitation of sending example data to the ChatGPT. ChatGPT reads data as a token and within this token limitation example data has to be sent. Now, ChatGPT is ready to generate responses to new requests. The algorithm of the proposed sentiment analysis using the ChatGPT model has been described below.

*Proposed ChatGPT algorithm:*
*Pseudo code:*
*Step 1: Initialize API key in a variable*
*import openai as ai*
*ai.api_key='API_Key'*
*Step 2: Initialize the data as text in a variable*
*text1='''Comments*
*Sentiment*
*How does speech therapy help with a nonverbal to speak*
     *1*
*because all they do there is play with toys with him every time*
     *0*
*I'm confused guys help my son is 3years old now*
*0*
*he does is mumbles only no proper words*
*1*
*but he goes to speech therapy every month*
*1*
*Does it help*
*0*
*Step 3: Define the ChatGPT model inside method:*
*def generate_gpt3_response(user_text, print_output=False):*
    *completions = ai.Completion.create(model='text-davinci-003',   #davinci:ft-personal-2023-02-02-06-04-19',*
    *temperature=0.5,*
    *prompt=user_text,*
    *max_tokens=100,*
     *n=1,*
    *stop=[" Human:", " AI:"],*
 *)*

  *// Displaying the output can be helpful if things go wrong*
  *if print_output:*
    *print(completions)*
  *// Return the first choice's text*
  *return completions.choices[0].text*

*Step 4: Call the method to identify the sentiment of the sentence.*
*text2="My baby is not responding and his eye contact is very low."*
*text3=text1+" "+text4+" "+text2*
*#result=generate_gpt3_response()*
*result=generate_gpt3_response(text3)*
*print(result)*

### D. Proposed System Architecture

According to Fig. 7, a general architecture has been given where each model is associated with the BERT cosine similarity model. The working flow of BERT and ChatGPT has been given below.
Fig. 7.  General flow of proposed system architecture.

Below is the algorithm summarizing the steps:

*1)* Select positive sentences from the input text.

*2)* Apply the BERT Cosine Similarity Model.

*3)* Calculate the cosine similarity between the input sentence and each positive sentence from the ASD symptoms dataset.

*4)* Select the sentence with the highest cosine similarity score.

*5)* Retrieve the label associated with the selected sentence from Table IV, indicating the corresponding ASD problem.

By utilizing the BERT Cosine Similarity Model and leveraging the labels from Table IV, the proposed system can effectively identify ASD problems based on the similarity between input sentences and the ASD symptoms dataset.

*The Algorithm in Python pseudo-code:*
*from sentence_transformers import SentenceTransformer, util*
*import pandas as pd*
*import pandasql as ps*

## IV. RESULTS AND DISCUSSION

### A. Result and Discussion of BERT Model

*1) Result*: The BERT model has been evaluated using some popular metrics like F1, Precision, Recall, Support, etc. The proposed research uses the BERT model as the binary classifier that will detect the sentences as positive or negative regarding ASD symptoms detection. The report of this binary classification has been given in Table III. But, before understanding the classification report, the confusion matrix of this proposed BERT model has been elaborated for a better clear view of this model.

Fig. 8. Confusion matrix of proposed BERT model.

*2) Discussion*: According to Fig. 8. The proposed confusion matrix has two axes. The Y-axis is a true sentiment and X-axis is a predicted sentiment. True sentiment has both values positive and negative whereas predicted sentiment has the same positive and negative values. The number of sentences is 11 which are true positive sentiments but predicted as negative. In the next step, the number of true

positives is 29 and the model has predicted it as true. According to Fig. 7, true negative sentences are 41, and the proposed model has predicted these sentences as negatives whereas six true negative sentences have been predicted by this proposed model as positives. The number of correct predictions according to the true sentiment is greater than wrong predictions. The F1 score, Precision, Recall, and Support have been given in Fig. 8.

The F1 score is an important metric for the evaluation of machine-learning models. The F1 score will be calculated by the combination of Precision and the Recall value. The equation of the F1 score calculation has been given here.

$$F1 = (2 * (Precision * Recall)) / (Precision + Recall)$$

The Precision can be calculated using this formula where the number of True Positives (TP) is divided by the Total Number of True Positives (TP) and False Positives.

$$Precision = (TP / (TP+FP))$$

The Recall can be formulated by the number of True Positives (TP) divided by the total number of True Positives (TP) and False Negatives (FN).

$$Recall = (TP / (TP+FN))$$

The macro average computes the arithmetic mean according to the class. It is a straightforward average calculation method where the weighted average method refers to the proportion of each class support that is related to the sum of all support values. The count of correct occurrences of the class in the proposed dataset is called support. The imbalance support indicates the low scores of the report then the classification model can be remodified again.

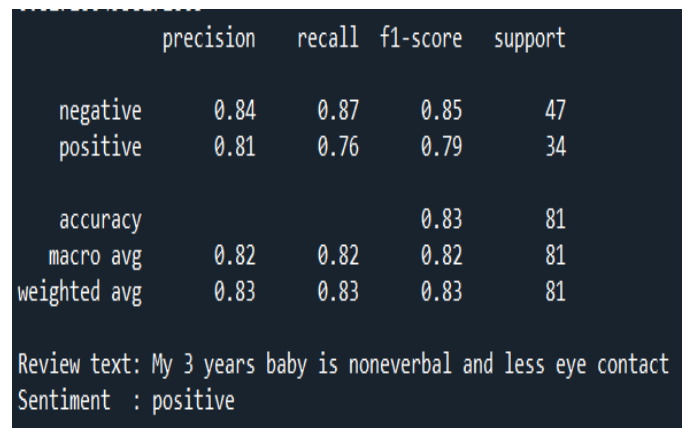

Fig. 9. Classification report of proposed BERT model.

Fig. 9 shows the classification report of the proposed BERT model where precision and recall values of negative and positive classes are 0.84, 0.87, 081, and 0.76 with support values 47 and 34. The F1 score of the negative and positive classes are 0.85 and 0.79. The accuracy of the proposed model is 0.83 (83%) according to the F1 score with 81 support values. The precision and recall values of macro and weighted averages are 0.82, 0.82, 0.83, and 0.83 where f1 scores are 0.82 and 0.83 with support values 81 and 81. An example

sentence has been sent to the proposed BERT model for sentiment prediction.

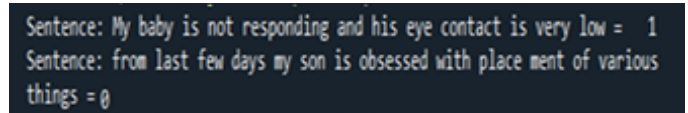
Review text: "My 3 years baby is nonverbal and less eye contact"

This sentence directly indicates the positive sentence of ASD symptoms because ASD children are nonverbal and have less eye contact. The predicted result can be seen in Fig. 9 as "Sentiment: positive".

### B. Result and Discussion of ChatGPT Model

*1) Result*: A pre-trained ChatGPT model has been used where the base model is 'text-davinci-003' which is a very powerful base language model in ChatGPT. Author Junjie Ye and et.al. described 'text-davinci-300' language model performance on various datasets. The classification report on 'text-davinci-300' language model has been elaborated in detail. The GPT series models like GPT-3, CodeX, InstructGPT, and ChatGPT have been considered to evaluate the performance on nine natural language understanding (NLU) tasks using 21 datasets as in [23]. The base models have been used to train their datasts. OpenAI has given the opportunity to train their base modeel on a particular dataset where each dataset has to be designed according to their dataset standard. However, the concern is that the base model is not fine-tuned as a ChatGPT pre-trained model. An API key is needed to use base ChatGPT base models and fine-tuned pre-trained base models. The fine-tuned pre-trained model has been considered in this research to utilize the advantages of fine-tuning and pre-trained. The main advantage is the accuracy of the prediction of the sentences regarding ASD symptoms.

The following code will show the initialization part of the fine-tuned pre-trained "text-davinci-003" base model of ChatGPT.

```
def generate_gpt3_response(user_text, print_output=False):
    completions = ai.Completion.create(model='text-davinci-003',    #davinci:ft-personal-2023-02-02-06-04-19',
    temperature=0.5,
    prompt=user_text,
    max_tokens=100,
        n=1,
    stop=[" Human:", " AI:"],
    )
```


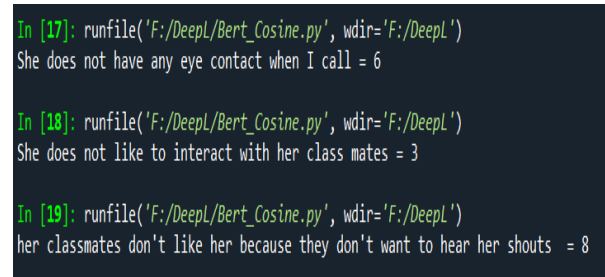
*2) Discussion*: The output from the proposed ChatGPT model according to the new parent's dialogues is good. An example sentence with sentiment value has to be sent to the ChatGPT model then it can understand the pattern and according to the pattern, it will start prediction according to the defined RLHF algorithm.

The output can be seen from the given Fig. 10 on sentences of parents' dialogues. The sentences are-

*a)* "*My* baby is not responding and his eye contact is very low."

*b)* "*from* last few days my son is obsessed with the placement of various things"

The first sentence is 1 means positive according to ASD symptoms whereas the second sentence is negative and ChatGPT returns 0.



```
Sentence: My baby is not responding and his eye contact is very low = 1
Sentence: from last few days my son is obsessed with place ment of various things = 0
```

Fig. 10. Output of the proposed ChatGPT model.

### C. Result and Discussion of BERT Cosine Model

*1) Result*: The proposed cosine similarity model is responsible for identifying ASD symptoms from positive ASD sentences that have been predicted by the machine learning algorithms. The model's output is depicted in Fig. 11, where the sentence " She does not have any eye contact when I call" is labeled with 6.

```
In [17]: runfile('F:/DeepL/Bert_Cosine.py', wdir='F:/DeepL')
She does not have any eye contact when I call = 6

In [18]: runfile('F:/DeepL/Bert_Cosine.py', wdir='F:/DeepL')
She does not like to interact with her class mates = 3

In [19]: runfile('F:/DeepL/Bert_Cosine.py', wdir='F:/DeepL')
her classmates don't like her because they don't want to hear her shouts  = 8
```

Fig. 11. Example output result of BERT cosine similarity.

*2) Discussion*: Similarly, the sentences " She does not like to interact with her classmates" and " her classmates don't like her because they don't want to hear her shouts" are labeled with 3 and 8, respectively. Referring to Table IV, we can determine that label 6 corresponds to Eye Contact problems, label 3 indicates Behaviour problems, and label 8 represents hyperactive problems. These labels provide insight into the specific ASD problems associated with the detected symptoms. Upon identifying the ASD problems, appropriate therapies can be initiated based on the specific problem identified. Tailoring the interventions according to the detected problems is crucial in providing targeted support to individuals with ASD. These targeted therapies have the potential to significantly reduce the symptoms associated with ASD and improve overall well-being. The ability of the proposed system to accurately identify ASD problems through the analysis of positive sentences enables a more focused and tailored approach to therapeutic interventions. This personalized approach holds great promise in positively impacting individuals with ASD and enhancing their quality of life. By leveraging the system's ability to identify ASD problems accurately, individuals with ASD can receive more effective and personalized support, leading to improved outcomes and overall well-being.

## V.  LIMITATION

The proposed system leverages both transformer-based and LLM-based machine learning models to enhance its performance. Quantum machine learning models can be employed to improve accuracy by applying them to a large dataset. Additionally, collecting more data, especially accurate ASD-related parent dialogs, can significantly enhance the training and testing scores of the models. According to the language model, it has been observed that they are not very efficient in calculations like aggregation-type natural language response generation. As an example, ChatGPT is not able to do the right calculation of the sum of multiple float values at a time. This is the main limitation of language models. It is vital to ensure that all components of the system are functioning properly for the cosine similarity part to work effectively. Any issues or malfunctions in the system's components can impact the performance of the cosine similarity model, as it relies on accurate processing and selection of positive sentences.

## VI.  CONCLUSION

The proposed system is designed to process natural language text extracted from parents' dialogues to detect ASD symptoms. It utilizes sentiment analysis techniques to determine whether a sentence expresses positive or negative sentiments regarding ASD symptoms. To accomplish this task, the system employs BERT and ChatGPT models that have been trained on the provided dataset. After performing sentiment analysis, the system selects only the positive sentences for further analysis using the cosine similarity model. The system utilizes an ASD symptoms dataset, where each sentence is labeled with a value corresponding to a specific ASD symptom. By calculating the cosine similarity between the input sentence and each sentence in the ASD symptoms dataset, the system identifies the label value of the sentence with the highest similarity score. This label value indicates the specific ASD problem associated with the input sentence. One significant advantage of the proposed system is that it relies solely on text-based analysis. By leveraging text-based analysis and prioritizing affordability and accessibility, the proposed system has the potential to facilitate ASD detection and support in underserved regions, thus bridging the gap in ASD diagnosis and intervention.

## FUTURE WORK

To further enhance the output and accuracy of the proposed the provided dataset can be a valuable approach. This model can leverage the dataset to make predictions and improve the system's performance. By incorporating these models into the system and training them using the proposed dataset for ASD detection, the system can benefit from their advanced techniques and potentially achieve superior results. However, it is important to consider that transformer-based and LLM-based models like BERT and ChatGPT may not perform optimally when dealing with aggregation-type sentences. Therefore, it is crucial to carefully assess the sentences in the dataset and choose appropriate models accordingly. In summary, training the Quantum machine learning models using the proposed dataset for ASD detection represents a promising future development for the system.

AUTHORS' PROFILE

Prasenjit Mukherjee has 14 years of experience in academics and industry. He completed his Ph.D. in Computer Science and Engineering in the area of Natural Language Processing from the National Institute of Technology (NIT), Durgapur, India under the Visvesvaraya PhD Scheme from 2015 to 2020. Presently, He is working as a Data Scientist at Vodafone Intelligent Solutions, Pune, Maharashtra, India, and doing his Post Doctoral (D.Sc.) in Computer Science from Manipur International University, Imphal, Manipur, India.

Gokul R S, a senior data scientist with over six years of experience in leading and executing data-driven projects for various domains. He is currently working as a deputy manager in Vodafone Intelligent Solutions, Pune in the area of Artificial Intelligence and Analytics. He received a B.Tech degree from Visvesvaraya Technological University, Karnataka. His research areas of interest include AI automation, machine learning, natural language processing, computer vision, and big data, prompt engineering, Quantum technologies, etc.
Sourav Sadhukhan has above 5 years of experience in Law and Management. He completed his Graduation in LLB from Calcutta University, Kolkata, India, and Post Graduate Diploma in Management from Pune Institute of Business Management, Pune, India. Presently he is a student of Executive Post Graduation in Data Science and Analytics from the Indian Institute of Management, Amritsar, India.

Dr. Manish Godse has 27 years of experience in academics and industry. He holds Ph.D. from Indian Institute of Technology, Bombay (IITB). He is currently working as an IT Consultant in the Bizamica Software, Pune in the area of Artificial Intelligence and Analytics. His research areas of interest include automation, machine learning, natural language processing and business analytics. He has multiple research papers indexed at IEEE, ELSEVIER, etc.

Dr. Baisakhi Chakraborty received the PhD. degree in 2011 from National Institute of Technology, Durgapur, India in Computer Science and Engineering. Her research interest includes knowledge systems, knowledge engineering and management, database systems, data mining, natural language processing, and software engineering. She has several research scholars under her guidance. She has more than 60 international publications. She has a decade of industrial and 22 years of academic experience.

# Optimizing Power Management in Distribution Networks: A Mathematical Modeling Approach for Coordinated Directional Over-Current Relay Control

Simardeep Kaur[1], Shimpy Ralhan[2], Mangal Singh[3], Mahesh Singh[4]

Department of EE, Shri Shankaracharya Technical Campus, Bhilai, Chhattisgarh, India[1, 2, 4]

Department of E&TC, Symbiosis Institute Technology, Symbiosis International (Deemed University), Pune, Maharashtra, India[3]

*Abstract*—Optimizing Power Management in Distribution Networks through Coordination of Directional Over-Current Relays summarizes a study or project focused on enhancing the management of power in distribution networks by optimizing the coordination of directional over-current relays. Directional over-current relays are critical components of power distribution systems, designed to safeguard the network against over-current faults while maintaining operational stability. Proper coordination of these relays is vital to ensure that faults are isolated and cleared efficiently without causing extensive disruptions. In this paper, a mathematical modeling approach is employed to address the optimization of power management in distribution networks. This approach likely encompasses the development of mathematical models and algorithms that consider factors such as fault types, fault locations, network topology, and relay settings to improve the coordination of directional over-current relays. Here, different optimization algorithms have been implemented to optimize the operating time of relays & hence power management. Cuckoo Search Algorithm (CSA), Fire-Fly Algorithm (FFA), Harmony Search Algorithm (HSA), and Jaya Algorithm are employed to solve the coordination problem for directional over-current relays (DOCRs) with different test systems. The outcomes of this research may have practical applications in power distribution systems, potentially leading to more resilient and responsive networks that better manage power distribution and reduce disruptions during faults and outages.

*Keywords—Optimization; Cuckoo Search Algorithm (CSA); Fire-Fly Algorithm (FFA); Harmony Search Algorithm (HSA); Jaya algorithm; directional over-current relays*

## I. INTRODUCTION

The duty of protective systems is to detect fault and remove it from the power network. In all the processes, the time of operation plays an important role. The accuracy and reducing the execution time of the protective relay is the challenging part of the optimization algorithm. The most important elements that are used in power system for protection are distance relays and overcurrent relays. For protection of power system elements, protection scheme with primary and back up protection are used. In any power system, primary protective relays must function at the instant of fault occurrence to remove the faulty section; at the condition, whenever the primary protective relay is unable to perform, then the backup protective relay is supposed to operate. It should operate after a certain period of time for protection of power system from

damage. The over-current protection relays are the frequently usable protection devices in the power system networks. For backup protection too, over-current relays are mostly used. But, the only protection scheme which provides the control to the power outages in some cases is the overcurrent protection. Unwanted relay tripping as a mal-operation for the backup protection relays has to be avoided. This is the major reason that over-current relay coordination in power system network is a major concern in protection system [1]. In the ring main distribution system for the management of power, the over-current relay coordination is a complex optimization problem with large number of constraints. The purpose is to find the minimum time of operation of primary relays as well as backup relays. It is to be noted that the mal-operation of relays is neglected during optimization. This results in making the problem more complex due to high number of constraints in modern day complex interconnected networks.

The optimum and accurate coordination of relays is necessary to recognize the fault efficiently within sort of time, to avoid possible outages and remove them from the power system network due to fault. The relay coordination problem is one of the most critical optimization problem because of large number of nonlinear constraints.

The motivation for this research stems from the growing importance of a robust, reliable, and efficient power distribution system. Modern society's increasing dependence on electricity, coupled with the advent of renewable energy sources, places new demands on distribution networks. The coordination of directional over-current relays becomes a vital consideration in ensuring that these networks can adapt to evolving conditions while continuing to provide a seamless power supply. Moreover, economic considerations drive utilities and power system operators to minimize downtime, reduce maintenance costs, and make efficient use of available resources. The potential benefits of an optimized relay coordination system are, therefore, multi-faceted, encompassing improvements in network resilience, safety, and cost-effectiveness.

Optimizing power management in distribution networks through the coordination of directional over-current relays offers a host of significant benefits. It enhances the overall reliability of power distribution, reducing service interruptions and downtime, which, in turn, leads to increased customer satisfaction and minimized economic losses. This optimization

also contributes to greater safety by swiftly isolating faults and preventing potential hazards. Furthermore, it enables utilities to operate more efficiently, saving on maintenance costs and utilizing network resources effectively. With a more resilient and responsive grid, integration of renewable energy sources becomes smoother, reducing environmental impact. In summary, the benefits encompass improved reliability, reduced downtime, enhanced safety, cost savings, efficient resource utilization, and environmentally responsible power management, ultimately fostering a more dependable and sustainable energy distribution infrastructure.

Power distribution networks play a pivotal role in ensuring a consistent and reliable supply of electricity, making the coordination of directional over-current relays a crucial aspect of network management. The literature on optimizing power management through relay coordination reveals a growing body of research aimed at enhancing the performance of distribution systems. S. S. Gokhale et al [2] have discussed about the relay coordination and the importance of the optimization of relay operating time. The phenomenon of Cuckoo search algorithm has been discussed and applied to optimize the operating time of relays. Single end fed network power system with six overcurrent protective relays is considered as a test system for relay coordination problem. Chabanloo et al [3] have discussed the modified objective function and various characteristics of overcurrent relay and distance protection has been studied. The application of genetic algorithm, in order to solve optimization problem has been discussed. Mousavi et al [4] have discussed about the objective function minimization with constraints in this article. Constraints always affect the results and the operation time of the algorithm. The handling of constraints would be different for different optimization algorithms. Jagdish Madhukar Ghogare et al [5] have discussed radial and loop system coordinates with genetic algorithm. The different operators of genetic algorithm along with case study of symmetrical and unsymmetrical information set has been implemented. The relay coordination problem identification with their constraints has been studied and calculated for ten relay test system. Divya S Nair et al [6] have briefly discussed about the protective system and use of appropriate protective relays to protect the power system elements. The calculation of constraints and objective function parameters has been discussed with the help of fourteen relay system. The system is further optimized with genetic algorithm. The effect of relay operation time with different fault condition has shown in this paper. Abdul Wadood et al [7] have used the root tree algorithm (RTO), inspired by the random movement of roots, to search for the global optimum, in order to best solve the problem of overcurrent relays (OCRs). C.A. Castillo et al [8] have proposed the invasive weed optimization for the relays with non-standardized inverse time curves for improving overcurrent relay coordination performance. The model and implementation of optimization algorithm for coordination must be capable of handling increased problem dimension and constraints. Zahra MORAVEJ et al [9] have implemented the grey wolf optimizer algorithm and it has been used as an optimization tool to find optimum settings. Ahmed Korashy et al [10] have proposed a modified version for Water Cycle

Algorithm (WCA), referred to as MWCA to effectively solve the optimal coordination problem of DOCRs. In the proposed technique, the search space has been reduced by increasing the C-value of traditional WCA, which effects on the balance between explorative and exploitative phases, gradually during the iterative process in order to find the global minimum.

The metaheuristic techniques are used on a daily basis for industrial planning, resource allocation, econometrics problems, scheduling, decision making engineering, and computer science applications. In this work, we have dealt with the comparative study of the different optimization techniques; namely, Cuckoo Search Algorithm, Firefly Algorithm, Harmony search algorithm and Jaya algorithm. These methodologies are applied for the coordination of directional overcurrent protective relays. The results obtained are validated when they accomplish all the constraints. The equality and inequality constraints show the coordination boundary for each and every primary and backup relay pair; which are having fault very near to the primary protective relays. The number of constraints will lead to an increase in the processing time of optimization process of any algorithm. For the small systems, it will take less time to get the optimum result, but in case of large systems, the number of constraints will increase leading to a large time for processing. If we reduce the constraints by neglecting them, the problem under consideration will not offer the appropriate results. For best results, the optimized value should follow the constraints religiously. Optimizing power management through the coordination of directional over-current relays brings about numerous implications, from immediate improvements in grid reliability and safety to longer-term economic benefits and environmental sustainability. These implications not only enhance the performance of power distribution networks but also contribute to the broader goals of energy sector efficiency, safety, and environmental responsibility.

Our paper is structured as follows: Section II highlights the basic function of relays and relay coordination in radial and ring main feeder system. Section III elaborates about the objective function and their constraints. Jaya algorithm is presented in Section IV, whereas, the different case studies have been discussed for different optimization algorithm and are presented in Section V along with the comparison of optimum results and their discussion with proposed Jaya algorithm. At last, Section VI provides the conclusion and remarks.

## II. DIRECTIONAL OVERCURRENT RELAY IN DISTRIBUTION NETWORK

Directional Overcurrent Relays are devices which provide the protection against the interruption of the healthy supply system from the unhealthy fault situations. In the electrical power system, the coordination is the major factor because the devices are interconnected. Therefore, when fault occurs at certain point, it will definitely affect the entire system and can lead to major damage in the system. The solution of such a problem is solved by the coordination of relays. The least operating time can be achieved by using the optimization tools.

## A. Coordination of Relays

Relay coordination is essential part of any protection system. When any network is protected with the distance relays, main and backup relay pairs are provided for each line. By arranging the overcurrent relays and distance relays, protection of lines gets expanded for better protection. If any disturbance occurs, at first, the primary distance (main) relay actuates. After that the overcurrent relay will be actuated. If this is unable to clear the fault, at a prior time and fails to actuate for any reason, distance relays will operate [11]. And, if it is also fails to operate, the backup protective overcurrent relay must immediately detach the faulty section from the network. As elaborated in Fig. 1 and Fig. 2, two constraints have to be added for coordination problems, as in (1) and (2) to create the sequential protection.

$$t_b\left(F_3\right) - t_{z2} \geq CI' \tag{1}$$

$$t_{z2} - t_m\left(F_4\right) \geq CI' \tag{2}$$

Fig. 1.   Coordination of overcurrent relays.

Fig. 2.   Distance and overcurrent relay coordination.

Where, $t_m$ is overcurrent relay operating time and the operating time of second zone protective relay is$t_{z2}$. At this condition when there is a new time interval for coordination (CI'); it should be defined between distance relays and overcurrent relays (not be the similar value as CI). This is used to establish the coordination of protective relay pairs

## B. Over-current Relays Coordination in Radial Feeder System

Whenever the fault occurs, it is detected by both primary protective relays and backup protective relays. The operating time of relays, i.e., primary and back up is different, since the primary protective relay operating time is less than the backup protective relays, the primary protective relay will operate first. There is a radial distribution feeder system with two relays as depicted in Fig. 3. When fault occurs at point labeled as F, the

relay $R_B$ will operate first. Assuming the relay tripping time of relay $R_B$ is set to 0.2 seconds, the relay $R_A$ should operate after 0.2 sec plus CI. If the backup protective relay activates before the time of working of primary relay, it is called mal-operation [3].

Fig. 3.   Simple radial feeder network.

## C. Coordination of Over-Current Protective Relay in Ring Main Feeder Distribution System

It is essential to maintain the selectivity and sensitivity of protective devices at point A and B. The test system is presented in Fig. 4, which allows to maintain the supply to all connected loads at the condition of fault on any of the part of network and keeps the supply continuous [12]. Here, relay 1, and relay 8 are non-directional relays, apart from those, remaining relays are directional over-current relays (relay 2, 3, 4, 5, 6, and 7). All the directional relays are having their direction of tripping, which are away from the connected bus, shown in Fig. 4.

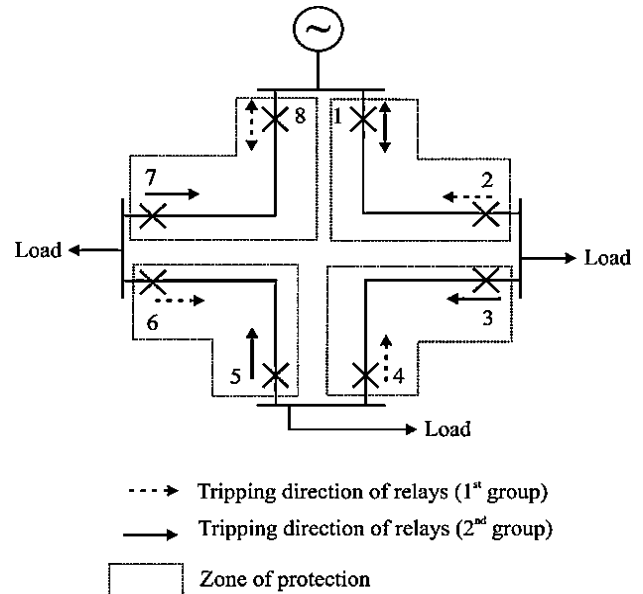

Fig. 4.   A simple ring main feeder network (relay1 & 8 are non-directional and remaining relays are directional).

For the purpose of relay coordination, relay number 2, 4, 6, and 8 will make a group. Similarly, relay numbers 1, 3, 5, and 7 will form another group. Relay coordination has to be established from the relay 2, for group one.

The relay operating times has to take as $T_{R8} > T_{R6} > T_{R4} > T_{R2}$ for group one. Similarly, for group two, the relay setting initiates from relay 7. Operating time of relay has to take as $T_{R1} > T_{R3} > T_{R5} > T_{R7}$ for group two. The real operation time of relays has a constrained problem. The operating time should follow all the constraints for better

selectivity and sensitivity of relay coordination. Since the size and complexity of the power system network goes on increasing, the number of constraints will increase and it becomes more complex problem to coordinate the relays.

### III. RELAY COORDINATION OPTIMIZATION PROBLEM

The ideal characteristics for IDMT relay shows that the operating time is inversely proportional to the fault current. Hence, overcurrent relay will operate fast after sensing a very large amount of current. However, IDMT relays are categorized into three types: standard inverse, extremely inverse and very inverse types. Relay characteristics depends on the type of standards selected for its operation. This can be defined by user or set by the ANSI, IEEE, IEC standards. Overcurrent relays are generally used for protection against inter phase faults and line to ground faults [13]. The operating time of the relay tracks the time over current curve, where the time delay be influenced by the value of current. There are two decisive factors, TDS and Plug Setting. The tripping time of the relay is closely related to TDS, plug setting and the fault current ($I_f$). The total operating time is given by a non-linear mathematical expression in (3) with respect to the constraint.

$$T = \frac{\alpha \times TDS}{\left(\dfrac{I_f}{PS \times CT_{pr}}\right)^{\beta}} - \gamma \tag{3}$$

$\alpha, \beta$ and $\gamma$ are constants. According to IEEE standards [14], the values of these constants are given by 0.14, 0.02 and 1.0, respectively. $I_f$ is the fault current at the primary terminal of current transformer (CT), where the fault occurs. $CT_{pr}$ represents the primary of CT. The ratio between $I_f$ and $CT_{pr}$ provides the current sensed by the protective relay denoted by $I_{relay}$ shown in (4).

$$I_{relay} = \frac{I_f}{CT_{pr}} \tag{4}$$

#### A. Relay Coordination Objective Function

The objective function is stated as the sum of operating times of all the primary relays expressed in terms of the product of Time dial setting (TDS) for each relay which is to be minimized, and a constant which is a function of ratio of fault current and pick up values of current. The inequality constraints framed according to close in fault and far end fault have the proper coordination margin for each primary/backup relay pair for a fault very close to relay pair.

To obtain the parameters of TMS and set $I_{set_i}$, the objective function and constraints of the problem is defined in (5) and (6) is given by

$$\text{Minimize}: \sum_{i=1}^{n} t_{op} \tag{5}$$

$$t_{op} = \left(TSM_i, I_{set_i}\right) = \frac{3TMS_i}{\log\left(\dfrac{I_{sc_i}}{I_{set_i}}\right)} \tag{6}$$

where n is the total number of protective relays,

$t_{op}$ is the operating time of $i_{th}$ relays,

*TSM* is the Time Setting Multiplier,

$I_{sc_i}$ is the short circuit current,

$I_{set_i}$ is the pre-fault current.

As in Fig. 5, a near end fault is a fault that occurs close to the relay and a far end fault is a fault that occurs at the other end of the line [15]. In directional over-current relays, the magnitude of the fault currents detected at different locations will be different. In Fig. 5, a radial feeder is shown which the simplest distribution system employing directional overcurrent relays R_primary and R_backup. Here, R_primary is the primary relay for the near end fault and R_backup is the backup relay for the same fault. The operating time of primary relay is T_primary for near-end fault and operating time of backup relay is T_backup which is greater than T_primary. Thus, the operating time of the backup protection should be equal to the operating time of primary protection plus the operating time of the primary circuit breaker.

Fig. 5. Near end and far end faults for primary relay.

In coordination studies, the sum of the tripping times of all the primary protective relays to clear a near or far end fault can be considered as an objective function that is to be reduced. Therefore, the objective function to minimize (Z) can be expressed as given in (7).

$$\text{Minimize } Z = \Sigma_{i=1}^{N} T_{pri}^{i} + \Sigma_{j=1}^{M} T_{pri}^{j} \tag{7}$$

$$\text{where, } T_{pri}^{i} = \frac{0.14 \times TDS^{i}}{\left(\dfrac{I_F^{i}}{\left(PS^{i}\right) \times CT_{pr}^{i}}\right)^{0.02} - 1} \tag{8}$$

$$T_{pri}^{j} = \frac{0.14 \times TDS^{j}}{\left(\dfrac{I_F^{j}}{\left(PS^{j}\right) \times CT_{pr}^{j}}\right)^{0.02} - 1} \tag{9}$$

$$i = 1, 2, 3 \dots N; j = 1, 2, 3 \dots n$$

where $T_{pri}$ is operating time of the primary relay; $CT_{pr}$ is the primary of CT and *TDS* is for Time Dial Setting for relay.

The essential constraints for optimization of relay coordination problem are given as in (10) and (11).

$$TSM_{\min i} \leq TSM_i \leq TSM_{\max i} \tag{10}$$

$$I^{Max}_{load_i} < I_{set_i} < I^{Min}_{fault_i} \tag{11}$$

The selection of TSM is used for each pair of main and backup relay (*m, b*). It is also used for errors regarding to zone of protection $z_m$. The failures are identified at the fault points. The operating time constraints give the range of operation of relays. The maximum and minimum value of fault current defines the pickup value of an overcurrent relay [16].

### B. Constraints of Relay Coordination

Three constraints are considered for the minimization problem. The first constraint is TDS of the relay, which is the delay in time. Earlier the relay get operates each and every time the fault current becomes equal to or above the Plug Settings of relay (12).

$$TDS^i_{\min} \leq TDS^i \leq TDS^i_{\max} \tag{12}$$

*i* varies between 1 and $N_i$. $TDS^i_{\min}$ and $TDS^i_{\max}$ are the limits between minimum and maximum value of TDS allowed, which are 0.05 and 1.10 sec, respectively. The second constraint concerning PS takes the form (13).

$$PS^i_{\min} \leq PS^i \leq PS^i_{\max} \tag{13}$$

where *i* varies between 1 and $N_j$. $PS^i_{\min}$ and $PS^i_{\max}$ are the minimum limits and maximum limits of PS which are 1.25 and 1.50, respectively. Relay coordination functioning time is related to the fault current which can be seen by the protective relays and the pickup current setting. Relay functioning time is also depends on the category of the relay and it can be determined by standard characteristic curves of the relay or mathematical formula [2]. Hence, the relay operating time is defined by (14).

$$T^i_{\min} \leq T^i \leq T^i_{\max} \tag{14}$$

$T^i_{\min}$ is the minimum value and $T^i_{\max}$ is the maximum values for the relay operating time, which are 0.05 and 1.00, respectively. The organization time interval between the primary protective relays and the backup protective relays essentially verified during the optimization procedure. The coordination constraint between the primary and backup protective relays for relay coordination is given as (15).

$$T_{backup} - T_{primary} \geq CTI \tag{15}$$

where $T_{primary}$ is the functioning time of primary protective relays and $T_{backup}$ is functioning time of backup protective relays. The minimum coordination time interval is shown by $CTI$. For electromechanical type of relays, $CTI$ varies between 0.30 sec and 0.40 sec. Similarly, for numerical relays, the value lie $CTI$ varies between 0.10 sec and 0.20 sec. The

value of $T_{backup}$ and $T_{primary}$ can be determined by (16) and (17), respectively.

$$T^i_{backup} = \frac{0.14 \times TDS^x}{\left(\frac{I^i_F}{\left(PS^x\right) \times CT^i_{pr}}\right)^{0.02} - 1} \tag{16}$$

$$T^i_{primary} = \frac{0.14 \times TDS^y}{\left(\frac{I^i_F}{\left(PS^y\right) \times CT^i_{pr}}\right)^{0.02} - 1} \tag{17}$$

where $T^i_{backup}$ is actuating time of the backup relay; $T^i_{primary}$ is actuating time of the primary relay; is the primary of CT and $TDS$ is for Time Dial Setting for relay.

## IV. JAYA ALGORITHM

The Jaya algorithm, proposed by Venkata Rao [17], is a global search-based population method. This algorithm is based on the concept that it always tries to reach the best solution and to avoid failure solutions. Moreover, it is easy to implement as it requires only common controlling parameters (population size and number of generations). The algorithms which fall under the category of evolutionary and swarm intelligence require proper tuning of specific parameters which are related to algorithm in addition to tuning of common controlling parameters. A change in the tuning of the algorithm specific parameters influences the effectiveness of the algorithm. The Jaya algorithm does not require any algorithm specific parameters and it only requires the tuning of the common controlling parameters for its working.

Step I: Declare all the design variables of the objective function. In the search space, generate the population size (N) which is random. Each variable in the population generated is a vector and there are n number of design variables and is given by (18)

$$x_{j=}x_{j,i}(l) + rand[0,1] \times \left(x_{j,i}(u) - x_{j,i}(l)\right) \tag{18}$$

$$i = 1,2,3\ldots.N; j = 1,2,3\ldots.n$$

Where $x_{j,i}(l)$ represents the minimum value and $x_{j,i}(u)$ represents the maximum value,

$rand[0,1]$ represents the generation of random numbers between 0 and 1, $N$ represents the population size.

Step II: Set the number of iterations in the counter and let the iteration counter be F. Call the fitness function and update the population size while it reaches the number of iterations. Consider the $G^{th}$ iteration and the absolute value of the candidate solution as $\left|x_{j,i,G}\right|$.

Step III: During the $G^{th}$ iteration, let the variable generated be $x_{j,i,G}$ which is used to generate a vector $x^v_{j,i,G}$ corresponding to it. This value obtained should lie within the

minimum and maximum bounds framed and can be given as (19)

$$x^v_{j,i,G} = \begin{cases} 2x^l_j - x^v_{j,i,G} & \text{if } x^v_{j,i,G} < x^l_j \\ 2x^u_j - x^v_{j,i,G} & \text{if } x^v_{j,i,G} > x^u_j \\ x^v_{j,i,G} & \text{else} \end{cases} \qquad (19)$$

Step IV: The expression for the vector at the $G^{th}$ iteration is given by (20)

$$x^v_{j,i,G} = x_{j,i,G} + r_{1,j,G}\left(x_{j,best,G} - \left|x_{j,i,G}\right|\right) - r_{2,j,G}\left(x_{j,worst,G} - x_{j,i,G}\right) \qquad (20)$$

where $x_{j,best,G}$ and $x_{j,worst,G}$ represent the values of the variable j for the best and the worst candidate, respectively, $r_{1,j,G}$ and $r_{2,j,G}$ are the random numbers in the range [0,1],

$$r_{1,j,G}\left(x_{j,best,G} - \left|x_{j,i,G}\right|\right)$$

represents the term working towards achieving the best solution,

$$r_{2,j,G}\left(x_{j,worst,G} - x_{j,i,G}\right)$$

represents the term working towards avoiding the worst solution.

Step V: At the end, depending on the objective function, vector $x^v_{j,i,G}$ is compared to its corresponding variable $x_{j,i,G}$ and if it has lower value, it survives to the consecutive generation or else it will be retained in the population. Fig. 6 shows the flow chart of Jaya algorithm [4].

The flowchart of Jaya algorithm is demonstrated in Fig. 6.

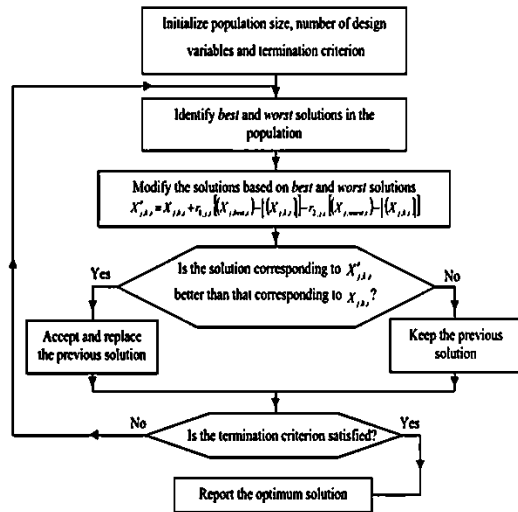

Fig. 6. Flow chart for Jaya algorithm.

The parameters of different optimization techniques used in this paper is listed in the Table I the number of iterations are kept equal for all the optimization techniques used [19, 20]. The algorithm parameters in the proposed method for optimizing power management through the coordination of directional over-current relays have a profound impact on the algorithm's performance and the outcomes of the optimization process. The choice of these parameters can significantly affect how quickly the algorithm converges to a solution and the quality of that solution. For instance, parameters related to learning rates, mutation rates, or step sizes can either expedite convergence or lead to overshooting the optimal solution if set too high, or slow down the process if set too low. The careful selection and tuning of algorithm parameters are pivotal to achieving effective and efficient power management optimization, ensuring robustness, scalability, and the ability to adapt to varying network conditions.

TABLE I. PARAMETERS OF OPTIMIZATION TECHNIQUES

| CS Parameters | FF Parameters | HS Parameters | Jaya Parameters |
|---|---|---|---|
| Discovery Rate of alien eggs = 0.25 No. of nests:10 Iteration=10 | No. of fireflies:100 Alpha = 0.5 Beta min=0.2 Gamma=1 Iteration=10 | Harmony memory size=10 Harmony consideration rate=0.9 Minimum Pitch Adjusting Rate=0.4 Maximum Pitch Adjusting Rate=0.9 | Population size=10 Run=10 Maximum fitness=100 |
| Maximum Iteration:100 | Maximum Iteration:100 | Maximum Iteration:100 | Maximum Iteration:100 |

## V. ANALYSIS OF JAYA ALGORITHM

### A. Analysis of 6-Bus, 10-Relays System

Single-line diagram of 220KV power system of Serum Institute, Pune India is shown Fig. 7 [18]. This is fed to Serum Substation 6 bus radial system. It has 10 relays, which is shown in Fig. 8. The short-circuit data are taken from the test data set. The CT ratio of 100/1 A is used for relay 1, 1000/1 A for relay 2, 300/1 A for relay 3 and 7, 500/1 A for relay 4 and 8, 600/1 A for relays 5, 6, 9, 10. The transformer rating for transformer $T_1$ has 400/220 KV, 315 MVA and %Z is 12.25%. Similarly for transformer $T_2$, 400/220 KV, 501 MVA, %Z is 12.25%, and for transformer $T_3$, 220/22 KV 30 MVA, %Z is 14.07%. Transmission line has double circuit line having lengths $L_1 = 13.6$ km, $L_2 = 12.40$ km; $L_3 = 45$ km; $L_4 = 36$ km; and line$L_5, L_6, L_7, L_8$ has length of 4 km. There are conductor spacing for vertical and horizontal line are 5.5 and 11 meters, respectively.

Fig. 7. Single line diagram of 6 bus, 10 relays test system.

The base MVA for calculating sequence currents is taken 500 MVA to construct sequence networks (positive, negative and zero). The load flow calculations are done with a conventional load flow analysis at all fault points based on those sequence networks. Primary and backup protective relay pairs are calculated and located in the system based on fault locations.

Table II demonstrates comparative analysis of some of the different nature inspired algorithms and the proposed Jaya algorithm. After the process of optimization, results in terms of relay operating time and total operating time for protective system given by some different algorithms. Minimum and maximum operating time limit has been set to 0.5 sec and 1 sec, respectively. Nineteen inequality constraint equations are formulated. The number of iterations would be same for all algorithms and is taken 100 iterations.

TABLE II. ANALYSIS OF 6 BUS, 10 RELAYS TEST SYSTEM FOR DIFFERENT OPTIMIZATION ALGORITHMS

Fig. 8 shows the comparative analysis chart of the 6 bus, 10 relays test system along their objective function results and respective optimization techniques.

Fig. 8. Objective function values from various optimization techniques for 6 bus test system.

The results obtained from different optimization algorithms along the proposed Jaya algorithm using conventional relay characteristic are shown in Table II. The aim of the relay coordination optimization problem is to reduce the total time of operating for relays. Table shows the operating time of each relays, which can be comparable with the result from different algorithms. The overall total relay operating time has to be minimized. Proposed Jaya algorithm gives the best result among other algorithms. The evaluation time for each algorithm are different as per their parameters and number of populations. The number of population will increase the possibility to reach the most optimum solution, but it would also take more time to evaluation.

TABLE III. STATISTICALLY ANALYSIS OF 6 BUS, 10 RELAYS TEST SYSTEM

| Parameter | CSA | FFA | HSA | JA |
|---|---|---|---|---|
| Mean | 0.2479 | 0.1633 | 0.06070 | 0.3208 |
| Standard Deviation | 0.1456 | 0.1228 | 0.06227 | 0.1406 |
| 95% CI for the mean | 0.1438 to 0.3520 | 0.07551 to 0.2512 | 0.01616 to 0.1052 | 0.2202 to 0.4214 |
| Standard error of the mean | 0.04603 | 0.03882 | 0.01969 | 0.01447 |

The statistical evaluation of the results obtained by different optimization techniques namely Cuckoo Search Algorithm (CSA), Fire-Fly Algorithm (FFA), Harmony Search Algorithm (HSA), and Jaya algorithm are presented in Table III. It shows the standard deviation and the standard error of the mean are 0.04603, 0.03882, 0.01969 and 0.01447 obtained by CSA, FFA, HSA and Jaya algorithm. From this table, it can be observed that the best value of standard deviation error is minimum (0.01447 sec) is obtained by Jaya which is the least value compared to the other techniques. This means that the Jaya algorithm gives the lowest standard deviation (0.01447 sec).

*B. Analysis of for 8-Bus, 14-Relays System*

The single line diagram for 8-bus test system is shown in Fig. 9 [1]. Which are contains 14 relays. There is also a link to additional network at various bus, as shown in Fig. 3, which are modeled by taking a base of 400 MVA for calculating the short circuit current. The short-circuit data for different fault conditions are obtained. The primary and back-up relay pairs are took from manual calculated short-circuit analysis and short circuit currents are calculated as per conventional load flow analysis. The CT ratio for relays 3, 7 9, 14 is considered as 800/5 A, for rest of relays CT ratio is considered is 1200/5 A. The population size is taken for a different algorithm is 10, and the number of iterations would be same for each algorithm, which has taken 100.

Comparative analysis of the various algorithms with the proposed Jaya algorithm is shown in Table IV. Finally the results in terms of relay operating time and TDS for main relays. Minimum and maximum operating time limit has been set to 0.5 sec and 1 sec, respectively. Twenty inequality constraint equations are formulated. The number of iterations would be same for all algorithms and is taken 100 iterations.

*C. Analysis of 14-Bus, 40-Relays System*

The single line diagram of IEEE 14-bus test network is shown in Fig. 11 [21], which contains 40 relays. The short-circuit data are taken from the test data set. In this network, the system has 5 generators, 20 transmission lines and it is fed through two transformers $T_1$ and $T_2$. The power base of the system is 138 kV, 100 MVA. The range of TDS is set to be in between 0.5 sec to 1 sec for all the algorithms. The CT ratio is considered as 500/1 A for all the relays.

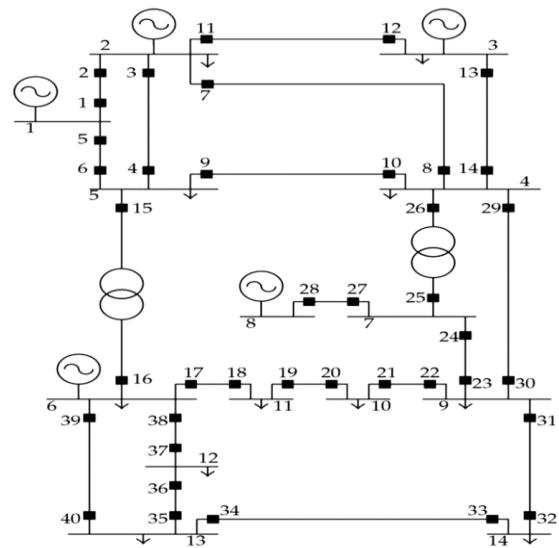

Fig. 11. Single line diagram of IEEE standard 14 bus test system.

The base MVA for calculating sequence currents is taken 500 MVA to construct zero sequence, positive sequence and negative sequence networks. The short circuit computation is completed with a conservative load flow analysis based on those sequence networks, at all fault points. Primary and backup protective relay pairs are recognized, and based on fault locations it is located in the system.

Fig. 12.  Objective function values for various optimization technique for 14 bus test system.

Comparative valuation of the different present algorithms and the proposed Jaya algorithm is shown in Table VI. The output is shown in terms of relay tripping time and total operating time for primary protective relays given by some different algorithms. Minimum and maximum operating time limit has been set to 0.5 sec and 1 sec respectively. The number of iterations would be same for all algorithms and is taken 100 iterations. The population size is taken 10 for Jaya algorithm. Fig. 12 shows the comparative analysis chart of the 14 bus, 40 relays test system along their objective function results and respective optimization techniques.

TABLE VII.    STATISTICALLY ANALYSIS OF 14 BUS, 40 RELAYS TEST SYSTEM

| Parameter | CSA | FFA | HSA | JA |
|---|---|---|---|---|
| Mean | 0.3638 | 0.3004 | 0.1708 | 0.1032 |
| Standard Deviation | 0.1387 | 0.09275 | 0.08119 | 0.06420 |
| 95% CI for the mean | 0.3194 to 0.4081 | 0.2707 to 0.3300 | 0.1448 to 0.1967 | 0.08266 to 0.1237 |
| Standard error of the mean | 0.02193 | 0.01466 | 0.01284 | 0.01015 |

The standard deviation and the standard error of the mean as shown in Table VII are 0.02193, 0.01466, 0.01284 and 0.01015 obtained by CSA, FFA, HSA and Jaya algorithm. From this table, it can be observed that the best value of standard deviation error is minimum (0.01015 sec) is obtained by Jaya which is the least value compared to the other techniques. This means that the Jaya algorithm gives the lowest standard deviation (0.01015 sec).

*D. Analysis of 30-Bus, 42 Relays Test System Network*

The single line diagram of IEEE 30-bus test network is shown in Fig. 13 [13], contains 42 relays.

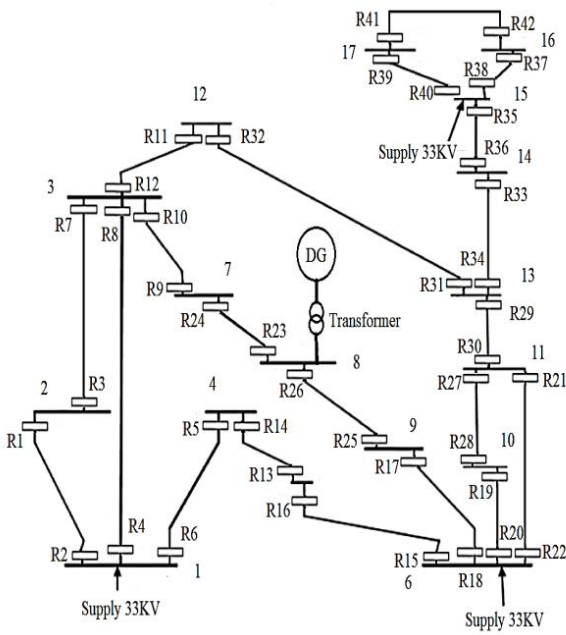
The short-circuit data are taken from the test data set. In this network, the system has 4 generators, 21 transmission lines and it is fed through 4 generators, two transformers $T_1$ and $T_2$. The range of TDS is set to be in between 0.5 sec to 1 sec for all the algorithms. The CT ratio is considered as 500/1 A for all the relays.


Fig. 13. Single line diagram of IEEE standard 30 bus test system.

Comparative valuation of the different present algorithms and the proposed Jaya algorithm is shown in Table VIII. The output is shown in terms of relay tripping time and total operating time for primary protective relays given by some different algorithms. Minimum and maximum operating time limit has been set to 0.5 sec and 1 sec respectively. The number of iterations would be same for all algorithms and is taken 100 iterations.

TABLE VIII. ANALYSIS OF 30 BUS, 42 RELAYS TEST SYSTEM FOR DIFFERENT OPTIMIZATION ALGORITHMS

Fig. 14. Objective function values for various optimization techniques for 30 bus test system.

Fig. 14 shows the comparative analysis chart of the 30 bus, 42 relays test system along their objective function results and respective optimization techniques.

TABLE IX. STATISTICALLY ANALYSIS OF 30 BUS, 42 RELAYS TEST SYSTEM

| Parameter | CSA | FFA | HSA | JA |
|---|---|---|---|---|
| Mean | 0.3107 | 0.2588 | 0.1772 | 0.1011 |
| Standard Deviation | 0.08308 | 0.08744 | 0.08243 | 0.06194 |
| 95% CI for the mean | 0.2849 to 0.3366 | 0.2194 to 0.3058 | 0.1515 to 0.2028 | 0.08181 to 0.1204 |
| Standard error of the mean | 0.01282 | 0.01349 | 0.01272 | 0.009558 |

The standard deviation and the standard error of the mean as shown in Table IX are 0.08308, 0.08744, 0.08243 and 0.06194 obtained by CSA, FFA, HSA and Jaya algorithm. From the above table, it can be observed that the best value of standard deviation error is minimum (0.06194sec) is obtained by Jaya which is the least value compared to the other techniques. This means that the Jaya algorithm gives the lowest standard deviation (0.06194sec).

The results obtained from different optimization algorithms along the proposed Jaya algorithm using conventional relay characteristic are shown in Table IX. The aim of the relay coordination optimization is to reduce the total operating time of all protective devices. Table shows the operating time of each relays, which can be comparable with the result from different algorithms. The value of objective function has to be minimized for relay coordination problem. Proposed Jaya algorithm gives the best result among other algorithms. The evaluation time for each algorithm is different as per their parameters and number of populations.

TABLE X. COMPARATIVE ANALYSIS OF RESULTS OBTAINED FROM DIFFERENT ALGORITHMS

| Relay System | Value of Objective Function (sec) | | | |
|---|---|---|---|---|
| | CS | FF | HS | Jaya |
| 10 relay system | 3.39 | 3.31 | 1.52 | 1.33 |
| 14 relay system | 3.42 | 3.30 | 1.35 | 1.15 |
| 40 relay system | 8.36 | 8.25 | 4.56 | 3.04 |
| 42 relay system | 9.62 | 8.34 | 5.52 | 4.13 |

Table IX shows the comparative analysis with optimized results of different optimization algorithms used for relay coordination optimization problem for four different test systems.

TABLE XI. STATISTICAL ANALYSIS OF OBJECTIVE FUNCTION

| Parameter | CSA | FFA | HSA | JA |
|---|---|---|---|---|
| Mean | 6.1975 | 5.8000 | 3.2375 | 2.4125 |
| Standard Deviation | 3.2653 | 2.8812 | 2.1191 | 1.4270 |
| 95% CI for the mean | 1.0017 to 11.3933 | 1.2153 to 10.3847 | -0.1344 to 6.6094 | 0.1418 to 4.6832 |
| Standard error of the mean | 1.6326 | 1.4406 | 1.0595 | 0.7135 |

The standard deviation and the standard error of the mean as shown in Table X are 1.6326, 1.4406, 1.0595 and 0.7135

obtained by CSA, FFA, HSA and Jaya algorithm. From this table, it can be observed that the best value of standard deviation error is minimum (0.7135 sec) is obtained by Jaya which is the least value compared to the other techniques. This means that the Jaya algorithm gives the lowest standard deviation (0.7135 sec).

Performance of the Jaya algorithm as the optimization tool for relay coordination operating time for different test systems has been evaluated. It has been observed that, the total sum of operating time of all the protective relays is given by the Jaya algorithm may be changed with the different evaluation, the number of constraints increases the overall evaluation time. It is also seen that some of relay TDS has been changed according to their parameters and limits of fitness, it would not much affect the overall operating time for relay coordination. It should be pointed that, the total operating time of all protective relays, is higher and for fault point at far-end when the fault is at the middle point, it is highest as compared to fault point at near-end, the proposed Jaya algorithm gives most appropriate results without any unbalanced operation of relays. It should also to be pointed that for the primary relays, relay operating time will rises as the change in the position of fault from near end to far end of the distributed feeders. The results undoubtedly indicate that the Jaya algorithm gives best optimum result as compare to the other algorithm used in relay coordination optimization.

## VI. CONCLUSION

In this study, we have successfully developed and implemented a novel approach to optimizing power management in distribution networks through the coordination of directional over-current relays. Through our work, we have achieved several significant outcomes. First and foremost, we have demonstrated a practical and effective mathematical modeling approach that accounts for the dynamic nature of distribution networks, enabling precise and adaptive relay coordination. Our algorithm has shown promising results in terms of enhancing the reliability of distribution networks, significantly reducing downtime during faults, and improving the overall safety of the power grid.

The proper tuning of the algorithm specific parameters is a very crucial factor which affects the performance of the above mentioned algorithms. The improper tuning of algorithm specific parameters either increases the computational effort or yields the local optimal solution. The four different test systems are considered. The execution of each algorithm has been set to 100 iterations keeping the initial conditions as same for all the four test systems as considered in our test system. Jaya algorithm is considered as best one among the four algorithms based on the results obtained in the work. Jaya algorithm is found to be very efficient as we can see that the variation in the solutions on the reaching towards the optima. It should be noted that the total operating time of all protective relays is higher for fault point at far-end; when the fault is at the middle point, it is highest as compared to fault point at near-end; thus, the proposed Jaya algorithm gives most appropriate results without any unbalanced operation of relays in the distribution systems. It should also to be pointed that for the primary relays, relay operating time will rises as the change

in the position of fault from near end to far end of the distributed feeders.

# Implementation of the REST API Model using QR Codes on Mobile Devices to Order Parking Tickets

Mauluddini Amras[1], Erwin Yulianto[2], Deshinta Arrova Dewi[3], Awan Setiawan[4]

Department of Informatics, Faculty of Engineering, Langlangbuana University, Bandung, Indonesia[1, 2, 4]
Faculty of Data Science and Information Technology-INTI International University, Nilai, Malaysia[1, 3]

*Abstract*—Many parking lots are still operate manually, and delays are commonly caused during the parking process when unforeseen events occur, such as when the parking ticket paper runs out or the ticket machines jam. New services are added to the parking system online with the aim of decreasing the amount of time that people spend waiting in line to park. This is done by conducting a parking booking system to obtain a parking ticket in the form of a QR Code as well as parking information, payment transactions, and other things that interfere with the parking process. In this study, the Forward Chaining Algorithm will be combined with the survey research method as the research methodology. The Rapid Application Development model is used for analysis and design (RAD). Representational State Transfer Application Programming Interface (REST API) is one of the solutions offered to overcome this problem. With the advent of online parking services, it is envisioned that customers who intend to park their vehicles in public spaces will be able to reserve a parking space in advance, greatly simplifying the process and eliminating the problem of the drawn out queue process.

*Keywords—Representational state transfer application programming interface (REST API); online parking ticket; quick response code (QR Code); smart city; public transport*

## I. INTRODUCTION

Parking service is one of the services in the field of services, where parking is almost available in all places, shopping centers, schools, and is also available on the side of the road. Parking is a necessity for vehicle owners and wants their vehicles to be parked in a place, where the place is easy to reach [1]. In Indonesia, having a place to store vehicles (parking lots) when visiting a place for shopping, playing, and other activities is a place that must be available.

Often the process of parking the vehicle will cause a queue if unwanted things such as the parking ticket paper run out, the ticket machine is jammed and other things will result in a long queue during the parking process. Determination of location and construction of parking facilities for the public is carried out by taking into account the general design of regional spatial planning, safety and smooth traffic, environmental sustainability, and convenience for service users [2]. However, currently there are still many parking places that use manual habits, namely after arriving at the parking lot, then pressing the button for a ticket and then entering the parking area and looking for a place to park. In addition, there are often long queues due to system errors, running out of ticket paper, and processing queues during the payment process.

Based on the preliminary description above, it can be concluded that several problem points that are the purpose of this activity include providing information and providing easy parking processes for users who will do parking. In addition, it also anticipates problems in the vehicle parking process such as the problem of running out of parking tickets, jammed ticket machines that can prolong the parking queue. Based on the preliminary description, this research aims to address several problem points, including:

*1)* Providing accessible information and streamlining the parking process for users.

*2)* Anticipating and preventing common issues encountered during the vehicle parking process, such as ticket shortages and queue delays.

The research problem revolves around the need for a more efficient and convenient parking experience, particularly in regions where parking services frequently face issues like long queues and technical disruptions. These problems stem from traditional, manual parking processes that may not align with modern expectations and urban development. The research seeks to answer the following questions:

*1)* How can the parking experience be improved for users?

*2)* What are the specific challenges associated with traditional parking processes?

*3)* How can the implementation of the REST API and QR Code technology enhance parking services?

The research objectives include:

*1)* To streamline the parking process, making it more user-friendly and efficient.

*2)* To identify and address common challenges in the existing parking systems.

*3)* To demonstrate the advantages of implementing the REST API and QR Code technology in the context of parking services.

This research is significant because it presents a solution to common issues encountered in parking services while aligning with the broader Smart City ecosystem. By implementing the REST API and QR Code technology, it seeks to enhance the parking experience for users, reduce queue times, and contribute to the efficiency and sustainability of urban transportation. The primary contribution of this research is the innovative application of REST API in online ticket ordering using mobile device QR Codes, offering a solution that

enhances the efficiency and convenience of parking services within the Smart City ecosystem. This contribution addresses issues commonly encountered in parking processes and aligns with modern urban development goals. The novelty that is unique in this research is the application of the REST API in ordering tickets online using a mobile device QR Code, which is part of one of the solutions in the Smart City ecosystem.

## II. LITERATURE REVIEW

### A. Representation State Transfer Application Programming Interface

In 2000, after the Web scalability crisis was averted, Fielding named and described the Web architectural style with a Ph. on. Web services are custom built web servers that support the needs of other sites or applications. Client programs use the Application Programming Interface (API) to communicate with web services. In general, an API provides a set of data and functions to facilitate interaction between computer programs and allow them to exchange information as shown in Fig. 1[3]:

Fig. 1. Data request process [3].

As it can be seen in Fig. 1 above, there is a web service system, the web service itself is a software system that is intended as a liaison for interaction between machines and other machines in a system [4].

Web APIs are the face of web services, listening directly to and responding to client requests. The REST architectural style is generally applied to the design of APIs for modern web services. The web API that fits the REST architectural style is the REST API. Having a REST API makes a web service "RESTful". REST APIs consist of a collection of interrelated resources. This collection of resources is known as the REST API resource model. A well designed REST API can attract client developers to use web services. In today's open market where competing web services compete for attention, an aesthetically pleasing REST API design is a must have feature [3], [13].

### B. Ticket

The ticket is an important document that must be owned by passengers who will make a trip, the document is issued by the company or related body that acts as the owner of the services offered [5]. By having a ticket, a person will get services on land, sea and air transportation, both domestic and international. However, if this ticket is not used in whole or only part of the routes listed on the ticket, it can be cashed back according to the agreed agreement. Some of the ticket types used to date is as follows [6]:

- Ticket Paper Manual is a ticket made of valuable paper/document in the form of a book which is issued by writing using a pen. This ticket, although it has been used for a long time, is still used by several airlines. The ticket book is printed on special paper so that it is not

easily counterfeited. There are audit coupons, agent coupons and passenger coupons that are useful as control over the issuance of a ticket.

- Ticket paper printers are those made of valuable paper/documents in the form of books issued by printing using a printer that is operated with a certain ticketing system. One ticket book consists of four flight coupons, audit coupons, agent coupons and passenger coupons.

- Electronic ticket is a ticket made electronically, where all flight and passenger data written in it are stored in an electronic document in the airline database or ticketing system Provider Company. Passengers only need to bring a printout of the data which can be reprinted repeatedly.

### C. Park

Based on the results of studies in Guidelines for Planning and Operation of Parking Facilities, measuring space requirements Parking at activity centers is determined according to the nature and purpose of the parking. In practice in the field, it must be adjusted to parking demand every type of vehicle [12].

Every trip using a vehicle begins and ends at the parking lot, therefore parking spaces are spread out at the origin of the trip, which can be in the car garage, yard, roadside, and the destination of the trip, in the parking lot, parking building or on the side of the road. Because the concentration of the destination of the trip is higher than the place of origin of the trip, it usually becomes a problem at the destination of the trip. Parking is a temporary state of immobility of a vehicle, while stopping is a temporary state of immobility of a vehicle with the driver not leaving the vehicle [7]:

- Parking tariff policy is determined based on location and time, the closer to the City activities the higher the tariff, the higher the higher the rate. This policy is directed at controlling the number of parkers in the city center or activity center and encouraging the use of public transportation.

- Parking space restriction policy, especially in the downtown area or activity center. This policy is usually carried out on roadside parking whose main purpose is to smooth traffic flow, as well as restrictions on offstreet parking spaces which are carried out through IMB (Building Permits).

- Strict law enforcement policies against violators of the provision that parking is prohibited and prohibited from stopping and parking outside the designated place for this purpose, law enforcement can be carried out through fines or with wheel locks.

### D. Quick Response Code

Since its introduction in 1994, the QR Code has gained widespread acceptance in various industries such as manufacturing, warehousing and logistics, retail, healthcare, life sciences, transportation, and office automation. Now with the tremendous growth of smartphones, QR Codes are also

being used in mobile marketing and advertising campaigns as a fast and effective way to connect with customers and provide end user content, including Web links, mobile coupons, airline boarding passes, etc. Successful implementation of QR Code in any of these fields requires knowledge of certain basic information about the QR Code itself and the technology associated with it. Although the QR Code was originally designed to track automotive components and systems through the manufacturing process and distribution supply chain, it quickly spread to almost every other area where traditional barcodes are used, as well as some entirely new ones [8]. The following is an example of the display of the QR Code which can be seen in Fig. 2.

Fig. 2.   QR code [8].

A QR Code (Quick Response Code) is a two dimensional (2D) matrix code belonging to a larger set of machine readable codes, all of which are often referred to as barcodes, regardless of whether they consist of bars, squares or other shaped elements. Compared to 1 D code, 2 D can hold a larger amount of data in a smaller space, and compared to other 2 D codes, QR Code can store more data. In addition, advanced error correction methods and other unique characteristics allow QR Codes to be read more reliably and at a higher speed than other codes. Like written language, barcodes are a visual representation of information. Unlike languages, however, which can be read by humans, barcodes are designed to be read and understood (decoded) by a computer, using a machine vision system consisting of an optical laser scanner or camera and barcode interpretation software. The rules used to create barcodes (grammar) and the characters they use (the alphabet) are called symbology [8].

Fig. 3.   QR code vs. barcode [8].

Unlike 1 D barcodes, QR Codes are 2D matrix codes that convey information not based on the size and position of the bars as seen in Fig. 3 above and spaced in one dimension (horizontal), but by arrangement of dark and light elements, called "modules"., in columns and rows, i.e. in both horizontal and vertical directions. Each dark or light module of a QR Code symbol a specific example of a code represents a 0 or 1, thus making it machine understandable [8].

QR Code modules perform several functions, some contain the actual data itself, while others are grouped into various function patterns that improve reading performance and allow

symbol alignment, error correction, and distortion compensation. The timing pattern allows the scanning device to know the symbol size. There is also a required "quiet zone", a buffer area four modules wide that contains no data, to ensure that the text or creation area is not mistaken for QR Code data. The function pattern on the QR Code can be seen in Fig. 4 below.

Fig. 4.   QR code function pattern [8].

Conventional 2D matrix codes require a lot of time to search for symbol codes to determine orientation angle, position (x and y coordinates), and size. To solve this problem, the QR Code was designed with a special position detection pattern located at the three corners of each symbol. The patterns have a 1:1:3:1:1 symmetric scan line ratio, which allows them to be scanned from any direction in a full 360 degrees. In addition, pattern position relationships allow quick access to relevant angle, position, and size information contained in the periphery of the code. As a result, QR Codes do not require lengthy code searches, enabling read speeds up to 20 times faster than conventional matrix codes. The position detection pattern search process can be performed by the scanning hardware, further increasing the overall speed by allowing image reading and data processing to be performed simultaneously [8].

Developing Android applications for a Parking Information System using Adobe AIR involves creating a mobile app that provides users with real-time parking information, such as available parking spots, pricing, location details, and navigation assistance. Adobe AIR is a cross-platform runtime that allows developers to build applications using web technologies like HTML, JavaScript, and ActionScript. [14]

A comprehensive review of the research entitled "Implementation of the REST API Model Using QR Codes on Mobile Devices to Order Parking Tickets" will include an understanding of the REST API concept, parking ticket ordering, and the use of QR Codes in the context of mobile applications. This research focuses on applying the REST API concept, ordering parking tickets, and using QR codes to create a solution that makes it easier to order parking tickets via mobile devices. This can improve user experience and efficiency in parking management, as well as utilize modern technology to overcome challenges in urban transportation and parking management.

## III.  RESEARCH METHOD

This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation, as well as the experimental conclusions that can be drawn.

### A. Data Collection Stage

The data collection stage was carried out with the Literature Study stage, carried out by searching for information from books, e-books, websites, modules, journals, internet browsing and various other literature related to making the Forward Chaining algorithm application. Next is the observation method or observation is direct observation, which is an activity that aims to obtain the necessary information by observing and recording and reviewing.

### B. System Development Stage

The stages of system development used in this application are the Rapid Application Development (RAD) model, with black box testing. The stages of the Rapid Application Development (RAD) method can be seen in Fig. 5 below:

Fig. 5. RAD phases [9].

The explanation of these stages can be seen in the following points: [10].

*1) Requirements planning*: The requirements planning phase combines elements of the systems planning and systems analysis phases of the SDLC. Users, managers, and IT staff members discuss and agree on business requirements, project scope, constraints, and system requirements. The requirements planning phase ends key issues and obtains management's permission to continue.

*2) User design*: During the user design phase, the user interacts with the systems analyst and develops models and prototypes that represent all system processes, outputs, and inputs. RAD groups or subgroups typically use a combination of JAD techniques and CASE tools to translate user requirements into a working model. User design is an interactive and continuous process that allows users to understand, modify, and ultimately agree on a system working model that meets their needs.

*3) Construction*: The construction phase focuses on the tasks of developing programs and applications that are similar to the SDLC. However, in RAD, users continue to participate and can still suggest changes or improvements as the actual screen or report is developed.

*4) Cutover*: The transition phase resembles the final tasks in the SDLC implementation phase, including data conversion, testing, switching to the new system, and user training. Compared with traditional methods, the whole process is compressed. As a result, new systems are built, shipped, and put into operation more quickly.

The Software Development Method using the RAD (Rapid Application Development) model has several advantages compared to other software development methods, especially in the context of project-based software development which requires flexibility, speed and high response to changing needs. Here are some of the advantages of RAD:

*1) Rapid development*: As the name suggests, RAD emphasizes on rapid development. In this model, the main focus is to produce a usable prototype or application quickly.

*2) High customer engagement*: RAD promotes active customer or stakeholder engagement.

*3) Flexibility*: The RAD model is very flexible and can handle changing requirements well.

*4) Better quality*: Through repeated iterations, RAD allows teams to identify and address problems earlier in the development cycle.

*5) Emphasis on reusability*: RAD encourages reusable component-based development that can save time and effort in subsequent project development.

*6) Cost efficiency*: While there are initial costs associated with developing a prototype, long-term savings can be achieved due to the reduction in changes that must be made in later stages of the project.

*7) Suitability for small-medium projects*: The RAD method is generally better suited for small to medium sized projects that require quick updates or upgrades.

*8) Concentrate on key functionality*: RAD focuses on the key functionality required by customers, avoiding features that may be unnecessary or annoying.

*9) Risk reduction*: By having prototypes that can be tested and evaluated, project risks can be reduced as problems can be identified early.

*10) Improved team collaboration*: RAD encourages active collaboration among development team members and stakeholders. This can result in a better understanding of needs and desired solutions.

In addition to the system development method using the Rapid Application Development (RAD) method, this study also uses Unified Modeling Language (UML) Diagrams as a tool in the analysis process and also in system design.

## IV. RESULT AND DISCUSSION

### A. Business Process Analysis

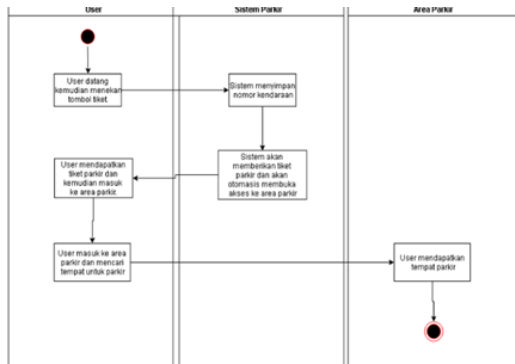
Based on the results of the data collection stages, the business processes in this research activity can be seen in the flowmap in Fig. 6 to Fig. 9 below:


Fig. 6.  Business process runs from manual parking entry process.

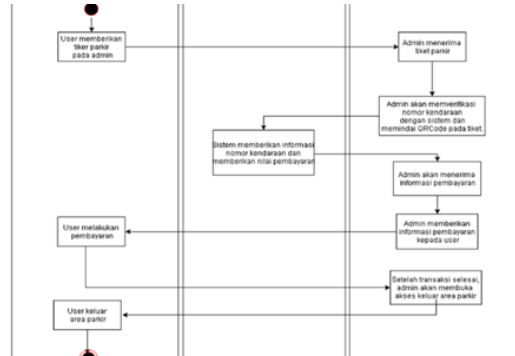

Fig. 7.  Business process running from manual parking exit process.

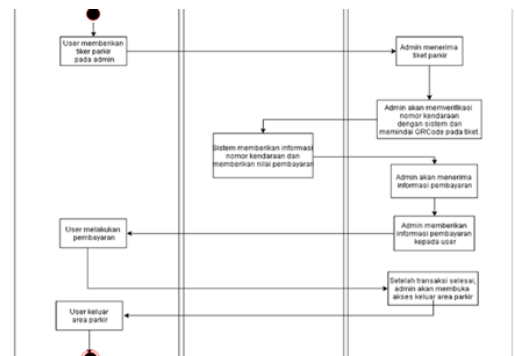

Fig. 8.  Business process proposed from manual parking entry process.

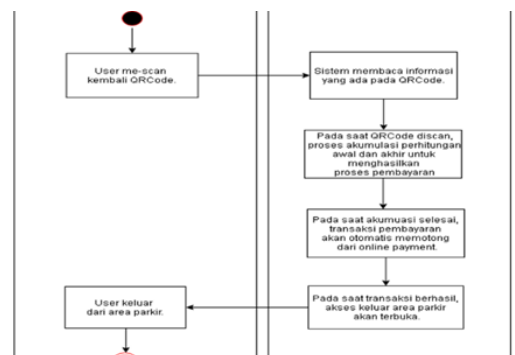

Fig. 9.  Business process proposed from manual parking exit process.

In general, the differences between current and proposed business processes based on Fig. 6 to Fig. 9 above are:

*1) Manual parking business processes:*

*a) Ticket Issuance*: In manual parking processes, when a vehicle arrives at the parking lot, a physical parking ticket is issued.

*b) Finding a Parking Spot*: The driver must manually find an available parking spot within the parking facility, which can sometimes be a time-consuming process, especially in crowded parking areas.

*c) Payment*: When leaving the parking area, the driver approaches a payment booth where they must provide the physical parking ticket and make the payment in cash or by card.

*d) Ticket Validation*: The parking ticket is manually validated by an attendant, and the gate is opened to allow the vehicle to exit the parking area.

*e)* Manual parking processes can face challenges such as ticket paper shortages, malfunctioning ticket machines, and extended waiting times, resulting in a less efficient and user-friendly experience.

*2)* Application of REST API in Ordering Tickets Online Using a Mobile Device QR Code:

*a) Ticket Ordering via Mobile App*: With the application of the REST API, users can order parking tickets online through a mobile app.

*b) QR Code Generation*: Upon ordering a parking ticket, a QR code is generated, typically displayed on the user's mobile device. This QR code serves as a digital ticket for entry and exit.

*c) Efficient Entry*: To enter the parking area, users simply need to display the QR code on their mobile device, which is then scanned by a QR code reader at the entrance gate.

*d) Online Payment*: Payment for parking can also be made online through the mobile app, reducing the need for cash payments and further expediting the process.

*e) QR Code Validation*: At the exit gate, the QR code is scanned again for validation, and the gate is opened for the user to exit.

*f)* Implementing REST API and QR Code technology offers several advantages, including faster entry and exit, reduced queues, reduced reliance on paper, and improved user convenience.

*B. Gap Analysis*

Below is a GAP Analysis table that describes the current and expected business processes. GAP analysis can be seen in Table I below:

TABLE I.     GAP ANALYSIS

| No | Business Process | Currently | Expected |
|----|------------------|-----------|----------|
| 1 | Parking Process | Manual parking process, to do parking, the user must be in the parking lot to press the ticket button and then park. | Automatic process where the previous parking process can make a booking to get a parking ticket. |
| 2 | Parking Ticket | Parking tickets currently still use paper a lot. | The expected parking ticket at this time is in addition to reducing paper in the form of a QR Code. |

In summary, manual parking business processes involve physical ticket issuance, manual search for parking spots, and payment at the booth, while the application of REST API with QR Codes allows for a more streamlined and efficient online ticket ordering process using mobile devices, reducing the reliance on physical tickets and facilitating quicker entry and exit from the parking facility.

### C. Functional Modelling Analysis

This functional modeling analysis will use the Unified Modeling Language (UML) as follows:

*1) Use case diagram*: Use Case Diagrams are used to find out what functions are in an information system and who has the right to use those functions [11]. Use Case Diagram can be seen in Fig. 10.

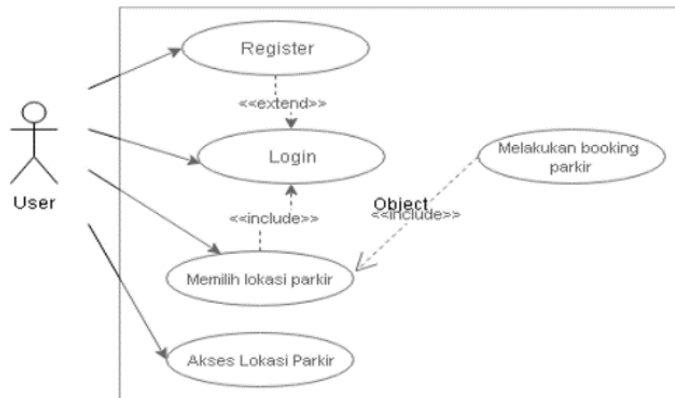

Fig. 10. Use case diagram.

*2) Class diagram*: The use of this class diagram will describe the structure in terms of defining the classes that will be created to build the system. Classes have what are called attributes and methods or operations [11]. Class Diagram can be seen in Fig. 11.

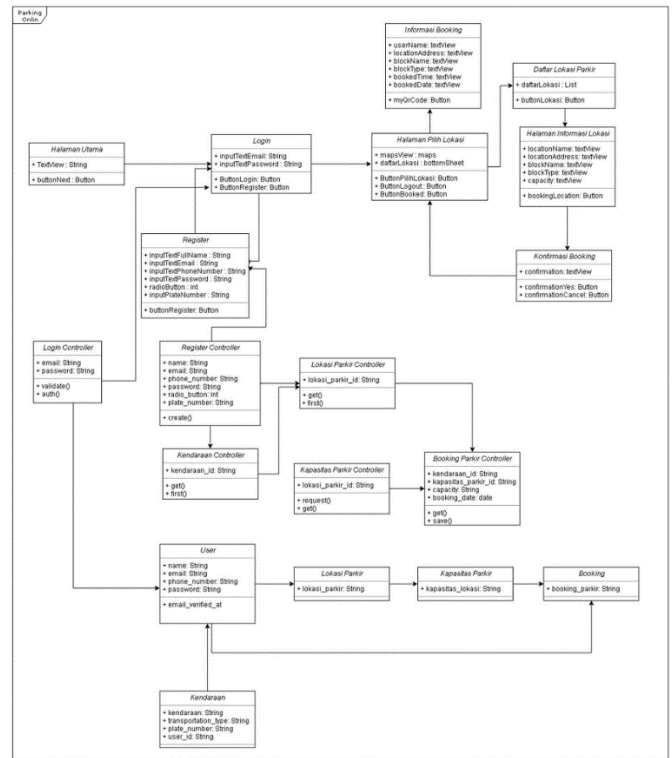

Fig. 11. Class diagram.

### D. Menu Structure Design

The design of this menu structure is a tool that is expected to make it easier for users to get to know this system better. The design of the menu structure of this system can be seen in Fig. 12.

Fig. 12. Menu structure design.

### E. Interface Implementation

Implementation of the interface of this system can be seen from the description of the following points:

*1) Maps page*: Maps page that is displayed when the application is accessed, and the user has logged in. The display of this map page can be seen in Fig. 13.
Fig. 13.  Menu structure design.

*2) Choose a parking location page*: The parking location page is the page that is displayed when the user presses the "choose location" button to select a location around them. The view of the page for choosing a parking location can be seen in the following Fig. 14.

Fig. 14.  Page view select parking location.

*3) Parking information page*: The parking information page is the page after we select a location for parking which is displayed when the application is accessed. The display of this main page can be seen in Fig. 15.

Fig. 15.  Parking information page display.

*4) Booking confirmation page*: The booking confirmation page is a confirmation page that is displayed when the user has pressed the booking location button. The display of this booking confirmation page can be seen in Fig. 16.

Fig. 16.  Booking confirmation page preview.

*5) QR code booking information page*: The QR Code booking information page is the page after making a booking and the QR Code will be displayed when the user presses the QR Code button. The display of this QR code booking information can be seen in Fig. 17.

Fig. 17.  Booking information page preview.

*6) QR code page*: The QR Code Page is intended to get parking access as a substitute for parking tickets. The display of this main page can be seen in Fig. 18.

Fig. 18.  QR code page preivew.

*7) QR code page*: QR Code Scan Result is the result when the QR Code is scanned to get parking access. The display of these results can be seen in Fig. 19.

Fig. 19. QR code scan result.

When discussing API transfer for QR-Code reading mode and measuring delay (response time in milliseconds), keep in mind that this delay can be influenced by various factors, including the quality of the hardware and software used, environmental conditions, and the quality of the QR code itself. Below is Table II that includes several situations that may affect QR-Code reading delay:

TABLE II.  FACTORS THAT HINDER THE TRANSFER OF QR CODE DATA USING THE REST API

| No | Factor / Issue | Estimated Delay (ms) | Description |
|----|----------------|----------------------|-------------|
| 1 | Environmental Conditions | 10-100 | Low light, glare, or shadows can slow down QR code reading. |
| 2 | QR Code Quality | 5-50 | Damaged or non-standard QR codes may require extra time for decryption. |
| 3 | Camera Hardware | 20-100 | The quality of the camera on mobile devices or QR code readers can affect response time. |
| 4 | Software Application | 10-50 | The performance of QR code reader software may vary based on the implementation and updates. |
| 5 | Processor Speed | 5-20 | Faster mobile device or QR code reader processors will read QR codes more quickly. |
| 6 | Network Overhead | 20-100 | If QR codes need to be fetched from a server over a network, network overhead can impact delay. |

The values in this table are general estimates and may vary depending on the actual circumstances. Some cases may experience higher or lower delays depending on the combination of these factors. Additionally, more advanced hardware and software may experience lower delays. Implementing REST APIs for online ticket booking using QR codes on mobile devices can have various advantages and disadvantages. Here are some of them:

*1) Excess*:

*a) Ease of Access and Use*: The REST API allows users to easily access the ticket booking system using their mobile devices. This provides convenience for users in ordering public transportation tickets.

*b) Scalability*: The REST API allows the system to easily scale to changing demands. It can handle traffic spikes that occur during peak hours or during special events.

*c) Interoperability*: REST APIs typically use common data formats such as JSON, which can be easily understood by various devices and platforms. This allows various third-party applications to integrate with the ticket booking system.

*d) Security*: REST APIs can be configured to implement security measures such as authentication, authorization, and data encryption to protect user information and payment transactions.

*e) R codes*: Using QR codes simplifies the check-in process on public transportation. Users simply display their QR code on their phone screen, and officers can quickly scan it to validate the ticket.

*2) Weakness*:

*a) Dependency on Internet Connection*: REST API requires a stable internet connection. If users are in an area with a weak signal or no internet connection, they may not be able to book tickets or display their QR code.

*b) Technical Errors*: In the event of technical glitches or server failure, users may experience difficulty booking tickets or using QR codes. This can disrupt the user experience.

*c) Data Security*: Although REST APIs can be regulated with security measures, the risk of data leakage remains. Users' personal data and payment information must be guarded very strictly.

*d) Development Cost*: Developing and maintaining a robust and reliable REST API can require a large investment in terms of human and financial resources.

*e) Need for Continuous Maintenance*: APIs need to be maintained and updated regularly to maintain their reliability. This requires additional effort and costs.

*f) Regulatory Compliance*: Online ticket booking systems must comply with various regulations, including data privacy and financial regulations, which can add complexity and operational costs.

Implementing REST APIs in online ticket ordering using QR codes on mobile devices can provide many benefits, but also has several challenges that must be overcome to achieve success in managing public transportation in a smart city ecosystem.

## V. CONCLUSION

The conclusions obtained from the activities that have been carried out include the existence of an online process that can facilitate the process of getting information about the place without having to look directly at the parking lot, making it easier for users to book a parking space. This activity can also anticipate problems in the vehicle parking process such as running out of parking tickets, jammed ticket machines that create long queues. With QR Code media as a substitute for parking tickets, it will save paper usage which is usually always thrown away after use, so this QR Code is one of the media used can replace paper tickets. Implementing the REST API in online ticket ordering using a QR code on a mobile

device is one of the best solutions for managing public transportation in the smart city ecosystem.

# Design of Distributed Cooperative Control for Multi-Missile System to Track Maneuvering Targets

Belkacem Kada[*], Khalid A. Juhany, Ibraheem Al-Qadi, Mostefa Bourchak
Aerospace Engineering Department, King Abdulaziz University, Jeddah, KSA

*Abstract*—The current paper provides unique smooth control methods for constructing resilient nonlinear autopilot systems and cooperative control protocols for single and multi-missile systems. To develop the single autopilots, a high-order framework based on asymptotic output stability principles and local relative degree for nonlinear affine systems is first applied. Then, using asymptotic exponential functions and graph theory, free-chattering distributed protocols are constructed to allow multi-missile systems to track and intercept high-risk targets. The Lyapunov approach is used to derive the essential requirements for smooth asymptotic consensus. The proposed method minimizes computing load while enhancing accuracy. The simulation results indicate the efficacy of the recommended strategies.

*Keywords—Multi-missile cooperative control; missile autopilot; smooth control; high-order sliding mode; target tracking*

## I. INTRODUCTION

To adhere to the intended trajectory, a modern tactical missile (TM) autopilot system must be able to stabilize the rotational dynamics of the missile and accurately monitor the sequence of acceleration commands issued by the navigation and guidance system. However, constructing a missile's autopilot is a difficult challenge due to the unpredictability in aerodynamic derivatives.

Early missile autopilots were built using traditional methods, notably linearized dynamic models within a gain scheduling control approach. Using linear design methodologies within a gain scheduling framework, on the other hand, frequently resulted in suboptimal control where no stability or performance certificate could be given by the closed-loop system constituted of the nonlinear plant and planned controller. Several nonlinear control strategies have been developed to reduce the needed gain scheduling.

A nonlinear pitch-axis autopilot involving scheduling linear $H_\infty$ control design under constant operating conditions and bounded scheduling variables was first discussed in [1]. In the work presented in [2], gain-scheduling and gap metric techniques were used to design a robust missile pitch-axis autopilot for an air-to-air missile. The connection between the loop-shaping theory and the gap metric technique was used to compute the operating points, and proportional-integral/proportional-type controllers were designed. The problem of the missile's autopilot design in the presence of hidden coupling terms was tackled in [3] using gain-scheduling control. The study introduced a self-scheduling method for preserving the local properties of the nonlinear gain-scheduled controller, which allows for consideration of

the hidden coupling terms during the design process. The nonlinear pitch dynamics of a tail-controlled, extremely agile missile were addressed in [4] by designing a gain-scheduled 4-loop autopilot. The requirements for an autopilot's design were methodically converted into hard and soft tuning objectives, and the resulting multi-model/multi-objective issue was then addressed with the help of a nonsmoothed optimization process.

Many design schemes have recently been developed to provide stringent performance requirements and ensure robustness across different flight conditions. The Linear Parameter Varying (LPV) approach was recently used conjointly with linear fractional transformation (LFT) in [5] to design specified structure autopilots that ensure robustness to a large class of uncertainty. The proposed LPV/LFT algorithm could handle slope-restricted nonlinearities and rate-bounded time-varying parameters using a nonsmooth optimization technique and using polytopic LPV weights within the four-block loop-shaping H∞ loop shaping theory, the authors, in [6], designed an output feedback controller to provide a missile longitudinal autopilot with robust H∞ performance. To accommodate the seeker field-of-view constraint while maintaining the system's resilience, an integrated missile guidance and control method was developed in [7] by appending the integral barrier Lyapunov function to dynamic surface control. As uncertain disturbances of the system, the authors treated target maneuvering and unmodeled disturbances with the influence of the disturbance rejection rate error. They employed an extended state observer for real-time estimates.

The study in [8] offered a sliding mode control (SMC) architecture for precision missile operation inside a nonlinear finite-time control framework, as opposed to the asymptotically convergent control framework. The study's most significant contribution was analysing the influence of boundary layer thickness on missile system reactions, with the assumption that reducing boundary layer thickness will improve the control performance of the SMC autopilot system.

On the other hand, as the multilayered missile defense system has been refined and target maneuverability has increased, the challenge of penetrating a target with a single traditional missile has increased in recent years. In such a case, cooperative guiding is recommended as a viable countermeasure to boost missile penetrability. To improve the lethality of multiple missiles, cooperative guiding laws must also meet time and space restrictions, in addition to attaining a minimal or even zero miss distance. Many recent studies [9-

14] have concentrated on the topic of distributed cooperative guidance of multi-missile systems.

In this study, we first suggested a new high-order SMC-based technique for developing the guidance law, which serves as the foundation for estimating the ideal flying AOA and normal acceleration trajectories. The goal of this technique is to look at the use of finite-time control for the longitudinal dynamics of a tactical missile, with the needed information acting as the control command. We propose a smooth control-based design of distributed consensus protocols for multi-missile system guiding in the second half. Free-chattering distributed protocols are constructed using asymptotic exponential functions and graph theory. The essential criteria for smooth asymptotic tracking are derived using the Lyapunov method.

## II. MISSILE DYNAMICS AND CONTROL OBJECTIVES

A TC system is a type of guided missile designed for use in combat situations with a relatively limited range, typically within the theatre of operations or on the battlefield. These missiles are designed to execute pinpoint attacks against hostile installations, vehicles, aircraft, and ships. Fig. 1 shows a typical TM model.

Fig. 1. Missile pitch-axis motion.

The Reichert's missile model [1], a hypothetical fin-controlled pitch-axis missile that serves as a standard in studies of nonlinear controller design for supersonic and hypersonic vehicles, is employed as the basis for the present study.

The nonlinear dynamic model presented below governs the missile's motion in the planar space.

$$\dot{M} = K_z M^2 \left[ C_{D_0} - C_z(\alpha, M) \sin\alpha \right] - \frac{g}{v_s} \sin\gamma \quad (1)$$

$$\dot{\alpha} = K_z M C_z(\alpha, M) co \frac{g}{v_s M} \cos\gamma + q \quad (2)$$

$$\dot{q} = K_m M^2 C_m(\alpha, M) \quad (3)$$

$$\dot{\gamma} = -K_z M C_z(\alpha, M) \cos\alpha - \frac{g}{v_s M} \cos\gamma \quad (4)$$

where:

- $M$ is the Mach number.

- $\alpha$ is the angle-of-attack (AOA) (rad).

- $q$ is the pitch rate (rad/s).

- $\gamma$ is the flight path angle (rad).

The nonlinear coefficients $C_z$ and $C_m$ characterize the missile aerodynamics model's and are given as time-varying parameters.

$$C_z = a_z \alpha^3 + b_z |\alpha| \alpha + c_z \left( 2 - \frac{M}{3} \right) \alpha + d_z \delta \quad (5)$$

$$C_m = a_m \alpha^3 + b_m |\alpha| \alpha + c_m \left( -7 + \frac{8M}{3} \right) + e_m q + d_m \delta \quad (6)$$

Considering the above four flight parameters as system's states and the fin deflection (6) as control input, model (1)-(4) becomes.

$$\dot{x} = f(x) + g(x)u$$
$$y = h(x) \quad (7)$$

with

$$x = [M \ \alpha \ q \ \gamma]^T \quad (8)$$

$$h = \eta(M, \alpha) \quad (9)$$

$$u = \delta \quad (10)$$

where the missile's normal acceleration $\eta$ is given by

$$\eta = K_z M^2 v_s C_z(\alpha, M) \quad (11)$$

and $f(x) \in \mathbb{R}^4$, $g(x) \in \mathbb{R}^4$, and $h(x) = \eta \in \mathbb{R}$ are uncertain bounded functions. $f(x), g(x)$ and $h(x)$ are uncertain due the uncertainty of the aerodynamics coefficients given in (5) and (6). The expended form of the model (7) is given below:

$$f_1(x) = -\frac{g}{v_s} \sin x_3 - K_z x_1^2 \left[ C_{D_0} - \left( a_z x_2^3 + b_z |x_2| x_2 + c_z \left( 2 - \frac{x_1}{3} \right) x_2 \right) \right] \sin x_2 \quad (12)$$

$$f_2(x) = +\frac{g}{v_s x_1} \cos x_3 + x_4 K_z x_1 \left[ a_z x_2^3 + b_z |x_2| x_2 + c_z \left( 2 - \frac{x_1}{3} \right) x_2 \right] \cos x_2 \quad (13)$$

$$f_3(x) = -K_z x_1 \left[ a_z x_2^3 + b_z |x_2| x_2 - \frac{g}{v_s x_1} \cos x_3 + \left( 2 - \frac{x_1}{3} \right) x_2 \right] \cos x_2 \quad (14)$$

$$f_4(x) = K_m x_1^2 \left[ a_m x_2^3 + b_m |x_2| x_2 \left( -7 - \frac{8x_1}{3} \right) x_2 \right] \quad (15)$$

$$g(x) = [0 \ 0 \ 0 \ K_m x_1^2 d_m]^T \quad (16)$$

$$h(x) = K_z x_1 \left[ a_z x_2^3 + b_z |x_2| x_2 + c_z \left( 2 - \frac{x_1}{3} \right) x_2 \right]. \quad (17)$$

Achieving the intended mission in a short time while accounting for external disturbances and model uncertainties is the goal of the present control design. The performance objectives for the closed-loop system encompass the achievement of finite-time closed-loop convergence, fast response to substantial manoeuvres, the system's ability to withstand and adapt to plant uncertainties and disturbances.

## III. HIGH-ORDER SLIDING MODE CONTROL TO MISSILE AUTOPILOT DESIGN

### A. Lie Derivatives for Nonlinear Affine Control

Consider a vector field $f(x) \in \mathbb{R}^n$ defined on open operating domain $D \in \mathbb{R}^n$ and a smooth map $m \in \mathbb{R}^p$. For any $x \in m$, The Lie derivatives, along the trajectory $f(x)$, for the map $m$ are given as follows:

$$L_f m(x) = \frac{d}{dt} m\big(\phi_i^f(x)\big)\Big|_{t=0} \tag{18}$$

where, $\phi_i^f(x)$ denotes the flow vector of $f(x)$ at time t. Using the chain rule, one can write

$$L_f m(x) = m^{(1)}(x) f(x) \tag{19}$$

with $m^{(1)} = \partial m / \partial x$ being the Jacobian matrix of $m$. Therefore, the $r$-derivative of $m$ is given as

$$\begin{cases} L_f^r m(x) = m^{(r-1)}(x) f(x) \\ L_f^0 m(x) = m(x) \end{cases} \tag{20}$$

According to the Lie derivatives properties, for a further vector $g$, expression (20) becomes

$$L_g L_f m(x) = \frac{\partial L_f m(x)}{\partial x} g(x) \tag{21}$$

### B. Sliding Mode Control Design

Consider the following tracking error to be the actual output of a multi-output system with $\in \mathbb{R}^p$.

$$e(y) = y - y_d \tag{22}$$

where, $y_d$ denotes the desired values of $y$. The system equilibrium point is located on the manifold $e_i^{-1}(0)) = \{x| e_i(x) = 0\}$).

Definition 1. The derivative degree $r$ in equation (20) extends, for the case (22), to the vector $r = \begin{bmatrix} r_1 & r_2 & \dots & r_p \end{bmatrix}^T$ for which expression (20) and (21), for a given initial condition $x_0$, become

$$\begin{cases} L_g L_f^k e_i(x) = 0 \\ L_g L_f^{r_i-1} e_i(x_0) \neq 0 \end{cases} \quad 0 \leq k \leq r_i - 2, 1 \leq i \leq p \tag{23}$$

Following is the calculation of the derivatives in (23) that appear in sequence.

$$\begin{bmatrix} L_f \\ L_f^k \\ L_g \end{bmatrix} e_i(x) = \begin{bmatrix} \sum_{i=1}^n \frac{\partial e_i}{\partial x_i} f_i(x) \\ L_f\left(L_f^{k-1} e_i(x)\right) \\ \sum_{i=1}^n \frac{\partial e_i}{\partial x_i} g_i(x) \end{bmatrix} \tag{24}$$

Lemma 1 [xx]. If and only if the following holds for any subset of the domain of the output $e_i$, then the relative degree $r_i$ is well-defined there.

$$L_g L_f^{r_i-1} e_i(x_0) = \tau \tag{25}$$

where $\tau$ is a constant.

Lemma 2 [xx]. For each $e_i$ with $r_i > 1$, a stable motion towards zero can be obtained for the sequence $\left(e_i, e_i^{(1)}, e_i^{(2)}, \dots, e_i^{(r_i-1)}\right)$ by designing the following sliding manifold that satisfies $\sigma_i^{-1}(0) = \{x| \sigma_i(x) = 0\}$

$$\begin{aligned} \sigma_i(x) = {}& L_f^{r_i-1} e_i(x) + \lambda_{r_i-2} L_f^{r_i-2} e_i(x) + \cdots \\ & + \lambda_1 L_f e_i(x) + \lambda_0 e_i(x). \end{aligned} \tag{26}$$

with $\lambda_j > 0$ $(j = r_i - 2, \dots, 0)$ define design parameters.

Lemma 3 [xx]: The following equation has a single local solution, denoted by the affine control u(x)

$$\begin{aligned} \big[L_f \sigma_i(x)\big] = \big[ & L_f^{r_i} e_i(x) + \\ & \lambda_{r_i-2} L_f^{r_i-1} e_i(x) + \cdots + \lambda_0 L_f e_i(x)\big] = 0 \end{aligned} \tag{27}$$

Remark 1: If a relative degree $r_i$ is defined for each output $y_i$ with respect to a control input $u$, then the smallest relative degree $\rho > 1$ is considered as the relative degree of the whole system (i.e., $\rho = \min(r_i)$, and $\rho > 1$).

Remark 2: A well-defined relative degree guarantees the applicability of such a controller over the working range, while the smallest relative degree simplifies the design task and gives a practical controller. The outer-loop sliding mode controller's primary characteristic is shown in the following block diagram.

### C. AOA Autopilot

With $e_2 = \alpha - \alpha_d = x_2 - x_{2,d}$ and $\frac{\partial \alpha_d}{\partial x} = \frac{\partial x_{2,d}}{\partial x}$, the Lie derivatives (24) are computed as follows

$$L_g \begin{bmatrix} e_1(x) \\ e_2(x) \\ e_3(x) \end{bmatrix} = L_g L_f \begin{bmatrix} e_1(x) \\ 0 \\ e_3(x) \end{bmatrix} = 0_{3x1} \tag{28}$$

$$L_g L_f^2 \begin{bmatrix} e_1(x) \\ e_2(x) \\ e_3(x) \end{bmatrix} = g(x) \begin{bmatrix} \frac{\partial f_1(x)}{\partial x_2} \\ 1 \\ \frac{\partial f_3(x)}{\partial x_2} \end{bmatrix} \tag{29}$$

Considering property (25), the AOA's relative degree is $r_\alpha = 2$. This proves that there exists a well-defined output-input assignment $\forall x \in O(x_0)$. According to the value of $r_\alpha$, the sliding manifold (26) becomes

$$\sigma(x) = \frac{\partial e_2}{\partial x} f + \lambda e_2 = \frac{\partial x_2}{\partial x} f + \lambda(x_2 - x_{2,d}) \tag{30}$$

Applying Lemma 3, the fin deflection that ensure $\sigma(x) = 0$ is derived as follows:

$$\delta(x) = \left(\frac{1}{1 + g(x)}\right) - \left(u(x) + K sat\left(\sigma(x)/\varepsilon\right)\right) \tag{31}$$

where the saturation function is implemented using a boundary layer $\varepsilon$ s

$$sat(^\sigma/_\varepsilon) = \begin{cases} ^\sigma/_\varepsilon & if\ |^\sigma/_\varepsilon| \leq 1 \\ sgn(^\sigma/_\varepsilon) & if\ |^\sigma/_\varepsilon| > 1 \end{cases} \quad (32)$$

In this design, the gain $K$ is provided to correct model uncertainties, unmodeled dynamics, and measurement noises, the coefficient sets the bandwidth of the error dynamics, and the layer $\varepsilon$ is introduced to dampen the babbling.

### D. Normal Acceleration Autopilot

The rate of the missile's acceleration is one of the primary variables managed by an autopilot system. Commonly symbolized by the letter "g" normal acceleration quantifies the gravitational pull experienced by the airframe in flight. Using normal acceleration autopilot to deflect the fins allows controlling a measured variable, which avoids the use of an estimator for $\alpha$. To do so, we compute the inverse transformation of Eq. (11).

$$\alpha(\eta, M) = K_z M^2 \begin{bmatrix} \dfrac{2b_z^2 - a_z c_z(2 - M/3)}{K_z^3 M^2 c_z^5 (2 - M/3)^5} \eta^3 \\ -\dfrac{b_z}{K_z^2 c_z^3 (2 - M/3)^3} |\eta|\eta \\ +\dfrac{1}{K_z M^2 c_z (2 - M/3)} \eta \end{bmatrix} \quad (33)$$

From (33), the time derivative of $\eta$ is given as follows

$$\dot{\eta} = \left(\frac{\partial \alpha}{\partial \eta}\right)^{-1} \left[ K_z M C_z(M, \eta) + q(M, \eta) - \frac{\partial P}{\partial M} \dot{M}(M, \eta) \right] \quad (34)$$

The sliding manifold and its corresponding control input are given as follows

$$\begin{cases} \sigma(x) = \dfrac{\partial \eta}{\partial x} f + \lambda(\eta - \eta_d) \\ \dfrac{\partial}{\partial \gamma} \dfrac{\partial \dot{\eta}}{\partial x} f(x) + \lambda \dfrac{\partial \dot{\eta}}{\partial \gamma} = 0 \end{cases} \quad (35)$$

## IV. DISTRIBUTED MISSILE AUTOPILOT DESIGN

In the context of a fixed topology, we present, in this section, the design of distributed consensus protocols $u_i$ to allow a multi-missile system, composed of $m$ agents, to track an AOA or normal acceleration commands to ensure a successful interception of high-risk targets. To do so, a consensus tracking error is defined as follows:

$$e_i = \sum_{j=0}^{n} a_{ij}(x_i(t) - x_j(t)) \quad (36)$$

where, $a_{ij}$ denote the elements of the the adjacent matrix $\mathcal{A}$ and $x_i \in \mathbb{R}^n$ denotes the individual missiles state vector.

Definition 2: Based on the consensus (36), we define, for each agent '$i$' (e.g., individual missile) the following inequality.

$$\|\psi_i(e_i)\|_2 \leq \|\psi_i(e_i)\|_1 \leq N\|\psi_i(e_i)\|_\infty \leq N\kappa \quad (37)$$

with $N = nm$ and $\kappa \in \mathbb{R}^+$

Definition 3: According to the communication graph $\mathcal{G}$ of the multi-missile system, we define a matrix $M$ such that $M = \mathcal{L} + \mathcal{D}_0$ with $\mathcal{L} = \mathcal{D} - \mathcal{A}$ being the Laplacian matrix associated with $\mathcal{G}$, $\mathcal{D}_0 = diag(a_{i0})$, and $\mathcal{D} = diag(d_i = \sum_{j=1}^{n} a_{ij})$.

Definition 4: The missiles' dynamics are bounded

$$\|f_i(x_i)\|_2 \leq \rho\|x_i\|_2, \|f_i(x) - f_i(y)\|_2 \leq \gamma\|x - y\|_2 \quad (38)$$

with $\rho, \gamma \in \mathbb{R}^+$.

Theorem 1: Based on the properties of the matrix $M$, If the fixed-time undirected graph $\mathcal{G}$ is connected and at least one $a_{i0} > 0$, the leader-follower consensus (36) is asymptotically guaranteed by the following distributed consensus control.

$$u_i = -k_1 e_i - k_2 \psi_i(e_i) \quad (39)$$

*where,* $k_1$, $k_2$ are the consensus gains satisfying.

$$\begin{cases} k_1 \geq \rho \dfrac{\lambda_{\max}(\boldsymbol{M})}{\lambda_{\min}^2(\boldsymbol{M})} \\ k_2 \geq \dfrac{\sqrt{\tilde{\boldsymbol{x}}_0^T(\boldsymbol{M} \otimes \boldsymbol{I}_N)\tilde{\boldsymbol{x}}_0}\sqrt{\lambda_{\max}(\boldsymbol{M})}}{t_s \lambda_{\min}(\boldsymbol{M})N\kappa}(1 + d_0) \\ t_s = \dfrac{\sqrt{\tilde{\boldsymbol{x}}_0^T(\boldsymbol{M} \otimes \boldsymbol{I}_N)\tilde{\boldsymbol{x}}_0}\sqrt{\lambda_{\max}(\boldsymbol{M})}}{k_2 \lambda_{\min}(\boldsymbol{M})N\kappa} \end{cases}$$

$$(40)$$

with $\lambda_{min}(M) > 0, \kappa > 0$, and $t_s$ is the settling time.

Proof:

For each agent $'i'$, let us consider a tracking error denoted as $\tilde{x}_i = x_i - x_0$. By employing the distributed consensus protocol (38), the multi-agent closed-loop system is written as follows:

$$\dot{\tilde{x}}_i = f_i(x_i) - f_0(x_0) - k_1 \sum_{j=1}^{n} a_{ij}(\tilde{x}_i - \tilde{x}_j) - k_2\psi_i(\tilde{e}_i) \quad (41)$$

where, $\tilde{e}_i = \sum_{j=0}^{n} a_{ij}(\tilde{x}_i - \tilde{x}_j)$. For the muti-agent system, we write

$$\dot{\tilde{x}} = F(\tilde{x}, \tilde{x}_0) - k_1(M \otimes I_N)\tilde{x} - k_2\Psi(\tilde{e}) \quad (42)$$

with

$$\tilde{x} = [\tilde{x}_1^T, \dots, \tilde{x}_n^T]^T,$$
$$F(\tilde{x}, x_0) = \left[(f_1(x_1) - f_0(x_0))^T, \dots (f_n(x_n) - f_0(x_0))^T\right]^T,$$
$$\Psi(\tilde{e}) = [\psi_1^T(\tilde{e}_1), \dots, \psi_n^T(\tilde{e}_n)]^T$$

where, $f_0(x_0)$ denotes the vector field of the leader dynamics and $x_0$ denotes its state vector. To demonstrate the effectiveness of the proposed control algorithm, we consider the following Lyapunov function candidate.

$$V = \frac{1}{2}\tilde{x}^T(M \otimes I_N)\tilde{x} \quad (43)$$

for which,

$$\dot{V} = \tilde{x}^T (M \otimes I_N)[F(\tilde{x}, x_0) - k_1 (M \otimes I_N)\tilde{x} - k_2 \Psi(\tilde{e})] \quad (44)$$

with $\lambda_{min}(M) > 0$, one can get

$$\begin{cases} \tilde{x}^T (M \otimes I_N)F((\tilde{x}, x_0)) = F^T((\tilde{x}, x_0))(M \otimes I_N)\tilde{x} \\ \qquad\qquad \le \rho \lambda_{max}(M) \|\tilde{x}\|_2^2 \\ \tilde{x}^T (M \otimes I_N)^2 \tilde{x} \, \lambda_{min}^2 \ (M) \|\tilde{x}\|_2^2 \end{cases} \quad (45)$$

It results,

$$\dot{V} \le -k_1 \lambda_{min}^2(M) \|\tilde{x}\|_2^2 - \rho \lambda_{max}(M)\|\tilde{x}\|_2^2 \\ + \lambda_{min}(M)\|\Psi(\tilde{e})\|_2 \|\tilde{x}\|_2 \quad (46)$$

Suppose that there exist $\kappa \in \mathbb{R}^+$ for which

$$\|\psi_i(e_i)\|_2 \le \|\psi_i(e_i)\|_1 \le N\|\psi_i(e_i)\|_\infty \le N\kappa \quad (47)$$

It results that condition (46) is achieved if and only if

$$k_1 \lambda_{min}^2(\boldsymbol{M})\|\tilde{\boldsymbol{x}}\|_2^2 - \rho\lambda_{max}(\boldsymbol{M})\|\tilde{\boldsymbol{x}}\|_2^2 = \left(k_1 - \rho\frac{\lambda_{max}(\boldsymbol{M})}{\lambda_{min}^2(\boldsymbol{M})}\right)\lambda_{min}^2(\boldsymbol{M})\|\tilde{\boldsymbol{x}}\|_2^2 \ge 0$$

$$k_2 \lambda_{min}(\boldsymbol{M})\|\boldsymbol{\Psi}(\tilde{\boldsymbol{e}})\|_2\|\tilde{\boldsymbol{x}}\|_2 - d_0 = \frac{k_2 \lambda_{min}(\boldsymbol{M})\sqrt{2V}}{\sqrt{\lambda_{max}(\boldsymbol{M})}}\|\boldsymbol{\Psi}(\tilde{\boldsymbol{e}})\|_2 - d_0 \ge 0 \quad (48)$$

where, $d_0$ is the maximum value of an eventual disturbance ($d_0 = 0$ for undisturbed system). With $k_1 \ge \rho\frac{\lambda_{\max}(M)}{\lambda_{min}^2(M)}$, $\dot{V}$ will satisfy

$$\dot{V} \le -\frac{k_2 \lambda(M)\sqrt{2V}_{min}}{\sqrt{\lambda(M)}_{max}\|\Psi(\tilde{e})\|_1} \le -\frac{k_2 \lambda(M)\sqrt{2V}_{min}}{\sqrt{\lambda(M)}_{max}N\|\Psi(\tilde{e})\|_\infty} \quad (49)$$

It follows,

$$\begin{cases} \sqrt{V} \le \sqrt{V_0} - \dfrac{k_2}{\sqrt{2}}\dfrac{\lambda(M)\|\Psi(\tilde{e})\|_\infty{}_{min}}{\sqrt{\lambda(M)}_{max}t} \\[2mm] t_s = \dfrac{\sqrt{\tilde{x}_0^T(M\otimes I_N)\tilde{x}_0}\sqrt{\lambda(M)_{max}}}{k_2\lambda(M)_{min}} \\[2mm] k_1 \ge \rho\dfrac{\lambda_{max}}{\lambda_{min}^{2(M)}} \\[2mm] k_2 \ge \dfrac{\sqrt{\tilde{x}_0^T(M\otimes I_N)\tilde{x}_0}\sqrt{\lambda(M)_{max}}}{t_s\lambda(M)_{min}(1+d_0)} \end{cases} \quad (50)$$

## V. RESULTS AND DISCUSSION
